3:06PM D47.00002 Higher throughput high resolution multi-worm tracker. AVELINO JAVER, KEZHI LI, BERTALAN GYENES, ANDRE BROWN, MRC CSC, Imperial College London, BEHAVIOURAL GENOMICS TEAM — We have developed a high throughput imaging system for tracking multiple nematode worms at high resolution. The tracker consists of 6 cameras mounted on a motorized gantry so that up to 48 plates (each with approximately 30 worms) can be imaged without user intervention. To deal with the high data rate of the cameras we use real time processing to find worms and only save the immediately surrounding pixels. The system is also equipped with automatic oxygen and carbon dioxide control for observing stimulus response behaviour. We will describe the design and performance of the new system, some of the challenges of truly high throughput behaviour recording, and report preliminary results on inter-individual variation in behaviour as well as a quantitative analysis of C. elegans response to hypoxia, oxygen reperfusion, and carbon dioxide.

3:30PM D47.00004 Physics of Fission and Fusion for the Diagnostics and Monitoring of the Deadliest Illness of Mankind. ARJUN SAXENA, Retired — The physics of fission and fusion has been well known for the past several decades. It has been used primarily for destructive purposes (e.g., nuclear armaments) with both processes. However for peaceful purposes, e.g., generation of energy, only fission has been used, but not yet fusion. It is also well known that the deadliest illness of mankind is the group of illnesses called mental illnesses. A large segment of the world population is afflicted by them causing more loss of human lives, destruction of families, businesses and overall economy than all the other illnesses combined. Despite outstanding advancements in medical research and huge investments, unfortunately no diagnostic techniques have yet been found which can characterize the patient’s mental illness. Consequently, no quantitative monitoring techniques are available to evaluate the efficacy of the various medicines used to treat the patients, and to develop them in the pharmaceutical labs. The purpose of this paper is to apply the constructive aspects of fission and fusion to identify the missing links in the diagnosis and treatment of mental illnesses. Each patient is a unique human being, not a disease or a group of symptoms. This makes it even more difficult to treat the patients suffering from mental illness...
Sparse Coding of Natural Human Motion Yields Eigenmotions Consistent Across People

Across People emergent run-and-tumble sparse activation of “eigenmotion” neurons, and is consistent with data on grasp-type specificity of specialised neurons in the premotor cortex. Our findings suggest the motor system can compose complex movement behaviours out of the spatially and temporally sparse activation of “eigenmotion” neurons, and is consistent with data on grasp-type specificity of specialised neurons in the premotor cortex.

A stochastic model for bacterial dynamics toward point food sources with emergent run-and-tumble. — HOSSEIN JASHNSAZ, TYLER NGUYEN, HORIA PETRACHE, STEVE PRESSE, Indiana University- Purdue University- Indianapolis, STATPHYSBIO TEAM — Despite stark differences in chemotactic signaling networks and flagellar physiology across bacterial species, all bacteria sense their environment through a series of stochastic detection events (“hits”) at their chemoreceptors and bias their random walk on the basis of this information. We present a general statistical model describing how bacteria locate point sources of food on the basis of stochastic event detection, rather than gradient information. We show how model parameters can be directly inferred using maximum likelihood methods from microscopy tracking data. We find that “run-and-tumble” dynamics naturally emerge from our statistical model and recapitulate known results from experiments when we consider bacterial dynamics in well-controlled chemotactrant gradients. However, our model goes beyond reproducing known run-and-tumble statistics. It also makes a number of predictions unique to bacteria tracking point sources. In our model, all parameters are directly inferred from tracking data thus there are no adjustable parameters; detection events by bacteria are assumed stochastic as they occur in nature; and our “top-down” modeling approach is broadly applicable across bacterial species.

Adhesion of D. discoideum on Hydrophobic Substrate

2:30PM D48.00001 Adhesion of D. discoideum on Hydrophobic Substrate

PLOSCARIU, Kansas State University — Adhesion by amoeboid cells, such as D. discoideum, is poorly understood but critical for other behaviors such as phagocytosis and migration. Furthermore, both leucocytes and breast cancer cells employ the amoeboid mode of movement at various points in their life-cycles. Hence, improved knowledge of amoeboid adhesion may lead to be new strategies for controlling other important cellular processes. This study regards adhesion by D. discoideum on silanized glass substrates. Reflection interference contrast microscopy is used in conjunction with other methods to determine the contact angle, cell-medium interfacial energy, and adhesion energy of these cells. The contact angle of individual cells settling under gravity onto a substrate is observed to increase as the size of the contact patch increases. This behavior occurs on slower time-scales than expected for the settling of inert vesicles. The implications of this observation on the nature of the underlying forces will be discussed. 

Energetic modeling and single-molecule verification of dynamic regulation on receptor protein diffusion by actin corals and lipid raft domains receptor

2:42PM D48.00002 Energetic modeling and single-molecule verification of dynamic regulation on receptor protein diffusion by actin corals and lipid raft domains receptor

CHIEN YU LIN, JUNG Y. HUANG, Department of Photonics, Chiao Tung University, LEU-WEI LO, Institute of Biomedical Engineering and Nanomedicine, National Health Research Institutes — To faithfully estimate a signal that varies in both space and time, the optimization strategy used by a live cell is to organize a collection of distributed and mobile receptors into a mobile active clustering. However, living eukaryotic cells are highly heterogeneous and stochastically dynamic. It is therefore important to develop an energetic model based on fundamental laws to verify that the underlying processes are energetically favorable. We developed an energetic model based on the generalized Langevin equation and the Cahn-Hilliard equation to simulate the diffusive behaviors of receptor proteins in the plasma membrane with a hierarchical structure of actin corals, lipid domains, and receptor proteins. Single-molecule tracking data of EGFR acquired on live HeLa cells agrees with the simulation results. We discovered that after ligand binding, EGFR molecules move into lipid nanodomains. The transition rates between different diffusion states of liganded EGFR molecules are regulated by the lipid domains. Our method captures both the sensitivity of single-molecule processes, statistic accuracy of data analysis, and the hierarchical structure of plasma membranes.

Possible Domain Formation In PE/PC Bilayers Containing High Cholesterol

2:54PM D48.00003 Possible Domain Formation In PE/PC Bilayers Containing High Cholesterol

MATTHEW HEIN, FAZLE HUSSAIN, JUYANG HUANG, Texas Tech University — Cholesterol is a significant component of animal cell membranes, and its presence has the effects of not only adding rigidity to the lipid bilayer, but also leading to the formation of lipid domains. Two other lipids of interest are phosphatidylethanolamine (PE), which constitutes about 45 percent of the phospholipids found in human nervous tissues, and phosphatidylcholine (PC), which is found in every cell of the human body. The maximum solubility of cholesterol is the highest molle fraction of cholesterol that the lipid bilayer can retain, at which point cholesterol begins to precipitate out to form cholesterol monohydrate crystals. We have measured the maximum solubility of cholesterol in mixtures of 16:0-18:1PE and 16:0-18:1PC using a new light scattering technique, which utilizes the anisotropic nature of light scattering by cholesterol crystals. This new method is highly accurate and reproducible. Our results show that the maximum solubility of cholesterol increases linearly as a function of the molar ratio POPC/(POPE+POPC), which suggests possible domain formation in mixtures of PE and PC containing maximum amount of cholesterol.
3:06PM D48.00004 Self-Healing of Polymer Networks with Reversible Bonds

Michael Rubinstein,
University of North Carolina at Chapel Hill — Self-healing polymeric materials are systems that after damage can revert to their original state with full or partial recovery of mechanical strength. Using scaling theory we study a simple model of autonomic self-healing of polymer networks. In this model one of the two end monomers of each polymer chain is fixed in space mimicking dangling chains attachment to a polymer network, while the sticky monomer at the other end of each chain can form pairwise reversible bond with the sticky end of another chain. We study the reaction kinetics of reversible bonds in this simple model and analyze the different stages in the self-repair process. The formation of bridges and the recovery of the material strength across the fractured interface during the healing period occur appreciably faster after shorter waiting time, during which the fractured surfaces are kept apart. We observe the slowest formation of bridges for self-adhesion after bringing into contact two bare surfaces with equilibrium (very low) density of open stickers in comparison with self-healing. The primary role of anomalous diffusion in material self-repair for short waiting times is established, while at long waiting times the recovery of bonds across fractured interface is due to hopping diffusion of stickers between different bonded partners. Acceleration in bridge formation for self-healing compared to self-adhesion is due to excess nonequilibrium concentration of open stickers. Full recovery of reversible bonds across fractured interface (formation of bridges) occurs after appreciably longer time than the equilibration time of the concentration of reversible bonds in the bulk. The model is extended to describe enhanced toughness of dual networks with both permanent and reversible cross-links.

3:42PM D48.00005 Assembly of transmembrane proteins on oil-water interfaces

Peter Yunker,
Georgia Institute of technology, Harvard University, New England Biolabs, Corey Landry, Louisiana State University, ShaoRong Chong, New England Biolabs, David Weitz, Harvard University — Transmembrane proteins are difficult to handle by aqueous solution-based biochemical and biophysical approaches, due to the hydrophobicity of transmembrane helices. Detergents can solubilize transmembrane proteins; however, surfactant coated transmembrane proteins are not always functional, and purifying detergent coated proteins in a micellar solution can be difficult. Motivated by this problem, we study the self-assembly of transmembrane proteins on oil-water interfaces. We found that the large water-oil interface of oil drops prevents nascent transmembrane proteins from forming non-functional aggregates. The oil provides a hydrophobic environment for the transmembrane helix, allowing the ectodomain to fold into its natural structure and orientation. Further, modulating the strength or valency of hydrophobic interactions between transmembrane proteins results in the self-assembly of spatially clustered, active proteins on the oil-water interface. Thus, hydrophobic interactions can facilitate, rather than inhibit, the assembly of transmembrane proteins.

3:54PM D48.00006 Bio-Inspired Composite Interfaces: Controlling Hydrogel Mechanics via Polymer-Nanoparticle Coordination Bond Dynamics

Niels Holtan-Andersen,
Massachusetts Institute of Technology — In soft nanocomposite materials, the effective interaction between polymer molecules and inorganic nanoparticle surfaces plays a critical role in bulk mechanical properties. However, controlling these interfacial interactions remains a challenge. Inspired by the adhesive chemistry in mussel threads, we present a novel approach to control composite mechanics via polymer-particle interfacial dynamics; by incorporating iron oxide nanoparticles (Fe3O4 NPs) into a catechol-modified polymeric network the resulting hydrogels are crosslinked via reversible coordination bonds at Fe3O4 NP surfaces thereby providing a dynamic gel network with robust self-healing properties. By studying the thermally activated composite network relaxation processes we have found that the polymer-NP binding energy can be controlled by engineering both the organic and inorganic side of the interface.

4:06PM D48.00007 Photo-induced Reshuffling of Covalent Networks for Shape Actuators

Mitchell Anthamatten, Yuan Meng,
University of Rochester, Dept. Chemical Eng. Team — Photo-responsive allyl sulfide linkages within a polymer network can undergo addition fragmentation chain transfer (AFC), in the presence of free radicals, to cause bond reshuffling. This phenomenon is employed to program a single-phase, two-way shape actuator that is thermal-responsive, even without an applied external load. Semicrystalline poly(caprolactone) networks containing allyl sulfide linkages are melted, strained to various elongations (hundreds of percent), and irradiated. Light causes a cascade of AFC events, resulting in rupture of some network strands, configurational relaxation of dangling ends, and reformation of network bonds. After irradiation, the resulting double networks assume a mechanical state-of-ease and chains are under permanent configurational bias; when cooled, they crystallize in a preferred direction leading to fully reversible shape actuation. The mechanism of shape actuation is investigated using a combination of calorimetry and X-ray scattering.

4:18PM D48.00008 TBD

4:54PM D48.00009 Mussel-inspired reversible metal-coordinate bonds as a pathway towards temporal control over the mechanical hierarchy of soft materials

Scott Grindy, Robert Learsch, Niels Holtan-Andersen,
Massachusetts Inst of Tech-MIT — Dynamic, reversible crosslinks have been shown to specifically control the mechanical properties of a wide variety of mechanically tough and resilient biomaterials. Here, we show that reversible histidine-metal ion interactions, long thought to contribute to the strong mechanical properties and self-healing nature of mussel byssal threads, can be used to control and engineer the hierarchical mechanical properties of model polyethylene glycol hydrogels orthogonally from the spatial structure of the material. We delve into the physics underlying these types of materials to properly understand how to explicitly engineer the mechanical properties of tough soft materials by utilizing their temporal hierarchy.

5:06PM D48.00010 Active Dynamic Frictional Probes

Joshua Steimel, Juan Aragones, Alfredo Alexander-Katz,
Massachusetts Inst of Tech-MIT — In biological systems there are a myriad of interactions occurring instantaneously and these interactions can vary drastically in the strength of the interaction, the speed at which this interaction occurs, and the duration of the interaction. When multiple interactions occur any of these factors can determine which particular interaction is dominant. However, currently it is extremely difficult to measure binding affinity, K_on, and K_off rates in a relatively high throughput manner. Here we propose a novel and versatile system that will be able to detect differences in binding affinity of wide range of transient interactions and will be able to extract the relevant time scales of these interactions. Our system will utilize ferromagnetic particles that can be easily functionalized with a receptor of interest and the substrate will be coated in the corresponding ligand. A rotating magnetic field will cause particles, henceforth referred to as rollers, to rotate and this rotational motion will be converted into translational motion via the effective frictional force induced by interaction that is being probed. By measuring the translation of the rollers to a baseline, where only hydrodynamic friction occurs, we can measure the relative strength of the interactions. We can also potentially measure kinetic information by changing the frequency at which the magnetic field rotates, since changing the frequency at which the bead rotates is akin to changing the time allowed for bond formation. We will measure a wide range of interaction including ionic, metal-ion coordination, IgG-Protein A complex, and biotin-streptavidin complex.
5:18PM D48.00011 Magnesium Dependence of the RNA Free Energy Landscape, RYAN HAYES, JEFFREY NOEL, Center for Theoretical Biological Physics, Rice University, ANA MANDIC, Department of Biomedical Engineering, University of Houston, PAUL WHITFORD, Department of Physics, Northeastern University, KARISSA SANBONMATSU, Theoretic Biology and Biophysics, Los Alamos National Labs, UDAYAN MOHANTY, Department of Chemistry, Boston College, JOSE ONUCHIC, Center for Theoretical Biological Physics, Rice University — The RNA free energy landscape is highly sensitive to ionic concentrations, and especially to Mg$^{2+}$, as most RNA tertiary structure will not form in the absence of Mg$^{2+}$. At physiological concentrations, the energy landscape must be smooth and funneled to fold on biological time scales, but changes in ionic concentration may affect the relative stability of alternative states. We perturb a structure-based model, which captures the funneled nature of the energy landscape, to include electrostatic effects. Our model includes explicit Mg$^{2+}$ and screening by implicit KCl. A dynamic model for the local competition between Manning condensed Mg$^{2+}$ and KCl is introduced, which makes the model more broadly applicable and transferable than a previous static model. We use the excess Mg$^{2+}$ ions associated with the RNA (I$^2_{2+}$) to test the model. I$^2_{2+}$ is an ideal metric because it is closely related to the Mg$^{2+}$-RNA interaction free energy, and is easily measurable in both experiment and simulation. The model captures intermediate states of a small pseudoknot missed by models without electrostatics.

5:30PM D48.00012 Exploiting Dynamic Bonds in Polymer-grafted Nanoparticle Networks to Create Mechanomutable, Reconfigurable Composites, ANNA C. BALAZS, MATTHEW J. HAMER, BALAJI V. S. IYER, VICTOR V. YASHIN, University of Pittsburgh — Via a new dynamic, three-dimensional computer model, we simulate the tensile deformation of polymer-grafted nanoparticles (PGNs) that are cross-linked by labile bonds, which can readily rupture and reform. For a range of relatively high strains, the network does not fail, but rather restructures into a stable, ordered structure. Within this network, the reshuffling of the labile bonds enables the formation of this new morphology. The studies reveal that the appropriate combination of stress-responsive hybrid materials and applied stress can yield distinct opportunities to dynamically switch between different structures, and thus, the properties of the material. Thus, the results provide guidelines for designing mechano-responsive hybrid materials that undergo controllable structural transitions through the application of applied forces.

Monday, March 2, 2015 2:30PM - 5:30PM – Session D49 GSOFT DBIO: Focus Session: Active Living Matter I 217D - Vernita Gordon, University of Texas at Austin

2:30PM D49.00001 Rheology of Active Gels, DANIEL CHEN, Department of Physics Brandeis University — Active networks drive a diverse range of critical processes ranging from motility to division in living cells, yet a full picture of their rheological capabilities in non-cellular contexts is still emerging, e.g., How does the rheological response of a network capable of remodeling under internally-generated stresses differ from that of a passive biopolymer network? In order to address this and other basic questions, we have engineered an active gel composed of microtubules, bidirectional kinesin motors, and molecular depletant that self-organizes into a highly dynamic network of active bundles. The network continually remodels itself under ATP-tunable cycles of extension, buckling, fracturing, and self-healing. Using confocal rheometry we have simultaneously characterized the network’s linear and non-linear rheological responses to shear deformation along with its dynamic morphology. We find several surprising and unique material properties for these active gels; most notably, rheological cloaking, the ability of the active gel to drive large-scale fluid mixing over several orders of flow magnitude while maintaining an invariant, solid-like rheological profile and spontaneous flow under confinement, the ability to exert micro-Newton forces to drive persistent directed motion of the rheometer tool. Taken together, these results and others to be discussed highlight the rich stress-structure-dynamics relationships in this class of biologically-derived active gels.

3:06PM D49.00002 Collective dynamics of sperm in viscoelastic fluid, CHIH-KUAN TUNG, Deptment of Biophysical Sciences, City University of Hong Kong — Active networks provide an unlimited path, microtubule loops allow the study of kinesin motility on distances exceeding that offered by a single microtubule. Moreover, the periodicity of the path allows for the comparison of trajectories between laps. Here we study the motility of quantum dot labeled kinesin on microtubule loops. Motility of kinesins over multiple laps is observed and their trajectories are extracted from kymograph using a custom algorithm. Distribution of velocities at given locations do not vary randomly but show a correlation with the presence of obstacles. Possible mechanisms responsible for the long range transport are discussed in the context of available theories.
We also study a related equilibrium model that clarifies the role of orientational fluctuations.

Chiral organization although the interactions are achiral. We elucidate under which conditions these chiral states will emerge and grow to large scales.

We perform large-scale molecular dynamics simulations (up to 

breaking is ubiquitous in biological systems, from DNA to bacterial suspensions. A key unresolved problem is how chiral structures may spontaneously emerge.

The paradigmatic model organism for chemotaxis is E. coli. E. coli has multiple flagella and uses these to swim with a run-and-tumble random walk, biasing its runs towards chemotactant. However, P. aeruginosa has only a single polar flagellum and therefore in a bulk fluid can only go forward and backward (with small changes in angle possible).

We find that the efficiency of P. aeruginosa chemotaxis depends strongly on the initial swimming direction as well as the steepness of the sensed gradient of chemotactant.

The cortical actin cytoskeleton is a quasi 2-D active material in which dynamics are dominated by rapid actin turnover and myosin-driven contractility. Here we present a reconstituted model system that emulates these processes in artificial cell-like compartments. By tuning physical and chemical parameters, we induce a non-equilibrium phase transition. We characterize the local dynamics of these reconstituted cortices by tracking embedded single-walled carbon nanotubes (SWNTs). We create high-resolution maps of the contractile actomyosin flows in a homogenous and during transition to an inhomogeneous steady state. We find evidence that connectivity percolation drives the non-equilibrium phase transition.
compaction that agrees with estimated compaction that we observe directly. This makes their dynamic behavior in restricted geometries very different from that observed in the bulk. Here we analyze the motion of spermatozoids confined to shallow chambers, investigating the nature of the cell trajectories and their accumulation near the side boundaries. Observed cell trajectories are composed of a succession of quasi-circular and quasi-linear segments. This suggests that the cells follow a path of intermittent trappings near the top and down surfaces separated by stretches of quasi-free motion near the center of the gap. Use of microstructured petal-shaped edges limits accumulation near the borders and contributes to increase the concentration in the chamber interior. System stabilization occurs over times of the order of minutes, which agrees well with a theoretical estimate that assumes that the cell mean-square displacement is largely due to the quasi-linear segments. Pure quasi-circular trajectories would require several hours to stabilize. Our estimates also indicate that stabilization proceeds 2.5 times faster in the rosette geometries than in the smooth-edged chambers, which is another practical reason to prefer the former.

5:06PM D49.00012 Shape-Conserved Dynamic Convection in the Process of Astér Formation from a System of Microtubules and Cross-Linked Kinesin Motors. K. KIM, A. SIKORA, WPI-AIMR, Tohoku University, Japan. H. NAKAZAWA, Dept of Biomolecular Engineering, Graduate School of Engineering, Tohoku University, Japan. M. UMETSU, WPI-AIMR/Dept of Biomolecular Engineering, Graduate School of Engineering, Tohoku University, Japan. W. HWANG, Dept of Biomedical Engineering/Materials Science and Engineering, Texas A&M University, USA; School of Computational Sciences, KIAS, Korea. W. TEIZER, WPI-AIMR, Tohoku University, Japan; Dept of Physics and Astronomy/Materials Science and Engineering, Texas A&M University, USA; We report fluorescence microscopy studies of a cellular element-based active system that is composed of rhodamine-labeled microtubules and functionalized kinesin motor proteins, cross-linked via streptavidin-coated quantum dots. The motor proteins organize microtubules into aster-like structures containing core aggregations of the quantum dot-motor protein complexes. The cores result from the dynamic condensation of sub-clusters that are connected to each other randomly. The inter-cluster distance decays exponentially with time during the condensation. Intriguingly, the shape defined by lines connecting the clusters is well conserved while the dynamic process reduces the size. This shape conservation is achieved by a dynamic balance with respect to the distance between sub-clusters. We explain this isomorphic contraction during the aster formation process using a simple mechanistic model.

5:18PM D49.00013 Broken detailed balance in active fluctuations of semiflexible filaments. JANNES GLADROW, Georg-August University of Göttingen, Germany. NIKTA FAKHRI, MIT. FRED C. MACKINTOSH, Vrije Universiteit, Netherlands. CHRISTOPH F. SCHMIDT, Georg-August University of Göttingen, Germany. CHASE P. BROEDERSZ, Princeton University — Non-equilibrium microscopic force generation in cells often results in stochastic steady-state fluctuations. In the cell cytoskeleton, for example, cytoplasmic myosins can drive vigorous conformational fluctuations of actin filaments and microtubules. We here present an analytical and numerical analysis of randomly driven shape fluctuations of semiflexible filaments in a viscoelastic environment. To detect and quantify non-equilibrium dynamics, we focus on the breaking of detailed balance in a conformational phase space subtended by eigenmodes of the beam equation. Molecular dynamics simulations reveal a non-zero circulatory flux in phase space induced by motor activity. Furthermore, we derived an analytical expression of nonequilibrium mode correlations that allows us to predict temporal effects of active molecular motors.

Monday, March 2, 2015 2:30PM - 4:54PM — Session D50 GSOFT GSNP: Focus Session: Dynamic Jamming Fronts and Shear Thickening

2:30PM D50.00001 Shear thickening and S-shaped flow curves. ROMAIN MARI, Levich Institute, CCNY, RYOHEI SETO, Levich Institute, CCNY / Okinawa Institute of Science and Technology. JEFFREY F. MORRIS, MORTON M. DENN, Levich Institute and Department of Chemical Engineering, CCNY — The discontinuous shear thickening (DST) of dense suspensions is a remarkable phenomenon in which the viscosity can increase by several orders of magnitude at a critical shear rate. It follows the phenomenology of a first order transition between two “states” that we have recently identified as Stokes flows with lubricated or frictional contacts, respectively. Here we extend the analogy further and show the existence of a non-monotonic steady state flow curve by means of stress-controlled simulations, analogous to a non-monotonic equation of state. While we associate DST to an S-shape flow curve, at volume fractions above the shear jamming transition the frictional state loses flowability and the flow curve reduces to an arch, permitting the system to flow only at small stresses. Whereas a thermodynamic transition leads to phase separation in the coexistence region, we observe a uniform shear flow all along the transition channel. A stability analysis suggests that uniform shear may be mechanically stable for the small Reynolds numbers and system sizes in a rheometer.

2:42PM D50.00002 Sedimentation of athermal particles in clay suspensions1. XAVIER CLOTET, ARSHAD KUDROLLI, Department of Physics, Clark University — We discuss sedimentation of athermal particles in dense clay suspensions which appear liquid-like to glass-like. These studies are motivated by the physics important to a diverse range of problems including remediation of oil sands after the extraction of hydrocarbons, and formation of filter cakes in bore wells. We approach this problem by first considering collective sedimentation of athermal spherical particles in a viscous liquid in quasi-two dimensional and three dimensional containers. We examine the system using optical and x-ray tomography techniques which gives particle level information besides global information on the evolution of the volume fraction. Unlike sediments in the dilute limit – which can be modeled as isolated particles that sediment with a constant velocity and slow down exponentially as they approach the bottom of the container – we find interaction between the different flow regimes leads to the emergence of a novel behavior during the sedimentation. We find significant avalanching behavior and cooperative motion as the grains collectively settle, and non-exponential increase in settling time. We discuss the effect of stirring caused by the sedimenting particles on their viscosity and consequently the sedimentation rates as a function of particle concentration.

1Supported by Petroleum Research Fund Grant PRF # 54045-ND9.

2:54PM D50.00003 Dynamic jamming fronts in iceberg-choked fjords. IVO PETERS, University of Chicago, JASON AMUNDSON, University of Alaska Southeast, RYAN CASSOTTO, University of New Hampshire, MARK FAHNESTOCK, University of Alaska Fairbanks, KRISTOPHER DARNELL, University of Texas Austin, MARTIN TRUFFER, University of Alaska Fairbanks, WENDY ZHANG, University of Chicago — During summertime at the glacier terminus at Jakobshavn Isbræ, Greenland, calving events are followed by rapid motion in the ice mélange in front of the terminus. Understanding the dynamics of ice mélange is important because it acts as a resisting force to calving events. We analyze this motion using time-lapse photography and terrestrial radar images. Large calving events last for approximately 5 minutes, during which ~ 10^{14} J of potential energy is released. Motion in the ice mélange quickly spreads out over at least 16 km down the fjord, and relaxes in about 1 hour. The ice mélange can be viewed as a dense granular system, which is packed close to the jamming point. A jammed ice mélange resists expansion of the glacier terminus much more strongly and reduces iceberg calving, which may therefore play a significant role in glacier evolution. In our images, we observe dynamic jamming fronts, which propagate one order of magnitude faster than the instantaneous speed of the calving iceberg. From the ratio between the speed of the front and the calving iceberg we calculate a compaction that agrees with estimated compaction that we observe directly.
In oscillatory shear, as the original scattering volume periodically comes back to the original position, we could better study the changes in autocorrelation of silica nanoparticle suspensions in PEG under different shear strain regimes using small angle x-ray scattering (SAXS) and x-ray photon correlation spectroscopy (XPatial dynamics and provide an explanation of why shear thickening becomes weaker in highly viscous solvent.

However, in the real application, high shear strain or rate is applied, where the viscoelastic properties are affected by the microstructural deformation by this modulus. In this regime, their microstructure does not change by shear, and the shear stress linearly responds to the applied strain.

By combining the fluctuation analysis in different regimes, we quantitatively show how the interactions between grains affect the suspension dynamics and provide an explanation of why shear thickening becomes weaker in highly viscous solvent.

For low viscosity suspending liquids, we show that, in the shear thickening regime, shear and normal stresses are highly coupled and exhibit significant fluctuations with time. As shear rate increases, the stress distributions evolve from Gaussian to more complex distributions. By contrast, for highly viscous solvents, stress fluctuations are greatly reduced and only show Gaussian distributions at different shear rates. Moreover, the fluctuation behaviors are associated with various relaxation modes of the system and therefore lead to different scalings of the power spectral density.

3:30PM D50.00007 Dynamics of Concentrated Silica Suspension under Oscillatory Shear Studied by SAXS and XPCS, JONGHUN LEE, XIAO-MIN LIN, ALEC SANDY, SURESH NARAYANAN, Argonne National Laboratory, X-RAY SCIENCE DIVISION TEAM, CENTER FOR NANOMATERIALS TEAM — The viscoelastic properties of complex fluids are often obtained by applying small amplitude oscillatory shear (SAOS). In this regime, their microstructure does not change by shear, and the shear stress linearly responds to the applied strain. However, in the real application, high shear strain or rate is applied, where the viscoelastic properties are affected by the microstructural deformation by this modulus. In this regime, their microstructure does not change by shear, and the shear stress linearly responds to the applied strain.

3:42PM D50.00008 Discontinuous shear thickening for frictional granular particles, MATTHIAS GROB, CLAUS HEUSSINGER, ANNETTE ZIPPELIUS, Institute for Theoretical Physics, Göttingen University — We study the rheology of frictional granular particles with analytical modelling and numerical simulations in two dimensions. We derive a phase diagram with a topology different from the well known Liu-Nagel phase diagram for frictionless particles with a zero stress critical point. In contrast to the frictionless scenario, jamming first occurs at finite stress at a critical packing fraction \( \phi_C \) while a finite yield stress emerges only at \( \phi_\text{y} > \phi_C \). Remarkably, the flow is reentrant and we observe discontinuous shear thickening in the flow curve for \( \phi_\text{r} < \phi_\text{y} \) with \( \phi_\text{y} > \phi_C \). All these features can be rationalized with a simple constitutive equation which contains the frictionless scenario as a limiting case.

3:54PM D50.00009 Material properties of the shear-thickened state in concentrated near-hardsphere colloidal dispersions, NORMAN WAGNER, COLIN CWALINA, Chemical and Biomolecular Engineering, University of Delaware — Reversible shear thickening is common in concentrated dispersions of Brownian hard-spheres at high shear rates. We confirm the existence of a well-defined colloidal shear-thickened state through experimental measurements of the shear stress and the first and second normal stress differences in the shear-thickened state as a function of the particle volume fraction \( \phi \) for a model dispersion of near hard-spheres. The shear stress and normal stress differences are observed to grow linearly with the shear rate in the shear-thickened state and both normal stress differences are observed to be negative. Our experimental results show that the shear-thickened state of colloidal dispersions can be described by three material properties: shear viscosity and first and second normal stress difference coefficients—that are a function of the volume fraction. All three material properties are found to diverge with a power law scaling with the approach to maximum packing, which is found to be 0.54 ± 0.01. We find the magnitude of the relative shear viscosity is greater than the magnitude of the dimensionless second normal stress difference, which is greater than the magnitude of the dimensionless first normal stress difference. These results are consistent with theoretical predictions for shear thickening by hydrocluster formation and quantitatively comparable to Stokesian Dynamics simulations.

4:06PM D50.00009 The reciprocal effect of lubrication and contact forces in shear-thickening of colloidal suspensions, SAFA JAMALI, ARMAN BOROMAND, JOAO MAIA, Case Western Reserve Univ — Recently, the shear-thickening of colloidal suspensions has been attributed to frictional contact forces at high shear rates. This emerging understanding of the contact forces in a suspension has brought back the well-known dilatancy theory which was rather dormant in the past two decades. Here, we study the necessity of short-range hydrodynamics and the correlation between the contact and lubrication forces in shear-thickening suspensions. We use a modified Dissipative Particle Dynamics method that includes squeeze mode lubrication potentials based on the two interacting colloids. The effect of simulation parameters and contact potentials on the rheological response of a suspension is studied. Our results show that although the quality of the shear-thickening behavior (whether DST can be obtained or not) is dominated by the contact potentials, the lubrication force is a prerequisite for any type of shear-thickening to be recovered. Needless to mention that this argument is valid for the high Péclet numbers, as opposed to shear-thinning regime which can be fully reproduced without the need to lubrication or contact potentials.
4:18PM D50.00010 Dynamic jamming under impact in shear thickening suspensions1, SHOMEEK MUKHOPADHYAY, Yale University — Shear thickening fluids such as cornstarch and water show remarkable impact response allowing, for example, a person to run on the surface. We perform constant velocity impact experiments and imaging in shear thickening fluids at velocities lower than 500 mm/s and suspension heights of a few cm. In this regime where inertial effects are insignificant, we find that fronts with a dynamically jammed (DJ) region behind it are generated under impact. When this front and the DJ region reaches the opposite boundary it is able to support large stresses like a solid. These stresses are sufficient to support the weight of a running person. In addition we find a shear thickening transition under impact due to collision of the fronts with the boundary. There is a critical velocity required to generate these impact activated fronts. Using the observations on fronts, DJ region and using energy balance arguments we construct a model to explain the phenomena of running on the surface of cornstarch suspensions. The model shows quantitative agreement with our measurements using high-speed video of running on cornstarch and water suspensions.

Monday, March 2, 2015 2:30PM - 5:30PM —  Session D51 GQI DCMP: Invited Session: Towards a Scalable Superconducting Quantum Computer  Grand Ballroom C1 - Michel Devoret, Yale University

2:30PM D51.00001 The surface code: processing experimental data, AUSTIN FOWLER, Google — The surface code requires only nearest neighbor interactions and fidelities above approximately 0.99, making it highly compatible with superconducting circuits. In this talk, I review the surface code, and highlight the challenges and available optimizations when classically processing the output of a 9-qubit slice of surface code.

3:06PM D51.00002 Bit-flip error correction with superconducting Xmon qubits, JOHN MARTINIS, UC Santa Barbara and Google Inc. — One of the outstanding challenges of quantum computation has been the realization of scalable qubits with high fidelity for all necessary operations. Here I discuss the design of a linear chain of 9 superconducting Xmon qubits that allows initialization, single and two qubit gates, and fast repetitive and simultaneous measurement with fidelity in the 99%-99.9% range. This performance has allowed us to perform bit-flip error correction with 8 repetition cycles that leads to improved lifetime of the state. The use of error correction based on the surface code enables all errors, both data and measurement, to be corrected to 1st and 2nd order.

3:42PM D51.00003 Detecting arbitrary quantum errors via stabilizer measurements, MATTHIAS STEFFEN, IBM — Fault tolerant quantum computing requires error correction, which relies on the ability to extract information about the error that occurred rather than the states of the data qubits themselves. Stabilizer codes are an attractive solution to this problem in which the parity of the data qubits is measured with the aid of additional ancilla qubits, resulting in the “stabilization” of a specific quantum state. Here, we perform syndrome (or error) extraction and arbitrary error detection by using a 2x2 lattice of superconducting qubits and simultaneous quantum non-demolition stabilizer measurements. In this experiment one of the Bell states is stabilized, and any arbitrary single-qubit bit or phase error can be detected without destroying the stabilized Bell state. This lattice is a representative of a primitive tile for the surface code which is a promising approach towards quantum error correction.

4:18PM D51.00004 Tracking a Quantum Error Syndrome in Real Time: Quantum Jumps of Photon Parity1, ROBERT SCHOELKOPF, Yale University — Dramatic progress has been made in the last decade and a half towards realizing solid-state systems for quantum information processing with superconducting quantum circuits. Artificial atoms (or qubits) based on Josephson junctions have improved their coherence times more than 100,000-fold, have been entangled, and used to perform simple quantum algorithms. The next challenge for the field is demonstrating quantum error correction that actually improves the lifetimes, a necessary step for building more complex systems. I will describe recent experiments with superconducting circuits, where we store quantum information in the form of Schrodinger cat states of a microwave cavity, containing up to 100 photons. Using an ancilla qubit, we then monitor the gradual death of these cats, photon by photon, by observing the first jumps of photon number parity. This represents the first continuous observation of a quantum error syndrome, and may enable new approaches to quantum information based on photonic qubits. The performance of this error-monitoring system and the prospects for reaching “breakeven,” where quantum error correction improves the lifetime of stored information, will be discussed.

1This work performed with many collaborators at Yale University, and supported by the Army Research Office, the Laboratory for Physical Science, and the NSF.

4:54PM D51.00005 Detecting bit-flip errors in a logical qubit using stabilizer measurements, DIEGO RISTE, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Quantum data is susceptible to decoherence induced by the environment and to control errors. A future-fault-tolerant quantum computer will use quantum error correction (QEC) to actively protect against both. In the smallest QEC codes, the information in one logical qubit is encoded in a two-dimensional subspace of a larger Hilbert space of multiple physical qubits. For each code, a set of non-demolition multi-qubit measurements, termed stabilizers, can discretize and signal physical qubit errors without collapsing the encoded information. Using a 5-qubit superconducting processor, we realize the two parity measurements comprising the stabilizers of the three-qubit repetition code protecting one logical qubit from physical bit-flip errors. We construct these stabilizers as parallelized indirect measurements using ancillary qubits, and evidence their non-demolition character by generating three-qubit entanglement from superposition states. We demonstrate stabilizer-based quantum error detection (QED) by subjecting a logical qubit in any initial state to bit-flip errors on its constituent three physical qubits. Crucially, and in contrast to previous QED implementations, this approach keeps the quantum information encoded at all times, meeting a fundamental requirement for fault tolerance.

Monday, March 2, 2015 2:30PM - 5:42PM —  Session D52 DCMP: Invited Session: DCMP Prize Session  Grand Ballroom C2 - Laura Greene, Universirty of Illinois-Urbana
GPa at T > c. However, metallization of hydrogen is still under debates. As an alternative, hydrogen dominated materials were extensively explored because of their lower materials, College of Physics, Jilin University — Hydrogen was predicted to metalize at high pressures and believed to be a room-temperature superconductor.

Materials, College of Physics, Jilin University — Hydrogen was predicted to metalize at high pressures and believed to be a room-temperature superconductor.

3:06PM D52.00002 Davison-Germer Prize Talk: Structure and Reactivity of Surfaces in Vacuum and Under Ambient Gas Pressures, MIQUEL SALMERON, Materials Science Division of the Lawrence Berkeley National Laboratory — The goal of surface science research is to provide atomic level understanding of the structural and dynamic properties of surfaces, a goal particularly relevant for chemical applications, including catalysis, photochemistry, batteries and fuel cells. With X-ray Photoemission Spectroscopy (XPS) we can determine the composition and electronic structure. With Scanning Tunneling Microscopy (STM) we can image atoms and molecules as they adsorb, diffuse and react on single crystal surfaces. STM uniquely permits to visualize and determine adsorbate-adsorbate interactions by making movies of their motion. I will show how water molecules diffuse, H-bond to each other, and wet the surface forming 2D films. We also imaged how H2 molecules adsorb and dissociate on a Pd surface, and how the movies revealed that a particular arrangement of substrate atoms is required to generate the active sites through fluctuations. To study surfaces in the presence of gases, in the Torr to Atmospheric pressure range, new instrumentation is needed. Over the last years we developed high pressure STM and XPS, which allows us to study surfaces under high coverage of adsorbates in equilibrium with gases near ambient pressures and temperature. I will show how under these conditions the structure of surfaces can be very different from that at low coverage, or even at high coverage but at low temperature. Adsorbates can induce dramatic restructuring of the surface, as I will show in the case of CO on Pt and Cu. Equally important, reactions on catalyst surfaces can now be followed in real time, by measuring composition with XPS, and structure with STM, during the reactions to extract kinetic parameters.

3:42PM D52.00003 Lars Onsager Prize Talk: Flow Equations for Hamiltonians, FRANZ WEGNER, Ruprecht-Karls-University Heidelberg — The equation dH(l) = GH(l) can describe the renormalization group equation for the Hamiltonian/Lagrangian H(l) and the generator G of the group. But it can also describe a Hamiltonian flow for bosons/fermions, which eliminates the off-diagonal matrix elements or (quasi-)particle violating terms by means of unitary transformations dH(l)/dl = [η(l), H(l)]. Typically off-diagonal matrix elements are eliminated for ∆E > l−1/2. The flow equation has been applied to numerous systems (F. Wegner, J. Phys. A: Math. Gen. 39 (2006) 8221, arXiv: cond-mat/0511660; S. Kehrein, The Flow Equation Approach to Many-Particle Systems, Springer 2006), among them to the two-dimensional Hubbard-model, spin-boson models, the Anderson impurity model, QED and QCD. A simple and surprising result (as compared to that by Frohlich) is obtained for the elimination of the electron-phonon interaction yielding an attractive interaction for all energies. (P. Lenz and F. Wegner, Nucl. Phys. B482 (1996) 693; arXiv: cond-mat/9604087)

4:18PM D52.00004 Julius Edgar Lilienfeld Prize Talk: Quantum spintronics: abandoning perfection for new technologies1, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago — There is a growing interest in exploiting the quantum properties of electronic and nuclear spins for the manipulation and storage of information in the solid state. Such schemes offer qualitatively new scientific and technological opportunities by leveraging elements of standard electronics to precisely control coherent interactions between electrons, nuclei, and electromagnetic fields. We provide an overview of the field, including a discussion of temporally- and spatially-resolved magneto-optical measurements designed for probing local moment dynamics in electrically and magnetically doped semiconductor nanostructures. These early studies provided a surprising proof-of-concept that quantum spin states can be created and controlled with high-speed optoelectronic techniques. However, as electronic structures approach the atomic scale, small amounts of disorder begin to have outsized negative effects. An intriguing solution to this conundrum is emerging from recent efforts to embrace semiconductor defects themselves as a route towards quantum machines. Individual defects in carbon-based materials possess general trends in connection with reduced dimensions, surprising findings including phonon-mediated pseudogaps, and technology potential.

4:54PM D52.00005 Experimental observation of high-temperature superconductivity in H2S at P~150 GPa, M. EREMETS, University of Mainz, Germany — We found that sulfur hydride transforms at P~90 GPa to a superconductor with Tc increasing with pressure to 150 K at approximately 200 GPa. Moreover, we found superconductivity with Tc ~ 190 K in a H2S sample pressurized to P > 150 GPa at T > 220 K. This superconductivity likely associates with the dissociation of H2S, and formation of SHn (n > 2) hydrides. We proved occurrence of superconductivity by the drop of the resistivity at least 50 times lower than the copper resistivity, the decrease of Tc with magnetic field, and the strong isotopic shift of Tc in D2S which evidences a major role of phonons in the superconductivity.

5:18PM D52.00006 High Tc phase of (H3S)2H3 at high pressures, TIAN CUI, State Key Laboratory of Superhard Materials, College of Physics, Jilin University — Hydrogen was predicted to metalize at high pressures and believed to be a room-temperature superconductor. However, metallization of hydrogen is still under debates. As an alternative, hydrogen dominated materials were extensively explored because of their lower metalization pressure. Here I present the high-pressure studies on structures, metalization, and superconductivity of (H3S)2H3 from ab initio calculations [1]. At lower pressures, two phases containing H2 units are stable with P1 (< 37 GPa) and Ccmm (37-111 GPa) symmetries, which are still insulators. Upon further compression, H2 units disappear and two new metallic structures with Im-3m and Im-3m symmetries are reconstructive above 111 GPa and 180 GPa, respectively. Remarkably, the estimated Tc of Im-3m phase at 200 GPa achieves a very high value of 191 ~ 204 K. Moreover, Tc decreases with pressure at an approximate rate of (∂Tc/∂P) of -0.12 K/GPa. Our predicted high Tc and its pressure dependence in Im-3m phase are subsequently verified by recent experiments [2]. Our findings support the conjecture that hydrogen-rich materials are a way to achieve a metallic phase with high Tc at accessible experimental pressures and represent a significant step toward the understanding of high-pressure behavior of metallic hydrogen.

2:30PM D53.00001 Manipulation of magnetic skyrmions with spin-polarized STM. KIRSTEN VON BERGMANN, Department of Physics, University of Hamburg, Germany — Spin textures of ultra-thin magnetic layers exhibit a surprising variety. The loss of inversion symmetry at the interface of magnetic layer and substrate gives rise to the so-called Dzyaloshinskii-Moriya interaction (DMI) which favors non-collinear spin arrangements with unique rotational sense [1]. An ideal tool to investigate such systems down to the atomic scale is spin-polarized scanning tunneling microscopy (SP-STM), which has enabled the discovery spin spirals with unique rotational sense at surfaces [2-4]. Recently, different interface-driven skyrmion lattices have been found, that either exist without external magnetic field [5,6] or are induced by it [7]. A tuning of the magnetic properties can be realized by tiny variations of the electronic structure due to stacking and hybridization of the magnetic layer. Isolated skyrmions can be stabilized in a wide magnetic field range [7] and the high lateral resolution of SP-STM together with its magnetic sensitivity enables a precise characterization of the evolution of size and shape of single skyrmions with field. A comparison to micromagnetic theory yields the material parameters including the DMI which is responsible for skyrmion formation. The writing as well as the deletion of individual skyrmions based on local spin-polarized current injection has been demonstrated [7]. A new mechanism to detect skyrmions using non-spin-polarized currents has been discovered and can be understood based on the mixing of spin-up and spin-down bands. These interface-induced non-collinear magnetic states offer new exciting possibilities to study fundamental physical properties on the atomic-scale and to tailor material properties for spintronic applications.

3:06PM D53.00002 Simulations of skyrmion manipulation in confined geometries. VINCENT CROS, Unit Mixte de Physique CNRS/Thales — No abstract available.

3:42PM D53.00003 Electrical Creation and Manipulation of Magnetic Skyrmion Bubbles. WANJUN JIANG, Materials Science Division, Argonne National Laboratory — Magnetic skyrmions are topologically stable spin textures, which exhibit many fascinating features including an emergent electromagnetic field and efficient manipulation. Nevertheless, until now this has been challenging to achieve at room temperature, which is a bottleneck for technological implementation of skyrmion-based spintronics. Towards this end, room-temperature electric-current creation of skyrmions in two different (metallic and insulating) commonly accessible materials system will be discussed. First, the experimental creation of magnetic skyrmions triggered by an electric current in Ta/CoFeB/TaOx trilayers is demonstrated. The skyrmion generation is enabled by laterally inhomogeneous current-induced spin-orbit torques. This process is analogous to the spontaneous droplet formation in surface-tension driven fluid flows. We establish a novel phase diagram that summarizes the dependence of skyrmion generation on the external magnetic fields, and the strength of in-plane currents. Furthermore, we reveal the efficient manipulation of these skyrmions by electric currents. More importantly, a prototype skyrmion racetrack memory device will be experimentally demonstrated. Secondly, the manipulation of skyrmion bubbles by using spin Hall spin torques in (Pt or W)/(Y,Bi)Fe2O12 (YIG-Bi) bilayers will be discussed. Using MOKE imaging, we have identified a hexagonal lattice of skyrmion bubbles (1.8-μm diameter). Subsequent current pulses through the Pt layer results both in the motion of some of the skyrmions and a reduction in size of others, which is consistent with different wall structures and resultant skyrmion numbers. Furthermore, we observe distinct anomalous Hall signals associated with the underlying magnetization textures, which may indicate topological Hall effects in bilayer.

2This work was performed in collaboration with W. Zhang, M. B. Jungfleisch, F. Y. Fradin, J. E. Pearson, O. Heinonen, S. G. E. te Velthuis, and A. Hoffmann (Argonne National Laboratory), P. Upadhyaya, G. Yu, Y. Tserkovnyak, K. L. Wang (UCLA), Q. H. Yang, Q.Y. Wen, and H. W. Zhang (UESTC, China).

4:18PM D53.00004 Creation and Dynamics of Individual Skyrmions in Helimagnets1. JIADONG ZANG, Johns Hopkins Univ — The physics and future applications of magnetic skyrmions in helimagnet have attracted great attentions in the past years. Now the major focus of this field is the ability of creating single skyrmions in a controlled manner, and exploring novel properties of skyrmions as quasi-particles. In this talk, I will introduce our recent work on creating a single skyrmion via electric current or geometric confinement. The time and position of the skyrmion can be accurately controlled. More importantly, the microscopic mechanism is clearly revealed by the analysis of the topological charge, which also explains the topological origin of the skyrmion stability for the first time. The distinct feature of the skyrmion is an emergent gauge field attached to it. The motion of a single skyrmion is realized by coupling this emergent gauge field to electric current or magnon current. I will show that an electric current or temperature gradient can result in a steady motion of a single skyrmion.

1This work was supported in part by the TIPAC, the U.S. Department of Energy, Office of Basic Energy Sciences under Award No. DEFG02-08ER46544, and NSF under ECCS-1408168.
Magnetic skyrmions are topologically protected particle-like spin structures, with a topology characterised by their Skyrmion number. They can arise due to various interactions, including exchange, dipolar and anisotropy energy in the case of bubbles (skyrmion bubbles) and an additional Dzyaloshinskii-Moriya interaction (DMI) in the case of chiral skyrmions. Numerical predictions suggest that they exhibit rich dynamical behaviour governed by their topology, such as the basic gyrotropic and breathing eigenmodes [1,2]. The dynamical experiments are performed on skyrmion bubbles in nanostructures from symmetric CoB/Pt multilayers, tailored for high-frequency dynamics. Asymmetric layers were also fabricated (Co layers in-between 5d-metals) in order to tune the DMI, as expected from recent experiments [4]. Stabilizing chiral skyrmions confined in such nanostructures is highly desirable due to their enhanced stability and smaller size that makes them ideal candidates for integration in recently proposed novel spintronics devices [3]. By investigating the size of magnetic domains in magnetic field cycles, and comparing to micromagnetic simulations, asymmetric multilayers were explored. By performing pump-probe dynamical X-ray imaging on confined skyrmion bubbles the first observation of their basic eigenmode dynamics was demonstrated [5]. In particular, we present picosecond nanoscale imaging data i) of the gyrotropic mode of a single skyrmion bubble in the GHz regime and ii) the breathing-like behaviour of a pair of skyrmionic configurations. The observed dynamics is used to confirm the skyrmion topology and show the existence of an unexpectedly large inertia that is key for describing skyrmion dynamics [1,5]. These results demonstrate new ways for observing skyrmion dynamics and provide a framework for describing their behaviour. The next step is to achieve chiral skyrmion dynamics on a DMI system.

8:00AM F1.00001 Black Phosphorus Boron Nitride Heterostructures, NATHANIEL GILLGREEN, YAFIS BARLAS, YANMENG SHI, JIAWEI YANG, University of California Riverside, TAKASHI TANIGUCHI, National Institute for Materials Science, CHUN NING (JEANIE) LAU, University of California Riverside — There has been significant recent interest in black phosphorus as a candidate for future electronics applications, as it possesses both a layer- and band gap and a relatively high mobility (compared to other 2D candidates). However, black phosphorus' degradation in ambient conditions constitutes a major roadblock in future applications. As a potential solution for this problem we explore the effects of encapsulating black phosphorus between hexagonal boron nitride. We will present the effects of this heterostructure on both the stability and transport properties of thin black phosphorus devices.

8:12AM F1.00002 Electronic Structure and Rashba Spin-Orbit Coupling in Black Phosphorus, ZORAN POPOVIC, JAMSHID MORADI KURDESTANY, SASHI SATPATHY, Department of Physics, University of Missouri, Columbia, MO 65221 — We investigate the electronic structure of black phosphorus using both the first-principles density-functional methods as well as a tight-binding model. The electronic structure in the gap region is described by a tight-binding Hamiltonian keeping the nearest-neighbor hopping and the $p$ orbitals. The calculated bond-centered Wannier functions lead to the bonding picture in terms of the occupation of the $p_x$ bond orbitals along the phosphorous-phosphorous bonds. We find that a symmetry-breaking external electric field introduces a Rashba spin-orbit coupling; however, its magnitude is small, phosphorus being a small-Z atom. The magnitude is enhanced significantly if the phosphorus is replaced by the larger-Z bismuth.

8:24AM F1.00003 Probing Anisotropic Excitonic Wavefunctions in Black Phosphorus using Scanning Tunneling Microscopy, AYELET NOTIS, CARLOS ARGUELLO, ETHAN ROSENTHAL, ABHAY PASUPATHY, Columbia University — Black phosphorus is a layered, van der Waals semiconductor that has several structural similarities to graphite. Ultrathin black phosphorus (phosphorene) is conjectured to have a thickness-tunable band gap and high carrier mobility, making it attractive for electronic and optical applications. Unlike graphene which is a truly planar structure, phosphorene layers have a pronounced c-axis corrugation. This causes the electronic structure to be anisotropic, with different effective masses, carrier velocities and dielectric constants parallel and perpendicular to the direction of the corrugation. This has been predicted to lead to anisotropic wavefunctions for hydrogenic states and excitons in the material. In this talk, we present recent scanning tunneling microscopy and spectroscopy (STM and STS) studies investigating the topographic features and electronic structure of black phosphorus. We show that the primary charge defects are acceptors. By studying the local electronic structure in the vicinity of these defects that create hydrogenic states within the bandgap, we directly probe excitonic wavefunctions and their anisotropy in this material. We will describe spatially-resolved measurements of the bandgap and its inhomogeneity in the presence of defects.

8:36AM F1.00004 Highly Anisotropic and Robust Excitons in Monolayer Black Phosphorus, XIAOMU WANG, Yale Univ, AARON M. JONES, KYLE L. SEYLER, Univ of Washington, VY TRAN, Washington University, YICHEN JIA, Yale Univ, HUAN ZHAO, HAN WANG, Univ of Southern California, LI YANG, Washington University, XIAODONG XU, Univ of Washington, FENGNIAN XIA, Yale Univ — Recently, black phosphorus emerged as a promising new 2D material due to its widely tunable and direct bandgap, high carrier mobility and remarkable in-plane anisotropic electrical, optical and phonon properties. However, current progress is primarily limited to its thin-film form, and its unique properties at the truly 2D quantum confinement have yet to be demonstrated. Here, we reveal highly anisotropic and tightly bound excitons in monolayer black phosphorus using polarization-resolved photoluminescence measurements at room temperature. We show that regardless of the excitation laser polarization, the emitted light from the monolayer is linearly polarized along the light effective mass direction and centers around 1.3 eV, a clear signature of emission from highly anisotropic bright excitons. In addition, photoluminescence excitation spectroscopy suggests a quasiparticle bandgap of 2.2 eV, from which we estimate an exciton binding energy of around 0.9 eV, consistent with theoretical results based on first-principles. The experimental observation of highly anisotropic, bright excitons with exceedingly large binding energy not only opens avenues for the future explorations of many-electron effects in this unusual 2D material, but also suggests a promising future in optoelectronic devices such as on-chip infrared light sources.

8:48AM F1.00005 Anisotropic transient reflection spectrum of Black Phosphorus thin films, SHAOFENG GE, ZHIMING ZHANG, QIU JUN, Peking Univ, JUNKU LIU, China Academy of Space Technology, XUEFENG LIU, QINSHENG WANG, DONG SUN, Peking Univ — We present an experimental investigation on the ultrafast dynamics of the black phosphorus film, which is studied by femtosecond transient reflection spectroscopy. The results show that the transient reflection spectrum is polarization sensitive to both pump and probe laser pulse. The pump polarization has effect on the absorption of photons which determines the magnitude of the signal while the probe polarization has effect on the shape of the signal which indicates it correspond to different dynamics for different probe polarization. Moreover, the temperature dependent and pump power dependent has been performed.

8:00PM EE2.00004 Beating liquid helium: the technologies of cryogen-free superconducting magnets, JOHN BURGOYNE, Oxford Instruments Omicron NanoScience — Cryogen-free superconducting magnets have been available now for almost 15 years, but have only become standard commercial products in more recent years. In this review we will consider the pros and cons of dry design including superconducting wire development and selection, thermal budgeting, and the alternative methods for achieving magnet cooling.

Tuesday, March 3, 2015 8:00AM - 11:00AM – Session F1 DMP: Focus Session: Beyond Graphene - Phosphorene II 001A - Xiaomu Wang, Yale University
9:00AM F1.00006 Tiling Phosphorene, ZHEN ZHU, DAVID TOMANEK, JIE GUAN, Michigan State University — We introduce a scheme to categorize the structure of different layered phosphorene allotropes by mapping their non-planar atomic structure onto a two-color 2D triangular tiling pattern. In the puckered structure of a phosphorene monolayer, we assign atoms in “top” positions to dark tiles and atoms in “bottom” positions to light tiles. Optimum sp² bonding is maintained throughout the structure when each triangular tile is surrounded by the same number N of like-colored tiles, with 0 ≤ N ≤ 2. Our ab initio density functional calculations indicate that both the relative stability and electronic properties depend primarily on the structural index N. The proposed mapping approach may also be applied to phosphorene structures with non-hexagonal rings and 2D quasicrystals with no translational symmetry, which we predict to be nearly as stable as the hexagonal network.

9:12AM F1.00007 Few-Layer Phosphorene and Arsenene Allotropes: A Computational Study, DAVID TOMANEK, ZHEN ZHU, JIE GUAN, Michigan State University — There has been rising interest in layered compounds of group V elements including phosphorus and arsenic 2D semiconductors with a substantial band gap and a high carrier mobility. Our ab initio density functional calculations suggest the existence of multiple sp² bonded phosphorene and arsenene allotropes that are stable as free-standing monolayers. We have found that α-P (black), β-P (blue), γ-P and δ-P allotropes of phosphorus are similarly stable, but display a different electronic structure. The monolayer of grey arsenic has a very similar structure as blue phosphorene and also has a wide band gap. The fundamental band gap of the compounds depends sensitively not only on the allotrope, but also the number of layers, the stacking arrangement, and in-layer strain. The energy penalty to interconnect different allotropes of the same element is unusually low, which becomes particularly valuable in assembling heterostructures with well-defined metallic and semiconducting regions in one contiguous layer.

9:24AM F1.00008 Lattice Stacking Interactions: Comparisons between bilayer graphene and silicene, DAVID CAREY, NATHANAEL ROOME, Univ of Surrey — The stacking arrangement of atoms in elemental 2D materials, such as graphene and silicene, plays a crucial role in determining their structural, electronic, and vibrational properties. The weaker π bonding in silicene results in atomic buckling, and previously we have found linear band dispersion in a low atom buckling geometry with a Fermi velocity about 2/3 that of graphene and electron-phonon matrix elements are about a factor of 25 times smaller than in graphene [1]. Here we investigate the properties of different stacking configurations of bilayer silicene with those of bilayer graphene (BLG). In the case of BLG there are two stable configurations AA and AB stacking, with no atomic buckling present. In the case of bilayer silicene the presence of buckling and the different stacking arrangements results in a range of stable configurations. We calculate the frequencies of the IR and Raman active modes as a means to identify the different bonding and stacking configurations. This approach of fingerprint identification is applicable to other elemental layered materials.

9:36AM F1.00009 SnS₂: An Emerging Layered Metal Dichalcogenide Semiconductor, YUAN HUANG, PETER SUTTER, Center for Functional Nanomaterials, Brookhaven National Laboratory — Layered materials are of interest for new physics and due to their promise for device applications. Recent research has extended from graphene to transition metal dichalcogenides, with a strong focus on MoS₂. Here, we report a comprehensive study of a new group IV metal dichalcogenide, tin disulfide (SnS₂) [1]. Using exfoliated from bulk crystals, we establish the characteristics of single- and few-layer SnS₂ in optical and atomic force microscopy, Raman spectroscopy and transmission electron microscopy. Band structure study show that SnS₂ is an indirect gap semiconductor over the entire thickness range from bulk to a single layer. Ultrathin transistors screened by a liquid gate show promising characteristics, such as on-off current ratios >10⁶, high carrier mobilities (up to 230 cm² V⁻¹ s⁻¹) and near-ideal subthreshold swing. SnS₂ transistors are efficient photodetectors, but similar to other dichalcogenides they show a relatively slow response to pulsed irradiation, likely due to adsorbate-induced long-lived extrinsic trap states.

9:48AM F1.00010 Semiconducting Behavior, Schottky Barriers and Field Effect Transistors in Ultrathin Rhenium Disulfide, CHRIS CORBET, CONNOR MCCHELLAN, AMRITESH RAI, SUSHANT SONDE, EMANUEL TUTUC, SANJAY K. BANERJEE, The University of Texas at Austin — We report the fabrication, characterization, and device characteristics of exfoliated dual-gated ReS₂ Field Effect Transistors (FETs). All devices were created on few-layer crystals isolated using micro-mechanical exfoliation of source material grown by chemical vapor deposition. The devices were fabricated with e-beam evaporated alumina gate dielectric and Cr/Au top-gate. The dual-gated FETs demonstrated current saturation and voltage gain with a subthreshold swing of 148 mV/decade.

9:00AM F1.00011 Rhenium Disulfide Depletion-Load Inverter, CONNOR MCCHELLAN, CHRIS CORBET, AMRITESH RAI, HEMA C.P. MOVVA, EMANUEL TUTUC, SANJAY K. BANERJEE, The University of Texas at Austin — Many semiconducting Transition Metal Dichalcogenides (TMD) materials have been effectively used to create Field-Effect Transistor (FET) devices but have yet to be used in logic designs. We constructed a depletion-load voltage inverter using ultrathin layers of Rhenium Disulfide (ReS₂) as the semiconductor channel. This ReS₂ inverter was fabricated on a single micromechanically-exfoliated flake of ReS₂. Electron beam lithography and physical vapor deposition were used to construct Cr/Au electrical contacts, an Alumina top-gate dielectric, and metal top-gate electrodes. By using both low (Aluminum) and high (Palladium) work-function metals as two separate top-gates on a single ReS₂ flake, we create a dual-gated depletion mode (D-mode) and enhancement mode (E-mode) FETs in series. Both FETs displayed current saturation in the output characteristics as a result of the FET “pinch-off” mechanism and On/Off current ratios of 10⁶. Field-effect mobilities of 23 and 17 cm²V⁻¹s⁻¹ and subthreshold swings of 97 and 551 mV/decade were calculated for the E-mode and D-mode FETs, respectively. With a supply voltage of 1V, at low/ negative input voltages the inverter output was at a high logic state of 900 mV. Conversely with high/positive input voltages, the inverter output was at a low logic state of 500 mV. The inversion of the input signal demonstrates the potential for using ReS₂ in future integrated circuit designs and the versatility of depletion-load logic devices for TMD research.

10:00AM F1.000111 Rhenium Disulfide Depletion-Load Inverter, CONNOR MCCHELLAN, CHRIS CORBET, AMRITESH RAI, HEMA C.P. MOVVA, EMANUEL TUTUC, SANJAY K. BANERJEE, The University of Texas at Austin — Many semiconducting Transition Metal Dichalcogenides (TMD) materials have been effectively used to create Field-Effect Transistor (FET) devices but have yet to be used in logic designs. We constructed a depletion-load voltage inverter using ultrathin layers of Rhenium Disulfide (ReS₂) as the semiconductor channel. This ReS₂ inverter was fabricated on a single micromechanically-exfoliated flake of ReS₂. Electron beam lithography and physical vapor deposition were used to construct Cr/Au electrical contacts, an Alumina top-gate dielectric, and metal top-gate electrodes. By using both low (Aluminum) and high (Palladium) work-function metals as two separate top-gates on a single ReS₂ flake, we create a dual-gated depletion mode (D-mode) and enhancement mode (E-mode) FETs in series. Both FETs displayed current saturation in the output characteristics as a result of the FET “pinch-off” mechanism and On/Off current ratios of 10⁶. Field-effect mobilities of 23 and 17 cm²V⁻¹s⁻¹ and subthreshold swings of 97 and 551 mV/decade were calculated for the E-mode and D-mode FETs, respectively. With a supply voltage of 1V, at low/ negative input voltages the inverter output was at a high logic state of 900 mV. Conversely with high/positive input voltages, the inverter output was at a low logic state of 500 mV. The inversion of the input signal demonstrates the potential for using ReS₂ in future integrated circuit designs and the versatility of depletion-load logic devices for TMD research.

10:12AM F1.00012 ABSTRACT WITHDRAWN —
10:24AM F1.00013 Field effect vs. Hall mobility in back-gated multilayered InSe FETs1, SUKRIT SUCHARITAKUL, NICHOLAS GOBLE, Case Western Reserve University, U. RAJESH KUMAR, RAMAN SANKAR, FANG CHENG CHOU, YIT-TSONG CHEN, National Taiwan University, XUAN GAO, Case Western Reserve University — 2D graphene-like materials, not only are interesting for their exotic transport behavior but also, hold promises for their mechanical robustness and many possibilities in miniaturization. As one material belonging to this category, InSe is not only a promising candidate for optoelectronic devices [1] but also has potential for ultrathin field effect transistor (FET) with high mobility transport [2]. Recent investigation [2] showed that exfoliated InSe FET device on PMMA substrate can yield field effect mobility as high as 1000 cm²/Vs at room temperature. In this work, various substrates such as PMMA, bare SiO₂, patterned SiO₂, and Si₃N₄ were used to fabricate InSe FET devices. Through back gating and Hall measurement, the devices’ field effect mobility and intrinsic Hall mobility were extracted at various temperatures to study the dielectric effect on the material’s intrinsic transport behavior. Overall trend of the devices’ mobility was found to increase as the temperature is reduced due to reduced phonon scattering. The sample’s field effect and Hall mobilities overall over the range of 77-300K fall in the range of 0.5-2.0 × 10⁵ cm²/Vs, better than the transition metal-dichalcogenides.

3X.P.A.G. acknowledges NSF CAREER Award (grant number DMR-1151354).

10:36AM F1.00014 Quasiparticle and Optical Properties of Mono- and Bi-layer SnS2: A First-Principles GW and GW+BSE Study1, MENG WU, DIANA QIU, STEVEN G. LOUIE, Physics Department, UC Berkeley and Lawrence Berkeley National Lab — Unlike most semiconducting transition metal dichalcogenides, SnS₂, another layered metal dichalcogenide, is calculated within density functional theory to be an indirect bandgap semiconductor in both its bulk and monolayer forms. Experimental characterization of mono- and bi-layer SnS₂ has been performed, but the details of its quasiparticle and excitonic properties remain unclear. Thus, we employ ab initio GW and GW+BSE calculations to study the quasiparticle band structure and optical absorption spectrum, respectively, of mono- and bi-layer SnS₂ with spin-orbit coupling included throughout the calculations. We further investigate the character of excitonic states contributing to the optical spectrum.

10:48AM F1.00015 Thickness-dependent Dielectric Constant of Few-layer In₂Se₃ Nano-flakes , DI WU, Department of Physics, University of Texas at Austin, ALEXANDER PAK, Department of Chemical Engineering, University of Texas at Austin, YINGNAN LIU, XIAOYU WU, YUAN REN, Department of Physics, University of Texas at Austin, YU-HAO TSAI, Department of Chemical Engineering, University of Texas at Austin, MIN LIN, HAILIN PENG, College of Chemistry and Molecular Engineering, Peking University, Beijing China, GYEONG HWANG, Department of Chemical Engineering, University of Texas at Austin, KEJI LAI, Department of Physics, University of Texas at Austin — The dielectric constant or relative permittivity of active materials in electronic devices is a critical parameter for charging and screening effects. For layered two-dimensional (2D) materials, it is of great interest to understand how their dielectric constants depend on dimensionality and the arrangement of crystal lattices. Here we present both experimental and theoretical investigations on the dielectric constant of a few-layer In₂Se₃ nano-flakes grown on mica substrates by van der Waals epitaxy. A nondestructive microwave impedance microscope (MIM) is employed to simultaneously quantify the number of layers and local electrical and optical properties. The measured effective dielectric constant increases monotonically as a function of the thickness and saturates to the bulk value at around 6-8 quintuple layers. The same trend of layer-dependent dielectric constant is also revealed through a density functional theory approach. Our results of the dielectric response are expected to be significant for the applications of layered materials in nano-devices.

Tuesday, March 3, 2015 8:00AM - 11:00AM — Session F2 DMP: Focus Session: Beyond Graphene - Optics in 2D semiconductors II 001B - Sefaattin Tongay, Arizona State University

8:00AM F2.00001 Measurement of the optical dielectric function of transition metal dichalcogenide monolayers: MoS₂, MoSe₂, WS₂ and WSe₂ . ALBERT RIGOSI, YILEI LI, ALEXEY CHERNIKOV, XIAN ZHANG, HEATHER HILL, AREND VAN DER ZANDE, DANIEL CHENET, EN-MIN SHIH, JAMES HONE, TONY HEINZ, Columbia Univ — We report a determination of the complex in-plane dielectric function of monolayer MoS₂, MoSe₂, WS₂ and WSe₂, for photon energies from 1.5 – 3 eV. The results were obtained from reflection spectra using a Kramers-Kronig constrained variational analysis. From the dielectric functions, we obtain the absolute absorbance of the monolayers. We also provide a comparison of the dielectric function for the monolayers with the corresponding bulk materials.

8:12AM F2.00002 Optical generation and detection of pure valley current in monolayer transition metal dichalcogenides1, WENYU SHAN, JIANHUI ZHOU, DI XIAO, Department of Physics, Carnegie Mellon University — Recent years have seen a surge of interest in the manipulation of the valley index of Bloch electrons, largely driven by its potential applications as valleytronics. Transition metal dichalcogenides are new types of two-dimensional materials with spin-valley coupling, and show some promise as a realization of valleytronics. In this work, we propose a practical scheme to generate a pure valley current in monolayer transition metal dichalcogenides by one-photon absorption of linearly polarized light. We show that the pure valley current can be detected by either photoluminescence measurements or the ultrafast pump-probe technique. Our method, together with the previously demonstrated generation of valley polarization, opens up the exciting possibility of ultrafast optical-only manipulation of the valley index. The tilted field effect on the valley current in experiment is also discussed.

8:24AM F2.00003 Photoluminescence and photocurrent measurement in monolayer MoTe₂, YA-QING BIE, GABRIELE GROSSO, DMITRI EFETOV, EFREN NAVARRO-MORATALLA, DIRK ENGLUND, PABLO JARILLO-HERRERO, Massachusetts Inst of Tech-MIT — 2D transition metal dichalcogenides (2D-TMD), such as MoS₂, WS₂, WSe₂, MoSe₂, have been verified with many remarkable physical properties including the indirect to direct band transition and valley dependent spin polarization. As one of the 2D-TMD family member, monolayer 2H-MoTe₂ is proved to be a direct bandgap semiconductor with strong spin orbital interaction and a significantly low bandgap ~ 1.10eV. However, the effect of the enhanced coulomb interaction arising from reduced dielectric screening in monolayer MoTe₂ has yet to be experimentally demonstrated. Here we employ the near infrared (NIR) photoluminescence and photocurrent measurement to study the quasi-particle interactions at different carrier concentration. This study sheds light on manipulating excitons in MoTe₂ and designing highly efficient NIR optoelectronic devices.
8:36 AM F2.00004 Excitons and Valley Dynamics in MoS$_2$, MoSe$_2$ and WSe$_2$ monolayers$^1$. XAVIER MARIE, Universite de Toulouse, INSA-CNRS-UPS, LPCNO — We have investigated the optical and valley properties for both neutral and charged excitons in transition metal dichalcogenide monolayers (ML): MoS$_2$, MoSe$_2$ and WSe$_2$. In WSe$_2$ MLs, we have combined linear and non-linear optical spectroscopy (one- and two-photon PLE, Second Harmonic Generation spectroscopy) to uncover the excited states of the neutral exciton. The clear identification of s and p exciton excited states combined with first principle calculations allows us to determine an exciton binding energy of the order of 600 meV. The deviation of the excited exciton spectrum from the standard Rydberg series will be discussed. Moreover we show that exciton valley coherence can be achieved following resonant one or two photon excitation [1]. The neutral and charged exciton dynamics have been measured by time-resolved photoluminescence and pump-probe Kerr rotation dynamics [2,3]. The neutral exciton valley polarization decays within about 6 ps, as a result of the intervalley coupling due the strong electron-hole Coulomb exchange interaction in bright excitons. The temperature dependence is well explained by the developed theory, taking into account the long-range exchange interaction [4]. In contrast the valley polarization decay time for the charged exciton is much longer ($\sim$ 1 ns) [5]. Finally we will compare the exciton dynamics in WSe$_2$ mono and bi-layers [6].

$^1$We acknowledge partial funding from Programme Investissements d’Avenir ANR-11- IDEX-0002-02, reference ANR-10-LABX-0037-NEXT, ERC Grant No. 306719 and ANR MoS2ValleyControl.

9:12 AM F2.00005 Imaging the grain boundaries in polycrystalline MoS$_2$ monolayer by non-invasive second harmonic generation. JINXIN CHENG, TAO JIANG, Fudan University, QINGQING JI, YANFENG ZHANG, Peking University, XINGAO GONG, WEI-TAO LIU, SHIWEI WU, Fudan University — Atomically thin transition metal dichalcogenide monolayers have showed intriguing physical properties for high performance quantum electronics. In order to utilize them in technological applications at industrial scale, mass production of this two dimensional materials via chemical vapor deposition (CVD) is demanded and urged. Despite the success of growing large-scale monolayer, limited grain size and emergence of grain boundary remain as the major hurdle being single crystalline sheets. To resolve this issue, it is necessary to image the grain and grain boundary, and further understand their formation with statistical significance. Here we used second harmonic generation (SHG) microscopy, a noninvasive coherent imaging technique, to image the grain and grain boundary in CVD grown monolayer molybdenum disulfide. The destructive interference between neighboring grains enabled us to pinpoint the location of grain boundary; the anisotropic polarization pattern permitted us to determine the type of grain boundary. Furthermore, this high-throughput characterization technique allows statistical analysis of hundreds of grain and grain boundary, unambiguously revealing that the CVD growth mechanism of monolayer MoS$_2$.

9:24 AM F2.00006 Tunable polaritons from plasmon-phonon coupling in hyperbolic media. SIYUAN DAI, Univ of California - San Diego, QIONG MA, Massachusetts Institute of Technology, SHOU-EN ZHU, Delft University of Technology, Netherlands, MENGKUN LIU, University of California, San Diego, TROND ANDERSEN, Massachusetts Institute of Technology, ZHE FEI, MICHAEL GOLDFLAM, MARTIN WAGNER, Univ of California - San Diego, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, MARK THIEMENS, Univ of California - San Diego, FRITZ KEILMANN, Ludwig-Maximilians-Universität and Center for Nanoscience, G.C.A.M. JANSSEN, Delft University of Technology, Netherlands, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology, MICHAEL FOGLER, D.N. BASOV, Univ of California - San Diego — Using infrared nano-imaging and nano-spectroscopy, we report on the tunable hyperbolic response in heterostructures comprised of a monolayer graphene deposited on hexagonal boron nitride (G-hBN). Electrostatic gating of the top graphene layer allows for modification of the wavelength and intensity of hyperbolic phonon polaritons in bulk hBN. When compared with the pristine hBN polaritons, the graphene modified ones exhibit a longer wavelength in the Type II hyperbolic region and shorter wavelength in the Type I region. Because of this modification, we achieve a 90% increase of the propagation length for graphene modified polaritons. This is a proof of principle of the tunable hyperbolic response in heterostructures comprising of G-hBN.
Intrinsic Exciton Linewidth in Monolayer Transition Metal Dichalcogenides

KAI HAO, GALAN MOODY, CHANDRIKER DASS, The University of Texas at Austin, CHANG-HSIAO CHEN, Institute of Atomic and Molecular Sciences, Academia Sinica, LAIN-JONG LI, King Abdullah University of Science & Technology (KAUST), AKSHAY SINGH, KHA TRAN, The University of Texas at Austin, GENEVIEVE CLARK, XIAODONG XU, University of Washington, GUNNAR BERGÄUSER, ERMIN MALIC, ANDREAS KNORR, Technische Universität Berlin, XIAOQIN LI, The University of Texas at Austin — Excitons in monolayer transition metal dichalcogenides (TMDCs) exhibit exceptionally large binding energy, strong optical absorption, and spin valley coupling. These characteristics make TMDCs a promising system for optoelectronics and valleytronics. An important yet unknown property of excitons in TMDCs is the intrinsic homogeneous linewidth, which reflect radiative recombination and irreversible dissipative decay. Here, we use optical coherent two-dimensional spectroscopy to reveal the exciton homogeneous linewidth in monolayer CVD grown Tungsten Diselenide (WSe2). With excitation density and temperature dependent measurements, exciton-exciton interaction and exciton-phonon interactions are quantitatively evaluated. Extrapolating to zero density and temperature, we obtain a residual homogeneous linewidth of \( \sim1.5 \text{ meV} \), which places a lower bound of 0.2 ps on the exciton radiative lifetime. This result is consistent with microscopic calculations, which suggest that fast radiative decay of delocalized excitons arises from their large oscillator strength.

We acknowledge AFOSR and NSF for funding.

Absorption spectrum and ultrafast response of monolayer and bilayer transition-metal dichalcogenides

VOLODYMYR TURKOWSKI, ALFREDO RAMIREZ-TORRES, TALAT S. RAHMAN, Department of Physics, University of Central Florida — We apply a combined time-dependent density functional theory and many-body theory approach to examine the absorption spectrum and nonequilibrium response of monolayer and bilayer MoS2, MoSe2, WS2 and WSe2 systems. A previous work we have already demonstrated [1] that the binding energies of these states in the monolayer systems are large which makes them available for room temperature applications. We analyze the possibility of ultrafast electron-hole separation in bilayer systems through inter-layer hole transfer, and show that such a possibility exists, in agreement with experimental observations. For doped systems we consider the possibility of Mahan excitonic states in monolayers and show that the binding energy of these states for the order of 10 meV. We perform a detailed analysis of the relaxation of band monolayers excited by ultrafast laser pulse by taking into account electron-phonon scattering effects, and demonstrate that ultrafast (10-100ps) processes, including luminescence, may be relevant for these materials.

Second-Harmonic Generation in a Phase-Match Free Nonlinear 2D Crystal

Mervin Zhao, Ziliang Ye, Yu Ye, Hanyu Zhu, Yuan Wang, Xiang Zhang, Univ of California - Berkeley — The second harmonic generation (SHG) produced from two-dimensional atomic crystals have been utilized to great effect in studying the grain boundaries and electronic structure of such crystals. However, the SHG in many transition metal dichalcogenides (TMDCs) only occur in odd numbered layers due to their noncentrosymmetric nature, limiting the application of their SHG. Here, we probe the SHG from the bulk noncentrosymmetric molybdenum disulfide (MoS2). Whereas the commonly studied 2H crystal phase’s antiparallel dipoles in adjacent layers give an oscillatory SH response, the parallel dipoles of each atomic layer in the 3R phase constructively interfere to amplify the second harmonic intensity. Due to this interference, we observed the phase-match free condition yielding a quadratic dependence between the intensity and layer number. Additionally, we probed the layer evolution of the A and B excitonic transitions in 3R-MoS2 using SHG spectroscopy. We find exciton splittings distinct from 2H-MoS2, resulting from the different interlayer interactions of the two polytypes.

Light matter interactions in 2D transitional metal dichalcogenides: excitonic emission and valley splitting

Ting Yu, Division of Physics and Applied Physics, School of Physical and Mathematical Sciences, Nanyang Technological University, 637371, Singapore — Two-dimensional (2D) semiconductors, such as transitional-metal-dichalcogenide monolayers (TMD 1Ls), have aroused great interest because of the underlying fundamental physics (e.g. many body effects and wealth excitonic states) and the promising optoelectronic applications such as light-emitting diodes and solar cells. Here, we report excitonic emission and valley splitting of monolayer WS2 and MoS2 under electrical, optical and magnetic manipulation. Through electrical and optical injection of charge carriers, tunable excitonic emission has been realized due to interplay of various excitonic states, and basic binding energies of trions have been extracted. At low temperature, the Zeeman shifts of excitons and trions have been determined by polarization-dependent photoluminescence measurements under perpendicular magnetic fields, which reveal the breaking of valley degeneracy. Our studies provide the fundamental understanding on large excitonic and unique valleytronic effects in TMD 1Ls. Moreover, we also develop multiple strategies for managing the light emission, which opens up many possibilities for improving the performance and creating the multifunction of 2D TMD-based light emitting applications.

Optical Properties and Band Gap of Single- and Few-Layer MoTe2 Crystals

Ozgur Burak Aslan, Columbia Univ, Claudia Ruppert, Technische Universität Dortmund, Tony Heinz, Columbia Univ — Single- and few-layer crystals of exfoliated MoTe2 have been characterized spectroscopically by photoluminescence, Raman scattering, and optical absorption measurements. We find that MoTe2 in the monolayer limit displays strong photoluminescence. On the basis of complementary optical absorption results, we conclude that monolayer MoTe2 is a direct-gap semiconductor with an optical band gap of 1.10 eV. This new monolayer material extends the spectral range of atomically thin direct-gap materials from the visible to the near-infrared.

Supported by the NSF through Grant DMR-1124894 for sample preparation and characterization by the O’/ce of Naval Research for analysis. C.R. acknowledges support from the Alexander von Humboldt Foundation.
8:36AM F3.00002 Imaging current in quantum spin Hall insulator InAs/GaSb

ERIC SPANTON, Stanford Institute for Materials and Energy Sciences — Scanning superconducting quantum interference device (SQUID) microscopy allows us to visualize how currents flow in materials by imaging magnetic fields. I will give an overview of our technique and focus on the quantum spin Hall edge states we observed in Si-doped InAs/GaSb quantum wells. The main feature of 2D topological insulators is the topologically-protected edge modes that are a result of their special band structure. We used a SQUID to image current in the edge modes, which are present when the chemical potential lies in or near the insulating gap. The unique spin-texture of the edge states restricts how electrons can backscatter, leading to ballistic transport in small enough devices. In more resistive, longer devices, the backscattering becomes weaker, and the resistance of the edges due to backscattering is flat and does not match any of the allowed backscattering mechanisms which have been theoretically investigated.

9:12AM F3.00003 Magnetotransport in the topological insulator candidate InAs/GaSb

THOMAS IHN, ETH Zurich — InAs/GaSb quantum wells have been proposed as an electrically tunable two-dimensional topological insulator system. Transport can be tuned from the electron to the hole regime where the Fermi-energy crosses the hybridization gap, where topological edge states are predicted to exist. We have investigated this material system using dc magneto-transport measurements at cryogenic temperatures. In high-mobility large-area samples, a resistivity maximum is observed at the charge-neutrality point. It increases strongly with magnetic field. At the same time, a strong non-local resistance appears which we describe by a model of helical and dissipative quantum Hall edge channels shorted by residual bulk conductivity. In an attempt to reduce the bulk conductivity, we have grown samples with slightly impure Gallium. Large-area devices show a peak resistance at the charge neutrality point enhanced by almost three orders of magnitude compared to the high-mobility samples. A requirement for observing the topological insulator state is the fabrication of devices smaller than the inelastic scattering length. We have developed an optimized fabrication recipe by comparing samples produced with wet and dry etching. The former turns out to be favorable for obtaining smooth edge potentials and a width-independent electron density. With this fabrication technology we have produced small-area Hall bar devices with widths and contact separations in the micrometer range. Surprisingly these devices do not exhibit a resistance maximum at charge neutrality like large-area devices, but rather show a plateau-like local resistivity at negative gate voltages. At the same time the Hall density saturates in these devices at finite electronic densities instead of turning into the edge regime, and a systematic non-local resistance signal appears in all devices. We discuss these findings in view of conflicting fabrication issues or the proposed helical edge modes.

9:48AM F3.00004 One-dimensional topological edge states of bismuth bilayers

ILYA DROZDOV, Princeton University — A quantum spin Hall (QSH) state of matter, also known as a two-dimensional (2D) topological insulator, is distinguished by one-dimensional (1D) chiral edge modes propagating along the perimeter of the system without backscattering. Among the first systems predicted to be a 2D topological insulator are bilayers of Bismuth (Bi) [1]. Despite being a well-known QSH candidate system which should in principle be accessible to scanning tunneling microscopy (STM) techniques, the experimental attempts carried out so far have suffered from edge imperfections and coupling of the edge states to the substrate. In this talk I will present recent STM experiments on bulk Bi crystals [2] which show that a subset of the predicted Bi-bilayers’ topological edge states are in fact decoupled from the states of the substrate which makes it possible to probe the 1D electronic channels experimentally using spectroscopic STM techniques. Spectroscopic features observed in STM are directly compared to model calculations. Furthermore, unique electronic structure of topological edge modes of Bi allows for quantum interference of edge-mode quasi-particles in confined geometries, which is visualized by STM and allows to reveal the absence of backscattering of electrons in the 1d edge channels - the key property of the QSH systems resulting in their remarkable coherent propagation. Additionally, I will present comparison to theoretical models of the edge state along with supporting experimental study of Bi(111) surface state’s electronic structure.

10:24AM F3.00005 Quantum spin Hall effect in InAs/GaSb bilayers subject to exciton condensation and magnetic field

DMITRY PIKULIN, Department of Physics and Astronomy and Quantum Matter Institute, University of British Columbia, Vancouver, Canada — Motivated by the recent experiments we study the phase diagram of the bilayer InAs/GaSb quantum wells in the presence of electron-electron interactions. The interactions lead to formation of thermodynamically stable exciton condensate. We show that in the presence of condensate but without external magnetic field the bilayer can be in three distinct insulating phases: trivial, topological, and spontaneously breaking time-reversal symmetry ones. In the applied magnetic field the bilayer remains gapped and undergoes a series of phase transitions changing from quantum spin Hall-like state to trivial insulator. We suggest transport and spectroscopic measurements for future experiments to substantiate our picture.

8:00AM F4.00001 Light: A Spectrum of Utility, the 2014-2015 Society of Physics Students Science Outreach Catalyst Kit

MARK SELLERS, Rhodes College, KEARNS LOUIS-JEAN, Xavier University of Louisiana, SOCIETY OF PHYSICS STUDENTS COLLABORATION, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY COLLABORATION — The Science Outreach Catalyst Kit (SOCK) is a set of activities and demonstrations designed to bolster the outreach programs of undergraduate Society of Physics Students (SPS) chapters, creating the framework for a lasting outreach program. Targeted for students ranging from kindergarten to high school, the SOCK allows students to actively engage in hands-on activities that teach them scientific skills and allow them to exercise their natural curiosity. The 2014-2015 SOCK united themes from the 2014 International Year of Crystallography and the 2015 International Year of Light to explore how light is used as a tool every day. This presentation will discuss the contents of the SOCK, which contains a large assortment of materials, such as diffraction glasses, polarizers, ultraviolet flashlights, etc. and describe the research and development of the activities. Each activity explores a different light phenomenon, such as diffraction, polarization, reflection, or fluorescence. These activities will promote critical thinking and analysis of data.

8:12AM F4.00002 ABSTRACT WITHDRAWN –
8:24AM F4.00003 Capacitively-coupled differential position detection in the development of a high-sensitivity torsion balance. CHARLES RACKSON, ALEX WATT, WOO-JOONG KIM, Seattle University, SEATTLE UNIVERSITY TEAM — We report on the development of a high-sensitivity torsion balance using a capacitively-coupled Wheatstone Bridge. The torsion balance will be employed to measure the Casimir Force, with a particular emphasis on the surface patch effects that are ubiquitous on metallic surfaces. We will show that these effects also play a significant role in another class of experiments involving quantum-point contacts between two metal wires.

8:36AM F4.00004 Mapped grid methods for Numerov propagation. CHRISTOPHER MADRID, JUAN BLANDON, Angelo State University, GREGORY PARKER, University of Oklahoma — The Computational toll of solving the Schroedinger equation for certain atomic systems is sometimes prohibitively heavy. We present a grid-mapping method which decreases the number of points needed, and at the same time maintains or increases accuracy for three-atom scattering. By developing a hyperspherical mapping method for Numerov propagation, scattering cross-sections can be found for a large range of energies. This method is useful for systems with very shallow bound states where the mapping will give a large number of data points inside the potential well while decreasing the number of points at a large hyper-radius. The change in grid sizes is controlled by a mapping function that is easily modified. Results are shown for scattering in the HeH₂ and HNe₂ systems.

8:48AM F4.00005 Simulation of Planetary Formation using Python. JAMES BUFKIN, DAVID BIXLER, Angelo State University — A program to simulate planetary formation was developed in the Python programming language. The program consists of randomly placed and massed bodies surrounding a central massive object in order to approximate a protoplanetary disk. The orbits of these bodies are time-stepped, with accelerations, velocities and new positions calculated in each step. Bodies are allowed to merge if their disks intersect. Numerous parameters (orbital distance, masses, number of particles, etc.) were varied in order to optimize the program. The program uses an iterative difference equation approach to solve the equations of motion using a kinematic model. Conservation of energy and angular momentum are not specifically forced, but conservation of momentum is forced during the merging of bodies. The initial program was created in Visual Python (VPython) but the current intention is to allow for higher particle count and faster processing by utilizing PyOpenCl and PyOpenGl. Current results and progress will be reported.

9:00AM F4.00006 Effects of Turbulence on Cosmic Ray Propagation in Protostar Systems. DONOVAN HERBERT, MARCO FATUZZO, Xavier University, FRED ADAMS, University of Michigan — The magnetic field associated with young stellar objects is expected to have an hour-glass geometry, i.e. the magnetic field lines are pinched together in the equatorial plane surrounding the forming star but are subsumed smoothly onto a background field at large distances. In such a structure, incoming cosmic rays experience both a funneling effect, which acts to magnify the flux impinging on the circumstellar disk, and a magnetic mirroring effect that acts to reduce that flux. These effects nearly cancel out for simple underlying magnetic field structures with respect to the leading order. However, the environments surrounding young stellar objects are expected to be highly turbulent and, thus, act to complicate these effects. We consider here how the presence of magnetic field fluctuations affects the process of magnetic mirroring, and thereby changes the flux of cosmic rays striking the circumstellar disks. These results may have significant consequences for the ionization fraction of the disk, which in turn dictates the efficiency with which disk material can accrete onto the central object.

9:12AM F4.00007 Transverse distortion effects on the Kasteleyn and KDP transition in spin ice. CURTISLEE THORNTON, TRINANJAN DATTA, Georgia Regents University — Geometrically frustrated pyrochlore oxides containing a rare-earth ion and a transition metal ion form a network of corner-sharing tetrahedra. Prominent examples include Dy₂Ti₂O₇ and Ho₂Ti₂O₇. Magnetic frustration in these compounds suppresses the formation of a long-range ordered ground state resulting in an exotic phase of matter called spin ice. Elucidating the role of external perturbations such as pressure and magnetic field is an important step towards understanding the novel KDP and Kasteleyn phase transitions arising in these classical spin ice materials. Utilizing an analytical approach based on the Husimi tree approximation, we investigate the effects of both transverse and uniaxial pressure distortion of the spin ice tetrahedra on both the KDP and Kasteleyn transition in the presence of an external magnetic field. Compared to the uniaxial distortion scenario, we find that including the effects of transverse distortion leads to further suppression of magnetization and heat capacity in both the Kasteleyn and KDP cases.

9:24AM F4.00008 ABSTRACT WITHDRAWN

9:36AM F4.00009 ABSTRACT WITHDRAWN

9:48AM F4.00010 Super Atomic Molecular Orbitals of Variably Protonated Symmetric Molecules. TANNER LATTA, KYLE DRAKE, G.P. ZHANG, Indiana State Univ — The molecular structure of symmetric molecules creates conducive conditions for delocalized orbitals. The π bonding delocalizes the valence electrons away from the individual molecules. These delocalized valence electrons allow the symmetric molecules to adapt the characteristics analogous to that of an individual atom, creating Super Atomic Molecular Orbitals, SAMOs. The symmetric molecule is then comparable to that of an individual atom with its regular atomic orbitals. When these symmetric molecules are protonated in any form, there are notable changes in the shapes of the Super Atomic Molecular Orbitals. We use the Density Functional Theory with a grid mesh method to compute the wavefunctions of these SAMOs. Then we examine the Rydberg States of these symmetric molecules through the calculated Eigenstates, and find an important trend in the filling of the SAMOs as well as relationships between variably protonated symmetric molecules. This is potentially very useful to understanding the photovoltaic effect in the fullerene- based solar cells.

10:00AM F4.00011 Comparative Study of Wavelet Basis Set and Finite-Difference Time-Domain Methods for the Time Propagation of Quantum and Classical Systems. EWA NOWARA, IRWIN GOLDBERG, St. Mary’s University (San Antonio, Texas), BRUCE JOHNSON, Rice University, RICHARD LOMBARDINI, St. Mary’s University (San Antonio, Texas) — An extensive comparison in error accumulation between a grid point method, in particular finite-difference time-domain (FDTD), and a basis set method using Daubechies wavelets is presented in the modeling of electromagnetic (EM) pulses (classical) in inhomogeneous media and quantum (QM) wavepackets interacting with various potentials. It is demonstrated that the density of wavelet functions needed to attain a certain level of accuracy is far less than needed for grid points (FDTD) translating to savings in computational memory and processing. Since neighboring wavelet basis functions have overlapping support, fictitious wavelet projections created by derivative matching (T.A. Driscoll and B. Fornberg) will be used to handle Dirichlet boundary conditions in both the EM and QM cases in order to prevent rapid error growth.
Anomaly.

Defects we consider break charge conservation symmetry and thereby provide insight into the anomalous nature of the 2/3 edge going beyond the U(1) chiral anomaly. In this talk we investigate the anomalous structure of the 2/3-edge state by testing its non-perturbative robustness to a particular type of defect. When charge conservation is broken, one might expect that there is something fundamentally anomalous about the ν = 2/3 state. However, we have protected gapless edge modes even if all symmetries are broken, including charge conservation. Since the edge protection for the 2/3 state exists even when charge conservation is broken, one might expect that there is something fundamentally anomalous about the ν = 2/3 edge beyond the usual U(1) chiral anomaly. This result contributes to understanding the relationship between temperature modification and the transverse modes of VCSEL.

10:24 AM F4.00013 Dissipative coherence of a superconducting qubit for microwave detection

TATCHER HSIEH, KATER MURCH, Washington University — Recent progress in coherent control and measurement of superconducting qubits has opened avenues to previously inaccessible regimes of metrology. Here we realize a detection scheme for microwave signals. Our scheme utilizes a superconducting transmon qubit coupled to a three-dimensional cavity. When subjected to a weak drive signal near resonance, the qubit equilibrates to a steady state coherence that arises from the competition between driven and dissipative dynamics. By measuring this steady state coherence with quantum state tomography, we map the quantum state to characteristics of the drive signal with shot noise-limited resolution. We report detection figures of merit and discuss applications to itinerant microwave fields.

10:36 AM F4.00014 Optimized reconstruction methods for imaging squeezed microwave states

ADITYA VENKATRAMANI, DAVID TOYLI, QNL, University of California, Berkeley, SAMUEL BOUTIN, Département de Physique, Université de Sherbrooke, ANDREW EDDINS, QNL, University of California, Berkeley, ALEXANDRE BLAIS, Département de Physique, Université de Sherbrooke, IRFAN SIDDIQI, QNL, University of California, Berkeley — Superconducting parametric amplifiers (paramps) are essential tools for quantum-limited measurement of superconducting qubits. A central feature of these devices is that they can ideally amplify information in one quadrature without adding noise while simultaneously squeezing fluctuations in the orthogonal quadrature. At microwave frequencies, moment-based reconstruction techniques are commonly utilized to image such squeezed states. Motivated by a desire to characterize and improve paramp squeezing performance, we have developed simulations to understand the application of these reconstruction techniques, with a focus on determining their performance at large signal gains where the amplifier output field becomes non-Gaussian. We make comparisons of this analysis to experimental data. We have also developed a complementary imaging method based on deconvolution techniques that is effective for high signal-to-noise ratios. This method benefits from a simple implementation and provides a best estimate for the output field Q function. We discuss experimental implementations of these techniques facilitated by the use of a broadband parametric amplifier.

10:48 AM F4.00015 Toroidal moment contributions to the multiferroic acoustic susceptibility

ALEXANDER PRICE, TRINANJAN DATTA, Georgia Regents University — We consider the effects of toroidal moment corrections to the acoustic susceptibility tensor of a material that is simultaneously ferroelectric and a canted antiferromagnet (multiferroic). Using the Landau-Lifshitz equation of motion for the magnetization, the Landau-Khalatnikov relaxation equation for the electric polarization, and an equation of motion for the toroidal moment coupling, we find that the previously vanishing susceptibility components in the multiferroic channel are now non-zero. Additionally, the toroidal corrections give rise to non-zero, asymmetric susceptibility components in the magnetic, electric, and multiferroic channels with both real and imaginary corrections to the susceptibility.

1 GRU Small Grants Program
8:36AM F5.00004 Role of the continuum states in the thermodynamics of the \( \nu = 1/3 \) fractional quantum Hall effect, PETER RAUM, VITO SCAROLA, Virginia Tech — The high energy excitations of fractional quantum Hall states dictate thermodynamics at experimentally accessible temperatures. We construct a microscopic formalism for the thermodynamics of the \( \nu = 1/3 \) Laughlin state as generated by a hard core repulsive model. We use exact diagonalization of the hardcore repulsive model for small system sizes to gather statistics for the excitations. These results are extrapolated to the thermodynamic limit using an ansatz partition function that captures the ground state, low-energy excitations, and high energy continuum states. The continuum states are found to play an important role at low temperatures, even below the characteristic gap.

8:48AM F5.00005 Anisotropic gapped excitation modes in the SLL from Light Scattering\(^1\), ARON PINCZUK, Columbia University, URSULA WURSTBAUER, TU München, ANTONIO L. LEVY, Columbia University, JOHN WATSON, GEOFF C. GARDNER, MICHAEL J. MANFRA, Purdue University, KEN WEST, LOREN PFIEFFER, Princeton University — The fascinating interaction physics in the SLL supports the emergence of exotic quantum phases and unconventional FQHE states as e.g. anisotropic, possibly nematic, FQHE states at \( \nu = 5/2 \) [1] and \( \nu = 7/3 \) [2]. We explore the fascinating physics of these states by studying low-lying collective excitation spectrum from resonant inelastic light scattering (RILS) experiments. Here, we focus on the filling factor range \( 5/2 > \nu > 2 \). We observe clear signatures from gapped modes that weaken with increasing temperature for several filling factors that are known from transport to be incompressible FQHE states like \( \nu = 2+1/2, 2+3/8 \) and \( 2+1/3 \). These modes exhibit a clear dependence on filling factor, unambiguously uncovering incompressible quantum states. The lowest mode exhibits a remarkably strong polarization dependence that can be interpreted as fingerprint for the lack of rotational symmetry of the ground state. This interpretation of the observed RILS mode would support nematic FQHE states in the SLL.

Spontaneous valley ordering in SnTe (001) surface states

Ming Xie, Department of Physics, The University of Texas at Austin, XIAO LI, Condensed Matter Theory Center, University of Maryland, FAN ZHANG, Department of Physics, The University of Texas at Dallas, ALLAN MACDONALD, Department of Physics, The University of Texas at Austin — In this work we study the spontaneous valley ordering in SnTe surface states. SnTe is a topological mirror insulator in which the bulk mirror symmetry allows robust surface states to appear on certain surfaces like (001), (111) and (110). These surface states provide a new platform to study multi-flavor Landau level physics in the quantum Hall regime. Attention has been drawn to the (001) surface by a recent experimental observation of a four-fold degenerate Landau level formed at zero energy [Science 341, 1496 (2013)]. This degeneracy arises because the single-particle bandstructure at low energies consists of four surface Dirac cones. In the presence of electron-electron interactions, however, this four-fold degeneracy is expected to be lifted. In this work we construct a theory to show that at all integer filling factors between -2 and +2 the ground state is a gapped quantum Hall state. We further demonstrate that these ground states are valley nematic phases, and discuss some experimental consequences.

Transmission Measurements in a Low Density Two-Dimensional Electron Gas in an Array of Antidots

Chi Zhang, Jian Mi, Peking University, Loren Pfieffer, Ken West, Princeton University — Under high magnetic fields, the microwave conductivity of a two-dimensional electron system containing an antidot array with fractional Landau filling was discovered [1]. On the other hand, at low temperature T=0.3 K, we have measured the transmission in the low density (n=0.6x10^11 cm^-2) ultraclean GaAs/AlGaAs sample with an array of antidots. In our measurements, we observed an interesting feature around the ν=1, 2, which may be related to the charged edge mode in the integer quantum Hall regime. [1] P. D. Ye, L. W. Engel, D. C. Tsui, J. A. Simmons, J. R. Wendt, G. A. Vawter, and J. L. Reno, Phys. Rev. B, 65, 121305 (2002).

Critical exponent in a projected lattice model for integer quantum Hall plateau transitions

Qiong Zhu, Xin Wan, Zhejiang University, R.N. Bhatt, Princeton University — Motivated by the recent numerical studies on the Chalker-Coddington network model with a larger-than-expected localization length critical exponent, we revisited the exponent calculation in the disordered Hofstadter model. We project the Hamiltonian into the lowest subband, which is the lattice analog of the lowest Landau level, and calculate the Chern number for individual eigenstates to analyze their localization properties. We compare the finite-size scaling of the total number of the conducting states, the width of the distribution of the conducting states, and the Hall conductance. We confirm that earlier calculations on the lattice model have also underestimated the localization length critical exponent and discuss the manifestation of the leading irrelevant scaling field.

Quantum Hall plateau transitions in the bulk entanglement spectrum

Xin Wan, Qiong Zhu, Zhejiang University, Guang-Ming Zhang, Tsinghua University — We discuss an alternative route to access the quantum Hall transitions via studying the so-called bulk entanglement spectrum. By partitioning the pure integer quantum Hall ground state in a checkerboard fashion we show the emergence of a quantum network with bulk gapless excitations at the Brillouin zone center without fine-tuning. The emergent critical theories have a one-to-one correspondence to the Chern number characterization of the original ground states [arXiv:1409.4916]. For example, the resulting critical theory for the ν=1 state is the (2+1)-dimensional relativistic quantum field theory characterized by a single Dirac cone spectrum and a pair of fractionalized zero-energy states. For the ν=2 state the critical theory exhibits a quadratic band crossing. The effect of disorder on the transitions will be presented.

Microwave Absorption of Edge States in Quantum Hall Droplets

Jie Zhang, Lingjie Du, Ruiyuan Liu, Ruirui Du, Department of Physics and Astronomy, Rice University, Houston, Texas, Loren Pfieffer, Ken West, Department of Electrical Engineering, Princeton University — Microwave absorption spectroscopy has been proposed as a unique tool in studies of edge physics of quantum Hall droplets (Cano et al., Phys. Rev. B 88, 165305 (2013)). In our ongoing experiment we pattern co-planar waveguide (CPW) and micrometer-size discs on the same chip of a high-mobility GaAs/AlGaAs two-dimensional electron gas. The CPW is placed inside a broadband sample holder, which is fitted with millimeter wave coax cables. The whole setup is top-loaded into a 300 mK helium3 cryostat equipped with a superconducting solenoid. In this talk the construction of the spectrometer, preliminary data, and discussions will be presented.

Thermal Hall Effect and Geometry with Torsion

Alexander Abanov, Andrey Gromov, Stony Brook University — We formulate a geometric framework that allows to study momentum and energy transport in non-relativistic systems. We show how momentum and energy current can be computed as responses to variations in geometry. It turns out that in the absence of Lorentz invariance the appropriate geometry is not Riemannian, but the Newton-Cartan geometry with temporal torsion. Our approach generalizes the classic Luttinger’s formulation of thermal transport. In particular, we clarify the geometric meaning of the fields conjugate to energy and energy current. These fields describe the geometric background with non-vanishing temporal torsion. We use the developed formalism to construct the equilibrium partition function of a non-relativistic system coupled to the NC geometry in 2+1 dimensions and to derive various thermodynamic relations. As a by-product we argue that the bulk thermal Hall conductance is not topologically protected.

Achromatic metasurface optical components by dispersive phase compensation

Federico Capasso, Harvard University — The replacement of bulk refractive elements with flat ones enables the miniaturization of optical components required for integrated optical systems. This process comes with the limitation that planar optics suffers from large chromatic aberrations due to the dispersion of the phase accumulated by light during propagation. We show that this limitation can be overcome by compensating the dispersion of the propagation phase with the wavelength-dependent phase shift imparted by a metasurface. We demonstrate dispersion-free multi-wavelength dielectric metasurface deflectors in the near-infrared and design an achromatic flat lens in the same spectral region. Our design is based on low-loss coupled dielectric resonators, which introduce a dense spectrum of modes to enable dispersive phase compensation. Achromatic metasurfaces will find applications as multi-band-pass filters, lightweight collimators, and chromatically-corrected imaging lenses.
8:36AM F6.00002 Scattering properties of semiconductor-based metamaterials with subwavelength cavities in the infrared region, ANDREY SEMICHAEVSKY, Lincoln University, PA, STEPHANIE LAW, University of Delaware — All-semiconductor (III-V) metamaterials for the IR have recently been proposed for applications in superlensing and sensing [1]. These 1-D structures have been shown to have negative effective refractive index at wavelengths around 8 µm. Some other metamaterial structures for the visible range [2] employed SiC spherical inclusions in a plasmonic (MgB2) host medium. In this paper we develop and model IR metamaterials that utilize both low-loss highly doped GaAs/InAs semiconductor thin films and 3-D structures, such as subwavelength resonant cavities. We predict the light scattering by these structures using experimentally measured dispersion relations for the doped semiconductor films. The frequency dispersions of permittivity are well fitted by the Drude model. Our future work will include the fabrication of the metamaterial structures and their optical characterization.

8:48AM F6.00003 Emission Testing Results of Thermally Stable, Metamaterial, Selective-Emitters for Thermophotovoltaics, KATHERINE LEVINSON, NORIHIKO NAKA, NICOLE PFIESTER, ABIGAIL LICHT, TOM VANDERELDE, Tufts — In thermophotovoltaics, the energy from a heated emitter is converted to electricity by a photovoltaic diode. A selective emitter can be used to emit a narrow band of wavelengths tailored to the bandgap of the photovoltaic diode. This spectral shaping improves the conversion efficiency of the diode and reduces undesirable diode heating. In our research, we study selective emitters based on metamaterials composed of repeating nanoscale structures. The emission characteristics of these materials vary based on the compositional structure, allowing the emitted spectrum to be tunable. Simulations were performed with CST Microwave Studio to design emitters with peak wavelengths ranging from 1-10 microns. The structures were then fabricated using physical vapor deposition and electron beam lithography on a sapphire substrate. Emitter materials studied include gold, platinum, and iridium. Here we report on the emission spectra of the selective emitters and the post-heating structural integrity.

9:00AM F6.00004 ABSTRACT WITHDRAWN —

9:12AM F6.00005 Enhancing harmonic generation using nonlinear Metamaterials, SINHARA SILVA, University of South Florida, Tampa, KIM SONJU, California State University, San Bernadino, JIANGFENG ZHOU, University of South Florida, Tampa — In this work, we demonstrate the double-resonator meta-atom design in a nonlinear metamaterial can significantly enhance harmonics in microwave frequency regime. Nonlinearity in the structure is introduced by adding a varactor diode in the common slit of the double split ring resonator (DSRR) design. By engineering the structure such that inner ring resonance frequency of the DSRR is twice as the outer ring resonance frequency, we have demonstrated that the second harmonic of the outer ring can be enhanced by factor of 70 compared to a conventional SRR structure. Furthermore, the second harmonic of the periodic arrays can be further improved by carefully positioning the unit cells. In addition, with the enhancement of the second harmonic, other higher order harmonics can be enhanced.

9:24AM F6.00006 Controlling the Polarization State of Light with a Dispersion-Free Metas-structure, SHANGCHI JIANG, Nanjing University — By combining the advantages of both a metallic metamaterial and a dielectric interlayer, we demonstrate the general mechanism to construct the dispersion-free metasstructure, in which the intrinsic dispersion of the metallic structures is perfectly cancelled out by the thickness-dependent dispersion of the dielectric spacing layer. As examples to apply this concept, a broadband quarter-wave plate and a half-wave plate are demonstrated. By selecting the structural parameters, the polarization state of light can be freely tuned across a broad frequency range, and all of the polarization states on the Poincare sphere can be realized dispersion free.

10:12AM F6.00008 Photon-Spin Drag on a Plasmonic Metasurface, XINGJIE NI, JUN XIAO, SUI YANG, YUAN WANG, University of California, Berkeley, XIANG ZHANG, University of California, Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — Classical polarized light carries spin and reveals spin-orbit coupling when propagating along a curved trajectory, however this interaction typically is very weak. Utilizing a metasurface can greatly enhance this interaction because it can bend light abruptly within an extremely small thickness due to the large induced momentum. This strong photonic spin-orbit coupling on a metasurface could drive the electrons collectively and lead to direct electric currents flowing transversely to the light-bending direction, even at normal incidence and without external magnetic fields. Such a photon-spin drag effect has never until now been demonstrated. Here we report the first direct observation of this effect on a metallic metasurface consisting of complementary nanoantennas. By inputting opposite photonic spins, we directly detect the changes inversion of the transverse current direction. This effect enables an electrical detection of photon spin-orbit interactions and provides a viable route to directly integrate modern electronic chips with the additional spin degree of freedom of light for future information processing and communication applications.

10:24AM F6.00009 Creation of optical near-field orbital angular momentum in a gold metasur-face, CHEN-BIN HUANG, CHING-FU CHEN. CHEN-TA KU, Natl Tsing Hua Univ, MING-YANG PAN, PEI-KUEN WEI, Academia Sinica — Nanocavities in a gold thin film is optimized and arranged to form a metasurface. We demonstrate both numerically and experimentally that surface plasmon vortex carrying optical orbital angular momentum can be generated using linearly-polarized optical excitation.

10:36AM F6.00010 Anisotropic Fabry Perot resonances in Metal-Dielectric Meta-Nano-Layer, DAVID KEENE, MATTHEW LEPAIN, MAXIM DURACH, Georgia Southern University — We theoretically propose a new type of mode which exists in a metal-dielectric metamaterial layer of nanoscopic width. These modes exhibit anisotropic dispersion and can be used for strongly directional emission as well as ultra-compact 90 degree polarization rotation. The anisotropic Fabry-Perot (FP) modes appear from regular FP resonances when metal strips are introduced into a dielectric layer forming a metalayer. Each regular FP resonance splits into two anisotropic FP resonances in this situation. In the metalayer structures considered in the paper a fraction of about 0.2 the lower-energy mode of a higher FP mode becomes degenerate with the higher-energy mode of a lower FR resonance and their interference produces transmission of TE polarized waves upon TM incidence from another side, promising 90 degree polarization rotators with dimensions on the order of 100 nm, an order of magnitude smaller than recently proposed by other authors. Although the described behavior is due to the metamaterial-like response of the metal-dielectric strip array the non-local effects in the structures will be discussed.

10:48AM F6.00011 Meta-Optics with Nanowire Grid Arrays: Hyperbolic Fabry-Perot Modes and Hyperbolic Tamm Plasmons, MAXIM DURACH, DAVID KEENE, MATTHEW LEPAIN, Georgia Southern Univ — In this talk we introduce a new class of structures — cavities formed by metal-dielectric metasurfaces. These cavities support a zoo of various resonances, including hyperbolic Tamm plasmons and hyperbolic Fabry-Perot modes, which feature anisotropic clover-leaf dispersion parallel to the metasurface and strong coupling between TM and TE polarizations in the modes. The properties and spectrum of the modes are highly tunable by the dimensional and material parameters of the structure and can be used for directional emission, modification of radiation produced by electric dipole emitters into magnetic dipole radiation as well as 90 degree polarization rotators and polarization rotation mirrors.

9:36AM F7.00007 Fermionic Symmetry Protected Topological Phase Induced by Interaction . SHANQIANG NING, Institute for Advanced Study, Tsinghua Univ, HONGCHEN JIANG, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, ZHENGXIN LIU, Institute for Advanced Study, Tsinghua Univ — It is known that interaction can reduce the classification of topological phases in free fermion systems, for instance, the Z classes of 1D Kitaev Majorana chains with time reversal symmetry reduce to Z2 under interaction. However, strong interactions can give rise to new SPT phases which have no counterparts in free fermion systems. In this talk, I illustrate this result through an concrete example. The symmetry group we consider is U(1)xZ2. There are no topological phases for non-interacting fermions with this symmetry. When interactions are turned on, a nontrivial topological phase appears owning to the existence of nontrivial projective representation. We illustrate this result by studying a three-legged ladder of spinless fermions with strong interactions. We show that there are two gapped SPT phases, the trivial one is adiabatically connected to the band insulator, while the states in the nontrivial phase cannot be adiabatically evolved into the trivial phase without breaking symmetry.

9:48AM F7.00008 Generic Symmetry Breaking Instability of Topological Insulators due to a Novel van Hove Singularity1 , XUGANG HE, Brookhaven National Lab and Stony Brook University, XIAOXIANG XI, Photon Sciences, Brookhaven National Lab, WEI KU, Brookhaven National Lab and Stony Brook University — We point out that in the deep band-inverted state, topological insulators are generically vulnerable against symmetry breaking instability, due to a divergently large density of states of 1D-like exponent near the chemical potential. This feature at the band edge is associated with a novel van Hove singularity resulting from the development of a Mexican-hat band dispersion. We demonstrate this generic behavior via prototypical 2D and 3D models. This realization not only explains the existing experimental observations of additional phases, but also suggests a route to activate additional functionalities to topological insulators via ordering, particularly for the long-sought topological superconductivities.

10:00AM F7.00009 Symmetry Protected Topological States of Interacting Fermions and Bosons , YI-ZHUANG YOU, CENKE XU, University of California, Santa Barbara — We study the classification for a large class of interacting fermionic and bosonic symmetry protected topological (SPT) states. We define a SPT state as whether or not it is separated from the trivial state through a bulk phase transition, which is a general definition applicable to SPT states with or without spatial symmetries. We show that in all dimensions short range interactions can reduce the classification of free fermion SPT states, and we demonstrate these results by making connection between fermionic and bosonic SPT states. We first demonstrate that our formalism gives the correct classification for several known SPT states, with or without interaction, then we will generalize our method to SPT states that involve the spatial inversion symmetry.

10:12AM F7.00010 Symmetry, Defects, and Gauging of Topological Phases , PARS A BONDERS O N, MAISSAM BARKESHLI, MENG CHENG, ZHENGHAN WANG, Station Q, Microsoft Research — We examine the interplay of symmetry and topological order in 2+1D topological phases of matter. We define the topological symmetry group, characterizing symmetry of the emergent topological quantum numbers, and describe its relation with the microscopic symmetry of the physical system. We derive a general framework to classify symmetry fractionalization in topological phases, including phases that are non-Abelian and symmetries that permute the quasiparticle types and/or are anti-unitary. We develop a theory of extrinsic defects (fluxes) associated with elements of the symmetry group G, which provides a general classification of symmetry-enriched topological phases derived from a topological phase of matter with symmetry. The algebraic theory of the defects (G-crossed braided tensor category), allows one to compute many properties, such as the topologically distinct types of defects, their fusion rules, quantum dimensions, zero modes, braiding transformations, a generalized Verlinde formula, and modular transformations of the G-crossed extensions of topological phases. We also examine the promotion of the global symmetry to a local gauge invariance, wherein the extrinsic defects are turned into deconfined quasiparticle excitations, which results in a different topological phase.

10:24AM F7.00011 Kondo Breakdown in Topological Kondo Insulators1 , ONUR ERTEN, Rutgers Univ, VICTOR ALEXANDROV, PIERS COLEMAN, Rutgers University — Motivated by the observation of light surface states of SmB6, we examine the effects of surface Kondo stackings (SF) on the electronic band structure of the topological Dirac fermions protected by the time-reversal symmetry. The presence of the Kondo effect at the surface disturbs the compensation between light and heavy electrons and dopes the Dirac cone. Dispersion of these uncompensated surface states are dominated by inter-site hopping, which leads to a much lighter quasiparticles. These surface states are also highly durable against effects of magnetism and decreasing the thickness of the sample.

1Work supported by Department of Energy grant DE-FG02- 99ER45790

10:36AM F7.00012 Dirac Fermions without bulk backscattering in rhombohedral topological insulators1 , CARLOS MERA ACOSTA, MATHEUS LIMA, LEANDRO SEIXAS, ANTONIO DA SILVA, ADALBERTO FAZZIO, Instituto de Fisica, Universidade de Sao Paulo, CP 66318, 05315-970, Sao Paulo, SP, Brazil — The realization of a spintronic device using topological insulators is not trivial, because there are inherent difficulties in achieving the surface transport regime. The majority of 3D topological insulators materials (3DTI) despite of support helical metallic surface states on an insulating bulk, forming topological Dirac fermions protected by the time-reversal symmetry, exhibit electronic scattering channels due to the presence of residual continuous bulk states near the Dirac-point. From ab initio calculations, we studied the microscopic origin of the continuous bulk states in rhombohedral topological insulators materials with the space group D3h(R3m), showing that it is possible to understand the emergence of residual continuous bulk states near the Dirac-point into a six bands effective model, where the breaking of the R3 symmetry beyond the 1 point has an important role in the hybridization of the ps, py and pz atomic orbitals. Within these model, the mechanisms known to eliminate the bulk scattering, for instance: the stacking faults (SF), electric field and alloy, generated the similar effect in the electronic states of the 3DTI. Finally, we show how the surface electronic transport is modified by perturbations of bulk with SF.

1We would like to thank the financial support by Fundação de Amaparo À Pesquisa do Estado de São Paulo (FAPESP).

10:48AM F7.00013 Berry curvature induced nonlinear Hall effect in time-reversal invariant materials1 , INTI SODEMANN, LIANG FU, Massachusetts Institute of Technology — It is well-known that a non-vanishing Hall conductivity requires time-reversal symmetry breaking. However, in this work, we demonstrate that a Hall-like transverse current can occur in second-order response to an external electric field in a wide class of time-reversal invariant and inversion breaking materials. This nonlinear Hall effect arises from the dipole moment of the Berry curvature in momentum space, which generates a net anomalous velocity when the system is in a current-carrying state. We show that the nonlinear Hall coefficient is a rank-two pseudo-tensor, whose form is determined by point group symmetry. We will describe the optimal conditions and candidate materials to observe this effect.

8:00AM F8.00001 Re-visiting the O/Cu(111) system - When metastable surface oxides could become an issue!, ALOYSIUS SOON, NORINA A. RICHERT, CHANG-EUN KIM, Department of Materials Science and Engineering, Yonsei University, CATHERINE STAMPFL, School of Physics, University of Sydney. — Surface oxidation processes are crucial for the functionality of Cu-based catalytic systems used for many industrially important chemical reactions. Based on recent findings in XPS and LEED experiments, we assess the stability and population of the experimentally proposed “8”-structure, a new surface oxide phase, on the Cu(111) surface. Using density-functional theory calculations in combination with ab initio atomistic thermodynamics and Boltzmann statistical mechanics, we find that the proposed oxide superstructure is indeed metastable and that the population of the “8”-structure is competitive with the known “29” and “44” oxide film structures on Cu(111). We show that the configuration of O and Cu atoms in the first and second layers of the “8”-structure closely resembles the arrangement of atoms in the first two layers of CuO(111), where the atoms in the “8”-structure are more constricted. CuO(111) has been suggested in the literature as the most active low index facet for reactions such as water splitting under light illumination. If the “8”-structure were to form during a catalytic process, it is therefore likely to be one of the reactive phases.

8:12AM F8.00002 Oxygen disorder, a way to accommodate large tensile strains in oxide thin films, Y.Y. ZHANG, R. MISHRA, Vanderbilt University, Oak Ridge National Laboratory, T.J. PENNYCOOK, University of Oxford, A.Y. BORISEVICH, Oak Ridge National Laboratory, S.J. PENNYCOOK, University of Tennessee, S.T. PANTELIDES, Vanderbilt University, Oak Ridge National Laboratory. — Strain induced by lattice mismatch of epitaxial layers is typically accommodated by misfit dislocations. In transition-metal oxides, other strain-relaxation modes have been observed (oxygen vacancy, octahedral tilts, etc.). Here we use density functional calculations to compare the total energies of different structures and to check for negative-frequency phonon modes, which is an good indicator of instability, and explore the stability of several oxide thin films. We find that when a ZrO2 thin film is sandwiched between SrTiO3 layers (7% biaxial tensile strain), disorder in the oxygen sublattice lowers the energy by 1.4 eV/ZrO2 formula unit and, in contrast, we find that if a (LaFeO3)/(SrFeO3) superlattice is grown on a substrate that imposes an overall biaxial tensile strain, there is a competition between O sublattice disorder, formation and ordering of O vacancies, and octahedral tilts. The mechanism for strain compensation varies with the extent of the strain. We conclude that oxygen-sublattice disorder is one of many ways that tensile strain can be accommodated in transition-metal oxide films.

8:24AM F8.00003 Thermodynamic stability and band alignment at SrTiO3/GaAs(001) interface1, JOELSON COTT, RAVI DROOPAD, BYOUNGHAK LEE, Texas State University, TX 78666, USA. — The successful epitaxial growth of SrTiO3 on Si showed that it is possible to integrate the functional oxides with semiconductors incorporating unique multifunctional properties of oxides into various existing semiconductor technologies. While SrTiO3 has been also deposited on GaAs without amorphous interfacial layers, the exact interface structure has been controversial. On one hand, scanning Transmission Electron Microscopy (STEM) shows As atoms at the interface. X-ray photoelectron spectroscopy (XPS) measurements, on the other hand, do not show peaks associated with As-O bonding, indicating that the GaAs/SrTiO3 interface does not involve an As/Oxide layer, contradicting to STEM observations. Using ab initio calculations, we determine the interface structure of a SrTiO3 film on a GaAs substrate to help clarify the apparent discrepancy between the XPS and the STEM measurements. The calculations reveal that, under the condition that allows atomically abrupt interfaces, the energetically most stable interface is As/Sr/TiO2 structure, in accordance with both XPS and STEM measurements. We discuss the band offsets and the possibility of in-gap states of various interface structures.

8:36AM F8.00004 Study of electronic structure and magnetism at the relaxed SrTiO3/LaMO3 interface, SOHAM GHOSH, EFSTRATIOS MANOUSAKIS, Florida State Univ. — We present a density functional theory study of the nature of bands in z-terminated metal oxides. It is shown that the bandstructure of pure SrTiO3 near the fermi surface is modified by the presence of surfaces, besides being sensitive to ionic relaxations and thickness of the material. We also study the cases where layers of LaMO3 (with M = Ti, Al) have been added to create an interface. We examine doping of the SrTiO3 surface bands by the added layers as a possible reason for the presence and localization of the induced electron gas and we study the character of these bands.

8:48AM F8.00005 Lattice-mismatch Strain Effects in Electron-Doped Calcium Manganese Oxide Thin Films1, CACIE HART, GRACE YONG, ZOEY WARECKI, ADEEL CHAUDHRY, PRAKASH SHARMA, ANTHONY JOHNSON, DAVID SCHAEFER, RAJESWARI KOLAGANI, Towson University. — Electron-doped Calcium Manganese Oxide (CaMnO3−δ) thin films are of interest for use as photocatalysts and fuel cell electrodes in renewable energy applications. Oxygen stoichiometry of the films is a key parameter for the functionality in these applications. Currently, we are investigating the properties of (CaMnO3−δ) films grown by pulsed laser deposition. The thin films are epitaxially grown on LaAlO3 and SrTiO3 substrates. Both of these substrates have larger in-plane lattice parameters than CaMnO3−δ, which leads to bi-axial tensile strain in the thin films. We have characterized the thickness dependence of structural, electrical, and morphological properties of these films using high resolution x-ray diffraction, temperature dependent electrical conductivity measurements, and atomic force microscopy. The thickness dependence is characteristically different from what has been previously observed in thin films of hole-doped manganites. Our results suggest that coupling between tensile strain and oxygen deficiency affect the electrical and structural properties of the material.

9:00AM F8.00006 Epitaxial growth of in-plane-dimerized, single phase NbO2 thin films for metal-insulator transition applications, AGHAM POSADAS, TOBIAS HADAMEK, ANDY O’HARA, ALEXANDER DEMKOV, University of Texas at Austin. — NbO2 is a exhibits a metal-insulator transition that may have potential applications in electronic devices. The strong conductivity change in NbO2 occurs along the dimerization direction and for devices utilizing NbO2 as a channel material (in-plane transport) such as transistors, one would like the dimerization direction to be in the plane of the film. The electrical properties of Nb oxides are strongly dependent on the oxidation state of Nb. It is therefore critical to be able to control the oxidation state of Nb during growth. Here, we describe the epitaxial growth of in-plane-dimerized NbO2 using molecular beam epitaxy on a variety of substrates (STO, LSAT, MgO, BTO and GdN), growth temperatures, and oxygen-to-niobium flux ratios. We show that the particular substrate used significantly affects the bulk and surface crystallinity, as well as the degree of oxidation. We also show the evolution of the valence and core level photoemission spectra of Nb oxides as a function of oxygen-to-niobium flux ratio and point out the optimum growth conditions to achieve phase-pure, epitaxial NbO2 films.
9:12 AM F8.00007 Band-gap engineering at a semiconductor - crystalline oxide interface. KAMYAR AHMADI-MAJLAN, MOHAMMADREZA JAHANGIR-MOGHADAM, Univ of Texas, Arlington. XUAN SHEN, Brookhaven National Laboratory, TIMOTHY DROUBAY, MARK BOWDEN, Pacific Northwest National Laboratory, MATTHEW CRYSLER, Univ of Texas, Arlington, DONG SU, Brookhaven National Laboratory, SCOTT A. CHAMBERS, Pacific Northwest National Laboratory. JOSEPH H. NGAI, Univ of Texas, Arlington — Abstract: The epitaxial growth of crystalline oxides on semiconductors provides a pathway to introduce new functionalities to semiconductor devices. Key to electrically coupling crystalline oxides with semiconductors to realize functional behavior is controlling the manner in which their bands align at interfaces. Here we apply principles of band gap engineering traditionally used at heterojunctions between conventional semiconductors to control the band offset between a single crystalline oxide and a semiconductor. Reactive molecular beam epitaxy is used to realize atomically abrupt and structurally coherent interfaces between SrZrxTi1−xO3 and Ge, in which the band-gap of the former is enhanced with Zr content x. We present structural and electrical characterization of SrZrxTi1−xO3-Ge heterojunctions for x = 0.2 to 0.75 and demonstrate the band offset can be tuned from type-II to type-I, with the latter being verified using photoemission measurements. The type-I band offset provides a platform to integrate the dielectric, ferroelectric and ferromagnetic functionalities of oxides with semiconducting devices.

9:24 AM F8.00008 Effect of post-deposition annealing on the structure and physical properties of strained epitaxial Ni1−xTi1−yO3 thin films1. TAMAS VARGA, TIMOTHY DROUBAY, LIBOR KOVARIK, SCOTT CHAMBERS, Pacific Northwest National Laboratory — Ferroelectrically induced weak ferromagnetism had been predicted in compounds MTIO3 (M=Fe,Mn,Ni) with the LINbO3-type structure. In order to stabilize this metastable structure by oxide heteroepitaxy, we attempted to grow epitaxial NiTiO3 films on Al2O3 and Fe2O3/Al2O3 substrates by pulsed laser deposition. Given the structural imperfections of the as-deposited films arising from the large lattice mismatch, which resulted in weak ferroic ordering, we investigated the effect of post-synthesis annealing on the films’ properties. Our structural data from x-ray diffraction and electron microscopy suggest that the crystalline quality of the Ni1−xTi1−yO3 films was greatly improved by annealing the films at 1000 °C for 8 hours. Our physical property characterization indicates increased ferromagnetism in the films. The specific changes in film structure and magnetic as well as polar properties will be discussed. These results suggest that the ferromagnetic properties of the films can be favorably altered by post-synthesis heat treatment.

9:36 AM F8.00009 Epitaxial Growth of CaIrO3 Single-Crystal Thin-Films. MARYAM SOURI, JOHN H. GRUENEWALD, JASMINKA TERZIC, GANG CAO, JOSEPH W. BRILL, SUNG S. AMBROSE SEO, Univ of Kentucky — Complex oxides containing 5d transition metals including iridates have attracted substantial attention due to their potential to create novel electronic and magnetic states that originate from strong spin–orbit coupling and the electron-correlation of 5d electrons. However, the progress of experimental research on the 5d transition-metal oxides is hindered by the limited number of available materials. To further understand the layered iridates (A2IrO3, A: alkaline-earth elements) featuring the J=1/2 Mott state, we have synthesized epitaxial thin-films of Ca2IrO3. The single crystal Ruddlesden-Popper (R-P) phase of Ca3n+1Ir2O3n+1 (n=1) is thermodynamically unstable; hence, we have used epitaxial-stabilization strategies to grow metastable thin-films of Ca2IrO3. The R-P phase of Ca3Ir4O7 is synthesized on yttrium aluminum oxide and lanthanum aluminum oxide substrates by pulsed laser deposition. We have studied the electronic structure of these films by transport and optical spectroscopic measurements. The dc-resistivity shows that these Ca2IrO3 thin-films are insulating with activation energy of about 100 meV. The optical spectroscopy shows that the optical gap energy is about 0.5 eV. We will discuss the electronic structure of Ca2IrO3 by comparing with Sr2IrO4 and Ba2IrO4.

9:48 AM F8.00010 Structure-Property relationship for H covered Fe3O4(001)1. FANGYANG LIU, Louisanna State Univ - Baton Rouge, ORHAN KIZILKAYA, Center for Advanced Microstructures and Devices, Louisiana State University, PHILLIP SPRUNGER, RICHARD KURTZ, RONGYING JIN, JIANDI ZHANG, WARD PLUMMER, Louisiana State Univ - Baton Rouge — Magnetite (Fe3O4), the oldest permanent magnetic material in a variety of applications.

1This work was supported in the Environmental Molecular Sciences Laboratory, a national scientific user facility sponsored by the Department of Energy’s Office of Biological and Environmental Research and located at Pacific Northwest National Laboratory.

10:00 AM F8.00011 Thin-film growth of the quasi-one-dimensional metal Li109Mo6O17. ALEXANDRA COTE, SAEED MOSHEFHEGYEGANEE, JOSUA L. COHN, University of Miami, JOHN J. NEUMEIER, Montana State University — Attempts to grow epitaxial thin films of Li109Mo6O17 by pulsed-laser deposition will be discussed. Single crystals of this quasi-one-dimensional (q1D) metal exhibit highly anisotropic Seebeck coefficients with ΔS ≈ S⊥ − S∥ ≈ 200 μV/K near 450 K (the b axis corresponds to the most conducting, q1D chain direction). Suitably oriented thin films could enable possible applications in energy detection using the transverse Seebeck effect. X-ray diffraction results will be presented for films grown from a polycrystalline target on several substrates under a narrow range of temperature and pressure conditions.

1This material is based upon work supported by the U.S. Department of Energy Office of Basic Energy Sciences grant DE-FG02-12ER46888 (Univ. Miami) and the National Science Foundation under grant DMR-0907036 (Mont. St. Univ.)

10:12 AM F8.00012 Superconducting single-crystalline YBa2Cu3O7−δ on SrTiO3 buffered Si (100). MOHAMMADREZA JAHANGIR-MOGHADAM, KAMYAR AHMADI-MAJLAN, Univ of Texas, Arlington. HAO ZHANG, Univ of Toronto, XUAN SHEN, National Laboratory of Solid State Microstructures, Nanjing University, MATTHEW CRYSLER, PATRICK CONLIN, RICKY HENSLEY, Univ of Texas, Arlington, DONG SU, Center for Functional Nanomaterials, Brookhaven National Laboratory, JOHN WEI, Univ of Toronto, JOSEPH NGAI, Univ of Texas, Arlington — The growth of crystalline oxides on semiconductors enables new functionalities to be integrated with semiconducting technologies. Here, thin films of optimally-doped (001)-oriented YBa2Cu3O7−δ are epitaxially integrated on silicon (001) through growth on a SrTiO3 buffer. The former is grown using pulsed-laser deposition and the latter is grown on Si using oxide molecular beam epitaxy. The single crystal nature of the SrTiO3 buffer enables very high transition temperatures to be achieved. For a 30 nm thick SrTiO3 buffer, YBa2Cu3O7-δ films exhibiting a transition temperature of ~ 95 K, and a narrow transition width (< 5 K) are achieved. The integration of single crystalline YBa2Cu3O7−δ on Si (001) paves the way for the potential exploration of cuprate materials in a variety of applications.
10:24AM F8.00013 Optical and magnetic properties of Ca$_3$CoMnO$_6$ thin films\textsuperscript{1}. JITENDRA SAHA, GYANESHWAR SHARMA, Graduate Student, SATYABRATA PATNAIK, Associate Professor, S PATNAIK TEAM — Ca$_3$CoMnO$_6$ is one of the initial one-dimensional Ising chain compounds that has shown large magnetoelectric coupling below its antiferromagnetic temperature (15 K). We report on the growth and characterization of Ca$_3$CoMnO$_6$ thin films deposited by pulse laser deposition. The films of thickness 220 nm are grown on 0001-oriented sapphire substrates at 750 °C. The band gap (∼ 1.73 eV) derived from UV visible absorption spectroscopy and temperature dependent resistivity is consistent with one another. It is seen that the films can be grown at various oxygen pressures but the optimal deposition pressure is found to be 5×10$^{-2}$ mbar. The effect of oxygen pressure on the texture of the film and band gap indicates that the oxygen vacancies play a major role in the optical and electrical properties of the films. AFM measurements show a homogeneous growth of the films. Magnetization measurement shows that the transition temperature increased to 39 K, much above the bulk Neel temperature. The increase in magnetic transition is supposed to be due to stronger inter-chain interaction caused by tensile strain effected by lattice mismatch.

10:48AM F8.00015 Effects of ferroelectric polarization on surface phase diagram: an evolutionary algorithm study of the BaTiO$_3$(001) surface\textsuperscript{1}. PENCHENG CHEN, YONG XU, NA WANG, Tsinghua University, ARTEM R. OGANOV, Stony Brook University, WENHUI DUAN, Tsinghua University — We have constructed the surface phase diagram of the BaTiO$_3$(001) surface by employing an evolutionary algorithm for surface structure prediction, where the ferroelectric polarization is included as a degree of freedom. Among over 1000 candidate structures explored, a surface reconstruction of $(2\times1)$-TiO is discovered to be thermodynamically stable and have the $p2mm$ plane group symmetry as observed experimentally. We find that the influence of ferroelectric polarization on the surface free energy can be either negligibly small or sizably large (over 1 eV per $(2\times1)$ supercell), depending strongly on the surface structure and resulting in a significant distinction of surface phase diagram with varying ferroelectric polarization. It is therefore feasible to control the surface stability by applying an external electric field. Our results may have important implications in understanding the surface reconstruction of ferroelectric materials and tuning surface properties.

Tuesday, March 3, 2015 8:00AM - 11:00AM
Session F9 DMP: Focus Session: van der Waals Bonding in Advanced Materials: Advances in Theory 006D - Adrienn Ruzsinszky-Perdew, Temple University

8:00AM F9.00001 Short-range Cut-Off of the Summed-Up van der Waals Series\textsuperscript{1}. ABHIRUP PATRA, JOHN P. PERDEW, Temple University — van der Waals interactions are important in typical van der Waals-bound systems such as noble-gas, hydrocarbon, alkali and alkaline-earth dimers. The summed-up van der Waals series \cite{1,2} works well and gives an accurate result at large separation between two atoms. But it has a strong singularity at short non-zero separation, where the two atoms touch. In this work we remove that singularity with a reasonable and physical choice of the cut-off distance. Only one fitting parameter has been introduced for the short-range cut off. The parameter in our model has been optimized for each system, and a system-averaged value has been used to get the final binding energy curves. When this correction is added to the binding energy curve from the semilocal density functional meta-GGA-M2S, we get vdW- corrected binding energy curve. These curves are compared with the results of other vdW-corrected methods such as PBE-D2 and vdW-DF2. Binding energy curves are in reasonable agreement with those from experiment. These curves also predict reasonably good equilibrium bond length. \cite{1,2}.

\textsuperscript{1}Supported by NSF (DMR)

8:12AM F9.00002 A van der Waals density functional built upon the electron-gas foundation\textsuperscript{1}. PER HYLDGAARD, Chalmers Univ. of Technology, Dept. of Microtechnology and Nanoscience –MC2, KRISTIAN BERLAND, Univ. of Oslo, Dept. of Physics, SMN, ELSEBETH SCHRÖDER, Chalmers Univ. of Technology, Dept. of Microtechnology and Nanoscience –MC2 — The vdW-DF method is designed to be a systematic extension of the constraint-based generalized-gradient approximation (GGA) and can therefore serve as general purpose density functional \cite{PRB 90,075148 (2014)}. Yet the early versions can have issues both with bulk systems and with weak chemisorption. We present a recent nonempirical version, vdW-DF-cx \cite{J. Chem. Phys. 140,18A539 (2014), PRB 89, 035412 (2014)}, that resolves these issues. The version is designed to have a consistent combination of exchange and correlation. We show that it performs well for inter-molecular binding and that it can even be better than PBE for describing cohesion and structure of molecules and solids.

8:24AM F9.00003 A Local Representation Of The Dielectric Response Function\textsuperscript{1}. DEYU LU, XI-AOCHUAN GE, Brookhaven National Laboratory — The screened dielectric response function ($\chi$) is a fundamental physical quantity that captures the many-electron correlation effects, key to the accurate description of van der Waals dispersion interaction in the ground state and a range of excited state properties. Although $\chi$ is non-local by definition, a real space partition of $\chi$ onto local structural motifs can help us gain further physical insight into, e.g., effective local screening properties. Because the construction of bare response function, $\chi_{0}$, is associated with the product of electron - hole orbitals, standard localization procedures for electron wave functions can not be directly applied. In this work, we propose a new method to decompose $\chi_{0}$ into contributions from local response functions. Exemplary results of finite and bulk systems are discussed.

8:36AM F9.00004 An Efficient Coupled Dipole Method: TCDM1, HYE-YOUNG KIM, Southeastern Louisiana Univ — An overview of a memory-efficient and cost-effective method, called Trace-Coupled Dipole Method (TCDM), which can accurately predict the van der Waals (vdW) forces between dielectric materials will be presented. CDM is an intrinsically atomistic method which includes all the many-body interaction terms self-consistently. TCDM, an alternative way to execute CDM, is to obtain VDW interaction energy by calculating the trace of a 3NX3 matrix, rather than its eigenvalues. It will be demonstrated that the power series expansion in TCDM is equivalent to that of the perturbation theory. The advantage of adopting TCDM over the conventional perturbation theory or CDM will also be discussed. The use of TCDM will make it practical for any interested future users to calculate the accurate VDW interaction in large systems like those found in computer simulation studies without serious increase in computational burden.

8:48AM F9.00005 Electronic Properties of Polarizable Systems with Self-Consistent Interatomic van der Waals Density Functional, NICOLA FERRI, Fritz Haber Institute der MPG, ROBERT A. DISTASIO JR., Princeton University, ALBERTO AMBROSETTI, Fritz Haber Institute der MPG, ROBERTO CAR, Princeton University, MATTHIAS SCHEFFLER, ALEXANDRE TKATCHENKO, Fritz Haber Institute der MPG — Ubiquitous long-range van der Waals (vdW) interactions play a fundamental role in the structure and stability of a wide range of systems. Within the DFT framework, the vdW energy represents a crucial, but tiny part of the total energy, hence its influence on the electronic density, n(r), and electronic properties is typically assumed to be rather small. Here, we address this question via a fully self-consistent (SC) implementation of the interatomic Tkatchenko-Scheffler vdW functional [1] and its extension to surfaces [2]. Self-consistency leads to large changes in the binding energies and electrostatic moments of highly polarizable alkali metal dimers. For some metal surfaces, vdW interactions increase dipole moments and induce non-trivial charge rearrangements, leading to visible changes in the metal workfunctions. Similar behavior is observed for molecules adsorbed on metals. Our study reveals a non-trivial connection between electrostatics and long-range electron correlation effects. [1] A. Tkatchenko and M. Scheffler PRL (2009). [2] V. G. Ruiz, W. Liu, E. Zojer, M. Scheffer, and A. Tkatchenko PRL (2012).

9:00AM F9.00006 Many-body dispersion meets non-local density functionals: A unified approach for van der Waals correlations, JAN HERMANN, MATTHIAS SCHEFFLER, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der Max-Planck-Gesellschaft — It is an ongoing challenge to develop an efficient method for van der Waals (vdW) non-local correlation within DFT which would be both accurate and broadly applicable. Current approaches can be loosely divided into the fragment-based ones, two-point density functionals and methods based on the density-density response function. The fragment-based models utilize parameters not derivable from the electron density. Two-point approaches are explicit density functionals, but difficult to generalize to include many-body correlations. Here, we show that these seemingly contrasting approaches can be unified within a single framework based on the adiabatic-connection formalism in the random-phase approximation. We use a local response-function model from the VV09 functional[1] together with the many-body dispersion approach to create an atom-based model with no external parameters. We introduce a consistent correlation-functional-based coupling of the short- and long-range correlation energy. We show that this unification provides new insights into the different approaches, naturally deals with the partitioning of ionic and delocalized states and paves path towards self-consistent description of many-body vdW correlations.

9:12AM F9.00007 Repulsive van der Waals forces and other delights from the Lifshitz approach, ADRIAN PARSEGIAN, Univ. Massachusetts, Amherst — No abstract available.

9:48AM F9.00008 Farsightedness of the Correlation Energy in Polarizable Non-Metallic Nanostructures, ALBERTO AMBROSETTI, Università degli Studi di Padova, NICOLA FERRI, Fritz-Haber Institut der Max Planck Gesellschaft, Berlin, ROBERT D. DAMSTASIO, Princeton University, Princeton, ALEXANDRE TKATCHENKO, Fritz Haber Institut der Max Planck Gesellschaft, Berlin — The success of semi-local approaches to the electron correlation energy is commonly attributed to the relative nearsightedness of the electronic matter—a powerful concept introduced by M. Kohn. However, recent theoretical and experimental evidence indicates that electron correlation can be characterized by strong “action at a distance”, especially in low-dimensional polarizable nanomaterials. Here we systematically analyze the influence of relevant properties, namely dimensionality, topology and polarizability, on the convergence and power laws governing the correlation energy. Using an accurate model system of coupled quantum harmonic oscillators we find that many-body effects can induce collective and strongly delocalized charge-fluctuation modes. These modes are ultimately responsible for a marked non-locality of the response, and an unconventional power-law decay of the dispersion interaction, which significantly deviates from the asymptotic predictions of finite-order perturbative theories. Notably, the degree of farsightedness of the correlation energy could possibly be tuned, opening the way to an appropriate control of the interaction in complex polarizable nanostructures.

10:00AM F9.00009 Van der Waals Interactions Between Subsystems with Overlapping Electron Density1, MICHELE PAVANELLO, Rutgers Univ - Newark — The subsystem formulation of DFT known as Frozen Density Embedding (FDE) provides a divide-and-conquer approach to Kohn–Sham DFT for weakly bound systems. We claim that a subsystem formulation of DFT can simplify both the theoretical framework and the computational effort for calculating the electronic structure of condensed phase systems. In addition, the naturally subsystem-like form of molecular aggregates makes subsystem DFT a better descriptor of the underlying physics than regular DFT of the supersystem. As an example, we present a novel van der Waals theory based on subsystem DFT which can treat seamlessly non-overlapping as well as overlapping subsystem electron densities. The theory is amenable to sensible approximations, such as RPA, and offers natural algorithms to fold in post-RPA corrections. Application of the theory to the computation of binding energies of dimers in the S22 set, as well as computation of selected potential energy surfaces is presented.

10:12AM F9.00010 Adiabatic-connection fluctuation-dissipation DFT for the structural properties of solids - the renormalized ALDA and other electron gas kernels1, CHRISTOPHER PATRICK, KRISTIAN THYGESEN, Department of Physics, Technical University of Denmark — The adiabatic-connection fluctuation-dissipation formula of density-functional theory (ACFD-DFT) provides a natural pathway for the calculation of electron correlation energies going beyond the random-phase approximation (RPA). The key ingredient of ACFD-DFT is the exchange-correlation kernel $\text{xc}$. Recent theoretical and experimental evidence indicates that the exchange-correlation kernel is the key to accurately model the van der Waals (vdW) forces between dielectric materials will be presented. CDM is an intrinsically atomistic method which includes all the many-body interaction terms self-consistently. TCDM, an alternative way to execute CDM, is to obtain VDW interaction energy by calculating the trace of a $3N\times3N$ matrix, rather than its eigenvalues. It will be demonstrated that the power series expansion in TCDM is equivalent to that of the perturbation theory. The advantage of adopting TCDM over the conventional perturbation theory or CDM will also be discussed. The use of TCDM will make it practical for any interested future users to calculate the accurate VDW interaction in large systems like those found in computer simulation studies without serious increase in computational burden.

10:24AM F9.00011 The role of delocalization error in non-covalent interactions from dispersion-corrected density-functional theory, ALBERTO OTERO DE LA ROZA, National Institute for Nanotechnology-NRC — Extensive benchmarking of dispersion-corrected density functional theory (dDFT) methods has shown that it is nowadays feasible to calculate, with great accuracy, binding energies of small dimers and lattice energies of molecular crystals. However, there are many outstanding questions that can only be answered by a proper understanding of the interplay between base functional and dispersion correction. In this talk, I explore how delocalization error from the exchange-correlation functional impacts the calculation of non-covalent donor-acceptor interactions. Delocalization error arises from the failure of most functionals to model the long-range behavior of the exchange-correlation hole. Its primary consequence for non-covalent interactions is that the stability of donor-acceptor interactions is overestimated. Errors caused by delocalization error are particularly harmful in systems with strong and extensive hydrogen-bonded networks (water clusters and ice) or strong donor-acceptor interactions (halogen bonding), and cannot be corrected using a pairwise dispersion correction. In addition, I present how delocalization error affects real-life applications of dDFT, such as molecular adsorption on iron-oxide nanoparticles and surfaces.

10:36AM F9.00012 Ultra-long-ranged dispersion interaction between degenerate molecules, JOHN DOBSON, Griffith Univ, ANDREAS SAVIN, CNRS, UPMC Sorbonne Universities — It is known (see e.g. [1]) that extended nano-systems with zero electronic gaps can exhibit dispersion interactions that fall off with unexpected powers of distance \( D \). We seek to find a similar phenomenon between finite molecules that have a strictly degenerate many-electron groundstate (zero gap). As a toy model we take \( H_2 \) with the atoms constrained to lie on an equilateral triangle of side \( a \), using a minimal (s) basis set, and with spin-orbit coupling omitted. Rotational symmetry at fixed spins guarantees a degenerate time-reversed pair of three-electron states. For sufficiently small atomic spacing \( a \) where inter-atomic hopping kinetic energy dominates the electron-electron repulsion, these degenerate time-reversed pairs of states are many-electron groundstates. We confirm this groundstate degeneracy via limited-basis CI calculations. We show that the resulting dispersion energy between two such constrained \( H_2 \) molecules falls off as \( D^{3.5} \) instead of the usual \( D^6 \). Within the classification scheme proposed in ref [2], this effect can be interpreted as a “type C non-additivity” of the dispersion interaction. This model may be relevant to metal atom clusters.

1 JFD acknowledges Australian Research Council Grant DP1096240. We benefited from discussions with Prof. Janos Anany and Dr. Ru-Fen Liu.

10:48AM F9.00013 Optimization of a van der Waals Density Functional for water, MICHELLE FRITZ, Universidad Autonoma de Madrid, MARIVI FERNANDEZ-SERRA, Stony Brook University, JOSE M. SOLER, Universidad Autonoma de Madrid — In particular, delicate systems, like liquid water, ab initio exchange and correlation functionals are simply not accurate enough for many practical applications. In these cases, fitting the functional to reference data is a sensible alternative to empirical interatomic potentials. However, a global optimization requires functional forms that depend on many parameters and the usual trial and error strategy becomes cumbersome and suboptimal. We present a general and powerful optimization scheme called data projection onto parameter space (DPPS). In an arbitrarily large parameter space, DPPS expands the vector of unknown parameters in vectors of known data. Poorly sampled subspaces are determined by the physically-motivated functional shape of ab initio functionals, using Bayes’ theory to combine this prior information with reference energies and electron densities of monomers, clusters, and condensed phases of water.

Tuesday, March 3, 2015 8:00AM - 11:00AM —
Session F10 DCMP: Magnetism and Topological Insulators 007A - Jim Eckstein, University of Illinois-Urbana

8:00AM F10.00001 Room Temperature Ferromagnetism on the Topological Insulators Surface by Proximity Effect, FERHAT KATMIS, MIT, VALERIA LAUTER, Oak Ridge National Lab., VAHID SAZGARI, ISMET I. KAYA, Sabanci University, DONALD HEIMAN, Northeastern University, JAGADEESH MOODERA, MIT — Generating exchange-induced ferromagnetism on the surface of a topological insulator (TI) with a ferromagnetic layer (FM) provides a cleaner approach for realizing a ferromagnetic TI that may lead to exhibiting other quantum functionality. Here we demonstrate further that room temperature magnetic state may be reached in the TI and FM heterostructures through magnetic proximity-induced time reversal symmetry breaking on the TI surface. Using different magnetic characterization methods we provide evidence of this enhanced proximity-induced magnetism in TI. We show that such effects persist up to room temperature, far above the Curie temperature of the FM, signifying a significantly different behavior in TI. The project supported by grants NSF (DMR-1207469), MIT MRSEC through the MRSEC Program of the NSF (DMR-0817962) and NSF (ECCS-1402738). 1. “Exchange-Coupling-Induced Symmetry Breaking in Topological Insulators”, Peng Wei, et al, PRL. 110, 186807 (2013).

8:12AM F10.00002 A first-principles study of magnetic phase transitions in Fe-doped Bi2Se3, JOEONGWOO KIM, SEUNG-HOON JHI, Pohang Univ of Sci & Tech — Magnetic impurities perturb helical surface states of topological insulators because they act as the spin-flipping scattering centers. Counter-intuitively, the energy gap of the surface states, presumably opened by such scattering, decreases with Fe concentration in Fe-doped topological insulating Bi2Te3 [1]. In addition, the ground magnetic phase of the compound is changed as Fe concentration is increased, which is atypical in dilute magnetic semiconductors. We study the magnetic phase transition and the behavior of surface states in Fe-doped Bi2Se3 using first-principles calculations. We find that the localized spin states of Fe atoms are aligned via hybridization with conduction electrons at dilute doping regimes (<1.7 %) but, at dense impurity levels (>1.7%), are ordered mainly via the super-exchange interaction. We show that topological surface states are sensitive to the type of magnetic ordering of adjacent Fe impurities and that the ground magnetic phase barely perturbs the linear band dispersion and the helical nature of the surface states. This finding explains the observation of the band gap of the surface-states in the presence of magnetic impurities.

8:36AM F10.00004 Signatures of Dirac fermion-mediated magnetic order 1, PAOLO SESSI, FELIX REIS, THOMAS BATHON, Institute of Physics, University of Wuerzburg, Germany, KONSTANTIN KOKH, OLEG TERESHCHENKO, Novosibirsk State University, Novosibirsk, Russia, MATTHIAS BODE, Institute of Physics, University of Wuerzburg, Germany — The spin-momentum locking of topological states offers an ideal platform to explore novel magneto-electric effects. These intimately depend on the ability to manipulate the spin texture in a controlled way. Here, we combine low-temperature scanning tunneling microscopy with single-atom deposition technique to directly map the evolution of the electronic properties of topological states under the influence of different magnetic perturbations. By analyzing energy-resolved quasi-particle interference maps, we reveal signatures of Dirac fermion-mediated surface magnetic order for extremely dilute adatom concentrations. By using different magnetic elements and coverages, we find that this striking observation crucially depends on two parameters: single adatoms magnetic anisotropy direction and energy-level alignment.

8:48AM F10.00005 Magnetization Dynamics of a Ferromagnet Attached to the Surface State of a Topological Insulator: A Time Dependent Keldysh Green Function Approach 1, FARZAD MAHFOUZI, NICHOLAS KIOUSIS, Department of Physics and Astronomy, California State University, Northridge — Motivated by the recent experiments on the Spin Orbit Torque (SOT) generated by the Topological Insulators (TI) we investigate the conditions under which the SOT due to the in-plane current flowing through the surface state can switch the magnetic orientation of a ferromagnet attached to the TI. Using the Keldysh Green function approach, we developed the theoretical formalism for a classical system coupled to an electronic system out of equilibrium due to both bias voltage and the adiabatic variation of the classical degree of freedom. In this approach the quantities of interest that are calculated have the form of the generalized Fisher-Lee formula describing the electronic current and spin accumulation in terms of the Green functions in a unified approach. We show that due to the Edlestein effect the direction of the easy axis changes with the applied voltage which makes it difficult to separate the SOT into field like and anti-damping like components.

9:00AM F10.00006 Magnetization switching of a nanomagnet by spin polarized surface states of a topological insulator 1, URMIMALA ROY, RIK DEY, TANMOY PRAMANIK, BAHINAM GHOSH, LEONARD F. REGISTER, SANJAY K. BANERJEE, Microelectronics Research Center, The University of Texas at Austin — Due to the spin-momentum helical locking, a charge current supported by the topological insulator (TI) surface states leads to a spin accumulation at the TI surface. In this theoretical study, we consider a thermally-stable, conducting nanomagnet subject to spin-polarized current injection from TI surface states, in order to evaluate possible non-volatile memory applications such as in spin-transfer-torque random access memory. We simulate parallel transport in the TI and the ferromagnetic metal, and evaluate the efficiency of magnetization switching for varying ease of transport between the TI and the ferromagnetic metal. With the assumed parameters, transport in the TI beneath the ferromagnetic metal is diffusive in nature at room temperature and is modeled by drift-diffusion simulation, which we believe to be sufficient for this purpose, and allows for rapid interpretation. We use self-consistent transport and magnetization dynamics calculation to predict switching time and energy spent per write operation. Based on our simulation, we believe that a large in-plane resistivity of the ferromagnetic layer—perhaps not a simple ferromagnetic metal layer—along with an interface with the TI that is transparent to charge transport, will lead to minimum switching time and write energy.

9:12AM F10.00007 The influence of proximity induced ferromagnetism, superconductivity and Fermi-velocity on evolution of Berry phase in Bi$_2$Se$_3$ topological insulator 1, PARIJAT SENGUPTA, University of Wisconsin-Madison — Bi$_2$Se$_3$ is a well-known 3D-topological insulators (TI) with a non-trivial Berry phase of $\pi$ attributed to the topology of the band structure. The Berry phase shows non-topological deviations from $\pi$ in presence of a perturbation that destroys time reversal symmetry and gives rise to a quantum system with massive Dirac fermions and finite band gap. Such a band gap opening is achieved on account of the exchange field of a ferromagnet or the intrinsic energy gap of a superconductor that influences the topological insulator surface states by virtue of the proximity effect. The Berry phase of such gapped systems with massive Dirac fermions is considered. Additionally, it is shown that the Berry phase for such a system also depends on the Fermi-velocity of the surface states which can be tuned as a function of the TI film thickness. The role of higher order warping terms in the surface state Hamiltonian which influences deviations to the Berry phase is evaluated. Finally, a connection between Berry phase and circular dichroism is examined through explicit calculation of the optical matrix elements.

9:24AM F10.00008 Quantum Anomalous Hall Effect in Magnetic Insulator Heterostructure 1, GANG XU, JING WANG, Stanford University, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, XIAOLIANG QI, SHOUCHENG ZHANG, Stanford University, STANFORD UNIVERSITY COLLABORATION, INSTITUTE OF PHYSICS, CAS, CHINA COLLABORATION, MAX PLANCK INSTITUTE FOR CHEMICAL PHYSICS OF SOLIDS, DRESDEN, GERMANY COLLABORATION — Based on ab initio calculations, we predict that a monolayer of Cr-doped (Bi$_2$Sb)$_3$Te$_3$ and Gd$_2$ heterostructure is a quantum anomalous Hall insulator with a non-trivial band gap up to 38 meV. The principle behind our prediction is that the band inversion between two topologically trivial fermionic insulators can result in a non-zero Chern number, which offers a better route toward novel topological materials.

9:36AM F10.00009 Persistent ferromagnetism and topological phase transition at the interface of a superconductor and a topological insulator 1, WEI QIN, ZHENYU ZHANG, University of Science and Technology of China — At the interface of an $s$-wave superconductor and a three-dimensional topological insulator, Majorana zero modes and Majorana helical states have been predicted to exist respectively around magnetic vortices and geometrical edges. Here we first show that randomly distributed magnetic impurities at such an interface will induce bound states that broaden into impurity bands inside (but near the edges of) the superconducting gap, which remains open unless the impurity concentration is too high. Next we find that an increase in the superconducting gap suppresses both the oscillation magnitude and period of the RKKY interaction between two magnetic impurities. Within a mean field approximation, the ferromagnetic Curie temperature is found to be essentially independent of the superconducting gap, an intriguing phenomenon due to a compensation effect between the short-range ferromagnetic and long-range anti-ferromagnetic interactions. The existence of robust superconductivity and persistent ferromagnetism at the interface allows realization of a novel topological phase transition from a non-chiral to a chiral superconducting state at sufficiently low temperatures, providing a new platform for topological quantum computation.

9:48AM F10.00010 Revealing dissipationless chiral edge channel in magnetic topological insulator via non-local transport measurement. WEI-LI LEE, Institute of Physics, Academia Sinica, Taipei, XUFENG KOU, Department of Electrical Engineering, University of California, Los Angeles, SHIH-TING GUO, Institute of Physics, Academia Sinica, Taipei, YABIN FAN, LEI PAN, MURONG LANG, Department of Electrical Engineering, University of California, Los Angeles, YING JIANG, Department of Materials Science and Engineering, Zhejiang University, Hangzhou, QIMING SHAO, ANDUN ZHONG, Kimia University of Technology, Tehran, AROOP DAS, University of Maryland at College Park, PENG WEI, MIT, BISWARUP SATPATHI, Saha Institute of Nuclear Physics, JAGADEESH M. MODDAR, MIT, DON HEIMAN, Northeastern University — The observation of dissipationless edge states, which are the hallmark of a topological state, is a key step toward understanding the quantum Hall effect (QHE) in topological insulators. In this work, we present the first observation of dissipationless chiral edge states in a thin film of magnetic topological insulator Cr$_x$(Bi$_9$Sb$_9$)$_2$Se$_3$ grown by MBE technique. The measurement of the dissipationless edge state was performed using a novel nonlocal transport technique, which allows us to access and manipulate the edge states in a controlled manner. The results demonstrate the potential of magnetic topological insulators for future spintronics applications.

10:00AM F10.00011 Inducing magnetism onto the surface of a topological crystalline insulator. BADDIH A. ASSAF, Northeastern University, FERNAT KATMIS, PENG WEI, MIT, BISWARUP SATPATHI, Saha Institute of Nuclear Physics, JAGADEESH M. MODDAR, MIT, DON HEIMAN, Northeastern University — Magnetically-doped topological crystalline insulators (TCI) have been predicted to host a quantum anomalous Hall effect characterized by a Chern number, as large as a C=4 [1]. An alternative way to achieve this quantum state is by inducing magnetism onto the surface via magnetic proximity with a ferromagnetic insulator such as EuS. Similar to the proximity effect achieved in EuS/Bi2Se3 bilayers [2], we have induced magnetism onto the TCI SnTe in an MBE-grown SnTe/EuS/SnTe trilayer. Transport measurements at T=2K exhibit an anomalous Hall effect that is induced at the SnTe surfaces by the insulating ferromagnet EuS. The in-plane magnetoresistance (MR) exhibits a pronounced hysteresis that is isotropic with the direction of the EuS magnetization. Unlike the case of ferromagnetic semiconductors and metals, where the in-plane MR is highly anisotropic as a result of spin-scattering, the present MR is evidence of additional conduction inside the domain-walls at the EuS-SnTe interfaces. Further MR measurements in the minor loop regime confirm this effect. This work is a significant step toward realizing quantum states in TCI thin films. [1] C. Fang, et al. Phys. Rev. Lett. 112, 046801 (2014). [2] P. Wei et al. Phys. Rev. Lett. 18, 186807 (2013).

10:12AM F10.00012 Electrically Tunable Magnetism in Magnetic Topological Insulators. SHOUCHENG ZHANG, JING WANG, BIAO LIAN, Stanford Univ — The external controllability of the magnetic properties in topological insulators would be important both for fundamental and practical interests. Here we predict the electric-field control of ferromagnetism in a thin film of insulating magnetic topological insulators. The decrease of band inversion by the application of electric fields results in a reduction of magnetic susceptibility, and hence in the modification of magnetism. Remarkably, the electric control of magnetic order could even induce the magnetic quantum phase transition from ferromagnetism to paramagnetism. We further propose a topological transistor device in which the dissipationless charge transport of chiral edge states is controlled by an electric field. The simultaneous electric control of magnetic order and chiral edge channel in such a device may lead to electronic and spintronic applications for topological insulators.

10:36AM F10.00014 Imaging Dirac-Mass Disorder from Magnetic Dopant-Atoms in the Ferromagnetic Topological Insulator Cr$_x$(Bi$_9$Sb$_9$)$_2$Se$_3$ – Part II. CHUNG KOO KIM, INHEE LEE, BNL, JINHO LEE, Brooklyn National Laboratory, JINHO LEE, Seoul National University, SIMON BILLINGE, Columbia University, RUIJIAN ZHONG, JOHN SCHNEELOCH, TIANGSHENG LIU, JOHN TRANQUADA, GENDA GU, Brookhaven National Laboratory, J. C. SEAMUS DAVIS, Cornell University — We present Part II of the spectroscopic imaging - scanning tunneling microscopy (SI-STM) study of ferromagnetic Cr$_x$(Bi$_9$Sb$_9$)$_2$Se$_3$ single crystals measured at 4.5 K. As Part II we show how both spectroscopic analysis in real and momentum space demonstrate the coincident Dirac mass gap identified. Distribution of gap width, gap center, and gap anisotropy will be discussed. The anticipated relationship $\Delta(r) \propto n(r)$ is confirmed throughout, and exhibits an electron-dopant interaction energy $J^* = 145$ meV$^{-1}$. These observations reveal how magnetic dopant atoms actually generate the TI mass gap and that, to achieve the novel physics expected of time-reversal-symmetry breaking TI materials, control of the resulting Dirac-mass gap disorder will be essential.

10:48AM F10.00015 Spin-based Mach-Zehnder interferometry in topological insulator p-n junctions. RONI ILAN, University of California, Berkeley, FERNANDO DE JUAN, JOEL MOORE, University of California, Berkeley and Lawrence Berkeley National Laboratory, Berkeley — A p-n junction, an interface between two regions of a material populated with carriers of opposite charge, is a basic building block of solid state electronic devices. From the fundamental physics perspective, it often serves as a tool to reveal the unconventional transport behavior of novel materials. We show that a p-n junction made from a three dimensional topological insulator in a magnetic field realizes an electronic Mach-Zehnder interferometer with virtually perfect visibility. This is owed to the confinement of the topological Dirac fermion state to a closed two-dimensional surface, which offers the unprecedented possibility of utilizing external fields to design networks of chiral modes wrapping around the bulk in closed trajectories, without the need of complex constrictions or etching. Remarkably, this junction also acts as a spin filter, where the path of the particle is tied to the direction of spin propagation. It therefore constitutes a novel and highly tunable spintronic device where spin polarized input and output currents are naturally formed and could be accessed and manipulated separately.

Tuesday, March 3, 2015 8:00AM - 11:00AM – Session F11 DCMP: Odd-Parity Superconductivity 007B - Daoxin Yao, Sun Yat-sen University
8:00AM F11.00001 Influence of Fermi Surface Geometry and Geometric Phases on Spin-Triplet correlations in Superconductor-Ferromagnet Hybrid Structures1, MATTHIAS ESCHRIG, Royal Holloway, University of London — During the past 15 years a new field has emerged, which combines superconductivity and spintronics, with the goal to pave a way for new types of devices for applications combining the virtues of both, namely quantum coherence and interference on one side, and spin-selectivity and spin magnetism on the other. The building block of this new “spin-supertronics” are spin-triplet Cooper pairs, which are generated at the interface between a conventional superconducting and a ferromagnetic material. Non-collinear magnetic inhomogeneity mixes triplet pairs among each other, thus creating long-ranged equal-spin Cooper pairs in the ferromagnet, and non-collinear inhomogeneity introduces geometric phases giving rise to unusual current phase relations. Considerable Fermi surface mismatch is unavoidable for hybrid structures involving strongly spin-polarized ferromagnets. We perform calculations showing that Fermi surface geometry has important implications for the sign and magnitude of induced triplet correlations in the superconductor, as well as for the generation of spin currents. We discuss under which conditions spin currents are generated, and how the triplet correlations can be maximized for applications.

8:12AM F11.00002 Proximity-induced triplet superconductivity in Rashba materials1, CHRISTOPHER REEG, SAURABH MAITI, DMITRII MASLOV, Univ of Florida - Gainesville — We study a proximity junction between a conventional $s$-wave superconductor and a conductor with Rashba spin-orbit coupling. Our specific focus is on the spin structure of the induced pairing in the Rashba conductor, where the mixing of spin-up and spin-down states converts the purely spin-singlet Cooper pairs of the superconductor into a mixture of spin-singlet and spin-triplet pairs. Because the induced triplet component of the pairing is generated entirely by a singlet order parameter and a single-particle spin-orbit term that preserves time-reversal symmetry, the triplet component is expected to persist even in the presence of disorder. We also propose an experimental setup to verify the triplet nature of the induced pairing.

8:24AM F11.00003 Possible correlation-driven odd-parity superconductivity in LaNi$_7$/8Co$_1$/8O$_3$ (111) bilayers, BING YE, ANDREJ MESAROS, YING RAN, Boston College — Using the functional renormalization group technique we demonstrate a route for potentially high temperature odd-parity superconductivity in ferromagnetic materials caused by repulsive electron interactions, where the superconducting pairing is driven by charge-density wave fluctuations. Our model is directly applicable to a lightly cobalt-doped LaNiO$_3$ bilayer grown in the (111) direction. As the on-site repulsive interaction grows, a charge-density wave state with a charge pattern that respects all point-group symmetries of the bilayer is replaced by a superconducting state with an $f$-wave pairing.

8:36AM F11.00004 Spin-Triplet Superconductivity in Sr$_2$RuO$_4$ due to Orbital and Spin Fluctuations: 2D fRG Analysis, MASHAISHI TSUCHIZU, YOUCHI YAMAKAWA, Department of Physics, Nagoya University, SEICHIKO ONARI, Department of Physics, Okayama University, HIROSHI KONTANI, Department of Physics, Nagoya University — We study the mechanism of the triplet superconductivity in Sr$_2$RuO$_4$, by applying the functional renormalization group (fRG) method to the multi-orbital Hubbard model [1]. Thanks to the vertex correction, we observe the strong spin and orbital fluctuations at $Q \approx (2\pi/3, 2\pi/3)$ in the quasi-one-dimensional Fermi surfaces (which are composed of $d_{xz}$ and $d_{yz}$ orbitals). Moreover, due to the cooperation of spin and orbital fluctuations, the triplet superconductivity emerges where the superconducting gap is given by the linear combination of $\Delta_k(k) \approx \sin(3k_x \pi, \sin(3k_y \pi)$ [2]. These results can also be confirmed by a diagrammatic calculation of the vertex correction.

8:48AM F11.00005 ABSTRACT WITHDRAWN —

9:00AM F11.00006 Search for half-flux-quantum Little-Parks oscillations in mesoscopic rings of Sr$_2$RuO$_4$. XINXIN CAI, BRIAN ZAKRZEWSKI, YIQUN YING, Pennysylvania State Univ, DAVID FOBES, TIJIANG LIU, ZHIQIANG MAO, Tulane University, YING LIU, Pennsylvania State Univ — Recent cantilever magnetometry measurements on micron-sized, doubly-connected crystals of Sr$_2$RuO$_4$ have indicated that a half-flux-quantum state may be present in this material. To provide independent evidence for the presence of this new topological object by electrical transport measurements and examine its stability, we carried out Little-Parks (L-P) oscillation measurements, which trace out the phase boundary indicated that a half-flux-quantum state may be present in this material. To provide independent evidence for the presence of this new topological object by electrical transport measurements and examine its stability, we carried out Little-Parks (L-P) oscillation measurements, which trace out the phase boundary of a system, on mesoscopic rings of Sr$_2$RuO$_4$. Sr$_2$RuO$_4$ rings were fabricated using a combination of mechanical exfoliation of Sr$_2$RuO$_4$ single crystals, photolithography, and focused ion beam techniques. Without an in-plane magnetic field, large-amplitude resistance oscillations of a full-flux quantum were found in the upper critical field data of Kittaka et al. [2009 Phys. Rev. B 80, 174514] are obtained.

This work is supported by DOE under grant DE-FG02-04ER46159.

9:12AM F11.00007 Large Chern Number and Edge Currents in Sr$_2$RuO$_4$. THOMAS SCAFFIDI, STEVEN SIMON, University of Oxford — Using the results of a previously reported microscopic calculation, we show that the most favored chiral superconducting order parameter in Sr$_2$RuO$_4$ has Chern number $|C| = 7$ in the weak coupling limit. This order parameter has a momentum dependence of the type $\sin(k_x) \cos(k_y) + i \sin(k_y) \cos(k_x)$ and lies in the same irreducible representation $E_u$ of the tetragonal point group as the usually assumed gap function $\sin(k_y) + i \sin(k_x)$. While the latter gap function leads to $C = 1$, the former leads to $C = -7$, which is only allowed for an $E_u$ gap function since the tetragonal symmetry only fixes $C$ modulo 4. Since it was shown that the edge currents of a $|C| > 1$ superconductor vanish exactly in the continuum limit, and can be strongly reduced on the lattice, this form of order parameter could help resolve the experimental observation of time-reversal symmetry breaking and yet the absence of observed edge currents in Sr$_2$RuO$_4$.

9:24AM F11.00008 Is the anisotropy of the upper critical field of Sr$_2$RuO$_4$ consistent with a helical $p$-wave state?, RICHARD KLEMM, Univ of Central Florida, JINGCHUAN ZHANG, QIANG GU, University of Science and Technology Beijing, CHRISTOPHER LOESCHER, Univ of Central Florida — We calculate the angular and temperature $T$ dependencies of the upper critical field $H_{c2}(\theta, \phi, T)$ for the $C_4v$ point group helical $p$-wave states, assuming a single uniaxial ellipsoidal Fermi surface, Pauli limiting, and strong spin-orbit coupling that locks the spin-triplet d-vectors onto the layers. Good fits to the Sr$_2$RuO$_4$ $H_{c2,0}(\theta, T)$ data of Kittaka et al. [2009 Phys. Rev. B 80, 174514] are obtained. Helical states with $\hat{d}(k) = k_x \hat{x} - k_y \hat{y}$ and $k_x \hat{x} + k_y \hat{y}$ or $k_x \hat{x} + k_y \hat{y}$ and $k_x \hat{x} - k_y \hat{y}$ produce $H_{c2}(90^\circ, \phi, T)$ that greatly exceed (or do not exhibit) the four-fold azimuthal anisotropy magnitudes observed in Sr$_2$RuO$_4$ by Kittaka et al. and by Mao et al. [2000 Phys. Rev. Lett. 84, 991], respectively.
9:36AM F11.00009 Possible f-wave pairing in the low-doping regime of monolayer MoS$_2$. CARSTEN HONERKAMP, JIE YUAN, RWTH Aachen University — We investigate the possible superconducting pairing state in a theoretical model for monolayer-MoS$_2$ by using the temperature-flow functional renormalization group (fRG). In the low doping regime, the dominant instability lies in the odd-parity pairing channel. It has a f-wave pairing structure within the D$_{3h}$ point-group symmetry. We also compute the fRG phase diagram below the van-Hove filling. In the superconducting regime, the critical temperature grows with increasing doping, comparable to the experiments. We demonstrate that the pairing is driven by ferromagnetic fluctuations. When the band filling is close to the van-Hove filling, the system favors a ferromagnetic state.

9:48AM F11.00010 Possible restoration of superconductivity in the quasi-one-dimensional conductor Li$_{1-y}$Mo$_y$O$_{17}$ in pulsed high magnetic field $H \approx 100 \, T$. OTAR SEPPER, ANDREI LEBED, University of Arizona — We present a theoretical study of restoration of superconductivity in the form of the triplet reentrant superconducting phase in the quasi-one-dimensional (Q1D) conductor. Substitution of known band and superconducting parameters of the presumably triplet Q1D superconductor Li$_{1-y}$Mo$_y$O$_{17}$ into our theoretical equations shows that such restoration can happen in non-destructive pulsed magnetic fields of the order of $H \approx 100 \, T$. We investigate in detail how small inclinations of a direction of magnetic field from its optimal experimental geometry decrease the superconducting transition temperature of the reentrant phase, which is important for its experimental discovery. If confirmed experimentally, the reentrant superconducting phase in Li$_{1-y}$Mo$_y$O$_{17}$ would be the first example of the survival of superconductivity in ultra high magnetic fields and would, in addition, unequivocally confirm the spin-triplet pairing nature in this compound.

10:00AM F11.00011 Fluctuation effects in a two-component p-wave superconductor. MARK H. FISCHER, EREZ BERG, Weizmann Institute of Science — For a tetragonal material, order parameters of $p_x$ and $p_y$ symmetry are related by rotation and hence have the same $T_c$. This degeneracy can be lifted by a symmetry-breaking field, like (uniaxial) in-plane strain, such that at $T_c$, the order parameter is only of $p_x$ or $p_y$. Only at a lower temperature also the respective other order parameter condenses. We analyze consequences of (thermal) fluctuations on these transition temperatures within a Ginzburg-Landau approach to obtain a comprehensive strain-temperature phase diagram. We find that the fluctuations can both enhance or suppress the effect of the symmetry breaking field, and even drive the system into a preemptive chiral phase. Possible consequences for the spin-triplet superconductor Sr$_2$RuO$_4$ will be discussed.

10:12AM F11.00012 Long range p-wave proximity effect into a disordered metal!. AYDIN CEM KESEK, CMTC, Univ. of MD, VALENTIN STANEV, CMTC, Univ.of MD, VICTOR GALITSKI, CMTC and JQI, Univ. of MD & School of Physics, Monash. — We use quasiclassical methods of superconductivity to study the superconducting proximity effect from a topological p-wave superconductor into a disordered one-dimensional metallic wire. We demonstrate that the corresponding Eliashberg equations with disorder reduce to a closed non-linear equation for the superconducting component of the matrix Green’s function. Remarkably, this equation is formally equivalent to a classical mechanical system (i.e., Newton’s equations), with the Green function corresponding to a coordinate of a fictitious particle and the coordinate along the wire corresponding to time. This mapping allows to obtain exact solutions in the disordered nanowire in terms of elliptic functions. A surprising result that comes out of this solution is that the p-wave superconductivity proximity-induced into the disordered metal remains long-range, decaying as slowly as the conventional s-wave superconductivity. It is also shown that impurity scattering leads to the appearance of a zero-energy peak.

This research was supported by DOE-BES DESC0001911 (VG & VS), NSF-CAREER DMR- 0847224 (ACK), and Simons Foundation.

10:24AM F11.00013 Colossal proximity effect in a superconducting triplet spin valve based on the half-metallic ferromagnet CrO$_2$. AMRITA SINGH, STEFANO VOLTAN, KAVEH LAHABI, JAN AARTS, Kamerlingh Onnes Laboratory — Combining superconductors (S) and ferromagnets (F) offers the opportunity to create a new class of superconducting spintron devices. In particular, the S/F interface can be specifically engineered to convert singlet Cooper pairs to spin-polarized triplet Cooper pairs. The efficiency of this process can be studied using a so-called triplet spin valve (TSV), which is composed of two F-layers and an S-layer. When the magnetization in the two F-layers are not collinear, singlet states can be drained from the S-layer, and injected as triplet generation is therefore signalled by a decrease of the critical temperature $T_c$. Here, we build highly efficient TSVs using a 100% spin-polarized half-metallic ferromagnet, CrO$_2$. The application of large out of plane magnetic fields results in an extremely strong suppression of $T_c$, by almost a Kelvin. The observed effect is nearly an order of magnitude larger than previous studies on TSVs with standard ferromagnets. Furthermore, we clearly demonstrate that this triplet proximity effect is strongly dependent on the transparency and spin activity of the interface. Our results are particularly important in view of the growing interest in generating long range triplet supercurrents for dissipationless spintronics.

10:36AM F11.00014 Quantum Limit in a Magnetic Field for Triplet Superconductivity in a Quasi-One-Dimensional Conductor1, ANDREI LEBED, OTAR SEPPER, Department of Physics, University of Arizona — We theoretically consider the upper critical magnetic field, perpendicular to a conducting axis in a triplet quasi-one-dimensional superconductor [1]. In particular, we demonstrate that, at high magnetic fields, the orbital effects against superconductivity in a magnetic field are reversible and, therefore, superconductivity can restore. It is important that the above mentioned quantum limit can be achieved in presumably triplet quasi-one-dimensional superconductor Li$_{1-y}$Mo$_y$O$_{17}$ [J.-F. Mercure et al., Phys. Rev. Lett. 108, 187003 (2012)] at laboratory available pulsed magnetic fields of the order of $H \approx 500 - 700 \, T$. [1] A.G. Lebed and O. Sepper, Phys. Rev. B 90, 024510 (2014).

10:48AM F11.00015 Universal spin-triplet superconducting correlation of Majorana Fermions, XIU LIU, JAY DEEP SAU, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, College Park, Maryland 20742-4111, USA. — In this work, we show that Majorana fermions (MFs) on the boundary of topological superconductors (TSCs) only have spin-triplet superconducting correlation no matter what the bulk superconducting gap is singlet or triplet. This is universal for all TSCs as long as they have, on the boundary, odd number of MFs for BDI or D class and odd number pairs of MFs for DIII class. As a result, the Andreev reflection induced by the Majorana fermions always introduces spin-triplet Cooper pairs in the leads. This spin-triplet condensate results in the the spin-orbit coupling (SOC) controlled oscillatory correlation critical current without $0 - \pi$ transition in the TSC/SOC-semiconductor/TSC Josephson junction. The observation of this unique current-phase relation can serve as a signal of Majorana fermions. Moreover our study open a new way to manipulate Majorana fermions based on their spin-triplet superconducting correlation.

Session F12 DMP GERA FIAP DCOMP: Focus Session: Thermoelectric Materials and Applications 007C - Lilia Woods, University of South Florida
Thermoelectric energy harvester based on quantum well superlattices

YUNJIN CHOI, ANDREW JORDAN, University of Rochester — We propose a nanoscale heat engine based on quantum well superlattices for harvesting thermal energy. A hot cavity is connected via superlattices to electronic reservoirs, and the electron transport through the superlattice by gaining energy from the hot cavity converts heat into electrical power. The energy gain is determined by the composite superlattices system. Therefore, the electric and heat current of electrons for simplified miniband transport of the superlattices give tunable conditions for the maximal generated power or efficiency. In addition, we analyze the phonon transport of the superlattices and show the reduction of the phonon thermal conductivity at high temperature which is beneficial for the highly efficient thermoelectric devices [1]. Combination of the electron and phonon transport shows an optimal configuration for the best performance of energy harvester. We discuss and compare our result with the energy harvester based on resonant quantum wells [2].

Self-propagating high temperature synthesis for compound thermoelectrics and new criterion for applicability of combustion processing

XINFENG TANG, XIANLI SU, Wuhan University of Technology, CITIRAD UHER, University of Michigan, TANG’S GROUP TEAM, UHER’S GROUP TEAM — Here we report compound thermoelectric materials (Bi$_2$Te$_3$, Bi$_2$Se$_3$, Cu$_2$Se, Cu$_5$SnSe$_3$, half-Heusler alloys, lead chalcogenides, skutterudites, and magnesium silicides) with thermoelectric properties comparable with materials prepared by the traditional routes of synthesis can be synthesized at a minimal cost and on the time scale of seconds using the self-propagating high temperature synthesis method. Moreover, we found that the criterion often quoted in the literature as the necessary preconditions for combustion synthesis, $T_{ad} \geq 1800$ K, is not universal and certainly not applicable to thermoelectric compound semiconductors. Instead, we offer new empirically-based criterion, $T_{ad}/T_{in} \geq 1$, i.e., the adiabatic temperature must be high enough to melt the lower melting point component, which covers all materials synthesized by self-propagating high temperature synthesis, including the high temperature refractory compounds for which the $T_{ad} \geq 1800$ K criterion was originally developed. Our work opens a new avenue for ultra-fast, low cost, mass production fabrication of efficient thermoelectric materials and the new criterion greatly broadens the scope of materials that can be successfully synthesized by self-propagating high temperature synthesis. 3

Automotive Thermoelectric Waste Heat Recovery

GREGORY P. MEISNER, General Motors Research and Development — Considerable fuel energy, as much as 70%, is not converted to useful work by internal combustion engines but is instead rejected as waste heat, and more than half of the waste heat, nearly 40% of fuel energy, is contained in vehicle exhaust gas. This provides an opportunity to recover some of the wasted fuel energy and convert it from heat into useful work, subject to the laws of thermodynamics, and thereby improve vehicle energy efficiency. Thermoelectric (TE) materials have been extensively researched and TE devices are now being developed for operation at high temperatures corresponding to automotive exhaust gases for direct solid-state conversion of heat into electricity. This has stimulated substantial progress in the development of practical TE generator (TEG) systems for large-scale commercialization. A significant enabler of this progress has been the US Department of Energy’s Vehicle Technologies Program through funding for low cost solutions for automotive TE waste heat recovery to improve fuel economy. Our current project at General Motors has culminated in the identification of the potential supply chain for all components and assembly of an automotive TEG. A significant focus has been to develop integrated and iterative modeling tools for a fully optimized TEG design that includes all components and subsystems (TE modules, heat exchangers, thermal interfaces, electrical interconnects, power conditioning, and vehicle integration for maximal use of TEG power). We have built and tested a new, low-cost Initial TEG prototype based on state-of-the-art production-scale skutterudite TE modules, novel heat exchanger designs, and practical solutions to the many technical challenges for optimum TEG performance. We will use the results for our Initial TEG prototype to refine our modeling and design tools for a Final automotive TEG system prototype. Our recent results will be presented. Thanks to: J.R. Salvador, E.R. Gundlach, D. Thompson, N.K. Bucknor, M.G. Reynolds, K. Rober, F.R. Anharmonic phonons in type I clathrates

KATSU MIYAKI, JIAZHENG WU, HIDEKAZU SHIMOTANI, Tohoku University — A systematic study on the anharmonicity of phonons is made for thermoelectric single crystal type-I clathrates based on their heat capacity $C_P$ at low temperatures (T) down to 360 mK. The low-T linear terms $\kappa_0 + \gamma T$ of $C_P$, including the tunneling-term of the atoms accommodated in the host cages ($\gamma T T > \alpha T$), and the Sommerfeld itinerant-electron term $(\gamma T)$ are successfully separated through careful measurements of single crystals with various carrier concentrations. The values of the density of anharmonic potentials are deduced. The effective mass $(m^*)$ enhancement is also determined from $\gamma T$ values and the electron-phonon interaction strength $(\lambda)$ can be evaluated from these values. It is shown that both the thermal conductivities $(\kappa)$ and the electron-phonon interaction strength $(\lambda)$ are quantitatively in good agreement with the $\alpha$ parameters deduced from the present experiments. The boson peaks observed at low energy excitations are discussed in relation to the $\alpha$ values.
9:24AM F12.00006 Large local distortions around the Ba site in Ba$_8$Ga$_2$$_x$X$_{38}$, X=Si, Sn$^1$. TREVOR KEIBER, Univ of California-Santa Cruz, FRANK BRIDGES, PATRICK NAST, UC Santa Cruz, SCOTT MEDLING, Australian National University, TOSHIRO TAKABATAKE, Hiroshima University — We report an Extended X-ray Absorption Fine Structure (EXAFS) analysis of thermoelectric type-I clathrates, Ba$_8$Ga$_{16}$X$_{38}$, X=Si,Sn. These clathrates have a cage-like crystal structure filled with “rattler” atoms (Ba) located near the center of the cages (Ga-X). In contrast to the results for Ba$_8$Ga$_{16}$Ge$_{38}$, our results show that for X=Si,Sn the average pair distances within the cages (Ga-Sn, Ga-Ga, Ga-Si, Sn-Sn) are significantly different than the average distances found from diffraction. Direct measurements of the Ba K edge suggests that the environment about Ba is very highly disordered for X=Sn,Si compared to X=Ge, with surprisingly short Ba-X/Ga distances; likely the Ba2 site is significantly off center. For Si, the Ba K first neighbor peak is substantially reduced in size and shifted to lower r due to interference effects from many different Ba neighbor distances. For X=Sn the Ba-Ga/Sn distances are even shorter, and there is a split peak with very low amplitude suggesting a very disordered environment. The mixed distances of the cage atoms, the very short Ba-Ga/X distances, as well as the disorder about the Ba site, suggest that the cage structure is buckled. This disorder will lead to increased scattering for both phonons and electrons.

9:36AM F12.00007 Effect of Alkaline Metal Filling on the Structural Properties of Type-II Clathrate A$_x$M$_{136}$(A = Na,K,Rb,Cs; M = Group IV Atom; 0$<x$$\leq$24). CHARLES MYLES, DONG XUE, Texas Tech University — Early investigations of the properties of the Type II clathrate Na$_x$Si$_{136}$ (0$<x$$\leq$24) $^1$[1] have found that, as the composition x increases, the Si$_{136}$ lattice exhibits framework contraction upon filling (0$<x$$<8$), followed by an expansion of the unit cell volume (9$<x$$<24$). Stimulated by this discovery of a non-monotonic structural response to cage filling by the guests, we have performed a systematic, first-principles study of the composition-framework interaction in the large and small cages in the Type II clathrates Si$_{136}$, Ge$_{136}$, and Sn$_{136}$. Our calculations are based on the VASP code and we have considered Na, K, Rb, and Cs guests for 0$<x$$\leq$24. An emphasis in our study is on how the guest atom size affects the dynamical behavior of the host material. We focus on the host lattice structural expansion or compression as x increases. We also present and discuss calculations of the effective potential energy curves for the guest-host interactions in these materials. Our results are correlated with the damping (or anharmonic) oscillations of the guests. These results are useful as an indication of the expected behavior of the guest “rattling” phonon modes in these materials. Among other results, we find that some guests are weakly bonded in the host cages and others are unstable around the cage centers.

9:48AM F12.00008 First Principles Study of the Vibrational and Thermal Properties of the Type-II Clathrates A$_x$Ga$_8$Sn$_{136}$-x (x = 8,16,24; A = Rb,Cs). DONG XUE, CHARLES MYLES, Texas Tech University — We have performed first-principles calculations of the vibrational and thermal properties of the semiconductor clathrates Rb$_x$Ga$_8$Sn$_{136}$-x and Cs$_x$Ga$_8$Sn$_{136}$-x for x = 8, 16, and 24. Our calculations used the VASP code to obtain the equilibrium geometries and the PHONOPY code to obtain the harmonic phonon modes. For x = 24, the phonon dispersion relations predict an upshift of the low-lying optical modes (~30cm$^{-1}$) in the presence of the light guest (“rattler”) Rb. We also find large isotropic atomic displacement parameters ($u_{iso}$) when the Rb occupies the large cages (Sn$_{28}$). The modes associated with these guests should contribute strongly to lowering the lattice thermal constant (kL). This is reinforced by our evaluation of the guest-associated effective potential energy curves E(x). Our calculated effective harmonic spring constants K for these guests show that a simple harmonic oscillator model is in good agreement with the first principles lattice dynamical calculations. The similarity between $\omega_{oa} = (K/M)^{1/2}$ and our computed guest phonon frequencies implies that anharmonic contributions to the guest vibrational modes are not significant. Our calculations of the vibrational contribution to the specific heat and our estimation of $k_L$ are also presented and discussed.

10:00AM F12.00009 Study on Transport and Mechanical Properties of La and Ce Double Filled p-type Skutterudites$^1$. TULASHI DAHAL, Department of Physics and TCSUH, University of Houston, TX 77204, SONIKA GAHALWAT, Department of Mechanical Engineering, University of Houston, TX 77204, QING JIE, HEE SEOK KIM, KESHAB DAHAL, WEISHUI LIU, Department of Physics and TCSUH, University of Houston, TX 77204, YUCHENG LAN, Department of Physics, Morgan State University, MD 21251, KENNETH WHITE, Department of Mechanical Engineering, University of Houston, TX 77204, ZHIFENG REN, Department of Physics and TCSUH, University of Houston, TX 77204, REN’S GROUP TEAM — Optimizing the thermoelectric performance of p-type skutterudites is extremely challenging due to several factors such as low Seebeck voltage and bipolar contribution in electrical and thermal conductivity at elevated temperature, leading to small ZT value. In this work, we report improved thermoelectric performance of La and Ce double filled p-type skutterudites by melting-quenching-annealing-ball milling-hot pressing. The observed high power factor (~35 μW cm$^{-1}$ K$^{-2}$ at 500 °C) and low thermal conductivity (~2.5 W m$^{-1}$ K$^{-1}$ at 500 °C) leads to a peak ZT about 1.1 in the optimized composition, With a ΔT of 475 °C between heat source and sink, the estimated output power density in the best sample is ~8 W cm$^{-2}$. The nano-indentation experiment reveals that the hardness and Young’s modulus of elasticity of the sample is much better than Bi$_2$Te$_3$ and PbTe-based samples, indicating skutterudites are suitable for practical applications where mechanical strength is also important.

10:12AM F12.00010 Local structure in ball-milled and Ni substituted Nd$_x$Fe$_{4-x}$Ni$_2$Sb$_{12}$.$^1$. FRANK BRIDGES, FELIPE RIVAS, MARKUS SHORT, TREVOR KEIBER, Physics Dept. UC Santa Cruz, Santa Cruz CA 95064, PETER ROGL, Institute of Physical Chemistry, University of Vienna, Austria — We report EXAFS measurements at the Nd L$_{III}$, Fe, and Sb K edges in Nd$_x$Fe$_{4-x}$Ni$_2$Sb$_{12}$. Recent measurements show thatball-milled Nd$_4$Fe$_{12}$Sb$_{12}$, with ~150 nm size particles, significantly improved the figure of merit (ZT) by 22 %, compared to material with 10 μm sized particles. Since ball milling can produce significant disorder and even amorphization, which would lower the thermal conductivity, we compared the local structure for ball-milled and hand ground samples. We find that the average local structure is essentially unchanged by ball milling; the reduced particle size reduces the phonon mean free path, thereby reducing the thermal conductivity. When Ni is substituted on the Fe site, together with a decreased concentration of Nd, we find the largest changes in disorder are about the Nd atoms; there is little disorder of the first few neighbors about the Fe site. Further the local distortions are not uniform; the lattice constant decreases with Ni concentration, but the Nd-Sb bond length slightly expands while the Sb-Sb contracts more than expected. Some consequences are discussed.

10:24 AM F12.00011 Thermoelectric properties of GeTe-CuInTe₂ alloys, SI HUI, Department of Mechanical Engineering, University of Michigan, Ann Arbor, JAMES SALVADOR, Chemical and Materials Systems Laboratory, GM R&D Center, Warren, HUI SUN, Department of Physics, University of Michigan, Ann Arbor, KEVIN PIPE, Department of Mechanical Engineering, Department of Electrical Engineering, University of Michigan, Ann Arbor, CTIRAD UHER, Department of Physics, University of Michigan, Ann Arbor — GeTe-AgSbTe₂ and PbTe-AgSbTe₂ alloys, known as TAGS and LAST respectively, are excellent thermoelectric materials. By alloying the matrix with other ternary compounds, the thermal conductivity is significantly reduced due to the enhancement of phonon scattering by formation of nano-sized secondary phases and disturbance to the lattice. Meanwhile, since the ternary compound AgSbTe₂ also exhibits good thermoelectric properties and Ag¹⁺ and Sb²⁺ tend to replace two Ge atoms at the same time, the mobility, and thus the power factor, will not be influenced much by this alloying. In this work, we replaced the ternary compound AgSbTe₂ by CuInTe₂ which does not contain the expensive element Ag and also exhibits good thermoelectric properties. We measured the Seebeck coefficient, electrical conductivity, thermal conductivity and Hall coefficient, and observed that CuInTe₂ almost has no influence on the power factor but does reduce the thermal conductivity. ZT was observed to improve to 1.2 at 800K for (Ge₃Te₇)₀.₉₇(CuInTe₂)₀.₀₃. We believe that ZT will be further enhanced at larger CuInTe₂ fractions due to further reduced thermal conductivity.

10:36 AM F12.00012 Thermoelectric and Lattice Dynamical Properties of Ge₃Sb₂Te₅, SAIKAT MUKHOPADHYAY, JIFENG SUN, Oak Ridge National Laboratory, Oak Ridge, TN, ALASKA SUBEDI, Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany, DAVID SINGH, Oak Ridge National Laboratory, Oak Ridge, TN — Ge₃Sb₂Te₅ (GST) has been widely used as phase-change materials in optical data storage media and nonvolatile RAM devices. At elevated temperature, GST is known to undergo subsequent structural transitions from a non-conducting amorphous to (metastable) disordered cubic phase and then to a conducting hexagonal phase above 300°C. Given that hexagonal-GST has already been reported to have promising thermoelectric properties and transport properties critically depend on the bonding information, a direct correlation between its structural- and transport properties needs to be established. In this talk, we will present the evolution of thermoelectric and lattice dynamical properties of GST in different phases via first principles calculations based on density functional theory. A better understanding of the origin of low-thermal conductivity in hexagonal-GST may provide critical information for further improvement of its thermoelectric figure of merit (ZT).

10:48 AM F12.00013 Calculation of Phonon Conductivity and Seebeck Coefficient in Cu-Ni Alloy, YUSUKE KONISHI, YOSHIHIRO ASAI, NRI-AIST — In recent years, thermoelectric materials have been attracting a lot of attention because they are expected to be applied for utilization of waste heat. Many kinds of materials are studied for this purpose; semiconductors, alloys, organic materials, etc. In 2010, a giant Peltier effect was observed in a Cu-Ni/Au junction [1]. It is considered that this giant Peltier effect is caused by nano-scale phase separation formed in the sputtering process. Although this material is a great candidate for a thermoelectric material, we need to find the condition for a large thermoelectric properties of Cu-Ni alloy by using nonequilibrium molecular dynamics simulation and calculated Seebeck coefficients via ab-initio methods. Tuesday, March 3, 2015 8:00 AM - 11:00 AM — Session F13 DCMP: Quantum Dots, Wires And Wells: Electronic Phenomena 007D - Paul Simmonds, Boise State University

8:00 AM F13.00001 Using Dissipation to Stabilize a Quantum Critical Point in Two Quantum Dots, GU ZHANG, Duke Univ, EDUARDO NOVAIS, UFABC, Brazil, HAROLD BARANGER, Duke Univ — We show how dissipation could be used to stabilize the two-impurity Kondo critical point in a double dot system. In the absence of dissipation, this intermediate coupling fixed point cannot be reached because charge transfer from the source to drain lead, always present in a realistic system, is a relevant perturbation. By using dissipative leads, as recently introduced in single dot experiments, this charge transfer can be suppressed, thus allowing the intermediate-coupling non-Fermi-liquid quantum critical point to be reached. We expect that when dissipation exceeds a critical value, zero conductance will be observed except at this critical point, which then is its experimental signature. We also studied the effect of dissipation on the two critical points at which the interdot exchange flows either to zero or infinity.

8:12 AM F13.00002 Stabilizing lateral strained-Si/SiGe material quantum dots, SERGEI STUDENIKIN, G. POULIN-LAMARRE, A. SACHRAJDA, National Research Council of Canada, T. LU, N. BISHOP, T. PLUYM, P. KOTULA, M. LILLY, M. CARROLL, Sandia National Laboratories — In enhancement-mode SiGe quantum dot structures [2], 2DEG electrons are generated via the application of a positive global gate. The carrier mobility in such structures is limited by disorder potential at the oxide/silicon interface. Recently it was shown that the deteriorating effect of charge fluctuations can be substantially mitigated by incorporating a shielding electron layer at the surface — a thin Si quantum well cap layer [1,2]. This cap layer can, however, cause instabilities, drifts and hysteretic behaviour. In this work we study the stability of a tunable quantum dot defined by lateral gates in a Si/SiGe structure with a thin silicon cap layer and Si3N4 dielectric layer between the global gate and the structure [2]. Different "stabilization" procedures are explored to stabilise the device using both dc transport and charge sensing measurements at 300 mK.

8:24 AM F13.00003 Beyond hydrostatic strain in empirical pseudopotentials for the electronic structure of InGaAs quantum dots, CEYHUN BULUTAY, ASLI CAKAN, Bilkent University — Self-assembled quantum dots (SAQDs) are among the prime candidates for realizing semiconductor quantum wire systems. Even though much progress has been achieved toward understanding their electronic structure, more efforts are needed to reach the desired quantitative level for a precise control of the carrier and nuclear spin degrees of freedom. In this respect, the empirical pseudopotential method has been highly successful for structures involving more than hundred thousand atoms. However, due to lack of self-consistency, their use in strained environments, as in SAQDs, requires vital improvement. The main contribution of this work is to develop empirical pseudopotentials valid for inhomogeneous strain environments caused by cation alloying in InGaAs SAQDs. In our presentation, we first validate our approach with the ab initio density functional theory results based on Projector Augmented-Wave technique. This is followed by a comparison of the electronic structure results with and without strain-dependent pseudopotentials for InGaAs SAQDs having an alloy composition of 20-30% indium, which is typically the case in the current samples.

Characterization of NiSi nanowires as field emitters and limitations of Fowler-Nordheim model at the nanoscale

AМИНА B. BELKADI, University of Colorado - Boulder, E. GALE, Khalifa University - KUSTAR, A.F. ISAKOVIC, Khalifa University - KUSTAR, KSRС — Nanoscale field emitters are of technological interest because of the anticipated faster turn-on time, better sustainability and compactness. This report focuses on NiSi nanowires as field emitters for two reasons: (a) possible enhancement of field emission in nanoscale field emitters over bulk, and (b) achieving the same field emission properties as in bulk, but at a lower energy cost. To this end, we have grown, fabricated and characterized NiSi nanowires as field emitters. Depending on the geometry of the NiSi nanowires (aspect ratio, shape etc.), the relevant major field emission parameters, such as (1) the turn-on field, (2) the work function, and (3) the field enhancement factor, can be comparable or even superior to other recently explored nanoscale field emitters, such as CdS and ZnO. We also report on a comparative performance of various nanoscale field emitters and on the difficulties in the performance comparison in the light of relatively poor applicability of the standard Fowler-Nordheim model for field emission analysis for the case of the nanoscale field emitters. Proposed modifications are discussed.

Ultra-low noise atomically patterned nanostructures in Si

SAQUIB SHAMIM, Department of Physics, Indian Institute of Science, Bangalore 560012, India, BENT WEBER, MICHELLE Y. SIMMONS, Centre of Excellence for Quantum Computation and Communication Technology, University of New South Wales, Sydney 2052, Australia, ARINDAM GHOSH, Department of Physics, Indian Institute of Science, Bangalore 560012, India — Advancement in scanning tunnelling microscopy (STM) based lithography has made it possible to achieve low resistivity atomic scale wires and single donor quantum dot devices in silicon. Due to extreme sensitivity of these devices to any disorder or charge traps, it is of paramount importance to explore the noise magnitude in these systems. Here we investigate low frequency noise measurements in two STM patterned atomic scale wires of phosphorous dopants in Si of diameters 4.5 nm and 1.5 nm. The variation of noise with gate voltage indicates that the noise arises due to trapping-detrapping of electrons between the wire and charged traps. The Hooge parameter for these wires is 10⁻¹² to 10⁻¹³ (for different gate voltages), which is one of the lowest reported for any one-dimensional system. The reason for such low noise magnitude can be two-fold. First, a complete monolithic fabrication procedure avoids any direct metallic contact to the one-dimensional system and hence prevents any Schottky barrier. Second possibility is that the Coulomb repulsion between the charges on traps doesn’t allow many traps to be activated simultaneously. Aimed at being the backbone of silicon quantum computation scheme, a reduced noise in these devices is technologically crucial.

Understanding electronic band-edge properties of GaSbAs/GaAs nanostructures through k.p theory simulations

CHRISTINA JONES, EMMANOUIL KIOUPAKIS, University of Michigan - Ann Arbor — Gallium antimonide (GaSb) nanostructures embedded in gallium arsenide (GaAs) have been predicted by theory and have been found experimentally to demonstrate both type-I and type-II band alignment. The ability of GaSb nanostructures to exhibit two band alignment types makes them versatile in applications such as LEDs, photodetectors, and charge-based memory elements. We present a systematic study of the mechanisms behind the band alignment type in order to understand the underlying physics behind the alignment transition and allow for prediction and optimization of electronic properties. We employ the eight-band k.p method through a commercially available software package (nextnano) to calculate the band structure by self-consistently solving the Schroedinger and Poisson equations including strain and polarization charges. Results obtained for GaSbAs/GaAs quantum wells show both type-I and type-II band alignment depending on strain and composition. Calculated band-edges are compared to published experimental results.

Resonant Subband Landau Level Coupling in GaAs/AlGaAs/GaAs Coupled Quantum Wells

LI-CHUN TUNG, University of North Dakota, DMITRY SMIRNOV, National High Magnetic Field Laboratory — Subband energies and intersubband couplings of symmetric GaAs/AlGaAs/GaAs coupled quantum wells have been investigated by magneto-infrared spectroscopy at 4K up to 35T. Most of the proposed quantum well infrared photodetectors consist of coupled quantum wells, and the detection of infrared photons is accomplished via exciting bound electrons of lower subbands to a continuous state via intersubband transitions. With the presence of a small in-plane magnetic field, subbands due to the mixing of wave functions of individual quantum wells are studied by the anti-level crossing resonance of the Landau levels belonging to different subbands. The observed coupling between the first subband of the coupled quantum wells (Symmetric mixing of the lowest subbands of the individual quantum wells) to the third subband is observed, while the others are forbidden. The symmetry selection rule for the intersubband transitions of symmetric coupled quantum wells will be discussed in the presentation.

Mott transition in the coupled quantum wells with the external periodic potential

OLEG BERMAN, ROMAN KEZERASHVILI, New York City College of Technology of CUNY, Brooklyn NY, USA, YURII LOZOVIK, Institute of Spectroscopy, Troitsk, Russia, KLAUS ZIEGLER, University of Augsburg, Augsburg, Germany — We study a system of spatially separated electrons and holes in two coupled quantum wells within a temperature-dependent mean-field approach. A periodic potential is applied to the quantum wells which allows us to modify the spectral properties of the electrons and the holes. This system exhibits a rich phase diagram, consisting of a BCS phase with electron-hole pairs, an electron-hole plasma and a bosonic Mott phase of tightly bound electron-hole pairs. The latter have no phase coherence in contrast to the pairs in the BCS phase. We discuss the transitions between the different phases in terms of temperature, density and interaction strength.

Terahertz spectroscopy of two-dimensional electron-hole pairs: probing Mott physics of magneto-excitons

QI ZHANG, WEILU GAO, Rice University, JOHN WATSON, MICHAEL MANFRA, Purdue University, JUNICHIRO KONO, Rice University — Density-dependent Coulomb interactions can drive electron-hole (e−h) pairs in semiconductors through an excitonic Mott transition from an excitonic gas into an e−h plasma. Theoretical studies suggest that these interactions can be strongly modified by an external magnetic field, including the absence of inter-exciton interactions in the high magnetic field limit in two dimensions, due to an e−h charge symmetry, which results in ultrastable magneto-excitons. Here, we present a systematic experimental study of e−h pairs in photo-excited undoped GaAs quantum wells in magnetic fields with ultrafast terahertz spectroscopy. We simultaneously monitored the dynamics of the intraexcitonic 1s→2p transition (which splits into 1s→2pυ and 1s→2pl transitions in a magnetic field) and the cyclotron resonance of unbound electrons and holes up to 10 Tesla. We found that the 1s→2pυ absorption feature is robust at high magnetic fields even under high excitation fluences, indicating magnetically enhanced stability of excitons. We will discuss the Mott physics of magneto-excitons as a function of temperature, e−h pair density, optical pump delay time, as well as magnetic field, and also compare two-dimensional excitons in GaAs quantum wells with three-dimensional excitons in bulk GaAs.
8:00AM F14.00001 Carbon defects as sources of the green and yellow luminescence bands in undoped GaN\(^1\), Denis Demchenko, Michael Reshchikov, Virginia Commonwealth University — In high-purity GaN grown by hydride vapor-phase epitaxy (HVPE), the commonly observed yellow luminescence (YL) band gives way to a green luminescence (GL) band at high excitation intensity. Based on hybrid functional calculations and experimental photoluminescence measurements, we propose that the GL band with a maximum at 2.4 eV is caused by transitions of electrons from the conduction band to the 0/+ level of the isolated C\(_N\) defect. The YL band with a maximum at 2.1 eV, related to the transitions via the /-0 level of the same defect can be observed only for some high-purity HVPE samples. However, in less pure GaN samples (HVPE samples with larger O and C concentrations, as well as all MOVCD grown samples), no GL band is observed and another YL band with a maximum at 2.2 eV dominates the PL spectrum. The latter is attributed to the C\(_N\)O\(_3\) complex.

8:12AM F14.00002 Density Functional Theory Calculations of Activation Energies for Carrier Capture by Defects in Semiconductors, Normand Modine, Alan Wright, Stephen Lee, Sandia National Laboratories — Carrier recombination due to defects can have a major impact on device performance. The rate of defect-induced recombination is determined by both defect levels and carrier capture cross-sections. Density functional theory (DFT) has been widely and successfully used to predict defect levels, but only recently has work begun to focus on using DFT to determine carrier capture cross-sections. Lang and Henry worked out the fundamental theory of carrier-capture by multiphonon emission in the 1970s and showed that, above the Debye temperature, carrier-capture cross-sections differ between defects primarily due to differences in their carrier capture activation energies. We present an approach to using DFT to calculate carrier capture activation energies that does not depend on an assumed configuration coordinate and that fully accounts for anharmonic effects, which can substantially modify carrier activation energies. We demonstrate our approach for the -3/-2 level of the Ga vacancy in wurtzite GaN. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

8:24AM F14.00003 Defect identification in semiconductors with positron annihilation: experiment and theory, Filip Tuomisto, Aalto University — Positron annihilation spectroscopy is a very powerful technique for the detection, identification and quantification of vacancy-type defects in semiconductors. In the past decades, it has been used to reveal the relationship between optoelectronic properties and specific defects in a wide variety of materials - examples include parasitic yellow luminescence in GaN, dominant acceptor defects in ZnO and broad-band absorption causing brown coloration in natural diamond. In typical binary compound semiconductors, the selective sensitivity of the technique is rather strongly limited to cation vacancies that possess significant open volume and suitable charge (negative of neutral). On the other hand, oxygen vacancies in oxide semiconductors are a widely debated topic. The properties attributed to oxygen vacancies include the inherent n-type conduction, poor p-type dopability, coloration (absorption), deep level luminescence and non-radiative recombination, while the only direct experimental evidence of their existence has been obtained on the crystal surface. We will present recent advances in combining state-of-the-art positron annihilation experiments and ab initio computational approaches. The latter can be used to model both the positron lifetime and the electron-positron momentum distribution - quantities that can be non-directly correlated in the experiments. We will present results from these methods to study vacancy-type defects in III-nitride semiconductors (GaN, AlN, InN) and oxides such as ZnO, SnO\(_2\), In\(_2\)O\(_3\) and Gd\(_2\)O\(_3\). We will show that cation-vacancy-related defects are important compensating centers in all these materials when they are n-type. In addition, we will show that anion (N, O) vacancies can be detected when they appear as complexes with cation vacancies.

9:00AM F14.00004 The role of surface kinetics on defect generation and propagation during epitaxy of WBG semiconductors, Angel Yanguang-Gil, Argonne Natl Lab — One of the greatest challenges in the application of WBG semiconductors to power electronics and optoelectronic applications is how to mitigate the impact of electrically active defects on device performance. While this is an issue that traditionally has been tackled through process development, from a fundamental point of view we still have a limited knowledge on the interplay between epitaxial growth and defect generation. This interaction goes both ways, with surface kinetics promoting the formation of surface defects that get incorporated into the bulk, and the surface defects and surface morphology driving the kinetics of the growth process. In this work we explore the interplay between surface kinetics and 0D and 1D defects during epitaxy. By combining molecular dynamics and kinetic Monte Carlo simulations we have focused on understanding how surface kinetics promotes the formation of defects, and identified the surface configurations that are more likely to lead to point defects incorporated in the bulk. Conversely, we have also studied the impact of existing defects, in particular the interaction of surface species and surface steps with threading dislocations. Our target materials are GaN, AlN, and SiC.

9:12AM F14.00005 Dilute-P GaNP Semiconductor Alloy for Visible Light Emitter, Chee-Keong Tan, Nelson Tansu, Center for Photonics and Nanoelectronics, Department of Electrical and Computer Engineering, Lehigh University — Group III-Nitride semiconductor alloy in particular InGaN alloy is widely employed as the active media for the solid state lighting applications. In addition to the InGaN alloy, dilute-As GaNAs alloy has recently been suggested as the potential material for high efficiency solid state lighting devices. In conjunction with dilute-As GaNAs alloy, dilute-P GaNP alloy has the potential for its use in light emitting applications. The literature on dilute-P GaNP alloy is severely limited, thus the understanding of electronic properties of dilute-P GaNP alloys is important. In this work we present the analysis of the electronic properties of dilute-P GaNP alloys through First-Principle Density Functional Theory (DFT). Our analysis shows that the replacement of N atoms with Phosphorus (P) atoms in the GaN alloy leads to significant changes in the band structure including the band gap and effective mass. In addition, our finding indicates minimal interband Auger recombination in the dilute-P GaNP alloys as compared to InGaN alloy, suggesting the potential of GaNP alloys as high efficiency visible light emitter. The electronic properties of the dilute-P GaNP alloys will be discussed in detail.

9:24AM F14.00006 The donor-acceptor relationship in HVPE GaN:Fe Substrates\(^3\), Ustun Sunay, University of Alabama at Birmingham — GaN is a wide bandgap semiconductor plagued by a high concentration of residual donors, typically from unintentionally incorporated Si or O. The effect of these donors can be masked by doping with deep acceptors, such as Fe, which compensates the donors creating a semi-insulating material that can be used for RF applications. Compensation is thought to occur when the Fe\(^{3+}\) acceptor captures a donor electron, creating Fe\(^{2+}\) and a partially compensated donor. A recent photo-EPR spectroscopy study of lightly Fe-doped (1x10\(^{17}\) cm\(^{-3}\)) bulk GaN showed the existence of neutral donors and Fe\(^{3+}\) simultaneously. The presence of both calls into question the current understanding of compensation. To further understand donor-acceptor compensation, bulk GaN grown via hydride vapor epitaxy was intentionally codoped with Si donors and Fe acceptors in ratios ranging from 0.01 to 1.55. Both species were present in 3.5 K EPR spectra, but the Fe\(^{3+}\) acceptor signal decreased, and the neutral donor signal increased monotonically as the Si:Fe ratio increased. While this shows that Fe\(^{3+}\) partially compensates the neutral donor, interpretation of photo-EPR experiments suggests that some donors and acceptors are not interacting and that there is a multi-step mechanism for compensation. Cathodoluminescence (CL) results showed striated regions of luminescence intensity which indicate defect concentration non-uniformity. The leading explanation for the EPR and CL results is a physical separation between the donors and acceptors, leading to local variations in the Si:Fe ratio.

9:36AM F14.00007 The Role of Oxygen on the Nature and Stability of Eu Centers in Eu doped Gallium Nitride, BRANDON MITCHELL, Department of Physics and Astronomy, University of Mt. Union, 1972 Clark Ave, Alliance, OH, 44601, USA, DOLF TIMMERMAN, ZHU WAXING, JUNICHI TAKATSU, MASAKI MATSUDA, Division of Materials and Manufacturing Science, Graduate School of Engineering, Osaka University, Suita, Osaka 565-0871, Japan, KATHARINA LORENZ, EDUARDO ALVES, Instituto Superior Técnico, Campus Tecnológico e Nuclear, Estrada Nacional 10, P-2695-066 Bobadela LRS, Portugal, ATSUŠI KOIZUMI, YASUFUMI FUJIWARA, Division of Materials and Manufacturing Science, Graduate School of Engineering, Osaka University, Suita, Osaka 565-0871, Japan, VOLKMAR DIEROLF, Department of Physics and Astronomy, Leibniz Universität Hannover, Department of Physics and Astronomy, Leibniz Universität Hannover, 30167 Hannover, Germany, and Department of Materials and Manufacturing Science, Graduate School of Engineering, Osaka University, Suita, Osaka 565-0871, Japan. — Growth of high quality, free-standing GaN substrates is essential for further improvement of nitride device performance. Unfortunately, many bulk growth methods introduce unacceptable amounts of O donors. Samples studied in this work were grown by the high-pressure nitrogen solution method on (0001) sapphire with Mg-doped GaN substrates characterized by 4 K electron paramagnetic resonance (EPR) spectroscopy. No EPR signal is detected in the undoped samples. However, a nearly isotropic spectrum with g-value of 1.984 and a line-width of 120 G is observed in the doped sample after illumination with 2.8 eV light. Concentration of the center was estimated to be 10^{17} cm^{-3} while secondary ion mass spectroscopy revealed Mg and O levels of 10^{16} cm^{-3}, Si, C, and Be levels of 10^{17} cm^{-3}. Time-dependent photo-EPR data were well fit by a single defect-to-band transition model with a defect level of 0.67 eV above the valence band. This value is close to that predicted for the Be acceptor. Together with the similar concentrations of the EPR center and Be, the data suggest that the signal may be due to the accidental Be; however, a review of the literature suggests additional possibilities, such as a vacancy-related defect.

9:48AM F14.00008 Computational nano-material design of exotic luminescent materials based upon europium doped gallium nitrides, AKIRA MASAGO, TETSUYA FUKUSHIMA, Graduate School of Engineering Science, Osaka University, KAZUNORI SATO, Graduate School of Engineering, Osaka University, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering Science, Osaka University — Eu-doped GaN has attracted much attention, because the red light luminescence ability provides us with expectations to realize monolithic full-color LEDs, which work on seamless conditions such as substrates, electrodes, and operating bias voltages. Toward implementation of multifunctional activity into the luminescent materials using the spinoidal nano-structures, we investigate atomic configurations and magnetic structures of the GaN crystal codoped with Eu, Mg, Si, O, and/or the vacancies using the density functional method (DFT) calculations. Our calculations show that the impurity clustered distributions are energetically favorable more than the homogeneous distribution. Moreover, analyses of the formation energy and binding energy suggest that the clustered distributions are spontaneously formed by the nano-spinoidal decomposition. Though the host matrix has no magnetic moments, the cluster has finite magnetic moments, where Zener’s p–f exchange interaction works between the Eu f-state and the nearby np-states.

10:00AM F14.00009 Stabilization of free-standing GaN foils by threading edge dislocations, ROMAN GRÖGER, Institute of Physics of Materials and CEITEC IPM, Academy of Sciences of the Czech Republic, LUCIEN LECONTE, Université Lille 1, France — Computational studies of core structures of 1/3(1120) threading edge dislocations in bulk GaN predict the existence of a 5/7-atom ring configuration when viewed along the [001] direction. While this agrees with recent high-resolution electron microscopy observations, previous studies also reveal the existence of an 8-atom ring configuration. We employ molecular statics calculations to show that the core stability of the threading edge dislocation in free-standing GaN foils depends on the foil thickness and the terminations of their surfaces. For the foil thickness above 6 nm, the edge dislocation is predicted to possess the 5/7-atom ring core structure. However, with decreasing thickness and depending on surface terminations the minimum energy core structure may change to both 8-atom ring and 4-atom ring configurations. By quantifying the interaction energy of the dislocation with the surface of the foil, we show that there exist conditions for which the threading edge dislocation in the foil is more stable than in the bulk.

10:12AM F14.00010 Atomic and electronic structures of (GaN)_{1-x}(ZnO)_{x} alloys: the role of short-range order, JIAN LIU, PHILIP ALLEN, State Univ of NY- Stony Brook — (GaN)_{1-x}(ZnO)_{x} solid solution is a promising photocatalyst for efficient water splitting under visible illumination. For theoretical modeling, the special quasirandom structure (SQS) method which assumes random site occupancy is widely used. We have previously shown, with density-functional theory (DFT) total energy calculations, cluster expansion, and Monte Carlo simulations, that short-range order (SRO) is significant due to the non-isovalency. Thus it is desirable to include SRO in the construction of supercells. Inspired by the SQS method, we construct the “special quasi-ordered structure” (SQoS) supercells. Subsequent DFT calculations show that the atomic and electronic structures of SQS and SQoS alloys differ significantly. The SRO and (x,T) dependence of the valence band maximum stem mainly from the anti-bonding hybrids of N2p and Zn3d states. This suggests the possibility of engineering the band gap by tuning SRO. We also explore bond length distribution and bond angle variation over the composition-temperature (x,T) phase space using bond valence method (BVM). The validity of our BVM model is tested by DFT total energy calculations.

Tuesday, March 3, 2015 8:00AM - 10:48AM — Session F15 DMP: Focus Session: Exciton and Electron Transport in Nanostructures 008B - Richard Haglund, Vanderbilt University

8:00AM F15.00001 Exciton Transport in Nanostructured Solids, VLADIMIR BULOVIC, M.I.T. — Transport of nanoscale energy in the form of excitons is at the core of operation of nanostructured optoelectronic devices such as solar cells, light-emitting diodes and excitonic transistors. Of particular importance is the relationship between exciton transport and bandcage disorder, the defining characteristic of molecular and nanostructured materials. The talk will present recent advancements in directly visualizing exciton transport, with spatial, temporal and spectral evolution recorded for molecular crystals, disordered thin films, and colloidal quantum dot solids. Our measurements demonstrate that the mechanism of exciton transport depends strongly on the nanostructure morphology and the design of nanoscale building blocks. In addition, the talk will show that the excitonic energy landscape can be directly manipulated in solid-state thin films using dipole–dipole interactions, which can be increased under mechanical pressure, or molecular doping with polar molecules, leading to dramatic shifts in the exciton energy structure.
8:36AM F15.00002 Spectral Road Map of Strain-Split Bulk GaAs Excitons: Evidence of Excitation-Induced Dephasing. DANIEL WEBBER, KIMBERLEY HALL, Dalhousie University, BRIAN WILMER, ALAN BRISTOW, West Virginia University, XINYU LIU, MARGARET DOBRWOLSKA, JACEK FURDYNA, University of Notre Dame — Thin films of bulk GaAs studied with two-dimensional coherent spectroscopy reveal strain-split heavy- (HH) and light-hole (LH) excitons with quantum interference. Excitation overlapping the HH continuum show strong excitation-induced dephasing (EID) and emission at the HH exciton for collinear polarization. The results are consistent with excitations beyond the perturbative $\chi^{(3)}$ regime. Cross-linear polarization suppresses the HH emission and enhances the LH exciton as well as HH bie exciton emission. Two-quantum spectra at low excitation concentrations are also consistent with HH and LH exciton interference and EID. Results are compared to four-wave mixing transients that require modelling for interpretation.

8:48AM F15.00003 Nonlinear, driven-dissipative hydrodynamics and effective chiral description of an exciton-polariton superfluid. MANAS KULKARNI, GERMAN KOLMAKOV, New York City College of Technology, City University of New York — Given recent remarkable experimental success on capturing hydrodynamic features of exciton-polariton condensates in optical microcavities and their potential implications for quantum and optical computing and information technologies, we present an effective chiral description for such systems. This description captures the fingerprints of hydrodynamics, namely, nonlinearity, dispersion and dissipation in the exciton-polariton system. The resulting chiral equation for the condensate perturbation wave dynamics is found to be of Burgers-type thereby providing a more transparent understanding of the complicated underlying coupled exciton-photon dynamics. By using analytical calculations and numerical simulations, we describe the phenomenon of polariton shock waves, solitons and defects in such systems. Our mapping is expected to have broad implications for other polariton and photon systems including dipolar exciton and magnon condensates. This mapping can further help one in engineering a delicate balance between the pump and damping to produce stable optical signals propagating in polariton circuits.

9:00AM F15.00004 Recipe for Topological Polaritons1, TORSTEN KARZIG, CHARLES-EDOUARD BARDYN, Caltech, NETANEEL LINDNER, Technion, GIL REFAEL, Caltech — The interaction between light and matter can give rise to novel topological states. This principle was recently exemplified in Floquet topological insulators, where classical light was used to induce a topological electronic band structure. Here, in contrast, we show that mixing single photons with excitons can result in new topological polaritonic states — or “topolaritons”. Taken separately, the underlying photons and excitons are topologically trivial. Combined appropriately, however, they give rise to non-trivial polaritonic bands with chiral edge modes allowing for unidirectional polariton propagation. The main ingredient in our construction is an exciton-photon coupling with a phase that winds in momentum space. We demonstrate how this winding emerges from spin-orbit coupling in the electronic system and an applied Zeeman field. We discuss the requirements for obtaining a sizable topological gap in the polariton spectrum.

1funded by the Institute for Quantum Information and Matter, the Bi-National Science Foundation and I-Core: the Israeli Excellence Center “Circle of Light”, and Darpa under funding for FENA, and the Swiss National Science Foundation.

9:12AM F15.00005 Topological Polaritons and Excitons in Garden Variety Systems1, CHARLES-EDOUARD BARDYN, TORSTEN KARZIG, GIL REFAEL, Caltech, TIM LIEW, Nanyang Technological University — Topological polaritons (aka topolaritons) present a new frontier for topological behavior in solid-state systems. They combine light and matter, which allows to probe and manipulate them in a variety of ways. They can also be made strongly interacting due to their excitonic component. Here we present a scheme which allows to realize topolaritons in garden variety zinc-blende quantum wells. Our proposal requires a moderate magnetic field and a potential landscape which can be implemented, e.g., via surface acoustic waves or patterning. We identify indirect excitons in double quantum wells as a particularly appealing alternative for topological states in exciton-based systems. Indirect excitons are robust and long lived (with lifetimes up to milliseconds), and, therefore, provide a flexible platform for the realization, probing, and utilization of topological coupled light-matter states.

9:24AM F15.00006 Excitonic condensation in spatially separated 1D systems1, DAVID ABERGEL, NORDITA — We introduce the concept of excitonic condensation between spatially separated ground state populations of 1D electrons and holes mediated by their attractive direct Coulomb interaction. Candidate systems for observing this phenomenon include semiconductor quantum wires, core-shell nanowires, stacked graphene nanoribbons, and carbon nanotubes. We focus on the core-shell nanowire system and present calculations of the excitonic gap (which characterizes the stability of the condensate) and the critical temperature of the condensate. We also discuss additional effects such as the dependence on the material parameters, the presence of multiple bands, and spin or valley degeneracy. We show that 1D systems may have substantial improvement in the critical temperature of the condensate over comparable 2D systems because the screening of the inter-layer Coulomb interaction is weaker.

9:36AM F15.00007 Kondo Physics in 4f metals: Gadolinium nanocontacts. BERNAT OLIVERA, CARLOS UNTIEDT, University of Alicante (Spain), ELKE SCHEER, University of Konstanz (Germany) — The study of electron transport in conducting materials at the nanoscale can be carried out by using Scanning Tunneling Microscope (STM) and Mechanically Controllable Break Junction techniques (MCBJ). At such scales, Kondo effect vanishes the magnetic properties of the 3d transition metals Fe, Co and Ni. The 4f rare earth metals are an interesting aim of study because of their strong magnetic properties among other things. At our laboratories we have measured gadolinium with both STM and MCBJ techniques. This work is supported by the LDRD program at ORNL. Portion of this research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.

9:48AM F15.00008 Theory of space charge limited currents in films and nanowires with dopants1, XIAOGUANG ZHANG, Department of Physics and Quantum Theory Project, University of Florida, SOKRATES PANTELIDES, Department of Physics and Astronomy, Vanderbilt University — We show that proper description of the space charge limited currents (SCLC) in a homogenous bulk material must account fully for the effect of the dopants and the interplay between dopants and traps [1]. The sharp rise in the current at the trap-filled-limit (TFL) is partially mitigated by the dopant energy levels and the Frenkel effect, namely the lowering of the ionization energy by the electric field, which is screened by the free carriers. In nanowires, lack of effective screening causes the trap occupation at small biases to reach a high level comparable to the TFL in bulk. This explains the high current density in SCLCs observed in nanowires. [1] X.-G. Zhang and S. T. Pantelides, Phys. Rev. Lett. 108, 266602 (2012).

10:00AM F15.00009 Long Minority Carrier Diffusion Lengths in Bridged Silicon Nanowires¹. DONG YU, MARK TRIPPLETT, YIMING YANG, UC Davis, FRANCOIS LEONARD, ALEC TALIN, Sandia National Lab, SAIF ISLAM, UC Davis — Nanowires have large surface areas which create new challenges for their optoelectronic applications. Lithographic processes involved in device fabrication and substrate interfaces can lead to surface defects and substantially reduce charge carrier lifetimes and diffusion lengths. Here, we show that using a bridging method to suspend pristine nanowires allows for circumventing detrimental fabrication steps and interfacial effects associated with planar device architectures. We report electron diffusion lengths up to 2.7 µm in bridged silicon nanowire devices, much longer than previously reported values for silicon nanowires with a diameter of 100 nm. Strikingly, electron diffusion lengths are reduced to only 45 nm in planar devices incorporating nanowires grown under the same conditions. The highly scalable and low-cost silicon nano-bridge devices with the demonstrated long diffusion lengths may find exciting applications in photovoltaics, image sensing and photodetectors.

10:12AM F15.00010 Analytical Perturbative Treatment of Multiterminal Nonequilibrium Anderson Impurity Models¹. NOBUHIKO TANIGUCHI, University of Tsukuba — We investigate analytically the nonequilibrium Anderson impurity model connecting with multiterminal leads. Within the validity of the second-order perturbation regarding the interaction strength, the full dependence on frequency and bias voltage of the nonequilibrium self-energy and spectral function is determined for a generic multiterminal setting where the current preservation has been an issue. Our analytical perturbative treatment respects the current conservation as well as the spectral sum rule, and it encompasses Fermi-liquid and non-Fermi-liquid behaviors, showing that increasing finite-bias voltage leads to a crossover from the Kondo resonance to the Coulomb blockade phenomena. Analysis on two-terminal and multiterminal settings shows that finite-bias voltage does not split the Kondo resonance in this order; no specific structure due to multiple leads emerges in the spectral function. Overall bias dependence is quite similar to finite-temperature effect, which could be understood by help of the Ward identity and the limit of $N \gg 1$ terminals.

¹Grant-in-Aid for Scientific Research (No.26060032, MEXT, Japan).

10:24AM F15.00011 Kondo effects and interference in transport through single molecules, JENS PAASKE, KIM GEORG LIND PEDERSEN, PER HEDEGAARD, The Niels Bohr Institute, University of Copenhagen — Quantum transport through single molecules or quantum dot arrays with spin-degenerate ground states can be dominated by Kondo effects at low temperatures. In contrast to the single impurity case, quantum interference plays a significant role in such ‘multi-orbital’ systems and may have a strong influence on the possible Kondo physics: deciding between single- or multi-channel screening and even ferromagnetic Kondo effect. We investigate a range of smaller molecules with source, and drain electrodes attached in different specific contacting geometries. The interacting pi-electron system is treated by means of exact diagonalization, and combining with a perturbative treatment of molecule-lead tunnel couplings, we calculate the zero-bias cotunneling conductance as a function of a gate-voltage shifting the Fermi level across a time dependent impurity in a linear chain are studied theoretically using the Floquet formalism. We obtain the exact reflection coefficient for a wide range of parameters. Our results compare well with known approximations in the high frequency regime. Furthermore, at lower frequencies we observe new features and a significant departure from the approximated predictions. Below a well defined frequency the impurity couples waves of differing $k$-values. As a result, the impurity not only splits the incident wave into a transmitting and a reflecting part of the same wave number $k$, but also waves of differing $k$ emerge from the perturbed site. The amplitude of these waves is also obtained.

10:36AM F15.00012 Quantum transport in linear chains under periodic perturbations, DANIEL THUBERG, SEBASTIAN REYES, Facultad de Física, Pontificia Universidad Católica de Chile, Avda.Vicuña Mackenna 4860, Macul, Santiago, Chile, SEBASTIAN EGGERT, Department of Physics, Univ. Kaiserslautern, Erwin Schrodinger Str., D-67663 Kaiserslautern, Germany — Quantum transport properties across a time dependent impurity in a linear chain are studied theoretically using the Floquet formalism. We obtain the exact reflection coefficient for a wide range of parameters. Our results compare well with known approximations in the high frequency regime. Furthermore, at lower frequencies we observe new features and a significant departure from the approximated predictions. Below a well defined frequency the impurity couples waves of differing $k$-values. As a result, the impurity not only splits the incident wave into a transmitting and a reflecting part of the same wave number $k$, but also waves of differing $k$ emerge from the perturbed site. The amplitude of these waves is also obtained.

Tuesday, March 3, 2015 8:00AM - 10:48AM — Session F16 DMP DCOMP: Focus Session: Search for New Fe-based Superconductors I 101AB
- Qiang Li, Brookhaven National Laboratory

8:00AM F16.00001 Why are the Tc,s so high in rare-earth doped CaFe2As2 single crystals and ultrathin FeSe epi-films?¹. C.W. CHU, TCSUH and Department of Physics, University of Houston — Recent reports of non-bulk superconductivity with unexpectedly high onset-Tc,s up to 49 K in the Pr-doped CaFe2As2 [(Ca,Pr)122] single crystals [1] and up to 100 K in one-unit-cell (1UC) FeSe epi-films [2], respectively, offer an unusual opportunity to seek an answer to the question posed in the title. Through systematic compositional, structural, resistive, and magnetic investigations on (Ca,R)122 single crystals with R = La, Ce, Pr, and Nd, we have observed a doping-level-independent Tc, a large magnetic anisotropy, and the existence of mesoscopic-2D structures in these crystals, thus providing evidence consistent with the proposed interface-enhanced Tc in these naturally assembled Fe-based superconductors. Similar resistive and magnetic measurements were also made on the 1-4UC FeSe ultra thin epi-films. We have detected a Meissner state below 1 Oe with extensive weak-links up to ∼ 100 K, unconnected small superconducting patches up to ∼ 40 K, and an unusual dispersion of diamagnetic moment with frequency up to 80 K. The unusual frequency dependences of the diamagnetic moment observed in the films at different temperature ranges suggest that collective excitations of electron and/or spin nature may exist in the FeSe films below 20 K and 40-80 K. The experimental results will be presented and the implications discussed.

¹Collaborators: Liangzi Deng, Bing Lv, Fengyan Wei, and Yu-Yi Xue, University of Houston; Li-Li Wang, Xu-Cun Ma, and Qi-Kun Xue, Tsinghua University, Beijing.
K-doping takes place at the spacing layer while FeAs layers remain intact. In contrast, Co substitution in BaFe$_2$As$_2$ hole asymmetry in the phase diagram of iron-based superconductors is well illustrated in doped BaFe$_{1+y}$As$_2$. The electron-to-conduction electron ratio in these systems is close to 1, which plays a crucial role in the electron-hole asymmetry. In this talk, I will present the magnetic and structural transitions of La$_{0.2}$Ba$_{1.8}$Fe$_2$As$_2$, La$_{0.5-x}$Na$_{0.5+x}$Fe$_2$As$_2$, or even compounds with other rare earth and alkali ions in the spacing layer, provides a new material platform for the study of iron-based superconductors. The material could be tuned from electron-doped to hole-doped by varying the ratio between the alkali metal and rare earth ions.

9:00AM F16.00004 The structural and magnetic phase transitions in a “parent” Fe pnictide compound. NI NI, Department of Physics and Astronomy, University of California, Los Angeles, JARED ALLRED, Materials Science Division, Argonne National Laboratory, HUJBIO CAO, WEI TIAN, Quantum Condensed Matter Division, Oak Ridge National Laboratory, LIAN LIU, Department of Physics, Columbia University, KYUIL CHOI, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, MATTHEW KROGSTAD, Materials Science Division, Argonne National Laboratory, JIE MA, Quantum Condensed Matter Division, Oak Ridge National Laboratory, KEITH TADDEI, Materials Science Division, Argonne National Laboratory, MAKARIY TANATAR, RUSLAN PROZOROV, Ames laboratory and Department of Physics and Astronomy, Iowa State University, MASAAKI MATSUDA, Quantum Condensed Matter Division, Oak Ridge National Laboratory, STEPHAN ROSENKRANZ, Materials Science Division, Argonne National Laboratory, YASUTOMO UEMURA, Department of Physics, Columbia University, SHAN JIANG, Department of Physics and Astronomy, University of California, Los Angeles — We will present transport, thermodynamic, synchrotron X-ray, neutron diffraction, SR, ARPES and polarized optical image measurements on the “parent” compound of the 112 high Tc superconducting Fe pnictide family. Structural and magnetic phase transitions are revealed. Detailed magnetic structure was solved by single crystal neutron diffraction. We will discuss the similarity and difference of these transitions comparing to the parent compounds of other Fe pnictide superconductors.

9:12AM F16.00005 Study on the non-bulk superconductivity in CaFe$_{2-x}$As$_2$ single crystals under different annealing conditions. K. ZHAO, B. LV, I. Z. DENG, Y. Y. XUE, Texas Center for Superconductivity and Department of Physics, University of Houston, C. W. CHU, Texas Center for Superconductivity and Department of Physics, University of Houston, Lawrence Berkeley National Laboratory, 1 Cyclotron Road, Berkeley — The interplay between SDW and tetragonal/collapsed tetragonal (Tc/T) structural transition in CaFe$_{2-x}$As$_2$ single crystals under different annealing conditions has been thoroughly investigated, while the occurrence of filamentary superconductivity with Tc ~ 10K remains mysterious. In this talk, I will present our studies on the interplay of magnetism, structural transition, and superconductivity in the undoped CaFe$_{2-x}$As$_2$ single crystals obtained under different synthetic conditions and annealing procedures. The dihedral shift has been detected for the first time and taken as an evidence of superconducting High temperature annealing and temperature annealing driving CaFe$_{2-x}$As$_2$ into the cT ground state and the T ground state, respectively. The superconducting signal is maximized in the condition where the sample reaches the unstable region at the border of these two. The detailed results and their implications will be presented and discussed.

9:24AM F16.00006 First-principles study on the specific heat of optimally hole-doped BaFe$_2$As$_2$ compound. HYUNGJU OH, SINISA COH, MARVIN L. COHEN, UC Berkeley, Lawrence Berkeley National Laboratory — We present density functional calculation of optimally K-doped BaFe$_2$As$_2$, including a modification of the GGA potential by adding a repulsive term (GGA + A). We tune the additional repulsive term until the occupied bandwidth of the M-point pocket agrees with experimental data. The calculated Sommerfeld coefficient and electron-phonon coupling constant yield a theoretical specific heat coefficient comparable to the experimental one. In addition, overall band structure and Fermi surface topology are improved with respect to the experiment. This work was supported by NSF Grant No. DMR10-1006184 and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by the DOE at Lawrence Berkeley National Laboratory’s NERSC facility.

9:36AM F16.00007 High-temperature superconductivity from fine-tuning of Fermi-surface singularities in iron oxypnictides. ALIAKSEI CHARNUKHA, Physics Department, University of California - San Diego, La Jolla, CA 92093, USA — In the family of iron-based superconductors, 1111-type materials exhibit superconductivity with the highest transition temperature Tc=55K. Early theoretical predictions of their electronic structure revealed multiple large circular sheets of the Fermi surface. Here we use ARPES to show that two prototypical compounds of the 1111 type are at odds with this description. Their low-energy band structure is formed by the edges of several bands, which are pulled to the Fermi level from the depths of the theoretically predicted band structure by strong electronic interactions. We further demonstrate that although their low-energy electronic looks remarkably similar, the Tc differs by a factor of 2. Upon closer examination we uncover that one of the bands in the higher-Tc compound sinks to 2.3meV below the Fermi level and thus does not produce a Fermi surface. And yet we find that it hosts a superconducting energy gap 10x larger than the same band in the lower-Tc sister compound. Our results show that the Fermi-surface singularities in the iron-oxypnictides dramatically affect their low-energy electronic properties, including superconductivity, and must therefore be explicitly taken into account in any attempt to understand the pairing mechanism.

9:48AM F16.00008 Mott Kondo Insulating Behavior in Iron-Oxylachalogenides. BYRON FREELON, Physics Department, Massachusetts Institute of Technology, Cambridge, MA, YUHAO LIU, Lawrence Berkeley National Laboratory, JUNG-LENG CHEN, Department of Physics, Tamkang University, LUIS CRACO, Instituto de Fisica. Universidad Federal de Mato Grosso, Curitiba, Brazil, MUKUL LAAD, The Institute of Mathematical Sciences, CIT Campus, Chennai, India, STEFANO LEONI, School of Chemistry, Cardiff University, JIAQI CHEN, LI TAO, MINGHU FANG, Department of Physics, Zhejiang University, Hangzhou, China, RXOKAN FLAUA, ZAHRAN YAMANI, Canadian Neutron Beam Centre, Canadian Neutron Beam Centre, National Research Council, Chalk River Labs, Chalk River Ontario, Canada, YI-SHENG LIU, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA, CHINGLIN CHANG, Department of Physics, Tamkang University, J.-H. GUO, ZAHID HUSSAIN, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA — The findings of unconventional high-Tc superconductivity (HTSC) in Fe arsenides and selenides have reinvigorated HTSC research. The outstanding debate over how the normal state gives way to HTSC in cuprates has emerged in discussions on possible HTSC mechanisms in Fe-based superconductors. Does Fe-based HTSC result as a pairing instability of a conventional Landau-Fermi liquid (NFL), or as one of a non-NFL, akin to the cuprates? One possible way to address this important question is to investigate Fe-based materials that exhibit a Mott insulating parent phase as in the cuprates. Here we present a study of such materials. We performed a combined experimental-theoretical investigation of the Fe-oxylachalogenides (FeOCh) series La$_2$O$_2$Fe$_2$O$_{12}$ (M =S, Se), the latest among the Fe-based materials with the potential to show unconventional high-Tc superconductivity (HTSC).
10:00AM F16.00009 Correlation effects in KFe$_2$As$_2$, RbFe$_2$As$_2$ and CsFe$_2$As$_2$. STEFFEN BACKES, HARALD O. JESCHKE, ROSER VALENTI, University Frankfurt — We perform a systematic LDA+DMFT study of the iron-pnictide series KFe$_2$As$_2$, RbFe$_2$As$_2$ and CsFe$_2$As$_2$ and compare with available experiments. We find not only strong orbital-dependent renormalizations and Fermi surface topology changes compared to the local-density approximation but also interesting features at higher binding energies. We discuss the observation of a possible orbitally-selective instability as a function of isoelectronic doping.

10:12AM F16.00010 Electronic Properties of Fe-based Ladder Compounds, FEI DU, Jilin University, KENYA OHGUSHI, Tohoku University, YUTAKA UEDA, Toyota Physical and Chemical Institute — The crystal structure of Fe-based superconductors found so far have two-dimensional conducting planes composed of a square lattice of Fe atoms coordinated tetrahedrally by pnictogens or chalcogens. Although there is no report on the discovery of superconductivity in Fe-based materials with one-dimensional structures, elucidating electronic states of such compounds is expected to give an important clue to the mechanism of superconductivity as well as a strong hint for searching new superconductors. We here report on electronic properties of a series of quasi-one-dimensional spin-ladder compounds AFe$_2$X$_2$ ($A = K$, Cs, Ba; $X = S, Se$) with a special focus on a solid-solution AFe$_2$($S_1-x$,$Se_x$)$_3$. We demonstrate that fruitful electronic states emerge as a consequence of the strong electron correlation effect and quantum fluctuations in a low dimensional crystal structure. The following is the list of papers directly related to this talk: [1] Y. Nambu, et al., Phys. Rev. B, 85 064413 (2012). [2] F. Du, et al, Phys. Rev. B 85, 214436 (2012). [3] F. Du, et al, Phys. Rev. B 90, 085143 (2014).

10:24AM F16.00011 H$_2$O(0) and the Kondo Effect in FeSe$_{0.7}$Te$_{0.9}$ Epitaxial Films, NICHOLAS CORNELL, ANVAR ZAKHIDOV, UT Dallas, MARCELO JAIME, MPA-CMMS, LANL, JUIE HUANG, HAYAN WANG, TAMU, MYRON SALAMON, UT Dallas — High-quality, [001]-oriented epitaxial films of FeSe$_{0.7}$Te$_{0.9}$ have been grown on SrTiO$_3$. They are found to have increased critical temperatures and critical fields relative to both bulk samples and thin films of the sister compound, FeSe$_{0.5}$Te$_{0.5}$. Critical field values in excess of 114 T have been reported based on WHH theory. In addition to these improved properties, some samples show resistance minima above Tc, reminiscent of the Kondo effect, presumably from excess Fe. We report results of a high field investigation of these thin films that reveals an empirical zero-temperature value of H$_c2(0)$ ≈ 46 T along [001], significantly less than the WHH estimate, but still exceeding the maximum strong coupling correction to the Pauli limit. Large negative magnetoresistance above the critical field confirms the presence of Kondo behavior in the normal state and persists without saturation up to 60 T. Why the measured critical field exceeds the paramagnetic limit remains a question. However, a Kondo temperature that exceeds the superconducting Tc can lead to overestimated WHH upper critical fields and could explain the wide variation in Tc and H$_c2$ among the “11” iron chalcogenides.

10:36AM F16.00012 High Critical Field Superconductivity in FeSe$_{0.1}$Te$_{0.9}$ Coated Carbon Nanotubes, HAIYAN WANG, post doc. NICHOLAS CORNELL, Professor, Texas A&M University, JUIE HUANG, graduate student in TAMU, MYRON SALAMON, ANVAR ZAKHIDOV, Professor of Physics, University of Texas at Dallas, ANVAR ZAKHIDOV AND HAIYAN WANG TEAM, UTD AND TAMU AFSOR TEAM — Thin films of FeSe$_{0.1}$Te$_{0.9}$, grown on SrTi03, have been shown to possess an increased critical temperature, field, and current relative to both bulk samples of FeSe$_{0.1}$Te$_{0.9}$ and thin films of the related compound FeSe$_{0.5}$Te$_{0.5}$. Empirical measurement of FeSe$_{0.1}$Te$_{0.9}$ thin films reveal a zero temperature Hc2(0) ~ 45T. Carbon nanotubes are a promising lightweight flexible material for superconducting applications and have proven a robust substrate when conformally coated by superconducting MgB2. Thin film coatings of FeSe$_{0.1}$Te$_{0.9}$ have been deposited via pulsed laser deposition on dry-drawn multiwall carbon nanotube sheets drawn from CVD grown forests. While true zero resistance isn’t achieved due to inter-connectivity issues or junction effects in multiwall CNT case, clear superconducting transitions with R reaching zero can be seen on other single wall CNT, and non-oriented carbon nanotube substrates. Properties of these superconducting FeSe$_{0.1}$Te$_{0.9}$@SWCNT thin films are discussed.

Tuesday, March 3, 2015 8:00AM - 11:00AM
Session F17 DMP: Focus Session: Two-dimensional Materials Design 102AB - Aleskey Kolmogorov, Binghamton University, SUNY

8:00AM F17.00001 New two dimensional compounds: beyond graphene, SEBASTIEN LEBEGUE, CRM2 Laboratory, Jean Barriol Institute, Nancy — In the field of nanosciences, the quest for materials with reduced dimensionality is only at its beginning. While a lot of effort has been put initially on graphene, the focus has been extended in the last past years to functionalized graphene, boron nitride, silicene, and transition metal dichalcogenides in the form of single layers. Although these two-dimensional compounds offer a larger range of properties than graphene, there is a constant need for new materials presenting equivalent or superior performances to the ones already known. Here I will present an approach that we have used to discover potential new two-dimensional materials. This approach corresponds to perform datamining in the Inorganic Crystal Structure Database using simple geometrical criteria, and allowed us to identify nearly 40 new materials that could be exfoliated into two-dimensional sheets. Then, their electronic structure (density of states and bandstructure) was obtained with density functional theory to predict whether the two-dimensional material is metallic or insulating, as well as if it undergoes magnetic ordering at low temperatures. If time allows, I will also present some of our recent results concerning the electronic structure of transition metal dichalcogenides bilayers.

8:36AM F17.00002 New-class of Semiconducting 2D materials: Tin Dichalcogenides (SnX2), CAN ATACA, Department of Materials Science and Engineering, Massachusetts Institute of Technology, KEDI WU, School for Engineering of Matter, Transport and Energy, Arizona State University, KAYAHAN SARITAS, Department of Materials Science and Engineering, Massachusetts Institute of Technology, SEFAATTIN TONGAY, School for Engineering of Matter, Transport and Energy, Arizona State University, JEFFREY C. GROSSMAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology — Recent studies have focused on a new generation of atomically thin films of semiconducting transition metal dichalcogenides (MX2) have been fabricated and investigated in monolayer, bilayer and few layer form. In this work, we investigated the electronic, optical and elastic properties of single and few layer and bulk SnX2 ($X=S$, Se) both theoretically and experimentally. Using density functional theory (DFT) we carried out stability analysis through phonon and electronic, optical and elastic structure calculations. Single-layer SnX2s are mechanically exfoliated and Raman and photoluminescence (PL) measurements are taken. UV-Vis absorption spectrum together with PL measurements and DFT calculations yield an indirect gap of ~ 2.5 eV for SnS2 and SnSe structures (bulk). Tunability of the energy band gap and indirect-direct gap transitions are investigated by controlling the number of layers and applied stress. Lowering the number of layers decreases the indirect gap (0.4-0.3 eV), but indirect-direct gap transition occurs when layer-layer distance is reduced. Due to flexibility in engineering the electronic and optical properties, SnX2 compounds are promising materials for future optoelectronic nanoscale applications.
8:48AM F17.00003 Computational design of p-type contacts for MoS$_2$-based electronic devices

PRIYANK KUMAR, Massachusetts Institute of Technology, TIZIANA MUSSO, ADAM FOSTER, Aalto University, JEFFREY GROSSMAN, Massachusetts Institute of Technology — The excellent physical and semiconducting properties of transition metal dichalcogenide (TMDC) monolayers make them promising for many applications. A well-known example is MoS$_2$, which has gained significant attention as a channel material for next-generation transistors. While n-type MoS$_2$ field-effect transistors (n-FETs) can be fabricated with relative ease, fabrication of p-FETs remains a challenge as the Fermi-level of elemental metals used as contacts are pinned close to the conduction band, leading to large p-type Schottky barrier heights (SBHs). Using \textit{ab initio} computations, we model and propose efficient hole contacts utilizing high work function oxide-based hole injection materials, with the aim of advancing p-type MoS$_2$ device technology. Our calculations will highlight the possibility to tune and lower the p-type SBH at the metal/semiconductor interface by controlling the structural properties of oxide materials. Taken together, our results provide an interesting platform for experimental design of next-generation MoS$_2$-based electronic and optoelectronic devices.

9:00AM F17.00004 Computational Design of 2D materials for Energy Applications

QIANG SUN, Peking University — Since the successful synthesis of graphene, tremendous efforts have been devoted to two-dimensional monolayers such as boron nitride (BN), silicene and MoS$_2$. These 2D materials exhibit a large variety of physical and chemical properties with unprecedented applications. Here we report our recent studies of computational design of 2D materials for fuel cell applications which include hydrogen storage, CO$_2$ capture, CO conversion and O$_2$ reduction.

9:12AM F17.00005 Systematic Enumeration of sp$^3$ Nanotethroes and Computational Study of their Properties

ENSNI XU, PAUL E. LAMMERT, Department of Physics, Pennsylvania State University, VINCENT H. CRESPI, Department of Physics, Material Science and Engineering and Chemistry, Pennsylvania State University — A novel 1D allotrope of carbon arise from slow decompression of solid benzene in high-pressure (GPa) cells, wherein columns of benzene, guided by “topochemical” constraint as six-valent 1D super-atoms, rehybridize into a crystal of sp$^3$ nanotethroes. We exhaustively enumerate the allowed hexavalent bonding topologies and discovered several new low-energy allotropes not previously described. The intermediate conformational nature of these systems — stiffer than a polymer, more reconfigurable than a nanowire or nanotube — allows the translational repeat unit for interatomic connectivity (“topological unit cell”) to deviate from the crystallographic unit cell. A topological unit of 12 carbons accommodates thirty-seven distinct chemically stable nanotethroes, fourteen of which are within 80 meV/carbon of the most stable member. Careful optimization of apriori helicity reveals the most stable structures to be chiral; several are stiffer (per carbon atom) than bulk diamond. They have the large gaps of saturated hydrocarbons, but reasonable routes exist towards producing semiconducting variants. We generalize Euler’s rules for ring counting to cover these systems, and propose a naming convention that can be generalized to handle a broad range of progenitor molecules.

9:24AM F17.00006 ABSTRACT WITHDRAWN

9:36AM F17.00007 A Pentagon Based Carbon Sheet

QIAN WANG, SHUNHONG ZHANG, Center for Applied Physics and Technology, Peking University, JIAN ZHOU, Physics Department, Virginia Commonwealth University, XIAOSHUANG CHEN, Shanghai Institute of Technical Physics, Chinese Academy of Science, YOSHIIKU KAWAZOE, Institute for Material Research, Tohoku University, Japan, PURU JENA, Physics Department, Virginia Commonwealth University, A INTERNATIONAL TEAM COLLABORATION — A new two-dimensional (2D) meta-stable carbon allotrope, penta-graphene, composed entirely of carbon pentagons and resembling the Cairo pentagonal tiling, is proposed. State-of-the-art theoretical calculations confirm that the new carbon polymorph is not only dynamically and mechanically stable, but also can withstand temperatures as high as 1000 K. Due to its unique atomic configuration penta-graphene has an unusual negative Poisson’s ratio (NPR) and ultra-high ideal strength that can even outperform graphene. Furthermore, unlike graphene that needs to be functionalized for opening a band gap, penta-graphene possesses an intrinsic quasi-direct band gap as large as 3.25 eV - close to that of ZnO and GaN. Equally important, when rolled up, penta-graphene can form a pentagon-based nanotube. The resulting penta-carbon nanotubes are semiconducting regardless of their chirality. When stacked in different patterns, dynamically and thermally stable 3D twin structures of T12-carbon are generated with band gaps even larger than that of T12-carbon. The versatility of penta-graphene and its derivatives are expected to have broad applications in nanoelectronics and nanomechanics.

9:48AM F17.00008 The size and shape dependence of graphene domain on the band gap of h-BN

CHERNO B. KAH, SALLIYA KIRIGEENAHAGE, LYLE SMITH, MING YU, CHAKRAM JAYANTHI, SHIYU WU, University of Louisville — This talk will report the structure and electronic characteristics of graphene domains embedded in a hexagonal boron-nitride sheet (h-BN) with the goal of band gap tuning in mind. Different shapes (triangular, circular, rectangular, and irregular structures) and sizes of graphene domains will be studied. The structural stability of these hybrid materials will be studied using a new generation of the semi-empirical Hamiltonian (SCELDAO) developed recently [arXiv:1408.4931]. It is found that the lattice mismatch between graphene domains and the h-BN generates large strain, leading to a reduction or a symmetry breaking of the hexagonal lattice of h-BN. The extent of the strain depends on the shape and the size of the domain, as well as on the distribution of B atoms around the graphene domains. This effect also creates impurity states in the band gap of h-BN and changes the band gap. The interplay between the shape and size of graphene domains, the local strain around the domains and the nature of the impurity states on the band gap of h-BN will be discussed.

10:00AM F17.00009 Plenty of motion at the bottom: atomically thin, free-standing liquid gold

PEKKA KOSKINEN, TOPI KORHONEN, Nanoscience center, Department of Physics, University of Jyvaskyla, Finland — Recent experiments have shown that, in addition to covalent materials, also metals like iron can display an atomically thin free-standing solid phase. This phase can be created when existing hole in free-standing graphene is patched by metal atoms. Here we investigate such a metal patch by density-functional -based electronic and molecular dynamics simulations, while the patching material is gold. Simulations show that while at room temperature gold displays a solid phase, at elevated temperatures it displays an atomically thin liquid phase. This stability of free-standing gold to remain planar even upon two-dimensional diffusion is outright remarkable and has its origins in relativistic effects.

10:12AM F17.00010 Dirac Loops in Carbon Allotropes

KIERAN MULLEN, BRUNO UCHOA, Homer L. Dodge Department of Physics and Astronomy, University of Oklahoma, D. GLATZHOFER, Department of Chemistry and Biochemistry, University of Oklahoma — We propose a family of structures that have “Dirac loops”: closed lines in momentum space with Dirac-like quasiparticles, on which the density of states vanishes linearly with energy. The structures all possess the planar trigonal connectivity present in graphene, but are three dimensional. We discuss the consequences of their multiply-connected Fermi surface for transport, including the presence of three dimensional Integer Quantum Hall effect. In the presence of spin-orbit coupling, we show that those structures may have topological surface states. We discuss the feasibility of realizing the structures as an allotrope of carbon.

10:24AM F17.00011 Effects of interlayer Sn-Sn lone pair interaction on the band gap of bulk and nanosheet SnO

1NAOTO UMEAWA, Natl Inst for Materials Sci, WEI ZHOU, Tianjin University — Effects of interlayer lone-pair interactions on the electronic structure of SnO are firstly explored by the density-functional theory. Our comprehensive study reveals that the band gap of SnO opens as increase in the interlayer Sn-Sn distance. The effect is rationalized by the character of band edges which consists of bonding and anti-bonding states from interlayer lone pair interactions. The band edges for several nanosheets and strained double-layer SnO are estimated. We conclude that the double-layer SnO is a promising material for visible-light driven photocatalyst for hydrogen evolution.

10:36AM F17.00012 Phosphorene Oxide: Stability and electronic properties of a novel 2D material

1GAOXUE WANG, RAVIDRA PANDEY, Michigan Tech Univ, SHASHI P. KARNA, US Army Research Laboratory — Phosphorene, the monolayer form of the (black) phosphorus, was recently exfoliated from its bulk counterpart. Phosphorene oxide, by analogy to graphene oxide, is expected to have novel chemical and electronic properties, and may provide an alternative route to synthesis of phosphorene. In this letter, we investigate physical and chemical properties of the phosphorene oxide including its formation by the oxygen adsorption on the bare phosphorene. Analysis of the phonon dispersion curves finds stoichiometric and non-stoichiometric oxide configurations to be stable at ambient conditions, thus suggesting that the oxygen sorption may not degrade the phosphorene. The nature of the band gap of the oxides depends on the degree of the functionalization of phosphorene; indirect gap is predicted for the non-stoichiometric configurations whereas a direct gap is predicted for the stoichiometric oxide. Application of the mechanical strain and external electric field leads to tunability of the band gap of the phosphorene oxide. In contrast to the case of the bare phosphorene, dependence of the diode-like asymmetric current-voltage response on the degree of stoichiometry is predicted for the phosphorene oxide.

8:00AM F18.00001 Observation of Antiferromagnetic Correlations in the Hubbard Model with Ultracold Atoms

1RANDALL HULET2. Rice University — Ultracold atoms on optical lattices form a versatile platform for studying many-body physics, with the potential of addressing some of the most important issues in strongly correlated matter. Progress, however, has been stymied by an inability to create sufficiently low temperatures in an optical lattice. In this talk, I will present our experimental results on the characterization of the three-dimensional Hubbard model near half-filling, realized using two spin-states of fermionic atomic lithium (6)Li). We have developed a compensated optical lattice that has enabled, for the first time, the achievement of temperatures that are below the tunneling energy, t. We use in-situ imaging to extract the central density of the gas, and to determine its local compressibility. For intermediate to strong interactions, we observe the emergence of a density plateau and a reduction of the compressibility, indicative of the formation of a Mott insulator. Comparisons to state-of-the-art numerical simulations of the Hubbard model over a wide range of interactions set an upper limit for the temperature T < t. The Hubbard model is known to exhibit antiferromagnetism at temperatures below the Neel temperature TN. We have detected antiferromagnetic correlations in this system by spin-sensitive Bragg scattering of light. We deduce the temperature of the atoms in the lattice by comparing the light scattering to determinantal quantum Monte Carlo and numerical linked-cluster expansion calculations to find that T/t = 0.51 ± 0.06, corresponding to 1.47N. Further refinement of the compensated lattice may produce even lower temperatures which, along with light scattering thermometry, have important implications for achieving other novel quantum states of matter.

8:36AM F18.00002 Spin Transport in a Unitary Fermi Gas

JOSEPH THYWIISSEN, University of Toronto — We study spin transport in a quantum degenerate Fermi gas of 40K near an s-wave interaction resonance. The starting point of our measurements is a transversely spin-polarized gas, where each atom is in a superposition of the lowest two Zeeman eigenstates. In the presence of an external gradient, a spin texture develops across the cloud, which drives diffusive spin currents. Spin transport is described with two coefficients: D∥, the transverse spin diffusivity, and γ, the Leggett-Rice parameter. Diffusion is a dissipative effect that increases the entropy of the gas, eventually creating a mixture of spin states. γ parameters the rate at which spin current precesses around the local magnetization. Using a spin-echo sequence, we measure these transport parameters for a range of interaction strengths and temperatures. At unitarity, for a normal-state gas initially at one fifth of the Fermi temperature, we find D∥ = 2.3(4) h/m and γ = 1.08(9), where m is the atomic mass. In the limit of zero temperature, γ and D∥ are scale-invariant universal parameters of the unitary Fermi gas. The value of D∥ reveals strong scattering and is near its proposed quantum limit, such that the inferred value of the transport lifetime τ∥ is comparable to h/ϵ. This raises the possibility that incoherent transport may play a role. The nonzero value of γ tells us that spin waves in unitary Fermi gas are dispersive, or in other words, that the gas has a spin stiffness in the long-wavelength limit. Time permitting, we will also discuss a time-resolved measurement of the contact, through which we observe the microscopic transformation of the gas from ideal to strongly correlated.
HENDRIK HAMANN, IBM T J Watson Research Center — In the past most information on the internet has been originated by humans or support topological quantum excitations such as Majorana and Weyl fermions. Generated synthetic gauge fields, such as artificial spin-orbit coupling or band hybridization in driven optical lattices. I will show that such FF superfluids can be generated when the spin populations are imbalanced.

This work is supported by ARO, AFOSR and NSF.

9:48AM F18.00004 Pairing phenomena in quasi-2D Fermi gases , MEERA PARISH, Univ Coll London — Quasi-two-dimensional Fermi systems are both of fundamental interest and technological importance. Recent advances in cold-atom experiments have now made it possible to investigate model quasi-2D Fermi gases in a controlled manner. In this talk, I will discuss the different regimes in the attractive Fermi gas and how these can be dramatically modified by the finite transverse width of the quasi-2D system. In particular, I find that the critical temperature for pairing and superfluidity can be enhanced by relaxing the transverse confinement and perturbing away from the 2D limit. I will also discuss the exotic phases that may be generated when the spin populations are imbalanced.

10:24AM F18.00005 Strongly Interacting Fermi Gases of Atoms and Molecules , MARTIN ZWIERLEIN, MIT-Harvard Center for Ultracold Atoms, Research Laboratory of Electronics, and Department of Physics, MIT, Cambridge, MA, USA — In recent years, ultracold gases of fermionic atoms have become a new platform for the realization of paradigmatic forms of strongly interacting matter. Feshbach scattering resonances allow to tune the interactions between atoms and to realize the crossover from Bose-Einstein condensation of molecules to Bardeen-Cooper-Schrieffer superfluidity of long-range Cooper pairs. On resonance, we encounter the unitary Fermi gas, with universal properties that closely correspond to those of dilute neutron matter in the crust of neutron stars, and to nuclear matter. I will present our recent study of solitonic excitations in this novel superfluid, the creation of planar solitons and the subsequent cascade into vortex rings and solitonic vortices. In the presence of spin imbalance, solitons are predicted stabilize, a hallmark of the Larkin-Ovchinnikov phase. To induce strong interactions one may also quench the atoms’ kinetic energy in optical lattices. Of great interest here is the realization of the Fermi-Hubbard model, believed to hold the key to understanding high-temperature superconductors. We recently realized imaging of fermionic atoms with single-site resolution in optical lattices, an important step towards the direct observation of magnetic order. Finally, strong, long-range dipolar interactions can lead to novel states of fermionic matter such as topological superfluids. We have created chemically stable, strongly dipolar fermionic molecules, opening up prospects for observing a strongly interacting degenerate Fermi gas with dominant dipolar interactions.

Tuesday, March 3, 2015 8:00AM - 11:00AM — Session F19 FIAP: Invited Session: Physical Analytics Mission Room 103B - Supratik Guha, IBM

8:00AM F19.00001 Physical Analytics: An emerging field with real-world applications and impact , HENDRIK HAMANN, IBM T J Watson Research Center — In the past most information on the internet has been originated by humans or computers. However with the emergence of cyber-physical systems, vast amount of data is now being created by sensors from devices, machines etc digitizing the physical world. While cyber-physical systems are subject to active research around the world, the vast amount of actual data generated from the physical world has attracted so far little attention from the engineering and physics community. In this presentation we use examples to highlight the opportunities in this new subject of “Physical Analytics” for highly inter-disciplinary research (including physics, engineering and computer science), which aims understanding real-world physical systems by leveraging cyber-physical technologies. More specifically, the convergence of the physical world with the digital domain allows applying physical principles to everyday problems in a much more effective and informed way than what was possible in the past. Very much like traditional applied physics and engineering has made enormous advances and changed our lives by making detailed measurements to understand the physics of an engineered device, we can now apply the same rigor and principles to understand large-scale physical systems. In the talk we first present a set of “configurable” enabling technologies for Physical Analytics including ultralow power sensing and communication technologies, physical big data management technologies, numerical modeling for physical systems, machine learning based physical model blending, and physical analytics based automation and control. Then we discuss in detail several concrete applications of Physical Analytics ranging from energy management in buildings and data centers, environmental sensing and controls, precision agriculture to renewable energy forecasting and management.

9:00AM F19.00003 Physics of Financial Markets: Can we Understand the Unpredictable Phenomenon of Flash Crashes? , H. EUGENE STANLEY, Boston University Center for Polymer Studies — Dangerous vulnerability is hiding in complex systems. Indeed, disasters ranging from abrupt financial “flash crashes” and large-scale power outages to sudden death among the elderly dramatically exemplify this fact. While we can understand the cause of most events in complex systems, sudden unexpected “black swans” whether in economics or in the “physicists world” cry out for insight. To design more resilient systems we will describe recent results seeking understanding of these black swans. In many real-world phenomena, such as brain seizures in neuroscience or sudden market crashes in finance, after an inactive period of time a significant part of the damaged network is capable of spontaneously becoming active again. The process often occurs repeatedly. To model this marked network recovery, we examine the effect of local node recoveries and stochastic contiguous spreading, and find that they can lead to the spontaneous emergence of macroscopic “phase-flipping” phenomena. The fraction of active nodes switches back and forth between the two network collective modes characterized by high network activity and low network activity. Furthermore, the system exhibits a strong hysteresis behavior analogous to phase transitions near a critical point [A. Majdanzic, B. Podobnik, S. V. Buldyrev, D. Y. Kenett, S. Havlin, and H. E. Stanley, “Spontaneous Recovery in Dynamic Networks,” Nature Physics 10 , 34 (2014)].

This work was carried out in collaboration with a number of colleagues, chief among whom are A. Majdanzic, B. Podobnik, S. V. Buldyrev, D. Y. Kenett, and S. Havlin.
I will also briefly discuss focus areas for future advances, and speculate on ultimate performance limits for coherent Raman imaging. Improvements in this field would provide an unprecedented combination of speed, sensitivity, and chemical selectivity \[1\]. Using this system we are able to obtain high quality Raman spectra in a reasonably short amount of time, sometimes less than a second. This has enabled us to conduct a variety of experiments that were previously inaccessible. Some of these experiments include investigations of the glass transition temperature in thin PS films, measures of enhanced surface mobility in glassy PS, and a simple picture of how we can use surface mobility to develop an understanding of the thin film glass transition. Finally, I will discuss the relation between the length scale of surface mobility to the long discussed yield and plastic flow, which has little impact on the flow stress. Eyring proposed that stress increases the rate of molecular rearrangements in solids and this is the source of nonlinearity in many models. Our group has developed an optical technique to measure molecular mobility and shown that mobility during deformation can increase by more than a factor of 1000. In this talk, I will highlight recent progress including understanding the role of deformation temperature and a comparison between molecular and mechanical relaxation times. Results from recent computer simulations and molecular theories will be discussed. Finally, some comments will be made on the deformation of polymer glasses in comparison to colloidal and metallic glasses.

**Tuesday, March 3, 2015 8:00AM - 11:00AM** — Session F20 DPOLY: Invited Session: Polymer Physics Prize

**8:00AM F20.00001 Polymer Prize Lecture: A perspective on the deformation of polymer glasses**, MARK EDIGER, Department of Chemistry, University of Wisconsin-Madison, Madison, WI 53706 — The mechanical properties of polymer glasses, including yield and plastic flow, are important for many applications. In contrast to the flow of polymer melts, plastic flow is poorly understood at a fundamental level. One reason for this is that the deformation of polymer glasses typically occurs in a highly nonlinear regime, e.g., doubling the strain rate has little impact on the flow stress. Eyring proposed that stress increases the rate of molecular rearrangements in solids and this is the source of nonlinearity in many models. Our group has developed an optical technique to measure molecular mobility and shown that mobility during deformation can increase by more than a factor of 1000. In this talk, I will highlight recent progress including understanding the role of deformation temperature and a comparison between molecular and mechanical relaxation times. Results from recent computer simulations and molecular theories will be discussed. Finally, some comments will be made on the deformation of polymer glasses in comparison to colloidal and metallic glasses.

**8:36AM F20.00002 Nanoparticles in liquid crystals, and liquid crystals in nanoparticles**, JUAN DE PABLO, Institute for Molecular Engineering, University of Chicago — Liquid crystals are remarkably sensitive to interfacial interactions. Small perturbations at a liquid crystal interface, for example, can be propagated over relatively long length scales, thereby providing the basis for a wide range of applications that rely on amplification of molecular events into macroscopic observables. Our recent research efforts have focused on the reverse phenomenon; that is, we have sought to manipulate the interfacial assembly of nanoparticles or the organization of surface active molecules by controlling the structure of a liquid crystal. This presentation will consist of a review of the basic principles that are responsible for liquid crystal-mediated interactions, followed by demonstrations of those principles in the context of two types of systems. In the first, a liquid crystal is used to direct the assembly of nanoparticles; through a combination of molecular and continuum models, it is found that minute changes in interfacial energy and particle size lead to liquid-crystal induced attractions that can span multiple orders of magnitude. Theoretical predictions are confirmed by experimental observations, which also suggest that LC-mediated assembly provides an effective means for fabricating plasmonic devices. In the second system, the structure of a liquid crystal is controlled by confinement in submicron droplets. The morphology of the liquid crystal in a drop depends on a delicate balance between bulk and interfacial contributions to the free energy; that balance can be easily perturbed by adsorption of analytes or nanoparticles at the interface, thereby providing the basis for development of hierarchical assembly of responsive, anisotropic materials. Theoretical predictions also indicate that the three-dimensional order of a liquid crystal can be projected onto a two-dimensional interface, and give rise to novel nanostructures that are not found in simple isotropic fluids.

**9:12AM F20.00003 Broadband Coherent Raman Scattering for Rapid Spectroscopic Imaging**, MARCUS CICERONE, National Institute of Standards and Technology — Over the past ten years, coherent Raman imaging (CRI) has evolved from a curiosity to a practical tool for investigating many classes of biological and material questions. An important key to this evolution has been the ability to rapidly obtain information from many spectral peaks. Most vibrational spectroscopic information is found in the fingerprint region where spontaneous Raman can be used to achieve >3 signal to noise ratio for weak fingerprint peaks in biological systems, but typically requires acquisition times of several seconds; too slow for imaging. Coherent Raman methods have previously been unable to acquire high quality fingerprint spectra. We have overcome this limitation by developing a highly efficient signal excitation paradigm and appropriately harnessing the nonresonant background (NRB) signal that accompanies the resonant signal of interest. With these and other innovations, we have developed a CRI approach based on broadband coherent anti-Stokes Raman scattering (BCARS) that provides an unprecedented combination of speed, sensitivity, and chemical selectivity \[1\]. Using this system we are able to obtain high quality Raman spectra in the fingerprint and CH stretch regions from biological specimens at 3.5 ms, enabling rapid, label-free chemical imaging of even delicate samples. I will briefly put our approach in context with the broader CRI field, describe key technical features of the present imaging system and provide application examples in materials and biology. I will also briefly discuss focus areas for future advances, and speculate on ultimate performance limits for coherent Raman imaging.

10:24AM F20.00005 Surface Mediated Self-Assembly of Amyloid Peptides1, ZAHRA FAHKRAAI, University of Pennsylvania — Amyloid fibrils have been considered as causative agents in many neurodegenerative diseases, including Alzheimer’s disease, Parkinson’s disease, type II diabetes and amyloidosis. Amyloid fibrils form when proteins or peptides misfold into one dimensional crystals of stacked beta-sheets. In solution, amyloid fibrils form through a nucleation and growth mechanism. The rate limiting nucleation step requires a critical concentration much larger than those measured in physiological conditions. As such the exact origins of the seeds or oligomers that result in the formation of fully mature fibrils in the body remain topic intense studies. It has been suggested that surfaces and interfaces can enhance the fibrillation rate. However, studies of the mechanism and kinetics of the surface-mediated fibrillation are technologically challenging due to the small size of the oligomer and proteofibril species. Using smart sample preparation technique to dry the samples after various incubation times we are able to study the kinetics of fibril formation both in solution and in the vicinity of various surfaces using high-resolution atomic force microscopy. These studies elucidate the role of surfaces in catalyzing amyloid peptide formation through a nucleation-free process. The nucleation free self-assembly is rapid and requires much smaller concentrations of peptides or proteins. We show that this process resembles diffusion limited aggregation and is governed by the peptide adhesion rate, two -dimensional diffusion of the peptides on the surface, and preferential interactions between the peptides. These studies suggest an alternative pathway for amyloid formation may exist, which could lead to new criteria for disease prevention and alternative therapies.

Session F21 GIMS: Focus Session: Advances in Scanned Probe Microscopy II: High Frequencies and Optical Techniques 201 - Fabian Natterer, National Institute of Standards and Technology

8:00AM F21.00001 Measurement of Radiation Pressure in an Ambient Environment, DAKANG MA, JOSEPH GARRETT, JEREMY MUNDAY, University of Maryland - College Park — Light has momentum and thus exerts “radiation pressure” when it is reflected or absorbed due to the conservation of momentum. Micromechanical transducers and oscillators are suitable for measurement and utilization of radiation pressure due to their high sensitivities. However, other light-induced mechanical deformations such as photothermal effects often obscure accurate measurements of radiation pressure in these systems. In this work, we investigate the radiation pressure and photothermal force on an uncoated silicon nitride microcantilever under illumination by a 660 nm laser in an ambient environment. To magnify the mechanical effects, the cantilever is driven optically from dc across its resonance frequency, and the amplitude and phase of its oscillation are acquired by an optical beam deflection method and a lockin amplifier. We show that radiation pressure and photothermal effects can be distinguished through the cantilever’s frequency response. Furthermore, in a radiation pressure dominant regime, our measurement of the radiation force agrees quantitatively with the theoretical calculation.

8:12AM F21.00002 Sensitivity Improvement and Cryogenic Application of Scanning Microwave Microscope, HIDEYUKI TAKAHASHI, YOSHINORI IMAI, ATSUTAKA MAEDA, Department of Basic Science, the University of Tokyo — The technique to probe the spatial distribution of electric properties has been more important in modern material science. Scanning near-field microwave microscope (SMM) can be a powerful tool to study inhomogeneous materials. Recently we have developed scanning tunneling/microwave microscope (STM/SMM) with high sensitivity[1,2]. The SMM probe is a modified coaxial resonator whose resonant frequency is 10.7 GHz and Q-factor is 1200-1300 at room temperature. It is applicable to measurements at cryogenic environment. By downsizing the resonator probe, we achieved stable operation down to liquid helium temperature. Q-factor is enhanced to 2000-3000 below 77 K. As an example of application of our STM-SMM, we present the study on inhomogeneous iron-based superconductor KFe2Se2. We successfully observed the characteristic mesoscopic phase separation of the metallic phase and the semiconducting phase by two different scanning modes; constant current mode and constant Q-factor mode. The spatial resolution is no worse than 200nm, which is comparable to curvature radius of a probe tip.

8:24AM F21.00003 Subsurface Imaging with the Scanning Microwave Microscope, JOSEPH KOPANSKI, LIN YOU, JONATHAN MICHELSOn, EMILY Hitz, YAW OBENG, Semiconductor and Dimensional Metrology Division, National Institute of Standards and Technology, BACK END OF THE LINE RELIABILITY & METROLOGY PROJECT TEAM — The scanning microwave microscope (SMM) forms images from the reflected amplitude and phase of an incident RF (~ 2.3 GHz) signal. The reflected signal is a function of the properties of the tip-sample contact, but can also be influenced by buried interfaces and subsurface variations of the sample permittivity. This mechanism allows limited imaging of conductors buried within dielectrics, voids within metal, or multiple metal layers with different permittivity. Subsurface SMM data acquisition modes include passive and various active data acquisition modes. The theory of sub-surface imaging with SMM and COMSOL multi-physics simulations of specific situations will be presented. Measurements of specifically designed test structures and correlation with simulations show the sensitivity and resolution of the technique applied to imaging subsurface metal lines embedded in dielectric. Applications include metrology for back end of the line (BEOL) multi-level metallization and three-dimensional integrated circuits (3D-ICs).

8:36AM F21.00004 Advances in imaging and quantification of electrical properties at the nanoscale using Scanning Microwave Impedance Microscopy (sMIM), STUART FRIEDMAN, YONGLIANG YANG, OSKAR AMSTER, Primenano, Inc — Scanning Microwave Impedance Microscope (sMIM) is a mode for Atomic Force Microscopy (AFM) enabling imaging of unique contrast mechanisms and measurement of local permittivity and conductivity at the 10’s of nm length scale. Recent results will be presented illustrating high-resolution electrical features such as sub 15 nm Moiré patterns in Graphene, carbon nanotubes of various electrical states and ferro-electrics. In addition to imaging, the technique is suited to a variety of metrology applications where specific physical properties are determined quantitatively. We will present research activities on quantitative measurements using multiple techniques to determine dielectric constant (permittivity) and conductivity (e.g. dopant concentration) for a range of materials. Examples include bulk dielectrics, low-k dielectric thin films, capacitance standards and doped semiconductors.

8:48AM F21.00005 Analytical quantitative theory of RF-SPM for nanocarbon electronics 1. SLAVA V. ROTKIN, Lehigh University, Department of Physics and Center for Advanced Materials and Nanotechnology — Among a variety of Scanning Probe Microscopy (SPM) tools RF- or microwave-SPM has recommended itself as a versatile characterization tool, recently demonstrated capability to map electronic properties of nanocarbon materials non-destructively and with nanometer resolution. The transparent theory of RF-SPM sensing mechanism is however lacking, mostly limited to numerical or empirical solutions, especially when studying low-dimensional quantum objects, such as nanotubes/nanowires (NT/NW), where the classical description is often invalid. One-dimensional electronic structure of the NT/NW, weak screening of Coulomb interaction and finite e-e compressibility were successfully taken into account to provide an analytic form of its quasi-stationary (due to low RF frequency of the excitation) selfconsistent response. SPM tip response function was, in turn, efficiently analyzed in multipole series, and non-perturbatively diagrammatically summed in the sense of the Random Phase Approximation. Resulting theory shows transparently the physics of RF-SPM sensing mechanism, simultaneously allowing a quantitative analysis of recent RF-SPM data on nanotube electronic devices [E. Seabron, S. MacLaren, X. Xie, SV. Rotkin, JA. Rogers, WL. Wilson, unpublished].

9:00AM F21.00006 Ferromagnetic Resonance detection using stroboscopic magneto optical Kerr effect, SEUNGHA YOON, NIST - Natl Inst of Stds & Tech, and University of Maryland, TAKAHIRO MORIYAMA, NIST - Natl Inst of Stds & Tech, and Kyoto University, ROBERT MICHAEL, NIST - Natl Inst of Stds & Tech — Ferromagnetic resonance (FMR) is a powerful method for measuring the magnetic properties of ferromagnets. A number of related optical techniques have become popular, including time-resolved magneto-optical Kerr effect (TR-MOKE) microscopy and Brillouin light scattering (BLS). In this presentation we describe a new, stroboscopic method of measuring FMR based on the magneto-optical Kerr effect (MOKE). We use a polarized telecommunications fiber laser (wavelength = 1550 nm) and a fiber modulator driven at a frequency of interest (1 GHz to 10 GHz) to create pulsed, linearly polarized light incident on a CoFeB thin film sample. Precession in the sample is driven via a coplanar waveguide in the sample holder while the reflected light is split by a polarization beam splitter and detected by a balanced detector. As the magnetic field is swept, oscillations in the Kerr angle and in the intensity mix to produce a DC resonance signal. The spectra are Lorentzian, with a superposition of symmetric and anti-symmetric shapes that depends on the phase of the optical and microwave signals. In the presentation, we will also discuss phase sensitive measurements with this technique as well as the advantages over other FMR techniques.

9:12AM F21.00007 Time-resolved scanning tunneling microscopy for studies of nanoscale magnetization dynamics, SEBASTIAN LOTH, Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — The time resolution of the scanning tunneling microscope can be boosted greatly by use of electronic pump probe measurement schemes. Pulse shaping of the input pulses can even overcome bandwidth limitations of the instrument and enables sub-nanosecond time resolution [1]. In this talk we will focus on applications of this technique for measurements of fast spin dynamics in nanomagnets. We use the probe tip of a low-temperature STM to arrange magnetic atoms into arrays of our own design. Thin insulating films decouple the atoms from the supporting metallic substrate so that the nanostructures show quantum-magnetic properties with discrete spin states. The time-domain information gained in pump probe spectroscopy quantifies the spin relaxation between metastable spin states [2]. It enables isolating the interaction between the nanomagnet and its environment. In particular, we find that the magnetic atoms of a spin-polarized STM tip interact significantly with the surface even at moderate tunneling conditions. This interaction acts analogously to a highly localized magnetic field. It depends exponentially on the tip-nanomagnet distance and can reach a strength of several tesla. We use this atomically localized magnetic field to control the spin state mixing of a nanomagnet in an avoided level crossing of low-energy spin states [3]. Furthermore, pump probe spectroscopy enables non-local measurements of magnetic states and highlights pathways to design and control magnetism at the single atom level.

9:48AM F21.00008 A low temperature ultrahigh vacuum scanning tunneling microscope with high-NA optics to probe optical interactions at the atomic scale, HAIGANG ZHANG, Argonne National Laboratory, Argonne, IL 60439, JOSEPH SMERDON, University of Central Lancashire, Lancashire, UK, OZGUN SUZER, HGST, a Western Digital Company, San Jose, CA 95135, HEATH KERSELL, Ohio University, Athens, OH 45701, JEFFREY GUEST, Argonne National Laboratory, Argonne, IL 60439 — The optical and photophysical properties of single molecules/atoms, defects, and nanoscale structures at surfaces hinge on structure at the atomic scale. In order to characterize and control this structure and unravel these correlations, we are developing a low temperature (LT) laser-coupled ultrahigh vacuum (UHV) scanning tunneling microscope (LT Laser UHV STM) based on the Pan-style STM scanner with integrated high-numerical-aperture (NA) optics for single particle spectroscopy measurements under the STM tip. Using slip-stick inertial piezo steppers, the sample stage can be coarsely translated in X and Y directions. For optical measurements, high-NA optics behind and above the sample focus laser excitation on and collect photons emitted from the tip-sample junction. The STM is cooled by a liquid helium bath surrounded by a liquid nitrogen jacket for operation near 5 K; two separate ultrahigh vacuum chambers are used for sample preparation and STM measurements, respectively. We will describe our progress in demonstrating this instrument and plans for experiments studying the correlation between structure and optical function in nanoscale systems.

10:00AM F21.00009 Metal-Insulator Phase transition of VO2 nano crystals studied by near-field nanoscopy, YOHANNES ABATE, Georgia State University — Near-field dipolar plasmon interactions of multiple infrared antenna structures in the strong coupling limit are studied using scattering-type scanning near-field optical microscope (s-SNOM) and theoretical finite-difference time-domain (FDTD) calculations. We monitor in real-space the evolution of plasmon dipolar mode of a stationary antenna structure as multiple resonantly matched dipolar plasmon particles are closely approaching. Interparticle separation, length and polarization dependent studies show that the cross geometry structure favors strong interparticle charge-charge, dipole–dipole and charge–dipole Coulomb interactions in the nanometer scale gap region, which results in strong field enhancement in cross-bowties and further allows these structures to be used as polarization filters. The nanoscale local field amplitude and phase maps show that due to strong interparticle Coulomb coupling, cross-bowtie structures redistribute and highly enhance the out-of-plane (perpendicular to the plane of the sample) plasmon near-field component at the gap region relative to ordinary bowties. Preliminary results on using VO2 film to tune infrared plasmon antenna resonances will be presented.
10:12AM F21.00010 Determination of the dielectric function of materials with scattering-type scanning near field optical microscopy. PENG XU, T.J. HUFFMAN, M.M. QAZILBASH, College of William and Mary, INHAE KWAK, AMLAN BISWAS, University of Florida —. In apertureless scattering-type near field optical and infrared microscopy has been widely employed for imaging a variety of systems at the nanoscale including semiconductor nanostructures, organic bio-systems, and phase coexistence during metal-insulator transitions. In apertureless, scattering-type near field infrared microscopy, one can measure both the near field amplitude and phase. To obtain the complex dielectric function of the material at nanometer length scales from the measured amplitude and phase, the inverse problem of near field interaction needs to be solved.

We employed the lightning rod model[1] to analyze the near field interaction and obtain the dielectric function numerically. We present results for near-field infrared measurements on transition metal oxides including those that exhibit optical contrast due to coexisting phases. [1] A. S. McLeod et al., Phys. Rev. B 90, 085136 (2014)

10:24AM F21.00011 Generalized method of eigenoscillations for near-field optical microscopy. BOR-YUAN JIANG, Univ of California - San Diego, LINGFENG ZHANG, Boston University, ANTONIO CASTRO NETO, National University of Singapore, DIMITRI BASOV, MICHAEL FOGLER, Univ of California - San Diego — Electromagnetic interaction between a sub-wavelength particle (the “probe”) and a material surface (the “sample”) is studied theoretically. The interaction is shown to be governed by a series of resonances (eigenoscillations), corresponding to surface polariton modes localized near the probe. The resonance parameters depend on the dielectric function and geometry of the probe, as well as the surface reflectivity of the material. Calculation of such resonances is carried out for several axisymmetric particle shapes (spherical, spheroidal, and pear-shaped).

For spheroids an efficient numerical method is proposed, capable of handling cases of large or strongly momentum-dependent surface reflectivity. The method is applied to modeling near-field spectroscopy studies of various materials. For highly resonant materials such as aluminum oxide (by itself or covered with graphene) a rich structure of the simulated signal is found, including multi-peak spectra and nonmonotonic approach curves. These features have a strong dependence on physical parameters, e.g., the probe shape. For less resonant materials such as silicon oxide the dependence is weaker, and the spheroid model is generally applicable.

10:36AM F21.00012 Cryogenic Near-Field Microscopy in Correlated Electronic Systems. ADRIAN GOZAR, Brookhaven National Laboratory — We present results on the performance of a scattering-based scanning near-field optical microscope. The instrument was designed for measuring nano-scale complex dielectric properties of materials in a variable-temperature environment. The setup has a 20 - 30 nm spatial resolution with sample temperatures in the 10 - 300 K range. Spectral operation is in the infrared to visible and 0.1 - 1 THz regions. We illustrate these capabilities with results in graphene and ultra-thin sub-surface oxide films.

10:48AM F21.00013 Radiation pressure excitation of Low Temperature Atomic Force & Magnetic Force Microscope (LT-AFM/MFM) for Imaging. OZGUR KARCII, UMIT CELIK, NanoMagnetics Instruments Ltd., AHMET ORAL, Middle East Tech Univ, NANOMAGNETICS INSTRUMENTS LTD. TEAM, MIDDLE EAST TECH UNIV TEAM — We describe a novel method for excitation of Atomic Force Microscope (AFM) cantilevers by means of radiation pressure for imaging in an AFM for the first time. Piezo excitation is the most common method for cantilever excitation, but it may cause spurious resonance peaks. A fiber optic interferometer with 1310 nm laser was used both to measure the deflection of cantilever and apply a force to the cantilever in a LT-AFM/MFM from NanoMagnetics Instruments. The laser power was modulated at the cantilever’s resonance frequency by a digital Phase Lock Loop (PLL). The force exerted by the radiation pressure on a perfectly reflecting surface by a laser beam of power P is F = 2P/c. We typically modulate the laser beam by ~ 800 µW and obtain 10nm oscillation amplitude with Q ~ 8,000 at 2.5x10^-4 mbar. The cantilever’s stiffness can be accurately calibrated by using the radiation pressure. We have demonstrated performance of the radiation pressure excitation in AFM/MFM by imaging a hard disk sample between 4-300K and Abrikosov vortex lattice in BSCCO single crystal at 4K to for the first time.

8:00AM F22.00001 ABSTRACT WITHDRAWN

8:12AM F22.00002 Kondo Effects in Single Layer Transition Metal Dichalcogenides. MICHAEL PHILLIPS1, VIVEK AJI2, University of California, Riverside — Inversion symmetry breaking and strong spin orbit coupling in two dimensional transition metal dichalcogenides leads to interesting new phenomena such as the valley hall and spin hall effects. They display optical circular dichroism and the ability to generate excitation with valley specificity. In this talk we report on the consequences of these properties on correlated states in hole doped systems focusing on the physics of the screening of magnetic impurities. Unlike typical metals, the breaking of inversion symmetry leads to the mixing of a triplet component to the Kondo cloud. Using a variational wave function approach we determine the nature of the many body state. With the ground state in hand we analyze the excitations generated by valley discriminating perturbations.

8:24AM F22.00003 Non-Fermi-liquid behavior and anomalous suppression of Landau damping in layered metals close to ferromagnetism. SAM RIDGWAY, CHRIS HOOLEY, Univ of St Andrews — We analyse the low-energy physics of nearly ferromagnetic metals in two spatial dimensions using the functional renormalization group technique. We find a new class of low-energy fixed point, at which the fermionic (electron-like) excitations are non-Fermi-liquid ($\epsilon_f = T/6$) and the magnetic fluctuations exhibit an anomalous Landau damping whose rate vanishes as $\Gamma_q \sim |q|^{1/3}$ in the low-$|q|$ limit. We discuss the physical nature of this fixed point, and highlight its possible applicability to experiments on UGe$_2$ and related compounds.

8:36AM F22.00004 Stable non-Fermi liquid phase of itinerant spin-orbit coupled ferromagnets. YASAMAN BAHRI, ANDREW POTTER, University of California, Berkeley — Direct coupling between gapless bosons and a Fermi surface results in the destruction of Landau quasiparticles and a breakdown of Fermi liquid theory. Such a non-Fermi liquid phase arises in spin-orbit coupled ferromagnets with spontaneously broken continuous symmetries due to strong coupling between rotational Goldstone modes and itinerant electrons. These systems provide an experimentally accessible context for studying non-Fermi liquid physics. Possible examples include low-density Rashba coupled electron gases, which have a natural tendency towards spontaneous ferromagnetism, or topological insulator surface states with proximity-induced ferromagnetism. Crucially, unlike the related case of a spontaneous nematic distortion of the Fermi surface, for which the non-Fermi liquid regime is expected to be masked by a superconducting dome, we show that the non-Fermi liquid phase in spin-orbit coupled ferromagnets is stable.
temperature- and angle-dependent in-plane and out-of-plane magnetoresistance measurements in the ultra-quantum limit on graphite. Our experiments reveal a rich structure, though the complicated phase transitions, suggesting more researches should be carried out to understand the mysterious transitions. We performed transport measurements in the quantum limit of graphite between 22T and 53T. Recently, another unexpected high-field transition was observed around 75T. The relative simple band structure at high fields, we establish the phase diagram of graphite in its ultra-quantum limit. Our results imply the existence of a topologically-protected chiral Fermi surface – an interacting, scale invariant, non-Fermi liquid phase found in quadratic semimetals which has been recently suggested to be realized in strongly correlated pyrochlore iridate systems. We develop a kinetic equation formalism to describe the d.c. transport properties, which are dominated by collisions, and consider the shear viscosity η as a model transport coefficient. The ratio of shear viscosity to entropy density η/s is a measure of the strength of interaction between the excitations of a quantum fluid. As a consequence of the quantum critical nature of the system, η/s is a universal number and we find it to be consistent with a bound proposed from gauge-gravity duality.

9:36AM F22.00009 Transport in two-dimensional disordered semimetals, MICHAEL KNAP, Harvard University, JAY D. SAU, University of Maryland, BERTRAND I. HALPERIN, EUGENE DEMLER, Harvard University — We theoretically study transport in two-dimensional semimetals. Typically, electron and hole puddles emerge in the transport layer of these systems due to smooth fluctuations in the potential. We calculate the electric response of the electron-hole liquid subject to zero and finite perpendicular magnetic fields using an effective medium approximation and a complimentary mapping on resistor networks. In the presence of smooth disorder and in the limit of weak electron-hole recombination rate, we find small but finite overlap of the electron and hole bands an abrupt upturn in resistivity when lowering the temperature but no divergence at zero temperature. We discuss how this behavior is relevant for several experimental realizations and introduce a simple physical explanation for this effect.

9:48AM F22.00010 Phase diagram of a semimetal in the magnetic ultra-quantum limit, ALDO ISIDORI, FRANK ARNOLD, Royal Holloway, University of London, ERIK KAMPERT, Hochfeld-Magnetlabor Dresden, BEN YAGER, MATTHIAS ESCHRIG, JOHN SAUNDERS, Royal Holloway, University of London — Semimetals like graphite have recently received compelling interest as they not only are able to host topologically non-trivial phases but also can be driven into the ultra-quantum limit by magnetic fields now achievable in modern-day laboratories. Thus, they provide insight into quantum-Hall physics and the physics of massless Dirac fermions in three dimensions. They also represent ideal model systems for studying magnetic-field driven density wave instabilities, as the onset field for such collective excitations is suppressed in semimetals. Using pulsed high-magnetic fields up to 60 T applied to a single crystal of natural Tanzanian graphite, we find a series of field-induced phase transitions into collinear charge-density wave states resulting from enhanced interactions between the lowest four Landau levels. By analysing magneto-transport data and calculating the renormalized Landau level structure at high fields, we establish the phase diagram of graphite in its ultra-quantum limit. Our results imply the existence of a topologically-protected chiral edge state at high fields supporting both charge and spin currents.

8:00AM F23.00001 Ammonium Azide under High Pressure — a combined Theoretical and Experimental Study1, HARRY RADOUSKY, JONATHAN CROWHURST, JOSEPH ZAUG, Lawrence Livermore National Laboratory, BRADLEY STEELE, AARON LANDERVILLE, IVAN OLEYNIK, University of South Florida — Efforts to synthesize, characterize and recover novel polynitrogen energetic materials have driven attempts to subject high nitrogen content precursor materials (in particular metal and non-metal azides) to elevated pressures. Here we present a combined theoretical and experimental study of the high pressure behavior of ammonium azide (NH₄N₃). Using density functional theory we have considered the relative thermodynamic stability of the material with respect to two other crystal phases, namely trans-tetrazene (TTZ), and also a novel material, hydronitrogen solid (HNS) of the form (NH₃)₄. Our calculations demonstrate that the HNS becomes stable only at pressures much higher (89.4 GPa) than previously predicted (36 GPa). Our Raman spectra are consistent with earlier reports up to lower pressures, and at higher pressures, while some additional subtle behavior is observed (e.g. mode splitting) there is again no evidence of a phase transition to either TTZ or the HNS.

8:12AM F23.00002 ABSTRACT WITHDRAWN —

8:24AM F23.00003 Calculations and experimental studies of bis-triaminoguanidium azotetrazolate (TAGzT) under high pressure — I.G. BATYREV, R.C. SAUSA, US Army Research Laboratory — Nitrogen-rich organic compounds may offer distinct advantages over conventional energetic materials for applications relating to gas generators, low-sensitivity propellants, and additives to pyrotechnics and explosives. We have performed plane-wave, density functional theory calculations of TAGzT, an energetic, nitrogen-rich salt, up to 40 GPa, and report the pressure dependences of polarizability, x-ray diffraction patterns, and dipole moments. These results are compared to those we obtain experimentally from Raman Spectroscopy,1 and x-ray diffraction analysis and infrared spectroscopy. Our results suggest TAGzT does not undergo any phase transitions within this pressure range. Mulliken and Hirshfeld population analysis of TAGzT at ambient and high pressure yields the change of charge distribution with an increase in pressure. We report and discuss this trend at the meeting. Also, we report trends in the pressure-induced modifications of both bond lengths and angles of TAGzT, and reveal how hydrogen bonding contributes to the stability of TAGzT under pressure.1 K.D. Behler, J.A. Ciezak-Jenkins, R.C. Sausa, J. Phys. Chem A. 117(8), 1737 (2013)

8:36AM F23.00004 Many-body Green’s function calculations of optical properties of LiF in extreme conditions1, CATALIN D. SPATARU, LUKE SHULENBURGER, Sandia National Labs, LORIN X. BENEDICT, Lawrence Livermore National Labs — We present Density Functional Theory (DFT) + quasiparticle (G0W0) + Bethe-Salpeter calculations of the real and imaginary parts of the long-wavelength dielectric function of LiF between ambient pressure and P= 5 Mbars. While the optical absorption spectrum is predicted to show dramatic pressure-dependent features above the optical gap, the index of refraction well below the gap is shown to exhibit the same trends as that seen in both DFT calculations and experiment: a linear increase with \( P \). This increase does not result from a decrease in the band gap, but rather follows from the increase in oscillator strength which counteracts a smaller increase in band gap with \( P \). Our calculations also suggest that the index of refraction (for visible and near-UV light) of the higher-\( T \) B2-phase should be close enough to that of the B1 (ambient crystalline) phase that a transition from B1 to B2 is not likely to present a substantial change in index. These findings may be of interest to researchers who use LiF as a window material in dynamic compression experiments.

1SNL is a multi-program laboratory operated by Sandia Corporation, a Lockheed Martin Co., for the U.S. DOE’s NNSA under contract DEAC04-94AL85000. Work at LLNL was performed under the auspices of the U.S. DOE under Contract No. DE-AC52-07NA27344.

8:48AM F23.00005 Strongly correlated valence electrons and core-level chemical bonding of Lithium at terapascal pressures, ANGUANG HU, FAN ZHANG, Defence Research and Development Canada at Suffield Research Centre — As the simplest pure metal, lithium exhibits some novel properties on electrical conductivity and crystal structures under high pressure. All-electron density functional theory simulations, recently developed by using the linear combination of localized Slater atomic orbitals, revealed that the bandwidth of its valence bands remains almost unchanged within about 3.5 eV even up to a terapascal pressure range. This indicates that the development from delocalized to strongly correlated electronic systems takes place under compression, resulting in metal-semiconductor and superconductivity transitions together with a sequence of new high-pressure crystal phases, discovered experimentally. In contrast to the valence bands, the core-level bands become broadening up to about 10 eV at terapascal pressures. It means the transformation from chemical non-bonding to bonding for core electrons. Thus, dense lithium under compression can be characterized as core-level chemical bonding and a completely new class of strongly correlated materials with narrow bands filled in s-electron shells only.
9:00AM F23.00006 Equation of state, thermodynamic and transport properties in liquid indium and iron under high pressure¹, HUAMING LI, YONGLI SUN, College of Physics and Optoelectronics, Taiyuan University of Technology, MO LI, School of Materials Science and Engineering, Georgia Institute of Technology — We apply a general equation of state of liquid [1] to study thermodynamic properties in liquid indium and iron under high temperature and high pressure. In particular, density, isothermal bulk modulus, and internal pressure are then analyzed in liquid indium and iron. Molar volume of molten indium is calculated along the isothermal line with good precision comparing with the known data from experiments in an externally heated diamond anvil cell. For liquid indium at given parameters, density anomaly, i.e. the molar volume, is observed along certain isobaric paths. In liquid iron, the entropy scaling law of self-diffusion coefficient and viscosity under high pressure (up to 350 GPa) and high temperature (up to 8000 K) are investigated. Comparisons are made with experimental data and other EOS models for liquid iron.

9:12AM F23.00007 Stable Xenon Nitride at High Pressures, YUNWEI ZHANG, FENG PENG, YANMING MA, State Key Lab of Superhard Materials, Jilin University — Nitrogen is the most abundant element on Earth and exists as inert N₂ molecules in the atmosphere. Noble gas nitrates are missing in nature because N₂ molecules do not interact with noble gases at ambient conditions, greatly impeding the understanding of physics and chemistry of such nitrates. We report here a pressure-induced chemical reaction of N₂ with xenon predicted using a swarm-structure searching calculation as implemented in the CALYPSO code [1-2]. This reaction leads to the formation of a hitherto unexpected Xe nitride at megabar pressure accessible to high-pressure experiments. The high-pressure phase with a hypervalent state of Xe by accepting unprecedented Xe-N covalent bonds appears to be the most stable stoichiometry. The Xe bonding situation in this new phase is substantially different from earlier high-pressure examples of ionic Xe bonding or van der Waals interactions.

9:24AM F23.00008 The phase diagram of solid hydrogen at high pressure: A challenge for first principles calculations¹, SAM AZADI, MATTHEW FOULKES , Imperial College London — We present comprehensive results for the high-pressure phase diagram of solid hydrogen. We focus on the energetically most favorable molecular and atomic crystal structures. To obtain the ground-state static enthalpy and phase diagram, we use semi-local and hybrid density functional theory (DFT) as well as diffusion quantum Monte Carlo (DMC) methods. The closure of the band gap with increasing pressure is investigated utilizing quasi-particle many-body calculations within the GW approximation. The dynamical phase diagram is calculated by adding proton zero-point energies (ZPE) to static enthalpies. Density functional perturbation theory is employed to calculate the proton ZPE and the infra-red and Raman spectra. Our results clearly demonstrate the failure of DFT-based methods to provide an accurate static phase diagram, especially when comparing insulating and metallic phases. Our dynamical phase diagram obtained using fully many-body DMC calculations shows that the molecular-to-atomic phase transition happens at the experimentally accessible pressure of 374 GPa. We claim that going beyond mean-field schemes to obtain derivatives of the total energy and optimize crystal structures at the many-body level is crucial.

9:36AM F23.00009 Novel chemistry of matter under high pressure, MAOSHENG MIAO, Beijing Computational Science Research Center — The periodicity of the elements and the non-reactivity of the inner-shell electrons are two related principles of chemistry, rooted in the atomic shell structure. Within compounds, Group I elements, for example, invariably assume the +1 oxidation state, and their chemical properties differ completely from those of the p-block elements. These general rules govern our understanding of chemical structures and reactions. Using first principles calculations, we demonstrate that under high pressure, the above doctrines can be broken. We show that both the inner shell electrons [1] and the outer shell empty orbitals [2] of Cs and other elements can involve in chemical reactions. Furthermore, we show that the quantized orbitals of the enclosed interstitial space may play the same role as atomic orbitals, an unprecedented view that led us to a unified theory for the recently observed high-pressure electride phenomenon [3].

9:48AM F23.00010 Multi-center semi-empirical quantum models for carbon under extreme thermodynamic conditions¹, NIR GOLDMAN, Lawrence Livermore Natl Lab — We report on the development of many-body density functional tight binding (DFTB) models for carbon accurate over thousands of GPa and tens of thousands of Kelvin. DFTB holds promise as a fast quantum simulation approach that can yield several orders of magnitude increase in computational efficiency over Kohn-Sham Density Functional Theory (DFT) while retaining most of its accuracy. However, standard DFTB can yield large errors for materials under high pressures and temperatures, where electrons can become delocalized. Here, we overcome these limitations by computing the environmental dependence of the DFTB Hamiltonian matrix elements directly from DFT. We include these results in DFTB calculations by either explicitly calculating three-center terms in the Hamiltonian, or by implicitly incorporating them in the diagonal matrix elements. We then determine a three-body repulsive energy for the implicit approach, which yields accurate equation of state and structural delocalized. Here, we overcome these limitations by computing the environmental dependence of the DFTB Hamiltonian matrix elements directly from DFT.

10:00AM F23.00011 Decomposition reactions in RDX at elevated temperatures and pressures¹, IGOR SCHWEIGERT, US Naval Research Laboratory — Mechanisms and rates of elementary reactions controlling condensed-phase decomposition of RDX under elevated temperatures (up to 2000 K) and pressures (up to a few GPa) are not known. Global decomposition kinetics in RDX below 700 K has been measured; however, the observed global pathways result from complex manifolds of elementary reactions and are likely to be altered by elevated temperatures. Elevated pressures can further affect the condensed-phase kinetics and compete with elevated temperatures in promoting some elementary reactions and suppressing others. This presentation will describe density functional theory (DFT) based molecular dynamics simulations of crystalline and molten RDX aimed to delineate the effects of elevated temperatures and pressures on the mechanism of initial dissociation and the resulting secondary reactions.

10:12AM F23.00012 Atomistic picture of the shock to deflagration transition in a solid explosive: ultra-fast chemistry under non-equilibrium, MITCHELL WOOD, MATHEW CHERUKARA, Materials Engineering, Purdue University, EDWARD KOBERT, Theoretical Division, Los Alamos National Lab, ALEJANDRO STRACHAN, Materials Engineering, Purdue University — We use large-scale molecular dynamics (MD) simulations to describe the chemical reactions following the shock-induced collapse of cylindrical pores in the high-energy density material RDX. For shocks with particle velocities of 2km/s, we find that the collapse of a 40 nm diameter pore leads to a deflagration wave, resulting in the first atomic-level description of this process. Pore collapse leads to ultra-fast, multi-step chemical reactions that occur under non-equilibrium conditions. The formation of exothermic product molecules within a few picoseconds of the pore collapse prevents the nanoscale hot spot from quenching. Within 30 ps, a local deflagration wave develops which propagates at speeds of ~ 0.25 km/s and consists of an ultra-thin reaction zone of only ~ 5 nm, thus involving large temperature and composition gradients. These results provide insight into the initiation of detonation, which is critical to understanding the performance and safety of this class of materials.

10:24AM F23.00013 Electride-like phases at extreme compression: towards bridging the gap between theory and experiment1, STANIMIR BONEV, Lawrence Livermore National Laboratory — The transformation of materials into electride-like structures under the application of extreme pressure has attracted a lot of interest recently. Theoretical studies have predicted the existence of low-coordinated crystal phases, where the conduction electrons are localized in the interstitial atomic regions, for a number of elements at high density. Most of these works have been limited to static lattice calculations. The pressures where such transformations are projected to occur are accessible in dynamically-driven experiments, but at elevated temperatures. In this talk I will discuss the temperature dependence of electride structures, both solids and liquids, as well as the requirements for their accurate simulation.

1This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344

10:36AM F23.00014 The effect of core level crossing on the high-pressure equation of state of osmium, JOHN WILLS, Los Alamos Natl Lab — The equation of state of the 5d transition metal osmium has been studied with a combination of experiment and theory at pressures up to 500 GPa. The experimental results show a c/a ratio increasing by approximately 1 percent over this pressure range and displaying anomalies at pressures near 180 GPa and near 400 GPa. We have use all-electron fully relativistic density functional theory (DFT) calculations to study the cold equation of state and structural parameters of osmium at pressures up to 500 GPa, using one LDA and two GGA functionals. The increase in the c/a ratio agrees well with experiment, and we find anomalies, although less extreme, near the experimentally observed pressures. We find that the high pressure anomaly coincides with the crossing and hybridization of the 4f(7/2) and 5p(3/2) semi-core levels. In this talk we discuss the theoretical results and methodology and the possible implication for the equations of state of the 5d transition and actinide metals.

10:48AM F23.00015 Dynamic compression experiments and first-principles simulations on liquid deuterium above the melt boundary to investigate the insulator-to-metal transition1, T.R. MATTSSON, M.D. KNUDSON, M.P. DESJARLAIS, R.W. LEMKE, K.R. COCHRANE, M.E. SAVAGE, D.E. BLISS, Sandia National Laboratories, Albuquerque, NM; J.K. ISA, A. BECKER, R. REDMER, Institute of Physics, University of Rostock, Germany. — Important phenomena at high pressure, for example in planetary science, occur at conditions that cannot be reached in shock impact experiments. Different techniques have therefore been developed at Sandia’s Z-machine. One new approach is shock-ramp loading. The accelerator delivers a two-step current pulse that accelerates the electrode, creating a well-defined shock, and subsequently produces ramp compression from the shocked state. The technique makes it possible to achieve cool (1000-2000 K), high pressure (above 300 GPa), high compression states (10-15 fold) in hydrogen, thus allowing experimental access to the region of phase space where hydrogen is predicted to undergo a first-order phase transition from an insulating molecular liquid to a conducting atomic fluid. Knowing the behavior of hydrogen under these conditions is of pivotal importance to understanding the physics of giant planets. We will survey theoretical predictions for the liquid-liquid insulator-to-metal transition in hydrogen and present the results of experiments on Z.

Tuesday, March 3, 2015 8:00AM - 11:00AM — Session F24 DMP: Superconducting Quantum Devices and Josephson Junctions 203AB - Laura Adams, Harvard University

8:00AM F24.00001 Direct measurements of the current-phase relation in long-range spin-triplet SFS Josephson junctions, DAVID HAMILTON, DALE VAN HARLINGEN, Univ of Illinois - Urbana, YIXING WANG, NORMAN BIRGE, Michigan State University — We present direct measurements of the current-phase relation (CPR) of Josephson junctions which use multiple ferromagnetic layers to generate long-range spin-triplet pair correlations. Using a phase-sensitive Josephson interferometry technique, we obtain the phase and temperature dependence of this spin-triplet supercurrent. We also demonstrate the use of an inductive shunt to enhance this technique at higher critical currents. Our data suggest that the current-phase relation of these junctions is harmonic in character. Further measurements are planned in order to determine the ground state phase shift of these junctions.

8:12AM F24.00002 Parity conservation in a Cooper-pair transistor, DAVID VAN WOERKOM, ATTILA GERESEI, SEBASTIAN RUBBERT, ANTON AKHMEROV, LEO KOUWENHOVEN, Delft Univ of Tech — In a small superconducting island, hosting an even number of electrons, all charge carriers form Cooper pairs, defining the ground state of the Cooper-pair transistor (CPT). An additional, unpaired electron can only occupy a higher energy level, determined by the superconducting order parameter. This even-odd (parity) energy difference makes the CPT a very sensitive charge detector as well as a prototype superconducting qubit, whose coherence relies on the conservation of the parity of the island. Here we report parity conservation in a niobium-based superconductor, NbTiN, for the first time. NbTiN is a popular superconductor since it can sustain high parallel and perpendicular magnetic fields which is often a requirement for hybrid devices. The parity conversation resulted in the first 2e-periodicity measurements in a non-Aluminium CPT. The highest reported parity lifetime ever, which was longer than one minute, was measured. The parity lifetime didn’t saturate down to a base temperature of 12mK, showing state-of-the-art device shielding of thermal photons. We show that our CPT is magnetic field compatible, opening new possibilities for coupling spin degrees of freedom to superconducting circuits and qubits and for topological superconductivity, enabling qubits based on Majorana fermions.
entirely of magnetic-field compatible materials, offering new opportunities for hybrid experiments combining microwave circuits with polarized spin ensembles. This flux-qubit like behaviour results from non-sinusoidal current-phase relations in the nanowire Josephson elements. These hybrid microwave circuits are made of conventional superconductor/ferromagnet (S/F) systems since long-range spin-triplet correlations (LRTCs) were predicted. Despite the many breakthroughs so far in this field, the ability to control the triplet generation reliably still needs to be realized before these devices can be used in technological applications. One possible direction to control the state in such structures is to manipulate the magnetizations of the various F layers within, specifically to switch between colinear and non-colinear directions between the layers. In this work, we report on the progress made to control LRTC generation in such a way.

Supported by the DOE-BES under grant DE-FG-02-06ER46341.

1Supported by Northrop Grumman Corporation and by IARP under SPAWAR contract N66001-12-C-2017.

8:36AM F24.00004 Control of triplet supercurrent in superconductor/ferromagnet hybrid systems , WILLIAM MARTINEZ, W.P. PRATT, JR., NORMAN O. BIRGE, Michigan State University — A lot of excitement has been generated in superconductor/ferromagnet (S/F) systems since long-range spin-triplet correlations (LRTCs) were predicted. Despite the many breakthroughs so far in this field, the ability to control the triplet generation reliably still needs to be realized before these devices can be used in technological applications. One possible direction to control the state in such structures is to manipulate the magnetizations of the various F layers within, specifically to switch between colinear and non-colinear directions between the layers. In this work, we report on the progress made to control LRTC generation in such a way.

Supported by the DOE-BES under grant DE-FG-02-06ER46341.

8:48AM F24.00005 Fabrication and characterization of single domain magnetic Josephson . MAZIN KHASAWNEH, BETHANY NIEDZIELSKI, ERICH GINGERICH, REZA LOLOEE, WILLIAM PRATT, JR, NORMAN BIRGE, Michigan State Univ — A nice effect that can be observed in Ferromagnetic (F) Josephson junctions is the crossover from a standard Josephson junction (0-junction) to a “π-junction” as a function of the thickness of the F layer, dp. This observation is interesting not only from the scientific point of view but also from a practical point of view, as it could be used in cryogenic memory, for example. In this work we are fabricating and measuring micron-scale Josephson junctions containing a soft magnetic material such as NiFe. Such junctions exhibit clear switching of the single-domain magnetic element as a function of applied field. We will report on our recent progress.

1Northrop Grumman

9:00AM F24.00006 Wireless Josephson Junction Arrays , LAURA ADAMS, Harvard University — We report low temperature, microwave transmission measurements on a wireless two-dimensional network of Josephson junction arrays composed of superconductor-insulator-superconductor tunnel junctions. Unlike their biased counterparts, by removing all electrical contacts to the arrays and superfluous microwave components and interconnects in the transmission line, we observe new collective behavior in the transmission spectra. In particular we will show emergent behavior that systematically responds to changes in microwave power at fixed temperature. Likewise we will show the dynamic and collective response of the arrays while tuning the temperature at fixed microwave power. We discuss these spectra in terms of the Berezinskii-Kosterlitz-Thouless phase transition and Shapiro steps. We gratefully acknowledge the support Prof. Steven Anlage at the University of Maryland and Prof. Allen Goldman at the University of Minnesota.

9:12AM F24.00007 ABSTRACT WITHDRAWN —

9:24AM F24.00008 $8\pi$-periodic Josephson effects in a quantum dot / quantum spin-Hall josephson junction system , HOI-YIN HUI, CMT-C, Univ of MD, College Park, JAY SAU, CMT-C and JQI, University of Maryland — Josephson junctions made of conventional $s$-wave superconductors display $2\pi$ periodicity. On the other hand, $\pi$-periodic fractional Josephson effect is known to be a characteristic signature of topological superconductors and Majorana fermions [1]. Zhang and Kane have shown that Josephson junctions made of topological superconductors are $8\pi$-periodic if interaction is used to avoid dissipation [2]. Here we present a general argument for how time-reversal symmetry and Z2 non-trivial topology constrains the Josephson periodicity to be $8\pi$. We then illustrate this through a microscopic model of a quantum dot in a quantum spin-hall Josephson junction.

9:36AM F24.00009 Superconducting-semiconducting nanowire hybrid microwave circuits , G. DE LANGE, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, P.O. Box 5046, 2600 GA Delft, The Netherlands, B. VAN HECK, Instituut-Lorentz, Universiteit Leiden, P.O. Box 9506, 2300 RA Leiden, The Netherlands, A. BRUNO, D. VAN WOERKOM, A. GEREDE, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, P.O. Box 5046, 2600 GA Delft, The Netherlands, S. R. PLISSARD, E. P. A. M. BAKKERS, Eindhoven University of Technology, 5612 MB Eindhoven, The Netherlands, A. R. AKHMEROV, L. DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, P.O. Box 5046, 2600 GA Delft, The Netherlands — Hybrid superconducting-semiconducting circuits offer a versatile platform for studying quantum effects in mesoscopic solid-state systems. We report the realization of hybrid artificial atoms based on Indium-Arsenide nanowire Josephson elements in a circuit quantum electrodynamics architecture. Transmon-like single-junction devices have gate-tunable transition frequencies. Split-junction devices behave as transmons near zero applied flux and as flux qubits near half flux quantum, wherein states with oppositely flowing persistent current can be driven by microwaves. This flux-qubit like behaviour results from non-sinusoidal current-phase relations in the nanowire Josephson elements. These hybrid microwave circuits are made entirely of magnetic-field compatible materials, offering new opportunities for hybrid experiments combining microwave circuits with polarized spin ensembles and Majorana bound states.

10:00AM F24.00011 Microwave Resonant Activation Results in Hybrid MgB2/I/Pb and MgB2/I/Sn Josephson Junctions with Low to Moderate Damping

The reflected wave is amplified by both SLUG and HEMT amplifiers before its phase is measured. Results of recent measurements on the cCPT will be compared with theoretical predictions.

10:12AM F24.00012 Improved tunable microstrip SQUID amplifier for the Axion Dark Matter xExperiment (ADMX)

We have demonstrated that the phase of the reflected wave from the cCPT can be measured with high accuracy. The results of recent measurements on the cCPT will be compared with theoretical predictions.

We have fabricated Josephson junctions by using a focused helium ion beam to irradiate a narrow barrier in the plane of a 25 mm thick Y-Ba-Cu-O film. We have measured the critical current of these junctions as a function of magnetic field and temperature. Our results are consistent with theoretical predictions.

10:36AM F24.00014 Transition from superconducting-normal metal to superconducting-insulating barrier in focused helium beam YBCO Josephson junctions

We report measurements of the Josephson tinctor transition (MIT) in high-temperature superconductors, planar Y-Ba-Cu-O Josephson junctions. The junctions were made by irradiation of a 1 nm barrier with a focused helium ion beam. Our data show that the MIT occurs at a temperature of about 1 K.

We have developed a model based on the Stewart-McCumber and Ambegaokar-Halperin models that includes the effect of self-field effects. Our model shows good agreement with experimental measurements.

This work was supported by the UC Scholars Program
8:00AM F25.00001 Hole motion in the Hubbard model. B. MORITZ, SLAC National Accelerator Laboratory, Y. WANG, C.J. JIA, Stanford University and SLAC National Accelerator Laboratory, C.-C. CHEN, Argonne National Laboratory, M. VAN VEENENDAAL, Argonne National Laboratory and Northern Illinois University, T. P. DEVEREAUX, Stanford University and SLAC National Accelerator Laboratory, K. WÖHLFELD, University of Warsaw and SLAC National Accelerator Laboratory — The motion of a single hole in the half-filled two-dimensional Hubbard model is not fully understood, despite the fact that it constitutes a crucial first step in unravelling the doping evolution of the electronic properties. Here we unambiguously show, using anglical-particle-hole breakup calculations, that the bandwidth renormalization is determined by a complex interplay between (i) the strong coupling of a hole to magnons and (ii) the strongly renormalized, but effectively free, next-nearest-neighbor hopping resulting from additional delocalization pathways. By studying the changes in the hole dynamics in the one-to-two-dimensional crossover regime we comment on applicability of the spin-charge separation ansatz and the spin density wave dispersion picture in the single-particle dynamics of the two-dimensional Hubbard model.

8:12AM F25.00002 Spectral properties of the two-dimensional Hubbard model with next-nearest-neighbor hopping near the Mott transition. MASANORI KOHNO, International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Japan — The single-particle spectral properties of the two-dimensional Hubbard model with next-nearest-neighbor hopping near the Mott transition are investigated using cluster perturbation theory [1]. Based on the consideration of how the next-nearest-neighbor hopping shifts the spectral-weight distribution, the spectral features are explained by tracing the origins back to those of the one-dimensional and two-dimensional Hubbard models [1-3]. From this viewpoint, various anomalous features observed in hole-doped and electron-doped cuprate high-temperature superconductors, such as the pseudogaps in different momentum regimes between hole-doped and electron-doped cuprates, are collectively explained as properties of a two-dimensional system with next-nearest-neighbor hopping near the Mott transition.

8:24AM F25.00003 Origin of the quasiparticle dispersion kinks in Bi-2212 determined from angle-resolved inelastic electron scattering\(^1\). SEAN VIG, ANSHUL KOGAR, Univ of Illinois - Urbana, VIVEK MISHRA, MIKE NORMAN, Argonne National Laboratory, GENDA GU, Brookhaven National Laboratory, PETER ABBAMONTE, Univ of Illinois - Urbana — The kink features in low energy photoemission and ARPES measurements in cuprate superconductors have been extensively studied using angle-resolved photoemission spectroscopy (ARPES). The existence of these kinks is a signature of a renormalization of the fermionic quasiparticles due to coupling to some bosonic collective mode at a scale related to the kink energy. In this talk, we will present angle-resolved inelastic electron scattering studies of the bosonic collective excitations in optimally doped Bi\(_2\)Sr\(_2\)Ca\(_{x}\)Cu\(_{2+x}\)O\(_{2+y}\). Performing a 2D momentum parameterization of these modes, we reconstruct the complete dynamical susceptibility, \(\chi(q,\omega)\), which we use to perform a one-loop self energy correction to the quasiparticle dispersion. The result reproduces well the dispersion observed with ARPES, indicating that these excitations are the origin of the observed kinks. I will discuss the implications of our study for phonon vs. spin fluctuation interpretation of these effects.

\(^1\)This work was supported as part of the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science

8:36AM F25.00004 Ultrafast quenching of electron-boson interaction and superconducting gap in a cuprate superconductor. WENTAO ZHANG, CHOOKYU HWANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, CHRISTOPHER SMALLWOOD, TRISTAN MILLER, GREGORY AFFELDT, Department of Physics, University of California, Berkeley, California 94720, USA, KOSHI KURASHIMA, Department of Applied Physics, Tohoku University, Sendai 980-8579, Japan, CHRISSJOZWIACKI, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, HIROSHI EISAKI, Electronics and Photonics Research Institute, National Institute of Advanced Industrial Science and Technology, Ibaraki 305-8568, Japan, TADASHI ADACHI, Department of Engineering and Applied Sciences, Sophia University, Tokyo, Japan, YOJI KOIKE, Department of Applied Physics, Tohoku University, Sendai 980-8579, Japan, JUNG-HAI LEE, LANZARA ALESSANDRA, Department of Physics, University of California, Berkeley, California 94720, USA — Ultrafast spectroscopy makes it possible to track similarities and correlations that are not evident in equilibrium. Time- and angle-resolved photoemission measurements on cuprate high-temperature superconductor reveals that below the superconductor’s critical temperature, ultrafast excitations trigger a synchronous decrease of electron self-energy and superconducting gap. In contrast, electron-boson coupling is unresponsive to ultrafast excitations above the superconductor’s critical temperature and in the metallic state of a related material. These findings open a new pathway for studying transient self-energy and correlation effects in solids.

8:48AM F25.00005 Calculation of RIXS spectra of cuprates using band structure parameters. YIFEI SHI, ISRAEL KLIICH, University of Virginia, DAVID BENJAMIN, EUGENE DEMLER. Harvard University — We explore the quasi particle theory to study the Resonant Inelastic X-ray Scattering(RIXS) by using the band structure parameters. We use both the determinant method(D. Benjamin, I. Kliich and E. Demler, Phys. Rev. Lett. 112, 247002(2014)) and the expansion in the core-hole potential. The methods are applied to the (Ca\(_1-x\)La\(_x\)\(_2\))Ba\(_2\)Cu\(_3\)O\(_y\) system with next-nearest-neighbor hopping near the Mott transition.

9:00AM F25.00006 Nernst Effect in HTC cuprate from BDW. CHUNXIAO LIU, University of Maryland College Park — The pseudogap regime in low hole doped high \(T_c\) cuprate superconductors exhibits peculiar experimental signatures like the detection of enhanced negative signals for Hall, Seebeck and Nernst coefficients. It has been suggested that some of these phenomena can be understood in terms of a competition between a bond density wave order and superconductivity. In this work, we theoretically studied the Nernst effect using a mean-field quasi-particle model with \(Q_1 = (0, 2\pi r /3)\) and \(Q_2 = (2\pi r /3, 0)\). By employing semi-classical Boltzmann dynamics, we have shown that the thermoelectric coefficient depends linearly on the absolute value of order parameter for small values of the induced gap and the contribution mainly comes from the small area of hot spot.

9:12AM F25.00007 Electronic structure of La\(_2\)CuO\(_4\) within self-consistent GW approximation. SANGKOOK CHOI, Rutgers University, Piscataway, NJ, USA, ANDREY KUTÉPOV, Ames Laboratory, Ames, IA, USA, KRISTJAN HAULE, Rutgers University, Piscataway, NJ, USA, MARK VAN SCHILFGAARDE, King’s college, London, UK, GABRIEL KÖTLIAR, Rutgers University, Piscataway, NJ, USA — La\(_2\)CuO\(_4\), the parent compound of the high-temperature superconductor, is a classic strongly-correlated material. We present a first-principles study on the excitations spectrum of La\(_2\)CuO\(_4\) within the self-consistent GW approximation based on full-potential linearized augmented-plane-wave methods. We compare the results of the Quasiparticle (QP) self-consistency and the fully self consistent approach. We find that the spin-polarized self-consistent GW calculation succeed in predicting the insulating ground state and anti-ferromagnetic superordering. It also describes charge-transfer character of the top of the valence band and reproduce the experimental spectral function well, including the weight of the copper d and the position of the lanthanum levels, but it overestimates the bandgap by 75%. We comment on the implications of our results for the implementation of GW+DMFT in a one shot, QP, and fully self consistent version.
9:24AM F25.00008 Strong Correlation of Electron Saddle Point Singularities to the Anomalous Isotope Effect in Zr, Nb, Sn, and YBa2Cu3O7. GUANG-LIN ZHAO, Physics Department, Southern University and A&M College — Anomalously small isotope effect in some high and low Tc superconductors such as Zr, Nb, Sn, and YBa2Cu3O7 (YBCO) created a great challenge for understanding. It has been shown by experiments and first-principles calculations that there exist extended saddle point singularities in the electronic structures of these materials. In this work, a new methodology is further implemented by integrating first-principles calculations of electronic structures of the materials into the theory of many-body physics for superconductivity. The aim is to seek a unified methodology to calculate the electronic and superconducting properties of these materials. It is demonstrated from first-principles that the extended saddle point singularities in Zr, Nb, Sn, and YBCO strongly correlate to the anomalous isotope effect in these superconductors. However, there still exist some differences between the calculated and experimental results that require further research work.

3The work was funded in part by NSF LASIGMA Project (Award No. EPS-1003897, NSF2010-15-RII-SUBR) and by AFOSR (Award No. FA9550-09-1-0367).

9:36AM F25.00009 Resonant tunneling of fluctuation Cooper pairs: Shapiro steps above superconducting critical temperature. ALEXEY GALDA, Materials Science Division, Argonne National Laboratory, ALEXANDER MEL’NIKOV, Institute for Physics of Microstructures, Russian Academy of Sciences, VALERII VINOKUR, Materials Science Division, Argonne National Laboratory — Superconducting fluctuations have proved to be an irreducible source of information about microscopic and macroscopic material parameters that could be inferred from experiments. According to common wisdom, the effect of thermodynamic fluctuations in the vicinity of the superconducting transition temperature, Tc, is to round off all of the sharp corners and discontinuities, which otherwise would have been expected to occur at Tc. Here we report the current spikes due to radiation-induced resonant tunneling of fluctuation Cooper pairs between two superconductors which grow even sharper and more pronounced upon approach to Tc. This striking effect offers an unprecedented tool for direct measurements of fluctuation Cooper pairs’ lifetime, which is key to our understanding of the fluctuation regime, most notably to nature of the pseudogap state in high temperature superconductors. Our finding marks a radical departure from the conventional view of superconducting fluctuations as blurring and rounding phenomenon.

9:48AM F25.00010 Inhomogeneities in a strongly correlated d-wave superconductors in the limit of strong disorder. DEBMALYA CHAKRABORTY, Indian Institute of Science Education and Research-Kolkata, Mohanpur Campus, India-741252, RAJDEEP SENARMA, Department of Theoretical Physics, Tata Institute of Fundamental Research, Mumbai-400005, India, AMIT GHOSAL, Indian Institute of Science Education and Research-Kolkata, Mohanpur Campus, India-741252 — The complex interplay of the strong correlations and impurities in a high temperature superconductor is analyzed within a Hartree-Fock-Bogoliubov theory, augmented with Gutzwiller approximation for taking care of the strong electronic repulsion. The inclusion of such correlations is found to play a crucial role in reducing inhomogeneities in both qualitative and quantitative manner. This difference is comprehended by investigating the underlying one-particle “normal states” that includes the order parameters in the Hartree and Fock channels in the absence of superconductivity. This amounts to the renormalization of disorder both on the lattice sites and also on links. These two components of disorder turn out to be spatially anti-correlated through self-consistency. Interestingly, a simple pairing theory in terms of these normal states is shown to show how disorder modifies the superconducting gap and reduces disorder. This effect puts a limit on long-range superconductivity, while fluctuations can persist to higher temperature. BCS-type model calculations are used to show how disorder modifies the superconducting gap and reduces Tc. Some ideas of how to recuperate a higher Tc from superconducting fluctuations are discussed.

10:00AM F25.00011 Effects of thermal disorder on electronic structure, electron-phonon coupling and spin-fluctuations in high-Tc cuprates, THOMAS JARLBORG, DPMC, University of Geneva, CH1211 Geneva 4 — The superconducting Tc’s are estimated from the values of electron-phonon and spin-phonon coupling in typical high-Tc cuprates. It is shown that the couplings are peaked for just a few q-vectors because of the 2-dimensional Fermi surface shape. The influence of few severe spin-phonon modes compensates the low electronic density-of-states, which allows for a high Tc. [1] Thermal disorder at moderately high temperature perturbs the strongly correlated modes through incoherent potential fluctuations of the Madelung terms, and electronic structure calculations show that the effective spin-phonon coupling suffers from lattice disorder. This effect puts a limit on long-range superconductivity, while fluctuations can persist to higher temperature. BCS-type model calculations are used to show how disorder modifies the superconducting gap and reduces Tc. Some ideas of how to recuperate a higher Tc from superconducting fluctuations are discussed.

10:12AM F25.00012 Pairing glue at finite temperature in high-temperature superconductors. A. REYMBAUT, RQMP, Phys. Dept. Université de Sherbrooke, QC J1K 2R1, G. SORDI, Phys. Dept. HTC, Royal Holloway, U. London, TW20 0EX, D. BERGERON, P. SEMIN, M. CHARLESBOIS, RQMP, Phys. Dept. Université de Sherbrooke, QC J1K 2R1, A.-M.S. TREMBLAY, RQMP, Phys. Dept. Université de Sherbrooke, QC J1K 2R1, K. CIFAR, ON M5G 1Z8, (2014). — Superconductivity has been documented in the weak to intermediate correlation regime, the strong-correlation limit is still largely unexplored. One of the best ways to access the frequencies relevant for the unconventional pairing dynamics present in doped Mott insulators is to study the anomalous spectral function associated with the frequency-dependent Gorkov function. Already studied at zero temperature,[2-4] that anomalous spectral function is difficult to obtain at finite temperature when one needs maximum entropy continuation methodology.[5] Indeed, this method requires a non-negative spectral function. In this talk we present the solution to this problem. Then we show our results for the Hubbard model on a 2x2 cluster solved with Cluster Dynamical Mean Field Theory (CDMFT) using Continuous-Time Quantum Monte-Carlo (CTQMC) in the hybridization expansion as an impurity solver.

10:24AM F25.00013 DMRG simulations of a 3 band Hubbard model for the cuprates. STEVEN WHITE, University of California, Irvine, DOUGLAS SCALAPINO, University of California, Santa Barbara — While both the hole and electron doped cuprates can exhibit d2̃ – 2̃-wave superconductivity, the local distribution of the doped carriers is known to be significantly different with the doped holes going primarily on the O sites while the doped electrons go on the Cu sites. Here we report the results of a density-matrix-renormalization-group calculation for a three-orbital conventional superconductivity has been documented in the weak to intermediate correlation regime, the strong-correlation limit is still largely unexplored.[1] One of the best ways to access the frequencies relevant for the unconventional pairing dynamics present in doped Mott insulators is to study the anomalous spectral function associated with the frequency-dependent Gorkov function. Already studied at zero temperature,[2-4] that anomalous spectral function is difficult to obtain at finite temperature when one needs maximum entropy continuation methodology.[5] Indeed, this method requires a non-negative spectral function. 10:24AM F25.00013 DMRG simulations of a 3 band Hubbard model for the cuprates, STEVEN WHITE, University of California, Irvine, DOUGLAS SCALAPINO, University of California, Santa Barbara — While both the hole and electron doped cuprates can exhibit d2̃ – 2̃-wave superconductivity, the local distribution of the doped carriers is known to be significantly different with the doped holes going primarily on the O sites while the doped electrons go on the Cu sites. Here we report the results of a density-matrix-renormalization-group calculation for a three-orbital model of a CuO2 lattice. In addition to the asymmetric dependence of the intra-unit-cell occupation of the Cu and O for hole and electron doping, we find important differences in the longer range spin and charge correlations. As expected, the pairwise response has an d2̃ – 2̃-like structure for both the hole and electron doped systems.

10:36AM F25.00014 DMFT+FLEX approach to unconventional superconductivity. MOTOHARU KITATANI, NAOTO TSUJI, HIDEO AOKI, Department of Physics, University of Tokyo — We propose to combine the dynamical mean field theory (DMFT) with the fluctuation exchange approximation (FLEX) to investigate strongly correlated systems and especially to obtain a phase diagram for d-wave superconductors such as the cuprates, which seems inaccessible to the DMFT due to the pair-breaking effective pairing interaction, so that the method can describe anisotropic pairing along with the local correlation effect that is important in Mott physics. We have applied the formalism to the two-dimensional repulsive Hubbard model to obtain superconducting transition temperature. The result does indeed exhibit a Tc-dome structure. We have traced back the origin of the dome to the local vertex correction from DMFT that gives a filling-dependent effect on the FLEX self-energy.
10:48AM F25.00015 Quantum oscillation signatures of spin-orbit interactions controlling the residual nodal bilayer-splitting in underdoped high-$T_c$ cuprates, NEIL HARRISON, Los Alamos National Labs, ARKADY SHEKHTER, National High Magnetic Field Laboratory, Tallahassee — We investigate the origin of the small residual nodal bilayer-splitting in the underdoped high-$T_c$ superconductor YBa$_2$Cu$_3$O$_{6.1}$-$x$ using the results of recently published angle-resolved quantum oscillation data [Sebastian et al., Nature 511, 61 (2014)]. A crucial clue to the origin of the residual bilayer-splitting is found to be provided by the anomalously small Zeeman-splitting of some of the observed cyclotron orbits. We show that such an anomalously Zeeman-splitting (or small effective $g$-factor) for a subset of orbits can be explained by spin-orbit interactions, which become significant in the nodal regions as a result of the vanishing bilayer coupling. The primary effect of spin-orbit interactions is to cause quasiparticles traversing the nodal region of the Brillouin zone to undergo a spin flip. We suggest that the Rashba-like spin-orbit interactions, naturally present in bilayer systems, have the right symmetry and magnitude to give rise to a network of coupled orbits consistent with experimental observations in underdoped YBa$_2$Cu$_3$O$_{6.1}$-$x$. This work is supported by the DOE BES proposal LANLF100, while the magnet lab is supported by the NSF and Florida State.

Session F26 DCP: Focus Session: At the Interface of Molecules and Materials I

8:00AM F26.00001 Tunable and responsive plasmonic properties of metal oxide nanocrystals, DELIA MILLIRON, The University of Texas at Austin — Degenerately doped metal oxide semiconductors, like ITO, exhibit plasmonic resonance near and mid-infrared wavelengths tunable by varying their composition. Nanocrystals of many such materials have now been synthesized and are emerging that leverage the responsiveness of their localized surface plasmon resonance (LSPR) to electronic charging and discharging. For example, electrochromic glass that can dynamically control heat loads in buildings is under development. In biological systems, plasmonic oxide nanocrystals can act as active sensors, where changes in their optical absorption indicates biochemical redox has occurred. Nonetheless, significant fundamental questions remain open regarding the nature of the infrared optical response in these doped oxides. Doping impurities influence the optoelectronic properties beyond simply donating free carriers. For example, the distribution of Sn in ITO was found to dramatically influence the line shape of the LSPR and the effective electron mobility. In addition, by post-synthetically modifying carrier concentrations (through photodoping or electrochemical doping), we have observed that aliovalent doping and electronic doping each modify LSPR spectra, providing access to a broad range of tunable optical properties. Heterogeneous broadening, uncovered by single nanocrystal spectroscopy, also contributes to ensemble line shapes, complicating direct interpretation of LSPR spectra. Finally, the possibility of electric field enhancement by metal oxide LSPRs is critically examined to suggest what future applications might be on the horizon.

8:36AM F26.00002 Tunable Plasmonic Nanoparticles with Catalytically Active High-Index Facets, HAO JING, University of South Carolina, NICOLAS LARGE1, Northwestern University, QINFENG ZHANG, University of South Carolina, PETER NORDLANDER, Rice University, HUI WANG, University of South Carolina — Noble metal nanoparticles have been of tremendous interest due to their intriguing size- and shape-dependent plasmonic and catalytic properties. Combining tunable plasmon resonances with superior catalytic activities on the same metallic nanoparticle, however, has long been challenging because nanoplasmonics and nanocatalysis typically require nanoparticles in two drastically different size regimes. Here, we demonstrate that creation of high-index facets on subwavelength metallic nanoparticles provides a unique approach to the integration of desired plasmonic and catalytic properties on the same nanoparticle. Through site-selective surface etching of metallic nanocuboids whose surfaces are dominated by low-index facets, we have controllably fabricated nanorice and nanodumbbell shaped particles, which exhibit drastically enhanced catalytic activities arising from the catalytically active high-index facets abundant on the particle surfaces. The nanorice and nanodumbbell particles also possess appealing tunable plasmonic properties that allow us to gain quantitative insights into nanoparticle-catalyzed reactions with unprecedented sensitivity and detail through time-resolved plasmon-enhanced spectroscopic measurements.

8:48AM F26.00003 Protected Noble-Metal Clusters at the Transition from Molecules to Materials, ROBERT L. WHETTEN, University of Texas, San Antonio — Protected noble-metal clusters are found at a molecular level of definite composition and structure up to a size of 145-165 metal atoms. Curiously, this size-range is also where several key signatures of metallic character begin to converge. These substances have been of great interest for many application-areas in the past couple decades, but the understanding of their structure and bonding, remarkable self-selection, electronic structure and optical properties has only recently started to reach a fundamental or molecular level of definition. This presentation emphasizes this recent progress and also outlines the prospects for extending the molecular domain of metallurgy well beyond the 200- atom range, thanks to advances in experimental & theoretical methods.

9:24AM F26.00004 ABSTRACT WITHDRAWN —

10:00AM F26.00005 Rich Information on Quantum States and Ways to Calculate It in The Absorption Spectra of Au$_{144}$ Gold Cluster Compound, XOCHITL LOPEZ-LOZANO, ROBERT L. WHETTEN, Department of Physics & Astronomy, The University of Texas at San Antonio, HANS-CHRISTIAN WEISSKER, Aix-Marseille Univ., CNRS, CInaM — In recent decades, the prevalent view has been that noble-metal clusters of intermediate size necessarily have smooth optical absorption spectra of low information content in the near-IR, VIS and near-UV regions. At most, one expects a broad, smooth localized surface plasmon resonance feature. Recently, we demonstrate that, in contrast to the commonly held view, the optical absorption of the most widely applied gold cluster, the thiolate-protected Au$_{144}$ cluster, exhibits a rich spectrum of bands that are individually visible over the entire near-IR, VIS and near-UV regions (1.0-4.0 eV), demonstrating high information content related to the quantum size effects which distinguish the nanoparticles from the bulk materials. In the calculation, the result is sensitive to the details of the structure. In the present work, we systematically compare the different structures actually used to date. We studied aspects like symmetry, geometry and type of ligands. In particular, we discuss the effect of their differences on the optical absorption spectra as well as how the theoretical methodology influences the final results.
Calculations and the Classical Picture of Charge Oscillations, HANS-CHRISTIAN WEISSKER, CNRS - CINAM, Centre Interdisciplinaire de Nanoscience de Marseille, XÓCHITL LÓPEZ-LOZANO, Department of Physics and Astronomy — The University of Texas at San Antonio One UTSA Circle, San Antonio, TX 78249 — The localized surface-plasmon resonance (LSPR) in metal clusters corresponds to a collective charge oscillation of quasi-free electrons of the metal. We use the real-time formulation [1] of time-dependent density-functional theory (TDDFT) with pseudopotentials to study the correspondence and differences of the quantum calculations with the classical picture. By means of animations, we discuss the real-time evolution of the electronic density for different geometries. While there is a clear correspondence between the overall picture of a charge oscillation and the actual dynamic in quantum-sized clusters, the situation is much more intricate owing to quantum effects and the atomistic inhomogeneity of the cluster. A fine pattern is present over the volume of the cluster even at moments of zero overall polarization. The difference between Ag and Au is clearly visible. Finally, we discuss the question of collective vs. molecular-like transitions; even for single transitions, the dynamics of the total density can be similar to the picture of a charge oscillation.

8:36AM F27.00002 Two-Dimensional Line Shapes in Electronic-Vibrational Spectroscopy as a Measure of Correlated Spectral Dynamics of Electronic and Vibrational Degrees of Freedom.

NICHOLAS LEWIS, HUI DONG, THOMAS OLIVER, GRAHAM FLEMING, University of California, Berkeley — 2D optical spectroscopies in many different frequency regimes have been useful to study the correlated spectral behavior for many different types of system degrees of freedom. The slope of the center-line of a feature in 2D electronic and 2D infrared spectroscopy has been shown to provide detailed information about the correlation functions that describe the system-bath coupling for the system degrees of freedom. Recently, we have demonstrated a new spectroscopic technique, 2D electronic-vibrational spectroscopy, that is capable of directly measuring the correlation between spectral motion of the electronic and vibrational degrees of freedom. Here we demonstrate that the center-line slope of a 2DEV resonance can be directly related to the correlation function for the vibrational degrees of freedom on the electronic excited state. We show experimentally that this can be observed in 2DEV spectra of the dye DTTCI. Finally, we show how 2DEV spectra can be used to directly measure the strength of system-bath coupling for the vibrational degrees of freedom on the electronic excited state versus those on the electronic ground state.

8:48AM F27.00003 Femtosecond Stimulated Raman Spectroscopy by Six-Wave Mixing. ANDREW MORAN, University of North Carolina — Knowledge of the structural changes that accompany photochemical reactions has motivated the development of a wide variety of time-resolved vibrational spectroscopies. For example, a technique known as femtosecond stimulated Raman spectroscopy (FSSR) has yielded important insights into numerous photochemical processes in the past 10-15 years. Simultaneous probing of all resonances in the fingerprint region of the vibrational spectrum and sensitivity to dynamics on the 100-fs time scale are the primary selling points for the FSSR technique. Despite its utility, FSSR is challenged by a large background of residual laser light and lower-order nonlinearities. In this talk, I will introduce a newly developed FSRS experiment in which five laser beams are used to eliminate the background of residual laser light and lower-order nonlinearities present in the traditional three-beam FSRS geometry. Applications to photoinduced reactions in triiodide and heme proteins will be discussed. It is envisioned that this approach will be useful for investigating photoinduced dynamics in a wide variety of condensed phase systems.

9:24AM F27.00004 Quantum Process Tomography by 2D Fluorescence Spectroscopy. LEONARDO A. PACHON, Institute of Physics, University of Antioquia. Department of Chemistry and Chemical Biology, Harvard University. — Characterization of quantum dynamics is one of the most important steps toward the implementation of any quantum technology and therefore, it is of fundamental relevance. Traditionally, dynamics are studied for particular initial preparations and hence, only partial information about the underlying physical processes is obtained. To overcome this drawback, a variety of proposals based on spectroscopic techniques have been suggested. Quantum Processes Tomography allows for the experimental reconstruction of the dynamics regardless the initial condition. Despite the success of QTP, the spectroscopic techniques they are based on require large samples to enhance the non-linear signal. Hence, particular features of the dynamics and realistic time scales are hidden by the incoherent average over the large structural and electronic heterogeneity. Based on recent progress on non-linear spectroscopies using collinear phase-modulated ultra-short pulses, which is suitable for single molecule spectroscopy, a formulation of single molecule QPT with classical light is provided here. This technique is applied to recover the dynamics of a model dimer. The single molecule character of this technique predicts longer coherence times than those techniques based on the phase-matching condition.

9:36AM F27.00005 Ultrafast 2D Fluorescence Spectroscopy using Spectrally Entangled Photon Pairs. MICHAEL RAYMER, University of Oregon — We propose entangled photon-pair two-dimensional fluorescence spectroscopy (EPP-2DFS) to probe the nonlinear electronic response of molecular systems. [1] The method, inspired by results in [2], uses a technique from quantum optics—a separated two-photon (Franson) interferometer, which generates time-delayed packets of time-frequency-entangled photon pairs. This interferometer is incorporated into the framework of a fluorescence-detected 2D optical spectroscopic experiment [3]. The continuous stream of entangled photons are phase-modulated in the interferometer, and used to excite a two-photon-absorbing sample, whose excited-state population is selectively detected by simultaneously monitoring the sample fluorescence and the transmitted exciting fields. In comparison to standard classical 2DFS techniques using coherent laser pulses and standard pulse-scanning sequences, advantages of this scheme include the suppression of uncorrelated background signals, the suppression of diagonal 2D spectral features, the enhancement and narrowing of off-diagonal spectral cross-peaks that contain information about electronic coupling, and the possibility for enhancement of simultaneous time- and frequency resolution, including spectral selectivity within an inhomogeneously broadened distribution. These effects arise from the properties of parametric down-conversion light source, which effectively creates a different interaction-scanning protocol than in standard laser-pulse scanning. We numerically simulate the EPP-2DFS observable for the case of an electronically coupled molecular dimer. The EPP-2DFS spectrum is greatly simplified in comparison to its standard classical 2D counterpart. Our results indicate that EPP-2DFS can provide previously unattainable resolution to extract model Hamiltonian parameters from electronically coupled molecular dimers.

10:12AM F27.00006 Surface Sum Frequency Generation of III-V Semiconductors1. ZHENYU ZHANG, JISUN KIM, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA, RAMI KHOURY, Department of Chemistry, Louisiana State University, Baton Rouge, LA, E.W. FLUMMEL, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA, LOUIS HABER, Department of Chemistry, Louisiana State University, Baton Rouge, LA — Optical sum frequency generation (SFG) is a well-established technique for surface and interface studies but its use has been limited mainly to centrosymmetric materials so far. Here, we demonstrate that femtosecond broadband SFG spectroscopy has the ability to identify surface molecular vibrations on the archetypical non-centrosymmetric semiconductor GaAs (001), in which the bulk SFG signal typically dominates over surface SFG contributions. Azimuthal angle dependence of the second order SFG nonlinear response from GaAs (001) surface in the reflection geometry in vacuum for all eight polarization combinations are detected and analyzed. The results agree with and extend upon previous second harmonic generation (SHG) studies and phenomenological analysis. In addition, carbon monoxide and methanol are employed as molecular-markers on the GaAs (001) surfaces. The C-O stretching mode of carbon monoxide and the methyl group stretching modes of methanol are clearly observed even though the bulk contribution dominates the SFG signal. Coherent heterodyne interference is proposed as the mechanism for the surface signal enhancement. Two other zinc blende type III-V semiconductors, GaP and GaSb, are also studied and compared.

10:24AM F27.00007 Probing Molecular Organization and Electronic Dynamics at Buried Organic Interfaces, SEAN ROBERTS, University of Texas at Austin — Organic semiconductors are a promising class of materials due to their ability to mold the charge transport capabilities of semiconductors with many of the processing advantages of plastics. In thin film organic devices, interfacial charge transfer often comprises a crucial step in device operation. As molecular materials, the density of states within organic semiconductors often reflect their intermolecular organization. Truncation of the bulk structure of an organic semiconductor at an interface with another material can lead to substantial changes in the density of states near the interface that can significantly impact rates for interfacial charge and energy transfer. Here, we will present the results of experiments that utilize electronic sum frequency generation (ESFG) to probe buried interfaces in these materials. Within the electric dipole approximation, ESFG is only sensitive to regions of a sample that experience a breakage of symmetry, which occurs naturally at material interfaces. Through modeling of signals measured for thin organic films using a transfer matrix-based formalism, signals from buried interfaces between two materials can be isolated and used to uncover the interfacial density of states.

10:36AM F27.00008 Stimulated Second Harmonic Generation for High-Sensitivity Interfacial Spectroscopy and Imaging, AARON GOODMAN, Department of Physics and Astronomy, Massachusetts Institute of Technology, WILLIAM TISDALE, Department of Chemical Engineering, Massachusetts Institute of Technology — Second-order nonlinear optical interactions such as sum- and difference-frequency generation are widely used for bioimaging and as selective probes of interfacial environments. However, inefficient nonlinear optical conversion often leads to poor signal-to-noise ratios and long signal acquisition times. Here, we demonstrate the dramatic enhancement of weak second-order nonlinear optical signals via stimulated sum- and difference-frequency generation. We present a conceptual framework to quantitatively describe the interaction and show that the process is highly sensitive to the relative optical phase of the stimulating field. To emphasize the utility of the technique, we demonstrate stimulated enhancement of second harmonic generation (SHG) from bovine collagen-I fibrils. Using a stimulating pulse fluence of only 3 nJ/cm², we obtain an SHG enhancement of > 10⁴ relative to the spontaneous signal. The stimulated enhancement is greatest in situations where spontaneous signals are the weakest - such as low laser power, small sample volume, and weak nonlinear susceptibility - emphasizing the importance of this technique for improving signal-to-noise ratios in biological imaging and interfacial spectroscopy.

Tuesday, March 3, 2015 8:00AM - 11:00AM — Session F28 GMAG DMP: Focus Session: Pyrochlores and Spinels 205 - Christopher Wiebe, University of Winnipeg

8:00AM F28.00001 From Spin Glass to Spin Liquid Ground States in Molybdate Pyrochlores, BRUCE GAULIN, LUCY CLARK, Department of Physics and Astronomy, McMaster University, GORAN NILSEN, Institute Laue-Langevin, EDWIN KERMARREC, Department of Physics and Astronomy, McMaster University, GEORG EHlers, Oak Ridge National Laboratory, KEVIN KNIGHT, ISIS Rutherford Appleton Laboratory, ANDREW HARRISON, Diamond Light Source, PAUL ATTFIELD, University of Edinburgh — The rare earth molybdate pyrochlores are a well-studied family of geometrically frustrated magnetic materials and in particular, the spin glass ground state in Y₄,M₂O₇ is of interest. Here we will present a study of the Lu-based analogue Lu₄,M₂O₇, which displays a transition to a spin glass state at T_g = 16 K and an unusual T^3 dependence of low temperature heat capacity. Our neutron scattering studies reveal a build-up of diffuse elastic magnetic scattering and the collapse of the inelastic magnetic scattering into the acoustic line at T_g. Furthermore we will show that Lu₄,M₂O₇ can be topochemically substituted for N³⁺, which consequently oxidizes the molybdenum cations and drives down their spin quantum number from Mo⁷⁺ to Mo⁵⁺. This new n oxide phase shows an absence of magnetic order despite strong antiferromagnetic exchange and the persistence of inelastic neutron scattering down to low energy scales. Our results on the oxynitride Lu₄,M₂O₇:N₂ are consistent with a gapless spin liquid, which highlights the significant role of quantum fluctuations [1]. [1] L Clark et al., Phys. Rev. Lett 113, 117201 (2014)

8:12AM F28.00002 Partially ordered state in stoichiometric Yb₂T₂O₇, KATE ROSS, Colorado State University, EDWIN KERMARREC, JONATHAN GAUDET, BRUCE GAULIN, McMaster University — The nature of the magnetic state below a first order transition at T_c = 265 mK in the Quantum Spin Ice Yb₂T₂O₇ is hotly debated. It has been proposed as a Quantum Spin Liquid (QSL) ground state, but some studies find evidence for long range ferromagnetic order; results seemingly vary from sample to sample. We will present low temperature neutron measurements on a polycrystalline sample of Yb₂T₂O₇ that is known to be stoichiometric. Our measurements reveal 1) there is a change of intensity at nuclear Bragg positions upon warming which does not occur sharply at T_c, and which involves an ordered moment size of \sim 1.1μB (58% of the saturation moment) and 2) the inelastic excitations below T_c suggest the presence of dispersive modes coexisting with incoherent low energy fluctuations. The data will be compared to Yb₂Sm₂O₇, which shows nearly identical behavior via inelastic neutron scattering. Our results suggest that the ground state in nominally pure Yb₂T₂O₇ and Yb₂Sm₂O₇ is not a conventionally ordered ferromagnet, but instead involves only partial polarization of the magnetic moments coexisting with a disordered component, a situation reminiscent of the partially polarized QSL called the Coulomb Ferromagnetic phase.

8:24AM F28.00003 Neutron spectroscopic study of Crystal-field excitation in Yb₂(Ti₂₋ₓYₓ)O₇₋ₓ , JONATHAN GAUDET, DALINI MAHARAJ, EDWIN KERMARREC, McMaster University, GARRETT GRANROTH, Oak Ridge National Lab, KATE ROSS, John Hopkins University, HANNA DABOWSKA, BRUCE GAULIN, McMaster University — Among the rare-earth titanate pyrochlores, Yb₂Ti₂O₇ has attracted much attention as a potential realization of a quantum spin ice [1]. While strong quantum effects are absent in classical spin ice compounds, they are thought to be significant in Yb₂Ti₂O₇ because of an ordering of Ti^3+ sites. A significant sample dependence in the low temperature heat capacity has been reported and attributed to an excess of Yb⁺³ (“stuffing”) in the structure [2]. Our measurements, carried out on two well-characterized samples with different levels of stuffing, allow us to discuss the impact of such disorder on the CEF levels. [1] K.A. Ross, L. Savary, B.D. Gaulin, L. Balents, Physical Review X, 1(2), 021002, (2011). [2] K.A. Ross, Th. Proffen, H.A. Dabkowska, J.A. Quilliam, L.R. Yaraskavitch, J.B. Kycia and B.D. Gaulin, Phys. Rev. B 86, 17442

8:36AM F28.00004 What is going on in Yb₂Ti₂O₇? , LUDOVIC JAUBERT, OIST, OWEN BENTON, OIST, JAPAN, MICHEL GINGRAS, University of Waterloo, Canada, JAAN OITMAA, UNSW, Australia, JEFF RAU, University of Waterloo, Canada, NIC SHANNON, OIST, Japan, RAJIV SINGH, UC Davis, USA — Yb₂Ti₂O₇ has become an excellent example of the complexity of frustrated magnets, showing properties of a spin liquid, dimensional reduction, ferromagnetism and multiple phase transitions. In this talk, we shall bring together many of these aspects into one general theoretical framework, showing how competing orderings can be aligned to explain several experimental features observed in bulk measurements (Hostel et al. PRB 2014) and neutron scattering (Chang et al. Nature Comm. 2012).
8:48AM F28.00005 Frozen Spin Ice Ground States in the Pyrochlore Magnet Tb$_2$Ti$_2$O$_7$, KATHARINA FRITSCH, Helmholtz-Zentrum Berlin für Materialien und Energie — The ground state nature of the candidate spin liquid pyrochlore magnet Tb$_2$Ti$_2$O$_7$ has remained a puzzle for over 15 years. Despite theoretical expectations of magnetic order below 1 K based on classical Ising-like Tb$^3+$ spins, early μSR and neutron scattering experiments showed no long range order down to 50 mK [1,2]. This motivated two theoretical scenarios to account for the apparently disordered ground state: a quantum spin ice scenario in which the classical spin order is suppressed by virtual crystal field excitations that renormalize the antiferromagnetic exchange [3], or a scenario arising from a yet to be observed structural distortion creating a non-magnetic singlet ground state [4]. I will discuss our time-of-flight neutron scattering measurements on Tb$_2$Ti$_2$O$_7$ that reveal a glassy spin ice ground state, characterized by frozen antiferromagnetic short range order and the formation of a $\sim 0.08$ meV energy gap in its spin excitation spectrum at the ($1/2,1/2,1/2$) quasi-ordering wave vectors. A new $H - T$ phase diagram for Tb$_2$Ti$_2$O$_7$ in [110] magnetic field will be presented[6]. I will further discuss recent experiments on slightly off-stoichiometric Tb$_{2+x}$Ti$_{2-x}$O$_7$-$y$ samples, which also display the same gapped spin ice correlations at ($1/2,1/2,1/2$) wave vectors.

9:24AM F28.00006 Magnetoelastic excitations in Tb2Ti2O7 in applied magnetic field, MARTIN RUMINY, MICHEL KENZELMANN, TOM FENNELL, Paul Scherrer Institut — The key puzzle in Tb$_2$Ti$_2$O$_7$ is how the expected long-range magnetic order and/or structural phase transition are suppressed, resulting in the stabilization of the spin liquid phase [1]. This spin liquid phase supports spin ice-like powerlaw correlations [2,3,4], and an array of anomalous magnetoelastic properties (see e.g. [5]). Recently we have discovered a microscopic coupling between the magnetic and lattice fluctuations, which form a hybrid propagating excitation with both spin and phonon components [6,7]. Using inelastic neutron scattering, we have now explored the effect of an applied magnetic field on the magnetoelastic coupling. I will show how these experiments cast light not only on the coupling between spins and phonons in Tb$_2$Ti$_2$O$_7$, but also on other unexplained phenomena in Tb$_2$Ti$_2$O$_7$, such as the field induced long-range antiferromagnetic order [8].

9:36AM F28.00007 The ground state of the Er$_3$Ti$_4$O$_7$ pyrochlore XY antiferromagnet: Energetic vs. order-by-disorder selection, JEFFREY G. RAU, University of Waterloo, SYLVAIN PETIT, LLB, CEA-CNRS, CEA-Saclay, MICHEL J. P. GINGRAS, University of Waterloo — Conclusive evidence of order by disorder is rare in real materials. One of the strongest cases presented, Er$_3$Ti$_4$O$_7$, is a microscopic coupling between the magnetic and lattice fluctuations, which form a hybrid propagating excitation with both spin and phonon components [6,7]. Using inelastic neutron scattering, we have now explored the effect of an applied magnetic field on the magnetoelastic coupling. I will show how these experiments cast light not only on the coupling between spins and phonons in Tb$_2$Ti$_2$O$_7$, but also on other unexplained phenomena in Tb$_2$Ti$_2$O$_7$, such as the field induced long-range antiferromagnetic order [8].

9:48AM F28.00008 Inelastic light scattering measurements of structural phase coexistence in ferrimagnetic spinel Mn$_3$O$_4$, SAMUEL GLEASON, TAYLOR BYRUM, ALEXANDER THALER, GREGORY MACDOUGALL, S. LANCE COOPER, Univ of Illinois - Urbana — The ferrimagnetic spinel Mn$_3$O$_4$ has a number of functional properties, e.g., magnetodielectricity, that are ascribed to a coupling between the spins and lattice of this material. Such a coupling is manifested in the symmetry-lowering structural distortion that occurs when Mn$_3$O$_4$ magnetically orders at $T = 33$ K. A recent x-ray diffraction study of polycrystalline Mn$_3$O$_4$ found that this distortion is not fully realized, i.e., the high-symmetry and low-symmetry structures coexist below $T = 33$ K due to strains from lattice mismatch. To extend this work, we use variable-pressure and variable-magnetic-field inelastic light scattering spectroscopy to study structural phase coexistence in single crystals of Mn$_3$O$_4$. We confirm the coexistence of tetragonal (high-symmetry) and orthorhombic (low-symmetry) phases below $T = 33$ K. Furthermore, we demonstrate that the application of hydrostatic pressure suppresses the tetragonal phase, while the application of magnetic field can bolster this phase. These results indicate that microscopic descriptions of functional behavior in Mn$_3$O$_4$ should consider effects due to structural phase coexistence. [2]

[1] Research was supported by the U.S. Department of Energy under Award DE-FG02-07ER46453. T. Byrum was partially supported by the National Science Foundation under Grant Number DGE-1144245.

10:00AM F28.00009 Neutron scattering investigation of magnetic phases in Mn$_3$O$_4$ with field applied away from the easy axis, ALEXANDER THALER, ALEXANDER ZAKJEVSKI, BRIAN NGUYEN, YEWON GIM, University of Illinois - Urbana, ANNE FARWICK, Xavier University, ADAM ACZEL, Oak Ridge National Laboratory, S. LANCE COOPER, GREGORY MACDOUGALL, University of Illinois - Urbana — Mn$_3$O$_4$ is an orbital ordered, magnetically frustrated spinel with strong spin-lattice coupling, which exhibits a series of low temperature magnetic and structural transitions. Recent data shows that the structural phases are radically different with applied field at several different angles to the easy axis. We will present data suggesting that the field-temperature phase diagram of this material is radically altered by varying the applied field direction.

10:12AM F28.00010 \( \mu \)SR study of real space magnetic phase separation in \( \text{Mn}_2\text{O}_4 \)\(^1\) \( \ldots \) ALEXANDER ZAKJEVS KII, ALEXANDER THALER, DALMAU REIG-\( \text{P} \)LESSIS, ISAAC BRODSKY, YE WON GIM, University of Illinois - Urbana, ADAM ACZEL, Oak Ridge National Laboratory, S. LANCE COOPER, GREGORY MACDOUGALL, University of Illinois - Urbana — The material \( \text{Mn}_2\text{O}_4 \) is a magnetically frustrated spinel which exhibits three distinct magnetic transitions below 42 K. Recent work has shown that the lowest of these is accompanied by an orthorhombic structural distortion, implying strong magneto-elastic coupling. Magnetic force microscopy (MFM) measurements indicate a substantial region of phase coexistence below this transition, with domain walls that order on the mesoscale. It is further suggested that a tradeoff in ordered volume with field may play a role in the recent quantum phase transition reported in this material. To follow up on these ideas, we have performed a series of zero- and transverse-field muon spin rotation measurements on single-crystal \( \text{Mn}_2\text{O}_4 \). The zero-field data clearly show the co-existence of ordered and disorder volumes, consistent with MFM results. Here we report these data, and further attempts to vary the ordered volume with applied field. We will discuss both zero- and transverse-field results within the context of the current understanding of the material.

\(^1\)This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under award number DE-FG02-07ER46453.

10:24AM F28.00011 Quantum Criticality in \( \text{FeSc}_2\text{S}_4 \) \( \ldots \) DANIEL ISH, University of California - Santa Barbara, LEON BALENTS, Kavli Institute for Theoretical Physics — Despite possessing a local spin 2 moment on the iron site and a Curie-Weiss temperature of 45 K, the site spinon \( \text{FeSc}_2\text{S}_4 \) does not magnetically order down to 50mK. Previous theoretical work by Chen and Balents advanced an explanation for this observation in the form of the \( J_2-\lambda \) model which places \( \text{FeSc}_2\text{S}_4 \) close to a quantum critical point on the disordered side of a quantum phase transition between a Néel ordered phase and a “Spin-Orbital Liquid” in which spins and orbitals are entangled, quenching the magnetization. We present new theoretical studies of the optical properties of the \( J_2-\lambda \) model, including a computation of the dispersion relation for the quasiparticle excitations and the form of the collective response to electric field. We argue that the latter directly probes a low energy excitation continuum characteristic of quantum criticality, and that our results reinforce the consistency of this model with experiment.

10:36AM F28.00012 Competition between the inter- and intra-sublattice interactions in \( \text{Yb}_2\text{V}_2\text{O}_7 \) \( \ldots \) ZHILING DUN, Department of Physics and Astronomy, University of Tennessee, JIE MA, HUIBO CAO, TAO HONG, MASA AKI MATA-SUDA, Quantum Condensed Matter Division, Oak Ridge National Laboratory, YIMING QIU, JOHN COPLEY, NIST Center for Neutron Research, JINGUANG CHENG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, MINSEONG LEE, EUN SANG CHOI, National High Magnetic Field Laboratory, Florida State University, STEVE JOHN STON, Department of Physics and Astronomy, University of Tennessee, Knoxville, HAI DONG ZHOU, Department of Physics and Astronomy, University of Tennessee, Knoxville, National High Magnetic Field Laboratory, Florida State University — We studied single crystals of \( \text{Yb}_2\text{V}_2\text{O}_7 \) using dc and ac susceptibility measurements, elastic and inelastic neutron scattering measurements, and linear spin wave theory. The experimental data shows a ferromagnetic ordering of \( \text{V}^{4+} \) ions at 70 K, a short-range ordering of \( \text{Yb}^{3+} \) ions below 40 K, and finally a long-range non-collinear ordering of \( \text{Yb}^{3+} \) ions below 15 K. With external magnetic field oriented along the [111] axis, the Yb-sublattice experiences a spin flop transition related to the “three-in-one-out” spin structure. By modeling the spin wave excitations, we extract the Hamiltonian parameters. Our results confirm that although the extra inter-sublattice Yb-V interactions dramatically increases the Yb ordering temperature to 15 K, the intra-sublattice Yb-Yb interactions, based on the pyrochlore lattice, still stabilize the Yb ions’ non-collinear spin structure and spin flop transition.

10:48AM F28.00013 Quantum spin state in a spin-1/2 breathing pyrochlore antiferromagnet \( \ldots \) KENTA KIMURA, Osaka University, SATORU NAKATSUJI, The University of Tokyo, TSUYOSHI KIMURA, Osaka University — A pyrochlore lattice antiferromagnet consisting of corner-sharing tetrahedra of magnetic ions has attracted much attention because the inherent geometrical frustration often leads to exotic magnetism such as quantum spin liquid [1]. The key building unit of pyrochlore magnet is a single spin tetrahedron. Thus, a material composed of a spin-tetrahedral unit is expected to provide important insights on physics of full pyrochlore lattice. Moreover, it may show exotic magnetism based on the unique properties of the single tetrahedron associated with the spin chirality. However, no spin-1/2 regular tetrahedral system has been reported to date. In this study, we report the characterization of a new Yb-based material \( \text{Ba}_3\text{Yb}_2\text{Zn}_5\text{Si}_11 \) [2]. This material is identified as a model system of a pseudospin-1/2 quantum antiferromagnet on breathing pyrochlore lattice characterized by an alternating array of small and large Yb tetrahedra. Despite antiferromagnetic interactions \( J \sim 7 \) K, a large amount of magnetic entropy (25%) remains at 0.38 K, indicating that each small Yb tetrahedron forms a unique doubly degenerate singlet state.

Tuesday, March 3, 2015 8:00AM - 11:00AM — Session F29 GMAG DMP FIAP: Focus Session: Spin-Orbit Effects 206A - Weigang Wang, University of Arizona

8:00AM F29.00001 Optical probe of spin-orbit fields in metallic magnetic structures \( \ldots \) MOHAMMAD MONTAZERI, PRAMEY UPADHYAYA, GUOQIANG YU, KIN L. WONG, MURONG LANG, YABIN FAN, PEDRAM KHALILI AMIRI, ROBERT N. SCHWARTZ, KANG L. WANG, Dep. of Electrical Engineering, University of California, Los Angeles — We report a novel self-consistent optical approach based on magneto-optical Kerr effect to directly and quantitatively probe the spin-orbit fields of magnetic devices with 1um diffraction limited spatial resolution. The optical probe is exemplified by investigating the spin-orbit fields in a magnetic stack of Ta(5 nm)/CoFeB(1.1 nm)/MgO(2.0 nm)/TaOx with enhanced perpendicular anisotropy. Both field-like and damping-like contributions were measured independently and their coefficients are quantified at \( 3.3 \times 10^{-2} \) and \(-2.0 \times 10^{-6}\) Oe/A cm\(^{-2}\), respectively. A detailed comparison with standard transport technique is presented in which a very good agreement were found. Our results establish the relevance of the optical methods for studying spin-orbit torque related physics. We acknowledge the support from the National Science Foundation (DMR-1411085) and the FAME Center, one of the six centers of STARnet, a Semiconductor Research Corporation program sponsored by MARCO and DARPA.
We study the interaction between two localized magnetic moments in the presence of the Rashba spin-orbit coupling and obtain expressions for the interaction,

\[
\mathbf{\mathbf{J}} = \mathbf{J}_1 + \mathbf{J}_2 + \mathbf{J}_3
\]

where \( \mathbf{J}_1 \) contains the RKKY, Dzyaloshinsky-Moriya, as well as a tensor part, viz.,

\[
\mathbf{J}_1 = J_1 \mathbf{S}_1 \cdot \mathbf{S}_2
\]

We will treating the nonmagnetic impurity scattering in the self-consistent Born approximation with ladder-type vertex corrections, we calculate the Rashba torques as deterministic magnetic reversal of perpendicularly magnetized square dots via in-plane dc and/or pulsed currents. We believe that integration of two emerging magneto-ionic gates into prototype spintronic devices will be discussed. In collaboration with U. Bauer, A. J. Tan, S. Emori, L. Yao, and S. van Dijken.

**8:12AM F29.00002 Detection of inverse Rashba-Edelstein effect at Cu/Bi interface using lateral spin valves**, MIREN ISASA, CIC nanogune, San Sebastián, Spain, M. CARMEN MARTINEZ-VELARTE, Universidad Zaragoza, Zaragoza, Spain, ESTITXU VILLAMOR, CIC nanogune, San Sebastián, Spain, LUIS MORELLÓN, Universidad Zaragoza, Zaragoza, Spain, JOSE M. DE TERESA, Universidad Zaragoza-CSIC, Zaragoza, Spain, MANUEL R. IBARRA, Universidad Zaragoza, Zaragoza, Spain, LUIS E. HUESO, FELIX CASANOVA, CIC nanogune, San Sebastián, Spain; IKERBASQUE, Bilbao, Spain — The spin-orbit coupling (SOC) can be exploited to generate and detect pure spin currents, which are key elements in the field of spintronics. One important example is the spin Hall effect. A novel SOC phenomenon, the inverse Rashba-Edelstein effect (IREE), is attracting a large interest. IREE arises from the Rashba coupling that appears at interfaces or surface states (SSs), leading to the conversion of a 3D spin current into a 2D charge current. An interesting system to study the IREE is thus the SS of a semimetal such as Bi. In this work [1], we study the spin-to-charge conversion in Bi using a device based on a lateral spin valve (LSV) geometry. We demonstrate a spin-to-charge current conversion in the LSV. The analysis of the obtained results leads us to argue that the spin-to-charge conversion occurs at the Cu/Bi interface, therefore detecting IREE. Moreover, we evaluate the IREE length, which characterizes the spin-to-charge conversion ratio, as a function of temperature. This ratio changes sign at a certain temperature threshold (125 K), in excellent agreement with the experimental observation of a change in the type of carriers that dominate the electronic transport in Bi.

**9:12AM F29.00005 Perpendicular Magnetization Switching via Current induced Spin-Orbit Torques on Flexible Substrate**, OUKJAE LEE, LONG YOU, JAEWON JANG, VIVEK SUBRAMANIAN, SAYEEF SALAHUDDIN, UC Berkeley, UC BERKELEY TEAM — Implementation of perpendicularly magnetized thin films and of electrically functional devices on flexible substrates may offer new degree of freedom such as strain effect on the ultrathin magnetic films with a strong spin orbit coupling. Moreover the flexibility has advantages in applications with bendable, stretchable and/or mobile environment. In this talk we present the magnetic characteristics of ultrathin multilayers with a sufficient PMA that were grown on a flexible plastic substrate by dc/rf magnetron sputtering. In addition we fabricate cross-Hall bar devices and demonstrate fully deterministic magnetic reversal of perpendicularly magnetized square dots via in-plane dc and/or pulsed currents. We believe that integration of two emerging technologies promises new spintronic devices that can be utilized in arbitrary surface geometries and be worked in ultra small dimensions.

---

**9:24AM F29.00006 Microscopic calculation of Rashba spin-orbit torques**, JUNJI FUJIMOTO, Osaka University, HIROSHI KOHNO, Nagoya University — We study current-induced spin-orbit torques (Rashba torques) in a two-dimensional Rashba ferromagnet, which may model the interface of the ferromagnetic — heavy and paramagnetic metals. Using the linear response theory and the Green’s function method and treating the nonmagnetic impurity scattering in the self-consistent Born approximation with ladder-type vertex corrections, we calculate the Rashba torques as functions of magnetization direction, strength of the spin-orbit coupling, and the chemical potential. It is found that the Rashba torques are independent of the direction of the magnetization for a parabolic dispersion in good metals, whereas they show a clear angular dependence for a tight-binding model. We will discuss our results comparing with other theoretical calculations [C. O. Paucar, X. Wang, M. Chshiev and A. Manchon, Appl. Phys. Lett. 102, 252403 (2013), K.-S. Lee, et al, arXiv:1409.8540] and the recent experiments.
Both lattice and spin subsystems.

To the lattice subsystem, we show that this novel extension enables the exchange of angular momentum and leads to the mutual thermalization of lattice vibrations. Using MD-SD simulations, we investigate the effect of these terms on the spin-lattice relaxation in BCC iron. By coupling a conventional spin-orbit coupling. These interactions are modeled in terms of the local magnetic anisotropies that arise as a consequence of the symmetry breaking due to relaxation process. To circumvent this drawback, we extend the conventional MD-SD approach by incorporating additional interaction terms that characterize coordinate-dependent exchange interaction, which allows the dynamic exchange of energy between the lattice and spin subsystems; however such exchange-effect of magnetism into the atomistic simulations of transition metals. The coupling between the atomic and spin degrees of freedom is established via a polarizer [1,2,3]. In this work, I will first present recent theoretical investigations on the spin-orbit torque that emerges at the interface between a topological insulator and a ferromagnetic metal. The ability to measure spin structure on the nanometer scale has attracted substantial interest for a long time. Spin-polarized scanning tunneling microscopy (SPSTM) is an excellent tool for studying fundamental aspect of magnetism at atomic scale. We combine a low temperature STM equipped with a vector magnet and a spin-polarizable tip, to probe superconductors with strong spin-orbit coupling, such as Pb, which is emerging as a platform for engineering topological superconductivity [1]. We observe anisotropic tunneling conductance between tip and substrate as a function of the angle of applied in-plane magnetic field. This finding suggests that SPSTM may provide a tool to locally measure spin-orbit coupling, even in non-magnetic substrates. [1] S. Nadj-Perge, I.K. Drozdov, J. Li, H. Chen, S. Jeon, J. See, A.H. Macdonald, B.A. Bernevig, A. Yazdani, Science 346, 602 (2014)

Spin-orbit-induced relaxation in combined molecular and spin dynamics simulations of BCC iron1, DILINA PERERA, The University of Georgia, MARKUS EISENBACH, Oak Ridge National Laboratory, DON NICHOLSON, University of North Carolina at Asheville, JUNQI YIN, University of Tennessee, G. MALCOLM STOCKS, Oak Ridge National Laboratory, DAVID P. LANDAU, The University of Georgia — The combined molecular and spin dynamics (MD-SD) method has emerged as a powerful tool for integrating the effect of magnetism into the atomistic simulations of transition metals. The coupling between the atomic and spin degrees of freedom is established via a coordinate-dependent exchange interaction, which allows the dynamic exchange of energy between the lattice and spin subsystems; however such exchange-based coupling alone cannot facilitate the transfer of angular momentum between the two subsystems. This results in an unrealistic depiction of the spin-lattice relaxation process. To circumvent this drawback, we extend the conventional MD-SD approach by incorporating additional interaction terms that characterize spin-orbit coupling. These interactions are modeled in terms of the local magnetic anisotropies that arise as a consequence of the symmetry breaking due to lattice vibrations. Using MD-SD simulations, we investigate the effect of these terms on the spin-lattice relaxation in BCC iron. By coupling a conventional thermostat to the lattice subsystem, we show that this novel extension enables the exchange of angular momentum and leads to the mutual thermalization of both lattice and spin subsystems.

8:00AM F30.00001 First-principles analysis of a Dzyaloshinskii-Moriya driven magnetic structure in a monolayer Cr on W(110). STEFAN BLÜGEL, BERND ZIMMERMANN, TIMO SCHENK, MARCUS HEIDE, YURYI MOKROUSOV, GUSTAV BİHLMAYER, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — The observation of a chiral magnetic spin spiral in a magnetic Mn monolayer on a W(110) substrate has opened a new vista in low-dimensional magnetism [1] with possible applications in spintronics. The origin was explained by the occurrence of the Dzyaloshinskii-Moriya interaction (DMI), which occurs due to the presence of a structure inversion-asymmetry. In this talk, we turn our attention to a monolayer Cr on W(110) [2]. We show by DFT calculations, that the DMI is so strong that it creates a non-collinear spin-spiral ground state, with excellent agreement to spin-polarized STM experiments [3]. We determine a considerable inhomogeneity of the spin spiral by means of a micromagnetic model. We compare our results to the systems Mn and Fe on W(110), where the direction of the spiral and period length are different. We present a minimal tight binding model [4] and show that indeed the sign and strength of the DMI reveals a non-trivial dependence on the electronic structure.

8:12AM F30.00002 Majorana bound state in a magnetic biskyrmion. GUANG YANG, RIKEN Center for Emergent Matter Science (CEMS), Wako 351-0198, Japan, DANIEL LOSS, Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland — Magnetic skyrmion, recently discovered [1] in thin film dipolar ferromagnet with uniaxial anisotropy, is a highly mobile nanoscale topological spin texture. We show that a magnetic skyrmion in proximity to an s-wave superconductor supports a zero-energy Majorana bound state in its core. The Majorana bound state can be manipulated through driving the motion of the magnetic skyrmion by electric current. We discuss the realization of non-Abelian statistics of such Majorana bound states.

8:24AM F30.00003 ABSTRACT WITHDRAWN

8:36AM F30.00004 Unraveling skyrmion spin texture using resonant soft x-ray scattering. SUJOY ROY, Lawrence Berkeley National Laboratory — The recent discovery of skyrmions, that were originally predicted in context of high energy physics, in magnetic materials has sparked tremendous interest in the research community due to its rich physics and potential in spintronics applications. Skyrmions have an unusual spin texture that manifests as magnetic knot and can be easily moved around. Understanding the fundamental physics and mechanisms for controlling their dynamical properties presents important scientific challenges. So far experimental verifications of the skyrmions in magnetic systems have come from neutron scattering and Lorentz transmission electron microscopy (TEM) measurements. In this talk we report the first observation of the skyrmions using resonant soft x-ray scattering. We have used soft x-rays tuned to the Cu L3 edge to diffract off the skyrmion lattice in a multiferroic Cu2OSeO3 compound. We show that in Cu2OSeO3 there exist two skyrmion lattices arising due to the two inequivalent Cu-O sublattices that have two different magnetically active d-orbitals. The two skyrmion sublattices are mutually rotated with respect to each other. The angle of rotation could be changed by an external magnetic field, thereby indicating possible existence of a new phase. We have also studied skyrmion spin texture in an ultra-thin Fe/Gd multilayer that shows perpendicular anisotropy. The Fe/Gd sample exhibits a near perfect aligned stripe phase. Within a small range of temperature and magnetic field we observe a hexagonal scattering pattern due to skyrmion bubbles. Analysis of the scattering pattern suggests that the skyrmion lattice unit cell contains two skyrmions. The skyrmion state is also revealed by Lorentz TEM images. The near room temperature discovery of skyrmion in a technology relevant material is a significant step towards using skyrmions in magnetic devices.

1Work at LBNL was supported by the Office of Basic Energy Sciences of the U.S. Department of Energy (Contract No. DE-AC02-05CH11231).

9:12AM F30.00005 X-ray microscope Imaging of skyrmions in Ultrathin Films with Strong Dzyaloshinskii-Moriya Interaction. SEONGHOON WOO, MIT, BENJAMIN KRUGER, MATHIAS KLÄUI, University of Mainz, PETER FISCHER, Lawrence Berkeley National Laboratory, GEOFFREY BEACH, MIT, MIT COLLABORATION, UNIVERSITY OF MAINZ COLLABORATION, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION — Spin textures stabilized by the Dzyaloshinskii-Moriya interaction (DMI) have been of considerable recent interest due to extraordinary static and dynamic behaviors derived from their topological nature. It has recently been shown that DMI can also manifest in buried ultrathin sputtered film stacks. Here we examine magnetic bubble domains in submicron patterned dots with strong DMI. We use magnetic transmission X-ray microscopy to image the evolution of the magnetization configuration as a function externally applied fields. We imaged a series of [Pt(3nm)/Co(0.9nm)/Co(0.9nm)/Co(0.9nm)] x 15, where the DMI is strong, and [Pt(3nm)/Co(0.9nm)/Pt(3nm)] x 15 stacks, where DMI is small enough due to symmetric structure, and 15 repeats were used to enhance XMCD contrast. We observed that the size of domain can be significantly narrower for the case of strong DMI and micromagnetic modeling confirmed the observation. We also imaged that magnetic bubbles can be easily nucleated and controlled using external fields in micrometersize-patterns. The static stability of bubbles for the same cases were tested using external bias field, showing skyrmionic bubble has larger bubble-collapse field by the factor of two. Other qualitative and quantitative measurements will also be presented.

9:24AM F30.00006 Skyrmions in quasi-2D chiral magnets with broken bulk and surface inversion symmetry1. JAMES ROWLAND, Ohio State University, SUMILAN BANERJEE, Ohio State University and Weizmann Institute of Science, MOHIT RANDERIA, Ohio State University — Most theoretical studies of skyrmions have focused on chiral magnets with broken bulk inversion symmetry, stabilized by easy-axis anisotropy [1]. Recently, we considered 2D systems with broken surface inversion [2] and showed that skyrmion crystals are more stable than in 3D, pointing out the importance of easy-plane anisotropy. In the present work we investigate quasi-2D systems which break both bulk and surface inversion symmetry. The Landau-Ginzburg free energy functional thus contains two Dzyaloshinskii-Moriya terms of strength $D_D$ and $D_R$ arising from Dresselhaus and Rashba spin-orbit coupling respectively. We trace the evolution of the phase diagram as $D_D/D_R$ is varied, and find that skyrmions are increasingly destabilized with respect to the cone phase as $D_D$ increases relative to $D_R$. We find an evolution from vortex-like skyrmions in the pure Dresselhaus limit to hedgehog-like skyrmions in the pure Rashba limit. We discuss the relevance of these results to existing experiments and the prospects of tuning the ratio of Dresselhaus and Rashba spin-orbit coupling via film thickness and strain. [1] M. Wilson et al., PRB 89, 094411 (2014). [2] S. Banerjee, J. Rowland, O. Ertan, and M. Randeria, PRX 4, 031045 (2014).

9:36AM F30.00007 Anisotropic Magnetoresistance in the Layered Chiral Helimagnet Cr$_{1/3}$Nb$_2$S$_6$, ALEXANDER BORINSTEIN, University of Colorado Boulder, NIRMAL GHIMIRE, DAVID MANDRUS, University of Tennessee, Oak Ridge National Laboratory, DAVID PARKER, Oak Ridge National Laboratory, MINHYEA LEE, University of Colorado Boulder — We study the magnetotransport properties and the low temperature specific heat in a highly anisotropic helimagnet Cr$_{1/3}$Nb$_2$S$_6$. We compare the dependence of both measurements on field orientation: within the crystallographic plane and normal to it. In transport measurements, the current always remains within the crystallographic ab-plane. We find a three times larger reduction in the resistivity when the magnetization is saturated normal to the plane compared to within the plane. This discrepancy occurs below 50 K $< T_C < 130$ K. In the same temperature range, an unusual field dependence of the Hall Effect is also observed. From first principles calculations, we connect the changes in resistivity to modification of the density of states dependent on the direction of spin polarization. The Sommerfeld constant for both spin orientations is discussed in relation to the transport behavior.

9:48AM F30.00008 Fermi Surface Induced Scalar Chiral Stripes in the Kondo Lattice Model on a Square Lattice, RYO OZAWA, Department of Applied Physics, University of Tokyo, KIPTON BARROS, GIA-WEI CHERN, SHI-ZHEN LIN, Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, MASAFUMI UDAGAWA, YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo, CRISTIAN BATISTA, Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory — The stability and controllability of emergent nano/mesoscale spin structures are one of the central issues for spintronics. The possibility of stabilizing non-coplanar spin structures in chiral magnets (e.g. skyrmion crystals) is opening a new avenue for controlling transport properties with small magnetic fields. An electron moving in a loop picks up a Berry phase proportional to the net scalar spin chirality of the underlying spin configuration that is enclosed by the loop. In other words, the scalar spin chirality acts as an effective magnetic field that couples to the electronic orbital motion. By solving the Kondo lattice model on a square lattice, we will show that mesoscale chiral stripes emerge in the vicinity of a Lifshitz transition of the Fermi surface. Our unbiased results are obtained by applying a novel algorithm which allows for very efficient simulations based on Langevin dynamics.

10:00AM F30.00009 Magnetoresistance measurements in a chiral magnet CrNb$_2$S$_6$ subject to locally applied magnetic field, YU MATSUMOTO, Osaka Prefecture Univ., YUSUKE KOUSAKA, JUN AKIMITSU, Aoyama Gakuin Univ., SADAUFUMI NISHIHARA, KATSUYA INOUE, Hiroshima Univ., ROBERT STAMPS, Univ. of Glasgow, ALEXANDER S. OVCHINIKOV, Ural Federal Univ., JUN-ICHIRO KISHINE, The Open Univ. of Japan, YOSHIHIKO TOGAWA, Osaka Prefecture Univ. — CrNb$_2$S$_6$ is one of interesting magnetic materials with structural chirality, wherein chiral magnetic orders are formed as a consequence of the competition between Heisenberg exchange and antisymmetric Dzyaloshinsky-Moriya (DM) interactions. Interestingly, a chiral helimagnetic order appears as the ground state at zero magnetic field, while it transforms into a chiral spin soliton lattice, a spin superlattice of forced ferromagnetic regions partitioned by a soliton with $2\pi$ rotation of spin magnetic moments, in the presence of magnetic field applied perpendicular to the chiral structural axis [1]. In this work, we have investigated the magnetoresistance (MR) in a micro-fabricated single crystal of CrNb$_2$S$_6$ by means of the standard ac transport measurement. We have found that the MR exhibits a hysteresis behavior during the magnetic field cycle, although a continuous negative MR is observed in a bulk single crystal [2]. In the presentation, we will show the MR changes induced by locally applied magnetic field and discuss their properties in terms of the macroscopic coherence of the chiral spin soliton lattice.

10:12AM F30.00010 Meron crystals and skyrmion fractionalization in chiral magnets, AVADH SAXENA, SHI-ZENG LIN, CRISTIAN D. BATISTA, Los Alamos National Lab — The recent discovery of skyrmions in chiral magnets, e.g. MnSi, has triggered enormous interest due to their huge potential for spintronics. Unlike magnetic domain walls, skyrmions can be manipulated with very small electric currents, thus rendering them as prime candidates for novel information storage devices with much lower power consumption. Here we study the equilibrium phase diagram of ultrathin chiral magnets with an easy-plane anisotropy $A$. The triangular skyrmion lattice phase that is obtained for $A = 0$ evolves through different structural phase transitions upon increasing $A$, which are related to the compact packings of disks with two different radii. Meanwhile, the topological charge of a skyrmion decreases continuously and we call this process skyrmion fractionalization. For a strong easy-plane anisotropy, a meron-antimeron crystal is stabilized. Akin to the case of skyrmions, the resulting merons can be manipulated with external current, and they behave like particles. Meron charge can be measured in transport experiments or by direct imaging of meron motion. Our work demonstrates that symmetric magnetic anisotropy can be used as a knob for tuning the topological character of the emergent mesoscale particles as well as the nature of the crystal that they form.

10:24AM F30.00011 Theory of electromagnons in CuO, KUN CAO, FELICIANO GIUSTINO, Department of Materials, University of Oxford, PAOLO RADAELLI, Clarendon Laboratory, Department of Physics, University of Oxford — Recently, an electromagnon excitation was found in the multiferroic phase of CuO for electric field parallel to the [101] direction, with excitation energy $\sim 3$ meV. We performed symmetry analysis to show that the experimentally measured electromagnon cannot be explained by the exchange-striction mechanism. We then studied the CuO electromagnons using ab-initio calculations and effective model simulations. The experimentally measured electromagnon was found to originate from the Dzyaloshinskii-Moriya interaction, with the magnon part corresponding to a phason mode. We further predict that a new high-energy electromagnon with selection rule $E-II$ [010] should also exist in the multiferroic phase of CuO, due to the exchange-striction mechanism.

10:36AM F30.00012 Wave Equation of Three-Dimensional Skyrmion Line, JUNICHI IWASAKI, Dept. of Applied Physics, Univ. of Tokyo, CHRISTOPH SCHUTTE, Institut für Theoretische Physik, Universität zu Köln, NAOTO NAGAOSA, RIKEN Center for Emergent Matter Science and Dept. of Applied Physics, Univ. of Tokyo — Magnetic skyrmion is a particle in magnets, which is now regarded as one of the most promising candidate for information carrier in future memory devices. In the bulk of chiral magnets, skyrmions form lines along the applied magnetic field. Previous studies report that extra energy is required to create skyrmion lines. Here, we raise a more fundamental question: how does the wave propagates in these one-dimensional “strings”? Surprisingly, the numerical simulation reveals that the waves propagating in positive and negative directions are different. This asymmetric feature is described by magnon contribution, which has, in general, $k$-linear term in its dispersion relation under the Dzyaloshinskii-Moriya interaction. Starting from the action of the spin system in chiral magnets, we derive the wave equation of the skyrmion line.

10:48AM F30.00013 Thermalization and dynamic phase transition of quantum spins\(^1\), MEHRTASH BABADI, Institute for Quantum Information and Matter, California Institute of Technology, Pasadena, CA 91125, EUGENE DEMLER, MICHAEL KNAP, Department of Physics, Harvard University, Cambridge, MA 02138 — We develop a controlled field theoretic technique for studying far-from-equilibrium dynamics of interacting quantum spins. This is achieved by combining the Majorana fermion representation of spins and 1/N expansion of the two-particle irreducible effective action (2PI-EA). We use the technique to study the relaxation dynamics of quantum spin spirals in the Heisenberg model. The non-equilibrium magnetization and spin correlations are found by solving the Kadannoff-Baym and Bethe-Salpeter equations resulting from the 1/N expansion of the 2PI-EA to the next-to-leading order. In three dimensions, we identify a dynamic phase transition in the steady state magnetization for spiral states near the Neél order. We further find a dynamical stabilization of the initial out-of-plane ordering instability in the course of the relaxation dynamics, in contrast to the linear response analysis.

Session F31 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors: Defects in Diamond and SiC  207A - Michael Flatte, University of Iowa

8:00AM F31.00001 Nuclear magnetic resonance of external protons using continuous dynamical decoupling with shallow NV centers1. CHARLES DE LAS CASAS, KENICHI OHNO, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago — The nitrogen vacancy (NV) center in diamond is a paramagnetic defect with excellent spin properties that can reside within a few nanometers of the diamond surface, enabling atomic-scale magnetic resonance sensing of external nuclear spins. Here we use rotating frame longitudinal spin relaxation ($T_1^L$) based sensing schemes, known as Continuous Dynamical Decoupling (CDD), to detect external nuclear spins with shallow NV centers (<5 nm from the surface). Distinguishing neighboring nuclear spins from each other requires the NV center be near enough to create differences in the hyperfine shifts and coupling strengths of the nuclei. However, spin coherence time and consequently the sensitivity of dynamical decoupling techniques degrade sharply as NVs become shallower. We use strong continuous driving to overcome this fast decoherence and detect an ensemble of external nuclear spins using a single shallow NV center with a short $T_2$ (<2μs) at magnetic fields as high as 0.5 Tesla. The increased sensitivity of this method relative to pulsed dynamical decoupling techniques demonstrates the benefits of CDD for sensing with very shallow NV centers.

8:12AM F31.00002 High-field optically detected magnetic resonance of a single nitrogen-vacancy center in diamond. VIKTOR STEPANOV, CHATHURANGA ABEYWARDANA, FRANKLIN CHO, RANA AKIEL, SUSUMU TAKASHI, University of Southern California — A nitrogen-vacancy center (NV) in diamond is a promising candidate for fundamental investigation of spin physics and applications to quantum information processing and quantum sensing because of its remarkable properties such as long lived coherence, superb photostability and capability to detect a single NV center using an optically detected magnetic resonance (ODMR) technique. Here, we discuss a platform to investigate a NV center at high magnetic fields. We will present the development of a high-field ODMR system consisting of a high-frequency excitation component, superconducting magnet, NV detection system, microscope system and sample stage. We also discuss ODMR and double electron-electron resonance measurements of a single NV center at high magnetic fields.

8:24AM F31.00003 Fast Room-Temperature Phase Gate on a Single Nuclear Spin in Diamond2. S. SANGTAWESIN, T.O. BRUNDAGE, J.R. PETTA, Department of Physics, Princeton University — Nuclear spins support long lived quantum coherence due to weak coupling to the environment, but are difficult to rapidly control using nuclear magnetic resonance as a result of the small nuclear magnetic moment. We demonstrate a fast ~ 500 ns nuclear spin phase gate on a $^{14}$N nuclear spin qubit intrinsic to a nitrogen-vacancy center in high purity diamond [1]. This phase gate is achieved by utilizing electron-nuclear hyperfine interaction. By driving off-resonant Rabi oscillations on the electronic spin, we can generate an arbitrary phase gate on the nuclear spin. We also demonstrate that repeated applications of $\pi$-phase gates can bang-bang decouple the nuclear spin from the environment, locking the spin state for up to 140 μs.

8:36AM F31.00004 Quantum control of orbital and spin dynamics in diamond using ultrafast optical pulses1. F. JOSEPH HEREMANS2, Institute for Molecular Engineering, University of Chicago — Optically addressable spin defects in solid-state materials have shown great potential for applications ranging from metrology to quantum information processing. Many of these experiments require a detailed understanding of the full Hamiltonian dynamics in order to develop precise quantum control. Here we use picosecond resonant optical pulses to investigate the coherent orbital and spin dynamics of the nitrogen-vacancy (NV) center in diamond, over timescales spanning six orders of magnitude. We implement an ultrafast optical pump-probe technique to study the NV center’s orbital-doublet, spin-triplet excited state [1]. These experiments reveal dynamics on femtosecond to nanosecond timescales due to the interplay between the ground and excited state orbital levels. This all-optical technique also provides a method to dynamically control the spin state of the NV center by harnessing the excited state structure. Through studying the spin dynamics of the NV center with coherent pulses of light, we are able to rotate the spin state on sub-nanosecond timescales. Furthermore, by tuning the excited-state spin Hamiltonian with an external magnetic field, we demonstrate arbitrary-axis spin rotations through controlled unitary evolution of the spin state. Extending this to the full excited-state manifold, we develop a time-domain quantum tomography technique to precisely map the NV center’s excited state Hamiltonian. These techniques generalize to other systems and can be a powerful tool in characterizing and controlling qubits in other optically addressable spin systems.

9:12AM F31.00005 Electron spin lifetimes in 1e14 cm$^{-3}$ proton irradiated SiC3. KYLE MILLER, JOHN COLTON, Brigham Young University, SAM CARTER, Naval Research Lab — Silicon vacancies created by irradiation with protons or electrons in 4H silicon carbide (SiC) are potential spintronic devices. In our experiments, electron spin states are polarized with 870 nm laser light, and we manipulate the spins with resonant microwaves at 10.47 GHz and a magnetic field of 350 mT. Spin states are detected by the change in photoluminescence from the silicon defects, and lifetimes are calculated through optically detected spin resonance and electron spin echo. We have measured $T_2$ lifetimes in 1e14 cm$^{-3}$ proton irradiated SiC to be about 16 μs at various temperatures, fairly independent with temperature. Future plans include studying how defect density will impact spin lifetimes.

Spin states of the silicon vacancy in silicon carbide

MICHELE BOCKSTEDTE, University of Salzburg, Austria, and University Erlangen-Nuernberg. Germany, FELIX SCHUETZ, University Erlangen-Nuernberg, Germany — SiC as a semi conductor fulfills all necessary requirements for implementing qubits via defect electron spins, such as the silicon vacancy, the di-vacancy or a complex of a silicon vacancy and a nitrogen impurity. The spin-selective fluorescence in contrast to the prototypical NV-center in diamond operates in the spectral range favorable for telecom applications.

Spin-manipulation of the intrinsic centers was demonstrated even at room temperature. For the silicon vacancy in SiC inter system crossings (ISCs) from high to yet unknown low spin states govern the spin-relaxation. By DFT and a DFT-based multi-reference Hamiltonian we analyze the spin physics of the defect. In 4H SiC distinct luminescence lines are obtained for the inequivalent defect sites in agreement with experiment. Our result thus establishes an assignment of the lines to the sites. Owing to the spin (S=3/2) and a stronger electron-phonon coupling in the excited state, we find ISCs distinct from the NV-center.

Near unity optical spin polarization of 20Si nuclei in silicon carbide

WENHAO HU, MICHAEL E. FLATTÉ, Department of Physics and Astronomy, University of Iowa — Recently, a decoherence-free subspace (DFS) system has been predicted in the substitutional nickel spin center of diamond [1]. Here we describe our investigations of substitutional transition metal dopants in 3C silicon carbide using density functional theory in the SGGA approximation. We used a 64-atom supercell for the silicon carbide host, inserted a dopant atom (Ni or Cr) at a single carbon or a single silicon site. The atomic positions were allowed to relax with a force precision of 0.1 mRy/a.u. The Heisenberg exchange coupling energy J was calculated as a function of hydrostatic strain. An antiferromagnetic-ferromagnetic transition can be seen in nickel spin centers at certain strains. A model of two spatially separated spins can be used to explain the dependence of J on the atomic separation. By applying a magnetic field, we predict two of the triplet states can be split off so as to create a DFS. Strain modulation and resonant microwave can be exploited to manipulate the qubit.

Finally, the experimental feasibility of our scheme is evaluated.

Tight-Binding Model for Exchange Interaction Between Transition Metal Dopants in Diamond and SiC

VICTORIA R. KORTAN, CÜNEYT SAHIN, MICHAEL E. FLATTÉ, Optical Science and Technology Center & Department of Physics and Astronomy, University of Iowa — Diamond and SiC are wide-band-gap semiconductors with long-lived spin lifetimes [1,2] and promising for quantum information technology device design. Spin initialization, manipulation and readout has already been demonstrated for the NV center in diamond [3] and the vacancy in SiC [4]. Transition metal spin centers offer additional benefits in tetrahedral hosts due to the crystal field splitting of the d-states into localized and extended states. For example, the application of strain in diamond allows switching between two spin states of a single Ni dopant [5]. Here we use a spds* tight-binding model including spin-orbit interaction to describe transition metal spin centers in diamond and 3C-SiC as well as the NV center in diamond and divacancy in 3C-SiC. The energy levels for an isolated dopant are taken from experiment, when available, and density functional theory calculations otherwise. We calculate and compare the wavefunctions of these spin centers, as well as the strength of the exchange interaction between pairs of them.

Isolation and Control of Spins in Silicon Carbide with Millisecond-Coherence Times

DAVID J. CHRISTLE, ABRAM L. FALK, PAOLO ANDRICH, PAUL V. KLIMOV, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago, JAWAD UL HASSAN, NGUYEN T. SON, ERIK JANZÈN, Department of Physics, Chemistry and Biology, Linköping University, TAKESHI OHSHIMA, Japan Atomic Energy Agency — The elimination of defects from silicon carbide (SiC) has facilitated its move to for implementing qubits via defect electron spins, such as the silicon vacancy, the di-vacancy or a complex of a silicon vacancy and a nitrogen impurity. The spin-selective fluorescence in contrast to the prototypical NV-center in diamond operates in the spectral range favorable for telecom applications.

Spin-manipulation of the intrinsic centers was demonstrated even at room temperature. For the silicon vacancy in SiC inter system crossings (ISCs) from high to yet unknown low spin states govern the spin-relaxation. By DFT and a DFT-based multi-reference Hamiltonian we analyze the spin physics of the defect. In 4H SiC distinct luminescence lines are obtained for the inequivalent defect sites in agreement with experiment. Our result thus establishes an assignment of the lines to the sites. Owing to the spin (S=3/2) and a stronger electron-phonon coupling in the excited state, we find ISCs distinct from the NV-center.

10:24AM F31.00011 Two-dimensional nanoscale imaging of gadolinium spins via scanning probe relaxometry with a single spin in diamond. MATTHEW PELLICCIONE, BRYAN MYERS, LAETITIA PASCAL, ANAND DAS, ANIA JAVICH, University of California, Santa Barbara — Spin-labeling of molecules with paramagnetic ions is an important approach for determining molecular structure, however current ensemble techniques lack the sensitivity to detect few isolated spins. In this talk, we demonstrate two-dimensional nanoscale imaging of paramagnetic gadolinium compounds using scanning relaxometry of a single nitrogen vacancy (NV) center in diamond. Gadopentenate dimeglumine attached to an atomic force microscope tip is controllably interacted with and detected by the NV center, by virtue of the fact that the NV exhibits fast relaxation in the fluctuating magnetic field generated by electron spin flips in the gadolinium. We demonstrate a reduction in the T1 relaxation time of the NV center by over two orders of magnitude, probed with a spatial resolution of 20 nm, limited by thermal drift in ambient conditions. We discuss the importance of mitigating drift to reach truly nanoscale imaging and present progress towards cryogenic scanning magnetometry, along with utilizing chemically functionalized tips to gain greater control over the Gd distribution on the tip. Our result exhibits the viability of the technique for imaging individual spins attached to complex nanostructures or biomolecules, along with studying the magnetic dynamics of isolated spins.

10:36AM F31.00012 Coherent Control of a Nitrogen-Vacancy Center Spin Ensemble with a Diamond Mechanical Resonator1, F. GUO, E.R. MACQUARRIE, T.A. GOSAVI, A.M. MOEHLLE, N.R. JUNGWIRTH, S.A. BHAVE, G.D. FUCHS, Cornell University — In contrast to the traditional coherent control of the nitrogen vacancy (NV) center in diamond’s triplet spin state with ac magnetic fields, we recently demonstrated that gigahertz-frequency lattice strain resonant with the m_s=+1 to -1 spin state splitting can also be used to drive spin transitions.1 We present coherent spin control over NV center ensembles with a bulk-mode mechanical microresonator that generates large amplitude ac stress within the diamond substrate. Using these structures, we mechanically drive coherent Rabi oscillations between the +1 and -1 states. We also accurately model the Rabi dephasing with a combination of a spatially inhomogeneous mechanical driving field and magnetic noise from a fluctuating spin bath. Understanding mechanically driven dynamics in spin ensembles could have applications in sensing and quantum optomechanics where interactions can be enhanced by the number of mechanical modes for quantum transitions, thus closing the loop on NV center ground state spin control and enabling the creation of a coherent Δ-system within the NV center ground state.

We gratefully acknowledge support from the ONR.

10:48AM F31.00013 Recursive polarization of nuclear spins in diamond at arbitrary magnetic field. DANIELA PAGLIERO, ABDELGHANI LARAOUI, JACOB HENSHAW, CARLOS MERILES, CUNY-City College of New York — We introduce an alternate route to dynamically polarize the nuclear spin host of nitrogen-vacancy (NV) centers in diamond. Our approach articulates optical, microwave and radio-frequency pulses to recursively transfer spin polarization from the NV electronic spin. Using two complementary variants of the same underlying principle, we demonstrate nitrogen nuclear spin initialization approaching 80% at room temperature both in ensemble and single NV centers. Unlike existing schemes, our approach does not rely on level anti-crossings and is thus applicable at arbitrary magnetic fields. This versatility should prove useful in applications ranging from nanoscale metrology to sensitivity-enhanced NMR.

Session F32 GMAG DMP: Focus Session: Manganeses

8:00AM F32.00001 Domain walls in improper ferroelectrics as functional oxide interfaces. MANFRED FIEBIG, Department of Materials, ETH Zurich, Vladimir-Prelog-Weg 4, 8093 Zurich, Switzerland — The coexistence of magnetic and electric order in multiferroics and the resulting magnetoelectric coupling have triggered an immense research interest. The most prominent mechanisms promoting magnetic and ferroelectric order, however, tend to be mutually exclusive. As a result, multiferroics are an inherently source of “unusual” ferroelectricity. In many cases the ferroelectric state is improper, i.e., induced by the ordering of a different parameter like magnetism or strain. This secondary nature can lead to properties not normally found in ferroelectrics. In my talk I will discuss consequences for the ferroelectric domain walls of various multiferroics. For example, in magnetically induced ferroelectrics like MnWO4 or TbMnO3 the electric polarization within the wall is expected to rotate instead of passing through zero, as in conventional displaceable ferroelectrics. This affects the distribution and propagation of the ferroelectric domains. In addition, a magnetic-field-induced rotation can reversible charge and discharge the domain walls. In strain-induced ferroelectrics like SrMnO3 the interplay of strain and oxygen vacancies leads to a polar state in which domain walls act as insulating boundaries to the conducting domains which therefore acts as nano-capacitors.

8:36AM F32.00002 Neutron Scattering Studies of Magnetic Structure and Excitations in Na5/8Mn2O3, ROBIN CHISNELL, NIST Center for Neutron Research, XIN LI, XIAOHUA MA, MIT, DONG SU, Brookhaven National Laboratory, LEI LIU, SHUYE PING ONG, HAILONG CHEN, ALEXANDRA TOUMAR, MIT, JUAN-CARLOS IDROBO, Oak Ridge National Laboratory, YUECHUAN LEI, MIT, JIANMING BAI, FENG WANG, Brookhaven National Laboratory, JEFFREY LYNN, NIST Center for Neutron Research, YOUNG LEE, GERBRAND CEDER, MIT — Na5/8Mn2O3 (TM=transition metal) materials consist of alternating layers of Na and TM ions with the TM ions arranged on a geometrically frustrated triangular lattice. Na can be easily and reversibly removed from these materials, making them of interest for application in rechargeable batteries and allowing for exploration of their rich phase diagrams as a function of Na concentration. Na ordering is an important factor in ground state selection, and is driven by electrostatic interactions in many Na1−xTMO2 systems. The series Na5/8Mn2O3 differs in that Na ordering is driven by a cooperative Jahn-Teller effect, due to the coexistence of Jahn-Teller active Mn3+ and non-active Mn4+ ions. We have recently shown the existence of a charge stripe ordering a in the material Na5/8Mn2O3 [1]. At low temperatures a magnetic stripe order also develops. We present neutron diffraction and inelastic scattering measurements and examine the details of the magnetic structure and excitations in the magnetic stripe ordered phase. [1] X. Li et al. Nature Mater. 13, 586 (2014)

8:48AM F32.00003 Scanning Tunneling Microscopy of Bilayer La2−2xSr1+x2Mn2O7 Single Crystals1, LEUJEN CHEN, XINZHOU TAN, SEONG HEON KIM, JEEHOON KIM, J.-S. ZHOU, J.B. GOODENOUGH, ALEX DE LOZANNE, University of Texas at Austin — We employed a spin-polarized scanning tunneling microscope to image the (001) surface topography and spectroscopy in La2−2xSr1+x2Mn2O7 (x=0.32, 0.40 & 0.52) single crystals below the Curie temperature. As the doping is increased from x=0.3 to x=0.5 the spins arrange themselves in antiferromagnetic, ferromagnetic, in-plane and out-of-plane configurations. From local density of states (LDOS) maps, we observed a charge density wave with a wavelength of about 1.6 nm along the tetragonal a or b axes in the x=0.32 sample, which is known to be ferromagnetic with spins perpendicular to the surface. On the other hand, the x=0.52 crystal is expected to be type A antiferromagnetic with spins parallel to the surface, which is confirmed by our LDOS maps.

9:00AM F32.00004 Inhomogeneity driven giant magneto-resistance in compressed LaMnO₃.
MARIA BALDINI, HPsynC, Carnegie Inst of Washington, TAKAKI MURAMATSU, Carnegie Inst of Washington, MOHAMMAD SHERAFATI, Department of Physics, University of Missouri, HO-KWANG MAO, Carnegie Inst of Washington, LORENZO MALAVASI, Department of Chemistry and INSTM, University of Pavia, PAOLO POSTORINO, Department of Physics, University of Rome "Sapienza", SASHI SATPATHY, Department of Physics, University of Missouri, VIKTOR STRUZHINKIN, Carnegie Inst of Washington — CMR in rare-earth manganites has been intensively studied over the past decades. However, the mechanism underlying the CMR is still not completely clarified. Up to now, CMR was only observed in doped manganites suggesting that the presence of mixed valence Mn ions is an essential ingredient of the CMR phenomenon. Since its discovery, phase separation has been established yet [1-5]. We performed high pressure transport measurement varying temperature and magnetic field in a pure compound LaMnO₃, and observe CMR at around 32 GPa. This result leaves aside many ambiguities inherent to compounds with complex chemical composition. We used pressure to modify the material’s property and to clarify in a clean way the role played by phase separation. We found that pressure induces the formation of a mixed phase which consists of two components: an insulating one with Jahn Teller distortion and a metallic one without distortion. The volume fraction of the metallic phase grows with pressure and the CMR is observed just below the percolation threshold. The experimental results are well reproduced by theoretical calculations and percolation theory.

9:12AM F32.00005 Polaron-Mediated Spin Correlations in Metallic and Insulating La₁₋ₓAₓMnO₃. JOEL HELTON, US Naval Academy, DANIEL PAJEROWSKI, YIMING QIU, YANG ZHAO, NIST Center for Neutron Research, DMITRY SHULYATEV, YAKOV MUKOVSKII, National University of Science and Technology "MISiS", GEORGII BYCHKOV, SERGEI BARILO, Belarus Academy of Sciences, JEFFREY LYNN, NIST Center for Neutron Research — Neutron spectroscopy measurements reveal short-range spin correlations near and above the ferromagnetic-paramagnetic phase transition in manganite materials of the form La₁₋ₓAₓMnO₃ (A=Ca, Sr, or Ba), including samples with an insulating ground state as well as colossal magnetoresistive samples with a metallic ground state. Quasielastic magnetic scattering is revealed that forms clear ridges running along the [100]-type directions in momentum space. A simple model consisting of a conduction electron hopping between spin polarized Mn ions that becomes self-trapped after a few hops captures the essential aspects of this magnetic component of the scattering. We associate this scattering component with the magnetic part of diffuse polarons, as we observe a temperature dependence similar to that of the diffuse nuclear scattering arising from individual polarons.

9:24AM F32.00006 Unexpected nanoscale metamagnetic transition in a colossal magnetoresistance manganite¹. LINGJIA SHEN, ELIZABETH BLACKBURN, ALEXANDER. T. HOLMES, EDWARD. M. FORGAN, Univ of Birmingham, UK, SEBASTIAN MUEHLBAUER, Forschungsneutronenquelle Heinz Maier-Leibnitz, Technische Universität München, Garching, Germany, ANDRE HEINEMANN, German Engineering Materials Science Centre, Helmholtz-Zentrum Geesthacht, Geesthacht, Germany — Intrinsic inhomogeneities, both on the nanometer and micrometer scale, are crucial to the phase separation seen in the colossal magnetoresistance (CMR) manganite manganites. The origin of these inhomogeneities has been an open question for the past decade [1, 2], but they clearly play an important role. To investigate these inhomogeneities, we have studied Pr₀.₇Ca₀.₃MnO₀.₉₇Ga₀.₀₃O₃ using small angle neutron scattering in fields up to 16 T. In zero field at ~220 K, there is a transition to a charge/orbital ordered (CO/OO) paramagnet, as in Pr₁₋ₓCaₓMnO₃ [3]. At 150 K, the CO/OO phase is destroyed by applying a field of 6 T, and we find that above this field, nanoscale inhomogeneities undergo a separate, uncoupled, metamagnetic transition. We have also explored metamagnetic avalanches at low temperature [4] in this material, and a possible link between the avalanches and the magnetic nanoscale phases will be illustrated. [1] E. Dagotto et al. Phys. Reports 344, 1-153 (2001). [2] K. H. Ahn et al. Nature, 428, 401 (2004). [3] Y. Tomioka et al. Phys. Rev. B 53, R1689 (1996). [4] C. Voille et al. Physical Review B, 68, 224412 (2003).

9:36AM F32.00007 Tunable metamagnetic transitions in double-perovskite EuₓCoMnO₃ single crystals. HWAN YOUNG CHOI, NARA LEE, Yonsei Univ, M.S. SEO, S.Y. PARK, Division of Materials Science, Korea Basic Science Institute, Daejeon 305-806, South Korea, Y.J. JO, Department of Physics, Kyungpook National University, Daegu 702-701, South Korea, Y.J. CHOI, Yonsei Univ — Double perovskite single crystals of EuₓCoMnO₃ were first synthesized using flux method and their magnetic properties were investigated. Magnetic field dependence of magnetization reveals a metamagnetic transition in as-grown crystals. Controlling valences of magnetic ions in different gas annealing conditions leads to the complete change of shapes and locations of metamagnetic transitions in the isothermal magnetization. This remarkable variation originates from the formation of magnetic clusters with different valences of magnetic ions.

9:48AM F32.00008 Spin excitations used to uncover the nature of the magnetically ordered ground state of Pr₀.₅Ca₀.₅MnO₃. RUSSELL EWINGS, TOBY PERRING, ISIS Pulsed Muon & Neutron Source, OLGA SIKORA, Department of Physics, National Taiwan University — We have used time-of-flight inelastic neutron scattering to measure the spin wave spectrum of the canonical half-doped manganite Pr₀.₅Ca₀.₅MnO₃, in its magnetic and orbitally ordered phase. Comparison of the data, which cover multiple Brillouin zones and the entire energy range of the excitations, with several different models shows that only the CE-type ordered state provides an adequate description of the magnetic ground state. We are able to rule out the Zener polaron and magnetic dimer models as magnetic ground states of the system, the former on the basis of gross features of the observed spin wave spectrum and the latter due to subtle discrepancies between the calculated and observed structure factors at certain positions in reciprocal space.

10:00AM F32.00009 A Combined Density Functional Theory and Monte Carlo Study of Manganites for Magnetic Refrigeration. ROMI KOROTANA, GIUSEPPE MALLIA, ZSOLT GERCSI, NICHOLAS HARRISON, Imperial College London — Perovskite oxides are considered to be strong candidates for applications in magnetic refrigeration technology, due to their remarkable properties, in addition to low processing costs. Manganites with the general formula RₓA₁₋ₓMnO₃, particularly for A=Ca and 0.2 < x < 0.7, undergo a field driven transition from a paramagnetic to ferromagnetic state, which is accompanied by changes in the lattice and electronic structure. Therefore, one may anticipate a large entropy change across the phase transition due to the first order nature. The present work aims to achieve an understanding of the relevant structural, magnetic, and electronic entropy contributions in the doped compound La₀.₇₅Ca₀.₂₅MnO₃. A combination of thermodynamics and first principles theory is applied to determine individual contributions to the total entropy change of the system. Hybrid-exchange density functional (B3LYP) calculations for La₀.₇₅Ca₀.₂₅MnO₃ predict an anti-Jahn-Teller polaron in the localised hole state, which is influenced by long-range cooperative Jahn-Teller distortions. Through the analysis of individual entropy contributions, it is identified that the electronic and vibrational terms have a deleterious effect on the total entropy change.
10:12AM F32.00010 Giant orthorhombic distortions by Cu\textsuperscript{2+} in ferrimagnetic spinel Mn\textsubscript{3}O\textsubscript{4}\textsuperscript{1} 
JAE-HO CHUNG, KEE HWAN LEE, HUN CHANG, IN YONG HWANG, Korea University, HYUN WOOK KANG, SU JAE KIM, SEONGSU LEE, Korea Atomic Energy Research Institute — Mn\textsubscript{3}O\textsubscript{4} is a tetragonal (c > a) spinel that exhibits noncollinear Yafet-Kittel ferrimagnetic ordering at low temperatures. We report large orthorhombic distortions in its ferrimagnetic phase stabilized by a few percent of Cu doping. The orthorhombic strains of the ferrimagnetic phases increased linearly to the doping and reached up to \( \varepsilon \approx 8 \times 10^{-3} \) for \( x = 0.19 \), which is three times larger than the saturated value under external magnetic fields. For high doping (\( x \geq 0.17 \)), the distortions first appeared in the paramagnetic phases and underwent further enhancement simultaneously with the onset of the noncollinear ferrimagnetic ordering. We present the rich magnetostructural phase diagram of Cu\textsubscript{x}Mn\textsubscript{3-x}O\textsubscript{4}, and argue that the dilute \( t_2 \) orbital degeneracy of Cu\textsuperscript{2+} under tetrahedral crystal field breaks the global symmetry and triggers the orthorhombic instability inherent in Mn\textsubscript{3}O\textsubscript{4}.

\textsuperscript{1}This work was supported by the National Research Foundation of Korea through the ARCNEX (NRF-2011-0031933).

10:24AM F32.00011 Magnetic Order and Frustration in Doped Sr\textsubscript{2}Mn\textsubscript{3}As\textsubscript{2}O\textsubscript{5}, CHRISTOPHER GEORGEN, CHIH-WEI CHEN, JIAKUI WANG, EMILIA MOROSAN, Rice University — Crystal structure is often key in dictating a material’s magnetic and physical properties. Two components of crystal structure that can be particularly influential are reduced dimensionality (1D or 2D) or geometric frustration. The layered crystal structure of Sr\textsubscript{2}Mn\textsubscript{3}As\textsubscript{2}O\textsubscript{5}, which crystallizes in the tetragonal I\text{4} /mmm space group, exhibits both these features. This compound is of particular interest because it consists of Fe pnictide-tetrahedral layers that alternate with Cu-O-like octahedral layers. This structure is a promising avenue to study geometric effects in relation to unconventional superconductivity. Here we report a magnetic study of the effects of 3d and 4d transition metal substitutions on the Mn site, with emphasis on the resulting long range and short range order. AC and DC magnetization data provide evidence for spin glass to cluster glass crossover with 4d metal doping, while 3d metal doping suppresses both the magnetic order and glassy state. This can be attributed to half-filled Mn 3d shells in a 2D magnetic structure as suggested by neutron diffraction data and band structure calculations.

10:36AM F32.00012 Spin reorientation and Ce-Mn coupling in antiferromagnetic oxypnictide CeMnAs\textsubscript{O}\textsuperscript{3}, DAVID VAKNIN, QIANG ZHANG, SPENCER PETERSON, KEVIN DENNIS, Ames Laboratory, Iowa State University, WEI TIAN, Oak Ridge National Laboratory — Structure and complex magnetic properties of CeMnAs\textsubscript{O}, a parent compound of the “1111”-type oxypnictides, have been investigated using neutron powder diffraction and magnetization measurements. Whereas there is no structural transition from the P\textsubscript{4}/mmn tetragonal phase below 420 K, CeMnAs\textsubscript{O} undergoes a C-type antiferromagnetic order with Mn\textsuperscript{2+} moments pointing along the c-axis below a relatively high Néel temperature of \( T_N = 345 \) K. Below \( T_{N2} = 35 \) K, two simultaneous transitions occur where the Mn moments reorient to the ab-plane preserving the C-type magnetic order, and Ce moments undergo long-range AFM ordering with moments in the ab-plane. Another transition to a noncollinear magnetic structure occurs below 7 K. We find that CeMnAs\textsubscript{O} primarily falls into the category of a local-moment antiferromagnetic insulator in which the nearest-neighbor interaction (\( J_1 \)) is dominant. The spin reorientation transition driven by the coupling between rare earth Ce and transition metal seems to be common to Mn, Fe and Cr ion, but not to Co and Ni ions in the iso-structural oxypnictides.

Tuesday, March 3, 2015 8:00AM - 11:00AM — Session F33 CSWP: Invited Session: Supporting the Recruitment and Retention of Women in Physics 
208 - Zahra Hazari, Florida International University

8:00AM F33.00001 Are you a “physics person”?: Understanding students’ experiences, identities, and beliefs\textsuperscript{1} — GEOFF POTVIN, Department of Physics, and STEM Transformation Institute, Florida International University — For several years, there has been much attention paid to the dearth of women in high school and undergraduate physics. Discussion has centered on various explanatory frameworks as to why women do not pursue physics in college as a career and on their persistence in such pursuits. In this talk, I will summarize efforts by our group to investigate recruitment and persistence issues for women in high school and undergraduate physics. Viewed through the lens of identity, we have repeatedly seen the importance of high school students’ beliefs about their ability to perform well (also known as self-efficacy) and persistence in science fields. In this presentation, I will build from research that suggests men and women draw from different types of experiences when evaluating their self-efficacy. I will demonstrate through a logistic regression analysis that self-efficacy is a positive predictor of success for women and men and persistence in science fields. In this presentation I will build from research that suggests men and women draw from different types of experiences when evaluating their self-efficacy. I will discuss the importance of persistence of women in physics. I will explore how women do that and what they can do to help them succeed. I will also present a variety of ways that women may develop their confidence in their ability to succeed in physics.

\textsuperscript{1}NSF Grant No. 1036617

8:36AM F33.00002 Understanding Women’s Success in Physics through Self-Efficacy — VASHTI SAWTELLE, Michigan State University — The underrepresentation of women in physics has been well documented and is a source of concern for both policy makers and educators. Considerable research has shown a connection between students’ confidence in their ability to perform well (also known as self-efficacy) and persistence in science fields. In this presentation, I will build from research that suggests men and women draw from different types of experiences when evaluating their self-efficacy. I will demonstrate through a logistic regression analysis that self-efficacy is a positive predictor of success for women and men and persistence in science fields. In this presentation I will build from research that suggests men and women draw from different types of experiences when evaluating their self-efficacy. I will discuss the importance of persistence of women in physics. I will explore how women do that and what they can do to help them succeed. I will also present a variety of ways that women may develop their confidence in their ability to succeed in physics.

9:12AM F33.00003 “We’re all unisex anyway”: The persistent discourse of gender neutrality in physics — ALLISON GONSALVES, McGill University — Doctoral physics students have stories about the kinds of actions, behaviours and ways of doing physics that enable them to be recognized as physicists. This presentation will illuminate some of these stories through a lens that scrutinizes how discourses about gender can shape both the stories that students tell and the behaviours they practice to achieve recognition in their field. Through observations, photo-elicitation, and life history interviews, eleven men and women shared stories about their experiences with physics, and the contexts that have enabled or constrained their participation in doctoral physics. The results of this study revealed that recognition was often achieved through the reproduction or reworking of persistent discourses of gender norms. This presentation will explore the particularly persistent discourse of gender neutrality in physics. I will explore how this discourse is constructed, how it can be contested, and how it may be constrained for both men and women students. The construction of physics as gender neutral can pose conflicts of identity for students who feel the need to refigure their gender performances in ways that permit recognition as “physics people.” This presentation will look at two case studies that demonstrate the conflict students experience between expressions of femininity and doing physics against the backdrop of gender neutrality. I will discuss the problematic of gender neutrality, and I will also discuss some of the creative solutions doctoral students adopt to navigate discourses of gender in this neutral terrain.
9:48AM F33.00004 Panel Discussion: Women in Physics Groups with A. Coil, C. Boekema, E. Yitamben, and J. Walrath — Panel Discussion: Women in Physics Groups with A. Coil, University of California; C. Boekema, San Jose State University; E. Yitamben, Purdue University; and J. Walrath, University of Michigan.

Tuesday, March 3, 2015 8:00AM - 11:00AM – Session F34 GERA: Focus Session: Novel Photophysics and Transport Mechanisms for Nanostructured Photovoltaics 210A -

8:48AM F34.00003 Free Charge Carriers in Lead Iodide Perovskites Revealed by Transient Absorption Spectroscopy, MINH TUAN TRINH, XIAOYANG ZHU, Columbia University — Lead iodide perovskites have emerged as the most-promising materials for low-cost thin film photovoltaics and other optoelectronic materials. Much experimental effort has been devoted to understanding fundamental properties and device performances, however the nature of photo-excitation in these materials remains debated. Using transient absorption spectroscopy, we study the dynamics of electrons and holes in photo-excited lead iodide perovskites. We show that, upon excitation with photon energy above the bandgap, hot electrons and holes are created. The e-h pair possess a transient dipole moment, which induces a transient Stark effect seen in subsequent optical transitions by the probe pulse. At high excitation densities, we find that carrier decay is well described by a third-order kinetic process, as expected from Auger recombination of free carriers. We also provide direct evidence for charge carrier traps on the surfaces and excitonic traps below the optical gaps in these materials.

9:00AM F34.00004 Enhanced Multiple Exciton Generation in Amorphous Silicon Nanoparticles1, ANDREI KRYJEVSKI, DEYAN MIHAYLOV, North Dakota State Univ, DMITRI KILIN, University of South Dakota — Multiple exciton generation (MEG) in nm-sized hydrogen-passivated silicon nanowires (NWs), and quasi two-dimensional nanofilms depends strongly on the degree of the core structural disorder as shown by the many-body perturbation theory (MBPT) calculations based on the DFT simulations. Here, we use the HSE exchange correlation functional. In MBPT, we work to the 2nd order in the electron-photon coupling and in the approximate screened Coulomb interaction. We also include the effect of excitons for which we solve Bethe-Salpeter Equation. We calculate quantum efficiency (QE), the average number of excitons created by a single absorbed photon, in 3D arrays of Si29H26 quantum dots, NWs, and quasi 2D silicon nanofilms, all with both crystalline and amorphous core structures. Efficient MEG with QE of 1.3 up to 1.8 at the photon energy of about 3Eg, where Eg is the gap, is predicted in these nanoparticles except for the crystalline NW and film where QE ≃ 1. MEG in the amorphous nanoparticles is enhanced by the electron localization due to structural disorder. The exciton effects significantly red-shift QE(E photon) curves. Nanometer-sized amorphous silicon NWs and films are predicted to have effective MEG within the solar spectrum range.

9:12AM F34.00005 Hot electron-generated plasmon resonance in ultrathin solar absorbers: Theory2, JIANTAO KONG, CHAOBIN YANG, JUAN M. MERLO, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, KRZYSZTOF KEMPA, Boston College — It has been proposed in a simple model calculation that hot electrons excited in a semiconductor can emit plasmons in an adjacent metallic nanostructure at very high rate. Exceeding that of phonon emission [1]. We demonstrate by FDTD simulations and quantum mechanical calculations that an ultrathin solar absorber with a composite metamaterial/plasmonic collector can emit plasmon. The composite collector has a dual function: it is designed to efficiently trap light and it is a plasmonic resonator tuned to absorb the energy of hot electrons, thus “protecting” them from phonon losses. We propose a specific structure where observation of this phenomenon can occur.

1We acknowledge NSF support (CHE-1413614) for method development

2Supported in part by the W.M. Keck Foundation.
9:24AM F34.00006 Electron mediated plasmon resonance in ultrathin solar absorbers: Experiment 1, CHAOBIN YANG, JUAN M. MERLO, AARON H. ROSE, JIANTAO KONG, MICHAEL J. BURNS, KRZYSZTOF KEMP, MICHAEL J. NAUGHTON, Boston College — We describe experimental progress on a hot electron PV structure based on hot electron plasmon protection (HELP) [1] that provides a path to solar efficiency in excess of the Shockley-Queisser limit. It combines hot electron recovery in ultrathin junctions with superabsorption in metamaterial/plasmonic nanosystems and a HELPP plasmon resonance energy transfer (PRET) mechanism. Measurements of optical absorbance (via reflectance and transmittance) of Ag nanopatterns on p- and n-type crystalline and amorphous Si absorbers were performed at incident wavelengths from 350 to 2,500 nm. In samples prepared with Ag nanopatterns with dimensions tuned to provide a resonance near 1,600 nm, we indeed observed such a resonance. We discuss these and other experimental results associated with hot electron facilitated plasmon resonances.

9:36AM F34.00007 Colloidal Nanoparticles for Intermediate Band Solar Cells, MARTON VOROS, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago, GREGELY ZIMANYI, Department of Physics, University of California, Davis — The Intermediate Band (IB) solar cell concept is a promising idea to transcend the Shockley-Queisser limit.[1] Using the results of first principles calculations, we proposed that colloidal nanoparticles (CNPs) are a viable and efficient platform for the implementation of the IB solar cell concept. We focused on CdSe and we showed that intragap states present in the isolated dots with reconstructed surfaces combine to form an IB in arrays of NPs, which is well separated from the valence and conduction band edges. We also showed that in solution such IB may be electron doped using, e.g. decamethylcobaltocene, thus activating an IB-induced absorption process. Our results, together with the recent report of a nearly 9% efficient CNP solar cell[2] indicate that colloidal nanoparticle intermediate band solar cells are a promising platform to overcome the Shockley-Queisser limit.

9:48AM F34.00008 The Molecular Photo-Cell: Quantum Transport and Energy Conversion at Strong Non-Equilibrium, SHIGERU AJISAKA, Department of Chemistry, Ben-Gurion University of the Negev, Beer-Sheva 84105, Israel, BOJAN ZUNKOVIC, Facultad de Ciencias Físicas y Matemáticas, Universidad de Chile, Casilla, JONATAN DUBI, Department of Chemistry, Ben-Gurion University of the Negev, Beer-Sheva 84105, Israel — The molecular photo-cell is a single molecular donor-acceptor complex attached to electrodes and subject to external illumination. Besides the obvious relevance to molecular photo-volts, the molecular photo-cell is of interest being a paradigmatic example for a system that inherently operates in out-of-equilibrium conditions and typically far from the linear response regime. Moreover, this system includes electrons, phonons and photons, and environments which induce coherent and incoherent processes, making it a challenging system to address theoretically. Here, using an open quantum systems approach, we analyze the non-equilibrium transport properties and energy conversion performance of a molecular photo-cell, including for the first time both coherent and incoherent processes and treating electrons, photons, and phonons on an equal footing. We find that both the non-equilibrium conditions and decoherence play a crucial role in determining the performance of the photovoltaic conversion and the optimal energy configuration of the molecular system.

10:00AM F34.00009 Experimental evidence of enhanced optical absorption in ultra-thin film CdTe PV absorbers via embedded metal nanopatterns, AARON H. ROSE, MICHELLE L. SOLOMON, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, Boston College — We show an increase of optical absorbance in ultra-thin film cadmium telluride solar absorbers by embedded metal nanopatterns (EMN) in the absorber material. Our experimental results are supported by FEM simulations, which also indicate minimal energy loss in the metal. As opposed to locating the metal nanostructures outside of the active region, e.g. at the back or top contact of a solar cell, embedding the structures within the active region gives the greatest absorbance enhancement [1-3]. Previous work has shown a similar increase in absorbance for an amorphous silicon solar medium [1-3], suggesting that EMN is a general light management scheme that can be applied to any thin film photoabsorber. Such light trapping may further yield a viable route to ultra-thin hot electron solar cells [4,5].

10:12AM F34.00010 Broadband Solar Energy Harvesting in Single Nanowire Resonators, YIMING YANG, XINGYUE PENG, STEVEN HYATT, DONG YU, UC Davis — Sub-wavelength semiconductor nanowires (NWs) can have optical absorption cross sections far beyond their physical sizes at resonances frequencies, offering a powerful method to simultaneously lower the material consumption and enhance photovoltaic performance. The degree of absorption enhancement is expected to substantially increase in materials with high refractive indices, but this has not yet been experimentally demonstrated. Here, we show that the absorption efficiency can be significantly improved in high-index NWs, by a direct observation of ~350% performance. The degree of absorption enhancement is expected to substantially increase in materials with high refractive indices, but this has not yet been experimentally demonstrated. Here, we show that the absorption efficiency can be significantly improved in high-index NWs, by a direct observation of ~350% performance. Our results, together with the recent report of a nearly 9% efficient CNP solar cell[2] indicate that colloidal nanoparticle intermediate band solar cells are a promising platform to overcome the Shockley-Queisser limit.

10:24AM F34.00011 Disentangling the roles of free-carrier density and mobility in the performance of CH₃NH₃PbI₃ perovskite films, ELBERT E.M. CHIA, CHAN LA-O-VORAKIAT, M.T. KHUC, R. HASELSBERGER, MARIA-ELISABETH MICHEL-BEYERLE, Division of Physics and Applied Physics, School of Physical and Mathematical Sciences, Nanyang Technological University, T. SAUM, HAI BIN SU, Y.M. LAM, School of Materials Science and Engineering, Nanyang Technological University, RUDOLPH A. MARCUS, Noyes Laboratory, California Institute of Technology — Apart from broadband absorption of solar radiation, the performance of photovoltaic devices is governed by two parameters: carrier mobility and carrier density. They indicate how many and how fast the free carriers drift away from the light-harvesting medium before loss mechanisms, such as carrier recombination, occur. However, these parameters are usually entangled as a product. Using time-resolved terahertz spectroscopy, the number density, mobility and quantum yield of charge carriers in a perovskite film have been disentangled. The free carrier recombination mechanisms and rates were determined, and hence the diffusion length. Our results suggest that perovskite-based solar cells can perform well even at low temperatures as long as the three-body recombination has not become predominant.

10:36AM F34.00012 Bond pathway analysis of NMR spectra for Li$_{1.2}$Mn$_{0.4}$Co$_{0.4}$O$_2$: pristine material. HAKIM IDDIR, BARIS KEY, FULYA DOGAN, JOHN RUSSELL, BRANDON LONG, JAVIER BARENO, JASON CROY, ROY BENEDEK, Argonne National Laboratory — NMR has been applied extensively to lithium ion battery cathode materials, of which layered-layered composites $x$Li$_2$MnO$_3$·(1−$x$)Li$_2$MnO$_2$ and Bond-Pathway-model analysis is applied to elucidate the atomic arrangement and domain structure of this material (in its pristine state, before electrochemical cycling). The simplest structural element of a domain consists of a stripe of composition LiMn$_2$ parallel to an in-layer crystallographic axis in a metal layer of the composite. A simple model of the composite structure may be constructed by a superposition of such stripes in an LiCoO$_2$ background. We show that such a model can account for most of the features of the observed NMR spectra. Support from the Vehicle Technologies Program U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy.

10:48AM F34.00013 Roll-to-Roll Production of Spray Coated N-doped Carbon Nanotube Electrodes for Supercapacitors\textsuperscript{1}, MEHMET KARAKAYA, JINGYI ZHU, ACHYUT RAGHAVENDRA, RAMAKRISHNA PODILA, Clemson University, SAMUEL PARLER, JAMES KAPLAN, Cornell Dubilier Electronics, Inc., APPARAO RAO, Clemson University, CORNELL DUBILIER ELECTRONICS, INC. COLLABORATION — Although nanocarbons are being increasingly used in energy storage, there has been a lack of inexpensive, continuous and scalable synthesis methods. Here we present a scalable roll-to-roll spray coating process for synthesizing supercapacitors from randomly oriented multi-walled carbon nanotubes electrodes on Al foils, which yield high power and energy densities (≈ 700 mW/cm$^2$ and 1 mWh/cm$^2$) and cycle stability (>10000 cycles) on par with Li-ion thin film batteries. Our cost analysis shows that the R2R spray coating process can produce supercapacitors with 10 times the energy density of conventional activated carbon devices at ~ 17% lower cost.

Tuesday, March 3, 2015 8:00AM - 10:48AM — Session F36 GSOFT DBIO: Focus Session: Biofunctionalized Nano-Materials

8:00AM F36.00001 Multi-scale morphology in self-assembly of peptides to proteins via a coarse-grain model\textsuperscript{1}, RAS PANDEY, University of Southern Mississippi, BARRY FARMER, Air Force Research Laboratory — Self-organizing structures of short peptides (6-7 residues) and proteins (136 residues) are studied by a coarse-grained Monte Carlo simulation. Peptides and proteins are described by coarse-grained chains of residues whose interactions are described by a knowledge-based residue-residue interaction potential that captures the compositional specificity. Large-scale computer simulations are performed to study the structural evolution e.g. aggregation, network, etc. at a range of temperatures and concentrations. A number of local and global physical quantities including structure factor are examined. We find that the residue interactions, concentration, and size of chains are very important in modulating the structure of emerging morphologies in the specified temperature range. Estimates are provided for the effective (fractal) dimension of the assembly over various length scales as a function of temperature.

8:12AM F36.00002 Interaction of Biofunctionalized Nanoparticles with Receptors on Cell Surfaces: MC Simulations, ELENA DORMIDONTTOVA, Physics Department and Institute of Materials Science, University of Connecticut, SHIHU WANG, Chemical Engineering Department, University of Michigan — One of the areas of active development of modern nanomedicine is drug/gene delivery and imaging application of nanoparticles functionalized by ligands, aptamers or antibodies capable of specific interactions with cell surface receptors. Being a complex multifunctional system different structural aspects of nanoparticles affect their interactions with cell surfaces and the surface properties of cells can be different (e.g. density, distribution and mobility of receptors). Computer simulations allow a systematic investigation of the influence of multiple factors and provide a unified platform for the comparison. Using Monte Carlo simulations we investigate the influence of the nanoparticle properties (nanoparticle size, polymer tether length, polydispersity, density, ligand energy, valence and density) on nanoparticle-cell surface interactions and make predictions regarding favorable nanoparticle design for achieving multiple ligand-receptor binding. We will also discuss the implications of nanoparticle design on the selectivity of attachment to cells with high receptor density while ‘ignoring’ cells with a low density of receptors.

8:24AM F36.00003 Prediction of Surface and pH-Specific Binding of Peptides to Metal and Oxide Nanoparticles, HENDRIK HEINZ, TZU-JEN LIN, FATEME SADAT EMAMI, HADI RAMEZANI-DAKHEL, University of Akron, RAJESH NAIK, Air Force Research Laboratory, MARC KNECHT, University of Miami, CAROLE C. PERRY, Nottingham Trent University, YU HUANG, University of California-Los Angeles — The mechanism of specific peptide adsorption onto metallic and oxidative nanostructures has been elucidated in atomic resolution using novel force fields and surface models in comparison to measurements. As an example, variations in peptide adsorption on Pd and Pt nanoparticles depending on shape, size, and location of peptides on specific bounding facets are explained. Accurate computational predictions of reaction rates in C-C coupling reactions using particle models derived from HE-XRD and PDF data illustrate the utility of computational methods for the rational design of new catalysts. On oxidic nanoparticles such as silica and apatites, it is revealed how changes in pH lead to similarity scores of attracted peptides lower than 20\%, supported by appropriate model surfaces and data from adsorption isotherms. The results demonstrate how new computational methods can support the design of nanoparticle carriers for drug release and the understanding of calcification mechanisms in the human body.
8:36AM F36.00004 Aqueous amino acids and proteins near solid surfaces: ZnO, ZnS, Au, and mica, MAREK CIEPLAK, Institute of Physics, Polish Academy of Sciences, Warsaw, Poland — We calculate potentials of the mean force for 20 amino acids in the vicinity of the (111) surface of Au, four surfaces of ZnO, and the (110) surface of ZnS using molecular dynamics simulations combined with the umbrella sampling method. In the case of Au, we compare results obtained within three different force fields: one hydrophobic (for a contaminated surface) and two hydrophilic — with and without polarization of the solid. The properties of water near the surface sensitively depend on the force field. All of these fields lead to good binding with very different specificities and to unlike patterns in the density and polarization of water. We demonstrate that binding energies of dipeptides are distinct from the combined binding energies of their amino acidic components. We show that ZnS is more more hydrophobic than ZnO and that the density profile of water is quite different than that forming near ZnO – it has only a minor articulation into layers. Furthermore, the first layer of water is disordered and mobile. In the case of ZnS, not all amino acids can attach to the surface and when they do, the binding energies are comparable to those found for the surfaces of ZnO (and to hydrogen bonds in proteins) but the nature of the specificity is distinct. The covalent bond with the sulfur atom on cysteine is modeled by the Morse potential. For the hydrophobic Au, adsorption events of a small protein (the tryptophan cage) are driven by attraction to the strongest binding amino acids. This is not so for ZnO, ZnS and for the hydrophilic models of Au – a result of smaller specificities combined with the difficulty for proteins, but sometimes not for single amino acids, to penetrate the first layer of water. Molecular dynamics studies of several proteins near mica with a net charge on its surface indicate existence of two types of states: deformed and unfolded. Using a coarse-grained model, we also study a glassy behavior of protein layers at air-water interfaces. REFERENCES: [1] A. Starzyk and M. Cieplak, Denaturation of proteins near polar surfaces, J. 9:12AM F36.00005 Aptamer functionalized lipid multilayer gratings for label free detection of specific analytes, PLENGCHART PROMMAPAN, Department of Physics, Florida State University, TROY W. LOWRY, Department of Physics and Integrative Nanoscience Institute, Florida State University, DAVID VAN WINKLE, Department of Physics, Florida State University, STEVEN LENHERT, Department of Biological Sciences and Integrative Nanoscience Institute, Florida State University — Lipid multilayer gratings have been formed on surfaces with a period of 700 nm. When illuminated with white light incident at about 50°, these gratings diffract green light perpendicular to their surface. We demonstrate the potential of these gratings as sensors for analytes by monitoring changes in the diffracted light due to the changes in the size and shape of the grating in response to analyte binding. To demonstrate this potential application, a lipid multilayer grating was functionalized with a thrombin binding aptamer. The selectivity of our aptamer functionalized lipid gratings was confirmed both by monitoring the diffracted light intensity and by fluorescence microscopy. Furthermore, the results show that the binding activity between the aptamer and thrombin depends on the relative composition of a zwitterionic lipid (DOTAP) and a cationic lipid (DOTAP). This work shows that nanostructured lipid multilayers on surfaces are a promising nanomaterial for label-free bio-sensing applications.

9:24AM F36.00006 Materials Integration by Nanointaglio, TROY LOWRY, Department of Biological Sciences and Integrative Nanoscience Institute, Department of Physics, Florida State University, AUBREY KUSI-APPIAH, Department of Biological Sciences and Integrative Nanoscience Institute, Florida State University, JINGJIAO GUAN, Department of Chemical and Biomedical Engineering, Florida State University, DAVID VAN WINKLE, Department of Physics, Florida State University, STEVEN LENHERT, Department of Biological Sciences and Integrative Nanoscience Institute, Florida State University — Nanointaglio is a printing process from a microstructured intaglio stamp that in combination with established microarray technology is suitable for heterogeneous materials integration of lipid multilayer micro- and nanostructures. Nanointaglio offers both size dependent functionality and massively parallel materials integration capabilities. The scalable, multi-integrative characteristics of nanointaglio have potential applications in high throughput screening and biosensor arrays.

9:36AM F36.00007 Protein-Polymer Functionalized Nanopatterned Surfaces, HOAYU WANG, PINAR AKCORA, Stevens Inst of Tech — Understanding and controlling the protein interactions with surfaces for biosensors and biomedical implants is a fundamental problem for biocompatible nanomaterial design. Proteins attached in ordered nanopores can exhibit superior biological activities compared to smooth microstructured surfaces. We developed heterogeneous and nanopatterned surfaces decorated with polymer brushes and proteins to control protein fates through elasticity. The heterogeneity of surfaces is controlled with well-defined chemistry, pattern size and geometry, stiffness of polymers and protein types. We will present our recent nanointaglio results on nanopatterned and biofunctionalized flat surfaces and discuss the pattern size effect on protein activity, hence conformation.

9:48AM F36.00008 Air-stable droplet interface bilayers, CHARLES COLLIER, ORNL, ORNL TEAM — Droplet interface bilayers are versatile model membranes useful for synthetic biology and biosensing; however, to date they have been for the most part confined to fluid reservoirs. Here, we demonstrate that when two or more water droplets meet on an oil-infused substrate, they exhibit noncoalescence due to the formation of a thin oil film that gets squeezed between the droplets from the bottom up. We show that when phospholipids are included in the water droplets, a stable droplet interface bilayer forms between the noncoalescing water droplets. As with traditional oil-submerged droplet interface bilayers, we were able to characterize ion transport by incorporating peptides into each droplet. We demonstrate the ability of these air-stable droplet interface bilayers (airDIBs) to incorporate ion channel transport by incorporating peptides into each droplet. We demonstrate the ability of these air-stable droplet interface bilayers (airDIBs) to incorporate ligand-gated ion channels via fusion of microsomes, which enables the biosensing of airborne matter.

10:00AM F36.00009 Interactions of Lysozyme and Azobenzene Derivatives in the Solution and on a Surface, TAO WEI, Lamar University, KATHERINE SHING, Mark Family Department of Chemical Engineering & Materials Science, Los Angeles, CA 90089-1211 — The reversible isomerization of the azobenzene and its derivatives can control protein structure in an aqueous environment with the alternation of visible and UV lights for very promising applications in drug delivery. However, an atomistic description of Aza-molecules and protein amino acid residues is still lacking. In this study we performed atomistic molecular dynamics simulation to study the interactions between a lysozyme molecule and the Azobenzene derivative (in the bulk solution and grafted on the Silica surfaces). Protein structural arrangements (i.e., the shape and secondary structures) and its mobility, as a function of tran/cis ratio in the bulk solution and on the self-assembling monolayer surface’s density and morphology, are systematically investigated.
It was found that the replication process can be electrically monitored by attaching a Klenow fragment of polymerase I to the surface of a carbon nanotube and monitoring the current along the tube [1]. In this talk, we report results from computational studies on DNA polymerase nanocircuits. We have first performed classical molecular dynamics (MD) calculations to get snapshots of different enzymatic stages, particularly the open state (no DNA binding) and the closed state (DNA double helix binding). We then used density functional theory (DFT) and Keldysh non-equilibrium Green’s function (NEGF) formalism to calculate transmission coefficients and currents for each enzymatic state. Our results show that the transmission spectrum and the currents change significantly when the enzyme moves from the open to the closed state. While the initial experiments did not show signal differences between dissimilar bases, the theoretical work in progress is investigating conditions where bases might have distinct signatures, which would allow for DNA sequencing.

10:24AM F36.00011 Graphene under one-dimensional periodic potentials using DNA-assembled parallel nanotubes as a periodic gate array. YONG WU, Univ of California - Riverside, SI-PING HAN, WILLIAM GODDARD, California Institute of Technology, MARC BOCKRATH, Univ of California - Riverside — Graphene under an applied one-dimensional (1D) periodic potential is predicted to show many interesting and unique phenomena such as electron supercollimation and additional Dirac points [1], and some progress has been made in observing graphene in this regime [2]. Here, we use parallel nanotubes assembled using DNA linkers [3] as a back gate to apply periodic or quasi-periodic 1D potentials to graphene layers. The pitch of the nanotube array can be controlled by the linker length which we can vary from 8nm-20nm. We can independently control the periodic potentials using the nanotube array and the carrier density using a top gate to study the transport properties of the system. Our latest results will be discussed.

Session F37 GQI: Focus Session: Semiconductor Qubits - Topological Qubits, Spin-orbit Effects and Micromagnets

8:00AM F37.00001 Superconducting Edge-Mode Transport in InAs/GaSb Double Quantum Wells. VLAD PRIBIAC, Kavli Institute of Nanoscience, Delft University of Technology — In proximity to a superconductor, topological insulators are predicted to host topological superconductivity, an exotic state of matter that supports Majorana zero-modes. Localized Majorana modes are expected to obey non-Abelian exchange statistics, making them interesting building blocks for topological quantum computing. Here we report supercurrent in the edge modes of Type-II InAs/GaSb quantum wells, a two-dimensional topological insulator (2D TI). By electrostatically-gating the devices we observe superconducting transport in all three regimes of the 2D TI: bulk electrons, edge modes and bulk holes. From superconducting quantum interference measurements, we extract the spatial distribution of the supercurrent in each regime. A clear transition to edge-dominated supercurrent is observed under conditions of high bulk resistivity, which we associate with the 2D topological phase.

8:36AM F37.00002 Quasiparticle parity lifetime of bound states in a hybrid superconductor-semiconductor quantum dot. ANDREW HIGGINBOTTOM, University of Copenhagen, Harvard University, SVEN ALBRECHT, GEDIMINAS KIRSANSKAS, University of Copenhagen, WILLY CHANG, University of Copenhagen, WENCHANG LU, JERRY BERNHOLC, North Carolina State University, PHILIP COLLINS, University of California Irvine — DNA polymerases are important enzymes that replicate DNA molecules with very low error rates – about one error in 10^12 bases. Recently, it was found that the replication process can be electrically monitored by attaching a Klenow fragment of polymerase I to the surface of a carbon nanotube and monitoring the current along the tube [1]. In this talk, we report results from computational studies on DNA polymerase nanocircuits. We have first performed classical molecular dynamics (MD) calculations to get snapshots of different enzymatic stages, particularly the open state (no DNA binding) and the closed state (DNA double helix binding). We then used density functional theory (DFT) and Keldysh non-equilibrium Green’s function (NEGF) formalism to calculate transmission coefficients and currents for each enzymatic state. Our results show that the transmission spectrum and the currents change significantly when the enzyme moves from the open to the closed state. While the initial experiments did not show signal differences between dissimilar bases, the theoretical work in progress is investigating conditions where bases might have distinct signatures, which would allow for DNA sequencing.

dependent width of the Hall bar enables us to map the averaged magnetic field of the micromagnet, which validates simulations of the inhomogeneous magnetic field profile created by the magnet. We can therefore deduce that our micromagnets can produce magnetic field differences over 200 nm of more than 200 mT.

We selected the material and improved the shape of the micromagnet in order to maximize field gradients and remanence. We perform Hall magnetometry of those improved micromagnets using Hall bars electrostatically defined in an AlGaAs/GaAs two-dimensional electron gas. The gate-voltage dependent width of the Hall bar enables us to map the averaged magnetic field of the micromagnet, which validates simulations of the inhomogeneous magnetic field profile created by the magnet. We can therefore deduce that our micromagnets can produce magnetic field differences over 200 nm of more than 200 mT.

10:24AM F37.00011 Hall magnetometry of micromagnets for single-electron spin qubits, DANY LACHANCE-QUIRON, JULIEN CAMIRAND LEMYRE, LAURENT BERGERON, MICHEL PIORO-LADRIÈRE, Université de Sherbrooke — The coherence time of a single-electron spin can reach tens of milliseconds when placed in the right environment [1]. The electric-dipole interaction between such a single spin and an electric field can be engineered by the inhomogeneous magnetic field of a micromagnet [2]. This effective spin-orbit interaction can be used to manipulate the spin through electric-dipole spin resonance [2], but also to couple a single spin to the electric field of a microwave cavity in the circuit QED architecture [3].

We selected the material and improved the shape of the micromagnet in order to maximize field gradients and remanence. We perform Hall magnetometry of those improved micromagnets using Hall bars electrostatically defined in an AlGaAs/GaAs two-dimensional electron gas. The gate-voltage dependent width of the Hall bar enables us to map the averaged magnetic field of the micromagnet, which validates simulations of the inhomogeneous magnetic field profile created by the magnet. We can therefore deduce that our micromagnets can produce magnetic field differences over 200 nm of more than 200 mT.

10:36AM F37.00011 Hall magnetometry of micromagnets for single-electron spin qubits, DANY LACHANCE-QUIRON, JULIEN CAMIRAND LEMYRE, LAURENT BERGERON, MICHEL PIORO-LADRIÈRE, Université de Sherbrooke — Integrating micrometric size ferromagnets to quantum dots have proven a powerful tool to rotate single spins. In previous approaches, the distance between the magnet and the quantum dots were limiting the magnetic field gradients, thus impeding spin rotation speeds in both GaAs [1] and Si [2] quantum dots. In this work, we first reduce the size of the magnet to improve the field gradients in the dots. Furthermore, we avoid the thick insulating layer between the magnet and the gates by patterning oxidized aluminum gates with a 2 nm thick native oxide. This allows us to bring the nanomagnet closer to the quantum dots, hence increasing the magnetic field gradients by a factor of ten compared to previous structures.

10:48AM F37.00013 High Fidelity Singlet-Triplet S–T+ Qubits in Inhomogeneous Magnetic Fields, CLEMENT WONG, MARK ERIKSSON, SUE COPPERSMITH, MARK FRIESEN, Univ of Wisconsin-Madison — We propose an optimal set of quantum gates for a singlet-triplet qubit in a double quantum dot with two electrons utilizing the S–T+ subspace. Qubit rotations are driven by the applied magnetic field and an orthogonal field gradient provided by a micromagnet. We optimize the fidelity of this qubit as a function of magnetic fields, taking advantage of “sweet spots” where the rotation frequencies are independent of the energy level detuning, providing protection against charge noise. We simulate gate operations and qubit rotations in the presence of quasistatic noise from charge and nuclear spins as well as leakage to nonqubit states, and predict that in silicon quantum dots gate fidelities greater than 99% can be achieved for two nearly-orthogonal rotation axes. Preprint: arXiv:1410.2310

Tuesday, March 3, 2015 8:00AM - 11:00AM — Session F38 Gqi: Focus Session: Quantum Error Correction II 212B - Austin Fowler, University of California, Santa Barbara

8:00AM F38.00001 Optimizing the frequency of post-selected quantum error correction in the [[7,1,3]] Steane code, ALI ABU-NADA, BEN FORTESCUE, MARK BYRD, Southern Illinois University Carbondale, SOUTHERN ILLINOIS UNIVERSITY CARBONDALE TEAM — A common assumption in analyses of error thresholds and quantum computing in general is that one applies fault-tolerant quantum error correction (FTQEC) after every logical gate. This, however, is known not to always be optimal if the FTQEC procedure itself can introduce errors. We investigate the effect of varying the number of logical gates between FTQEC operations, and in particular the case where failure of a postselection condition in FTQEC may cause FTQEC to be skipped with high probability. By using a simplified model of errors induced in FTQEC, we derive an expression for the logical error rate as a function of error-correction frequency, and show that in this model the optimal frequency is insensitive to postselection failure probability for a large range of such probabilities. We compare the model to data derived from Monte Carlo simulation for the [[7,1,3]] Steane code.

8:12AM F38.00002 How Often Must We Apply Syndrome Measurements, YAAKOV WEINSTEIN, MITRE — Quantum information is encoded into Quantum Error Correction codes to protect it from decoherence. The detection and correction of possible errors is done via syndrome measurements. Standard quantum fault tolerance approaches assume that syndrome measurements are applied after the implementation of any gate. However, this is resource intensive utilizing much time and many qubits. In this talk we explore whether it is necessary to apply syndrome measurements so often. We examine different syndrome measurement techniques for the [[7,1,3]] code and compare the output state fidelity based on how often syndrome measurements are applied and the error environment. In this way we demonstrate the tradeoff between accuracy and resource consumption.
Thus, we conclude that the ancilla-assisted gate synthesis is the best for a fault-tolerant QFT so far. To the initial expectation, the total resource required to perform specific single-qubit rotations required for the QFT exactly. It is unknown, however, which approach is better for the QFT. We estimated the resource requirements for a fault-tolerant quantum Fourier transform (QFT) to perform specific single-qubit rotations required for the QFT exactly. It is known, however, which approach is better for the QFT. We estimated the resource requirements for a QFT in each case, where the resource is measured by the total number of the \( \pi/8 \) gates denoted by \( T \), which is called the \( T \) count. Contrary to the initial expectation, the total \( T \) count for the state distillation is considerably larger than those for the ancilla-free and ancilla-assisted gate synthesis. Thus, we conclude that the ancilla-assisted gate synthesis is the best for a fault-tolerant QFT so far.

8:24AM F39.00003 Imaging non-Gaussian output fields produced by Josephson parametric amplifiers: experiments1, D.M. TOYLI, A.V. VENKATRAMANI, Quantum Nanoelectronics Laboratory, UC Berkeley, S. BOUTIN, Departement de Physique, Universite de Sherbrooke, A. EDDINS, Quantum Nanoelectronics Laboratory, UC Berkeley, N. DIDIER, Department of Physics, McGill University and Departement de Physique, Universite de Sherbrooke, A.A. CLERK, Department of Physics, McGill University, A. BLAIS, Departement de Physique, Universite de Sherbrooke, I. SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley — In recent years, squeezed microwave states have become the focus of intense research motivated by applications in continuous-variables quantum computation and precision qubit measurement. Despite numerous demonstrations of vacuum squeezing with superconducting parametric amplifiers such as the Josephson parametric amplifier (JPA), most experiments have also suggested that the squeezed output field becomes non-ideal at the large (>10dB) signal gains required for low-noise qubit measurement. Here we describe a systematic experimental study of JPA squeezing performance in this regime for varying lumped-element device designs and pumping methods. We reconstruct the JPA output fields through homodyne detection of the field moments and quantify the deviations from the ideal squeezed state using maximal entropy techniques. These methods provide a powerful diagnostic tool to understand how effects such as gain compression impact JPA squeezing. Our results highlight the importance of weak device nonlinearity for generating highly squeezed states.

8:36AM F39.00004 Theory of Dispersion Engineering in Traveling-Wave Kinetic Inductance Amplifiers1, ROBERT ERICKSON, MICHAEL VISSERS, DAVID PAPPAS, National Institute of Standards and Technology — Coplanar-waveguide parametric amplifiers of length extending to the order of a meter have been patterned from superconducting materials using long meandering geometries fabricated on cm2 chips [B. H. Eom, et al., Nat. Phys. 8, 623 (2012)]. These waveguides have highly reactive impedance and operate below the critical current by leveraging the low-temperature nonlinear kinetic inductance \( L(x,t) \) of the underlying superconductor, where \( L(x,t) = L_0(x) \left[ 1 + \left[ I(x,t) / I_c \right]^2 \right] \) at point \( x \) along the waveguide and time \( t \). Here, \( L_0(x) \) is the linear kinetic inductance at \( x \), \( I_c \) is a scaling constant, and \( I(x,t) \) is the total microwave current within the waveguide. As a consequence of the nonlinear kinetic inductance, degenerate four-wave mixing between a pump and signal can result in an idler product as well as significant signal gain as the pump transfers energy to these two side features. Frequency stops and other periodic loadings may be engineered to mitigate effects of higher pump harmonics as well as enhance signal gain, via alteration of phase mismatch. We describe here a simple band theory applicable to the waveguide frequency spectrum that allows us to optimize stop gaps and nonlinear signal gain.

8:48AM F39.00005 Frequency Comb Generation in Superconducting Resonators1, DAVID PAPPAS, ROBERT ERICKSON, MICHAEL VISSERS, HSIANG-SHENG KU, NIST — We have generated frequency combs spanning 0.5 to 20 GHz in superconducting λ/2 resonators at \( T = 3 \) K. Thin films of niobium-titanium nitride enabled this development due to their low loss, high nonlinearity, low frequency dispersion, and high critical temperature. The combs nucleate as sidebands around multiples of the pump frequency. Selection rules for the allowed frequency emission are calculated using perturbation theory, and the measured spectrum is shown to agree with the theory. Sideband spacing is measured to be accurate to 1 part in 109. The sidebands coalesce into a continuous comb structure observed to cover at least several frequency octaves. Generation of combs in this frequency range allows for unprecedented analysis of this non-linear phenomena in the time domain.

9:00AM F39.00006 Phase-matched Josephson traveling-wave parametric amplifier for superconducting qubit readout - theory, KEVIN O’BRIEN, NSF Nano-scale Science and Engineering Center (NSEC), University of California, Berkeley, CHRIS MACKLIN, IRFAN SIDDIQI, QNL, University of California, Berkeley, XIANG ZHANG, NSF Nano-scale Science and Engineering Center (NSEC), University of California, Berkeley — Josephson parametric amplifiers approach quantum-noise-limited performance and are used in experiments requiring high-fidelity detection of single-photon-level microwave signals. Current Josephson parametric amplifiers couple the Josephson junction (a nonlinear inductor) to a resonant cavity, achieving high gain at the expense of limited instantaneous bandwidth. In contrast, Josephson traveling wave parametric amplifiers (JTWPAs) avoid this gain-bandwidth trade-off by employing long propagation lengths rather than a resonant cavity. A major challenge in JTWPa design is that optimum parametric gain is only achieved when the four-wave mixing process is phase matched. We show that by adding a series of resonant elements to the transmission line, phase matching and exponential gain can be achieved. Generation of higher harmonics is automatically suppressed due to the junction plasma resonance. We present the theory and selected results, including the gain, bandwidth, and dynamic range of the amplifier. The simultaneous achievement of high gain (greater than 20 dB), large instantaneous bandwidth (greater than 2 GHz), and high dynamic range make the JTWPa a promising device for the simultaneous readout of frequency-multiplexed superconducting qubits.

9:12AM F39.00007 Phase-matched Josephson traveling-wave parametric amplifier for superconducting qubit readout - experiment1, CHRIS MACKLIN, QNL, University of California, Berkeley, K. O’BRIEN, NSF Nano-scale Science and Engineering Center (NSEC), University of California, Berkeley, B. H. EOM, QNL, University of California, Berkeley, M. E. SCHWARTZ, QNL, University of California, Berkeley, D. HOVER, V. BOLKHOVSKY, S. TOLPYGO, G. FITCH, T. WEIR, MIT Lincoln Laboratory, W.D. OLIVER, MIT Lincoln Laboratory and Research Laboratory of Electronics, Massachusetts Institute of Technology, X. ZHANG, NSF Nano-scale Science and Engineering Center (NSEC), University of California, Berkeley, I. SIDDIQI, QNL, University of California, Berkeley — We have developed a new generation of Josephson traveling wave parametric amplifiers (JTWPAs) utilizing the technique of resonant phase matching. Due to its transmission line geometry, the JTWPa is not limited by the gain-bandwidth tradeoffs inherent in resonator-based parametric amplifiers. We present experimental results on the amplifier performance of the JTWPa, demonstrating gain in excess of 20 dB over an instantaneous bandwidth of more than 2 GHz with a 1 dB compression power of -100 dBm. The system noise temperature with the JTWPa is less than a factor of 3 above the quantum limit as measured using a 3D transmon in the weak measurement regime to provide a precise power calibration at the relevant experimental reference plane. We also utilize quantum weak measurement to provide an independent measure of the quantum measurement efficiency, in good agreement with the noise power measurement. We demonstrate projective qubit readout with a raw measurement fidelity exceeding 98% in an 80 ns integration window, and extrapolate this performance to a multi-qubit system.

9:24AM F39.00008 High-Fidelity Measurements of Long-Lived Flux Qubits. DAVID HOVER, MIT Lincoln Laboratory, CHRIS MACKLIN, KEVIN O’BRIEN, University California Berkeley, ADAM SEARS, JONILYN YODER, TEO GUDMUNSDEN, JAMIE KERMAN, VLADIMIR BOLKHOVSKY, SERGEY TOLPYGO, GEORGE FITCH, TERRY WEIR, MIT Lincoln Laboratory, ARCHANA KAMAL, SIMON GUSTAVSSON, FEI YAN, Research Laboratory of Electronics, MIT, JEFF BIRENBAUM, IRFAN SIDDIQI, University California Berkeley, TERRY ORLANDO, Research Laboratory of Electronics, MIT, JOHN CLARKE, University California Berkeley, WILL OLIVER, MIT Lincoln Laboratory;Research Laboratory of Electronics, MIT — We report on high-fidelity dispersive measurements of a long-lived flux qubit using a Josephson superconducting traveling wave parametric amplifier (JTWA). A capacitively shunted flux qubit that incorporates high-Q MBE aluminum will have longer relaxation and dephasing times when compared to a conventional flux qubit, while also maintaining the large anharmonicity necessary for complex gate operations. The JTWA relies on a Josephson junction embedded transmission line to deliver broadband, nonreciprocal gain with large dynamic range. This research was funded in part by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), and by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract number FA8722-05-C-0001. 9:36AM F39.00009 Quantum-limited Amplification via Dissipation in Superconducting Circuits. A. METELMANN, A.A. CLERK, McGill University, Department of Physics — The development of parametric amplifiers based on superconducting circuits has led to an impressive improvement in the precision and sensitivity of measurements in the quantum regime. However, standard cavity-based parametric amplifiers suffer from a fixed gain-bandwidth product. Moreover they are reciprocal devices, i.e., they amplify in both directions, leading to the requirement of additional noisy elements as circulators in the measurement chain. In our recent work we discussed a phase-insensitive quantum amplifier which utilizes dissipative interactions in a parametrically-coupled three-mode bosonic system [PRL 112, 133904 (2014)]. The use of dissipative interactions provides a fundamental advantage over standard cavity-based parametric amplifiers: large photon number gains are possible with quantum-limited added noise, with no limitation on the gain-bandwidth product. In this talk we present how this can be extended to phase-sensitive amplifiers and discuss the possibilities of making the amplifier directional.

9:48AM F39.00010 Dispersive qubit measurement using an on-chip parametric amplifier: theory. BENJAMIN LEVITAN, SAEED KHAN, McGill University, ANDREW EDDINS, DAVID TOYLI, IRFAN SIDDIQI, University of California, Berkeley, AASHISH CLERK, McGill University — Superconducting circuits directly integrating qubits and parametric amplifiers are a promising avenue for scalable measurement in circuit QED architectures. In such devices, the qubit is not protected against the amplified fluctuations of the paramp; understanding the backaction characteristics is thus crucial. We discuss recent theory work examining measurement-induced dephasing in a system where a flux-pumped paramp is directly coupled to a qubit, both in the limit of weak and strong dispersive coupling. We show that by careful design choices, the measurement-induced dephasing can be near quantum-limited despite the lack of circulators or explicitly directional amplifiers to protect the qubit. This work is supported by ARO.

10:00AM F39.00011 Dispersive qubit measurement using an integrated on-chip parametric amplifier1, A. EDDINS, D.M. TOYLI, E.M. LEVENVSON-FALK, QNL, University of California, Berkeley, B.A. LEVITAN, S. KHAN, A.A. CLERK, Department of Physics, McGill University, I. SIDDIQI, QNL, University of California, Berkeley — Superconducting parametric amplifiers (paramps) enable readout of superconducting qubits with unparalleled speed and efficiency. A variety of amplifier designs have been successfully used for readout; however, the most widely used devices require additional microwave components between qubit and paramp, limiting measurement efficiency and scalability. Our work aims to integrate qubit and amplifier on-chip, exploiting two-mode operation of the paramp to minimize measurement backaction on the qubit. To this end, we have developed a flux-pumped, high dynamic range amplifier compatible with qubit integration, and characterized the combined qubit-paramp circuit. We will discuss device design considerations and fabrication, studies of measurement-induced qubit dephasing in the presence of amplification, and prospects for enhanced weak, continuous measurements as well as strong, projective readout.

1This work was supported by funding from the Army Research Office.

10:12AM F39.00012 Broadband Kinetic Inductance Based Traveling Wave Amplifier for Qubit Readout. , MICHAEL VISSERS, ROBERT ERICKSON, HSJANG-SHENG KU, JIANSONG GAO, DAVID PAPPAS, NIST - Boulder — A broadband quantum-limited amplifier is desirable for multiplexed readout of superconducting qubits and detectors. The kinetic inductance traveling-wave parametric amplifier (KIT) is a new type of amplifier that utilizes the intrinsic dissipationlessness nonlinearity of kinetic inductance of superconductors like NbTiN and TiN for parametric amplification. The amplifier consists of a several meter long CPW transmission line fabricated from a 20nM NbTiN film on an intrinsic Si wafer. The transmission line is dispersion engineered with impedance loadings to achieve the ideal phase matching which leads to broadband gain. We measure over 20dB of gain across several GHz of bandwidth with a high gain-saturation power and dynamic range.

10:24AM F39.00013 A dispersion-engineered Josephson junction-based travelling wave parametric amplifier with low loss dielectric. , J. MUTUS, Google Santa Barbara, T. WHITE, I.-C. HOI, UC Santa Barbara, R. BARENDRES, Google, Santa Barbara, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara, Z. CHEN, B. CHIARO, UC Santa Barbara, A. FOWLER, Google, Santa Barbara, A. DUNSWORTH, UC Santa Barbara, E. JEFFREY, Google, Santa Barbara, J. KELLY, UC, Santa Barbara, A. MEGRANT, C. NEILL, P.J.J. O’MALLEY, UC Santa Barbara, P. ROUSHAN, Google, Santa Barbara, C. QUINTANA, UC Santa Barbara, D. SANK, Google, Santa Barbara, A. VAINSENCHER, J. WENNER, UC Santa Barbara, J. GAO, NIST, S. CHAUDHURI, Stanford, A.N. CLELAND, UC Santa Barbara, J.M. MARTINIS, University of California and Google, Santa Barbara — Travelling wave parametric amplifiers (TWPA) promise wide-band performance with high saturation power for amplifying microwave frequency signals. Designing a TWPA requires a careful balance of many parameters in order to approach quantum-limited noise performance with sufficient gain and saturation power. We present a design based on an LC-ladder transmission line of Josephson junctions and parallel plate capacitors using low-loss amorphous silicon dielectric. Crucially, we have inserted λ/4 resonators at regular intervals along the transmission line in order maintain the phase matching condition between pump, signal and idler in order to increase gain. The design and performance of the device will be presented, demonstrating high-gain, wide bandwidth and high dynamic range.

10:36AM F39.00014 Enhancing bandwidth of Josephson parametric amplifiers with impedance engineering. TANAY ROY, VADIRAJ A M, SUMAN KUNDU, MEGHAN PATANKAR, RAJAMANI VIJAYARGHAVAN, Tata Institute of Fundamental Research, Mumbai, India — Josephson parametric amplifiers (JPAs) are a crucial component of superconducting quantum information processing systems since they enable fast, high-fidelity measurement of qubits. However, JPAs based on a single SQUID oscillator suffer from two major drawbacks — narrow bandwidth and gain saturation at low signal powers, and are typically suited to single qubit experiments only. With the rapid development of multi-qubit systems, there is a practical need to develop an amplifier with larger bandwidth and signal handling capacity, while maintaining gain and noise performance. We will describe a new method to enhance the bandwidth by introducing a frequency dependent shunting impedance for the JPA. To prevent gain saturation, we also replace the single SQUID with a SQUID array. With an appropriate choice of device parameters, numerical calculations indicate the possibility of obtaining 20 dB gain with 700 MHz of bandwidth and near quantum limited noise performance. We will present experimental results demonstrating bandwidth enhancement and discuss strategies for optimizing overall amplifier performance.
semiflexible polymers. For many semiflexible chains, crystallization or thermal degradation can preclude the IN transition, so that $T_N$, BRANDON SMITH, Penn State University, Department of Chemical

8:00AM F41.00001 BREAK –

8:36AM F41.00002 Addition of ferrocene controls polymorphism and enhances charge mobilities in poly(3-hexylthiophene) thin-film transistors . BRANDON SMITH, Penn State University, Department of Chemical Engineering, MICHAEL CLARK, The Dow Chemical Company, CHRISTOPHER GIOCECCO, ALEC LARSEN, JOHN ASBURY, Penn State University, Department of Chemistry, ENRIQUE GOMEZ, Penn State University, Department of Chemical Engineering. — Crystalline organic molecules often exhibit the ability to form multiple crystal structures depending on the processing conditions. Exploiting this polymorphism to optimize molecular interaction between adjacent molecules within the unit lattice of conjugated polymers is an approach to enhance charge transport within the material. We have demonstrated the formation of different π-π stacking poly(3-hexylthiophene-2,5-diyl) polymers in films spin coated from ferrocene-containing solutions using varying incident X-ray diffraction. As a result, we found that the addition of ferrocene to casting solutions yields thin-film transistors which exhibit significantly higher source-drain current and charge mobilities than neat polymer devices. Insights gleaned from ferrocene/poly(3-hexylthiophene) mixtures can serve as a template for selection and optimization of next generation small molecule/polymer systems possessing greater baseline charge mobilities. Ultimately, the development of such techniques to enhance the characteristics of organic transistors without imparting high costs or loss of advantageous properties will be a critical factor determining the future of organic components within the electronics market.

8:48AM F41.00003 Predicting nematic coupling constants of semiflexible polymers from MD simulations , WENLIN ZHANG, ENRIQUE GOMEZ, SCOTT MILNER, Pennsylvania State University — The nematic phase is important for many semiflexible polymers. For example, semiflexible polymers with nematic phase can be directly used in many applications, including displays and high strength fibers. The existence of nematic phases also enables better processing of functional semiflexible polymers including conducting conjugated polymers. The nematic coupling constant $\alpha$, together with the chain stiffness $\kappa$, governs chain alignment and the isotropic-to-nematic (IN) transition temperature $T_{IN}$ for semiflexible polymers. For many semiflexible chains, crystallization or thermal degradation can preclude the IN transition, so that $T_{IN}$ cannot be used to estimate $\alpha$. We combine self-consistent field theory (SCFT) with atomistic molecular dynamics (MD) simulations of semiflexible chains under external tension in the isotropic phase to estimate the nematic coupling constant $\alpha$. Using our mean-field model, we can obtain the variational free energy of a given polymer, from which the IN transition temperature $T_{IN}$ can be determined. We apply our method to estimate $\alpha$ and $T_{IN}$ of a commonly studied conjugated polymer, poly(3-hexylthiophene) (P3HT). Using the estimated $T_{IN}$, we predict P3HT is nematic after melting from crystal.

9:00AM F41.00004 Heteroatom-Containing Contorted Molecular Semiconductors . NICHOLAS DAVY, Department of Chemical and Biological Engineering, Princeton University, GABRIEL MAN, Department of Electrical Engineering, Princeton University, SEAN PARKIN, Department of Chemistry, University of Kentucky, ANTOINE KAHN, Department of Electrical Engineering, Princeton University, YUEH-LIN LOO, Department of Chemical and Biological Engineering, Princeton University — Contorted polyaromatic hydrocarbons (c-PAHs), such as contorted hexabenzocoronene (c-HBC), are promising active ingredients for organic photovoltaic (OPV) devices due to their inherent stability, tunable frontier energy levels, and synthetic accessibility. The utility of c-HBC derivatives in OPV devices, however, has been limited by the large band gaps of these materials and, as a consequence, their reduced ability to absorb a broad range of the solar spectrum. Here, we report on the synthesis and photophysical characterization of tetrazabenzo[4,5-f]coronene (c-TBFDBC) and tetrabenzothienodibenzocoronene (c-TBTDBC) — a pair of heteroatom-containing c-PAHs that show broader absorption of the solar spectrum compared to c-HBC, with maximum absorptivities above 10^5 cm^-1 M^-1 in both the near-UV and in the visible. Bilayer OPV devices comprising c-TBFDBC or c-TBTDBC and C70 outperform those having c-HBC in photocurrent production and power conversion efficiency. External quantum efficiency spectra indicate improved light harvesting by both donor and acceptor molecules on annealing. Grazing incidence X-ray diffraction experiments reveal increases in the crystallinity of donor and acceptor layers on annealing and a preference for edge-on orientation in c-HBC and c-TBFDBC.

9:12AM F41.00005 Manipulating the backbone structure of semiconducting polymers . CHRISTINE LUSCOMBE, University of Washington, Seattle — π-Conjugated polymers are being used in the fabrication of a wide variety of organic electronic devices such as organic field-effect transistors (OFETs), organic photovoltaic (OPV) devices, and organic light-emitting diodes (OLEDs). The advances made in organic electronics have been driven by the syntheses of π-conjugated polymers with increasingly complex structures but have only relied on an Edisionian approach. Despite these advances, there are many contradictory reports in the literature about our understanding of the performance of π-conjugated polymers in many applications. Our group has been studying and developing techniques to grow semiconducting polymers using a living polymerization method. This has allowed us to synthesize polymers with control over the backbone structure of semiconducting polymers, star-shaped P3HT, as well as hyperbranched P3HT. It also allows us to accurately control the molecular weights of P3HT and produce materials with a narrow molecular weight distribution. In this presentation, our work towards creating brush polymers will be presented where a series of fully conjugated graft copolymers containing poly(3-hexylthiophene) (P3HT) side chains and a p-type carbazole-diketopyrrolopyrrole donor-acceptor backbone were synthesized via a graft through Suzuki polymerization.

9:48AM F41.00006 Synthesis and Self-Assembly of Rod-Coil Mitkaoarm Star Copolymers of Poly(3-dodecythiophene) and Poly(methyl methacrylate) with high rod fractions . JICHEOL PARK, Pohang Univ of Sci & Tech, HONG CHUL MOON, University of Minnesota, CHUNG-ROYNG CHOI, JIN KON KIM, Pohang Univ of Sci & Tech — Poly(3-dodecylthiophene)-b-poly(methyl methacrylate) diblock copolymer (P3DDT-b-PMMA) can self-assemble into various microdomains such as spheres, cylinders, and lamellae depending on weight fraction of P3DDT. However, only fibril morphology was formed when weight fraction of P3DDT was major ($w_{P3DDT}$ ~ 0.76). Here, we introduce a new approach to obtain microdomain structures even at high $w_{P3DDT}$ by using well-defined A$_2$B mitkaoarm star copolymer composed of P3DDT and PMMA ([(P3DDT)$_2$PMMA]. We found via small angle X-ray scattering and transmission electron microscopy that (P3DDT)$_2$PMMA showed PMMA cylinder packed hexagonally in the matrix of P3DDT and body-centered-cubic spheres of PMMA for $w_{P3DDT}$ of 0.66 and 0.75, respectively. This because of much reduction of the rod-rod interaction in (P3DDT)$_2$PMMA compared with (P3DDT-b-PMMA) diblock copolymers.
10:00AM F41.00007 A Quantum Chemical Study of Structural and Electronic Properties of DTBT and DTBT:C70 Complexes. Organic photovoltaic (OPV) devices containing the diethyl benzothiadiazole (DTBT) based conjugated polymers are promising candidates for solar energy harvesting. Practical realization of OPV devices requires further improving their performance, which relies on the fundamental understanding of the morphology and electronic properties of DTBT-based polymers. Nevertheless, even the conformational properties of DTBT have not been fully revealed yet. Here, we present the quantum chemical calculations of the structural and electronic properties of DTBT as well as DTBT:C70 complexes at the molecular level. These first principles principles include the two-dimensional potential energy surface, the band gap, DTBT:C70 equilibrium distance as well as the energy level offset at the interface compared to the energy levels of the individual material. The computed results are compared to the available experimental data.

10:12AM F41.00008 Theoretical modelling of high-dielectric constant donors for high-conversion organic film solar cells. KENJI MISHIMA, KOICHI YAMASHITA, The University of Tokyo, JST-CREST. In this contribution, we report our theoretical design of high dielectric-constant donors based on the DFT and TD-DFT quantum chemistry calculations. The motivation of our study lies in the importance of high-dielectric constant donors and acceptors for purposes of separating photo-generated excitons efficiently and preventing them from recombining, thus leading to high photo-conversion efficiency in the organic solar cells. Our theoretical design guideline is to bind the conventional thiophene-related one-dimensional donor molecules via benzene rings two-dimensionally, which leads to extended pi-conjugation and their high dielectric constants. Our numerical results indicate that the dielectric constant increases monotonically with the size of the molecule. The dielectric constant of the two-dimensionally extended thiophene donor amounts to 13.6, which is more than three times as much as that of the conventional P3HT donor molecule (~4). By using PCBM molecule as an acceptor, the total amount of photo-induced transferred charge transfer from the donor to the acceptor is comparable to that of the P3HT/PCBM system.

10:48AM F41.00011 High-throughput organic semiconductor discovery combining tight-binding and first-principles calculations, ANDRE LEITAO BOTELHO, TIM MUELLER, Johns Hopkins University. We present the combination of a tight-binding model and first-principles calculations as a two-step screening for the accelerated discovery of organic semiconductors. For the tight-binding model, we select the adapted Su-Schrieffer-Heeger Hamiltonian for its ability to provide both the electronic structure and optimized geometry based solely on the structural formula. We produce two sets of parameters, one to match the optical gaps to exciton energies from TDDFT, and another set to match the transport gaps to HOMO/LUMO energies from DFT with an experimental correction factor. Although the fittings use fewer than one thousand oligomers, the predictive results for the remaining one million oligomers agree with DFT (coefficient of determination of up to 0.8) and can be used as a pre-screening step. With the same set of parameters, we also calculate the charged states to predict the Marcus theory reorganizational energies as an estimate the conductivities of holes and electrons. Based on the calculated properties, we discuss materials selection for photovoltaics and transistors.

Session F42 DPOLY: Wetting, Adhesion and Dynamics of Polymer Films and Interfaces 214B -
Ryan Hayward, University of Massachusetts, Amherst

8:00AM F42.00001 BREAK

8:36AM F42.00002 Molecular Velcro constructed from polymer loop brushes showing enhanced adhesion force, TIAN ZHOU, BIAO HAN, LIN HAN, CHRISTOPHER LI, Drexel University, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING TEAM, SCHOOL OF BIOMEDICAL ENGINEERING, SCIENCE AND HEALTH SYSTEMS TEAM. Molecular Velcro is commonly seen in biological systems as the formation of strong physical entanglement at molecular scale could induce strong adhesion, which is crucial to many biological processes. To mimic this structure, we designed, and fabricated polymer loop brushes using polymer single crystals with desired surface functionality and controlled chain folding. Compared with reported loop brushes fabricated using triblock copolymers, the present loop brushes have precise loop sizes, loop grafting density, and well controlled tethering locations on the solid surface. Atomic force microscopy-based force spectroscopy measurements using a polymer chain coated probe reveal that the adhesion force are significantly enhanced on the loop brush surface as compared with its single-strand counterpart. This study directly shows the effect of polymer brush conformation on their properties, and suggests a promising strategy for advanced polymer surface design.

8:48AM F42.00003 Probing the adhesion of particles to responsive polymer coatings with hydrodynamic shear stresses, RYAN TOOMEY, GULNUR EFE. University of South Florida. Lower critical solution temperature (LCST) polymers in confined geometries have found success in applications that benefit from reversible modulation of surface properties, including drug delivery, separations, tissue cultures, and chromatography. In this talk, we present the adhesion of polystyrene microspheres to cross-linked poly(N-isopropylacrylamide), or poly(NIPAAm) coatings, as studied with a spinning disk method. This method applies a linear range of hydrodynamic shear forces to physically adsorbed microspheres along the radius of a coated disk. Quantification of detachment is accomplished by optical microscopy to evaluate the minimum shear stress to remove adherent particles. Experiments were performed to assess the relationship between the surface chemistry of the microsphere, the thickness and cross-link density of the poly(NIPAAm) coating, the adsorption (or incubation) time, and the temperature on the detachment profiles of the microspheres. Results show that both the shear modulus and slow dynamic processes in the poly(NIPAAm) films strongly influence the detachment shear stresses. Moreover, whether an adsorbed microsphere can be released (through a modulation in the swelling of the poly(NIPAAm) coating by temperature) depends on both the surface chemistry of the microsphere and the extent of the adsorption time. Finally, the results show that the structure of the poly(NIPAAm) coating can significantly affect performance, which may explain several of the conflicting findings that have been reported in the literature.
mechanisms during solvent-based fabrication of polymer blends

1. The nanoscale dynamics of solvated systems. Forces and hydrodynamic interactions; the latter are extremely long ranged in 2D fluids. This study positively demonstrates a new method to visualize in situ unexpected particle pairing, both dynamic and static, was observed in films thin compared to particle diameter, suggesting a complicated interplay of capillary forces. Selecting appropriate viewing conditions to avoid charging and beam damage artifacts (neither trivial concerns), individual particles could be followed in competition with the relaxation of the contact angle at the three-phase contact line. Here, we study the dynamics of stepped interfaces of thin polystyrene films on hydrophilic substrates. Annealing the polymeric film above its glass transition temperature induces flow which is precisely monitored using ex- and in-situ atomic force microscopy. Both pinned and receding contact line regimes are observed, corresponding to capillary levelling and dewetting of the liquid film. Rescaling with regard to the viscosity, surface tension and film thickness collapses the data on a master curve, providing a universal time for the transition between both regimes. In addition, we prove that the pinned interface exhibits self-similar height profiles which are captured by a thin film model in lubrication approximation.

2. In one or more external stimuli as well as photocatalytic activity. For this we are inspired from nature to produce surfaces with a dual-scale hierarchical roughness morphology control with the ultimate goal of precise, yet affordable, morphology manipulation for a large spectrum of applications. When and where phases are formed, and how they evolve to form the final structure. We utilize a linear stability analysis to identify which mechanism of phase-separation is chosen for a given processing condition. Finally, we construct a mode diagram that maps processing conditions with individual modes. The films. Hence, it is of paramount importance to understand morphology evolution during fabrication. However, it is challenging to experimentally visualize morphology evolution during processing (processes involved are highly dynamic at low scale and typical components do not show high contrast). Consequently, details of morphology evolution during solvent-based thinning deposition are still under debate. Here, we identify four modes of phase formation and subsequent propagation within the thinning film during solvent-based fabrication. We unravel the origin of this behavior. Specifically, we focus on fundamental questions, when and where phases are formed, and how they evolve to form the final structure. We utilize a linear stability analysis to identify which mechanism of phase-separation is chosen for a given processing condition. Finally, we construct a mode diagram that maps processing conditions with individual modes. The idea introduced here enables choosing processing conditions to tailor film morphology characteristics and paves the ground for a deeper understanding of morphology control with the ultimate goal of precise, yet affordable, morphology manipulation for a large spectrum of applications.

3. Support from the UMass MRSEC is acknowledged.

10:12AM F42.00010 How do evaporating thin films evolve? Unravelling phase-separation mechanisms during solvent-based fabrication of polymer blends. OLGA WODO, State Univ of NY - Buffalo, BASKAR GANAPATHYSUBRAMANIAN, Iowa State University — Solvent-based fabrication is a flexible and affordable approach to manufacture organic thin films made from any combination of polymer, copolymers and/or small molecules. The properties of products made from such films can be tailored by the morphology of the films. Hence, it is of paramount importance to understand and control morphology evolution during fabrication. However, it is challenging to experimentally visualize morphology evolution during processing. Processes involved are highly dynamic at low scale and typical components do not show high contrast. Consequently, details of morphology evolution during solvent-based thinning deposition are still under debate. Here, we identify four modes of phase formation and subsequent propagation within the thinning film during solvent-based fabrication. We unravel the origin of this behavior. Specifically, we focus on fundamental questions, when and where phases are formed, and how they evolve to form the final structure. We utilize a linear stability analysis to identify which mechanism of phase-separation is chosen for a given processing condition. Finally, we construct a mode diagram that maps processing conditions with individual modes. The idea introduced here enables choosing processing conditions to tailor film morphology characteristics and paves the ground for a deeper understanding of morphology control with the ultimate goal of precise, yet affordable, morphology manipulation for a large spectrum of applications.

10:24AM F42.00011 Polymeric surfaces exhibiting photocatalytic activity and controlled anisotropic wettability. SPIROS H. ANASTASIADIS, MELANI A. FRYSALI, LAMPROS PAPOUTSAKIS, GEORGE KENANAKIS, EMMANUEL STRATAKIS, MARIA VAMVAKIKA, Foundation for Research and Technology - Hellas and Univ. of Crete, Greece, GRIGORIS MOUNTRICHAS, STERGIOS PISPAS, National Hellenic Research Foundation, Greece — In this work we focus on surfaces, which exhibit controlled, switchable wettability in response to one or more external stimuli as well as photocatalytic activity. For this we are inspired from nature to produce surfaces with a dual-scale hierarchical roughness and combines them with the appropriate inorganic and/or polymer coating. The combination of the hierarchical surface with a ZnO coating and a pH- or temperature-responsive polymer results in efficient photo-active properties as well as reversible superhydrophobic / superhydrophilic surfaces. Furthermore, we fabricate surfaces with unidirectional wettability variation. Overall, such surfaces require advanced design, combining hierarchically structured surfaces with suitable polymeric materials. Acknowledgment: This research was partially supported by the European Union (European Social Fund, ESF) and Greek national funds through the “ARISTEIA II” Action (SMART-SURF) of the Operational Programme “Education and Lifelong Learning,” NSRF 2007-2013, via the General Secretariat for Research & Technology, Ministry of Education and Religious Affairs, Greece.
10:36AM F42.00012 The Role of Contact Angle on the Depletion Layer when at the Interface Between Water and a Hydrophobic Surface, ADELE POYNOR, SHANNON PETERSEN, BROOKE OLLANDER, Allegheny College — By definition hydrophobic substances hate water. Water placed on a hydrophobic surface will form a drop in order to minimize its contact area. What happens when water is forced into contact with a hydrophobic surface? One theory is that an ultra-thin low-density depletion layer forms near the surface. We investigate the role of contact angle on depletion layer using the surface sensitive technique of Surface Plasmon Resonance.

10:48AM F42.00013 Wetting Properties of Chemically Modified Surfaces: The role of hydrogen bonding, SELEMON BEKELE, MESFIN TSIGE, The University of Akron, Department of Polymer Science, Akron, Ohio — Many industrial processing operations involve the spreading of a liquid on a solid material. Controlling the wetting of one material by another is of crucial importance in such applications as adhesion, coating, and oil recovery. A strategy often employed to control the wettability of solid surfaces is a combination of surface patterning and chemical surface modification. In order to understand the effect of surface chemistry on the wetting process, we have carried out all-atom molecular dynamics (MD) simulations of a water droplet spreading on pure and oxidized polystyrene surfaces. Our previous results show that the contact angle generally decreases with increasing oxygen concentration and there is a correlation between the spreading and hydrogen bonding. In this talk, we will present results on the structure and dynamics of the hydrogen bonds in the interfacial region between water and the polystyrene substrate. We will discuss our findings on hydrogen bond lifetimes, time correlations functions and number of hydrogen bonds per water molecule for the hydrogen bonds around the water/polystyrene interface which are found to play a role in the spreading process.

Tuesday, March 3, 2015 8:00AM - 11:00AM
Session F43 DPOLY: Blends and Block Copolymers 214C - Ron Jones, National Institute of Standards and Technology

8:00AM F43.00001 BREAK

8:36AM F43.00002 Controlling Phase Separation of Interpenetrating Polymer Networks by Addition of Block Copolymers, BRIAN ROHDE, RAMANAN KRISHNAMOORTI, MEGAN ROBERTSON, University of Houston, Department of Chemical and Biomolecular Engineering — Interpenetrating polymer networks (IPNs) offer a unique way to produce mechanically superior thermostets blends relative to the neat components. In this study, IPNs were prepared consisting of polycyclopentadienentane (polyDCPD), contributing high fracture toughness, and an epoxy resin (the diglycidyl ether of bisphenol A cured with nadic methyl anhydride), contributing high tensile strength and modulus. In the absence of compatibilization, the simultaneous curing of the networks leads to a macroscopically phase separated blend that exhibits poor mechanical behavior. To control phase separation and drive the system towards more mechanically robust nanostructured IPNs, block copolymers were designed to compatibilize this system, where one block possesses affinity to polyDCPD (polyisoprene in this study) and the other block possesses affinity to NOCA (poly(c-caprolactone) in this study). The influence of the block copolymer composition on the degree of phase separation and interfacial adhesion in the IPN was studied using a combination of small-angle scattering and imaging techniques. The resultant mechanical properties were explored and structure-property relationships were developed in this blend system.

8:48AM F43.00003 Melt-Miscibility in Block Copolymers Containing Polyethylene and Substituted Polynorbornene Blocks, WILLIAM MULHEARN, RICHARD REGISTER, Princeton Univ — Block copolymers containing a crystallizable block, such as polyethylene (PE), and a high-*T_g* amorphous block are potentially interesting materials since the rigid glassy block can mitigate the poor yield strength of the PE crystals. However, chemical incompatibility between blocks, quantified by the Flory interaction parameter *q* or the interaction energy density *X*, drives microphase separation at low temperatures or high chain lengths. To prepare a high molecular weight PE-containing block copolymer that is easy to process (i.e. with a desired low-viscosity melt) it is necessary to select amorphous blocks that have low mixing energies with PE. The only suitable polymers currently known are chemically similar to PE and therefore have similarly low glass transition temperatures. We investigate a series of both low- and high-*T_g* polymers based on substituted norbornene monomers, polymerized via ring-opening metathesis polymerization (ROMP). Several ROMP polymers of this type exhibit high *T_g* and low interaction energy against PE. For example, hydrogenated poly(cyclohexyl norbornene) has *T_g* = 88 °C and has interaction energy density *X_{1p,CyN,PE} ≈ 0.8 MPa*, comparable to the interaction energy density between PE and hydrogenated polysoprene. The miscibility of an amorphous block can be further tuned by statistical copolymerization of norbornene units with aromatic side-groups (high Hildebrand solubility parameter) and norbornene units with aliphatic side-groups (low Hildebrand solubility parameter).

9:00AM F43.00004 Fluctuation Effects in AB/A/B Diblock Copolymer-Homopolymer Ternary Mixtures near the Lamellar-Disorder Transition, TIMOTHY GILLARD, ROBERT HICKEY, BRIAN HABERSBERGER, TIMOTHY LODGE, FRANK BATES, University of Minnesota — By definition hydrophobic substances hate water. Water placed on a hydrophobic surface will form a drop in order to minimize its contact area. What happens when water is forced into contact with a hydrophobic surface? One theory is that an ultra-thin low-density depletion layer forms near the surface. We investigate the role of contact angle on depletion layer using the surface sensitive technique of Surface Plasmon Resonance.

9:12AM F43.00005 How to Place Block Copolymer Molecules at the Interface of a Binary Blend, ZHONG-REN CHEN, YICI XU, SHUO ZHONG, Ningbo University — Block copolymers have been used to reduce the domain size of immiscible polymer blends and thus improve the mechanical and other properties. The effectiveness of this method, however, depends on the percentage of these polymeric surfactants residing at the interface of the blend. In fact, theoretical as well as experimental work indicate that a large percentage of block copolymers form micelles in the bulk of one or both of the component polymers. These micelles may serve as weak spots initiating crack propagation. Previous work have been focused on the design of molecular architecture and synthesis of new block copolymers to address this problem. In this presentation, a simple mixing strategy is applied to make each block copolymer molecule stay at the interface. As one example, when this strategy is used to mix natural rubber (NR) with butadiene rubber (BR), a small amount of low molecular weight block copolymer (LIR) improves both processing characteristics such as melt viscosity and mechanical properties of cured samples, such as crack resistance. AFM micrographs show the much smaller domain size; and an original real-time monitoring system reveals the lowest crack growth rate. Using a model A/B/A/B binary blend, we have witnessed by microscopy that all block copolymer molecules form micelles at the first mixing step, and all of these micelles are disappeared and all block copolymer molecules stay at the interface after the second mixing step.
9:24AM F43.00006 Pressure dependence of various phase transitions for the miscible block copolymer blends, DU YEOL RYU, YONGHOON LEE, HOYEON LEE, YEONGSIK KIM, Yonsei University, YONSEI UNIVERSITY TEAM — The phase behavior of block copolymer (BCP) blends composed of the weakly interacting (with no specific interaction) polystyrene-b-poly-(n-butyl methacrylate) (PS-b-PnBMA) and deuterated polystyrene-b-poly-(n-hexyl methacrylate) (dPS-b-PnHMA) were investigated by Small-Angle Neutron Scattering (SANS) and Depolarized Light Scattering (DPLS) measurements. The various composition-dependent phase behaviors were generated due to a miscible phase between the PnBMA and PnHMA blocks in the BCP blends. To elucidate the origin and difference in baroelasticity of weakly interacting BCP blends, the pressure dependence of transition temperatures was evaluated using enthalpic and volumetric changes at phase transitions. We also demonstrate that the entropic compressibility for the miscible BCP blends is a baroelastic indicator, which was characterized by the negative volume change on mixing (Vmix) at transitions.

9:36AM F43.00007 Crystallization of a bimodally distributed copolymer system and a blend containing propylene-ethylene moieties, ONYENKACHI WAMUO, YING WU, SHAW HSU, University of Massachusetts, Amherst, CHARLES(CHUCK) PAUL, ANDREA EODICE, Henkel Corporation — The competitive crystallization behavior of a multicomponent system is fundamentally interesting and has significant practical implications. The relative molecular weight and molecular architecture of the polymers involved needs to be considered carefully in the characterization of the entire crystallization process; nucleation and the crystal growth phase. We have considered two types of propylene-ethylene copolymers with virtually the same chemical composition but different block sequences. A comparison is being made between a bimodally distributed copolymer and a random copolymer. The unique feature of the bimodal system is the presence of a two-step crystallization process, where the longer sequences nucleated first and additional shorter segments are transported onto the crystal growth front. This system is compared to a copolymer of virtually identical random copolymer that is nucleated differently. Calorimetric, diffraction and spectroscopic measurements have been employed in order to understand the dynamics and mechanism of crystallization and the size and perfection of the crystals formed. The relative efficiency of crystallization by controlling the polymer configuration can then be compared to the traditional approach using a nucleation agent to affect the crystallization behavior. This new approach not only provides extremely fast crystallization but also overcomes practical considerations such as dispersion of the nucleation agents.

9:48AM F43.00008 Understanding How the Presence of Uniform Electric Fields Can Shift the Miscibility of Polystyrene / Poly(vinyl methyl ether) Blends, ANNIKA KRISA, CONNIE B. ROTH, Department of Physics, Emory University — Techniques which can externally control and manipulate the phase behavior of polymer systems, without altering chemistry on a molecular level, have great practical benefits. One such possible mechanism is the use of electric fields, shown to cause interfacial instabilities, orientation of morphologies, and phase transitions in polymer blends and block copolymers. We have recently demonstrated that the presence of uniform electric fields can also strongly enhance the miscibility of polystyrene (PS) / poly(vinyl methyl ether) (PVME) blends [J. Chem. Phys. 2014, 141, 134908]. Using fluorescence to measure the phase separation temperature $T_s$ of PS/PVME blends with and without electric fields, we show that $T_s$ can be reproducibly and reversibly increased by 13.5 +/- 1.4 K for electric fields of 17 kV/mm for this lower critical solution temperature (LCST) blend. This increase in blend miscibility with electric fields represents one of the largest absolute shifts in $T_s$ ever recorded, well outside of experimental error. The best theoretical prediction for the expected shift in $T_s$ with electric field for this system is still two orders of magnitude smaller than that observed experimentally. We discuss the limitations of this theoretical prediction and consider possible factors affecting miscibility that may need to be also included.

10:00AM F43.00009 Magnetic Field Alignment of PS-P4VP: a Non-Liquid Crystalline Coil-Block Copolymer, YEKATERINA ROKHLENKO, KAI ZHANG, Yale University, STEVEN LARSON, PADMA GOPALAN, University of Wisconsin-Madison, COREY O’HERN, CHINEDUM OSUJI, Yale University — Magnetic fields provide the ability to control alignment of self-assembled soft materials such as block copolymers. Most prior work in this area has relied on the presence of ordered assemblies of anisotropic liquid crystalline species to ensure sufficient magnetic anisotropy to drive alignment. Recent experiments with poly(styrene-b-4-vinylpyridine), a non-liquid crystalline BCP, however, show field-induced alignment of a lamellar microstructure during cooling across the order-disorder transition. Using in situ x-ray scattering, we examine the roles of field strength and cooling rate on the alignment response of this low MW coil-block BCP. Alignment is first observed at field strengths as low as 1 Tesla and improves markedly with both increasing field strength and slower cooling. We present a geometric argument to illustrate the origin of a finite, non-trivial magnetic susceptibility anisotropy for highly stretched surface-tethered polymer chains and corroborate this using coarse-grained molecular dynamics simulations. We rationalize the magnetic field response of the system in terms of the mobility afforded by the absence of entanglements, the intrinsic anisotropy resulting from the stretched polymer chains and sterically constrained conjugated rings, and the large grain size in these low molecular weight materials.

10:12AM F43.00010 Phase Behavior of Binary Blend Consisting of Asymmetric Polystyrene-block-poly(2-vinylpyridine) Copolymer and Asymmetric Deuterated Polystyrene-block-poly(4-hydroxystyrene) Copolymer Having Hydrogen Bonding, JONGHEON KWAK, SANG HYUN HAN, HONG CHUL MOON, Pohang Univ of Sci & Tech, VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas, JIN KON KIM1, Pohang Univ of Sci & Tech — We investigated the phase behavior of a binary blend of asymmetric polystyrene-block-poly(2-vinylpyridine) copolymer (PS-b-P2VP) and deuterated polystyrene-block-polyhydroxystyrene copolymer (dPS-b-PH5) blends. The blend showed highly asymmetric lamellar microdomains. To explain the unexpected results, we study, via small angle X-ray scattering (SAXS) and neutron reflectivity (NR), the exact location of shorter dPS block in the mixture near the interface of the microdomains.

10:24AM F43.00011 Quenching Phase Separation by Vapor Deposition Polymerization, RAN TAO, MITCHELL ANTHAMATTEN, University of Rochester — Initiated chemical vapor deposition (CVD) is a solventless, free radical technique predominately used to deposit homogeneous films of linear and crosslinked polymers directly from gas phase feeds. We report a template-free method to fabricate continuous-phase porous polymer films by simultaneous phase separation during iCVD. Phase separation during film growth is achieved by condensing an inert porogen, along with initiator, monomer, and crosslinker. When the vapor mixture transports to the cooled substrate, phase separation occurs along with polymerization and crosslinking, which quench the state of phase separation. The kinetics of spontaneously phase separation can be quantitatively understood on the basis of Cahn-Hilliard theory. A series of films were grown by varying monomer and porogen’s degree of saturation. Deposited films were studied by electron microscopy and spectroscopic techniques.
10:36AM F43.00012 Understanding Segregation Processes in Blends of Bottlebrush-Linear Polymer Thin Films, INDRANIL MITRA, University of Houston, XIANYU LI, Envia Systems, STACY L. PESEK, Rice University, BORIS MAKARENKO, University of Houston, BRAD S. LOKITZ, DAVID UHRIG, JOHN F. ANKNER, Oak Ridge National Laboratory, RAFAEL VERDÚZCO, Rice University, GILA E. STEIN, University of Houston — Bottlebrush polymer thin films have potential to generate surface coatings for a variety of applications ranging from tailored surface wettability and adhesion, anti fouling surface coatings and self-assembled photonics. In this study, we examined the phase behavior for athermal blends of bottlebrush polystyrene (PS) and linear deuterated polystyrene (dPS) in thin films. The bottlebrush loading was 10% by volume, and the ratio of linear dPS chain length to bottlebrush PS side chain length was systematically varied in the range of $\alpha = 0.3 - 4.1$. The depth-dependent concentration of inter-modulation products was measured using dynamic secondary ion mass spectroscopy. When $\alpha < 2$, the bottlebrushes are dispersed throughout the film thickness with a slight excess at the free surface and substrate interface. When $\alpha > 8$, the bottlebrushes are depleted from the interior of the film and segregated at the interfaces. This behavior is consistent with wetting and dewetting transitions at a melt/brush interface and entropic attraction of highly branched polymers to surfaces. This work demonstrates that brushlike surfaces and interfaces can be generated in a linear polymer film through spontaneous, entropy driven segregation of properly designed bottlebrush additives.

10:48AM F43.00013 Using $\beta$-NMR to Measure Surface Segregation of Short Chains in Binary Blends of Polystyrene, JAIN MCKENZIE, TRIUMF, DAVID L. CORTIE, University of British Columbia, CHAD R. DALEY, PENDAR MAHMOUDI, NASSER M. ABUKHDEIR, MARK W. MATSEN, University of Waterloo, ROBERT F. KIEFL, University of British Columbia, C. D. PHILIP LEVY, TRIUMF, W. ANDREW MACFARLANE, University of British Columbia, GERALD D. MORRIS, MATTHEW R. PEARSON, TRIUMF, JAMES A. FORREST, University of Waterloo — A problem of significant interest in the studies of polymers at interfaces is the segregation of short chain polymers to the interface in a system with both long and short chains. It is difficult to study the segregation as methods used to introduce contrast between short and long chains often have an effect rather than just simple to the different chain lengths. We have shown that $\beta$-detected nuclear spin relaxation of $^3\text{Li}^+$ can distinguish the two chains sizes without the need for any label. This, combined with the depth profiling ability of the technique, means we can determine the effective concentration of short and the chain blend without the need to introduce another pendent factor. We have performed experiments on a 50/50 blend of 627 kg/mol and 0.980 kg/mol polystyrene-d8 and at depths ranging from 2.5 to 79 nm from the free surface. The results show definite surface segregation of short chains to the free surface. We theoretically examine the segregation of short chains to the surface of the binary blend using self-consistent field theory (SCFT). The model used in the calculation assumes an incompressible melt consisting of the freely-jointed polymer chains with either $N_0$ or $N_1$ monomers.

Tuesday, March 3, 2015 8:00AM - 11:00AM –
Session F44 GSNP GSOFT: Focus Session: Extreme Mechanics: Snapping, Jumping and Popping 214D - Doug Holmes, Boston University

8:00AM F44.00001 Yanking a chain: Lift-off and snapping, PIERRE-THOMAS BRUN, MIT, BASILE AUDOLY, UPMC / CNRS, ALAIN GORIELY, DOMINIC VELLA, University of Oxford — We revisit the first mechanics problem that everyone meets in high school: a chain on a frictionless pulley. Rather than considering the problem of a mass on each end of the string, however, we suppose that one end is subject to a constant acceleration. This simple change has some dramatic consequences for the ensuing motion: the chain ‘lifts off’ from the pulley, the free end accelerates faster than the end that is being pulled and finally the chain undergoes a dramatic reversal of curvilinear reminiscent of the crack or snap of a whip. We present simple experiments, numerical simulations and theoretical arguments that explain some but not all of these phenomena.

8:12AM F44.00002 Unraveling the chain fountain, JOHN BIGGINS, MARK WARNER, University of Cambridge — If a chain is initially at rest in a beaker at a height $h_1$ above the ground, and the end of the chain is pulled over the rim of the beaker and down towards the ground and then released, the chain will spontaneously “flow” out of the beaker under gravity. Furthermore, the beads do not simply drag over the edge of the beaker but form a fountain reaching a height $h_2$ above it. I will show that the formation of a fountain requires that the beads come into motion not only by being pulled upwards by the part of the chain immediately above the pile, but also by being pushed upwards by an unexpected reaction force from the pile of stationary chain. I will propose possible origins for this force, argue that its magnitude will be proportional to the square of the chain velocity, and predict and verify experimentally that $h_2 \propto h_1^2$. I will also discuss the case where the pot is tilted, and show, experimentally and theoretically, that the chain rises and falls in an inverted catenary, and discuss the appropriate boundary conditions at the ends of the chain.

8:24AM F44.00003 Jumping, snapping and popping at nanometer scale, DAVID HAVILAND, Royal Institute of Technology — The ‘jump-to-contact’ instability is well known in Atomic Force Microscopy. When a tip attached to a soft cantilever approaches a surface, the large attractive force gradient disrupts the quasi-static force balance and the tip snaps into contact with the surface. Less appreciated is the converse instability, where a soft liquid-like polymer surface jumps to meet the tip. This nano-scale pop is inaudible, but it does leave a distinctive signature if one carefully monitors the cantilever’s steady state dynamics when driven at frequencies close to the cantilever resonance the spectrum can be transformed to reveal the in-phase quadrature forces acting on the tip, as a function of oscillation amplitude. We present experimental measurements and theoretical modelling that reveals the drive tones. When many intermodulation products are measured close to the cantilever resonance the spectrum can be transformed to reveal the in-phase and quadrature forces acting on the tip, as a function of oscillation amplitude. We present experimental measurements and theoretical modelling that reveals the drive tones.

8:36AM F44.00004 TBD, KEITH SEFFEN, Cambridge University, UK — No abstract available.

9:12AM F44.00005 The chocolate-egg problem: Fabrication of thin elastic shells through coating, ANNA LEE, JOEL MARTHELOT, PIERRE-THOMAS BRUN, PEDRO M. REIS, Massachusetts Institute of Technology — We study the fabrication of thin polymeric shells based on the coating of a curved surface by a viscous fluid. Upon polymerization of the resulting thin film, a slender solid structure is delivered after demolding. This technique is extensively used, empirically, in manufacturing, where it is known as rotational molding, as well as in the food industry, e.g. for chocolate eggs. This problem is analogous to the Landau-Levich-Derjaguin coating of plates and fibers and Bretherton’s problem of film deposition in cylindrical channels, albeit now on a double-curved geometry. Here, the balance between gravity, viscosity, surface tension and polymerization rate can yield a constant thickness film. We seek to identify the physical ingredients that govern the final film thickness and its profile. In our experiments using organosilicon, we systematically vary the properties of the fluid, as well as the curvature of the substrate onto which the film is coated, and characterize the final thickness profile of the shells. A reduced model is developed to rationalize the process.
9:24AM F44.00006 Folding of non-Euclidean curved shells, NAKUL BENDA, ARTHUR EVANS, University of Massachusetts Amherst, SARAH INNES-GOLD, Tufts University, LUIS MARIN, University of Massachusetts Amherst, ITAI COHEN, Cornell University, CHRISTIAN SANTANGELO, RYAN HAYWARD, University of Massachusetts Amherst — Origami-based folding of 2D sheets has been of recent interest for a variety of applications ranging from deployable structures to self-folding robots. Though folding of planar sheets follows well-established principles, folding of curved shells involves an added level of complexity due to the inherent influence of curvature on mechanics. In this study, we use principles from differential geometry and thin shell mechanics to establish fundamental rules that govern folding of prototypical curved sheets. In particular, we show how the normal curvature of a crease line controls whether the deformation is smooth or discontinuous, and investigate the influence of shell thickness and boundary conditions. We show that snap-folding of shells provides a route to rapid actuation on time-scales dictated by the speed of sound. The simple geometric design principles developed can be applied at any length-scale, offering potential for bio-inspired soft actuators for tunable optics, microfluidics, and robotics.

9:36AM F44.00007 Curvature-induced symmetry breaking selects elastic wrinkling patterns, NORBERT STOOP, ROMAIN LAGRANGE, DENIS TERVERGAN, PEDRO REIS, JOERN DUNKEL, Massachusetts Institute of Technology — Wrinkling in curved bilayer surfaces is a ubiquitous phenomenon, including embryogenesis, biological tissue differentiation or structure formation in heterogeneous thin films. Due to curved substrate and the strong nonlinearity in the elastic strains, predictions for the wrinkling morphology are notoriously difficult to obtain using classical analysis. Here, we derive a generalized Swift-Hohenberg theory to describe these morphologies and their pattern selection. Testing the theory against experiments on spherically shaped surfaces, we find quantitative agreement with analytical predictions for the phase transition curves separating labyrinth, hybrid and hexagonal wrinkling phases. Our approach builds on general differential-geometric principles and can be extended to arbitrarily shaped surfaces.

9:48AM F44.00008 Bi-stable characteristics of thick-walled domes with applications to soft material snapping, AMIT MADHUCHAR, UIUC — Bi-stable structures can exhibit interesting mechanical properties which makes them the focus of research in the field of extreme mechanics. Fast transitions can occur between equilibrium states with very little actuation force. One such bi-stable structure is the thick-walled dome. In this work, we apply finite element techniques to examine the stability of such spherical, thick-walled domes undergoing large deformation. We apply the following methods to two structures: a single-layered system as well as bi-layered colloidal microparticles which actuate through pH driven mismatched swelling. The presence of a metastable state is identified by the energy characteristics alone. Monotonically increasing energy represents a mono-stable structure. Bi-stability occurs when we achieve a local energy minimum at some non-zero displacement. Of more interest is the region near the transition of these states where we find a so called pseudo-bi-stable state where small perturbations results in fast transition from the elevated energy state, or snapping. We use our simulations to map out the critical geometric parameters that govern this behavior in order to design a dome to snap. Experimental results are used to validate the simulation results.

10:00AM F44.00009 Morphing and Snapping of Plates and Shells via Swelling, DOUGLAS HOLMES, Boston University, MATTEO PEZZULLA, PAOLA NARDINOCCHI, Università degli Studi di Roma “La Sapienza”, STEVEN SHILLIG, Virginia Tech — Non-homogenous swelling will induce curvature within thin structures - beams will bend and plates will morph into shells. In this work, we examine the dynamics of swelling plates by attaching with either positive or negative Gaussian curvature. The swelling process is driven by a concentration gradient between two partially swollen structures, and the curvature of the final shell is dictated by the geometric arrangement of the swelling materials. The dynamics of this process are driven by diffusion and the geometry of the contact line. We demonstrate that these dynamic deformations can occur over a much faster timescale if the structure is confined. Beginning with a beam bent into an arch, we show how this swelling leads to a snap-through instability with dynamics similar to an arch compressed by a point load. The swelling-induced morphing presented in this talk provides a very simple and controllable way to achieve complex shell structures from simple building blocks.

10:12AM F44.00010 Interface adhesion between 2D materials and elastomers measured by buckle delamination, CHRISTOPHER BRENNAN, NANSHU LU, Univ of Texas, Austin — A major application for 2D materials is creating electronic devices, including flexible and wearable devices. These applications require complicated fabrication processes where 2D materials are either mechanically exfoliated or grown via chemical vapor deposition and then transferred to a host substrate. Both processes require intimate knowledge of the interactions between the 2D material and the substrate to allow for a controllable transfer. Although adhesion between 2D materials and stiff substrates such as silicon and copper have been measured by bulge or peeling tests, adhesion between 2D materials and soft polymer substrates are hard to measure by conventional methods. Here we propose a new method of measuring adhesion between two materials by using mature cantilever beam techniques. In this work, we present buckle delamination in 2D atomic layers and measuring the buckle profile using an atomic force microscope, we can readily extract 2D-elastomer adhesion energy. Here we look at the adhesion of MoS2 and graphene to PDMS. The measured adhesion values are found insensitive to the applied strains in the substrate and are one order smaller than 2D-silicon oxide adhesion which is mainly attributed substrate surface roughness differences.

10:24AM F44.00011 Harnessing snap-through instability for shape-recoverable energy-absorbing structure, SUNG KANG, SICONG SHAN, JORDAN RANNEY, PAI WANG, FRANCISCO CANDIDO, JENNIFER LEWIS, KATIA BERTOLDI, Harvard Univ — Energy absorbing materials and structures are used in numerous areas for maintaining structural integrity, protection and comfort. To absorb/dissipate energy from shock/vibration, one generally relies on processes such as plastic deformation and damping as the case of metal foams and suspensions. Because plastic deformation and damping induce irreversible change in the energy-absorbing systems such as shape changes and degradation of damping elements by heat dissipation, it would be desirable to develop a new energy-absorption mechanism with reversibility. Furthermore, it would be desirable to implement energy-absorption mechanisms whose behavior is not affected by the rate of loading. Here, we report a shape-recoverable system that absorbs energy without degradation by harnessing multistability in elastic structures. Using numerical simulations, we investigate geometrical parameters that determine the onset of the snap-through and multi-stability. We subsequently manufacture structures with different geometrical parameters and sizes using a scalable direct-write 3D printing approach. We experimentally demonstrate reversible energy- absorption in these structures at strain rates over three orders of magnitude, with reduced peak acceleration under impact by up to one order of magnitude compared with control samples. Our findings can open new opportunities for scalable design and manufacturing of energy-absorbing materials and structures.

10:36AM F44.00012 Non-porous Elastic Sheets with Negative Poisson’s Ratio, FARHAD JAVID, School of Engineering and Applied Science, Harvard University, EVELYN SMITH-ROBERGE, Department of Mathematics and Statistics, McGill University, MATTHEW INNES, ALI SHANIAN, Rolls-Royce Energy, KATIA BERTOLDI, School of Engineering and Applied Science, Houston University, HARVARD UNIVERSITY COLLABORATION, ROLLS-ROYCE ENERGY COLLABORATION — Negative Poisson’s ratio (NPR) materials—materials that contract (expand) in transverse directions when compressed (stretched) uniably—have attracted significant interest both because of their unusual properties and their many potential applications. However, complex fabrication processes, high porosity, and low structural stiffness of most of the proposed NPR materials have significantly limited their practical applications. In this work, a novel NPR material is designed by coupling the in- and out-of-plane (popping) deformations in an elastic sheet with a periodic distribution of dimples. As a result, such NPR material has zero porosity, relatively high structural stiffness, and can be made from both hard and soft materials using industrial fabrication techniques.
steady states. As in the equilibrium scenario, the components of the metric are given by the time-integrals of correlation functions in nonequilibrium steady states, after a suitable renormalization of heat. With a novel expansion formula for the governing master equation, we propose an exact expression for Physical Science and Technology, University of Maryland, College Park — Within the linear response regime, minimally dissipative transitions between equilibrium states are given by the geodesics of a thermodynamic metric in parameter space. We derive an analogous geometric structure for transitions between nonequilibrium steady states, after a suitable renormalization of heat. With a novel expansion formula for the governing master equation, we propose an exact expression for the metric. As in the equilibrium scenario, the components of the metric are given by the time-integrals of correlation functions in nonequilibrium steady states.
9:36AM F45.00007 Work fluctuations for a colloidal particle in a time-varying optical trap in analogy with gas in expansion and compression\textsuperscript{1}. HYUK KYU PAK, UNIST, DONGYUN LEE, Pusan National University, CHULAN KWON, Myeongji University — The fluctuation theorem provides a rigorous statistical rule for thermally fluctuating quantities such as work, heat, and entropy production in nonequilibrium thermodynamic processes. However, testing the theorem needs small systems where the fluctuations are more observable. Therefore, there are great difficulties in the experimental measurements. In this work, we investigate the motion of a colloidal particle trapped in a harmonic potential with time-varying stiffness. Here, we estimate the work done on the particle during compression and expansion by measuring its particle position in the first time. The resultant probability distributions of the work in both processes satisfy very well the Jarzynski equality and the Crooks fluctuation theorem. Because this isoenthalpic expansion and compression process in a soft wall qualitatively mimics that in a rigid wall, it offers valuable tool for extracting work from micromechanical heat engines.

\textsuperscript{1}This research is supported by the U. S. Army Research Office under contract number W911NF-13-1-0390.

9:48AM F45.00008 Engineering Maxwell’s Demon\textsuperscript{1}. ZHIYUE LU, University of Maryland at College Park, DIBYENDU MANDAL, UC Berkeley, CHRISTOPHER JARZYNSKI, University of Maryland at College Park — We describe a hypothetical machine, with moving, mechanical components, that acts as an autonomous Maxwell’s demon. The machine operates in two useful modes. It can act as an information engine by rectifying the thermal motions of surrounding gas particles to lift a mass against gravity, while writing information to a stream of bits. Alternatively, it can act as an eraser, harnessing the energy of a falling mass to erase information from a stream of bits. We solve for the phase diagram and compute the efficiency of our model, both analytically and numerically. Our model provides a simple example of a mechanical machine that is driven by the information entropy of a stream of bits, rather than a difference in temperatures or chemical potentials.

10:00AM F45.00009 Work Relations from Doi-Peliti Field Theory. ANDREW BAISH, BENJAMIN VOLLMAYR-LEE, Bucknell University — We develop a field-theoretic description of non-equilibrium work relations, using Doi-Peliti field theory. We consider classical particles on a lattice, with pair interactions and a local potential, coupled to a thermal bath. Work protocols are imposed by varying the local potential, which drives the system out of equilibrium. In this framework, work relations appear simply as the result of a gauge-like transformation.

10:12AM F45.00010 Experimental test of Generalized Fluctuation Dissipation Theorems during a transient\textsuperscript{1}. SERGIO CILIBERTO, ISAAC THEURKAUFF, ARTYOM PETROSYAN, ENSL-CNRS — In recent years the study of the Fluctuation Dissipation Theorem (FDT) in out of equilibrium system have received a lot of attention both theoretically and experimentally. Several Generalized FDT (GFDT) have been proposed but many theoretical results concern the steady state regimes and only a few the transient regimes. We report here an experiment in which two formulations of GFDT have been tested during the relaxation dynamics of a liquid crystal quenched near the critical point of Fredericksz transition, which is similar to a second order phase transition and it presents a critical slowing down. Thus the relaxation dynamics after the quench is sufficiently slow to perform several measurements. During the relaxation, the equilibrium FDT is strongly violated and this allows us to test the two GFDT. One is based on a transient fluctuation theorem and the time dependent distribution function. The other is a generalization of the Hatano-Sasa relations for transient state and has the very clear interpretation that the violation of the equilibrium FDT is related to the heat fluxes. The advantages and draw back of the two GFDT are discussed from an experimental point of view.

10:24AM F45.00011 Nonequilibrium equalities in absolutely irreversible processes. YUTO MURASHITA, KEN FUNO, MASAHIITO UEDA, University of Tokyo — Nonequilibrium equalities have attracted considerable attention in the context of statistical mechanics and information thermodynamics. Integral nonequilibrium equalities reveal an ensemble property of the entropy production $\sigma$ as $\langle e^{-\sigma} \rangle = 1$. Although nonequilibrium equalities apply to rather general nonequilibrium situations, they break down in absolutely irreversible processes, where the forward-path probability vanishes and the entropy production diverges. We identify the mathematical origins of this inapplicability as the singularity of probability measure. As a result, we generalize conventional integral nonequilibrium equalities to absolutely irreversible processes as $\langle e^{-\sigma} \rangle = 1 - \lambda_S$, where $\lambda_S$ is the probability of the singular part defined based on Lebesgue’s decomposition theorem. The acquired equality contains two physical quantities related to irreversibility: $\sigma$ characterizing ordinary irreversibility and $\lambda_S$ describing absolute irreversibility. An inequality derived from the obtained equality demonstrates the absolute irreversibility leads to the fundamental lower bound on the entropy production. We demonstrate the validity of the obtained equality for a simple model.

10:36AM F45.00012 Work Relations Connecting Nonequilibrium Steady States Without Detailed Balance. YING TANG, RUOISHI YUAN, PING AO, Shanghai Jiao Tong Univ — Bridging equilibrium and nonequilibrium statistical physics attracts sustained interest. Hallmarks of nonequilibrium systems include a breakdown of detailed balance, and an absence of a priori potential function corresponding to the Boltzmann-Gibbs distribution, without which classical equilibrium thermodynamical quantities could not be defined. Here, we construct dynamically the potential function through decomposing the system into a dissipative part and a conservative part. We then develop a nonequilibrium theory by defining thermodynamical quantities based on the potential function. We elucidate this procedure explicitly in a class of time-dependent linear diffusive systems without mathematical ambiguity. We also obtain the exact work distribution, and generalized work relations for the calculation of free energy difference between nonequilibrium steady states. Our results demonstrate that concepts for equilibrium can be naturally extended to nonequilibrium steady state, which provides a platform to study thermodynamics of systems without detailed balance.

Tuesday, March 3, 2015 8:00AM - 11:00AM — Session F46 DBIO: Invited Session: DBIO Award Symposium 217A - Wolfgang Losert, University of Maryland

8:00AM F46.00001 Max Delbruck Prize in Biological Physics Award Lecture. STANISLAS LEIBLER, Rockefeller University and Institute for Advanced Study — .
Using evolutionary sequence variation to make inferences about protein structure and function, LUCY COLWELL, Cambridge University — The evolutionary trajectory of a protein through sequence space is constrained by its function. Collections of sequence homologs record the outcomes of millions of evolutionary experiments in which the protein evolves according to these constraints. The explosive growth in the number of available protein sequences raises the possibility of using the natural variation present in homologous protein sequences to infer these constraints and thus identify residues that control different protein phenotypes. Because in many cases phenotypic changes are controlled by more than one amino acid, the mutations that separate one phenotype from another may not be independent, requiring us to understand the correlation structure of the data. To address this, we build a maximum entropy probability model for the protein sequence. The parameters of the inferred model are constrained by the statistics of a large sequence alignment. Pairs of sequence positions with the strongest interactions accurately predict contacts in protein tertiary structure, enabling all atom structural models to be constructed. We describe development of a theoretical inference framework that enables the relationship between the amount of available input data and the reliability of structural predictions to be better understood.

Dynamics of living matter: can we “see” collective motions in proteins? , DOEKE HEKSTRA, Green Center for Systems Biology, UT Southwestern Medical Center — Proteins are ideal model systems for quantitative study of the interplay of physical and evolutionary forces. Collective, anharmonic motions of amino acid residues within proteins are thought to be central to their function, and to explain, in large part, the complex dependence of protein function on its constituent parts. Currently, the experimental characterization of such motions poses a major stumbling block on the way to a physical understanding of protein function and evolution. We are addressing this problem in two ways. First, alternate conformations of protein residues can often be distinguished in the electron density estimated from room-temperature X-ray crystallography. The dense packing of residues in the folded protein requires that such conformational variations must propagate through networks of amino acids to preclude local steric clashes. Fraser and colleagues showed that such steric conflicts can be used to extract contact networks of residues collectively switching conformation. We ask if these networks are conserved over homologous sequences and connected to the functional reaction coordinate, both of which would demonstrate their fundamental importance. I will describe recent results for the family of PDZ domains: small ligand-binding proteins for which a network of energetically and conformationally coupled residues controlling ligand affinity has been demonstrated previously by a range of methods. Second, the analysis of collective motions in proteins, by nearly any means, is indirect: nothing is seen moving. To directly induce and “see” motions on a range of time scales, we developed a new approach based on (a) electric field pulses to induce motions within a protein crystal and (b) time-resolved crystallography to observe these motions. Since proteins generically have a heterogeneous, modifiable charge distribution, this method could provide a powerful, general way of probing the collective motions, and excited states, of proteins in kinetic and atomic detail. I will present initial experiments showing the method is feasible. Taken together, these experiments begin to provide a basis for the development of a physical theory of proteins consistent with their function and adaptation — the source of their survival throughout the evolutionary process.

Heredity in Evolution & Evolution of Heredity. OLIVIER RIVOIRE, CNRS & Université Grenoble Alpes — The inheritance of characteristics induced by the environment has often been opposed to the theory of evolution by natural selection. However, although evolution by natural selection requires new heritable traits to be produced and transmitted, it does not prescribe, per se, the mechanisms by which this is operated. The mechanisms of inheritance are not, however, unconstrained, because they are themselves subject to natural selection. We introduce a schematic, analytically soluble mathematical model to compare the adaptive value of different schemes of inheritance. Our model allows for variations to be inherited, randomly produced, or environmentally induced, and, irrespectively, to be either transmitted or not during reproduction. The adaptation of the different schemes for processing variations is quantified for a range of fluctuating environments, following an approach that links quantitative genetics with stochastic control theory.

Associative memory through self-assembly. ZORANA ZERAVIC, Rockefeller University — Self-assembly has recently emerged as a powerful technique for synthesizing structures on the nano- and micro-scale. The basis of this development is the use of biopolymers, like DNA, to design specific interactions between multiple species of components, allowing the spontaneous assembly of complex structures. Here we address a fundamental limitation of the existing approaches to self-assembly: Namely, every target structure must have its own dedicated set of components, which are programmed to assemble only that very structure. In contrast, in biological systems, the same set of components can assemble many different complexes. Inspired by this, we extend the self-assembly framework to mixtures of shared components capable of assembling distinct structures at will.

Docking Prediction of a Water Soluble Porphyrin and Tubulin Assisted with Resonance Raman and Vibrational Mode Analysis. BRADY MCMICKEN, Univ of Texas, San Antonio; 711th Human Performance Wing, Optical Radiation Bioeffects Branch, LORENZO BRANCADON, Univ of Texas, San Antonio, ROBERT THOMAS, 711th Human Performance Wing, Optical Radiation Bioeffects Branch, JAMES PARKER, Univ of Texas, San Antonio; 711th Human Performance Wing, Optical Radiation Bioeffects Branch — The ability to modify protein conformation by controlling its partial unfolding may have practical applications such as diminishing its function or blocking its activity. One method used to induce partial unfolding of a protein involves the use of a photosensitizer non-covalently bound to a protein that triggers photochemical reactions upon irradiation leading to protein conformational changes. We are investigating the photoinduced conformational changes of tubulin mediated by a bound water-soluble porphyrin that acts as a photosensitizer. Analysis of how tubulin conformational changes affect its biological function or blocking its activity.

8:36AM F46.00002 Using resonance Raman and vibrational mode analysis, BRADY MCMICKEN, Univ of Texas, San Antonio; 711th Human Performance Wing, Optical Radiation Bioeffects Branch, LORENZO BRANCADON, Univ of Texas, San Antonio, ROBERT THOMAS, 711th Human Performance Wing, Optical Radiation Bioeffects Branch — The ability to modify protein conformation by controlling its partial unfolding may have practical applications such as diminishing its function or blocking its activity. One method used to induce partial unfolding of a protein involves the use of a photosensitizer non-covalently bound to a protein that triggers photochemical reactions upon irradiation leading to protein conformational changes. We are investigating the photoinduced conformational changes of tubulin mediated by a bound water-soluble porphyrin that acts as a photosensitizer. Analysis of how tubulin conformational changes affect its biological function or blocking its activity.

8:12AM F47.00002 Broad-band opsin for effective stimulation of cells by white light. SUBRATA BATABYAL, GREGORY CERVENKA, YOUNG-TAE KIM, SAMARENDRA MOHANTY, University of Texas System — Currently, use of optogenetic sensitization of retinal cells combined with activation/inhibition has potential as alternative to retinal implants that would have required electrodes inside every single neuron for high visual resolution. However, clinical translation of optogenetic activation for restoration of vision suffers from the drawback that narrow spectral sensitivity of opsin requires active stimulation by blue laser or LED having intensity much higher than ambient light. In order to allow ambient-light based stimulation paradigm, here we report development of broad-band opsin that has broad spectral excitability in the entire visible spectrum. The cells sensitized with the broad-band opsin showed order of magnitude higher excitability with white light as compared to that using only the narrow-band light components. The use of broad-band opsin construct will allow higher sensitivity of the opsin-sensitized neurons in degenerated retina to ambient white light, and therefore, significantly lower activation-threshold in contrast to conventional approach of intense, narrow-band light based active-stimulation.
8:24AM F47.00003 Photoconductivity in DNA-Porphyrin Complexes¹, PEI MYINT, EMMA OXFORD, COLLENCE NYAZENGA, WALTER SMITH, Haverford College, ZHENQING QI, A.T. JOHNSON, University of Pennsylvania — We have measured the photoconductivity of λ-DNA that is modified by intercalating a porphyrin compound, meso-tetrakis(N-methyl-4-pyridinium)porphyrin (TMPyP), into its base stacks. Intercalation was verified by a red shift and hypochromism of the Soret absorption peak. The DNA/porphyrin strands were then deposited onto oxidized silicon substrates which had been patterned with interdigitated electrodes, and blown dry. Electrical measurements were carried out under nitrogen, using illumination from a 445 nm laser; this wavelength falls within the absorption peak of the DNA/porphyrin complexes. When initially measured under dry nitrogen, the resulting device showed no photoconductivity or dark conductivity. However, at relative humidities of 30% and above we do observe dark conductivity, and also photoconductivity that grows with time. Photoconductivity gets larger at higher relative humidity. Remarkably, when the humidity is lowered again, some photoconductivity is now observed, indicating a change that persists for more than 24 hours. It may be that the humidity alters the structure of the DNA, perhaps allowing for better alignment of the bases.

8:36AM F47.00004 Optimization of a Quantum Biomimetic Photocell, NATHANIEL GABOR¹, VIVEK AJI, YAFIS BARLAS, University of California Riverside — We propose and describe the structure, function, and optimization of a biologically inspired two-channel quantum photocell. The photocell, which operates as a dual quantum heat engine, simultaneously performs the critical tasks of absorption, power conversion, and energy release. Graphene has been suggested as the stochastic solar photon irradiance, we determine the spectrum of optimal absorption characteristics and charge transfer probabilities necessary for the input supply to exactly meet the output demand. Strikingly, the regulation optimization spectrum peaks in the red and blue portions of the terrestrial solar irradiance, and exhibits close correspondence to the action spectrum of chlorophyll-based photosynthetic organelle. Moreover, a comparison of structure and function of the proposed two-color photocell to photosynthetic chlorophyll complexes in green plants may answer the question: why on Earth are terrestrial plants green?

8:48AM F47.00005 A Classical Theory of Multichromophoric Resonance Energy Transfer, SEBASTIAN DUQUE, Grupo de Física Atómica y Molecular, Instituto de Física, Facultad de Ciencias Exactas y Naturales, Universidad de Antioquia UdeA. Medellín, Colombia, Paul BRUMLER, Chemical Physics Theory Group, Department of Chemistry and Center for Quantum Information and Quantum Control, University of Toronto, Toronto, Canada, LEONARDO A. PACHON, Grupo de Física Atómica y Molecular, Instituto de Física, Facultad de Ciencias Exactas y Naturales, Universidad de Antioquia UdeA. Medellín, Colombia — Based on classical electrodynamics, a classical theory of multichromophoric resonance energy transfer is formulated. In the maximum coupling configuration between N₂ acceptors and N₃ donors, the present theory predicts a first-order-in-the-interactions enhancement of the energy transfer rate by a factor N₃ and additional second-order-in-the-interactions enhancement arising from the interaction between donors. The theory is applied to predict the transfer rate of the LH II and results are found to be in good agreement with experimental results.

9:00AM F47.00006 ABSTRACT WITHDRAWN —

9:12AM F47.00007 Coherent dimer dynamics in a dissipative environment maintained by an off-resonant single mode, ELLIOTT LEVI, BRENDON LOVETT, University of St Andrews — The role of quantum coherence in efficient energy harvesting has recently been the subject of intense research. In this paper, we explore the extent to which quantum coherence can be induced in a previously incoherent two level system (TLS) by strongly coupling to a single, off-resonant, bosonic mode. The rest of the environment is assumed to comprise a Markovian bath of bosonic modes. The TLS could, for example, represent the position of the exciton in an energy transfer dimer system. The TLS-single mode coupling strength is varied for several different forms of bath spectral density in order to assess whether the coherent dynamics of the TLS are modified. We find a clear renormalisation of the site population oscillation frequency, which also causes an altered interaction with the bath. This new interaction can cause enhanced or reduced coherent behaviour of the TLS depending on the parameters. We will discuss the usefulness and pitfalls of exploiting such a dynamics-altering tool in a quantum device.

9:24AM F47.00008 Identification of nucleobases using variable currents through graphene nanopores: A first principles study, J.T. HARALDSEN, Department of Physics and Astronomy, James Madison University, H. MCFARLAND, Department of Biology, James Madison University, T. AHMED, Theoretical Division, Los Alamos National Laboratory, J.-X. ZHU, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, A.V. BALATSKY, Institute for Materials Science, Los Alamos National Laboratory — Nanopore-based technology has the potential to be an efficient method for DNA/RNA base sequencing, as well as an identifier of other biomolecules. However, the thickness of the nanopore substrate is critical for the identification of individual nucleobases due to resulting noise and resolution problems. Recent work has been suggested as the possibility of nanopore substrates due to its atomic thickness and high strength. In this study, we examine a possible device mechanism for the voltage dependence of nucleobases passing through a graphene nanopore. We utilize density functional theory with a generalization gradient approach on a graphene ribbon with a nucleobase in order to calculate the transmission spectra for each base. Transmission spectra for each base allows for the calculation of the ballistic current and differential current as a function of voltage. We show that applying various bias voltages across a graphene ribbon for the general, energy-minimized position of the translocated nucleobase, it is possible to distinguish individual bases using the resulting current. Overall, our goal is to improve nanopore device design by helping to further DNA/RNA nucleobase identification and sequencing.

9:36AM F47.00009 Physical limits to biomechanical sensing, FARZAN BEROZ, CHASE P. BROEDERSZ, NED S. WINGREEN, Princeton University — Experiments have shown that eukaryotic cells such as fibroblasts and mesenchymal stem cells are able to accurately probe and respond to the elastic properties of their microenvironment. These cells navigate across gradients in stiffness, a phenomenon that has been called “ durotaxis.” Spatial heterogeneity in the cell’s elastic environment produces sampling noise in local probing of stiffness, which places fundamental limits on the accuracy with which a cell can sense stiffness gradients. To determine the biophysical limits of durotaxis, we develop a quantitative model of a cell as a stiffening-measuring device in a disordered fiber network with two dimensions. We find that local stiffness measurements follow a broad distribution spanning several orders of magnitude.

9:48AM F47.00010 Graphene Nanonet for Biological Sensor, NARAE SHIN, TAEKYEONG KIM, Seoul Natl Univ, JAESUNG PARK, Pohang University of Science and Technology, HYE JIN JIN, HYUNGWOO LEE, KYUNG-EUN BYUN, Seoul Natl Univ, CHANG-SEUK LEE, Soonchunhyang Univ, KWANG S. KIM, Pohang University of Science and Technology, BYUNG HEE HONG, Seoul Natl Univ, TAE HYUN KIM, Soonchunhyang Univ, SEUNGHUN HONG, Seoul Natl Univ — Graphene nanoribbons (GNRs) have been drawing attentions because they exhibited improved transconductances compared with graphene, and their edges could be functionalized with various chemicals or biological molecules. Herein, we developed a facile method to fabricate graphene nanonet (GNN) patterns over a large surface area for biological applications. In this method, the networks of V₂O₅ nanowires were adsorbed selectively in the desired regions on a graphene layer, and they were utilized as a shadow mask during the reactive ion etching on the graphene layer. This fabrication process allowed us to prepare large scale patterns of GNN structures which were comprised the continuous networks of GNRs with chemical functional groups on their edges. The chemical functional groups in the GNN could be functionalized with biological molecules such as DNAs for biological applications. Using the GNN-based biochip devices, we have successfully achieved the fluorescence imaging of the GNN channels and the electrical detection of the DNAs at InN concentrations. Our method could be a powerful strategy to mass-produce GNR-based devices and should enable various practical bio-applications.
10:00AM F47.00011 Optical detection of cellular activation by optical stimulation, SARMISHTHA SATPATHY, University of Texas at Arlington, SUBRATA BATBHYAL, University of Texas System, YOUNG-TAE KIM, SAMARENDRA MOHANTY, University of Texas at Arlington — Despite the many advantages of patch clamp recordings, there have been efforts to find alternative methods for measuring action potentials in neurons as electrode methodologies have limited spatial resolution, rely on mechanical stability, and are hence cumbersome to use. Here, we report use of optical methods that allow detection of cells with increased spatial information. We demonstrate use of calcium dyes or genetic voltage/ion indicators for optical detection of influx of Ca\(^{2+}\) ions as a measure of optical stimulation. We also show that phase information of light transmitted or reflected from the activated cell can be used to non-invasively measure changes in optical path length of the cells during optical activation. Further, we report use of polarized light for wide-field detection of optogenetically-stimulated activity in cells, requiring no exogenous labeling, making it possible to detect cellular activity with high spatial and temporal resolution by wide-field polarimetric/phase imaging. With optical detection of neural activities, the whole process of identification, activation and detection can be made non-invasive added with the advantages of high throughput and least requirement of mechanical stability and contamination.

10:12AM F47.00012 Ultra-low field T1 vs. T1rho at 3T and 7T: study of rotationally immobilized protein gels and animal brain tissues, HUI DONG, Shanghai Institute of Microsystem and Information Technology, Chinese Academy of Sciences, BEN INGLIS, Henry H. Wheeler Jr. Brain Imaging Center, University of California, Berkeley, IAN BARR, College of Chemistry, University of California, Berkeley, JOHN CLARKE, Department of Physics, University of California, Berkeley — Clinical magnetic resonance imaging (MRI) machines operating in static fields of typically 1.5 T or 3 T can capture information on slow molecular dynamics utilizing the so-called T1rho technique. This technique, along with frozen-density DFT to achieve efficient quantum-mechanical description of explicit solvent. Calculations have so far investigated copper ion attachment to CXXC motifs present in Atox1. The addition of the platinum ion and the competition between the two metals is currently being studied. These calculations could contribute towards accurate simulation of MR images/signals and extraction of parameters of clinical importance through comparison of the measured and the simulated images/signals.

10:24AM F47.00013 New formulation of Magnetization Equation for Flows Under NMR/MRI Excitation (I), DILIP DE, MOSES EMETERE, VICTOR OMOTOSHO, Covenant University — We have obtained for the first time from the Bloch NMR equations the correct dependence of the single component of magnetization, \(M_y\), and \(M_z\) at resonance (NMR/MRI) on relaxation times, if \(B_1\) field (pulsed or continuous), blood(nuclear spin) flow velocity, etc. in the rotating frame of reference. The equations are applicable for both CW and pulsed NMR experiments with or without flow of spins. Our approaches can be extended easily to include gradient fields and diffusion of spins, if needed in NMR/MRI experiments. We also discuss the application of our equations to a specific case of low excitation scheme: Free induction decay (FID). The first time new equations of single component of MR magnetization and further equations that can be derived with the methodologies used here, can be applied towards accurate simulation of MR images/signals and extraction of parameters of clinical importance through comparison of the measured and the simulated images/signals.

10:36AM F47.00014 The reference-probe model in avian magnetoreception, MARIA PROCOPIO, THORSTEN RITZ, University of California, Irvine — The sensory mechanism that allows magneto-sensitive organisms to detect the direction of the geomagnetic field for navigation purposes is still largely unclear. One of the two leading hypothesis stipulates that photoinduced radical-pair reactions in photoreceptor proteins act as the primary magnetic sensor in migratory birds. In recent years the radical-pair mechanism has been receiving considerable support, qualifying the avian compass as a plausible emergent property of photochemical reactions. However, the relevance of the reference character has not been studied yet. Here we introduce a method to investigate the contribution of the reference character to optimality and robustness. By analytical and computational studies, we find that the probe character is crucial for optimality, while the reference character captures robust features. Our results suggest the reference-probe model to contain both optimal and robust design features.

Tuesday, March 5, 2013 8:00AM - 10:48AM
Session F48 DBIO: Focus Session: Physics of Proteins I

10:00AM F48.00001 Reversible cluster formation in concentrated monoclonal antibody solutions, P. DOUGLAS GODFRIN, University of Delaware, LIONEL PORCAR, PETER FALUS, Institut Laue-Langevin, ISIDRO ZARRAGA, Genentech Inc., NORM WAGNER, University of Delaware, YUN LIU, University of Delaware/NIST — Protein cluster formation in solution is of fundamental interest for both academic research and industrial applications. Recently, industrial scientists are also exploring the effect of reversible cluster formation on biopharmaceutical processing and delivery. However, despite of its importance, the understanding of protein clusters at concentrated solutions remains scientifically very challenging. Using the neutron spin echo technique to study the short time dynamics of proteins in solutions, we have recently systematically studied cluster formation in a few monoclonal antibody (mAb) solutions and their relation with solution viscosity. We show that the existence of anisotropic attraction can cause the formation of finite-sized clusters, which increases the solution viscosity. Interestingly, once clusters form at relatively low concentrations, the average size of clusters in solutions remains almost constant over a wide range of concentrations similar to that of micelle formation. For a different mAb we have also investigated, the attraction is mostly induced by hydrophobic patches. As a result, these mAbs form large clusters with loosely linked proteins. In both cases, the formation of clusters all increases the solution viscosity substantially. However, due to different physics origins of cluster formation, solutions viscosities for these two different types of mAbs need to be controlled by different ways.

8:12AM F48.00002 Simultaneous Platinum and Copper Ion Attachment to a Human Copper Chaperone Protein, MIROSLAV HODAK, North Carolina State University, JOHN CVITKOVIĆ, Worcester Polytechnic Institute, COREY YU, OLEG DMITRIEV, University of Saskatchewan, GEORGE KAMINSKI, Worcester Polytechnic Institute, JERRY BERNHOLC, North Carolina State University — Cisplatin is a potent anti-cancer drug based on a platinum ion. However, its effectiveness is decreased by cellular resistance, which involves cisplatin attaching to copper transport proteins. One of such proteins is Atox1, where cisplatin attaches to the copper binding site. Surprisingly, it was shown that both cisplatin and copper can attach to Atox1 at the same time. To study this dual metal ion attachment, we use the KS/FD DFT method, which combines Kohn-Sham DFT with frozen-density DFT to achieve efficient quantum-mechanical description of explicit solvent. Calculations have so far investigated copper ion attachment to CXXC motifs present in Atox1. The addition of the platinum ion and the competition between the two metals is currently being studied. These calculations start from a molecular mechanics (MM) structural model, in which glutathione groups provide additional ligands to the Pt ion. Our goals are to identify possible Cu-Pt structures and to determine whether copper/platinum attachment is competitive, independent, or cooperative. Results will be compared to the 1H, 13C, and 31P NMR experiments, in which binding of copper and cisplatin to Atox1 produces distinct secondary chemical shift signatures, allowing for kinetic studies of simultaneous metal binding.

1H, 13C, and 31P NMR experiments, in which binding of copper and cisplatin to Atox1 produces distinct secondary chemical shift signatures, allowing for kinetic studies of simultaneous metal binding.

10:48AM F48.00003 Testing magnetic field changes inside the brain using ULF MRI, JOHN CLARKE, Department of Physics, University of California, Berkeley — The use of magnetic resonance imaging (MRI) for clinical applications has led to the development of high-field magnets and advanced MR pulse sequences. However, the use of magnetic resonance imaging (MRI) machines operating in static fields of typically 1.5 T or 3 T can capture information on slow molecular dynamics utilizing the so-called T1rho technique. This technique, along with frozen-density DFT to achieve efficient quantum-mechanical description of explicit solvent. Calculations have so far investigated copper ion attachment to CXXC motifs present in Atox1. The addition of the platinum ion and the competition between the two metals is currently being studied. These calculations start from a molecular mechanics (MM) structural model, in which glutathione groups provide additional ligands to the Pt ion. Our goals are to identify possible Cu-Pt structures and to determine whether copper/platinum attachment is competitive, independent, or cooperative. Results will be compared to the 1H, 13C, and 31P NMR experiments, in which binding of copper and cisplatin to Atox1 produces distinct secondary chemical shift signatures, allowing for kinetic studies of simultaneous metal binding.
8:24AM F48.00003 Native dynamics from diversity in NMR structures. HEIKO LAMMERT, JOSE ONUCHIC, Rice Univ — Protein function relies on the characteristic dynamics that arise in the protein’s unique native structure, controlled by the smooth, funneled energy landscape evolved to enable fast and reliable folding. Structure-based models draw on energy landscape theory to build an ideally funneled energy landscape only from a protein’s native structure. Simplified interactions of homogeneous strength are used to eliminate energetic frustration. The dynamics of the model are controlled by geometric constraints imposed by the native fold. The energy landscapes of many actual proteins are smooth enough to let such unfrustrated models describe their folding mechanisms. But conflicting functional demands upon the sequence may introduce sufficient frustration into the energetics to affect the dynamics. For such cases heterogeneous interactions can be optimized based on additional data. We use the diversity among the conformations deposited in a set of NMR structures to estimate the extent of fluctuations in the native state to build an improved model of protein S6. Qualitative modifications bring the observed mechanism into agreement with experiment, and matching of the entire fluctuation profile leads to similar contact maps as optimization based on either phi-values of sequence data.

8:36AM F48.00004 Redox-controlled proton gating in bovine cytochrome c oxidase I. JOSE ONUCHIC, Rice University — Cytochrome c oxidase is the terminal enzyme in the electron transfer chain of essentially all organisms that utilize oxygen to generate energy. It reduces oxygen to water and harnesses the energy to pump protons across the mitochondrial membrane in eukaryotes and the plasma membrane in prokaryotes. The mechanism by which proton pumping is coupled to the oxygen reduction reaction remains unresolved, owing to the difficulty of visualizing proton movement within the massive membrane-associated protein matrix. Here, with a novel hydrogen/deuterium exchange resonance Raman spectroscopy method, we have identified two critical elements of the proton pump: a proton loading site near the propionate groups of heme a, which is capable of transiently storing protons uploaded from the negative-side of the membrane prior to their release into the positive-side of the membrane and a conformational gate that controls proton translocation in response to the change in the redox state of hemeo. These findings form the basis for a postulated molecular model describing a detailed mechanism by which unidirectional proton translocation is coupled to electron transfer from heme a to heme a3, associated with oxygen chemistry occurring in the heme a1 site, during enzymatic turnover. Each time heme a undergoes an oxidation-reduction transition a proton is translocated across the membrane accounting for the observation that two protons are translocated during the oxidative phase of the enzyme cycle and two more are translocated during the reductive phase. This work was done in collaboration with Drs. Tsuyoshi Egawa and Syun-Ru Yeh.

9:12AM F48.00005 Dissecting the relationship between protein structure and sequence variation I, AMIR SHAHMORADI, CLAUS WILKE, Univ of Texas, Austin, WILKE LAB TEAM — Over the past decade several independent works have shown that some of the structural properties of proteins are capable of predicting protein evolution. The strength and significance of these structure-sequence relations, however, appear to vary widely among different proteins, with absolute correlation strengths ranging from 0.1 to 0.8. Here we present the results from a comprehensive search for the potential biophysical and structural determinants of protein evolution by studying more than 200 structural and evolutionary properties in a dataset of 209 monomeric enzymes. We discuss the main protein characteristics responsible for the general patterns of protein evolution, and identify sequence divergence as the main determinant of the strengths of virtually all structure-evolution relationships, explaining ~ 10 – 30% of observed variation in sequence-structure relations. In addition to sequence divergence, we identify several protein structural properties that are moderately but significantly coupled with the strength of sequence-structure relations. In particular, proteins with more homogeneous back-bone hydrogen bond energies, large fractions of helical secondary structures and low fraction of beta sheets tend to have the strongest sequence-structure relation.

9:24AM F48.00006 Develop Infrared Structural Biology for Probing Structural Dynamics of Protein Functions I, AIHUA XIE, ZHOUYANG KANG, OLIVER CAUSEY, CHARLES LIU, Oklahoma State University — Protein functions are carried out through a series of structural transitions. Lack of knowledge on functionally important structural motions of proteins impedes our understanding of protein functions. Infrared structural biology is an emerging technology with powerful applications for protein structural dynamics. One key element of infrared structural biology is the development of vibrational structural marker (VSM) database library that translates infrared spectroscopic signals into specific structural information. We report the development of VSM for probing the type, geometry and strength of hydrogen bonding interactions of buried COO− side chains of Asp and Glu in proteins. Quantum theory based first principle computational studies combined with bioinformatic hydrogen bond analysis are employed in this study. We will discuss the applications of VSM in mechanistic studies of protein functions. Infrared structural biology is expected to emerge as a powerful technique for elucidating the functional mechanism of a broad range of proteins, including water soluble and membrane proteins.

9:36AM F48.00007 ABSTRACT WITHDRAWN —

9:48AM F48.00008 ABSTRACT WITHDRAWN —

10:00AM F48.00009 Building toy models of proteins using coevolutionary information I, RYAN CHENG, MOHIT RAGHUNATHAN, JOSE ONUCHIC, Rice University — Recent developments in global statistical methodologies have advanced the analysis of large collections of protein sequences for coevolutionary information. Coevolution between amino acids in a protein arises from compensatory mutations that are needed to maintain the stability or function of a protein over the course of evolution. This gives rise to quantifiable correlations between amino acid positions within the multiple sequence alignment of a protein family. Here, we use Direct Coupling Analysis (DCA) to infer a Potts model Hamiltonian governing the coevolutionary information. We report the development of VSM for probing the type, geometry and strength of hydrogen bonding interactions of buried COO− side chains of Asp and Glu in proteins. Quantum theory based first principle computational studies combined with bioinformatic hydrogen bond analysis are employed in this study. We will discuss the applications of VSM in mechanistic studies of protein functions. Infrared structural biology is expected to emerge as a powerful technique for elucidating the functional mechanism of a broad range of proteins, including water soluble and membrane proteins.

If the temperature decreases under 0 °C during a cycle, the water situated between the grains experiences a strong dilatation during the freezing step and a contraction during the ice melting step. In this case, we show how the freeze-thaw transition affects the packing fraction of the pile.

We present experimental results concerning the effect of thermal cycling on the packing fraction of equal spheres with the presence of water. First, we minimize the effect of avalanching and shear localization. We observe that the resistance against deformation of the wet (partially saturated) sand is much smaller than that of the dry sand, and that the latter dissipates more energy under flow. Second we show experimentally that the sliding friction on sand is greatly reduced by the addition of some— but not too much—water. The formation of capillary water bridges increases the shear modulus of the sand, which is smaller than that of the dry sand, and that the latter dissipates more energy under flow. Second we show experimentally that the sliding friction on sand is greatly reduced by the addition of some— but not too much—water. The formation of capillary water bridges increases the shear modulus of the sand, which facilitates the sliding.

In the present study, we perform analogous simulations for wet particles. We account for capillary and viscous interaction forces between particles, which result from the liquid bridges, and allow for liquid transfer between the particles and the liquid bridge. It is found that the bifurcation of the inertial regime observed with van der Waals force has been shown to lead to bifurcation of the inertial regime into two regimes: (a) a cohesive rate-independent regime and (b) an inertial regime. In the present study, we perform analogous simulations for wet particles. We account for capillary and viscous interaction forces between particles, which result from the liquid bridges, and allow for liquid transfer between the particles and the liquid bridge. It is found that the bifurcation of the inertial regime observed with van der Waals interaction persists for capillary cohesion and that the span of the cohesive rate-independent regime increases with liquid loading in the pendular regime. A simple model for steady shear rheology is obtained by blending the results in various regimes. The presentation will also discuss the effect liquid viscosity on the flow behavior.
9:24AM F49.00006 Flow and clogging of submerged hoppers. JUHA KOIVISTO, DOUGLAS DURIAN, University of Pennsylvania. The discharge rate for granular hoppers was recently found to depend on the filling height when the hopper is submerged in water. This effect is further studied with an automated experimental setup consisting of cylindrical flat bottomed hoppers with various diameters and orifices. The grains are spherical glass beads of diameter 1.1 ± 0.1 mm. The flow rate is measured with an electric scale connected to a computer. With this, we confirm the counterintuitive surge in the flow rate as the filling height decreases toward zero. We also find a similar surge for dry gains, but the size of the effect is much smaller and the knowledge is previously unseen. In both cases we notice that the flow of grains near the wall changes from creep like behavior to mass flow as the hopper diameter decreases. The hypothesis for the surge effect is changes in compaction stresses and force chains. To alter such behavior, on-going work includes changing the fluid pressure and flow rate near the orifice as well as changing the roughness of the walls. Work has also begun on clogging for small orifices in submerged hoppers, where preliminary observations show an exponential distribution of flow durations.

9:36AM F49.00007 Armoring, stability, and transport driven by fluid flow over a granular bed. BENJAMIN ALLEN, ARSHAD KUDROLLI, Department of Physics, Clark University. We discuss experiments investigating the evolution of a granular bed by a fluid flow as a function of shear rate at the fluid-bed interface. This is a model system to investigate a variety of physical examples including wind blowing over sand, sediment transport in rivers, tidal flows interacting with beaches, flows in slurry pipelines, and sand proppants in hydraulic fracturing. In order to examine the onset and entrainment of the granular bed under steady state conditions, we have constructed a novel conical rheometer system which allows a variable amount of shear to be applied to the granular bed. The grain-fluid system is index matched so that we can visualize the grains away from the sides as well as visualize the fluid flow above and below the interface by using fluorescent tracer particles. We demonstrate that the onset of erosion arises as particles rotate out of their stable position highlighting the importance of torque balance to onset. We find significant armoring of the bed, as the bed is sheared by the fluid flow. Above onset, at least three distinct regions of bed mobility can be found. We will discuss the measured integrated granular flux as a function of shear rate and compare them with empirical laws found in the geophysical literature.

9:48AM F49.00008 Creep and Dynamical Heterogeneities of Fluid-Driven Granular Flows. CARLOS ORTIZ, MORGANE HOUSSAIS, DOUGLAS DURIAN, DOUGLAS JEROLMACK, Univ of Pennsylvania. Earth’s surface is a fluid-sediment interface evolving through fluid-driven granular flow. To probe long-time dynamics, we construct an annular chamber that mimics an infinitely-long river channel. We use non-Brownian, spherical plastic grains, fully submerged in a less dense index-matching fluid. We drive the packs with a laminar flow and record dynamics by laser scanned particle tracking. “Bed load” grains near the surface exhibit relatively fast shear. By long-time averaging grain trajectories, we find that grains deep in the pack, which appear frozen by eye, exhibit a slow creep dynamics. The transition between bed load and creep occurs at a critical value of the local relaxation time, characterized by a critical dimensionless shear rate, the viscous number. We also characterize the important length and time scales for dynamical heterogeneities as a function of depth and find that grain dynamics are spatially and temporally heterogeneous at all depths. The dynamics slow down monotonically as a function of depth, but the domain size is largest at the transition to creeping. We propose a new phase diagram for fluid-sheared granular transport, where “bed load” sediment transport is defined as a dense granular flow driven by fluid shear from above and granulic creep from below.

10:00AM F49.00009 Onset and cessation of grain motion in riverbed erosion experiments. JULIA SALEVAN, ABRAM CLARK, Yale University, MARK SHATTUCK, City College of New York, COREY O’HERN, NICHOLAS OUELLETTE, Yale University. Erosion due to fluid flow plays a principal role in shaping landscapes. However, the complexity of the coupling between hydrodynamic shear, sediment transport, and internal granular bed rearrangements limits our understanding of the particle-scale physics that governs erosion. In particular, it is unclear whether particle rearrangements as a function of depth and find that grain dynamics are spatially and temporally heterogeneous at all depths. The dynamics slow down monotonically as a function of depth, but the domain size is largest at the transition to creeping. We propose a new phase diagram for fluid-sheared granular transport, where “bed load” sediment transport is defined as a dense granular flow driven by fluid shear from above and granulic creep from below.

10:12AM F49.00010 Jamming and unjamming in model riverbeds. ABE CLARK, JULIA SALEVAN, Yale University, MARK SHATTUCK, City College of New York, NICHOLAS OUELLETTE, COREY O’HERN, Yale University. When fluid flows laterally over a granular bed, it exerts shear stress on the particles. The ratio of this stress to the gravitational stress is known as the Shields number, and bulk sediment transport is thought to occur once the Shields number has passed a critical threshold. However, the particle-scale mechanisms that control this transition are not well understood. Here, we perform molecular dynamics simulations of a model riverbed to understand the particle-scale origins of jamming and unjamming in these systems. The particles interact via purely repulsive harmonic forces and are coupled to the flow using a Stokes-like drag model. The interstitial fluid velocity is determined from the local packing density using a relation similar to Darcy’s law. Near the transition to sediment transport, we observe hysteresis and avalanches, and connect their statistical properties to the packing geometry at the particle scale.

10:24AM F49.00011 Erosion and flow of hydrophobic granular materials. BRIAN UTTER, THOMAS BENNS, BENJAMIN FOLTZ, JOSEPH MAHLER, James Madison University. We experimentally investigate submerged granular flows of hydrophobic and hydrophilic grains both in a rotating drum geometry and under erosion by a surface water flow. While slurry and suspension flows are common in nature and industry, effects of surface chemistry on flow behavior have received relatively little attention. In the rotating drum, we use varying concentrations of hydrophobic and hydrophilic grains of sand submerged in water rotated at a constant angular velocity. Sequential images of the resulting avalanches are taken and analyzed. High concentrations of hydrophobic grains result in an effectively cohesive interaction between the grains forming aggregates, with aggregate size and repose angle increasing with hydrophobic concentration. However, the formation and nature of the aggregates depends significantly on the presence of air in the system. We present results from a related experiment on erosion by a surface water flow designed to characterize the effects of heterogeneous granular surfaces on channelization and erosion.

10:36AM F49.00012 Fluid and particulate suspension flows at fracture junctions. TAK S. LO, JOEL KOPLIK, The Levich Institute and the Physics Department, City College of New York, CUNY. Suspended particles can be a serious problem in geological contexts such as fluid recovery from reservoirs because they alter the rheology of the flowing liquids and may obstruct transport by narrowing flow channels due to deposition or gravitational sedimentation. In particular, the irregular geometry of the fracture walls can trap particles, induce jamming and cause unwanted channeling effects. We have investigated particle suspension flows in tight geological fractures using lattice Boltzmann methods in the past. In this work we extend these studies to flows at a junction where two fractures intersect, an essential step towards a complete understanding of flows in fracture networks. The fracture walls are modeled as realistic self-affine fractal surfaces, and we focus on the case of tight fractures, where the wall roughness, the aperture and the particle size are all comparable. The simulations provide complete detail on the particle configurations and the fluid flow field, from which the stresses in the fluid and the forces acting on the bounding walls can be computed. With these information, phenomena such as particle mixing and dispersion, mechanical responses of the solid walls, possible jamming and release at junctions, and other situations of interest can be investigated.

8:00AM F50.00001 Controlling disordered materials from the boundaries1. A. ALAN MIDDLETOWN, SEAN SWEENEY, Syracuse University — We study general models of materials with frozen disorder, such as spin glasses or solids with heterogeneities, and ask how domain walls or optical fracture surfaces can be controlled by selection of the boundary conditions on the surface of a given sample. We have developed and applied algorithms for optimal ground states that can explore all possible sets of boundary conditions (e.g., the boundary conditions for a disordered Ising model on a square lattice with sides \( L \), with sizes up to \( L = 2048 \)) and thereby rapidly determine all possible paths for domain walls for certain two-dimensional models. We apply this algorithm to uncorrelated and power-law correlated disorder. While this computation has implications for the uniqueness of the ground state in disordered magnetic materials, it fits within a broader set of questions on the sensitivity of the interior of disordered material, as might be seen in the force chains in a given granular packing, when one considers all possible boundary conditions. Interior regions that are shielded by disorder from boundary effects then act as rigid sets of degrees of freedom.

8:12AM F50.00002 Connecting glassy dynamics to micro-scale elasticity. WENHAI ZHENG, MATTIEU WYART, DAVID PINE, Center for Soft Matter Research, Department of Physics, New York University — We report a new experimental method for exploring the connection between the dynamics and structure in colloidal glasses. Using ellipsoids of controlled size and eccentricity as passive micro-probes, we explore the rheological properties of the local environment of the colloidal glass, in particular fluctuations in the local elasticity. We do this by measuring the random fluctuations in the rotational motion of the probe ellipsoids using depolarized light scattering. This is facilitated by index matching the spherical colloidal particles that form the glass to the background fluid: the only optical contrast is provided by the ellipsoids. Decoupling the optical anisotropy from the eccentricity of the probe particles further enhances the sensitivity of the probe to rotational motion.

8:24AM F50.00003 Jamming and free energy landscapes for three caged soft disks. XIN DU, Graduate student, ERIC WEEKS, Professor — We use a Monte Carlo simulation to study jamming in a model of three soft Brownian disks with harmonic repulsive potential confined in a circular corral. For large corrals, the disks can freely rearrange where one particle passes in between the other two, but for small corrals rearrangements become rare. Rearrangement events correspond to the system crossing over the energy barrier. With low temperature and/or small corral size, the energy barrier becomes larger and the system approaches a glass transition. We calculate the Helmholtz free energy from the distribution of configurations in the system and quantify both the entropic and potential components of the free energy barrier. In a hard disk model, the free energy barrier for rearrangements is entirely entropic. By comparing the entropic component of the soft model to a model of hard disks, we model the soft disks as hard disks with a temperature-dependent effective size. We find that our results are generalizable to other soft disk potentials as well.

8:36AM F50.00004 Microscopic Theory of Activated Penetrant Diffusion in Liquids and Glasses. RUI ZHANG, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — We formulate a force-level, self-consistent, nonlinear Langevin equation theory for the long-time diffusivity of a penetrant in molecular and polymeric supercooled liquids and glasses. The theory predicts that for a wide range of penetrant to matrix molecular unit size ratios (\( R \)), activated hopping is the dominant transport mechanism. The penetrant diffusivity (\( D \)) and jump distance exhibit different R-dependences in three dynamic regimes: \( R<0.5 \), \( 0.5<R<1 \), \( R>1 \), which are physically distinguished by the nature of the matrix motion required to facilitate hopping. The penetrant diffusion constant decreases the fastest with \( R \) in the first regime where the matrix behaves as a harmonic amorphous solid. The other two regimes involve larger scale, anharmonic matrix motions. Below and above the matrix glass transition temperature, \( D \) exhibits an Arrhenius and supra-Arrhenius temperature dependence, respectively. The reduction of \( D \) associated with penetrant-matrix attractive forces has also been studied. Our approach to theoretical calculations agrees reasonably well with experiments for both fast transport (e.g., gas permeation) and slow transport (e.g., barrier materials) systems, covering more than 10 orders of magnitude of variation of the diffusion constant.

8:48AM F50.00005 Antiferromagnetic Ising Model in Hierarchical Networks1. XIANG CHENG, STEFAN BOETTCHER, Department of Physics, Emory University — The Ising antiferromagnet is a convenient model of glassy dynamics. It can introduce geometric frustrations and may give rise to a spin glass phase and glassy relaxation at low temperatures [1]. We apply the antiferromagnetic Ising model to 3 hierarchical networks which share features of both small world networks and regular lattices. Their recursive and fixed structures make them suitable for exact renormalization group analysis as well as numerical simulations. We first explore the dynamical behaviors using simulated annealing and discover an extremely slow relaxation at low temperatures. Then we employ the Wang-Landau algorithm to investigate the energy landscape and the corresponding equilibrium behaviors for different system sizes. Besides the Monte Carlo methods, renormalization group [2] is used to study the equilibrium properties in the thermodynamic limit and to compare with the results from simulated annealing and Wang-Landau sampling.

9:00AM F50.00006 Protein crowding in solution, frozen, and freeze-dried states: small-angle neutron and X-ray scattering study of lysozyme/sorbitol/water systems. SUSAN KRUEGER, NIST, SHEILA KHODADADI, Delft Univ. of Tech., NICHOLAS CLARK, NIST and Amgen, ARNOLD MCAULEY, Amgen, VIVIANA CRISTIGLIO, ILL, NARAYANAN THIYENCHERI, ESF, JOSEPH CURTIS, NIST, EVGENIY SHALAEV, Allergan — For effective preservation, proteins are often stored as frozen solutions or in glassy states using a freeze-drying process. However, aggregation is often observed after freeze-thaw or reconstitution of freeze-dried powder and the stability of the protein is no longer assured. In this study, small-angle neutron and X-ray scattering (SANS and SAXS) have been used to investigate changes in protein-protein interaction distances of a model protein/cryoprotectant system of lysozyme/sorbitol/water, under representative pharmaceutical processing conditions. The results demonstrate the utility of SANS and SANS methods to monitor protein crowding at different stages of freezing and drying. The SANS measurements of solution samples showed at least one protein interaction peak corresponding to an interaction distance of \( \sim 90 \text{ Å} \). In the frozen state, two protein interaction peaks were observed by SANS with corresponding interaction distances at \( 40 \text{ Å} \) as well as \( 90 \text{ Å} \). On the other hand, both SANS and SAXS data for freeze-dried samples showed three peaks, suggesting interaction distances ranging from \( \sim 15 \text{ Å} \) to \( 170 \text{ Å} \). Possible interpretations of these interaction peaks will be discussed, as well as the role of sorbitol as a cryoprotectant during the freezing and drying process.
9:12AM F50.00007 Typical Value of Susceptibilities in the Three Dimensional Edwards-
Anderson Spin Glass Model in an External Field, SHENG FENG, KA-MING TAM,
Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA, YE FANG, J. RAMANULIJA,
JE Division School of Electrical Engineering and Computer Science, Louisiana State University, Baton Rouge, LA 70803, USA, JUANA MORENO, MARK JARRELL,
Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA. — We study the Edwards-Anderson model on a simple cubic lattice with a
finite constant external field using a Monte Carlo simulation code, which employs graphics processing units to dramatically speedup the simulation. Conventional indicators, such as the Binder ratio and correlation length, do not show any signs of a phase transition. We also studied R12, or the ratio of spin glass susceptibilities at finite wavenumbers, and show it is quite noisy that a systematic analysis cannot come to clear conclusion. This is largely due to the fact that the susceptibilities follow a broad, fat-tailed distribution, and the average is possibly dominated by rare events. Therefore we propose to study the typical value of these parameters by taking the geometric average over different disorder realizations, and compare it with the average linear measurements. We argue that the typical value should be also studied in additional to conventional linear average value, to provide another perspective for the study of phase transition in spin glasses.

9:24AM F50.00008 Dimensional dependence of mobility correlations and dynamic heterogeneity
in two-dimensional and three-dimensional glass forming fluids, ELIJAH FLENNER,
GRZEGORZ SZAMEL, Colorado State Univ — We examine mobility correlations and heterogeneous
dynamics in simulations of glass-forming two-dimensional and three-dimensional binary Lennard-Jones fluids. We compare the relationships between the dynamic correlation length $\xi_d$, the dynamics susceptibility $\chi_d$, and the alpha-relaxation time $\tau_\alpha$, by analyzing four-point structure factors $S_3(q,t)$ that are designed to investigate heterogeneous dynamics. We find that the relationships between $\xi_d$, $\chi_d$, and $\tau_\alpha$ depend strongly on dimension. Specifically, in two dimensions these relationships depend on whether the underlying dynamics is Newtonian or Brownian, but there is no dynamics dependence in three dimensions. Furthermore, in systems undergoing Newtonian dynamics $\xi_d$ grows much faster with $\tau_\alpha$ in two-dimensions than three-dimensions. Therefore, we demonstrate that dynamic heterogeneities have different properties in two and three dimensional glass forming fluids.

9:36AM F50.00009 Correlations of structure and dynamics in colloidal supercooled liquids.
MOYOSORE ODUNSI, ERIC WEEKS, Emory Univ — We are studying the correlations between measured quantities in colloidal samples that are in equilibrium. We track the movement of particles in systems using confocal microscopy. We see correlations between a particle’s displacement during short time scales and its long term displacement. In addition, we look at correlations between a particle’s displacement during different time scales and structural variables such as its vononoi volume or local volume fraction. We study how these correlations vary as the colloidal volume fraction approaches the glass transition volume fraction.

9:48AM F50.00010 Measurement of Stress Networks in 3D Colloidal Glasses, NEIL LIN,
MATTHEW BIERBAUM, JAMES SETHNA, ITAI COHEN, Department of Physics, Cornell University — We measure the inhomogeneous stress fields in a 3D colloidal glass by using a confocal microscope to image a binary suspension’s microstructure. Despite extensive studies of the contact forces in static systems (e.g., granular systems and emulsions), it has been difficult to measure these inhomogeneous stress fields in thermal systems. We determine these particle level Brownian stresses from all particle positions using the “Stress Assessment from Local Strucutural Anisotropy” (SALSA) method. First, we show that SALSA method accurately reports the stress field of a colloidal glass at particle-level resolution using molecular dynamics simulations. Furthermore, we quantify the measured pressure statistics and examine the q-model, Edwards ensemble and other theoretical predictions. Finally, the SALSA method enables us to investigate the underlying origin of the mechanical heterogeneities by comparing stress distribution with particle configuration.

10:00AM F50.00011 Physical Aging in a Colloidal Glass Subjected to Concentration Jump
Conditions, XIAOGUANG PENG, GREGORY B. MCKENNA, Department of Chemical Engineering, Texas Tech University, Lubbock, 79409, Texas, USA. — We have prepared a thermo-sensitive core-shell PS-PNIPAM/AA latex system and have investigated the aging dynamics of its colloidal dispersions subsequent to the temperature (or concentration)-jump perturbations using sequential creep experiments to probe the response of the system. The aging experiments were performed in the vicinity of the glass transition concentration, or temperature as evidenced by the strongly varying relaxation time with decreasing temperature (or increasing concentration). The aging results from the current colloidal glass study are compared with those expected in the Kovacs’ catalogue of experiments in structural recovery of glassy polymers, viz., intrinsic isotherms, asymmetry of approach and memory events [1]. We found that colloidal glass displays aging behavior and time-aging-time superposition is valid here. There are similarities in aging dynamics between colloidal glasses and molecular glasses, and differences also persist.

We gratefully thank the National Science Foundation under the Grant No. CBET 1133279 and the John R. Brandyford Endowment at Texas Tech University and each partially support this work.

10:12AM F50.00012 Structural signatures of dynamic heterogeneities in monolayers of colloidal
ellipsoids, ZHONGYU ZHENG, YUREN WANG, Institute of Mechanics, Chinese Academy of Sciences, YIOLONG HAN, Hong Kong University of Science and Technology — When a liquid is supercooled towards the glass transition, its dynamics drastically slows down, whereas its static structure remains relatively unchanged. Finding a structural signature of the dynamic slowing-down is a major challenge, yet it is often too subtle to be uncovered. Here we discover the structural signatures for both translational and rotational dynamics in monolayers of colloidal ellipsoids by video-microscopy experiments and computer simulations. The correlation lengths of the dynamic slowest-moving clusters, the static glassy clusters, the static local structural entropy and the dynamic heterogeneity follow the same power-law divergence, suggesting that the kinetic slowing down is caused by a decrease in the structural entropy and an increase in the size of the glassy cluster. Ellipsoids with different aspect ratios exhibit single- or double-step glass transitions with distinct dynamic heterogeneities. These findings demonstrate that the particle shape anisotropy has important effects on the structure and dynamics of the glass. The power-law divergence of the static correlation length with exponent -1 suggests that the glass transition is likely a two-dimensional Ising-type critical phenomenon.

10:24AM F50.00013 Dynamics approaching the 2D colloidal glass transition, SKANDA VIVEK,
ERIC WEEKS, Emory University — We make 2D colloidal glasses by allowing bidisperse silica particles of diameters 2.53 and 3.38 $\mu$m to settle down under gravity in a monolayer at a coverslip interface. Controlling the area fraction gives us a wide range of behaviour, from liquid-like to supercooled and glassy. We use this model glass forming system to study the dynamics on approaching the glass transition, in 2D. We measure the increasing alpha relaxation times as the area fraction is increased toward the glass transition. We measure the growth of dynamical heterogeneity on approaching the glass transition. We quantify dynamical heterogeneity through the non-Gaussian parameter and the four point susceptibility $\chi_4$. Further, we measure the probability of local cage rearrangements as a function of waiting time (time since quench), for different area fractions, and relate this to other dynamical quantities such as diffusion coefficients, dynamical heterogeneity, etc. For glassy samples, we observe the slowing down of mean square displacements with waiting time, a sign of aging.
bubbles do not present a threat to humans, as their brains develop at the same speed as people’s, and begin their life as naive as an infant. I show that evolved brains that can learn can be transplanted onto physical robots, who then learn about our world by interacting with it. Such robots can learn to play games like chess. I will discuss what I believe is the central reason behind this failure, and how using the biological process of evolution can overcome that problem. For over fifty years, engineers have attempted to achieve machine intelligence that rivals human performance, but with only limited success in some specialized arenas such as chess. Session F51 DCMP GSOFT DPOLY: Invited Session: Smart Assemblies: Self-Replication, Computation and Error-Free Self-Assembled Systems  
Grand Ballroom C1 - Pablo Damasceno, University of Michigan

8:00AM F51.00001 Self-Replication of Colloidal Clusters , MICHAEL BRENNER, Harvard University — No abstract available.

8:36AM F51.00002 The Evolutionary Path Towards Sentient Robots , CHRIS ADAMI, Michigan State University — For over fifty years, engineers have attempted to achieve machine intelligence that rivals human performance, but with only limited success in some specialized arenas such as chess. I will discuss what I believe is the central reason behind this failure, and how using the biological process of evolution can overcome that problem. I show that evolved brains that can learn can be transplanted onto physical robots, who then learn about our world by interacting with it. Such robots do not present a threat to humans, as their brains develop at the same speed as people’s, and begin their life as naive as an infant.

9:12AM F51.00003 Simple self-replicators: growth via self-assembly and fissioning via bursting bubbles , DAMIEN WOODS, California Institute of Technology — We explore the principles of and experimentally demonstrate an autonomous and natural scheme for molecular self-replication. The talk will discuss a design for a simple DNA self-replicator that in principle exhibits exponential population growth, is limited by resource consumption, and has the potential to exhibit complicated population dynamics such as competition between species for a common food source. The replicating species are DNA nanotubes made from single-stranded tiles. Our proposed model for self-replication is designed around two basic principles that are ubiquitous on the Earth, and indeed on any oceanic world with crashing waves: growth via molecular self-assembly and fragmentation via violent hydrodynamic flows in bursting bubbles. The talk will focus on recent work to carefully characterise and understand both of these principles. In particular, on the nucleation and growth properties of various kinds, or species, of single-stranded tile nanotubes, and on the capability of bursting bubbles to break these micron-length structures. The proposed experimental system is conceptually very simple, completely autonomous, has the potential for information-based evolution, exploits energy from the environment to release replicated structures, and uses physically plausible mechanisms that could be implicated in the origin of life. The is joint work with collaborators Erik Winfree, Bernard Yurke, Joy Hui and Rizal Hariadi.

9:48AM F51.00004 Self-Replication, Exponential Growth, Selection and Competition in Artificial Systems , PAUL CHAIKIN, New York University — Self-replication and evolution under selective pressure are inherent phenomena in life, but few artificial systems exhibit these phenomena. We have designed a process and a system of DNA origami tiles that exponentially replicate a seed pattern, doubling the copies in each diurnal-like cycle of temperature and UV illumination, producing more than 7 million copies in 24 cycles. We use this system to demonstrate exponential selection: two similarly-growing sub-populations, one with a “red” dye incorporated, the other with a “green” dye, can be controlled by colored light. The light heats one species reducing its replication rate. The progeny of the non-absorbing species replicate preferentially and take over the system. The species selection is enhanced by competition for a resource, critical crosslinking strands required for replication. This addressable selectivity of different constituents in the same solution should be adaptable to the selection and evolution of multi-component nanoscopic-microscopic self-replicating materials. Materials that multiply exponentially and can be selected for specific properties may provide a new paradigm for design from the nanoscopic to the microscopic. Further such systems can provide insights into diverse problems ranging from the origin of life to information, computation and materials science.

1:04AM F51.00005 Self-assembly of multicomponent structures near and far from equilibrium , STEVE WHITELAM, Lawrence Berkeley National Laboratory —

Tuesday, March 3, 2015 8:00AM - 11:00AM
Session F52 DCMP: Invited Session: Tunable Topological States in Monolayer and Bilayer Graphene  
Grand Ballroom C2 - Allan MacDonald, University of Texas at Austin
8:00AM F52.00001 Direct capacitive probe of valley order in a bilayer graphene quantum Hall ferromagnet. ANDREA YOUNG, University of California, Santa Barbara — Bilayer graphene is a highly tunable quantum Hall system: both the spin and valley splitting can be manipulated independently of the electron density. Recent experiments have revealed a rich phase diagram of gapped ground states corresponding to diverse spin/valley isospin polarizations; however, all of these studies are indirect, relying on the dependence of features associated with gapped states on electric or magnetic field to infer the isospin ordering of these states. In this talk, I will describe a capacitive technique capable of directly detecting the valley component of the isospin order. By sensitively measuring the difference in capacitance between top and bottom gates of a dual-gated bilayer graphene device, we extract layer-charge response—the tendency of the layer polarization to change in response to a change in chemical potential of the entire bilayer. The asymmetric capacitance reflects the ground state layer polarization, and thus, in the zero Landau level (zLL), the valley polarization. In agreement with theoretical expectations, we find that the phase diagram of the octet zLL is, for the most part, characterized by the filling of pairs of degenerate sublevels with different orbital quantum numbers. Surprisingly, however, we also observe numerous additional states at intermediate electric fields, associated with an "odd" layer occupation. Finally, we find that phase transitions between states with different layer polarization are characterized by large anomalies in the asymmetric capacitance, which persist well into the compressible state of the Landau level.

8:36AM F52.00002 Topological phases in the zeroth Landau level of bilayer graphene. ZLATKO PAPIC, Perimeter Institute — Over the past years, a remarkable variety of novel correlated states was discovered in graphene and its bilayer in a magnetic field. These states exhibit previously unseen richness due to an interplay of electron spin, valley and orbital degrees of freedom. They are further enriched by their high degree of tunability, e.g. via the in-plane magnetic or the perpendicular electric field, which allows one to probe their properties in a more flexible and direct way than in GaAs semiconductor systems. In this talk I will present a theoretical overview of the phase diagram of the partially-filled zeroth Landau level of bilayer graphene. Using realistic large-scale numerical calculations[1] that incorporate strong mixing between orbitally degenerate sublevels, as well as the screening of the Coulomb interaction, we identify several robust quantum Hall states with odd denominators such as ν = −4/3, −5/3, −8/5. Although these states bear some relation to their more familiar analogs in GaAs, their collective excitations are expected to be different, as we illustrate on an example of the ν = −1 state that acquires a neutral gap in bilayer graphene. Furthermore, we find evidence for the existence of an incompressible, even-denominator ν = −1/2 state, and argue that this state is in the universality class of the non-Abelian Moore-Read state or its particle-hole conjugate, while other candidates such as the 331 state are unlikely to describe it. Finally, it will be shown that symmetry breaking, induced by an electric field applied perpendicular to the basal plane, is a useful experimental knob to tune the quantum phase transitions between integer or fractional states in bilayer graphene at a fixed filling factor[2]. These results illustrate the potential of bilayer graphene as a model platform to study the emergent topologically ordered phases and transitions between them via symmetry breaking.[1] Z. Papic and D. Abanin, Phys. Rev. Lett. 112, 046602 (2014). [2] Patrick Maher, Lei Wang, Yuanda Gao, Carlos Forsythe, Takashi Taniguchi, Kenji Watanabe, Dmitry Abanin, Zlatko Papic, Paul Cadden-Zimansky, James Hone, Philip Kim, and Cory R. Dean, Science 345, 61-64 (2014).

9:12AM F52.00003 Even-denominator fractional quantum Hall effect in multi-terminal suspended bilayer graphene. ALBERTO MORPURGO, University of Geneva — I will discuss magneto-transport experiments through multi-terminal suspended bilayer graphene devices of very high quality (mean-free path larger than the device size; density of charge inhomogeneity 10⁻⁷ cm⁻²). The multi-terminal geometry enables independent measurements of the longitudinal and transverse magneto resistance, which are essential to properly measure quantum Hall states. At high magnetic field, different fractional states emerge on the hole side, including states at ν = −4/3 and ν = −1/2 that are fully developed (plateau in Rₓᵧ quantized with an accuracy better than 0.5%, and a concomitant minimum in Rₘᵧ) and other states (e.g., at −5/2, −2/3, −8/5), which manifest themselves through a small change in a clear minimum in Rₓᵧ. These results are consistent with predictions of recent theory by Papic and Abanin, that describes the mixing of the degenerate, zero-energy N=0 and N=1 Landau levels of graphene bilayers due to e-e interactions, and which indicates that the even denominator ν = −1/2 state is of the Moore-Read type. If time allows, I will also discuss our recent experiments of suspended multi-terminal 4-layer graphene, on which we made different interesting observations. One is an integer quantum Hall effect consistent with an even larger degeneracy of the E=0 Landau levels, for which it may be interesting to start exploring theoretically possible new physics in the fractional regime. The second is the occurrence of an unexpected gapped insulating state at zero magnetic field. Together with previous experiments on suspended monolayer, bi, and trilayers, this observation points to an even-odd effect of e-e interaction (at zero magnetic field) in graphene multilayers: even layers are gapped by e-e interactions while odd layers stay conducting, due to the presence of a Dirac-like band in their electronic structure. A comparison of the gapped state in bilayers and four-layers show that the magnitude of the effect of e-e interaction is not becoming smaller with increasing layer thickness, suggesting that interactions remain important even in even thicker layers.

I am grateful to my collaborators, D.K. Ki, A. Grushina, D. Abanin, V. Falko, M. Koshino, E. McCann, M. Potemski, C. Fagueras, A. Nicolet.

9:48AM F52.00004 Electron-hole asymmetry in the integer and fractional quantum Hall effect in bilayer graphene. ANGELA KOU, Yale University — The nature of fractional quantum Hall (FQH) states is determined by the interplay between the Coulomb interaction and the symmetries of the system. The unique combination of spin, valley, and orbital degeneracies in bilayer graphene is predicted to produce an unusual and tunable sequence of FQH states. In this talk, I will present local electronic compressibility measurements of the lowest Landau level in bilayer graphene performed using a scanning single-electron transistor. In the integer quantum Hall regime, we find that the background compressibility between filling factors breaks particle-hole symmetry and instead obeys a ν → ν+ 2 symmetry. We also find the above-mentioned ν → ν+ 2 symmetry in the FQH regime; we observe incompressible FQH states at filling factors ν = 2p + 2/3 with hints of additional states appearing at ν = 2p+ 3/5, where p = −2, −1, 0 and 1. These observations highlight the importance of the orbital degeneracy for many-body states in bilayer graphene.

10:24AM F52.00005 Chemical potential and tunneling in bilayer graphene using double bilayer graphene heterostructures.1 EMANUEl TUTUC, The University of Texas at Austin — Vertical heterostructures consisting of atomic layers separated by insulators can open a window to explore the role of electron interaction in these materials, otherwise not accessible in single layer devices. We describe here one such heterostructure, consisting of two bilayer graphene flakes separated by a hexagonal boron-nitride dielectric. Using the top layer as a resistively detected Kelvin probe we map the chemical potential of the bottom bilayer graphene as a function of electron density, perpendicular magnetic field, and transverse electric field. At zero magnetic field the chemical potential reveals a strongly non-linear dependence on density, with an electric field induced energy gap at charge neutrality. The data allow a direct measurement of the electric field-induced bandgap at zero magnetic field, the orbital Landau level energies, and the broken symmetry quantum Hall state gaps in high magnetic fields[1]. In samples where the two layers are rotationally aligned the interlayer tunneling current measured as a function of interlayer bias reveals a gate-tunable negative differential resistance thanks to momentum conserving tunneling[2]. Remarkably, the resonance width has a weak temperature dependence in the range 1.5 K to 200 K.

Session F53 GMAG DCMP: Invited Session: Physics at Magnetic Interfaces, Both Engineered and Unexpected  Grand Ballroom C3 - Barry Zink, University of Denver

8:00AM F53.00001 Kondo Physics at Interfaces in Metallic Non-Local Spin Transport Devices

Chris Leighton, University of Minnesota — Despite the maturity of metallic spintronics there remain large gaps in our understanding of spin transport in metals, particularly with injection of spins across ferromagnetic/non-magnetic (FM/NM) interfaces, and their subsequent diffusion and relaxation. Unresolved issues include the limits of applicability of Elliott-Yafet spin relaxation, quantification of the influence of defects, surfaces, and interfaces on spin relaxation at nanoscopic dimensions, and the importance of magnetic and spin-orbit scattering. The non-local spin-valve is an enabling device in this context as, in addition to offering potentially disruptive applications, it allows for the separation of charge and spin currents. One particularly perplexing issue in metallic non-local spin valves is the widely observed non-monotonicity in the T-dependent spin accumulation, where the spin signal actually decreases at low T; in contrast to simple expectations. In this work, by studying an expanded range of FM/NM combinations (encompassing NiO, Fe2O3, Ni, Fe, Co, Cu, and Al), we demonstrate that this effect is not a property of a given FM or NM, but rather of the FM/NM pair. The non-monotonicity is in fact strongly correlated with the ability of the FM to form a dilute local magnetic moment in the NM. We show that local moments, resulting in this case from the ppm-level tail of the FM/NM interdiffusion profile, suppress the injected spin polarization and diffusion length via a novel manifestation of the Kondo effect, explaining all observations associated with the low T downturn in spin accumulation [1]. We further show: (a) that this effect can be promoted by thermal annealing, at which point the conventional charge transport Kondo effect is simultaneously detected in the NM, and (b) that this suppression in spin accumulation can be quenched, even at interfaces that are highly susceptible to the effect, by insertion of a thin non-moment-supporting interlayer. Important implications for room temperature devices will be discussed.

8:36AM F53.00002 Spin-orbit torques in magnetic bilayers

Paul Haney, National Institute for Standards and Technology — Spintronics aims to utilize the coupling between charge transport and magnetic dynamics to develop improved and novel memory and logic devices. Future progress in spintronics may be enabled by exploiting the spin-orbit coupling present at the interface between thin film ferromagnets and heavy metals. In these systems, applying an in-plane electrical current can induce magnetic dynamics in single domain ferromagnets, or can induce rapid motion of domain wall magnetic textures. There are multiple effects responsible for these dynamics. They include spin-orbit torques and a chiral exchange interaction (the Dzyaloshinskii-Moriya interaction) in the ferromagnet. Both effects arise from the combination of ferromagnetism and spin-orbit coupling present at the interface. There is additionally a torque from the spin current flux impinging on the ferromagnet, arising from the spin hall effect in the heavy metal. Using a combination of approaches, from drift-diffusion to Boltzmann transport to first principles methods, we explore the relative contributions to the dynamics from these different effects. We additionally propose that the transverse spin current is locally enhanced over its bulk value in the vicinity of an interface which is oriented normal to the charge current direction.

9:12AM F53.00003 Anomalous net magnetization in collinear antiferromagnets with uncompensated surfaces

Frances Hellman, UC Berkeley Physics and Materials Sciences and Engineering Departments, and Materials Sciences Division, LBNL — Like ferromagnets (FM), antiferromagnets (AFM) exhibit spontaneous long-range spin order below a transition temperature. The traditional FM order parameter is the spontaneous magnetization, while that of a simple AFM is the staggered magnetization, sometimes called the Neel vector N. The net magnetization M of a perfect AFM is (seemingly) zero at all temperatures T; however, defects such as vacancies, grain boundaries, and even surfaces create an M(T) which has a non-trivial relationship to the staggered magnetization N(T), even in ideal systems. As a specific example, we consider AFM CoO, which consists of AFM-coupled FM (111) planes; (111)-oriented epitaxial films with an odd number of planes will exhibit non-zero M due to uncompensated surfaces. These uncompensated surfaces were used to produce an artificially-structured FM semiconductor using epitaxial layers of AFM CoO with a doped semiconductor Al:ZnO (AZO). Both M(T) and the anomalous Hall effect show oscillatory behavior with thickness of either CoO (odd vs even numbers of planes) or AZO (~1 nm RKKY-like oscillations related to the AZO Fermi wavevector due to electron-induced coupling between Co moments at its two CoO surfaces). Mean field theory and Monte Carlo simulations show that M(T) of collinear AFM such as CoO with uncompensated surfaces exhibits T-dependence unlike that of N(T), of the absolute value of its individual layers, or m(T) of any single atomic plane including the uncompensated surface, due to incomplete cancellations of different planes. This phenomenon is valid even in the limit of semi-infinite systems; it is a topological state due to the presence of a free surface. Modifications of surface exchange coupling (leading to ordinary or extraordinary transitions), due to electron correlations in these Mott insulators, changes in crystal fields, spin-orbit coupling, or an incomplete (rough) surface, result in compensation points and highly non-Brillouin-like M(T).

9:48AM F53.00004 Interface-induced magnetism and strong correlation in oxide heterostructures

Susanne Stember, University of California, Santa Barbara — Two-dimensional electron gases (2DEGs) at interfaces between two insulating oxides have attracted significant attention because they can exhibit unique properties, such as strong electron correlations, superconductivity and magnetism. In this presentation, we will discuss the emergent properties of 2DEGs in SrTiO3 quantum wells that are interfaced with Mott insulating rare earth titanates (RTIO3). We show that the magnetic properties of the 2DEG can be tuned to be either (incipient) ferromagnetic or (incipient) antiferromagnetic, depending on the specific RTIO3 that interfaces it. The thickness of the quantum well is a critical tuning parameter and determines the onset of magnetism, the proximity to a quantum critical point, and the onset of non-Fermi liquid behavior for those quantum wells that are in proximity to an antiferromagnetic transition. We will also discuss the role of symmetry-lowering structural transitions in the quantum well.
growth of bilayers. We detail our CVD synthesis of the monolayer TMDs (MoS\textsubscript{2}, WSe\textsubscript{2}) that are produced in quantities exceeding a million tons a year annum are a good example. In recent years, techniques honed to cater for the high-\texttau; superconductor boom have been applied to produce a range of oxide thin films and nanoparticles, which exhibit magnetic properties that are quite different to those of the bulk material. Oxide-oxide interfaces are full of surprises, especially when one of them is polar, inducing electronic reconstruction to avoid a polar catastrophe. The formation, location and magnetism of the resulting two-dimensional electron gas will be discussed. The data give lie to the common assumption of additivity of the magnetism of a thin film and its substrate. More puzzling is the elusive temperature-independent, anhysteretic magnetism of some thin films and nanoparticles, which cannot be accommodated in the current paradigm of magnetism in solids. Classical micromagnetic analysis would suggest that only a tiny fraction of the sample volume is involved (\approx 10^{-3} for thin films, \approx 10^{-6} for nanoparticles), yet there are no signs of collective magnetic order such as increasing coercivity at low temperatures or a Curie point at high temperature. The anhysteretic magnetisation curve is temperature-independent (unlike that of a superparamagnet). In CeO\textsubscript{2} nanoparticles there is a characteristic length scale of order 100 nm required for the appearance of the anomalous magnetic response. We propose that an analogy to terms of giant orbital paramagnetism due to coupling with zero-point fluctuations of the vacuum electromagnetic field, which predicts a magnetization curve of the form \textit{M} = M_{0}\left(1+x^{2}\right)^{1/2}, where \textit{x} = \textit{CB}; the constant \textit{C} corresponds to the characteristic wavelength and lengthscale, 330 nm in this case.

Tuesday, March 3, 2015 11:15AM - 2:15PM
Session G1 DMP: Focus Session: Beyond Graphene - Growth I
001A - John Schaibley, University of Washington

11:15AM G1.00001 An In-Plane Epitaxial Heterostructure of Two-Dimensional Crystals. GONG GU, University of Tennessee, Knoxville — By adapting the concept of epitaxy to two-dimensional (2D) space, a single-atomic-layer, in-plane heterostructure of a prototypical material system, graphene and hexagonal boron nitride (h-BN), has been grown. It is shown by multiple complementary experimental techniques that monolayer crystalline h-BN grows from fresh edges of monolayer graphene with lattice coherence, forming an abrupt 1D interface. The challenges of obtaining truly 2D heterostructures with lattice coherence and sharp interface unassisted by templates in the third dimension will be discussed. Importantly, the h-BN lattice orientation is solely determined by the graphene, forging configurations favored by the supporting substrate, a polycrystalline Cu foil with an anisotropic (100) surface. To illustrate this important feature of heteropaxty in 2D, this talk will briefly discuss the graphene/Cu(100) and h-BN/Cu(100) orientational relations when the two materials are grown alone on Cu foils. For a counterintuitive reason, when grown alone, h-BN strictly aligns to Cu(100) exhibiting four and only four symmetrically equivalent orientations, while graphene shows a wide spread of rotations. The energetically favored h-BN/Cu(100) orientational alignment is overridden when h-BN is grown as an “epistrip” templated by a graphene edge. This talk will allude to the interesting physics of the 1D boundary states that has been theoretically predicted, such as spin polarization. As an intermediate step towards establishing the long-predicted planar magnetic properties of graphene, this work reports on the scanning tunneling microscopy and tunneling spectrum mapping, although the sought-after spin polarization is destroyed by the presence of the Cu substrate.

This work was partially supported by DARPA (approved for public release; distribution is unlimited) and NSF (ECCS-1231808). A portion of this research was conducted at the Center for Nanophase Materials Sciences (CNMS), sponsored at Oak Ridge National Laboratory through the Scientific User Facilities Division, by Office of Basic Energy Sciences, US Department of Energy (DOE), who also supported the work at Sandia under contract DE-AC04-94AL85000. Support received by contributors to the work also includes: Natural Science Foundation of China (Grants 11034006 and 11204286), National Key Basic Research Program of China (Grant 2014CB921103), and the Laboratory Directed Research and Development Program of Oak Ridge National Laboratory. Computational resources at the National Energy Research Scientific Computing Center of the US DOE were used.

11:51AM G1.00002 Wafer-Scale Monolayer Films of Semiconducting Metal Dichalcogenides for High-Performance Electronics. SAIEN XIE, KIBUM KANG, LUIJIE HUANG, YIMO HAN, PINSHANE HUANG, KIN FAI MAK, CHEOL-JOO KIM, DAVID MULLER, JIWWONG PARK, Cornell University — Two-dimensional semiconducting transition metal dichalcogenides (TMDs) have shown their potential in electronic and photonic devices, with complete knowledge of the electronic properties, controlled synthesis of ultrathin films has enabled the demonstration of materials with limited structural and electrical uniformity, hindering further technological applications. Here we present a 4-inch scale growth of continuous monolayer molybdenum disulphide (MoS\textsubscript{2}) and tungsten disulphide (WS\textsubscript{2}) films that show excellent structural and electrical uniformity over the entire wafer using metal-organic chemical vapor deposition. The resulting monolayer films show high mobility of 30 cm\textpersecond;\textpervolt\textpercentimeter\textsuperscript{2} at room temperature, as well as the phonon-limited transport of MoS\textsubscript{2} regardless of the channel length and device location. They allow for the batch fabrication of monolayer MoS\textsubscript{2} field effect transistors with a 99% yield, which display spatially-uniform n-type transistor operation with a high on/off ratio. We further demonstrate the multi-level growth and fabrication of vertically-stacked monolayer MoS\textsubscript{2} films and devices, which could enable the development of novel three-dimensional circuitry and device integration.

12:03PM G1.00003 Synthesis and Investigation of van der Waals Heterostructures. KATHLEEN MCREARY, AUBREY HANBICKI, JAMES CULBERTSON, BEREND JONKER, Naval Research Laboratory — The recent isolation of single-nanometer MX\textsubscript{2} (M = Mo, W; X = S, Se, Te) TMDs has demonstrated that reducing dimensionality can alter the material properties. In particular, MoS\textsubscript{2}, MoSe\textsubscript{2}, WSe\textsubscript{2}, and WS\textsubscript{2} exhibit an abrupt transition from indirect to direct bandgap semiconductors at monolayer thickness. Monolayer TMDs are promising materials for electronic components due to their high mobility, high on/off ratio, and low standby power dissipation. Additionally, selective layer-by-layer stacking to form vertically-stacked monolayer MoS\textsubscript{2} films and devices, which could enable the development of novel three-dimensional circuitry and device integration.

12:15PM G1.00004 Large Area Growth and Characterization of Monolayer MoS\textsubscript{2}. PAYAM TAHERI, Physics Department, The State University of New York at Buffalo, JIEQIONG WANG, Department of Materials Science, Xin Jiaotong University, China, HUI SITNG, Physics Department, The State University of New York at Buffalo, JOEL DESTINO, Chemistry Department, The State University of New York at Buffalo, FRANK BRIGHT, Chemistry Department, The State University of New York at Buffalo, ATHOS PETROU, HAO ZENG, Physics Department, The State University of New York at Buffalo — Two-dimensional transition metal dichalcogenides have garnered extensive attention due to their direct band gap with great potential in semiconductor application complementing graphene. While most of the experiments were carried out on either exfoliated films or CVD grown crystals, sample size are restricted in hundreds of micrometers. Synthesis of large-area samples was less successful. Here, we report the growth of cm\textsuperscript{2}-scale molybdenum disulphide (MoS\textsubscript{2}) monolayer with a facile method by sulfurizing molybdenum trioxide film on sapphire substrates. Uniformity and quality of the monolayer films were verified by Raman, PL mapping and PL efficiency. A quasi- molten phase of the precursor in the initial stage of the reaction is found to be crucial for the monolayer growth.
12:27PM G1.00005 Direct growth of hexagonal boron nitride on epitaxial graphene1, PATRICK MENDE, JUN LI, RANDALL FEENSTRA, Carnegie Mellon University - Department of Physics — In this work, we demonstrate recent attempts at achieving the direct growth of hexagonal boron nitride (h-BN) on epitaxial graphene. By exposing our graphene samples (grown on Si-face SiC) to a low-pressure (~1 × 10⁻⁴ Torr) background of borazine at temperatures exceeding 1000°C, we obtain in-situ low-energy electron diffraction patterns consistent with the presence of many randomly oriented grains of h-BN. We find that increasing the growth temperature leads to the development of a preferential orientation, with the h-BN aligning with the underlying SiC substrate. Atomic-force microscopy and low-energy electron microscopy (LEEM) show triangular crystals exceeding 1 μm in extent. Additionally, using a first-principles method for examining low-energy electron reflectivity spectra, we are capable of determining the coverage of h-BN on our samples. We show that our method is sufficiently robust to discriminate between various combinations of numbers of h-BN monolayers (MLs) and graphene MLs based on unique features in their spectra. Prospects for improvement of the h-BN crystallinity, as well as the controlled growth of a specific number of MLs are discussed.

1This work was supported in part by the Center for Low Energy Systems Technology (LEAST), one of the six SRC STARnet Centers, sponsored by MARCO and DARPA.

12:39PM G1.00006 Chemically controlled dislocation migration in two-dimensional MoS₂, XIAOLONG ZOU, MINGJIE LIU, BORIS YAKOBSON, Department of Materials Science and NanoEngineering, Dept. of Chemistry, and Smalley Institute for Nanoscale Science and Technology, Rice University — As an additional Gibbs degree of freedom, chemical potential plays an important role in determining various properties of hetero-elemental two-dimensional (2D) materials, ranging from the equilibrium shape [1], to defect structures [2,3], electronic [3], and magnetic properties [4]. Here, by first-principles calculations, we demonstrate how the chemical potential control can be adopted as a feasible strategy to tune the dislocation dynamics in 2D MoS₂. Depending on the structures of the migrating dislocations, two different dynamic mechanisms are revealed, either through the direct bond-rebinding (BR) mechanism, where only single metal atom moves significantly, or concerted migration (CM), in which case several atoms rearrange concurrently. The migration barriers for CM mechanism could be 2 to 4 times larger as the BR ones. Our detailed analyses show that under certain range of chemical potential some dislocations with high mobility could nevertheless also have quite high stability, which opens up the possibility of enhanced plasticity and suggests intriguing future applications.

12:51PM G1.00007 Growth, transfer, structural, optical, and electrical properties of large-size transition-metal dichalcogenide monolayer single-crystals1, ZHENG YANG, BO HSU, JIAO XIAO, GEORGE POULOS, Univ of Illinois - Chicago, YANG RESEARCH GROUP TEAM — We report growth, transfer process, as well as structural, optical, and electrical properties of large-size and high-quality two-dimensional transition-metal dichalcogenide MX₂ (M=Mo, W; X=S, Se) single-crystalline triangular-shape nanosheets composed of one to a few monolayers. A vapor-trapping enhanced chemical vapor deposition approach was employed for the MX₂ monolayer single crystal growth. The number of layers, crystallinity, and uniformity of the as-grown MX₂ were characterized and confirmed by Raman and photoluminescence measurements. The MX₂ monolayer single-crystal triangles show comparable size and uniformity to the state-of-the-art results reported as of now. The optical properties of the MX₂ were studied based on the analysis of the photoluminescence results. The electrical properties including resistivity, mobility, carrier type and concentration, and contact resistance of the MX₂ were characterized by both three-terminal field-effect transistor and Hall effect transport measurements. The Hall bar devices were fabricated by lithography and dry-etching of the as-grown single-crystalline MX₂. The transfer process of the MX₂ from growth substrate (SiO₂-on-Si) to various substrates was successfully demonstrated.

1Acknowledgement to the funding support from Ignite Award.

1:03PM G1.00008 Vacancy-induced growth of inversion domains in transition-metal dichalcogenide monolayer: an atomic view of defect dynamics, JUNHAO LIN, Vanderbilt University/ORNL, WU ZHOU, ORNL, SOKRATES PANTELIDES, Vanderbilt University — In this work, we systematically study the nucleation and growth of inversion domains within a monolayer MoSe₂. We use a focused electron beam to generate and excite Se vacancies in the monolayer, and monitor their dynamics through sequential atomic-scale Z-contrast imaging. We find that Se vacancies are first randomly created and then preferentially agglomerate into line defects under the energy transferred from the electron beam. Successive evolution of these line defects induces nucleation of distinct triangular inversion domains within the MoSe₂ layer and generates conductive 60⁰ grain boundaries within the semiconducting matrix. Density functional theory shows that the nucleation of inversion domain lowers the system energy due to the release of vacancy-induced lattice shrinkage. Migration of the grain boundaries can be further activated by deformation of the peripheral lattice, giving rise to the growth of the inversion domain. The grain nucleation and growth process observed under energy transferred from the electron beam can provide new insights into the structural stability of TMDC monolayers under severe (e.g. high temperature) working conditions.

1:15PM G1.00009 Development of Novel Two-dimensional Layers, Alloys and Heterostructures, ZHENG LIU, School of Materials Science & Engineering, Nanyang Technological University, Singapore — The one-atom-think graphene has fantastic properties and attracted tremendous interests in these years, which opens a window towards various two-dimensional (2D) atomic layers. However, making large-size and high-quality 2D layers is still a great challenge. Using chemical vapor deposition (CVD) method, we have successfully synthesized a wide varieties of binary 2D materials. Ternary 2D alloys including BCN and MoS₂-Se₂(1−x) are also prepared and characterized. In addition, synthesis of 2D heterostructures such as vertical and lateral graphene/h-BN, vertical and lateral TMDs are also demonstrated. Complementary to CVD grown 2D layers, 2D single-crystal (bulk) such as Phosphorene (P), WTe₂, SnSe₂, PtS₂, PtSe₂, PdSe₂, WSe₂Te₂(1−x), Ta₃N₅Se, and T₄₄N₄Se₄ are also prepared by solid reactions. There work provide a better understanding of the atomic layered materials in terms of the synthesis, atomic structure, alloying and their physical properties. Potential applications of these 2D layers e.g. optoelectronic devices, energy device and smart coating have been explored.
1:27PM G1.00010 The kinetics of white graphene (h-BN) growth on the planarized Ni foil surfaces1, MYUNG JONG KIM, HYUNJIN CHO, SUNGCHAN PARK, KIST, DONG-IL WON, SANG OOK KANG, Korea University, SEONG-SOO PYO, DO-CHAN KIM, SOO-MIN KIM, KIST, HWAN CHUL KIM, Chonbuk National University, KIST COLLABORATION, KOREA UNIVERSITY COLLABORATION, CHONBUK NATIONAL UNIVERSITY COLLABORATION — Morphology of the surface and the grain orientation of the metal catalysts have been considered as two important factors for the growth of h-BN by a CVD method. We report correlation between growth rate of h-BN and orientation of nickel grains. The surface of the nickel foil was first planarized by electrochemical polishing and subsequently annealed in atmospheric pressure hydrogen to suppress the effect from the surface morphology. The atmospheric annealing with hydrogen reduced nucleation site of h-BN such that large crystal size mainly has grown from the grain boundary and has no nucleation sites in the nickel foil. Higher growth rate of h-BN was observed from the nickel grains that has (110) or (100) orientation due to higher surface energy.

1:39PM G1.00011 Nanoscale topographical replication of graphene architecture by manufactured DNA nanostructures, YOUNGKWON MOON, Department of Physics, Sungkyunkwan University, JIHOON SHIN, Sungkyunkwan Advanced Institute of Nanotechnology (SAINT), Sungkyunkwan University, SOONBEOM SEO, Department of Physics, Sungkyunkwan University, SUNG HA PARK, Department of Physics, Sungkyunkwan Advanced Institute of Nanotechnology (SAINT), Sungkyunkwan University, JOUNG REAL AHN, Department of Physics, Sungkyunkwan University — Despite many studies on how geometry can be used to control the electronic properties of graphene, certain limitations to fabrication of designed graphene nanostructures exist. Here, we demonstrate controlled topographical replication of graphene by artificial deoxyribonucleic acid (DNA) nanostructures. Owing to the high degree of geometrical freedom of DNA nanostructures, we controlled the nanoscale topology of graphene. The topography of graphene replicated from DNA nanostructures showed enhanced thermal stability and revealed an interesting negative temperature coefficient of sheet resistivity when underlying DNA nanostructures were denatured at high temperatures.

1:51PM G1.00012 Seeded Growth of Highly Crystalline Molybdenum Disulphide Monolayers at Controlled Locations, CARL NAYLOR, GANGHEE HAN, NICHOLAS KLYBERT, JINGLIE PING, A.T. CHARLIE JOHNSON, Univ of Pennsylvania — Various approaches have been demonstrated for growth on insulating substrates of molybdenum disulphide (MoS₂), but to date growth of isolated crystalline flakes has been only at random locations. We have developed a method to obtain MoS₂ flakes in precisely defined locations. By patterning molybdenum source material that acted both as material feedstock and growth seed at predetermined areas across a wafer, we were able to grow isolated flakes of MoS₂ at these locations with micrometre-scale resolution. These MoS₂ flakes are predominantly of monolayer thickness and high material quality, as confirmed by atomic force microscopy, transmission electron microscopy, Raman and photoluminescence spectroscopy. Since the monolayer flakes are isolated and in predetermined locations, fabrication of transistor structures requires only a single lithographic step. Thus we are able to obtain multiple arrays of MoS₂ transistors, that are highly crystalline and monolayer, making this method ideal for large scale production. Device measurements showed a carrier mobility and on/off ratio that exceeded 10 cm²/V·s and 10⁶, respectively. This growth technique provides a path for in-depth physical analysis of monolayer MoS₂ as well as fabrication of MoS₂-based integrated circuits.

2:03PM G1.00013 Wafer-scale arrayed p-n junctions based on few-layer epitaxial GaTe, XIANG YUAN, LEI TANG, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai 200433, China, WEIDAHU, National Laboratory for Infrared Physics, Shanghai Institute of Technical Physics, Chinese Academy of Sciences, Shanghai 200033, China, FAXIAN XIU, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai 200433, China — Two dimensional (2D) materials have showed appealing applications in electronics and optoelectronics. Gapless graphene presents ultra-broadband and fast photosponse while the 2D semiconducting MoS₂ and GaTe exhibit highly sensitive and tunable responsivity to the visible light. However, the device yield and its repeatability call for a further improvement of 2D materials to render large-scale uniformity. Here we report 2D material growth of the wafer-scale GaTe by molecular beam epitaxy. To develop the arrayed p-n junctions, the few-layer GaTe was grew on three-inch Si wafers. The resultant diodes reveal good rectifying characteristics and photoresponse with maximum photodetection responsivity of 2.74 A/W and photovoltaic external quantum efficiency up to 62%. The photocurrent reaches saturation very fast within 22 μs and shows no sign of device degradation after 1.37 million cycles of operation. Most strikingly, such high performance has been achieved across the entire wafer, making the volume production of devices accessible. Finally, several photo-images was acquired by using these photodiodes with a reasonable contrast and resolution, demonstrating for the first time the potential for these 2D technology coming into the real life.

11:15AM G2.00001 k·p theory for two-dimensional transition metal dichalcogenide semiconductors, ANDOR KORMANYOS, GUIDO BURKARD, University of Konstanz — We present k·p Hamiltonians (for a review see [1]) parametrised by ab initio density functional theory calculations to describe the dispersion of the valence and conduction bands at their extrema (the K, Q, Γ, and M points of the hexagonal Brillouin zone) in atomic crystals of semiconducting monolayer transition metal dichalcogenides. We review the parametrisation of the essential parts of the k·p Hamiltonians for MoS₂, MoSe₂, WS₂, and WSe₂, including the spin-splitting and spin-polarisation of the bands We use k·p theory to analyse: i) optical transitions in two-dimensional transition metal dichalcogenides over a broad spectral range; ii) to discuss magnetotransport properties of the charge carriers in the K and −K valleys.

11:27AM G2.00002 Magneto-optics in WSe₂ and MoSe₂ monolayers1, BERNHARD URBASZEK, GANG WANG, LOUIS BOUET, ETIENNE PALLEAU, MAEL VIDAL, XAVIER MARIE, THIERRY AMAND, Toulouse University - CNRS — We perform photoluminescence (PL) experiments at T=4K on MoSe₂ and WSe₂ in magnetic fields up to 9T applied perpendicular to the monolayer (ML) plane. In both systems the neutral exciton is spectroscopically well separated from the charged exciton (trion). For both exciton complexes in both systems we observe a clear Zeeman splitting of the order of -2meV at 9T between the σ⁺ and σ⁻ polarized PL components, from the K⁺ and K⁻ valley, respectively. The extracted g-factors for both exciton complexes in both materials are of the order of g ≈ -4. This indicates a dominant contribution from the transition metal valence band d-orbitals to the exciton magnetic moment, contributions from the valley magnetic moments are discussed. In ML MoSe₂ the exciton valley polarization can be tuned with the magnetic field, independent of the excitation laser polarization. In the investigated ML WSe₂ sample the evolution of the valley polarization depends for the trion both on the applied magnetic field and the excitation laser helicity, for the neutral exciton only on the latter. In the absence of optical orientation, the trion polarization amplitude increases linearly with the applied magnetic field, albeit with opposite signs in MoSe₂ compared to WSe₂.

1We acknowledge partial funding from ERC Grant No. 306719.
11:39 AM G2.00003 Experimental evidence for dark excitons in monolayer transition metal dichalcogenide crystals, XIAOXIAO ZHANG, YUMENG YOU, Columbia University, FRANK ZHAO, Harvard University, TONY HEINZ, Columbia University — Transition metal dichalcogenides in the family of MoS$_2$, WSe$_2$, and WTe$_2$ have been identified as direct-gap semiconductors in the limit of monolayer thickness. In addition to the optically bright states associated with dipole-allowed excitonic transitions between these bands, it is predicted that excitonic states will form that are optically dark either because of momentum or spin selection rules. In this paper, we report studies of the temperature dependence of the bright exciton population using photoluminescence and time-resolved photoluminescence spectroscopy. The experimental results indicate the presence of dark states lying below the optically bright states in some members of this family of materials. These states, unlike the usual bright states, are not constrained by rapid radiative decay and offer new avenues for control of the valley and spin degrees of freedom.

11:51 AM G2.00004 Probing the valley Hall effect in MoS$_2$ transistors, KIN FAI MAK, Penn State University — Two-dimensional (2D) atomic layers of molybdenum disulfide (MoS$_2$) possess a new valley degree of freedom (DOF) that has finite Berry curvatures. As a result, not only optical control of the valley DOF is allowed, but each valley is also predicted to exhibit an anomalous Hall effect whose sign depends on the valley index. In this talk, we will discuss our recent observation of this new valley Hall effect (VHE) in monolayer MoS$_2$ transistors. This is manifested experimentally as a finite anomalous Hall effect when circularly polarized light is used to preferentially excite electrons into a specific valley. We will describe the dependence of the anomalous Hall conductivity on photon helicity, photon energy, doping levels and crystal symmetry, and will compare these observations with theoretical predictions. Possibilities of using the valley DOF as an information carrier in next-generation electronics and optoelectronics will also be discussed.

12:27 PM G2.00005 Magneto-optical Kerr effect in Transition Metal Dichalcogenides, RYUJI SUZUKI, Department of Applied Physics and Quantum Phase Electronics Center (QPEC), University of Tokyo, SANDOR BORDACS, Budapest university of technology and economics, YOSHINORI TOKURA, YOSHIIRO IWASA, RIKEN CENTER for Emergent Matter Science (CEMS); Department of Applied Physics and Quantum Phase Electronics Center (QPEC), University of Tokyo — Transition-metal dichalcogenides (TMDs) are attracting a great deal of interest beyond graphene materials because of their rich physical properties. The key of the monolayer TMDs in contrast to the bulk is the broken inversion symmetry, which results in novel valley properties, coupled with spins through their strong spin-orbit interaction. On the other hand, 3R-MoS$_2$ is known to keep the broken inversion symmetry and thus strong valley polarization in PL spectra even in multilayers, providing opportunities to investigate properties of monolayers with use of bulk materials and the stacking dependent properties between the 2H (centrosymmetric) and 3R-non-centrosymmetric) [R. Suzuki et al., Nat. Nano. 9, 611 (2014)]. In this presentation, we report comparative studies of 3R MoS$_2$ and 2H series of TMDs on magnetooptical properties, with a particular focus on magneto-optical Kerr effect (MOKE) spectroscopy. We found systematic evolution of MOKE spectra in the 2H series of TMDs, and more interestingly, that 3R polytypes displayed significant difference not only in exciton dimensionality and but also in the $g$ values estimated from the excitons peak splitting in the MOKE spectra. Discussion will be given based on the electronic structures and the spin-orbit interactions.

12:39 PM G2.00006 Valley entanglement of carriers in monolayers of transition-metal dichalcogenides, ALEXEY BELYANIN, Texas A&M University, MIKHAIL TOKMAN, Institute of Applied Physics, Russian Academy of Sciences — The entanglement of two quantum systems or ensembles is usually considered as a result of coupling between them. This coupling can be mediated by classical electromagnetic fields. At the same time, one can also entangle non-interacting quantum systems by a quantum field. Here we consider the optical excitation of electron-hole or exciton states near the band gap of a transition-metal dichalcogenide monolayer in two valleys K and K' with opposite valley indices. We show that a linearly polarized single-photon field in a cavity or a stationary stream of linearly polarized single photons gives rise to an efficient entanglement of non-interacting carriers in different valleys, i.e. the generation of electron states entangled with respect to the valley degree of freedom. An intuitive explanation of this effect is that the carriers "view" linearly polarized photons as entangled left- and right-circularly polarized photon states. Valley entanglement of carriers gives rise to peculiar properties of the reemitted optical field and photocurrent fluctuations.

12:51 PM G2.00007 Electrical Valley Excitation by Spin Injection in Monolayer Transition Metal Dichalcogenide Heterojunction, YU YE, XIAOBO YIN, University of California, Berkeley, HAILONG WANG, Institute of Semiconductors, Chinese Academy of Sciences, ZILIANG YE, HANYU ZHU, YUAN WANG, University of California, Berkeley, JIANHUA ZHAO, Institute of Semiconductors, Chinese Academy of Sciences, XIZANG ZHANG, University of California, Berkeley — Embracing the spin degree of freedom of charge carriers enables nonvolatile electronic with increased operation speed and reduced power consumption. Recently discovered atomic materials of monolayer transition metal dichalcogenides (TMDs) possess unbalanced carrier distribution in the momentum space and introduce a new independent valley of freedom. Here we demonstrate experimentally the unique spin and valley locking relationship in TMDs and report a new scheme of electronic devices taking advantages of both degrees of freedoms. A valley-polarized light-emitting device is achieved experimentally through spin injection using (Ga, Mn)As as a spin aligner. The electrical generation and the control of valley polarization in TMD semiconductors through spin manipulation opens the new dimension in utilizing both spin and valley degrees of freedom for next-generation electronics and computing.

1:03 PM G2.00008 Interplay of spin, valley and layer pseudospins in folded MoS$_2$ bilayers, TAO JIANG, HENGUI LIU, DI HUANG, SHUAI ZHANG, YINGGUO LI, XINGAO GONG, Fudan University, YUEN-RON SHEN, Fudan University and University of California at Berkeley, WEI-TAO LIU, SHIWEI WU, Fudan University — Two dimensional material such as graphene and transition metal dichalcogenide is beyond graphene materials because of their rich physical properties. The key of the monolayer TMDs in contrast to the bulk is the broken inversion symmetry, which results in novel valley properties, coupled with spins through their strong spin-orbit interaction. Different from sheet paper, each of two dimensional materials has its own crystal lattice. In two-dimensional materials one can also entangle non-interacting quantum systems by a quantum field. Here we consider the optical excitation of electron-hole or exciton states near the band gap of a transition-metal dichalcogenide monolayer in two valleys K and K' with opposite valley indices. In this talk, we will present our recent study of folded MoS$_2$ bilayers, which were obtained by folding exfoliated MoS$_2$ monolayers. As characterized by second harmonic generation and photoluminescence, folded bilayers can exhibit broken inversion symmetry and reduced interlayer coupling, evoking strong valley and/or spin polarization that results in valley-mixed states. We show that a linearly polarized single photon field in a cavity or a stationary stream of linearly polarized single photons gives rise to an efficient entanglement of non-interacting carriers in different valleys, i.e. the generation of electron states entangled with respect to the valley degree of freedom. An intuitive explanation of this effect is that the carriers "view" linearly polarized photons as entangled left- and right-circularly polarized photon states. Valley entanglement of carriers gives rise to peculiar properties of the reemitted optical field and photocurrent fluctuations.

1:15 PM G2.00009 Hofstadter spectrum in MoS$_2$, YEN-HUNG HO, Physics, National Tsing Hua University, Taiwan, WU-PEI SU, Physics and Texas Center for Superconductivity, University of Houston, TX, MING-FA LIN, Physics, National Cheng Kung University, Taiwan — In studying the Hofstadter problem of monolayer molybdenum disulfide (MoS$_2$), we systematically demonstrate the magnetic energy spectra due to various hoppings between $d$-orbital electrons. The magnetoelectronic spectrum shows a mirror symmetry as a result of the particle-hole symmetry in the Bloch bands. At small field, specific Landau fan diagrams can be ascribed to certain Bloch-band singularities. In the spectrum of real MoS$_2$, we further illustrate a breaking of spectral symmetry, the spin and valley polarization, and a flux-dependent energy gap. Our numerical results can facilitate the qualitative understanding of topological nature of $d$-bands and provide a basis for exploring the Landau levels in transition-metal dichalcogenides.

---

1: Yen-Hung HO, Physics, National Tsing Hua University, Taiwan, WU-PEI SU, Physics and Texas Center for Superconductivity, University of Houston, TX, MING-FA LIN, Physics, National Cheng Kung University, Taiwan — In studying the Hofstadter problem of monolayer molybdenum disulfide (MoS$_2$), we systematically demonstrate the magnetic energy spectra due to various hoppings between $d$-orbital electrons. The magnetoelectronic spectrum shows a mirror symmetry as a result of the particle-hole symmetry in the Bloch bands. At small field, specific Landau fan diagrams can be ascribed to certain Bloch-band singularities. Spatially-resolved measurements of these Hall effects have recently been achieved in monolayer MoS$_2$. In monolayers of transition metal dichalcogenides (1L-TMDs), a valley degree of freedom emerges for charge carriers due to the absence of spatial inversion symmetry. Strong spin-orbit interaction couples spin and valley, resulting in correlated spin, valley, and charge transport such as transverse Hall effects. Spatially-resolved measurements of these Hall effects have recently been achieved in monolayer MoS$_2$ necessitating a detailed picture for understanding transport and relaxation mechanisms in 1L-TMDs that considers carrier, valley, and spin motion and generation processes. Here, we study spin and valley Hall effects in 1L-TMD devices by simulating the transport of spin- and valley-polarized carriers with a generalized drift diffusion model incorporating circularly polarized optical excitation. Spin and valley accumulation and the transverse voltage are analyzed in different device geometries. We compare the electron and hole contributions to the transverse voltage and discuss the potential for a measurement of the valley relaxation times of free carriers in 1L-TMDs.

Valley selective optical Stark effect in monolayer WS$_2$. EDBERT J. SIE, JAMES W. MCIVER, MIT, YI-HSIEN LEE, NTHU Taiwan, LIANG FU, JING KONG, NUH GEDIK, MIT — Monolayer semiconductors, such as WS$_2$, have a pair of valleys that, by time-reversal symmetry, are energetically degenerate. Lifting the valley degeneracy in these materials is of great interest because it would allow for valley specific band engineering and offer additional control in valleytronic applications. Here we show that circularly polarized light, which breaks time-reversal symmetry, can be used to lift the valley degeneracy by means of the optical Stark effect. We demonstrate that this effect is capable of raising the exciton level in monolayer WS$_2$ by as much as 18 meV in a controllable valley selective manner. The resulting energy shift is extremely large, comparable to the shift that would be obtained using a very high magnetic field (200 Tesla). These results offer a novel way to control valley degree of freedom, and may provide a means to realize new valley-selective Floquet topological state of matter.

Valley-Exciton Locked Optical Selection Rule in Monolayer WS$_2$. JUN XIAO, ZILIANG YE, YING WANG, YUAN WANG, XIANG ZHANG, UC Berkeley — Layered transition metal dichalcogenide (TMDC) with hexagonal lattice structure has six valleys at corners of the Brillouin zone. The nontrivial Berry curvature distribution renders the adjacent valleys with distinguishable valley angular momentum. Recent studies reported strong excitonic effect in monolayer WS$_2$ and each excitonic state is identified with a well-defined orbital angular momentum, however the anticipated selection rules involve nonlinear optical processes are not clear. Here we show valley angular momentum (VAM) together with exciton angular momentum (EAM) impose different valley-exciton locked selection rules for second harmonic generation (SHG) and two photon luminescence (TPL) in monolayer WS$_2$. Moreover, the two-photon induced valley populations yield net circular polarized photoluminescence after a sub-ps interexciton relaxation. The work demonstrates a new approach to control valley population at different excitonic states for next generation of optical circuits and quantum information computing.

Trion dynamics in Transition Metal Dichalcogenide Monolayers. AKSHAY SINGH, KHA TRAN, Uni of Texas, Austin, SANWENG WU, JASON ROSS, University of Washington, GALAN MOODY, National Institute of Standards and Technology, XIAODONG XU, University of Washington, ELAINE LI, Univ of Texas, Austin — Transition Metal Dichalcogenides (TMD’s) in the monolayer limit, exhibit interesting phenomena including increased photoluminescence, spin-valley coupling and many-body effects. Excitons (bound electron-hole pairs) and trions (charged excitons) in these materials have unusually large binding energy and dominate the optical response near the band gap. In particular, trions can drift under application of an electric field and have higher spin lifetimes increasing applications in quantum spin models. We study the temporal dynamics of excitons and trions including their formation and lifetimes using time resolved two-color pump-probe spectroscopy on a monolayer TMD (MoSe$_2$). Trions are observed to have vastly different temporal dynamics with much slower decay than excitons. We also observe rapid formation of trions when resonantly pumped while a slow rise (in temporal response) is seen for other excitation energies. We suggest that localization of trions needs to be taken into account to explain these observations.

Session G3 FEd: Invited Session: NSF-Funded Physics Education: Celebrating Accomplishments and Looking Forward

11:15AM G3.00001 NSF Support for Physics at the Undergraduate Level: A View from Inside. DUNCAN MCBRIDE, National Science Foundation (Retired) — NSF has supported a wide range of projects in physics that involve undergraduate students. These projects include NSF research grants in which undergraduates participate: Research Experiences for Undergraduates (REU) centers and supplements; and education grants that range from upper-division labs that may include research, to curriculum development for upper- and lower-level courses and labs, to courses for non-majors, to Physics Education Research (PER). The NSF Divisions of Physics, Materials Research, and Astronomy provide most of the disciplinary research support, with some from other parts of NSF. I recently retired as the permanent physicist in NSF’s Division of Undergraduate Education (DUE), which supports the education grants. I was responsible for a majority of DUE’s physics grants and was involved with others overseen by a series of physics rotators. There I worked in programs entitled Instrumentation and Laboratory Improvement (IIL); Course and Curriculum Development (CCD); Course, Curriculum, and Laboratory Improvement (CCLI); Transforming Undergraduate STEM Education (TUES); and Improving Undergraduate STEM Education (IUSE). NSF support has enabled physics Principal Investigators to change and improve substantially the way physics is taught and the way students learn physics. The most important changes are increased undergraduate participation in physics research; more teaching using interactive engagement methods in classes; and growth of PER as a legitimate field of physics research as well as outcomes from PER that guide physics teaching. In turn these have led, along with other factors, to students who are better-prepared for graduate school and work, and to increases in the number of undergraduate physics majors. In addition, students in disciplines that physics directly supports, notably engineering and chemistry, and increasingly biology, are better and more broadly prepared to use their physics education in these fields. I will describe NSF support for undergraduate physics with both statistics and examples. In addition I will talk about trends in support for undergraduate physics at NSF and speculate about directions such support might go.

1 Contents of this paper reflect the opinions of the author and do not necessarily reflect those of the National Science Foundation.
11:51 AM G3.00002 The Impact of NSF-funded Physics Education Research at the University of Washington, PAULA HERON, University of Washington — It is now well known that many students who complete introductory physics courses are unable to apply fundamental concepts in situations that involve qualitative reasoning. Systematic investigations have helped researchers understand why so many students fail to develop robust and coherent conceptual frameworks, and have led to the development of new teaching practices and materials that are far more effective than conventional ones. The Physics Education Group at the University of Washington has played a leading role in raising awareness of the need to improve instruction, and in supporting physics faculty in their efforts to do so. With support from the National Science Foundation, the group has helped build a research base that instructors can draw on, and has produced practical, flexible instructional materials that promote deeper learning in physics classrooms. Both “Tutorials in Introductory Physics” (Pearson, 2002) and “Physics by Inquiry” (Wiley, 1996) have been developed in an iterative process in which ongoing assessment of student learning plays an integral role. These materials have had a widespread and significant impact on physics teaching and on student learning from kindergarten through graduate school. In this talk I will describe the role of research in curriculum development, and speculate on the next generation of tools and resources to support physics teaching and learning.

12:27 PM G3.00003 The Maryland PERG: Two decades of learning how students learn1, EDWARD REDISH, University of Maryland — Over the past twenty years, the University of Maryland’s Physics Education Research Group (UMd-PERG) has carried out educational research and development using a variety of NSF funding opportunities, building from basic research in cognitive modeling, to instructional materials development, to basic research on professional development. The group has drawn on opportunities in teacher training, K-12 teaching and learning, and university level research and development. In this talk I will recap some of the key lessons we have learned and how it all fits together.

1 This work has been supported by many grants from the NSF over a 20 year period.

1:03 PM G3.00004 An NSF rotator’s perspective: view from inside the hamster wheel, GARY WHITE, AAPT and The George Washington University — Duncan McBride served as my unofficial mentor during my time at NSF as a “rotator” (or, in NSF-speak, an IPA, short for an Intergovernmental Personnel Act assignee), from fall 2012 through summer of 2013. A rotator’s main job is to help keep the wheels of the grant submission process turning, shepherding individual proposal jackets through the submission cycle. While most proposals are eventually “Declined” it is the few that are funded that evoke the most vivid memories of my time there. I hope to relay a little bit about what that was like on a daily basis, to give one hamster’s take on the machinations of the NSF machine, and testify to Duncan McBride’s critical role in establishing physics as the leader in disciplinary based educational research (DBER). It was a heady experience in many ways, despite the sheer girth of proposal jackets to be processed and the uncertain footing upon which federal employees tread these days.

1:39 PM G3.00005 The SCALE-UP Project1, ROBERT BEICHNER, North Carolina State University — The Student Centered Active Learning Environment with Upside-down Pedagogies (SCALE-UP) project was developed nearly 20 years ago as an economical way to provide collaborative, interactive instruction even for large enrollment classes. Nearly all research-based pedagogies have been designed with fairly high faculty-student ratios. The economics of introductory courses at large universities often precludes that situation, so SCALE-UP was created as a way to facilitate highly collaborative active learning with large numbers of students served by only a few faculty and assistants. It enables those students to learn and succeed not only in acquiring content, but also to practice important 21st century skills like problem solving, communication, and teamwork. The approach was initially targeted at undergraduate science and engineering students taking introductory physics courses in large enrollment sections. It has since expanded to multiple content areas, including chemistry, math, engineering, biology, business, nursing, and even the humanities. Class sizes range from 24 to over 600. Data collected from multiple sites around the world indicates highly successful implementation at more than 250 institutions. NSF support was critical for initial development and dissemination efforts.

Tuesday, March 3, 2015 11:15AM - 2:15PM –
Session G4 FGSA: Invited Session: Physics Beyond the Lab: Science and Communication Mayor Cockrell Room 004 - Valerie Gray, College of William and Mary

11:15 AM G4.00001 Communicating Science in the Capitol: The Graduate Student Voice, TYLER GLEMBO, APS — Fundamental scientific research, as a majority federally funded initiative, is becoming more deeply embedded in politics. Since the end of the Space Race, funding of basic physical sciences research as a percent GDP has continuously declined, indicating that policy makers see funding scientific research as less of a priority than they once did. A lack of understanding about both science and how science is done amongst members of Congress has led to both reduced prioritization and also to misguided attempts at regulation, such as making peer review a public process and considering Congressional oversight for specific grants. Here we will examine a few current issues in science policy, the effect on graduate students, and why the student voice is effective. We will also consider the positive or negative effects such public engagement may have on our scientific careers and ways in which you can get involved.

12:27 PM G4.00003 Science publishing: A day in the life of an APS editor, KATHERINE THOMAS, Physical Review Letters, American Physical Society — I will share my experience in working as an editor for a scholarly journal. The talk will include information on my career path, the skills and qualifications needed, and give insight into my day-to-day activities.

1:03 PM G4.00004 Panel Discussion –
Tuesday, March 3, 2015 11:15AM - 2:15PM –
Session G5 FIAP: Integer Quantum Hall Effects Juan Gorman Room 005 - Ramesh Mani, Georgia State University
11:15AM G5.00001 Mach-Zehnder interferometry with periodic voltage pulses¹. PATRICK HOFER, CHRISTIAN FLINDT, University of Geneva — We investigate theoretically a Mach-Zehnder interferometer driven by periodic voltage pulses. We illustrate how the electronic energy distribution of the driven contact influences the visibilities of the Aharonov-Bohm oscillations in the current and in the noise. For the current, the visibility factors in analogy to the static case and we find a universality at path-length differences equal to multiples of the spacing between the voltage pulses. In the noise oscillations, we find additional features which are characteristic to time-dependent transport. Finite electronic temperatures are found to have a qualitatively different influence on the current and the noise.

11:27AM G5.00002 Evolution of the linear-polarization-angle-dependence of the radiation-induced magnetoresistance-oscillations with the microwave power². TIANYU YE, RAMESH MANI, Department of physics and Astronomy, Georgia State University, Atlanta, GA 30303, USA, WERNER WEGSCHREIDER, Laboratorium fur Festkorporphysik, ETH Zurich, 8093 Zurich, Switzerland — Microwave radiation-induced magnetoresistance oscillations (MRIMRO) are huge photo-excited oscillations in the resistance in a transverse magnetic field, which are sensitive to different aspects of the microwave radiation such as the microwave frequency, microwave power, and linear polarization angle. As a consequence, MRIMROs are potentially interesting for sensing applications. In order to better understand the role of the microwave power and the linear polarization angle in MRIMROs, the role of these variables have been more carefully examined in this experimental study. Thus, the diagonal resistance $R_{xx}$ was measured as a function of both the microwave power ($P$) and the linear polarization angle ($\theta$) at the MRIMRO extrema. Color contour plots reveal that $R_{xx}$ vs $\theta$ follows a cosine square function at relatively low microwave power with systematic lineshape distortions occurring with increasing microwave power. Here, we demonstrate that the non-linearity of $R_{xx}$ vs $P$ relation is the main factor that influences the lineshape distortion from the sinusoidal $R_{xx}$ vs $\theta$ relation observed at low $P$.

11:39AM G5.00003 Tunneling spectroscopic evidence of quasiparticle crystallization near $v = 1$ quantum Hall ferromagnet. JOONHO JANG, BENJAMIN HUNT, RAYMOND ASHOORI, Massachusetts Inst of Tech-MIT, LOREN PFEIFFER, KEN WEST, Princeton University — We have used Time Domain Capacitance Spectroscopy to measure the density of states of 2 dimensional holes in Carbon doped GaAs at temperature of 20 mK and high magnetic fields. Filling factor dependent anomalous features, which is antisymmetric in energy and density, were observed around the quantum Hall ferromagnet $v = 1$. The analysis of the quasiparticle dynamics around $v = 1$ is consistent with the picture that holes are dressed by interactions with bosonic degrees of freedom. We attribute this bosonic mode to the gapless Goldstone mode emergent due to the development of crystalline order of charged quasiparticles.

11:51AM G5.00004 Dynamics of Quantal Heating in Electron Systems with Discrete Spectra. WILLIAM MAYER, SCOTT DIETRICH, SERGEY VITKALOV, Physics Department, City College of the City University of New York, New York 10031, USA, ALEXEY BYKOV, Novosibirsk State University, Novosibirsk 630090, Russia; A.V.Rzhanov Institute of Semiconductor Physics, Novosibirsk 630090, Russia — The temporal evolution of quantal Joule heating of 2D electrons in GaAs quantum well placed in quantizing magnetic fields is studied using a difference frequency method. The method is based on measurements of the electron conductivity oscillating at the beat frequency $f_1 - f_2$ between two microwaves applied to 2D system at frequencies $f_1$ and $f_2$. The method provides direct access to the dynamical characteristics of the heating and yields the inelastic scattering time $\tau_{in}$ of 2D electrons. The obtained $\tau_{in}$ is strongly temperature dependent, varying from 0.13 ns at 5.5K to 1 ns at 2.4K in magnetic field $B = 0.33T$. When temperature $T$ exceeds the Landau level separation the relaxation rate $1/\tau_{in}$ is proportional to $T^2$, indicating the electron-electron interaction as the dominant mechanism limiting the quantal heating. At lower temperatures the rate tends to be proportional to $T^3$, indicating considerable contribution from electron-phonon scattering.

12:03PM G5.00005 The Quantum Hall Effect with electron-boson interaction is not exact. KARIN EVERSCHOR-SITTE, MATTHIAS SITTE, ALLAN MACDONALD, Univ of Texas, Austin — The quantum Hall effect (QHE) normally refers to quantized Hall conductivity due to Landau quantization, as observed in 2D electron systems. The precision of the QHE which occurs near integer Landau level filling factors has been verified to more than 8 figures. There are no known limitations to the accuracy of the QHE in the limit of zero temperature. Here, we show explicitly within a toy model that electron-boson interactions can sometimes lead to corrections to the exact quantization of the Hall conductivity.

12:15PM G5.00006 Intersubband Oscillations in GaAs Quantum Wells with Three Populated Subbands. JESSE KANTER, SCOTT DIETRICH, WILLIAM MAYER, Graduate Center, City University of New York, New York 10016, USA, SERGEY VITKALOV, CUNY-CCNY, ALEXEY BYKOV, Novosibirsk State University, Novosibirsk 630090, Russia; A.V.Rzhanov Institute of Semiconductor Physics, Novosibirsk 630090, Russia — The magnetotransport of highly mobile 2D electrons is studied in GaAs quantum wells with three occupied subbands. The lower two subbands have nearly the same energy while the third subband has a much higher energy ($E_1 \approx E_2 < < E_3$). Observed magneto-intersubband oscillations (MISO) obey the relation $\Delta_{ij} = (E_i - E_j) = \hbar \omega_c$ for oscillations between the $i^{th}$ and $j^{th}$ bands where $\omega_c$ is the cyclotron frequency and $k$ is an integer. The slight difference in the energies of the lower subbands produces noticeable interference effects in the magnetoresistance. By analyzing the amplitude of each component of the MISOs separately, the temperature dependence of the quantum lifetime $\tau_q^{(i)}$ of electrons in $i^{th}$ subband is extracted. The studies indicate that $\tau_q^{(1)} \approx \tau_q^{(2)} > \tau_q^{(3)}$ while it appears that $\tau_q^{(3)} < \tau_q^{(1,2)}$ which can be related to a reduced electron density in the third subband.

Enhancement of spin susceptibility of low-density two-dimensional electrons in a high quality Si/SiGe quantum well. TZU-MING LU, XIAOYAN SHI, WEI PAN, Sandia National Laboratories, SHI-HSIEN HUANG, CHEEWEE LIU, JIUN-YUN LI, National Taiwan University — We report magneto-transport measurement results of two-dimensional electrons in a high quality Si/SiGe quantum well under tilted magnetic fields. The electron peak mobility reaches \( 2 \times 10^{11} \) cm\(^2\)/Vs and the density is varied from 0.8 to 2.1 \( 10^{11} \) cm\(^{-2}\). Under tilted magnetic fields, two Landau levels with opposite spins are brought into energetic coincidence. From the coincidence angles we determine the effective spin susceptibility \( g \approx m^* \). At \( n = 2.1 \times 10^{11} \) cm\(^{-2}\) \( g \approx m^* \approx 4 \) (in units of \( m_e \)). Consistent with previous work \( \approx Lai et al, PRL 96, 076805 (2006) \). Our results further show that the spin susceptibility is enhanced by 20\% at \( 0.8 \times 10^{11} \) cm\(^{-2}\) from its high density value. Surprisingly, unlike previous results in modulation doped Si/SiGe quantum wells, a resistance peak is observed at \( n = 3 \) when Landau level coincidence occurs in our undoped Si/SiGe field-effect transistor sample. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

Experimental Study of Low Density Quantum Hall Fabry-Perot Interferometer. SIMAS GLINSKIS, SANGHUN AN, WOO WON KANG, Univ of Chicago, LEONIDAS OCOLA, Argonne National Lab, LOREN PFIEFFER, KEN WEST, KIRK BALDWIN, Princeton — In this talk we report on interference oscillations observed in Fabry-Perot 1.5\( \mu \)m diameter interferometers fabricated from low density, high mobility AlGaAs/GaAs heterostructures. The Fabry-Perot interferometers were fabricated using e-beam lithography and inductively coupled plasma etching to minimize sample damage. Optimization of the quantum point contacts were made by systematically varying the etching depth and monitoring the resistance of the device. So far we have been able to detect clear interference oscillations which are observed at integer quantum Hall states. The interference oscillations occur in the low magnetic field side of the Hall plateaus when there is substantial backscattering at the quantum point contacts. A linear relationship between filled Landau levels and oscillation frequencies establishes that our interferometers are in the Coulomb dominated regime described by the interacting model of quantum Hall Fabry-Perot interferometers. Study of interference oscillations in the fractional quantum Hall states are currently under progress and will be discussed.

Theory of Transport Phenomena in Coherent Quantum Hall Bilayers. ALLAN H. MACDONALD, HUA CHEN, University of Texas at Austin, INTI SODEMANN, Massachusetts Institute of Technology — We will describe a theory that allows to understand the anomalous transport properties of the excitonic condensate state occurring in quantum Hall bilayers in terms of a picture in which the condensate phase is nearly uniform across the sample, and the strength of condensate coupling to layer tunneling processes is substantially reduced compared to the predictions of disorder-free microscopic mean-field theory. These ingredients provide a natural explanation for recently established I-V characteristics which show conductance quantization. Experimentally, the conductance quantization is observed in the two-layer quantum Hall regime, at the inner and outer edges of Corbino rings. We propose a microscopic picture in which disorder is the main agent responsible for the reduction of the effective interlayer tunneling strength.

1:03PM G5.00010 Transient Features in Charge Fractionalization and Non-equilibrium Bosonization. BERND ROSENOW, ALEXANDER SCHNEIDER, University of Leipzig, MIRCO MILLETARI, NUS Centre for Advanced 2D Materials and Graphene Centre — In quantum Hall edge states and in other one-dimensional interacting systems, charge fractionalization can occur due to the fact that an injected charge pulse decomposes into eigenmodes propagating at different velocities. If the original charge pulse has some spatial width due to injection with a given source-drain voltage, a finite time is needed until the separation between the fractionalized pulses is larger than their width. In the formalism of non-equilibrium bosonization, the above physics is reflected in the separation of initially overlapping square pulses in the effective scattering phase. When expressing the single particle Green function as a functional determinant of counting operators containing the scattering phase, the time evolution of charge fractionalization is mathematically described by functional determinants with overlapping pulses. We develop a framework for the evaluation of such determinants, and compare our theoretical results with recent experimental findings.

1:15PM G5.00011 Transient Features in Charge Fractionalization and Non-equilibrium Bosonization. BERND ROSENOW, ALEXANDER SCHNEIDER, University of Leipzig, MIRCO MILLETARI, NUS Centre for Advanced 2D Materials and Graphene Centre — In quantum Hall edge states and in other one-dimensional interacting systems, charge fractionalization can occur due to the fact that an injected charge pulse decomposes into eigenmodes propagating at different velocities. If the original charge pulse has some spatial width due to injection with a given source-drain voltage, a finite time is needed until the separation between the fractionalized pulses is larger than their width. In the formalism of non-equilibrium bosonization, the above physics is reflected in the separation of initially overlapping square pulses in the effective scattering phase. When expressing the single particle Green function as a functional determinant of counting operators containing the scattering phase, the time evolution of charge fractionalization is mathematically described by functional determinants with overlapping pulses. We develop a framework for the evaluation of such determinants, and compare our theoretical results with recent experimental findings.

1:51PM G5.00014 Hall Viscosity and Momentum Transport in Lattice and Continuum Models of the Integer Quantum Hall Effect in Strong Magnetic Fields, THOMAS TUEGEL, TAYLOR HUGHES, Univ of Illinois - Urbana — Hall viscosity describes non-dissipative transport in systems with broken time-reversal and parity symmetries. We develop a new method for computing the Hall viscosity of lattice systems in strong magnetic fields based on momentum transport, which we compare to the method of momentum polarization used by Tu et al. [Phys. Rev. B 88, 195412 (2013)] and Zalewski et al. [Phys. Rev. Lett. 110, 236801 (2013)] for noninteracting systems. We compare the Hall viscosity of square-lattice tight-binding models in magnetic field to the integer quantum Hall effect (IQHE) showing agreement when the magnetic length is much larger than the lattice constant, but deviation as the magnetic field strength increases. We also relate the Hall viscosity of relativistic electrons in magnetic field (the Dirac IQHE) to the conventional IQHE. The Hall viscosity of a lattice Chern insulator in magnetic field agrees with the Dirac Hall viscosity when the magnetic length is much larger than the lattice constant. We also show that the Hall viscosity of the lattice model deviates further from the continuum model if the C4 symmetry of the square lattice is broken, but the deviation is again minimized as the magnetic length increases.

2:03PM G5.00015 Relaxation of the electron wave packet in the quantum Hall edge1,2, ARTUR SLOBODENIUK, EDVIN IDRISOV, EUGENE SUKHORUKOV, Univ of Geneva — Recently, single-electron wave packets in the quantum Hall edge (QHE) become very important objects in the so called electron optics. The properties of these excitations are well known only in the case of free-fermion description of the QHE. The role of the Coulomb interaction in such systems have not received a clear theoretical description yet. We propose the method of calculation of characteristics of single-electron excitations of the QHE which takes into account this interaction. We realise it on the QHE with filling factor ν = 2. The difference of the obtained quantum state with the free-fermion answer is investigated. It is shown that role of the Coulomb interaction is crucial and it’s effects can be measured in the Hong-Ou-Mandel and Hanbury-Brown-Twiss experiments. As an example, the influence of Coulomb interaction for the case of electronic Mach-Zehnder interferometer is calculated.

Session G6 DMP DCOMP: Focus Session: Ferroic Materials by Design
006A - Sang-Wook Cheong, Rutgers University

11:15AM G6.00001 Revealing and understanding the behavior of structural domain walls from first principles1,2, JORGE INIGUEZ, ICMAB-CSIC — Ferroelectric and ferroelastic domain walls (DWs) are becoming the focus of renewed excitement. Modern experimental techniques permit an unprecedented control on domain structures, and it is now possible to produce materials with a large volume fraction occupied by the DWs themselves. Also, recent experiments show that DWs can display distinct properties not present in the domains, which suggests the possibility of using the walls themselves as the functional material in nano-devices. In this talk I will review recent projects in which we have used theory and first-principles simulation to reveal and explain a variety of DW-related effects. The presentation will include the formation of novel two-dimensional crystals at the DWs of a ferroelastic material, the occurrence of ferroic orders (ferroelectric, ferromagnetic) confined at the DWs of various compounds, and cases in which peculiar (and useful) responses and switching properties rely on existence of a multi-domain state. I will also summarise experimental evidence for most of these incredible findings, which clearly ratify domain and domain-wall engineering as a powerful strategy to obtain novel functional nano-materials. / Work done in collaboration with many researchers, the main ones being: J.C. Wójcik (ICMAB-CSIC), C. Magén (INA at U. Zaragoza), M. Mostovoy (U. Groningen), P. Zubko (U. College London), as well as the groups of Beatriz Noheda (U. Groningen), R. Ramesh (UC Berkeley) and J.-M. Triscone (U. Geneva).

11:51AM G6.00002 Magnetic charge and magnetoelectricity in hexagonal manganites and ferrites1,2, MENG YE, DAVID VANDERBILT, Rutgers Univ — Magnetoelectric (ME) materials are of fundamental interest and are investigated for their broad potential for technological applications. Commonly the dominant contribution to the ME response is the lattice-mediated one, which is proportional to both the Born effective charge Zm and its analogue, the dynamical magnetic charge Zmu. A previous study has shown that exchange striction acting on noncollinear spins induces much larger magnetic charges than when Zmu is driven by spin-orbit coupling. The hexagonal manganites RMnO3 and ferrites RFeO3 (R = Sc, Y, In, Ho-Lu) exhibit strong couplings between electric, magnetic and structural degrees of freedom, with the transition-metal ions in the basal plane are antiferromagnetically coupled through super-exchange so as to form a 120° spin arrangement. Here we present a theoretical study of the magnetic charges, and of the spin-lattice and spin-electronic ME constants, in these hexagonal manganites and ferrites, clarifying the conditions under which exchange striction leads to enhanced Zm’s and anomalously large in-plane spin-lattice ME effects.

1Supported by ONR Grant N-00014-12-1-1035

12:03PM G6.00003 Ferroelectrics with a trilinear coupling of three lattice modes: Response to electrical boundary conditions from first principles, ANDREW T. MULDER, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — Recent progress in the design of functional materials has led to the discovery of several ferroelectrics with the polarization coupled trilinearly to two nonpolar lattice modes. Because nonpolar lattice modes in perovskites play a key role in determining electronic and magnetic properties, these materials have a polarization that is strongly coupled to other functionality by design. But many properties of trilineral ferroelectrics remain unknown, and general design rules have been difficult to uncover. For example, the electrical properties are unclear because trilineral ferroelectrics may have a conventional ferroelectric mechanism, or may not (like an improper ferroelectric). Understanding the polarization response to electrical boundary conditions is therefore an open question that will impact the application of trilinear ferroelectrics to practical devices. In this talk, we use first principles methods to study the single domain polarization response to changing electrical boundary conditions in a variety of trilinear ferroelectrics. We clarify the design rules, the connection to phenomenological models (proper, improper, and weak ferroelectricity), and we show how epitaxial strain can tune a single trilinear ferroelectric between proper and improper ferroelectricity.
12:15PM G6.00004 Epitaxial-strain-induced insulating phase in 1:1 SrCrO$_3$/SrTiO$_3$ superlattices: A first-principles study, YUANJUN ZHOU, KARIN RABE, Rutgers University — Using first principles calculations, we studied the structure and electronic properties of the 1:1 superlattice combining the magnetic metallic oxide SrCrO$_3$ and the band insulator SrTiO$_3$. We determined the epitaxial-strain-dependent ground-state structures of the superlattice using the “stacking” method. An insulating polar ground state is found when the tensile strain is greater than 2.2%. The insulating character of this phase is related to the $d_{x^2-y^2}$, $d_{z^2}$ orbital ordering of the Cr $t_d$ electrons. Specifically, the 1:1 periodic superlattice structure eliminates the Cr-O-Cr bonds in the direction normal to the interface, which reduces the hopping of 3d electrons in this direction. The band widths of $d_{xy}$ and $d_{xz}$ for Cr are thus significantly reduced, enhancing the effect of the in-plane polar distortions in the SrCrO$_3$ layer responsible for opening the the band gap. The elucidation of this mechanism opens a new approach to band engineering, encouraging further investigations on related metallic/dielectric superlattice systems.

12:27PM G6.00005 Trilinear couplings and the multi-mode anti-ferroelectric transition of PbZrO$_3$: a first-principles investigation, JORGE INIGUEZ$^2$, ICMA-CSC, MASSIMILIANO STENGEL, ICREA and ICMA-CSC, SERGEY PROSANDEEV, LAURENT BEAULIEU, University of Arkansas — We have studied ab initio the phase transition in PbZrO$_3$, a perovskite oxide usually presented as the prototypic anti-ferroelectric. Our work reveals the crucial role that anti-ferrodistortive modes—invoking concerted rotations of the oxygen octahedra in the structure—play in the transformation, as they select the observed anti-ferroelectric phase, among competing structural variants, via a cooperative trilinear coupling. The resulting picture is that of a complex transition whose multi-mode character is essential to its very occurrence, and poses the provocative question of whether such an intricate behavior can be taken as representative of anti-ferroelectricity in perovskite oxides.

2Current address: Luxembourg Institute of Science and Technology (LIST)

12:39PM G6.00006 A new class of in-plane Ferroelectric Mott insulators via oxide heterostructuring, CHANUL KIM, Columbia Univ, HYOWON PARK, University of Illinois at Chicago, CHRIS MARIANETTI, Columbia Univ, MARIANETTI GROUP TEAM$^2$ — We propose simple design rules based on charge transfer, cation ordering, and size mismatch to design a new class of in-plane ferroelectric Mott insulators in perovskite-based transition metal oxides. Ab Initio DFT+U calculations are then used to selectively scan phase space based on these rules. We begin by exploring pairs of A-type ions (A, A’), and pairs of B-type ions (B, B’) in AAB’BO$_6$ which will have nominal charge transfer consistent with valencies that are conducive to a low Mott gap insulator. Additionally, the A-type ions are chosen to have a large size mismatch and stereochemical effect. The ordering of A/A’ and B/B’ still retains C$_4v$ symmetry which may be spontaneously broken to yield an in-plane ferroelectric. We uncover a number of materials which are strong candidates to be in-plane ferroelectric Mott insulators in experiment, including BaBiVCuO$_6$, BaBiVNiO$_6$, PbLaVCuO$_6$. Finally, we will discuss potential applications of in-plane ferroelectric Mott insulators such as ferroelectric photovoltaks, Mott FET, and optoelectronic devices.

12:51PM G6.00007 Why is the electrocaloric effect so small in ferroelectrics? , GIAN G. GUZMAN-VERRI, Argonne National Laboratory, PETER B. LITTLEWOOD, Argonne National Laboratory and The University of Chicago — Ferroelectrics are attractive candidate materials for environmentally friendly solid state refrigeration free of greenhouse gases. Their thermal response upon variations of external electric fields is largest in the vicinity of their phase transitions, which may occur near room temperature. The magnitude of the effect, however, is too small for useful cooling applications even when they are driven close to dielectric breakdown. Insight from microscopic theory is therefore needed to characterize materials and provide guiding principles to search for new ones with enhanced electrocaloric performance [1]. Here, we present meaningful figures of merit derived from well-known microscopic models of ferroelectricity which provide insight into the relation between the strength of the effect and the characteristic interactions of ferroelectrics such as dipole forces. We find that the long range nature of these interactions results in a small effect. A strategy is proposed to make it larger by shortening the correlation lengths of fluctuations of polarization [2].

1:03PM G6.00008 Strain–Induced Geometric Ferroelectricity in Perovskite–structured Fluoroscorpates , NENIAN CHARLES, Drexel University, JAMES RONDINELLI, Northwestern University — Using first-principles density functional theory calculations we investigate geometric ferroelectricity in epitaxially strained double-perovskite fluorides, Na$_3$ScF$_6$ and K$_2$NaScF$_6$. The experimental room temperature crystal structures of the fluoroscorpates are centrosymmetric, i.e. Na$_3$ScF$_6$ (P2$_1$/n) and K$_2$NaScF$_6$ (Fm3m). However, in their prototypical cubic geometry, we identify soft infrared active modes that are strongly sensitive to pressure: Ferroelectric instabilities are found for negative hydrostatic pressures $\sim$ 6 GPa. For Na$_3$ScF$_6$ we observe octahedral rotations ($a^* - a^* - c^*$ tilt system) are in strong competition with acentric polar distortions, and as a result exceedingly large tensile strain above 8% are required to stabilize a Pm polar phase. We demonstrate that the strain mismatch required to stabilize the ferroelectric phase can be reduced to approximately 4% with chemical substitution in (a$^$2$b^*c^*$) K$_2$NaScF$_6$ by reducing the tendency to octahedral rotations. Our study provides new insights that may prove useful in guiding experimental efforts towards identifying functional polar fluoroperovskites.

1:15PM G6.00009 Tuning the structure of oxide thin films with strain, ELIZABETH NOWADNICK, ANDREW MULDER, CRAIG FENNIE, Cornell University — Octahedral rotations are ubiquitous in perovskite oxides and play an important role in determining the functionality of these materials, for example impacting magnetism and ferroelectricity. Pressure applied to bulk perovskites, as well as biaxial strain in epitaxially grown thin films, couples to the octahedral rotations. By performing first principles density functional theory calculations for a wide variety of ABO$_3$ perovskite oxides, we present a systematic study of the structural response of these systems to pressure and strain. We find that the octahedral rotations respond to pressure and biaxial strain in distinct ways. With pressure, the relative compressibilities of the A012 and BO$_3$ polyhedra govern the response of the octahedral rotations, whereas the response to biaxial strain arises from an interplay of the out of plane axis relaxation and the polyhedral compressibilities. Our findings offer insight into how to optimize the sensitivity of octahedral rotations to strain and pressure.
1:27PM G6.00010 First-principles studies of lone-pair-induced distortions in epitaxial phases of perovskite SnTiO$_3$ and PbTiO$_3$. KRISHNA PITIKE, LYDIE LOUIS, University of Connecticut - Storrs, WILLIAM PARKER, Purdue University, SERGE NAKHMANSON, University of Connecticut - Storrs — In this project, a computational investigation utilizing density functional theory methods is carried out to elucidate the differences in stereochemical lone-pair activity of Pb and Sn A-site ions in epitaxial polar ATiO$_3$ perovskites. The contrasting tendencies for the lead- and tin-based compounds to form different phases under biaxial tension are connected to the amount of charge concentrated within the lone pair orbits. Specifically, phases are energetically more preferable when as much charge as possible is dissipated out of the lobe, thus lowering the cost of Coulomb repulsion between the lone pair and the surrounding oxygen cage. The insights gained about the electronic-level underpinnings of transitional behavior in such lone-pair active epitaxial ferroelectrics may be used in the design of a new generation of more efficient electromechanical and electrooptical devices.

1:39PM G6.00011 Tuning ferroelectric polarization in $A\prime A'MnWO_6$ double perovskites through $A$ cation substitution. JOSHUA YOUNG, Drexel University, JAMES RONDINELLI, Northwestern University — Magnetic ferroelectric materials, which exhibit simultaneous magnetic and electric polarizations, have generated significant interest for application in novel electronic devices. Recent experimental work has shown that the double perovskite NaLaMnWO$_6$ exhibits anti-ferromagnetic order, while computational studies predict it to also exhibit a spontaneous polarization of 16 $\mu$C/cm$^2$ owing to an octahedral rotation induced improper mechanism. Using first principles density functional theory calculations, we investigate nine isostructural $A\prime A'MnWO_6$ compounds through chemical substitution of alkali metal ($A\prime$=Na, K, Rb) and rare earth cations ($A$=La, Nd, Y), and find that the ferroelectric polarization can be enhanced by up to 150% by maximizing the difference in ionic size of the $A$ and $A'$ cations. We then identify the microscopic features responsible for this polarization through an examination of the tolerance factors, bond valences, and atomic displacement patterns. We anticipate that the crystal-chemistry criteria and analysis presented here can be extended to additional members of this family as well as guide the targeted design of novel multiferrics.

1:51PM G6.00012 First principles study of the band gaps and edges of (111) epitaxially strained SrTiO$_3$. SEBASTIAN E. REYES-LILLO, Molecular Foundry, Lawrence Berkeley National Laboratory, ROBERT F. BERGER, Department of Chemistry, Western Washington University, JEFFREY B. NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory; Department of Physics, University of California-Berkeley — SrTiO$_3$ is a tunable material with potential use in energy applications. Previous experimental and first principles results demonstrated controllable manipulation of the electronic band gap in (001) biaxially strained, and predicted a large room-temperature band gap reduction (0.3 eV) for (111) epitaxial growth at small and large strains. In this work, we revisit and examine the effect of (111) epitaxial strain on the structural and electronic properties of SrTiO$_3$ using density functional theory calculations at low and room temperatures. Under (111) epitaxial strain at low temperature, we find that SrTiO$_3$ has an antiferrodistortive ground state at large compressive strains ($\sim-1\%$) and a ferroelectric phase transition between $-1\% < \eta < 4\%$ biaxial strains. While structural distortions widen the band gap compared to the paraelectric phase, an effective reduction of band gap is observed for the distorted structure at large compressive strains compared to bulk. This work is supported by DOE, computational resources are provided by NERSC.

2:03PM G6.00013 First principles investigations of structural, elastic, dielectric and piezoelectric properties of {Ba,Sr,Pb}TiO$_3$, {Ba,Sr,Pb}ZrO$_3$ and {Ba,Sr,Pb}{Zr,Ti}O$_3$ ceramics. BERNA AKGENC, Kırklareli University Department of Physics, Faculty of Science, Kavaklı, 39060, Kırklareli, Turkey, CETIN TASSEVEN, Department of Physics, Faculty of Science, Yildiz Technical University, Davutpaşa Campus, Esenler, 34210, Istanbul, Turkey, TAHIR CĄĠIN, Department of Materials Science and Engineering, Texas A&M University, College Station, TX 77843-3003, USA — We use first-principle density-functional study of structural, anisotropic mechanical, dielectric, and piezoelectric properties of {Ba,Sr,Pb}TiO$_3$, {Ba,Sr,Pb}ZrO$_3$ and {Ba,Sr,Pb}{Zr,Ti}O$_3$ alloys in cubic perovskite structures at zero temperature. Because there is significant interest in finding new piezoelectrics that do not contain toxic elements such as lead. In this study, we compare piezoelectric response of those alloys to synthesize outstanding piezoelectric materials. In perovskite structures, the spontaneous polarization is due to enormous values of Born effective charges computed by linear response within density functional perturbation theory, which are much larger than predicted nominal charge. We deeply investigated the effects of composition, order and site defects structure on piezoelectric constants.

11:15AM G7.00001 Possible Chern insulators based on novel ferromagnetic substrates. JIANPENG LIU, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University — Previous work has opened the possibility that one can obtain non-zero Chern numbers from the surface bands of atomic layers with strong spin-orbit coupling deposited on insulating ferromagnetic thin films. Following this idea, we carry out a theoretical search for Chern (i.e., quantum anomalous Hall) insulators formed by depositing heavy adatoms on top of stable insulating ferromagnetic substrates such as CrSiTe$_3$ and CrGeTe$_3$. These materials have a layered structure with weak van der Waals interlayer coupling, so it seems likely that thin films with clean surfaces will be experimentally stable. Moreover, the insulating character of these materials, with magnetization normal to the surface, are promising for realizing Chern-insulator states when adatoms are added. By searching over a series of heavy elements, we found non-zero Chern numbers in Bi and Tl-deposited CrSiTe$_3$ thin films, although with slightly negative indirect energy gaps. We expect that a global energy gap could be opened up by some further engineering, such as by applying epitaxial strain or additional atomic substitution.

11:27AM G7.00002 Tunable topological electronic structure of silicene on semiconducting Bi/Si(111)-root3xroot3 substrate: a first-principles. CHIA-HSIU HSU, ZHI-QUAN HUANG, BO-HUNG CHOU, FENGCHUAN CHUANG, Natl. Sun Yat-sen U., HSIN LIN, Natl. U. of Singapore, ARUN BANSIL, Northeastern U. — Using first-principles calculations to obtain the crystal and electronic structures, we show that the 1x1 phase of silicene is energetically more favorable than the root3xroot3 silicene superstructure on a semiconducting Bi/Si(111)- root3xroot3 substrate. The band gap of the system is found to be influenced strongly through the participation of Bi-orbitals, which possess a larger spin-orbit coupling strength compared to Si. In particular, the non-trivial (topological) band gap of a few meV in freestanding 1x1 silicene enlarges to 150 meV and becomes trivial in the presence of the substrate. We further show how an out-of-the-plane external electric field can be used to tune the band gap and restore the non-trivial topological phase.
Amplified topological characteristics of MBE-grown Bi$_2$Se$_3$/II-VI semiconductor superlattices \(^1\), Zhiyi Chen, Lukas Zhao, Inna Korzhovska, Maria Tamargo, Lia Krusic, City College of New York - CUNY — Access to charge transport in Dirac surface states of topological insulators (TIs) such as Bi$_2$Se$_3$ is faced with two big challenges: one is significant bulk conduction and another is intermixing of topological states with nontopological 2DEG quantum well states formed by bending of bulk electronic bands near the surface. The latter effect is thought to arise via charge transfer from surface adatoms and, therefore, the choice of layers abutting topological surfaces can be critical. Here we report a successful molecular beam epitaxy growth of Bi$_2$Se$_3$ on ZnS/CD$_3$Se$_{1-x}$Se superlattices that improve topological characteristics of individual 8 - 10 nm thick TI layers. We show that in these superlattices the two-dimensional (2D) weak antilocalization quantum correction to classical magnetoresistance, associated with topological Berry phase, scales with the number of TI layers, with one quantum channel per layer. The Berry phase of \(\pi\) obtained independently from Shubnikov de Haas quantum oscillations demonstrates robust topological interfaces in the multilayer structure.

\(^1\)Supported by NSF-DMR-1122594 and DOD-W911NF-13-1-0159

Quantum Anomalous Hall Effect in Magnetic Semiconductors \(^1\), Chaoxing Liu, The Department of Physics, Pennsylvania State University — In the quantum anomalous Hall effect, dissipationless charge currents are carried by chiral edge states and the Hall conductance is quantized, similar to the quantum Hall effect. Different from the conventional quantum Hall effect that requires strong magnetic fields, the quantum anomalous Hall effect is induced by strong exchange coupling between electron spin and magnetic moments in magnetic materials, so it can be realized at zero magnetic field, enabling the potential application of electronic devices with low energy consumption. Recent experiments on Cr-doped MnTe \(^2\) and V doped BiSbTe \(^3\) thin films has observed the quantized Hall conductance at zero magnetic field and confirmed this novel effect. In this talk, I would like to discuss our recent work on the quantum anomalous Hall effect in magnetic semiconductors. I will first introduce two key ingredients, inverted band structures and ferromagnetic insulators, for the quantum anomalous Hall effect in realistic characteristics of magnetic materials. Then, based on these two ingredients, I will discuss different classes of materials for the quantum anomalous Hall effect, focusing on magnetically doped InAs/GaSb quantum wells and magnetically doped LaOSe$_2$ films. For magnetically doped InAs/GaSb quantum wells, we will show how band edge singularity can enhance spin susceptibility and lead to the quantum anomalous Hall state at a relatively high critical temperature. For magnetically doped LaOSe$_2$ films, we find the quantum anomalous Hall effect can be tuned electrically by a gate voltage and identify layer dependent spin texture as the underlying physical reason. Finally, we will also discuss disordered transport and anisotropic magnetoresistance in the quantum anomalous Hall regime.

12:27PM G7.00005 ABSTRACT WITHDRAWN

12:39PM G7.00006 Electrically tunable multiple Dirac cones in thin films of (LaO)$_2$(SbSe)$_2$ family of materials \(^1\), Xiaoyu Dong, Jianfeng Wang, Department of Physics and State Key Laboratory of Low-Dimensional Quantum Physics, Tsinghua University, Beijing 100084, China, RuiXing Zhang, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802-6300, USA, - Wenhui Duan, Bangfen Zhu, Department of Physics and State Key Laboratory of Low-Dimensional Quantum Physics, Tsinghua University, Beijing 100084, China, Jorge Sofo, Chaoxing Liu, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802-6300, USA — Two-dimensional Dirac physics has aroused great interests in condensed matter physics due to its importance in both fundamental physics and device applications. The ability to control the properties of Dirac cones is essential for the occurrence of various new phenomena and the development of next-generation electronic devices. Based on first-principles calculations and an analytical effective model, we propose a new Dirac system with eight Dirac cones in thin films of the (LaO)$_2$(SbSe)$_2$ family of materials with an external gate voltage. The advantage of this system lies in its tunability: the existence of gapless Dirac cones, their positions, Fermi velocities and anisotropy all can be controlled by an experimentally feasible gate voltage. We identify the layer dependent spin texture induced by spin-orbit coupling as the underlying physical reason for the tunability of Dirac cones in this system. As a consequence, we show that the electrically tunable quantum anomalous Hall effect with a high Chern number can be induced by introducing magnetization into this system.

12:51PM G7.00007 An Efficient numerical method to calculate the conductivity tensor for disordered topological matter \(^1\), Jose H. Garcia, Universidade Federal do Rio de Janeiro, Lucian Covaci, Universiteit Antwerpen, Tatiana G. Rapporto, Universidade Federal do Rio de Janeiro — We propose a new efficient numerical approach to calculate the conductivity tensor in solids. We use a real-space implementation of the Kubo formalism where both diagonal and off-diagonal conductivities are treated in the same footing. We adopt a formulation of the Kubo theory that is known as Bostain formula and expand the Green’s functions involved in terms of Chebyshev polynomials using the kernel polynomial method. Within this method, all the computational effort is on the calculation of the expansion coefficients. It also has the advantage of obtaining both conductivities in a single calculation step and for various values of temperature and chemical potential, capturing the topology of the band-structure. Our numerical technique is very general and is suitable for the calculation of transport properties of disordered systems. We analyze how the method’s accuracy varies with the number of moments used in the expansion and illustrate our approach by calculating the transverse conductivity of different topological systems.

12:03PM G7.00008 Topological phases in rocksalt rare-earth binary compounds \(^1\), Hsin Lin, Mingen Zhang, Guoqing Chang, National University of Singapore, Yu-An Chen, Timothy Hsieh, Massachusetts Institute of Technology, Arun Bansil, Northeastern University, Liang Fu, Massachusetts Institute of Technology — Using first-principles calculations, we have investigated the electronic properties of bulk lanthanum monopnictides (LaX, X = N, P, As, Sb, Bi) and their thin films. We predict that lanthanum nitride (LaN) harbors a three-dimensional (3D) Dirac semimetal phase, and undergoes a phase transition driven by Coulomb interaction. Other lanthanum monopnictides are found to be semimetals with a nontrivial Z2 band topology. Furthermore, we find both two-dimensional (2D) Dirac semimetal and topological insulator phases in thin films of lanthanum monopnictides. The gapless Dirac states in bulk lanthanum monopnictides and their thin films can be attributed to the crystalline symmetry protection.

1:15PM G7.00009 Giant magnetoresistance and band structure of topological semimetal RhSb₃
KEFENG WANG, LIMIN WANG, Y. NAKAJIMA, RENXIONG WANG, JIE YONG, J. PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland College Park — Recently materials with skutterudite structure such as CoSb₃ were predicted to provide a promising platform for the realization of new topological materials such as topological insulators and Dirac-Weyl semimetals. Here we report a detailed study of the electronic structure and magnetotransport properties of high quality RhSb₃ single crystals. First-principles electronic structure calculations reveal a highly dispersive band with Sb-p and Rh-3d weight that shows apparent band inversion. Inclusion of spin-orbit coupling leaves the Fermi level pinned to a doublet, indicating a topological semimetal. Our synthesized high-quality single crystals show typical metallic behavior but with very small residual resistivity ratio, a sign of semimetal behavior, in zero field. We will present magnetotransport data that exhibits a very large magnetoresistance that hints of a very sensitive evolution of electronic properties and Dirac-like spectrum.

1:27PM G7.00010 SmO thin films: a flexible route to correlated flat bands with nontrivial topology
DEEPA KASINATHAN, Max Planck Institute for Chemical Physics of Solids, Dresden, KLAUS KOEPERNIK, IFW Dresden, P.O. Box 270116, D-01171 Dresden, LIU HAO TJENG, MAURITIS HAVERKORT, Max Planck Institute for Chemical Physics of Solids, Dresden — Using density functional theory based calculations, we show that the correlated mixed-valent compound SmO is a 3D strongly topological semi-metal as a result of a 4f-5d band inversion at the X point. We also show that the topological non-triviality in SmO is very robust and prevails for a wide range of lattice parameters, making it an ideal candidate to investigate topological nontrivial correlated flat bands in thin-film form. Moreover, the electron filling is tunable by strain. In addition, we find conditions for which the inversion is of the 4f-6s type, making SmO to be a rather unique system. The similarities of the crystal symmetry and the lattice constant of SmO to the well studied ferromagnetic semiconductor EuO, makes SmO/EuO thin film interfaces an excellent contender towards realizing the quantum anomalous Hall effect in a strongly correlated electron system.

1:39PM G7.00011 Topological transport and atomic tunneling-clustering dynamics for aged Cu-doped Bi₂Te₃ crystals
FENGQI SONG, TAISHI CHEN, WENKAI HUANG, ZHAOGUO LI, XUEFENG WANG, Nanjing University, COLLABORATIVE INNOVATION CENTER OF ADVANCED MICROSTRUCTURES COLLABORATION — Here we report the suppression of the bulk conductance of the material by four orders of magnitude by intense aging in (Cu₀.₁Bi₀.₉)₂Te₃₀₀ crystals. The weak antilocalization analysis, Shubnikov de Haas oscillations and scanning tunneling spectroscopy corroborate the transport of the topological surface states. The aging method therefore leads to an optimized band-insulating Ti crystal and appeals to a free-of-IB crystal. STM visualizes the novel defect features of Cu dopants and their dynamics during the aging process, based on which the details of the aging process are further revealed by ab initio calculations. These calculations suggest that there exists a diffusion barrier at the interface of the Bi₂Te₃ QLS. During the aging process, Cu atoms freely migrate inside the QLS and frequently hit the barrier. The dopant atoms will also form clusters in between the QLS, leaving disorder within the QLS. This leads to a pronounced mobility suppression of the bulk electrons, finally allowing the observation of the TSS-related electron transport in bulk crystal samples. An atomic tunneling-clustering picture across a diffusion barrier of 0.57eV is proposed. (Nature Commun. 5, 5022(2014))

2:03PM G7.00013 Surface Shubnikov-de Haas oscillations of the topological hole conduction in the bulk insulator Tl₁−ₓBi₁+xSe₂
GAKU EGUCHI¹, KYOTO UNIV, KENTO KURODA², MAURITIS HAVERKORT, Max Planck Institute for Chemical Physics of Solids, Dresden — Density functional theory calculations predict that Bi₃Te₃ is a 3D topological insulator. Here, we report our study on Bi₂Se₃ thin films using scanning tunneling microscopy. Using the results on Bi₂Se₃, we fabricate thin Tl₁−ₓBi₁+xSe₂, grown from a liquid precursors, within which the Bi₂Se₃ surface is quenched. The Tl₁−ₓBi₁+xSe₂ constitutes a 3D Dirac fermion fluid that shows a strong antilocalization behavior, which is caused by the spin-orbit coupling and many-body effects. The results suggest that topological superconductors can be engineered with Dirac fermions.

Tuesday, March 3, 2015 11:15AM - 2:15PM
Session G8 DCMP: From Single Molecules to Molecular Assemblies on Surfaces II 006C - Pengpeng Zhang, Michigan State University
11:15AM G8.00001 Self-Assembly and Molecular Dynamics Studies: Ab Initio and Molecular Dynamics Studies, ALEXANDER ST. JOHN, CARLOS WEXLER, Univ of Missouri - Columbia — Spontaneous molecular self-assembly is a promising route for bottom-up manufacturing of two-dimensional (2D) nanostructures with specific topologies on atomically flat surfaces. Of particular interest is the possibility of selective lock-and-key interaction of guest molecules inside cavities formed by complex self-assembled host structures. Our host structure is a monolayer consisting of interdigitated 1,3,5-tristryrylbenzene substituted by alkoxy peripheral chains containing n = 6, 8, 10, 12, or 14 carbon atoms (TSB3,5-CN) deposited on a highly ordered pyrolytic graphite (HOPG) surface. Using ab initio methods from quantum chemistry and molecular dynamics simulations, we construct and analyze the structure and functionality of the TSB3,5-CN monolayer as a molecular sieve.

11:27AM G8.00002 Highly-Oriented Molecular Assembly on Monolayer Graphene for Boosting Photon Harvesting in Bilayer Organic Solar Cells, KILWON CHO, Department of Chemical Engineering, Pohang University of Science and Technology — A novel approach to dramatically enhance the photon harvesting in organic solar cells was demonstrated by utilizing a graphene-organic heterointerface. A large area, residue-free monolayer graphene was inserted at anodic interface to serve as an atomically thin, transparent and highly conductive epitaxial template for organic crystal growth with specific orientation. The anisotropic nature of optoelectronic properties of organic semiconductor molecules provided a significant enhancement in exciton diffusion length, optical absorption, charge carrier lifetime as well as the energy level alignment at metal-organic and organic-organic interfaces. Especially, the exciton diffusion length increases up to nearly 100 nm, which allows the device thickness to be doubled to yield 5 times higher power conversion efficiency in comparison to conventional planar heterojunction organic photovoltaic cells. Theoretical simulations as well as systematic studies on the film structure and optoelectrical properties were performed to corroborate our new findings.

11:39AM G8.00003 Ultrastron exciton-photon coupling in single and coupled organic microcavities, BIN LIU, ROSEMARY BRAMANTE, BRENT VALLE, KENNETH SINGER, Case Western Reserve University, TAWFIK KHATTAB, JARROD WILLIAMS, ROBERT TWIEC, Kent State University — We have demonstrated ultrastron light-matter coupling in organic planar microcavities composed of a neat glassy organic dye film between two metallic (aluminum) mirrors in a half-cavity configuration. Such cavities are characterized by Q factors around 10. Tuning the thickness of the organic layer enables the observation of the ultrastron coupling regime. Via reflectivity measurements, we observe a very large Rabi splitting around 1.227 eV between upper and lower polariton branches at room temperature, and we detect polariton emission from the lower polariton branch via photoluminescence measurements. The large splitting is due to the large oscillator strength of the neat dye glass, and to the match of the cavity Q-factor with the width of the dye material. We also investigated the ultrastron coupling between excitonic states of neat glassy organic dye and cavity modes within coupled microcavity structures. The high-reflectivity mirrors are formed from distributed Bragg reflectors (DBR), which are multilayered films fabricated using the coextrusion process, containing alternating layers of high (SAN25, n=1.57) and low (Dyneon THV 220G, n=1.37) refractive index dielectric polymers. Nonlinear optical measurements will be discussed.

This research was supported by the National Science Foundation Center for Layered Polymer Systems (CLiPS) under grant number DMR-0423914.

11:51AM G8.00004 Single molecule dissociation by tunneling electrons in NO-Co-Porphyrin complex on Au(111): A novel mechanics revealed by scanning tunneling spectroscopy and first-principles thermodynamic simulation, YUNHEE CHANG, Graduate School of Nanoscience and Technology, KAIST, HOWON KIM, Dept. of Physics, Korea University, EUI-SUP LEE, Graduate School of Nanoscience and Technology, KAIST, WON-JUN JANG, Dept. of Physics, Korea University, YONG-HYUN KIM, Graduate School of Nanoscience and Technology, KAIST, SE-JONG KAHNG, Dept. of Physics, Korea University — To microscopically understand the mechanisms of electron-induced NO dissociations, we performed first-principles density-functional theory (DFT) calculations for NO-CoTPP on Au(111). We explain the scanning tunneling microscopy (STM) results that the dissociations of NO were induced by both positive and negative voltage pulses with threshold voltages, ~0.68 V and 0.74 V, respectively, at 0.1 nA tunneling current, showing power law relations between tunneling current and dissociation yield. To evaluate first-principles thermodynamics of the NO dissociation, we considered not only adsorption-desorption energetics, zero-point energy, and vibrational free energy at experiment temperature from first-principles, but also the chemical potential of NO gas at the cryogenic ultra-high vacuum condition. Using first-principles thermodynamics for the NO dissociation, we argue that the dissociations are induced with inelastic electron tunneling through molecular orbital resonances.

12:03PM G8.00005 Growth of Thin, Anisotropic, π-Conjugated Molecular Films by Step-Wise ‘Click’ Assembly of Molecular Building Blocks: Characterizing Reaction Yield, Surface Coverage, and Film Thickness vs. Addition Step Number, ABEL DEMISSIE, GREG HAUGSTAD, C. DANIEL FRISBIE, University of Minnesota — Molecular electronics is an active field of nanotechnology that has gained much interest due to the advent of modern microscopy techniques, and thin film synthesis using click chemistry — an approach which has enabled scientists to achieve a sub-angstrom control of monolayer length. Among the major challenges to grow oriented, surface-confined wires by click chemistry is development of synthetic routes that yield monodisperse wires, and lack of systematic way to measure the surface coverage of molecules. In this work, we report a comprehensive characterization of π-conjugated oligophenylene imine (OPI) wires synthesized step-wise by imine condensation click chemistry. OPI wire synthesis began with a self-assembled monolayer (SAM) of 4-formyliphenol or 4-aminothiophenol on Au, followed by alternate addition of terephthaldehyde or phenylenediamine. OPI wires were characterized after each monomer addition using Rutherford backscattering spectrometry, x-ray photoelectron spectroscopy, cyclic voltammetry, reflection-absorption infra-red spectroscopy, and nuclear reaction analysis. We have determined an average extent of reaction greater than 98% completion for each growth step using five different techniques. Overall, these nanoscale scale surface characterization techniques proved to be an extremely sufficient method for monitoring wire growth and surface coverage.

12:15PM G8.00006 Direct Patterning of Organic Self-Assembled Monolayer (SAM) on GaAs Surfaces via Dip-Pen Nanolithography (DPN), PENG XIONG, TIMOTHY KEIPER, Department of Physics, Florida State University, XIAOLEI WANG, JIANHUA ZHAO, Institute of Semiconductors, CAS — Hybrid structures of functional molecules and solid-state (SS) materials have attracted extensive interest in surface nanoscience and molecular electronics. The formation and micro/nano patterning of organic SAMs on SS surfaces are a key step in fabricating such devices. Here we report realization of high quality MHA SAMs on GaAs and direct formation of micro/nanoscale patterns of MHA SAM on the surface by micro-contact printing (µCP) and DPN. The process begins with the preparation of an oxide-free surface of GaAs, for which we employed treatment by an ammonium polysulfide ((NH₄)₂S₉) solution. The treatment strips native oxides from GaAs creating an atomic layer of sulfur covalently bonded to the fresh surface. Formation of high-quality SAMs of thiol molecules on GaAs then proceeds through exchange of the sulfur and the thiol terminal of the molecules. The effects of the sulfur-passivation and formation of MHA SAM on the treated surface were confirmed by XPS, HRTEM, and DPN. To the best of our knowledge, this is a first realization of direct DPN of nanoscale organic SAM on a semiconductor free of surface oxide. We further evidence the utility of the hybrid platform by demonstrating directed self-assembly of Au nanoparticles onto MHA/ODT SAM templates on GaAs.
12:27PM G8.00007 The S(2p) Core Level Binding Energies for Alternative Adsorption Sites and the Example of Thiol Self Assembly*, JUANJUAN JIA, VLADIMIR ESAULOV, Universite Paris Sud, ABDELKADER KARA1, University of Central Florida — Results of an investigation of the characteristics of thiol SAMs obtained by vacuum evaporative adsorption, useful for reactive substrates, are presented along with core level binding energy (BE) calculations. Thiold ended SAMs of 1,4-benzenedimethanethiol (BDMT) are obtained by evaporation on Au. They display an unconventional BE structure at about 161 eV, which is close to a known BE of an S atom on Au. S(2p) core level BE calculations for molecules chemisorbed on hollow, bridge and atop sites are reported and suggest that the 161 eV peak is indeed due to an alternative adsorption site, which can be associated to an atom configuration. This must therefore not be confused with atomic sulfur and dissociation processes with S-C bond scission.

12:39PM G8.00008 Spatial Arrangement of Organic Compounds on a Model Mineral Surface: Implications for Soil Organic Matter Stabilization*, HAIKE AMBAYE, LOUKAS PETRIDIS, ORNL, SINDHU JAGADAMMA, MICHAEL KILBEY, University of Tennessee, VALERIA LAUTER, BRADLEY LOKITZ, MELANIE MAYES, ORNL — Stability of organic carbon compounds in soil is important for global climate futures which could be affected by the complexity of the mineral-organic carbon interfaces. We examined the nanoscale structure of model interfaces by depositing films of organic carbon compounds of contrasting chemical character, hydrophilic glucose, deuterated-amphiphilic stearic acid (SA) and Natural Organic Matters (NOM) onto a soil mineral analogue (Al₃(OH)₄). The NOM was separated into its component such components as NOM-Phiic and NOM-Phobic when it is deposited onto the soil mineral. We used Neutron Reflectivity technique to understand the depth-organization of the thin films. The result indicates that glucose molecules reside in a layer between Al₂O₃ and stearic acid and SA self-assembles. No self-assembly of SA was observed when SA and NOM-Phobic was deposited on the mineral soil. Molecular dynamics simulations reveal the thermodynamic driving force behind glucose partitioning on the mineral interface.

1Funded by ORNL Director’s Research and Development Program. Research at ORNL was sponsored by the BES, DOE.

12:51PM G8.00009 Sliding friction of thick and thin oxygen layers on spin crossover materials*, ZACHARY B. FREDRICS, K. M. STEVENS, DANIEL DOUGHERTY, JACQUELINE KRIM, North Carolina State University — Friction at the nanoscale is known to encompass phononic, electrostatic, conduction electronic and magnetic effects [1], with relatively little known about magnetic contributions to friction [2]. To probe such effects we have employed a quartz crystal microbalance technique to record the sliding friction associated with thin and thick films of solid and liquid oxygen, a paramagnetic material, atop nanoscale films of the spin-crossover material Fe([H₂Bpz₂]₂)bpv, which is diamagnetic at cryogenic temperatures and paramagnetic at room temperature. Previously these systems have been shown to be frictionally sensitive to the application of small fields, for Pb(111) substrates [3]. We observe changes in dissipation as well for Fe([H₂Bpz₂]₂)bpv, in response to externally applied magnetic fields. We will report our efforts to model the frictional interaction, which is reduced in the presence of a weak applied magnetic field, and is also observed to be temperature dependent.

1:03PM G8.00010 Imaging Surface Reactions of Formaldehyde on TiO₂*, ZHENRONG ZHANG, Department of Physics, Baylor University, MIRU TANG, Department of Chemistry and Biochemistry, Southern Illinois University, ZHI-TAO WANG, Pacific Northwest National Laboratory, ZHU KE, YAOBIAO XIA, KENNETH PARK, Department of Physics, Baylor University, IGOR LYUBINETS, ZDENEK DOHÁLEK, Pacific Northwest National Laboratory, QINGFENG GE, Department of Chemistry and Biochemistry, Southern Illinois University — Formaldehyde is involved in many surface catalytic and photo-catalytic reactions on metal oxides. We studied surface reactions of formaldehyde on reduced TiO₂(110) surfaces using variable-temperature scanning tunneling microscopy (STM) and density functional theory (DFT). STM images taken from a same area at various temperatures clearly show that formaldehyde preferentially adsorbs on the bridge-bonded oxygen vacancy (V₂O) defect sites. Bias-dependent STM images suggest the bonding configurations of the Ti-bound CH₂O and the V₂O-bound CH₂O. The isothermal time dependent images show the rotation of V₂O-bound CH₂O and the two diffusion channels of formaldehyde at different temperatures. We also directly observed the formation of formaldehyde dimmer.

1:15PM G8.00011 Water adsorption on non polar ZnO surfaces: from single molecules to multilayers*, STEPHANE KENMOE, P. ULRICH BIEDERMANN, Max-Planck Institute fuer Eisenforschung — The interface between water and ZnO plays an important role in many domains of technological relevance. Following the vital role of adsorbed water on substrate properties and the fascinating properties of interfacial water, there is a great interest in characterizing this interface. We use DFT to study the possible aggregation regimes that can form on the ZnO non-polar low-index (1010) and (1120) surfaces. We study the adsorption of water monomers, small water clusters like water dimers, water chains, ladder-like water structures, water thin films and water multilayers. Based on this, trends in binding energy as well as the binding mechanisms are analyzed to understand the driving forces and the nature of the fundamental interactions that stabilize the adsorbed layers.

1:27PM G8.00012 Adsorption, vibration and diffusion of oxygen on Ag(110)*, KATAK RAWAL, SAMPOYO HONG, University of Central Florida, AKI PULKINEN, Lappeenranta University of Technology, MATTI ALATALO, University of Oulu, TALAT RAHMAN, University of Central Florida — We have performed density functional theory calculations for the adsorption, vibration and diffusion of oxygen on Ag(110). At low coverage, O₂ adsorbs at the four-fold hollow (FFH) with the molecular axis aligned along the [110] direction. The dissociation of O₂ is easier along the [001] direction than along the [110] direction. For O₂ species in FFH aligned along the [001] the O-O intra-molecular stretching mode is coupled with the substrate vibration and thus its dissociation can be induced by surface phonon. In addition, O diffusion barrier from FFH to next FFH along the [110] is small (0.07 eV only) but is by far larger (0.4 eV) along [001]. On the other hand, O species in the short-bide (SB) site prefers to diffuse along the [001] (to FFH) rather than along the [110] direction (to next SB). Finally, the preference of atomic oxygen to form O-Ag-O complex on Ag(110) is responsible for disordering of the surface by means of substantial lateral and vertical displacements of Ag atoms in the topmost layer. In fact, such disordering phase of Ag(110) may act as a precursor of the reconstructed phase of Ag(110).

1Work supported in part by NSF under grant CHE-1310327
on the adsorption energy of CO thin film. The adsorption/desorption energy for desorption was obtained. (XPS) and Auger Electron Spectroscopy (AES). Our results revealed that carbon dioxide interacts with CuFeO2 forming Fe carbonates compounds on its surface.

resulted with highly epitaxial crystal structure. The adsorption/desorption of CO2 and H2O process was also monitored with X-ray Photoelectron Spectroscopy (XPS). A standard UHV chamber, The CuFeO2 thin film grown using Pulsed Laser Deposition (PLD) over an Al2O3 (0001) substrate with controlled O2 atmosphere was employed to investigate the effective thermal conductivity (Keff) and thermal boundary resistances (Rbd) of polymer composites containing carbon nanotubes (CNTs) and inorganic nanoparticles. By considering the synergistic effect of CNTs and nanoparticles, our model more accurately predicted Keff of 3-phase composites than effective medium theories (EMTs). Complex morphology of CNTs (diameter, length) and the heat transfer at interfaces (Rbd) were quantified to study their influences on Keff. By matching the simulated Keff with the measured Keff, Rbd of polymer-CNT and polymer-nanoparticle could be estimated. The results showed that Keff of composites increases when CNT fraction increases and when Rbd of polymer-nanofillers (CNTs and nanoparticles) decreases. CNT bundle was built to investigate its effect on Keff of composites, which had not been considered in EMTs. It was found that when CNT bundles increase, Keff decreases in the composites with random and parallel CNTs, whereas, Keff increases in those with perpendicular CNTs.
11:51AM G9.00004 High-throughput computational search for new high mobility transparent (semi)conducting oxides, GEOFFROY HAUTIER, Université catholique de Louvain — Transparent conducting oxides (TCOs) are large band gap materials (to favor transparency) doped with electrons (n-type) or holes (p-type). TCOs are essential to many technologies from solar cell to transparent electronics. We will discuss several unsolved problems with promising electronic structures and present preliminary experimental results. Beyond the description of new TCO candidates, I will chemically rationalize our findings, highlighting several design strategies towards the development of future high mobility TCOs.

12:27PM G9.00005 Transparent Conductive Oxides as Near-IR Plasmonic Materials for Energy Conversion, ARRIGO CALZOLARI, CNR-NANO-S3, ALICE RUINI, Universita’ di Modena e Reggio Emilia, ALESSANDRA CATELLANI, CNR-NANO-S3, MARCO BUONGIORNO NARDELLI, University of North Texas — Using first principles calculations, we investigate the origin of near-infrared plasmonic activity in M-doped ZnO, one of the most promising transparent conducting oxide (TCO) materials. Our results [1-2] predict realistic values for the plasma frequency and the free electron density as a function of the M-doping, in agreement with recent experimental results. Then we characterize the plasmon properties of In-doped nanowires that have been envisaged as plasmonic nanoparticles for energy conversion applications.

12:39PM G9.00006 Engineering the bandgap of ferroelectric ZnSnO\textsubscript{3} via sulfur substitution, BRIAN KOLB, ALEXIE KOLPAK, MIT — Since its recent discovery, ferroelectric ZnSnO\textsubscript{3} has been investigated for utility in a number of applications. Its strong remnant polarization and good conductivity, for example, make it attractive as a photovoltaic material, but its relatively large 3 eV bandgap limits its potential usefulness. We find that the bandgap of ZnSnO\textsubscript{3} is highly sensitive to changes in lattice volume, which can be effected either with application of external strain or by substituting sulfur for oxygen. Upon forming the fully-substituted ZnSnS\textsubscript{3}, the bandgap reduces to a near-optimal 1.3 eV while retaining many of the important properties of the oxide, including a strong polarization. In this talk we describe the physics governing the tunable electronic structure of ZnSnO\textsubscript{3}, discuss the stability of the ZnSnS\textsubscript{3} analogue, and propose a route to its use in a photovoltaic cell by growth on a GaN substrate.

12:51PM G9.00007 p-type transparent conducting chalcogenides, HONGLIANG SHI, BAYRAMMURAD SAPAROV, DAVID SINGH, ATHENA SEFAT, MAO-HUA DU, Oak Ridge National Lab, MATERIALS SCIENCE & TECHNOLOGY DIVISION COLLABORATION — Transparent conducting materials are an important component in many optoelectronic devices ranging from solar cells to transparent electronics. A good transparent conducting material must allow high optical transmittance across a wide optical spectrum, requiring a large optical band gap (>3.0 eV), and have high conductivity. However, in materials high conductivity and large band gaps usually do not coexist. At present, only a few materials are known to be reasonably good n-type transparent conducting oxides (TCOs). The p-type TCOs are still plagued by their poor hole conductivity, usually two orders of magnitudes lower than the highest electron conductivity in the n-TCOs. Chalcogenides usually have better hole conductivity, but their band gaps are usually too small. In this study, first-principles calculations are used to design new chalcogenides with large band gaps. New ternary chalcogenides, i.e., C\textsubscript{5}S\textsubscript{2}Zn\textsubscript{4}Se\textsubscript{4} and C\textsubscript{5}S\textsubscript{2}Zn\textsubscript{3}Te\textsubscript{4}, are found by calculations to be chemically stable and have both large band gaps (>3.0 eV) and small effective masses. These new ternary chalcogenides are synthesized and found to be air stable.

1:03PM G9.00008 Comparative first principles study for Li, Na, and Mg storage at rutile, anatase, bronze, and amorphous TiO\textsubscript{2}, KONSTANTINOS KOTSIS, FLEUR LEGRAIN, SERGEI MANZHOS, National University of Singapore — TiO\textsubscript{2} has been studied very extensively and its applications in various fields, e.g. applications in energy storage and catalysis are well known [1, 2]. Crystalline, amorphous and amorphous/crystalline titania have emerged as anode materials for Li and post-Li batteries due to good capacity, high rates [2, 3], and safety. Which is why the electronic and atomic structures as well as the properties of various crystalline TiO\textsubscript{2} phases have recently attracted much research interest. Amorphous TiO\textsubscript{2} (a-TiO\textsubscript{2}) phase also looks promising based on the few available studies but is much less explored [3, 4, 5, 6]. We have previously shown that amorphization of Si improves storage energetics of Li, Na, Mg [7], and there are reasons to believe that a-TiO\textsubscript{2} will achieve the same. At high rates of charge-discharge, capacitive contribution to the specific capacity of titania electrodes becomes significant [8, 9, 10]. Therefore, interfacial effects are critical for the performance of titania-based anodes and need to be understood. We present a comparative first principles study of Li, Na, and Mg storage at rutile (R), anatase (A1), and (B) (110) surfaces) and amorphous TiO\textsubscript{2} and compare the results to Li, Na, Mg.

1:15PM G9.00009 Probing for cationic dopants in lanthanum manganite for solid oxide fuel cell applications, SRIDEVI KRISHNAN, VINITH SHARMA, Material Science and Engineering, Institute of Materials Science, University of Connecticut, Storrs, MANOJ K MAHAPATRA, PRABHAKAR SINGH, Material Science and Engineering, Center for Clean Energy Engineering, University of Connecticut, Storrs, RAMPAL RAMPRASAD, Material Science and Engineering, Institute of Materials Science, University of Connecticut, Storrs — Solid oxide fuel cells (SOFC) are an efficient source of clean energy. Long-term stability of SOFC cathodes is ensured along with thermophysical characteristics. Sr-doped LaMnO\textsubscript{3} is one of the active material for this application. A suitable choice of the dopant has a significant influence on the stability and performance of the cathode material at elevated operating temperature. Using first principles computations, we compare the stability of the LaMnO\textsubscript{3} host for a range of cationic dopants including alkali, alkaline earth metals, 3d, 4d and 5d transition metal elements in the absence and presence of an oxygen vacancy. The stability of doped LaMnO\textsubscript{3} against decomposition to various combinations of metals and oxides is assessed using a linear programming based algorithm, and the oxygen vacancy promoters are identified. Properties of the dopants like the ionic radius, oxidation state, magnetic moment and Mendeleev number are correlated with their potential usefulness. We find that the bandgap of ZnSnO\textsubscript{3} is highly sensitive to changes in lattice volume, which can be effected either with application of external strain or by substituting sulfur for oxygen. Upon forming the fully-substituted ZnSnS\textsubscript{3}, the bandgap reduces to a near-optimal 1.3 eV while retaining many of the important properties of the oxide, including a strong polarization. In this talk we describe the physics governing the tunable electronic structure of ZnSnO\textsubscript{3}, discuss the stability of the ZnSnS\textsubscript{3} analogue, and propose a route to its use in a photovoltaic cell by growth on a GaN substrate.

1:27PM G9.00010 Designing brownmillerite SrCoO\textsubscript{2.5} (BM-SCO) as a cathode material — a first principles study of oxygen diffusion process in BM-SCO, CHANDRIMA MITRA, TRICIA MEYER, HO NYUNG LEE, FERNANDO REBOREDO, Oak Ridge National Laboratory — The discovery and design of new materials for next generation energy devices are crucial steps towards addressing various energy-related issues. ABO\textsubscript{3−x} type perovskite oxides have emerged as promising candidates for cathode/electrolyte materials in solid oxide fuel cells (SOFC’s). In this work, we investigate oxygen diffusion in brownmillerite oxide SrCoO\textsubscript{2.5} (BM-SCO), employing a first principles approach. Our calculations indicate highly anisotropic diffusion pathways, which result from its anisotropic crystal structure. The one-dimensional vacancy channels are found to be reasonably good n-type transparent conducting oxides (TCOs). New ternary chalcogenides, i.e., C\textsubscript{5}S\textsubscript{2}Zn\textsubscript{4}Se\textsubscript{4} and C\textsubscript{5}S\textsubscript{2}Zn\textsubscript{3}Te\textsubscript{4}, are found by calculations to be chemically stable and have both large band gaps (>3.0 eV) and small effective masses. These new ternary chalcogenides are synthesized and found to be air stable.

1:39PM G9.00011 A DFT study of oxygen reduction reaction on single-atom Pt nanocatalyst , YOUNGJOO TAK, NORINA A. RICHTER, ALOYSIUS SOON, Global E3 Institute, Department of Materials Science and Engineering, YonseiUniversity, Seoul 120-749, Korea — Platinum is one of the most broadly used catalyst for many chemical reactions (e.g. oxygen reduction reaction). Although its great reactivity, platinum catalysis has not met enthusiastic reception from industry due to its high price. Pt/C catalyst is widely used to come over this problem, but still considered as an imperfect solution because of its poor stability [1,2]. Recently, platinum single-atom catalyst with TiN support has suggested and proved to be stable on the N vacancy site of TiN support under N-lean condition [3]. In this work, we present density-functional theory (DFT) study of the oxygen reduction reaction on single Pt atom embedded on the surfaces of TiN(100) and TiC(100) within the computational hydrogen model (CHE) [4].

1:51PM G9.00012 Gold-doped graphene as a cost-effective, highly stable and active electrocatalyst for the oxygen reduction reaction: prediction from first principles. SERGEY STOLBOV, MARIOL ALCANTARA ORTIGOZA, University of Central Florida — One of the main obstacles hindering large scale practical application of hydrogen fuel cells is a prohibited cost of the Pt (or Pt-based) catalysts for the oxygen reduction reaction (ORR) on the fuel cell cathode. In this work, we consider Au-doped graphene as an alternative to Pt for facilitating ORR. Our first-principles calculations show that Au atoms incorporated into graphene di-vacancies form a thermodynamically and electrochemically stable structure. Furthermore, calculation of the binding energies of the ORR intermediates reveals that Au-C bonding makes the C atoms neighboring to Au optimally reactive for ORR. The calculated ORR free energy diagrams suggest that the Au-graphene structures have an ORR onset potential as high as that of Pt. We also demonstrate that the linear relation among the binding energy of the reaction intermediates assumed in a number of works on computational high-throughput material screening does not hold, at least for this none purely transition-metal material.

2:03PM G9.00013 ABSTRACT WITHDRAWN

Tuesday, March 3, 2015 11:15AM - 2:15PM
Session G10 DCMP: Interacting Dirac and Parabolic Semimetals 007A - Igor Herbut, Simon Fraser University

11:15AM G10.00001 Influence of electronic band topology on phonon properties in Dirac materials1, ION GARATE, KUSH SAHA, KATHERINE LEGARE, Université de Sherbrooke — In Dirac materials, the interaction between electrons and long-wavelength phonons has been shown to induce and stabilize topological insulator [1-2]. Here report on a theoretical study of the converse effect, namely the influence of band topology on phonon properties. We calculate how electron-phonon interactions change the bulk phonon dispersion as a function of pressure and temperature, in both trivial and topological phases. We find that (i) topological insulators are more prone to lattice instabilities than trivial insulators, and (ii) Raman and neutron scattering measurements can be used to determine the electronic band topology.

11:27AM G10.00002 Weyl Semimetal in the Limit of Strong Coulomb Interactions , AKIHKO SEKINE, KENTARO NOMURA, Institute for Materials Research, Tohoku University — Weyl semimetals have a topological property such that an energy gap opens only if the Weyl nodes with opposite chirality meet and annihilate each other. Then it is expected that Weyl semimetals are stable against perturbations. Motivated by this, we study the stability of a time-reversal symmetry broken Weyl semimetal with two nodes against strong 1/r long-range Coulomb interactions. We consider the case where magnetic impurities are doped into a 3D topological insulator, and take into account the 1/r Coulomb interactions between the bulk electrons. In this case, the system can be described by the U(1) lattice gauge theory. With the use of the strong coupling expansion of the lattice gauge theory and the mean-field approximation, we analyze the system from the strong coupling limit. It is shown that parity (spatial inversion) symmetry of the system is spontaneously broken in the strong coupling limit, and a different type of the Weyl semimetal, in which time-reversal and parity symmetries are broken, appears in the strong coupling limit.

11:39AM G10.00003 Topological Mott Insulator in Three-Dimensional Systems with Quadratic Band Touching , LUKAS JANSSSEN, IGOR HERBUT, Simon Fraser University — We will discuss the effects of the long-range Coulomb interaction in three-dimensional systems in which conduction and valence bands touch quadratically at the Fermi level. Such band structure is realized in various strongly spin-orbit-coupled materials, such as HgTe, α-Sn, and some pyrochlore iridates. We will argue that these systems may be unstable towards spontaneous formation of the strong topological Mott insulator already at weak long-range Coulomb interaction. The mechanism of the instability can be understood as the collision of a non-Fermi-liquid fixed point, discovered by Abrikosov in the 70s and revisited recently, with another, critical, fixed point, which approaches it in the coupling space as the system's dimensionality approaches a certain “critical dimension” from above. Some universal characteristics of this scenario, the width of the non-Fermi-liquid crossover regime, and the observability of the topological Mott phase will be discussed. Reference: I. F. Herbut and L. Janssen, Phys. Rev. Lett. 113, 106401 (2014).

11:51AM G10.00004 Interacting Weyl semimetals: characterization via the topological Hamiltonian and its breakdown , WILLIAM WITCZAK-KREMPA, Perimeter Institute for Theoretical Physics, MICHAEL KNAP, Harvard University, DMITRY ABANIN, Perimeter Institute for Theoretical Physics — Weyl semimetals (WSMs) have robust linearly-dispersing excitations. Unusual properties arise from the latter, such as anomalous electrodynamics responses and open Fermi arcs on boundaries. We derive a simple criterion to identify and characterize WSMs in an interacting setting using the exact electronic Green’s function at zero frequency, which defines a topological Bloch Hamiltonian. We apply this criterion by numerically analyzing, via cluster and other methods, interacting models with and without time-reversal symmetry. We thus identify mechanisms for how interactions move and renormalize Weyl fermions. Our methods remain valid in the presence of long-ranged Coulomb repulsion. Finally, we introduce a WSM-like phase for which our criterion breaks down, due to fractionalization of the electron.

12:03PM G10.00005 ABSTRACT WITHDRAWN
12:15PM G10.00006 Magnetotransport properties of three-dimensional Weyl semimetals

NAVNEETH RAMAKRISHNAN, MIRCO MILLETARI, SHAFFIQUE ADAM, Natl Univ of Singapore — We investigate theoretically the transport and magnetotransport properties of three-dimensional Weyl semimetals. We consider the RPA-Boltzmann transport theory relevant for non-interacting electrons scattering off randomly distributed charged impurities, and employ an effective medium theory to average over the resulting spatially inhomogeneous carrier density profile. Our formalism allows us to smoothly connect results for the minimum conductivity near the Dirac point with known results for the conductivity at high carrier density. In the presence of a non-quantizing magnetic field, we predict that the magnetoresistance shows a transition from quadratic at low magnetic fields to linear at higher fields. In addition, our formalism can qualitatively explain some recent unexpected experimental results on the mixed-chalcogenide compound TIBiS2Se. This work is supported by the Singapore National Research Foundation NRF-NRFF2012-01.

1:27PM G10.00007 Interaction-driven phase instabilities in two-dimensional quadratic band touching systems

JAMES MURRAY, National High Magnetic Field Laboratory, Tallahassee, KELLY PAWLAK, University of California, Santa Barbara, OSKAR VAFEK, National High Magnetic Field Laboratory and Florida State University — Quadratic band touching (QBT) systems, in which an upward-dispersing and a downward-dispersing energy band meet at a single point in momentum space, have emerged as an attractive arena in which to study multicriticality and intertwined orders driven by electron interactions. Analogous to the two-valley QBT occurring in bilayer graphene, single-valley QBTs such as those arising on checkerboard and kagome lattices exhibit phase instabilities in multiple channels even for arbitrarily weak interactions. Using a Wilsonian renormalization group procedure, we show - without requiring spin-orbit coupling or special values of the interaction - that the leading instabilities in the half-filled system are toward quantum anomalous Hall or quantum spin Hall phases. Upon doping away from half-filling, the repulsive interactions lead to superconductivity in s-wave or d-wave channels.

12:39PM G10.00008 Calculation of the magneto-optical response of Kane fermions in HgCdTe

JOHN MALCOLM, ELISABETH NICOL, University of Guelph — The concentration x = x_c ≈ 0.17 in Hg_xCd_{1-x}Te describes a critical value in the phase transition between semimetal (x < x_c) and semiconductor (x > x_c). At this critical value, the low-energy quasiparticle dispersion exhibits a node at the intersection of two doubly degenerate linear cones and an equally degenerate flat band: quasiparticles that have been dubbed Kane fermions [1]. We present our results for the calculation of the magneto-optical spectra of these Kane fermions in the three-dimensional material, which can be compared to experiment, and also for those confined to only two-dimensions. The latter allows for a direct comparison to the analogous theoretical Dirac-Weyl system in two dimensions with pseudospin one [2].

12:51PM G10.00009 Topological property and phase transition in three dimensional Dirac semimetal

YONGPING DU, BO WAN, XIANGANG WAN, Nanjing University — Based on first-principles calculations and effective model analysis, we find a new three dimensional Dirac semimetal. This material has a Dirac point protected by crystal symmetry. It can be driven into various topological phases and Weyl semimetal state by breaking symmetries. This material may have linear quantum magnetoresistance, quantum spin Hall effect.

1:03PM G10.00010 Dirac Circles and Quantum Hall Effect in 3D Inversion-Symmetric Crystals

BENJAMIN J. WIEDER, Department of Physics and Astronomy, University of Pennsylvania, YOUNGKUK KIM, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, C.L. KANE, Department of Physics and Astronomy, University of Pennsylvania — In the presence of inversion and time-reversal symmetries, materials with weak spin-orbit coupling may host topologically protected Dirac line nodes. A band inversion transition in these systems can produce a line node which closes on itself and forms a protected Dirac circle. The surfaces parallel to this circle host zero-energy puddles in momentum space which are flat if the inverting bands have the same effective mass. In cases with differing effective masses, the surface modes disperse, but the bulk Dirac circle remains gapless. Adding an external magnetic field perpendicular to this circle creates surface Landau levels, whose number can be controlled by tuning the field strength. When a new level is created or destroyed, the bulk becomes gapless and the zero-temperature bulk conductivity displays a sharp peak. The sequence of conductivity peaks describes an unusual manifestation of the integer quantum hall effect. We characterize surface and bulk transport as a function of magnetic field strength and in the presence of disorder.

1:15PM G10.00011 Topological Node-Line Semimetal in Three Dimensional Graphene Networks

HONGMING WENG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, YUNYE LIANG, New Industry Creation Hatchery Center, Tohoku University, Japan, QIUNAN XU, Institute of Physics, Chinese Academy of Sciences, RUI YU, International Center for Materials Nanoarchitectonics (WPI-MANA), National Institute for Materials Science, ZHONG FANG, XI DAI, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, YOSHIYUKI KAWAZOE, New Industry Creation Hatchery Center, Tohoku University, Japan & Thermophysics Institute, Siberian Branch, Russian Academy of Sciences, Russia — Graphene, a two dimensional (2D) carbon sheet, acquires many of its amazing properties from the Dirac point nature of its electronic structures with negligible spin-orbit coupling. Extending to 3D space, graphene networks with negative curvature, called Mackay-Terrones crystals (MTC), have been proposed and experimentally explored, yet their topological properties remain to be discovered. Based on the first-principle calculations, we report an all-carbon MTC with topologically non-trivial electronic states by exhibiting node-lines in bulk. When the node-lines are projected on to surfaces to form circles, “drumhead” like flat surface bands nestled inside of the circles are formed. The bulk node-line can evolve into 3D Dirac point in the absence of inversion symmetry, which has shown its plausible existence in recent experiments.

1:27PM G10.00012 Topological states of Sb thin films over doped graphene

CHI-HSUAN LEE, CHIH-KAI YANG, National Chengchi University — Electronic properties of Sb thin films on pure, boron-doped, and nitrogen-doped graphene are investigated using density functional calculations. Various stacking configurations are taken into consideration. Sb films on boron-doped graphene have stronger interaction than those on pure or nitrogen-doped graphene. Dirac cones also occur in these systems and can serve as conduits for spin-polarized conduction. The results are useful for applications in topological transport and spintronics.

1:39PM G10.00013 ABSTRACT WITHDRAWN
1:51PM G10.00014 Phonon analogue of topological nodal semimetals. HOI CHUN PO, YASAMAN BAHRI, ASHVIN VISHWANATH, Univ of California - Berkeley — Recently, Kane and Lubensky proposed a mapping between bosonic phonon problems on isostatic lattices to chiral fermion systems based on factorization of the dynamical matrix [Nat. Phys. 10, 39 (2014)]. The existence of topologically protected zero modes in such mechanical problems is related to their presence in the fermionic system and is dictated by a local index theorem. Here we adopt the proposed mapping to construct a two-dimensional mechanical analogue of a fermionic topological nodal semimetal that hosts a robust bulk node in its linearized phonon spectrum. Such topologically protected soft modes with tunable wavevector may be useful in designing mechanical structures with fault-tolerant properties.

2:03PM G10.00015 Photoinduced Topological phase Transition in a 2D Fermi System with a Quadratic Band Crossing. XIAOTING ZHOU, GREGORY A. FIETE, Department of Physics, Univ of Texas, Austin — Recent years, physicists have been gripped by the topological phases in condensed matter systems, and many attentions have been concentrated on the pursuit of new topological matters. The achievement of the topological control by the external fields provides a new direction. Using Floquet theory, we demonstrate that, a topologically stable quadratic band-crossing point (QBCP), carrying a Berry flux $\pm 2\pi i$ (or $-2\pi i$), would be splitted into 2 Dirac points with Berry flux $\pi$ (or $-\pi$), by the irradiation of a linearly polarized light. And the QBCP will either be lifted due to the breaking of the time-reversal symmetry, or go to a trivial QBCP with distinct topological properties, by introducing a circularly polarized light. Therefore, the manipulation of band structure could be realized.

Tuesday, March 3, 2015 11:15AM - 2:15PM – Session G11 DMP: Focus Session: Superconductivity in the 2D Limit

11:15AM G11.00001 Superconductivity in Electric Double Layer Capacitor under Pressure. M. MCCANN, MARTIN MISEK, KONSTANTIN KAMENEV, ANDREW HUXLEY, Centre for Science at Extreme Conditions, The University of Edinburgh — Chemical doping generally provides the most common method for tuning into the superconducting state of a material yet can be difficult to control and also potentially introduces structural disorder complicating the underlying physics. Electric Double Layer devices however provide a means to electrostatically dope materials with high electric fields allowing continuous tuning of a 2D superconducting state thus avoiding such issues. One such device is the Electric Double Layer Capacitor which can detect the onset of superconductivity through AC magnetisation measurements. We make use of a similar device in an attempt to electrostatically dope and tune the superconductivity in the cuprate compound La$_1.9$Sr$_0.07$CuO$_4$ as well as investigating whether application of pressure improves its efficiency.

11:27AM G11.00002 Doping evolution and polar surface reconstruction of the infinite-layer cuprate Sr$_{1−x}$La$_x$CuO$_2$. JOHN HARTER, Department of Physics, Cornell University, LUIGI MARITATO, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University, KYLE SHEN, Department of Physics, Cornell University — We use angle-resolved photoemission spectroscopy to study the doping evolution of infinite-layer Sr$_{1−x}$La$_x$CuO$_2$ thin films grown by molecular-beam epitaxy. At low doping, the material exhibits a dispersive lower Hubbard band typical of the superconducting cuprate parent compounds. Electron diffraction probes reveal a $p(2 \times 2)$ reconstruction of the surface. Using a number of simple assumptions, we develop a model of this reconstruction based on the polar nature of the infinite-layer material. As carriers are added to the system, a continuous evolution from Mott insulator to superconducting metal is observed as a coherent low-energy band develops with a concomitant remnant lower Hubbard band, gradually lifting in the Mott gap. This two-component spectral function emphasizes the important role that strong local electron correlations play in the electronic structure of Sr$_{1−x}$La$_x$CuO$_2$ even at relatively high doping levels. Finally, we confirm the theoretical prediction of a thickness-controlled transition in ultrathin films of SrCuO$_2$ grown on nonpolar SrTiO$_3$, highlighting the diverse structural changes that can occur in polar complex oxide thin films.

11:39AM G11.00003 Oxygen redistribution and induced high-Tc superconductivity at the CaCuO$_2$/SrTiO$_3$ interface. CLAUDIA CANTONI, Oak Ridge National Laboratory, DANIELE DI CASTRO, CNR-SPIN and Dipartimento di Ingegneria Civile e Ingegneria Informatica, Universitá' di Roma Tor Vergata, Via del Politecnico 1, I-00133 Roma, Italy, CARMELA ARUTA, CNR-SPIN, Dipartimento di Scienze Fisiche, Via Cintia, Mont S. Angelo, 80126 Napoli, Italy, GIUSEPPE BAILESTRINO, CNR-SPIN and Dipartimento di Ingegneria Civile e Ingegneria Informatica, Universitá’ di Roma Tor Vergata, Via del Politecnico 1, I-00133 Roma, Italy — High-Tc cuprate superconductors (HTS) can be extended and anisotropy of the 2D-superconductivity and the Rashba spin-orbit field can be largely modulated by controlling the 2D-QW subband filling. Our results indicate a route to manipulate selectively the electronic properties of QWs at the LaAlO$_3$/SrTiO$_3$ interface, naturally suggesting the opportunity to exploit similar interfaces as a charge reservoir to dope a cuprate IL. We have explored the system in which LAO is replaced by the insulating IL CaCuO$_2$ (CCO/STO interface) and found a Tc of 50 K. This interface closely reproduces the IL/CR native interface of HTS and can be used to extract important information on the physical processes occurring in HTS. Present atomicly resolved ABF-STEM and EELS measurements, which combined with XAS uncover the existence of interfacial apical O atoms. We will discuss their electronic signature for superconductivity.

11:51AM G11.00004 Engineering LaAlO$_3$/SrTiO$_3$ quantum wells by selective orbital occupancy. GERVASI HERRANZ, Institute for Materials Science of Barcelona ICMAB-CSIC — The two-dimensional confinement of electrons in quantum wells (QWs) along the interface between two semiconductors such as Si or GaAs has been fundamental for technology as well for the development of new fundamental concepts. More recently, the discovery of 2D-QWs in oxides, with the flagship interface between LaAlO$_3$ and SrTiO$_3$, has been heralded as a milestone in the research of 2D electron systems. Unlike more conventional 2D-QWs based on III-V or II-VI semiconductors, carriers at LaAlO$_3$/SrTiO$_3$ populate narrow 3d-bands, where strong correlations underlie complex phases not present in conventional semiconductors. In LaAlO$_3$/SrTiO$_3$ not all the electrons reside in the same QW subband and, indeed, they behave differently depending on which orbital are they occupying. Here we demonstrate that the symmetry of the conduction band inside the QWs can be selected, disclosing unprecedented ways to tailor the electron properties. More specifically, we show that the spatial extension and anisotropy of the 2D-superconductivity and the Rashba spin-orbit field can be largely modulated by controlling the 2D-QW subband filling. Our results indicate a route to manipulate selectively the electronic properties of QWs at the LaAlO$_3$/SrTiO$_3$ interface, opening new prospects to understand the link between orbital symmetry and 2D-superconductivity and to achieve enhanced properties suitable for spin-dependent transport.
12:27PM G11.00005 Top gating control of superconductivity at the LaAlO3/SrTiO3 interfaces. ALEXIS JOUAN, SIMON HURAND, CHERYL FEUILLET-PALMA, GYANENDRA SINGH, JEROME LESUEUR, NICOLAS BERGAL, Laboratoire de Physique et d’Etude des Matériaux - CNRS - ESPCI ParisTech - UPMC, EDOUARD LESNE, NICOLAS REYREN, Unite Mixte de Physique CNRS-Thales, 1 Av. A. Fresnel, 91767 Palaiseau, France — Transition metal oxides display a great variety of quantum electronic behaviors. Epitaxial interfaces involving such materials give a unique opportunity to engineer artificial materials where new electronic order parameters take place. It has been shown that a superconducting two-dimensional electron gas could form at the interface of two insulators such as LaAlO3 and SrTiO3 [1], or LaTiO3 and SrTiO3 [2]. An important feature of these interfaces lies in the possibility to control their electronic properties, including superconductivity and spin-orbit coupling (SOC) with field effect [3-5]. However, experiments have been performed almost exclusively with a metallic gate on the back of the sample. In this presentation, we will report on the realization of a top-gated LaAlO3/SrTiO3 device whose physical properties, including superconductivity and SOC, can be tuned over a wide range of electrostatic doping. In particular, we will present a phase diagram of the interface and compare the effect of the top-gate and back-gate. Finally, we will discuss the field-effect modulation of the Rashba spin-splitting energy extracted from the analysis of magneto-transport measurements. Our result paves the way for the realization of mesoscopic devices where both superconductivity and SOC can be tuned locally.

12:39PM G11.00006 Electric field modulation of superconductivity and kondo effect in LaAl1−xCrxO2/SrTiO3 interfaces, GYANENDRA SINGH, ALEXIS JOUAN, SIMON HURAND, CHERYL PALMA, LPEM -CNRS-ESPCI ParisTech-UPMC, 10 Rue Vauquelin - 75005 Paris, France, PRAMOD KUMAR, ANJANA DOGRA, RAMESH BUDHANI, National Physical Laboratory, New Delhi 110012, India, JEROME LESUEUR, NICOLAS BERGAL, LPEM -CNRS-ESPCI ParisTech-UPMC, 10 Rue Vauquelin - 75005 Paris, France — Two-dimensional electron gas exhibit superconductivity and spin orbit coupling (SOC) at the interfaces of two insulators LaOx/SrTiO3 (where x = Al, Ti and Ga) [1-3], whereas no conductivity is seen when X is replaced by Cr and Mn [4]. We present low temperature measurements of LaAl1−xCrxO2/SrTiO3 interfaces for Cr doping of x = 0, 0.1, 0.2. We show a sharp superconducting transition (Tc) at 175 mK for undoped sample (x = 0) which becomes broader for the Cr doping of x = 0.1 with Tc of 100 mK. Further Cr doping to x = 0.2 indicate no sign of superconductivity. We have analyzed the results with hallmark carrier density and SOC as a function of Cr doping. The temperature dependent sheet resistance below 50 K display an upturn for x = 0 which becomes more pronounced with Cr doping. We discuss the results on the basis of kondo scattering which can be modulated by varying the carrier density.

12:51PM G11.00007 Enhanced transition temperature due to tetragonal domains in two-dimensional superconducting strontium titanate, HILARY NOAD, SIMES, SLAC National Accelerator Laboratory; Department of Applied Physics, Stanford University, KATJA NOWACK, Department of Applied Physics, Stanford University, ERIC SPANTON, SIMES, SLAC National Accelerator Laboratory; Department of Applied Physics, Stanford University, HISASHI INOUE, Department of Applied Physics, Stanford University, MINU KIM, CHRIS BELL, YASUYUKI HIKITA, SIMES, SLAC National Accelerator Laboratory, HAROLD Y. HWANG, SIMES, SLAC National Accelerator Laboratory; Department of Physics and Applied Physics, Stanford University, KATHRYN MOLER, SIMES, SLAC National Accelerator Laboratory; Departments of Physics and Applied Physics, Stanford University, MATS HORSDAL, University of Oslo, Norway, TIMO HYART, University of Jyväskyla, Finland, GINIYAT KHALILULLIN, Max Planck Institute for Solid State Research, Germany, BERND ROSENOW, Leipzig University, Germany — We show, how in principle, a coherent coupling between two superconductors of opposite parity can be realised in a three-layer oxide heterostructure. Due to strong intrasubband spin-orbit coupling in the middle layer singlet Cooper pairs are converted into triplet ones, and vice versa. The result is a large enhancement of the triplet order parameter that persist well beyond the native triplet critical temperature.

1:03PM G11.00008 Enhancing Triplet Superconductivity by the Proximity to a Singlet Superconductor in Oxide Heterostructures1, MATS HORSDAL, University of Oslo, Norway, TIMO HYART, University of Jyväskyla, Finland, GINIYAT KHALILULLIN, Max Planck Institute for Solid State Research, Germany, BERND ROSENOW, Leipzig University, Germany — We propose a new mechanism of the interfacial superconductivity observed in many heterostructures composed of different materials including high-temperature superconductors. Our proposal is based on the use of the Ginzburg–Landau equations applicable to a wide class of systems. The system under consideration is assumed to have, alongside the superconducting order parameter, also another competing order that might be a charge- or spin-density wave. At certain temperatures or doping level the superconducting state is not realized (thus, “hidden”), while the amplitude of another order parameter corresponds to a minimum of the free energy. We also assume that at an interface or at a defect, the non-superconducting order parameter is suppressed (strongly or weakly), e.g., due to an enhanced impurity scattering. The local superconductivity is shown to emerge at the interface, and the spatial dependence of the corresponding order parameter is described by the Gross–Pitaevskii equation. The quantized values of the temperature and doping levels, at which Δ(x) arises, are determined by the “energy” levels of the linearized Gross–Pitaevskii equation, i.e., of the Schrodinger equation. Interestingly, the local superconductivity arises even at a small suppression of the rival order.

1:27PM G11.00010 A The effects of non-linear electron-phonon interactions on superconductivity and charge-density-wave correlations, SHAOZHI LI, STEVE JOHNSTON, Department of physics and Astronomy, Univ of Tennessee, Knoxville — Linear treatments of the electron-phonon (e-ph) interaction, derived from Taylor expansions of the lattice potential, often predict large lattice distortions in the strong coupling limit; however, the prediction of large lattice displacements violates the assumptions underlying the linear model, indicating that the higher-order non-linear terms should also be included. In this talk, we examine non-linear e-ph interactions in a two-dimensional Holstein-like model using non-perturbative determinant quantum Monte Carlo. We show that even small non-linear interactions dramatically suppress charge-density-wave formation and s-wave superconductivity that are predicted by the linear e-ph model. These effects are attributed to a combined hardening of the phonon frequency and a renormalization of the effective linear coupling to weaker values.
To test this, we compare the behavior of edge and corner junctions on a patterned bilayer of Nb and Bi$_2$ phase-sensitive Josephson interferometry. It is predicted that the proximity region should have p-wave pairing symmetry with spin-dependent chiral components.

We are exploring the nature of the proximity-induced order in 3D topological insulators in contact with an s-wave superconductor by group methods to extract universal transport characteristics of superconductor/quantum spin Hall heterostructures where the native edge states serve as a group method.

Institute of Technology, Pasadena, CA 91125, USA — Interfacing s-wave superconductors with quantum spin Hall systems provides a promising route to "engineering" topological superconductivity. Given exciting recent progress on the fabrication side, identifying experiments that definitively expose the topological superconducting phase (and clearly distinguish it from a trivial state) raises an increasingly important problem. With this goal in mind we use renormalization group methods to extract universal transport characteristics of superconductor/quantum spin Hall heterostructures where the native edge states serve as a lead. Interestingly, arbitrarily weak interactions induce qualitative changes in the behavior relative to the free-fermion limit, leading to a sharp dichotomy in conductance for the trivial (narrow superconductor) and topological (wide superconductor) cases. Furthermore, we find that strong interactions can in principle induce power-law-localized "parafermion" excitations at a superconductor/quatum spin Hall junction.

Layered group-VI dichalcogenides are two dimensional materials that engender novel coupled spin and valley physics. Characterized by strong spin-orbit coupling and inversion symmetry breaking, they give rise to novel phenomena such as the spin Hall effect and valley Hall effect. In this talk, we focus on the intrinsic and substrate induced superconducting phases expected in this new class of materials. Generically, two types are expected: (1) Cooper pairing with finite center-of-mass momentum, and (2) zero momentum pairs analogous to the conventional BCS phase. We establish the conditions for the realization of each type. Time permitting, we will discuss the nature of the quasiparticles resulting from valley-discriminating pair-breaking processes.

Though precise superconducting nature of the system is still under theoretical debate, the observation motivates the study of superconductivity in this atomic layer system. In particular, the valley-spins locking of the p-doped MoS$_2$ monolayer suggests possibility of exotic type of superconductivity in the system. We use two-step perturbative renormalization group treatment to study superconducting instabilities in various channels and discuss the possibility of an exotic modulated superconductor.

The practicality and robustness of this novel scheme for producing a 1D p-wave superconductor is discussed [2].

The superconducting proximity effect in a synthetic helical liquid, formed in a quantum wire in the presence of a spatially periodic Rashba interaction [1]. The implications for transport in normal-superconductor junctions in this system will be discussed.

The presence of a vortex in the order parameter winding around the wire is essential to have a non-trivial invariant. In addition, we present a full phase diagram of the model as a function of chemical potential, flux and superconducting pairing, emphasizing that not all regions present a fully gapped superconducting state.

By computing the topological invariant of the system from both a continuum Dirac fermion model and a lattice realization of a TI. We demonstrate that the presence of a vortex in the order parameter winding around the wire is essential to have a non-trivial invariant. In addition, we present a full phase diagram of the model as a function of chemical potential, flux and superconducting pairing, emphasizing that not all regions present a fully gapped superconducting state.

In recent work, we showed how a topological state can be induced from regular or irregular scattering in (i) p-wave superconducting wires and (ii) Rashba wires in proximity to an s-wave superconductor. We also related the topological properties of such nanowires to their normal state properties as well as conductance [2]. In the present work, we build on these results and study the correlation between parity-crossings in the superconducting state and the normal state properties of a hybrid nanostructure. Surprisingly, we find that the crossing points are not as well defined as the statistics are for other universality classes. We obtain formulae for mean spacing between parity crossings as well as crossing statistics in disordered wires/cavities. We finally discuss under what conditions these crossings signal Majorana fermions. [1] I. Adagideli et al. [2] I. Adagideli, M. Wimmer, A. Teker, Phys Rev B 89, 144506 (2014)

12:03PM G12.00005 Probing the Superconducting Proximity Effect in a Topological Insulator using Scanning Tunneling Microscopy

IAN DAYTON, Department of Physics and Astronomy, Michigan State University, DUCK-YOUNG CHUNG, Materials Science Division, Argonne National Laboratory, THOMAS CHASAPIS, Department of Chemistry, Northwestern University, ERIC GOODWIN, REZA LOOOLEE, Department of Physics and Astronomy, Michigan State University, MERCOURI KANATZIDIS, Department of Chemistry, Northwestern University, STUART TESSMER, Department of Physics and Astronomy, Michigan State University — Topological insulators (TI) embody a new state of quantum matter characterized by topological invariants; this contrasts with superconductors (S), as superconductivity arises from a spontaneously broken symmetry of the underlying electron system. When a superconductor is placed on the surface of a topological insulator, the behavior of the superconducting condensate across the S/TI interface offers the opportunity to study the interplay between these two distinct quantum states. In this talk, we present our progress in applying cryogenic Scanning Tunneling Microscopy measurements to probe the local density of states in proximity to Pb/Bi2Se3 interfaces.

12:15PM G12.00006 Non-contact current-phase measurements of topological weak links with scanning SQUID

C.A. WATSON, I. SOCHNIKOV, J.R. KIRITLEY, K.A. MOLER, Stanford University, M. DENG, W. CHANG, P. KROGSTRUP, T.S. JESPERSEN, J. NYGARD, C.M. MARCUS, University of Copenhagen, I. MAIER, C. GOULD, G. TKACHOV, E.M. HANKIEWICZ, C. BRÜNE, H. BUHMANN, L.W. MOLENKAMP, University of Würzburg — Topological superconductivity has recently generated substantial interest as a pathway to Majorana physics in the solid state. Experimental efforts have focused on the superconducting proximity effect in topologically non-trivial junctions, but proof of the topological nature of the induced superconductivity remains elusive. We employ scanning superconducting quantum interference device (SQUID) susceptometry to study conventional superconducting Nb rings interrupted by weak links of 3D topological insulator HgTe and Al rings with InAs nanowire junctions. Varying the flux through each ring, we directly measure the current-phase relation (CPR) of the junction. Forward skewness in the CPR of 3D-HgTe which persists even in junctions long compared to the mean free path suggests that helicity may play a role in the high transmittance of Andreev Bound States that carry the Josephson current. Progress In InAs nanowire junction CPR measurements is also discussed. These measurements showcase the CPR as a fundamental characteristic of superconducting weak links and establish scanning SQUID microscopy as a powerful probe for performing such measurements.

12:27PM G12.00007 Observation of anomalous current phase relation on Pb-Bi2Te3 Josephson devices

YUAN PANG, JIE SHEN, JUNHUA WANG, JUNYA FENG, FANMING QU, ZHAOZHEN LU, JIE FAN, GUANGTONG LIU, ZHONGQING JI, XIUNIAN JING, CHANGLI YANG, Institute of Physics, CAS, QINGFENG SUN, X. C. XIE, ICQM, Peking University, LIANG FU, Department of Physics, Massachusetts Institute of Technology, LI LU, Institute of Physics, CAS — Josephson devices based on s-wave superconductor Pb and 3D topological insulator Bi2Te3 have been fabricated and investigated down to low temperatures. Anomalous current phase relation (CPR) was observed, indicating the existence of an unconventional component of superconductivity. Our experiment demonstrates that hybrid devices based on s-wave superconductor and 3D topological insulator might provide a platform for searching for and manipulating Majorana bound state.

12:39PM G12.00008 Anomalous Resistance Increase on Topological Insulator Bi2Te3 Nanotubes with Superconductor Contacts

RENZHONG DU, YUEWEI YIN, LUDI MIAO, AOKUI SUN, QI LI, Department of Physics, Pennsylvania State University — Topological superconductivity has gained much attention in recent years since it has been predicted to exhibit exotic behaviors and host the Majorana states. We report transport studies on topological insulator Bi2Te3 nanotube with Nb superconductor contacts. The Bi2Te3 nanotubes were synthesized by solution phase method and have previously been proved to possess robust surface states with long phase coherency against strong bulk disorders. Superconducting Nb contacts on the nanotubes were fabricated by electron beam lithography process. An anomalous resistance upturn of the resistance in the nanotube was observed when the contacts became superconducting. When applying a magnetic field, the resistance upturn is reduced gradually and disappears when the magnetic field exceeds the Hc2 of Nb. From both the temperature and magnetic field dependence of the resistance upturn, we conclude that the resistance upturn is associated superconducting transition of the contact leads. Combination of Au and Nb leads have been fabricated with different channel length and the detailed experimental results will be discussed.

12:51PM G12.00009 Phase diagram for topological superconductivity in topological insulator nanowires

FERNANDO DE JUAN, University of California Berkeley, JENS BARDARSON, Max Planck Institute for Complex Systems, Dresden, RONI ILAN, University of California Berkeley — A topological insulator nanowire can be used as a platform to produce one dimensional topological superconductivity in the presence of magnetic fields and the proximity effect from a nearby superconductor. In this work, we discuss the conditions under which this can happen by computing the topological invariant of the system from both a continuum Dirac fermion model and a lattice realization of a TI. We demonstrate that the presence of a vortex in the order parameter winding around the wire is essential to have a non-trivial invariant. In addition, we present a full phase diagram of the model as a function of chemical potential, flux and superconducting pairing, emphasizing that not all regions present a fully gapped superconducting state. Implications for transport in normal-superconductor junctions in this system will be discussed.

1:03PM G12.00010 Superconducting proximity effect in a synthetic helical liquid

MARIANA MALARD, University of Brasilia, GEORGE JAPARIDZE, Ilia State University, HENRIK JOHANNESSON, University of Gothenburg — We explore the possibility of a superconducting proximity effect in a synthetic helical liquid, formed in a quantum wire in the presence of a spatially periodic Rashba interaction [1]. The practicality and robustness of this novel scheme for producing a 1D p-wave superconductor is discussed [2].

1:27PM G12.000012 Fermion Fractionalization to Majorana Fermions in Dimerized Kitaev Superconductor, RYOHEI WAKATSUKI, MOTOHIKO EZAWA, University of Tokyo, YUKIIO TANAKA, Nagoya University, NAOTO NAGAOSA, University of Tokyo, RIKEN CEMS — We study theoretically a one-dimensional dimerized Kitaev superconductor model which belongs to BDI class with time-reversal, particle-hole, and chiral symmetries. There are two sources of the particle-hole symmetry, i.e., the sublattice symmetry and superconductivity. Accordingly, we define two types of topological numbers with respect to the chiral indices of normal and Majorana fermions, which offers an ideal laboratory to examine the interference between the two different physics within the same symmetry class. Phase diagram, zero-energy bound states, and conductance at normal metal/superconductor junction of this model are unveiled from this viewpoint. Especially, the electron fractionalization to the Majorana fermions showing the splitting of the local density of states is realized at the soliton of the dimerization in this model.

1:39PM G12.00013 Majorana edge states in single layer graphene, LIN WANG, MINGWEI WU, University of Science and Technology of China, 96 JinZhai Road, Hefei, Anhui 230026 — We investigate the Majorana edge states in single layer graphene near the Dirac point with the Rashba spin-orbit coupling. We find that there exist naturally induced out-of-plane Zeeman splitting in the proximity of an s-wave superconductor. By calculating the topological invariant, we show the topological phase diagram. In the topological nontrivial regime, we study the Majorana edge states in the case of zigzag or armchair ribbon. For these two cases, both have two Majorana edge states along one edge. However, there exist strong anisotropies in the localization length, the group velocity and the momentum of the Majorana fermions in two ribbons. In addition, the effects of the in-plane Zeeman splitting and the disorder on the Majorana edge states are also discussed.

5:11PM G12.00014 Time-Reversal-Invariant $Z_4$ Fractional Josephson Effect, FAN ZHANG, University of Texas, Dallas, CHARLES KANE, University of Pennsylvania — We study the Josephson junction mediated by the quantum spin Hall edge states and show that electron-electron interactions lead to a dissipationless fractional Josephson effect in the presence of time-reversal symmetry. Surprisingly, the periodicity is $\pi$, corresponding to a Josephson frequency $eV/2h$. We estimate the magnitude of interaction-induced many-body level splitting responsible for this effect and argue that it can be measured by using tunneling spectroscopy. For strong interactions we show that the Josephson effect is associated with the weak tunneling of charge e/2 quasiparticles between the superconductors. Our theory describes a fourfold ground state degeneracy that is similar to that of coupled "fractional" Majorana modes but is protected by time-reversal symmetry. [Reference: PRL 113, 036401 (2014).]

2:03PM G12.00015 Magnetotransport response in the 3D topological insulator Bi2Te3 with indium superconducting electrodes, ZHUO WANG, TIANYU YE, RAMESH MANI, Georgia State University — 3D Topological insulators (TIs) include novel surface states which are protected by time reversal symmetry from backscattering by impurities. Recently, the superconducting proximity effect at the interface between a TI and a superconductor has been a focus of attention. Hence, our study explores the magnetotransport behavior of thin Bi$_2$Te$_3$ flakes with superconducting electrodes in a Hall bar configuration. Such specimens exhibit a magnetotransport anomaly resulting from the proximity effect. To better understand this magnetotransport anomaly, we examine here the effect of biasing thin Bi$_2$Te$_3$ flakes samples of different thicknesses simultaneously with both a dc and a low-frequency ac current through the same pair of contacts at the ends of the device. Here, we report the role of finite bias and electron heating on the observed effects.

Tuesday, March 3, 2015 11:15AM - 2:15PM – Session G13 DMP: Focus Session: Electrostatic Control of Phenomena at Complex Oxide Interfaces 007D - Rositsa Pentcheva, University of Duisburg-Essen

11:15AM G13.00001 Interrelation of polarity, screening, structure, and electronic states at nickelate interfaces, SOHRAB ISMAIL-BEIJI, Yale University — A basic property of metal oxides is ionicity: the metal (cation) and oxygen (anion) sites have different electron densities and thus different charge states. This then permits the existence of polarity whether (1) in static form deriving from the choice of the terminating atomic plane at an interface, or (2) in dynamic form through the existence of ferroelectricity which permits switching of the polarity at an interface. The polarity drives the accumulation of charge, modification of the atomic-scale structure, and alteration of the electronic states at an interface. Here we describe an interconnected body of recent collaborative work on nickelate interfaces where electronic transport is strongly modified by the presence of ferroelectricity and induced out-of-plane Zeeman splitting in the proximity of a s-wave superconductor. By calculating the topological invariant, we show the topological phase diagram. In the topological nontrivial regime, we study the Majorana edge states in the case of zigzag or armchair ribbon. For these two cases, both have two Majorana edge states along one edge. However, there exist strong anisotropies in the localization length, the group velocity and the momentum of the Majorana fermions in two ribbons. In addition, the effects of the in-plane Zeeman splitting and the disorder on the Majorana edge states are also discussed.

11:51AM G13.00002 Electrolyte Gating of SrTiO$_3$ Nanostructures, SAM STANWYCK, Department of Applied Physics, Stanford University, Stanford, CA, 94305, USA, PATRICK GALLAGHER, MENEYOUNG LEE, DAVID GOLDBER-GORDON, Department of Physics, Stanford University, Stanford, CA, 94305, USA — We report low-temperature transport measurements of a two-dimensional electron system (2DES) at the surface of Strontium Titanate. We use electrolyte gating to create the 2DES, and nanopatterning techniques to create gate-tunable submicron constrictions. We observe universal conductance fluctuations, from which we extract an electron dephasing rate linear in temperature, characteristic of electron-electron interaction in a disordered conductor. Furthermore, the dephasing rate has a temperature-independent offset, suggestive of unscreened local magnetic moments in the sample. Finally, we demonstrate that protecting the Strontium Titanate with a thin layer of hexagonal Boron Nitride allows us to create a 2DES with dramatically increased mobility, while also preventing surface electrochemistry.

12:03PM G13.00003 A high-mobility electronic system at an electrolyte-gated oxide surface, PATRICK GALLAGHER, MENEYOUNG LEE, TREVOR PETACH, Department of Physics, Stanford University, Stanford, California 94305, USA, SAM STANWYCK, Department of Applied Physics, Stanford University, Stanford, California 94305, USA, JAMES WILLIAMS, Department of Physics, Stanford University, Stanford, California 94305, USA, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, 1-1 Namiki, Tsukuba, 305-0044, Japan, DAVID GOLDBER-GORDON, Department of Physics, Stanford University, Stanford, California 94305, USA — Electrolyte gating is a powerful technique for accumulating large carrier densities in surface two-dimensional electron systems (2DES). Yet this approach suffers from significant sources of disorder: electrochemical reactions can damage or alter the surface of interest, and the ions of the electrolyte and various dissolved contaminants sit Angstroms from the 2DES. In this talk, we demonstrate that this disorder can be minimized by protecting the sample with a chemically inert, atomically smooth sheet of hexagonal boron nitride (BN). We illustrate our technique with electrolyte-gated strontium titanate, whose mobility improves more than tenfold when protected with BN. We find this improvement even for our thinnest BN, of measured thickness 6 Angstrom, with which we can accumulate electron densities nearing $10^{14}$ cm$^{-2}$. Our technique is portable to other materials, and should enable future studies where high carrier density modulation is required but electrochemical reactions and surface disorder must be minimized.

12:15PM G13.00004 LaAlO$_3$/SrTiO$_3$ field-effect nanodevices using in-situ-grown Au top gates$^1$, YUN-YI PAI, MENCHEH HUANG, Univ of Pittsburgh, HYUWONG WEE, LEE, CHANG-BEMO EOM, Univ of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — Conductive atomic force microscope (c-AFM) lithography can create a wide range of nanostructures based on the LaAlO$_3$/SrTiO$_3$ system, including field effect transistor$^2$, single-electron transistor$^2$ and superconducting nanoelectronic$^3$. However, the operating range of gated devices is often limited by tunneling through insulating barriers. Using in-situ Au deposited on top of LaAlO$_3$, we create vertical field-effect devices with significantly lower leakage due to the large bandgap of LaAlO$_3$. We describe the fabrication process for vertical field-effect nanodevices and show representative transport measurements both at room temperature and low temperatures.

$^1$We gratefully acknowledge support for this work from NSF (DMR-1124131 and DMR-0704022 and DMR-1234096) and AFOSR (FA9550-10-1-0524 and FA9550-12-1-0342).

12:27PM G13.00005 Large Thermopower of δ-doped LaTiO$_3$/SrTiO$_3$ Interfaces and it’s Field Dependence$^1$, R.C. BUDHANI, Indian Institute of Technology, Kanpur & National Physical Laboratory, New Delhi, SHUBHANKAR DAS, P.C. JOSHI, A. RASTOGI, Z. HOSSAIN, Indian Institute of Technology, Kanpur — We will present the magneto-thermopower (S(T, H)) of interfacial delta LaTiO$_3$/SrTiO$_3$ heterostructure by an iso-structural antiferromagnetic perovskite LaCrO$_3$. The thermoelectric power of 2-dimensional electron gas (2DEG) of pure LaTiO$_3$/SrTiO$_3$ at 300 K is $\approx 118 \mu V/K$, but increases dramatically to 337 $\mu V/K$ on inserting 5 uc LaCrO$_3$ at the interface. The negative sign of the thermoelectric power confirms the electron as major carriers in these interfaces. A linear temperature dependence of S(T) has been observed in the temperature range 100 K to 300 K which is in agreement with the theory of diffusion thermopower of 2DEG. The S(T) shows a distinct enhancement at temperature $< 100$ K, where a Kondo-type minimum has been observed in sheet resistance. We attribute this maximum in S(T) to Kondo scattering of conduction electron by localized impurity spin at the interface. The S in this temperature range is suppressed significantly ($< 20\%$) by moderate magnetic field ($\lesssim 13 T$) applied either perpendicular or parallel to the film surface. The isotropic nature of the suppression of S by magnetic field further strengthen the Kondo based interpretation of S(T, H).

$^1$We acknowledge IIT Kanpur and CSIR India for funding this research work.

12:39PM G13.00006 Contrasting electrostatic tuning of the superconducting LaAlO$_3$/SrTiO$_3$ interface by top and back gating, ZHUOYU CHEN, HISASHI INOUE, YANWU XIE, HONGTAO YUAN, Stanford Univ, YASUYUKI HIKITA, SLAC Nat Acc Lab, HAROLD Y. HWANG, Stanford Univ & SLAC Nat Acc Lab, HWANG TEAM — We report an experimental study of electrostatic tuning of the superconducting interface in dual gated LaAlO$_3$/SrTiO$_3$ controlled by the electric field effect. The dual gate devices are formed by simultaneously gating from the top of the epitaxial LaAlO$_3$ layer and the back of the SrTiO$_3$ substrate. Along with electrostatic doping to tune the carrier density, the quantum well profile of the interface electron system is modified due to the inversion asymmetry of the structure, resulting in the modulation of the effective disorder of the system (carrier mobility). We find therefore a strong contrast in the superconducting phase transition by top versus back gating. Simultaneous gating provides a unique opportunity to tune both the carrier density and disorder in this 2D superconducting system.

12:51PM G13.00007 Electric field control of thermoelectric effect in oxide interface LaAlO$_3$/SrTiO$_3$, TOMOYA ASABA, FAN YU, GANG LI, BENJAMIN LAWSON, COLIN TINSMAN, University of Michigan, JOCHEN MANNHART, Max Planck Institute for Solid State Research, LU LI, University of Michigan — Oxide interface LaAlO$_3$/SrTiO$_3$ (LAO/STO) has been attracting huge interest and the origin of the magnetic-field-induced phase transition is yet to be understood. However, thermoelectric power studies, a powerful tool for detecting phase transitions, have been sparsely reported so far. In this study we measured the carrier density dependence of thermopower to understand the origin of this phase transition. Below critical carrier density, thermopower is found to increase dramatically while the interface is still conductive. These results may not only help in understanding the physics around the phase transition but also shed light on the significance of this system as a thermoelectric material.
Vis a well-established, potentially quite exotic, feature. We measure the resistance of the LAO/STO interface in an in-plane magnetic field perpendicular to well have more in common with each other than with LAO/STO. In these two systems, spin-orbit coupling effects are for many purposes unimportant or negligibly confined by at least one order of magnitude, in a regime closer to that achieved in graphene. Nonetheless, graphene and, for example, GaAs/AlGaAs quantum confinement of electrons is no longer synonymous with semiconducting quantum well. The mobile electrons at the metallic LAO/STO interface are better of Technology, E. COBANERA, Utrecht University, T. HYART, University of Jyväskylä, A.D. CAVIGLIA, Delft University of Technology — Today, the planar structures, we have investigated the possible coupling of the two superconducting sheets, tuning one of the two by electric field. We have also realized bilayer interfaces, where two superconducting liquids are separated by the LaAlO interfaces characteristic lengths (the coherence length and the superconducting thickness) as a function of the gate voltage by measuring the critical magnetic fields in 3 parallel and perpendicular geometry. We have also realized bilayer interfaces, where two superconducting liquids are separated by the LaAlO interfaces. In this work, we have mapped the evolution of the superconducting properties upon gate voltage tuning, revealing a surprising change in thickness of the superconducting layer across the phase diagram. Using a single LaAlO/SrTiO interface, we have realized field effect transistors and estimated the origin of such properties and explore potential application. We demonstrate the modulation of electrical transport properties in LAO/STO interface by electric field effect using electric double layer transistor (EDLT) configuration. In initially metallic samples, reversible metallic-insulating phase transition, field-effect transistor operation and electron mobility enhancement were observed in liquid-gated LaAlO/SrTiO interface. Due to enhancement of mobility, we can observe quantum oscillations of the conductance at liquid-gated LAO/STO interface.

1:03PM G13.00008 Link Between Mobile Band Population and Superconductivity in SrTiO3/LaAlO3 Interface, ERAN MANIV, MOSHE BEN SHALOM, ALON RON, IZHAR NEDER, MOSHE GOLDSSTEIN, ALEXANDER PALEVSKI, YORAM DAGAN, Tel Aviv University — The entire superconducting phase diagram of SrTiO3/LaAlO is scanned using back gate voltage. The superconducting transition temperature Tc and critical field Hc are recorded along with the Hall resistance and Shubnikov-de Haas (SdH) effect. The latter is sensitive only to the density of the mobile band while the former probes all bands. We find that Tc and Hc follow a similar non-monotonic gate voltage dependence as the SDH frequency and the low field Hall. This suggests that the mobile band is getting depopulated at high gate voltages resulting in the reduction of Tc on the overdoped side. We discuss a possible scenario for this peculiar behavior.

1:15PM G13.00009 External voltage control of LaAlO/SrTiO3 interface structure, HIROMASA FUJII, Osaka Univ., MAKOTO MINOHARA, KEK, CHRISTOPHER BELL, YASUYUKI HIKITA, HAROLD Y. HWANG, Stanford Univ., TSUYOSHI KIMURA, YUSUKE WAKABAYASHI, Osaka Univ. — Physical properties of the LaAlO (LAO)/SrTiO3 (STO) interface are controlled by external voltage such as voltage-induced metal-insulator transition [1] and superconductivity-insulator transition [2]. The modulated parameters by external voltage are not only the carrier density but also the Hall mobility [3]. In order to clarify local electric field and polarization around the interface, we have investigated the effect of external voltage on the interface structure at room temperature by means of a surface x-ray diffraction technique, crystal truncation rod (CTR) scattering. Our measurements were performed at BL-4C of the Photon Factory, KEK, Japan. A 5-unit-cell thick sample was prepared using the pulsed laser deposition technique. The scattered x-ray intensity profile shows slight external voltage dependence, which means that the interface structure is changed by the external voltage. We also found that the voltage dependence of the scattering intensity exhibits hysteresis. Least squares refinement revealed that main atomic displacement induced by the external voltage occur in the LAO. The displacements in STO at the interface are of the order of sub-pm, which is much larger than expected for bulk STO (∼0.01 pm).

1:27PM G13.00010 Superconducting properties of single and bilayer LaAlO/SrTiO3 interfaces, STEFANO GARIGLIO, ALEXANDRE FETE, DANFENG LI, WEI LIU, MARGHERITA BOSELLI, DQMP, University of Geneva, NICOLA LAS REYREN, Unite Mixte de Physique CNRS-Thales, JEAN-MARC TRISCON, DQMP, University of Geneva — The two-dimensional electron liquid present at the LaAlO/SrTiO3 interface exhibits superconductivity and hosts a large spin-orbit interaction. Quite remarkably, both phenomena can be controlled by an electric field. In this work, we have mapped the evolution of the superconducting properties upon gate voltage tuning, revealing a surprising change in thickness of the superconducting layer across the phase diagram. Using a single LaAlO/SrTiO interface, we have realized field effect transistors and estimated the characteristic lengths (the coherence length and the superconducting thickness) as a function of the gate voltage by measuring the critical magnetic fields in parallel and perpendicular geometry. We have also realized bilayer interfaces, where two superconducting liquids are separated by the LaAlO interfaces. In such structures, we have investigated the possible coupling of the two superconducting sheets, tuning one of the two by electric field.

1:39PM G13.00011 Domination of spin-orbit coupling in magnetotransport at the LaAlO/SrTiO3 interface, M. DIEZ, University of Leiden, A.M.R.V.L. MONTEIRO, G. MATTONI, E. MULAZIMOGLU, Delft University of Technology, E. COBANERA, Utrecht University, T. HYART, University of Jyväskylä, A.D. CAVIGLIA, Delft University of Technology — Today, the planar confinement of electrons is no longer synonymous with semiconducting quantum wells. The mobile electrons at the metallic LAO/STO interface are better confined by at least one order of magnitude, in a regime closer to that achieved in graphene. Nonetheless, graphene and, for example, GaAs/AlGaAs quantum well have more in common with each other than with LAO/STO. In these two systems, spin-orbit coupling effects are for many purposes unimportant or negligibly weak, and neither system has ever shown superconductivity. In contrast, spin-orbit coupling effects are strong at the LAO/STO interface, and superconductivity is a well established, potentially quite exotic, feature. We measure the resistance of the LAO/STO interface in an in-plane magnetic field perpendicular to the current, for a wide range of applied fields B, temperatures, and carrier densities controlled by a back-gate voltage Vg. Our measurements show dramatic, fast and very large drops in magnetoresistance, either as a function of B or Vg, decrease slowly with temperature and seem suggestive of magnetic ordering. However, we compare very well with an alternative explanation that strongly suggests that the effect of spin-orbit coupling on the band structure alone can dominate magnetotransport.

11:15AM G14.00001 Nano-Josephson Superconducting Tunnel Junctions Direct-patterned in Y-Ba-Cu-O with a Focused Helium Ion Beam. SHANE CYBART, UC San Diego — Functional oxide materials are very sensitive to disorder and many transition from metal to insulator as disorder increases. This phenomenon has been used for many years to fabricate Josephson junctions in cuprate high-transition-temperature \( T_c \) superconductors like \( \text{YBa}_2\text{Cu}_3\text{O}_7 \) (YBCO). In this approach, ion irradiation is used to selectively disorder a nanoscale region of material between two superconducting electrodes, that serves as a Josephson barrier. Historically, the barriers created in this manner have been tens of nanometers in length which only allowed for the creation of superconductor-reduced-\( T_c \)-superconductor-junctions. We have reduced the length of the Josephson barriers to just a few nm by using a 500 pm diameter focused beam of helium ions. The smaller length of these barriers allows us to change the properties continuously from reduced \( T_c \) superconductor to normal metal, to insulator as a function of irradiation dose. We present data for several Josephson junctions fabricated in this manner using controlled doses. Our results are well-described by the Blonder, Tinkham, Klapwijk model (BTK) for microscopc electrical transport at an interface between a superconductor and a normal material. This model uses a single parameter related to barrier strength (irradiation dose in our experiments) and can describe current-voltage characteristics for barriers ranging from a strong barrier, such as an insulator in a tunnel junction, to a weak barrier like a normal metal. In the case of a strong barrier (a tunnel barrier) the only transport mechanism for Cooper pairs is direct Josephson tunneling whereas in the case of weaker barriers both tunneling and Andreev reflection occur. This technique could provide a reliable method for the realization of reproducible high-\( T_c \) Josephson junctions. I will present details of the technique and analysis of the results.

11:51AM G14.00002 Controlled fabrication of sub-15nm nanostructures of an arbitrary conductive material1. HANNAH HUGHES, TYLER MORGAN-WALL, NIKOLAUS HARTMAN, NINA MARKOVIC, Johns Hopkins University — Traditional lithographic techniques that are used to produce low-dimensional nanostructures are often limited in both the minimum achievable size and the control over the final resistance of the device. To achieve such control, we had developed a wet etching method with in-situ monitoring of resistance, but this method relies on an oxide layer to electrically isolate the monitoring circuit from the etching solution. We will present a more general method for fabricating sub-15 nm nanostructures out of various conductive materials without a need for an oxide layer.

12:03PM G14.00003 Black Silicon Formation in Cryogenic Reactive Ion Etching. DAVID ABI SAAB, PHILIPPE BASSET, Universite Paris Est, ESIEE Paris, ESYCOM, MATTHEW J. PIEROTTI, MATTHEW L. TRAWICK, University of Richmond, DAN E. ANGELESCU, Universite Paris Est, ESIEE Paris, ESYCOM — We present both experimental data and computational modeling that explain some aspects of the formation of black silicon during cryogenic reactive ion etching (RIE) processes. We generate a phase diagram that predicts combinations of RIE parameters that lead to different black silicon geometries. We also show that the combination of needle- and hole-like features of various heights and depths in black silicon creates a uniquely smooth transition in refractive index that is responsible for the material’s low optical reflectivity. These details are captured by our model and confirmed by focused ion beam (FIB) nanotomography and scanning electron microscopy of black silicon surfaces during various stages of development. The model also correctly describes dynamical characteristics such as the dependence of aspect ratio on process time, and the prediction of new etching fronts appearing at topographical saddle points.

12:15PM G14.00004 Spin-filtering in nickel-oxide atomic junctions . RAN VARDIMON, MARINA KLIONSKY, OREN TAL, Weizmann Institute of Science, OREN TAL GROUP TEAM — Generating a highly spin-polarized current governed by electrons of a single spin type is of central importance for realization of nanoscale spintronics. We report on the detection of up to 100% spin-polarized currents across nickel-oxide atomic junctions formed between two nickel electrodes under cryogenic vacuum conditions. The degree of spin polarization is probed by analyzing the quantum shot noise resulting from the discrete statistics of electron transport. In sharp contrast to the insulating character of bulk nickel-oxide, our results can be explained by the emergence of a local half-metallic electronic structure, stemming from the distinct orbital hybridization of the low-coordinated junction atoms. These findings illuminate new directions for spin transport manipulations by atomic-scale material design.

12:27PM G14.00005 Evolution of Ni nanofilaments and electromagnetic coupling in the resistive switching of NiO1. YUXIANG LUO, Tsinghua University, China, DEPARTMENT OF PHYSICS, TSINGHUA UNIVERSITY, BEIJING, CHINA TEAM — Resistive switching effect in conductor/insulator/conductor thin-film stacks is promising for resistance random access memory with high-density, fast speed, low power dissipation and high endurance, as well as novel computer logic architectures. NiO is a model system for the resistive switching effect and the formation/rupture of Ni nanofilaments is considered to be essential. However, it is not clear how the nanofilaments evolve in the switching process. Moreover, since Ni nanofilaments should be ferromagnetic, it provides an opportunity to explore the electromagnetic coupling in this system. Here, we report a direct observation of Ni nanofilaments and their specific evolution process for the first time by a combination of various measurements and theoretical calculation. We found that multi-nanofilaments are involved in the low resistance state and the nanofilaments become thin and rupture separately in the RESET process with subsequent increase of the rupture gaps. Theoretical calculations reveal the role of oxygen vacancy amount in the evolution of Ni nanofilaments. We also demonstrate electromagnetic coupling in this system, which opens a new avenue for multifunctional devices.

12:39PM G14.00006 Electronic Transport properties of SET and REST states of interfacial phase-change memory , HISAOK NAKAMURA, JUNJI TOMINAGA, YOSHIHIRO ASAI, AIST, IVAN RUNGGER, AWADHESH NARAYAN, STEFANO SANVITO, School of Physcs. AMBER and CRANN, Trinity College — The phase change memory (PCM) is one of most promising nonvolatile information storage technologies. Recently, the superlattice structure of GeTe/Sb2Te3 is proposed as PCM to reduce the resistive switching energy. This PCM is called interfacial PCM (IPCM) and it is considered that SET and RESET states are realized only by the flip-flop transition of Ge atoms in crystal phase because of small loss of entropy. Furthermore, the GeTe is sandwiched by Sb2Te3 topological insulator. In this study, we performed the first principles electric transport calculations including spin-orbit interactions. We presents the mechanism of resistive switch by the transition of Ge atoms as well as the volume change effect and the role of spin-orbit interaction to resistance ration of SET and RESE states.
12:51PM G14.00007 A mesoscopic magnetron as an open quantum system. TADEUSZ PUDLIK, Physics Department, Boston University, ANTONIO CASTRO NETO, Physics Department, Boston University; Department of Physics, National University of Singapore, DAVID CAMPBELL, Physics Department, Boston University — The emergence of materials with room temperature electron mean free paths of a micron or more opens up new possibilities in the design of solid state devices. One such potential new paradigm are solid state quasi-free electron devices, which promise to combine the wide frequency tunability of classical vacuum tube devices with the small size and low costs of semiconductor technology. As a step towards realistic models of these devices, we develop a quantum mechanical description of a mesoscopic magnetron, in which the vacuum chamber of traditional magnetron is replaced with a semiconductor. We show that the problem can be mapped to a Bose-Hubbard dimer coupled to a dissipative bath and study the effect of the band structure of the medium on device performance.

1:03PM G14.00008 Interplay between magnetic anisotropy and vibron-assisted tunneling in a single-molecule magnet transistor1, KYUNGWA PARK, ALEXANDER MCCASKY, YOH YAMAMOTO, MICHAEL WARNOCK, Virginia Tech, ENRIQUE BURZURI, HERRE VAN DER ZANT, TU Delft — Molecules trapped in single-molecule devices vibrate with discrete frequencies characteristic to the molecules, and the molecular vibrations can couple to electronic charge and/or spin degrees of freedom. For a significant electron-vibron coupling, electrons may tunnel via the vibrational excitations unique to the molecules. Recently, electron transport via individual anisotropic magnetic molecules (referred to as single-molecule influences electrons transport via a single-molecule magnet Fe₄, by using a model Hamiltonian with parameter values obtained from density-functional theory (arXiv:1411.2677). We show that the magnetic anisotropy of the Fe₄ induces new features in vibrational conductance peaks and creates vibrational satellite peaks. The main and satellite peak heights have a strong, unusual dependence on the direction and magnitude of applied magnetic field, because the magnetic anisotropy barrier is comparable to vibrational energies.

1:15PM G14.00009 Single Molecule Magnetic Force Detection with a Carbon Nanotube Resonator1, KYLE WILICK, SEAN WALKER, JONATHAN BAUGH, Institute for Quantum Computing, University of Waterloo — Single molecule magnets (SMMs) sit at the boundary between macroscopic magnetic behaviour and quantum phenomena. Detecting the magnetic moment of an individual SMM would allow exploration of this boundary, and could enable technological applications based on SMMs such as quantum information processing. Detection of these magnetic moments remains an experimental challenge, particularly at the time scales of relaxation and decoherence. We present a technique for sensitive magnetic force detection that should permit such measurements. A suspended carbon nanotube (CNT) mechanical resonator is combined with a magnetic field gradient generated by a ferromagnetic gate electrode, which couples the magnetic moment of a nanomagnet to the resonant motion of the CNT. Numerical calculations of the mechanical resonance show that resonant frequency shifts on the order of a few kHz arise due to single Bohr magneton changes in magnetic moment. A signal-to-noise analysis based on thermomechanical noise shows that magnetic switching at the level of a Bohr magneton can be measured in a single shot on timescales as short as 10μs. This sensitivity should enable studies of the spin dynamics of an isolated SMM, within the spin relaxation timescales for many available SMMs.

1:27PM G14.00010 Leakage radiation microscopy for observation of non-transparent samples. JUAN M. MERLO, FAN YE1, MICHAEL J. BURNS, MICHAEL J. NAUGHTON2, Boston College — Surface plasmon interactions are confined to be proximate to the surface on which they are excited, such that common optical microscopic imaging is precluded. In order to overcome this limitation, the leakage radiation microscopy technique can be employed to obtain images of interactions at a metallic surface where the surface plasmon propagates [1]. A disadvantage of this configuration is that the metallic layer must be optically thin, resulting in the (additional) direct observation of the excitation source. Here, we describe a leakage radiation microscope that can be used to observe plasmonic interactions in optically non-transparent samples [2]. We show that theoretically-calculated values of the surface plasmon wavelength and propagation length agree with the measured values. This configuration opens the possibility to study important effects where samples are optically non-transparent, as in plasmonic cavities, without the use of time-consuming near-field scanning optical microscopy.

1:39PM G14.00011 Random Telegraph Signal in a Metallic Double-Dot System1, YUVAL VARDI, AVRAHAM GUTTMAN, ISRAEL BAR-JOSEPH, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot 76100, Israel — Double quantum dot systems offer a unique opportunity for studying the world of quantum transport. This stems from the ability to localize an electron in a limited region in space on the dot, and monitor its presence and properties. Another system, in which electrons can be stored and measured, is an electronic trap in solid. The electrons in such a trap are better isolated from the environment. However, their measurement and control are more difficult. Here we demonstrate how these two systems, metallic double-dots and electronic traps, are combined to yield a hybrid structure in which an electron can be stored for long durations and can be easily detected and measured. We investigate the dynamics of a single electron surface trap, embedded in a self-assembly metallic double-dot system. The charging and discharging of the trap by a single electron is manifested as a random telegraph signal of the current through the double-dot device. We find that we can control the duration that an electron resides in the trap through the current, varying it between fractions of a second to more than an hour, at the Coulomb blockade region. We suggest that the observed switching is the electrical manifestation of the optical blinking phenomenon, commonly observed in semiconductor quantum dots.

1Supported by the W.M. Keck Foundation.

this technique should be applicable to other nanoscale devices, providing a general route for tuning device properties. We reproducibly achieve high rectification ratios at low operating voltages for molecular junctions based on a family of symmetric small-gap molecules. This establishes the feasibility of exploiting quantum transport to transform the performance horizons of Si devices fabricated in an industrially scalable manner.

11:15AM G15.00001 Ultrafast mid-infrared intraexcitonic spectroscopy of monolayer MoS2

SOONYOUNG CHA, School of Electrical and Electronic Engineering, Yonsei University, Seoul, Korea, JI HO SUNG, MOON-HO JO, Division of Advanced Materials Science, Pohang University of Science and Technology (POSTECH), Pohang, Korea, HYUNYOUNG CHOI, School of Electrical and Electronic Engineering, Yonsei University, Seoul, Korea. — The optical properties of transition metal dichalcogenide (TMD) are currently active research topics for understanding the two-dimensional nature of carrier dynamics. For monolayer TMDs, reduced dielectric screening invokes strong Coulomb interactions, which lead to the large exciton binding energy. Recent theory predicts that the subset of excitons is much richer, such that internal transitions between excitons (ex. 1s, 2s, 2p) should prevail the photo-induced optical response. We performed ultrafast optical pump and mid-infrared (IR) probe spectroscopy to investigate transient intraexcitonic dynamics in a monolayer MoS2. To obtain a complete excitonic dynamics, the probe photon energy is tuned over a broad range from mid-IR to IR, 0.24 eV to 0.66 eV. Our study reveals that the mid-IR responses exhibit photo-induced absorption after 3.1 eV pump excitation, which then relax within tens of picosecond and show multiple intraexcitonic and interexcitonic transitions. Our experiment shows that the fast decay component of the dynamics closely follows transient dynamics of so called A-exciton population, suggesting the photo-induced absorption indeed originates from the internal excitonic transitions.

11:27AM G15.00002 Infrared nano-imaging of plasmonic hotspots on graphene nano-bubbles

ZH FEI, UC San Diego & Argonne Natl Lab, JONATHAN FOLEY, Argonne Natl Lab, WILL GANNETT, ALEX ZETTL, UC Berkeley, MENGKUN LIU, Stony Brook University, GUANGXIN NI, SIYUAN DAI, UC San Diego, FRITZ KEILMANN, Ludwigs-Maximilians-Universität, ANTONIO CASTRO NETO, National University of Singapore, STEPHEN GRAY, GARY WIEDERRECHT, Argonne Natl Lab, MICHAEL FOGLER, DIMITRI BASOV, UC San Diego — One of the most interesting phenomena in plasmonics is the appearance of strong enhancements of electromagnetic energy by forming plasmonic hot spots for various applications including bio-sensing, single molecule fingerprinting, surface enhanced spectroscopy, and etc. Here, we demonstrate by infrared nano-imaging that nano-bubbles formed on graphene/hexagonal boron nitride heterostructures are ideal for trapping electromagnetic energy thus forming ultra-confined plasmonic hot spots. The distributions of these hot spots are sensitively dependent on the size and shape of these nano-bubbles as well as the ingredients inside. Further analysis indicates that the observed plasmonic hotspots are formed due to a significant enhancement of the plasmon wavelength and intensity above graphene nano-bubbles filled with air or other low-k dielectric materials. Our work presents a novel scheme for plasmonic hot spots formation and sheds light on future applications of graphene nano-bubbles for plasmon-enhanced single molecule characterization.

11:39AM G15.00003 Temperature-induced plasma excitations in gapped graphene and silicene

ANDRII IUROV, University of New Mexico and Hunter College, CUNY, GODFREY GUMBS, Hunter College, CUNY and Donostia International Physics Center (DIPC), DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate — Both closed-form analytic and numerical results are presented for the polarization function, as well as the plasma excitations of gapped graphene and silicene. The calculations are carried out within the random phase approximation (RPA). We investigate the behavior of the plasmon dispersion as a function of sublattice potential difference in silicene. These results could be used to compare the effective mass model with the tight-binding approximation at finite temperature in which spin-orbit coupling is included.

12:03PM G15.00005 Dynamics of Ion-Gating 2D Crystals Using a Solid Polymer Electrolyte

HU-MIN LI, BUCHANAN BOURDON, University of Notre Dame, YU-CHUAN LIN, JOSHUA ROBINSON, The Pennsylvania State University, ALAN SEABAGH, University of Notre Dame, CENTER FOR LOW ENERGY SYSTEMS TECHNOLOGY (LEAST) TEAM — Ion-gating can significantly increase the static carrier density of graphene due to the formation of an electric double layer (EDL); however, the dynamics of ion-gating have not been extensively reported. A comprehensive understanding of ion dynamics is important because it establishes the timescales required to achieve EDL equilibrium, and directly affects the operating speed of devices and circuits employing electrolytic gates. Here, ion dynamics are measured on epitaxial graphene Hall-bar devices that are electrolytically gated with polyethylene oxide and lithium perchlorate. The time constants for EDL formation and dissipation are measured as a function of temperature. The measured formation time is longer than the dissipation time, because ion diffusion resulting from a concentration gradient must be opposed during EDL formation. These results quantitatively agree with COMSOL multiphysics simulations. EDL dissipation follows a stretched exponential decay described by the Kohlraus-Williams-Watts (KWW) equation. The temperature-dependent relaxation times extracted from the KWW fit follow the Vogel-Fulcher-Tammann (VFT) temperature dependence. At temperatures approaching the glass transition temperature of the electrolyte, the relaxation times exceed several hours, demonstrating the long timescales over which the EDL can persist in the absence of a gate bias.
Electronic transport in graphene/CdSe nanoparticle monolayer/graphene tunneling devices, DATONG ZHANG, Columbia University, CHENGLIANG LU, National Center for Nanoscience and Technology, AREND VAN DER ZANDE, PHILIP KIM, IRVING P. HERMAN, Columbia University — We fabricated graphene/CdSe nanoparticle monolayer/graphene sandwich device structures. The CdSe nanoparticle monolayer is formed on a liquid-air surface before transferring it onto the bottom graphene layer that had been micro-exfoliated onto a 285 nm SiO2/Si substrate. The top graphene layer is transferred to the targeted area on the CdSe nanoparticle monolayer via a dry transfer technique. Tunneling-type vertical transport is observed, which is fitted by tunneling models that suggest that ligand shell instead of nanoparticle core is the major barrier of tunneling. Photoconductivity is enhanced but with low exciton separation efficiency when the laser is on the junction area, also suggesting that ligand shell is the major barrier of electronic transport in the sandwich structure.

PVA:LiClO4: a robust, high T_g polymer electrolyte for adjustable ion gating of 2D materials, ERICH KINDER, SUSAN FULLERTON, Univ of Notre Dame, Dept. of Electrical Engineering, CENTER FOR LOW ENERGY SYSTEMS TECHNOLOGY TEAM — Polymer electrolytes are an effective way to gate organic semiconductors and nanomaterials, such as nanotubes and 2D materials, by establishing an electrostatic double layer with large capacitance. Widely used solid electrolytes, such as those based on polyethylene oxide, have a glass transition temperature below room temperature. This permits relatively fast ion mobility at T = 23 °C, but requires a constant applied field to maintain a doping profile. Moreover, PEO-based electrolytes cannot withstand a variety of solvents, limiting its use. Here, we demonstrate a polymer electrolyte using polyvinyl alcohol (PVA) with T_g > 23 °C, through which a doping profile can be defined by a potential applied when the polymer is heated above T_g, then “locked-in” by cooling the electrolyte to room temperature (< T_g) to limit ion mobility. Current-voltage measurements of a graphene field effect transistor verify the “lock-in” process, showing constant drain current regardless of the applied electrolyte gate bias. Hall bar measurements are used to quantify the charge carrier density. Owing to PVA’s chemical stability, photolithography can be performed directly on the polymer electrolyte, which allows for the deposition of a patterned, metal gate directly on the electrolyte, as well as the ability to pattern the electrolyte itself.

Near-field optical second-harmonic technique for detection and characterization of semiconductor thin film electron-scattering domain boundaries, FARZAD SHAHIF, The University of Texas at Austin, TOMMASO ORZALI, Gennadi Bersuker, Sematech, DOWNER MICHAEL, The University of Texas at Austin — Understanding electron transport in epitaxial semiconductor thin films and low dimension systems is crucial for new electro-optic devices. III-V films grown on Si integrate high carrier mobility into the established Si platform, but are susceptible to formation of sub-micron anti-phase domains that possess unwanted Ga-Ga or As-As electron-scattering defects at their boundaries. Optical second-harmonic generation provides sensitive, specific and noninvasive but so far only spatially-integrated characterization for these defects [1]. We introduce a fiber based nearfield scanning optical second harmonic microscopy for the first time to fully resolve the electron scattering boundaries on III-V/Si films. This technique reveal variations in electron scattering boundaries structure as growth conditions, epitaxial film composition, and substrate vary, and are compared with surface topography, darkfield transmission electron microscopy and electron back scatter diffraction. Suppression of the electron-scattering boundaries has been explored.

Semiclassical Boltzmann Theory Studies of the Electronic Resistances of Multilayered Silicene Junctions, YUNPENG WANG, X-G. ZHANG, JAMES FRY, HAI-PING CHENG, University of Florida — A layer-by-layer investigation is carried out to understand electron transport across metal-semiconductor-metal junctions. Structures of junctions are optimized using first-principles density functional theory with the generalized gradient approximation. The semiclassical Boltzmann theory of the electronic transport is revisited and applied to multilayer silicene and hexagonal BN based junctions. The calculated resistance is smaller than, but converges to that calculated by the Landauer formula. Owing to the thickness of the barrier increases. Our calculation results provide an upper limit on the transmission coefficient per channel, ~ 0.05, below which the Landauer formula is applicable for calculating the resistance. In addition, we find that the resistance of a junction is not determined entirely by the average transmission, but also by the distribution of the transmission over the first Brillouin zone.

Localized surface plasmon effects of two dimensional lattice of metal nanoslads, YUKARI ODA, RYOKO SHIMADA, Japan Women’s University, JAPAN WOMEN’S UNIVERSITY TEAM — Localized surface plasmon (LSP) of metal nanoparticles results from non-propagating excitation of their conduction electrons coupled to the electromagnetic field. LSP localizes the electric field and enhances light emission from fluorescent materials. In this study, a two dimensional (2D) lattice of silver (Ag) nanoslads was fabricated by nanosphere lithography (NSL) method utilizing self-assembled, close-packed hexagonal structures of polystyrene spheres as the masking etching. This 2D lattice was subjected to the electric field for investigating a role of the periodicity of metal islands in the LSP effect. 9,10-di(2-naphthyl)anthracene (ADN), a well-known blue-emitting material in the field of electroluminescence, was used for the study of the enhancement of emission due to the LSP effect. Hybrid thin films of poly(methyl methacrylate) containing ADN were prepared with spin-casting onto the 2D lattice of Ag nanoslads. Transmission and photoluminescence measurements were conducted for these hybrid thin films at room temperature. Detailed results will be presented on site.

Spatially indirect exciton condensate in bilayer systems, FEI XUE, FENGCHENG WU, ALLAN MACDONALD, Department of Physics, University of Texas at Austin — Bilayer equilibrium exciton condensates have attracted attention in recent years because of their interesting and anomalous transport properties. Here we report on the microscopic derivation of bosonic effective Hamiltonians which include exciton-exciton interaction terms and account realistically for band-structure and dielectric environment effects. We describe in detail the microscopic origin of different contributions to exciton-exciton interaction. We apply our theory to the case of transition metal dichalcogenides, addressing specifically the role of the excitonic flavor multiplicity in that system.

Coulomb drag in coupled electronic systems of different dimensionalities, BEN YU-KUANG HU, The University of Akron — Coulomb drag occurs when two electrically independent electronic systems are situated in close enough proximity to each other that the Coulomb coupling between the two systems causes an electric current in one system to drag along a carriers in the other system. The magnitude of this effect is quantified by the drag rate. We derive the formalism to determine the drag rate in systems of different dimensionalities (for example, one-dimensional quantum wires coupled to two-dimensional quantum wells), based on coupled transport equations. We discuss how the hybrid coupled plasmons of the systems of different dimensionalities can affect the drag, and we investigate the effect that plasmons in the higher-dimensional system can have on the drag rate of the carriers in the lower-dimensional system.
1:39PM G15.00013 Three-dimensional plane-wave full-band quantum transport using empirical pseudopotentials1. JINGTIAN FANG, WILLIAM VANDENBERGHE, MASSIMO FISCHETTI, Univ of Texas, Dallas — We study theoretically the ballistic performance of future sub-5 nm Field-Effect Transistors (FETs) using an atomic quantum transport formalism based on empirical pseudopotentials, with armchair Graphene Nanoribbons (aGNRs), Silicon Nanowires (SiNWs) and zigzag Carbon Nanotubes (zCNTs) as channel structures. Due to the heavy computational burden from the plane-wave basis set, we restrict our study to ultrasmall devices, characterized by 5 nm channel lengths and 0.7 nm × 0.7 nm cross-sectional areas. Band structure calculations show that aGNRs have an oscillating chirality-dependent band gap. SiNWs with dimer lines N=3p+1 have large band gaps and aGNRFETs show promising device performance in terms of high Ion/Ioff, small drain-induced barrier lowering and limited short channel effects due to their very thin body and associated excellent electrostatic control. N=3p+2 aGNRs have small band gaps and band-to-band tunneling generates a large current at high bias. We also discuss spurious solutions introduced by the envelope function approximation. Device characteristics of SiNWFETs and zCNTFETs are compared to aGNRFETs as well.

1We acknowledge the support of Nanoelectronics Research Initiative's (NRI's) Southwest Academy of Nanoelectronics (SWAN).

1:51PM G15.00014 Dynamic Control of Thermal Emission with Plasmonically Active Graphene Metasurfaces, VICTOR BRAR, MICHELLE SHERROTT, Caltech, MIN JANG, Seoul National University, SEYoon KIM, Laura Kim, Josue Lopez, Caltech, MANSoo ChoI, Seoul National University, LUKE SWEATLOCK, Northrop Grumman Aerospace Systems, HARRY ATWATER, Caltech — Thermal emission is typically viewed to be broadband, unpolarized and isotropic, with a spectral profile and intensity that depend on the emissivity of the material, and that vary only with changes in temperature. In this talk we demonstrate that the intensity, polarization and spectrum of thermal emission at constant temperature can be dynamically controlled through electrostatic gating of plasmonic graphene resonators on a heated SiNx substrate. We show that the plasmonic resonances in graphene act as antenna that to out-couple the thermal energy of substrate phonons and graphene electrons to create narrow, mid-infrared spectral features in the thermal emission profile. By varying the gate voltage and resonator width, we show that these features can be effectively turned on and off at kHz rates, and tuned across a broad frequency range. Our measurements show that at 7μm the emissivity of the surface can be varied by 0.02, and that the emitted radiation is polarized, with a modulated power density of 0.02W/m2 over 100cm-1 of bandwidth.

2:03PM G15.00015 Graphene-enabled electrically switchable radar absorbing surfaces, OSman Balci, Emre Ozan Polat, Nurbek Kakenov, CosKun Kocabas, Bilkent University — Radar absorbing materials are used in stealth technologies for concealment of an object from radar detection. Resistive and/or magnetic composite materials are used to reduce the backscattered microwave signals. Inability to control electrical properties of these materials however, hinders the realization of active camouflage systems which require adaptive surfaces operating in microwave frequencies. Here, using large-area graphene electrodes, we demonstrate a new class of active surfaces which enables unprecedented ability to control reflection, transmission and absorption of microwaves by electric means. Instead of tuning bulk material property, our strategy relies on electrostatic tuning of the charge density on an atomically thin electrode which operates as a tunable metal in microwave frequencies. Notably, we fabricated large area adaptive radar absorbing surfaces with tunable reflection suppression ratio up to 50 dB with operation voltages less than 5 V. These electrically switchable radar absorbing surfaces provide a significant step in realization of active camouflage systems and adaptive cloaking in microwave frequencies, which cannot be realized by conventional materials.

Tuesday, March 3, 2015 11:15AM - 2:15PM
Session G16 DMP: Comp: Focus Session: Iron Based Superconductors: Local Probes 101AB
- Alexander Balatsky, Los Alamos National Laboratory/Nordita

11:15AM G16.00001 Quasiparticle interference (QPI) as a model-free phase sensitive tool to determine the pairing symmetry in Fe based superconductors (FeBS). IGOR MAZIN, Naval Research Lab, PETER HIRSCHFELD, University of Florida, ILYA EREMEN, University of Bochum — QPI has been successfully used to identify the d-wave pairing in high-Tc cuprates[1]. However, applying the same technique to FeBS has been confounded by difficulties not present in in cuprates, where QPI is dominated by several hot spots, thus calling for a more detailed analysis. This talk aims at providing such theoretical framework and clarifying some misconceptions regarding QPI in superconductors (partially pointed out before, but not generally appreciated). We emphasize that detailed comparison of the calculated model QPI maps with the experiment, as often attempted, is hardly helpful because the result depends not only on the assumed pairing symmetry but of numerous uncontrolled approximations. Instead, we suggest that the T dependence (but not the detailed q dependence at any given T) bears clear qualitative fingerprints of the s± or d± symmetry, independent of the details of impurity scattering, electronic structure etc. We propose an experiment that should unambiguously distinguish between the two symmetries in question. [1] Hanaguri et al, Science, 323, 923 (2009)

11:27AM G16.00002 STM investigation of FeSe1-xSx.1+ M. IAVARONE, S.A. MOORE, E. LECHNER, Department of Physics, Temple University, Philadelphia, PA 19122. J. CURTIS, Department of Physics, Drexel University, Philadelphia, PA 19104, O.S. VOLKova, A.N. VASILIEV, Low Temperature Physics and Superconductivity Department, Physics Faculty, M.V. Lomonosov Moscow State University, Moscow 119991, Russia, D.A. CHAREEV, Institute of Experimental Mineralogy, Russian Academy of Sciences, 142432 Chernogolovka, Moscow District, Russia, G. KARAPETROV, Department of Physics, Drexel University, Philadelphia, PA 19104 — FeSe has the simplest structure among the Fe-based superconductors, and this very simplicity could provide the most appropriate venue of understanding the superconducting mechanism of Fe-based superconductors. High quality FeSe single crystals were grown in evacuated quartz ampoules using a KCl/AlCl flux and the structure of tetragonal P4/nmm was demonstrated by x-ray diffraction. Low temperature STM measurements were performed on FeSe1-x-Sx with x=0.04 and 0.09. Effects of multiband superconductivity and vortex matter as a function of doping will be presented.

G.K. and A.N.V. acknowledge the support by a grant from U.S. Civilian Research & Development Foundation (CRDF Global).

11:39AM G16.00003 Real Space Imaging of the Atomic-Scale Magnetic Structure of Fe1y+Te, PETER WAHL, University of St Andrews, MOSTFA ENAYAT, ZHI-XIANG SUN, UDAI RAJ SINGH, RAMAKRISCHNA ALURU, STEFAN SCHMAUS, ALEXANDER YARESKO, YONG LIU, CHENGTIAN LIN, MAX-Plank-Institut fuer Festkoerperforschung, VLADIMIR TSURKAN, ALOIS LOIDL, JOACHIM DEISENHOFER, Universitaet Augsburg — High temperature superconductivity, both in cuprate as well as iron pnictide materials, occurs in close proximity to the superconducting transition temperatures. A detailed understanding of the superconducting mechanism of Fe1y+Te, the non-superconducting parent compound of the iron chalcogenides, by spin-polarized low temperature scanning tunneling microscopy. Our images of the magnetic structure reveal that magnetic order in the monoclinic phase is truly a unidirectional stripe order, whereas in the orthorhombic phase at higher excess iron concentrations (y > 0.12), a transition to a phase with coexistence of stripes in both directions is observed.
11:51AM 16.00004 Visualization of electronic nematicity in the iron pnictides, ETHAN ROSENTHAL, Columbia University — The nematic state from which superconductivity emerges in the iron pnictides continues to confound. We use scanning tunneling microscopy (STM) and spectroscopy (STS) to image both long-range nematic order and nematic fluctuations across the doping phase diagram in Co-doped NaFeAs. We associate twinning domains with long-range order and directly visualize the temperature and doping dependence of these features. Anisotropic electronic structure is found to persist outside of the ordered nematic phase. With the aid of a novel experimental setup which combines simultaneous STS and variable, uniaxial strain, we determine the relationship between strain and nematic fluctuations which gives rise to the anisotropy.

12:27PM 16.00005 Observation of van Hove singularity and quasiparticle interference in KFe2As2 superconductors revealed by STM/STS measurements, HAI-HU WEN, DELONG FANG, ZENGYI DU, ZHENYU WANG, HUAN YANG, XIAOXIN DING, Nanjing University — We have conducted STM/STS investigations on the KFe2As2 superconducting single crystals down to 0.45 K under magnetic field. Clear electronic standing waves have been observed allowing us to investigate the quasiparticle interference (QPI). Interestingly we observed a sharp peak of local density of states (LDOS) near the Fermi energy showing evidence of strongly enhanced DOS both below and above Tc. We also found a peak at xopt and a Tc vs λab dependence similar on both sides of xopt. Near the underdoped edge of the dome λab increases sharply, suggesting that superconductivity competes with another phase. Indeed MFM vortex imaging shows correlated defects parallel to twin boundaries only in underdoped samples and not for x ≥ xopt. Furthermore, in underdoped samples we report stripes parallel to twin boundaries that are visible even in the absence of vortices.

12:39PM 16.00006 Local characterization of superconductivity in BaFe2(As1−xPax)2, OPHIR AUSSLANDER, YUVAL LAMHOT, ALON YAGIL, NADAV SHAPIRA, Technion – Israel Institute of Technology, SHIGERU KASAHARA, TATSUYA WATASHIGE, Kyoto University, Japan, TAKASADA SHIBAUCHI, University of Tokyo, Japan, YUJI MATSUDA, Kyoto University, Japan — We use magnetic force microscopy (MFM) to characterize superconductivity across the superconducting dome in BaFe2(As1−xPax)2, an isovalently doped pnictide that exhibits a peak in the penetration depth (λab) at optimal doping (xopt), as shown previously in sample-wide measurements. Our local measurements show a peak at xopt and a Tc vs λab dependence similar on both sides of xopt. Near the underdoped edge of the dome λab increases sharply, suggesting that superconductivity competes with another phase. Indeed MFM vortex imaging shows correlated defects parallel to twin boundaries only in underdoped samples and not for x ≥ xopt. Furthermore, in underdoped samples we report stripes parallel to twin boundaries that are visible even in the absence of vortices.

12:51PM 16.00007 ABSTRACT WITHDRAWN —
1:39PM G16.00011 57As and 59Co NMR studies of SrCo$_2$As$_2$\textsuperscript{1}, YUJI FURUKAWA, Ames Laboratory, Dept. of Phys. and Astro, Iowa State Univ., VASILY OGLOBLINCHEV, Institute of Metal Physics, Ural Div. of Russian Academy of Sci., Ekaterinburg, Russia, ABHISEK PANDEY, DAVID C. JOHNSTON, Ames Laboratory, Dept. of Phys. and Astro, Iowa State Univ. — After the discovery of unconventional superconductivity in Fe pnictides with the ThCr$_2$Si$_2$-type structure, much attention has been paid to the related materials AM$_2$As$_2$ (A = Ca, Sr, and Ba, and M = Co, Ni, Mn, and Cu). We have been studying the electronic and magnetic properties of these related materials systematically. Among them, metallic SrCo$_2$As$_2$ is an interesting system [1] because inelastic neutron scattering measurements indicate strong stripe-type antiferromagnetic correlations [2], similar to the Fe pnictide superconductors. In order to investigate the magnetic and electronic properties of SrCo$_2$As$_2$ from a microscopic point of view, we carried out 57As and 59Co NMR in the temperature range T = 1.3 – 300 K. In this talk, based on 59Co NMR data including 75As NMR results published previously [1], we discuss the characteristic magnetic fluctuations in the system and compare them with those measured from NMR data for another cobalt arsenide BaCo$_2$As$_2$.

1:51PM G16.00012 57Fe Mössbauer study of iron-silicide superconductor Lu$_3$Fe$_2$Si$_2$\textsuperscript{1}, XIAOMING MA, Ames Laboratory/ Iowa State University, Ames, IA 50011, USA and Institute of Applied Magnetics/ Lanzhou University, Lanzhou, Gansu 730000, China, SHENG RAN, Ames Laboratory/ Iowa State University, Ames, IA 50011, USA, HUA PANG, FASHEN LI, Institute of Applied Magnetics/ Lanzhou University, Lanzhou, Gansu 730000, China, PAUL CANFIELD, SERGEY BUD’KO, Ames Laboratory/ Iowa State University, Ames, IA 50011, USA — In order to investigate the changes of the hyperfine parameters of a compound when it goes into a superconducting state from a normal state, we studied Lu$_3$Fe$_2$Si$_2$, Lu$_2$Fe$_2$Si$_3$, and LuFe$_2$Si$_3$, which is a superconductor with a transition temperature, T$_C$ ∼ 6 K and the Fe has been proved to be non-magnetic in a previous Mössbauer study\textsuperscript{[1]}. We performed detailed 57Fe Mössbauer spectra measurement on Lu$_2$Fe$_2$Si$_3$, from room temperature down to 4.4 K with particular attention paid to region near T$_C$. No clear feature that can be associated with the superconducting transition was found in the hyperfine parameters. Detailed hyperfine parameters and recoilless fraction as a function of temperature will be presented and discussed.

Tuesday, March 3, 2015 11:15AM - 2:15PM –
Session G17 DCMP: Graphene: Quantum Hall Effects
102AB - Fan Zhang, University of Texas at Dallas

11:15AM G17.00001 Collective Edge Modes near the onset of a graphene quantum spin Hall state, GANPATHY MURTHY, Department of Physics and Astronomy, University of Kentucky, Lexington KY 40506-0055, USA, EFRAT SHIMSHONI, Department of Physics, Bar-Ilan University, Ramat-Gan 52900, Israel, HERBERT FERTIG, Department of Physics, Indiana University, Bloomington, IN 47405, USA — Graphene subject to a strong, tilted magnetic field exhibits an insulator-metal transition tuneable by tilt-angle, which is attributed to the transition from a canted antiferromagnetic (CAF) to a ferromagnetic (FM) bulk state at filling factor ν = 0. We develop a theoretical description for the spin and valley edge textures in the two phases, and the implied evolution in the nature of edge modes through the transition. Based upon numerical Hartree-Fock calculations, we derive a simple description of the spin-valley domain wall for arbitrary Zeeman energy E$_z$, parameterized by two canting angles. Low-energy charged excitations can be constructed by imposing a slowly varying spin rotation on this state. In the CAF, these involve binding a vortex (meron) of the bulk state to a spin twist at the edge, so that the bulk spin stiffness controls the excitation energy. As the CAF-FM transition is approached (E$_z$ → E$_z^*$), the bulk stiffness vanishes linearly with (E$_z^*$ − E$_z$) and the vortex unbinds from the edge, yielding a gapless edge excitation characteristic of a quantum spin Hall state. Our model predicts the E$_z$-dependence of the activation gap in edge transport, and offers a qualitative picture of how this transport should evolve with filling factor.

11:27AM G17.00002 Oscillatory magnetotransport between co-propagating quantum Hall edge channels in graphene p-n junctions, SEI MORIKAWA, SATORU MASUBUCHI, RAI MORIYA, Institute of Industrial Science, University of Tokyo, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, TOMOKI MACHIDA, Institute of Industrial Science, University of Tokyo — We conducted magnetotransport measurements in high-quality dual-gated graphene p-n-junctions. As we used hexagonal boron nitride as a dielectric layer, Fabry-Perot interference patterns\textsuperscript{2} can be observed clearly in zero magnetic fields, owing to the extremely high carrier mobility of our devices\textsuperscript{3}. Moreover, the two-terminal resistance R exhibited oscillatory behavior as a function of the magnetic field B, whose oscillation period ∆B differed from both the conventional Shubnikov-de Haas effect (∆B ∝ B) and the Aharonov-Bohm effect with magnetic flux penetrating through the gated region (∆B = const). The oscillatory behavior of R was well reproduced by our numerical calculation under the assumption that R oscillated as a function of the magnetic flux penetrating through the insulating region between the co-propagating p and n quantum Hall edge channels\textsuperscript{4}.

11:39AM G17.00003 Ising quantum Hall ferromagnetic states in bilayer graphene. RENÉ CÔTE, WENCHEン LUO, ALEXANDRE BÉDARD-VALLÉE, University of Sherbrooke — We present a study of the phase diagram of the chiral two-dimensional electron gas (C2DEG) in the higher Landau levels, $|N| \geq 1$, of a chirally stacked bilayer graphene as a function of magnetic field $B$ and interlayer electrical bias $\Delta V$. In the Hartree-Fock approximation, the ground states of the C2DEG are respectively valley-pseudospin or spin Ising quantum Hall ferromagnets at odd or even filling factors of the quartet of states in levels $|N| \geq 1$ [1]. Changing the magnetic field or the bias introduces first order phase transitions between the different Ising ground states that are characterized by a discontinuity in the transport gap $\Delta t$. The C2DEG shows a hysteretic behavior with respect to the bias $\Delta V$ with a marked difference between positive $N > 0$ and negative $N < 0$ Landau levels [2]. We discuss the relevance of our results with recent experimental measurements of broken-symmetry gaps in bilayer graphene [3].

11:51AM G17.00004 Quantum Hall ferromagnetism in gapped bilayer graphene with trigonal warping effects. XIAO LI, Condensed Matter Theory Center, University of Maryland, FAN ZHANG, Department of Physics, The University of Texas at Dallas, QIAN NIU, ALLAN MACDONALD, Department of Physics, The University of Texas at Austin — The interplay between nontrivial Fermi surface topology and electron-electron interactions often leads to interesting phenomena in the quantum Hall regime. Bilayer graphene provides a unique platform to explore such physics, because the combined effects of trigonal warping and interlayer bias give rise to a nontrivial bandstructure at low energies. In the presence of a small perpendicular magnetic field, the highest valence-band Landau level of gapped bilayer graphene becomes three-fold degenerate excluding the spin degrees of freedom, with the three Landau levels corresponding to semiclassical orbits centered on different points in momentum space. Such a Landau level structure has been observed in a recent experiment [Phys. Rev. Lett. 113, 116602 (2014)]. In this work we construct a theory to show how the electron-electron interactions break this three-fold orbital degeneracy, and give rise to a gapped quantum Hall state at all intermediate integer filling factors. We further demonstrate that the resulting ground state breaks rotational symmetry and discuss some experimental consequences.

12:03PM G17.00005 Chiral symmetry breaking and the Quantum Hall Effect in monolayer graphene1, MALCOLM KENNETT, Physics Department, Simon Fraser University, BITAN ROY, Condensed Matter Theory Center, University of Maryland — Monolayer graphene in a strong magnetic field exhibits quantum Hall states at filling fractions $\nu = 0$ and $\nu = \pm 1$ that are not explained within a picture of non-interacting electrons. We propose that these states arise from interaction induced chiral symmetry breaking orders. We argue that when the chemical potential is at the Dirac point, weak onsite repulsion supports an easy-plane antiferromagnet state, which simultaneously gives rise to ferromagnetism oriented parallel to the magnetic field direction, whereas for $|\nu| > 1$, easy-axis antiferromagnetism and charge-density-wave order coexist. We perform self-consistent calculations of the magnetic field dependence of the activation gap for the $\nu = 0$ and $|\nu| = 1$ states and obtain excellent agreement with recent experimental results.

1Supported by NSF-JQI-PFC, LPS-CMTC, NSERC

12:15PM G17.00006 Quantum Hall Effect (QHE) in ABA stacked trilayer graphene. PETR STEPANOV, YAFIS BARLAS, NATHANIEL GILLGREEN, University of California, Riverside, TAKASHI TANIGUCHI, National Institute for Materials Science, JEANIE LAU, University of California, Riverside — Since its experimental discovery in 2004 graphene was under extensive research as a promising counterpart of silicon for the future electronics application as well as an excellent model of 2 dimensional electron gas. Here we investigate quantum Hall effect in ABA trilayer graphene – hexagonal boron nitride heterostructures. Landau Levels (LL) crossings at low filling factors were observed and explored at different external electric fields. The formation of the QH states as an interaction of monlayer-like and bilayer-like branches will be discussed. We will present the most recent experimental results.

12:27PM G17.00007 Optical study of nonuniform quantum-Hall ferromagnetic states in bilayer and trilayer graphene. MANUEL BARRETTE, RENÉ CÔTE, Université de Sherbrooke — The chiral two-dimensional electron gas in the $N = 0$ Landau level of a Bernal-stacked bilayer graphene is host to a variety of broken-symmetry ground states that can be described as layer, spin, or orbital quantum Hall ferromagnets (QHFs). At filling factors $\nu = 1, 3$, an externally applied electric field between the two layers can induce a transition from uniform to nonuniform orbital QHF states with an helical oriskyrtomic texture of electric dipoles [1]. A similar skyrmionic texture can also arise in the $N = 0$ Landau level of an ABC-stacked trilayer graphene. In this talk, we discuss the optical properties of these textured ground states. We compute their electromagnetic absorption as well as the Kerr and Faraday rotations induced by their collective excitations and show that each textured phase has a distinct optical signature.

12:39PM G17.00008 Broken Symmetry States in Twisted Bilayer Graphene. YOUNGWOOK KIM, JONG MOK OK, JUN SUNG KIM, Department of Physics, Pohang University of Science and Technology, Korea, JAESUNG PARK, SUYONG JUNG, Center for Quantum Measurements, Korea Research Institute of Standards and Science, Korea, DONG SU LEE, Soft Innovative Materials Research Center, Korea Institute of Science and Technology, Korea, INTEK SONG, HEE CHEUL CHOI, Department of Chemistry and Division of Advanced Materials Science, Pohang University of Science and Technology, Korea, K. WATANABE, T. TANIGUCHI, National Institute for Materials Science, Japan — Graphene bilayer with multiple degeneracy provides an access to rich quantum Hall states (QHS) with broken symmetry, arising from electron-electron interactions and Zeeman splitting. Here, we present quantum Hall effect in high-quality twisted bilayer graphene. At high density regime, we found several QH plateaus are suppressed or emerged with magnetic fields, indicating transitions between different QH states. We ascribe this to imperfect screening of twisted bilayer, which results in different Landau levels formation on each layer and their mixings. As low density regime, odd integer QHS are observed, suggesting an important role of the interlayer charge transfer for stabilizing broken symmetry QHS.
12:51PM G17.00009 Collective spin excitations in magnetically ordered graphene Quantum Hall insulator¹, JOSE LADO, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory — At half filling, the application of a perpendicular magnetic field in graphene results in a very large density of states at the Fermi energy, due to the n=0 Landau levels. Interactions are known to lead to some sort of electronic order that leads to a band-gap opening. Experimental evidence [1] suggest that electronic order is antiferromagnetic, and can be tuned into ferromagnetic upon application of a large in-plane field. This behaviour is properly captured by mean field Hubbard model [2]. In this talk, by using tight binding models and calculating responses within the random phase approximation [3], we show the different collective modes of bulk and edges associated to the different electronically ordered phases. Furthermore, we discuss the coupling of these spin waves to quasiparticles transport at the edges and discuss how this can affect local spin transport.

¹ We acknowledge financial support from Spinograph.

1:03PM G17.00010 Imaging the charge profile of graphene in quantum Hall states, YONGTAO CUI, ERIC MA, GEORGI DANKOV, FRANÇOIS AMET, Stanford Univ, VITTO HAN, Columbia Univ, MICHAEL KELLY, DAVID GOLDhaber-Gordon, Stanford Univ, CORY DEAN, Columbia Univ, ZHI-XUN SHEN, Stanford Univ — Under quantum Hall conditions, discrete energy levels (Landau levels) form in a two dimensional electron gas (2DEG) system. Spatial reconstructions of carriers due to electrostatics can occur for a non-uniform charge profile, giving rise to highly insulating incompressible regions. In this work we use microwave impedance microscope to image the quantum Hall states in graphene devices. First, scanning images clearly show dividing regions of insulating bulk and conductive edges. We study the evolution of the edge patterns as the carrier density is tuned through multiple Landau levels. Furthermore, a finite voltage bias on the tip can induce a local charge perturbation, which leads to an extra incompressible ring that moves along with the tip during scanning. Such incompressible ring can be used to probe the variations of the local carrier profile. Our results indicate that the carrier density in graphene tuned by the back gate tends to increase toward the edge due to electrostatic screening. This is in contrast to the case of conventional semiconductor 2DEG systems, where the carrier density always decreases toward the edge due to charge depletion. We will discuss how this charge profile affects the formation of the incompressible stripes.

1:15PM G17.00011 Measurement of energy gaps of integer and fractional quantum Hall states in suspended bilayer graphene devices, YANMENG SHI, YONGJIN LEE, SHI CHE, ZIQI PI, TIM ESPIRITU, KEVIN MYHRO, PETR STEPANOV, NATHANIAL GILLGREEN, Univ of California - Riverside, DMITRY SMIRNOV, National High Magnetic Field Laboratory, FL, CHUN NING LAU, Univ of California - Riverside — Coulomb drag between electrons in closely spaced two-dimensional electron systems has provided an exciting avenue for research on quantum Hall systems. Employing dual-gated, encapsulated graphene double layers separated by a thin hBN dielectric, we investigate density tunable magneto and Hall drag in quantum Hall bilayer systems. Large variations of magneto-drag and Hall-drag are observed, which can be related to the Landau level (LL) filling status of both driving and drag layers. The measured drag resistivity tensor can be associated with the tensor product of the differential magneto- and Hall-drag in quantum Hall bilayer systems. Large variations of magneto-drag and Hall-drag are observed, which can be related to the Landau level (LL) filling status of both driving and drag layers. The measured drag resistivity tensor can be associated with the tensor product of the differential magneto-resistivity tensors of the drive and drag layers [1]. The temperature and field dependence of magneto-drag can be described in terms of the phase space for Coulomb scattering between LLs in the drag and drive layers. In the strong interaction regime and ultra-low temperature, we observe the effect of symmetry broken integer Quantum Hall States in magneto and Hall drag signals. [1] F. von Oppen, S. Simon, and A. Stern, Phys. Rev. Lett. 87, 106803 (2001).

1:27PM G17.00012 Wess-Zumino-Witten terms in graphene Landau levels, JUNHYUN LEE, SUBIR SACHDEV, Department of Physics, Harvard University — We consider the interplay between the antiferromagnetic and Kekulé valence bond solid orderings in the zero energy Landau levels of neutral monolayer and bilayer graphene. We establish the presence of Wess-Zumino-Witten terms between these orders: this implies that quantum fluctuations are described by the deconfined critical theories of quantum spin systems. We present implications for experiments, including the possible presence of excitonic superfluidity in bilayer graphene.

1:39PM G17.00013 Coulomb drag in graphene quantum Hall bilayer systems, XIAOMENG LIU, Harvard University, LEI WANG, Columbia University, KIN CHUNG FONG, Raytheon BBN Technologies, YUANDA GAO, PATRICK MAHER, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, JAMES HONE, CORY DEAN, Columbia University, PHILIP KIM, Harvard University — Coulomb drag between electrons in closely spaced two-dimensional electron systems has provided an exciting avenue for research on quantum Hall systems. Employing dual-gated, encapsulated graphene double layers separated by a thin hBN dielectric, we investigate density tunable magneto and Hall drag in quantum Hall bilayer systems. Large variations of magneto-drag and Hall-drag are observed, which can be related to the Landau level (LL) filling status of both driving and drag layers. The measured drag resistivity tensor can be associated with the tensor product of the differential magneto-resistivity tensors of the drive and drag layers [1]. The temperature and field dependence of magneto-drag can be described in terms of the phase space for Coulomb scattering between LLs in the drag and drive layers. In the strong interaction regime and ultra-low temperature, we observe the effect of symmetry broken integer Quantum Hall States in magneto and Hall drag signals. [1] F. von Oppen, S. Simon, and A. Stern, Phys. Rev. Lett. 87, 106803 (2001).

1:51PM G17.00014 Fractional Quantum Hall Effect in the Second Landau Level of bilayer graphene, GEORGI DANKOV, FRANCOIS AMET, MENCYOUNG LEE, ANDREW BESTWICK, KEVIN THARRATT, CHI-TE LIANG, DAVID GOLDhaber-Gordon, Stanford University — Bilayer graphene exhibits rich Quantum Hall physics due to valley, spin and orbital degrees of freedom that lead to a variety of polarization states. We study the Fractional Quantum Hall Effect (FQHE) in ultra-clean multiterminal bilayer graphene devices on boron nitride with a local graphite gate at magnetic fields of up to 45 T. We measure mobility of up to 1 million cm²/V·s and very low disorder. In addition to the broken-symmetry integer states, we unambiguously resolve a variety of fractions and focus on a series of fractions in the Second Landau Level, which do not follow particle-hole asymmetry. From the magnetic field dependence of the fractions, we find that some of these fractions have spin-polarized ground states while others are unpolarized, and we present a possible explanation for this difference. This work provides insights into how the symmetry-breaking electron-electron interactions and Zeeman splitting interact to produce a rich landscape of composite fermions in the Second Landau Level of bilayer graphene.

2:03PM G17.00015 Effect of tunable superlattice on quantum Hall effect in graphene, SUDIPTA DUBEY, MANDAR DESHMKH, Tata Institute of Fundamental Research — We have studied quantum Hall effect in tunable superlattice in graphene created using combination of back gate and an array of top-gates pinned to the same potential. In our device we are in the regime when superlattice period is larger than the magnetic length and superlattice amplitude can be tuned to be larger than Landau level spacing. We observe robust plateaus when charge carrier in adjacent region is of the same polarity. However when we have a series of p-n junction, the high superlattice amplitude leads to large local electric field in p-n junction causing collapse of Landau level and hence incomplete equilibration. We have also studied charge transport at low magnetic field where we have higher number of edge states circulating within a strip of back-gated or top-gated region.

Tuesday, March 3, 2015 11:15AM - 2:15PM — Session G18 DCMP GQI: Invited Session: Quantum Trajectories and State Estimation Mission Room 103A - Klaus Moelmer, Aarhus University, Denmark
11:15AM G18.00001 Stochastic action principle approach to continuous quantum measurement
ANDREW JORDAN, University of Rochester — New features in fundamental quantum physics appear in generalized (or weakened) measurements that are no longer simple projections. A sequence of weak measurements can also be made effectively continuous, producing monitored state evolution in the form of a quantum stochastic process. Previous theoretical investigations of this topic have mainly focused on using Langevin-type Stochastic Schrodinger equations to generate and study the quantum trajectories. Here, we reformulate the theory of continuous quantum measurement as a stochastic path integral, describing all possible quantum trajectories moving between initial and final quantum states. In order to do this, an auxiliary set of variables is introduced to impose the intrinsic state disturbance, doubling the state space of the system. The stochastic action encodes both the Hamiltonian and measurement dynamics. This formulation is well suited to finding the most-likely quantum path between chosen boundary conditions on the quantum states separated in time via a principle of least action. This action principle leads to a set of coupled nonlinear ordinary differential equations for the most likely path, structurally similar to Hamilton’s equations. I will present predictions for the single and multiple qubit cases. Comparison to recent experiments with superconducting transmon qubits will be discussed. This formalism sheds new light on the conditional dynamics of monitored open quantum systems.

11:51AM G18.00002 Ensembles of quantum trajectories— a window into qubit measurement dynamics
STEVEN WEBER, UC Berkeley — A central feature of quantum mechanics is that a measurement result is intrinsically probabilistic. Consequently, continuously monitoring a quantum system will randomly perturb its natural unitary evolution. An accurate measurement record documents this stochastic evolution and can be used to reconstruct the quantum trajectory of the system state in a single experimental iteration. We use weak measurements to track the individual quantum trajectories of a superconducting qubit that evolves under the competing influences of continuous weak measurement and Rabi drive. We analyze large ensembles of such trajectories to examine their characteristics and to determine their statistical properties. For example, by considering only the subset of trajectories that evolve between any chosen initial and final states, we can deduce the most probably path through quantum state space.

12:27PM G18.00003 Quantum State Smoothing1, HOWARD WISEMAN, Centre for Quantum Dynamics, Griffith University — Under noisy observations, one can estimate the state of the measured system, if its a priori statistics are given. In the continuous time situation, three different types of estimation can be distinguished: filtering, which is estimating of the state at time t from earlier records; retro-filtering, which is estimating it from later records; and smoothing, which is estimating it from both earlier and later records. Of the three, smoothing allows the greatest precision. Smoothing has been well developed in classical systems, but its application to quantum systems is very recent. Previous works have used the term “quantum smoothing” to mean estimating classical parameters, [Tsang, Phys. Rev. Lett 102, 250403 (2009); Yonezawa et al., Science 337, 1514-1517 (2012)]. This is essentially classical smoothing in which the noisy observation of the classical parameters is mediated by a quantum system. Here we introduce quantum state smoothing, where the state of a partially observed open quantum system itself is smoothed. We achieve this by applying classical smoothing to a hypothetical unobserved noisy measurement record that induces (in part) the stochastic dynamics (“quantum trajectories”) of the system. Using the formalism of linear quantum trajectories, we simulate quantum state smoothing for a qubit, and quantify how well it works. Our investigations shed new light on the nature of open quantum systems and the applicability of classical concepts. Applications to continuous measurement of solid-state qubits will be presented.

1:03PM G18.00004 Unravelling quantum jumps by watching the fluorescence of a qubit, PHILIPPE CAMPAGNE-IBARCO, Laboratoire Pierre Aigrain, Ecole Normale Superieure, Paris — When the main source of qubit relaxation comes from its coupling to a photonic channel, each relaxation event is associated with the release of a photon. The corresponding discrete quantum jumps of the qubit state can be observed by counting the number of photons released. This discreetness of the quantum jumps is in fact related to the nature of the light detector. What does the evolution of the qubit state become if fluorescence is measured using a heterodyne detector instead? In this talk, an experiment will be discussed, in which the records of heterodyne measurements of fluorescence is used to reconstruct the quantum trajectories of a qubit during relaxation. Using a large number of experiments, it is shown that these trajectories can be used to better predict the probability to find given measurement outcomes during the evolution. This heterodyne measurement of the fluorescence is a quantum demolition continuous measurement, which is very different from the more common dispersive measurement sensitive to qubit occupation. These trajectories are thus expected to exhibit some exotic properties, particularly when using past and future knowledge. Besides, using measurement based feedback based on the fluorescence signal alone, it is possible to stabilize any chosen qubit state. This work thus demonstrates that relaxation into an efficiently monitored channel is not a limit for quantum information protocols but can instead be a resource.

1:39PM G18.00005 Prediction, Retrodiction, and Smoothing for a Continuously Monitored Superconducting qubit, KATER MURCH, Physics Department, Washington University, St. Louis — The quantum state of a superconducting transmon qubit inside a three-dimensional cavity is monitored by reflection of a microwave field on the cavity. Measurement outcomes at different times are correlated, and knowledge of later measurement outcomes can be used to provide statistical information about earlier probe results. For a driven, damped and continuously monitored quantum system, the information inferred from measurement data yields a quantum trajectory given by the matrix \( \rho \), which is conditioned on probe results up to \( t \). Further probing after the time \( t \) can be incorporated into an auxiliary matrix \( E_t \). We show that the combination of \( \rho \) and \( E_t \) makes nontrivially different and more precise predictions for the outcomes of measurements in the past. Our experiments verify the predictions of both projective and weak value (weak) measurements conditioned on full measurement records.

Tuesday, March 3, 2015 11:15AM - 2:15PM –
Session G19 FLAP DMP: Invited Session: Caloric Materials and Advances in Solid State Cooling Technologies
Mission Room 103B - Jun Cui, Pacific Northwest National Laboratory

11:15AM G19.00001 Magnetocaloric cooling: the phenomenon and materials1, VITALIJ PECHARSKY, Ames Laboratory and Department of Materials Science and Engineering, Iowa State University — The discovery of the giant magnetocaloric effect in Gd2Si2Ge2 and other R2T1 compounds (R = rare earth metal and T = a Group 14 element) generated a broad interest in the magnetocaloric effect and magnetic refrigeration near room temperature in particular, and in magnetostuctural transitions in general. Reports on the giant magnetocaloric effect in other systems soon followed. These include MnFeP4-xAs1-x and related compounds, La(Fe1-xSi1-x)3, and their hydrides, Mn(As1-xSb1-x), CoMnSi1-xGe1-x and related compounds, Ni2MnGa and some closely related Heusler phases, and a few non-metallic systems. A common feature observed in all giant magnetocaloric effect materials is the enhancement of the magnetic entropy change by the overlapping contribution from the lattice. In addition to the interplay between magnetic and lattice entropies, both of which are intrinsic materials’ parameters that in principle can be modeled theoretically from first principles, extrinsic parameters such as microstructure and nanostructure, have been found to play a role in controlling both the magnetostuctural transition(s) and magnetocaloric effect. Both the intrinsic and extrinsic parameters are, therefore, important in order to maximize magnetocaloric effect. The role of different control parameters and the potential pathways towards materials exhibiting advanced magnetocaloric effect will be discussed.

1 This work is supported by the Division of Materials Science and Engineering, Office of Basic Energy Sciences of the U.S. Department of Energy under contract No. DE-AC02-07CH11358 with Iowa State University.
11:51 AM G19.00002 Elastocaloric cooling materials and systems, ICHIRO TAKEUCHI, University of Maryland and Maryland Energy and Sensor Technologies — We are actively pursuing applications of thermoelastic (elastocaloric) cooling using shape memory alloys. Latent heat associated with martensitic transformation of shape memory alloys can be used to run cooling cycles with stress-inducing mechanical drives [1]. The coefficient of performance of thermoelastic cooling materials can be as high as 11 with the directly measured DT of around 17 °C. Depending on the stress application mode, the number of cycles to fatigue can be as large as of the order of 10^5. Efforts to design and develop thermoelastic alloys with long fatigue life will be discussed. The current project at the University of Maryland is focused on development of building air-conditioners, and at Maryland Energy and Sensor Technologies, smaller scale commercial applications are being pursued. This work is carried out in collaboration with Jun Cui, Yiming Wu, Suxin Qian, Yunho Hwang, Jan Muehlbauer, and Reinhard Radermacher, and it is funded by the ARPA-E BEETIT program and the State of Maryland.

12:27PM G19.00003 Modeling and design aspects of active caloric regenerators, KURT ENGELBRECHT, Technical University of Denmark — A cooling device based on a solid caloric material using, for example, the elastocaloric, magnetocaloric, barocaloric or electrorcaloric effect has the potential to replace vapor-compression based systems for a variety of applications. Any caloric device using a solid refrigerant may benefit from using a regenerative cycle to increase the operating temperature span. This presentation shows how all active caloric regenerators can be modeled using similar techniques and how they are related to passive regenerator performance. The advantages and disadvantages of using a regenerative cycle are also discussed. The issue of hysteresis in caloric materials is investigated from a system/thermodynamic standpoint and the effects on cooling power and efficiency are quantified using a numerical model of an active regenerator using model caloric materials with assumed properties. The implementation in a working device will be discussed for elastocaloric and magnetocaloric cooling devices. It is shown that demagnetization effects for magnetocaloric systems and stress concentration effects in elastocaloric system reduce the overall effect in the regenerator and care must be taken in regenerator design for both technologies. Other loss mechanisms outside the regenerator such as heat leaks are also discussed. Finally, experimental results for active magnetic regenerative cooler are given for a range of operating conditions. The most recently published device uses a regenerator consisting of Gd and three alloys of GdY and has demonstrated a COP over 3.

1:03PM G19.00004 ABSTRACT WITHDRAWN —

1:39PM G19.00005 Effective Mass of Thermoelectric Materials with Non-Parabolic Kane Bands, G. JEFFREY SNYDER, Northwestern University MSE — Effective mass is a concept commonly used to describe electronic transport in semiconductors using a classical analogy to the kinetic theory of gases. We describe many important electronic transport parameters explicitly with an electronic band mass including: Density of states, charge carrier concentration, mobility, and in particular for thermoelectrics, the Seebeck coefficient. For systems with known electronic band structures these properties can be calculated leading to subtly different definitions of effective mass. In the free electron or parabolic band model the effective masses are the same and we use the term effective mass interchangeably. However the differences between these definitions or uses of effective mass become apparent in non-parabolic band structures where it is desirable to describe the transport in terms of a effective mass that changes with energy (or Fermi Level). For example Kane bands, which become more linear and less parabolic at higher energy, have an increased density of states and therefore higher DOS effective mass than a parabolic band. While it is often assumed that also results in a higher thermopower (Seebeck coefficient), calculations of thermopower and Hall carrier concentration from the Kane model show the thermopower is actually reduced. Examples in thermoelectric materials will be discussed.

11:15AM G20.00001 Big science with little data: separating random waves from vortices in atmosphere and ocean fluid dynamics1, OLIVER BUHLER, Courant Institute of Mathematical Sciences, New York University — How to extract physical and conceptual meaning from limited data sets has been a perennial problem in atmosphere ocean science. This is especially pressing in the current era of large-scale numerical models that seek, for the first time, to simulate directly all the most energetic scales in these systems. This effort requires observational guidance at unprecedented small spatial scales. Progress in extracting physical meaning from data is therefore inseparable from progress in climate simulation and forecasting overall. For example, the successful planning of costly satellite missions depends crucially on the physical nature of the expected motions that are to be observed. In many cases, data are obtained along one-dimensional ship or flight tracks, in which case there are both kinematic and dynamic aliasing effects that obscure the physical meaning of the data. Here kinematic refers to well-known aliasing effects that arise when three-dimensional flow fields are observed only along a line. Dynamics aliasing refers to the more subtle situation when physically different processes project into the same data stream. Indeed, it is well known in atmosphere ocean science that random waves and vortices overlap and intermingle in a complex wave-turbulence jigsaw puzzle, which we need to solve! This talk describes recent progress on this problem, which led to a new method to decompose one-dimensional data into its wave and vortex constituents. The new method works by combining a new Helmholtz decomposition method for one-dimensional velocity spectra with a theoretical energy equi-partition result that allows fingerprinting and identifying the random wave component in the track data. Applications of the new method to oceanic data sets and to the famous Gage–Nastrom spectrum in the atmosphere are presented, with surprising results.

11:51AM G20.00002 Convection, Stability, and Turbulence1, CHARLES R. DOERING2, University of Michigan — Many natural flows are driven by buoyancy forces, perhaps the most familiar being those resulting from density variations due to temperature or compositional differences in the presence of a gravitational field. Buoyancy-driven flows of this sort play a major role in geophysical fluid mechanical processes and their transport properties and are central to climate dynamics. The simplest setting to study this phenomena is so-called Rayleigh–Bénard convection, the buoyancy driven flow in a horizontal layer of fluid heated from below and cooled from above. This seminal problem has received tremendous attention over the last century but many riddles remain, especially regarding strongly nonlinear turbulent convection. In this presentation, following an introduction to the phenomena and its applications along with a review of the current state of theory and experiments on high Rayleigh number convection, I will describe some recent results that mathematical analysis has contributed to our understanding of turbulent heat transport.

12:27PM G20.00003 A look at two disparate limits of the climate system: oceanic submesoscales and global energy balance1. BALU NADIGA, LANL — A common theme underlying this journey across scales is that of energy balance. The first topic considers scales from a few tens of meters to a few tens of kilometers and grapples with a fundamental question that concerns energetics of ocean circulation: how does ocean circulation equilibrate in the presence of continuous large-scale forcing and a tendency of geostrophic turbulence to confine energy to large and intermediate scales. In particular, interior instabilities are shown to provide an energy pathway between the largely-balanced, energetic oceanic mesoscales and smaller unbalanced scales (J. Fluid Mech. (2014), vol. 756, pp. 965-1006; doi:10.1017/jfm.2014.464). The second topic zooms out to the global scale and considers global warming from an energy balance perspective. With the global ocean sequestering in excess of 90% of the recent warming due to energy imbalance at the top of the atmosphere, sensitivity of warming and depth of penetration of warming are characterized in a probabilistic fashion.

1Supported in part by the LDRD program at LANL (project number 20110150ER)

1:03PM G20.00004 Stochastic models for tropical convection and extreme rainfall events1, SAMUEL STECHMANN, University of Wisconsin-Madison — In the Tropics, storms and convection occur intermittently and have a major impact on weather and climate. In recent years, tropical rainfall statistics have been shown to conform to paradigms of critical phenomena and statistical physics. To gain further insights into these statistics and extreme events, this talk presents simple stochastic models for the statistics of precipitation events and water vapor dynamics (local in space, and evolving in time). Through exact solutions and simple numerics, a suite of observed rainfall statistics is reproduced by the model, including power-law distributions and long-range correlations. The key ingredients of the model are the dynamics of column water vapor, governed by a combination of Gaussian stochastic forcing and nonlinearities provided via a threshold and/or stochastic trigger. Finally, these statistics are being explored in climate model simulations with collaborators.

1:39PM G20.00005 Climate Variability and Nonequilibrium Steady-States1, JEFFREY WEISS, University of Colorado, Boulder — The climate system is forced by incoming solar radiation and damped by outgoing long-wave radiation. As a result, the climate system is not in thermodynamic equilibrium but is better conceptualized as residing in a nonequilibrium statistically steady-state. Nonequilibrium steady-states have internal fluctuations which appear as natural variability of the climate system. Additionally, the phase space has nonzero probability current loops which are manifested as preferred patterns of natural climate variability. Nonequilibrium steady-states are often modeled by stochastic Langevin dynamics, and many aspects of the physics of these models are well understood. Simple stochastic models have been applied to a variety of climate phenomena including El-Niño, the North Atlantic Gulf Stream, surface temperature patterns, ocean heat content, and atmospheric Storm Tracks. In their simplest form, these models describe a stable steady-state with linear nonconservative damping perturbed by additive Gaussian white noise and thus fall into the class of models capturing nonequilibrium steady-states where previous results from Langevin models apply while the climate context motivates additional new questions.

11:15AM G21.00001 An ultra-low field electron paramagnetic resonance technique for biomedical research. P. BHUPATHI, Physics Department, California Institute of Technology, I. HAHN, Jet Propulsion Laboratory, California Institute of Technology — Conventional electron paramagnetic resonance (EPR) imaging systems use high magnetic fields confined to small spaces and therefore have limitations on the sample size and safety issues related to the high level of radiation. We are developing an ultra-low field SQUID (Superconducting Quantum Interference Device)-magnetometer system for EPR detection from room temperature samples in magnetic fields of a few Gauss, corresponding to EPR frequencies of a few MHz. Operation at low EPR excitation frequencies of a few MHz ensures negligible sample heating and high penetration depth in biological systems. A new measurement system consists of a specially designed low noise, non-magnetic 4K dewar with a hollow tail housing a superconducting second order gradiometer inductively coupled to a two-stage dc SQUID amplifier. This unique gradiometer design allows a sample at room temperature to be positioned at the middle turns, which significantly improves the signal-to-noise ratio. We present preliminary results and discuss the prospects for in vivo biomedical EPR imaging.

11:27AM G21.00002 A Nanocoaxial-Based Electrochemical Sensor for the Detection of Cholera Toxin1, MICHELLE M. ARCHIBALD, BINOD RIZAL, TIMOTHY CONNOLLY, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, THOMAS C. CHILES, Boston College — Sensitive, real-time detection of biomarkers is of critical importance for rapid and accurate diagnosis of disease for point of care (POC) technologies. Current methods do not allow for POC applications due to several limitations, including sophisticated instrumentation, high reagent consumption, limited multiplexing capability, and cost. Here, we report a nanocoaxial-based electrochemical sensor for the detection of bacterial toxins using an electrochemical enzyme-linked immunosorbent assay (ELISA) and differential pulse voltammetry (DPV). Proof-of-concept was demonstrated for the detection of choler toxin (CT). The linear dynamic range of detection was 10 ng/ml – 1 µg/ml, and the limit of detection (LOD) was found to be 2 ng/ml. This level of sensitivity is comparable to the standard optical ELISA used widely in clinical applications. In addition to matching the detection profile of the standard ELISA, the nanocoaxial array provides a simple electrochemical readout and a miniaturized platform with multiplexing capabilities for the simultaneous detection of multiple biomarkers, giving the nanocoax a desirable advantage over the standard method towards POC applications.

11:39AM G21.00003 Symmetric and Asymmetric Split Ring Resonators for Biosensing at Terahertz Frequencies1, GUILLERMO NARANJO, XOMALIN PERALTA, Univ of Texas, San Antonio — Food allergies have become a major health concern around the world. Peanut allergies are particularly important because they affect over 5 million people in the United States. We are proposing to develop a metamaterial-based sensor for peanut allergens. The detection mechanism we will tap into is the change in a metamaterial’s resonant response due to the presence of a biomolecule in the gap region. Using a commercial-grade simulator based on the finite-difference time-domain method, we have simulated the terahertz transmission and reflection spectra of three different split-ring resonator designs with and without a biomolecule present. By modifying the overall symmetry of the resonator and the geometry of the gap region, we have modified the resonant response and increased its sensitivity. The increased sensitivity is demonstrated by repeating the simulations with a layer of peroxidase conjugated immunoglobulin G (PX-IgG) in the gap region and quantifying the resulting resonant shift. These results are the basis for the proposed allergen sensors.

1UTSA MBRS-RISE Research Training Program.
11:51AM G21.00004 On-chip cell sorting via patterned magnetic traps . TOM BYVANK, MICHAEL PRIKOCKIS, AARON CHEN, BRANDON MILLER, JEFFREY CHALMERS, RATNASINGHAM SOORYAKUMAR, Ohio State University — Due to their importance in research for the diagnosis and treatment of cancer, numerous schemes have been developed to sort rare cell populations, e.g., circulating tumor cells (CTCs), from a larger ensemble of cells. Here, we improve upon a previously developed microfluidic device (Lab Chip 13, 1172, (2013)) to increase throughput and sorting purity of magnetically labeled cells. The separation mechanism involves controlling magnetic forces by manipulating the magnetic domain structures of the embedded permalloy microdisks with weak external fields. These forces move labeled cells from the input flow stream into an adjacent buffer flow stream. Such magnetically activated transfer separates the magnetic entities from their non-magnetic counterparts as the two flow streams split apart and move toward their respective outputs. Purity of the magnetic output is modulated by the withdrawal rate of the non-magnetic output relative to the inputs. A proof of concept shows that CTCs from metastatic breast cancer patients can be sorted, recovered from the device, and confirmed as CTCs using separate immunofluorescence staining and analysis. With further optimizations, the channel could become a useful device for high purity final sorting of enriched patient cell samples.

12:03PM G21.00005 Neuroelectronic device based on nanocoax arrays . JEFFREY R. NAUGHTON, JACLYN N. LUNDBERG, JUAN A. VARELA, MICHAEL J. BURNS, THOMAS C. CHILES, JOHN P. CHRISTIANSON, MICHAEL J. NAUGHTON, Boston College — We report on development of a nanocoax-based neuroelectric array. The device has been used in real time to noninvasively couple to a ganglion sac located along the main nerve cord of the leech Hirudo medicinalis. This allowed for extracellular recording of synaptic activity in the form of spontaneous synapse firing in pre- and post-synaptic somata, with the next target being recording of local field potentials from rat hippocampal cells. We also discuss an alteration of the architecture to facilitate optical integration of the nanoarray, toward utilizing the so-modified device to elicit / inhibit action potentials in optogenetically-modified cells.

12:15PM G21.00006 Intracavity Microfluidic Laser Device for Single Cell Analysis , PAUL COURLEY, HighLight Research Lab — An intracavity microfluidic laser device has been developed to study bioparticles ranging in size from 50 nm to 20 µm (virions to organelles to whole cells). The versatile device can be operated used in several modes including static or flowing fluids, with or without molecular labels, and microscopic imaging and/or spectroscopy. It enables advantageous new ways to perform analyses of bioparticles for applications including cell biology, detection of disease and pathogens, environmental monitoring, pharmaceuticals, agriculture, and food processing. This talk will briefly summarize the physics of the device including its laser optics, fluid dynamics, and intracavity light interaction with cells. The talk will then focus on results of a study of mitochondria in normal and cancer liver cells. The study examines the transformation of intracellular and isolated mitochondria from the normal to disease state. The results highlight the unique utility of the device to rapidly assess biophysical changes arising from altered biomolecular states of cells and organelles.

12:27PM G21.00007 Individual Mammalian Cell Magnetic Measurements with a Superconducting Quantum Interference Device . JOHANNA C. PALMSTROM, Gabilan Stanford Graduate Fellow, Geballe Laboratory for Advanced Materials, Stanford University, KIMBERLY BREWER, SUI SENG TEE, Department of Radiology, Stanford University School of Medicine, ERIC THEIS, Geballe Laboratory for Advanced Materials, Stanford University, BRIAN RUTT, Department of Radiology, Stanford University School of Medicine, KATHRYN A. MOLER, Geballe Laboratory for Advanced Materials, Stanford University — Magnetism can be introduced into otherwise nonmagnetic cells by the uptake of superparamagnetic iron oxide (SPION) nanoparticles. SPION nanoparticles are used in numerous biomedical applications including cellular therapies and targeted drug delivery. Currently there are few tools capable of characterizing individual magnetic nanoparticles and the magnetic properties of individual mammalian cells loaded with SPION. Our scanning superconducting quantum interference devices (SQUIDs) are good candidates for these measurements due to their high sensitivity to magnetic dipole moments (approx. 200 µm/√Hz). In this study, we use a scanning SQUID to image the magnetic flux from SPION loaded H1299 lung cancer cells. We find that the magnetic moment spatially varies inside the cell with each cell having a unique distribution of moments. We also correlate these magnetic images with optical and scanning electron microscope images. These results show that the SQUID is a useful tool for imaging biological magnetism. The visualization of single cell magnetism and the quantification of magnetic dipole moments in magnetically labeled cells can be used to optimize conventional biological magnetic imaging techniques, such as MRI.

12:39PM G21.00008 Interaction-Free Quantum Electron Microscope in Free-Space1 . YUJIA YANG, CHUNG-SOO KIM, RICHARD HOBBES, VITOR MANFRINATO, ORHAN CELIKER, Massachusetts Institute of Technology, PIETER KRUIT, TU Delft, KARL BERGGREN, Massachusetts Institute of Technology — We propose the design and theoretical analysis of a quantum electron microscope (QEM), which utilizes interaction-free quantum measurement with electrons for nanoscale imaging. The QEM can be used to image electron-irradiation-sensitive materials, such as biological samples, with a high resolution and low radiation damage. Our QEM scheme is an electron interferometer with a storage resonator. The incoming electron beam is asymmetrically split into a strong reference beam and a weak sample beam, both of which are stored in the resonator. Only the weak sample beam transmits through the sample for multiple times. We propose to build the QEM with free-space electron optics. We develop a scattering matrix method to theoretically analyze the contrast mechanism, radiation damage, and measurement accuracy. We propose an electron-mirror-based storage resonator and we have performed electron optics simulation of electron trajectories within the resonator. We also report experimental implementation and characterization of the electron beam-splitter to be used in the QEM. Thin crystals fabricated with focused ion beam and nano-gratings fabricated with electron-beam lithography are two candidate beam-splitters, both of which are characterized by electron diffraction.

12:51PM G21.00009 Light localization properties of biological cells via confocal imaging1 . PEETYUSH SAHAY, HEMENDRA M. GHIMIRE, HUDA ALMABADI, PRABHAKAR PRADHAN, Univ of Memphis — Detection and characterization of the spatial refractive index fluctuations of very weakly disordered dielectric media has ample applications in various fields ranging from soft condensed matter to biological research. We report a study of the submicron scale degree of the structural disorder of heterogeneous weakly disordered optical dielectric media, such as biological cells, by quantifying their submicron scale light-localization properties. Confocal microscopy is used to construct disordered optical lattices of these dielectric media. Light-localization properties are studied by the statistical analysis of the inverse participation ratio (IPR) of the localized eigenfunctions of these optical lattices at the submicron scales. The method is described and its importance is highlighted. As one of the applications, we demonstrate that using this method, different types of normal and cancerous cells can be distinguished by quantifying the structural disorder inside the cells via their confocal micrographs. Other potential applications of the technique to characterize weakly disordered media, as well as biological cells, in particular cancer detection, are also discussed.

1NIH and University of Memphis
1:03PM G21.00010 Enhanced partial wave spectroscopy (EPWS) for nanoscale sensitive structural disorder measurement in weakly disordered media1, HUDA ALMABADI, PEEYUSH SAHAY, PRABHAKAR PRADHAN, Univ of Memphis — Based on mesoscopic physics approach, partial wave spectroscopy (PWS) technique was introduced earlier for the measurement of the nanoscale structural disorder in very weakly disordered optical media, such as biological cells. We describe a modification and further improvement of this technique, by introducing an enhanced back reflection system to further increase the measurement sensitivity of the PWS technique. As a result, a nanoscale level of fluctuation or nanoscale alteration in a disordered medium can be measured with even higher sensitivity and accuracy. In this enhanced-PWS (EPWS) technique, semi-transparent metallic thin films are used to create a cavity like structure that holds the sample; this leads to an increased back reflected light intensity, which eventually results in high sensitivity in the nanoscale structural disorder measurements. Reflection coefficients of the backscattered signal obtained from the simulated disordered media, within the cavity, with varying refractive index fluctuation values, were statistically analyzed using mesoscopic physics approach. The results, of a sample with and without metallic cavity inside the system show a significantly high back reflected intensity with the metallic cavity case. We also discuss the possible applications of the developed technique in ultra-sensitive detection of cancer by the characterization of nanoscale fluctuations in biological cells.

1 NIH and University of Memphis

1:15PM G21.00011 Quantitative ultrasonic bone assessment using backscatter measurements at 1 MHz, PHILIP SPINOLO, Rhodes College. Department of Physics, BRENT HOFFMEISTER, Rhodes College, SANG-ROK LEE, University of Memphis, Department of Health and Sport Sciences, JINSONG HUANG, University of Tennessee Health Science Center, College of Medicine — Osteoporosis is a complicated metabolic degenerative bone disease affecting millions of Americans. The current standard for diagnosis is an x-ray technique called DXA, but ultrasound may offer a cheaper, more portable diagnosis method that may also be sensitive to bone strength in ways DXA is not. Ultrasonic backscatter techniques in the 5 MHz range have been shown to be sensitive to changes in bone mineral density (BMD) associated with osteoporosis. These techniques measure the power ratio between an earlier and later part of the backscatter signal. These ratios (called nMBD or nBAR in the time domain) depend on ultrasonic attenuation in bone which is known to correlate with BMD. This study measured nMBD and nBAR using a 1 MHz transducer. Lower frequency transducers increase signal penetration into bone. Linear regression analysis was used to investigate correlations between nMBD and nBAR and the density and microstructural characteristics of bone such as the structural model index (SMI) and trabecular number (TbN). Good linear correlations were observed for nMBD and nBAR vs. BMD at r=0.75 and r=0.70, respectively, comparable to correlations obtained using a 5 MHz transducer. Correlations with SMI and TbN were within the r=0.65-0.75 range.

1:27PM G21.00012 Thermal (rf) and non-thermal mechanisms of nanoparticles induced/enhanced cancer cell apoptosis, JAREK WOSIK, University of Houston, DHIYA KETHARNATH, University of Missouri Kansas City, MATTJEW J. WARE, BIANA GODIN, The Methodist Hospital Research Institute, WANADA ZAGODZODN-WOSIK, University of Houston — It was demonstrated that the rf procedures can be non-invasive and cancer selective when combined with nanoparticles (NPs) that work as rf heating enhancers. However, there are disparities, between theory and experimental results, especially for non-magnetic NP. Therefore, it is necessary to elucidate the physical mechanisms that control the reported rf heating. We have constructed an apparatus for rf heating, which allows for applying either E_r or H_r fields in the kHz-MHz frequency range. Our results of specific absorption rate (SAR) measurements for both magnetic and nonmagnetic of NPs indicate that rf electric field also plays the role in heating of magnetic NPs and that in the nonmagnetic case only interface losses are responsible for the observed heating. In search for a more efficient and non-thermal method, we have explored a cancer cell death through mechanical stress imposed on the cell membrane. We have designed a special setup to apply either static or magnetic fields or gradients (up 300T/m) to cultured cancer cell lines with/without PNs added. The fields and gradients, and forces applied were simulated using HFSS/Maxwell software. Pancreatic adenocarcinoma cell line, AsPC-1 stained with DRAQ7 were studied. Very strong dependence of number of dead cells on applied field strength was observed. Discussion of the two mechanisms (rf and non-rf) of observed apoptosis will be presented.

1:39PM G21.00013 Precise control of DNA recapture in solid-state nanopore, YING HU, ZHI ZHOU, XINYAN SHAN, ZHI XU, XUEDONG BAI, XINGHUA LU, None — Solid-state nanopore is a novel experimental method in detecting and analyzing single biomolecules such as DNA, protein and virus. The dynamic behavior of such molecules in a microfluidic system can be investigated by the back-and-forth translocation control. Such motion control is made possible by fast changing of the polarity of the driving voltage, and the repeat measurement of a single molecule is expected to increase the signal-to-noise-ratio (SNR) significantly. However, due to the existence of membrane capacitance and electrolyte resistance, transient current spike arises as driving voltage changes. Such current spike saturates the data acquisition system and leads to difficulty in detecting fast returned molecules. Simulation shows that the electric field in electrolyte is proportional to the ionic current and increases dramatically during the transient charging period. This extra electric force pulls the molecule back to the pore faster than expected. Our study demonstrates that the transient current can be compensated by modifying the profile of the driving voltage. With such improvement, the observed distribution of recaptured translocation events matches perfectly with the prediction by drift-diffusion transport equation. This finding will help building precise control technique towards DNA sequencing in nanopore.

1:51PM G21.00014 Assessing the performance of trans rectal ultrasound to measure prostate weight and its association with other diagnostic factors, IRENE B. HELENOWSKI, BORKO D. JOVANOVIC, ROBIN G. LEIKIN, MICHAEL J. GURLEY, CHRISTOPHER K. MITCHELL, TIMOTHY M. KUZEL, Northwestern University — Trans rectal ultrasound is fast becoming an important tool used in the prognosis of prostate cancer. But how does it compare to other measures, such as the actual weight of the prostate obtained after radical prostatectomy? Here, we assess the association of prostate weight obtained via trans rectal ultrasound and actual specimen weight obtained after radical prostatectomy with body mass index (BMI) using linear regression models adjusted for Gleason score, pre-operative PSA, and age applied to subsets of Euro-Americans (n = 242) and African Americans (n = 34). The roles of both prostate weight and BMI are themselves part of ongoing research focused on prostate cancer prognosis. Our preliminary results show a marginal relationship between BMI and specimen weight obtained after surgery in Euro-Americans but no relationship between BMI and ultrasound measured weight in either race subset. Therefore, further work pertaining to the performance of trans rectal ultrasound may be warranted. This work is supported by the Northwestern University SPORE in Prostate Cancer (NIH/NCI P50 CA 90386).
2:03PM G21.00015 How to get into that “room at the bottom” of DNA analysis1, DANIEL BERARD, FRANCOIS MICHAUD, SARA MAHSHID, JALAL MOHAMMED AHAMED, McGill University, PIERRE BERUBE, ROBERT SLADEK, Genome Quebec Innovation Centre, WALTER REISNER, SABRINA LESLIE, McGill University — Linearly extending long DNA molecules in sub-50 nm nanochannels for genomic analysis, while retaining their structural integrity, is a major technological challenge. We employ “Convex Lens-induced Confinement” (CLIC) microscopy to gently load DNA into nanogrooves from above, overcoming the limitations of side-loading techniques used in direct-bonded nanofluiddic devices. In the CLIC technique, the curved surface of a convex lens is used to deform a flexible coverslip above a glass substrate, creating a nanoscale gap that can be tuned during an experiment to load and confine molecules into nanoscale features embedded in the bottom substrate. Since DNA molecules are loaded into the embedded nanotopography from above, CLIC eliminates the need for the high pressures or electric fields required to load DNA into direct-bonded nanofluiddic devices. To demonstrate the versatility of CLIC, we confine DNA to a variety of nanostructures, demonstrating DNA nanochannel-based stretching and denaturation mapping. In particular, we have successfully extended DNA in 27 nm channels, achieving high stretching (90 percent) that is in good agreement with Odijk deflection theory, and we have mapped genomic features using denaturation analysis.

11:15AM G22.00001 Entanglement entropy near Kondo-destruction quantum critical points1, KEVIN INGERSENT, University of Florida, JEDEDIAH PIXLEY, University of Maryland, CHRISTOPHER WAGNER, TATHAGATA CHOWDHURY, University of Califonia, MATTHEW MIECNIKOWSKI, University of Colorado Boulder — We study the impurity entanglement entropy S_e in quantum impurity models that feature a Kondo-destruction quantum critical point (QCP) arising from a pseudogap in the conduction-band density of states and/or from an additional coupling of the impurity to a bosonic bath. On the local-moment (Kondo-destroyed) side of the QCP, the entanglement entropy contains a critical component that can be related to the order parameter characterizing the phase transition. In Kondo models describing a spin-S impurity, S_e assumes its maximal value ln(2S + 1) at the QCP and throughout the Kondo phase, independent of particle-hole (a)symmetry and irrespective of whether the Kondo phase features exact, over-, or under-screening of the impurity spin. In Anderson models, by contrast, S_e takes a nonuniversal value at the QCP. At particle-hole symmetry, S_e rises monotonically on passage from the local-moment phase to the Kondo phase, while breaking this symmetry can lead to a cusp peak in S_e due to a divergent charge susceptibility at the QCP. Implications of these results for quantum-critical systems and quantum dots are discussed.

11:27AM G22.00002 Low temperature phases of the periodic Anderson model with electron-phonon correlation 1, ENZHI LI, Louisiana State University, PENG ZHANG, Carnegie Institution of Washington, SHUXIANG YANG, KA-MING TAM, JUANA MORENO, MARK JARRELL, Louisiana State University — We study the periodic Anderson model with the conduction electrons coupled to phonons. It has been shown by using the dynamical mean field theory that the model contains two disordered phases, the Kondo singlet phase for strong hybridization and the local moment phase for weak hybridization. In the hybridization-temperature plane, these two phases are separated by a first order phase transition line which terminates at a second order phase transition point. At low temperature the entropy in the Kondo singlet phase is quenched by the formation of a Fermi liquid, while the local moment phase will have residual entropy unless it is quenched by ordering. We calculate the lattice charge susceptibility to demonstrate that the conduction electrons form a charge density wave ordering below a critical temperature.

11:39AM G22.00003 Kondo-Heisenberg Lattice: Majorana fermions Mean field approach, SAYED ALI AKBAR GHORASHI, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX — We study Kondo lattice model including direct antiferromagnetic Heisenberg exchange interaction using Majorana fermions representation at half filling. An O(3)-symmetric Mean field Hamiltonian is derived on bipartite lattice. Different kind of possible spin-spin correlations functions between conduction band spins, c-electrons, and localized spin, f-electron in both on site and different sublattices are calculated in translationally invariant solution of the mean field Theory. Finite temperature behavior of Majoranas pairs correlations are investigated for some special limit of some of the mean filed parameters.

11:51AM G22.00004 Magnetic Excitons in Heavy Fermion Semimetals, PETER RISEBOROUGH, Physics Dept. Temple University — A magnetic excitation is a precursor magnetic exciton, similar to an antiparamagnon in a metal, which exists in strongly correlated semiconductors. The magnetic exciton has a spectrum which resembles the broadened dispersion relation of an antiparamagnon for excitation energies greater than the semi-conducting gap, but becomes sharp for energies less than the semi-conducting gap. The narrowness of the spectral feature is due to the absence of decay channels into the continuum of electron-hole pairs. Such excitations have been observed by inelastic neutron scattering experiments on the heavy-fermion semiconductors SmB6 and YbB12. However, magnetic excitons have not been observed in cerium based heavy-fermion semiconductors nor has their occurrence been linked to the vicinity of a quantum critical point. Here we investigate this problem using a phenomenological model for both the “nematic” (i.e. tetragonal symmetry-broken) and superconducting phases. Based on recent field-angle-dependent heat capacity and thermal conductivity data, as well as Kerr effect measurements, we consider a chiral d + id superconducting state that also breaks time-reversal symmetry. We find that in the presence of an orthorhombic/nematic order parameter, the system displays two sequential superconducting transitions: in the first, at Tc, the system enters a superconducting phase whereas in the second, at T^* < Tc, time-reversal symmetry is broken. Near the second transition, a “soft” but damped collective mode related to gap amplitude fluctuations emerges, which could be manifested in Raman scattering data. Between these two transitions, we find an unusual \omega log(\omega) dependence of the low-energy density of states, and show how it impacts the properties of several thermodynamic quantities in the T^* < T < Tc regime.

12:15PM G22.00006 Crossover from non-Fermi liquid to Fermi liquid behavior and the superconducting dome in heavy electron systems. PEDRO SCHLOTTMANN, Florida State University — A nested Fermi surface and the remaining interaction between the carriers after the heavy particles are formed give rise to itinerant antiferromagnetism. We consider an electron and a hole pocket, separated by a wave vector $Q$, and Fermi momenta $k_{F_1}$ and $k_{F_2}$, respectively. The order is gradually suppressed by increasing the mismatch of the two Fermi momenta and a QCP is obtained as $T_N \to 0$. For critical mismatch of the Fermi vectors (tuned QCP) the specific heat over $T$ increases as $-\ln(T)$ as $T$ is lowered. And the linewidth of the quasi-particles is linear in $T$ and $\omega$. With increasing nesting mismatch and decreasing temperature the specific heat and the linewidth display a crossover from non-Fermi liquid ($\sim T$) to Fermi liquid ($\sim T^2$) behavior. If in addition the vector $Q$ is commensurate with the lattice (Umklapp with $Q = G/2$), pairs of electrons can be transferred between the pockets. To avoid the QCP this process may lead to superconductivity and a superconducting dome above the quantum critical point. We investigate the conditions under which such a dome arises.

12:27PM G22.00007 Temperature-dependent behavior of mixed-valent SmS: a DFT+DMFT study. CHANG-JONG KANG, HONG CHUL CHOI, KYOO KIM, B. I. MIN, Pohang University of Science and Technology (POSTECH) — We have investigated temperature-dependent behaviors of electronic structure and resistivity in a mixed-valent golden phase of SmS (g-SmS), based on the dynamical mean-field theory band structure calculations. Upon cooling, the coherent Sm 4f bands are formed to produce the hybridization-induced pseudo-gap near the Fermi level, and accordingly the topology of Fermi surface is changed. Also we have discussed the topological nature in g-SmS. From the analysis of anomalous resistivity behavior in SmS, we have identified universal energy scales, which characterize the Kondo/mixed-valent semimetallic systems.

12:39PM G22.00008 The Ising-Anisotropic Kondo Lattice in a transverse field: EDMFT study and implications for the global phase diagram. EMILIAN MARIUS NICA, Department of Physics and Astronomy, Rice University, Houston, Texas 77005, KEVIN INGERSENT, Department of Physics, University of Florida, P.O. Box 118440, Gainesville, Florida 32611, QIMIAO SI, Department of Physics and Astronomy, Rice University, Houston, Texas 77005 — Heavy-fermion materials exhibit a rich variety of phase transitions. Of particular interest are quantum phase transitions and the associated breakdown of the Fermi liquid picture. A theoretical example of this is the Kondo destruction effect in the context of local quantum criticality [1]. To capture this effect and others, a zero-temperature global phase diagram for heavy-fermion systems is proposed [1]. It incorporates the competition between the Kondo effect (promoted by exchange coupling $J_K$) and the variable quantum fluctuations of the local-moment magnetism (parameterized by $G$). We investigate this competition in the Ising-anisotropic Kondo lattice with a transverse magnetic field, where the field serves to tune $G$. We determine a zero-temperature phase diagram of this model within the extended dynamical mean-field theory (EDMFT), and discuss the implications of our results for the global phase diagram of heavy-fermion systems.

12:51PM G22.00009 Super-Symplectic spin and heavy fermion systems. ALINE RAMIRES, PIERS COLE-MAN, Rutgers University — Heavy-fermion materials are systems in which the presence of local moments leads to new physics. The phase diagram of these systems is very rich, usually presenting an antiferromagnetic (AFM) phase, a heavy Fermi liquid regime (HFL), and non-Fermi-liquid behavior above the AFM quantum critical point (QCP). Our understanding of what happens to the local moments in different extremes of this phase diagram is based in two different representations for the spin: a Schwinger boson representation, appropriate for the description of AFM, and an Abrikosov fermion representation, suitable for the understanding of the HFL development. The theoretical approaches to this problem so far have been restricted to describe only extremes of this phase diagram, and are not reliable for the description of the more interesting region of the diagram, around the QCP. In this region the magnetic and Kondo energy scales interplay and can lead to dramatic changes in the character of the quantum phase transition. Here we use supersymmetric symplectic spins in order to investigate this intermediate regime.

1:03PM G22.00010 Enhanced Pairing Correlations near a Quantum Critical Point in Two Impurity Anderson Model with a Pseudogap. ANG CAI, Rice University, JEDEDIAH PIXLEY, University of Maryland, QIMIAO SI, Rice University — Significant progress has been made on the understanding of quantum critical heavy fermion metals. In addition to the spin density wave quantum critical point (QCP), a Kondo destruction QCP beyond the Landau framework has been discovered. However, its implications on the formation of unconventional superconductivity remain unclear. Motivated by a cluster-EDMFT approach [1], we address this question in simplified models for Kondo destruction QCP, as arising in the two impurity pseudogap Anderson model. We study the model using the continuous time quantum Monte-Carlo method, with either an Ising or Heisenberg inter-impurity RKKY interaction. For each case we have found a QCP distinct from both the Kondo destruction criticality of a single impurity pseudogap Anderson model and the quantum criticality of the conventional two impurity model. We observe critical local moment fluctuations with a power-law divergence in the staggered spin susceptibility, and show that the single-particle spectral function obeys power-law over temperature scaling. We find that the singlet pairing susceptibility is significantly enhanced near the QCP. Implications for unconventional superconductivity in quantum critical heavy fermion systems will be discussed. [1] J.H. Pixley, A. Cai, Q.-Si, arXiv:1409.1090

1:15PM G22.00011 Numerical study of the periodic Anderson model with a quarter-filled conduction band. SHUXIANG YANG, JUANA MORENO, MARK JARRELL, Louisiana State Univ - Baton Rouge — Using the dynamical cluster approximation with continuous-time quantum Monte Carlo as the cluster solver and the recently introduced dual-fermion method, we study the underlying physics of the periodic Anderson model where the conduction band is near quarter-filling while the f-band electron band is half filled. For these parameters, the RKKY coupling changes its nature from ferromagnetic to anti-ferromagnetic, yielding an interesting phase-diagram. Especially, we find the charge ordering of the conduction band is strongly enhanced, which could be due to the proximity to a quantum critical point.

1:27PM G22.00012 Unconventional Superconductivity in the Vicinity of the Local Quantum Critical Point. QIMIAO SI, Rice University, JEDEDIAH PIXLEY, Condensed Matter Theory Center, University of Maryland, LILIL DENG, KEVIN INGERSENT, University of Florida — Unconventional superconductivity and its relationship with quantum criticality remains a central question in strongly correlated electron systems. In the case of heavy fermion metals, the existence of antiferromagnetic quantum critical points (QCPs) is well established. Theoretical work has identified the existence of a local QCP where the Kondo effect is driven critical concomitant with the vanishing of the magnetic order parameter. Experiments on the heavy fermion compound CeRhIn$_5$ and other materials have provided strong evidence that such a QCP drives unconventional superconductivity. With this in mind we solve the periodic Anderson model using a cluster extended dynamical mean field theory. We show that the Kondo energy scale is continuously suppressed at the antiferromagnetic critical point, and we determine the scaling form of the order parameter susceptibility and find remarkable agreement with well-established experiments in the related heavy fermion system CeCu$_{2−x}$Au$_x$. Most importantly, we find that the singlet pairing susceptibility is strongly enhanced at the QCP, which points towards a new pairing mechanism associated with both magnetic and local critical fluctuations.
1:39PM G22.00013 Metamagnetism in CeCoIn$_5$ and the Single Energy Scale Model. A. THANIZHAVEL, N. SANGEETA, S. RAMAKRISHNAN, Tata Institute of Fundamental Research, B. WHITE, BRIAN MAPLE, University of California, San Diego, ULRICH WELP, Argonne National Labs, PRADEEP KUMAR, University of Florida, V. CELLI, BELLAVE SHIVARAM, University of Virginia — The anisotropic linear and nonlinear magnetic response of the non-ordering heavy electron compound CeCoIn$_5$ will be presented. Many heavy electron materials exhibit a peak in the linear susceptibility at a temperature $T_1$ which correlates with the metamagnetic critical field, $H_c$. There is also a peak in the nonlinear susceptibility $\chi_2$ at $T_2 = 0.5T_1$; in many materials and this feature has been explained recently with a single energy scale model. In CeCoIn$_5$, however, a plateau rather than a peak is observed in the linear susceptibility which evolves into a paramagnetic type divergence upon further cooling. This apparent violation of the “ideal” metamagnetic behavior is resolved here. The single energy scale model augmented with a paramagnetic contribution successfully accounts for the observed linear and nonlinear anisotropic magnetic response in CeCoIn$_5$.

1:51PM G22.00014 Quantum criticality driven by geometrical frustration. PHILIPP GEGENWART, Experimentalphysik VI, Augsburg University, Germany, Y. TOKIWA, Kyoto University, Japan, C. STINGL, Experimentalphysik VI, Augsburg University, Germany, T. TAKABATAKE, Hiroshima University, Japan — Geometrical frustration describes situations where interactions are incompatible with the lattice geometry and stabilizes exotic phases such as spin liquids which cannot be classified by conventional order parameter theory and display emergent excitations. Whether geometrical frustration of magnetic moments in metals can induce unconventional quantum critical points is an active area of research. We focus on the heavy-fermion metal CeRhSn with two-dimensional triangular configuration of the Kondo ion. Low-temperature thermodynamic experiments prove zero-field quantum criticality. A striking anisotropy of the linear thermal expansion, displaying critical and non-critical behavior along and perpendicular to the basal plane, respectively, is ascribed to the effect of strong geometrical frustration. We further find evidence of fluctuating local 4f moments, implying a novel quantum critical spin liquid state with fractionalized quasiparticles.

2:03PM G22.00015 Many-body instabilities and mass generation in slow Dirac materials. CHRISTOPHER TRIOLA, William & Mary Coll, JIANXIN ZHU, Center for Integrated Nano Technology, Los Alamos National Laboratory, ALBERT MIGLIORI, Seaborg Institute, Los Alamos National Laboratory, ALEXANDER BALATSKY, Institute for Materials Science, Los Alamos National Laboratory — Some Kondo insulators are expected to possess topologically protected surface states with linear Dirac spectrum, the topological Kondo insulators. Because the bulk states of these systems typically have heavy effective electron masses, the surface states may exhibit extraordinarily small Fermi velocities that could force the effective fine structure constant of the surface states into the strong coupling regime. Using a tight-binding model we study the many-body instabilities of these systems and identify regions of parameter space for which antiferromagnetic, ferromagnetic and charge density wave instabilities occur.

1Work Supported by USDOE BES E304.

11:15AM G23.00001 Challenges for large scale ab initio Quantum Monte Carlo. PAUL KENT, Oak Ridge National Lab — Ab initio Quantum Monte Carlo is an electronic structure method that is highly accurate, well suited to large scale computation, and potentially systematically improvable in accuracy. Due to increases in computer power, the method has been applied to systems where established electronic structure methods have difficulty reaching the accuracies desired to inform experiment without empiricism, a necessary step in the design of materials and a helpful step in the improvement of cheaper and less accurate methods. Recent applications include accurate phase diagrams of simple materials through to phenomena in transition metal oxides. Nevertheless there remain significant challenges to achieving a methodology that is robust and systematically improvable in practice, as well as capable of exploiting the latest generation of high-performance computers. In this talk I will describe the current state of the art, recent applications, and several significant challenges for continued improvement.

1Supported through the Predictive Theory and Modeling for Materials and Chemical Science program by the Office of Basic Energy Sciences (BES), Department of Energy (DOE).

11:51AM G23.00002 SILK QMC, sign-learning simulations of molecular systems. XIAOYAO MA, Department of Physics and Astronomy, Louisiana State University, FRANK LOFFLER, Center for Computation and Technology, Louisiana State University, KAROL KOWALSKI, Environmental Molecular Sciences Laboratory, Pacific Northwest National Laboratory, RANDALL HALL, Department of Natural Sciences and Mathematics, Dominican University of California, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University — The Sign Learning Kink (SILK) based Quantum Monte Carlo (QMC) is used to calculate the ground state energies for H$_2$O, N$_2$ and F$_2$ molecules. This method is based on Feynman’s path integral formalism and has two stages. The first, learning stage, reduces the minus sign problem by optimizing the Slater states which are used in the second, QMC stage. We test our method using different vector spaces and compare our results with other Quantum Chemical methods. We also perform exact diagonalization in those vector spaces as a benchmark. In each vector space and for each molecule, we perform SILK QMC for different bond lengths demonstrating that the SILK method is accurate for equilibrium and non-equilibrium geometries.

1Louisiana Alliance for Simulation-Guided Materials Applications (LA-SiGMA)

12:03PM G23.00003 Development and Use of Quantum Chemistry Methods on Intel Many-Integrated Core Units. EDOARDO APRA, Pacific Northwest National Laboratory — We will describe the approach we have taken in porting quantum chemistry algorithms based on local basis functions to the Intel MIC hardware. The implementation completed in the NWChem code shows the feasibility of effectively combining the processing power of traditional CPU architecture and coprocessor hardware on Petascale class computers. Benchmarks of scientific applications will be presented to illustrate the performances of large scale calculations.

3This work was conducted in the William R. Wiley Environmental Molecular Sciences Laboratory (EMSL), a national scientific user facility sponsored by DOE’s Office of Biological and Environmental Research and located at PNNL
12:15PM G23.00004 A scalable sparse eigensolver for petascale applications, MURAT KECELİ, Chemical Sciences and Engineering Division, Argonne National Laboratory, Lemont, Illinois 60439, HONG ZHANG, PETER ZAPOL, Mathematics and Computational Science Division, Argonne National Laboratory, Lemont, Illinois 60439, DAVID DIXON, Department of Chemistry, The University of Alabama, Tuscaloosa, Alabama 35487, ALBERT WAGNER, Chemical Sciences and Engineering Division, Argonne National Laboratory, Lemont, Illinois 60439 — Exploiting locality of chemical interactions and therefore sparsity is necessary to push the limits of quantum simulations beyond petascale. However, sparse numerical algorithms are known to have poor strong scaling. Here, we show that shift-and-invert parallel spectral transformations (SIPs) method can scale up to two-hundred thousand cores for density functional based tight-binding (DFTB), or semi-empirical molecular orbital (SEMO) applications. We demonstrated the robustness and scalability of the SIPs method on various kinds of systems including metallic carbon nanotubes, diamond crystals and water clusters. We analyzed how sparsity patterns and eigenvalue spectrum of these different type of applications affect the computational performance of the SIPs. The SIPs method enable us to perform simulations with more than five hundred thousands of basis functions utilizing more than hundreds of thousands of cores. SIPs has a better scaling for memory and computational time in contrast to dense eigensolvers, and it does not require fast interconnects.

12:27PM G23.00005 Simulation of high-Tc superconductors using the DCA+ algorithm, PETER STAAR, IBM Research Zurich — For over three decades, the high Tc-cuprates have been a gigantic challenge for condensed matter theory. Even the simplest representation of these materials, i.e. the single band Hubbard model, is hard to solve quantitatively and its phase-diagram is therefore elusive. In this talk, we present the recent algorithmic and implementation advances [1,2] to the Dynamical Cluster Approximation (DCA+). The algorithmic advances allow us to determine self-consistently a continuous self-energy in momentum space, which in turn reduces the cluster-shape dependency of the superconducting transition temperature and thus accelerates the convergence of the latter versus cluster-size. Furthermore, the introduction of the smooth self-energy suppresses artificial correlations and thus reduces the fermionic sign-problem, allowing us to simulate larger clusters at much lower temperatures. By combining these algorithmic improvements with a very efficient GPU accelerated QMC-solver [3], we are now able to determine the superconducting transition temperature accurately and show that the Cooper-pairs have indeed a d-wave structure, as was predicted by Zhang and Rice.

1:03PM G23.00006 A New Class of $J_{eff}=1/2$ Mott Insulators, TURAN BIROL, KRISTJAN HAULE, Rutgers, The State University of New Jersey — We predict a novel class of Jeff=1/2 Mott insulators in a family of Ir and Rh fluoride compounds with the K$_2$GeF$_6$ crystal structure that are previously synthesized, but not characterized extensively. First principles calculations in the level of all electron Density Functional Theory + Dynamical Mean Field Theory (DFT+DMFT) indicate that these compounds have large Mott gaps and some of them exhibit unprecedented proximity to the ideal, SU(2) symmetric Jeff=1/2 limit.

1:15PM G23.00007 Petascale electronic structure code with a new parallel eigensolver, EMIL BRIGGS, WENCHANG LU, MIROSŁAW HODAK, YAN LI, CT KELLEY, JERZY BERNHOLC, NCSU — We describe recent developments within the Real Space Multigrid (RMG) electronic structure code. RMG uses tetrahedron basis sets, and subspace diagonalization to solve the Kohn-Sham equations. It is designed for use on massively parallel computers and has shown excellent scalability and performance, reaching 6.5 PFLOPS on 18k Cray compute nodes with 28k CPU cores and 18k GPUs. For large problems, the diagonalization becomes computationally dominant and a novel, highly parallel eigensolver was developed that makes efficient use of a large number of nodes. Test results for a range of problem sizes are presented, which execute up to 3.5 times faster than standard eigensolvers such as Scalapack. RMG is now an open source code, running on Linux, Windows and Macintosh systems. It may be downloaded at:

1:27PM G23.00008 Full potential KKR approach to the calculation of Hellmann-Feynman force and total energy1, YANG WANG, Pittsburgh Supercomputing Center, Carnegie Mellon University, G.M. STOCKS, Oak Ridge National Laboratory — The Korringa-Kohn-Rostoker (KKR) method is an ab initio electronic structure calculation method based on multiple scattering theory. Unlike the traditional approach, the full-potential KKR method, as well as its linear scaling approach, namely the full-potential LSMS method, does not make a spherical geometry assumption for the LDA potential and the charge density, i.e., the muffin-tin approximation. Consequently, these full-potential methods allow to calculate the Hellmann-Feynman force acting on each ion in the unit cell. In this presentation, we show an implementation of the full-potential KKR and LSMS methods, discuss the force and total energy calculation in the framework of multiple scattering theory, and finally discuss our approach to overcoming the major computational bottleneck in a full-potential calculation by employing GPGPU acceleration technique.

1:39PM G23.00009 Linear-scaling density-functional theory with wavelets: challenges and opportunities for petascale and beyond, LAURA RATCLIFF, Leadership Computing Facility, Argonne National Laboratory, LUIGI GENOVESE, STEPHAN MOHR, THIERRY DEUTSCH, CEA, INAC-SP2M, LSim, Grenoble, France — Density-functional theory (DFT) has been used to study a wide range of materials in simulations with a moderate level of parallelism. A common approach divides the electronic orbitals between MPI tasks, however this limits the number of tasks that can be used for a given system. The most straightforward path to exploiting petascale machines is therefore to increase the size of the system being studied. However, standard implementations of DFT scale cubically with the number of atoms so that the time rapidly increases for large systems. Algorithms must therefore be designed with reduced scaling, such as the linear-scaling approach in BigDFT, which uses an adaptive localized basis set that is itself represented in an underlying wavelet basis set. It thus retains all the benefits of wavelets, such as systematic convergence, while also presenting some new advantages, e.g. the definition of a fragment approach. Nonetheless, as we move towards the exascale, there remain a number of challenges associated both with increasing parallelism and the treatment of large systems. We will outline the algorithms and parallelization used in BigDFT and present some recent results which have been facilitated by this approach, as well as discussing some of the future challenges.

1:51PM G23.00010 Functional derivatives for multi-scale modeling, SAMUEL REEVE, ALEJANDRO STRACHAN, Purdue Univ — As we look beyond petascale computing and towards the exascale, effectively utilizing computational resources by using multi-fidelity and multi-scale materials simulations becomes increasingly important. Determining when and where to run high-fidelity simulations in order to have the most effect on a given quantity of interest (QoI) is a difficult problem. This work utilizes functional uncertainty quantification (UQ) for this task. While most UQ focuses on uncertainty in output from uncertainty in input parameters, we focus on uncertainty from the function itself (e.g. from using a specific functional form for an interatomic potential or constitutive law). In the case of a multi-scale simulation with a given constitutive law, calculating the functional derivative of the QoI with respect to that constitutive law can determine where a fine-scale model evaluation will maximize the increase in accuracy of the predicted QoI. Additionally, for a given computational budget the optimal set of coarse and fine-scale simulations can be determined. Numerical calculation of the functional derivative has been developed and methods of including this work within existing multi-fidelity and multi-scale orchestrators are explored.
2:03PM G23.00011 DMRG study of Many-Body Localization . XIONGJIE YU, BRYAN CLARK, University of Illinois, Urbana-Champaign, DAVID PEKKER, University of Pittsburgh — Numerical studies on many-body localization (MBL) problems have heavily relied on exact diagonalization (ED) techniques so far which has severely limited the system size that can be studied. Here we report a density matrix renormalization group (DMRG) based method for simulations in the many-body localized phase allowing us to reach size systems inaccessible to ED. We describe our techniques and report on our results applying DMRG to larger systems.

Tuesday, March 3, 2015 11:15AM - 2:15PM — Session G24 DCOMP: Electronic Structure Methods II 203AB - James Chelikowski, University of Texas at Austin

11:15AM G24.00001 Improved forces and nonlocal operators using high-order integration1 . GRADY SCHOFIELD, N. SCOTT BOBBITT, CHARLES LENA, JAMES R. CHELIKOWSKY, University of Texas at Austin — We present a new high-order modification to the finite-difference based real space pseudopotential density functional theory method. By giving a high-order treatment to the nonlocal pseudopotential terms in the Hamiltonian, as well as all quantities of interest obtained by post-processing the wavefunctions, we improve the accuracy of total energy, interatomic forces, vibrational modes, and anharmonic effects. We demonstrate the power of this new technique by computing vibrational modes for a few common molecules containing atoms that are more difficult for high-accuracy force calculations, such as oxygen and nitrogen, due to the depth of the pseudopotential. The reduction in numerical noise as atoms move over the grid allows using a larger grid spacing than would be required with a conventional finite difference based discretization. Savings in both memory and computational time, due to a smaller spectral radius, will be discussed.

11:27AM G24.00002 Electronic correlation contributions to structural energies1 . ROGER HAYDOCK, University of Oregon — The recursion method is used to calculate electronic excitation spectra including electron-electron interactions within the Hubbard model. The effects of correlation on structural energies are then obtained from these spectra and applied to stacking faults. http://arxiv.org/abs/1405.2288

1Supported by the Richmond F. Snyder Fund and Gifts

11:39AM G24.00003 Optimization algorithm for the generation of ONCV pseudopotentials1 . MARTIN SCHLIPF, FRANCOIS GYGI, Univ of California - Davis — We present an optimization algorithm to construct pseudopotentials and use it to generate a set of Optimized Norm-Conserving Vanderbilt (ONCV) pseudopotentials[1] for elements up to Z=83 (Bi) (excluding Lanthanides). We introduce a quality function that assesses the agreement of a pseudopotential calculation with all-electron FLAPW results, and the necessary plane-wave energy cutoff. This quality function allows us to use a Nelder-Mead optimization algorithm on a training set of materials to optimize the input parameters of the pseudopotential construction for most of the periodic table. We control the resulting pseudopotentials on a test set of materials independent of the training set. We find that the automatically constructed pseudopotentials provide a good agreement with the all-electron results obtained using the FLEUR code [2] with a plane-wave energy cutoff of approximately 60 Ry.

11:51AM G24.00004 MBTS Boundary Conditions in Continuous Systems . G. A. BENESH, Department of Physics, Baylor University, ROGER HAYDOCK, Department of Physics, University of Oregon — Boundary conditions imposed on a local system that is joined to a larger substrate system often introduce unphysical reflections that affect eigenstate energies, densities of states, and charge densities. These problems are common in both atomic cluster and surface slab calculations. Solutions of the Schrodinger equation for the physical system do not possess such reflections; these wave functions carry current smoothly across the (artificial) boundary between the local system and the underlying medium. Previously, Haydock and Nex derived a non-reflecting boundary condition for discrete systems [Phys. Rev. B 75, 205121 (2006)]. Solutions satisfying this maximal breaking of time-reversal symmetry (MBTS) boundary condition carry current away from the boundary at a maximal rate—in much the same way as the exact wave functions for the physical system. The MBTS boundary condition has proved useful in discrete systems for constructing densities of states and other distributions from moments or continued fractions. The MBTS approach has now been extended to studies employing continuous spatial wave functions, including surface slab calculations and model systems. Results are compared with free slab calculations, embedding calculations, and experiment.

12:03PM G24.00005 Quantal Density Functional Theory (QDFT): Further understandings . VIRAJT SAHNI, The Graduate Center, CUNY, XIAO-YIN PAN, TAO YANG, Ningbo University — We consider electrons in the following external fields: (a) \( A (\mathbf{r}, t) = - \nabla v(\mathbf{r}) \), (b) \( B (\mathbf{r}) = \nabla \times A (\mathbf{r}) \), and (c) \( E (\mathbf{r}) = - \nabla v(\mathbf{r}) \). The basic variables for these systems are for (a) the density \( \rho (\mathbf{r}, t) \) and physical current density \( j(\mathbf{r}, t) \), (b) the \( \mathbf{r} \) and (paramagnetic) \( j(\mathbf{r}, t) \), (c) \( \rho (\mathbf{r}) \) and \( j(\mathbf{r}) \), and (d) \( \rho (\mathbf{r}) \). In QDFT, the local potential of the model fermions is the work done in a conservative effective field. In each of the above cases the effective field is representative of the same correlations, viz. due to the Pauli exclusion principle, Coulomb repulsion and Correlation-Kinetic effects.

12:15PM G24.00006 Sum frequency generation spectroscopy from first principles1 . QUAN WAN, GIULIA GALLI, Univ of Chicago — Sum frequency generation (SFG) spectroscopy is widely used to study the structural and dynamical properties of surfaces and interfaces. Within the dipole approximation, SFG signals are solely determined by the surface, and bulk contributions vanish. However, the bulk portion of a material may contribute to SFG spectra through higher multipole excitations, e.g. quadrupole, which usually are difficult to separate in the measured spectra. Here we present a first principles theoretical framework, to compute SFG spectra of molecular solids and fluids. Within the dipole approximation, we computed the dipole and polarizability using maximally localized Wannier functions (MLWF) and density functional perturbation theory [1]. We then extended our method to include quadrupole contributions, and we computed quadrupole moments and their derivatives using MLWF and a real-space correction scheme [2], and an electric enthalpy functional. We applied our approach to investigate the ice Ih surface and we present results obtained by both finite differences and ab initio molecular dynamics [3] simulations. [1] Wan et al. J. Chem. Theory Comput. 9, 4124 (2013) [2] Stengal et al. Phys. Rev. B 73, 075121 (2006) [3] Qbox Code http://eslab.ucdavis.edu/software/qbox

A first principles method for simulating phonons in strongly disordered materials. TOM BERLLIN, OLIVIER DELAIRE, BEN LARSON, Oak Ridge National Laboratory — At the microscopic level the flow of vibrational heat is encoded not only in the energies of phonons but also in their lifetimes. In many functional materials these phonon lifetimes are controlled by strong disorder. Such systems are difficult to understand from conventional perturbation theories or mean field treatments. Here we will present an affordable and accurate first principles method for simulating phonons in strongly disordered materials. The method will be illustrated with applications ranging from thermoelectrics to nuclear fuels. TB was supported as a Wigner Fellow at the Oak Ridge National Laboratory, OD was supported by the US DOE-BES, Materials Science and Engineering Division, and BL was supported by the CMSNF Energy Frontier Research Center.

Real-Space Multiple-Scattering X-ray Absorption Spectroscopy Calculations of $d$- and $f$-state Materials using a Hubbard Model. CHRISTIAN VORWERK, KEVIN JORISSEN, JOHN REHR, Department of Physics, University of Washington, Seattle, Washington 98195 USA, AHMED TOWFIQ, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545 USA — We present calculations of the electronic structure and x-ray spectra of materials with correlated $d$- and $f$-electron states treated with the Hubbard model in a real-space multiple scattering (RSMS) formalism, and using a rotationally invariant local density approximation (LDA+$U$). Values of the Hubbard parameter $U$ are calculated ab initio using the constrained random-phase approximation (cRPA). The real-space Green’s function approach with Hubbard model corrections is an efficient way to describe localized electron states in strongly correlated systems, and their effect on core-level x-ray spectra. The method is shown to give the correct density states of $s$ and $x$-ray absorption spectra for Transition Metal- and Lanthanide-oxides such as Ce2O3 and NIO, where the traditional RSMS calculations fail.

Partial Rayleigh-Ritz procedure for quasi-minimal basis sets. VINCENT MICHAUD-RIOLUX, HONG GUO, McGill University — Recent Kohn-Sham DFT solver implementations [1-3] concentrate on building a subspace spanned by the occupied Kohn-Sham orbitals via Chebyshev filtering [1]. The Rayleigh-Ritz procedure is generally performed to populate the Kohn-Sham orbitals correctly and constitutes a bottleneck in large electronic structure simulations. We found that the full diagonalization of the projected Hamiltonian can be avoided; only the partly occupied subspace is the eigenvalue problem. The occupied subspace can be obtained from the orthogonal complement of the former. For quasi-minimal basis sets, the size of the eigenvalue problem can be reduced significantly at the cost of constructing an orthogonal supplement. The method can also be used with nonminimal basis sets such as atomic orbitals by preforming a second projection of the Kohn-Sham Hamiltonian. The partial Rayleigh-Ritz procedure was implemented in our real space electronic structure calculator, which we used to conduct a performance comparison of the state-of-the-art Rayleigh-Ritz procedure against the partial Rayleigh-Ritz procedure. [1] Zhou, et al., Phys. Rev. E 74, 066704 (2006). [2] Motamarri, et al., Journal of Computational Physics 253, 308 (2013). Spectral function from Reduced Density Matrix Functional Theory. PINA ROMANIELLO, STEFANO DI SABATINO, LPT, CNRS, IRSAMC, University Toulouse III - Paul Sabatier, France and European Theoretical Spectroscopy Facility, JAN A. BERGER, LCPQ, IRSAMC, University Toulouse III - Paul Sabatier. CNRS, France and European Theoretical Spectroscopy Facility, LUCIA REINING, LSI, Ecole Polytechnique, CNRS, CEA-DSM, France and European Theoretical Spectroscopy Facility — In this work we focus on the calculation of the spectral function, which determines, for example, photoemission spectra, from reduced density matrix functional theory. Starting from its definition in terms of the one-body Green’s function we derive an expression for the spectral function that depends on the occupied electronic state of the actual occupation numbers and on an effective energy [1] which accounts for all the charged excitations. This effective energy depends on both the two-body as well as higher-order density matrices. Various approximations to this expression are explored by using the exactly solvable Hubbard chains [2].

Kohn-Sham Band Structure Benchmark Including Spin-Orbit Coupling for 2D and 3D Solids. WILLIAM HUHN, Department of Mechanical Engineering and Materials Science, Duke University, Durham, NC, USA, VOLKER BLOM, Department of Mechanical Engineering and Material Science, Duke University, Durham, NC, USA — Accurate electronic band structures serve as a primary indicator of the suitability of a material for a given application, e.g., as electronic or catalytic materials. Computed band structures, however, are subject to a host of approximations, some of which are more obvious (e.g., the treatment of the exchange-correlation of self-energy) and others less obvious (e.g., the treatment of core, valence electrons, or valence electrons, handling of relativistic effects, or the accuracy of the underlying basis set used). We here provide a set of accurate Kohn-Sham band structure benchmarks, using the numeric atom-centered all-electron electronic structure code FHI-aims combined with the "traditional" PBE functional and the hybrid HSE functional, to calculate core, valence, and low-lying conduction bands of a set of 2D and 3D materials. Benchmarks are provided with and without effects of spin-orbit coupling, using quasi-degenerate perturbation theory to predict spin-orbit splittings.

Self diffusion of water molecules simulated by model inter-atomic potentials determined by a combination of first-principles calculation and multi-canonical ensembles: exchange-correlation functional dependence. YOSHIHIKIDE YOSHIMOTO, Dept. of Computer Science, Graduate School of Information Science and Technology, The University of Tokyo — Water is an ubiquitous substance and is both scientifically and technologically important. In this study, the self diffusion of water molecules are simulated using Kumagai-Kawamura-Yokokawa type inter-atomic potentials [1] whose parameters are determined by a combination of first-principles calculation and multi-canonical ensembles [2,3]. Because of the property of multi-canonical ensemble, the determined potentials keep the thermodynamics of the reference first-principles simulations to a maximum extent. The author used PBE, PBE0, B3LYP, and B3LYP with DFT-D3 exchange-correlation potentials for the reference first-principles calculations to determine the model parameters. The obtained diffusion coefficients significantly depend on the choice of the exchange correlation functionals and the combination of B3LYP and DFT-D3 [4] produced the best agreement with the experimental one.

Quantum pressure in molecules and solids: Influence of magnetic fields and spin-orbit coupling on electron localization

This work was supported by NSF, USAF, and DOE.

First-principles study of two-dimensional electrile: Yttrium carbide. CHANDANI NANDADASA, SUNGHO KIM, SEONG-GON KIM, Mississippi State University, Starkville, MS 39762, USA, YOUNG LEE, SUNG KIM, Center for Integrated Nanostructure Physics (CINAP), Institute for Basic Science (IBS), Department of Energy Science, Sungkyunkwan University, Korea — Electrides are an exclusive class of ionic compounds in which electrons serve as anions. We have performed first-principles density functional theory (DFT) calculations to investigate the structural, electronic and magnetic properties of two-dimensional layered-structure yttrium carbide (Y2C). Generalized gradient approximation (GGA) with Projector Augmented Potentials (PAW) was used to obtain optimized lattice parameters, energy band structure, charge density and density of states (DOS) plots for Y2C. The theoretically predicted structure of Y2C is in good agreement with the experimental results. The band crossing the Fermi energy level proved that Y2C has metallic properties. Additionally projected electronic density of states profiles were obtained to identify the electronic contribution from Y, C and non-atomic orbital located in interstitial site. The results of these calculations indicate that the presence of trapped electrons within the Y2C layers. Furthermore, surface energies of Y-Y and Y-C were calculated and charge densities were plotted with these surfaces. Magnetization density plots were used to obtain magnetic properties.

Topological Pair-Density-Wave Superconducting States

This work was supported in part by the NSF grants DMR-1064319 and DMR-1408713 at UIUC, PHY11-25915 at KITP and DOE Award No. DE-FG02-07ER46453

Accessing topological superconductivity via a combined STM and renormalization group analysis

The search for topological superconductors (SC) has recently become a key issue in condensed matter physics, because of their possible relevance to Majorana states, non-Abelian statistics and fault-tolerant quantum computing. A new scheme is proposed here, which links as directly as possible the experimental search to a material-based microscopic theory. To this, the scanning tunneling microscopy (STM), which typically uses a phenomenological Ansatz for the SC gap functions is elevated to a theory, where a multi-orbital functional RG (IRG) analysis allows for an unbiased microscopic determination of the material-dependent pairing potentials. The conductance spectra are predicted for a normal metal-insulator-topological superconductor (N-I-S) junction, which imitates the STM setup and, therefore, is directly accessible to spectroscopic experiments. The strength of the combined approach is demonstrated for hexagonal systems, i.e. doped graphene and water-intercalated sodium cobaltates, where the lattice symmetry and electronic correlations can lead to a time-reversal symmetry breaking (chiral) topological SC state.

Low-Temperature Thermal Transport at the Interface of a Topological Insulator and a d-Wave Superconductor

We consider the low-temperature thermal transport properties of the 2D proximity-induced superconducting state formed at the interface between a topological insulator (TI) and a d-wave superconductor (dSC). This system is a playground for studying massless Dirac fermions, as they enter both as quasiparticles of the dSC and as surface states of the TI. For TI surface states with a single Dirac point, the four nodes in the interface-state quasiparticle excitation spectrum coalesce into a single node in the presence of an Ising spin symmetry. This topological PDW order parameter here is a Majorana zero mode (MZM) at an open boundary and at a junction with a uniform one-dimensional state emergent in extended Heisenberg-Hubbard models in two-leg ladders is topological in the presence of an Ising spin symmetry. This topological PDW order parameter is a charge-one can obtain a single Majorana fermion regardless of the sweep velocity.
12:03PM G25.00005 Interface effects and electronic transport in superconducting heterostructures with spin-orbit coupling\textsuperscript{1}, NAYANA SHAH, University of Cincinnati, KUEI SUN, The University of Texas at Dallas. Study on electronic transport in superconducting heterostructures with spin-orbit coupling (SOC) has become an active field for exploring spintronic properties or topological states of matter. For example, recently observed zero-bias conductance peaks in one-dimensional superconductor-semiconductor heterostructures in the presence of SOC and magnetic field are of interest for realizing Majorana fermions. However, most study considers SOC only in bulk materials, while the interface effects, which can significantly alter the physics in spin-active systems, have not been fully analyzed for systems with SOC. Here we construct a general model to describe interfaces in a superconductor-normal metal junction with bulk SOC. We also systematically investigate the trend of conductance as the system parameters vary. Our results are of interest for understanding a variety of transport behaviors in the presence of SOC and are of relevance also for characterizing interfaces in experimental systems.

12:15PM G25.00006 Point defects and Majorana doublets in 3D time-reversal invariant topological superconductors and superfluids, MENGXING YE, University of Michigan, ZHENG-CHENG GU, Perimeter Institute for Theoretical Physics, KAI SUN, University of Michigan — In this talk, we study topological point defects in 3D time-reversal invariant topological superconductors and superfluids, focusing on the Majorana zero modes hosted at these defects. We will address the exotic properties of these Majorana modes especially the nontrivial exchange group and its connection to fermion parity. In contrast to 2D chiral topological superconductors, in which the braiding of Majorana zero modes has been studied extensively and well understood, the time-reversal invariant topological superconductors allow richer structures at topological defects and thus result in more sophisticated response as we exchange these defects.

12:27PM G25.00007 Nonmagnetic impurity effects in a superconducting topological insulator, YUKI NAGAI, YUKIHIRO OTA, MASAHIKO MACHIDA, CSSE, Japan Atomic Energy Agency — Unconventional features in superconductivity are revealed by responses to impurity scattering. We study nonmagnetic impurity effects in a superconducting topological insulator, focusing on an effective model of Cu-doped topological insulator Bi\textsubscript{2}Se\textsubscript{3}. Typically, this superconducting compound is considered to be dirty owing to the copper intercalated process. Using a self-consistent T-matrix approach for impurity scattering, we examine in-gap states in density of states. It is well known that the unconventional superconductors such as p-wave diminish via non-magnetic impurity scattering, different from the robustness of an s-wave state (Anderson’s theorem). We show that the impurity effects are well characterized by a simple material variable, which measures relativistic effects in the Dirac Hamiltonian. We find that the topological superconductor has two aspects, p- and s-wave features, depending on the weight of relativistic effects. The topological superconductors can not be simply regarded as one of the conventional unconventional superconductors.

12:39PM G25.00008 Sensitivity of a 3D fully-gapped topological superconductor to nonmagnetic impurities, YUKIHIRO OTA, YUKI NAGAI, MASAHIKO MACHIDA, Japan Atomic Energy Agency — Topological superconductors (TSC) are notable materials, owing to the mathematical curiosity and the application potential. The bulk TSC can emerge by copper intercalation into topological insulator Bi\textsubscript{2}Se\textsubscript{3}. In this paper, we theoretically study the non-magnetic impurity effects in the mean-field model of Cu\textsubscript{x}Bi\textsubscript{2}Se\textsubscript{3}, focusing on the odd-parity fully-gapped superconducting state. Calculating the density of states with a self-consistent T-matrix approach, we test the presence of mid-gap states, leading to pair-breaking effects. Remarkably, the sensitivity to non-magnetic impurities strongly depend on a normal-state dispersion character, i.e., either non-relativistic or relativistic dispersion relations. We show unification picture for understanding this intriguing result, deriving a low-energy effective superconducting theory.

12:51PM G25.00009 Crossed surface flat bands in superconducting Weyl semimetals, KEIJI YADA, BO LU, MASATOSHI SATO, YUKIO TANAKA, Nagoya University — Weyl semimetal is a new phase of matter where topological magnetic monopoles emerge in momentum space at so-called Weyl points.[1] Owing to the presence of the Weyl points, zero energy flat band called Fermi arc appears as a surface bound state between the Weyl points projected to the surface Brillouin Zone.[2] In this talk, we will show that the superconducting state with point nodes in doped Weyl semimetal may have more exotic surface bound states, i.e. “crossed flat bands”. [3] With the help of the crossed flat bands, the divergent behavior of the normalized conductance at zero bias voltage appears. This divergent behavior has never been seen in other superconducting system with point nodes. We found three conditions for the realization of the crossed flat bands mentioned below. i) a uniform pairing such as BCS s-wave pairing, ii) broken time reversal symmetry iii) magnetic mirror reflection symmetry. [1] S. Murakami, New J. Phys. 9, 356 (2007) [2] G. Xu et al., Phys. Rev. Lett. 107, 186806 (2011) [3] B. Lu, K. Yada, M. Sato and Y. Tanaka, arXiv:1406.3804

1:03PM G25.00010 Generating Giant Spin Currents by Majorana Flat Bands in Nodal Topological Superconductors, NOAH FANQI YUAN, YAO LU, JAMES JUN HE, KAM TUEN LAW, The Hong Kong University of Science and Technology — When a normal lead is coupled to a single Majorana fermion, electrons with certain spin polarization can undergo equal spin Andreev reflections, in which the reflected holes have the same spin as the incoming electrons. Moreover, electrons with opposite spin are all normally reflected. This process is called Majorana fermion induced selective equal spin Andreev reflections (SESARs) [1]. As a result of SESARs, spin polarized currents can be generated at the normal lead. Nevertheless, in this case, the maximum conductance of the normal lead/superconductor junction is 2e\textsuperscript{2}/h [2]. In this work, we show that Majorana fermions associated with Majorana flat bands in nodal topological superconductors can also induce SESARs. Importantly, due to the large number of Majorana fermions, the conductance at the normal lead/nodal topological superconductor junction is enormous. As a result, giant spin currents can be generated in the normal lead. Particularly, we point out that U$\uparrow$\textsubscript{3} can be the candidate to induce giant spin currents.

1:15PM G25.00011 Detecting Majorana Fermions in Ferromagnetic Atomic Chains in Proximity to Spin-orbit Coupled s-wave Superconductor, TONG ZHOU, NOAH FANQI YUAN, JAMES JUN HE, YAO LU, VIC KAM TUEN LAW, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China, PATRICK LEE, Department of Physics, Massachusetts Institute of Technology, Cambridge MA 02139, USA — Recently, it was proposed that Majorana bound states could be observed experimentally in ferromagnetic atomic chains on the surface of two-dimensional superconducting lead (Pb). Using the scanning tunneling microscope (STM), the experimental group obtained the spatially resolved density of states and observed zero bias peaks at the end of the chains. In this work, we study the topological phases of the proposed system. With realistic parameters, we study the transport properties at different positions along the chains. At zero temperature, resonant zero bias peaks emerge at the ends of the chains in the topological regimes, thus confirming the existence of Majorana bound states in the system. However, our transport calculation shows that at finite temperature, conductance peaks at zero bias also arise in the trivial regime due to the presence of low-energy fermionic end states in the system. Therefore, this would suggest that the experimentally observed zero bias peaks can have alternative theoretical explanations.
1:27PM G25.00012 Tunneling spectroscopy and Majorana modes emergent from topological gapless phases in high-$T_c$ cuprate superconductors\(^1\) CHUNG-YU MOU, JUN-TING KAO, Department of Physics, National Tsing Hua University, Taiwan, SHIN-MING HUANG, Graphene Research Centre and Department of Physics, National University of Singapore, Singapore, CHANG C. TSUEI, IBM Thomas J. Watson Research Center, Yorktown Heights, NY 10598, U.S.A. — We explore possible signatures for observing Majorana Fermions in the tunneling spectroscopy of high-$T_c$ cuprate superconductors. We find that as long as the Rashba spin orbit interaction is in presence either through the proximity effect due to an electrode made by heavy metal or by the intrinsic nature of cuprates, in addition to the Heisenberg spin exchange interaction, the Dzyaloshinskii-Moriya and spin dipole-dipole interactions are induced. As a result, $p$-wave superconductivity is induced with the gap function $\Delta$-vector being not aligned with the internal magnetic field of the spin-orbit interaction. Most importantly, the ground state goes through transitions into gapless phases with split nodal points. The split nodal structure always results in Majorana modes for any interfaces that are not exactly in (100) or (010) directions. Hence for general interfaces, existence of Majorana bound states is a robust feature. Our results indicate that these Majorana modes would result in a small plateau in tunneling spectrum near zero bias peak and in $4\pi$ periodicity in typical SIS$^2$ junctions. As a result, it is easy for a $\pi$-ring in tricrystal experiments to hold Majorana Fermions and exhibit periods of two flux quanta in external magnetic fields.

\(^1\)We acknowledge support from Ministry of Science and Technology of Taiwan.

1:39PM G25.00013 Time-Reversal-Invariant Topological Superconductivity in n-type Doped BiH, FAN YANG, CHENG-CHENG LIU, Beijing Institute of Technology, YU-ZHONG ZHANG, Tongji University, YUGUI YAO, Beijing Institute of Technology, DUNG-HAI LEE, University of California, Berkeley — Intrinsic and symmetry protected topological states have attracted lots of interest in condensed matter physics recently. In particular, time reversal symmetry protected fermion topological insulators have been theoretically predicted and experimentally verified. However despite considerable experimental and theoretical works, definitive evidence for time reversal invariant topological superconductivity is still lacking. Here we propose that upon electron doping the hydrogenated single bilayer Bi, namely BiH, will exhibit time reversal invariant topological superconductivity. If confirmed experimentally this material will constitute the first example of TIR topological superconductor.

1:51PM G25.00014 Vanishing edge currents and orbital angular momentum in non-$p$-wave topological chiral superconductors\(^1\) WEN HUANG, EDWARD TAYLOR, McMaster University, CATHERINE KALLIN, McMaster University, and Canadian Institute for Advanced Studies — The edge currents of two dimensional topological chiral superconductors with nonzero Cooper pair angular momentum--e.g., chiral $p$-, $d$-, and $f$-wave superconductivity--are studied. Bogoliubov-de Gennes and Ginzburg-Landau calculations are used to show that in the continuum limit, only chiral $p$-wave states have a nonzero edge current and orbital angular momentum. Outside this limit, when lattice effects become important, edge currents in non-$p$-wave superconductors are comparatively smaller, but can be nonzero. Using Ginzburg-Landau theory, a simple criterion is derived for when edge currents vanish for non-$p$-wave chiral superconductors on a lattice. The implications of our results for putative chiral superconductors such as Sr$_2$RuO$_4$ and UPt$_3$ are discussed.

\(^1\)Work supported by NSERC, CIFAR, Canada Council Killam programs (CK) and the National Science Foundation (CK)

2:03PM G25.00015 Non-topological nature of the edge current in a chiral $p$-wave superconductor\(^1\), EDWARD TAYLOR, University of Toronto, WEN HUANG, McMaster University, SAMUEL LEDERER, Stanford University, CATHERINE KALLIN, McMaster University — The edges of time reversal symmetry breaking topological superconductors support chiral Majorana bound states as well as spontaneous charge currents. The Majorana modes are a robust, topological property, but the charge currents are non-topological—and therefore sensitive to microscopic details—even if we neglect Meissner screening. We give insight into the non-topological nature of edge currents in chiral $p$-wave superconductors using a variety of theoretical techniques, including lattice Bogoliubov-de Gennes equations, the quasiclassical approximation, and the gradient expansion, and describe those special cases where edge currents do have a topological character. While edge currents are not quantized, they are generally large, but can be substantially reduced for a sufficiently anisotropic gap function, a scenario of possible relevance for the putative chiral $p$-wave superconductor Sr$_2$RuO$_4$.

11:15AM G26.00001 The Non-Adiabatic dynamics of Singlet Fission in Polyacenes\(^1\), STEPHEN BRADFORTH, Univ of Southern California — Singlet fission involves the splitting of a single excitation into two coupled triplet excitations and is manifested in an increasing range of aromatic crystals and amorphous thin films. If the energy of the lowest triplet state is one half (or less) of the first singlet excited state, as it is for tetracene or pentacene and their derivatives, singlet fission may occur between two adjacent chromophores. Since there is no change in the overall spin state of the system, singlet fission can be exceptionally fast, occurring on the fs – ps range. If the triplets can diffuse away from the fission site they are available to the efficiency and speed of this process.

11:51AM G26.00002 Extracting Molecular Dynamics from Ion Imaging Experiments of Carboxyl Sulfide, WEI WEI, COLIN WALLACE, SIMON NORTH, Texas A&M Univ — Photodissociation of carboxyl sulfide at 215nm are studied in details with sliced ion imaging experiments. Energy partitioning as well as vector correlations between carboxyl sulfide transition dipole moments, CO recoil velocity vector and angular momentum will be revealed. They can provide valuable information about symmetry of excited states which are involved in photodissociation process. These results can reveal information about non-adiabatic dynamics in carboxyl sulfide excited states. The results will be compared with both computational chemistry study conducted by G. McBane and coworkers. The result will also be compared with previous study on dynamics from carboxyl sulfide photodissociation at longer wavelength by Bersohn and coworkers.
12:03PM G26.00003 Vibronic interactions in multi-chromophores. LYUDMILA SLIPCHENKO, Purdue University — Understanding and control of excitation energy transfer and electron-phonon interactions is quintessential for advances in solar energy utilization. Recently, we developed a vibronic model that is capable of predicting vibronic spectra in complex multi-chromophore systems. Parameters to the model are obtained from electronic structure calculations on monomer units of a multi-chromophore. This model can account for multiple vibrational modes, asymmetric wave functions, and inter-chromophore vibrations. Using this model, we explored vibronic spectra in a series of flexible bichromophores with available high-resolution experimental spectra. One of the goals of this work was to understand the effects of asymmetry in monomer units on vibronic interactions in bichromophores. Detailed investigation of diphenylmethane, partially deuterated diphenylmethane, and diphenylethane resulted in intriguing observation that asymmetry leads to a partial localization of one of the exciton states but leaves the other one delocalized. Extension of the developed methodology to modeling spectroscopy and dynamics in synthetic and biological multi-chromophore systems such as photosynthetic proteins will be also discussed.

12:39PM G26.00004 Non-Adiabatic Dynamics in the UV Photodissociation of Alkyl Radicals, JINGSONG ZHANG, Department of Chemistry and Air Pollution Research Center University of California, Riverside — This presentation focuses on the ultraviolet (UV) photodissociation dynamics of a series of prototypical alkyl radicals (ethyl, propyl, and butyl) using the high-n Rydberg atom time-of-flight (HRTOF) technique. Upon excitation to the 3s state at 246-nm, ethyl dissociates into H atom and ethylene. Bimodal profile in the product translational energy distribution and energy-dependent product angular distribution indicate two different dissociation pathways that are influenced by conical intersection. A slow and isotropic component corresponding to unimolecular dissociation of the hot radical after internal conversion from the 3s state to the ground state. A fast and anisotropic component corresponds to a direct, rapid H-atom scission via a nonclassical H-bridged transition state from the 3s state to yield H + C2H4. Upon excitation to the 3p state at 237 nm, i- and n-propyl radical dissociate into H atom and propene products. The product translational energy release of both n- and i-propyl radicals also have bimodal distributions. The H-atom product angular distribution in n-propyl is anisotropic, while that in i-propyl is isotropic. The bimodal translational energy distributions indicate two dissociation pathways: (i) a unimolecular dissociation pathway from the ground-state propyl after internal conversion from the 3p state, and (ii) a repulsive pathway directly connected with the excited state of the propyl radical. The UV photodissociation dynamics of the n- and i-propyl radicals are also investigated. The photodissociation mechanisms and the possible role of conical intersections will be discussed.

1:15PM G26.00005 Ultraviolet photodissociation dynamics of the cyclohexyl radical, MICHAEL LUCAS, YANLIN LIU, JINGSONG ZHANG. Univ of California - Riverside — Cycloalkanes are important components in conventional fuels and oil shale derived fuels and the combustion of cyclohexane fuels leads to the production of benzene, a pollutant precursor. One of the pathways from cyclohexane to benzene is through sequential hydrogen loss, including the cyclohexyl radical as an intermediate. The ultraviolet (UV) photodissociation dynamics of the cyclohexyl (c-C6H11) radical was studied for the first time using the high-n Rydberg atom time-of-flight (HRTOF) technique in the range of 232-262 nm. The translational energy distributions of the H-atom loss product channel, P(Ef)^i, show a large translational energy release and a large fraction of average translational energy in the total excess energy, ⟨Ef⟩, from 232-262 nm. The H-atom product angular distribution is anisotropic with a positive β parameter. The most likely H-atom loss pathway is an axial H ejection from the i-C-carbon in cyclohexyl to form cyclohexene + H, which along with the positive β parameter, indicates that the transition dipole moment, μ, is perpendicular to the ring. The P(Ef) and anisotropy of the H-atom loss product channel are significantly larger than those expected for a statistical unimolecular dissociation of a hot radical, indicating a non-statistical dissociation mechanism. The dissociation mechanism is consistent with direct dissociation on a repulsive excited state surface or on the repulsive part of the ground state surface to produce cyclohexene + H, possibly mediated by a conical intersection. Cyclohexyl is the largest radical so far showing a direct dissociation mechanism.

1:27PM G26.00006 Photoisomerization dynamics of a rhodopsin-based molecule (potential molecular switch) with high quantum yields. ROLAND ALLEN, Texas A&M University, CHEN-WEI JIANG, Xi’an Jiaotong University, XIU-XING ZHANG, Weinan Normal University, AI-PING FANG, HONG-RONG LI, RUI-HUA XIE, FU-LI LI, Xi’an Jiaotong University — It is worthwhile to explore the detailed reaction dynamics of various candidates for molecular switches, in order to understand, e.g., the differences in quantum yields and switching times. Here we report density-functional-based simulations for the rhodopsin-based molecule 4-[4-Methylbenzylidene]-5-p-tolyl-3,4-dihydro-2H-pyrrrole (MDP), synthesized by Sampredo et al. We find that the photoisomerization quantum yields are remarkably high: 82% for cis-to-trans, and 68% for trans-to-cis. The lifetimes of the S1 excited state in cis-MDP in our calculations are in the range of 900-1800 fs, with a mean value of 1270 fs, while the range of times required for full cis-to-trans isomerization is 1100-2000 fs, with a mean value of 1530 fs. In trans-MDP, the calculated S1 excited state lifetimes are 860-2140 fs, with a mean value of 1330 fs, and with the full trans-to-cis isomerization completed about 200 fs later. In both cases, the dominant reaction mechanism is rotation around the central C==C bond (connected to the pyrrole ring), and de-excitation occurs at an avoided crossing between the ground state and the lowest singlet state, near the midpoint of the rotational pathway.

Session G27 DCP: Focus Session: Chemical Physics of Clusters: Bridging from Angstrom-scale Clusters to Micron-scale Aerosol Particles II
11:15AM G27.00001 Low temperature thermodynamics of water clusters studied by nanocalorimetry , BERND VON ISSENDORFF, Physikalisches Institut, Universität Freiburg — Water exhibits many unusual properties, which mirror the complexity of its hydrogen network structure. It is therefore not surprising that water clusters and nanoparticles are special in many aspects as well. We have recently shown that negatively charged water clusters exhibit a melting-like transition at surprisingly low temperatures (at about 120 K for H$_2$O$_{14}$) [1]. Further studies have shown that this behavior depends only weakly on the charge state of the cluster or on the type of impurity incorporated [2]. Furthermore the size dependence indicates that the transition does not extrapolate to the melting transition of normal ice, but rather to the glass transition of amorphous ice, which occurs at about 136 K. This can be rationalized by the fact that water clusters with few hundred molecules do not form a crystalline network like bulk ice, but exhibit structures much closer to that of the amorphous forms of solid water.

11:51AM G27.00002 Melting behavior of metallic clusters: An order parameter by instantaneous normal modes , TEN-MING WU, Institute of Physics, National Chiao-Tung University — In this paper, we investigated the melting behaviors of Ag$_{17}$Cu$_2$ and Ag$_{14}$ metallic clusters, which were generated by isothermal Brownian-type molecular dynamics simulation with the empirical many-body Gupta potentials, from low to high temperatures. For the two clusters, the temperature variation in the specific heat exhibited a maximum at a temperature, which was defined as the cluster melting temperature. However, an additional prepeak at a lower temperature was found in the specific heat variation of Ag$_{14}$ but no prepeak was found in that of Ag$_{17}$Cu$_2$. The instantaneous normal mode (INM) analysis was used to dissect dynamics of the two clusters. A new order parameter associated with a cluster was proposed to describe the melting behaviors of the cluster; the order parameter can be defined using either the INM vibrational density of states or three orthogonal eigenvectors describing the rotational motions of the cluster by considering it as a rigid body. For the two metallic clusters studied, our results showed the mutual agreement for the order parameter defined by the two methods. The interpretation by the order parameter for the melting transition of a cluster was consistent with the temperature variation in the specific heat of the cluster. Furthermore, the new order parameter provided a connection between the melting of clusters and the concept of broken symmetry, which was successfully applied for understanding the melting transition of bulk systems.

12:03PM G27.00003 Structural determination of metal nanoparticles from their vibrational (phonon) density of states$^1$ , IGNACIO GARZON, Universidad Nacional Autonoma de Mexico, HUZIEL SAUCEDA, Universidad Nacional Autonoma de Mexico — The vibrational (phonon) density of states of metal nanoparticles with size between 2-6 nm can be measured using nuclear resonant inelastic x-ray or plasmon resonance Raman scattering. In this work, we present atomistic calculations, based on a semiempirical tight-binding many-body Gupta potential, of the vibrational density of states (VDOS) for FCC, decahedral, and icosahedral (ICO) gold and silver nanoparticles with sizes ~4 nm (~2000 atoms). The calculated VDOS are compared with experimental data, recently published for gold and silver nanoparticles of similar size, obtained through plasmon resonance Raman scattering. The best agreement between the calculated and measured VDOS’s is obtained for the ICO morphology for both metal nanoparticles. These results indicate that most of the nanoparticles in the experimental samples should have icosahedral structures. The present study also shows that, as in the case of molecular systems and small clusters, vibrational spectroscopy of metal nanoparticles with few nanometers in size, together with theoretical calculations, are powerful tools for their structure determination. with your abstract body.

$^1$Work supported by CONACYT-Mexico under Project 177981.

12:15PM G27.00004 Simulation studies of glassy nanoclusters , RICHARD BOWLES, Dept. Chemistry, University of Saskatchewan — Glassy materials are amorphous solids usually formed by rapidly cooling a liquid below its equilibrium freezing temperature, trapping the particles in a liquid-like structure at the glass transition temperature. While appearing throughout nature and industry, these systems continue to challenge the way we think about the dynamics and thermodynamics of condensed matter and a fundamental understanding of the glass state remains elusive. This talk describes molecular simulation studies of glassy behaviour in binary Lennard–Jones nanoclusters. We show that the relaxation dynamics of the clusters is nonuniform and the core of the cluster goes through a glass transition at higher temperatures than at the surface. As the nanoclusters are cooled, they also exhibit a fragile–strong crossover in their dynamics and we explore how this phenomena is linked to the potential energy landscape of the clusters. Finally, we compare the properties of nanoclusters formed through vapour condensation, directly to the glassy state, with those of glassy clusters formed through traditional annealing. Nanoclusters exhibit some unique glassy features, while also offering potential insights into the development of supercooled liquids.

12:51PM G27.00005 Effects of Thermal Annealing and X-ray Exposure on Local Structures Surrounding Co in Y-Codoped CeO$_2$ Nanocrystals , TAI-SING WU, HORNG-TAY JENG, National Tsing Hua University, Taiwan, SHIH-LIN CHANG, National Synchrotron Radiation Research Center, Taiwan, YUN-LIANG SOO, National Tsing Hua University, Taiwan — Codoping of Y and Co in CeO$_2$ has been found to incur an unconventional bandgap narrowing effect in the host nanocrystal material. The dormant bandgap-tuning ability of Y appears to be turned on by the Co codopant in the oxygen-vacancy-rich CeO$_2$ host. The physical mechanism underlying such effect has also been revealed by DFT calculations. Synchrotron-Radiation-based X-ray absorption analysis has further demonstrated that the Co codopant atoms can be located in either of two different local bonding environments in the CeO$_2$ host. Thermal annealing is capable of driving Co atoms from one bonding environment to the other. On the other hand, when exposed to x-rays of sufficient photon energy, Co can resume the original local structure as in the as-made sample. A simple model is proposed to explain such intriguing interplay between the effects of annealing and x-ray exposure in these codoped nanoceria systems.

1:03PM G27.00006 The correspondence between the infrared vibrational spectra and the underlying hydrogen bonding network in aqueous clusters: caveats and tactics$^1$ , SOTIRIS XANTHEAS, Pacific Northwest National Laboratory — The structural – spectral correspondence relates the observed infrared (IR) vibrational spectra to the underlying molecular structure. In the case of hydrogen bonded clusters the IR ”fingerprint” region in the 3,000 – 4,000 cm$^{-1}$ spectral range provides a direct probe of the connectivity and dynamics of the cluster’s hydrogen bonding network. For medium size (~20) aqueous neutral and ionic clusters, the presence of several closely lying isomers that differ substantially in the oxygen atom network complicates both the sampling of the respective potential energy surfaces as well as the accurate determination of their energy order. Traditionally, a hierarchical procedure based on initial sampling with classical potentials and subsequent refinement with electronic structure methods has been used. We will highlight representative examples for the (H$_2$O)$_{20}$, (H$_2$O)$_{25}$ and H$_2$O$^+$/(H$_2$O)$_{20}$ clusters [1-3] where sampling with classical potentials fails to produce the most stable minima and outline approaches and strategies that are based on a combination of enhanced sampling of configurations in conjunction with electronic structure theory to obtain realistic cluster configurations that are consistent with the measured IR spectra.

The field direction dependence of \( \kappa \) is consistent with monopole excitations. However, the temperature dependence indicates that the energy gap is at most 0.2 K, which is much smaller than \( \Delta \sim 4 \) K. This reduction of gap suggests the band formation of monopole excitations, giving rise to coherent heat conduction of “quantum” monopoles. Unlike diffusive monopoles in classical spin ice, the mean free path of these quantum monopoles is extremely long \( \sim 100 \) nm.

12:15PM G28.00004 Phase transitions and charge ordering in a square spin ice model with conserved monopole density

These monopole dimers are charge neutral, and the interactions between them have also been investigated using our algorithm. In the cases of high monopole densities, we have argued that artificial spin ice can be arranged in extended lattices. Tailoring the geometry and the magnetic material of these lattices, the magnetic interactions and magnetization reversal energy barriers can be tuned [1,2]. This enables interesting interaction schemes to be examined on adjustable length and energy scales. As a result such nano-magnetic systems represent an ideal playground for the study of physical model systems, being facilitated by direct magnetic imaging techniques [3]. One particularly interesting case is that of systems exhibiting frustration, where competing interactions cannot be simultaneously satisfied. This results in a degeneracy of the ground state and intricate thermodynamic properties [1-4]. An archetypical frustrated physical system is water ice. Similar physics can be mirrored in nano-magnetic arrays, by tuning the arrangement of neighboring magnetic islands, referred to as artificial spin ice. Thermal excitations in such systems resemble magnetic monopoles [4]. In this presentation key concepts related to nano-magnetism and artificial spin ice will be introduced and discussed, along with recent experimental and theoretical developments. [1] V. 11:39AM G28.00003 Ordering, thermal excitations and phase transitions in dipolar coupled mono-domain magnet arrays

Yoshi Tokuwa, Daiki Terazawa, Yusuke Shimoyma, K. W. Schlax, J. A. Moyer, A. Thaler, K. Sendzikoski, G. J. MacDougall, P. Schiffer, J. D. Van Harlingen, University of Illinois at Urbana-Champaign — The spin ice pyrochlore class of frustrated magnets exhibits quasiparticle excitations that behave like Dirac monopoles on the pyrochlore lattice. We are studying single crystals of the spin ice Dy2Ti2O7 using dc SQUID magnetometry to look for thermal fluctuations in the monopole density. Specifically, we are seeking to observe a local excess of monopole magnetic charge induced by the simultaneous application of a temperature gradient, which should create a gradient in the monopole density, and a parallel field, which drives the flow and counterflow of oppositely-charged monopoles. This configuration should allow us to investigate the distribution, dynamics, and relaxation of the monopole-like excitations in spin ice pyrochlores.

12:27PM G28.00005 What is the quantum ground state of dipolar spin ice? , PAUL MCLCARTY, ISIS Neutron and Muon Source, STFC, OLGA SOKORA, NTU, RODERICH MOESSNER, MPIPKS, KARLO PENC, Institute for Solid State Physics and Optics, Budapest, FRANK POLLACK, MPIPKS, NIC SHANNON, Okinawa Institute of Science and Technology — Recent work on Dy2Ti2O7 spin ice has revealed a partial loss of residual entropy deep within the spin ice state [1]. It has been known for some time that the spin ice materials should have either magnetically ordered [2] or quantum spin liquid [3] ground states and this latest work hints at the possibility of determining them experimentally. We study a natural model for the dipolar spin ice materials and map out the entire ground state phase diagram in the presence of quantum tunneling between the ice states [4]. In the classical case, we show that the ground state of our 3D long-range interacting model can be determined from those of a short-range interacting 2D model and, remarkably, in the quantum case, only a very small tunneling coupling compared to the dipolar coupling is necessary to enter the quantum spin liquid state.

12:39PM G28.00006 Demagnetization Effects in Dipolar Systems , PATRIK HENELIUS, MIKAEL TWENGSTROM, 2 Department of Theoretical Physics, The Royal Institute of Technology, Sweden, LAURA BOVO, 2 London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, UK, MICHEL J. P. GINGRAS, Department of Physics and Astronomy, University of Waterloo, Canada & Canadian Institute for Advanced Research, Canada, STEVEN T. BRAMWELL, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, UK — The internal magnetic field of a uniformly magnetized body depends in general on the shape of the object. The calculation of this field, and the associated demagnetization factors, is a classical subject in the study of magnetism. Here we revisit the relationship between the demagnetization factor obtained through fluxmetric, magnetometric and bulk susceptibility techniques. Apart from simple uniaxial systems we also consider more complicated systems, such as the dipolar spin ice model on a pyrochlore lattice, where we compare our results to experimental bulk susceptibility measurements performed on a variety of sample shapes.

12:51PM G28.00007 Magnetic Susceptibility of Spin Ice , MIKAEL TWENGSTROM, 2 Department of Theoretical Physics, KTH, Sweden, LAURA BOVO, 2 London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, UK, TOM FENNELL, 2 Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, Switzerland, STEVEN T. BRAMWELL, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, UK, OLEG A. PETRENKO, University of Warwick, Department of Physics, UK, MICHEL J. P. GINGRAS, Department of Physics and Astronomy, University of Waterloo, Canada. Canadian Institute for Advanced Research, Canada, PATRIK HENELIUS, Department of Theoretical Physics, KTH, Sweden — The magnetic susceptibility of a spin ice material is a sensitive probe of the relevant physics in different temperature ranges. At high temperatures, where crystal field excitations dominate the susceptibility, the spin ice picture is not applicable. However, at temperatures below 10 K, the Ising anisotropy is well developed and the dipolar spin ice model (DSIM) can be employed. In this study we present experimental susceptibility data between 0.4 K and 10 K and revisit the DSIM in order to theoretically model this data. We find that the DSIM provides a good semi-quantitative description of both the temperature dependence of the uniform bulk susceptibility and the Q-dependent susceptibility measured by neutron scattering.

3 Neutron scattering

1:03PM G28.00008 Pseudo-spin model and neutron scattering studies of hydrogen disorder in D2O , DAVID JONATHAN P. MORRIS, Xavier University, Cincinnati, OH, USA, KONRAD SIEMENSMYER, BASTIAN KLEEMKE, JENS-UWE HOFFMANN, ILLA GLAVATSKYI, KLAUS SEIFERT, Helmholtz-Zentrum Berlin for Materials and Energy, Berlin, Germany, SERGEI ISAKOV, ETH Zurich, Switzerland, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, ALAN TENNANT, Oak Ridge National Laboratory, Oak Ridge, TN, USA — The crystal structure of water is made up of a regular lattice of oxygen atoms connected by hydrogen bonds with an intermediate hydrogen atom. The hydrogen atom is displaced from the midpoint between nearest neighbor oxygen-oxygen atoms. Therefore the H-bond between neighboring hydrogen and oxygen can either be short or long. These H-bonds are known to obey the famous "ice rules" where each oxygen has two neighboring hydrogen sitting on the close site and two neighboring hydrogen sitting on the further site. The ice rules do not specify which hydrogen bonds will be short and which will be long for any particular oxygen, i.e. they do not describe long-range order, merely that there will be two short and two long bonds for a particular oxygen atom allowing for disorder. Here we will present a pseudo-spin model of water ice and diffuse neutron scattering measurements from D2O. The displacements of hydrogen away from the midpoint between neighboring oxygen-oxygen are treated as interacting Ising spins (σ = ±1). The diffuse neutron scattering measurements allow us to test the resulting theoretical predictions.

1:15PM G28.00009 Critical dynamics and finite-time scaling in spin ice systems , CLAUDIO CASTELNOVO, JAMES HAMP, University of Cambridge, ANUSHYA CHANDRAN, Perimeter Institute, RODERICH MOESSNER, MPIPKS — Spin ice materials such as Dy2Ti2O7 and Ho2Ti2O7 provide a rare instance of emergent gauge symmetry and fractionalisation in three dimensions. Magnetic frustration leads to highly degenerate yet locally constrained ground states. Their elementary excitations carry a fraction of the magnetic moment of the microscopic spin degrees of freedom and can be thought of as magnetic monopoles. One of the distinguishing manifestations of this emergent "Coulomb phase" is a liquid-gas phase diagram that appears in an applied magnetic field—a feature that is expected in itinerant charge liquids but unprecedented in localised spin systems. Monopoles act as facilitators to the spin dynamics. At low temperatures they are sparse and dynamics becomes slow, leading to an interplay between emergent topological properties and lattice response and equilibration properties. In this work, we investigate the dynamics in spin ice close to the critical end point of the liquid gas phase diagram. Critically divergent length scales give rise to finite time scaling properties that reflect the universal scaling exponents at the critical point. We use our results to explain these exponents by tuning the approach direction in the field-temperature plane.

1:27PM G28.00010 A Measure of Monopole Inertia in the Quantum Spin Ice Yb2Ti2O7 , LIDONG PAN, N. J. LAURITA, Institute for Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University, KATE A. ROSS, Institute for Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University; NIST Center for Neutron Research, EDWIN KERMARREC, Department of Physics and Astronomy, McMaster University, BRUCE D. GAULIN, Department of Physics and Astronomy; and Brockhouse Institute for Materials Research, McMaster University; Canadian Institute for Advanced Research, N. PETER ARMITAGE, Institute for Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University. — We report a time domain terahertz spectroscopy study of quantum spin ice material Yb2Ti2O7. We measure the complex dynamic susceptibility of Yb2Ti2O7 in the temperature range between 1.4K and 20K. The data are consistent with a picture where the emergent magnetic monopoles are the principle degrees of freedom. Among other measures, we observe a zero crossing in the real part of the frequency dependent susceptibility. Such a feature is not possible without introducing inertial effects e.g. a mass dependent term to the equations of motion. Through a comparison of the magnetic spectral weight with numerical data that estimates the low temperature monopole density, we derive a value for the magnetic monopole mass.
Real time imaging of magnetic excitations in the spin ice Ho$_2$Ti$_3$O$_7$. LYA SOCHNIKOV, Stanford University — Theoretically, a special form of spin frustration in classical spin ices results in emergence of excitations that are directly mapped to magnetic monopoles. Experimentally, many aspects of the energetics of the magnetic excitations in spin ices are still not well understood, in part, because of scarcity of experimental tools that can explicitly and directly test for monopole dynamics. Using scanning Superconducting QUantum Interference Device (SQUID) microscopy we obtain real time images of spontaneous magnetic field fluctuations in the spin ice Ho$_2$Ti$_3$O$_7$. We determine a distribution of activation energies of spontaneous magnetic excitations from the temperature and frequency dependence of the observed field fluctuations. We discuss an agreement of the extracted energy distributions with the expected ones for monopole excitations. This study opens new horizons for studies of real space and real time magnetic fluctuations and their relations to emergent phenomena in a variety of frustrated magnets.

Tuesday, March 3, 2015 11:15AM - 2:15PM –
Session G29 GMAG: Cooperative Phenomena in Magnetism I
206A - Yang Zhao, National Institute of Standards and Technology

A minimal tight-binding model for ferromagnetic canted bilayer manganites. CHRISTOPHER LANE, Northeastern Univ., M. BAUBLITZ, Boston U., H. LIN, NUS, H. HAFIZ, R.S. MARKIEWICZ, B. BARBIELLINI, Northeastern U., Z. SUN, D.S. DESSAU, UC Boulder, A. BANSIL, Northeastern U. — Half-metallicity in materials has been a subject of extensive research due to its potential for applications in spintronics. Ferromagnetic manganites have been seen as a good candidate, and aside from a small minority-spin pocket observed in La$_{2-x}$Sr$_{1.2}$Mn$_2$O$_7$ ($x = 0.38$), transport measurements show that ferromagnetic manganites essentially behave like half metals. Here we develop robust tight-binding models to describe the electronic band structure of the majority as well as minority spin states of ferromagnetic, spin-canted antiferromagnetic, and fully antiferromagnetic bilayer manganites. Both the bilayer coupling between the Mn$_2$O$_7$ planes and the mixing of the $|x^2 - y^2 >$ and $|3z^2 - r^2 >$ Mn 3d orbitals play an important role in the subtle behavior of the bilayer splitting. Effects of $k_z$ dispersion are included.

High Pressure Transport Studies of NdIn$_3$. KENNETH PURCELL, Univ of Southern Indiana, DAVID GRAF, National High Magnetic Field Laboratory, TAKAO EBIHARA, Shizuoka University — NdIn$_3$ is a cubic antiferromagnetic metal that orders with a Neel temperature of 5.9 K and belongs to a family of rare earth intermetallic compounds RIn$_3$ that have a cubic AuCu$_3$-type crystal structure. At 0.5 K and the magnetic field applied in 100 direction, NdIn$_3$ exhibits metamagnetic transitions at 7.8 T and 8.9 T before entering a field induced paramagnetic state at 11.1 T. We report high pressure transport studies of single crystal NdIn$_3$ and the effect that pressure has on the Neel temperature, critical field, and metamagnetic transitions observed in the magnetoresistance. Comparisons to the behavior of the pressure induced superconductor CeIn$_3$ will be discussed.

Giant proximity effect and critical opalescence in EuS. TIMOTHY CHARLTON, Rutherford Appleton Laboratory, Science and Technology Facilities Council, United Kingdom., SILVIA RAMOS, JORGE QUINTANILLA, School of Physical Sciences, University of Kent, Canterbury, Kent, United Kingdom., ANDREAS SUTER, Paul Sherrer Institut, Switzerland, JAGADEESH MOODERA, Francis Bitter Magnet Laboratory, Massachusetts Institute of Technology, Cambridge, MA, United States. — The proximity effect is a type of wetting phenomenon where an ordered state, usually magnetism or superconductivity, “leaks” from one material into an adjacent one over some finite distance. For superconductors, the characteristic range is of the order of the coherence length, usually hundreds of nm. Nevertheless much longer, “giant” proximity effects have been observed in cuprate perovskite junctions. Such giant proximity effects can be understood by taking into account the divergence of the pairing susceptibility in the non-superconducting material when it is itself close to a superconducting instability: a superconducting version of critical opalescence. Since critical opalescence occurs in all second order phase transitions, giant proximity effects are expected to be general, therefor there must be a giant ferromagnetic proximity effect. Compared to its superconducting counterpart, the giant ferromagnetic proximity effect has the advantage that the order parameter (magnetization) can be observed directly. We have fabricated Co/EuS thin films and measured the magnetization profiles as a function of temperature using the complementary techniques of low energy muon relaxation and polarized neutron reflectivity. Details of the proximity effect near $T_c^{EuS}$ will be presented.

1:39PM G28.00011 Real time imaging of magnetic excitations in the spin ice Ho$_2$Ti$_3$O$_7$. LYA SOCHNIKOV, Stanford University — Theoretically, a special form of spin frustration in classical spin ices results in emergence of excitations that are directly mapped to magnetic monopoles. Experimentally, many aspects of the energetics of the magnetic excitations in spin ices are still not well understood, in part, because of scarcity of experimental tools that can explicitly and directly test for monopole dynamics. Using scanning Superconducting QUantum Interference Device (SQUID) microscopy we obtain real time images of spontaneous magnetic field fluctuations in the spin ice Ho$_2$Ti$_3$O$_7$. We determine a distribution of activation energies of spontaneous magnetic excitations from the temperature and frequency dependence of the observed field fluctuations. We discuss an agreement of the extracted energy distributions with the expected ones for monopole excitations. This study opens new horizons for studies of real space and real time magnetic fluctuations and their relations to emergent phenomena in a variety of frustrated magnets.

11:39AM G29.00003 $1/(N - 1)$ expansion, NRG, NCA, and exact $T \to \infty$ limit for the Green’s function of an SU($N$) Anderson impurity. AKIRA OGURI, Department of Physics, Osaka City University, RUI SAKANO, ISSP, University of Tokyo — We study the Green’s function of the $N$-orbital Anderson impurity in a wide range of the Coulomb interaction $U$, frequency $\omega$, and temperature $T$, carrying out the calculations with the $1/(N - 1)$ expansion [1], the numerical renormalization group (NRG), the non-crossing approximation (NCA), and the exact expression that is available at high temperatures or the high-bias limit of a nonequilibrium steady state [2]. Comparisons of these approaches are made, specifically, for the $N = 4$ particle-hole symmetric case. The $1/(N - 1)$ expansion is a new large $N$ approach based on the perturbation theory in $U [1]$, and is complementary to the NCA which uses the power series expansion in the hybridization matrix element $\gamma$. The calculations with this approach are carried out up to order $1/(N - 1)^2$, which reasonably capture the fluctuations beyond the random phase approximation (RPA) especially at low energies. We also discuss the $N$ dependence for $N > 4$. [1] A.O., R. Sakano, and T. Fuji, PRB 84, 113301 (2011).

11:51AM G29.00004 High Pressure Transport Studies of NdIn$_3$. KENNETH PURCELL, Univ of Southern Indiana, DAVID GRAF, National High Magnetic Field Laboratory, TAKAO EBIHARA, Shizuoka University — NdIn$_3$ is a cubic antiferromagnetic metal that orders with a Neel temperature of 5.9 K and belongs to a family of rare earth intermetallic compounds RIn$_3$ that have a cubic AuCu$_3$-type crystal structure. At 0.5 K and the magnetic field applied in 100 direction, NdIn$_3$ exhibits metamagnetic transitions at 7.8 T and 8.9 T before entering a field induced paramagnetic state at 11.1 T. We report high pressure transport studies of single crystal NdIn$_3$ and the effect that pressure has on the Neel temperature, critical field, and metamagnetic transitions observed in the magnetoresistance. Comparisons to the behavior of the pressure induced superconductor CeIn$_3$ will be discussed.

12:03PM G29.00005 Giant proximity effect and critical opalescence in EuS. TIMOTHY CHARLTON, Rutherford Appleton Laboratory, Science and Technology Facilities Council, United Kingdom., SILVIA RAMOS, JORGE QUINTANILLA, School of Physical Sciences, University of Kent, Canterbury, Kent, United Kingdom., ANDREAS SUTER, Paul Sherrer Institut, Switzerland, JAGADEESH MOODERA, Francis Bitter Magnet Laboratory, Massachusetts Institute of Technology, Cambridge, MA, United States. — The proximity effect is a type of wetting phenomenon where an ordered state, usually magnetism or superconductivity, “leaks” from one material into an adjacent one over some finite distance. For superconductors, the characteristic range is of the order of the coherence length, usually hundreds of nm. Nevertheless much longer, “giant” proximity effects have been observed in cuprate perovskite junctions. Such giant proximity effects can be understood by taking into account the divergence of the pairing susceptibility in the non-superconducting material when it is itself close to a superconducting instability: a superconducting version of critical opalescence. Since critical opalescence occurs in all second order phase transitions, giant proximity effects are expected to be general, therefor there must be a giant ferromagnetic proximity effect. Compared to its superconducting counterpart, the giant ferromagnetic proximity effect has the advantage that the order parameter (magnetization) can be observed directly. We have fabricated Co/EuS thin films and measured the magnetization profiles as a function of temperature using the complementary techniques of low energy muon relaxation and polarized neutron reflectivity. Details of the proximity effect near $T_c^{EuS}$ will be presented.

12:15PM G29.00006 Hole Properties In and Out of Magnetization Plateaus in 2-d Antiferromagnet. IMAM MAKHUFUDZ, PIERRE PUJOL, Laboratoire de Physique Théorique–IRSAMC, CNRS and Université de Toulouse, UPS, France — We study the signatures of magnetization plateaus and the presence or absence of Goldstone modes in terms of their effects on the physics of holes in hole-doped two-dimensional antiferromagnet defined on square lattice. Holes with quadratic dispersion around Fermi point existing at infinitesimally small doping and linear dispersion around nearly circular Fermi surface at finite but low doping are investigated. They are coupled to an effective gauge field, generated by the spin sector, which subsequently mediates interaction between the holes. We find that out-of-plateaus case leads to algebraically decaying long-range interaction between fermionic holes with both Coulombic and dipolar forms, whereas in-plateaus case leads to short-range (local) interaction. We show that the spectral peak is significantly broadened in the out-of-plateaus case, while the spectral weight is still sharply-peaked in the in-plateau case. This conclusion holds in both infinitesimally small doping limit and in the more realistic finite doping case. We also extend the result obtained for 1-D system where finite hole doping gives rise to a shift in the magnetization value of the plateaus. Reference: arXiv:1411.1713

12:27PM G29.00007 Emergence of New Magnetic Plateaus in Sheets of Magnetic Dimers, S. HARAVIFARD, UChicago/Argonne National Lab, D. GRAF, National High Magnetic Field Lab, A. FEIGUIN, Northeastern Univ, C.D. BATISTA, Los Alamos National Lab, J.C. LANG, Argonne National Lab, D. SILEVITCH, UChicago, G. SRAJER, Argonne National Lab, H.A. DABKOWSKA, B.D. GAULIN, McMaster Univ, S.W. TOZER, National High Magnetic Field Lab, T.F. ROSENBAUM, UChicago — SrCu2(BO3)2 has corner-sharing Cu2+ spin 1/2 dimers lying on a square lattice, corresponding to the two-dimensional Shastry-Sutherland model. At low temperatures and fields exceeding 20 T, there is a Bose-Einstein condensation of triplet excitations of the dimers. At higher magnetic fields, plateaus have been observed in the magnetization, which have been interpreted in terms of preferred filling of the singlet ground state with increasing densities of triplet roton states. We apply hydrostatic pressures up to 9 GPa to study the movement and suppression of the quantized magnetic plateaus identified at ambient pressure as well as the emergence of new superstructure configurations.

12:39PM G29.00008 Magnetism in RFe2Ge2 (R = Y, Lu, Tb) as seen by 57Fe Mössbauer spectroscopy1, SERGEY L. BURKOV, Ames Lab/ISU, MARCOS A. AVILA, UFABC, XIAOMING MA, Landzhou U. and Ames Lab/ISU, SHENG RAN, HYUNSOO KIM, PAUL C. CANFIELD, Ames Lab/ISU — Magnetic properties of RFe2Ge2 (R = Y, Lu, Tb) were studied using neutron scattering dependent (4.6 - 300 K) Mössbauer spectroscopy and specific heat capacity. In the paramagnetic state all three compounds have similar evolution of the isomer shift and quadrupolar splitting. Magnetic phase transitions can be detected both in LuFe2Ge2 and TbFe2Ge2, with an indication of very small iron magnetic moment in the ordered state for LuFe2Ge2. The Debye temperature evaluated from the temperature-dependent isomer shift for these three compounds is significantly higher that inferred from specific heat capacity measurements, that might indicate presence of magnetic correlations. The results will be compared with the bulk measurements.

1Supported by US DOE, BES under Contract No. DE-AC02-07CH11358 and China Scholarship Council.

12:51PM G29.00009 Quadrupolar order triggered by magnetic order in GdB4, HOYOUNG JANG, SSRL, SLAC National Accelerator Laboratory, B.Y. KANG, B.K. CHO, School of Materials Science and Engineering, Gwangju Institute of Science and Technology (GIST), J.-S. LEE, SSRL, SLAC National Accelerator Laboratory — Various electronic and magnetic properties and phase transition of Gd and Gd compounds have been measured. For example, 4f delocalization of Gd metal was revealed by resonant inelastic x-ray scattering study with high pressure condition [1]. Meanwhile, extremely large magnetic susceptibility in GdB4 was reported [2] – which is unexpected in the general Gd configuration. We investigated GdB4 by resonant soft x-ray scattering (RSXS) experiment at GTEM edge. In (100) reflection, huge RSXS signal was observed, which corresponds to the reported antiferromagnetic (AFM) order by neutron scattering measurement [3]. Besides, unexpected RSXS signal was also detected in different photon polarization, which cannot be explained by the reported AFM structure. The energy dependence of the unexpected signal might to 2 spin-coupling the different origin with the AFM order. We deduce that the unexpected signal comes from Gd quadrupolar order, which is triggered by magnetostriiction through the AFM order.

1:03PM G29.00010 Condensation of collective charge ordering in Chromium, A. SINGER, M. MARSH, S. DIETZE, Department of Physics, University of California-San Diego, V.V. UHLMIR, Center for Magnetic Recording Research, University of California-San Diego, Y. LI, D.A. WALKO, E.M. DUFRESNE, G. SRAJER, Advanced Photon Source, Argonne National Laboratory, M.P. COSGRIFF, P.G. EVANS, Department of Materials Science and Engineering, University of Wisconsin Madison, E.E. FULLERTON, Center for Magnetic Recording Research, University of California-San Diego, O.G. SHPYRKO, Department of Physics, University of California-San Diego — Here we report on the dynamics of the structural order parameter in a chromium film using synchrotron radiation in response to photo-induced ultra-fast excitations. Following transient optical excitations the effective lattice temperature of the film rises close to the Neel temperature and the charge density wave (CDW) amplitude is reduced. Although we expect the electron charge ordering to vanish shortly after the excitation we observe that the CDW is never completely disrupted, which is revealed by its unmodified period at elevated temperatures. We attribute the persistence of the CDW to the long-lived periodic lattice displacement in chromium. The long-term evolution shows that the CDW revives to its initial strength within 1 ns, which appears to behave in accordance with the temperature dependence in equilibrium. This study highlights the fundamental role of the lattice distortion in charge ordered systems and its impact on the re-condensation dynamics of the charge ordered state in strongly correlated materials.

1:15PM G29.00011 Direct probe of Fermi surface evolution at a pressure-induced quantum phase transition, D.M. SILEVITCH, University of Chicago, YEJUN FENG, Argonne National Laboratory, A. PALMER, YISHU WANG, T.F. ROSENBAUM, University of Chicago — The nature of a material's Fermi surface is crucial to understanding its electronic, magnetic, optical, and thermal characteristics. Traditional measurements such as angle resolved photoemission spectroscopy and de Haas-van Alphen quantum oscillations can be difficult to perform in the vicinity of a pressure-driven quantum phase transition. We demonstrate here that magnetic x-ray diffraction in combination with Hall effect characteristics. Traditional measurements such as angle resolved photoemission spectroscopy and de Haas-van Alphen quantum oscillations can be difficult to perform in the vicinity of a pressure-driven quantum phase transition. We demonstrate here that magnetic x-ray diffraction in combination with Hall effect measurements in a diamond anvil cell can provide valuable insight into the Fermi surface evolution in spin- and charge-density-wave systems near quantum phase transitions. In particular, we delineate the critical pressure and absence of Fermi surface reconstruction at the spin-flip transition in elemental chromium.

1:27PM G29.00012 Factors influencing achievement of chemical order in tetragonal FeNi, NINA BORDEAUX, ANA MARIA MONTES-ARANGO, Northeastern University, JIAXING LIU, KATAYUN BARMAK, Columbia University, LAURA HENDERSON LEWIS, Northeastern University — Chemically ordered ferromagnetic compounds with the L10 structure have attracted wide interest for rare-earth-free permanent magnets applications. In particular, L10-structured FeNi is a promising candidate due to the abundance and low cost of the constituent elements and high theoretical maximum energy product (BH)max = 42 MGOe [1]. Synthesis of L10 FeNi has been hindered by extremely sluggish kinetics below the equilibrium order-disorder temperature TOD = 320 °C and the phase is known to form in meteorites over millions of years. In this work, the thermodynamic stability of the L10 phase and kinetics of the L10 → fcc magnetostructural phase transformation are quantitatively determined via magnetic and thermal measurements of bulk L10 FeNi extracted from meteorites. Influences on phase transformation kinetics, including effects of magnetism, will be discussed. [1] L. H. Lewis, et al., IEEE Mag Lett 5 (2014) 550104.

1:39PM G29.00013 Phase Transitions on Random Lattices: How Random is Topological Disorder?1, HATEM BARGHATHI, THOMAS VOJTA, Missouri Univ of Sci & Tech — We study the effects of topological (connectivity) disorder on phase transitions. We identify a broad class of random lattices whose disorder fluctuations decay much faster with increasing length scale than those of generic random systems, yielding a wandering exponent of ν > 2 rather than the usual Harris criterion ν = 2, making topological disorder less relevant than generic randomness. The Imry-Ma criterion is also modified for first-order transitions to survive in all dimensions d > 1. These results explain a host of puzzling violations of the original criteria for equilibrium and nonequilibrium phase transitions on random lattices. We discuss applications, and we illustrate our theory by computer simulations of random Voronoi and other lattices.

1:51PM G29.00014 Pressure Dependence of Magnetism in KCuF$_3$

BRIAN NGUYEN, ALEXANDER THALER, Univ of Illinois - Urbana, CLARINA DELA CRUZ, Oak Ridge National Lab, GREGORY MACDOUGALL, Univ of Illinois - Urbana — The perovskite KCuF$_3$ is a prototypical compound for studying both orbital ordering and 1-D Heisenberg antiferromagnetism. In the conventional Kugel-Khomskii picture, this material undergoes a Jahn-Teller distortion at T$_{JT}=800$ K causing long-range ordering of 3d Cu$^{2+}$ orbitals, effectively driving the spin interactions 1-D. A second magnetic transition to 3-D antiferromagnetism is observed at the Néel temperature, T$_N=39$ K. Recent data by Lee et al. suggests a new interpretation where Cu$^{2+}$ orbitals do not order until a glassy structural transition at T$_s=50$ K, and this transition is a necessary precursor to 3-D ordering of spins. It was later shown that the glassy transition can be suppressed to zero temperature with pressures as low as P=$7$ kbar, implying that spin order should follow suit. Contrary to this prediction, single crystal neutron scattering measurements by our group demonstrated a moderate increase in T$_N$ with pressure, opposite of predictions. However, some evidence for uniaxial strain complicated interpretation. In an attempt to resolve this issue, we performed neutron powder diffraction measurements in helium gas and clamp pressure cells. We will present these data and discuss them in the context of the Lee et al. model.

2:03PM G29.00015 Neutron Study of the Magnetic Structures and Phase Transitions in RCuAs$_2$ (R=Pr, Nd, Tb, Dy, Ho, Yb), YANG ZHAO, Department of Materials Science and Engineering, University of Maryland, College Park, Maryland 20742, USA, J. W. LYNN, NIST Center for Neutron Research, Gaithersburg, Maryland, 20899, USA, GOHIL S. THAKUR, ZEBA HAQUE, L.C. GUPTA, A-K. GANGULI, Department of Chemistry, Indian Institute of Technology Delhi, India — Neutron diffraction and inelastic scattering studies have been carried out on polycrystalline samples of the above titled materials as a function of temperature and applied magnetic field to determine the magnetic structures, order parameters, and overall spin dynamics. The space group of this compound is P4/nmm with typical (tetragonal) lattice parameters a $\sim$ 3.9 Å and c $\sim$ 10.0 Å. PrCuAs$_2$ develops commensurate magnetic order at T$_N=6.4$ K with an ordered moment of 1.24 $\mu_B$ oriented along the c-axis. The ordering wave vector is (0.0,1/2), with a $\Gamma_7$ representation. NdCuAs$_2$ orders at T$_N=3.54$ K with the same ordering wave vector (with the $\Gamma_7$ or $\Gamma^0_9$ representations), but with the moment direction in the a-b plane along [110] of magnitude 3.5 $\mu_B$. TbCuAs$_2$ and HoCuAs$_2$ exhibit incommensurate order at T$_N=9.1$ and 4.0 K, respectively. The results for the inelastic scattering will be discussed.

Tuesday, March 3, 2015 11:15AM - 2:15PM
Session G30 GMAG DMP FIAP: Focus Session: Skyrmions III

11:15AM G30.00001 Tailoring magnetic skyrmions at transition-metal interfaces, BERTRAND DUPÉ, MARKUS HOFFMAN, CHARLES PAILLARD, STEFAN HEINZE, Christian Albrechts University of Kiel — Skyrmions in magnetic materials offer attractive perspectives for future spintronic applications [1] since they are localized, topologically stabilized spin structures which can be manipulated at electric current densities which are by orders of magnitude lower than those required for moving domain walls. Recently, it has been discovered that due to the broken inversion symmetry at surfaces magnetic skyrmions can also occur in ultra-thin transition metal films at surfaces [2,3]. Here, we use first-principles electronic structure theory to show how transition-metal interfaces can be modified such that they exhibit skyrmion phases and to explain the observation of individual skyrmions in an ultra-thin film composed of Pd and Fe on the Ir(111) surface [3,4]. We determine the magnetic interactions in this system using density functional theory and explain the occurrence of skyrmion phases in an external magnetic field using Monte-Carlo simulations. Our work paves the way to tailor the properties of skyrmions at transition-metal interfaces.

11:27AM G30.00002 Oxygen-enable control of Dzyaloshinskii-Moriya Interaction in Fe/Ir(001) bilayers, ABDERREZAK BELABBES, King Abdullah Univ, GUSTAV BIHLMAYER, STEFAN BLÜGEL, Peter Grünberg Institut and Institute for Advanced Simulation, D-59225 Jülich, Germany, AURELIEN MANCHON, King Abdullah Univ — Using relativistic first principles calculations, we demonstrate that the magnitude and sign of the Dzyaloshinskii-Moriya interaction (DMI) of Fe/Ir(001) interface can be controlled by tuning the coverage of the oxygen capping layer, which changes the spin-wave length and the depth of the energy minimum. In addition, we explain how the magnetic interactions [Exchange interaction, DMI, and the magnetocrystalline anisotropy (MAE)] at such transition metal interface are modified in the presence of Oxygen, which might prevent any stable magnetic order due to the small energy scale. We observe a change sign of the DMI when the coverage exceeds 50%. In particular, we found that due to the C4 breaking symmetry and the large spin-orbit interaction of the Ir substrate the DMI exceeds a critical strength and competes with the exchange interaction and causes homochiral magnetic structures. This study reveals that in realistic systems capped by an oxide, such as HM/F/MOx (HM is a heavy metal, F a ferromagnet an MOx=MgOx, CoOx, TaOx etc., the DMI can be tuned by changing the oxidation conditions of the capping layer, offering a convenient way to control it. Therefore, understanding of the these phenomena may have impact in the context of facilitating applications in spintronics.

11:39AM G30.00003 Imprinting topological domain structure in epitaxial Ni/Fe/Co/Cu(001), ALI TAN, JIA LI, ZI QIANG QU, University of California Berkeley, ELKE ARENHOLZ, ANDREAS SCHOLL, Lawrence Berkeley National Laboratory, CHANYONG HWANG, Korea Research Institute of Standards and Science — A vortex state can be stabilized in magnetic thin films by reducing the lateral dimension of the thin film such that the shape anisotropy imposes flux-closure on the magnetic domains. In the language of skyrmions, a vortex state has a topological skyrmion charge $Q = \pm 1/2$, with vorticity $w = \pm 1$ and helicity $\gamma = \pm \pi/2$. By tuning the interlayer coupling strength, various domain structures can be imprinted on the adjacent ferromagnetic layer. We investigated domain imprinting by cobalt (Co) vortices on nickel (Ni) layer through a face-centered-cubic (fcc) iron (Fe) interlayer in a Ni/Fe(wedge)/Co/disks/Cu(001) trilayer system. Using element-specific X-ray Magnetic Circular Dichroism, we observed a strong antiferromagnetic IEC for 5 ML thick Fe interlayer. From the domain images of each elements obtained using Photoemission Electron Microscopy (PEEM), we observed that the relative strength of the bilinear and biquadratic exchange coupling changes as a function of Fe interlayer thickness, leading to non-collinear coupling between Ni and Co around 5.5 ML of Fe. The resulting Ni domain structures have topological skyrmion charge $Q = \pm 1/2$, with vorticity $w = \pm 1$ but varying helicity $\gamma$. 

This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under award number DE-FG02-07ER46453.
11:51AM G30.00004 Biskyrmion bubble lattice in Fe/Gd alloy thin films, JAMES LEE, Lawrence Berkeley National Laboratory and University of Oregon, Eugene, XIAOWEN SHI, JORDAN CHESS, University of Oregon, Eugene, SERGIO MONTOTOYA, Center for Magnetic Recording Research, University of California, San Diego, SHRAWAN MISHRA, Lawrence Berkeley National Laboratory, LEV SAKHAROV, University of Oregon, Eugene, DANIEL PARKS, Lawrence Berkeley National Laboratory, BEN MCMORRAN, University of Oregon, Eugene, STEVEN KEVAN, Lawrence Berkeley National Laboratory and University of Oregon, Eugene, ERIC FULLERTON, Center for Magnetic Recording Research, University of California, San Diego, SUJOY ROY, Lawrence Berkeley National Laboratory — Magnetic bubbles with topologically non-trivial twists, called “skyrmion bubbles,” exhibit particle-like properties and novel magnetic interactions with each other. They are seen in non-centrosymmetric crystals, such as MnSi, and monolayers of Fe on Ir(111) substrates. Our study considers whether skyrmion bubbles can also form in soft ferromagnetic alloys with perpendicular anisotropy. Using resonant X-ray scattering at the Fe L3 and Gd M2 transition edges, we show that triangular lattices of skyrmion bubbles form in Fe/Gd thin films in a limited temperature and magnetic field range. Uniaxial anisotropy in the resonant scattering pattern indicates the lattice unit cell contains two skyrmions. Lorentz TEM images reveal that the repeating unit is a bound pair of bubbles called biskyrmions. Adjusting the composition of the films can shift the temperature range of the biskyrmion lattice by 100 K, allowing the lattice to form at room temperature. Fe/Gd thin films may prove a promising material for spintronics.

12:03PM G30.00005 Investigation of the Stripe-Bubble Phase in La2-2xSr1+2xMn2O7(x=0.32) by Magnetic Force Microscopy, JUYOUNG JEONG, JINHO YANG, CALDES, Institute for Basic Science and Department of Physics, Pohang Univ of Sci & Tech, JUAN HERNANDO, JABEEL KIM, CALDES, Institute for Basic Science, ILKYU YANG, Department of Physics, Pohang Univ of Sci & Tech, JIANSHI ZHOU, Texas Material Institute, the University of Texas at Austin, NELIZA LEON, ROMAN MOVSHEVICH, Los Alamos National Laboratory, ALEX DE LOZANNE, Department of Physics, the University of Texas at Austin, H.W. YEOM, CALDES, Institute for Basic Science and Department of Physics, Pohang Univ of Sci & Tech, J.B. GOODENOUGH, Texas Material Institute, the University of Texas at Austin, NESTOR HABERKORN, Centro Atomico Bariloche, JEEHOON KIM, CALDES, Institute for Basic Science and Department of Physics, Pohang Univ of Sci & Tech — We constructed a home-built low temperature magnetic force microscope (LTMFM) with the fiber interferometer detection scheme: The base temperature is 4 K and magnetic field range is up to 6 T. The MFM system is applied to investigate unconventional magnetism of La2-2xSr1+2xMn2O7(x=0.32) in a wide span of temperature and magnetic field. We imaged spin reorientation transition and found two types of bubble domains. The behavior of bubble domains shows the same upon field cycle, indicating a reversible magnetization property reported previously in the bulk magnetization measurement. The origin of the two types of the bubble domains will be discussed by comparing MFM and bulk magnetization data.

12:15PM G30.00006 Metastable multi-domain state in ultrathin films with Dzyaloshinskii-Moriya Interaction, PARNIKA AGRAWAL, SEONHOON WOO, GEOFFREY BEACH, MIT — Helical spin structures such as skyrmions and chiral domain walls are stabilized in magnetic films with strong Dzyaloshinskii-Moriya interaction (DMI) [1,2]. The chiral spin state is the ground state when the ratio of the effective DMI field to anisotropy field is greater than 2/p [3]. However, even when the DMI is too weak to generate a chiral ground state, such states can be metastable if the uniform state is appropriately perturbed [1,4]. Here, we show that an in-plane applied field reduces the energy barrier for domain wall formation, and provides a simple technique to generate a multistate domain uniform in magnetic films. Further, we identify that the threshold between the stable single-domain state and the metastable multidomain state can be controlled by two parameters—magnetizing energy and geometrical confinement. We use these parameters to create isolated geometrically confined magnetic bubbles in patterned disks of Pt/Cr/GdOx multilayers. These bubbles may provide insight into the mechanism of creation of skyrmions in magnetic thin films with strong DMI.

12:27PM G30.00007 Tailoring the topology of an artificial magnetic skyrmion, JIA LI, University of California, Berkeley — A skyrmion is a topological twist of a continuous field that was first proposed by Skyrme to describe discrete nucleons. In condensed-matter physics, skyrmions emerge as topological invariant spin textures in two dimensional Heisenberg spin lattice. Evidence of skyrmions in condensed matter physics appeared after the discovery of the Quantum Hall Effect in which the lowest energy charged excitations can be mapped onto two-dimensional magnetic skyrmion states. Despite theoretical predictions, it remains an experimental challenge to realize an artificial magnetic skyrmion whose topology can be well controlled and tailored so that its topological effect can be revealed explicitly in a deformation of the spin textures. Here we report epitaxial magnetic thin films in which an artificial skyrmion is created by embedding a magnetic vortex into an out-of-plane aligned spin environment. By changing the relative orientation of the central vortex core polarity and the surrounding out-of-plane spins, we are able to control and tailor the system between two skyrmion topological states. An in-plane magnetic field is used to annihilate the skyrmion core by converting the central vortex state into a single domain state. Our result shows distinct annihilation behaviour of the skyrmion core for the two different skyrmion states, suggesting a topological effect of the magnetic skyrmions in the core annihilation process.

1:03PM G30.00008 Interlayer Exchange Coupling: A route to stabilize skyrmions in magnetic multilayers, ASHIS KUMAR NANDY, NIKOLAI S. KISELEV, STEFAN BLÜGEL, IAS-1, PGI-1, Forschungszentrum Jülich and JARA, Jülich, Germany — Magnetic skyrmion is a topologically nontrivial spin texture with particle like properties, which may emerge under an appropriate applied magnetic field in any magnetic thin layer or multilayer with surface or interface induced Dzyaloshinski-Moriya interaction. However, magnetic fields required to stabilize skyrmions can be extremely large. We present an approach, which allows the stabilization of skyrmions in such magnetic multilayers even at zero magnetic field. It is based on fine-tuning the interplay between internal and interfaces induced interactions by adjusting the thicknesses and interface compositions of multilayers. Our multiscale approach is based on DFT calculations and atomistic spin dynamic simulations, which predicts the existence of a skyrmion lattice and isolated skyrmions in a thin film of a transition-metal monolayer grown on a heavy metal substrate. The simulated skyrmions exhibit high stability in an applied magnetic field and temperature. We provide a description for the complex phases occurring in such systems and present a magnetic phase diagram for a prototype example of Mn/W(001).

1:15PM G30.00009 Novel rare-earth free magnetic nanostructures1, BHASKAR DAS, BALAMURUGAN BALASUBRAMANIAN, PINAKI MUKHERJEE, PRIYANKA MANCHANDA, RALPH SKOMSKI, University of Nebraska, Lincoln, NE 68588, GEORGE HADJIPANAYIS, University of Delaware, Newark, DE 19716, DAVID SELLMYER, University of Nebraska, Lincoln, NE 68588 — Magnetic nanostructuring including stabilization of novel structures without critical elements, easy-axis alignment, and self-assembly are important for creating new magnetic materials. We use a single-step evaporation of a cluster-deposited nanoparticle array to fabricate large area magnetic nanostructures from magnetic materials with potential for high-energy magnet or spintronics applications.1 For example, MnSi nanoclusters of diameter about 8 nm form hexagonal D8h structure and show strong ferromagnetic properties with a high Tc = 590 K, an appreciable K1 = 12 Mergs/cm3, and a high J=1.25 kG. This result is in a sharp contrast to the antiferromagnetic ordering observed in bulk MnSi with T= 100 K, and is supported by DFT calculations. On the other hand, MnSi nanoclusters form B20-type cubic crystal structure and are ferromagnetically below T = 25 K. Skyrmion-type spin textures have been observed in MnSi thin films and evidence for such structures in nanoclusters will be discussed.

1 This research is supported by U.S. DOE-BES-DMSE (DE-FG02-04ER46152) and NCMN.

1:27PM G30.00010 Growth and Properties of Skyrmionic MnSi Nanowires and Thin Film on Silicon . ZHENG GAI, Oak Ridge National Laboratory, Oak Ridge, TN, JIEYU YI, SIWEI TANG, University of Tennessee, Knoxville, TN, IVANJ. KRAVCHENKO, GUIXIN CAO, Oak Ridge National Laboratory, Oak Ridge, TN, DAVID MANDRUS, University of Tennessee, Knoxville, TN, OAK RIDGE NATIONAL LABORATORY, OAK RIDGE, TN COLLABORATION, UNIVERSITY OF TENNESSEE, KNOXVILLE, TN COLLABORATION — Magnetic skyrmion lattice, a vortex-like spin texture recently observed in chiral magnets, is of great interest to future spin-electronic data storage and other information technology applications. The skyrmion lattice in MnSi appears in a small region (known as the A phase) of the H-T phase diagram in bulk samples, but in 2D samples like thin films the skyrmion phase is much more robust. If skyrmion ordering can persist in one-dimensional MnSi nanowires and 2D films, then these systems may be very promising for spintronics applications as the magnetic domains and individual skyrmions could be manipulated with small currents. We have systematically explored the synthesis of single crystal MnSi nanowires via controlled oxide-assisted chemical vapor deposition and observed a characteristic signature of skyrmion magnetic ordering in MnSi nanowires. The SiO2 layer plays a key role for the high yield, correct stoichiometric and crystalline growth of the B20 MnSi nanowires. A growth phase diagram was constructed. For the thin films, an unique growth receipt was developed for the growth of high quality of thin films. The structure and magnetic properties of the films at different thickness were studied.

1:39PM G30.00011 Manipulating Topological States by Imprinting Non Collinear Spin Textures . PETER FISCHER, Lawrence Berkeley Natl Lab, ROBERT STREUBEL, LUYANG HAN, Institute for Integrative Nanosciences IFW Dresden, MI-YOUNG IM, Lawrence Berkeley Natl Lab, FLORIAN KRONAST, Helmholtz-Zentrum Berlin fuer Materialien und Energie GmbH, ULRICH K. ROESSLER, Institute for Theoretical Solid State Physics IFW Dresden, FLORIN RADU, ABRUDAN, Helmholtz-Zentrum Berlin fuer Materialien und Energie GmbH, GUNGUN LIN, OLIVER G. SCHMIDT, DENYS MAKAROV, Institute for Integrative Nanosciences IFW Dresden — Topological magnetic states, such as chiral skyrmions, are of great scientific interest and show huge potential for novel spintronics applications, provided their topological charges can be fully controlled. So far skyrmionic systems have been observed in noncentrosymmetric crystalline materials with low symmetry and at low temperatures. We propose theoretically and demonstrate experimentally the design of spin textures with topological charge densities that can be tailored at ambient temperatures. Tuning the interlayer coupling in vertically stacked nanopatterned magnetic heterostructures, such as a model system of a Co/Pd multilayer coupled to Permalloy, the in-plane non-collinear spin texture of one layer can be imprinted into the out-of-plane magnetised material. We observe distinct spin textures, e.g. vortices, magnetic swirls with tunable opening angle, donut states and skyrmion systems of Dn symmetry. We show that applying a small magnetic field, a reliable switching between topologically distinct textures can be achieved at remanence.

1:51PM G30.00012 Dzyaloshinkii-Moriya interaction mediated by combined exchange and Rasha bands . ANIRBAN KUNDU, SHUFENG ZHANG, Univ of Arizona — Domain wall structure determined by the competition among exchange, anisotropy, and magnetostatics does not have a preferred wall chirality, i.e., the clockwise and anti-clockwise spin rotations of the domain wall are equally probable. Dzyaloshinskii-Moriya interaction (DMI) has been identified as the dominant mechanism for the observed chiral domain walls in ultrathin ferromagnetic CoNi films. We show that the DMI arises from the interplay between the ferromagnetic exchange coupling and the interface Rashba spin-orbit coupling; these two couplings generally exists for ultrathin films with perpendicular magnetic anisotropy. The DMI displays an oscillatory dependence on the distance of two magnetic ions. In the limit that the Rashba coupling is much smaller than the exchange coupling, the strength of the DMI is linear with respect to the Rashba coupling. In the opposite limit, the DMI depends on the quadratic Rashba coupling. We apply our results to study the chiral dependence of the domain walls. In particular, we quantitatively relate the Rashba coupling strength to the wall structure and map out the preferred Neel or Bloch walls with definite chirality. The results agree with the experiment.

2:03PM G30.00013 Observation of Skyrmions in Mn-Pt-Sn based Heusler material. AJAYA KUMAR NAYAK, ROSHNEE SAHOO, Max Planck Institute for Chemical Physics of Solids, JOHANNES WILD, Faculty of the Institute of Experimental and Applied Physics, Regensburg, Germany, DANIEL EBKE, Max Planck Institute for Chemical Physics of Solids, JOSEF ZWECK, Faculty of the Institute of Experimental and Applied Physics, Regensburg, Germany, STUART PARKIN, Max Planck Institute of Microstructure Physics, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids — Mn2YZ based Heusler materials often exhibit collinear spin alignment. However, in a recent work we found Mn2RhSn displays a non-collinear magnetic structure. The presence of noncollinear spin alignment with lack of inversion symmetry sets up a perfect condition for skyrmions in Mn2RhSn. However, experimentally it is still to be verified. To find skyrmions in Heusler system we search for materials with large spin-orbit coupling and lack of inversion symmetry. Here we present the experimental evidence of skyrmions in Mn-Pt-Sn Heusler compound. This sample shows an order-disorder transition around 400 K, followed by a spin-reorientation transition at low temperature. Our magnetization and ac-susceptibility measurements display a similar type of behavior that generally found in the skyrmion system. We have performed high resolution Lorentz transmission electron microscopy measurements to get a direct evidence of skyrmions in Mn-Pt-Sn sample. Our results show evolution of skyrmions in particular fields and temperature intervals.

1:03PM G31.00009 ABSTRACT WITHDRAWN
1:15PM G31.00009 Z2 symmetry-protected topological phases in SU(3) AKLT model. TAKAHIRO MORIMOTO, HIROSHI UEDA, TSUTOMU MOMOI, AKIRA FURUSAKI, RIKEN — We study Z2 symmetry-protected topological (SPT) phases in one-dimensional systems with Z2 × Z2 symmetry. We construct MPS wavefunctions for Z2 SPT phases by using non-trivial cocycles of the group cohomology H2(Z2 × Z2, U(1)) = Z2. Their parent Hamiltonian turns out to be an SU(3) version of the AKLT model consisting of bilinear and biquadratic terms of su(3) operators in the Z representation. We apply iDMRG method to the SU(3) bilinear-biquadratic model of general coupling constants. We determine its phase diagram in which the nontrivial Z2 SPT phase is present for a parameter range including the point of vanishing biquadratic term as well as the SU(3) AKLT point. We find a continuous phase transition from the Z2 SPT phase to an SU(3) dimer phase, where we obtain a central charge c = 16/5 from a scaling of the entanglement entropy. We also discuss that an S = 1 spin chain with staggered quadrupole couplings reduces to the SU(3) AKLT model in the strong coupling limit.

1:27PM G31.00010 Symmetry fractionalization in SU(2n) antiferromagnetic Heisenberg chains, ANDREAS WEICHSELBAUM, Ludwig Maximilians University, THOMAS QUELLA, University of Cologne — We explore generalizations of the Affleck-Kennedy-Lieb-Tasaki (AKLT, 1987) model for spin-1 antiferromagnetic Heisenberg chains to higher-rank SU(2n) symmetries. In particular we show that by proper tuning of higher order spin interactions there also exist exact low-dimensional matrix-product ground states with fractionalized edge states, and that these states are adiabatically connected to the ground state of the plain SU(2n) Heisenberg model. The parameter space is explored using state of the art density matrix renormalization group (DMRG), explicitly utilizing SU(N) symmetry up to N=6 based on the QSpace tensor library.

1:39PM G31.00011 Unusual Magnetic Response of an S = 1 Antiferromagnetic Linear-Chain Material, J.S. XIA, M.W. MEISEL, Dept. of Physics and NHMFL, Univ. of Florida, A. OZAROWSKI, NHMFL, Florida State Univ., P.M. SPURGEON, A.G. GRAHAM, J.L. MANSON, Dept. of Chem. and Biochem., Eastern Washington Univ. — An S = 1 antiferromagnetic polymeric chain, [Ni(HF2)3(Cpy)]BF4 (py = pyridine), has been identified to have nearest-neighbor antiferromagnetic interaction J/kB = 4.86 K and single-ion anisotropy D/kB = 4.3 K, while avoiding long-range order down to 25 mK. With D/J = 0.88, this system is close to the D/J ≈ 1 gapless quantum critical point between the topologically distinct Haldane and Large-D phases. The magnetization was studied over a range of temperatures, 50 mK ≤ T ≤ 1 K, and magnetic fields, B ≤ 10 T. The results allow an upper bound of the critical field, Bc, which closes the Haldane gap, to be estimated. Specifically, Bc(4.2 K) < (35 ± 10) mT, which is close to the predicted 46 mT [1] when using the reported 12 values of J, D, and g. In low fields, the magnetic signal increases with decreasing T for 400 mK < T < 800 mK but is independent of T for 50 mK ≤ T < 400 mK. This observation is consistent with a significant increase in the specific heat arising from the accumulation of entropy in the vicinity of the quantum critical point.

1:51PM G31.00012 Evolution of Spinons with Magnetic Heavy Fermion Yb2Pt2Pb1, W.J. GANNON, L. WU, Stony Brook University, USA, I.A. ZALIZNYAK, Brookhaven National Laboratory, USA, F. DEMME, Rutherford Appleton Laboratory, UK, M.C. ARONSON, Stony Brook University and Brookhaven National Laboratory, USA — The antiferromagnetic (AF) metal Yb2Pt2Pb has a layered crystal structure, with Yb ions arranged in chains along the c-axis, while pairs of chains form orthogonal dimers in the tetragonal a-b plane, an in-plane structure that is topologically equivalent to the Shasyu-Sutherland lattice (SSL). In zero magnetic field, 70% of the magnetic spectral weight is static, consisting of AF Bragg peaks corresponding to moments that order at TN = 2.07 K, while fluctuations of the Yb moments, present even at T = 0, are responsible for the remaining 30%. The low energy magnetic excitation spectrum observed in neutron scattering experiments is unambiguously one-dimensional, consisting exclusively of gapped, Heisenberg-like spinons that disperse along the Yb chain direction, while remaining dispersionless in the SSL layers. As field is increased, the static magnetic order is suppressed and a rapidly evolving set of longitudinal modes with dispersions both parallel and perpendicular to the Yb chains is observed, until the Yb moments are fully polarized at fields above 2.3 T. This places Yb2Pt2Pb very near but on the ordered side of the quantum critical point that links quantum mechanical Heisenberg and classical Ising physics in one dimension.

11:15AM G32.00001 Strain driven anisotropic magnetoresistance in antiferromagnetic La0.4Sr0.6MnO3 thin films, T. ZAC WARD, Oak Ridge National Laboratory, A.T. WONG, University of Tennessee, YAYOI TAKAMURA, University of California, Davis, ANDREAS HERKLOTZ, Oak Ridge National Laboratory — Antiferromagnets (AFM) are a promising alternative to ferromagnets (FM) in spintronic applications. The reason stems from the fact that at high data storage densities stray fields could destroy FM set states while AFMs would be relatively insensitive to this data corruption. This work presents the first ever example of antiferromagnetic La0.4Sr0.6MnO3 thin films stabilized in different strain states. Strain is found to drive different types of AFM ordering, and these variations in ordering type are shown to have a profound impact on both the magnitude and character of the materials' resistive response to magnetic field direction, or anisotropic magnetoresistance (AMR) behavior (one standard of spintronic suitability). The compressively strained film shows the highest recorded AMR response in an ohmic AFM device of 63%, while the tensile strained film shows a typical AFM AMR of 0.6%. These findings demonstrate the necessity of understanding electron ordering in AFM spintronic applications and provide a new benchmark for AMR response.

11:27AM G32.00002 Magnetic anisotropy and anisotropic damping in LSMO/STO(001). HANKYU LEE, IGOR BARSKOV, LIU YANG, University of California, Irvine, ADRIAN SWARTZ, BONGJU KIM, HAROLD HWANG, Stanford University, ILYA KRIVOROTOV, University of California, Irvine — La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO) is a promising material for spintronics applications due to its half-metallic nature. To successively exploit LSMO, both the anisotropy (MA) and damping need to be well understood and, ultimately, controlled. Here, we study 30 nm epitaxial LSMO thin films grown by pulsed laser deposition on TiO$_2$ terminated (001)SrTiO$_3$. By means of angle- and frequency dependent ferromagnetic resonance (FMR) at room temperature, we separate various contributions to the in-plane MA: i) The four-fold magnetocrystalline anisotropy is present but negligibly small. ii) The strongest contribution $B_{uni} = 4.2$ mT is uniaxial with EA along [010]. While uniaxial MA in LSMO systems is commonly related to terrace formation from the substrate miscut, we find that the terrace direction and the MA symmetry axis do not correlate, indicating a different origin of the MA. By evaluating the FMR linewidth, three nonlinear magnetic damping channels due to the two-magnon scattering are found: j) The dominant four-fold contribution with maxima along $<100>$ axes emerges due to the crystalline defects. jj) A two-fold contribution with the maximum along [010] and jjj) a small two-fold contribution with maximum perpendicular to the terraces are identified.

11:39AM G32.00003 Anisotropic magnetotransport behavior in electronic phase-separated La$_{0.67}$Ca$_{0.33}$MnO$_3$ (LCMO) films under anisotropic strain$^1$. LONGQIAN HU, LIUQI YU, STEPHAN VON MOLNAR, PENG XIONG, Florida State University, LINGFEI WANG, WENBIN WU, University of Science and Technology of China — Anisotropic transport measurements have been performed on LCMO films grown on NdGaO$_3$ (001) substrates. Three samples from a film 48 nm thick were post-annealed for 1.5h, 5h and 20h to produce increasing degrees of anisotropic strain, which promotes electronic phase separation (PS). As demonstrated previously, the presence and growth of antiferromagnetic insulating (AFI) regions in the samples can be controlled by the strain, resulting in a state of coexisting ferromagnetic metallic (FMM) and AFI domains. To study the effects of the strain anisotropy on the PS and formation of the AFI states, we carried out simultaneous magnetotransport measurements along the two orthogonal in-plane directions using an L-bar geometry. Substantial anisotropy in the temperature and magnetic field dependent resistivity between the two directions was observed, implying the formation of the AFI states has an orientation preference under the anisotropic strain. These differences are dramatically enhanced with increasing strain. Furthermore, accompanying the emergence of the AFI states, a glass-like behavior signified by time relaxation was observed in the field-dependent resistivity, which provides new insight into the dynamics of the phase-separated AFI and FMM domains.

11:51AM G32.00004 Critical thickness for ferromagnetism in LaMnO$_3$ films. HANS HILGENKAMP, MESA+ Institute for Nanotechnology, University of Twente, The Netherlands — We studied LaMnO$_3$ (001) films, deposited by pulsed laser deposition, with thicknesses ranging from 1 unit cell to 24 unit cells. Using Scanning SQUID Magnetic Microscopy, the local magnetization was mapped for these films with micrometer resolution. We find that the magnetic ground state of the films switches sharply from antiferromagnetic to ferromagnetic state when the film thickness exceeds a critical value of 5 unit cells. The films remain electrically insulating. The magnetic transition at the critical thickness is qualitatively explained in terms of an internal electronic reconstruction in the polar LaMnO$_3$ thin films, driven by a polar catastrophe.

12:27PM G32.00005 Tunneling Anisotropic Magnetoresistance with Half-Metallic Electrodes. J .D. BURTON, EVGENY T. TSYPMBAL, University of Nebraska - Lincoln — Tunneling anisotropic magnetoresistance (TAMR) is the difference in resistance of a magnetic tunnel junction due to a change in direction of the magnetization of one or both of the magnetic electrodes with respect to the flow of current, i.e. tunnel magnetization in the plane differs from magnetization out of the plane. The origin of the effect is spin-orbit coupling (SOC). We will present results of first-principles density functional calculations of the TAMR effect in a half-metallic material, i.e., a metal that has free carriers only in one spin channel. In particular we explore the TAMR effect in magnetic tunnel junctions with La$_{0.75}$Sr$_{0.3}$MnO$_3$ (LSMO) electrodes and a SrTiO$_3$ (STO) tunneling barrier. We find ~ 500% difference in resistance between magnetization in the plane and out of the plane. This large TAMR effect originates from the half-metallic nature of LSMO: when magnetization is out-of-plane SOC contributions to the transmission comes only from spin-flip scattering, which is still inherently small due to the half-metallicity. For in-plane magnetization, however, there is a large non-spin-flip SOC contribution to the conductance. The spin-flip vs. non-spin-flip dichotomy along with the orbital character of the states on the Fermi surface of LSMO leads to the large TAMR effect. This effect should be a general feature of half-metallic or highly spin-polarized magnetic electrodes and could open the door to enhanced spintronic device functionalities.

12:39PM G32.00006 Metal-insulator transition at a surface of a ferromagnetic-metal La$_{0.75}$Ca$_{0.3}$MnO$_3$/SrTiO$_3$(100) thin film. ROYTA SHIMIZU, AIMAIR, Tohoku University, SHUNYA NAKAMURA, YASUNOBU ANDO, EMI MINAMITANI, Department of Materials Engineering, The University of Tokyo, KATSUYA IWAYA, RIKEN, AIMAIR in Tohoku University, TAKEO OHSAWA, NIMS, AIMAIR in Tohoku University, SATOSHI WATANABE, Department of Materials Engineering, The University of Tokyo, TAKAO OHSAWA, AIMAIR, Tohoku University, JST-PRESTO — We have performed low-temperature scanning tunneling microscopy/spectroscopy (STM/STS) measurements on a ferromagnetic-metal La$_{0.75}$Ca$_{0.3}$MnO$_3$/SrTiO$_3$(100) thin film surface. Our topographic images show two-domain zigzag patterns with $(\sqrt{2} \times \sqrt{2})$ periodicities in the perovskite structure. In addition, we measured an energy gap at the Fermi level in our STS spectra, in contrast to the ferromagnetic-metal properties obtained by ensemble measurements. First-principle calculations suggest that the topmost zigzag structure is caused by the structural relaxation based on the orthorhombic nature in bulk, suppressing the carrier itinerancy.

12:51PM G32.00007 Magneto-thermoelectric transport in ferromagnetic La$_{2/3}$Sr$_{1/3}$MnO$_3$ thin films$^1$. CONG TINH BUI, FRANCISCO RIVADULLA, University of Santiago de Compostela — La$_{2/3}$Sr$_{1/3}$MnO$_3$ (LSMO) thin films have been widely utilized in spintronics because of its nearly full spin-polarization and high Curie temperature. However, the spin-dependent thermoelectric effects in this material such as spin Seebeck effect (SSE), anomalous Nernst effect (ANE), planar Nernst effect (PNE), which might either interfere the performance of the spintronic devices or be utilized for other potential applications, have not been attended adequately. Herein, we present the observation of PNE and ANE in thin films of LSMO grown epitaxially on SrTiO$_3$ substrate. Through a careful control of the thermal gradients, the ANE can be suppressed and separated from the symmetric PNE response. The observation of sign change of ANE over the temperature, which can be understood in terms of Mott relation between anomalous Nernst and Hall coefficients, leads to the intrinsic scattering mechanism of anomalous Hall effect. We also observe a perfect correspondence between the magneto-thermal effects and their electrical counterparts. Finally, the absolutely comparable ANE and PNE signals using either Pt or Au exclude any contribution from SSE within our resolution limit.

1:03PM G32.00008 Bismuth Manganite Thin Film Characterization. DANIEL PAJEROWSKI, LISA KRAVER, BRUCE RAVEL, JULIE BORCHERS, National Institute of Standards and Technology, HYOUNG JEEN JEEN, Pusan National University, AMLAN BISWAS, University of Florida — We have performed detailed characterization of bismuth manganite (BMO) deposited via pulsed laser deposition onto crystalline strontium titanate. BMO is a ferromagnet that has a pseudo-perovskite structure. Actually, the structure deviates from perovskite depending upon growth conditions, and one important parameter is the oxygen content. Thin films of BMO are interesting because they can show ferroelectricity as well as ferromagnetism, but it is not entirely clear why. Another open question is why BMO films are reported to have much less magnetism than expected, based upon comparative measurements of BMO powders. Neutron reflectometry is useful to interrogate these issues because neutrons are sensitive to oxygen content and polarized neutrons can probe the depth dependence of magnetism. These neutron data are supported by high-resolution transmission electron microscopy, X-ray diffraction, and temperature dependent X-ray absorption studies. By considering these techniques in concert, a consistent model of the film is presented.

1:15PM G32.00009 Epitaxial growth of ultra thin films of electron doped manganites. SRIMANTA MIDDEY, M. KAREEV, D. MEYERS, X. LIU, Y. CAO, S. TRIPATHI, Department of Physics, University of Arkansas, Fayetteville, Arkansas 72701, USA, D. YAZICI, M.E. MAPLE, Department of Physics, University of California, San Diego, La Jolla, California 92093, USA, P.J. RYAN, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, J. CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville, Arkansas 72701, USA — We report on the fabrication of ultra-thin films of the electron doped manganese in a layer-by-layer growth mode on SrTiO3 (001) substrates by pulsed laser interval deposition. A combination of RHEED (reflection high energy electron diffraction), synchrotron based x-ray diffraction and x-ray absorption spectroscopy measurement confirmed the excellent structural, chemical, and electronic quality. All grown films show a ferromagnetic ground state as revealed by both dc magnetization and x-ray magnetic circular dichroism (XMCD) measurements and remain insulating. The present study opens exciting possibilities of merging this electron doped material with the other hole doped systems to fabricate oxide based spintronic junction.

1:27PM G32.00010 Enhancement of Magnetic Anisotropy in Ultrathin Epitaxial La0.67Sr0.33MnO3 Thin Films via Nanostructure Engineering. ANIL RAJAPITAMAHUNI, LE ZHANG, JOHN BURTTON, VIJAY SINGH, EVGENY TSYMBAL, XIA HONG, University of Nebraska-Lincoln — We report a more than ten-fold enhancement of magnetic anisotropy in nanostructured La0.67Sr0.33MnO3 (LSMO) thin films grown epitaxially on (001) SrTiO3 substrates. We have etched periodic linear trenches in 6 nm LSMO films, and investigated magnetic anisotropy in these nanostructured thin films via the planar Hall effect (PHE). These trenches have depth of 2 nm and periodicities of 200 - 400 nm. The PHE resistance of the un-patterned LSMO films exhibits sinusoidal angular dependence in an in-plane magnetic field, and shows four-fold sharp resistance switching below a critical magnetic field of 400 Oe, corresponding to a biaxial magnetic anisotropy of > 10^5 erg/cm^3 along <110> directions. In the nanostructured samples, we observe an additional two-fold resistance switching feature, which persists in magnetic fields higher than 4000 Oe, corresponding to a uniaxial magnetic anisotropy > 1x10^6 erg/cm^3 along one of the biaxial magnetic easy axes. This significant enhancement of magnetic anisotropy cannot be accounted for by shape anisotropy or a uniform strain modulation. We also discuss the effects of the orientation and periodicity of the nano-trenches on the anisotropy enhancement.

1:39PM G32.00011 ABSTRACT WITHDRAWN —

1:51PM G32.00012 Control of the magnetic properties of LaMnO3 epitaxial thin films grown by Pulsed Laser Deposition1. BENJAMIN MARTINEZ, ICMAB - CSIC, JAUME ROQUETA, ICN2, Institut Catala de Nanociencia I Nanotecnologia, ALBERTO POMAR, LLUIS BALCELLS, CARLOS FRONTERA, ZORICA KONSTANTINOVIC, FELIP SANDIUMENG, ICMAB - CSIC, JOSE SANTISO. ICN2, Institut Catala de Nanociencia I Nanotecnologia, ADVANCED MATERIALS CHARACTERIZATION TEAM, THIN FILMS GROWTH TEAM — LaMnO3 (LMO), the parent compound of colossal magnetoresistance based manganites has gained renewed attention as a building block in heterostructures with unexpected properties. In its bulk phase, stoichiometric LMO is an A-type antiferromagnetic (AFM) insulator (T_N = 140K) with orthorhombic structure that easily accommodate an oxygen excess by generating cationic (La or Mn) vacancies. As a result, a fraction of Mn^{4+} changes to Mn^{4+} leading to a double-exchange mediated ferromagnetic (FM) behavior. In thin films the AFM phase has been elusive up to now and thin films with FM ordering are usually reported. In this work, we have systematically studied the growth process of LaMnO3 thin films by pulsed laser deposition on SrTiO3 (001) substrates under different oxygen partial pressures (PO2). A close correlation between the structure (explored by XRD) and the magnetic properties (SQUID measurements) of the films with PO2 has been identified. At high PO2 FM behavior is observed. In contrast, at very low PO2, the results obtained for unit cell volume (close to stoichiometric bulk values) and magnetic moment (0.2 µB/Mn) strongly indicate antiferromagnetic ordering.

1We acknowledge financial support from the Spanish MINECO (MAT2012-33207).

2:03PM G32.00013 Electrical transport and magnetic properties of epitaxial LSMO films grown on STO substrates1. WEI YUAN, YUELEI ZHAO, TANG SU, QI SONG, WEI HAN, Peking Univ., JING SHI, University of California, Riverside — La0.7Sr0.3MnO3 (LSMO) is a very attractive material for spintronics due to its half-metallic ferromagnetic properties. The LSMO films are epitaxially grown on STO (100) substrates using pulsed laser deposition. The effects of substrate temperature, laser power, oxygen pressure, and annealing on the LSMO growth are systematically investigated by the reflection high energy electron diffraction and atomic force microscopy. Under the optimized growth condition, we have achieved atomically flat LSMO thin films with a wide terrace width of more than 5 micro-meters. The electrical transport properties of LSMO films with various thicknesses ranging from 8 to 20 monolayers are studied by measuring the resistivity as a function of temperature. We find that the growth condition plays an important role in the critical film thickness for the metal-insulator transition and the Curie temperature.

11:15 AM G33.00001 Bulk Modulus of Spherical Palladium Nanoparticles by Chen-Mobius Lattice Inversion Method\textsuperscript{1}, ESAM ABDUL-HAFIDH, Yanbu University College — Palladium is a precious and rare element that belongs to the Platinum group metals (PGMS) with the lowest density and melting point. Numerous uses of Pd in dentistry, medicine and industrial applications attracted considerable investment. Preparation and characterization of palladium nanoparticles have been conducted by many researchers, but very little effort has taken place on the study of Pd physical properties, such as, mechanical, optical, and electrical. In this study, Chen-Mobius lattice inversion method is used to calculate the cohesive energy and modulus of palladium. The method was employed to calculate the cohesive energy by summing over all pairs of atoms within palladium spherical nanoparticles. The modulus is derived from the cohesive energy curve as a function of particles’ sizes. The cohesive energy has been calculated using the potential energy function proposed by (Rose et al., 1981). The results are found to be comparable with previous predictions of metallic nanoparticles.

11:27 AM G33.00002 Using magnetization measurements to detect small amounts of plutonium hydride formation in plutonium metal. C.H. MIELKE, Los Alamos Natl Lab, J.W. KIM, Rutgers Center for Emergent Materials, E-D. MUN, Simon Fraser University; J.P. BAIARDO, A.I. SMITH, S. RICHMOND, J. MITCHELL, D. SCHWARTZ, V.S. ZAPF, Los Alamos National Laboratory — We report the formation of plutonium hydride in 2 at.% Ga-stabilized $\delta$-Pu, with 1 atomic % H charging. We show that magnetization measurements are a sensitive, quantitative measure of ferromagnetic plutonium hydride against the nonmagnetic background of plutonium. It was previously shown that at low hydrogen concentrations, hydrogen forms super-abundant vacancy complexes with plutonium, resulting in a bulk lattice contraction. Here we use magnetization, X-ray and neutron diffraction measurements to show that in addition to forming vacancy complexes, at least 30% of the H atoms bond with Pu to precipitate PuH$_x$, largely on the surface of the sample with $x \sim 1.9$. We observe magnetic hysteresis loops below 40 K with magnetic remanence, consistent with precipitates of ferromagnetic PuH$_{1.9}$.

11:39 AM G33.00003 Influence of van der Waals corrected xc-functional on the anisotropic mechanical properties of coinage metals. JI-HWAN LEE, JONG-HUN PARK, YOUNG-KWANG JUNG, ALOYSIUS SOON, Global E3 Institute and the Department of Materials Science and Engineering, Yonsei University, Seoul 121-749, South Korea — Current materials-related calculations employ the density-functional theory (DFT), commonly using the (semi-)local-density approximations for the exchange-correlation (xc) functional. The accuracy to studying the electronic structure depends not only on the employed approximation to the xc potential but also upon the system which is being investigated. The difficulties in arriving at a reasonable description of van der Waals (vdW) interactions by DFT-based models, is to date a big challenge. This stems from the well-known fact that vDW interaction is a non-local correlation effect which is not captured in the deployed (semi-)local xc functionals. In this work, using various flavours of vdw-corrected DFT xc functionals, we study the lattice and mechanical properties (including the elastic constants and anisotropic stress-strain curves) of the coinage metals (copper, silver, and gold), and critically assess the reliability of the different vdW-corrected DFT methods in describing their anisotropic mechanical properties which are less reported on in the literature.

11:51 AM G33.00004 High-precision study of time- and temperature-dependence of the elastic properties of $^{239}$Pu. B. MAJOROV, B.J. RAMSHAW, Los Alamos National Laboratory, A. SHEKHTER, National High Magnetic Field Laboratory, J.B. BETTS, F. FREIBERT, A. MIGLIORI, Los Alamos National Laboratory — It is important to determine the origin of changes in elastic properties in $^{239}$Pu as a function of time. The measurement of mechanical resonance frequencies can be made with extreme precision and used to compute the elastic moduli without corrections giving important insight in this problem. The precision of these measurements enabled observation of changes in elastic properties of 1 part in 107 for measurements lasting hours up to several days. The most likely source of these changes include a) ingrowth of radioactive decay products such as He and U, b) the introduction of radiation damage, c) phase instabilities associated with transformations to the delta phase or to Pu$_2$Ga. Using Resonant Ultrasound Spectroscopy, measurements were made of the mechanical resonance frequencies of 300mg cylinders of fine-grained polycrystalline alpha-phase $^{239}$Pu with about 600PPM Ga. We present the surprising result that at temperatures below 60K, there is a strong dependence on temperature of the rate of change of elastic moduli with time. Older results showed that the sign of this rate of change reverses at higher temperature. Such studies of nascent state are key to exploring damage evolution and its impact on specific volume and elastic moduli. Future studies will continue these measurements to above ambient temperatures.

12:03 PM G33.00005 First-principles study of energy, structure and atomic solubility of twinning-associated boundaries in hexagonal metals. ANIL KUMAR, JIAN WANG, CARLOS TOME, Los Alamos National Laboratory — HCP metals are widely used as structural materials in many industries, ranging from transport and energy to biomedical applications due to their low density, high specific strength. Twining is one of the important plastic deformation modes in HCP metals. Understanding atomic structure and damage evolution and its impact on specific volume and elastic moduli. Future studies will continue these measurements to above ambient temperatures.

12:15 PM G33.00006 Ti$_{1-x}$Au$_x$ Alloys: Hard Biocompatible Metals and Their Possible Applications\textsuperscript{1}, ETERI SVANIDZE, Rice University, TIGLET BESARA, Florida State University, M. FEVIZI OZAYDIN, Texas A&M, YAN XIN, KE HAN, Florida State University, HONG LIANG, Texas A&M, THEO SIEGRIST, Florida State University, EMILIA MOROSAN, Rice University — The search for new hard materials is often challenging from both theoretical and experimental points of view. Furthermore, using materials for biomedical applications calls for alloys with high biocompatibility which are even more sparse. The Ti$_{1-x}$Au$_x$ (0.22 \leq x \leq 0.8) exhibit extreme hardness and strength values, elevated melting temperatures (compared to those of constituent elements), reduced density compared to Au, high malleability, bulk metallicity, high biocompatibility, low wear, reduced friction, potentially high radio opacity, as well as osseointegration. All these properties render the Ti$_{1-x}$Au$_x$ alloys particularly useful for orthopedic, dental, and prosthetic applications, where they could be used as both permanent and temporary components. Additionally, the ability of Ti$_{1-x}$Au$_x$ alloys to adhere to ceramic parts could reduce the weight and cost of these components.

\textsuperscript{1}The work at Rice was supported by NSF DMR 0847081 (E.M. and E.S.).
12:27PM G33.00007 Ab initio phase stability at high temperatures and pressures in the V-Cr system. ALEXANDER LANDA, PER SODERLING, LIN YANG, Lawrence Livermore National Laboratory — Vanadium metal has seen a surge in research, experimental and theoretical, driven mainly by its importance in applications but also because of its surprising destabilization of the body-centered cubic (bcc) ground-state phase close to 60 GPa. The phase stability of vanadium metal and vanadium-chromium alloys at high temperatures and pressures is explored by means of first-principles electronic-structure calculations. Utilizing the self-consistent ab initio lattice dynamics approach in conjunction with density-functional theory, we show that pressure-induced mechanical instability of body-centered cubic vanadium metal, which results in formation of a rhombohedral phase at around 60 GPa at room temperature, will prevail significant heating and compression. Further, employing the transition state theory at high stabilization of the body-centered cubic phase occurs at elevated pressure. Computing support for this work came from the LLNL Computing Grand Challenge program. This work performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344 and funded by the Laboratory Directed Research and Development Program at LLNL under project tracking code 11-ER-033.

12:39PM G33.00008 Structure and dynamics of bulk liquid iron near melting. A first principles study1. DAVID J. GONZALEZ, MIRIAM MARQUES, LUIS E. GONZALEZ, Dept. Fisica Teorica, Atomica y Optica, Facultad de Ciencias, Universidad de Valladolid, 47011 Valladolid — First principles molecular dynamics simulations, based on the density functional theory and the projector augmented wave technique, have been performed in order to study several static and dynamic properties of bulk liquid Fe at a thermodynamic state near melting. As for the static properties, the obtained results for the pair distribution function and the static structure factor show a good agreement with the available X-ray and neutron diffraction data. The calculated dynamical principle reveals collective density excitations with an associated dispersion relation which closely follows recent experimental data; moreover, its slope at the long-wavelength limit provides an estimate for the velocity of sound. The dynamical structure factors have been calculated and they are compared with their experimental counterparts, which have recently been measured by inelastic X-ray diffraction experiments. Finally, results are also reported for some transport coefficients.

12:51PM G33.00009 Evidence for reentrant strain glass behavior in a ferroelastic-martensitic system Ti-Pd-V. XIAOMING ZHANG, GUIZHOU XU, ENKE LIU, WENHONG WANG, GUANGHENG WU, Institute of Physics, Chinese Academy of Sci (CAS), INSTITUTE OF PHYSICS TEAM — The concept of strain glass (SG) has recently received much attention because of its unique properties such as shape memory effect, superelasticity, and stress-tuned intelligent damping behavior. Recent in-situ TEM experiments have proved that, only local-symmetry change in the crystal structure has been observed during the SG transition, but the macroscopic symmetry of the structure is still not completely uncerntained. In this presentation, we report the discovery of reentrant-strain-glass (RSG) behavior in a ferroelastic-martensitic system Ti50Pd50-Vx (x is from 6 to 12). Unlike the SG, with decreasing of temperature, the RSG system first undergoes a macroscopic martensitic transition and then the martensite variants further transforms to a frustrated glassy state below a critical temperature. The X-ray diffraction and high resolution TEM results further indicate the RSG no longer remains the average structure of the high-temperature parent phase, but rather low-temperature martensitic phase. This new discovery may open a new research field and may lead to new insights into a range of possible applications of this unique class of materials.

0:03PM G33.00010 Studying the enhanced ductility in bimodal nanocrystalline metals using a model with tunable crystallinity and crystallite stiffness. GUO-JIE JASON GAO, Department of Mechanical Engineering, National Taiwan University, YUN-JIANG WANG, Institute of Mechanics, Chinese Academy of Sciences, SHIGENOBU OGATA, Department of Mechanical Science and Bioengineering, Osaka University — We propose a polycrystalline model composed of small and large particles, where crystallinity and stiffness of each crystallite can be separately tuned by varying the number ratio of small/large particles [H. Shiba et al., Phys. Rev. E. 81, 051501 (2010)], and implementing 2D molecular dynamics (MD) simulations to study the shear deformation of the model consist of stiff crystallites, soft crystallites, or stiff and soft crystallites. We find the flow stress increases monotonically with increasing crystallite stiffness, and it can be systematically adjusted via changing the ratio of soft/stiff crystallites. We address the application of our results to study the enhanced ductility found in bimodal nanocrystalline metals, where shear localization and propagation are presumably weakened due to crystallites of two properties.

1:15PM G33.00011 Magnetic and Structural Properties in Non-Stoichiometric Gallium Deficient Ni2MnGa1−x Heusler Alloys, IAN FERRALLI, ANTHONY RUFFINO, MICHAEL PIERCE, LINDA BARTON, Rochester Institute of Technology — Magnetic data show that off-stoichiometric gallium deficient Heusler alloys of the form Ni2MnGa1−x have martensite transition temperatures that increase strongly with x, while their ferromagnetic Curie temperatures remain nearly unchanged. The martensite transition approaches room temperature for x = 0.13. Within the tetragonal martensite phase, bulk magnetic properties depend strongly on stresses within the sample. These effects were investigated using neutron and X-ray diffraction and neutron scattering experiments. These treatments effect the bulk coercivity but do not move the transition temperatures. As the martensite forms, lattice elongations of >3% are observed using XRD. Domain properties are reported, for both structural grains and magnetic ones, within the martensite phase, from optical and MFM imaging.

1:27PM G33.00012 A search for new cobalt-based high temperature superalloys. CHANDRAMOULI NYSHADHAM, JACOB HANSEN, Brigham Young University, STEFANO CURTAROLO, Duke University - Center for Materials Genomics, GUS L.W. HART, Brigham Young University — The discovery of a high temperature Co0.5Al0.5W [1] superalloy has provided a promising avenue for further search of other Co-based superalloys. The L12 Co0.5Al0.5W system is found to have higher strength and melting temperature than common Ni-based alloys. The high strength of super alloys is generally attributed to the stable or metastable austenitic face-centered cubic crystal structure. We performed an extensive series of ab-initio calculations to search for stable or metastable Co-based ternary alloys of the form Co5Al5W5. A 32 atom cell special quasi random structure (SQS-32) is considered to mimic the properties of the alloy at high temperatures. The DFT calculations for over 780 different Co-based ternary systems and the potential candidates of the future high temperature super alloys is presented.

1:39PM G33.00013 Ab Initio Investigation of He Bubbles at the Y2Ti2O7-Fe Interface in Nanostructured Ferritic Alloys, CELINE HIN, THOMAS DANIELSON, Virginia Tech — Nanostructured ferritic alloys are promising materials candidates for the next generation of nuclear reactors due to their ability to withstand high temperatures and pressures, high neutron flux and especially, the presence of high concentrations of transmutation product helium. As helium diffuses through the matrix, large number densities of complex oxide nanoclusters act as trapping sites for individual helium atoms and helium clusters. Consequently, there is a significant decrease in the amount of helium that reaches grain boundaries, mitigating the threat of pressurized bubble formation and embrittlement. In order to understand the trapping phenomena of the oxides, the interface between the nanoclusters and the iron matrix must be modeled. We present results obtained using density functional theory on the structural and thermodynamic properties of the Y2Ti2O7-Fe interface containing helium. In addition, helium bubbles of varying sizes have been introduced in order to observe the effects of a growing helium bubble.
it is unclear how coverage efficiency competes with mechanical cost as thickness is decreased, and what wrapping shapes will emerge. We characterize these phenomena and propose explanations.

1 Supported by the US DOE under Contract No. DEAC02-05CH11231 under the Materials Project Center grant (award no. EDCBEE).

RADHAKRISHNA T G, ANIL VIR, JASON PICARDO, PUSHPAVANAM SUBRAMANIAM, Indian Institute of Technology Madras — In this work, the effect of Marangoni flows on mass transfer is investigated for stratified flow of two immiscible liquids in a microchannel. Experiments involving reactive extraction of carboxylic acids from organic phase using aqueous sodium hydroxide are performed. Often in analysis, the liquid-liquid interface is assumed to be flat. However, a deforming interface was observed for certain flow rate ratios. The conditions under which the interface deforms are determined. The experiments are complemented with mathematical modeling and simulation. Navier-Stokes equation and transport equation are simplified using the lubrication approximation and an approximate solution is obtained. The interphase mass transfer and hydrodynamics are coupled through the shear stress boundary condition. In cases where the interface is flat, the transport equation is solved numerically using finite difference method. In cases where the interface deforms, the evolution of interface is captured using kinematic boundary condition and the transport equation is solved numerically.

11:27AM G34.00002 Radiation Pressure Induced Nonlinear Optofluidics in Liquid Droplets1, 2, PENG ZHANG, SUNGHWAN JUNG, Department of Biomedical Engineering and Mechanics, Virginia Tech, Blacksburg, VA 24060, YONG XU, ARAM LEE, Department of Electrical and Computer Engineering, Virginia Tech, Blacksburg, VA 24060 — In the present study, we analyze a nonlinear optofluidic process associated with a high quality (Q) factor whispering gallery mode (WGM) in liquid droplets. Optical radiation pressure induced droplet deformation can produce a frequency shift proportional to the WGM power. Droplet deformation will be obtained both theoretically and numerically by boundary element method. We will show that the nonlinear optofluidic effect is stronger than temperature-induced nonlinearity. Using liquid properties that are experimentally attainable (e.g., oil drop in water), we find that measurable WGM resonance shift may be generated by only a few photons. This technique may also lead to the possibility of fluid viscosity and interfacial tension measurement by non-destructive optical forces.

11:39AM G34.00003 From viscous to elastic sheets: Dynamics of smectic freely floating films1, 2, KIRSTEN HARTH, KATHRIN MAY, TORSTEN TRITTEL, RALF STANNARIUS, Otto von Guericke University Magdeburg — Oscillations and rupture of bubbles, composed of an inner fluid separated from an outer fluid by a membrane, represent an old but still immensely active field of research. Membrane properties except surface tension are often neglected for simple fluid films (e.g. soap bubbles), whereas they govern the dynamics in systems with more complex membranes (e.g. vesicles). Due to their layered phase structure, smectic liquid crystals can form stable, uniform and easy-to handle fluid films of immense aspect ratios. Recently, freely floating bubbles detached from a support were prepared. We analyze the relaxation from strongly non-spherical shapes and the rupture dynamics of such bubbles using high-speed video recordings. Peculiar dynamics intermediate between those of simple viscous fluid films and an elastic response emerge: Oscillations, slowed relaxation and even the formation of wrinkles and extrusions. We characterize these phenomena and propose explanations.

11:51AM G34.00004 Thin sheets achieve optimal wrapping of liquids 1, JOSEPH PAULSEN, VINCENT DÉMERY, BENNY DAVIDOVITCH, CHRISTIAN SANTANGELO, THOMAS RUSSELL, NARAYANAN MENON, Univ of Mass - Amherst — A liquid drop can wrap itself in a sheet using capillary forces [Py et al., PRL 98, 2007]. However, the efficiency of “capillary origami” at covering the surface of a drop is hampered by the mechanical cost of bending the sheet. Thinner sheets deform more readily by forming small-scale wrinkles and stress-focussing patterns, but it is unclear how coverage efficiency competes with mechanical cost as thickness is decreased, and what wrapping shapes will emerge. We place a thin (~ 100 nm) polymer film on a drop whose volume is gradually decreased so that the sheet covers an increasing fraction of its surface. The sheet exhibits a complex sequence of axisymmetric and polygonal partial, and fully- wrapped shapes. Remarkably, the progression appears independent of mechanical properties. The gross shape, which neglects small-scale features, is correctly predicted by a simple geometric approach wherein the exposed area is minimized. Thus, simply using a thin enough sheet results in maximal coverage.
12:15PM G34.00006 Simple analytical model of evapotranspiration in the presence of roots. CESARE CEJAS, Laboratoire Microfluidique, MEMS, Nanostuctures (MMN), ESPCI, Paris, JEAN-CHRISTOPHE CASTAIN, Solvay Research and Innovation Centre-Aubervilliers, LARRY HOUGH, CNRS Complex Assemblies of Soft Matter COMPASS (UM13254), CHRISTIAN FREITIGNY, CNRS Sciences et Ingenerie de la Matiere Mole (SIMM) UMR7615, REMI DREYFUS, CNRS Complex Assemblies of Soft Matter COMPASS (UM13254), COMPASS TEAM — Water is essential for plant growth. The loss of water via evaporation in soil remains to be an important limiting factor for root growth and consists of well-debated mechanisms. The presence of a plant also provides an additional pathway for water transport in the form of transpiration. Prediction of total evapotranspiration flux permits estimation of the remaining quantity of water in the soil. Using a controlled visual 2D model set-up, we perform evaporation experiments with real root systems under different relative humidity conditions. We use the results on mass loss and evaporation front positions to develop a simple model, based on basic principles of evaporation flux, which predicts the position of the evaporating front and the total mass of water that is lost from the evapotranspiration of water out of the granular medium. The model also helps predict the lifetime of the plant — an important application in agriculture.

12:27PM G34.00007 Growth and densification of frost around a circular cylinder under humid air on cross flow1. VICTOR MADRID, FAUSTO SANCHEZ, SIMON MARTINEZ, ARTURO MORALES, UNIVERSIDAD AUTONOMA DE NUEVO LEON, FIME — Formation, growth and densification of frost around a circular cylinder under humid air on cross flow at different Reynolds numbers has been numerically studied using the finite volume method. The frost formation phenomenon takes place when humidity goes through a desublimation phase change at a temperature lower than its solidification point. Continuity, momentum, energy and mass transport equations have been solved for a whole domain including both phases, gas and solid, and the two components in the gas phase, i.e. dry air and humidity. The mass of water that goes from the gas to the solid phase is used as a source term in the mass conservation equation for solid phase and as a sink for the gas phase, affecting source terms in all the other conservation equations (energy and momentum) also. A volume of fraction conservation equation for solid phase is used to obtain local fractions of ice droplets, considering formally as frost those fraction values greater than a critical value. Once those local fractions are known, local frost properties such as density and thermal conductivity can be calculated as functions of the phase fraction allowing to compute the evolution of growth and local properties of frost.

12:39PM G34.00008 Parallel magnetic resonance imaging of gas-liquid flows. CHRISTOPH MUELLER, Laboratory for Energy Science and Engineering, ETH Zurich, ALEXANDER PENN, Laboratory for Energy Science and Engineering, ETH Zurich and Institute for Biomedical Engineering, University and ETH Zurich, KLAAS P. PRUESSMANN, Institute for Biomedical Engineering, University and ETH Zurich — Gas-liquid flows are commonly encountered in nature and industry. Experimental measurements of gas-liquid flows are challenging since such systems can be visually opaque and highly dynamic. Here we report the implementation of advanced magnetic resonance imaging (MRI) strategies allowing us to probe the dynamics (voidage and velocity measurements) of gas-liquid flows with ultra-fast acquisition speeds. Specifically, parallel MRI which exploits the spatial encoding capabilities of multiple receiver coils was implemented. To this end a tailored, 16 channels MR receive array was constructed and employed in the MR acquisition. A magnetic susceptibility matched gas-liquid system was set-up and used to probe the motion, splitting and coalescence of bubbles. The temporal and spatial resolution of our acquired data was 5 ms and 3.5 mm x 3.5 mm, respectively. The total field of view was 200 mm x 200 mm. We will conclude with an outlook of future possible additional advances in MRI that have the potential to reduce substantially the acquisition time, providing flexible gains in temporal and spatial resolution.

12:51PM G34.00009 Air flows generated by an impacting drop. IRMGARD BISCHOFBERGER, Univ of Chicago, BAHNI RAY, TAEHUN LEE, JEFF MORRIS, CCNY, SIDNEY R. NAGEL, Univ of Chicago, UNIVERSITY OF CHICAGO COLLABORATION, CCNY COLLABORATION, — A drop impacting a solid surface with sufficient velocity will splash and emit many small droplets. Lowering the ambient air pressure suppresses splashing completely. This effect, robustly found for different liquid and substrate properties, raises the fundamental question of how air affects a spreading drop. We visualize the air induced capillary waves which sharpen a collision front. Computers with high-speed video imaging. Comparison with the air flow created by an impacting solid sphere allows us to decouple the vorticity components of the falling drop from that of the spreading liquid. Our studies reveal the emergence of vorticity on two length scales. On larger scales, the airflow induced in the drop’s wake leads to vortex structures due to interaction with the substrate. On smaller scales, the spreading of the drop generates a vortex ring above the outer edge of the spreading liquid. We show that this vorticity generation is governed by a balance between inertial and viscous forces.

1:03PM G34.00010 Flow reversing in the gas layer in droplet impact. ZHEN JIAN, PASCAL RAY, CHRISTOPHE JOSSENRAND, STEPHANE ZALESKI, Univ Pierre et Marie Curie — Recent numerical and experimental studies demonstrated the crucial role of surrounding gas in droplet impact. While the high pressure and high temperature gas effect in droplet splashing is still far from a crystal clear comprehension, Complicated dynamics occur in a small temporal and spatial scale before direct contact with the target surface, which are related to the origin of the splashing. Direct numerical simulations were executed with a code called Gerris for both droplet impact on a liquid surface and on a solid substrate. New dynamics in the gas layer between the droplet and the target surface were discovered. Unexpectedly, a “reversing” gas flow (towards the center) is observed as the droplet approaches the target surface. With further descending of the droplet, the flow is reversed and evacuates towards the outside. The reversing of the flow motion direction is followed by the pressure jump and the dimple formation which have been reported as some crucial gas dynamics in droplet splashing mechanism in our previous work. An aerodynamic mechanism is proposed for the flow reversing dynamics.

1:15PM G34.00011 Simulation of splashing of micro-scale droplets on a dry surface. ARNOUT BOELENS, ANDRZEJ LATKA, CACEY STEVENS, JUAN DE PABLO, University of Chicago — Results are presented for the simulation of micro-scale droplets splashing on a dry surface. The simulations are performed using a Volume Of Fluid approach and a Finite Volume technique. The contact line is described using a Generalized Navier Boundary Condition with a dynamic microscopic contact angle. Both the gas phase and the liquid phase are assumed to be incompressible. The results of these simulations show good agreement with experiments. Independent of the wetting properties of the surface, simulations reveal the formation of a liquid sheet with an apparent contact angle approaching 180 degrees. This liquid sheet breaks up into smaller droplets as the spreading progresses. When the pressure of the system is reduced, the droplet does not break up and splashing is suppressed. Depending on the velocity with which the contact line moves, different flow regimes are observed. One of these regimes involves air bubbles becoming entrained in the liquid phase, similar to what is observed during wetting failure in coating processes. Mesh resolution is critical to describe contact line behavior, liquid sheet formation, and to reproduce the effect of pressure. In this work, the resolution is of the order of 10 nm, and the droplets are several hundred microns large.
1:27PM G34.00012 Comparison of splashing of low- and high- viscosity liquids . CACEY STEVENS, ANDRZEJ LATKA, SIDNEY NAGEL. The James Franck Institute and Department of Physics, University of Chicago — The splash of a liquid drop on a dry surface was shown to be suppressed at low ambient air pressure [1-3]. However the mechanism by which air causes a drop to splash remains unresolved. This is further complicated by the finding that there are two distinct splashing regimes that depend on the viscosity of the liquid. Accordingly, we determine the evolution of splashing at both low and high viscosities. A high-viscosity drop splashes by emitting a thin sheet of liquid from the spreading drop long after it has first contacted the solid. This film subsequently breaks up into smaller droplets to form the splash. We have found that there is also a delay in the ejection of a thin sheet when a low-viscosity drop splashes. This suggests a common mechanism of delayed thin sheet ejection for splashing in both viscosity regimes. We also show how the ejection time of the thin sheet depends on liquid viscosity and ambient air pressure. [1] L. Xu, W. W. Zhang, and S. R. Nagel, Phys. Rev. Lett., 94(18), 184505 (2005). [2] L. Xu, Phys. Rev. E, 75(5), 056316 (2007). [3] A. Latka et. al., Phys. Rev. Lett., 109(5), 054501 (2012).

1:39PM G34.00013 Force response of actively deformed microdroplets: dependence on the solid/liquid boundary condition . JONAS HEPPPE, INM - Leibniz Institute for New Materials and Saarland University, Experimental Physics, D-66123, Saarbruecken, Germany, JOSHUA D. MCGRAW, Saarland University, Experimental Physics, D-66123, Saarbruecken, Germany, ROLAND BENNEWITZ, INM - Leibniz Institute for New Materials, D-66123, Saarbruecken, Germany, KARIN JACOBS, Saarland University, Experimental Physics and INM, D-66123, Saarbruecken, Germany — In fluid dynamics, the solid/liquid boundary condition can play a major role in the flow behavior of a liquid. For example, in the dewetting of identical polymer films on weak slip or strong slip substrates, large qualitative and quantitative differences are observed. Therefore, when applying an external load to a liquid resting on such substrates, the measured reaction forces and the ensuing flow should also depend on the boundary condition. We present atomic force microscopy measurements in which the reaction force of a cantilever is measured as the tip pierces liquid polymer micro sized droplets and films. These indentations are done on substrates with tuned slip. Accessing the size, depth and rate dependence of the resulting force distance curves, we show an influence of the slip condition on the dissipated energy and adhesion.

1:51PM G34.00014 Lyapunov Based Predictions of Droplet Shapes in Thermocapillary Driven Nanofilms , ZACHARY NICOLAOU, SANDRA TROAIN, California Institute of Technology, MC 128-95, Pasadena, CA — Previous work in our group has focused on the spontaneous formation of pillar arrays in nanoscale molten films subject to an extremely large transverse thermal gradient. The shape of these formations is influenced by the relative strength of thermocapillary to capillary forces which is strongly dependent on the system geometry, fluid properties, magnitude of the initial thermal gradient, and whether volume is conserved or not. Here we examine the parameter regime corresponding to steady state shapes resembling either isolated or extended sinusoidal-like waveforms. The stability of these one dimensional and axisymmetric shapes is investigated by a combination of Lyapunov analysis, asymptotic techniques and numerical simulations. Our findings indicate that radially symmetric arrays with small peak heights are linearly stable to perturbations. The existence of such stable states for parameter values accessible to experiment offers an intriguing route for non-contact fabrication of optical and photonic components.

2:03PM G34.00015 Improved Measurement of the 3D Dominant Mode Wavelength in NanoBénard Instability . KEVIN FIEDLER, SANDRA TROAIN, California Institute of Technology, MC 128-95, Pasadena, CA — Molten nanofilms exposed to an initial uniform and very large transverse thermal gradient ($10^5$ to $10^7$ C/cm) are prone to spontaneous formation and growth of nanopillars typically separated by tens of microns or less. Linear stability analysis of the corresponding interface equations suggest these formations result either from electrostatic attraction between the molten film and proximate substrate due to fluctuation induced surface image charge or fluctuation induced thermocapillary forces leading to 3D Bénard-like structures. In this talk, we discuss a number of improvements to our original experimental system including image analysis of structure formation at much earlier times. Our current measurements indicate even closer agreement with the thermocapillary mechanism proposed.

Tuesday, March 3, 2015 11:15AM - 2:03PM — Session G35 DAMOP: Dipolar Gases, Rydberg Atoms, Cold Molecules, and Few-body Systems 210B - Colin Parker, University of Chicago

11:15AM G35.00001 Roton phenomena and stability properties of dipolar condensates . ALEKSEY FEDOROV, Russian Quantum Center, IGOR KURBAKOV, YURIII LOZOVIK, Institute of Spectroscopy RAS — Experimental and theoretical studies of novel quantum phenomena in dipolar systems have a great impact for atomic physics. These systems provide an interface between physics of strongly and weakly correlated matter. Being typical for strongly correlated systems, the roton-maxon excitation spectrum, originally observed in superfluid helium, occurs to appear in a weakly interacting dipolar gas. Due to the contribution, two dipolar bosonic systems are under consideration: dipolar excitons in semiconductor layers of heterostructures and tilted dipolar particles in a quantum layer. In weak correlation regime, we predict a generation of the roton-maxon excitation spectrum for BEC of dipolar excitons in a semiconductor layer. We discuss observation of the roton-maxon spectrum for exciton BEC in GaAs heterostructures. We calculate the stability diagrams for 2D tilted bosonic dipolar particles in a quantum layer. Breaking of the rotational symmetry for a system of tilted dipoles leads to the appearance of optical and photonic components.

11:27AM G35.00002 Dipolar Quasi-2D Bosons with Non-zero Dipole Tilt Angle . PENGTAO SHEN, KHANDKER QUADER, Department of Physics, Kent State University, Kent, OH 44242 — We study properties of dipolar bosons in quasi-2D geometry, with dipoles oriented at an angle to the direction perpendicular to the confining 2D plane. Starting from time-dependent Gross-Pitaevskii equations, and the resulting Bogoliubov-de Gennes equations, we calculate the excitation spectrum of the Bose-Einstein condensate, and explore possible instabilities of the system as the tilt angle, system density and the relative strength of the dipole-dipole interaction are varied. We study how the depletion of the condensate varies with respect to these parameters. We also explore the effect of the anisotropic dipolar interaction on results in different momentum directions.

1A.K.F. is supported by the Dynasty Foundation fellowship
11:51AM G35.00004 Competing instabilities of a Dipolar Fermi Gas, AHMET KELES, George Mason University, University of Pittsburgh, ERHAI ZHAO, George Mason University — Recent experiments in the cold atom Fermi gas have explicitly shown the deformation of the Fermi surface in the presence of long range dipolar interactions. Motivated by this, we investigate the competing instabilities of a dipolar Fermi gas within the functional renormalization group approach. We analyze the flow of the effective action in the particle-particle as well as particle-hole channel, consider the self energy term, and discuss the interplay of different instabilities at low temperatures.

12:15PM G35.00006 Photonic Controlled-Phase Gate Based on Rydberg Interactions, MOHAMMADSADEGH KHAZALI, KHAMAT HESHAMI, CHRISTOPH SIMON, Institute for Quantum Science and Technology, University of Calgary — Photons are ideal carriers of information in quantum communication. Since they do not interact, the implementation of deterministic photonic quantum computation depends on the creation of a non-permanent strong interaction between single photons. The implementation of neutral Rydberg atom gates inspired the development of photonic gates, using the coherent reversible mapping of the quantum states of photons onto highly interacting Rydberg atoms. Here we propose an interaction-based two-qubit gate between photons stored in Rydberg levels of an atomic ensemble. We perform a detailed study of errors due to the many-body interaction between Rydberg spin-waves, and we propose a compensation scheme for these errors. Furthermore we completely separate interaction and propagation by eliminating the Rydberg level from the storage process. Our proposed controlled-phase gate can achieve 99% fidelity with current technology.

12:27PM G35.00007 Rydberg Impurity Probes in Ultracold Gases, MARK MITCHISON, Imperial College London, TOMI JOHNSON, National University of Singapore, University of Oxford, MARTIN PLENIO, Universität Ulm, Imperial College London, DIETER JAKSCH, University of Oxford, National University of Singapore — Impurities immersed in ultracold gases can act as highly sensitive, tunable and potentially non-destructive probes of their environment. In this setting, we propose the use of an atomic impurity in a Rydberg state to measure density fluctuations via Ramsey interferometry. The rapid collisional dynamics of the light Rydberg electron interacting with the heavy gas particles, combined with the capability to quickly change the state of the impurity with optical pulses, make such a probe ideal for measuring local properties of ultracold gases. Our proposed device promises angle-resolved density measurements with sub-micron spatial resolution, and with no need to integrate over the line of sight. We outline how Rydberg impurity probes could be applied to study various interesting quantum states of current experimental relevance. We also discuss the possibility of using multiple Rydberg atoms to extract the spatial pair distribution function \( g^{(2)}(r) \). Our work is placed in the context of other recently proposed impurity-based probes.

12:39PM G35.00008 Revealing the origin of super-Efimov states in the hyperspherical formalism, CHAO GAO, Institute for Advanced Study, Tsinghua University, Beijing 100084, China, JIA WANG, Department of Physics, University of Connecticut, STORRS, CONNECTICUT 06269 USA, ZHENHUA YU, Institute for Advanced Study, Tsinghua University, Beijing 100084, China — Quantum effects can give rise to exotic Borromean three-body bound states even when any two-body subsystems can not bind. An outstanding example is the Efimov states for certain three-body systems with resonant s-wave interactions in three dimensions. These Efimov states obey a universal exponential scaling that the ratio between the binding energies of successive Efimov states is a universal number. Recently a field-theoretic calculation predicted a new kind of universal three-body bound states for three identical fermions with resonant p-wave interactions in two dimensions. These states were called "super-Efimov" states due to their binding energies \( E_n \approx E_0 \exp(-2e^{\nu_0/n_0+\phi}) \) obeying an even more dramatic double exponential scaling. The scaling \( \phi_0 = 4/3 \) was found to be universal while \( E_0 \) and \( \theta \) are the three-body parameters. Here we use the hyperspherical formalism and show that the "super-Efimov" states originate from an emergent effective potential \(-1/4\rho^2-(\kappa_0+1/4)/\rho^2\ln^2(\rho)\) at large hyperradius \( \rho \). Moreover, our numerical calculation indicates that the three-body parameters \( E_0 \) and \( \theta \) are also universal for pairwise interparticle potentials with a van der Waals tail.

12:51PM G35.00009 Three-body scattering hypervolume for bosons with two-body repulsive Gaussian potentials, SHANGGUO ZHU, SHINA TAN, Georgia Inst of Tech — It has been known that the three-boson low energy effective interaction influences the dynamic and the static properties of many bosons, including the ground state energy of a dilute Bose-Einstein condensate. The three-body scattering hypervolume, which is a three-body analogue of the two-body scattering length, characterizes this effective interaction. For bosons with two-body repulsive Gaussian potentials, we determine the scattering hypervolume by solving the three-body Schrödinger equation numerically, and matching the solution with the asymptotic expansions for the wave function at large hyperradii.
or simply by the interfaces themselves, effects a splitting in the topological degeneracy which generally scales as $L^2$, where $L$ is the size of the system and $K$ is the Luttinger parameter. However, when the interfaces are sufficiently smooth, as in the case of a harmonic confining potential, the splitting becomes exponentially small in the system size. We also discuss the experimental implications of the novel ground state degeneracy, as manifest for example in the response to simple dipole modulations of the harmonic trap potential.

1:15PM G35.00011 Few Body Physics in Synthetic Dimensions with SU(N) Interactions\(^1\), SUDEEP K. GHOSH, UMESH K. YADAV, VIJAY B. SHENOY, Department of Physics, Indian Institute of Science — Cold atomic systems with SU(N) symmetric interactions have been of recent experimental and theoretical interest. Motivated by this, we study few body physics in such systems which also realize synthetic dimensions (Celi et al., PR Letters 112, 043001) within the cold atom setting by coupling the atomic hyperfine states via light. Choosing the light appropriately also provides ability to control magnetic flux in the plaquettes of the synthetic lattice. Using a combination of exact diagonalization and analytical methods, we uncover the novel physics that emerges in the interplay of non-local interactions in synthetic dimensions and the magnetic flux. Attractive SU(N) interactions, in absence of flux, obtains a sequence of many-particle “baryonic” bound states. We show how the presence of flux stabilizes a different sequence of baryonic states, presenting a detailed few body phase diagram. We also discuss consequences of our findings to the many body setting, pointing out the novel phases that can be realized in these systems. These results will be of interest to both experimentalists (suggesting systems with novel physics), as well as theorists for exploring the novel phases realized.

\(^1\)S.K.G. acknowledges support from CSIR, India via SRF grants. U.K.Y. acknowledges support from UGC, India via Dr. D.S. Kothari Post-doctoral Fellowship scheme. V.B.S. is grateful to DST, India and DAE, India (SRC grant) for generous support.

1:27PM G35.00012 A microwave trap for sympathetic cooling of polar molecules\(^1\), DEVIN DUNSEITH\(^2\), STEFAN TRUPPE, RICHARD HENDRICKS, BEN SAUER, EDWARD HINDS, MICHAEL TARBUTT, Imperial College, London — We have been developing techniques to cool molecules into the microkelvin regime. One method is to use sympathetic cooling, using ultracold atoms as a refrigerant to cool molecules. Previous work has suggested that atoms and molecules can be trapped in the antinode of a Fabry-Perot microwave cavity. We couple microwave power into this cavity from a rectangular waveguide via a small hole in one mirror. We have developed an analytical model that helps us understand this coupling, and gives us an idea of how the size of the hole affects the cavity's coupling and finesse. We carried out finite-difference time-domain simulations and performed experiments on a prototype cavity to verify this model. We have now designed and built this trap for operation under ultra high vacuum, with the ability to cool the mirrors to 77 K and couple in up to 2 kW of microwave power. This will allow us to trap molecules with a moderate dipole moment at temperatures of hundreds of millikelvin, as well as atoms at a few millikelvin. We will present our work in creating and understanding the microwave trap, as well as our first results demonstrating trapping of lithium atoms in the microwave trap.

1:39PM G35.00013 Hybrid Decelerator for Cold Molecular Beams, IGOR LYUKSYUTOV, Texas A&M University — We shall discuss design, simulation and operation of the hybrid decelerator to produce cold molecules. Hybrid decelerator is a combination of the counter rotating source of slow molecular beam with the single stage magnetic decelerator. We operate counter rotating source which provide intense beam of molecules/atoms with the speed smaller than 50 m/s. This beam can be a source for the single stage magnetic decelerator. For example, by decreasing the molecular oxygen speed with mechanical decelerator down to 50 m/s, one can use a single stage magnetic decelerator with a maximum current less than 360 A, to decrease the speed of oxygen molecules to about 2 m/s. Thus, the use of the magnetic stage in hybrid magneto-mechanical decelerator, can provide slow molecular beams with high intensity.

1:51PM G35.00014 Ultracold nonreactive molecules in an optical lattice, ANDRIS DOCAJ, Rice University, MICHAEL L. WALL, JILA, NIST, CU-Boulder, KADEN R.A. HAZZARD, Rice University — Nonreactive (NR) ultracold molecules in optical lattices are free from the two-body losses that occur in chemically reactive molecules, opening up new possibilities for quantum science. Despite the absence of chemical reactions, NR molecules scatter in extremely complex ways – not captured by a delta function pseudopotential – due to the enormous number of rotational and vibrational states. We calculate the bound state energies of two NR molecules confined to a single site of an optical lattice, as a first step towards deriving an effective lattice model that can describe many molecules in a lattice. To describe the short-range collisional properties, which are presently experimentally unknown, we employ random matrix theory. However, our formalism is capable of handling arbitrary short-range collisional physics.

Session G36 DAMOP: Topological Phases and Majorana Fermions in Cold Atoms

11:15AM G36.00001 Topological States in a One-Dimensional Fermi Gas with Attractive Interactions, JONATHAN RUHMAN, EREZ BERG, EHUD ALTMAN, Weizmann institute of science — We show that a single one-dimensional Fermi gas with Rashba-like spin-orbit coupling, a Zeeman field and intrinsic attractive interactions exhibits a novel topological superfluid state, which forms in spite of total number conservation and the absence of a single particle gap. Topological ground state degeneracy is associated with interfaces between two distinct phases that naturally form in the harmonic confining potential due to the spatial variations of the chemical potential. We find that backscattering by impurities, or simply by the interfaces themselves, effects a splitting in the topological degeneracy which generally scales as $1/L^{K/2}$, where $L$ is the size of the system and $K$ is the Luttinger parameter. However, when the interfaces are sufficiently smooth, as in the case of a harmonic confining potential, the splitting becomes exponentially small in the system size. We also discuss the experimental implications of the novel ground state degeneracy, as manifest for example in the response to simple dipole modulations of the harmonic trap potential.

11:27AM G36.00002 One-dimensional topological chains in two-dimensional non-topological optical lattices\(^1\), LEI JIANG, CHUANWEI ZHANG, University of Texas at Dallas — Majorana fermions appear near the topological phase boundary. In 2D, Majorana fermions are found when vortices, which stand for topological defects, are formed in topological superfluids. Due to the complications to generate 2D topological superfluids in experiments, Majorana fermions are not easily achievable in 2D systems. In our work, we show, by imprinting 1D local potentials in a finite 2D system, we can realize a 1D topological chain on demand even in originally non-topological 2D systems. A pair of zero-energy Majorana fermions can be stable in this system and exist at the ends of the topological chain. We also demonstrate the possibility to arrange an array of Majorana fermions by separating topological chains with non-topological ones. Similar results can be obtained in 3D optical lattices. Compared with strictly 1D systems, quantum fluctuations are strongly suppressed in such high dimensional optical lattices. Because all requirements of our model are within the reach of current experiments, our proposed scheme may provide an experimental feasible platform for observing Majorana states in 2D ultra-cold atom optical lattices.

\(^1\)We acknowledge supports from ARO, AFOSR and NSF.
11:39AM G36.00003 Dynamical detection of a topological phase transition in one-dimensional spin-orbit-coupled Fermi gases1, F. SETIAWAN, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park, KRISHNENDU SENGUPTA, Indian Association for the Cultivation of Science, Kolkata, India, IAN SPIELMANN, Joint Quantum Institute, National Institute of Standards and Technology, and University of Maryland, College Park, JAY SAU, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park — We theoretically study the dynamics of topological phase transition in one-dimensional (1D) spin-orbit coupled (SOC) Fermi gases with attractive interaction as a means of detecting the phase transition. The transition from conventional (trivial) superfluid to topological superfluid phase happens as the intensity of the Raman lasers (Zeeman field) is ramped above the critical value. To minimize effect of heating, we propose to ramp from a conventional superfluid phase through the topological phase transition and back. We calculate the momentum distribution of the atoms after the ramp by solving the time-dependent Bogoliubov-de Gennes (BdG) equations self-consistently with the initial state of the Fermi gas being the thermal state. We show that the phase transition can be detected by measuring the signal of the momentum distribution with the ramp rate.

11:51AM G36.00004 Distribution functions and probes of far-from-equilibrium topological matter1, YUNXIANG LIAO, MATTIEH FOSTER, Rice University — We investigate radio-frequency (RF) spectroscopy and superconductor-normal metal tunneling as probes of out-of-equilibrium topological systems. As an example, we study a 2D p-i-p superfluid following an instantaneous quench of the coupling strength [Foster et prl 2013, PRL 2014]. The long-time asymptotic order parameter of this system can be constant or time-periodic. In both cases, the post-quench Cooper pairs each occupy a linear combination of two states, with coefficients determined by the distribution function. In strong quenches where the order parameter is periodic, the bases are two Floquet states with opposite quasi-energy. We derive expressions for the RF and tunneling spectra for these post-quench states, examining both average values and harmonics. While the distribution function strongly affects the RF signal, it disappears from the tunneling spectrum. We show that the bulk RF signal obtained by occupying the lower Floquet band is dramatically different from that of the post-quench states. This is intimately related to the difference between the topology of the state, which cannot change under closed evolution, versus the topology of the non-equilibrium excitation spectrum. We also look for signatures of Majorana edge states in systems with an edge. We compute the local RF signal, which depends upon the non-equilibrium excitation spectrum of bulk and edge states as well as their occupation.

12:03PM G36.00005 Fractional Angular Momentum in Cold-Atom Systems, YUHE ZHANG, Pennsylvania State Univ, SREEJITH GANESH JAYA, NORDITA, Roslagstullsbacken 23, 10691 Stockholm, Sweden, NATHAN D GEMELKE, JAINENDRA K JAIN, Pennsylvania State Univ — The quantum statistics of bosons or fermions are manifest through the even or odd relative angular momentum of a pair. We show theoretically that, under certain conditions, a pair of certain test particles immersed in a fractional quantum Hall (FQH) state possesses, effectively, a fractional relative angular momentum, which can be interpreted in terms of fractional braid statistics. We propose that the fractionalization of the angular momentum can be detected directly by measuring the pair correlation function and rotating the sample. In a fractional quantum Hall state, the FQH state will also provide direct evidence for the effective magnetic field resulting from Berry phases arising from attached vortices, and of excitations with a fractional particle number, analogous to the fractional charge of the electron fractional quantum Hall state. We extend our work to investigate the quasiholes in 5/2 FQH state which are believed to obey non-Abelian statistics. We will study the effect of non-Abelian statistics for test particles binding quasiholes in a Moore-Read Pfaffian state, which is produced for bosons subject to a three-body contact interaction, and also for bosons with two-body contact interaction.

12:15PM G36.00006 Rotational properties of two-component Bose gases in the lowest Landau level1, MARIUS MEYER, Univ of Oslo, GANESH JAYA SREEJITH, PCS Max Planck Institute, SUSANNE VIEFERS, Univ of Oslo — We study the rotational (yrast) spectra of dilute two-component atomic Bose gases in the low angular momentum regime, assuming equal interspecies and intraspecies interaction. Our analysis employs the composite fermion (CF) approach including a pseudospin degree of freedom. While the CF approach is not a priori expected to work well in this angular momentum regime, we show that composite fermion diagonalization gives remarkably accurate approximations to low energy states in the spectra. For angular momenta 0 < \lambda < M (where N and M denote the numbers of particles of the two species, and M ≥ N), we find that the CF states span the full Hilbert space and provide a convenient set of basis states which, by construction, are eigenstates of the symmetries of the Hamiltonian. Within this CF basis, we identify a subset of the basis states with the lowest \lambda-level kinetic energy. Diagonalization within this significantly smaller subspace constitutes a major computational simplification and provides very close approximations to ground states and a number of low-lying states within each pseudospin and angular momentum channel.

12:27PM G36.00007 Probing Fractional Quantum Hall Physics with Rotating Bose Gases, LOUIS JACOME, JIANSHI ZHAO, NATE GEMELKE, Pennsylvania State University — Rapidly rotating and repulsively interacting Bose gases are expected to exhibit character reminiscent of the fractional quantum Hall effect (FQH) in two-dimensional electron gases. Such states are expected to possess excitations with fractionalized braid statistics, although no convincing measurement of this behavior has yet been made in either system. In this talk, we describe progress toward realizing FQH physics using cold Rb-87 atoms confined to an optical lattice with rotating lattice sites. The inclusion of high resolution optical microscopy to perform occupancy-resolved detection expands on previous measurements, and promises new avenues to directly interrogate novel behavior including pair-correlation and braiding statistics as proposed recently [1]. Finally, we discuss new emergent phenomena in chains of tunnel-coupled FQH droplets, including the existence of a novel class of insulating and superfluid states which exhibit local fractional Hall character, and dissipationless transport phenomena governed by new topological invariants. 12:39PM G36.00008 Emergent Fermi Sea in A System of Interacting Bosons1, YINGHAI WU, Max Planck Institute of Quantum Optics, JAINENDRA JAIN, The Pennsylvania State University — An understanding of the possible ways in which interactions can produce fundamentally new emergent many-body states is a central problem of condensed matter physics. We ask if a Fermi sea can arise in a system of bosons subject to contact interaction. Based on exact diagonalization studies and variational wave functions, we predict that such a state is likely to occur when a system of two-component bosons in two dimensions, interacting via a species independent contact interaction, is exposed to a synthetic magnetic field of strength that corresponds to a filling factor of unity. The bosons each bind a single vortex as a result of the repulsive interaction, and these fermionic bound states, namely composite fermions, form a spin-singlet Fermi sea.

12:51PM G36.00009 Few-body treatment of the quantum Hall system\textsuperscript{1} , CHRIS GREENE, KEVIN DAILY, RACHEL WOOTEN, Purdue University — The quantum Hall system is perhaps the simplest real physical system to exhibit complicated, highly-correlated quantum behavior\textsuperscript{2}. Our initial theoretical exploration of this problem approaches it from a few-body perspective using the adiabatic hyperspherical representation developed originally for atomic systems. Such a 2D system with interacting charged particles that move in an external magnetic field can be simulated for cold atoms using artificial vector gauge potentials.

1:03PM G36.00010 Majorana modes in single channel cold atomic gases with short-ranged attractive interactions\textsuperscript{1} , JAY SAU, XIAOPENG LI, Condensed Matter Theory Center and Joint Quantum Institute at the University of Maryland — Majorana modes have been predicted to exist in topological superfluids that generated by a combination of spin-orbit coupling and short-ranged attractive interactions. One dimensional superfluids with intrinsic interactions, however, present a precarious competition between phase fluctuations and topological superfluidity. Previously, it has been argued that the Majorana nature survives with some modification in multi-channel and proximity-induced superfluidity systems of ultra-cold atoms. This discussion is more subtle in the single channel case because the universal properties of one dimensional fermions with attractive interactions are known to be described by a simple Luttinger liquid in the low-energy limit. In this talk, we will discuss the properties of Galilean invariant one dimensional fermi gases with attractive interactions and show how they display properties consistent with both being a topological (or non-topological) superfluid and a Luttinger liquid.

\textsuperscript{1}Condensed Matter Theory Center and Joint Quantum Institute at the University of Maryland

1:15PM G36.00011 Floquet FFLO superfluids and Majorana fermions in a shaken fermionic optical lattice , ZHEN ZHENG, The University of Texas at Dallas; University of Science and Technology of China, CHUNLEI QU, The University of Texas at Dallas, XUBO ZOU, University of Science and Technology of China, CHUANWEI ZHANG, The University of Texas at Dallas — Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) superfluids, Cooper pairings with finite momentum, and Majorana fermions (MFs), quasiparticles with non-Abelian exchange statistics, are two topics under intensive investigation in the past several decades, but unambiguous experimental evidences for them have not been found yet in any physical system. Here we show that the recent experimentally realized shaken optical lattice provides a new pathway to realize FFLO superfluids and MFs. By tuning the shaking frequency and amplitude, various coupling between the s- and p-orbitals of the lattice (denoted as the pseudo-spins) can be generated. We show that the combination of the inverted s- and p-band dispersions, the engineered pseudo-spin coupling, and the on-site attractive interaction, naturally allows the observation of FFLO superfluids as well as MFs in different parameter regions.

1:27PM G36.00012 Majorana edge modes in Kitaev model on honeycomb lattice\textsuperscript{1} , MANISHA THAKURATHI, Indian Institute of Science, Bengaluru, India, KRISHNENDU SENGUPTA, Indian Association for the Cultivation of Science, Kolkata, India, DIPTIMAN SEN, Indian Institute of Science, Bengaluru, India — We study the Majorana modes, both equilibrum and Floquet, which can appear at the edges of the Kitaev model on the honeycomb lattice. We first present the analytical solutions known for the equilibrium Majorana edge modes for both zigzag and armchair edges of a semi-infinite Kitaev model and chart the parameter regimes of the model in which they appear. We then examine how edge modes can be generated if the Kitaev coupling on the bonds perpendicular to the edge is varied periodically in time as periodic $\delta$-function kicks. We derive a general condition for the appearance and disappearance of the Floquet edge modes as a function of the drive frequency for a generic $d$-dimensional integrable system. We confirm this general condition for the Kitaev model with a finite width by mapping it to a one-dimensional model. Our numerical and analytical study of this problem shows that Floquet Majorana modes can appear on some edges in the kicked system even when the corresponding equilibrium Hamiltonian has no Majorana mode solutions on those edges. We support our analytical studies by numerics for finite sized system which show that periodic kicks can generate modes at the edges and the corners of the lattice.

\textsuperscript{1}We thank CSIR, India and DST, India for financial support.

1:39PM G36.00013 Fractionalized Majorana modes in ultracold bosonic systems\textsuperscript{1} , MOHAMMAD F. MAGHREBI, Joint Quantum Institute. University of Maryland College Park, SRIRAM GANESHAN, Condensed Matter Theory Center, University of Maryland College Park, DAVID CLARKE, Station Q, ALEXEY GÖRSHKOV, Joint Quantum Institute, and the National Institute of Standards and Technology, JAY DEEP SAU, Condensed Matter Theory Center and the Joint Quantum Institute at the University of Maryland College Park — Fractionalized Majorana fermions, also known as parafermions, are exotic topologically protected modes that go beyond the simplest non-Abelian anyons, Majorana fermions. They commute up to a nontrivial phase factor in contrast to the minus sign for fermions. These modes are proposed to emerge in devices fabricated from a fractional quantum Hall system and a superconductor. With recent advances towards the realization of fractional quantum Hall states of bosonic ultracold atoms, we propose a realization of parafermions in a system consisting of two Bose-Einstein-condensate trenches within a bosonic fractional quantum Hall state. We show that parafermionic zero modes emerge at the endpoints of the trench and give rise to a topologically protected degeneracy. We also discuss methods for preparing and detecting these modes.

1:51PM G36.00014 Extracting Entanglement Entropy Via Non-Destructive Imaging of an Ultracold Atomic Gas , CRAIG PRICE, QI LIU, NATHAN GEMELKE, Pennsylvania State Univ — Entanglement plays an important role in determining the thermodynamic ground state of many many-body quantum systems, and recent theoretical studies have provided evidence that broad classes of quantum critical and topologically ordered states may be characterized by the scaling properties of their entanglement entropy (EE)\textsuperscript{1,2}. We describe how EE can be extracted in a QND imaging process, in which slicing of the beam provides information is transferred from one quantum gas to another using pairwise entangling schemes, and how the subsequent non-local thermal back-action of detection may be used to probe pre-existing entanglement in the sample. We discuss related applications of quantum collisional microscopy, including minimally destructive imaging of non-equilibrium quantum gases, and the algorithmic cooling of a Mott-insulator by non-destructive detection and removal of thermal defects.\textsuperscript{[1]} V. Vedral, M.B. Plenio, M.A. Rippin, P. L. Knight. Quantifying Entanglement. Phys. Rev. Lett. 78, 2275 (1997) \textsuperscript{[2]} G. Vidal, J. I. Latorre, E. Rico, and A. Kitaev. Entanglement in quantum critical phenomena. Phys. Rev. Lett. 90, 227902 (2003)
2:03PM G36.00015 Two-dimensional topological order of kinetically constrained quantum particles. STEFANOS KOURTIS, TCM Group, Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, United Kingdom — Motivated by recent experimental and theoretical work on driven optical lattices, we investigate how imposing kinetic restrictions on quantum particles that would otherwise hop freely on a two-dimensional lattice can lead to topologically ordered states. The kinetically constrained models introduced here are derived as an approximate generalization of strongly interacting particles hopping on Haldane and equivalent lattices and are pertinent to systems irradiated by circularly polarized light. After introducing a broad class of models, we focus on particular realizations and show numerically that they exhibit topological order, by observing topological ground-state cross-overs as well as the appearance of corresponding invariants. Apart from potentially being crucial for the interpretation of forthcoming cold-atom experiments, our results also hint at unexplored possibilities for the realization of topologically ordered matter. A further implication, relevant to fractional quantum Hall (FQH) physics, is that the correlations responsible for FQH-like states can arise from processes other than density-density interactions.

Tuesday, March 3, 2015 11:15AM - 2:15PM –
Session G37 GQI: Focus Session: Semiconductor Qubits - SiGe, Isotopic Purification, and Electrical Control 212A - Andrea Morello, University of New South Wales

11:15AM G37.00001 An Exchange-Only Qubit in Isotopically Enriched $^{28}$Si. MARK GYURE, HRL Laboratories, LLC — We demonstrate coherent manipulation and universal control of a qubit composed of a triple quantum dot implemented in an isotopically enhanced Si/Ge heterostructure, which requires no local DC magnetic fields for operation. Strong control over tunnel rates is enabled by a dopantless, accumulation-only device design, and an integrated measurement dot enables single-shot measurement. Reduction of magnetic noise is achieved via isotopic purification of the silicon quantum well. We demonstrate universal control using composite pulses and employ these pulses for spin-echo-type sequences to measure both magnetic noise and charge noise. The noise measured is sufficiently low to enable the long pulse sequences required for exchange-only quantum information processing. Sponsored by United States Department of Defense. The views and conclusions contained in this document are those of the authors and should not be interpreted as representing the official policies, either expressly or implied, of the United States Department of Defense or the U.S. Government. Approved for public release, distribution unlimited.

11:51AM G37.00002 Accumulation-Only Device Architecture for Si/Ge Single Quantum Dots. T.M. HAZARD, D. ZAJAC, X. MI, J.R. PETTA, Department of Physics, Princeton University — Accumulation mode devices with overlapping gate architectures have been successfully realized in both Si/Ge heterostructures [1] and Si MOS devices [2]. The increased control of tunneling rates, inter-dot tunnel couplings and confinement potentials over previous depletion mode designs make the overlapping gate architecture preferable. Material quality and device geometry have important implications for Si/Ge quantum dots as potential hosts for spin qubits. Here we have fabricated and characterized quantum dots made with this accumulation mode architecture. We also perform numerical simulations to optimize device geometry for tight confinement potentials and reduced cross-coupling between accumulation gates. In addition to device improvements, we have also implemented a compact filtering system on the DC gate lines to achieve sub-40 mK electron temperatures.

1Research was supported by the Sloan and Packard Foundations, Army Research Office and DARPA.

12:03PM G37.00003 A Reconfigurable Device Architecture for Si/Ge Quantum Dots. D. ZAJAC, T.M. HAZARD, X. MI, J.R. PETTA, Department of Physics, Princeton University — Depletion mode architectures for gate-defined quantum dots have been successful in the implementation of single, double and triple quantum dots. However, scaling up to more complicated devices presents serious lithographic challenges for depletion mode devices. We present a reconfigurable, accumulation-only mode lateral quantum dot device. We demonstrate full control of the device as both a single quantum dot with a single dot sensor and a double quantum dot with a single dot sensor. We reach the few electron regime in both operating modes.

1Sponsored by the Sloan and Packard Foundation, Army Research Office and DARPA.

12:15PM G37.00004 Probing the mobility-limiting mechanisms in undoped Si/Ge heterostructures. XIAO MI, THOMAS M. HAZARD, CHRISTOPHER M. PAYETTE, KE WANG, DAVID M. ZAJAC, JEFFREY V. CADY, JASON R. PETTA, Department of Physics, Princeton University — Silicon is an ideal host material for spin-based semiconductor quantum dot qubits due to weak hyperfine coupling and a route to isotopic purification. Si quantum dots formed in undoped Si/Ge quantum wells have recently allowed measurements that were previously only possible in the GaAs system [1, 2]. We report the growth of Si/Ge quantum wells with mobilities reaching 260,000 cm$^2$/Vs at a density of $7 \times 10^{11}$ cm$^{-2}$. We systematically investigate a series of 26 wafers with different growth profiles and impurity levels, and find that the mobility is limited by scattering from both oxygen impurities in the quantum wells and interface charges at the surface of the wafer.

1This work is sponsored by the United States Department of Defense with partial support from the NSF through the Princeton Center for Complex Materials (DMR-0819860) and CAREER program (DMR-0846341).

12:27PM G37.00005 Understanding the Fong-Wandzura Sequence. DANIEL ZEUCH, N.E. BONESTEEL, Department of Physics and NHMFL, Florida State University — In exchange-only spin quantum computation, qubits are encoded into the Hilbert space of three or more spin-1/2 particles (e.g. electron spins in quantum dots), and quantum gates are realized by sequences of Heisenberg exchange operations, or “exchange-pulses,” acting on pairs of spins. It is easy to obtain pulse sequences for single-qubit gates, but difficult for entangling 2-qubit gates due to the large Hilbert space of six spins. The shortest known 2-qubit gate sequence, obtained by Fong and Wandzura via a numerical search [1], consists of 12 exchange pulses. Unlike a longer 2-qubit gate sequence constructed analytically in [2], this 12-pulse sequence has, until now, escaped intuitive explanation. Here, we analyze this sequence using techniques introduced in [2]. We find the 12-pulse sequence naturally decomposes into three parts, each consisting of the same partial pulse sequence acting on four spins at a time. This reduced sequence preserves certain total spin quantum numbers in a way that naturally suggests how it can be used to construct a leakage free entangling 2-qubit gate.

12:39PM G37.00006 Entangling multi-dot spin qubits\(^1\). V. SRINIVASA, Laboratory for Physical Sciences, University of Maryland, College Park, MD. J.M. TAYLOR, Joint Center for Quantum Information and Computer Science, Joint Quantum Institute, National Institute of Standards and Technology, Gaithersburg, MD. C. TAHAN, Laboratory for Physical Sciences, College Park, MD — Single quantum bits encoded in the spins of two or three electrons confined within multiple semiconductor quantum dots provide practical advantages over individual electron spin qubits, in terms of both faster control via applied electric fields and protection from collective decoherence mechanisms. However, implementing rapid and robust entangling gates between these multi-electron, multi-dot qubits remains a current challenge. While the exchange interaction gives rise to rapid gates, it is limited in range and requires accompanying methods for suppressing leakage. Alternatively, the long-range Coulomb interaction can be used to couple both adjacent and spatially separated qubits, and rapid gates are possible through microwave manipulation of the extended charge distribution associated with a multi-dot system. We theoretically investigate different approaches for entangling qubits in double [1] and triple dots. By analyzing the coupling in the presence of charge noise and relaxation, we identify optimal regimes of operation for two-qubit gates and compare their performance for GaAs and Si quantum dots.

\(^1\)Support from DARPA MTO and the NSF-funded Physics Frontier Center at the JQI is gratefully acknowledged.

12:51PM G37.00007 Full-scope modeling of semiconductor devices for quantum information processing. JOHN KING GAMBLE, ANDREW BACZEWSKI, Sandia National Labs, ADAM FREES, University of Wisconsin-Madison, N. TOBIAS JACOBSON, INES MONTANO, RICHARD P. MULLER, ERIK NIELSEN, Sandia National Labs — Recent outstanding experimental advances in semiconductor-based quantum information processing have placed the fundamental building blocks of a quantum computer within reach. Typical computational simulation of these devices either focuses on the large-scale, semiclassical device physics or more detailed quantum mechanics within an idealized physical system. Here, we present results for full-scope simulation, where detailed multi-valley effective mass theory is coupled to large-scale device physics. This enables the simulation of the quantum properties and operation of a device directly from a physical design. This work opens the door for physics-targeted device optimization and an unprecedented level of predictive power. The authors gratefully acknowledge support from the Sandia National Laboratories Truman Fellowship Program, which is funded by the Laboratory Directed Research and Development (LDRD) Program. Sandia is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

1:03PM G37.00008 Electron Spin Resonation in Si/SiGe Quantum Dot Ensembles. RYAN M. JOCK, J.-H. HE, A.M. TYRYSKIN, S.A. LYON, Princeton University, C.-H. LEE, S.-H. HUANG, C.W. LIU, National Taiwan University — Single electron spin states in Si/SiGe quantum dots have shown promise as qubits for quantum information processing. Our previous ensemble microwave measurements of electron spins in gated Si/SiGe quantum dots have displayed relaxation (\(T_1\)) and coherence (\(T_2\)) times of 250 \(\mu\)s at 350 mK. These experiments used conventional X-band (10 GHz) pulsed Electron Spin Resonance (eESR), on a large area, double-gated, undoped Si/SiGe heterostructure, in which holes with a 300 nm diameter and 700 nm period were lithographically defined in the lower gate. Quantum dots were electrostatically induced in a natural Si quantum well, with their confinement potential controlled by the gates. Electron spin coherence in these first generation quantum dot devices was observed to be \(T_1\)-limited at stronger confining potentials. By tailoring the quantum dot size and spacing we can modify the electron confinement barrier and electron wave function size, helping us probe the mechanisms limiting coherence in silicon quantum dots. We will report results on dots with lithographic diameters of 150 to 300 nm and a 375 to 700 nm period. The device with smaller dots and larger spacing displays an extended electron relaxation times (\(T_1 = 1-2\) ms) at 350 mK. Furthermore, we observe a \(T_2\) of 310 \(\mu\)s, that is neither \(T_1\)-limited nor temperature dependent. This narrows the field of possible coherence limiting mechanisms, which will be discussed.

1:15PM G37.00009 Electrical assessments of \(^{28}\)Si enriched and deposited in situ to <1 ppm. \(^{29}\)Si, JOSHUA POMEROY, National Institute of Standards and Technology, KEVIN DWYER, HYUN-SOOG KIM, University of Maryland — We are enriching \(^{29}\)Si to better than 99.99999%, depositing epitaxial films, and measuring materials properties to improve our deposition process so that our enriched films can be used to fabricate quantum devices. Recent reports of spin-echo measurements in donor ensembles and single spins have both demonstrated spectacular coherence time and line width improvements due to enriched \(^{28}\)Si. In order to realize the benefits of our enrichment, the electrical properties of our films need to be similar quality to commercial wafers. Therefore, we are using C-V, g-V, Hall and other techniques commonly used for quantifying defect densities, mobility, carrier density, etc. to benchmark the viability of using our enriched films for quantum device fabrication.

1:27PM G37.00010 Dependence of \(^{28}\)Si concentration on deposition temperature in \(^{29}\)Si epilayers. KEVIN DWYER, JOSHUA POMEROY, HYUN SOO KIM, DAVID SIMONS, National Institute of Standards and Technology — In an effort to gain predictive power for the enrichment of \(^{29}\)Si epilayers deposited at elevated temperatures, we correlate the \(^{28}\)Si concentration due to natural abundance silane adsorption with measured IMS values. We have previously shown very high enrichments up to 99.99996 % (0.3 ppm \(^{28}\)Si) using mass filtered ion beam deposition. However, the incorporation at higher deposition temperatures of naturally abundant silane gas from our ion source has the potential to reduce the final film enrichment. Knowledge of the expected reduction in \(^{28}\)Si concentration is important because removal of the 4.7% \(^{29}\)Si nuclear spins in natural silicon allows for exceedingly long coherence (\(T_2\)) times of qubits, approaching an hour at room temperature for \(^{11}\)B nuclear spins. This makes incorporation of highly enriched \(^{28}\)Si into devices critical for solid state quantum information.

1:39PM G37.00011 Feasibility study of simultaneous capacitance detection during STM of silicon. HYUN KIM, KEVIN DWYER, Univ of Maryland-College Park, JOSHUA POMEROY, National institute of standards and technology — We are examining the feasibility of capacitance detection during STM to image buried metal nanostructures in silicon. As the hydrogen STM lithography for quantum information enables us to fabricate the atomically precise devices such as single atom qubits, the accurate alignment of metal contacts such as electrodes to the buried nanostructures on the surface becomes very challenging. Using SCM with STM gives benefits to locate the buried nanostructures and image the surface morphology simultaneously.

1:51PM G37.00012 Two-Dimensional Electron Gases in Nanomembrane-based Epitaxial Si/SiGe Heterostructures\(^1\). YIZE LI, PORNATIT SOOKCHOO, XIAORUI CUI, ROBERT MOHR, DONALD SAVAGE, RYAN FOOTE, R.B. JACOBSON, JOSE SANCHEZ-PEREZ, XIAN WU, DAN WARD, SUSAN COPPERSMITH, MARK ERIKSSON, MAX LAGALLY, University of Wisconsin-Madison — To assess possible improvements in the electronic performance of two-dimensional electron gases (2DEGs) in silicon, SiGe/Si/SiGe heterostructures are grown on fully elastically relaxed single-crystal Si nanomembranes fabricated through a strain engineering approach. This procedure eliminates the formation of dislocations in the heterostructure. Top-gated Hall bar devices are fabricated to enable magnetoresistance and Hall effect measurements. Both Shubnikov de Haas oscillations and the quantum Hall effect are observed at low temperatures, demonstrating the formation of high-quality 2DEGs. Values of charge carrier mobility as a function of carrier density extracted from these measurements are at least as high or higher than those obtained from companion measurements made on heterostructures grown on conventional strain graded substrates. In all samples impurity scattering appears to limit the mobility.

The spin-2 AKLT state on the square lattice is a universal resource for quantum computation. This work was supported in part by the National Science Foundation.
12:15PM G38.00006 Quantum Circuit Complexity of Random Singlet Phases1, NOAH BRAY-ALI, Joint Quantum Institute, University of Maryland, College Park and National Institute of Standards and Technology, Gaithersburg, MD 20899 — We use quantum circuit complexity to characterize the entanglement of random singlet phases in one-dimension. Random singlet phases are infinite-randomness fixed points of the strong-disorder renormalization group. They arise in strongly-correlated, quantum many-body systems of bosons, fermions, or anyons, and have long-range entanglement. We compute the depth of the local quantum circuit required to generate the random singlet phase and find that it scales as a super-linear, universal power of the system size.

12:27PM G38.00007 An Efficient Construction of a Matrix Product State for a Free Fermion Ground State1, MATTHEW FISCHMAN, Applied Physics, California Institute of Technology, Pasadena, California 91125, USA, STEVEN WHITE, Department of Physics and Astronomy, University of California, Irvine, California 92697, USA — Here we present an efficient and numerically stable procedure for creating the Matrix Product State of a pure fermionic Gaussian state, such as the ground state of a quadratic Hamiltonian. The algorithm produces a minimal number of nearest neighbor gates that, when applied to a product state, forms the many-body ground state. We will cover the procedure for both number conserving Hamiltonians as well as more general parity conserving Hamiltonians, where we will utilize the formalism of Majorana modes. Comparisons to previous methods and applications will be discussed.

1MF is thankful for funding from the NSF Graduate Research Fellowship.

12:39PM G38.00008 What constitutes a resource state for measurement-based quantum computation?2, ELEANOR RIEFFEL, NASA Ames Research Center, HOWARD WIEMAN, Griffith University — Support for universal measurement-based quantum computation (MBQC) is a sufficient condition for states to be considered resources for MBQC, but seems too strong as a necessary condition given known classes of MBQCs that appear to give an advantage over classical computing but which are not universal. We propose some minimal criteria that states must meet in order to be considered resource states for MBQC. We introduce (PRA 89, 032323 (2014)) the notion of inherently measurement-based computations, and give a series of necessary conditions for families of MBQCs to be considered inherently measurement-based. We propose that for a state to be considered a resource for MBQC it must, at minimum, support a family of MBQCs that is inherently measurement-based. Using these criteria, we explain why discord-free states cannot be resources for MBQC, in spite of claims to the contrary. We conclude with some open questions.

12:51PM G38.00009 Shortcuts to Adiabaticity in Quantum Many-Body Systems, ADOLFO DEL CAMPO, University of Massachusetts Boston — The nonadiabatic dynamics of a many-body system driven through a quantum critical point leads unavoidably to the formation of excitations, in agreement with the Kibble-Zurek mechanism. A way out of this scenario relies on the use of shortcuts to adiabaticity, where the formation of excitations is suppressed by assisting the dynamics with auxiliary multiple-body nonlocal interactions. We propose an alternative scheme which circumvents practical challenges to realize shortcuts to adiabaticity in mesoscopic systems by tailoring the functional form of the auxiliary counterdiabatic interactions. A driving scheme resorting in few-body short-range interactions is shown to generate an effectively adiabatic dynamics.

1:27PM G38.00010 Quantum algorithms, quantum field theory, and computational complexity . KEITH LEE, CQIQC — Quantum field theory provides the framework for the Standard Model of particle physics and plays a key role in physics. However, calculations are generally computationally complex and limited to weak interaction strengths. I’ll describe an extension of our quantum algorithm for computing relativistic scattering amplitudes in scalar quantum field theories to fermionic theories. The algorithms run in polynomial time and thus achieve exponential speedup over known classical methods. One of the motivations for this work comes from computational complexity theory. Ultimately, we wish to know what is the computational power of our universe. Studying such quantum algorithms probes whether a universal quantum computer is powerful enough to represent quantum field theory; in other words, is quantum field theory in BQP? Conversely, one can ask whether a given quantum field theory can implement a universal quantum computer; is quantum field theory BQP-hard? I’ll describe our approach to addressing the question of BQP-hardness.

2:03PM G38.00011 Are Qubits Fundamentally Flawed for General-purpose Quantum Computing? , CHENG-HSIAO WU, Missouri Univ. of Science and Technology — When two qubits are employed for the addition operation of two bits, it is not the superposition of 4 states that are relevant for the quantum computing. Rather, it is the 4 symbolic substitution rules that are contained in 2 bits. Thus general-purpose quantum paralleling computing is rule-based, not logic-gate based. This is a great departure. The quantum processor (US patent 8,525,544) contains 4 instructions and stores two data. The flaws of qubit concept are explained. Internal coupling (the entanglement) and external coupling (the readouts) must be integrated as one system. The quantum computing architecture is thus in cellular automata with one such processor in each cell. When the cell-to-cell interconnections are altered, a “new kind of science” appears and explained. Reversible quantum computing is not as stringent as the unitary operation implies.

11:15AM G39.00001 Improving the dynamic range of the Josephson Bifurcation Amplifier1, LASZLO SZOCS, MICHAEL HATRIDGE, SHYAM SHANKAR, ANIRUDH NARLA, KATRINA SLIWA, MICHEL DEVORET, Yale Univ — The dynamic range of the Josephson Bifurcation Amplifier (JBA), acting as a phase-sensitive amplifier, can be improved by combination of several junctions in series and parallel in place of the single junction present in the original device. By analyzing the circuit Hamiltonian for a system with many amplifiers tiled in parallel, each containing junctions wired in series, a potential increase in the amplifier’s dynamic range can be obtained while maintaining GHz-range tunability. Theoretical results and preliminary experimental data will be presented.

1Work supported by IARPA, ARO, and NSF.
11:27AM G39.00002 Multi-mode directional parametric devices, LEONARDO RANZANI, ADAM SIROIS, NIST, Boulder - University of Colorado, Boulder, MANUEL CASTELLANOS-BELTRAN, RAYMOND SIMMONDS, JOHN TEUFEL, JOSE AUMENTADO, NIST, Boulder — Josephson parametric amplifiers (JPAs) are very common in quantum information measurement systems, because they can operate close to the standard quantum limit, but require an external circulator to achieve unidirectionality. A possible way to achieve directional amplification without a circulator is to increase the number of coupled modes. By parametrically coupling three or more modes, and selecting the right amplitude and phase for the mode coupling rates, we can realize a non-trivial interference between different internal parametric processes and obtain unidirectional frequency conversion or amplification. In this talk we are going to discuss some recent progress on the experimental implementation of directional lumped-element Josephson parametric devices based on multiple coupled modes.

11:39AM G39.00003 Directional Amplification using Josephson Ring Modulators1, M. HATRIDGE, K.M. SLIWA, A. NARLA, S. SHANKAR, M.H. DEVORET, Department of Applied Physics, Yale University — Quantum limited parametric amplifiers usually amplify in reflection, so that the input and output signals travel on the same physical port. Circulators and isolators are thus required both to separate input and output signals with minimal loss of signal-to-noise ratio and to avoid backward irradiation of the signal source. These devices are bulky, dissipative, and operate in large magnetic fields which make them incompatible with integration on chip. By interfering the non-reciprocal mixing processes present in Josephson Ring Modulators, directional amplification can be realized. The theory and performance of a novel directional amplifier will be presented.

1Work supported by: IARPA, ARO, and ONR.

11:51AM G39.00004 A new implementation of a Josephson microwave circulator1, K.M. SLIWA, M. HATRIDGE, A. NARLA, S. SHANKAR, M.H. DEVORET, Department of Applied Physics, Yale University — Circulators are essential microwave components in superconducting qubit experiments, particularly those which also use parametric amplifiers. These amplifiers typically operate in reflection, and circulators both separate input from output, and protect the qubit from dephasing due to tones reflected off the amplifier. Unfortunately, their large size and the large magnetic fields they need to operate make them impossible to integrate on chip. Here we present the theory and experimental performance of a microwave circulator based not on ferrite materials, but on the interference of non-reciprocal mixing processes present in Josephson Ring Modulators.

1Work supported by: IARPA, ARO, and ONR.

12:03PM G39.00005 Qubit readout with Josephson Photomultipliers, GUILLAUME RIBEILL, IVAN PECHENIKSKII, TED THORBECK, University of Wisconsin, Madison, CALEB HOWINGTON, MATTHEW HUTCHINGS, Syracuse University, LUKE GOVIA, FRANK WILHELM, Saarland University, B.L.T. PLOURDE, Syracuse University, ROBERT MCDERMOTT, University of Wisconsin, Madison — Continued progress in superconducting qubits will require the development of scalable quantum-limited measurement tools. We have recently introduced a scalable superconducting qubit measurement protocol involving the state-selective ringup of a readout cavity followed by photodetection with the Josephson photomultiplier (JPM), a current-biased Josephson junction. Here we describe the experimental realization of this protocol. We discuss JPM optimization for high quantum efficiency, and describe integration of the JPM with a transmon qubit for high-fidelity dispersive readout. In addition, we discuss prospects for JPM readout of larger multi-qubit circuits.

12:15PM G39.00006 Readout of superconducting qubits with a Josephson photomultiplier1, CALEB HOWINGTON, MATTHEW HUTCHINGS, Syracuse University, GUILLAUME RIBEILL, ROBERT MCDERMOTT, University of Wisconsin, Madison, B.L.T. PLOURDE, Syracuse University — A Josephson photomultiplier (JPM) formed from a current-biased Josephson junction is the centerpiece of an alternative method for measuring the state of a superconducting qubit in a microwave cavity compared to conventional linear amplification followed by heterodyne readout. This approach, which involves mapping the qubit state onto the cavity photon occupation followed by photon detection with the JPM, reduces the requirements on bulky microwave hardware and amplifiers in the cryostat. We will discuss the implementation of superconducting microwave cavities and transmon qubits tailored for this readout technique. Furthermore, we will present steps towards the readout of multiple qubits in a common cavity with the JPM-based protocol.

1We acknowledge support from ARO under contract W911NF-14-1-0080.

12:27PM G39.00007 Efficient photon detection with a Josephson Parametric Amplifier, W.F. KINDEL, JILA, University of Colorado, M.D. SCHROER, JILA, M.R. VISSERS, J. GAO, D.P. PAPPAS, NIST, K.W. LEHNERT, JILA, University of Colorado — Josephson Parametric Amplifiers (JPAs) are an important resource in quantum limited measurement, feedback and nonclassical state generation. To study the JPA transformation, we use a superconducting qubit-cavity system to launch single photons or, n=1 Fock states, into a JPA, which measures the state. From repeated measurements, we can infer the state’s loss of purity as a results of the JPA transformation. We will present our estimates of the JPA’s efficiency as a photon detector in comparison to Gaussian characterization methods.

12:39PM G39.00008 Towards a lossless and integrable circulator for quantum superconducting microwave systems: Theory of operation1, JOSEPH KERCKHOFF, BENJAMIN J. CHAPMAN, JILA, University of Colorado, KEVIN LALUMIERE, ALEXANDRE BLAIS, Université de Sherbrooke, K.W. LEHNERT, JILA, University of Colorado and NIST — Lossless and integrable microwave circulators operating in the 4-8 GHz band are a critical, missing component in superconducting microwave quantum technology. Circulators are non-reciprocal devices used to impose a unidirectional flow of microwave signals. We report on progress towards an all-superconducting microwave circuit potentially capable of integrating with other quantum technologies and replacing many instances of the lossy and non-integrable ferrite circulators used in all contemporary quantum microwave experiments. Non-reciprocity is achieved through relatively weak (sub-Gauss) and slow (∼ 100 MHz) dynamically-modulated magnetic fields that tune the linear susceptibility of SQUID arrays in a four-port, resonant circuit. Our design’s basic theory of operation will be covered in this presentation.

1This work is supported by ARO under the contract W911NF-14-1-0079.
Towards a lossless and integrable circulator for quantum superconducting microwave systems: design and initial testing\(^1\), BENJAMIN J. CHAPMAN, JOSEPH KERCKHOFF, JILA, University of Colorado Boulder, KEVIN LALUMIERE, ALEXANDRE BLAIS, Sherbrooke University, K.W. LEHNERT, JILA, National Institute of Standards, Boulder, CO, University of Colorado Boulder — Microwave circulators enforce a single propagation direction for the signals in an electrical network. Commercial circulators, however, are lossy and cannot be integrated near superconducting circuits because of the large magnetic fields they emit. We report on progress toward the development of a lossless, on-chip, active circulator for superconducting microwave circuits in the 4-8 GHz band. Non-reciprocity is achieved by the active modulation of circuit elements on a slow time scale (100 MHz). The circulator’s active components are dynamically tunable inductors constructed from series arrays of SQUIDs. SQUID inductance is tuned by varying the magnetic flux through the SQUID’s loop with fields weaker than 1 G. Device features include a tunable bandwidth between 10-100 MHz, a tunable center frequency between 4-8 GHz, a high (-93 dBm) saturation power, a factor of 50 separation between the center and reverse isolation frequencies, low loss, and 1 mm\(^2\) footprint. This presentation will cover the design and initial testing of the device.

Using photovoltage to measure device-relevant exciton diffusion in luminescent and non-luminescent organic semiconducting materials. Tyler Mullenbach, Russell Holmes, University of Minnesota — Exciton diffusion is a prominent component of many emerging organic optoelectronic devices and is commonly described by the exciton diffusion length ($L_D$). Excitons are commonly tracked by measuring their end-of-life products: photons (from radiative decay) or charge carriers (from exciton dissociation). While tracking luminescence provides an accepted means of measuring $L_D$ for many materials, non-luminescent (dark) materials and states are inaccessible via such techniques. For dark materials, the charge carriers generated from exciton dissociation are tracked to estimate $L_D$ (e.g., by fitting device external quantum efficiency), despite the fact that photogenerated carriers are often subject to recombination events prior to collection as current. Here, we present an alternate method of measuring $L_D$, equally applicable to luminescent and dark materials, that uses photovoltage instead of current to determine the number of excitons reaching the dissociating interface in an organic photovoltaic device. Use of the photovoltage sidesteps charge carrier recombination providing an unbiased measurement of $L_D$. The technique is verified against previous luminescence-based methods, and measurements of $L_D$ are presented for a variety of dark materials including fullerenes.

Using Mass Transport to Guide the Purification of Small Molecule Organic Semiconductors via Sublimation. N. T. Morgan, Y. Zhang, University of Minnesota, Minneapolis, Matthew L. Grandbois, Engineering & Process Sciences, Core R&D, The Dow Chemical Company, Bruce M. Bell, Analytical Sciences, Core R&D, The Dow Chemical Company, Russell J. Holmes, E. L. Cussler, University of Minnesota, Minneapolis — Organic electronic materials have garnered considerable commercial attention for next generation display and solid-state lighting applications. Widespread adoption of these technologies is slowed by considerable production costs, partially due to an expensive purification step. This work explores the current method of industrial purification, thermal gradient sublimation, in order to isolate the fundamental mechanisms limiting sublimation rate and controlling product deposition. For the archetypical hole transport materials, N,N'-bis(naphthalen-1-yl)-N,N'-bis(phenyl)-benzidine (NPD) and 4,4',4''-tris(carbazol-9-yl) triphenylamine (TCTA), a combination of viscous flow and physical vapor deposition are shown to be rate-limiting at constant sublimation temperature. Surprisingly, diffusion through the solid feed, reaction at the feed particle surface, and mass transfer within the bed of feed particles are not rate limiting in the case. This mechanism is different from that which is observed in many industrial sublimation systems. These results can be used to guide the design and operation of future large-scale purification systems, which are critical for the widespread adoption of organic optoelectronic devices.

Separation of Carrier-Transport and Light-Emission Functions in a Light-Emitting Organic Transistor with Bilayer Configuration. Hui Shang, Hidekazu Shimotani, Department of Physics, Tohoku University, Japan, Kanagasekaran Thangavel, Katsumi Tanigaki, WPI-AIMAR, Tohoku University, Japan, Nano Solid State Physics Team — Organic single crystal based ambipolar light-emitting field effect transistors is treated as the candidate to realize laser. However, the active layer should contain both superb luminescent property and high charge-carrier mobility, which are always competing with each other in one material. Our basic concept for solving this problem is divide these two factors into two layers, and the combination of these two layers acts as the active layer of LEFET. Bottom layer with high carrier mobility can be assigned as carrier transporter, and top layer with high PL efficiency was assigned as light emitter. After injection, the carriers will have a recombination in the bottom layer and formed exciton will transfer into the top layer with light emission. In this work, we fabricated bilayer structure device, in which tetracene was used as bottom crystal and 4-(dicyanomethylene)-2-methyl-6-(p-dimethylaminostyryl)-4H-pyran (DCM) doped tetracene was laminated on tetracene as light emitter. We have successfully observed light emission from top crystal, from which our aforementioned hypothesis was preliminary proved. Details will be reported in the presentation.

Tuning the opto-electronic properties of donor-acceptor polymers with molecular doping. Elizabeth Von Hauff, VU Amsterdam — Organic semiconductors offer vast potential for low cost, flexible energy production. The photocurrents in organic solar cells, however, are inherently limited by the poor electrical properties of the active layer. In this talk, strategies to increase the power conversion efficiency of polymer-fullerene solar cells by microscopically tuning the transport properties of the donor material are discussed. We observe that molecular doping the active layer of the device leads to increased charge separation efficiency and photocurrents. To investigate the influence of doping on the transport properties, impedance spectroscopy, a powerful, non-destructive technique, was applied. This allows us to probe carrier dynamics at different operational points in the current-voltage characteristics, and thereby correlate material properties with device performance.

12:27PM G41.00005 Polymorphism in Core-Chlorinated Naphthalene Tetracarboxylic Diamide Thin Films. Geoffrey Purdum, Dept. of Chemical and Biological Engineering, Princeton University, Princeton, NJ 08544, Falk May, BASF SE, GVM/M - B009, 67056 Ludwigshafen, Germany, Nan Yao, Princeton Institute for Science and Technology of Materials, Princeton University, Princeton, NJ 08544, Thomas Weitz, BASF SE, GVE/F - J542, 67056 Ludwigshafen, Germany, Yueh-Lin LoO, Dept. of Chemical and Biological Engineering, Princeton University, Princeton, NJ 08544 — Polymorphism within organic semiconductors can play a critical role in device performance, as some packing motifs may be more favorable to charge transport than others. As-evaporated polycrystalline thin-films of core-chlorinated naphthalene tetracarboxylic diimides (NTCDI-I) adopt a triclinic polymorph that is not different from those of single crystals grown via physical-vapor transport. Exposing these thin-films to saturated vapors of select organic solvents, such as those of acetone and chloroform, induces structural transformation; thermally evaporated films convert from the triclinic polymorph to a monoclinic polymorph that was reported for solution-grown single crystals. Isothermal transformations are well described by second-order Avrami kinetics; molecular dynamic simulations give us insight into how solvents induce different kinds of favorable molecule-molecule interactions. Interestingly, the surface energy of the underlying substrate also plays a role in determining the rate of transformation; the rate of transformation is 2× and 4× faster on hexamethyldisilazane modified-Si/SiO$_2$ compared to on Si/SiO$_2$ and octadecyltrichlorosilane modified-Si/SiO$_2$ respectively.

12:39PM G41.00006 Small Conjugated Molecules: Orbital Energy Modeling Using Tuned Range-Separated Functional. Ram Bhatta, Mesfin Tsige, Department of Polymer Science, The University of Akron — Small conjugated molecules (SCMs) have potential to be efficient electron donors for organic solar cells because of their structural simplicity, good control over synthetic reproducibility and low purification cost. Density functional theory (DFT) and time dependent DFT (TD-DFT) computations can guide for designing high-performing SCMs by modeling their orbital energies. However, the accuracy of computed orbital energies depends on the choice of the level of the theory. We present DFT and TD-DFT calculations on 12 different SCMs using range-separated functional, LC-BLYP and the popular hybrid functional, B3LYP. Systematic calculations of the highest occupied molecular orbital (HOMO) energies, the lowest unoccupied molecular orbital (LUMO) energies as well as the singlet and triplet excitation energies are performed. We found that the LC-BLYP results are strongly dependent on the range-separation parameter. The computed results are compared with experimental data.

Work supported by the National Science Foundation (Grant No. DMR0847580)
12:51PM G41.00007 Low Field Electronic Behavior and Contact Impedance of Organic Single Crystal Transistors, EMMILY BITTLE, JAMES BASHAM, National Institute of Standards and Technology, THOMAS JACKSON, Penn State University, ANNA JURCHESCU, Wake Forest University, DAVID GUNDLACH, National Institute of Standards and Technology — Organic electronic devices are attractive for a range of existing and emerging electronic applications. Most technological demonstrations of organic transistors rely on their large signal response for pixel control or logic. However, considerable application space requires analog circuits, e.g., distributed signal conditioning in sensor arrays. Charge transfer and trapping mechanisms differ significantly in organic as compared to inorganic transistors, and as a result commonly used analogies to inorganic band transport are not directly applicable. In this work, we present a detailed investigation of organic transistor behavior at small signals to understand this behavior at the device level.

1:03PM G41.00008 Site energies and charge transfer rates near pentacene grain boundaries from first-principles calculations, HAJIME KOBAYASHI, YUICHI TOKITA, Sony Co. — Charge transfer rates near pentacene grain boundaries are determined by calculating the site energies and transfer integrals of 37 pentacene molecules using first-principles calculations. The site energies decrease considerably near the grain boundaries, and electron traps of up to 300 meV and hole barriers of up to 400 meV are generated. The charge transfer rates across the grain boundaries are found to be reduced by three to five orders of magnitude with a grain boundary gap of 4 Å because of the reduction in the transfer integrals. The electron traps and hole barriers also reduce the electron and hole transfer rates by factors of up to 10 and 50, respectively. It is essential to take the site energies into consideration to determine charge transport near the grain boundaries. We show that the complex site energy distributions near the grain boundaries can be represented by an equivalent site energy difference, which is a constant for any charge transfer pass. When equivalent site energy differences are obtained for various grain boundary structures by first-principles calculations, the effects of the grain boundaries on the charge transfer rates are introduced exactly into charge transport simulations, such as the kinetic Monte Carlo method.

1:15PM G41.00009 Nanoscale domains in thin-film pentacene seen by mid-infrared near-field spectroscopy, FRITZ KEILMANN, BERT NICKEL, CHRISTIAN WESTERMEIER, CLEMENS LIEWALD, Ludwig-Maximilians-Universitaet Muenden, SERGIU AMARIE, ADRIAN CERNESCU, Neaspec GmbH Martinsried — The coexistence of structural phases in thin-film pentacene was known from X-ray diffraction, yet the scale of domain sizes remained unknown due to large-scale averaging. Infrared spectroscopy (classical FTIR) can distinguish different structural phases by slightly shifted molecular vibrational resonances but with spatial resolution not better than about 10 micrometer. When FTIR is paired with near-field microscopy performed by back-scattering infrared radiation from an AFM tip (“nano-FTIR” allowing 20 nm resolution), Bulk-Phase (BP) domains were readily observed to form <100 to 300 nm wide ellipsoids which significantly grow over months at atmospheric conditions, at the cost of the surrounding Thin-Phase (TFP) pentacene. Both the domain interfaces and their continuing dimensional evolution may point to hidden problems for solar conversion systems development, possibly also with molecular materials beyond pentacene. C. Westermeier, A. Cernescu, S. Amarie, C. Liewald, F. Keilmann, B and B. Nickel, Sub-micron phase coexistence in small-molecule organic thin films revealed by infrared nano-imaging, Nature Communications 5, 4101, DOI:10.1038/ncomms5101 (2014)

1:27PM G41.00010 Tunable Molecular Orientation and Elevated Thermal Stability of Vapor-Deposited Organic Semiconductors, DIANE WALTERS, SHAKEEL DALAL, University of Wisconsin-Madison, IVAN LYUBIMOV, JUAN DE PABLO, University of Chicago, MARK EDIGER, University of Wisconsin-Madison — Physical vapor deposition is commonly used to prepare organic glasses that serve as active layers in organic electronic devices. Orienting the molecules in such layers can significantly enhance device performance. We apply a high-throughput characterization scheme to investigate the effect of the substrate temperature (T_substrate) on glasses of three organic materials utilized as semiconductors. Using spectroscopic ellipsometry, we find that molecular orientation in these glasses is continuously tunable and controlled by T_substrate/T_g, where T_g is the glass transition temperature. All three molecules can produce highly anisotropic glasses; the dependence of molecular orientation upon substrate temperature is remarkably similar and nearly independent of molecular length. All three compounds form “stable glasses” with high density and thermal stability similar to stable glasses of model glass formers. Simulations reproduce the experimental trends and explain molecular orientation in the deposited glasses in terms of the surface properties of the equilibrium liquid. By showing that organic semiconductors form highly oriented stable glasses, these results provide an avenue for systematic performance optimization of active layers in organic electronics.

1:39PM G41.00011 GIWAXS characterization of amorphous, anisotropic, vapor-deposited organic semiconductor films, ANKIT GUJRAL, University of Wisconsin-Madison, KATHRYN O’HARA, MICHAEL CHABINYC, University of California, Santa Barbara, MARK EDIGER, University of Wisconsin-Madison — Vapor-deposited organic glasses can be produced with enhanced thermal stability and tunable molecular packing by controlling deposition conditions, such as the rate of deposition and the substrate temperature. Recent work in organic electronics has also shown improved charge carrier mobility associated with anisotropic molecular packing. In this work, grazing-incidence wide angle x-ray scattering (GIWAXS) is used to characterize the structural anisotropy in glasses of a hole transport material, TPD, prepared by physical vapor deposition. A Hermans’ order parameter is used to quantify the changes observed in the scattering patterns of glasses prepared at different substrate temperatures. The order parameter correlates closely with spectroscopic ellipsometry measurements showing different molecular orientations depending upon the substrate temperature during deposition. Additionally, the GIWAXS measurements indicate there is a change in structure at the surface of the film compared with the bulk, providing insight into the formation of stable glasses. These findings may contribute in understanding the enhanced charge carrier mobility observed for anisotropic glasses used in OLEDs.

1:51PM G41.00012 Device applications and structural and optical properties of Indigo – A biodegradable, low-cost organic semiconductor, ZHENGJUN WANG, KELLY L. PISANE, Department of Physics and Astronomy, West Virginia University, CONSTANTINOS SIERROS, Department of Mechanical and Aerospace Engineering, West Virginia University, MOHINDAR S. SHERARA, Department of Physics and Astronomy, West Virginia University, DIMITRIS KORAKAKIS, Lane Department of Computer Science and Electrical Engineering, West Virginia University — Currently, memory devices based on organic materials are attracting great attention due to their simplicity in device structure, mechanical flexibility, potential for scalability, low-cost potential, low-power operation, and large capacity for data storage [1]. In a recent paper from our group, Indigo-based nonvolatile organic write-once-read-many-times (WORM) memory device, consisting of a 100nm layer of indigo sandwiched between an indium tin oxide (ITO) cathode and an Al anode, has been reported [2]. This device is found to be at its low resistance state (ON state) and can be switched to high resistance state (OFF state) by applying a positive bias. In this work, the time constant for the current ratio of the device being up to 1.02 × e6. A summary of the results along with the structural and optical properties of indigo powder will be reported. Analysis of x-ray diffraction shows a monoclinic structure with lattice parameters a=0.924(0.577) , b=0.1222nm and β=117°. Optical absorption shows a band edge at 1.70 eV with peak of absorption occurring at 1.90 eV. These results will be interpreted in terms of the HOMO-LUMO bands of Indigo.

11:15AM G42.00001 Get in Line: Orienting Cylinders in Block Copolymer Thin Films via Shear, RALEIGH DAVIS, RICHARD REGISTER, Princeton University, PAUL CHAIKIN, New York University — Block copolymer thin films have garnered much attention for their potential as nanolithographic masks. For many patterning applications, however, the need to impart well-defined order to the microdomains is paramount. One method to achieve long-range orientational order in thin films is through the use of shear. The ease with which orientation is achieved as well as the ultimate quality of alignment is strongly influenced by the copolymer composition and molecular weight, film thickness, and shearing conditions, as revealed using a series of cylinder-forming poly(styrene)-poly(hexylmethacrylate) (PS-PHMA) copolymers. Quality of in-plane alignment is assessed via atomic force microscopy, quantified through an orientational order parameter \( \psi \). The ease with which alignment is achieved is determined by measuring \( \psi \) as a function of applied shear stress and comparing the results to a melting-recrystallization model which allows for the determination of two key alignment parameters: the critical stress needed for alignment \( \sigma_c \), and an orientation rate constant \( \Gamma \). The \( \psi \) vs. stress behavior, including the time-dependence, is well captured by the model. For monolayers, as \( \psi \) stress fraction or overall molecular weight increases, \( \sigma_c \) also increases, while \( \Gamma \) greatly decreases. As the number of cylinder layers is increased, \( \sigma_c \) decreases to a plateau. The ultimate quality of alignment is studied by comparing \( \psi \) vs. lattice defect density for well-aligned films; \( \psi \) is limited by both undulations in the cylinder trajectories as well as the present of isolated dislocations.

11:27AM G42.00002 How Mechanical Deformation of Polymers during Vitrification Alters the Subsequent Stability of the Glass, LAURA A. G. GRAY, CONNIE B. ROTH, Dept. of Physics, Emory University, Atlanta, GA — How stress and mechanical deformation impart mobility to polymer glasses have been studied primarily for materials where the glassy state was formed stress free. Here, we investigate the stability of polymer glasses where a stress condition is applied during the formation of the glassy state (thermal quench). Previously we found [Gray et al., Macromolecules 2014, 47, 6686] that poly(styrene) macromolecularly imprinted by elongational flow deforms to form a non-conducting polystyrene phase and (often unintended) stress [Macromolecules 2012, 45, 1701]. We constructed a unique jig to apply a known stress to free-standing films during the thermal quench. We used ellipsometry to measure the physical aging rate of polystyrene films by quantifying the time-dependent decrease in film thickness that results from an increase in average film density during aging. As the magnitude of stress during vitrification increases, the physical aging rate quickly transitions over a small range of stresses to a faster aging rate, indicating the resulting glass is less stable [Soft Matter 2014, 10, 1572]. To explore this unique finding, we have constructed a computer-controlled apparatus to measure and apply stress and strain to polymer films during aging in order to characterize the temperature-dependent stress build up.

11:39AM G42.00003 Lithium dendrite growth through solid polymer electrolyte membranes, KATHERINE HARRY, NICOLE SCHAUSER, NITASH BALSA, UC Berkeley — Replacing the graphite-based anode in current batteries with a lithium foil will result in a qualitative increase in the energy density of lithium batteries. The primary reason for not adopting lithium-foil anodes is the formation of dendrites during charging. In this study, stop-motion X-ray microtomography experiments were used to directly monitor the growth of lithium dendrites during electrochemical cycling of symmetric lithium-lithium cells with a block copolymer electrolyte. In an attempt to understand the relationship between viscoelastic properties of the electrolyte on dendrite formation, a series of complementary experiments including cell cycling, tomography, and rheology, were conducted above and below the glass transition temperature of the non-conducting poly(styrene) block; the conducting phase is a mixture of rubbery poly(ethylene oxide) and a lithium salt. The tomography experiments enable quantification of the evolution of strain in the block copolymer electrolyte. Our work provides fundamental insight into the dynamics of electrochemical deposition of metallic films in contact with high modulus polymer electrolytes. Rational approaches for slowing down and, perhaps, eliminating dendrite growth are proposed.

11:51AM G42.00004 DNA-programmed Nanoparticle Self-Assembly and Crystallization via Multi-Scale Modelling & Simulation, TING LI, MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208, USA, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, NORTHWESTERN UNIVERSITY TEAM — In the past decades, DNA hybridization has proven promising to rationally guide nanoparticles to assemble into 1D, 2D and 3D structures, lattices and recently, faceted single crystals. In this sense, a gold nanoparticle coated by a dense shell of DNA behaves as a “programmable atom equivalent.” Using a scale-accurate coarse-grained model with explicit DNA chains, we identify that the key ingredient for achieving successful 3D crystallization is in the kinetics of DNA hybridization. We predict phase diagrams and propose suitable DNA linker sequences for optimal assembly. We determine the equilibrium shape of single crystals by computing surface energies. Surface energy fluctuations are further estimated for different surface orientations, and are shown to be critical in determining the equilibrium shape of a crystal. In addition, we apply a model with implicit DNA chains to study the kinetics of crystalization into faceted single crystals.

12:03PM G42.00005 Chain exchange in triblock copolymer micelles, JIE LU, TIMOTHY LODGE, FRANK BATES, University of Minnesota — Block polymer micelles offer a host of technological applications including drug delivery, viscosity modification, toughening of plastics, and colloidal stabilization. Molecular exchange between micelles directly influences the stability, structure and access to an equilibrium state in such systems and this property recently has been shown to be extraordinarily sensitive to the core block molecular weight in diblock copolymers. The dependence of micelle chain exchange dynamics on molecular architecture has not been reported. The present work conclusively addresses this issue using time-resolved small-angle neutron scattering (TR-SANS) applied to complimentary S-EP-S and EP-S-EP triblock copolymers dissolved in squalane, a selective solvent for the EP blocks, where S and EP refer to poly(styrene) and poly(ethylene-propylene), respectively. Following the overall SANS intensity as a function of time from judiciously deuterium labelled polymer and solvent mixtures directly probes the rate of molecular exchange. Remarkably, the two triblocks display exchange rates that differ by approximately ten orders of magnitude, even though the solvophilic S blocks are of comparable size. This discovery is considered in the context of a model that successfully explains S-EP diblock exchange dynamics.

12:15PM G42.00006 Mechanics of helical mesostructures from polymer-nanoparticle hybrids, JONATHAN PHAM, JIMMY LAWRENCE, GREGORY GRASON, TODD EMRICK, ALFRED CROSBY, University of Massachusetts Amherst — We describe the fabrication and mechanics of polymer and nanoparticle (NP)-based high-aspect ratio mesostructures, which we refer to as ribbons, with nm-scale cross-sections and up to cm-scale lengths. When placed into a fluid like water, interfacial tension associated with the ribbons’ intrinsic geometric asymmetry balances the elastic cost of bending, turning ribbons into helices with tunable preferred curvature. This universal, elastocapillary-based mechanism enables the reversible formation of helices from a variety of polymer and NP compositions, as demonstrated with specific examples of poly(methyl methacrylate), CdSe quantum dots, and gold NPs with polystyrene-azide and undecene ligands. Using custom-designed characterization methods, we quantitatively show that helices are highly stretchable with force-stretch relationships described by a nonlinear spring of finite extensibility. At small strains, these helices generate nN forces, offering mesostructures with a stiffness similar to single polymer chains (ca. 10^-6 N/m), and when fully stretched, they display properties similar to synthetic polymer nanofibers. These mesostructures offer a novel platform for engineering tunable materials with a broad range of mechanical properties and organic or inorganic functionality.
12:27PM G42.00007 Simple, generalizable route to highly aligned block copolymer thin films
, ZHE QIANG, KEVIN CAVICCHI, BRYAN VOGT, Univ of Akron — Macroscopic alignment of block copolymer domains in thin films is desired for many applications, such as cell responsive surfaces or optical polarizers. Alignment generally requires specialized tools that apply external fields, shear force gradient, or produce topological patterned substrates. This requirement limits the broad academic application of aligned BCPs. Here, we describe a simple modification of commonly utilized solvent vapor annealing (SVA) process for macroscopic alignment of BCPs. Adhering a flat, crossed elastics layer to the BCP film leads to partial alignment of the ordered BCP domains. The role of elastomer properties, solvent quality, drying rate and degree of segregation of the block copolymer will be discussed to provide generalized rules for alignment with this technique. Cylindrical nanostructures formed in polystyrene-block-polydimethylsiloxane can be transformed into arrays of silica lines and increasing the thickness from a monolayer to bilayer can effectively halve the spacing of the lines. These results illustrate a generalized method for BCP alignment and a potential route for the generation of complex hierarchical assembled structures.

12:39PM G42.00008 Nanoscale physical properties of polymer glasses formed by solvent-assisted laser depo

, KIMBERLY SHEPARD, CRAIG ARNOLD, RODNEY PRIESTLEY, Princeton University — High-energy, low-density nanostructured polymer glasses are formed via the solvent-assisted laser deposition technique MAPLE (Matrix Assisted Pulsed Laser Evaporation). During film deposition, micro- to nano-size polymer/solvent clusters are ejected via laser ablation from a frozen dilute polymer solution. During flight to the substrate under vacuum, the clusters experience rapid cooling and solvent stripping, forming polymer nanoglobules. Bulk polymer films are formed via the gradual assembly of these spherical-like nanostructured building blocks (i.e. nanoglobules). The MAPLE process thus enables investigation of the exceptional properties of glasses formed under extreme processing conditions. In the bulk state, we probe the effect of process parameters and chemical identity of the thermal behavior of a series of methacrylate polymers. We also employ multiple techniques to directly measure the properties of the polymer nanoglobules and connect the results to the global film properties.

Session G43 DPOLY DBIO GSOFT: Focus Session: Fluids Under Confinement and in Biological Systems

11:15AM G43.00001 Stiff Filamentous Viruses Probe the Mobility of Counterions During Nanopore Translocations , ANGUS MCMULLEN, JAY TANG, DEREK STEIN, Brown University — We study the electrophoresis of two different filamentous viruses and double-stranded DNA through solid-state nanopores. The two viruses we examine, fd and M13, are both 880 nm in length, 6.6 nm in diameter, very stiff, and monodisperse. They only differ in their linear charge density, which is 30% lower for M13 than for fd. Filamentous viruses are therefore ideal for testing transport models and for comparisons with DNA dynamics. We find that the mean translocation speed of fd virus is related to the nanopore diameter, D, and the virus diameter, d, as ln([D/d])−1, in agreement with the conventional electrokinetic model of translocations. In order to obtain quantitative agreement between that electrokinetic model and the measured translocation dynamics, however, one must conclude that the mobility of counterions within a few Angstroms of the polymer surface is strongly reduced from the bulk value. Similar reductions in counterion mobility near fd, M13, and dsDNA explain their dynamics over a wide range of ionic strengths. This work was supported by NSF Grant CBET0846505, NSF Grant PHY1069375 and Oxford Nanopore Technologies.

11:27AM G43.00002 Salmonella detection in a microfluidic channel using orbiting magnetic beads1. MATT BALLARD, ZACHARY MILLS, DREW OWEN, SRINIVAS HANASOGO, PETER HESKETH, ALEXANDER ALEXEEV, Georgia Institute of Technology — We use three-dimensional simulations to model the detection of salmonella in a complex fluid sample in a microfluidic channel. Salmonella is captured using magnetic microbeads orbiting around soft ferromagnetic discs at the microchannel bottom subjected to a rotating external magnetic field. Numerical simulations are used to model the dynamics of salmonella and microbeads throughout the detection process. We examine the effect of the channel geometry on the salmonella capture, and the forces applied to the salmonella as it is dragged through the fluid after capture. Our findings guide the design of a lab-on-a-chip device to be used for detection of salmonella in food samples in a way that ensures that salmonella captured by orbiting microbeads are preserved until they can be extracted from the system for testing, and are not washed away by the fluid flow or damaged due to the experience of excessive stresses. Such a device is needed to detect bacteria at the food source and prevent of consumption of contaminated food, and also can be used for the detection of a variety of biomaterials of interest from complex fluid samples.

11:39AM G43.00003 Sequencing proteins with transverse ionic transport , PAUL BOYNTON, MASSIMILIANO DI VENTRA, University of California, San Diego — De novo protein sequencing is essential for understanding cellular processes that govern the function of living organisms. By obtaining the order of the amino acids in the protein, one can determine both its secondary and tertiary structures through protein structure prediction, which is used to create models for protein aggregation diseases such as Alzheimer’s Disease [1]. Mass spectrometry is the current technique of choice for de novo sequencing, but because some amino acids have the same mass the sequence cannot be completely determined in many cases. In this paper we propose a new technique for de novo protein sequencing that involves translocating a polypeptide through a synthetic nanochannel and measuring the ionic current of each amino acid through an intersecting perpendicular nanochannel, similar to that proposed in [2] for DNA sequencing. Indeed, we find that the distribution of ionic currents for each of the 20 proteinogenic amino acids encoded by eukaryotic genes is statistically distinct, showing this technique’s potential for de novo protein sequencing.

11:51 AM G43.00004 Nanoscale Electrospray Ion Sources and a New DNA Sequencing Technique. WILLIAM MAULBETSCHE, Brown University, JOSEPH BUSH, Bronx Community College, DEREK STEIN, Brown University, STEIN LAB TEAM — Electrospray ion sources are used to transfer biochemical samples from solution into a charged gas phase for analysis, especially by mass spectrometry. Traditional ion sources require a background gas and high voltages, and waste most of the sample passed through the source’s micrometer-scale tip. However, by scaling down the ion source to the nanoscale, we greatly reduce voltage and sample volume requirements, while eliminating the need for a background gas to desolvate droplets. We report experiments investigating the onset and characteristics of electrospray from glass capillaries whose tips were pulled down to an inner diameter on the order of 100 nanometers. Nanoscale ion sources serve as an integral part of a DNA sequencing technique we will describe, whereby DNA bases are identified by the molecular masses of the nucleotides. This work was supported by NIH grant 1R21HG005100-01 and by Oxford Nanopore Technologies, Ltd.

12:03PM G43.00005 Statics and dynamics of softly confined polymers. ANDREA SCAGLIRANI, MAURO SBRAGAGLIA, Department of Physics, University of Rome “Tor Vergata”, MARCELLO SEGA, Department of Computational Biological Chemistry, University of Vienna — A variety of biological and technological problems where long chain molecules are constrained in spaces small compared to the molecule size (like membrane nanopores or nanofluidic slits) motivated recently a growing effort to understand the dynamics and structural scaling properties of polymers confined by solid walls. Our focus is, instead, on polymers confined in different geometries by soft interfaces, mimicking, e.g., DNA packaging inside cell nuclei or, mutatis mutandis, viral capsids. Soft-confinement is achieved by a proper choice of the solvation energies such that the polymer is trapped in one of the two phases of a binary mixture of immiscible liquids. We perform Molecular Dynamics simulations of polymers coupled with a fluctuating lattice Boltzmann method for the embedding matrix. Slab and droplet configurations are considered. In the former case we address the transition among various regimes of size scaling at changing the slab width. Under shear, the droplet is distorted from its equilibrium spherical shape and we explore how the transition from an isotropic geometry to a quasi-tube-like one affects polymer size scaling and knotting degree. Finally, we show how the feedback on the solvent induces viscoelastic rheology that can be related to polymer entanglement.

12:15PM G43.00006 Threading moieties play a significant role in determining the DNA binding properties of binuclear ruthenium complexes. THAYAPARAN PARAMANATHAN, Department of Physics, Bridgewater State University, Bridgewater, MA, ANDREW CLARK, Department of Physics, Northeastern University, Boston, MA, FREDRIK WESTERLUND, PER LINCOLN, Department of Chemical and Biological Engineering, Chalmers University of Technology, Gothenburg, MICAH J. MCCAULEY, Department of Physics, Northeastern University, Boston, MA, IOULIA ROUZINA, Department of Biochemistry, Molecular Biology and Biophysics, University of Minnesota, Minneapolis, MN, MARK C. WILLIAMS, Department of Physics, Northeastern University, Boston, MA — Binuclear ruthenium complexes are of interest due to their selective DNA binding properties, which make them potential candidates for chemotherapy. These dumbbell shaped molecules have to thread through the DNA base pairs to reach their final threaded intercalation state. Here we study the binuclear ruthenium complex, \( \Delta \Lambda^\mu \text{-bidppz}(bpy)_2\text{Ru}^{4+} \), and compare it with the previously studied \( \Delta \Lambda^\mu \text{-hidppz}(phen)_2\text{Ru}^{4+} \). Both have the same intercalating bridge unit, but different threading moieties. In this study, we stretch a single DNA molecule held with optical tweezers in the presence of the ligand at various concentrations and hold the DNA at constant force until an equilibrium DNA elongation is reached. The extension of the DNA obtained as a function of time during binding yields the kinetics and equilibrium binding properties of the ligand. The preliminary data suggests that the binuclear complex with bpy in the threading moiety shows stronger affinity and an order of magnitude faster on rate, compared to its counterpart with phen in the threading moiety. This confirms the hypothesis that the extra aromatic ring of phen interferes with the threading intercalation process.

12:27PM G43.00007 Physics and (patho)physiology in confined flows: from colloidal patterns to cytoplasmic rheology and sickle cell anemia. L. MAHADEVAN, Harvard University — I will discuss a few problems that involve the interaction of fluids and solids in confined spaces. (i) Jamming in pressure-driven suspension flows that show a transition from Stokes flows to Darcy flows as the solids start to lock, as in evaporative patterning in colloids (e.g., coffee stain formation). (ii) Jamming and clogging of red blood cells, as in sickle-cell pathophysiology, with implications for other diseases that involve jamming. (iii) The mechanical response of crowded networks of filaments bathed in a fluid, as in the cytoskeleton, that can be described by poroelasticity theory. In each case, I will show how simple theories of multiphase flow and deformation can be used to explain a range of experimental observations, while failing to account for others, along with some thoughts on how to improve them.

1:03PM G43.00008 Quantifying the molecular mechanism for highly stereo-selective DNA threading intercalation. ALI ALMAQWASHI, Northeastern University, JOHANNA ANDERSSON, Uppsala University, PER LINCOLN, Chalmers University of Technology, IOULIA ROUZINA, University of Minnesota, FREDRIK WESTERLUND, Chalmers University of Technology, MARK C. WILLIAMS, Northeastern University — DNA threading intercalators, such as binuclear ruthenium complexes, are regarded as potential DNA-targeted therapeutic drugs because of slow kinetics and high affinity. Recent bulk studies reported that poly(dADT) threading intercalation by the binuclear ruthenium complex \( \mu \text{-dpzip(phen)}_2\text{Ru}^{4+} \) is highly stereo-selective. The largest fractional binding was achieved for \( \Delta \Lambda^\mu \text{-Piz} \), with the \( \Lambda \) (right handed) configuration at the distal imidazophenanthroline (ip) subunit and the \( \Lambda \) (left handed) configuration at the distal imidazophenanthroline (ip) subunit. To quantify this highly stereo-selective molecular mechanism, we used optical tweezers to probe single \( \lambda \)-DNA molecules elongation due to the threading intercalation by each of \( \Delta \Lambda^\mu \text{-Piz} \) and \( \Delta \Lambda^\mu \text{-Piz} \). While maintaining a DNA stretching force of 30 pN and a ligand concentration of 5 nM, the elongation was traced until reaching equilibrium. Then it was traced back to the free DNA extension by rinsing out the bound ligands. We found that the equilibrium elongation for \( \Delta \Lambda^\mu \text{-Piz} \) is 30% larger, and the affinity is 50% higher relative to \( \Delta \Lambda^\mu \text{-Piz} \). Further force-dependent study will quantitatively determine the differences in the zero-force binding site size, affinity and the DNA structural dynamics for association and dissociation.

1:15PM G43.00009 Improving signal-to-noise performance for DNA translocation in solid-state nanofluidic channels. THOLOMEOUS MACHIELSE, ADRIAN BALAN, University of Pennsylvania, JIANXUN LIN, PEIJIE ONG, Columbia University, REBECCA ENGELKE, Univ of Pennsylvania, KENNETH SHEPARD, Columbia University, MARIJA DRNĐIC, Univ of Pennsylvania — DNA sequencing using solid-state nanofluidic channels is impeded by the relatively high noise and low bandwidth of the current state-of-the-art translocation measurements. We measure the ion current noise through SiN nanofluidic channels at bandwidths up to 1 MHz. At these bandwidths, the input-referred current noise is dominated by the amplifier’s voltage noise acting across the total capacitance at the amplifier input. By reducing the nanopore membrane capacitance we are able to transition to a regime in which current noise is dominated by the effects of the capacitance of the amplifier itself. Advances in bandwidth and signal-to-noise ratio necessary for DNA sequencing will require lower capacitance devices as well as new amplifier designs with reduced input capacitance and noise characteristics.

1:27PM G43.00010 DNA translocation measurements through low-capacitance solid-state nanopore chips at high bandwidths, CHEN-CHI CHIEN, DAVID NIEDZWIECKI, BARTHOLOMEUS MACHIELSE, ADRIAN BALAN, University of Pennsylvania, JIANXUN LIN, PEIJIE ONG, KENNETH SHEPARD, Columbia University, MARIJA DRNDIC, University of Pennsylvania — We perform DNA translocation measurements with low-noise solid state nanopore chips. We obtain higher ion current signal-to-noise ratio and better resolution in ion current signals than previously reported in solid state nanopores at high bandwidths with chip capacitance lowering techniques of applying extra insulation on the chip surface. We show measurements of ion current during translocation of DNA molecules through thin silicon nitride (SiN) nanopores of small diameters at megahertz bandwidths with enhanced ion current signal-to-noise ratios. We further discuss how these results possibly pave the way towards identifying intramolecular DNA sequences with solid-state nanopores.

1:39PM G43.00011 Up and down events in nanoparticle translocation through solid-state nanopores, MEHDI ZANJANI, REBECCA ENGELKE, JENNIFER LUKES, MARIJA DRNDIC, University of Pennsylvania — We study translocation of nanoparticles through solid-state nanopores. Normally, nanoparticle passage is expected to decrease ion current inside the nanopores, as in the case of typical Coulter counters. However, recent experiments have reported translocation events that show an increase in the ion current. We refer to such decrease and increase in ion current as down events and up events respectively. We use theoretical methods to study such events and to determine the conditions under which they happen. A transition nanopore diameter, \( d_t \), is calculated from the theoretical model; up events are observed for nanopore diameters smaller than \( d_t \), while for nanopore diameters larger than \( d_t \), down events will occur. We also discuss how a simple mechanism can be implemented to distinguish nanoparticles of different shapes and sizes based on such up and down translocation events.

1:51PM G43.00012 Structural Integrity of Proteins under Applied Bias during Solid-State Nanopore Translocation \( t \), MOHAMMAD R. HASAN, RAJA RAHEEL KHANZADA, MOHAMMED A. I. MAHMOOD, ADNAN ASHAFAQ, University of Texas at Arlington, SAMIR M. IQBAL, Nano-Bio Lab, Electrical Engineering, Bioengineering, University of Texas at Arlington — The translocation behavior of proteins through solid-state nanopores can be used as a new way to detect and identify proteins. The ion current through a nanopore that flows under applied bias gets perturbed when a biomolecule traverses the Nanopore. It is important for a protein detection scheme to know of any changes in the three-dimensional structure of the molecule during the process. Here we report the data on structural integrity of protein during translocation through nanopore under different applied biases. Nanoscale Molecular Dynamic was used to establish a framework to study the changes in protein structures as these travelled across the nanopore. The analysis revealed the contributions of structural changes of protein to its ion current signature. As a model, thymopin protein crystalline structure was imported and positioned inside a 6 nm diameter pore in a 6 nm thick silicon nitride membrane. The protein was solvated in 1 M KCl at 295 K and the system was equilibrated for 20 ns to attain its minimum energy state. The simulation was performed at different electric fields from 0 to 1 kCal/(mol.˚A.e). RMSD, radial distribution function, movement of the center of mass and velocity of the protein were calculated. The results showed linear increments in the velocity and perturbations in ion current profile with increasing electric potential.

Session G44 GSNP: Focus Session: Extreme Mechanics: Contortion of Filaments, Ribbons and Bundles

11:15AM G44.00001 Spontaneous formation of singularities in twisted ribbons, JULIEN CHOPIN, ESPCI, ARSHAD KUDROLLI, Clark University — We present experimental results on the spontaneous formation of a triangular tessellation of a thin elastic ribbon which is twisted with a prescribed longitudinal tension. We find that triangular patterns arise out of a period doubling of a primary longitudinal instability as the twist is increased in contrast with theoretical development assuming infinitely thin, inextensible sheet. Using x-ray tomography, we are able to reconstruct the 3D shape of the ribbon which can then be precisely characterized by measuring locally the mean and Gaussian curvature. We discuss quantitatively the structures of singularities (d-cones and ridges) as a function of nondimensional parameters characterizing the twist, the tension, and the geometry of the ribbon. Because the observed singularities occur away from walls and boundaries, the twisted ribbon configuration provides a unique opportunity to address the spontaneous formation of localized structures with great experimental flexibility.

11:27AM G44.00002 Perversions driven spontaneous symmetry breaking in heterogeneous elastic ribbons, SHUANGPING LIU, ZHENWEI YAO, MONICA OLVERA DE LA CRUZ, Northwestern Univ — Perversion structures in an otherwise uniform helical structure are associated with several important concepts in fundamental physics and materials science, including the spontaneous symmetry breaking and the elastic buckling. They also have strong connections with biological motifs (e.g., bacteria shapes and plant tendrils) and have potential applications in micro-muscles and soft robotics. In this work, using a three-dimensional elastomeric bi-stripe model, we investigate the properties of perversions that are independent of the specific ribbon shapes. Several intrinsic features of perversions are revealed, including the spontaneous condensation of energy as well as the distinct energy transfer modes within the perversion region. These properties of perversions associated with the storage of elastic energies can be exploited in the design of actuator devices.

11:39AM G44.00003 Deswelling and buckling of a temperature-sensitive hydrogel toroid, MICHAEL DIMITRIYEV, YA-WEN CHANG, ANTÓN SÓUSLOV, ALBERTO FERNANDEZ-NIEVES, PAUL GOLDBART, Georgia Institute of Technology — Temperature-sensitive hydrogels lose volume with increasing temperature by expelling water from their polymer matrix, which becomes effectively hydrophobic above a certain critical temperature. Whilst the temperature response of a spherically shaped sample of hydrogel has been well studied, less is known about the response of a toroidal sample. We present a model for the behavior of a hydrogel toroid for two cases of heating protocol: (i) the quasistatic limit, in which the sample loses volume but is found to maintain its toroidal shape; and (ii) the rapid quench limit, after which the sample is found to have maintained its volume but may have undergone a macroscopic, qualitative change of shape to a buckled toroid. For the quench-limit case, we develop a criterion for the stability of the rotationally symmetric state of the toroid, by utilizing an effective elastic ring model. When this criterion is no longer met, a long-wavelength deformation leads to a buckling instability of the toroid in a manner analogous to the buckling of an Euler rod.
12:27PM G44.00005 Stretchability of freestanding and polymer-supported serpentine thin films\textsuperscript{1}, NANNSHU LU, SHIXUAN YANG, University of Texas at Austin — High-performance stretchable electronics integrate high-quality inorganic electronic materials such as metal, semiconductor and oxide with deformable polymer substrates. To minimize strains in inorganic materials under large deformation, metal and ceramic thin films can both be patterned into meandering serpentine ribbons which can rotate and twist to accommodate the applied strain. We have systematically investigated the effects of geometry and substrate stiffness on the stretchability of serpentine through both theoretically and experimental means. For freestanding serpentine, closed-form analytical solutions are obtained and validated by experiments. To investigate the effect of substrates, indium tin oxide (ITO) serpentine are patterned on both polyimide and elastomeric substrates with systematically changing geometries. While stiff substrates such as polyimide almost completely prevents the rotation or twist of the serpentine, soft substrates can provide serpentine with reasonable freedom of rotation and twisting, which yields stretchability of ITO ribbons beyond 100\%. But new failure mechanisms have been found on soft substrates.

12:39PM G44.00006 Coiling of elastic rods from a geometric perspective, MOHAMMAD JAWED, PIERRE-THOMAS BRUN, PEDRO REIS, Massachusetts Institute of Technology — We present results from a systematic numerical investigation of the pattern formation of coiled obtained when a slender elastic rod is deployed onto a moving substrate; a system known as the elastic sewing machine (ESM). The Discrete Elastic Rods method is employed to explore the parameter space, construct phase diagrams, identify their phase boundaries and characterize the morphology of the patterns. The nontrivial geometric nonlinearities are described in terms of the gravito-bending length and the deployment height. Our results are interpreted using a reduced geometric model for the evolution of the position of the contact point with the belt and the curvature of the rod in its neighborhood. This geometric model reproduces all of the coiling patterns of the ESM, which allows us to establish a universal link between our elastic problem and the analogous patterns obtained when depositing a viscous thread onto a moving surface; a well-known system referred to as the fluid mechanical sewing machine.

12:51PM G44.00007 The shape of strings to come: How topological defects twist, bend, and wrinkle filament bundles\textsuperscript{1}. ISAAC BRUSS, GREGORY GRASON, Univ of Mass - Amherst — Topological defects are crucial to the thermodynamics and structure of condensed matter systems. For instance, when incorporated into crystalline membranes like graphene, 5- and 7-fold disclinations produce conical- and saddle-like geometries respectively. A recently discovered mapping between the inter-filament spacing within a deformed bundle and the metric properties of curved surfaces, suggests previously unexplored parallels between the two, specifically in regards to how 2D patterning promotes 3D shape transitions. This discovery is poised to describe the structure of a host of filamentous materials—both biological and microfabricated—that exhibit distinctive shapes and packings. Motivated by the filamentous analogs to the conical and saddles shapes found in thin membranes, we investigate for the first time the interplay between defects in the cross section of a bundle and its global structure, using a combination of continuum elasticity theory and numerical simulation of cohesive bundles with a fixed packing topology. Focusing primarily on the instability response to disclinations, we predict a host of new equilibria structures, some of which are without direct parallel to the analogous membrane, including torsional wrinkling, radial kinking, and helical winding.

1:03PM G44.00008 Rotation of a Thin Elastic Rod Injected into a Cylindrical Constraint\textsuperscript{1}, CONNOR MULCAHY, Massachusetts Institute of Technology, TIANXIANG SU, NATHAN WICKS, JAHIR PABON, Schlumberger-Doll Research, PEDRO REIS, Massachusetts Institute of Technology — We report the results from an experimental investigation of the buckling of a thin elastic rod injected into a horizontal cylindrical constraint, with an emphasis on comparing the two cases of rotating, or not, the rod at the injection site. We are particularly interested on the total length of rod that can be injected into the pipe prior to the onset of helical buckling. This instability arises due to the frictional rod-constraint contact that eventually leads to the buildup of axial stress on the rod, above a critical value. We explore the dependence of the buckling conditions on the physical and control parameters of the system (e.g. material and geometric parameters, injection speed and rotation frequency) and rationalize the underlying physical mechanism through a reduced model.

\textsuperscript{1}Funding and support provided by Schlumberger-Doll Research.

1:15PM G44.00009 Stress localisation in annular sheets, GERT VAN DER HEIJDEN, EUGENE STAROSTIN, University College London — For very thin sheets stretching is much more costly in terms of energy than bending. The limiting behaviour of thin sheets is therefore governed by geometry only and thus applies to a wide range of materials at vastly different scales: it is equally valid for a microscopic graphene sheet and a macroscopic sail. We derive new geometrically-exact equations for the deformation of annular strips. We use a formulation in which the inextensibility constraint is used to reduce the problem to a suitably-chosen reference curve (here the circular centreline). The equations are therefore ODEs, which allow for a detailed bifurcation analysis. Closed conical solutions are found for centreline lengths \( L < L_c = 2\pi \kappa_0 \), where \( \kappa_0 \) is the geodesic curvature of the strap. For such 'short' strips we find in addition a second branch of solutions easily reproduced in a paper strip. For 'long' strips (\( L > L_c \)) we find modes of undulating solutions. All non-conical solutions turn out to feature points of stress localisation on the edge of the annulus, the outer edge for short solutions and the inner edge for long solutions. Our theory may be used to investigate singularities of constrained or loaded sheets more general than conical ones.

1:27PM G44.00010 Large-deformation dynamics of an elastic filament at a fluid interface, SRINIVASA GOPALAKRISHNAN GANGA PRASATH, JOEL MARTELOT, RAMA GOVINDARajan, TCIS, TIIFR Hyderabad and Dept. of Physics, UMass Amherst, TCIS, TIFR Hderabad and DEPT. OF PHYSICS, UMASS AMHERST COLLABORATION — We study the dynamics of a thin elastic filament at the interface of two fluids and observe the time evolution in its shape when released from an initial configuration with a large curvature. The unfolding of the filament is driven by a competition between bending energy and viscous dissipation. We experimentally study the overdamped regime of this system by varying fluid viscosity (\( \nu \)), length (\( L_f \)) diameter (\( d \)) and elastic modulus (\( E \)) of the filament with similar initial conditions and observe the kinematics of the filament straightening. The time-dependence for this process can be collapsed by scaling time by \( \nu L_f^4 / Ed \). However, the characteristic time is a very small fraction of this time-scale. We perform numerical computations parallel to the experiments to get access to the dynamics of the filament to resolve this puzzle. An understanding of the time-dependence will enable the use of this technique to measure interfacial properties.
1:39PM G44.00011 Elasto-capillary windlass: from spider web to synthetic actuators1, HERVÉ ELETTRO, ARNAUD ANTKOWIAK, SÉBASTIEN NEUKIRCH, Institut d’Alembert, FRITZ VOLLRATH, Oxford Silk Group, INSTITUT D’ALEMBERT TEAM, OXFORD SILK GROUP TEAM — Spiders’ threads display a wide range of materials properties. The glue-covered araneid capture silk is unique among all silks because it is self tensing and remains taut even if compressed, allowing both thread and web to be in a constant state of tension. Here we demonstrate how this effect is achieved by unraveling the physics allowing the nanolitre glue droplets straddling the silk thread to induce buckling, coiling and spooling of the core filaments. Our model explains this windlass activation as a structural phase transition, which shows that fibre spooling results from the interplay between elasticity and capillarity. Fibre size is the key as such a capillary windlass requires micrometer-sized fibres in order to function. Our synthetic capillary windlasses point towards design principles for new bioinspired synthetic actuators.

1:51PM G44.00012 Variability of Fiber Elastic Moduli in Composite Random Fiber Networks Makes the Network Softer, EHSAN BAN, CATALIN PICIU, Rensselaer Polytech Inst — Thermal fiber networks are assemblies of beams or trusses. They have been used to model mechanics of fibrous materials such as biopolymer gels and synthetic nonwovens. Elasticity of these networks has been studied in terms of various microstructural characteristics such as the stiffness of their constituent fibers. In this work we investigate the elasticity of composite fiber networks made from fibers with moduli sampled from a distribution function. We use finite elements simulations to study networks made by 3D Voronoi and Delaunay tessellations. The resulting data collapse to power laws showing that variability in fiber stiffness makes fiber networks softer. We also support the findings by analytical arguments. Finally, we apply these results to a network with curved fibers to explain the dependence of the network’s modulus on the variation of its structural parameters.

Tuesday, March 3, 2015 11:15AM - 2:15PM — Session G45 DPOLY: Focus Session: Polymers in Batteries and Electrochemical Capacitors I

11:15AM G45.00001 Electrostatic Assembly of Nanomaterials for Hybrid Electrodes and Supercapacitors, PAULA HAMMOND, Massachusetts Institute of Technology — Electrostatic assembly methods have been used to generate a range of new materials systems of interest for electrochemical energy and storage applications. Over the past several years, it has been demonstrated that carbon nanotubes, metals, metal oxides, polymeric nanomaterials, and biotemplated materials systems can be incorporated into ultrathin films to generate supercapacitors and battery electrodes that illustrate significant energy density and power. The unique ability to control the incorporation of such a broad range of materials at the nanometer length scale allows tailoring of the final properties of these unique composite systems, as well as the capability of creating complex micron-scale to nanoporous morphologies based on the scale of the nanomaterial that is absorbed within the structure, or the conditions of self-assembly. Recently we have expanded these capabilities to achieve new electrodes that are templated atop electrospun polymer fiber scaffolds, in which the polymer can be selectively removed to achieve highly porous materials. Spray-layer-by-layer and filtration methods of functionalized multiwall carbon nanotubes and polyaniline nanofibers enable the generation of electrode systems with unusually high surface. Incorporation of pseudocapacitive nanoparticles can enhance capacitive properties, and other catalytic or metallic nanoparticles can be implemented to enhance electrochemical or catalytic function.

11:51AM G45.00002 High Energy Density and High Temperature Multilayer Capacitor Films for Electric Vehicle Applications1, IMRE TREUFELD, MICHELLE SONG, LEI ZHU, ERIC BAER, Case Western Reserve University, JOE SNYDER, Orbital Research Inc., DEEPAK LANGHE, Polymer Plus LLC. — Multilayer films (MLFs) with high energy density and high temperature capability (>120 °C) have been developed at Case Western Reserve University. Such films offer a potential solution for electric car DC-link capacitors, where high ripple currents and high temperature tolerance are required. The current state-of-the-art capacitors used in electric cars for converting DC to AC use biaxially oriented polypropylene (BOPP), which can only operate at temperatures up to 85 °C requiring an external cooling system. The polycarbonate (PC)/poly(vinylidene fluoride) (PVDF) MLFs have a higher permittivity compared to that of BOPP (2.3), leading to higher energy density. They have good mechanical stability and reasonably low dielectric losses at 120 °C. Nonetheless, our preliminary dielectric measurements show that the MLFs exhibit appreciable dielectric losses (20%) at 120 °C, which would, despite all the other advantages, make them not suitable for practical applications. Our preliminary data showed that dielectric losses of the MLFs at 120 °C up to 400 MV/m and 1000 Hz originate mostly from impurity ionic conduction.

12:03PM G45.00003 Orientationally Ordered Lamellar Block Copolymer Films for Electrostatic Capacitor Applications, CHRISTOPHER GRABOWSKI, Air Force Research Laboratory, SAUMIL SAMANT, ALAMGIR KARIM, Univ. of Akron, MICHAEL DURSTOCK, Air Force Research Laboratory — Improving the maximum operating voltage of an electrostatic capacitor requires materials that can better suppress breakdown initiation and/or forestall breakdown propagation. Progress has been made in developing layered architectures through polymer co-extrusion and inorganic nanocomposites, which create tortuous pathways to the applied electric field, resulting in increased breakdown strength. Block copolymer films provide another route to achieve such layered structures, while allowing more control over orientation, domain size, and morphology. We report the dielectric performance of micron-thick linear diblock copolymer films consisting of polystyrene-b-poly-2-vinylpyridine and polystyrene-b-poly methyl methacrylate, focusing on molecular weight ratios that yield lamellar and spherical morphologies. Specialized techniques such as cold-zone soft shear annealing allow for the precise control of lamellae orientation (layering parallel or perpendicular to the applied electric field). Our results indicate dielectric breakdown performance for parallel ordered lamellae is greater than comparable perpendicularly lamellae and as-cast films with no induced microphase separation, which we attribute to the presence of interfacial layers that act as barriers to the applied field.

12:15PM G45.00004 Origins of enhanced capacity retention in copolymerized sulfur-based composite cathodes for Li-S batteries, CHRISTOPHER SOLES, VLADIMIR OLESHKO, JENNY KIM, STEVEN HUDSON, NIST, KOOKEON CHAR, Seoul National University, JARED GRIEBEL, ADAM SIMMONDS, RICHARD GLASS, JEFF PYUN, University of Arizona — Poly(sulfur-random-(1,3-diisopropenylbenzene) (poly(S-r-DIB)) copolymers synthesized via inverse vulcanization form high molecular mass electrochemically active polymers capable of enhanced capacity (1005 mAh/g at 100 cycles) and lifetimes over 500 cycles as cathodes for Li-S batteries. In this presentation we characterize the morphology when the poly(S-r-DIB) copolymers are mixed conductive carbon to form functional Li-S cathodes. Scanning and transmission electron microscopy are used to demonstrate that the use elemental sulfur leads to heterogeneous aggregates of carbon nanoparticles and poor mixing with the sulfur, forming a loosely percolated network of electrically conductive pathways and extended micro- and mesoscale porosity. The poly(S-r-DIB) copolymers tend to mix more intimately with the carbon nanoparticles because of a stronger cohesion between the components. This increases the compositional homogeneity, increases the contact between the electrochemically active components and improves the physico-mechanical stability of the cathode which leads to increased capacity and enhanced cycle life in a full battery. We also introduce a new Li ion microscopy technique as a tool for characterizing battery materials.
12:27PM G45.00005 Effect of Molecular Weight on Mechanical and Electrochemical Performance of All Solid-State Polymer Electrolyte Membranes1, RUIXUAN HE, University of Akron, DANIEL WARD, Miami University, MAURICIO ECHEVERRI, Kent Displays Inc., THEIR KYU, University of Akron — Guided by ternary phase diagrams of polyethylene glycol diacrylate (PEGDA), succinonitrile plasticizer, and LiTFSI salt, completely amorphous solid-state transparent polymer electrolyte membranes (ss-PEM) were fabricated by UV irradiation in the isotropic melt state. Effects of PEGDA molecular weight (700 vs 6000 g/mol) on ss-PEM performance were investigated. These amorphous PEMs have superionic room temperature ionic conductivity of $\sim 10^{-3}$ S/cm, whereby PEGDA6000-PEM outperforms its PEGDA700 counterpart, which may be ascribed to lower crosslinking density and greater segmental mobility. The longer chain between crosslinked points of PEGDA6000-PEM is responsible for greater extensibility of $\sim 80\%$ versus $\sim 7\%$ of PEGDA700-PEM. Besides, both PEMs exhibited thermal stability up to 120 °C and electrochemical stability versus Li$^+$/Li up to 4.7V. LiFePO$_4$/PEM/Li and Li$_2$Ti$_3$O$_7$ /PEM/Li half-cells exhibited stable cyclic behavior up to 50 cycles tested with a capacity of $\sim 140\text{mAh/g}$, suggesting that LiFePO$_4$/PEM/Li$_2$Ti$_3$O$_7$ may be a promising full-cell for all solid-state lithium battery.

1We thank NSF-DMR 1161070 for providing funding of this project.

12:39PM G45.00006 Stacked Polymer nanofiber array for high-performance supercapacitors1, SHIREN WANG, Texas A&M Univ, JENNY QIU, Texas Tech University — The vertically aligned polyaniline (PANI) nanowires arrays and monolayer graphene sheets were layer-by-layered deposited to specific substrate for tailored structures. Driven by external voltage, aniline molecules and graphene oxide were alternatively assembled for hierarchical porous three-dimensional nanostructures while graphene oxide was in-situ reduced to graphene during the assembly process. As-produced stacked arrays were used as the electrodes of an ultra-capacitor, and an unusual electrochemical behavior was discovered. The capacitance increases as the stack of nanowire arrays increases, resulting in high energy density and high power density at same time. Further analysis found that the distinctive electrochemical behavior originates from the electrode/electrolyte interactions and the dependence on the diffusion and charge transferring process. The specific energy density was as high as 137 Wh/Kg while power density is in excess of 2000 W/Kg. This work pointed a simple pathway to tailor polymer structure and electrochemistry for robust design of high-performance ultra-capacitor at a limited lateral size.

12:51PM G45.00007 Sprayable, Paintable Layer-by-Layer Polyaniline Nanofiber/Graphene Electrodes for Electrowe Storage , SE RA KWON, JU-WON JEON, JODIE LUTKENHAUS, Department of Chemical Engineering, Texas A&M University — Sprayable batteries are growing in interest for applications in structural energy storage and power or flexible power. Spray-assisted layer-by-layer (LbL) assembly, in which complementary species are alternately sprayed onto a surface, is particularly amenable towards this application. Here, we report on the fabrication of composite films containing polyaniline nanofibers (PANI NF) and graphene oxide (GO) sheets fabricated via spray-assisted LbL assembly. The resulting films are electrochemical reduced to yield PANI NF/electrochemically reduced graphene (ERGO) electrodes for use as a cathode in non-aqueous energy storage systems. Through the spray-assisted LbL process, the hybrid electrodes could be fabricated 74 times faster than competing dip-assisted LbL assembly. The resulting electrodes are highly porous (0.72 void fraction), and are comprised of 67 wt% PANI NF and 33 wt% ERGO. The sprayed electrodes showed better rate capability, higher specific power, as well as more stable cycle life than dip-assisted LbL electrodes. It is shown here that the spray-assisted LbL approach is well-suited towards the fabrication of paintable electrodes containing polyaniline nanofibers and electrochemically reduced graphene oxide sheets.

1:03PM G45.00008 Superionic solid-state polymer electrolyte membrane for high temperature applications1, THEIR KYU, University of Akron, RUIXUAN HE, JINWEI CAO, University of Akron — Completely amorphous, flexible, solid-state polymer electrolyte membranes (ss-PEM) consisted of polyethylene glycol diacrylate/succinonitrile plasticizer (SCN)/lithium trifluorosulfonyl imide were fabricated via UV polymerization. The room temperature ionic conductivity of our ss-PEM is extremely high (i.e., $10^{-3}$/S/cm), which is already in the superionic conductor range of inorganic and/or liquid electrolyte counterparts. Of particular interest is that our ss-PEM is thermally stable up to 140°C, which is superior to the liquid electrolyte counterpart that degrades above 80°C. The ss-PEM exhibits cyclic stability in both LiFePO$_4$/Li and Li$_2$Ti$_3$O$_7$/Li half-cells up to 50 cycles tested. The trend of conductivity enhancement with temperature is reproducible in the repeated cycles, showing melting transitions of the SCN plastic crystals. In the compositions close to the solid (SCN plastic crystal)-liquid coexistence line, polymerization-induced crystallization occurs during photo-curing. The effect of solid-liquid segregation on ionic conductivity behavior is discussed.

1:15PM G45.00009 Spatial position control of nanofeatures assisted by nanoporous templates fabricated by block copolymer based lithography, DONG HYUN LEE, DONG-EUN LEE, Dankook Univ — Herein, we demonstrated a unique method to control spatial arrangement of nanofeatures by using topographically patterned substrates. The thin films of block copolymers (BCPs) were firstly prepared on a thin layer of poly(vinyl alcohol) (PVA). Then to induce ordering of the BCPs, the thin films were solvent-annealed, DONG HYUN LEE, DONG-EUN LEE, Dankook Univ — Herein, we...
2:03PM G45.00013 Effect of Mobile Ions on the Electric Field Needed to Orient Charged Diblock Copolymer Thin Films, ASHKAN DEHGHAN, McMaster Univ, Michael Schick, University of Washington, An-Chang Shi, McMaster Univ, POLYMER THEORY MCMASTER UNIVERSITY TEAM, POLYMER THEORY UNIVERSITY OF WASHINGTON TEAM — We examine the behaviour of lamellar phases of charged, diblock copolymer, thin films with mobile counter-ions in the presence of an electric field. We employ self-consistent field theory, and focus on the aligning effect of the electric field on the lamellae. Of particular interest are the effects of the mobile ions on the critical field, which is the value of the field required to reorient the lamellae from the parallel configuration favoured by the surface interaction to the perpendicular orientation favoured by the electric field. We find that the critical field depends strongly on the location of the mobile ions within the system. In the case in which mobile ions are confined such that each charged lamella is electrically neutral, the presence of ions lowers the critical electric field. However, if ions are free to locate anywhere within the system, so that only the system as a whole is electrically neutral, then the presence of ions can increase the critical electric field. The presence of ions in the system introduces a new mixed phase, parallel in the bulk, parallel at the surfaces, in addition to those reported previously.

11:15AM G46.00001 Deterministic Modelling of Carbon Nanotube Near-Infrared Solar Cells, DARIN BELLISARIO, Massachusetts Institute of Technology, Dept. of Chemistry — With solution-process-ability, scale-able fabrication and purification, and cheap input materials, semiconducting single-walled carbon nanotube (SWNT) networks represent promising materials for near-IR solar cell (SC) applications. This promise has motivated a body of work not only developing solar cells but also exploring alignment/deposition methods and SWNT photovoltaic (PV) physics. Despite this interest, there is to date no quantitative model of SWNT solar cell operation analogous to bulk semiconductor p-n junction PVs, allowing a rigorous understanding of the physical tradeoffs driving experimental observations and informing what research will enable technological progress. In this work we have derived the steady state operation of planar heterojunction SWNT PVs from the fundamental light absorption, exciton transport, and free carrier transport behaviors of single nanotubes. Our method can treat arbitrary distributions of nanotube chiralities, lengths, orientations, defect types and concentration, bundle fraction and size, density, dielectric environment, electrode combinations, etc. We achieve this by treating individual SWNT properties as random variables, and describing the network by the dependent distributions of those properties, yielding coupled stochastic differential equations for light absorption, exciton transport, and free carrier transport. Applying the model to monochiral (6,5) films in aligned and isotropic configurations, we find that there is a strongly optimal film thickness less than at which photo-injecting networks transport light from the electrodes to the nanotubes and beyond the optimal thickness, the network is not efficient. The network is optimal for a SWNT exciton transport relative to exceptional intra-SWNT diffusion, vertically-aligned films are unambiguously favored at densities above 3% of close-packed; at lower densities however an optimum emerges at an intermediate angle to compensate for weaker light absorption of vertical nanotubes. Films with in-plane aligned nanotubes are unambiguously the worst design.

11:51AM G46.00002 Exotic Forms of Silicon for Energy Applications, J. P. CRAIG TAYLOR, Colorado School of Mines — Over the last few decades many exotic forms of carbon, such as carbon-60, carbon nanotubes, and graphene, have generated novel scientific discoveries and revolutionized many important applications. Similarly potential transformative breakthroughs may be expected with exotic forms of silicon. Such structures include, but are not necessarily limited to, (1) those formed under high pressure that are metastable at ambient pressure, (2) single layers of Si (silicene), (3) nanoflakes, (4) porous Si, and (5) any other structures that differ in their structural, optical or electronic properties from bulk diamond Si. Silicon is an abundant, non-toxic element around which an advanced technology exists for semiconductor devices based on diamond Si. One of these exotic forms of silicon could form the basis for the next revolution in electronics or even opto-electronics, since it comes from the exhibit direct or, nearly direct, band gaps. Recent results toward producing pure and dopable semiconductor out of Si nanodots imbedded in amorphous matrices and in clathrate Si and clathrate Si-Ge alloys will be discussed.

**11:27AM G47.00002 Does Tensile Rupture of Tumor Basement Membrane Mark the Onset of Cancer Metastasis?**

1 SAI PRAKASH, Chemical and Biomolecular Engineering, Johns Hopkins University — Recognizing a conceptual analogy from polymer physics and reasoning via induction, we infer the plausibility that a malignant tumor (carcinoma) grows in size until a threshold determined by its mechanochemical state in relation to its microenvironment whence, peripheral cells undergo epithelial-to-mesenchymal transitions (EMT) facilitating metastasis. This state is equated to the tensile yielding/rupture of the proteolytically-weakened basement membrane (BM) that encapsulates the growing neoplasm. BMs are typically constituted of tri-continuous hydrogel networks of collagen-IV, laminin, and interstitial fluid, with connector proteins such as nidogens, and perlecans. We test this postulate by formulating a theoretical model based on continuum fluid-solid mechanics, diffusion, and biochemical kinetics of energy metabolism. Herein, a prototypical, viscous tumor spheroid grows radially, consuming metabolic nutrients while being constricted by an elastic BM ca. 0.5–2 microns-thick, and cell adhesion molecules (CAMs), chiefly cadherins and integrins. The model is computationally analyzed via Comsol[1]. Results validate the a priori conjecture, and predict subsequent crack-tip stresses shifting strains on the CAMs from compressive to tensile, that might also indicate mechanotransduced switches in their conformations, such as from non-invasive, adhesive E-cadherins to invasive, non-adhesive N-cadherin phenotypes.

**11:39AM G47.00003 Mechanical properties of growing melanocytic nevi and the progression to melanoma**

ALESSANDRO TALONI, CNR-IERI, Via R. Cozzi 53, 20125 Milano, Italy, ALEXANDER ALEMI, LASSP, Department of Physics, Clark Hall, Cornell University, EMILIO CIUSANI, Istituto Neurologico Carlo Besta, Milano, Italy, JAMES P. SETHNA, LASSP, Department of Physics, Clark Hall, Cornell University, STEFANO ZAPPETTI, CNR-IERI, Via R. Cozzi 53, 20125 Milano, Italy, CATERINA A. M. LA PORTA, Department of Biosciences, University of Milano, NATIONAL RESEARCH COUNCIL OF ITALY TEAM, LASSP, DEPARTMENT OF PHYSICS, CORNELL UNIVERSITY TEAM, ISTITUTO NEUROLOGICO CARLO BESTA COLLABORATION, DEPARTMENT OF BIOSCIENCES, UNIVERSITY OF MILANO TEAM — Melanocytic nevi are benign proliferations that sometimes turn into malignant melanoma in a way that is still unclear from the biochemical and genetic point of view. Diagnostic and prognostic tools are then mostly based on dermoscopic examination and morphological analysis of histological tissues. To investigate the role of mechanics and geometry in the morphological dynamics of melanocytic nevi, we present a computational model for cell proliferation in a layered non-linear elastic tissue. Our simulations show that the morphology of the nevus is correlated to the initial location of the proliferating cell starting the growth process and to the mechanical properties of the tissue. We also demonstrate that melanocytes are subject to compressive stresses that fluctuate widely in the nevus and depend on the growth stage. Numerical simulations of cells in the epidermis releasing matrix metalloproteinases display an accelerated invasion of the dermis by destroying the basal membrane. Moreover, we show experimentally that osmotic stress and collagen inhibit growth in primary melanoma cells while the effect is much weaker in metastatic cells.

**12:03PM G47.00005 Reusable Floating-Electrode Sensor for Real-Time Electrophysiological Monitoring of Nonadherent Cells**

VIET ANH PHAM BA, Seoul Natl Univ, VAN-THAO TA, Hanoi Natl Univ of Education, JUHUN PARK, EUN JIN PARK, SEUNGHUN HONG, Seoul Natl Univ — We herein report the development of a reusable floating-electrode sensor (FES) based on aligned single-walled carbon nanotubes, which allowed quantitatively monitoring the electrophysiological responses to nicotine compared to normal cells, which was attributed to the overexpressed nicotinic acetylcholine receptors (nAChRs) in the SCLC cells. Importantly, using only a single device could measure repeatedly the responses of multiple individual cells to various drugs, enabling statistically meaningful measurements without errors from the device-to-device variations of the sensor characteristics. As results, that the treatment with drugs such as genistin or daidzein reduced Ca$^{2+}$ influx in SCLC cells was found. Moreover, tamoxifen, has been known as an anti-estrogen compound, was found to only partly block the binding of daidzein to nAChRs. Our FES can be a promising tool for various biomedical applications such as drug screening and therapy monitoring.

**12:15PM G47.00006 Thermorheology of living cells—impact of temperature variations on cell mechanics**

JOSEF KAS, TOBIAS KIESSLING, ANATOL FRITSCH, ROLAND STANGE, University of Leipzig — Upon temperature changes, we observe a systematic shift of creep compliance curves J(t) for single living breast epithelial cells. We use a dual-beam laser trap (optical stretcher) to induce temperature jumps within milliseconds, while simultaneously measuring the mechanical response of whole cells to optical force. The cellular mechanical response was found to differ between sudden temperature changes compared to slow, long-term changes implying adaptation of cytoskeletal structure. Interpreting optically induced cell deformation as a thermorheological experiment allows us to consistently explain data on the basis of time–temperature superposition, well known from classical polymer physics. Measured time shift factors give access to the activation energy of the viscous flow of MCF-10A breast cells, which was determined to be ~ 80 kJ/mol. The presented measurements highlight the fundamental role that temperature plays for the deformability of cellular matter. We propose thermorheology as a powerful concept to assess the inherent material properties of living cells and to investigate cell regulatory responses upon environmental changes.
generate virtual tumors and study their morphology and cell subtype populations as a function of time. Specifically, we have measured the absolute optical extinction for intra-cellular material (lysates) in aqueous suspension. Measurements were conducted over a wavelength range of 250 to 1000 nm with 1 nm resolution using Light Transmission Spectroscopy (LTS). This provides both the absolute extinction of materials under study and, with Mie inversion, the absolute number of particles of a given diameter as a function of diameter in the range of 1 to 3000 nm. Our preliminary studies show significant differences in both the extinction and particle size distributions associated with cancer versus normal cells, which appear to be correlated with differences in the particle size distribution in the range of approximately 50 to 250 nm. Especially significant is a clearly higher density of particles at about 100 nm and smaller for normal cells.

Department of Physics, Harper Cancer Research Institute, and the Office of Research at the University of Notre Dame

Role of differential physical properties in emergent behavior of 3D cell co-cultures — DAN KOLBMAN, MOUMITA DAS, Rochester Institute of Technology — The biophysics of binary cell populations is of great interest in many biological processes, whether the formation of embryos or the initiation of tumors [1]. During these processes, cells are surrounded by other cell types with different physical properties, often with important consequences. For example, recent experiments on a co-culture of breast cancer cells and healthy breast epithelial cells suggest that the mechanical mismatch between the two cell types may contribute to enhanced migration of the cancer cells [2]. Here we explore how the differential physical properties of different cell types may influence cell-cell interaction, aggregation, and migration. To this end, we study a proof of concept model—a three-dimensional binary system of interacting, active, and deformable particles with different physical properties such as elastic stiffness, contractility, and particle-particle adhesion, using Langevin Dynamics simulations. Our results may provide insights into emergent behavior such as segregation and differential migration in cell co-cultures in three dimensions.

Specifically, we explore whether leader cells are required to describe our expanding sheets of cells and whether the answer depends on individual cell activity.

Metastatic process begins when cells leave the primary tumor, either as individual cells or collectively migrating groups. Here we present data on the migration speed, but with a decrease in collective motion and increasing chaotic movement fields of groups of cells. I will describe how an underlying wave-like process of the cellular scaffolding that drives persistent migration contributes to the ability of cells to move collectively. I will further show that the same internal waves also allow cells to recognize and follow surface nanotopography on scales comparable to these internal waves. This facilitates contact guidance by the cells.

A computational model of cell-microenvironment interactions — STEPHEN BURKE, University of California, San Diego — The cell-microenvironment interaction is an important component of many biological processes, such as tissue healing, tumor invasion, and wound healing. The model is capable of representing various aspects of the interaction, including cell-cell and cell-matrix interactions, and can be used to study the effects of different microenvironments on cell behavior.

In one of the models, we consider the migration of cells through a collagen gel, which is a common extracellular matrix found in many biological environments. The model includes a three-dimensional binary system of interacting, active, and deformable particles with different physical properties such as elastic stiffness, contractility, and particle-particle adhesion, using Langevin Dynamics simulations. Our results may provide insights into emergent behavior such as segregation and differential migration in cell co-cultures in three dimensions.

12:51PM G47.00009 Modeling mechanical interactions between cancerous mammary acini — JEFFREY WANG, Harvard University, JAN LIPHARDT, Stanford University, CHRIS RYCROFT, Harvard University — The rules and mechanical forces governing cell motility and interactions with the extracellular matrix of a tissue are often critical for understanding the mechanisms by which breast cancer is able to spread through the breast tissue and eventually metastasize. Ex vivo experimentation has demonstrated the formation of long collagen fibers through collagen gels between the cancerous mammary acini responsible for milk production, providing a fiber scaffolding along which cancer cells can disorganize. We present a minimal mechanical model that serves as a potential explanation for the formation of these collagen fibers and the resultant motion. Our working hypothesis is that cancerous cells induce this fiber formation by pulling on the gel and taking advantage of the specific mechanical properties of collagen. To model this system, we employ a new Eulerian, fixed grid simulation method to model the collagen as a nonlinear viscoelastic material subject to various forces coupled with a multi-agent model to describe individual cancer cells. We find that these phenomena can be explained by two simple ideas: cells pull collagen radially inwards and move towards the tension gradient of the collagen gel, while being exposed to standard adhesive and collision forces.

12:51PM G47.00010 Wave-Based Mechanisms for Contact Guidance and Collective Cell Migration — WOLFGANG LOSERT, University of Maryland — The migration of cells in streams, and the crossover from collective behavior to individual cell migration is one of the key physical steps in cancer metastasis. This migration occurs in the context of a microenvironment with specific mechanics and texture that may guide the metastatic process. Studies on cell lines indicate that an increasing metastatic potential of cells is associated not with changes in migration speed, but with a decrease in collective motion and increasing chaotic movement fields of groups of cells. I will describe how an underlying wave-like process of the cellular scaffolding that drives persistent migration contributes to the ability of cells to move collectively. I will further show that the same internal waves also allow cells to recognize and follow surface nanotopography on scales comparable to these internal waves. This facilitates contact guidance by the cells.

12:51PM G47.00011 Computational model for chromosomal instability — STEFANO ZAPPERI, CNR-ICN, Milano, Italy, ISI Foundation, Torino, Italy. Aalto University, Finland, ZSOLT BERTALAN, ZOE BUDRIKIS, ISI Foundation, Torino, Italy., CATERINA LA PORTA, Department of Bioscience, University of Milano, Italy. — Faithful segregation of genetic material during cell division requires alignment of the chromosomes between the spindle poles and attachment of their kinetochores to each of the poles. Failure of these complex dynamical processes leads to chromosomal instability (CIN), a characteristic feature of several diseases including cancer. While a multitude of biological factors regulating chromosome congression and bi-orientation have been identified, it is still unclear how they are integrated into a coherent picture. Here we address this issue by a three dimensional computational model of motor-driven chromosome congression and bi-orientation. Our model reveals that successful cell division requires control of the total number of microtubules: if this number is too small bi-orientation fails, while if it is too large not all the chromosomes are able to congress. The optimal number of microtubules predicted by our model compares well with early observations in mammalian cell spindles. Our results shed new light on the origin of several pathological conditions related to chromosomal instability.

12:51PM G47.00012 Computational modeling of the spatiotemporal dynamics of cancer stem cells — ALEXANDRA SIGNORIELLO, MARCUS BOSENBERG, Yale University, MARK SHATTUCK, City College of New York, COREY O’HERN, Yale University — Cancer stem cells can differentiate into any cell type in a particular tumor, and thus can reform a tumor even when seeded from a single cell. Despite their importance, the identification of stem cells, their interactions, and how and why they malfunction to cause cancer and form tumors are not well understood. We have developed discrete element modeling (DEM) simulations to investigate the role of stem cells in the formation of heterogeneous cell populations in melanoma tumors. The DEM simulations include elastic, excluded volume, and signaling interactions between cells and rates for cell differentiation, apoptosis, and growth. The DEM is calibrated to results from experimental studies of melanoma tumor growth in mouse models. We use the simulations to generate virtual tumors and study their morphology and cell subtype populations as a function of time.

2:03PM G47.00013 Characterization of Collective Cell Migration Dynamics — RACHEL LEE, Univ of Maryland-College Park, HAIYCEN YUE, WOUTER-JAN RAPPEL, Univ of California-San Diego, WOLFGANG LOSERT, Univ of Maryland-College Park — During cancer progression, tumor cells invade the surrounding tissue and migrate throughout the body, forming clinically dangerous secondary tumors. This migratory process begins when cells leave the primary tumor, either as individual cells or collectively migrating groups. Here we present data on the migration dynamics of epithelial sheets composed of many cells. Using quantitative image analysis techniques, we are able to extract motion information from time-lapse images of cell lines with varying malignancy. Adapting metrics originally used to study fluid flows we are able to characterize the migration dynamics of these cell lines. By describing the migration dynamics in great detail, we are able to make a clear comparison of our results to a simulation of collective cell migration. Specifically, we explore whether leader cells are required to describe our expanding sheets of cells and whether the answer depends on individual cell activity.

Session G48 DBIO: Focus Session: Physics of Proteins II
217C - Katherine Niessen, State University of New York, Buffalo

11:15AM G48.00001 Probing the conformational changes of proteins in liquid water by dielectric terahertz spectroscopy, ALI CHARKHESHT, DEEPU GEORGE, NGUYEN VINH, Virginia Tech — Proteins solvated in their biological milieu are expected to exhibit strong absorption in the terahertz range that contain information on their global and sub-global collective vibrational modes (conformational dynamics) and global dynamical correlations among solvent water molecules and proteins. Measurements in this region, however, are challenging due to the strong absorption of water and often severe interference artifacts. In response, we have developed a highly sensitive dielectric terahertz frequency-domain system and a terahertz-time domain system for probing the collective dynamics in aqueous solution. Using these techniques we explore the complex dielectric response from 5 GHz up to 3 THz that directly probes such questions as the hydration level around proteins and the large scale vibrational modes of biological polymers. We make a direct comparison to the existing molecular dynamic simulations and normal mode calculations and investigate the dependence of the terahertz frequency dynamics on protein concentration. Our measurements shed light on the macromolecular motions in a biologically relevant water environment.

11:27AM G48.00002 Nature of Light-Harvesting-System Excited States Prepared by Thermal Light, JUAN DAVID BOTERO, Univ de Antioquia, PAUL BRUMER, University of Toronto, LEONARDO PACHON, Univ de Antioquia, GRUPO DE FISICA ATOMICA Y MOLECULAR TEAM, CHEMICAL PHYSICS THEORY GROUP TEAM — The nature of excited states produced by incoherent natural thermal light is analyzed in the context of light-harvesting system. In the absence of proteomic environments or solvents, it is shown that natural thermal light generates extremely long-lasting coherent dynamics in photosynthetic light-harvesting systems provided by the super-Ohmic character of the radiation, the lack of pure dephasing dynamics and the small energy gap between donors and acceptors. Although this unexpected result has the potential of changing the entire direction of the discussion on the nature of excited states prepared by sunlight, when the environment is considered, the extremely long-lasting coherences induced by incoherent light are removed and stationary coherences are established in the photosynthetic light-harvesting system.

11:39AM G48.00003 The Hydrophobic Solvation Energies of Molecular-Scale Cavities Depend on the Detailed Structure of the Molecular Surface, ROBERT HARRIS, B. MONTGOMERY PETTITT, University of Texas Medical Branch — Both the energy \( \Delta G_{\text{vdw}} \) of inserting an uncharged molecular cavity into solution have often been assumed to increase linearly with the solvent-accessible surface area \( \mathcal{A} \), in analogy with the energy of forming macroscopic cavities in solution. Because these energies are assumed to increase with \( \mathcal{A} \), they have often been assumed to drive protein collapse during folding. However we have shown that for molecular-scale cavities neither of these energies are simple linear functions of \( \mathcal{A} \). Additionally, for both alanine and glycine peptides we have shown that \( \Delta G_{\text{vdw}} \) decreases with \( \mathcal{A} \), implying that \( \Delta G_{\text{vdw}} \) opposes folding for these systems. We also show that \( \Delta G_{\text{rep}} \) is linear in \( \mathcal{A} \) for large molecules but linear in the solvent-accessible volume \( \mathcal{V} \) for small molecules is inconsistent with our findings. Any theory that can accurately predict \( \Delta G_{\text{vdw}} \) or \( \Delta G_{\text{rep}} \) will have to consider the details of the molecular shape rather than relying on coarse measures, such as \( \mathcal{A} \) and \( \mathcal{V} \).

11:51AM G48.00004 Novel Photodynamics in Phytochrome & Cyanobacteriochrome Photosensory Proteins, DELMAR LARSEN, University of California, Davis — The photodynamics of recently characterized phytochrome and cyanobacteriochrome photoreceptors are discussed. Phytochromes are red/far-red photosensory proteins that utilize the photoisomerization of a linear tetrapyrrole (bilin) chromophore to detect the red to far-red light ratio. Cyanobacteriochromes (CBCRs) are distantly related cyanobacterial photosensors with homologous bilin-binding GAF domains, but exhibit greater spectral diversity. The excited-state mechanisms underlying the initial photoisomerization in the forward reactions of the cyanobacterial photoreceptor Cph1 from Synechocystis, the RcaE CBCR from Fremyella diplosiphon, and Npr6012g4 CBCR from Nostoc punctiforme were contrasted via multipulse pump-dump-probe transient spectroscopy. A rich excited-state dynamics are resolved involving a complex interplay of excited-state proton transfer, photoisomerization, multilayered inhomogeneity, and reactive intermediates, and Le Chatelier redistribution. NpR6012g4 exhibits a high quantum yield for its forward photoreaction (40%) that was ascribed to the activity of hidden, productive ground-state intermediates via a “second chance initiation dynamics” (SCID) mechanism.

12:27PM G48.00005 Pushing single molecule techniques to microsecond resolution proves that T4 Lysozyme is a Brownian ratchet, MAXIM V. AKHTEROV, Dept. of Physics and Astronomy, Univ of California Irvine, YONGKI CHOI, Dept. of Physics and Astronomy, Univ of California Irvine; TIVOLI J. OLSEN, Dept. of Chemistry, Univ of California Irvine, PATRICK C. SIMS, Dept. of Physics and Astronomy, Univ of California Irvine, MARIAM IFTIKHAR, Dept. of Chemistry, Univ of California Irvine, O. TOLGA GUL, BRAD L. CORSO, Dept. of Physics and Astronomy, Univ of California Irvine, GREGORY A. WEISS, Dept. of Chemistry, Univ of California Irvine, PHILIP G. COLLINS, Dept. of Physics and Astronomy, Univ of California Irvine — Single-molecule techniques can monitor conformational dynamics of proteins, but such methods usually lack the resolution to directly observe conformational pathways or intermediate conformational states. We have recently described a single-molecule electronic technique that breaks this barrier. Using a 1 MHz-bandwidth carbon nanotube transistor, the transition pathways between open and closed conformations of T4 lysozyme have been recorded with a microsecond resolution. We directly resolve a smooth, continuous transition with an average duration of 37 microseconds. Unexpectedly, the mechanical closing and re-opening of the enzyme haveidentical distributions of transition durations, and the motion is independent of the enzyme catalyzing the substrate. These results illustrate the principle of microscopic reversibility applied to a Brownian ratchet, with lysozyme tracing a single pathway for closing and the reverse pathway for enzyme opening, regardless of its instantaneous catalytic productivity.

\[ \Delta G_{\text{vdw}} = \mathcal{A} \]
12:39PM G48.00006 Detection Enhancement of Protein Structural Vibrations: Measurements and Calculations, KATHERINE NIESSEN, MENGYANG XLI, SUNY at Buffalo, Physics, EDWARD SNELL, VIVIAN CODY, JAMES PACE, Hauptman-Woodward Medical Research Institute, Buffalo, NY, MARIUS SCHMIDT, University of Wisconsin, Physics, ANDREA MARKEZL, SUNY at Buffalo, Physics. — Narrow band intramolecular protein vibrations have been successfully measured using crystal anisotropy THz microscopy (CATM), a near-field technique, on protein crystals [1]. To address the question of how these motions are related to protein function we developed a variation of this technique to rapidly measure a variety of protein crystals. The variation anisotropy measurement consists of introducing a wire-grid polarizer in the THz path and rotating the polarizer between measurements, instead of the sample. While the resulting anisotropic spectra confirm reproducibility and protein specific nature of the response the signal is not directly related to the absorption spectra and in fact shows more structure than CATM. This is due to the polarization sensitivity of the electro-optical detection crystal and the changing THz polarization direction and amplitude at the detector [2]. This combination leads to an enhancement of specific resonances and increased sensitivity to rotation of the THz polarization from the sample itself. Preliminary calculations suggest that the technique is sensitive to the birefringence associated with anisotropic absorbance. The results and significance of these measurements on protein and sucrose crystals and the calculated expected response will be discussed. 1. Acbas, G., et al. (2014). Nat Commun 5. 2. Planken, P.C.M., et al. (2001). J. Opt. Soc. Am. B. 18(3).

12:51PM G48.00007 Microtubule Severeing Stymied by Free Tubulin, JENNIFER ROSS, MEGAN BAILEY, Univ of Massachusetts - Amherst — Proper organization of the microtubule cytoskeletal network is required to perform many necessary cellular functions including mitosis, cell development, and cell motility. Network organization is achieved through filament remodeling by microtubule-associated proteins (MAPs) that control microtubule dynamics. MAPs that stabilize are relatively well understood, while less is known about destabilizing MAPs, such as severing enzymes. Katanin, the first-discovered microtubule-severing enzyme, is a AAA+ enzyme that oligomerizes into hexamers and uses ATP hydrolysis to sever microtubules. Using quantitative imaging on reconstituted microtubule severing assays in vitro we investigate how katanin can regulate microtubule dynamics. Interestingly, we find microtubule dynamics inhibits katanin severing activity; dynamic microtubules are not severed. Using systematic experiments introducing free tubulin into the assays we find that free tubulin can compete for microtubule filaments for the katanin proteins. Our work indicates that katanin could function best on stable microtubules or stable regions of microtubules in cells where free tubulin is sequesters, low, or depleted.

1:03PM G48.00008 Stereoelectronic Determinants of Color Vision: Engineering Protein Mimics of Pigmented Rhodopsins and Designing New Protein Fusion Tags, BABAK BORHAN, Michigan State University — The field of protein engineering has undergone phenomenal growth from its inception approximately 20 years ago. A wide variety of topics have been addressed, including the construction of new protein folds, the introduction of metal binding sites that are both structural and catalytic, the development of novel enzymatic activity and the creation and optimization of new ligand binding sites. However, left behind has been the issue of protein/chromophore interactions. Protein-chromophore interactions are a central component of a wide variety of critical biological processes such as color vision and photosynthesis. To understand the fundamental elements that contribute to spectral tuning of a chromophore inside the protein cavity, we redesigned small cystosolic human proteins to fully encapsulate all-trans-retinal and form a covalent bond as a protonated Schiff base. These systems, using rational mutagenesis, have led to restructurizing the electrostatic environment within the binding pocket of the host protein, enabling the regulation of the absorption maximum of the pigment over 200 nm. So far our work has shown that the manipulation of the electrostatic potential projected by the protein onto the chromophore has a powerful effect on the absorption properties of the ligand. We have parlayed these results towards developing new protein fusion tags and pH responsive protein dyes.

1:39PM G48.00009 Obtaining structural information of small proteins using solid-state nanopores and high-bandwidth measurements, DAVID NIEDZWIECI, CHRISTOPHER LANCI, JEFFERY SAVEN, MARLIA DRNDIC, University of Pennsylvania — The use of biological nanopores sensors to characterize proteins has proved a fruitful field of study. Solid-state nanopores hold several advantages over their biological counterparts, including the ability to tune pore diameter and their robustness to external conditions. Despite these advantages, the use of solid-state nanopores for protein analysis has proved difficult due to rapid translocation times of proteins and poor signal-to-noise of small peptides. Recently, improvements in high-bandwidth acquisition and in signal-to-noise have made the study of small peptides using solid-state nanopores feasible. Here we report on the detection and characterization of peptides as small as 33 amino-acids in length using sub-10 nm thin silicon nitride nanopores, giving high signal levels, combined with high-bandwidth electronics. In addition we show differentiation between monomers and dimer forms of the GCN-4 p1 leucine zipper, a coil-coil structure, and compare this with the unstructured 33-mer. The differentiation between these two forms demonstrates the possibility of extracting useful structural information from short peptide sequences using modern solid-state nanopore systems.

1:51PM G48.00010 Determination of Kinetic Isotope Effects in Yeast Alcohol Dehydrogenase Using Transition Path Sampling, MATTHEW VARGA, STEVEN SCHWARTZ, Univ of Arizona — The experimental determination of kinetic isotope effects in enzymatic systems can be a difficult, time-consuming, and expensive process. In this study, normal mode centroid molecular dynamics (CMD) was applied to the transferring hydride/deuteride in order to correctly incorporate quantum effects into the molecular simulations. Though previous studies have used rTPS to calculate reaction rate constants in various model and real systems, it has not been applied to a system as large as YADH. Due to the fact that particle transfer is not wholly indicative of the chemical step, this method cannot be used to determine reaction rate constants in YADH. However, it is possible to determine the transition rate constant of the particle transfer, and the kinetic isotope effect of that step. This method provides a set of tools to determine kinetic isotope effects with the atomistic detail of molecular simulations.

2:03PM G48.00011 ABSTRACT WITHDRAWN —

Tuesday, March 3, 2015 11:15AM - 2:15PM — Session G49 GSOFT: Fracture, Friction, and Deformation 217D - Mike Salerno, Sandia National Laboratories

11:15AM G49.00001 Popping balloons: formation of a crack network in rubber membranes, SEBASTIEN MOULINET, MOKHTAR ADDA-BEDIA, Lab. de Physique Statistique, EQUIPE MORPHOGENESE ET PHENOMENES MULTI-ECHELLE TEAM — Everyone can make the observation: a rubber balloon inflated until it spontaneously pop breaks into a large number of shreds. In contrast, a balloon pierced with a needle at an early stage of its inflation breaks into two large pieces. Using model latex balloons, we have experimentally investigated the transition between these two breaking regimes. We have showed that, above a threshold stress in the latex membrane, a single crack become unstable and separates into two new cracks. Then, a cascade of tip-splitting generates a network of cracks that eventually form a large number of fragments. We have observed that the instability of the crack occurs when it reaches a limit velocity that could the speed of sound. By studying the energy balance during the explosion, we can determine the intrinsic fracture energy of rubber, a measurement difficult to achieve with usual tensile testing.
11:27AM G49.00002 Do thermal fluctuations stabilize an extensible buckling rod? , DESHPREET BEDI, XIAOMING MAO, Univ of Michigan - Ann Arbor — The classical problem of a rod buckling under a compressive force, "Euler buckling," has long been studied and solved in physics; however, the classical theory of Euler buckling does not take into account thermal fluctuations. At small enough scales, entropic effects become significant, and a more intricate analysis incorporating thermal fluctuations is needed, for instance, in the study of biopolymers and nanotubes. In this talk, we discuss buckling of an extensible, semi-flexible rod embedded in two and three dimensions. We systematically examine the problem both analytically, using a momentum-space renormalization group procedure, and numerically, using Monte Carlo simulations, to determine the topology of the phase diagram containing the unbuckled and buckled states. In two dimensions, for instance, we determine that thermal fluctuations tend to stabilize the straight-rod state over the buckled state and that this stabilization increases with temperature. We also analyze the mechanical response of the rod in order to study the differing scaling regimes of the system.

11:39AM G49.00003 Localized Disturbance in a 2D Cohesive Granular Packing, JENNIFER RIESER, University of Pennsylvania, MATHILDE LAPLAGNE, University of Pennsylvania and Ecole Polytechnique, DOUGLAS DURIAN, University of Pennsylvania — How the local structural configuration influences large-scale deformation in disordered materials is not known. Inspired by nano-indentation experiments, we characterize the response of disordered granular packing to a localized disturbance by driving a triangular wedge into the packing. The extent of the disturbance is explored by performing experiments with several wedge angles. The two-dimensionality of the system allows for direct observation of all particle dynamics during the indentation. The grains can be cohesive, with an attraction governed by tunable capillary forces that are induced through an interstitial fluid. Topological quantities derived from a radical Voronoi diagram as well as the resulting triangulation are used to characterize local structure within the packing. Dynamics are characterized by local deformations to the triangulation as well as the local non-affine motion. For all wedge angles, a boundary develops between moving and static grains. This size and shape of this boundary depend on the indenter angle, and in all cases, the size of the boundary increases with time. During the deformation, non-affine grain motion occurs both throughout the moving region as well as along the boundary, while holes tend to develop primarily along this boundary.

11:51AM G49.00004 Shells on lattice-mismatched colloidal spheres, cubes, and peanuts, MELINDA SINDORO, STEVE GRANICK, Univ of Illinois - Urbana — Cavities form spontaneously due to geometrical frustration when crystalline shells is gradually grown on non-linear surfaces. This we conclude experimentally from growing lattice mismatched shells on colloidal spheres, cubes, and peanuts, all of them providing different local curvature. According to the core shape, the underlying interfacial curvature promotes different cavity formation which we can follow over time. During the deformation, non-affine grain motion occurs both throughout the moving region as well as along the boundary, while holes tend to develop primarily along this boundary.

12:03PM G49.00005 Adhesion and Wetting of Soft Nanoparticles on Textured Surfaces: Transition between Wenzel and Cassie-Baxter States, ZHEN CAO, University of Connecticut, MARK STEVENS, Sandia National Laboratories, JAN-MICHAEL CARRILLO, Oak Ridge National Laboratory, ANDREY DOBRYNNIN, University of Connecticut — We use a combination of the molecular dynamics simulations and scaling analysis to study interactions between gel-like nanoparticles and substrates covered with rectangular shape posts. Nanoparticle in contact with a substrate undergo a first order transition between Wenzel and Cassie-Baxter states depending on nanoparticle shear modulus. The strength of nanoparticle-substrate interactions, height of the substrate posts and nanoparticle size, $R_p$. There is a range of system parameters where these two states coexist such that the average indentation $\delta$ produced by substrate posts changes monotonically with nanoparticle shear modulus. We have developed a model that describes deformation of nanoparticle in contact with patterned substrate. The effect of the patterned substrate can be taken into account by introducing an effective work of adhesion, $W_{eff}$, which describes the first order transition between Wenzel and Cassie-Baxter states. There are two different shape deformation regimes for nanoparticles with shear modulus $G_p$ and surface tension $\gamma_p$. Shape of small nanoparticles with size $R_p < \sqrt{3} G_p / \gamma_p W_{eff}^{-1/2}$ is controlled by capillary forces while deformation of large nanoparticles, $R_p > \sqrt{3} G_p / \gamma_p W_{eff}^{-1/2}$, is determined by nanoparticle elastic and contact free energies.

12:15PM G49.00006 Self-affine parameters of fracture surfaces of high strength steels, MOISES HINOJOSA, ELISA SCHAEFFER, YOSHUA GUZMAN, JORGE ALDACO, Universidad Autónoma de Nuevo León — We report the experimental study of crack nucleation and propagation on AISI 4340 and Premoment steels, submitted to different thermal treatments that resulted in different properties and microstructures. Crack initiation and propagation under fatigue, tension and impact conditions were analyzed at different lengthscales. The SEM fractographic study allowed the correlation of the observed mechanisms with the patterns observed on the fracture surfaces. The scaling properties were explored and correlated to the observed mechanisms. Using the topographic data of 3D reconstructed surfaces obtained by laser scanning, we calculated both global and local roughness exponents using different variable-bandwidth methods, obtaining the statistical distributions as a function of the orientation. Although the results tend to the same average global value (close to 0.8) for both steels regardless of the heat-treating condition, their statistical distributions are sensitive to the anisotropy of the microstructure, we also found a correlation of the local roughness exponents with the local orientation of the microstructure and the dimples observed on the fracture surfaces.

12:27PM G49.00007 Probing Interfacial Friction and Dissipation in Granular Gold Nickel Alloys with a Quartz Crystal Oscillator in an External Magnetic Field, K.M. STEVENS, J. KRM, North Carolina State University — We present here a quartz crystal microbalance study of two-phase gold nickel alloys whose internal granular properties are probed by exposure to a fluctuating external magnetic field. The work is motivated by prior studies demonstrating that granular two-phase materials exhibited lower friction and wear than solid solution alloys with identical compositions [1]. In particular, we report a “flexing” effect which appears when an external magnetic field is applied, and is manifested as a decrease in the magnitude of oscillation amplitude that is synchronized with the applied field; the effect is not seen on the complimentary solid solution samples. The effect is consistent with internal interfacial friction between nickel and gold grains, indicating a degree of freedom which may decrease friction even in the absence of an external magnetic field. This is supported through analysis of energy dissipation in the system, using the Butterworth-Van Dyke equivalent circuit model [2]. Data and interpretation are also presented that rule out alternate explanations such as giant magnetoresistance [3] and/or other resistive phenomenon within the film.

Funding provided by NSF DMR0805204. Thanks to L. Pan for sample preparation.
12:39PM G49.00008 Stick-slip patterns in a model frictional interface, GEORGIOS TSEKENIS, DEMET TATAR, SHMUEL RUBINSTEIN, DAVID WEITZ, MICHAEL AZIZ, FRANS SPAEPEN, Harvard University — We present measurements of the local displacements during slip-stick motion of two rough surfaces sliding over one another. The surfaces are cast in polymer and have roughness on the order of 30 \( \mu \text{m} \). The displacements are observed by confocal microscopy of embedded fluorescent particles, and measured by PIV. The displacement patterns during large and small slip events are directly observed and analyzed by statistical methods.

12:51PM G49.00009 Stiff particles on highly compliant solid substrates: adhesion or wetting?, KATHARINE JENSEN, ERIC DUFRESNE, Yale University — The classic theories of contact mechanics with deformable materials account only for the competition between adhesion energy and elasticity. However, for compliant materials, solid surface tension also plays an important role in resisting shape change, and may significantly modify the physics of contact with soft matter. We report experiments bringing small, stiff spheres into adhesive contact with compliant silicone substrates. We observe the quasi-static deformation of the substrate in two sticky situations: with zero applied force, where the spheres are allowed to settle to an equilibrium position, and during forced withdrawal from contact starting from an initial condition of zero displacement. In both cases, we map the profiles of the deformed silicone surface, and compare to capillary and elastic theories. The similarities – and differences – between our experimental measurements and the classic theories point to a crossover form a capillary-dominated near field response close to the contact line to an elastic-dominated response in the far field.

1:03PM G49.00010 Single-asperity friction during quasi-static sliding, TRISTAN SHARP, Johns Hopkins University, LARS PASTEWKA, Karlsruhe Institute of Technology, MARK ROBBINS, Johns Hopkins University — The static friction of an asperity is investigated using atomic-scale simulations. We explore scale effects by varying the sphere radius \( R \) and the contact radius \( a \) from nanometers to micrometers. We first consider commensurate contact between bare lattices with repulsive interactions across the interface. In small contacts, all contacting atoms move coherently and the friction coefficient \( \mu \) is independent of contact radius and load. In larger contacts, interfacial slip is mediated by localized dislocations, and the static friction coefficient \( \mu \sim \left( \frac{a_0}{a} \right)^{1.2} \), where \( a_0 \) is the nearest-neighbor spacing. In very large contacts \( \mu \) stops decreasing and begins to increase with \( a \), at fixed \( R \). The results are in sharp contrast to Cattaneo-Mindlin continuum theory where \( \mu \) is independent of contact size. Separate simulations are performed to connect the results to the dislocation-based models of contact-size effects due to Hurtado and Kim, and Gao, which assume adhesion interactions between surfaces and find \( \mu \sim \left( \frac{a_0}{a} \right)^{1.5} \). Simulations for incommensurate contacts show a transition from superlubricity for rigid contacts to a finite friction associated with the Peierls stress in very large contacts. Support from: DMR-1006805; NSF IGERT-0801471; OCI-0963185; CMMI-0923018

1:15PM G49.00011 Penetration drag in loosely packed granular materials, STEPHAN BLESS, MEHDI OMIDVAR, MAGUED ISKANDER, New York University, Dept Civil & Urban Eng'ng, NEW YORK UNIVERSITY COLLABORATION — The drag coefficient for penetration of granular materials by conical-nosed penetrators was computed by assuming the particles are non-interacting and rebound elastically off of the advancing penetrator. The solution was \( C = 4 \sin(\theta) \) where \( \theta \) is the half angle of the cone. Experiments were conducted in which the drag coefficient was measured over the range 30 to 80 m/s for four types of sand: Ottawa silica sand, crushed quartz glass, coral sand, and aragonite sand. The sands were tested at relative densities of 40 and 80%. The drag coefficients for the low density materials were in excellent agreement with this simple model. The high density material had a drag considerably larger than predicted, presumably because of particle-to-particle interactions.

1:27PM G49.00012 Geometrically Frustrated Fracture Mechanics, NOAH MITCHELL, James Franck Institute, University of Chicago, VINZENZ KONING, VINCENZO VITTELI, Instituut-Lorentz, Universiteit Leiden, WILLIAM T. M. IRVINE, James Franck Institute, University of Chicago — When a flat elastic sheet is forced to conform to a surface with Gaussian curvature, stresses arise in the sheet. The mismatch between initial and final metrics gives rise to new fracture behavior which cannot be achieved by boundary loading alone. Using experiments of PDMS sheets frustrated on 3D-printed surfaces and a linearized analytical model, we demonstrate the ability of curvature to govern the sheets’ fracture phenomenology. In this talk, we first show that curvature can both stimulate and suppress fracture initiation, depending on the position and orientation of the initial slit. Secondly, we show that curvature can steer the path of a crack as it propagates through the material. Lastly, the curvature can arrest cracks which would otherwise continue to propagate.

1:39PM G49.00013 Kibble-Zurek Mechanism in Microscopic Acoustic Cracking Noises, HAMED O. GHAFFARI, University of Toronto, PHILIP BENSON, University of Portsmouth, K. XIA, R. PAUL YOUNG, University of Toronto — The fast evolution of microstructure is key to understanding “cracking” phenomena. It has been proposed that formation of a nonlinear zone around a moving crack tip controls the crack tip velocity. Progress in understanding the physics of this critical region has been limited by our lack of hard data describing the detailed physical processes that occur within. For the first time, we show that the signature of the non-linear elastic zone around a microscopic dynamic crack maps directly to generic phases of acoustic noises, supporting the formation of a strongly weak zone near the moving crack tips. We additionally show that the rate of traversing to non-linear zone controls the rate of weakening, i.e. speed of global rupture propagation. We measure the power-law dependence of nonlinear zone size on the traversing rate, and show that our observations are in agreement with the Kibble-Zurek mechanism (KZM). In addition, we illustrate that cracks exhibiting global rupture fronts with velocity faster than Rayleigh waves (i.e., super-shear rupture fronts) display a complex configuration of non-linear zone prior to the fast weakening phase.

1:51PM G49.00014 Optical Characterization of Temperature-Dependent Microstructure of Polymeric Asphalt Binders, ADAM RAMM, FARBOD SHAFIEI, Physics Dept., Univ of Texas, Austin, MARYAM ZAMANI, Physics Dept., Shahid Beheshti University, Iran, SHARMIN SULTANA, AMIT BHASIN, Civil Eng. Dept, Univ of Texas, Austin, M. C. DOWNER, Physics Dept., Univ of Texas, Austin — Asphalt binders used in construction of pavements must be chemically engineered to withstand wide climatic variations. Ideal binders possess high stiffness at high temperatures, low stiffness with high relaxation rates at low temperatures, and high resistance to fatigue cracking at intermediate temperatures. Such bulk properties are conventionally measured with rheometers, but appear to be closely connected with temperature-dependent microstructural changes. AFM has been used to observe such microstructures, but is only possible near room temperature [1]. Here we characterize asphalt binder microstructure over a wide range of temperatures and chemical compositions using noninvasive optical microscopy correlated with linear and second-harmonic optical scatter to measure statistical fluctuations. For example, micron-size “bee”-structures previously observed by AFM [1] are resolved optically, and are observed to vary as temperature and composition change, while inducing corresponding changes in optical scatter. We will present these and other optical measurements, and discuss their connection to bulk material properties. [1] Pauli et al., Internat. J. Pavement Engin. 12, 291 (2011).
2:03PM G49.00015 Rings and rackets from single-wall carbon nanotubes: manifestations of mesoscopic mechanics, YUEZOU WANG, University of Minnesota, Twin Cities, MATTHEW SEMLER, North Dakota State University, Fargo, IGOR OSTANIN, University of Minnesota, Twin Cities, ERIK HOBBIE, North Dakota State University, Fargo, TRAIAN DUMITRICĂ, University of Minnesota, Twin Cities — We combine distinct element method simulations and experiments to understand the stability of rings and rackets formed by single-wall carbon nanotubes assembled into ropes. Bending remains a soft deformation mode in ropes because intra-rope sliding of the constituent nanotubes occurs with ease. Our simulations indicate that the formation of these aggregates can be attributed to the mesoscopic mechanics of entangled nanotubes and to the sliding at the rope contacts. Statistical analysis of fluctuations in ROI indicates that the stability of the experimental aggregates can be largely explained by the competition between bending and van der Waals adhesion energies. Our results and simulation method should be useful for understanding nanoscale fibers and self-assembling process in general.

11:15AM G50.00001 Human movement stochastic variability leads to diagnostic biomarkers In Autism Spectrum Disorders (ASD), DI WU, Physics, Indiana Univ - Bloomington, Bloomington, IN; ELIZABETH B. TORRES, Dept. of Psychology, Rutgers Univ, New Brunswick, NJ; JORGE V. JOSE, Physics, Indiana Univ - Bloomington, Bloomington, IN; cell and Integrative Physiology, Indiana Univ. School of Medicine, Indianapolis, IN — ASD is a spectrum of neurodevelopmental disorders. The high heterogeneity of the symptoms associated with the disorder impedes efficient diagnoses based on human observations. Recent advances with high-resolution MEM wearable sensors enable accurate movement measurements that may escape the naked eye. It calls for objective metrics to extract physiological relevant information from the rapidly accumulating data. In this talk we’ll discuss the statistical analysis of movement data continuously collected with high-resolution sensors at 240Hz. We calculated statistical properties of speed fluctuations within the millisecond time range that closely correlate with the subjects’ cognitive abilities. We computed the periodicity and synchronicity of the speed fluctuations from their power spectrum and ensemble averaged two-point cross-correlation function. We built a two-parameter phase space from the temporal statistical analyses of the nearest neighbor fluctuations that provided a quantitative biomarker for ASD and the periodicity and synchronicity of the speed fluctuations from their power spectrum and ensemble averaged two-point cross-correlation function. We built a two-parameter phase space from the temporal statistical analyses of the nearest neighbor fluctuations that provided a quantitative biomarker for ASD and adult normal subjects and further classified ASD severity. We also found age related developmental statistical signatures and potential ASD parental links in our movement dynamical studies. Our results may have direct clinical applications.

11:27AM G50.00002 Adaptation tunes cortical dynamics to a critical regime during vision, WOODROW SHEW, WESLEY CLAWSON, University of Arkansas, JEFF POBST, YAHYA KARIMIPANAH, NATHANIEL WRIGHT, RALF WESSEL, Washington University, St. Louis, SHEW LAB TEAM, WESSEL LAB TEAM — A long-standing hypothesis at the interface of physics and neuroscience is that neural networks self-organize to the critical point of a phase transition, thereby optimizing aspects of sensory information processing. This idea is partially supported by strong evidence for critical dynamics observed in the cerebral cortex, but has not been tested in systems with significant sensory input. Thus, the foundations of this hypothesis — the self-organization process and how it manifests during strong sensory input — remain unstudied experimentally. Here we report microelectrode array measurements from visual cortex of turtles during visual stimulation of the retina. We show experimentally and in a computational model that strong sensory input initially elicits cortical network dynamics that are not critical, but adaptive changes in the network rapidly tune the system to criticality. This conclusion is based on observations of multifaceted scaling laws predicted to occur at criticality. Our findings establish sensory adaptation as a self-organizing mechanism which maintains criticality in visual cortex during sensory information processing.

11:39AM G50.00003 Rich club neurons dominate Information Transfer in local cortical networks, SUNNY NIGAM, MASANORI SHIMONO, OLAF SPORNS, JOHN BEGGs, Indiana Univ - Bloomington — The performance of complex networks depends on how they route their traffic. It is unknown how information is transferred in local cortical networks of hundreds of closely-spaced neurons. To address this, it is necessary to record simultaneously from hundreds of neurons at a spacing that matches typical axonal connection distances, and at a temporal resolution that matches synaptic delays. We used a 512 electrode array (60 μm spacing) to record spontaneous activity at 20 kHz, simultaneously from up to 700 neurons in slice cultures of mouse somatosensory cortex for 1 hr at a time. We used transfer entropy to quantify directed information transfer (IT) between pairs of neurons. We found an approximately lognormal distribution of firing rates as reported in in-vivo. Pairwise information transfer strengths also were nearly lognormally distributed, similar to synaptic strengths. 20% of the neurons accounted for 70% of the total IT coming into, and going out of the network and were defined as rich nodes. These rich nodes were more densely and strongly connected to each other expected by chance, forming a rich club. This highly uneven distribution of IT has implications for the efficiency and robustness of local cortical networks, and gives clues to the plastic processes that shape them.

11:51AM G50.00004 Clique of functional hubs orchestrates population bursts in developmentally regulated neural networks, ALESSANDRO TORCINI, STEFANO LUCCIOlI, Istituto dei Sistemi Complessi - CNR, Sesto Fiorentino (Italy), PAOLO BONIFAZI, ESHEL BEN-JACOB, Beverly and Sakler Faculty of Exact Sciences School of Physics and Astronomy, Tel Aviv University, 69978 Ramat Aviv, Israel, ARI BARZILAI, Department of Neurobiology, George S. Wise Faculty of Life Sciences and Sagol School of Neuroscience, Tel Aviv University, Israel — It has recently been discovered that single neuron stimulation can impact network dynamics in immature and adult neuronal circuits. Here we report a novel mechanism which can explain in developing neuronal circuits, typically composed of only excitatory cells, the peculiar role played by a few specific neurons in promoting/arresting the population activity. For this purpose, we consider a standard neuronal network model, with short-term synaptic plasticity whose population activity is characterized by bursting behavior. The addition of developmentally regulated constraints on single neuron excitability and connectivity leads to the emergence of functional hub neurons, whose stimulation/deletion is critical for the network activity. Functional hubs form a clique, where a precise sequential activation of the neurons is essential to ignite collective events without any need for a specific topological architecture. Unsupervised time-lagged firings of supra-threshold cells, in connection with coordinated entrainments of near-threshold neurons, are the key ingredients to orchestrate population activity.

12:03PM G50.00005 Neural mechanism to construct a future timeline. KARTHIK SHANKAR, Boston University — Computing the set of possible future states is an important cognitive feature that aids in planning toward a goal. The brain must perform this computation swiftly, and more importantly without destroying the current state of memory. Here we propose a neural mechanism that periodically modifies the synaptic weights in a mathematically principled way to achieve the construction of the future timeline. Preliminary evidence of synaptic modifications in synchrony with the theta rhythm suggests that this mechanism could take place in the Hippocampus. The hypothesis also predicts that the time cells observed in the Hippocampus should exhibit phase precession with respect to the theta rhythm as the future timeline is cognitively constructed.

12:15PM G50.00006 Local structure of subcellular input retinotopy in an identified visual interneuron1. YING ZHU, Structural and Computational Biology & Molecular Biophysics program, Baylor College of Medicine, Houston, TX, 77030, FABRIZIO GABBIANI, Department of Neuroscience, Baylor College of Medicine, Houston, TX, 77030, FABRIZIO GABBIANI’S LAB TEAM — How does the spatial layout of the projections that a neuron receives impact its synaptic integration and computation? What is the mapping topography of subcellular wiring at the single neuron level? The LGMD (lobula giant movement detector) neuron in the locust is an identified neuron that responds preferentially to objects approaching on a collision course. It receives excitatory inputs from the entire visual hemifield through calcium-permeable nicotinic acetylcholine receptors. Previous work showed that the projection from the locust compound eye to the LGMD preserved retinotopy down to the level of a single ommatidium (facet) by employing in vivo widefield calcium imaging. Because widefield imaging relies on global excitation of the preparation and has a relatively low resolution, previous work could not investigate this retinotopic mapping at the level of individual thin dendritic branches. Our current work employs a custom-built two-photon microscope with sub-micron resolution in conjunction with a single-facet stimulation setup that provides visual stimuli to the single ommatidium of locust adequate to explore the local structure of this retinotopy at a finer level.

12:27PM G50.00007 Nonlinear Dynamic Theory of Acute Cell Injuries and Brain Ischemia1. DOAA TAH, Department of Physics and Astronomy, Wayne State University, FIKRA ANGGRAINI, DONALD DEGRACIA, Department of Physiology, School of Medicine, Wayne State University, ZHI-FENG HUANG, Department of Physics and Astronomy, Wayne State University — Cerebral ischemia in the form of stroke and cardiac arrest brain damage affect over 1 million people per year in the USA alone. In spite of close to 200 clinical trials and decades of research, there are no treatments to stop post-ischemic neuron death. We have argued that a major weakness of current brain ischemia research is lack of a deductive theoretical framework of acute cell injury to guide empirical studies. A previously published autonomous model based on the concept of nonlinear dynamic network was shown to capture important facets of cell injury, linking the concept of therapeutic to bistable dynamics. Here we present an improved, non-autonomous formulation of the nonlinear dynamic model of cell injury that allows multiple acute injuries over time, thereby allowing simulations of both therapeutic treatment and preconditioning. Our results are connected to the experimental data of gene expression and proteomics of neuron cells. Importantly, this new model may be constructed as a novel approach to pharmacodynamics of acute cell injury. The model makes explicit that any pro-survival therapy is always a form of sub-lethal injury. This insight is expected to widely influence treatment of acute injury conditions that have defied successful treatment to date.

12:39PM G50.00008 ABSTRACT WITHDRAWN —

12:51PM G50.00009 Interpreting collective neural activity underlying spatial navigation in virtual reality. LEENOY MESHULAM, JEFF GAUTHIER, DAVID TANK, WILLIAM BIALEK, Princeton University — Traditionally, cognitive-demanding processes like spatial navigation were studied by recording the activity of single neurons. However, recent technological progress allows imaging the simultaneous activity of large neuronal populations in awake behaving animals. This progress in experimental work calls for a similar adjustments of the modeling frameworks. To achieve a description of the “real thermodynamics” of the neural system, we construct maximum entropy models for optical imaging data spanned by the network states. The model proposes that the information that comes to be recorded in the brain is first orthogonalized (as in Gram-Schmidt orthogonalization) and then inscribed in synaptic weights. While the orthogonalized versions of input vectors with ±1 components are stored in the model brain, the original vectors/patterns are retrieved exactly when checked for retrieval. Simulations are presented that give insight into the energy landscape in the space of stored patterns ($\frac{p}{N}$). The model predicts the number of components stored in the model brain is $N$ by $p$ and become zero around $\frac{p}{N}$. The model also predicts the information that comes to be recorded in the brain is first orthogonalized and then inscribed in synaptic weights. While the orthogonalized versions of input vectors with ±1 components are stored in the model brain, the original vectors/patterns are retrieved exactly when checked for retrieval. Simulations are presented that give insight into the energy landscape in the space spanned by the network states.

How to generate a sound-localization map in fish

J. Leo Van Hémmen, Physik Department, TU Munich — How sound localization is represented in the fish brain is a research field largely unbiased by theoretical analysis and computational modeling. Yet, there is experimental evidence that the axes of particle acceleration due to underwater sound are represented through a map in the midbrain of fish, e.g., in the *torus semicircularis* of the rainbow trout (Wubbels et al. 1997). How does such a map arise? Fish perceive pressure gradients by their three otolithic organs, each of which comprises a dense, calcareous, stone that is bathed in endolymph and attached to a sensory epithelium. In rainbow trout, the sensory epithelia of left and right utricle lie in the horizontal plane and consist of hair cells with equally distributed preferred orientations. We model the neuronal response of this system on the basis of Schüff’s vector detection hypothesis (Schüff et al. 1975) and introduce a temporal spike code of sound direction, where optimality of hair cell orientation θj with respect to the acceleration direction θa is mapped onto spike phases via a von-Mises distribution. By learning to tune in to the earliest synchronized activity, nerve cells in the midbrain generate a map under the supervision of a locally excitatory, yet globally inhibitory visual teacher.

The neural circuit and synaptic dynamics underlying perceptual decision-making

Feng Liu, School of Physics, Nanjing University — Decision-making with several choice options is central to cognition. To elucidate the neural mechanisms of multiple-choice motion discrimination, we built a continuous recurrent network model to represent a local circuit in the lateral intraparietal area (LIP). The network is composed of pyramidal cells and interneurons, which are directionally tuned. All neurons are reciprocally connected, and the synaptic connectivity strength is heterogeneous. Specifically, we assume two types of inhibitory connectivity to pyramidal cells: opposite-feature and similar-feature inhibition. The model accounted for both physiological and behavioral data from monkey experiments. The network is endowed with slow excitatory reverberation, which subserves the buildup and maintenance of persistent neural activity, and predominant feedback inhibition, which underlies the winner-take-all competition and attractor dynamics. The opposite-feature and opposite-feature inhibition have different effects on decision-making, and only their combination allows for a categorical choice among 12 alternatives. Together, our work highlights the importance of structured synaptic inhibition in multiple-choice decision-making processes. Reference: Cheng Xue and Feng Liu. J. Neurosci. 34, 13444-13457 (2014).

Session G51 GSOFT GSNP: Invited Session: Frontiers of Soft Matter II

Grand Ballroom C1 - M.

11:15AM G51.00001 Entangled active matter: from ants to living cells1, Franoise Brochard-Wyart, Institut Curie — We introduce the field of “Entangled Active Matter” where the building blocks are transiently bound. We will point out strong similarities between aggregates of ants and cells! We will use multicellular aggregates, a model system for tissues. We characterize the tissue mechanical properties using pipette aspiration technique. The aggregate exhibits a viscoelastic response. We observe aggregate reinforcement with pressure, which may results in pulsed contractions or “shivering.” We interpret this reinforcement as a mecha-sensitive active response of the acto-myosin cortex. We describe the spreading of aggregates on rigid and soft substrates, varying both intercellular and substrate adhesion. We find both partial and complete wetting, with a precursor film forming a cellular monolayer in a liquid or gas phase. We model the dynamics of spreading from a balance between active cellular driving forces and permeation of cells to enter into the film. Finally we study the motility of aggregates induced by chemical or rigidity gradients, or spontaneous: on soft substrate, the precursor film is unstable, leading to a symmetry breaking and a global motion of the aggregate. We describe the shapes of migrating aggregates, the flow and the force field responsible of the motion. We monitored the center of mass motion and we characterize the stick-slip motions.

11:51AM G51.00002 Free-standing thermalized graphene: a hard/soft hybrid1, David Nelson, Department of Physics, Harvard University — Understanding deformations of macroscopic thin sheets and plates has a long and rich history, culminating with the Föppl-von Karman equations in 1904. These highly non-linear equations are characterized by a dimensionless coupling constant (the “Föppl-von Karman number”) that can easily reach $k = 10^{7}$ in an ordinary sheet of writing paper. Since the late 1980’s, it has been clear that thermal fluctuations in microscopically thin elastic membranes fundamentally alter the long wavelength physics, leading to a negative thermal expansion coefficient, and a strongly scale-dependent bending energy and Young’s modulus. Recent experiments from the McEuen group at Cornell that twist and bend individual atomically-thin free-standing graphene sheets (with $k = 10^{13}$) call for a theory of the mechanical deformation of thermally excited membranes with large Föppl-von Karman number. We present here results for the bending and pulling of thermalized graphene ribbons and tabs in the cantilever mode.

12:27PM G51.00003 Liquids Gone With the Wind, David Quéré, ESPCI, Paris — Self-propelling fluidic devices naturally result from some asymmetry of wettability, geometry or temperature. Here we consider the case of motions arising from the air around, forced by some trick to flow in an asymmetric way. We first consider vapor flows generated in a Leidenfrost situation, and made anisotropic by textures decorating the hot substrate. We discuss how the force and speed arising from these rectified vapor flows can be optimized. Then, we observe drops on a fiber placed in a symmetric wind. In a well-defined window of wind speed, the drop is found to self-propel along the fiber, which is analyzed. We also show that this effect makes drops moving in opposite direction bounce on each other, which generates fascinating 1-D dynamics.

In collaboration with Guillaume Dupeux, Philippe Bourrinane, Dan Soto, Hélène de Maleprade, Pierre-Brice Bintein, Hadrien Bense and Christophe Clanet.

1:03PM G51.00004 Directed assembly in soft matter by energy stored in inclusions, Kathleen Stebe, University of Pennsylvania — We have been exploiting fields that arise spontaneously when microparticles are placed in contact with deforming matter to direct assembly. In one context, we use capillary interactions that occur between anisotropic microparticles at fluid interfaces. The fluid interface deforms owing to the particle presence, creating an area field that bears the signature of the particle shape and wetting. We use curvature fields to direct particles to migrate, orient and assemble. In another context, we exploit elastic energies and defect fields that arise in liquid crystals. When a nematic liquid crystal is confined using surfaces with complex topographies and well-defined anchoring energies, the director field and associated defect fields can be molded to store elastic energy which can be used to steer particles into rich assemblies. In a final context, we study the interaction of colloidal particles on giant vesicles under tension, in which particles interact via bending energies to interact with each other.
1:39PM G51.00005 The Extreme Mechanics of Soft Structures¹. PEDRO REIS, Massachusetts Institute of Technology — I will present a series of experimental investigations on the rich behavior of soft mechanical structures, which, similarly to soft materials, can undergo large deformations under a variety of loading conditions. Soft structures typically comprise slender elements that can readily undergo mechanical instabilities to achieve extreme flexibility and reversible reconfigurations. This field has come to be warmly known as Extreme Mechanics, where one of the fundamental challenges lies in rationalizing the geometric nonlinearities that arise in the post-buckling regime. I shall focus on problems involving thin elastic rods and shells, through examples ranging from the deployment of submarine cables onto the seabed, locomotion of unflagellated bacteria, crystallography of curved wrinkling and its usage for active aerodynamic drag reduction. The main common feature underlying this series of studies is the prominence of geometry, and its interplay with mechanics, in dictating complex mechanical behavior that is relevant and applicable over a wide range of length scales. Moreover, our findings suggest that we rethink our relationship with mechanical instabilities which, rather than modes of failure, can be embraced as opportunities for functionality that are scalable, reversible, and robust.

Session G52 DCMP: Invited Session: Spin-Momentum Coupling in Topological Insulator Surfaces and Semiconductors Grand Ballroom C2 - Daniel Ralph, Cornell University

11:15AM G52.00001 Spin Circuit Model for Spin Orbit Torques in 2D Channels¹. SEOKMIN HONG, School of Electrical and Computer Engineering, Purdue University — Recently, the unique coupling between charge and spin in topological insulators has been explored through various types of electrical measurements, which could have interesting applications. In this talk, we present a spin circuit model [1] for spin orbit torques in topological insulator surface states and other 2D channels. We show with a simple example that results from the circuit model agree well with those obtained from nonequilibrium Green’s function (NEGF) based quantum transport simulation. Some predictions [2] of our model have already received experimental support and we hope this model can provide a unifying framework that can be used to critically evaluate experimental results, to explore new types of devices as well as to answer fundamental questions regarding these materials. The model for spin-orbit torques described here can be incorporated into a broader spin-circuit approach [3] which, we believe, provides a natural platform for multi-physics, multi-component spintronic devices.

11:51AM G52.00002 Magnetization switching through giant spin-orbit torque in the magnetically doped topological insulators¹. YABIN FAN, University of California, Los Angeles — Recent demonstrations of magnetization switching induced by in-plane current in heavy metal/ferromagnetic heterostructures (HMFHs) have drawn great interest to spin torques arising from the large spin-orbit coupling (SOC)...[1-3] in heavy metals. Considering the intrinsic strong SOC, topological insulators (TIs) are expected to be promising candidates for exploring spin-orbit torque (SOT)-related physics. In this talk, we report the magnetization switching through giant SOT in the magnetically doped TI structures. In particular, we demonstrate the magnetization switching in a chromium-doped TI bilayer heterostructure, and the current induced SOT possibly has contribution from the spin-momentum locked surface states of TI. The critical current density for switching is below 8.9 × 10⁴ A/cm² at 1.9 K. Moreover, we use second-harmonic methods to measure the spin torque efficiencies which are more than three orders of magnitude larger than those reported in heavy metals. The giant SOT and efficient current-induced magnetization switching exhibited by the bilayer heterostructure may lead to innovative spintronics applications such as ultralow power dissipation memory and logic devices.

¹We are grateful to the support from the DARPA Mesos program under contract No.N66001-12-1-4034 and N66001-11-1-4105. We also acknowledge the support from the Western Institute of Nanoelectronics (WIN) and the support from the FAME center.

12:27PM G52.00003 Spin-transfer torque generated by a topological insulator. ALEX MELNNIK, Cornell Univ — Magnetic devices are a leading contender for the implementation of memory and logic technologies that are non-volatile, that can scale to high density and high speed, and that do not wear out. However, widespread application of magnetic memory and logic devices will require the development of efficient mechanisms for reorienting their magnetization using the least possible current and power. We report experiments showing that charge current flowing in-plane in a thin film of the topological insulator Bi₂Se₃ at room temperature can exert a strong spin-transfer torque on an adjacent metallic ferromagnetic layer, with a direction consistent with that expected from a topological surface state. The spin torque efficiency per unit charge current density in the Bi₂Se₃ is larger than any previously measured at room temperature. Our data suggest that topological insulators could enable very efficient electrical manipulation of magnetic materials at room temperature, for memory and logic applications. Related publications: A. R. Melnnik, J. S. Lee, A. Richar'della, J. L. Grab, P. J. Mintun, M. H. Fischer, A. Vaezi, A. Manchon, E.-A. Kim, N. Samarth, D. C. Ralph, Nature 511, 449-451 (2014).
spin-mixing conductance of \(3\) from the confined mode to the spin sink of ferromagnetic material in the surrounding film. Though unexpected for insulating systems, the measured intralayer scales like the surface-to-volume ratio of the mode, indicating an interfacial damping effect (similar to spin pumping) due to the transfer of angular momentum is created within an extended, unpatterned YIG film by means of the intense local dipolar field of a micromagnetic tip. The damping of the confined mode spin ensembles. Electron spin resonance spectroscopy corroborates spin transport in strong field gradients. These experiments, supported by microscopic Monte Carlo modeling, provide a unique insight into the intrinsic dynamics of pure spin currents needed for nanoscale devices that seek to control spins. In addition, we observe a dependence of the damping of a confined mode of precessing ferromagnetic magnetization on the size of the mode. The micron-scale mode is created within an extended, unpatterned YIG film by means of the intense local dipolar field of a micromagnetic tip. The damping of the confined mode scales like the surface-to-volume ratio of the mode, indicating an interfacial damping effect (similar to spin pumping) due to the transfer of angular momentum from the confined mode to the spin sink of ferromagnetic material in the surrounding film. Though unexpected for insulating systems, the measured intralayer spin-mixing conductance of \(3 \times 10^{11}\) m\(^{-2}\) demonstrates efficient intralayer angular momentum transfer.

1:03PM G52.00004 Observation of chiral currents at the magnetic domain boundary of a topological insulator. YIHUA WANG, Stanford University — The broken time-reversal symmetry (TRS) states on the surface of a three-dimensional topological insulator (3D-TI) promise many exotic quantum phenomena. Breaking TRS opens a band gap on the surface Dirac cone and transforms the metallic surface into a Chern insulator. The TRS-broken surface states coupled to a superconductor are predicted to lead to Majorana fermions, which are the fundamental ingredients of topological quantum computation. Just as the surface Dirac cone is a signature of the non-trivial topological bulk band structure of a time-reversal invariant 3D-TI, bulk-boundary correspondence dictates that the TRS-broken surface states with a nonzero Chern number is manifested by a gapless chiral edge state (CES) at the domain boundary. In the special case where the domain boundary is the edge of the sample surface, CES along the edge leads to a quantized anomalous Hall conductance, which was recently measured in a magnetically doped 3D-TI. More generally, a magnetic domain boundary on the surface of TI hosts a CES, which is yet to be directly demonstrated because any local change of conductivity due to the CES does not affect conductance globally. Here we use a scanning superconducting quantum interference device (SQUID) to show that in a uniformly magnetized topological insulator - ferromagnetic insulator (TI-FMI) heterostructure current flows at the edge of the surface of the topological insulator when the Fermi level is gate-tuned to the surface band gap. We further induce micron-scale magnetic structures using the field coil of the SQUID and show that there emerges a chiral edge current at the magnetic domain boundary. In both cases the magnitude of the chiral edge current depends on the chemical potential rather than the applied current. Such magnetic nano-structures, which can be readily created on a TI in an arbitrary geometry, provide a versatile platform for detecting topological magneto-electric effects and may allow the engineering of magnetically defined quantum bits and spin-based electronics. Hybridization with conventional superconductors may open the door to topological quantum computation.

1:39PM G52.00005 Current-induced spin polarization in anisotropic spin-orbit fields. VANESSA SIH, University of Michigan — Current-induced spin polarization is a phenomenon in which carrier spins are oriented when subjected to current flow. However, the mechanism that produces this spin polarization remains an open question. Existing theory predicts that the spin polarization should be proportional to the spin-orbit splitting yet no clear trend has been observed experimentally. We perform experiments on semiconductor samples designed so that the magnitude and direction of the in-plane current and applied magnetic field can be varied and measure the electrical spin generation efficiency and spin-orbit splitting using optical techniques. Contrary to expectation, the magnitude of the current-induced spin polarization is shown to be larger for momentum directions corresponding to smaller spin-orbit splitting. In addition, angle-dependent measurements demonstrate that the steady-state in-plane spin polarization is not along the direction of the spin-orbit field, which we attribute to anisotropic spin relaxation. Furthermore, we show that this electrically-generated electron spin polarization can produce a nuclear spin hyperpolarization through dynamic nuclear polarization.

11:15AM G53.00001 Atomic spin chains as testing ground for quantum magnetism, SANDER OTTE, Kavli Institute of Nanoscience, Delft University of Technology — The field of quantum magnetism aims to capture the rich emergent physics that arises when multiple spins interact, in terms of elementary models such as the spin \(\frac{1}{2}\) Heisenberg chain. Experimental platforms to verify these models are rare and generally do not provide the possibility to detect spin correlations locally. In my lab we use low-temperature scanning tunneling microscopy to design and build artificial spin lattices with atomic precision. Inelastic electron tunneling spectroscopy enables us to identify the ground state and probe spin excitations as a function of system size, location inside the lattice and coupling parameter values. Two types of collective excitations that play a role in many dynamic magnetic processes are spin waves (magnons) and spinons. Our experiments enable us to study both types of excitations. First, we have been able to map the standing spin wave modes of a ferromagnetic bit of six atoms, and to determine their role in the collective reversal process of the bit (Spinelli et al., Nature Materials 2014). More recently, we have crafted antiferromagnetic spin \(\frac{1}{2}\) XXZ chains, which allow us to observe spinon excitations, as well as the stepwise transition to a fully aligned phase beyond the critical magnetic field (Toskovic et al., in preparation). These findings create a promising experimental environment for putting quantum magnetic models to the test.

11:51AM G53.00002 Spatially-resolved measurement of spin transport across nanoscale interfaces. ROHAN ADUR, The Ohio State University — Spintronics uses spin for information processing and storage. Mechanisms for spin relaxation in bulk systems have been extensively studied. However, a clear understanding of few-spin systems remains challenging. We report spatially-resolved magnetic resonance studies of a “spin nanowire” formed by nitrogen vacancies in diamond. The result reveals that the lifetime of the spin ensemble is dominated by spin transport from the ensemble into the adjacent spin reservoir, which is in striking contrast to conventional spin-lattice relaxation measurements of isolated spin ensembles. Electron spin resonance spectroscopy corroborates spin transport in strong field gradients. These experiments, supported by microscopic Monte Carlo modeling, provide a unique insight into the intrinsic dynamics of pure spin currents needed for nanoscale devices that seek to control spins. In addition, we observe a dependence of the damping of a confined mode of precessing ferromagnetic magnetization on the size of the mode. The micron-scale mode is created within an extended, unpatterned YIG film by means of the intense local dipolar field of a micromagnetic tip. The damping of the confined mode scales like the surface-volume ratio of the mode, indicating an interfacial damping effect (similar to spin pumping) due to the transfer of angular momentum from the confined mode to the spin sink of ferromagnetic material in the surrounding film. Though unexpected for insulating systems, the measured intralayer spin-mixing conductance of \(3 \times 10^{11}\) m\(^{-2}\) demonstrates efficient intralayer angular momentum transfer.

1:03PM G53.00004 Full control of the spin-wave damping in a magnetic insulator using spin orbit torque. OLIVIER KLEIN, SPINTEC, UMR CEA/CNRS/UFJ-Grenoble 1/Grenoble-INP, INAC, 38054 Grenoble, France — The spin-orbit interaction (SOI) has been an interesting and useful addition in the field of spintronics by opening it to non-metallic magnet. It capitalizes on adjoining a strong SOI normal metal next to a thin magnetic layer. The SOI introduces a charge current, $J_c$, into a spin current, $J_s$, with an efficiency parametrized by $\gamma_{SO}$. The spin Hall angle. An important benefit of the SOI is that $J_c$ and $J_s$ are linked through a cross-product, allowing a charge current flowing in-plane to produce a spin current flowing out-of-plane. Hence it enables the transfer of spin angular momentum to non-metallic materials and in particular to insulating oxides, which offer improved performance compared to their metallic counterparts. Among all oxides, Yttrium Iron Garnet (YIG) holds a special place for having the lowest known spin-wave (SW) damping factor. Recently we have observed that spin current through the YIG-Pt interface has been subject to debate. While numerous experiments have reported that $J_s$ produced by the excitation of ferromagnetic resonance (FMR) in YIG can cross efficiently the YIG-Pt interface and be converted into $J_c$ in Pt through the inverse spin Hall effect (ISHE), most attempts to observe the reciprocal effect, where $J_c$ produced in Pt by the direct spin Hall effect (SHE) is transferred to YIG, resulting in damping compensation, have failed. This has been raising fundamental questions about the reciprocity of the spin transparency of the interface between a metal and a magnetic insulator. In this talk it will be demonstrated that the threshold current for damping compensation can be reached in a 5 $\mu$m diameter YIG(20nm)—Pt(7nm) disk. Reduction of both the thickness and lateral size of a YIG-structure were key to reach the microwave generation threshold current, $J_t$. The experimental evidence rests upon the measurement of the ferromagnetic resonance linewidth as a function of $J_c$, using a magnetic resonance force microscope (MRFM). It is shown that the magnetic losses of spin-wave modes existing in the magnetic insulator can be reduced or enhanced by at least a factor of five depending on the polarity and intensity of the in-plane dc current, $J_{dc}$. Complete compensation of the damping of the fundamental mode by spin-orbit torque is reached for a current density of $J_{dc} \sim 3 \times 10^{11}$A.m$^{-2}$, in agreement with theoretical predictions. At this critical threshold the MRFM detects a small change of static magnetization, a behavior consistent with the onset of an auto-oscillation regime. This result opens up a new area of research on the electronic control of the damping of YIG-nanostructures.

1:39PM G53.00005 X-ray Imaging of Spin Wave Dynamics at the Nanoscale. HENDRIK OHLDAG, SLAC, Stanford University — Imaging current induced magnetization dynamics has so far remained an elusive task, due to the lack of microscopy techniques with combined high spatial and temporal resolution, and elemental magnetic sensitivity. Using synchrotron radiation, we have been able to create the first x-ray images of spin waves generated in nano-contact spin torque oscillators realized on different ferromagnetic thin films, using the x-ray magnetic circular dichroism (XMCD) effect as a probe. In nanocontacts with perpendicular magnetic anisotropy, we directly observed the appearance of a highly localized mode beneath the nanocontact with large precession angle. In samples with an easy-plane magnetic anisotropy, we have been able to implement time-resolution in the measured process and to create a movie of the spin waves. We observed that the spin wave dynamics is excited on the side of the nanocontact where the internal field in the thin film is at a minimum. Around this field minimum, the spin wave extends with a radius of approximately 250 nm, demonstrating the localized nature of the mode. Finally, our measurements show that the spin wave has a node in amplitude, around which the magnetic field points in two opposite out-of-plane directions.

H1.00001 UNDERGRADUATE RESEARCH

H1.00002 Electromagnetic cavities as an analog to chaos regularization of quantum tunneling rates. RACHEL O'WEN, Western Washington University, JOHN RODGERS, University of Maryland — For double-well potentials separated by a tunneling barrier, it has been shown theoretically that quantum mechanical tunneling rates vary greatly with well geometry. Chaotic wells exhibit statistically smaller fluctuations in energy level splitting than those characterized by nonchaotic dynamics. This phenomenon (chaos regularization) can be analyzed by examining the statistical spacing in symmetric and anti-symmetric wave states produced by tunneling. Exploiting the similarity of transverse electromagnetic waves in large cavities and quantum mechanical wave functions in symmetric double-wells, chaos regularization in electromagnetic structures was studied experimentally and numerically. The resonant frequencies in rectangular (integrable) and bowtie (chaotic) cavities coupled via short sections of cutoff waveguides were simulated using finite element code and measured using a vector network analyzer. The ensemble difference in the measured anti-symmetric and symmetric resonant frequencies squared (analogous to splitting in energy levels) showed remarkably good agreement with theory. In the rectangular cavity we observed quantized resonances spaced across a wide range of frequencies whereas in the bowtie cavity the resonances were grouped randomly close to the theoretical curve.
H1.00003 Quantifying the Relationship between Surface Hydrophobicity and Depletion Layer Thickness

JARED NUTTER, SHANNON PETERSEN, RYAN SAYKO, ADELE POYNOR, Allegheny College — When water comes into contact with an extended hydrophobic surface, a uniform region of low density forms, called the depletion layer. This phenomenon has only been experimentally verified on surfaces with contact angles $>100^\circ$, but understanding how the thickness of the depletion layer changes with the hydrophobicity at intermediate contact angles is one of the underlying mechanisms behind several biological systems including colloidal self-assembly, protein folding, and fluid flow across membranes. We aim to quantify this relationship by using self-assembled monolayers of 1-octadecanethiol and 1-mercaptoheptadecanoic acid on gold to produce surfaces with contact angles between $55^\circ$ and $107^\circ$. We then use surface plasmon resonance spectroscopy to determine the thickness of the depletion layer formed for each surface.

H1.00004 Dependence of the Contact Angle on Self-Assembled Monolayer Production Method

BROOKE OLLANDER, SHANNON PETERSEN, RYAN SAYKO, ADELE POYNOR, Allegheny College — When water is forced in contact with a hydrophobic surface, it attempts to reduce its contact by forming a depletion layer. A depletion layer is defined as a nanometer scale low density region of water molecules at the surface. To alter the hydrophobicity of the slide, self-assembled monolayers (SAMs) are formed by utilizing the following organothiol solutions: 11-mercaptoundecanoic acid (hydrophilic) and 1-octadecanethiol (hydrophobic). The contact angle of slides with different organothiol solution exposure times is measured using a homemade goniometer and ImageJ software.

H1.00005 Flow Rate In Microfluidic Pumps As A Function Of Tension and Pump Motor Head Speed

ANTHONY IRWIN, KRISTA MCBRIDE, Belmont University — As the use of microfluidic devices has become more common in recent years the need for standardization within the pump systems has grown. The pumps are ball bearing rotor microfluidic pumps and work off the idea of peristalsis. The rapid contraction and relaxation propagating down a tube or a microfluidic channel. The ball bearings compress the tube (occlusion) and move along part of the tube length forcing fluid to move inside of the tube in the same direction of the ball bearings. When the ball bearing rolls off the area occupied by the microfluidic channel, its walls and ceiling undergo restitution and a pocket of low pressure is briefly formed pulling more of the liquid into the pump system. Before looking to standardize the pump systems it must be known how the tension placed by the pumps bearing heads onto the PDMS inserts channels affect the pumps performance (mainly the flow rate produced). The relationship of the speed at which the bearings on the motor head spin and the flow rate must also be established. This research produced calibration curves for flow rate vs. tension and rpm. These calibration curves allow the devices to be set to optimal user settings by simply varying either the motor head tension or the motor head speed.

H1.00006 Photoemission spectroscopy and X-ray diffraction analysis of 3D topological and Kondo insulators

PAVEL SHIBAYEV, Princeton University, HASAN GROUP TEAM — The advantage of studying 3D topological insulators (TIs), compounds that have attracted the attention of many in the condensed matter field, is the ability for their existence at room temperature and no magnetic fields, allowing both for resolving their band structure via angle-resolved photoemission spectroscopy (ARPES) and understanding electrical transport and other properties via X-ray diffraction (XRD) and point-contact spectroscopy (PCS). A comprehensive quantitative analysis of Bi$_2$Se$_3$, a 3D TI, was carried out using these methods. The Bi$_2$Se$_3$ crystals were synthesized in-house at Princeton University. A first-principles calculation based on density functional theory, DFT, was performed using the Abinit software. The band structure of the crystal was then resolved via ARPES at the Advanced Light Source in LBNL, resulting in a surprisingly stark and clear single Dirac cone. A large band gap was confirmed, suggesting an increased potential for applications. In contrast, Kondo insulators are found in rare-earth based materials with f-electron degrees of freedom. Photon energy dependent dispersion relationships and temperature dependence studies were performed on a Kondo candidate CeB$_6$ via ARPES, showing an even number of Dirac cones and a non-TI behavior. Analysis of I-V characteristics through PCS will follow, in addition to characterization via Bruker XRD for both compounds.

2 Research group led by Professor M. Zahid Hasan (Princeton University)

H1.00007 Structure Property Relationships in Imidazole-based Deep Eutectic Mixtures

LOGAN TERHEGGEN, TYLER COSBY, JOSHUA SANGORO, Univ of Tennesse, Knoxville — Deep eutectic mixtures of levulinic acid with a systematic series of imidazoles are measured by broadband dielectric spectroscopy, differential scanning calorimetry, and Fourier transform infrared spectroscopy to investigate the impact of steric interactions on charge transport and structural dynamics. An enhancement of dc conductivity is found in each of the imidazoles upon the addition of levulinic acid. However, the extent of increase is dependent upon the alkyl substitution on the imidazole ring. These results highlight the importance of molecular structure on hydrogen bonding and charge transport in deep eutectic mixtures.

H1.00008 Laser Induced Breakdown Spectroscopy of Metals

ANDRIA PALMER, CARLOS LAWHEAD, LASZLO UJJ, University of West Florida — Laser Induced Breakdown Spectroscopy (LIBS) is a very practical spectroscopy to determine the chemical composition of materials. Recent technical developments resulted in equipment used on the MARS Rover by NASA. It is capable of measuring the emission spectra of laser induced plasma created by energetic laser pulses focused on the sample (rocks, metals, etc.). We have develop a Laser Induced Breakdown Spectroscopy setup and investigated the necessary experimental and methodological challenges needed to make such material identification measurements. 355 and 532 nm laser pulses with 5 ns temporal duration was used to generate micro-plasma from which compositions can be determined based on known elemental and molecular emission intensities and wavelengths. The performance of LIBS depends on several parameters including laser wavelength, pulse energy, pulse duration, time interval of observation, geometrical configuration of collecting optics, and the properties of ambient medium. Spectra recorded from alloys (e.g. US penny coin) and pure metals will be presented.

H1.00009 Differential Conductance Measurements of MgB$_2$/I/Pb Heterojunctions and all-MgB$_2$ Junctions

DAVID CUSICK, Taylor University, MATTHEW ECKHARDT, Indiana Wesleyan University, WENQING DAI, QI LI, Pennsylvania State University, KE CHEN, DANIEL CUNNANE, Temple University, C.G. ZHUANG, None, X.X. XI, Temple University, MICHIO NAITO, Tokyo University of Agriculture and Technology, ROBERTO RAMOS, Indiana Wesleyan University — We present our work characterizing several types of Magnesium Diboride Josephson junctions, including MgB$_2$/I/Pb heterojunctions and all-MgB$_2$ junctions. We report on the I-V and dI/dV-V data collected at various temperatures using both a cryocooler-based experimental platform between 2 and 20 Kelvin and using a $^3$He probe platform between 0.3 and 1.0 Kelvin. These were both developed by undergraduates in a liberal arts university. Using high-sampling rates with a 24-bit data acquisition card and access to a broad range of temperatures, we track and report energy gap distributions and temperature-dependent features of dI/dV peaks of MgB$_2$, comparing these with theoretical predictions.

1 R.C.R. acknowledges support from National Science Foundation Grant # DMR-1206561.

Volume phase transition and corresponding change in composition of polymeric microgels. Janna Mino, Christian Gunder, Kiril Streletzky, Cleveland State University — Temperature sensitive polysaccharide microgels and parent amphiphilic polymer solution were studied in parallel with Dynamic (DLS) and Static Light Scattering (SLS) spectroscopies. The microgels showed a reversible volume phase transition which was accompanied by a significant change in microgel volume and composition. Coupling DLS and SLS techniques on microgels and polymer solutions allowed to deduce microgel size, structure, molecular weight and a relative change in microgel water content during the volume phase transition. It also allowed comparing controlled dewetting transition in microgels with corresponding phase transition in parent polymer solution. Light scattering findings were tested with SEM imaging.

Synthesis and Characterization of Tetraphiafulvalene Derivatives, Mark Bartolo, Stephen Tsui, Cal State Univ - San Marcos, Eric Reinheimer, Rigaku — We synthesize tetraphiafulvalene (TTF) derivative materials in an effort to identify conducting and magnetic properties. The doping of these TTF derivatives include tetracyanoethylene (TCN), 7,7,8,8-tetracyanoquinodimethane (TCNQ), and para-dinitrobenzene (pDNB). We examine these TTF containing donor-acceptor complexes through their structural and electronic transport characteristics.

Determination of stimulation focality in heterogeneous head models during transcranial magnetic stimulation (TMS), Erikl Lee, Ravi Hadimani, David Jiles, Department of Electrical and Computer Engineering, Iowa State University — Transcranial Magnetic Stimulation (TMS) is an increasingly popular tool used by both the scientific and medical community to understand and treat the brain. TMS has the potential to help people with a wide range of diseases such as Parkinson's, Alzheimer's, and PTSD, while currently being used to treat people with chronic, drug-resistant depression. Through computer simulations, we are able to see the electric field that TMS induces in anatomical human models, but there is no measure to quantify this electric field in a way that relates to a specific patient undergoing TMS therapy. We propose a way to quantify the focality of the induced electric field in a heterogeneous head model during TMS by relating the surface area of the brain being stimulated to the total volume of the brain being stimulated. This figure would be obtained by conducting finite element analysis (FEA) simulations of TMS therapy on a patient specific head model. Using this figure to assist in TMS therapy will allow clinicians and researchers to more accurately stimulate the desired region of a patient's brain and be more equipped to do comparative studies on the effects of TMS across different patients.

Electronic Resonance Enhancement in Raman and CARS Spectroscopy: Surface Enhanced Scattering of Highly Fluorescent Molecules, Carlos Lawhead, Laszlo Ujj, University of West Florida — Surface enhanced Raman spectroscopy (SERS) is an extremely useful tool in increasing sensitivity of Raman spectroscopy; this technique significantly increases the signal from vibrational resonances which can overcome background fluororesces. Silver nanoparticles coated substrates and the silver nanoparticles in solution were used on a variety of fluorescent molecules in order to overcome sample complexities and measure the vibrational spectra. The possible enhancement of SERS using a coherent Raman (CARS) method was investigated, but enhancement factors due to Surface Enhanced CARS have yet to be verified. The instrument used was developed in the University of West Florida Physics Department utilized the second harmonic of a Nd:YAG laser to provide the excitation wavelength at 532 nm and is capable of both transmission and reflection Raman measurements.

Fluorescence and Bonding of Quantum Dots on DNA Origami Constructs, Matthew Kessinger, Timothy Corigan, Concord, David Neff, Michael Norton, Marshall University, CONCORD UNIVERSITY COLLABORATION — Semiconductor quantum dots (QDots) have historically been of interest to the scientific community since their creation for various applications ranging from solar energy to optical labeling. In this study, bioconjugated CdSe/ZnS core/shell QDots were synthesized and functionalized with 3-mercappropionic acid using both traditional ligand exchange as well as newly developed in situ functionalization techniques used to increase the quantum yield of the QDots. Their fluorescence and bonding to both gold as well as DNA origami were investigated for use in self assembled DNA constructs. It is believed that controlling the attachment and spacing of these nanoparticles on DNA origami could be used in a variety of optical labeling and sensing applications. Commercially available biotin and streptavidin functionalized quantum dots were also examined, and subject to the same experiments with gold nanoparticles as the MPA functionalized QDots.

Analysis of layer-by-layer thin-film oxide growth using RHEED and Atomic Force Microscopy, Eli Adler, M.C. Sullivan, Ithaca College, Department of Physics and Astronomy, Araceli Gutierrez-Llorente, H. Jiores, A. Woll, J.D. Brock, Cornell High Energy Synchrotron Source, Cornell University — Reflection high energy electron diffraction (RHEED) is commonly used as an in situ analysis tool for layer-by-layer thin-film growth. Atomic force microscopy is an equally common ex situ tool for analysis of the film surface, providing visual evidence of the surface morphology. During growth, the RHEED intensity oscillates as the film surface changes in roughness. It is often assumed that the maxima of the RHEED oscillations signify a complete layer, however, the oscillations in oxide systems can be misleading. Thus, using only the RHEED maxima is insufficient. X-ray reflectivity can also be used to analyze growth, as the intensity oscillates in phase with the smoothness of the surface. Using x-ray reflectivity to determine the thin film layer deposition, we grew three films where the x-ray and RHEED oscillations were nearly exactly out of phase and halted deposition at different points in the growth. Pre-growth and post-growth AFM images emphasize the fact that the maxima in RHEED are not a justification for determining layer completion.

Enhanced Scattering of Highly Fluorescent Molecules, Stephen Tsui, Cal State Univ - San Marcos, Eric Reinheimer, Rigaku — We synthesize tetraphiafulvalene (TTF) derivative materials in an effort to identify conducting and magnetic properties. The doping of these TTF derivatives include tetracyanoethylene (TCN), 7,7,8,8-tetracyanoquinodimethane (TCNQ), and para-dinitrobenzene (pDNB). We examine these TTF containing donor-acceptor complexes through their structural and electronic transport characteristics.

H1.00016 Developing a protocol for creating microfluidic devices with a 3D printer, PDMS, and glass

H1.00017 Highly Porous Regenerated Cellulose Fiber Mats via the Co-Forcespinning of Cellulose Acetate for Separator Applications. ALEJANDRO CASTILLO, YUANBING MAO, University of Texas Pan-American Chemistry — Improvements in battery technology are necessary for the transition away from a fossil fuel based economy. An important bottle-neck in battery efficiency is the quality of the separator, which separates the cathode and anode to prevent a short-circuit while still allowing the ions in solution to flow as close to unobstructed as possible. In this work solutions of cellulose acetate, polyvinylidifluorine (pvdf), and polyvinylpyrrolidone (ppv) dissolved in a 2:1 v/v acetone/dimethylacetamide solvent mixture were Forcespun to create nonwoven fiber mats of nanoscale diameter. These mats were then soaked in a NaOH solution so as to both strip the ppv from the fiber as well as regenerate cellulose from its acetate derivative for the purpose of creating high surface area, nanoporoporous, hydrophilic, and ionically conductive cellulose/pvdf nonwoven mats for the purposes of testing their suitability as battery separators.

H1.00018 IR spectroscopy of an OH hindered rotor in ZnO

H1.00019 Temperature dependence measurements for Cadmium Telluride (CdTe) solar cells. FERNANDA DUARTE, WEINING WANG, Department of Physics, Seton Hall University — Traditional silicon (Si)-based solar cells have been studied broadly and have already reached their maximum efficiency. However, their cost is relatively high, preventing them from being widely used. Unlike Si-based solar cells, Cadmium Telluride (CdTe) solar cells are considerably cheap, yet the record efficiency is still lower than that of traditional silicon-based solar cells. More studies are needed to understand and improve the efficiency of CdTe solar cells. In this work, we report our studies of the temperature dependence of CdTe solar cell parameters using the temperature-varying apparatus designed and built by us in-house. This temperature-varying apparatus will be incorporated with a solar cell testing station in order to measure the solar cell parameters while varying the temperature. The solar cell parameters will be measured at different temperatures (within a 100 K temperature range), and the effects of temperature on the open-circuit voltage, short-circuit current and efficiency of the solar cells will be reported. These results allow us to further understand the physics of CdTe solar cells and shine light on how to improve the efficiency of CdTe solar cells.

H1.00020 Systematic Studies of Phase Transitions in Thermos-Responsive Polymers Used in Targeted Drug Delivery. JANAE BRADLEY, Univ of Missouri - Columbia, DANIEL DENMARK, SARATH WITANACHCHI, University of South Florida — Thermoresponsive polymers such as poly-N-isopropylacrylamide (PNIPAM) can undergo reversible phase transitions in aqueous solutions under varying temperature. They are ideal candidates for the polymer shell of a targeted drug delivery capsule. Concentration and pH can affect the lower critical solution temperature (LCST) of the PNIPAM polymer and its physical properties. In this work, a systematic study of the factors that influence the LCST of the PNIPAM polymer mixed with Fe304 nanoparticles (MNPs) during thermal bath heating is presented. A series of PNIPAM solutions with varying concentrations of PNIPAM with MNPs were prepared and characterized using scanning electron microscopy. In-situ transmission measurements were used to determine the LCST of PNIPAM concentrations. A systematic decrease in the LCST was observed as the concentration of PNIPAM was increased. In addition, the impact of pH on the LCST of PNIPAM was examined by increasing the basicity of the PNIPAM solutions by adding adjusted KOH pellets. An increase in the thermal stability of the LCST was observed when the basicity of the PNIPAM solution was increased. The results from this study provide valuable information towards using these thermo-responsive polymers in targeted drug delivery.

H1.00021 Superconducting Resonators: Protecting Schrodinger’s Cat

H1.00022 Capacitance measurements of defects in solar cells: checking the model assumptions
H1.00023 Does a simple lattice protein exhibit self-organized criticality? , DANA GIBBON, ALISSA RUNYON, ARUN BAJRACHARYA, JOËLLE MURRAY, Linfield College — There are many unanswered questions when it comes to protein folding. These questions are interesting because the tertiary structure of proteins determines its functionality in living organisms. How do proteins consistently reach their final tertiary structure from the primary sequence of amino acids? What explains the complexity of tertiary structures? Our research uses a simple hydrophobic-polar lattice-bound computational model to investigate self-organized criticality as a possible mechanism for generating complexity in protein folding and protein tertiary structures.

H1.00024 Development of TiO$_2$-Xwt\%InVO$_4$ Photocatalytic Nano-composites for Ambient Light Assisted Water Detoxification , SESHA SRINIVASAN, Florida Polytechnic University, College of Innovation and Technology, JEREMIAH WILSON, Tuskegee University, Department of Physics, ERIC VICKERS, RYAN INTELLIGA, Florida Polytechnic University, College of Engineering — We have developed nano-composites of TiO$_2$-Xwt\%InVO$_4$ for environmental and biomedical research applications. TiO$_2$ is commonly used as catalyst that utilizes the UV portion of the sun light spectrum to induce photo-oxidation and photo-reduction processes. We hypothesized that the combination of InVO$_4$ and TiO$_2$ will result in a material that will catalyze organic contaminants through photo-oxidation under visible light. We combined TiO$_2$ with 2,4,6,8,10wt\% of InVO$_4$ via wet ball milling process. We have compared the various concentrations of InVO$_4$ on TiO$_2$ matrix by SEM, BET surface area analyzer, FTIR, XRD, and photodegradation of the organic contaminant Methyl Orange. After characterization we found that 4wt\% InVO$_4$-TiO$_2$ mixture displayed the most promising characteristics for photo-oxidation under visible light. From the BET surface area analysis it showed the largest surface area out of the prior mentioned TiO$_2$ = Xwt\%InVO$_4$ mixtures and a degradation amount equivalent to 50\% of Methyl Orange contaminant over 7 hours under visible light. In conclusion, TiO$_2$-Xwt\%InVO$_4$ displayed evidence of photo-oxidation under visible light conditions.

H1.00025 Toward a Rb MOT for Undergrad Research and Advanced labs at Bridgewater State University , EDWARD DEVENEY, Bridgewater State University — The seminal paper for the undergraduate MOT appeared in AJP (63 (4), 1995) by C. Wieman, G. Flowers and S. Gilbert; ‘Inexpensive laser cooling and trapping experiment for undergraduate laboratories’. They wrote: “Because of this visual appeal and the current research excitement in this area, we felt that it was highly desirable to develop an atom trapping apparatus that could be incorporated into the undergraduate laboratory classes.” From our observations, it seems that while there are extraordinary examples of MOTs thriving in a few undergraduate labs, MOT experiments have yet to be widely incorporated into the undergraduate curriculum – likely because they are, in fact, not trivial to make. With the benefit of 20 years evolution since this 1st undergraduate MOT paper, we report the progress at BSU of constructing a 85Rb MOT that incorporates significant simplifications and straightforward techniques that include: using a single ECDL laser for both trapping and re-pumping (using an EOM to add FM sidebands) and combining a purchased stabilized HeNe with the ECDL in a Fabry-Perot Interferometer to correct and sufficiently stabilize the ECDL for trapping. When completed we will revisit the question of do-ability for the undergraduate research/advanced lab. The BSU MOT was planned with and is currently being built with the help and guidance of David DeMille and his research group at Yale University [including J. Barry Thesis, Yale].

H1.00026 Optical V-Band Observations of Active Galactic Nuclei , TAYLOR HUTCHISON, RAINA MUSSO, FRANCIS MACINNIS, MARK BOTTORFF, Southwestern University — Students at Southwestern University participated in an international observing campaign to study twelve active galactic nuclei (AGN). As part of this project, the students measured optical V-band light variations of four targets within the range of 4.5° to 8° from the Galactic Center. The students used the 18.2-meter studentscope at the Tenerife Astronomical Observatory and the Cerro Tololo Inter-American Observatory. The students analyzed the data using statistical methods and compared their results with previous studies. The students’ observations provided new insights into the optical variations of AGN and contributed to our understanding of the dynamics of active galactic nuclei.

H1.00030 Origins of Nonlinearity in Superconductive Passive Circuits , SEAN HAMILTON, Grand Valley State University, STEPHEN REMILLARD, Hope College — The distinct origins of even and odd order nonlinear behavior in type II cuprate superconductors have yet to be fully elucidated. Microwave intermodulation distortion (IMD) was examined in a YBCO superconducting thin-film hairpin resonator at 840 MHz. Measurements of the temperature dependence of IMD near Tc support the view that the nonlinear Meissner effect is responsible for the occurrence of both 2\textsuperscript{nd} and 3\textsuperscript{rd} order IMD tones near Tc as well as their suppression in an applied magnetic field. However, at lower reduced temperatures (T/Tc less than 0.95), where the influence of the nonlinear Meissner effect is less pronounced, 3\textsuperscript{rd} order IMD is unaffected by a static magnetic field, while 2\textsuperscript{nd} order IMD decays exponentially after a static magnetic field is removed with a temperature dependent time constant. It is apparent that the magnetically induced remnant vortex state contributes to the 2\textsuperscript{nd} order nonlinearity, but not to the 3\textsuperscript{rd} order nonlinearity, and that this effect is diminished close to Tc due to degradation of the remnant vortex state.

1 This research was funded by the National Science Foundation under grant number DMR-1206149.

H1.00031 Measuring and Modeling the Plasma Temperature and Density in WIRX , MICHAEL MORKEN, DARREN CRAIG, Wheaton College (IL) — We develop a theoretical model and experimental techniques to provide a better picture of how the adjustable parameters such as the current, and electrode geometry affect the temperature and density of WIRX plasmas. Our model predicts the plasma temperature and density by balancing the Ohmic heating with convective losses. The Ohmic heating is measured directly as the product of the voltage drop between the electrodes and the plasma current. Temperature and density are measured independently using spectroscopic methods. Stark broadening of the H-\beta line is used to measure density. To measure the electron temperature of the plasma the line ratios of various hydrogen transitions were compared with the predictions of the Boltzmann thermal equilibrium model and the coronal equilibrium model. Preliminary experimental results are consistent with the plasma parameters predicted by our model. This work will be used to inform future modifications to the experiment with the intent of producing higher temperatures in WIRX plasma, making magnetic reconnection more probable. Work supported by US DOE.
H1.00032 Two Dimensional Intermodulation Distortion Scanning of Superconducting Filter Resonators, MICHAEL BISCHAK, STEPHEN REMILLARD, Hope College — Nonlinear superconducting conductivity produces distortion that has usually been measured globally across the entire sample. In order to fully understand the origin of non-linearity, local methods must be used to examine specific points in the sample. The nonlinear Ohm’s law, \( V = IZ(I) \) includes the current dependence in the impedance. The method in this work raster scans a magnetic loop probe across a sample. In order to address limited resolution, we reduced the size of the magnetic loop probe. Using the electromagnetic field solver, sonnet, two dimensional current simulations of superconducting microwave filters composed of Ti2Ba2CaCu2O8 or of YBa2Cu3O7 reveal microwave current which is bunched up at the corners and sides of the sample. Two dimensional images of third order intermodulation distortion made with the magnetic probe at the same corners and edges reveal elevated distortion in the same places. Using the magnetic probe, third order intermodulation was seen to come from the same corners and edges where the current is bunched. This research was funded by the National Science Foundation under grant number DMR-1260149.

H1.00033 Raman spectroscopy of single-walled carbon nanotubes of different lengths exposed to microwave radiation, P. BHATNAGAR, Angelo State Univ, S. FERGUSON, University of Texas - Dallas, G. SESTRIC, I. WRIGHT, S. WILLIAMS, Angelo State Univ — Carbon nanotubes have been observed to emit ultraviolet, visible, and infrared radiation when exposed to microwave fields. Although there is considerable controversy concerning the mechanism responsible for the emissions, the results of recently-performed experiments suggest that the emissions may be the result of field emission-induced luminescence. We have performed experiments in which both short (0.5 \( \mu \)m - 2 \( \mu \)m) and long (5 \( \mu \)m - 30 \( \mu \)m) single and double-walled carbon nanotubes were exposed to 2.46 GHz microwaves at a pressure of approximately \( 10^{-6} \) torr. A comparison of the spectra of the radiation emitted from the nanotubes suggests that the longer nanotubes emitted radiation of greater intensity than the shorter nanotubes, which is consistent with field emission-induced luminescence. Moreover, structural modification of the carbon nanotubes due to microwave irradiation has been studied using the Raman spectroscopy G-band and D-band intensities, which suggests that microwave radiation at relatively low powers can lead to new nanotube defects, especially in the case of the long nanotube samples.

H1.00034 Study of the angular distributions of X-rays emitted following L3 ionization of gold atoms by electron impact, I. WRIGHT, G. SESTRIC, S. FERGUSON, S. WILLIAMS, Angelo State University — Theoretical work suggests that when an atomic inner-shell vacancy with total angular momentum \( j \) greater than 1/2 is created by interaction with a photon or charged particle the vacancy will be aligned due to the magnetic sublevels of the ion having nonstatistical populations. The experiments we performed, testing this theory, involved measurements of the angular distributions of gold L\( \alpha \), L\( \beta \), and L\( \gamma \) X-rays at forward angles in the range 0 degrees to 25 degrees emitted after being bombarded with 15-keV electrons. After corrections for absorption of the characteristic X-rays within the gold target, our results suggest that the angular distributions of the L\( \alpha \), L\( \beta \), and L\( \gamma \) X-rays are essentially isotropic, as no angular dependence was observed in our data outside of experimental uncertainties. However, the results of our experiments suggest that the angular distribution of the gold L\( \beta \) X-rays may be weakly anisotropic.

H1.00035 A Study of Two Dimensional Electron Gas Using 2D Fourier Transform Spectroscopy, CARL MCINTYRE, Colorado Mesa University, JAGANNATH PAUL, DENIS KARAISKAJ. University of South Florida — The dephasing of FES was measured in a symmetrically modulated doped 12 nm single quantum well GaAs/AlGaAs two dimensional electron gas system using time integrated four wave mixing (TIFWM) and a two dimensional Fourier transform spectroscopy (2DFTS). At high in-well carrier densities of \( \sim 4 \times 10^{11} \) cm\(^{-2}\), many body effects that are prevalent and measurable with non-linear optical spectroscopy. Effects of exciton-exciton and exciton-phonon scattering events, exciton populations, and biexciton formation are detectable at these carrier concentrations. Homogeneous linewidths obtained from 2DFT and TIFWM yield a zero Kelvin linewidth of 1.42 meV and an acoustic phonon scattering coefficient of 158 \( \mu \) eV/K. These observations indicate a rapid increase in homogeneous linewidth with increased temperature.

H1.00036 Analytically Evaluating Sums in Quantum and Statistical Physics Using Integral Transforms, JOHN VASTOLA, University of Central Florida — Evaluating sums analytically is a problem that is easy to pose and to give approximate solutions to, but that is difficult to exactly solve in general. Many results that are known are byproducts of Fourier analysis, which requires guessing that a series corresponds to a function. A more systematic method of evaluating sums using integral transforms is proposed which can reproduce many results obtained using other techniques. In particular, representing polynomials as Laplace transforms gives some nontrivial exact results. Some applications of the method are demonstrated, and extensions of the method using integral representations of frequently appearing functions are suggested. One useful representation of the gamma function is supplied, and used to provide both well-known and more obscure results. Interestingly, the application of this integral representation to evaluating sums suggests the introduction of a novel integral transform, which itself can be used to evaluate sums. Some of the transform’s properties are given, and its usefulness in other areas (like solving differential equations) is touched upon. Some physical problems involving the partition functions of statistical mechanics, and some infinite sums appearing in quantum mechanics, are considered.

H1.00037 In-air Rutherford Backscattering and Particle Induced X-ray Emission for Biophysics and Material Science Research, JAMES BECKER, None — Rutherford Backscattering (RBS) and Particle Induced X-ray Emission (PIXE) are methods of nondestructive analysis of elemental composition. Rebounding particles or emitted x-rays can be “collected” and then analyzed to reveal the number ratio of the elements in a sample. Due to the nondestructive feature of these processes, RBS and PIXE are useful in many diverse fields of study such as archaeology, art, and biology; however, these experiments usually require large, expensive particle accelerators and detectors. Instead, I am attempting to use a radioactive source, photodiodes, and computer software to perform the same methods at a fraction of the cost. I am exploring cost, time, and resolution benefits and losses of my approach versus the traditional accelerator-based approach.

H1.00038 Relativistic Quantum Mechanical Calculations on Alkali Atoms and Dimers from Cesium to Ununennium, CHUKVUNOSO ARINZE, WALTER ERLMLER, University of Texas at San Antonio — Ab initio calculations using relativistic effective core potentials, and intermediate angular momentum coupling of electrons are carried out on the alkali metal atoms, and dimers from cesium through ununennium. A spin-orbit configuration interaction (SOCl) method is employed that includes a spin-orbit coupling operator and a relativistic effective core potential in the Schrodinger Hamiltonian operator. The energy levels from these calculation are found to reproduce the positions of the experimental spectral lines and predict lines not heretofore observed for both of these atoms.
H1.00039 Re-Examining Gravitational Tunneling Radiation when taking into account Quantum Gravity Effects\footnote{H1.00039 Re-Examining Gravitational Tunneling Radiation when taking into account Quantum Gravity Effects}, JOHN VALENTINE, TREVOR PRESCOTT, GARDO BLADO, Houston Baptist Univ — Although shown to theoretically exist, Hawking Radiation has yet to be detected. The paper entitled “Gravitational Tunneling Radiation”\cite{rabinowitz1999} by Mario Rabinowitz proposed a possible explanation by considering the gravitational tunneling effects in the presence of other bodies in the vicinity of the black hole. Rabinowitz showed that the power radiated (through gravitational radiation) by a black hole, $P_{\text{H}}$, is related to the power generated by Hawking Radiation, $P_{\text{SH}}$ by $P_{\text{H}} \approx \frac{T^3}{16\pi} \sim P_{\text{SH}}$ where $T$ is the gravitational tunneling probability. The presence of other bodies lowers the gravitational barrier which in turn increases the gravitational tunneling probability thereby decreasing the Hawking radiation, $P_{\text{H}}$. In this paper, we examine the modification of $T$ in the presence of quantum gravity effects by incorporating the Generalized Uncertainty Principle.

\begin{equation}
\text{H1.00040 A Novel Method of Line Detection using Image Integration Method},
\end{equation}

DAVISON LIN, BO SUN, Oregon State University — We developed a novel line detection algorithm based on image integration method. Hough Transformation uses spatial image gradient method to detect lines on an image. This is problematic because if the image has a region of high noise intensity, the gradient would point towards the noisy region. Denoising the noisy image requires an application of sophisticated noise reduction algorithm which increases computation complexity. Our algorithm can remedy this problem by averaging the pixels around the image region of interest. We were able to detect collagen fiber lines on an image produced by confocal microscope.

\begin{equation}
\text{H1.00041 Exploring the Power Output of Small Wind Turbines in Urban San Antonio, Texas},
\end{equation}

JOSE CASILLAS, STEPHANIE SPERDUTI, ROSA CARDENAS, The University of the Incarnate Word — The means of transporting power from a centralized power plant by transmission lines has several disadvantages. Electricity transmission and distribution networks are costly, require long planning processes and are unsightly to residents. These networks are also susceptible to natural disasters creating massive disruptions to consumers. For these reasons distributed power sources such as solar panels and small wind turbines are becoming a more desirable and viable means of energy production. We report on the status of a study to determine the maximum output power of small wind turbines in urban San Antonio, Texas. Wind speed data along with power measurements from small wind turbines in urban San Antonio will be reported.

\begin{equation}
\text{H1.00042 Analyzing Hurricane Sandy},
\end{equation}

ANGELYN CONVERTINO, STEPHAN MEYER, BECCA EDWARDS, Southwestern University — Post-tropical Storm Sandy underwent extratropical transition shortly before making landfall in southern New Jersey October 29 2012. Data from this system was compared with data from Hurricane Ike (2008) which represents a classic hurricane with a clear eye wall and symmetry after landfall. Storm Sandy collided with a low pressure system coming in from the north as the hurricane made landfall on the US East coast. This contributed to Storm Sandy acting as a non-typical hurricane when it made landfall. Time histories of wind speed and wind direction were generated from data provided by Texas Tech’s StickNet probes for both storms. The NOAA Weather and Climate program were used to generate radar loops of reflectivity during the landfall for both storms; these loops were compared with time histories for both Ike and Sandy to identify a relationship between time series data and storm-scale features identified on radar.

\begin{equation}
\text{H1.00043 Using budget-friendly methods to analyze sport specific movements},
\end{equation}

LINDSAY JACKSON, SARAH WILLIAMS, DAVON FERRARA, Belmont University — When breaking down the physics behind sport specific movements, athletes, usually professional, are often assessed in multimillion-dollar laboratories and facilities. Budget-friendly methods, such as video analysis using low-cost cameras, iPhone sensors, or inexpensive force sensors can make this process more accessible to amateur athletes, which in-turn can give insight into injury mechanisms. Here we present a comparison of two methods of determining the forces experienced by a cheerleader during co-education stuntng and soccer goailes while side-diving. For the cheerleader, accelerometer measurements were taken by an iPhone 5 and compared to video analysis. The measurements done on the soccer players were taken using FlexiForce force sensors and again compared to video analysis. While these budget-friendly methods could use some refining, they show promise for producing usable measurements for possibly increasing our understanding of injury in amateur players. Furthermore, low-cost physics experiments with sports can foster an active learning environment for students with minimum physics and mathematical background.

\begin{equation}
\text{H1.00044 Porphyrin Induced Laser Deactivation of Trypsinogen-Trypsin Conversion},
\end{equation}

JOANNA PERIDO, Undergraduate Researcher, LORENZO BRANCALEON, Professor, PI — Pancreatitis is caused by the inflammation of the pancreas, where the digestive enzyme trypsin is activated from the precursor enzyme trypsinogen while still in the pancreas. The presence of trypsin in the pancreas causes auto-activation of trypsinogen, resulting in greater inflammation and auto-digestion of the pancreas. In severe cases, this cascade effect can lead to organ failure, diabetes, and pancreatic cancer. Our hypothesis is that if trypsinogen is prevented from auto-activating into trypsin, then this cascade can be stopped. We propose to do this by inducing conformational changes in trypsinogen when bound to a photoactive porphyrin dye. Porphyrins are comprised of four linked heterocyclic groups forming a flat ring, and bind well with proteins such as trypsinogen. In this study we used spectroscopic techniques to probe the binding of meso-tetrakis (4-sulfonatophenyl) porphyrin (TSP) to trypsinogen in vitro, as a preliminary step to then prompt and characterize conformational changes of trypsinogen through irradiation. If conformational changes are detected the trypsinogen will be tested for trypsin inactivation. This investigation may provide promising initial results to the possible use of porphyrins as an inhibitor of the self-activation of trypsinogen into trypsin, and a potential inhibitor of pancreatitis.

\begin{equation}
\text{H1.00045 Synthesizing new, high-temperature superconductors},
\end{equation}

CLAIRE WEAVER, Hofstra University, MEIGAN ARONSON, Brookhaven National Laboratory and Stony Brook University — Currently, there is no accepted theory behind type-II, high-temperature superconductors, but there is a distinct relationship between anti-ferromagnetism and superconductivity. Our research focuses on synthesizing new superconducting materials by observing the link between atomic structure and magnetic moments of anti-ferromagnetic compounds and attempting to reproduce the molecular physics of these known materials in new compounds. Consider the square-planar arrangement of the transition metal Fe in the Fe-pnictide superconductors of the ZrCuSiAs “11 11” and the ThCrSi “122” structure types. We believe that the physics behind this superconductor, where Fe has d$^6$ valence electrons, contributes to the superconducting state, not the presence of Fe itself. For this reason, we are synthesizing materials containing neighboring transition metals, like Mn and Co, combined with other elements in similar crystal lattice arrangements, having ionization properties that hopefully impose d$^6$ valence electrons on the transition metals.

\begin{equation}
\text{H1.00046 Re-Examining Gravitational Tunneling Radiation when taking into account Quantum Gravity Effects},
\end{equation}

\begin{equation}
\end{equation}
Our newly developed mathematical methods of extracting vector correlation information from sliced imaging anisotropy will permit detailed study of a variety of photodissociation systems. Comparisons between these simulations and our experimental images will be presented. We are optimistic that induced chemical reactions require detailed experimental results which measure vector properties. Sliced velocity mapped ion imaging is a powerful method to about excited states symmetry, non-adiabatic dynamics and the forces and torques operating during fragmentation. Accurate molecular descriptions of photo- - Vector correlations between parent molecule transition dipole moments, photofragment velocity angular momentum vectors, can provide valuable information about excited states symmetry, non-adiabatic dynamics and the forces and torques operating during fragmentation. Accurate molecular descriptions of photo-induced chemical reactions require detailed and experimentally investigated as a function of a sharp spectral phase-step. The phase-step introduces asymmetric diagonal and off-diagonal features into the stimulated emission spectra that are sensitive to the single-photon transitions of IR-125. The sharp phase-step causes enhanced absorption of the high frequency components and a sharp narrow-band emission of low frequency. We calculate the frequency-dispersed nonlinear spectrum versus the phase step to fourth-order in the field. We show that the third-order polarization of the sample is sensitive to phase changes in the excitation spectrum and it is responsible for the observed narrowband feature in the experiments.

H1.00048 Adsorption of CO Molecules on Si(001) at Room Temperature

EONMI SEO, Korea University of Science & Technology, Korea Research Institute of Standards and Science, DAEJEON EOM, Korea Research Institute of Standards and Science, HANCHUL KIM, Department of Physics, SooMyung Women's University, Korea. JA-YONG KOO, Korea University of Science & Technology, Korea Research Institute of Standards and Science — Initial adsorption of CO molecules on Si(001) is investigated by using room-temperature (RT) scanning tunneling microscopy (STM) and density functional theory calculations. Theoretical calculations show that only one adsorption configuration of terminal-bond CO (T-CO) is stable and that the bridge-bond CO is unstable. All the abundantly observed STM features due to CO adsorption can be identified as differentially configured T-CO. The initial sticking probability of CO molecules on Si(001) at RT is estimated to be as small as ~ 1 x 10^-4 monolayer/Langmuir, which is significantly increased at high-temperature adsorption experiments implying a finite activation barrier for adsorption. Thermal annealing at 900 K for 5 min results in the dissociation of the adsorbed CO molecules with the probability of 60-70% instead of desorption, indicating both a strong chemisorption state and an activated dissociation process. The unique adsorption state with a large binding energy, a tiny sticking probability, and a finite adsorption barrier is in stark contrast with the previous low-temperature (below 100 K) observations of a weak binding, a high sticking probability, and a barrierless adsorption. We speculate that the low-temperature results might be a signature of a physisorption state in the condensed phase.

H1.00049 Multidimensional stimulated emission with a single phase-shaped pulse

ARKAPRABHA KONAR, RACHEL GLENN, VADIM. V. LOZOVOY, MARCOS DANTUS, Michigan State University — Two-dimensional optical signals from a single-pulse excitation are experimentally and theoretically investigated as a function of a sharp spectral phase-step. The phase-step introduces asymmetric diagonal and off-diagonal features into the stimulated emission spectra that are sensitive to the single-photon transitions of IR-125. The sharp phase-step causes enhanced absorption of the high frequency components and a sharp narrow-band emission of low frequency. We calculate the frequency-dispersed nonlinear spectrum versus the phase step to fourth-order in the field. We show that the third-order polarization of the sample is sensitive to phase changes in the excitation spectrum and it is responsible for the observed narrowband feature in the experiments.

H1.00050 Spectroscopic Studies of Imidizolium and Pyridinium Based Ionic Liquids

RYAN BOOTH, JAIME STEARNS, Air Force Research Laboratory — Ionic liquids (ILs) have been shown to be extremely useful in areas ranging from chemical synthesis to energetic materials. Furthermore, ILs are thought to be a potential replacement for hydrazine as satellite propellants because a subset are hypergolic with nitric acid. While ILs are useful, however, there is a lack of understanding of the microscopic origins for their macroscopic properties (e.g. viscosity). An example of this is that [emim]⁺[tf2N⁻] is three times less viscous than its methylated counterpart [emim]⁺[tf2N⁻] and there is some discord regarding the reason. We have investigated the molecular properties of such IL pairs using UV and IR spectroscopy in the gas phase on both imidazolium and pyridinium-based (pyr) ILs. UV data show that the photophysics of [emim]⁺[tf2N⁻] is different than [emim]⁺[tf2N⁻] in that there is a lack of evidence for the existence of a charge transfer (CT) state (as was seen in [emim]⁺[tf2N⁻]). Preliminary UV spectra for the [pyr]⁺ILs show at least two distinct peaks in the region from 208-270 nm, which are tentatively established as CT states between the anion and cation. IR spectra deliver structural information for both sets of ILs and should provide insight into the correlation between microscopic and macroscopic properties.

H1.00051 Strong field ionization tomography with two-color circularly polarized femtosecond laser fields

MAITHREYI GOPALAKRISHNAN, CHRIS MANCUSO, DANIEL HICKSTEIN, PATRIK GRYCHTOL, RONNY KNUT, FRANKLIN DOLLAR, DMITRIY ZUSIN, CHRISTIAN GENTRY, EMRAH TURGUT, JENNIFER ELLIS, HENRY KAPTEYN, MARGARET MURNANE, JILA and Department of Physics, University of Colorado Boulder and NIST, OFFER KFIR, OREN COHEN, Solid State Institute and Physics Department, Technion and Department of Physics and Optical Engineering, Ort Braude College, XIAO-MIN TONG, Division of Material Science, Faculty of Pure and Applied Science, Institute of Tsukuba, MING-CHANG CHEN, Institute of Photonics Technologies, National Tsing Hua University — Recent experiments using two-color circularly polarized laser fields have demonstrated that high-harmonic generation (HHG), a versatile spectroscopy and tomographic reconstruction techniques, we identify low-energy structures in the 3D photoelectron angular distributions that correspond to the rescattering of electrons with the ion. The observation of rescattering structures confirms the proposed explanation for HHG under two-color fields and paves the way for next-generation spectroscopies to investigate molecular structure.

H1.00052 DC Sliced Ion Imaging Study of Photodissociation Dynamics: Comparison between Conditions of Simulations and Experiments

COLIN J. WALLACE, WEI WEL, SIMON W. NORTH, Texas A&M — College Station — Vector correlations between parent molecule transition dipole moments, photofragment velocity angular momentum vectors, can provide valuable information about excited states symmetry, non-adiabatic dynamics and the forces and torques operating during fragmentation. Accurate molecular descriptions of photo-induced chemical reactions require detailed and experimentally investigated as a function of a sharp spectral phase-step. The phase-step introduces asymmetric diagonal and off-diagonal features into the stimulated emission spectra that are sensitive to the single-photon transitions of IR-125. The sharp phase-step causes enhanced absorption of the high frequency components and a sharp narrow-band emission of low frequency. We calculate the frequency-dispersed nonlinear spectrum versus the phase step to fourth-order in the field. We show that the third-order polarization of the sample is sensitive to phase changes in the excitation spectrum and it is responsible for the observed narrowband feature in the experiments.

H1.00053 ABSTRACT WITHDRAWN —
1. Measure support a model of core-hole decay in which charge is redistributed from Xe to the F ligands and energetic F ions are produced by Coulombic

2. Rostock, Germany, CHRISTOPH SCHICK, Institute of Physics, University of Rostock, Germany — We present a new method for the determination of the vapour

3. Rostock, Germany, OLAF KESSLER, Faculty of Mechanical Engineering, University of Rostock, Germany, UDO KRAGL, Institute of Chemistry, University of

4. MATHIAS AHRENBERG, Institute of Physics, University of Rostock, Germany, MARTIN BECK, Ludwig Maximilian University, ZOU FINFROCK, Argonne National Laboratory, ANTHONY DIAZ, Central Washington University, GERALD SEIDLER, University of Washington, JOSEPH PACOLD, Lawrence Berkeley National Laboratory, DEVON MORTENSEN, University of Washington, WILLIAM REICHLIN, Central Washington University, ZOU FINFROCK, Argonne National Laboratory, ANTHONY DIAZ, Central Washington University, GERALD SEIDLER, University of Washington — Compounds, molecules, and nanoparticles containing lanthanides as primary constituents or as dopants are widely used in applications including luminescent
dyes and lighting phosphors. Recent work has shown that x-ray spectroscopy methods can be used to monitor the sequence of excited states that leads to luminescence in lanthanide materials. Here, we use x-ray spectroscopy methods to monitor the sequence of excited states that leads to luminescence in lanthanide materials. Here, we use x-ray spectroscopy methods to monitor the sequence of excited states that leads to luminescence in lanthanide materials.
Intermolecular coupling and dynamics through infrared nano-spectroscopic imaging

Benjamin Pollard, Eric A. Muller, Omar Khatib, Markus B. Raschke, Univ. of Colorado - Boulder — Intermolecular interactions and coupling on the nanoscale lead to a variety of structural phases and degrees of crystallinity in soft-matter and biological systems, producing unique functional properties. We combine multi-spectral vibrational scattering-scanning near-field optical microscopy (s-SNOM) with multimodal scanning probe imaging to investigate structure-function relationships in soft matter. Using vibrational resonances as sensitive reporters of local structure, coupling, and dynamics, we resolve spectral shifts and line broadening on the nanoscale. These spectral shifts allow us to map intermolecular electric fields across nanoscale domains through solvatochromism or transition dipole coupling. Similarly, linewidths relate directly to the spatially-varying coupling dynamics of vibrational oscillators. Comparing spectral maps of peak position and linewidth to maps of adhesion and Young's modulus, for example, provides insight into the structure-function relationship dictating nanoscale self assembly in, e.g., block copolymer thin films.

Sucralose Destabilization of Protein Structure

Inha Cho, Lee Chen, Nimesh Shukla, Christina Othon, Wesleyan Univ — Sucralose is a commonly employed artificial sweetener. Sucralose behaves very differently than its natural disaccharide counterpart, sucrose, in terms of its interaction with biomolecules. The presence of sucralose in solution is found to destabilize the native structure of the globular protein Bovine Serum Albumin (BSA). The melting temperature decreases as a linear function of sucralose concentration. We correlate this destabilization with the increased polarity of the sucralose molecule as compared to sucrose. The strongly polar nature is observed as a large dielectric friction exerted on the excited state rotational diffusion of tryptophan using time-resolved fluorescence anisotropy. Tryptophan exhibits rotational diffusion proportional to the measured bulk viscosity for sucrose solutions over a wide range of concentrations, consistent with a Stokes-Einstein diffusional model. For sucralose solutions however, the diffusion is linearly dependent with the concentration, strongly diverging from the viscosity predictions. The polar nature of sucralose causes a dramatically different interaction with biomolecules than natural disaccharide molecules.

Time-resolved phase-sensitive second harmonic generation spectroscopy of electron injection at the water/air interface

Jan Verlet, Durham University — A new methodology is developed to probe the real-time dynamics of species at interfaces based on phase-sensitive second harmonic generation. The key attributes of the method are that the measured signal is linear with concentration and can independently measure the real and imaginary part of the second-order non-linear susceptibility. We apply this methodology to probing the dynamics of the hydrated electron at the water/air interface, produced by charge-transfer-to-solvent from a precursor ion (iodide in this case). Preliminary results indicate a fast decay on a sub-picosecond timescale of the real (non-resonant) part of the second-order non-linear susceptibility, which we associate with the charge-transfer dynamics at the water/air interface.

Electric Field: Maker and Breaker of Molecular co-operativity: the paradigm of (CH\(_3\)OH)\(_n\)−(H\(_2\)O)\(_n\) \(n = 1-4\) hetero-clusters

Rajeev Pathak, Dept of Physics, University of Pune — Hydrogen-bonded hetero-clusters of methanol and water: (CH\(_3\)OH)\(_n\)−(H\(_2\)O)\(_n\) \(n = 1-4\), when subjected to an externally applied dipolar electrostatic field, exhibit remarkable stability up to their characteristic maximal field threshold strengths. Moderate fields below the threshold endow a given cluster with enhanced stability against dissociation, whereas beyond the threshold its HOMO-LUMO gap abruptly closes down, resulting into structural breakdown. The electric field thus plays a dual role of a maker and breaker of molecular co-operativity in a hydrogen-bonding scenario. Ab initio investigations on these clusters employing M06-2X hybrid functional with a 6-311++G(2d, 2p) basis set reveal the structural evolution of the conformers with increasing electric field strengths: structural deformations, enhancement in their dipole moments with concomitant decrease in their HOMO-LUMO gaps interspersed with abrupt changes in these attributes when the clusters “open out.” Energetics quantify the stability of the clusters in field, while the IR vibrational spectra bring out shifts in the normal modes with marked emergence of exotic low-frequency O-H stretches as precursors of breakdown at the threshold field strengths.

Hose sucralose destabilizes the native structure of the globular protein Bovine Serum Albumin (BSA), the melting temperature decreases as a linear function of sucralose concentration. We correlate this destabilization with the increased polarity of the sucralose molecule as compared to sucrose. The strongly polar nature is observed as a large dielectric friction exerted on the excited state rotational diffusion of tryptophan using time-resolved fluorescence anisotropy. Tryptophan exhibits rotational diffusion proportional to the measured bulk viscosity for sucrose solutions over a wide range of concentrations, consistent with a Stokes-Einstein diffusional model. For sucralose solutions however, the diffusion is linearly dependent with the concentration, strongly diverging from the viscosity predictions. The polar nature of sucralose causes a dramatically different interaction with biomolecules than natural disaccharide molecules.

We use a 2D Ising lattice gas model to conduct Monte Carlo simulations of the heterogeneous nucleation of a liquid droplet from the supersaturated vapor phase, as triggered by a soluble nanoscopic aerosol particle. The liquid droplet that forms is a cluster of both solvent and solute particles. As a function of the size n of the droplet, we observe a solubility transition: At smaller n, the droplet consists of a compact solute cluster wetted by solvent, while at larger n the solute dissolves and is more uniformly distributed within the droplet. We evaluate the free energy of formation of a droplet as a function of n, and identify conditions at which nucleation is a two-step process. That is, two free energy barriers are encountered as the droplet grows, one associated with the solubility transition, and the other with the nucleation of the bulk solvent phase. We also evaluate the nucleation rate from the mean first passage time for the droplet to reach the critical size for the formation of the bulk phase, and quantify the influence on the rate due to solute solubility, and due to the relative heights of the barriers for the solubility and bulk transitions.

Two-step nucleation: Monte Carlo simulation of heterogeneous nucleation of liquid droplets on soluble nanoscopic aerosols

Oleksandr Zavalov, Sophie McGibbon-Gardner, Peter Poole, Dept of Physics, St. Francis Xavier University, Antigonish, Nova Scotia, Canada, Richard Bowles, Dept of Chemistry, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, Ivan Saka-Voivod, Dept of Physics and Physical Oceanography, Memorial University of Newfoundland, St. John's, Newfoundland, Canada — We use a 2D Ising lattice gas model to conduct Monte Carlo simulations of the heterogeneous nucleation of a liquid droplet from the supersaturated vapor phase, as triggered by a soluble nanoscopic aerosol particle. The liquid droplet that forms is a cluster of both solvent and solute particles. As a function of the size n of the droplet, we observe a solubility transition: At smaller n, the droplet consists of a compact solute cluster wetted by solvent, while at larger n the solute dissolves and is more uniformly distributed within the droplet. We evaluate the free energy of formation of a droplet as a function of n, and identify conditions at which nucleation is a two-step process. That is, two free energy barriers are encountered as the droplet grows, one associated with the solubility transition, and the other with the nucleation of the bulk solvent phase. We also evaluate the nucleation rate from the mean first passage time for the droplet to reach the critical size for the formation of the bulk phase, and quantify the influence on the rate due to solute solubility, and due to the relative heights of the barriers for the solubility and bulk transitions.

Landscapes, kinetics, paths and statistics of curl flux, coherence, entanglement and energy transfer in non-equilibrium quantum systems

Zhedong Zhang, Jinhui Wang, Suny Stony Brook — We developed a population and flux landscape theory for general non-equilibrium quantum systems. We illustrated our theory by modelling the quantum transport of donor-acceptor energy transfer. We found two driving forces for the non-equilibrium quantum dynamics. The symmetric part of the driving force corresponds to the population landscape contribution which mainly governs the equilibrium part of dynamics while the anti-symmetric part of the driving force generates the non-equilibrium curl quantum flux which leads to the detailed-balance-breaking and time-irreversibility. The multi-loop structure of the flux emerges which forms the flux-landscape. Improving the voltage and electronic coupling in general facilitates the quantum transport by reducing the population landscape barriers.
H1.00067 Sensitivity of chiral 3-methylcyclopentanone structure, electric moment and thermodynamic parameters to medium polarity. WATHEQ AL-BASHEER, Department of Physics, King Fahd University of Petroleum & Minerals, SAID AL AZAR, Basic Sciences Department, Dar Al Uloom University. The location of Ni is one of the tasks of this kind of catalyst. R(+)-3-methylcyclopentanone (R3MCP) is a chiral ketone which can exist in as many as five conformers with two dominant conformers at room temperature: equatorial-methyl and axial-methyl. Density Functional Theory (DFT) calculations of the optimized geometries of R(+)-3-methylcyclopentanone (R3MCP) individual dominant conformers were performed in 10 common solvents of wide polarity range, under the framework of polarizable continuum model (PCM). DFT correlation function type B3LYP using a powerful basis set (aug-cc-pVDZ) yielded different linear correlation between solvent polarity and R3MCP equatorial and axial conformers Gibbs free and zero-point energies, entropies, vibrational modes frequencies, in addition to heat capacity resulting from translational, electronic, rotational and vibrational motion. Furthermore, DFT calculations of the R3MCP equator and axial conformers electric dipole and quadrupole moments components in 3D were also carried out and found to have a linear correlation with solvent polarity and cavitation energy. An observed trend for the standard Gibbs energies for the rotational equilibrium of R3MCP to be strongly-solvent dependent will be presented.

H1.00068 1 D Simulation of Capacitively Coupled Water Vapor Plasma. ZIANE KECHIDI1, None, A.H. BELBACHI TEAM, M. ANNOUN COLLABORATION, W.W. GRAHAM COLLABORATION. The results of a 1D simulation of a capacitively coupled water vapor discharge is reported. The simulated plasma consists of two electrodes separated by gap distance of 1 mm operating at 13.56 MHz with 26 species and 62 dominant reaction channels. The input parameters under which the plasma can be created is explored and space and time profiles of the electron densities are presented. The model finds that plasma ignition cannot be obtained in the present configuration and at pressures of greater than 0.1 atmosphere. The model has also be used to demonstrate the impact of rotational and vibrational excitation of water molecules in suppressing electrical breakdown.

H1.00069 Charge Conservation in BDG Formalism and its Effect in Calculating Berry Phase of Transporting a Localized BDG Quasiparticle around a Vortex in Superfluids/Superconductors. YIRUO LIN, TONY LEGGETT, University of Illinois at Urbana-Champaign. We examine charge conservation in BDG formalism and discuss the consequence of violating the charge conservation in Berry phase calculation of transporting a localized BdG quasiparticle around a vortex in superfluids/superconductors. We calculate explicitly the Berry phase in a model system in which the vortex is replaced by a 1D annulus ring geometry with quantized superfluid center-of-mass winding number and a localized Zeeman field is imposed to trap a quasiparticle with definite spin orientation.

H1.00070 Parahydrogen Induced Polarization by Pairwise Replacement on Pt and Ir Nanoparticles. CLIFFORD BOWERS, RONGHUI ZHOU, EVAN ZHAO, WEI CHENG, LUKE NEAL, HELENA WEAVER, Univ of Florida - Gainesville. Parahydrogen Induced Polarization (PHIP) is a robust and scalable method for production of bulk quantities of hyperpolarized fluids. The symmetrization order inherent in parahydrogen is transformed via symmetry breaking hydrogenation reaction into NMR-observable hyperpolarization. Spin polarization of order unity can be obtained. A key requirement of PHIP is pairwise hydrogenation by addition of H atoms originating from the same H2 molecule. PHIP using supported metal catalysts is a promising recent development because it exploits the advantages over homogeneous and supported metal complexes. The present work demonstrates a new PHIP mechanism involving the pairwise replacement of parahydrogen into propane (the substrate) over TiO2 supported Ir and Pt nanoparticle catalysts. Analysis of the stereoselectivity of the pairwise replacement process is facilitated by density matrix spectral simulations. The cis and trans dispositions of the symmetrization order give strikingly different PHIP spectra. The observed stereoselectivity of the pairwise replacement step, together with control experiments, rule out an alternative mechanism involving dehydrogenation of free propane over the catalyst.

H1.00071 Promoting alkali and alkaline-earth metals on MgO for enhancing CO2 capture by first-principles calculations. HYOSEOK KIM, WON BO LEE, KIWOONG KIM, Sogang Univ. The CO2 capture properties of Alkali(Li, Na, K, Rb, and Cs-) and Alkaline-Earth metal(Ba, Ca, Sr, and Ba-) promoted MgO sorbents are investigated by first principles density functional theory on the basis of PW91/GGA augmented with DFT+D2. Calculated Adsorption energy on the metal-promoted MgO sorbents is higher than Pure MgO sorbents, except for the Na-promoter. These results indicate that the CO2 capture capacity is improved by metal promotion. Li, Ca, and Sr were identified as adequate promoters among 9 metals, considering bind stability and regenerability.

H1.00072 Diffusion of a particle on a static rugged energy landscape with spatial correlations. BIMAN BAGCHI, SAIKAT BANERJEE, Indian Institute of Science. Despite the broad applicability of the problem, we have limited knowledge about the effect of ruggedness on diffusion at a quantitative level. Every study seems to use the expression of Zwanzig [Proc. Natl. Acad. U.S.A. 85, 2029 (1988)] who derived the effective diffusion coefficient, \[ D_{eff} = D_0 \exp(-3\beta \epsilon^2) \] We introduce and study two models of Gaussian random energy surface; a discrete lattice and a continuous field. Our simulations show that Zwanzig's expression overestimates diffusion in the uncorrelated Gaussian random lattice. The disparity originates from the presence of "three-site traps" (TST) on the energy landscape – which are formed by the presence of deep minima flanked by high barriers on either side. Using mean first passage time (MFPT) formalism, we derive a general expression for the effective diffusion coefficient, \[ D_{eff} = D_0 \exp(-3\beta \epsilon^2) \{ 1 + \text{erf}(\beta \epsilon / 2)^2 \}^{-1} \] in the presence of TST. In presence of spatial correlation we derive a more general form of the expression, which reduces to Zwanzig's form in certain limit. We characterize the same using non-Gaussian order parameter, and show that this "breakdown" scales with ruggedness following an asymptotic power law. The breakdown of Zwanzig's elegant expression was perhaps anticipated but was not clearly demonstrated earlier.

H1.00073 New insides in the characterization of HDS industrial catalysts by HAADF-STEM. PAZ DEL ANGEL, ARTURO PONCE, JOSEFINA ARELLANO, MIGUEL J. YACAMAN, Universidad de Texas, San Antonio. MARTHA HERNANDEZ-PICHARDO, Instituto Politecnico Nacional. The role of Ni is one of the tasks of this kind of catalyst. The used catalysts was a state-of- the-art commercial nickel-molybdenum alumina-supported formulation, including organic agent modifier. This type of material belongs to a novel family of catalysts specially designed for ultra-low sulfur production from straight-run gas oil (SRGO), cycle oil, coker gas oil, or their combinations at operating conditions of commercial interest in hydrotreating units at industrial scale. Aberration corrected HAADF-STEM allowed to observe the nanostructure and location of MoS2 and its interaction with the alumina. The results indicate that the MoS2 is highly dispersed on the alumina, however the location of Ni is one of the task of this kind of catalyst.
AuCl

We conclude that the origin of the p-type doping in as well as the effect of the adsorbate concentration. As a result, we find that especially AuCl mechanisms while considering all possible configurations and concentrations. In particular, we show that the formation of the tetrahedral subunits are important

We thank NSERC for financial support and Compute Canada for computational resources.

AuCl

We investigate the rectification behavior of the diblock dipyrimidinyldiphenyl molecule and its derivates with computing free energies of both face-centered cubic (FCC) and hexagonal close-packed (HCP) hard sphere crystals with a precision of 10^{-6} hartree. The finite models prefer a rippled/twisted structure morphology over the planar or helical ones. The rippled/twisted models appear to be structurally more stable. We simulated STEM images of the theoretical models to compare it with the experimental ones. In contrast with infinite models, the finite models predict a rippled/twisted structure morphology over the planar or helical ones. The rippled/twisted models appear to be structurally more stable.

We thank NSERC for financial support and Compute Canada for computational resources.

H.1.00081 First-Principles Investigations of Lead-Free Formamidinium Based Hybrid Perovskites, ALTYNBEK MURAT, UDO SCHWINGENSCHLOGL, PSE Division, KAUST, Saudi Arabia — Hybrid organic-inorganic perovskite solar cells have recently emerged as the next-generation photovoltaic technology. Most of the research work has been focused on the prototype MAPbI$_3$ perovskite (MA = Methylammonium = CH$_3$NH$_3$) and its analogues that have lead to power conversion efficiencies in excess of 15%. Despite the huge success, these materials are still non-optimal in terms of optical absorption where the bandgaps are greater than 1.6 eV as well as the toxicology issue of lead. Thus, investigation and development of lead-free perovskites with bandgaps closer to optimal, allowing greater spectral absorption, is of great interest. In this work, we perform first principles calculations to study the structural, optical, and electronic properties of new derivatives of MAPbI$_3$ in which the organic MA cation is replaced by other organic amines of similar size such as Formamidinium (FA) and/or the Pb cation replaced by similar elements such as Sn. In particular, we investigate the role and effect of FA and Pb cations on the electronic and optical properties and analyze to which extend the bandgaps can be tuned.

H.1.00082 Dye attached fullerene and P3HT complexes, AMANDA GARNICA, LUIS BASURTO, RAJENDRA ZOPE, TUNNA BARUAH, University of Texas at El Paso — We study the electronic structure of C60 fullerenes functionalized with thiophene-diketo-pyrrolopypyropheophorbide based chromophores using density functional theory combined with large polarized basis sets. These chromophores have electron donor character and thus the functionalization of the fullerene produces donor-acceptor (DA) systems. We examine in detail the effect of the linker and the addition site on the electronic structure of the fullerenes. We further study how the charge transfer excited states of these DA complexes and also that of the complexes of these functionalized fullerenes with the poly(-3-ethylthiophene-2,5-diyl) (P3HT) are studied using the perturbative A-$\Delta$-SCF method. The exciton binding energies in the functionalized fullerene-P3HT complexes are found to be smaller compared to similarly prepared phenyl-C61-butyric acid methyl ester (PCBM)-P3HT complex.

H1.00083 Electronic structure and charge transfer excitation energies of three endohedral fullerene- ZnTPP/ZnPc dyads, FATEMEH AMERIKHEIRABADI, LUIS BASURTO, RAJENDRA ZOPE, TUNNA BARUAH, The University of Texas at El Paso — Organic donor-acceptor (D-A) moieties make up the main component of organic photovoltaics (OPVs). It has been proved that the open circuit voltage of these devices which is a parameter in efficiency determination, is directly related to the charge transfer excited states of the D-A pairs. Fullerenes having lots of interesting acceptor properties and porphyrins as well as phthalocyanines possessing intriguing donor characteristics, are shown to be promising nominees. In this work, we computationally analyze three donor-acceptor dyads of Zn-tetraphenyl porphyrin and Zn-phthalocyanine with novel endohedral fullerenes: Sc$_2$NOC$_8$H$_{38}$ZnP, Y$_3$NOC$_8$H$_{38}$ZnP and Sc$_2$NOC$_8$H$_{38}$ZnP. The Sc$_2$NOC$_8$H$_{38}$ and Y$_3$NOC$_8$H$_{38}$ belong to a particular class of fullerenes called trimaltic nitride endohedral fullerenes where the trimalletic nitrides form the endohedral units. Density functional theory, as implemented in NRLMOL code, is used to study the electronic structure and the related properties of these DA complexes. The charge transfer excitation energies are calculated using the perturbative delta self-consistent method recently developed in our group. We find that the CT excitation energies are larger for endohedral fullerene based dyads compared to similar C$_60$ based dyads.

H.1.00084 Current flow in biased bilayer graphene: the role of sublattices, CARLOS PAEZ, Universidad Estadual de Campinas-FCA, DARIO BAHAMON, MacGrafe -Graphene and Nano-Materials Research Center, Mackenzie Presbyterian University, ANA PEREIRA, Universidade Estadual de Campinas-FCA — We investigate here how the current flows over a bilayer graphene in the presence of an external electric field perpendicularly applied (biased bilayer). Charge density polarization between layers in these systems is known to create a layer pseudospin, which can be manipulated by the electric field. Our results show that current does not necessarily flow over regions of the system with higher charge density. Charge can be predominantly concentrated over one layer, while current flows over the other layer. We find that this phenomenon occurs when the charge density becomes highly concentrated over only one of the sublattices, as the electric field breaks layer and sublattice symmetries for a Bernal-stacked bilayer. For bilayer nanoribbons, the situation is even more complex, with a competition between edge and bulk effects for the definition of the current flow. We show that, in spite of not flowing trough the layer where charge is polarized to, the current in these systems also defines a controllable layer pseudospin.

H.1.00085 PHYSICS EDUCATION

H.1.00086 Visualizations of Illinois Educational Data, CACEY STEVENS, The James Franck Institute and Department of Physics, University of Chicago, MICHAEL MARDER, Department of Physics, The University of Texas at Austin, SIDNEY NAGEL, The James Franck Institute and Department of Physics, University of Chicago — We examine data from scores on standardized exams taken by students in the state of Illinois. In order to analyze the factors affecting school performance in mathematics, we represent the data through visualizations, an approach commonly used to identify patterns in studies of physical systems. Exam scores for different schools are shown to depend on program type, location, and poverty concentration. For most schools in Illinois, test scores decline linearly with increased poverty concentration. However schools in Chicago show deviations from the linear trend. For any given poverty level, schools in Chicago perform better than those in other communities of Illinois. We also compare different school types, such as neighborhood, magnet, and charter programs, at each grade level. The city’s selective enrollment programs show notably superior achievement at the high school level. This is less pronounced at earlier grades.

H.1.00087 Lab-in-a-box @ school: Exiting hands-on experiments in soft matter physics1, KARIN JACOBS, MARTIN BRINKMANN, FRANK MULLER, Experimental Physics, Saarland University, Saarbruecken, Germany — Soft materials like liquids and polymers are part of everyday life, yet at school, this topic is rarely touched. Within the priority program SPP 1064 ‘Nanos- and Microfluidics’ of the German Science Foundation, we designed an outreach project that allows pupils (age 14 to 18) to perform hands-on experiments (www.labinabox.de). The experiments allow them e.g. to feel viscosity and viscoelasticity, experience surface tension or see structure formation. We call the modulus operandi ‘subjective experiments’ especially catch the attention of girls without disadvantaging boys. Both are fascinated by the hands-on experiments. We further study the charge transfer excited states of these DA complexes and also that of the complexes of these functionalized fullerenes with the poly(-3-ethylthiophene-2,5-diyl) (P3HT) are studied using the perturbative A-$\Delta$-SCF method. The exciton binding energies in the functionalized fullerene-P3HT complexes are found to be smaller compared to similarly prepared phenyl-C61-butyric acid methyl ester (PCBM)-P3HT complex.

1Financial support of the German Science Foundation DFG is acknowledged.

H.1.00088 QUANTUM INFORMATION, CONCEPTS AND COMPUTATION
H1.00089 Approach to solving spin-boson dynamics via non-Markovian quantum trajectories
- ZENG-ZHAO LI, Beijing Computational Science Research Center, CHO-TUNG YIP, Hong Kong Polytechnic University, HAI-YAO DENG, Hong Kong Polytechnic University and National Institute for Materials Science, MI CHEN, Fudan University, TING YU, Stevens Institute of Technology, J. Q.’ YOU, Beijing Computational Science Research Center, CHI-HANG LAM, Hong Kong Polytechnic University — We develop a systematic and efficient approach for numerically solving the non-Markovian quantum state diffusion equation for an open quantum system that can be strongly coupled to an environment. As an important application, we consider a real-time simulation of a spin-boson model in a strong coupling regime that is difficult to deal with using conventional methods. We show that the non-Markovian stochastic Schrödinger equation can be efficiently implemented as a real-time simulation for this model, so as to give an accurate description of spin-boson dynamics beyond the rotating-wave approximation.

H1.00090 Relation between Full Counting Statistics and the flow of Shannon entropy
- MOHAMMAD ANSARI, YULI NAZAROV, Kavli Institute for nanoscience, Delft University of Technology — We show that microscopic theory of counting statistics that is applicable for many quantum noise analysis, has an internal and fundamental correspondence to the Renyi entropy flow in the quantum system. This analogy reveals an interesting step towards understanding quantum thermodynamics. We also further extend the formulation for the flows of entropy using full counting statistics and determine novel quantum terms in the statistical moment measurements.

H1.00091 Coherent control of multipartite excitonic entanglement in quantum dot arrays
- JUAN E. ROLON, JOAQUIN E. DRUT, University of North Carolina at Chapel Hill — We propose a coherent control scheme for multipartite entanglement of exciton states in optically driven quantum dot arrays (QDAs) coupled by charge tunneling and resonant energy transfer (RET) processes. An adiabatic manipulation of the entanglement dynamics is devised by pulse shaping and time-dependent electric field sweeps. By varying the inter-dot distance and number of quantum dots (QDs) comprising the QDA, the excitonic qubit manifolds are obtained by a Feshbach projection over the resulting multilevel exciton configurations. We identify regimes in which the dynamics is confined to decoherence-free excitonic qubit manifolds taking into account spontaneous recombination and non-Markovian effects introduced by a phonon bath. We present results for entanglement monotonies and measures such as the entanglement of formation and entanglement entropy for different QDA geometries and carrier injection conditions. Our results indicate that in spite of the effects of phonon-assisted relaxation, entanglement can be optimized and transferred between QDs by the controlled interplay of system geometry, pulse shaping, RET and carrier tunneling.

H1.00092 Anisotropic exchange coupling in a nanowire double quantum dot with strong spin-orbit coupling
- RUI LI, J.Q. YOU, Beijing Computational Science Research Center — A spin-orbit qubit is a hybrid qubit that contains both orbital and spin degrees of freedom of an electron in a quantum dot. Here we study the exchange coupling between two spin-orbit qubits in a nanowire double quantum dot (DQD) with strong spin-orbit coupling (SOC). We find that while the total tunneling in the DQD is irrelevant to the SOC, both the spin-conserved and spin-flipped tunnellings are SOC dependent and can compete with each other in the strong SOC regime. Moreover, the Coulomb repulsion between electrons can combine with the SOC-dependent tunnellings to yield an anisotropic exchange coupling between the two spin-orbit qubits. Also, we give an explicit physical mechanism for this anisotropic exchange coupling.

H1.00093 Spin decoherence of mobile impurity in a one dimensional spin bath
- TRITHEP DEVAKUL, ADRIAN FEIGUIN, Northeastern University — We study the spin decoherence of a mobile impurity interacting locally with a one dimensional spin bath. In contrast to the central spin model, where a single central spin interacts with the bath via long ranged interactions, our model considers only local exchange interactions, while allowing the impurity to move to neighboring sites via hopping t. We consider a spin-1/2 impurity, and study the decoherence, tracing over the position degree of freedom. In the large t limit, the delocalized impurity behaves identically to a localized spin interacting with the bath, same as a central spin. This model allows one to treat a spin problem – which inherently builds up long-range entanglement within the bath – instead as a Hamiltonian with only local interactions. Numerical calculations are done at various regimes of parameters, and comparison with the central spin model is discussed.

H1.00094 Finite-temperature reservoir engineering and entanglement dynamics
- SERGUEI FE-DORTCHENKO, Université Paris Diderot, ARNE KELLER, Université Paris-Sud 11, THOMAS COUDREAU, PEROLA MILMAN, Université Paris Diderot — We propose experimental methods to engineer reservoirs at arbitrary temperatures which are feasible with current technology. Our results generalize to mixed states the possibility of quantum state engineering through controlled decoherence. Finite-temperature engineered reservoirs can lead to the experimental observation of thermal entanglement—the appearance and increase of entanglement with temperature—to the study of the dependence of finite-time disentanglement and revival with temperature, quantum thermodynamical effects, and others, enlarging the comprehension of temperature-dependent entanglement properties. Our proposal is discussed in detail in two model systems, consisting of different modes of a single photon and a trapped-ion system.

H1.00095 Reproducing the D-Wave Entanglement Results in Candidate Models
- TAMEEM ALBASH, University of Southern California, ITAY HEN, FEDERICO SPEDALIERI, Information Science Institute, DANIEL LIDAR, University of Southern California — The demonstration of entanglement on the D-Wave devices [1] relies on the assumption that the populations derived from measurement correspond to energy eigenstate populations of the quantum Hamiltonian. We therefore ask whether leading model candidates for the D-Wave devices are able to reproduce this entanglement signature. We focus our work on a quantum adiabatic Markovian master equation (ME) [2] and a Monte Carlo rotor model (SSSV) [3]. We show that the ME reproduces both the energy spectrum and the thermal state populations of the quantum Hamiltonian extremely well, hence agreeing with the experimental results. SSSV on the other hand fails to reproduce either, a consequence of the absence of discrete energy states in this model.

H1.00096 Using the SLUG as a First Stage, Low Noise Microwave Amplifier for Superconducting Qubit Readout
- EDWARD LEONARD JR., TED THORBECK, SHAOJIANG ZHU, ROBERT MCDERMOTT, Univ of Wisconsin, Madison — The SLUG (Superconducting Low-inductance Undulators Galvonometer) microwave amplifier is a large bandwidth, high saturation power, high gain, and low noise microwave element designed as a first stage cryogenic amplifier for dispersive readout of superconducting qubits. High forward gain is paired with simultaneous high reverse isolation such that bulky, expensive cryogenic circulators and isolators might be eliminated from the microwave readout chain. Here we present recent experimental data on SLUG gain, noise, and reverse isolation. We achieve gain over 10 dB at 7 GHz across a band of several hundred MHz, with system added noise of order one photon. For appropriate flux bias of the device, reverse isolation is better than -20 dB. These qualities make the SLUG a very desirable first stage amplifier for a scalable superconducting qubit readout.
H1.00097 Dynamic nuclear polarization of nitrogen-vacancy centers in diamond. WEN-HUI HU, Beijing Computational Science Research Center, NAN ZHAO COLLABORATION — Single nitrogen-vacancy (NV) centers in diamond triggered the research for wild applications in quantum information processing and quantum metrology. One of the most important advantages of the NV centers is the long coherence time of the center electron spins. Dynamic nuclear polarization (DPN) has been introduced as an efficient method to protect the spin coherence. The coherence time $T_2^*$ should have been prolonged of two orders theoretically, nevertheless less than one order in experiments. In this work, we theoretically study the DNP process in a high-purity diamond, where the dipole-dipole hyperfine interaction between the center electron spins and the bath $^{13}$C nuclear spins is dominant. The simulations show that the saturated polarization of the nuclear bath depends on the spin-lock period and the efficiency of the initialization laser, accompanied with the magnitude of the external magnetic field. The polarization saturation comes from the capability of the polarization transfer and the equilibrium of probability distribution between the polarized and unpolarized states.

H1.00098 Phase noise of a cavity electromechanical oscillator at millikelvin temperatures. JUNHO SUH, SUNGWAN CHO, SANG GOON KIM, SEUNG-BO SHIM, Korea Research Institute of Standards and Science — The frequency stability of a mechanical resonator is an important factor in its application to quantum information technology. We investigate the phase noise in a self-oscillation of a micromechanical resonator, parametrically driven by a superconducting microwave resonator at millikelvin temperatures. Possible physical origins of the noise are also discussed.

H1.00099 Investigation of the thermal motion and mode coupling in a micromechanical resonator, SEUNG-BO SHIM, SUNGWAN CHO, SANG GOON KIM, Korea Research Institute of Standards and Science, SUNG UN CHO, YUN PARK, Seoul National University, JUNHO SUH, Korea Research Institute of Standards and Science — We have investigated the thermal motion and mode coupling in a micromechanical resonator. The mechanical resonator was designed for dielectric gradient force actuation scheme. The laser reflection measurement method enabled multi-mode detection of the thermal motion up to $5^{th}$ mode at room temperature. With these multi-modes, we could investigate the energy transfer between first and second mode by applying mechanical sideband signals. We have utilized the second mode as a phonon cavity and observed the coupling and interaction between two modes. Here, we will discuss about the room temperature mechanical mode detection method and mode coupling effect in the micromechanical resonator.

H1.00100 Construction of a Confocal Fluorescence Microscope to Image Nitrogen Vacancy Centers. JORDAN STROMAN, JAMES GRIFFIN, GARY HARRIS, Howard University — Long term atomic memory can be achieved using nitrogen vacancy centers (NV). Howard University is optimizing the process of creating nitrogen vacancy centers using hot filament chemical vapor deposition (HFCVD). In order to provide reliable feedback concerning the presence, concentration, and orientation of these color centers, an optical system capable of performing confocal laser scanning fluorescence microscopy has been constructed. This system consists of a 200mw laser that emits light with a wavelength of 532nm. This light is focused on a sample using a Nikon Oil Objective Lens with a numerical aperture of 1.3. The sample rest on a piezoelectric stage with a resolution of 20nm in the $x$, $y$ and $z$ direction. This optical system can confirm and locate NV centers with a resolution of 200nm.

1Supported by a grant from the National Science Foundation DMR-1231319

H1.00101 Digital quantum simulation of Heisenberg spin systems in circuit QED. MARKUS OPPLIGER, YVES SALATHE, MINTU MONDAL, JOHANNES HEINSOO, PHILIPP KURPIERS, ANTON PÓTOCNIK, STEFAN FILIPP, ANDREAS WALLRAFF, ETH Zurich, Switzerland, ANTONIO MEZZACAPA, URTZI LAS HÉRAS, LUCAS LAMATA, ENRIQUE SOLANO, University of the Basque Country, Bilbao, Spain — A Quantum simulator realized by a well-controlled quantum system allows to simulate a wide range of complex quantum systems that are very difficult to study with classical computing. We use a promising quantum simulator based on circuit quantum electrodynamics (QED) to digitally simulate the isotropic Heisenberg XXZ interaction between two spin 1/2 particles. Since the XYZ interaction does not occur directly in the Jaynes-Cummings Hamiltonian, the interaction is decomposed into a set of single- and two-qubit gates. The resulting quantum state is analyzed by state tomography for different interaction times after each step. As our approach can be generalized further, this experiment is a first step towards simulating large spin systems in a circuit QED architecture.

H1.00102 High-fidelity quantum memory utilizing inhomogeneous nuclear polarization in a quantum dot. WENKUI DING, ANQI SHI, Wuhan University, JIANGQING YU, Beijing Computational Science Research Center, WENXIAN ZHANG, Wuhan University — We numerically investigate the encoding and retrieval processes for a quantum memory realized in a semiconductor quantum dot, by focusing on the effect of inhomogeneously polarized nuclear spins whose polarization depends on the local hyperfine coupling strength. We find that the performance of the quantum memory is significantly improved by the inhomogeneous nuclear polarization, as compared to the homogeneous one. Moreover, the narrower the nuclear polarization distribution is, the better the performance of the quantum memory is. We ascribe the performance improvement to the full harnessing of the highly polarized and strongly coupled nuclear spins, by carefully studying the energy transfer processes. Our results shed new light on the implementation of a quantum memory in a quantum dot.

1The National Basic Research Program of China (Grant No. 2013CB922003 and 2014CB921401), the National Natural Science Foundation of China under Grant No. 11275139 and 91121015, the NSAF Grant No. U1330201.

H1.00103 A photon-photon quantum gate using a multilevel atomic system, YUUKI TOKUNAGA, NTT SC Labs. — We propose a method for a quantum gate between photons assisted by a multilevel atom system. The atomic system is supposed to be in a cavity or a one-dimensional waveguide. The system can transfer a quantum state between a photon and the atom, and also works as a quantum gate for consecutively input photons. This system could be used as a building block for a universal quantum computation. We also discuss the characteristics of such quantum gates with several different multilevel system.

H1.00104 Riemannium nucleus and quantum solution to the Riemann hypothesis (RH). CARLOS FIGUEROA-NAVARRO, Departamento de Ingeniería Industrial, Unidad Regional Centro, Universidad de Sonora, JULIO CAMPOS-GARCIA, Departamento de Ciencias de la Salud, Unidad Cajeme, Universidad de Sonora, MARTIN MOLIDAR-TABARES, Organismo de Cuenca Noroeste, Comisión Nacional del Agua, LAMBERTTO CASTRO-ARCE, Departamento de Física e Ingeniería, Unidad Regional Sur, Universidad de Sonora — Is there an energy spectrum according to the primes numbers? This raises the question whether physical systems whose spectrum is the Riemann zeta function; ie, is there a spectrum of resonances of a nucleus that are the zeros of the zeta function? The renowned HR is basically preceded by the Euclid principle, the Euler product and the Gauss theorem. The best mathematical interpretation is the one that threw Riemannian revolution. HR holds that the nontrivial zeros of the zeta function keep the harmony of primes, but this is not fully tested. There are two possibilities: The HR can be true, then the primes have harmony, but if false, they nest in the chaos. The idea of this is important for studying models of quantum chaos is getting stronger in the last decade. These investigations lead us to believe that a highly mathematical problem becomes a physical problem; because according to Hugh Montgomery and Michael Berry the variations of the zeros, with drums and quantum billiards, can provide a physical model for explain the primes. In this paper, we generate the Mount Riemann by using MATHEMATICA and we get the profile that relates the prime numbers with the zeros of the zeta function; also we explain how quantum helps to explain the famous old problem known as the conjecture of Riemann.
H1.00105 Distribution of quantum Fisher information in asymmetric cloning machines \(^1\), XING XIAO, YAO YAO, Beijing Computational Science Research Center, LEI-MING ZHOU, Key Laboratory of Quantum Information, University of Science and Technology of China, XIAOGUANG WANG, Zhejiang Institute of Modern Physics, Department of Physics, Zhejiang University — An unknown quantum state cannot be copied and broadcast freely due to the no-cloning theorem. Approximate cloning schemes have been proposed to achieve the optimal cloning characterized by the maximal fidelity between the original and its copies. Here, from the perspective of quantum Fisher information (QFI), we investigate the distribution of QFI in asymmetric cloning machines which produce two nondiagonal copies. As one might expect, improving the QFI of one copy results in decreasing the QFI of the other copy, roughly the same as that of fidelity. It is perhaps also unsurprising that asymmetric phase-covariant cloning outperforms universal cloning in distributing QFI since a priori information of the input state has been utilized. However, interesting results appear when we compare the distributabilities of fidelity (which quantifies the full information of quantum states), and QFI (which only captures the information of relevant parameters) in asymmetric cloning machines. Unlike the results of fidelity, where the distributability of symmetric cloning is always optimal for any d-dimensional cloning, we find that any asymmetric cloning outperforms symmetric cloning on the distribution of QFI for \(d \leq 18\), whereas some but not all asymmetric cloning strategies could be worse

\(^1\)supported by the NNSFC (Nos. 11247006, 11025527 and 11475146), the National 973 program(No. 2012CB921602)

H1.00106 Quantum Information in Biological Systems, SHANTILAL GORADIA, Retired — We can derive strong coupling and also recover Newtonian gravity with a quantum mechanical approach implicitly implying the variation of universal constant of gravity on a cosmic scale. Since constancy of \(G\) does not lead to cosmological constert, we derive 137 (described as the hand of God by Feynman) as a natural logarithm of the age of the universe in Planck times (10E60). Since we use Boltzmann equation on his tomb to do that, we describe that equation as the heart of God! Since otherwise, no theory including the string theory can so far come up with 137 mathematically. Maximum potential ON and OFF signals of interactions of 10E60 ever since the big bang could provide the fundamental basis of information system in the universe including in biology, implying the sperm of a man carries the genetic information of the male which when combined with the genetic information of a female egg decides the characteristics of the offspring. We may never know the exact language of nature. We speculate the string theory may be able to step in to show some deeper light in that direction.

H1.00107 Two-Slit Particle Experiment and the CMB, ALFRED PHILLIPS JR., Source Institute — Both Einstein and Feynman discussed the difficulty of understanding the two slit experiment for particles. We show a connection between this experiment and the Cosmic Microwave Background. We have not yet determined whether this new connection necessitates a modification of metrics such as that of Robertson-Walker or how much light this new connection sheds on the dark energy (cosmological constant) problem.

H1.00108 MATTER AT EXTREME CONDITIONS —

H1.00109 RKKY and Dzyaloshinsky-Moriya Interaction in the Electron Gas, MOHAMMAD MAHDI VALIZADEH, SASHI SATPATHY, Department of Physics & Astronomy, University of Missouri, Columbia, MO 65211, USA — We illustrate the origin of the Dzyaloshinsky-Moriya interaction \(S_1 \times S_2\) between two localized spins embedded in a solid by considering the example of the electron gas with spin-split bands, which serves as a simple pedagogical model for the understanding of this interaction. In this case, where symmetry is broken, the magnetic interaction acquires the Dzyaloshinsky-Moriya term in addition to the well-known RKKY interaction term \(S_1 \cdot S_2\), so that the net interaction has the form \(J = J_{\text{RKKY}} + J_{\text{DM}}\). For the standard electron gas with spin degenerate states, the DM term vanishes yielding the well known RKKY interaction results. Explicit expressions for the magnitudes of the interactions are obtained for the electron gas in two and three dimensions. This simple model serves as a pedagogical example for the origin of the Dzialoshinski-Moriya interaction in a system with broken time-reversal symmetry.

H1.00110 Chromium based Spinels under Compressions, YUEJIAN WANG, ILIAS EFTHIMIOPOULOS, Oakland University, THOMAS AHEARN, Oakland, VLADIMIR TSURKAN, JOACHIM DEISENHOFER, ALOIS LOIDL, University of Augsburg — The Chromium (Cr) based spinels, ACr2X4, represent a prototype system for the study of magnetism in solid [1]. More recently, multiferroicity has been found in members of this series [2]. However, the origin of the ferroic properties is not well understood; Given the strong interplay between structural and ferroic properties in this system, the structural evolution induced by pressure may shed light on the multiferroicity [3]. High-pressure X-ray diffraction and Raman spectroscopic studies have been conducted on ZnCr2Se4 and ZnCr2S4. The study elucidated the phase transformation of these spinels under high pressures by the X-ray data and the structural evolution induced by pressure may shed light on the multiferroic properties induced by the structural transitions were discussed.

H1.00111 SURFACES, INTERFACES AND THIN FILMS —

H1.00112 Directed Chemical Transport and Separation by Hydrogel Films containing Static and Dynamic Chemical Potential Gradients, TSUNG-HAN TSAI, CHUNJIE ZHANG, HYUNG-JUN KOO, PAUL V. BRAUN, University of Illinois at Urbana-Champaign — Materials that can manipulate the anisotropic molecular transport through built-in chemical potential gradients offer new opportunities to process chemical agents. Different from electrophoresis and microfluidics, here the chemical potential gradients, which provide the driving forces for molecular transport, are incorporated in the diffusion media. The autonomous systems can independently control the anisotropic flux of molecules and thus do not need external inputs such as electric fields and flowing carrier phases. As model systems, we used hydrogels containing static and dynamic built-in chemical potential gradients to direct molecular transport, concentrate dilute analyte and separate mixtures. The static gradients are based on electrostatic and supramolecular interactions which are specifically designed for the target molecules. The dynamic active chemical potential gradients triggered by reversible ion exchange process can alter the hydrophilicity gradually to transport or separate target molecules.

H1.00113 A density functional theory investigation of select transition metal dichalcogenides, RODRICK KUATE DEFO, Physics Department, Harvard University, GEORGIOS TRITSARI, SEAS, Harvard University, SHIANG FANG, EFTHIMIOS KAXIRAS, Physics Department, Harvard University — As a result of the extensive work done on graphene, leading to advances in sample preparation, optical detection, and transfer and manipulation of 2D materials, there has been a resurgence of interest in layered materials from which single sheets can be extracted, such as molybdenum disulfide. Particularly intriguing is the fact that layered MoS2 transitions from an indirect band gap in the bulk to a direct band gap in the monolayer opening up the possibility of optoelectronic applications. These results have been verified using density functional theory and, further, dependence of the band gap on lattice strain has been investigated. This dependence is crucial in understanding emergent properties of compounds consisting of MoS2 layered with other materials where there is a lattice mismatch. MoSe2, MoS2, WS2, WSe2 and WS2e have also been studied. Finally, dielectric functions have also been obtained for these compounds to explore the effect particularly of the asymmetric atom configurations on polarization of the material.
H1.00114 Monomer Adsorption on 6-Atoms Wide Zigzag (111) Terraces\textsuperscript{1}, ALAIN PARES, Villanova University, DAVID GRUMBINE, JR, St. Vincent College — We study monomer adsorption on six-atoms wide, zigzag (111) terraces, with first- (V), second- (W), and third-neighbor (U) interactions, specializing to repulsive first-neighbors. All possible crystallization patterns, or phases, that may exist are expected to occur at relatively low temperatures. Under these conditions, the energy phase diagram is three-dimensional and depends on the dimensionless variables, $v = U/W$, $u = U/V$, and $w = W/V$. The chemical potential energy of the monomers, $\mu$, in the medium to which the terrace is exposed depends on the pressure, if the medium is a gas, or the concentration if the medium is solution. There are 95 phases, or crystallization patterns, of the adsorbates with coverages ranging from 1/5 to 8/9. In particular, we find that there are 10 distinct 1/2, 2/3, and 4/9 coverage phases, and 9 distinct 1/3 coverage phases.

\textsuperscript{1}Work supported in part by NICS supercomputing grant # CHE040001.

H1.00115 Interplay between Self-Assembled Structures and Energy Level Alignment of Benzamidine on Au(111) Surfaces\textsuperscript{1}, GUI LI, Lawrence Berkeley Natl Lab, JEFFREY NEATON, Lawrence Berkeley Natl Lab; UC-Berkeley; Kavli Energy NanoSciences Institute at Berkeley — Using van der Waals-corrected density functional theory (DFT) calculations, we study the adsorption of benzene-diamine (BDA) molecules on Au(111) surfaces. We find that at low surface coverage, the adsorbed molecules prefer to stay isolated from each other in a monomer phase, due to the inter-molecular dipole-dipole repulsions. However, when the coverage rises above a critical value of 0.9nm², the adsorbed molecules aggregate into linear structures via hydrogen bonding between amine groups, consistent with recent experiments [Haxton, Zhou, Tamblyn, et al, Phys. Rev. Lett. 111, 265701 (2013)]. Moreover, we find that these linear structures at high density considerably reduces the Au work function (relative to a monomer phase). Due to reduced surface polarization effects, we estimate that the resonance energy of the highest occupied molecular orbital of the adsorbed BDA molecule relative to the Au Fermi level is significantly lower than the monomer phase by more than 0.5 eV, consistent with the experimental measurements [DellAngela, Kladnik, and Cossaro, et al, Nano Lett. 10, 2470 (2010)].

H1.00116 Benzene Derivatives Adsorbed to the Ag(111) Surface: A Binding Site Study \textsuperscript{1}, DANIEL MILLER, SCOTT SIMPSON, NINA TYMINSKA, EVA ZUREK, University at Buffalo, ZUREK GROUP TEAM — Dispersion corrected Density Functional Theory (DFT) calculations were employed to study the interaction of benzenes mono and disubstituted with functional groups encompassing a region of the activated/deactivated spectrum. Benzenes substituted with weak activating or deactivating groups like methyl and fluoro, respectively, do not have a strong site preference for adsorption to the Ag(111) surface. Strong activating (N(CH₃)₂) and deactivating (NO₂) groups, on the other hand, have a distinct site preference. The nitrogen in the former prefers to lie above a silver atom (top site), but in the latter an Hhcp site of the Ag(111) surface is favored. Benzenes derivatized with classic activating groups donate electron density from the highest occupied molecular orbital (HOMO) of the molecule to the surface, and those functionalized with deactivating groups withdraw electron density from the surface into orbitals that are unoccupied in the gas phase. In the case of disubstituted benzenes, the strong activating/deactivating groups control the site preference and other groups assume sites that are, to a large degree, dictated by their positions on the benzene ring. Surface adsorption alters the relative stabilities of the ortho, meta and para positional isomers of disubstituted benzenes.

\textsuperscript{1}A portion of this research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility

H1.00117 Quasi-1D States Confined in a Self-Assembled Organic Super-Lattice of TTF-TCNQ on Ag(111)\textsuperscript{1}, SEOKMIN JEON, Oak Ridge National Laboratory (ORNL), PANCHAPAKESAN GANESSH, BOBBY SUMPTER, ORNL, JORGE IRIBAS CERDÁ, Instituto de Ciencia de Materiales de Madrid, PETRO MAKSYMOVYCH, ORNL, CNMS TEAM, ICCM-CSIC TEAM — Organic charge transfer complexes (CTC) have drawn much attention due to their potential applications to conducting or semiconducting organic thin films and contacts in devices. TTF-TCNQ is a historic organic CTC with one of the highest conductivity values among numerous organic conductors. As a two-component molecular material, TTF-TCNQ in a low-dimension form on a surface naturally creates monolayer super-lattices with corrugated electrostatic potential and adsorbate-induced strain. Generally this will lead to strong confinement of the surface states, although the detailed response of the surface electronic structure remains to be understood. We investigated TTF-TCNQ monolayer films grown on Ag(111), Au(111) and Ag(100) surfaces using STM/STS at 4.3 K. Confinement of sp-derived surface states was indeed ubiquitous, including spontaneous formation of quantum dots and quasi-1D bands. The small periodicity of the lattice caused a complete depopulation of the surface states, with only 1 eV upshift of the band minimum — much stronger effect than normally observed in assemblies. This also allows us to infer the height of the confining potential using 1D Kronig-Penney model and critically assess the long-standing problem of molecule-surface charge transfer.

\textsuperscript{1}A portion of this research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility

H1.00118 Adsorption of pentacene on (100) vicinal surfaces: role of coordination, surface chemistry and vdWs effects\textsuperscript{1}, JERONIMO MATOS, ABDELKADER KARA, University of Central Florida — In contrast to low miller index surfaces, vicinal surfaces are characterized by steps and step edges that not only present an interesting atomic landscape for the adsorption organic molecules, but also a unique electronic structure resulting in part from the low coordinated atoms at the step edges. The adsorption of pentacene on the stepped (511), (711), (911) surfaces (respectively 3, 4 and 5-atom wide terraces) of Cu and Ag (coagined transition metals); Pt (reactive transition metal); and Ni (reactive, magnetic transition metal) are studied using density functional theory, in order to investigate the support effects arising from differing surface chemistry. We compare the adsorption energy, adsorption geometry and electronic structure predicted by the PBE functional with those obtained from one of the optimized vdW-DF methods: optB88-vdW.

\textsuperscript{1}Work supported by the U.S. Department of Energy Basic Energy Science under Contract No DE-FG02-11ER16243

H1.00119 Electron configuration and correlation effects in organometallic molecules from constraint density functional theory \textsuperscript{1}, KENJI NAWA, KOHIJ NAKAMURA, TORU AKIYAMA, TOMONORI ITO, Mie University, MICHAEL WEINERT, University of Wisconsin-Milwaukee — Interest in single organometallic molecule and that adsorbed on solid surfaces has rapidly increased because of possible novel applications. For molecules with transition metals (TMs), the d-electron configuration is an essential aspect of their electronic and magnetic properties, and correlation effects can be not excluded. Here, we investigate systematically the electron configuration and correlation effects for prototypical organometallic molecules of tridimensional metalloocene (TM Cp₂) and planer phthalocyanine (TMCp). Calculations were carried out based on the constraint density functional theory (DFT) by using the full-potential linearized augmented plane wave method that incorporates an on-site Coulomb interaction correction $U$. We find that these correlation effects play a key role in determining the ground state of the organometallic molecules. The calculated ground states of TMCp, where TM = Cr, Mn, Fe, Co, and Ni, obtained by constraint DFT with $+U$ reproduce the experimentally determined structures of $3E_{2g}$, $6A_{1g}$, $1A_{1g}$, $2E_{1g}$, and $3A_{2g}$, respectively. Results for the TMCp will be also presented.

H1.00120 MAGNETISM –
H1.00121 Structural and Magnetic Properties of Mn$_{1.5}$X$_{0.5}$Sn (X = Cr, Mn, Fe, Co) Melt-spin Ribbons

R. FUGLSBY, P. KHAREL, Department of Physics, South Dakota State University, Brookings, SD, W. ZHANG, S. VALLOPPILLY, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE, Y. HUH, Department of Physics, South Dakota State University, Brookings, SD, D.J. SELLMYER, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE — Mn$_{1.5}$X$_{0.5}$Sn (X = Cr, Mn, Fe, Co) nanomaterials in a hexagonal Ni$_2$In-type crystal structure have been prepared using arc-melting and melt spinning. All the samples show moderate saturation magnetization at 100 K with a highest value of 458 emu/cm$^3$ for Mn$_{1.5}$Fe$_{0.5}$Sn, but their Curie temperatures (Tc) are less than 300 K. The highest Tc is 206 K for the Fe containing sample. All samples except the Cr containing one show irreversibility between the zero-field-cooled and field-cooled measurements at the low temperature, showing a spin reorientation or spin-glass-like behavior. The magnetic anisotropy constants calculated at 100 K are on the order of 1 Merg/cm$^3$. The magnetic properties of these materials have substantially improved due to vacuum annealing, where the Tc for Mn$_3$Sn annealed at 450 °C has increased by about 75 K from 190 K to 265 K.

H1.00122 Noncollinear ferromagnetic easy axes in spin valves induced by oblique deposition

ROBERTO RODRIGUEZ, Pontificia Universidad Católica de Chile, THIAGO BUENO, DANIEL PARREIRAS, Universidade Federal de Minas Gerais, Brazil, SEBASTIAN MICHEA, Pontificia Universidad Católica de Chile, MARIO ARAUJO, WALDEMAR MACEDO, Laboratório de Física Aplicada, Centro de Desenvolvimento da Tecnologia Nuclear, Belo Horizonte, MG, Brazil, KLAUS KRAMBROCK, ROBERTO PIANAGO, Universidade Federal de Minas Gerais, Brazil — In this work we investigate the magnetic properties of Py/Ru/FeCo/InMn spin valves grown by oblique magnetron sputtering. The in-plane angular dependence of the ferromagnetic resonance (FMR) was used to obtain the relevant magnetic anisotropies. As we show, the deposition geometry employed in the sample preparation setup can be used to induce noncollinear easy axes of the ferromagnetic (FM) layers of the spin valve. We could directly observe the non-collinearity on the symmetry shift of the angular dependence of the FMR resonances fields of the two FM layers. The observations of the present study suggest that, by combining oblique deposition and appropriate angles of incidence of the deposition flux, the uniaxial (and unidirectional) axes of individual FM layers can be precisely engineered in spin valve fabrication.

H1.00123 Temperature and size dependent magnetic hyperthermia studies of Dextran coated Fe$_3$O$_4$ and Co$_x$Fe$_{3-x}$O$_4$ ferrofluids

H. NEMALA, M. PALIHAWADANA ARACHCHIGE, G. LAWES, Department of Physics and Astronomy, Wayne State University, Detroit, Michigan, 48202, V.M. NAIK, Department of Natural Sciences, University of Michigan-Dearborn, Dearborn, Michigan, 48128, R. NAIK, Department of Physics and Astronomy, Wayne State University, Detroit, Michigan, 48202 — Magnetic hyperthermia (MHT) using magnetic nanoparticles (MNPs) is a promising technique for cancer therapy. The dominant mechanism of heat generation in MHT using superparamagnetic MNPs is the Néel relaxation in response to an applied ac magnetic field. The efficiency of heating depends on the particle size, particle size distribution and the intrinsic magnetic properties of the MNPs. In this study, we have prepared Fe$_3$O$_4$(8-14 nm) and Co$_x$Fe$_{3-x}$O$_4$ (10 nm) MNPs by the co-precipitation method and characterized using XRD, TEM, Zeta potential and DC magnetometry measurements. The MNPs are found to be polydisperse and form stable colloidal suspensions in weakly basic solutions (zeta potential −20 mV) with their hydrodynamic radii ranging from 80 to 120 nm. The specific power loss (SPL) was determined as a function of temperature using MHT measurements (140-235 °C and 188-375 kHz) by incorporating heat losses due to nonadiabatic sample conditions. The SPL values at 298 K measured with 235 °C and 375 kHz range from 20-95 W/g for the MNPs, and SPL monotonically decrease with increasing in temperature. The results are in agreement with the linear response theory. Details of the measurement and analyses will be presented.

H1.00124 First Successful Fabrication of Nanoparticles of magnetocaloric Gd$_5$Si$_2$Ge$_{1-x}$Si$_x$

RAVI L. HADIMANI, Iowa State Univ, SHALABH GUPTA, Ames Laboratory, US Dept. of Energy, SHANE M. HARSTAD, VITALIJ K. PECHARSKY, DAVID C. JILES, Iowa State Univ, IOWA STATE UNIVERSITY COLLABORATION, AMES LABORATORY, US DEPT. OF ENERGY COLLABORATION — The Gd$_5$(Si$_2$Ge$_{1-x}$)$_x$ system has been widely studied in bulk form due to its interesting properties at the phase transition. There are a few reports on the fabrication of thin films of this material but, there are no reports in the literature on synthesis and characterization of nanoparticles of this material. Unlike films, which are expected to have low refrigeration capacity due to low volume, nanoparticles have the potential to overcome the problem if a scalable and cost-effective method of nanoparticle fabrication can be developed. In this work, we have synthesized sub-micron particles of Gd$_5$Si$_2$ by high-energy ball-milling varying milling times and milling intensity. We have investigated their microstructure, crystal structure, composition and magnetic properties. We have determined the milling time beyond which the particles become non-crystalline and lose the long range ordering. We also show that the coercivity of the particles increases with increasing the milling time. Particles agglomerate at long milling times and the particles that are milled longer than 20 min no longer undergo magnetic phase transition close to 340 K, which is present in a bulk material.

1Work at Ames Laboratory was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering. Ames Laboratory is operated for DoE by Iowa State University under Contract No. DE-AC02-07CH11358.

H1.00125 Experimental Realization of Artificial Skyrmion Lattices

DUSTIN GILBERT, BRIAN MARANVILLE, NIST Center for Neutron Research, ANDREW L. BALK, Center for Nanoscience and Technology, NIST, BRIAN J. KIRBY, NIST Center for Neutron Research, PETER FISCHER, Advanced Light Source; University of California, Santa Cruz, DANIEL T. PIERCE, JOHN UNGURIS, Center for Nanoscale Science and Technology, NIST, JULIE A. BORCHERS, NIST Center for Neutron Research, KAII LII, University of California, Davis — Magnetic skyrmions exhibit topologically protected states, offering new mechanisms for high density/low dissipation information storage, and also exhibiting a host of unique topological phenomena. In bulk crystals, chiral spin textures are only found in certain systems and in limited regions in the temperature-magnetic field parameter space. We present experimental evidence of room-temperature artificially structured skyrmion lattices fabricated by carefully controlling the three dimensional anisotropy of a Co on/Pd hybrid structure. The hybrid structures were fabricated by patterning chirality controlled vortex-state Co nanodot arrays on top of a Co/Pd multilayer with perpendicular anisotropy, chirality control was confirmed by microscopy and magnetometry. The vortex polarity is set by an external magnetic field to manifest the skyrmion state, and confirmed by magnetometry measurements. The chiral structure of the nanodots is imprinted into the Co/Pd underlayer, as revealed by polarized neutron reflectometry and spin-transport studies. These artificial skyrmion lattices offer a convenient platform to explore skyrmion physics. This work has been supported by the NSF (DMR-1008791 and ECCS-1232275).
H1.00126 Anatomy of Dzyaloshinskii-Moriya Interaction at Co/Pt Interfaces. HONGXIN YANG, Spintec/INAC, Grenoble France. STANISLAS ROHART, ANDRE THIAVILLE. LPS, Universit Paris-Sud, CNRS UMR 8602, F-91405 Orsay, France. ALBERT FERT. Unit Mixte de Physique CNRS/Thales, 91767 Palaiseau and Universit Paris-Sud, 91405 Orsay, France. MAIRBEK CHISHIEV. Spintec/INAC, Grenoble France — Dzyaloshinskii-Moriya Interaction (DMI)[1] was recognized to play a crucial role at ferromagnetic (FM)/heavy metal (NM) interfaces to create magnetic skyrmions[2]. DMI also plays an essential role for fast domain wall dynamics driven by spin-orbit (SO) torques[3]. Here, we clarify the main features and microscopic mechanisms of DMI in Co/Pt bilayers by ab initio. We find that large anticlockwise DMI of the bilayers has a predominant contribution from DMI pair couplings between spins of interfacial Co layer. This DMI between interface Co spins is directly related to the change of SO energy in the adjacent Pt when Co spin chirality is reversed. DMI does not extend significantly into other Co layers and is very weak between the proximity-induced spins in Pt. It was suggested[4] that DMI at FM/NM interfaces is directly related to the proximity induced moment in NM. However, we find the opposite result; i.e. Pt moment reduction slightly increases the DMI[5]. [1] I. E. Dzialoshinskii, Sov. Phys. JETP 5, 1259 (1957); T. Moriya, Phys. Rev. 120, 91 (1960). [2] A. Fert et al. Nat. Nanotech. 8, 152 (2013). [3] A. Thiaville, et al, Europhys. Lett. 100, 57002 (2012). [4] K. Ryu et al, Nat. Nanotech. 8, 527 (2013). [5] H. Yang et al, submitted

H1.00127 Theory of damping for the standing spin waves. IRINA BARIAKHTAR, Boston College, USA, VICTOR BARIAKHTAR, Institute of Magnetism, Ukraine — It is well known, that the thin magnetic films exhibit dependency of the magnetic dispersion on the wave vector. This is due to the fact that in films with their thickness comparable to the exchange length, the wave vector of the spin waves becomes of the order of the exchange length because of the boundary conditions for magnetization. These kinds of thin films were studied at first by Kittel [1]. The standing spin waves are characterized by the fact, that under certain conditions they do not correlate to an alternating magnetic field within or outside the film [2]. The damping theory for the standing spin waves was not well studied yet. This problem appears interesting, since the distance between the neighboring standing spin waves increases with increasing number of frequency as n, and the attenuation increases with a mode number increase as n^4. In other words, high-frequency modes of the standing spin waves are not created if the exchange relaxation mechanism is valid. The standing spin waves properties are being well studied experimentally lately [3]. The authors would like to compare their theoretical results to the experimental data.

H1.00128 Controlling strain anisotropy in iron-palladium thin films using perovskite-oxide substrates. RENEW HARTON, VLADIMIR STOICA, ROY CLARKE. University of Michigan — In this study, iron-palladium (FePd) thin films were deposited on (100) barium-titanate (BaTiO_3) and (100) strontium-titanate (SrTiO_3) substrates. Both BaTiO_3 and SrTiO_3 have a perovskite crystal structure and exhibit similar structural phases, such as tetragonal and cubic, at various temperatures. In contrast to SrTiO_3, BaTiO_3 exhibits ferroelectric and piezoelectric behavior in all of its structural phases except the cubic phase. In the tetragonal phase, the strain anisotropy of BaTiO_3 is two-fold about the in-plane c-axis, while in the cubic phase the epitaxial strain in the substrate plane is four-fold. In this investigation, the effect of strain on the magnetism and structure of FePd/SrTiO_3 and FePd/BaTiO_3 heterostructures was studied using the Magneto-Optic Kerr Effect (MOKE), Atomic Force Microscopy (AFM) and X-Ray diffraction (XRD) analysis to investigate the correlation between the magnetic anisotropy, morphology and structure of the FePd films.

H1.00129 Synthesis of magnetic GdC_2 nanoparticles using cavitation plasma. RAKESH CHAUDHARY, ALI R. KOYMEN, Department of Physics, The University of Texas at Arlington — Gadolinium dicarbide (GdC_2) nanoparticles were synthesized using Gd electrodes in toluene. Gd nanoparticles are formed in plasma caused due to collapse of cavitation bubbles using ultrasonication in electric field between Gd wire electrodes. The presence of a single phase of GdC_2 nanocrystals have been determined by X-Ray Diffraction (XRD) and High Resolution Transmission Electron Microscopy (HRTEM). The GdC_2 nanoparticles have tetragonal crystal structure. Transmission Electron Microscopy (TEM) shows that the nanoparticles range in size of 4-45 nm in diameter. Magnetization measurements performed using a Superconducting Quantum Interference Device (SQUID) magnetometer shows GdC_2 nanoparticles are paramagnetic in nature. To the best of our knowledge, this is the first synthesis of GdC_2 in single phase form, allowing further characterization of physical properties.

H1.00130 Magnetic and Structural characterization of Co nanowires using advanced electron microscopy techniques. JESUS CANTU-VALLE, FRANCISCO RUIZ-ZEPEDA, JOHN EDER SANCHEZ, FERNANDO MENDOZA-SANTOYO, ARTURO PONCE, University of Texas at San Antonio, UTS TEAM — We report the magnetic imaging and crystalline structure of high aspect ratio cobalt nanowires. Experimental results of magnetization reversal in cobalt nanowires are presented to illustrate the functionality of the in situ magnetization process through the manipulation of the objective lens. By making use of this applicability, we measure the magnetization and show experimental evidence of the magnetic flux distribution in polycrystalline cobalt nanowires using off-axis electron holography. The retrieved phase map can distinguish the magnetic contribution from the crystalline contribution with high accuracy. To determine the size and orientation of the grains within the Co nanowires, PED-assisted orientation mapping was performed. Finally, the magnetic analysis performed at individual nanowires was correlated with the crystalline orientation map, obtained by PED-assisted crystal phase orientation mapping. The large shape anisotropy determines the major magnetization direction rather than the magneto-crystalline anisotropy in the studied nanowires. The combination of the two techniques allowed us to directly visualize the effects of the crystallographic texture on the magnetization of the nanowire.

1The authors would like to acknowledge Dr. B.J.H. Studler for providing the samples and financial support from NSF PREM #DMR 0934218, CONACYT, #215762 and Department of Defense #64756-RT-REP.

H1.00131 Magnetic properties of Ru-Ti doped Strontium hexaferrite nanocrystalline particles. ABDEL ALSMADI, Kuwait University, S. MAHMOOD, University of Jordan, I. BSOL, Al-Ibn University — We carried out a systematic study on the effect of the substitution of Ti^{2+} and Ru^{4+} ions for Fe^{3+} ions on the magnetic properties of the strontium ferrite SrFe_{12-x}Ru_xTi_{12}O_{39} nanoparticles with (0 ≤ x ≤ 1), using vibrating sample magnetometry, electrical resistivity, and Mössbauer spectroscopy. A clear irreversibility between the zero-field-cooled and field-cooled curves was observed below room temperature and the zero-field-cooled magnetization curves displayed a broad peak at a temperature T_M. These results were discussed within the framework of random particle assembly model and associated with the magnetic domain wall motion. The resistivity data show some kind of a transition from insulator to perfect insulator around \( T_M \). With Ru-Ti substitution at 5 K, the saturation magnetization showed small variations with x slightly increased up to x = 0.2 and then starts to decrease for x between 0.2 and 0.5, while the coercivity decreased monotonically, recording a reduction of about 93% at x = 0.4. These results were discussed in light of the single ion anisotropy model and the cationic distributions based on the results of the Mössbauer spectroscopy data.

3Thank ANR SOSPIN, ESPERADO and a CNRS postdoctoral fellowship.
H1.00132 Doping controlled spin reorientation in dysprosium-samarium orthoferrite single crystals

SHIXUN CAO, WEIYAO ZHAO, BAOJUAN KANG, JINCANG ZHANG, WEI REN, Shanghai University — As one of the most important phase transitions, spin reorientation (SR) in rare earth transition metal oxides draws much attention of emerging materials technologies. The origin of SR is the competition between different spin configurations which possess different free energy. We report the control of spin reorientation (SR) transition in perovskite rare earth orthoferrite Dy$_{1-x}$Sm$_x$Fe$_2$O$_4$, a whole family of single crystals grown by optical floating zone method from $x=0$ to 1. Temperature dependence of the magnetizations under zero-field-cooling (ZFC) and field-cooling (FC) processes are studied. We have found a remarkable linear change of SR transition temperature in Sm-rich samples for $x>0.2$, which covers an extremely wide temperature range including room temperature. The $\alpha$-axis magnetization curves under FC process bifurcate from and then jump down to that of warming process (ZFC and FCW curves) in single crystals when $x>0.5-0.9$, suggesting complicated 4f-3d electron interactions among Dy$^{3+}$, Sm$^{3+}$, Fe$^{3+}$, and Sm$^{3+}$-Fe$^{3+}$ sublattices of diverse magnetic configurations for materials physics and design. The magnetic properties and the doping effect on SR transition temperature in these single crystals might be useful in the spintronics device application.

3This work is supported by the National Key Basic Research Program of China (Grant No. 2015CB921600), and the National Natural Science Foundation of China (NSFC, Nos. 51372149, 50932003, 11274222)

H1.00133 Crystal structure and magnetic properties of 5d double perovskite oxide Sr$_2$EuOsO$_6$

JIANFENG HE, National Institute for Materials Science (NIMS), HAI L. FENG, Max Planck Institute for Chemical Physics of Solids, YAHUA YUAN, YOSHIHIRO TSUJIMOTO, KAZUNARI YAMURA, National Institute for Materials Science (NIMS), SUPERCONDUCTING PROPERTIES UNIT, NATIONAL INSTITUTE FOR MATERIALS SCIENCE TEAM, GRADUATE SCHOOL OF CHEMICAL SCIENCES AND ENGINEERING, HOKKAIDO UNIVERSITY TEAM, MATERIALS PROCESSING UNIT, NATIONAL INSTITUTE FOR MATERIALS SCIENCE TEAM — Polycrystalline Sr$_2$EuOsO$_6$ has been synthesized with high-pressures and temperatures. It crystallizes in a monoclinic double perovskite structure and shows an antiferromagnetic-like transition at 51 K in a magnetic susceptibility measurement. The transition has been further characterized by specific measurements and electrical resistivity measurements. The results are compared with the magnetic properties of Ba$_2$EuOsO$_6$ [1] and other double perovskite oxides containing Os(V) atom. We will discuss role of spin-orbit coupling and spin polarization on the gapped electronic structure of Sr$_2$EuOsO$_6$ and other related compounds.

H1.00134 Thermal fluctuations in novel artificial spin ice

HENRY STOPPEL, ERIK OSTMAN, UU, AARON STEIN, CFN, UNNAR ARNALS, UI, VASSILIOS KAPAKIS, BJORGVIN HJORVARSSON, UU, UU TEAM1, CFN COLLABORATION1, UI COLLABORATION1 — Artificial spin ice (ASI) is used as a model material to investigate frustrated systems. The square and kagome ASI has been extensively investigated since there discovery. Novel ASI structures like the Shakti lattice, have been proposed and already realized. In this structure what is not an adaption of natural magnetic materials the lattice topology leads to a high degree of degeneracy. We present here the results of Photoemission electron microscopy (using XMCD) to image the magnetization of nano-islands in a Shakti ASI. By using a three layer of Pd-Fe-Pd we can tune the Curie temperature of our magnetic material by varying the thickness of the Fe-layer. Beside a statistical analysis of the frozen-in ground state, we present also a temperature series, in which we could visualize the two energy levels of the small and large islands and due to this the different blocking temperatures for these islands. This comparison of these measurements with previous measurements on squared ASI give us a better understanding of the magnetic ordering and the thermal fluctuations in the novel Shakti ASI.

H1.00135 Negative magnetization and exchange bias in Y$_1-x$Pr$_x$CrO$_3$ with $(0>x>0.3)$

E. VERDIN, Departamento de Fisica, Universidad de Sonora, A. DURAN, Centro de Nanociencias y Nanotecnologia-UNAM, F. MORALES, E. ESCUDERO, Instituto de Investigaciones en Materiales-UNAM — Rare earth orthochromites compounds with perovskite structure have attracted great interest because its potential applications as data storage and spintronics. We report studies of the crystalline structure, thermal, and magnetic properties performed in the compound Y$_{1-x}$Pr$_x$CrO$_3$ with $0<x<0.3$. We found changes in the specific heat and in the magnetization when the Pr atoms are substituted into the compound. The antiferromagnetic transition, $T_N$, increases when the Pr atoms are substituted into the compound which is clearly observed by specific heat and magnetization measurements. We also found an exchange bias and magnetization reversal when the magnetization-temperature (M-T) curves were measured in field cooled mode (FC). All these changes are attributed to the influence of the Dzialoshinskii-Moriya indirect interaction that we related to the octahedral distortion, because the Pr substitution affecting the Cr-O bond lengths.

H1.00136 Neutron diffraction study on the phase diagram in multiferroic DyFeO$_3$

JINCHEN WANG, JUANJUAN LIU, JIEMING SHENG, Remin Univ of China, ZHYING ZHAO, XIA ZHAO, XUEFENG SUN, University of Science and Technology of China, SERGEY DANILKIN, Australian Nuclear Science and Technology Organisation, WEI BAO, Remin Univ of China — The discovery of the multiferroic effect in perovskite DyFeO$_3$ has generated many interests due to a witnessed strong magnetoelectric coupling. In this low temperature and high magnetic-field study, the $\alpha$- and $\alpha$'-phase boundaries are determined by neutron diffraction studies. The multiferroic effect is observed only in the phase area where the applied magnetic field breaks the long-range order (LRO) AF order of the Dy ions into a short-range order (SRO). Our results suggest the mechanism of the remarkably strong multiferroic effect in the prototype rare-earth orthoferrite DyFeO$_3$ ought to be investigated through the interplay between the weak ferromagnetism of Fe and the antiferromagnetic SRO of Dy spins.

H1.00137 Engineering magnetic properties and microstructure of La$_2$CoMnO$_6$ thin films by tailoring the oxygen stoichiometry

BENJAMIN MARTINEZ, REGINA GALCERAN, CARLOS FRONTERA, LLUIS BACCELLS, JOSE CISNEROS-HERNÁNDEZ, ICMAB-CSIC, JAUME ROQUETA, JOSE SANTISO, ICN2-CSIC, ALBERTO POMAR, FELIP SANDIUMENGE, ICMAB-CSIC, ADVANCED MATERIALS CHARACTERIZATION TEAM, THIN FILMS GROWTH TEAM — We report on the magnetic and structural properties of ferromagnetic-insulating La$_2$CoMnO$_6$ thin films grown on top of (001) STO substrates by means of RF sputtering technique. Insulating ferromagnets are of interest because of the exchange splitting of the bands allowing obtaining tunnel barriers with different height for spin-up and spin-down carriers. Belonging to the perovskite family, this material can be easily integrated in spintronic devices, such as magnetic tunneling junctions and spin filters, with upgraded and distinctive functionalities.

An exhaustive structural analysis, by using synchrotron X-ray diffraction, allows identifying a close correlation between the film composition and their magnetic properties. Both Curie temperature and the features of the hysteresis loops turn out to be dependent on the oxygen stoichiometry. In situ annealing conditions confirm the insulating character of the films.

H1.00138 Magnetic and thermoelectric properties of Fe\(_{3-x}\)Co\(_x\)O\(_4\) thin films and CoFe\(_2\)O\(_4/\)Fe\(_3\)O\(_4\) superlattices. QUANG NGUYEN VAN, University of Ulsan, Korea. M. JUAN CHRISTIAN, Institute of Physics and Chemistry for Materials of Strasbourg, Unif 7504 UDS-CNRS, Strasbourg, France. ANH TUYAN DUC, VOOLEM SHIN, RHM. S. H, MINH NHI NGUYEN THI, SUNGLAE CHO, University of Ulsan, Korea — Microcrystalline ferrites are used as a medium for the magnetic recording and storage of information. Magnetite, Fe\(_3\)O\(_4\), is a ferrimagnet with a cubic inverse spinel structure and exhibits a metal-insulator, Verwey, transition at about 120 K. It is predicted to possess as half-metallic nature, ~100% spin polarization, and high TC 2850 K. Cobalt ferrite, Co\(_x\)O\(_4\), is one of the most important members of the ferrite family, which is characterized by its high H\(_c\), moderate magnetization and very high magnetocrystalline anisotropy. Here we report on the magnetic and thermoelectric properties of Fe\(_{3-x}\)Co\(_x\)O\(_4\) (x = 0 to 1) thin films and CoFe\(_2\)O\(_4/\)Fe\(_3\)O\(_4\) superlattices grown on MgO (100) by MBE. XRD and RHEED patterns confirmed the inverse spinel structure of the Fe\(_3\)O\(_4\) films. Magnetic properties of the Fe\(_{3-x}\)Co\(_x\)O\(_4\) films are markedly sensitive to the Co content. The Verwey transition was disappeared in Co-doped films. A negative MR curve with butterfly shape was observed with low Co content but disappeared for the samples with x = 0.8 and 1. Seebeck coefficients increased with Co concentration: -70 \(\mu\)V/K for x=0 and -220 \(\mu\)V/K for x=1. We will also discuss on the relationship between magnetic and thermoelectric characteristics in CoFe\(_2\)O\(_4/\)Fe\(_3\)O\(_4\) superlattices with the modulations of 5, 10, and 20 nm.

H1.00139 Magnetic and electrical properties on possible room temperature hybrid multiferroic BaTiO\(_3/\)La\(_{2/3}\)Sr\(_{1/3}\)MnO\(_3\). JOHN EDWARD ORDOÑEZ, MARIA ELENA GOMEZ, WILSON LOPERA MUÑOZ, Universidad del Valle, Cali, Colombia. PEDRO ANTONIO PRIETO, Center for Excellence on Novel Materials — CENM, Cali, Colombia. THIN FILM GROUP TEAM, CENTER OF EXCELLENCE ON NOVEL MATERIALS — CENM, Cali, Colombia. THIN FILM GROUP TEAM. — We addressed to deposit the ferromagnetic phase of the La\(_{1-x}\)Sr\(_x\)MnO\(_3\) and the ferroelectric BaTiO\(_3\) for possible hybrid multiferroic heterostructure. We have optimized the growth parameters for depositing BaTiO\(_3\) (BTO) / La\(_{2/3}\)Sr\(_{1/3}\)MnO\(_3\) (LMO) / (001) SrTiO\(_3\) by sputtering RF and DC, respectively, in pure oxygen atmosphere and a substrate temperature of 830°C. Keeping fixed the magnetic layer thickness (t\(_{\text{M}}\) = 40 nm) and varying the thickness of the ferroelectric layer (t\(_{\text{BTO}}\) = 20, 40, 80, 100 nm). We want to point out the influence of the thicknesses ratio (t\(_{\text{BTO}}\)/t\(_{\text{SMO}}\)) on electrical and magnetic properties. From x-ray diffraction (XRD) analysis, we found the bragg peaks for LSMO maintain its position but BTO peak shift to lower Bragg angle indicating a strained BTO film. Magnetization and polarization measurements indicate a possible multiferroic behavior in the bilayers. Hysteresis loop measurements of bilayers show ferromagnetic behavior.

H1.00140 Magnetization fluctuation in FeB nanomagnets under asymmetric magnetization-potential. SHINJI MIWA, Osaka Univ. HITOSHI KUBOTA, KAY YAKUSHIJI, AIIST, SHOTA ISHIBASHI, AKIO FUKUSHIMA, SHINJI YUASA, AIIST, YOSHISHIGE SUZUKI, Osaka Univ. — Thermal fluctuation of magnetizations gives understandings of physics in magnetic materials and noise in magnetic devices. It is theoretically calculated using the Fokker-Planck equation and the fluctuation-dissipation theorem, [1] and is experimentally characterized using magnetoresistive devices [2]. In the present study, the magnetization-fluctuation under asymmetric magnetization potential has been investigated. Magnetic tunnel junctions (MTJs) [CoFeB (3 nm)/ MgO (1 nm)/ FeB (2 nm)] were employed to conduct the study. The FeB layer (120 nm in a diameter) is a magnetic free layer whose magnetic anisotropies are 8 mT (in-plane) and 97 mT (perpendicular). The asymmetric magnetization-potential was prepared using magnetic field application (110 mT) tilted from the film normal (10 deg.). [3] Unlike the first-order response to the thermal fluctuation, [2] the second-order response is identified as a Lorentzian power spectrum whose peak appears at 0 Hz. To derive the analytic formula, fourth-order moments were calculated using the quasi-normality hypothesis \(\langle AB \rangle \langle CD \rangle = \langle AB \rangle \langle CD \rangle + \langle AC \rangle \langle BD \rangle + \langle AD \rangle \langle BC \rangle \). As a results, the obtained formula quantitatively reproduces the experiment.

H1.00141 Exchange interaction reduction as a precursor to laser-induced demagnetization in ferromagnets. GUOPING ZHANG, YIHUA BAI, Indiana State University. THOMAS F. GEORGE, University of Missouri-St. Louis — Laser-induced femtosecond demagnetization in a ferromagnet presents an opportunity to develop all-optical ultrafast magnetic storage devices, but its underlying mechanism is under intense debate. The controversy has been on the first several hundred femtoseconds, where the spin moment is reduced sharply up to 50% or higher, but the optically accessible electrons are very few. This apparent contradiction is puzzling. Here we show that a small number of excited electrons is enough to trigger a strong band structure relaxation. In all of the three 3d ferromagnets investigated here, this band relaxation sharply reduces the exchange splitting and spin moment. For fcc Ni, for every electron excited, the spin moment can be reduced by 0.23 \(\mu\)B or more. Our first-principles calculation, free of fitting parameters of any kind, finally explains the experimental findings and presents a paradigm for future experiments.

H1.00142 A mechanical analogy for spin currents and torques. YAROSLAW BAZALIY, University of South Carolina — We map the problem of spin-transfer torques in nanostructures with diffusive spin currents on a mechanical problem involving elastic strings connecting points of attachment that slide along the fixed straight rails. The obtained mechanical analogy provides a qualitative understanding of the effects of spin relaxation on spin torques, and of the phenomenon of sign-changing angular dependence \([1-3]\) of the efficiency factor \(g(\theta)\).

H1.00143 Ultra Low Energy Switching of Ferromagnet with Perpendicular Anisotropy on Topological Insulator by Voltage Controlled Magnetic Anisotropy

BAHMIMAN GHOSH, TANMOY PRAMANIK, RIK DEY, ÜRMİMALA ROY, LEONARD REGISTER, SANJAY BANERJEE, Microelectronics Research Center, Univ of Texas at Austin — We propose and demonstrate, through simulation, an ultra low energy memory device on a topological insulator thin film. The device consists of a thin layer of Fe deposited on the surface of a topological insulator, Bi$_2$Se$_3$. The top surface of Fe is covered with MgO so that the ferromagnetic layer has perpendicular anisotropy. Current is passed on the surface of the topological insulator which switches the magnetization of the Fe ferromagnet through strong exchange interaction, between electrons contributing to the surface current on the Bi$_2$Se$_3$, and the d electrons in the ferromagnet, and spin transfer torque due to shunting of current through the ferromagnet. Voltage controlled magnetic anisotropy enables ultra low energy switching. Our micromagnetic simulations, predict switching time of the order of 2.4 ns and switching energy of the order of 0.16 fJ for a ferromagnetic bit with thermal stability of 90 k$_B$T. The proposed structure combines the advantages of both large spin torque from topological insulators and those of perpendicular anisotropy materials.

H1.00144 Capturing the Magnetic and Structural Phase Transition of Feruh by Extreme Ultraviolet Light

DMITRIY ZUSIN, PATRIK GRYCHTOL, CHRISTIAN GENTRY, MARGARET MURNANE, HENRY KAPTEYN, JILA, University of Colorado, Boulder, CO 80309, SOPHIE CANTON, Max-Lab, Lund University, SE-223 63 Lund, Sweden, RONNY KNUT, JUSTIN SHAW, HANS NEMBACH, THOMAS SILVA, Electromagnetics Division, National Institute of Standards and Technology, Boulder, CO 80305, ALEJANDRO CEBALLOS, CATHERINE BORDEL, PETER FISCHER, FRANCES HELLMAN, University of California, Berkeley, CA 94720 — The temperature dependent transition from the anti-ferromagnetic to the ferromagnetic phase in FeRh is accompanied by a modification of its crystal lattice. The interplay between the magnetic and the structural transition is a matter of strong debate. It is important to better understand the mechanism(s) of the transition since it can be induced by femtosecond laser pulses and, unlike slower (nano-second) magnetic phase transitions, does not seem to be limited by heat transfer. In this work, we use extreme ultraviolet light generated by a tabletop high harmonics source to perform element-selective investigations of the temperature-dependent magneto-optical response of a thin film FeRh sample. We study the optically induced phase transition using two ultrafast pump-probe spectroscopy approaches: by monitoring the time-resolved transversal mageto-optical Kerr effect (T-MOKE) and the transient change in reflectivity.

H1.00145 The effects of shape anisotropy and exchange coupling on spin precession frequencies in exchange coupled Co/Cu/Pt trilayers

SAM KERAMATI, UDAY SINGH, SETH KURFMAN, CH. BINEK, S. ADENWALLA, Univ of Nebraska - Lincoln — Ultrafast high-power laser systems have successfully opened up the field of magnetization dynamics, studying subpicosecond laser-induced spin precession dynamics, demagnetization processes and magnetization reorientation. Here we investigate laser-induced magnetization dynamics in a series of photolithographically patterned microstructures of exchange coupled trilayers of Co/Cu/Pt grown on Si substrates. The microstructures have different shape anisotropies as well as different exchange coupling parameters. The latter determines the magnetization state, varying from ferromagnetically to anti-ferromagnetically coupled. We explore how the different spin precession frequencies of the constituent exchange coupled magnetic layers with unequal relaxation times can trade-off with the differing shape anisotropies. The key physical point is that the precession frequency of ferromagnetic materials and their damping parameter vary with the effective field which depends on both the shape anisotropy, and exchange coupling, while their corresponding effects can be modulated through the action of the intense pump beam. Precession frequency maps of the behavior of the exchange coupling parameter of the samples with respect to their shape anisotropy and their laser-induced modulated precession frequencies will be generated through a pump-probe experiment to address the above-mentioned objective of our work.

H1.00146 Electron Irradiation Induced Modification of Ferromagnetism in (Ga,Mn)As

JIA LUO, GANG XIANG, Department of Physics and Key Laboratory for Radiation Physics and Technology of Ministry of Education, Sichuan University — The ferromagnetism properties of diluted magnetic semiconductor (Ga,Mn)As firstly improved by energetic electron irradiation, through a sequence of irradiation doses. We did a systematic study of magnetization as a function of temperature and additional magnetic field. SQUID measurements demonstrate the T$_C$ of all (Ga,Mn)As film increased from 40K to 60K after irradiation. At the same time, electron irradiation improved the crystal quality and electric properties. The irradiation process decreases the resistance by a factor of 1/2 in the range of 10K to 50K, and transforms (Ga,Mn)As samples from insulator behavior to metallic behavior. SIMS and transport measurements confirm that the rearrangement of Mn interstitials plays a key role in the improvement of ferromagnetism properties. We infer that electron irradiation paves a new path to room-temperature ferromagnetism of (Ga,Mn)As.

H1.00148 Dynamics of bright and dark localized excitonic magnetic polarons in CdMnTe spin glass compound

YURIY GNATENKO, PETRO BUKIVSKIJ, YURIY PIRYATINSKI, Institute of Physics of National Academy of Science of Ukraine — The measurements of the magnetic properties of spin glass (SG) system indicate that the magnetic relaxation is characterized by a broad range of times below T$_f$. Here, for the first time, we have investigated time-resolved photoluminescence spectra of Cd$_{1-x}$Mn$_x$Te SG compound at the temperature below the freezing temperature T$_f$. This enables us to study the dynamics of different localized excitonic magnetic polarons (LEMPs) at T =0.7T$_f$ excited in the crystal regions where various microscopic magnetic spin states (MMSSs) are formed. It was found that there is a broad distribution of the lifetimes of the LEMPs which have different lifetimes but same energies. It was shown that the presence of the long-lived LEMPs is caused by the admixture of the optically active bright exciton states to the dark exciton states as a result of the local magnetic fields formation. The lifetimes of these dark LEMPs correspond to hundreds of nanoseconds. It was also found that the decay process of the PL exciton band intensity is described by the Kohlrusch–Williams–Watts stretched exponential function which describes the relaxation processes which correspond to the emission of the LEMPs formed in the crystal region of the finite clusters as well as the infinite cluster. These complex dynamical phenomena, observed for Cd$_{1-x}$Mn$_x$Te at low temperatures, reflect the spatially heterogeneous dynamics in the SG system which is due to the presence of different MMSSs below T$_f$.

H1.00149 Ferruquadrupolar phase of the Heisenberg model with bilinear and biquadratic interactions. ANTONIO PIRES, Universidade Federal de Minas Gerais — The Heisenberg antiferromagnet with bilinear and biquadratic exchange interactions has been studied using several techniques. In contrast to bilinear interactions models, quantum spin models with biquadratic interactions present a phase diagram qualitatively different from their classical counterparts, as for instance nonmagnetic phases such as the quadrupolar phase. In this work I study the ferruquadrupolar phase of the $S = 1$ Heisenberg model with bilinear and biquadratic exchange interactions on the square lattice using a SU(3) Schwinger boson formalism in a mean field approximation. This nonmagnetic phase is characterized by a finite quadrupole moment. I will calculate the quadrupole moment and the static spin structure factor for several values of the parameters involved in the model. The results obtained will also be compared with the ones obtained from other theories.  

1 I acknowledge support from CNPQ.

H1.00150 Effect of Zn substitution on the magnetic properties of Skyrmion Cu$_2$OSeO$_3$. TIEN-YU WEI, HUNG-CHENG WU, KAKARLA DEVI CHANDRASEKHAR, HUNG-DUEN YANG, Natl Sun Yat Sen Univ, NATIONAL SUN YAT-SEN UNIVERSITY TEAM — There is a considerable interest in the new magnetic state, the “Skyrmion state (A-phase),” whose magnetic properties have a remarkable characteristic as a vortex-like spin orientation. The polycrystalline (Cu$_{1-x}$Zn$_x$)$_2$OSeO$_3$ ($x = 0.0$ to $0.20$) samples were synthesized using solid state reaction method and studied by X-ray diffraction, X-ray absorption spectra and magnetic measurements. Variation of lattice constant with Zn doping follows the Vegard’s law which signifies the successful substitution of Zn in place of Cu up to $x$ less than 0.20. The Cu L$_{2,3}$ spectra show 2+ valence state for all samples. The Curie temperature decrease with Zn doping indicate the ferrimagnetic ordering is gradually suppressed. Moreover, we have noticed another magnetic phase for the doping level $x$ between 0.05 and 0.2, whose magnetic transition also shifted to low temperature for higher Zn doping. The H-T magnetic phase diagrams of the samples from ac susceptibility have been established with increasing Zn doping. The explanations for the observations of doping effects on the A-phase of Skyrmion Cu$_2$OSeO$_3$ will be discussed.

H1.00151 Effect of Ni substitution on the magnetic properties of Skyrmion Cu$_2$OSeO$_3$. CHUNG-LUN HUANG, HUNG-CHENG WU, KAKARLA DEVI CHANDRASEKHAR, HUNG-DUEN YANG, Natl Sun Yat Sen Univ, NATIONAL SUN YAT-SEN UNIVERSITY TEAM — Chiral magnetic lattice shows many exotic physical properties such as spin ice/spin liquid order, topological insulators and magneto-electric coupling. The chiral magnetic lattice of Cu$_2$OSeO$_3$ exhibits such kind of unique magnetic ordering where spins form the vortex like ordering called as Skyrmion. In this poster, the effects of isovalent ion doping on the Skyrmion phase of Cu$_2$OSeO$_3$ were presented. Polycrystalline (Cu$_{1-x}$Ni$_x$)$_2$OSeO$_3$ ($x = 0.0$ to $0.1$) samples were prepared by standard solid-state methods. Temperature and magnetic field dependent AC and DC magnetic measurements were performed. The Curie temperature decreases obviously with increasing Ni concentration by using ac susceptibility $(\chi_{ac})^{-1}$. Systematic H-T phase diagrams indicating the effects of Ni doping are established and will be discussed.

H1.00152 High pressure and doping effect on the magnetic properties of CaMn$_2$O$_4$. KUN-JU HSIEH, HONG-CHENG WU, KAKARLA D. CHANDRASEKHAR, HUNG-DUEN YANG, Natl Sun Yat Sen Univ, NATIONAL SUN YAT-SEN UNIVERSITY TEAM — Polycrystalline Ca$_{1-x}$Sr$_x$Mn$_2$O$_4$ ($x = 0.05, 0.10, 0.15, 0.20$) compounds were synthesized using solid state reaction method. Samples were characterized by X-ray diffraction and magnetization measurements. The lattice constants (a, b, c) determined by Rietveld refinement increases with Sr substitution. CaMn$_2$O$_4$ shows antiferromagnetic transition $T_N$ near 220 K due to the Mn(III)-O-Mn(III) superexchange interaction. High-pressure effect on the $T_N$ of CaMn$_2$O$_4$ has been investigated by piston-cylinder type high pressure apparatus designed for MPMS-XLT magnetometer. It is found that the $T_N$ increases with applying pressure up to 17.7 kbar at a rate of 0.487(22) K/kbar and decreases with higher Sr content.

H1.00153 Exact Diagonalization of a Quantum Ising Model with Long-Range Interactions. SHANNA MUEHE, THOMAS GUNN, Univ of West Florida, C.C.-JOSEPH WANG, None, CHRISTOPHER VARNEY, Univ of West Florida — Due to the rapid advance of quantum spin simulators in ultra-cold ions, the varying interaction for spin models in two-dimensional lattices have become feasible for experimental exploration for exotic states of collective states of multiple spins. It is particularly interesting for the case of a triangular lattice with antiferromagnetic interaction between spins. When the Ising spin-spin interaction is uniform and restricted between nearest neighbors, the spins are geometrically frustrated. When the system interaction becomes long ranged, the geometric frustration is lost but the spins are frustrated by the long-range interaction. In the latter case, the underlying orders present in the ground state are unclear and understanding these states in finite spin systems is crucial for the benchmarking of experimental observations. Here, we investigate the quantum dipolar Ising model with exact diagonalization to analyze the ground state, order parameters, and excitations and provide a baseline for comparison with experiments.

H1.00154 Exchange interaction between J-multiplets. NAOYA IWAWARA, LIVIU CHIBOTARU, Theory of Nanomaterials Group, Katholieke Universiteit Leuven — The crystal-field levels in lanthanides and other metal complexes with unquenched orbital momentum originate from the ground atomic $J$-multiplet. It was long believed that the exchange interaction between $J$-multiplets is basically described by Heisenberg form, $J_1$ - $J_2$. In this work, Anderson’s superexchange model is applied for analytical derivation of exchange interaction between arbitrary $J_1$ and $J_2$ multiplets [1]. The structure and the energy spectrum of the obtained exchange Hamiltonian are significantly different from those of a Heisenberg Hamiltonian. Besides, it is also found that the 1/$U$ approximation [2] is not applicable for the description of exchange spectrum, since it gives qualitatively different predictions compared to the present treatment. Similar results are obtained for the exchange interaction between $J$-multiplet ($J_1$) and isotropic magnetic center ($S_2$).

H1.00155 The origin of magnetic ordering in quasi-two-dimensional quantum magnets Cu$_{tn}$Cl$_2$ and Cu(en)(H$_2$O)$_2$SO$_4$. ALZBETA ORENDACOVA, P.J. Safarik University, Park Angelinum 9, 041 54 Kosice, Slovakia, LUCIA BARANOVA, Technical University of Kosice, Vysokeškolska 4, 042 00 Kosice, Slovakia, ROBERT TARASENKO, MARTIN ORENDAC, ALEXANDER FEHER, P.J. Safarik University, Park Angelinum 9, 041 54 Kosice, Slovakia, RUDOLF SYKORA, DOMINIK LEGUT, VSB-Technical University of Ostrava, 17. listopadu 15, Ostrava 70833, Czech Republic — A comparative analysis of magnetic properties of Cu(en)(H$_2$O)$_2$SO$_4$ (en = C$_5$H$_7$N$_2$) (1) and Cu(tn)Cl$_2$ (tn = C$_5$H$_7$N$_2$) (2) has been performed to search for the origin of magnetic ordering observed in (1) at $T_c = 0.9$ K while hidden in (2). Previously, both materials were approximated by a quasi-two-dimensional (2d) spin 1/2 Heisenberg model on the square lattice with effective intralayer and interlayer coupling $J/K_B = 3$ and $J'/K_B = 10^{-14}$, respectively. The first principles calculations revealed in (1) a spatial anisotropy of exchange coupling within a layer, $J_1/J_2 = 0.15$, in accordance with a proposed data to toy behavior. Considering only effect of interlayer coupling, $T_c = 0.8$ K was evaluated, while $T_c = 0.85$ K when a weak Ising-like spin anisotropy, $\Delta = 0.015$ was introduced into Heisenberg layers. The effects of spin and spatial anisotropy on the ordering of (1) and the absence of a phase transition in (2) are discussed.

1 Supported by CFNT MVEP, ITMS2622012005, APVV 0132-11, SK-CZ-2013-0083, CZ.1.07/2.3.00/30.0055, and CZ.1.05/1.1.00/02.0070.
H1.00156 Thermodynamic properties of a layered $S = 7/2$ Heisenberg magnet Gd(OH)CO$_3$.1

MARTIN ORENDAČ, MARTIN ULICNY, ERIK CIZMAR, ALZBETA ORENDAČOVA, P. J. Safarik University, Park Angelinum 9, 040 01 Kosice, Slovakia, YUN-CONG CHEN, ZHAO-SHA MENG, MING-LIANG TONG, Sun Yat-Sen University, Guangzhou, 510275, P. R. China. — Thermodynamic quantities and ESR spectra of Gd(OH)CO$_3$ (I) are reported. The material may be considered to consist of weakly coupled layers with potentially triangular arrangement of exchange paths within each layer. Different bridging groups and distances among Gd$^{3+}$ ions may be responsible for spatial anisotropy of magnetic coupling. Preliminary analysis of magnetic susceptibility using Curie-Weiss law yielded $\theta = -1.05$ K indicating weak antiferromagnetic coupling and consequently, spin frustration in (I). More detailed simultaneous analysis of specific heat, susceptibility and magnetization studied down to nominally 0.45 K revealed non-negligible role of single-ion anisotropy. Using the model of weakly interacting $S = 7/2$ trimers, the gross features of measured data may be explained while assuming single-ion anisotropy $D/k_B \approx 0.6$ K and effective intratramer magnetic coupling $|J/k_B| \approx 0.3$ K. The obtained $D$ value reasonably reproduces the position and shape of ESR line. The performed analysis suggests that magnetism in (I) is governed predominantly by crystal field effects and frustration plays a minor role.

H1.00157 The structural, electronic and magnetic properties of Ga$_8$-xMn$_x$As$_8$ clusters.1 GANXU GU, GANG XIANG, College of Physical Science and Technology, Sichuan University — We systematically investigate the ground-state magnetic properties of Ga$_8$-xMn$_x$As$_8$ clusters ($x = 0, 2, 4, 6, 8$) within the framework of density functional theory (DFT) using a strategy that successively adopts the particle swarm optimization (CALYPSO) code and fixed spin-moment (FSM) method. The results show that for Ga$_8$-xMn$_x$As$_8$ in the ground states or low-lying isomers, Mn atoms tend to assemble at the core of the clusters and the ferrimagnetic Mn-Mn couplings are identified for Ga$_8$-xMn$_x$As$_8$ ($x = 4, 6$, and $8$), while GaMn$_8$ and Ga$_6$Mn$_2$As$_8$ are nonmagnetic. The possibility of multiple ground states of Ga$_8$-xMn$_x$As$_8$ ($x = 4, 6$, and $8$) is also demonstrated. The binding energy and LUMO-HOMO gap analysis show that Ga$_8$-xMn$_x$As$_8$ clusters with large $x$ are more likely synthesized and exhibit stronger chemical reactivity.

H1.00158 Quantum oscillations of the mechanical forces in rotating molecular magnets. GWANG-HEE KIM, Sejong University — We study a rotating nanomagnet that exhibits beat structure of the quantum forces. We show that such forces are originated from tunneling between two entangled states of spin and mechanical angular momentum. They can be observed in the presence of a static magnetic field gradient with ac magnetic field and disappear on increasing total angular momentum and parameter which depends on the moment of inertia and the tunnel splitting.

H1.00159 Uniaxial-pressure dependence of the magnetization dynamics in the high-symmetry single-molecule magnet Mn$_{12}$-MeOH. JAMES H. ATKINSON, Dept. of Physics, University of Central Florida, Orlando, FL, and the Dept. of Physics, Amherst College, Amherst, MA, LAXMI BHASKARAN, STEPHEN HILL, National High Magnetic Field Laboratory and Dept. of Physics, Florida State University, Tallahassee, FL, YURI MYASOEDOV, ELI ZELDOV, Dept. of Condensed Matter Physics, Weizmann Institute of Science, Rehovot, Israel, IRAN FOTOH, Dept. of Physics, University of Central Florida, Orlando, FL, JOHNathan BesNel, B. K. CELESTE, G. K. GORDON, J. A. KAspin, J. P. PIZZETTI, I. ZILCH, Dept. of Physics, Amherst College, Amherst, MA, ADeline FORNUET, GEORGE CHRISTIOU, Dept. of Chemistry, University of Florida, Gainesville, FL — The single-molecule magnet [Mn$_{12}$O$_{12}$(OC$_2$H$_5$)$_{16}$(CH$_3$OH)$_4$]CH$_3$OH ("Mn$_{12}$-MeOH") is a high-symmetry sibling of the Mn$_{12}$-Acetate SMM that offers a prime opportunity to explore the consequences of molecular symmetry. A previous study [1] has shown that applied pressure induced changes in the Mn$_{12}$-Acetate's anisotropy parameters. Here we present the results of a study in which uniaxial pressure was applied to a crystalline sample of Mn$_{12}$-MeOH in order to examine how the pressure affects the quantum tunneling of magnetization at low temperature. We find that the pressure induces an increase in the resonant tunneling rate manifested as a change in the height of the tunneling steps in the magnetic hysteresis. These results suggest that pressure is altering symmetry-breaking terms in the molecule’s spin Hamiltonian, giving rise to increased tunneling.

H1.00160 Phase transitions of a quantum chain with four-spin interactions in longitudinal and transverse magnetic fields. B. BOECHAT, J. FLORECIO, A. SAGUIA, Universidade Federal Fluminense, O. F. DE ALCANTARA BONFIM, University of Portland — We study the ground-state properties of a spin-1/2 model on a chain containing four-spin Ising-like interactions in the presence of both transverse and longitudinal magnetic fields. We use entanglement entropy and finite-size scaling methods to obtain the phase diagrams of the model. Our numerical calculations reveal a rich variety of phases and the existence of multi-critical points in the system. We identify phases with both ferromagnetic and anti-ferromagnetic orderings. We also find periodically modulated orderings formed by a cluster of like-spins followed by another cluster of opposite like-spins. The quantum phases in the model are found to be separated by either first or second order transition lines.

H1.00161 Quantum criticality in a magnetic chain with two- and four-spin interactions in a transverse field. O. F. DE ALCANTARA BONFIM, University of Portland, A. SAGUIA, B. BOECHAT, J. FLORECIO, Universidade Federal Fluminense — We use entanglement entropy and finite-size scaling methods to investigate the ground-state properties of a spin-1/2 Ising chain with two-spin ($J_1$) and four-spin ($J_2$) interactions in a transverse magnetic field ($B$). We concentrate our study on the unexplored critical region $B = 1$ and obtain the phase diagram of the model in the ($J_1$, $J_2$) plane. The phases found include ferromagnetic (F), antiferromagnetic (AF), as well as more complex phases involving spin configurations with multiple periodicity. The system presents both first and second order transitions separated by tricritical points. We find an unusual phase boundary on the semi-infinite segment ($J_4 < -1$, $J_2 = 0$) separating the F and AF phases.

H1.00162 Unusual Phase Transitions in Single Crystals of Gd$_{3}$Si$_{1-x}$Ge$_{2}$ and Gd$_{3}$Si$_{1-x}$Ge$_{2}$6.1 R.L. HADIMANI, Iowa State Univ, Y. MELIKHOV, Polish Academy of Science, D.L. SCHLAGEL, T.A. LOGRASSO, K.W. DENNIS, R.W. MCCALLUM, Ames Laboratory, US Dept. of Energy, D.C. JILES, Iowa State Univ, IOWA STATE UNIVERSITY COLLABORATION, POLISH ACADEMY OF SCIENCE COLLABORATION, AMES LABORATORY, US DEPT. OF ENERGY COLLABORATION — Gd$_{3}(Si_{1-x}Ge_{x})$ has been widely studied over the composition range 0.41 $< x <$ 0.51 where the coupled magnetic and structural first order phase transitions occur close to room temperature. It has a mixed phase region in the phase diagram with both orthorhombic I and orthorhobic II phases for compositions 0.32 $< x <$ 0.41. Previously we have used modified Arrott plots to determine the second order phase transition temperature when it is suppressed by the first order phase transition in samples with compositions $x < 0.51$. We also used these modified Arrott plots on the mixed phase composition of Gd$_{3}Si_{1-x}Ge_{2}$ ($x = 0.375$) to determine the second order phase temperatures of both the monoclinic and the orthorhobic II phases. We have now investigated two more single crystals of Gd$_{3}Si_{1-x}Ge_{2}$ and Gd$_{3}Si_{1-x}Ge_{2}$6, whose compositions fall in the mixed phase region of orthorhombic I and orthorhobic II phases. The temperature above which the low temperature quantum oscillations of the samples were estimated to be 383 K for Gd$_{3}Si_{1-x}Ge_{2}$ and 365 K for Gd$_{3}Si_{1-x}Ge_{2}$6. These temperatures are much higher than the expected second order phase transition temperature of orthorhobic II phase (280 K). This may be due to the presence of the orthorhombic I phase in larger volume fraction.
H1.00163 Evidence for a magnetic metallic R phase in Vanadium dioxide VO$_2$, HUI XING, PAYAM TAHERI, PEIHONG ZHANG, HAO ZENG, Department of Physics, The State University of New York at Buffalo — Vanadium dioxide VO$_2$ has garnered extensive research interests for over decades due to its metal-insulator transition (MIT) around 340 K (Ref. 1). Much is known for the physics behind the MIT (including a correlated structural transition and the involvement of several intermediate states). On the other hand, the magnetic property across the MIT is much less known. Although there are no fundamental arguments against the possibility of forming local magnetic moments in VO$_2$. So far, only the M2 phase has been confirmed to possess local magnetic moments. However, our temperature-dependent magnetic susceptibility measurements of VO$_2$ show a sudden jump at the MIT. This jump cannot be attributed to a simple Pauli susceptibility from conducting electrons. In a recent paper, we pointed out local magnetic moments may form in the metallic R phase. The formation of local moment would naturally explain the extremely high magnetic susceptibility of VO$_2$ above the phase transition temperature. We further discuss the magnetoresistance (MR) measured across the MIT, which shows different magnitude and field dependence in M1 and R phase, including the MR in the metallic phase suppressed to lower temperature in a VO$_2$ electric double layer transistor device using ionic liquid as gate dielectrics. 1. F. J. Morin, Phys. Rev. Lett. 3, 34 (1959). 2. Xun Yuan et al., Phys. Rev. B 86, 235103 (2012).

H1.00164 Control of proliferation rate of N27 dopaminergic neurons using Transcranial Magnetic Stimulation orientation, YIWEI MENG, RAVI HADIMANI, VELLAREDDY ANANTHARAM, ANUMANATA KANTHASAYAM, DAVID JILES, None — Transcranial magnetic stimulation (TMS) has been used to investigate possible treatments for a variety of neurological disorders. However, the effect that magnetic fields have on neurons has not been well documented in the literature. We have investigated the effect of different orientation of magnetic field generated by TMS coils with a monophasic stimulator on the proliferation rate of N27 neuronal cells cultured in flasks and multi-well plates. The proliferation rate of neurons would increase by exposed horizontally adherent N27 cells to a magnetic field pointing upward through the neuronal proliferation layer compared with the control group. On the other hand, proliferation rate would decrease in cells exposed to a magnetic field pointing downward through the neuronal growth layer compared with the control group. We confirmed results obtained from the Trypan-blue and automatic cell counting methods with those from the CyQuant and MTS cell viability assays. Our findings could have important implications for the preclinical development of TMS treatments of neurological disorders and represents a new method to control the proliferation rate of neuronal cells.

H1.00165 Accurate projected augmented wave (PAW) datasets for rare-earth elements (RE=La-Lu), MEHMET TOPSAKAL, RENATA WENTZCOVITCH, Univ of Minn - Minneapolis — We provide accurate projected augmented wave (PAW) datasets for rare-earth (RE) elements with some suggested Hubbard U values allowing efficient plane-wave calculations. Solid state tests of generated datasets were performed on rare-earth nitrdes. Through density of state (DOS) and equation of state (EoS) comparisons, generated datasets were shown to yield excellent results comparable to highly accurate all-electron full-potential linearized augmented plane-wave+local orbital (FLAPW+LO) calculations. Hubbard U values for trivalent RE ions are determined according to hybrid functional calculations. We believe that these new and open-source PAW datasets will allow further studies on rare-earth materials.

H1.00166 Half-metallic magnetism and the search for better spin valves, KARIN EVERSCHOR-SITTE, MATTHIAS SITTE, ALLAN MACDONALD, Univ of Texas, Austin — We propose a simple formula for the temperature dependence of tunneling magnetoresistance to shed light on ongoing efforts to optimize spin valves. It captures a mechanism in which spin valve performance at finite temperatures is limited by uncorrelated thermal fluctuations of magnetization orientations on opposite sides of a tunnel junction. Furthermore, it directly reveals the advantages for spin-valve optimization by using materials with a high spin polarization of Fermi-level tunneling electrons, and by using materials with high ferromagnetic transition temperatures. We show that our theory is in good agreement with recent experimental studies of the temperature-dependent magnetoresistance of high-quality tunnel junctions with MgO barriers. We conclude that half-metallic ferromagnets can yield better spin-value performance than current elemental transition metal ferromagnet/MgO systems only if their ferromagnetic transition temperatures exceed ~ 900 K.

H1.00167 Nonlinear damping effects in spin torque dynamics of magnetic tunnel junctions, IGOR BARSUKOV, YU-JIN CHEN, HAN KYU LEE, University of California, Irvine, ALEXANDRE CONGALVES, CBPF, Rio de Janeiro, Brazil, JORDAN KATINE, HGST, San Jose, CA, RODRIGO ARIAS, Universidad de Chile, Santiago, Chile, BORIS IVANOV, Academy of Sciences, Kiev, Ukraine, ILYA KRIVOROTOV, University of California, Irvine — Performance of nanoscale spin torque devices such as memory (STT-MRAM) and oscillators critically depends on magnetic relaxation. It is commonly assumed that magnetization dynamics in the presence of spin torque can be understood as simple competition between antidamping arising from spin torque and Gilbert damping of the free layer. However, we have performed nonlocal spin torque measurements in magnetic tunnel junctions (MTJ) and found that the spin torque driven dynamics can strongly depend on the nature of the MTJ nanopillars, for example, whether they are patterned or not. We have performed nonlocal spin torque measurements in magnetic tunnel junctions (MTJ) with in-plane magnetiizations of the free layer and SAF layers by spin torque ferromagnetic resonance. We find an excitation spectrum associated with standing spin waves of the free layer. By varying the external field, the energy of a higher-order spin wave mode increases twice the energy of the main mode. This opens up a nonlinear, resonant relaxation channel, giving rise to a damping increase of approximately 20%. With increasing spin torque provided by a DC bias current, we find that this relaxation channel competes with antidamping in a nonlinear manner, increasingly contributing to and even dominating the relaxation at subcritical currents.

H1.00168 Generation of Spin and Orbital Current in Carbon Nanotubes by Spin-rotation Coupling, MASATO HAMADA, SHUICHI MURAKAMI, Tokyo Institute of Technology — Spin-rotation coupling represents a coupling between the electron spins and mechanical rotations, and may be used for generation of spin currents by mechanical rotation. In our presentation we consider carbon nanotubes, and use one of the phonon modes called a twist mode. This mode gives rise to a rotation around the tube axis and eventually an effective Zeeman field parallel to the axis is generated by spin-rotation coupling. We calculate this generated spin current by solving the spin diffusion equation. We hypothesize that effective orbital magnetic field in the radial direction is generated by the radial magnetic field, and discuss the generated orbital current.

H1.00169 Spin Torque Driven Anti-vortex Dynamics in Patterned Nanomagnets, MUSTAFA METE, AHMET COSKUNER, ALI TAH A HABIBOGlu, VEDET KARAKAS, YELIHA BILAL KALYONCU, AISHA GOKCE, OZHAN OZATAY, Bogazici University, ANNA GIORDANO, MARIO CARPENTIERI, University of Calabria, GIOVANNI FINOCCHIO, University of Messina, FEDERICA CELEGATO, CNR-Institute of Materials for Electronics and Magnetism, PAOLA TIBERTO, Istituto Nazionale di Ricerca Metrologica — Recent studies have shown that unconventional spin configurations in patterned nanomagnets like vortices are potentially applicable to ultrafast memory, rf oscillators and detectors utilizing the static and dynamic response of these structures under external magnetic field and current bias. Due to the difficulties of stabilizing an isolated anti-vortex, there is still much to be explored about the stability and dynamics of this structure. In this study, we report on our investigation of stable anti-vortex formation conditions and the subsequent magnetic field/dc current driven excitations. Permalloy based asteroid geometry devices exhibit anti-vortex nucleation at the center with the application of an in-plane AC demagnetizing field and an out of plane magnetic field. Changes in the stable localization of the spins immediately motivates the characterization of the dynamic response to the application of spin torque from a spin-polarized current as sensed using the anisotropic magnetoresistance effect (AMR). We will present the field and current dependence of the anti-vortex gyration frequency, the bandwidth and power in the asteroid devices. This work allows the evaluation of anti-vortex structures to be utilized in practical on-chip microwave oscillators.
Molecular beam epitaxy (MBE) grown (001)-oriented Cr intriguing compounds in chromium chalcogenides family because of its unusual magnetic and magneto-transport properties. Here we have presented studies of [2] J. Lee et al., Nanotechnology 25, 045604 (2014); T. Tanaka et al., IEEE Transactions on Magnetics 150, 3000503 (2014).

This mechanism behind an unusually large thermal hysteresis ($\Delta T \approx 200$ K) in In$_{1-x}$Mn$_x$Se, which extends up to room temperature, is not completely understood at this time. Typically, thermal hysteresis in most materials has a $\Delta T \approx 20$ K occurring well below room temperature. The host III-V semiconductors themselves are among the best non-linear optical materials.

Hard magnetic phase evolution in nanocrystalline mechanically milled amorphous Pr$_x$Co$_{2-y}$B powder. CAJETAN NLEBEDIM, Ames Laboratory, U.S. Department of Energy, HUSEYIN UCAR, PARANS PARANTHAMAN, Oak Ridge National Laboratory, U.S. Department of Energy, HUSEYIN UCAR, PARANS PARANTHAMAN, Oak Ridge National Laboratory, U.S. Department of Energy — In this work, the evolution of the structural and magnetic properties of Pr$_x$Co$_{2-y}$B with mechanical milling and heat-treatment is presented. Understanding the phase evolution of magnetic properties in hard magnetic materials is crucial for developing high performance permanent magnets. Mechanical alloying/milling offers a traditional and easily deployable approach to synthesizing nanostructured materials. Nevertheless, such can result in amorphization due to high defect density leading to disorder in atomic arrangement. The crystalline phase can be thermally recovered but requires the understanding of how the properties evolve with temperature, in order to achieve useful hard magnetic properties desired for developing permanent magnets. This work shows how properties such as energy product, coercivity, remanent magnetization, saturation magnetization and Curie temperature evolve when PrCoB alloy transitions from amorphous to crystalline phase. The presentation will also include how different levels of amorphization affect the magnetic properties.

Effect of 3d-metal doping on magnetic properties of Fe$_3$Se$_4$. RENAT SABIRIANOV, NABIL AL-AQTA$SH$, Univ of Nebraska - Omaha, DEBASISH SENGUPTA, CFDRC — Fe$_3$Se$_4$ exhibits large magnetocrystalline anisotropy (MAE) and coercivity up 40kOe. The large anisotropy of Fe$_3$Se$_4$ should be accompanied by large magnetization for permanent magnet applications. The magnetization of Fe$_3$Se$_4$ suffers from antiferromagnetic (AFM) superexchange coupling of Fe across the Se planes. We present density functional theory study of the magnetic properties of Fe$_3$Se$_4$ doped with TM (Co, Cr, Ni and Mn). TM ions doped in Fe sites, Fe$_x$M$_{1-x}$(TM)$_y$Se$_4$ (x = 0.5), to examine a potential increase of the magnetization and Curie temperature of Fe$_3$Se$_4$. We performed screening of the exchange interactions and magnetization modifications upon the substitution of Fe by 3d-transition metals at various Fe sites in the Fe$_3$Se$_4$. We find that the doping of Fe$_3$Se$_4$ with 3d-elements does not remove AFM coupling across layers. The increase in the strength of exchange interactions on doping with Cr should increase the Curie temperature of the system. We compare the results of doped alloy with the ones for Fe$_3$Se$_4$ and the theoretical calculations for Fe$_3$Se$_4$. Cr$_3$Te$_4$ has ferromagnetic coupling and magnetization larger than one possible in Fe$_3$Se$_4$. Magnetization per unit cell is 18.24$\mu_B$. MAE of this material is large (MAE = 1.67 MJ/m$^3$).

Effects of TiN buffer layer on microstructure and magnetic anisotropy of FePt thin films. ZHAOGUO QIU, Department of Physics, University of Texas at Arlington; School of Materials Science and Engineering, South China University of Technology, GUANGBING HAN, Department of Physics, University of Texas at Arlington, DECHANG ZENG, School of Materials Science and Engineering, South China University of Technology, J. PING LIU, Department of Physics, University of Texas at Arlington, UNIVERSITY OF TEXAS AT ARLINGTON COLLABORATION, SOUTH CHINA UNIVERSITY OF TECHNOLOGY COLLABORATION — FePt films were deposited at room temperature on TiN buffer layer followed by annealing. The effects of thickness of the TiN layer on the microstructure and magnetic properties of FePt films were investigated. It was found that TiN layer has significant effects on the magnetic anisotropy of the FePt films. The L1$_0$ phase transformation of the FePt films with TiN layer was more completely than that without a TiN layer. The FePt film with TiN (111) layer of 30nm thickness exhibited out-of-plane anisotropy and enhanced ordering parameter. When the thickness of TiN (111) layer further increased, the coercivity tended to decrease. The anisotropy gradually switched from out-of-plane to in-plane when the annealing temperature was increased to 700 degree. The in-plane coercivity was increased to 9.6 kOe when the thickness of randomly oriented TiN layer was 80nm. The high in-plane coercivity may come from the smooth surface morphology of FePt films induced by the small relaxation of internal stress of the thick TiN layer.

Transient Reflectivity of a Low-Dimensional Quantum Magnet. MICHAEL BISHOP, Natl High Magnetic Field Lab, HAIDONG ZOU, University of Tennessee Knoxville, STEPHEN MCGILL, Natl High Magnetic Field Lab — Frustrated, low-dimensional spin systems have drawn wide interest due to their ability to exhibit novel quantum phenomena such as superconductivity, spin-liquid phases, and gapped spin excitations (e.g. Haldane, Spin-Peierls, etc.). SrCu$_2$BO$_2$$_2$, a close experimental realization of the Shastry-Sutherland model, is a one such quantum system in which the singlet ground state is separated from the excited triplet state by an energy gap (35 K) that can be closed by high magnetic fields (>20 T). Furthermore, high magnetic field magnetization measurements reveal an unusual series of plateaus which occur when the magnetic field-tuned density of states becomes commensurate with the lattice periodicity. We have investigated the coupling of singlet and triplet pairing in SCBO to changes in its electronic structure using transient near-infrared reflectivity measurements. We investigated the temperature and magnetic field dependences of the transient reflectivity, and we will discuss these behaviors and their correlation with dimer spin excitations.

Strong effect of low-dimensional Fe-doped cobalt niobate on a strongly ferrimagnetic system. CAJETAN NLEBEDIM, Ames Laboratory, U.S. Department of Energy, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University — In this work, the first investigation of the effect of Fe-doped cobalt niobate (CoNb$_2$O$_6$) imbedded in the matrix of a strongly ferrimagnetic cobalt-iron oxide, is presented. The temperature dependence of the magnetic properties and how they change with variations in the concentration of CoNb$_2$O$_6$ is also presented. CoNb$_2$O$_6$ is a prototypical low-dimensional material belonging to the pyrochlore-type AB$_2$O$_6$ systems. Its low-dimensional magnetic characteristics can help in understanding the magnetic properties of higher order systems. It has been investigated for applications in resonators and capacitors. This work shows that the magnetization of the ferrimagnetic phase is strongly affected by the concentration of Co ions in the low-dimensional phase, below 15 K but changes in coercivity with temperature were predominantly due to the ferrimagnetic phase. The systematic variation in the concentration of both phases and the cation ratio in each phase, enable us to understand the variation of the magnetic properties with temperature. This work provides useful insights into tuning the magnetism in strongly magnetic materials with transition metal AB$_2$O$_6$ systems imbedded in their matrices.

Crystallization behavior and recoilless fraction determination of amorphous and nanocrystalline Fe$_{56}$Co$_{24}$Nb$_{14}$Si$_{3}$Cu$_{1}$ system. MONICA SORESCU, JULIA LIMONGELLI, CHRISTOPHER STROH, Duquesne University, KEVIN BYERLY, Spang — Amorphous ferrimagnetic alloy with the composition Fe$_{56}$Co$_{24}$Nb$_{14}$Si$_{3}$Cu$_{1}$ was obtained by rapid quenching from the melt. Samples cut from the ribbons were annealed at 450, 550, 650 and 750 C in a vacuum furnace. 57Fe Mossbauer spectroscopy was used to identify the phases formed based on the refined values of the hyperfine parameters. The as-quenched specimen was analyzed with a hyperfine magnetic field distribution and corresponded to an in-plane orientation of the magnetic moment directions. The sample annealed at 450 C was found to be in a nanocrystalline state due to observation of the (FeCo)-Si alloy with the DO3 structure. The balance of the composition was represented by a metalloid-enriched amorphous grain boundary phase. In contradistinction to this, the samples annealed at 550-750 C were totally crystallized, but the new phases formed were alpha-(FeCo), (FeCo)$_2$(BSi) and (FeCo)$_3$(BSi). The f factor value dropped from 0.6 to 0.37 for the sample annealed at 450 C, consistent with the onset of nanocrystallization in the system. For the completely crystallized specimens, the f factor maintained values close to 0.5. This indicates that the presence of quenched-in stresses may play a role in the ability of samples to undergo recoilless emission and absorption of gamma rays.
H1.00182 Scaling and memory effects in the reentrant spin glass phase of nanostructured Mn$_2$TaS$_5$. **PAUL SHAND, JOHN DANKER, XUN XIAO, TIM KIDD, LAURA STRAUSS**, University of Northern Iowa — We have investigated the nature of the reentrant spin glass phase of nanostructured Mn-intercalated Ta$_2$S$_5$. The sample consisted of bundles of nanoscale fibers with an average atomic concentration of intercalated Mn of 22%. The sample exhibits a ferromagnetic transition at 74 K and a transition to a cluster glass state at 40 K. The ac susceptibility measured in small dc bias fields near the cluster glass transition exhibited scaling behavior, indicating a magnetic-field dependent crossover to glassy dynamics. At temperatures below the cluster-glass transition, the nature of the dynamics was probed by ac susceptibility and zero-field cooled (ZFC) magnetization measurements. Aging and memory effects were observed, consistent with the non-equilibrium dynamics exhibited by glassy magnetic systems. In particular, we probed the ZFC magnetization memory effect as a function of cooling rate, aging time and magnetic field. The behavior is explained in terms of domain growth within the framework of droplet theory.

H1.00183 Enhanced Tunneling Magneto-resistance in Voltage-controlled CoFeB/MgO Junctions. **HAMD ALMASI, MENG XIU, CHRISTIAN GENTRY, DI YU, TY NEWHOUSE-ILLIGE**, Department of Physics, University of Arizona, Tucson, Arizona 85721, USA, Y.H. LIU, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, USA, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439, USA, S.G.E. TE VELTHUIS, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, USA, WEIGANG WANG, Department of Physics, University of Arizona, Tucson, Arizona 85721, USA — Perpendicular magnetic anisotropy (PMA) at the CoFeB/MgO interface originates from the hybridization of d orbitals of Fe and Co and the Pz orbital of Oxygen. Due to different electronic band structures, the hybridization of the d orbitals of Fe and Co is likely different, therefore contributing unequally to the total PMA. This difference has been probed by an X-ray magnetic circular dichroism (XMCD). The orbital moment of Fe was found to be much larger than that of Co by XMCD. These results demonstrated that Fe contributes most to the PMA at the interface. MTJs with Fe-rich electrodes were fabricated and a substantially larger PMA was achieved. With further optimization in post-growth thermal annealing, we have achieved over 150% TMR in these voltage-controllable CoFeB/MgO MTJs.

3This work was supported in part by NSF (ECCS-1310338) and by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA. Work at ANL was supported by the DOE-BES, MSE and SURF.

H1.00184 Fermi level tuning of highly spin-polarized complex Heusler alloys via materials genome. **SUDIP PANDEY, ABDIEL QUETZ, ANIL ARYAL, MICHAEL FRALAIDE**, Southern IL Univ-Carbondale, TAPAS SAMANTA, Louisiana State University, Baton Rouge, KAMRAN MUNIRA, WILLIAM BUTLER, University of Alabama, Tuscaloosa, IGOR DUBENKO, Southern IL Univ-Carbondale, DIPANJAN MAZUMDAR, SHANE STADLER, Louisiana State University, Baton Rouge, NAUSHAD ALI, Southern IL Univ-Carbondale — Heusler alloys are the largest family of half-metals (100% spin-polarized at the Fermi level) and most promising for spintronic device applications. Many half-metallic full-Heusler alloys are predicted from *ab-initio* calculations, but may or may not be experimentally realizable. Here, we present a novel strategy to utilize these predicted materials to tune the Fermi level of well-known, highly spin-polarized Heusler alloys. We start with the test sample of [Co$_x$MnSi]$_{1-x}$[Co$_x$CrGe]$_{1-x}$, and, by controlling the ratio of these materials, we are able to shift the Fermi level of Co$_x$MnSi. Experimentally, we study the structural and magnetic properties of such Heusler alloys by room temperature X-ray diffraction (XRD) and taking magnetization measurements. It was found that these complex combinations of materials are single phase even though some components (Co$_x$CrGe for example) might not be stable in bulk form alone.

H1.00185 Phase Transitions and Magnetocaloric Effects in GdNi$_2$Mn$_x$. **ANIL ARYAL, ABDIEL QUETZ, SUDIP PANDEY**, Southern IL Univ-Carbondale, TAPAS SAMANTA, Louisiana State University, ICOR DUBENKO, Southern IL Univ-Carbondale, SHANE STADLER, Louisiana State University, NAUSHAD ALI, Southern IL Univ-Carbondale — The structural and magnetic properties of the GdNi$_2$Mn$_x$ system (for $x = 0.5, 0.6, 0.8, 1.0, 1.2, 1.4, 1.5$) have been studied by x-ray diffraction and magnetization measurements. A rhombohedral Pn$\overline{3}$m-type structure was observed in the XRD data. A second order magnetic phase transition from ferromagnetic (FM) to paramagnetic (PM) was found, characterized by a long-range exchange interaction as predicted by mean field theory. A magnetic entropy change of $\Delta S_{M} = 3.1$ J/kg K and 2.9 J/kg K for $\Delta H = 5$ T was observed in the vicinity of the Curie temperature ($T_C$) for GdNi$_2$Mn$_{0.8}$ and GdNi$_2$Mn$_{1.4}$ respectively. In spite of the low values of $\Delta S_{M}$, the relative cooling power (RCP) was found to be 176 J/kg for the GdNi$_2$Mn$_{0.8}$ compound.

2This work was supported by the Office of Basic Energy Sciences, Material Science and Engineering Division of the U.S. Department of Energy (USDOE-DE-FG02-06ER46291 and DE-FG02-13ER46946).

H1.00186 Influence of Ga content on structure and anomalous Hall effect of Fe$_{1-x}$Ga$_x$ thin films on GaSb(100). **THI MINH HAI NGUYEN, ANH TUAN DUONG, YOOLEEMI SHIN, VAN QUANG NGUYEN, SUNGLAE CHO**, Univ of Ulsan, Korea — The Fe-Ga alloys have recently attracted great interests because they exhibited ferromagnetic properties with high Curie temperature, high saturation magnetization and unique magnetoresistive properties which are promising to real applications such as actuators, acoustic sensors, torque sensors, and positioning devices in particular for nano and nanoelectromechanical systems and the integrated magnetostriective devices. Recently, electrical spin injection from Fe$_x$Ga$_{0.5}$ produces an electron spin polarization above 70% on GaAs(001). However, the out-of-plane saturation field and magnetization decrease rapidly with Ga content. The Fe$_{1-x}$Ga$_x$ thin films ($x=0.4, 0.5$) have been grown on GaSb(100) substrate using MBE. An epitaxial film with bcc $\alpha$-Fe crystal structure (A2) was observed in Fe$_{0.5}$Ga$_{0.5}$ film, while an impure Fe$_x$Ga phase with DO$_2$ structure appeared in Fe$_{0.3}$Ga$_{0.7}$ film. The saturated magnetizations are $570$emu/cm$^3$ and $180$emu/cm$^3$ and the coercivities are $170$ and $364$Oe at room temperature for Fe$_{0.5}$Ga$_{0.4}$ and Fe$_{0.5}$Ga$_{0.5}$, respectively. A hysteresis trend in Hall resistance vs. magnetic field was observed for Fe$_{0.5}$Ga$_{0.5}$ film. However, there is a weak hysteresis in Fe$_{0.5}$Ga$_{0.6}$ film.
H1.00187 Magnetic Properties of MnFe2Ga Heusler Alloys — AHMED A. ELGENDY, MOHAMMAD SALEHI-FASHAMI, University of Delaware, DAVID SELLMYER, University of Nebraska, GEORGE HADJIPANAYIS, University of Delaware — Recently, MnFe2Ga Heusler alloys have attracted significant attention due to their interesting physical properties such as large magnetic-field-induced strain, giant magnetocaloric effects, large magnetoresistance, and exchange bias behavior [1-2]. These properties make them promising candidates for various practical applications in the field of smart materials, magnetic refrigeration and spintronics. In this work, we prepared MnFe2Ga alloys by melt-spinning and sputtering and studied the structural and magnetic properties. The melt-spun ribbons were prepared with a wheel speed of 30 m/s. The ribbons were annealed at different temperatures for 1 hour and ground to make fine powders. The ground powders were used to make the target that is used in the cluster gun for the fabrication of MnFe2Ga nanoparticles. The structure of the as-made, annealed ribbons, and powders displayed a face-centered-cubic structure. The microstructure of the as-made ribbons showed equiaxed grains with an average size of 3-5 µm while the annealed ribbons showed bigger grains with small particles covering homogeneously their surface. The magnetic properties show an enhancement of magnetization while coercivity remains the same with values M(3T) and HC of 85 emu/g and 150 Oe, respectively. Transmission electron microscopy with elemental mapping is currently underway to determine the structure and composition of the surface nanoparticles. The work was supported by DOE-BES-DMSE (Grant No. DE-FG02-04ER4612).

H1.00188 Growth and Structural Study of Epitaxial NaMnF3 Thin Films on SrTiO3 — AMIT KC, TRENT JOHNSON, PAVEL BORISOV, DAVID LEDERMAN, WWU — Perovskite fluorides (ABF3) exhibit many interesting phenomena, e.g. dipolar and magnetic long-range order superconductivity, as well as magnetoelastic coupling. Recently, G. C. Garcia-Castro et al. predicted that orthorhombically distorted Pnma NaMnF3 perovskite should have a particularly soft ferroelectric mode, and is expected to demonstrate ferroelectric order regardless of elastic strain, despite the competing antiferrodistortive instability. Thus, in combination with weak ferromagnetic order, this material is expected to be multiferroic. Here, we report the growth of epitaxial NaMnF3 thin films on SrTiO3(100) single crystal substrates via Molecular Beam Epitaxy (MBE). Structural qualities of the films were studied as a function of the substrate temperature and film thickness by the techniques of X-ray diffraction (XRD), in-situ reflection high-energy electron diffraction (RHEED), and atomic force microscopy (AFM). The best films were smooth single phase NaMnF3, grown with four in-plane and two out-of-plane twin domains.

H1.00189 Developing Nuclear Magnetic Resonance Force Microscopy (NMRFM) as an Electronic Probe of Nanoscale Condensed Matter Systems — JEREMY W. PASTER, DANIEL M. TENNANT, SHIRIN MOZAF-FARI, JOHN T. MARKERT, Department of Physics, The University of Texas at Austin — The investigation of NMR via magnetic force coupling in a large field gradient has led to vast improvements in spatial resolution over the conventional inductive method. It has been demonstrated that nanoscale force sensors could be scaled to distinguish a single nuclear spin, assuming experimental noise can be minimized and other specious force signatures stifled. Accordingly, there are many efforts aimed at repurposing NMR for 3D imaging on the atomic scale [1]. In addition to proof-of-concept experiments aimed at separately resolving some of the eventual experimental barriers to atomic resolution, some of us have directed our attention to using NMR to probe the electronic environment in larger condensed matter systems which are not well suited for other scanning probe microscopy techniques and which are prohibitively small for inductive NMR detection. Previously, we proposed using NMRFM to probe superconducting transitions in microcrystals. In parallel, we rewound our investigation of thin films [2] to explore two-dimensional conducting interfaces between oxide interfaces. Presented here is a survey of the technical impediments as well as current strategies for unlocking this exciting potential for NMRFM, as a tool to investigate sub-surface electronic transport in microscale and nanoscale condensed matter systems.

H1.00190 Competition between itinerant ferromagnetism and spin-density wave antiferromagnetism in FeGa — YAN WU, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, 70803, HUIBO CAO, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, 37831, GREGORY MCCANDLES, JULIA CHAN, Department of Chemistry, The University of Texas at Dallas, Richardson, 75080, AMAR KARKI, RONGYING JIN, JOHN DITUSA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, 70803 — The metallic magnetFeGa displays a rich magnetic behavior that includes transitions between a FM ground state to an AFM intermediate state above 360 K as well as incommensurate spin density wave order between these temperatures. Our refinement of the diffraction data has uncovered the existence of a small non-coplanar moment which may be the origin of our previously discovered topological Hall Effect. Presented here is a survey of the technical impediments as well as current strategies for unlocking this exciting potential for NMRFM, as a tool to investigate sub-surface electronic transport in microscale and nanoscale condensed matter systems.

H1.00191 COMPLEX STRUCTURED MATERIALS INCLUDING GRAPHENE —

H1.00192 Thickness dependence of mechanical properties of free-standing graphene oxide papers — TAO GONG, Advanced Institute of Nano Technology (SAIN), Sungkyunkwan University, DO VAN LAM, Nano Mechatronics, Korea University of Science and Technology, SEJEONG WON, Korea Advanced Institute of Science & Technology, RENLONG LIU, School of Mechanical Engineering, SKKU, HWANGBO YUN, Korea Institute of Machinery & Materials, SANGHYUK Kwon, JINSEONG KIM, School of Mechanical Engineering, SKKU, KE SUN, SANGHYUK Kwon, JINSEONG KIM, School of Mechanical Engineering, SKKU, KE SUN, SAIN, SAIMOON LEE, Nano-Mechanical Systems Research Division, KIMM, CHANGGU LEE, Advanced Institute of Nano Technology, and School of Mechanical Engineering, Sungkyunkwan University, GRAPHENE ENGINEERING LAB TEAM, NANOMECHANICS LAB COLLABORATION — We have characterized thickness dependence of mechanical properties, such as Young's modulus, fracture strength, fracture strain and toughness, of graphene oxide papers using tensile and bulge test methods. The GO papers were made from Hummer's method and the fabricated GO paper's thickness varied from 0.1 ~ 100 µm. The measured Young's modulus and fracture strength decreased with increasing thickness ranging from 44.6 ~ 8.5 GPa and 170.2 ~ 40MPa respectively. Through TEM, SEM and AFM characterization, the inner structure and surface morphology such as crack formation and roughness change are the keys to the variation of mechanical properties in the GO papers by the thickness. The thicker GO papers are weaker because it has more manufacturing voids in it that cause it to fail easily and less stiff. Surface wrinkle and residual stress are the mechanism of terraced fracture strain.

H1.00193 ABSTRACT WITHDRAWN —
H1.00194 Transition metals-graphene interaction: the role of the screened van der Waals energy. ALBERTO AMBROSETTI, PIER LUIGI SILVESTRELLI, Università degli Studi di Padova — The interaction of graphene with transition metals is of particular interest for practical applications, which include for instance the efficient production of high-quality graphene. The accurate theoretical description of transition metals-graphene interfaces, however, is a particularly challenging problem due to the complex interplay between van der Waals (vdW) and hybridization effects. Here we apply the DFT/vdW-WF2s method [1], which allows to augment semi-local Density Functional Theory through the introduction of screened vdw interactions. Notably, we find that a reliable modeling of the van der Waals interaction should account for complex metal screening effects, that are due to the combined contributions of the p- and s-like quasi-free electrons, and the more localized d-states. The resulting geometry and energetic properties are in good agreement with experimental data and sophisticates theoretical calculations. Moreover, the Maximally Localized Wannier Functions underlying the DFT/vdW-WF2s method allow for an intuitive understanding of the complex binding mechanism.

H1.00195 Synthesis of carbon nano-structures using organic-molecule intercalated taeniolite layered silicates. TAKAAKI MAEZUMI, NOBORU WADA, Toyo University, Japan — By calcining organic-molecule intercalated taeniolite layered silicates, carbon nano-structures were made between the 2:1 layered silicate sheets. Raman scattering, XRD, TGA and SEM were used to characterize the samples. Large taeniolite crystals (NaLiMg2Si2O10(F) were first prepared by melting appropriate chemicals at high temperatures using a platinum crucible. Then, the taeniolite crystals made were cation-exchanged with Li\textsuperscript{+}, K\textsuperscript{+}, NH\textsubscript{4}\textsuperscript{+}, Ca\textsuperscript{2+} and Mg\textsuperscript{2+} in salt solution. Finally, various organic molecules such as ethylene glycol, pyridine and so on were intercalated into the taeniolite crystals, and calcinated under a N\textsubscript{2} atmosphere at about 1000K. The resulting crystals are usually gray or black. X-ray (001) diffraction spectra which exhibited a sharp G-band peak with a high G-band/D-band ratio indicated that the carbon structures were relatively well crystallized. Cation and organic-molecule dependence on the carbon structures will be discussed. In addition, evidence for stage-2 taeniolite will be presented.

H1.00196 A first principles study on CVD graphene growth on copper surfaces: C-C bonding reactions at graphene edges. NOBUO TAJIMA, TOMOAKI KANEKO, JUN NARA, National Institute for Materials Science, Materials Research Consortium for Energy Efficient Electronic Devices (MARCEED), OHNO TAKAHISA, National Institute for Materials Science, Materials Research Consortium for Energy Efficient Electronic Devices (MARCEED). University of Tokyo — Graphene has attracted considerable research interest owing to its potential applications in electronics and photonics. Here, molecular dynamics simulations are performed to study frictional behaviors of atomic force microscope tip and substrate on graphene. The sub-peaks (i.e., low and high frequency components) in the Raman spectrum of graphene substituted with B, N and BN. The dielectric function and hence the absorption spectrum of single layer graphene sheet have been calculated. Ab-initio calculations based on density functional theory (DFT) have been performed to study the changes in the absorption spectrum of graphene substituted with B, N and BN. The dielectric function and hence the absorption spectrum of single layer graphene sheet have been calculated. The present study can be concluded as, the individual B and N doping does not significantly affect the imaginary dielectric function and hence the absorption spectrum. However, red shift in the absorption towards visible range of the radiation at high doping is found to occur in case of B/N co-doping at high doping concentration. It can be inferred that the graphene can alter the optical properties of graphene to make it reflect in the visible region.

H1.00199 Molecular dynamics simulation of graphene friction: the interplay of tip, graphene and substrate. MINWOONG JOE, CHANGGU LEE, Sungkyunkwan Univ — Graphene is a promising future platform material that could be harnessed in wealth of new applications by virtue of its superior electronic and mechanical properties. Also, atomically thin graphene provides an ideal testbed for investigating fundamental aspects of nanoscale friction. Here, molecular dynamics simulations are performed to study frictional behaviors of atomic force microscope tip on graphene. The effects of tip crystallinity, scan direction (or graphene orientation), and graphene thickness are examined. Puckering hypothesis is revisited with comparison by rigid-supported/suspended graphene cases. Our studies provide broader perspectives into the friction mechanism on graphene.

H1.00200 Effect of Ar Overpressure Ratio on the Growth of Graphene on Cu(111)\textsuperscript{2}. HEIKE GEISLER, SEAMUS MURRAY, SUNY College at Oneonta, ENG WEN ONG, TYLER MOWLL, University at Albany-SUNY, PARUL TYAGI, Global Foundaries, CARL A. VENTRICE, JR., SUNY Polytechnic Institute — A graphene growth study was performed on Cu(111) in a UHV chamber by CVD using ethylene. The sample holder consisted of an oxygen series button heater with Ta heat shields to allow annealing the crystal to 900 °C at pressures as high as 100 mTorr. The crystal structure of the surface was determined using LEED. Growth attempts on the clean Cu(111) surface at ethylene pressures as high as 5 mTorr only resulted in broad diffraction arcs out of phase with the substrate. Therefore, the carbon deposition rate, which depends on the ethylene partial pressure, was increased by using an Ar atmosphere at about 1000K. The resulting crystals were first prepared by melting appropriate chemicals at high temperatures using a platinum crucible. Growth attempts on the clean Cu(111) surface at ethylene pressures as high as 5 mTorr only resulted in broad diffraction arcs out of phase with the substrate. At 50 mTorr of ethylene and no Ar overpressure, broad diffraction arcs were observed in LEED that were ±15° out of phase with the substrate. The carbon deposition rate, which depends on the ethylene partial pressure, has a large effect on the quality of the graphene film.

H1.00201 Origin of the 2450 cm\textsuperscript{-1} peak (G* band) in the Raman spectrum of graphene. RAKRISHNA PODILA, Clemson University, RAHUL RAO, Honda Research Institute US, MEHMET KARAKAYA, JINGYI ZHU, APPARAO RAO, Clemson University, DEPARTMENT OF PHYSICS AND ASTRONOMY, CLEMSON NANOMATERIALS CENTER, CLEMSON UNIVERSITY TEAM, HONDA RESEARCH INSTITUTE TEAM — Here, we report the Raman studies of mechanically exfoliated and chemical vapor deposited (CVD) pristine, ionirradiated, and N-doped graphene (SLG, BLG, and FLG), which identify the origin of the so-called G*-band in graphene ~ 2450 cm\textsuperscript{-1}. Our results show that the asymmetry of the G*-band clearly increases with interlayer stacking, with the high frequency peak exhibiting more sensitivity to intralayer defects compared to the lower component. The sub-peaks (i.e., low and high frequency components) in the G*band were observed to merge with increasing excitation energy and could be understood in terms of the energy dependent scattering rates of photo-excited carriers.
Force-displacement measurements will be presented for these samples. We checked the resistivity values of the graphene sheet which varies with growth conditions. Furthermore, Raman, atomic force microscopy (AFM), I-V and light emitting diodes (OLED) were efforts in progress to replace brittle indium tin oxide (ITO) electrode with a flexible graphene electrode because ITO raw materials are becoming increasingly expensive, and its brittle nature makes it unsuitable for flexible devices. In this work, we grow graphene on Pt and Cu substrates using chemical vapour deposition (CVD) and transferred it to a polymer material (PVA) using lamination technique. We used hydrogen bubbling method for separating graphene from Pt and Cu catalyst to reuse the substrates many times. After successful transfer of graphene on polymer samples, we checked the resistivity values of the graphene sheet which varies with growth conditions. Furthermore, Raman, atomic force microscopy (AFM), I-V and Force-displacement measurements will be presented for these samples.

Non-covalent interactions in the colloidal graphene dispersions, DORSA PARVIZ, Texas A&M Univ, ZINU YU, SRiya DAS, FAHMIDA IRIN, RONALD HEDDEN, Texas Tech Univ, MICAH GREEN, Texas A&M Univ — We have studied stabilization mechanisms in colloidal dispersions of pristine graphene. Electrostatic and steric stabilization in presence of pyrene derivative as dispersants depends on the dispersant concentration, functional groups and the solution pH. The graphene/dispersant yield obtained by pyrene derivatives was considerably higher compared to conventional dispersants. Pyrene-graphene π-π interactions were combined with a designer functional group (polydimethylsiloxane (PDMS)) to synthesize a polymer with dual functionality as dispersant and polymer matrix. The same strategy was applied to produce graphene/polymer and graphene/ PS films. Controllable crumbling of graphene nanosheets was induced through rapid evaporation of dispersion droplets within a spray dryer. Dimensional transition of 2D nanosheets to 3D crumpled particles was directly observed. Multi-faced dimpled morphology of pristine graphene was different than highly wrinkled morphology of crumpled graphene oxide. Changing the compressive forces during drying allowed for controllable folding of the nanosheets, while the unfolding of the redispersed crumpled particles was controlled by the solvent choice.

Surface plasmons in doped graphene excited by the Attenuated Total Reflection technique in the THz regime, F. RAMOS-MENDIETA, Departamento de Investigacion en Fisica, Universidad de Sonora, Hermosillo, Sonora, Mexico., J.A. HERNANDEZ-LOPEZ, M. PALOMINO-OVANDO, Facultad de Ciencias Fisico-Matematicas, Benemerita Universidad Autonoma de Puebla, Puebla, Mexico — Surface plasmons of transverse electric (TE) and transverse magnetic (TM) polarization in doped free-standing graphene are numerically investigated at THz frequencies. For detecting these modes sufficient sensitivity of the prism-based Otto configuration is demonstrated. Complete agreement with the TM dispersion relation is found in doped graphene of Fermi level μ = 0.8 eV, perfect absorption due to wave interference is also observed. On the other hand, TE surface plasmons are special surface vibrations without induced surface charge; they are self-sustained oscillations (unique of graphene) that arise in frequency ranges where the imaginary part of the graphene dynamical conductivity is negative. We found that TE plasmons are excited for angles of incidence very close to the critical angle between prism and air, as predicted from their dispersion relation. Reflection profiles and field intensities of these waves are presented for μ = 0.2, 0.3 eV. This work was supported by SESIC Mexico, Promep Grant FOFM-2008 and by CONACyT, Mexico.

Hetero epitaxial graphene on various substrates, GARY HARRIS, HNF-Howard University, GURPREET KAUT, CRAWFORD TAYLOR, Howard University — Large-scale production of graphene is pivotal for the development of graphene-based electronics. These results focus on the synthesis and characterization of graphene layers. Two methods were used to grow graphene films. First, graphene films were epitaxially grown on silicon carbide substrates by thermal decomposition of SiC at high temperature and low pressure. In-house built reactor consisting of induction furnace was used to form epitaxial graphene for electronic applications. Second, chemical vapor deposition method was used for direct graphene synthesis on 3C-SiC with the use of copper as a catalyst. In thermal CVD process, hydrogen and methane gases were used as precursors. Methane acts as a carbon source and annealing and cooling were done hydrogen environment. Different polytypes of silicon carbide (6H-SiC and 3C-SiC) and their crystal orientations were exploited as substrates to form epitaxial graphene. Hetero epitaxial 3C-SiC epilayer was first deposited on Si substrate using chemical vapor deposition technique in cold wall, low pressure, and horizontal CVD reactor. The reactor temperature, argon pressure, flow rate, temperature of the growth substances (propane, silane, hydrogen and argon) was investigated to control the growth of 3C-SiC and silicon sublimation rate. The resulting graphene films were confirmed using Raman spectroscopy. Further, graphene films have been characterized with the tools of atomic force microscopy (AFM) and scanning electron microscopy (SEM). Mobility, electrical resistivity and carrier density measurements were taken using hall measurements.

Graphene oxide membrane for liquid phase organic molecular separation, RENLONG LIU, GIRISH ARABALE, JINSEON KIM, KE SUN, YONGWOON LEE, CHANGKOOK RYU, CHANGGU LEE, Sungkyunkwan Univ — The selective permeation of organic solvents and water through graphene oxide (GO) membranes has been demonstrated. Water was found to permeate through GO membranes faster than various alcohols. The permeation rates of propanol are about 80 times lower than that of water. Taking advantage of the differences in the permeation rates, we separated water from the alcohol and obtained alcohols with high purity. For ethanol and 1-propanol, binary solutions of the alcohol and water were filtered efficiently to produce alcohols with concentration of about 97%. However, the selectivity of the filtration of methanol is significantly lower than those of the other alcohols. To understand the mechanism we followed the structural changes in the GO membranes by X-Ray diffraction analysis. From the X-ray diffraction results we speculate that the selectivity of the permeation of water and alcohols is closely related to the molecular sizes of the solvents and their polarity. In order to demonstrate the potential applications of this process for the selective removal of water from aqueous organic mixtures, we performed the separation of water from a bio-oil containing 73% of water. The majority of the water was filtered out resulting in a higher purity bio-oil.

Magneto-electronic and optical properties of transition metal dicalcogenide monolayers, YEN-HUNG HO, Physics, National Tsing Hua University, Taiwan, CHIH-WEI CHIU, MING-FA LIN, Physics, National Cheng Kung University, Taiwan, WU-PEI SU, Physics and Texas Center for Superconductivity, University of Houston, TX — A generalized tight-binding model is utilized to study the Landau level spectra of various transition metal dicalcogenide monolayers. The intrinsic spin-orbit coupling effectively gives rise to multiple splitting of Landau levels. With a close inspection of wavefunction characteristics, these levels can be classified into specific groups in terms of their orbital, spin and valley signatures. In the calculation of magneto-absorption spectra, the physical origins of optical selection rules are clearly resolved. Compounds are different from one another in terms of transition energies and appearance of twin peaks. Our numerical results clearly demonstrate the magnetic control of spin and valley charge carriers and provide a basis for future experiments.
H1.00208 Understanding the optical and electronic properties of Ga-doped graphene\textsuperscript{1}. N. C. CREANGE, C. CONSTANTIN, Department of Physics and Astronomy, James Madison University, J.-X. ZHU, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, A.V. BALATSKY, Institute for Materials Science, Los Alamos National Laboratory, J. T. HARALDSEN, Department of Physics and Astronomy, James Madison University — We simulate the optical and electrical responses in gallium-doped graphene, using density functional theory with a local density approximation. We show the effects of impurity doping (0-3.91\%) in the graphene sheet and for each doping percentage the change in electron density, refractive index, and optical conductivity are reported. Here, gallium atoms are placed randomly (using a 5-point average) throughout a 128-atom sheet of graphene. These calculations demonstrate the effects of hole doping due to direct atomic substitution, where we find a disruption in the electron density for small doping levels, which is due to impurity scattering of the electrons. However, there seems to be a doping percentage, above which we have calculated, at which the system transitions to produce metallic or semi-metallic behavior. These calculations are compared to a purely theoretical 100\% sheet for comparison of conductivity. Furthermore, we examine the change in the electronic band structure and density of states, where the introduction of gallium electronic bands produces a shift in the electron bands and dissolves the characteristic Dirac cone within graphene.

H1.00209 Van der Waals Epitaxy of Two-Dimensional $\alpha$-MoO$_3$ Nanosheets using Mica as Grown Templates\textsuperscript{1}. WANG DI, ZHOU YU, WANG MU, PENG RUWEN, XIONG XIANG, Nanjing University — The orthorhombic Molybdenum trioxide, $\alpha$-MoO$_3$, is one kind of graphene-like layered materials. Since the great promise for future electronic and optoelectronic application, this molybdenum-based two-dimensional (2D) layer material has recently attracted much attention. In this work, we report a Van der Waals epitaxy of $\alpha$-MoO$_3$ nanosheets on mica substrate under ambient pressure. This simple physical vapor-phase deposition process is proposed to mediate through the weak Van der Waals interaction between layered $\alpha$-MoO$_3$ and mica substrate. As a result, the grown $\alpha$-MoO$_3$ nanosheets, whose lateral dimension is up to 0.1mm and thickness less than 2.8 nm (about bilayer MoO$_3$ octahedral structure), exhibit defined lattice orientation. From bulk to bilayer, Raman spectra of $\alpha$-MoO$_3$ nanosheets show independent with layered number, which unlike to MoO$_3$ nanosheets. The measurement of electric resistances at room temperature shows the conductance of original $\alpha$-MoO$_3$ nanosheets is already high, moreover, which can be greatly improved by hydrogen doping. Our works indicate that VDWE with mica templates is a simple and feasible strategy to grow high-quality ultrathin $\alpha$-MoO$_3$ nanosheets, which have superiorities for investigating its novel physical properties and potential application in future.

H1.00210 Photoluminescence Quenching in Single-Layer MoS$_2$ via Oxygen Plasma Treatment, NARAE KANG, HARI P. PAUDEL, MICHAEL N. LEUENBERGER, LAURENE TETARD, SAIFUL I. KHONDAKER, NanoScience and Technology Center and Department of Physics, University of Central Florida — Ultrathin two-dimensional (2D) layer transition dichalcogenides (TMDs) families have emerged as a new class of semiconducting candidates due to its intrinsic bandgap. The ability to control the properties of 2D TMDs will become a key in the development of future electronic and optoelectronic applications; however, altering the properties via creating and manipulating defects through external control is not fully investigated yet. In this work, we studied tunable optical properties of single-layer (SL) MoS$_2$, by applying time-dependent oxygen plasma exposure. As the exposure time increased, the strong photoluminescence (PL) of SL MoS$_2$ changed to complete quenching accompanied by clear changes in Raman spectra with gradual reduction of MoS$_2$ peaks as well as an appearance of oxidation-induced peak of Mo-O bonds formation. Using band structure calculations, we found that the creation of Mo-O$_x$ disordered-domains led to plasma-induced direct-to-indirect bandgap transition in defected SL MoS$_2$, resulting in PL quenching with lattice distortion. Our results suggest new opportunities of tailoring and understanding the properties of 2D TMDs.

H1.00211 Scanning Photocurrent Microscopy on Single-Layer CVD MoS$_2$, MoSe$_2$, and Alloys, EDWIN PRECIADO, VELVEL KLEE, DAVID BARROSO, Univ of California - Riverside, KRISTOPHER ERICKSON, Sandia NL, MARK TRIPLETT, Univ of California - Davis, ARIANA NGUYEN, CHRIS LEE, HSU LU, SARAH BOBEK, JOHN MANN, Univ of California - Riverside, ALEC TALIN, FRANCOIS LEONARD, Sandia NL, LUDWIG BARTELS, Univ of California - Riverside — We report scanning photocurrent measurements on CVD-grown single-layer films of MoS$_2$, MoSe$_2$, and MoS$_2$-(1-x)Se$_x$. Measurements of electric resistances at room temperature shows the conductance of original $\alpha$-MoO$_3$ nanosheets is already high, moreover, which can be greatly improved by hydrogen doping. Our works indicate that VDWE with mica templates is a simple and feasible strategy to grow high-quality ultrathin $\alpha$-MoO$_3$ nanosheets, which have superiorities for investigating its novel physical properties and potential application in future.

H1.00212 Lateral hydrogenated graphene/h-BN Tunneling Magnetoresistance Devices, SHAYAN HEMMATIYAN, CRISTIAN CERNOV, ARTEM ABANOV, Department of Physics, Texas A&M University, College Station, Texas 77843-4242, USA, MARCO POLINI, NEST, Istituto Nanoscience - CNR and Scuola Normale Superiore, I-56126 Pisa, Italy, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin, Austin, Texas 78712-1081, USA, JAIRIO SINOVA, Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany — Based upon first principle calculations, we propose a practical heterostructure of hydrogenated graphene on the top of hexagonal-boron nitride, which exhibits ferromagnetic properties and relatively large spin orbit coupling. We propose to use this functional substrate for the lateral spin valve systems.

H1.00213 The Optical Properties of Germanane, PATRICK ODENTHAL, WALID AMAMOU, DANTE O’HARA, Univ of California - Riverside, LUYI YANG, W. D. RICE, SCOTT CROOKER, National Magnetic Field Laboratory, Los Alamos National Laboratory, ROLAND KAWAKAMI, Univ of California - Riverside, The Ohio State University — Hydrogenated 2D germanium, known as germanane (GeH), is predicted to be a direct bandgap semiconductor with high electron mobility (\$10^4$ cm$^2$/Vs) and circularly polarized optical selection rules. However, very little experimental work on the optical properties of germanane has been reported to date. Here, we present temperature-dependent photoluminescence (PL) and photoluminescence excitation spectroscopy (PLE) data on several-layer germanane grown by Molecular Beam Epitaxy (MBE). We observe a broad PL band that is Stokes-shifted by hundreds of meV below the predicted direct bandgap of 1.53 eV. The PL intensity increases by several orders of magnitude upon decreasing the temperature from room temperature to 4K.

H1.00214 Adsorption of Fluorine on single layer MoS$_2$: a first principles study\textsuperscript{1}. CONRAD TROHA, DUY LE, TALAT S. RAHMAN, Department of Physics, University of Central Florida — One of the effective methods for tuning properties of single layer MoS$_2$ is to impose interactions with adsorbates. Using density functional theory, with the optB88-vdW exchange correlation functional, we have studied the adsorption of fluorine atoms on a single layer MoS$_2$. We find that fluorine atoms prefer to adsorb on top of sulfur atoms in $(2 \times 2)$, $(3 \times 3)$, and $(4 \times 4)$ overlayer structures and that at 1/9 ML or smaller coverage, the interactions between fluorine atoms are small and can be ignored. The band structures of the considered overlayer structures suggest that the adsorption of fluorine atoms introduces defect state inside the band-gap of MoS$_2$. This state disperses near the Fermi level in the $(2 \times 2)$ overlayer structure and is dispersionless in the $(3 \times 3)$ or larger overlayer structures.

\textsuperscript{1}Work supported in part by DOE Grant DE-FG02-07ER15842.
Carrier lifetimes are measured at different pump fluences, from which we propose possible carrier relaxation mechanisms. In suspended bulk MoS\textsubscript{2} pressure for different pump fluences. Both a fast and a slow carrier lifetime are acquired in monolayer MoS\textsubscript{2} which makes it a promising candidate for future photonic and field-effect transistor (FET) applications. Our ultrafast measurement utilizes optical 400nm-pump acoustic phonons with a peak frequency around 38GHz are observed. Phonon lifetime and amplitude at different pump fluences have also been investigated.

H1.00223 Hydrogen Molecule Adsorption on a Borophene-Titanium System.

GREGORIO RUIZ-CHAVARRIA, Universidad Autonoma Chapingo — From the synthesis of graphene have developed a wide range of researchs on their use, both theoretical and experimental. So there have been research on graphene-based electronics, but also on issues of energy, particularly hydrogen adsorption on graphene-based systems. Given the potential represented by these structures is very natural to wonder about similar structures, but based in elements near carbon. One of the lines developed very recently consider the boron as the element to build graphene-like structures. Different studies, both theoretical and experimental have been made where the studied structures are graphene type or fullerene, where boron is used in place of carbon. We will use as a starting point the proposed structures by Xiaoao[1] and Tang[2]. This structure is known as the borophene, which in first place will be decorated with titanium and then, this system interact with hydrogen molecule. In our calculation we use functional density theory, atomic pseudopotentials, Born approximation and molecular dynamic.

H1.00224 Transport Properties Across Misoriented Bilayer MoS2 using Ab-initio Calculations.

KUAN ZHOU, SUPENG GE, DARSHANA WICKRAMARATNE, ROGER LAKE, Univ of California - Riverside — Fabrication of electrical and opto-electronic devices with vertically stacked transition metal dichalcogenides (TMDCs), leads to interfaces that are misoriented. Prior experimental and theoretical studies of misorientation in graphene bilayers demonstrated that a few degrees of misorientation is sufficient to decouple the low energy states of the individual layers. Experimental and ab-initio calculations have shown the bandgap of misoriented bilayer MoSremains indirect. The transport properties across the misoriented interface of the bilayer TMDCs is currently unknown. The coherent interlayer transmission across two stacks of MoSis calculated for unrotated and rotated MoSbilateral layers using ab-initio calculations. The energy dependence of the interlayer transmission is analyzed.

H1.00225 Fluorinated graphene as an efficient diffusion barrier in Ge semiconductor devices.

WEI REN, HENG GAO, Shanghai University — We evaluate the efficient diffusion barrier effects of the fluorinated graphene from the first principles. By taking its advantage of impermeability, we discover such monoatomic layer can suppress the formation of the unstable interfacial oxide in Ge-based semiconductor devices. To elucidate the physical mechanism governing this shielding functionality, nudged elastic band method is adopted to calculate the barrier height of one oxygen or one germanium atom penetrating the pristine graphene and fluorinated graphene. The energy of the adsorbed O or Ge atom on different sites of the graphene is calculated, namely three positions on the honeycomb lattice, bridge, hollow, and top. Our results reveal that both the O and Ge atoms adsorbed on the graphene are most stable on the bridge site, followed by the top and hollow sites with higher energies. Different penetration paths of O and Ge atoms are considered, and the calculated values of the energy barriers for both graphene and fluorinated graphene exhibit superior impermeability and hence to hinder diffusion of O and Ge atoms across the graphene and fluorinated graphene. This latter insulating structure is expected to expedite the implementation of germanium as channel materials in next-generation nanoelectronic devices.

H1.00226 Fabrication of graphene field-effect transistor on top of ferroelectric single-crystal substrate.

NAHEE PARK, HAEYONG KANG, YOURACK LEE, JEONG-CYUN KIM, JOONG-CYU KIM, YOOJOO YUN, JEONGMIN PARK, TAESOO KIM, JUNG HO KIM, YOUNG SEON SHIN, YOUNG HEE LEE, DONGSEOK SUH, Center for Integrated Nanostructure Physics (CINAP/IBS) and Dept. of Energy Science (DOES), Sungkyunkwan University — In the analysis of Graphene field-effect transistor, the substrate material which has the direct contact with Graphene layer plays an important in the device performance. In this presentation, we have tested PMN-PT(1-x)Pb(Mg1/3Nb2/3)O3-xPbTiO3 substrate as a gate dielectric of Graphene field-effect transistor. Unlike the case of previously used substrates such as silicon oxide or hexagonal Boron-Nitride(h-BN), the PMN-PT substrate can induce giant amount of surface charge that is directly injected to the attached Graphene layer due to its ferroelectric property. And the hysteresis of polarization versus electric field of PMN-PT can cause the device to show the ferroelectric nonvolatile memory. This latter insulating structure is expected to expedite the implementation of graphene-based devices. To elucidate the physical mechanism governing this shielding functionality, nudged elastic band method is adopted to calculate the barrier height of one oxygen or one germanium atom penetrating the pristine graphene and fluorinated graphene. The energy of the adsorbed O or Ge atom on different sites of the graphene is calculated, namely three positions on the honeycomb lattice, bridge, hollow, and top. Our results reveal that both the O and Ge atoms adsorbed on the graphene are most stable on the bridge site, followed by the top and hollow sites with higher energies. Different penetration paths of O and Ge atoms are considered, and the calculated values of the energy barriers for both graphene and fluorinated graphene exhibit superior impermeability and hence to hinder diffusion of O and Ge atoms across the graphene and fluorinated graphene. H1.00227 Study of quantum capacitance in N doped few layer graphene.

MEHMET KARAKAYA, JINGYI ZHU, RAMAKRISHNA PODILA, Clemson University, ANURAG SRIVASTAVA, IIITM- Gwalior, Madhya Pradesh, India, APPARAO RAO, Clemson University, DEPARTMENT OF PHYSICS AND ASTRONOMY, CLEMSON NANOMATERIALS CENTER, CLEMSON UNIVERSITY TEAM, IIITM- GWALIOR, MADHYA PRADESH, INDIA TEAM — The intrinsically small density of states at the Fermi level in graphene results in a small serial quantum capacitance CQ, which diminishes the total device capacitance value (Curat) in supercapacitors. In this work, we studied CQ of N doped graphene in pyrrolic(N1), graphitic (N2) and pyridinic (N3) configurations. The observed CQ value for sample N1 was significantly different from samples N2 and N3, as predicted by DFT calculations, thus implying that precisely engineered dopant configurations, rather than concentration, can enhance CQ. Such approaches are pivotal for alleviating the existing bottlenecks in both graphene-based device scaling and supercapacitor electrode limitations.

H1.00228 Effect of adsorbed gases on the G and D’ peaks of the Raman spectrum of graphene.

GINA GREENIDGE, JOSHUA HALPERN, Department of Chemistry, Howard University, Washington, DC 20059 — The ability of graphene to function as a gas sensor for polar molecules has been widely investigated by monitoring the conductivity of graphene near the Dirac point. Here we demonstrate that Raman spectroscopy can also monitor the interaction of these molecules with graphene. Using a Raman microscope we observe measureable changes in the width and position of the G peak, and the intensity of the D’ prime peak upon exposure to water vapor (H2O and D2O). The changes are reversible. Baking the material at 350 °C restores the graphene spectrum to its original state. We are investigating the effects of additional gases as well as the relationship of these shifts to the conductivity and the gas-graphene interaction.

H1.00220 Effect of Al$_2$O$_3$ deposition on electronic Transport in Graphene: DFT-NEGF study. TOMOAKI KANEKO, TAKAHIRO OHNO, National Institute for Materials Science, MATERIALS RESEARCH CONSORTIUM FOR EFFICIENT ELECTRONIC DEVICES TEAM, UNIVERSITY OF TOKYO TEAM — In order to screen the charged impurities and to prevent the adsorption of contaminant on graphene, the deposition of high-k materials such as Al$_2$O$_3$ on graphene surface is important issue for graphene device application. Since the interfacial structure of graphene and high-k materials are not identified, theoretical study on the interfacial structure dependence on electronic transport is highly demanded. In this paper, we performed the electronic transport simulation in graphene under Al$_2$O$_3$ based on the density functional theories (DFT) and nonequilibrium Green’s function method (NEGF). We investigated the effect of Al$_2$O$_3$ surface termination on the electronic transport properties. According to the calculation of stability of interfaces and electronic structures, the graphene’s linear band structure is preserved in O$_2$ deficient condition. In O$_2$ rich condition, on the other hand, the graphene’s unique electronic structure is disturbed. These properties are important for the electronic transport in graphene under Al$_2$O$_3$. Graphene shows relatively good transport properties in O$_2$ deficient condition, but transport is considerably suppressed in O$_2$ rich condition. Our results suggest O$_2$ deficient condition is desirable for the device application.

H1.00230 Asymmetric capacitance and ambipolar metal insulator transition in black phosphorus. YU SAIITO, YOSHIHIRO IWASA, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, The University of Tokyo, Japan — Black phosphorus is a van der Waals type semiconducting layered material with a puckered honeycomb structure where each phosphorus atom is covalently bonded with three adjacent phosphorus atoms and has a direct band gap of 0.3 (bulk) - 2 (monolayer) depending on the number of layers [1], which can be promising material for optoelectronics such as photodetectors. In this presentation, by using ionic liquid gating method, we report the ambipolar transistor operation and the field effect controlled ambipolar metal-insulator transition in black phosphorus thin flake. We observed a large modulation of the sheet resistance by more than 4 orders of magnitude in both electron channel and hole channel. These results suggest black phosphorus will be a key material not only for understanding the physics of the conduction channel produced by ionic gating, but also potential functions including formation of p-n junction and therefore lateral tunnel diode utilizing intrinsic narrow band gap.

H1.00231 Graphene/GaN diodes for ultraviolet and visible photodetectors. FANG LIN, SHAOWEN CHEN, JIE MENG, GEOFFREY TSE, XUEWEN FU, FUJUN XU, BO SHEN, ZHIMIN LIAO, DAPENG YU, Peking Univ, NANOLAB TEAM — The Schottky diodes based on graphene/GaAs interface are fabricated and demonstrated for the dual-wavelength photodetection of ultraviolet (UV) and green lights. The physical mechanisms of the photoelectric response of the diodes with different light wavelengths are different. For UV illumination, the photo-generated carriers lower the Schottky barrier and increase the photocurrent. For green light illumination, as the photon energy is smaller than the bandgap of GaN, the hot electrons are accelerated and contribute to the photoresponse leading up to 0.5 A/W photoresponsivities and high external quantum efficiencies of up to ∼90%. Also, these transistors display fast photoresponsive transient times of several ms, providing an alternative route toward multi-wavelength photodetectors.

H1.00232 Exciton Radiative Lifetimes in Layered Transition Metal Dichalcogenides. MAURIZIA PALUMMO, Department of Physics, University of California, Berkeley, CA 94720, USA, MARCO BENARDI, Department of Physics, University of Rome Tor Vergata, Italy, JEFFREY C. GROSSMAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology, MA 02139, USA — Light emission in two-dimensional (2D) transition metal dichalcogenides (TMDs) changes significantly with the number of layers and stacking sequence. While the electronic structure and optical absorption are well understood in 2D-TMDs, much less is known about exciton dynamics and radiative recombination. In this talk, we show first-principles calculations of intrinsic exciton radiative lifetimes at low temperature (4 K) and room temperature (300 K) in TMD monolayers with different chemical formula MX2 (M=W or Mo and X=S or Se), bilayer and bulk MoS2, and in two MX2 hetero-bilayers. Our results elucidate the time scale and microscopic origin of light emission in TMDs, which have been the subjects of recent intense investigation. We find radiative lifetimes of a few ps at low temperature and a few ns at room temperature in the monolayers, and slower radiative recombination in bulk and bilayer than in monolayer MoS2. The MoS2/WS2 and MoSe2/WS2 hetero-bilayers exhibit long-lived (~30 ns at room temperature) inter-layer excitons constituted by electrons localized on the Mo-based and holes on the W-based monolayer; this finding agrees with recent ultrafast spectroscopy experiments. We discuss how the radiative lifetime tunability can be employed to manipulate excitons in 2D-TMDs.

H1.00233 ABSTRACT WITHDRAWN

H1.00234 Photoconductivity spectroscopy of epitaxial germanane devices. ELIZABETH BUSHONG, YUNQIU KELLY LUO, The Ohio State University, JEREMIAH VAN BAREN, WALID AMAMOU, PATRICK O'DENTHAL, DANTE O'HARA, University of California, Riverside, IGOR PINCHUK, JYOTI KATOCH, ADAM AHMED, The Ohio State University, ROLAND KAWAKAMI, The Ohio State University; University of California, Riverside — Germanene, a 2D sheet of hydrogen terminated germanium atoms, has recently generated a great deal of interest. Unlike graphene, which has been the focus of 2D materials for almost a decade, germanene has a direct band gap (~1.5 eV) and strong spin-orbit coupling. Additionally, it is predicted that changing the surface functionalization of germanene will allow tuning of the band gap, which makes it promising for electronic and optoelectronic applications. Here, we investigate wavelength dependent absorption and transport properties of optically excited carriers via photoconductivity on germanane. Samples with thicknesses ranging from several atomic layers up to 250 nm have been studied. We observe an absorption edge as a function of wavelength, as expected for a semiconducting material. There appears to be a small shift to shorter wavelengths for thinner samples. The dependence on intensity and temperature are also investigated, as well as the bias dependence. These results have implications for the use of germanane in future applications.

H1.00235 Planar Nanoscale Capacitors from Laterally Stacked Graphene - Boron Nitride Layers. V. OUNG OZCELİK, ENGIN DURGUN, SALIM CIRACI, Bilkent University — We propose a nanoscale planar capacitor model consisting of laterally stacked two-dimensional insulating BN layers placed between two commensurate and metallic graphene layers. First-principles calculations of structure optimized total energy and self-consistent field potential performed on these nanoscale capacitors for different levels of charging and different number of BN layers indicate the photo-electrical response is not from the area surrounding the electrical contacts. It was found that the three-layer WSe2 FETs display a strong photoresponse, providing an alternative route toward multi-wavelength photodetectors. Using graphene as a transparent electrode, the diodes show a ~ mS photoresponse, using an alternative route toward multi-wavelength photodetectors.

H1.00236 High Photoresponsivity and Extrinsic Quantum Efficiency in Tri-Layer Tunsten Diselenide Phototransistors. ZHENGUANG LU, YOHAN PRADHAN, KOMALAVALLI THIRUVAVUKRASU, JONATHAN LUDWIG, DANIEL RHODES, DMITRY SMIRNOV, LUIS BALICAS, National High Magnetic Field Lab, Florida State University, 1800 E. Paul Dirac Dr. Tallahassee, FL 32310 — We report on the photoresponse properties of three-layer tungsten diselenide field-effect transistors (FETs) fabricated by mechanical exfoliation of bulk crystals on SiO2/substrate connected with Au/Ti contacts. These devices exhibit two-terminal field-effect hole mobilities of about 350 cm2/Vs at 300K increasing up to 500 cm2/Vs at T<50 K. The photoresponse properties were carried out at room temperature using various excitation wavelengths (405nm, 532nm, 670nm). In addition, we mapped photocurrent of this device with a laser spot size considerably smaller than the area of the conducting channel which indicate the photo-electrical response is not from the area surrounding the electrical contacts. It was found that the three-layer WS2 FETs display a strong photocurrent response leading up to 0.5 A/W photoresponsivities and high external quantum efficiencies of up to ~90%. Also, these transistors display fast photoresponsive transient times of several ms.
Study of Charge Density Wave Modulations in the Extended Hubbard Model

SAUMYA BISWAS, ROGER LAKE, University of California Riverside — Charge density wave (CDW) modulations in a two-dimensional lattice are modeled in the mean field approximation using the extended Hubbard Hamiltonian. The electron phonon coupling is included with an on-site interaction term. The effect of coupling strength and Fermi level on the CDW wavelength and amplitude is examined. Periodic and closed boundary conditions are considered. The effect of potential modulation by electrostatic gating on the CDW phase and wavelength is calculated.

Magneto-photoconductivity of atomically thin transition metal dichalcogenides

M. EGÍNGLIGIL, C. ZOU, N. PEIMYÜO, B. CAO, X. SHEN, J. SHANG, C. CONG, T. YU, Nanyang Technological University — Photoinduced effects of two-dimensional (2D) transition metal dichalcogenides (TMDs) are of great interest since the bandgap of these materials corresponds to visible range of spectrum. For instance, in molybdenum disulphide (MoS$_2$) — a 2D semiconductor TMD and a non-centrosymmetric crystal, inherent broken inversion symmetry in monolayers leads to a large spin-orbit interaction which splits the valence band (VB) by 160 meV and gives rise to strong excitonic transitions due to the direct band gap at low energy K and $\bar{K}$ valleys. The same broken inversion symmetry together with time reversal symmetry is responsible for spin-valley coupling in monolayer MoS$_2$ and similar TMDs (such as tungsten disulphide, WS$_2$). Spin-valley coupled band edges in TMDs result in different localization behaviors for different scattering mechanisms. In this work, we present our magneto-photoconductivity studies of mono- and bilayer field-effect transistor devices of MoS$_2$ and WS$_2$, and discuss our results in terms of localization effects.

Lateral MoS$_2$ p-n junctions formed by chemical doping method

WON JONG YOO, MIN SUP CHOI, DESHUN QU, DAELYONG LEE, XIAOCHI LIU, YOUNGDAE JANG, CHANGSI KIM, JUNGJIN RYU, Sungkyunkwan Univ — Interests on transition metal dichalcogenides, especially MoS$_2$, are growing immensely due to its semiconducting nature with visible light range bandgap and strong light absorption property, which can pave the way to replace Si-based electronics and realize flexible and transparent electronics. For more versatile applications and industrialization, however, a proper doping process is required because various devices such as photonics and tunneling devices are composed of p-n junctions. Here, we demonstrated the formation of lateral MoS$_2$ p-n junction by using partially stacked of HBN and p-doping with AuCl$_3$ solution. The fabricated devices showed an ideal rectifying behavior with ideality factor about 1. Under the exposure of monochromatic light, it revealed the properties of conventional p-n diode and also highly efficient photonic properties, showing feasibility to be applied for photovoltaic cells and photodetectors. Furthermore, we fabricated novel tunneling devices with similar device structure where local gates are located under MoS$_2$. Its Fermi level can be effectively controlled by local gate modulation, so that the tunneling current can flow by band-to-band tunneling. This study provides an effective way to realize the practical devices such as photonics and tun

Carbon nanotube networks grown on varios carbon nanostructures: SWCNT, MWCNT and Graphene

YOUNGWOON Kwon, ANVAR ZAKHIDOV, Univ of Texas, Dallas, ALAN G. MACDIARMID NANOTECH INSTITUTE TEAM — Secondary growth of carbon nanotubes (CNT) on the various nanoscale substrates has been performed by using chemical vapor deposition (CVD). Spinnable CNT yarns, single wall CNT sheets and graphene flakes, in NMP have been used as scaffolds for such secondary networks. The CNT yarn drawn from spinnable CNT forest is one of the promising applications of the CNT. However, orientation of the yarn and comparatively high sheet resistance make them harder for applications. Processing secondary CVD grows CNTs on the CNT yarn without any orientation of the secondary grown CNTs. Thus, this decreases the effect of the orientation of the CNT yarn and also decreases sheet resistance since the yarn have more contact each other. This after-treating will make more application possible. Furthermore, since CNT yarn does not make perfect surface and have gap between each bundle, arranging yarns to certain directions allows to growth CNT forest with specific pattern such as check pattern. Also it is possible not to make vertical CNT forest to the substrate by stack multi-layer of CNT yarn so that make felt-like-sheet of CNTs. The secondary growth of CNTs on CNTs, Its Fermi level can be effectively controlled by local gate modulation, so that the tunneling current can flow by band-to-band tunneling. This study provides an effective way to realize the practical devices such as photonics and tun

Structural transition and chemical properties of one dimensional boron ribbons and chains from first principles

MINGJIE LIU, VASILI I. ARTYUKHOV, BORIS I. YAKOBSON, Department of Materials Science and NanoEngineering, Rice University, Houston, TX — The past decade has brought great progress in fabrication and characterization of single-atom chains of carbon (carbyne). Very recently novel atomic chain compositions such as BN and CsI were reported. The extreme and unusual properties of such 1D materials motivate the search for other possible compositions with interesting behaviors. We use first-principles calculations to uncover the rich structural and mechanical properties of 1D boron. While the ground state structure of linear boron is a two-atoms-wide ribbon, tension can unravel it into a single-atom string structure. We analyze the mechanical and electronic properties of these two “phases” and study the thermodynamics and kinetics of transition between them using static first-principles calculations and semiempirical (DFTB) molecular dynamics. The interesting properties of 1D boron nanostructures make them an attractive system for experimental investigations.

H1.00245 Non-covalent functionalization of single wall carbon nanotubes and graphene by a conjugated polymer

JILLIJI JIWIJU, KAUST, PSE Division, Thuwal 23955-6900, Kingdom of Saudi Arabia, AYJAMAL ABDURAHMAN, OĞUZ GÜLSEREN, Department of Physics, Bilkent University, 06800 Ankara, Turkey, UDO SCHWINGENSCHÖGL, KAUST, PSE Division, Thuwal 23955-6900, Kingdom of Saudi Arabia — We report first-principles calculations on the binding of poly[(9,9-bis-(6-bromohexyl)fluorene-2,7-diy1-co-(benzene-1,4-diy1)] to a (8,0) single wall carbon nanotube (SWCNT) and to graphene. Considering different relative orientations of the subsystems, we find for the generalized gradient approximation (GGA) a non-binding state, whereas the local density approximation (LDA) predicts reasonable binding energies. The results coincide after inclusion of van der Waals (vdW) corrections, which demonstrates a weak interaction between the polymer and SWCNT/graphene, mostly of van der Waals type. Accordingly, the density of states shows essentially no hybridization. The physisorption mechanism explains recent experimental observations and suggests that the conjugated polymer can be used for non-covalent functionalization. (Reference: Appl. Phys. Lett. 105, 013103, 2014)

H1.00246 Design of Inorganic Electrides

YUNWEI ZHANG, HUI WANG, YANCHAO WANG, YANMING MA, State Key Lab of Superhard Materials, Jilin University — Electrides, in which all of or part of the valence electrons occupy interstitial regions in the crystal and behave as anions, have been synthesized at ambient or high-pressure conditions [1]. Their loosely bound anionic electrons make electrides good candidates for electro-active materials. Here, we report a developed methodology to systematically design electrides for given chemical systems. The new approach is based on the swarm-intelligence CALYPSO algorithm on structure prediction [2] and requires only the chemical compositions to predict the electrode phases. In contrast to the traditional ground state structure prediction method where the total energy was solely used as the fitness function, we adopted a new fitness function in combination with the first-principles calculation to select the optimal solutions for a description of given chemical systems. The experimentally known electrides have been successfully reproduced. The results suggested that our approach is reliable and can be widely applied into prediction of new electrodes.

H1.00247 Monte Carlo(MC) simulation study on ammonia anchored TON zeolite for carbon dioxide capture

HANSOL WEE, WONBO LEE, Sogang Univ — If zeolites are modified by ammonia, the electronic effect in ammonia resulted in different surface basicity of the zeolite materials. So, ammonia anchored materials show better adsorption rate of CO2 than pure materials at low pressure. MC simulations for CO2 adsorption were performed at 298K. The results show that, at pressure 1000 kpa CO2 loading is 1.404 mol/kg at ammonia anchored TON, and 0.529 mol/kg at pure TON. However, at high pressure, the ammonia effect becomes marginal. Ammonia anchored TON structures may be used to adsorb CO2 more effective than normal TON structure.

H1.00248 Anisotropic mechanical properties of hexagonal SiC sheet: a molecular dynamics study

MING YU, Univ of Louisville, EMILY LIU, duPont Manual High School, CONGYAN ZHANG, Univ of Louisville — The anisotropic mechanical properties of hexagonal SiC sheet have been studied using an efficient quantum mechanics molecular dynamics scheme based on a robust semi-empirical Hamiltonian (referred as SCED-LCAO) [PRB 74, 15540; PHYSE 42, 2]. It was found that the SiC sheet could sustain the heavy load up to about 20 %. In particular, it was found that the SiC sheet also shows large difference in the strain direction. It will quickly crack after 20 % of strain in armchair the direction, but it will be slowly destroyed after 30% in the zigzag direction, indicating the anisotropic nature of the mechanical properties of the SiC sheet. The nominal and 2D membrane stresses will be analyzed, from which we will obtain the 2D Young’s modulus at infinitesimal strain and the third-order (effective nonlinear) elastic modulus for the SiC sheet. The detail results and discussions will be reported in the presentation.

H1.00249 Towards first-principles based prediction of highly accurate electrochemical Pourbaix diagrams

ZHENHUA ZENG, Purdue University, MARIA CHAN, Argonne National Laboratory, JEFF GREELEY, Purdue University — Electrochemical Pourbaix diagrams lie at the heart of aqueous electrochemical processes and are central to the identification of stable phases of metals for processes ranging from electrocatalysis to corrosion. Even though standard DFT calculations are potentially powerful tools for the prediction of such Pourbaix diagrams, inherent errors in the description of strongly-correlated transition metal (hydr)oxides, together with neglect of weak van der Waals (vdW) interactions, has limited the reliability of the predictions for even the simplest bulk systems; corresponding predictions for more complex alloy or surface structures are even more challenging.

Through introduction of a Hubbard U correction, employment of a state-of-the-art van der Waals functional, and use of pure water as a reference state for the calculations, Pourbaix diagrams are systematically calculated. The strong performance is illustrated on a series of bulk transition metal (Mn, Fe, Co and Ni) hydroxide, oxyhydroxide, binary and ternary oxides where the corresponding thermodynamics of oxidation and reduction can be accurately described with standard errors of less than 0.04 eV in comparison with experiment.

H1.00250 Preferential adsorption positions for an adsorbed Li atom on the layered black phosphorus structures

CONGYAN ZHANG, MING YU, University of Louisville — The preferential adsorption positions for an adsorbed Li atom on the layered black phosphorus were determined by mapping out the total energy as a function of its positions on the layered black phosphorus using the density functional theory based method (referred as VASP) [Phys. Rev. B 48, 13115 (1993)]. Various possible adsorption positions including the top of the bridge, the valley, and the interstitial positions of the puckered layers have been studied. It is found that the adsorption energy strongly depends on these positions with different environment. In particular, the most preferential adsorption positions for an adsorbed Li atom are found at the valleys and the interstitials of the puckered layers. The analysis of structural and electronic properties of the black phosphorus layer with the adsorbed Li atom will be discussed.

H1.00251 Ab initio NMR Confirmed Evolutionary Structure Prediction for Organic Molecular Crystals

CONG-HUY PHAM, International School for Advanced Studies (SISSA), Trieste (Italy), EMINE KUCUKBENLI, Ecole Polytechnique federale de Lausanne (EPFL), Lausanne (Switzerland), STEFANO DE GIRONCOLI, International School for Advanced Studies (SISSA), Trieste (Italy) — Ab initio crystal structure prediction, molecular flexibility and difficulties in addressing the dispersion interaction from first principles [1]. We recently implemented vdW-aware density functionals and demonstrated their success in energy ordering of aminoaicid crystals [2]. In this work, we combine this development with the evolutionary structure prediction method where the total energy is selected as the fitness function, we adopted a new fitness function in combination with the first-principles calculation to select the optimal solutions for a description of organic molecular crystals. We thoroughly assess the applicability of evolutionary structure prediction to address such real world problems. We validate the newly predicted structures with ab initio NMR chemical shift data using second-order referencing for an improved comparison with experiments [4].

H1.00252 Exceptional Optoelectronic Properties of Si-related compounds. Bing Huang, Houlong Zhuang, Min Yoong, ORNL, SU-Huai Wei, NREL, Bobby Sumpter, ORNL — The search of new silicon-related functional compounds are of great interests but still very chalenging. In the last few decades, researchers have heavily studied the structural and electronic properties of silicon in order to improve its optical absorption in the visible light range using analyses of metastable silicon phases, silicon-based alloys, and silicon-based superlattices. In this talk, I will present our recent theoretical efforts on searching and designing new silicon phases, from bulk to two-dimensional (2D) silicon, with exceptional optoelectronic properties. Especially, we find that chemically functionalized 2D silicon and silicon alloys could be the best candidates to create efficient thin-film solar absorbers and silicon-based, white-light-emitting diodes, paving the way for new “green” energy applications.

H1.00253 Maximizing the bandgap of BCN nanoribbons. Raissi Baldez, Paulao Piquini, Alex Schmidt, Universidade Federal de Santa Maria, Marcelo Kuroda, Auburn University — Carbon and boron-nitride based compounds share many electronic and structural features. This fact permits mixed carbon-boron-nitride catalysts to be easily synthesized without significant structural changes. Further, the partially ionic character of the boron-nitrogen bonds allow to modulate the electronics of carbon based materials, introducing a variability that can be used to tune the electronic properties according to the boron and nitrogen contents. Graphene and graphene nanoribbons have emerged as promising materials for electronic applications, due to the high mobility of charge carriers. In this work we use the genetic algorithm approach to search for configurations with variable B, C and N contents that maximize the band gap of BCN nanoribbons. Different stoichiometries are analyzed and the structural patterns that lead to the maximal band gaps are presented.

H1.00254 Pd/W(110) as a highly CO tolerant electrocatalyst for hydrogen oxidation: insight from first principles. Nagendra Dhakal, Sergey Stolbov. University of Central Florida — Platinum perfectly catalyzes hydrogen oxidation reaction on the hydrogen fuel cell anodes. However, it has at least two drawbacks: a) it is too expensive; b) it has a low tolerance to CO poisoning. Pt-Ru bi-functional catalysts are more tolerant to CO, but they are still very expensive. In this work, we performed first-principle studies of stability reactivity of M/W(110) structures, where M=Pd,Ru, Au monolayers. All three systems are found to be stable: formation energy of MLs is significantly higher than cohesive energy of the M-elements. The calculated binding energies of H, H2, OH, CO, and H2O were used to obtain the reaction free energies. Analysis of the free energies suggest that Au-W bonding does not activate sufficiently Au monolayer, whereas Ru/W(110) is still too reactive for the CO removal. Meanwhile, Pd/W(110) is found to catalyze hydrogen oxidation and at the same time to be highly tolerant to the CO poisoning. The latter finding is explained by the fact that CO binds much weaker to Pd on W(110) than to Pt, while the OH binding energy is strong enough to ensure CO oxidation. The obtained results are traced to the electronic structure of the systems.

H1.00255 Electronic and vibrational properties of monolayer and bilayer TaSe2. Mack Adrian Dela Cruz, Jia-an Yan, Department of Physics, Astronomy, Geosciences, Towson University — Distinct from MoS2, two-dimensional atomic crystal of tantalum diselenide (TaSe2) is metallic and exhibits charge-density wave (CDW) transitions. Using density-functional theory, we present a first-principles study of the electronic and vibrational properties of monolayer and bilayer TaSe2 without including the CDW-induced structural distortions. For monolayer 1T-TaSe2, the frequencies of the Raman active modes are 159 cm^-1 (E1g) and 226 cm^-1 (A1g), while the Raman-active modes for monolayer 2H-TaSe2 are at 138 cm^-1 (E1g), 214 cm^-1 (E2g), and 241 cm^-1 (A1g). For bilayer TaSe2, different stackings of monolayer 2H-TaSe2 and 1T-TaSe2 phases have been calculated. Electronic band structures and vibrational properties of four energetically favorable configurations will be presented. Finally, the spin-orbit coupling on the structural and electronic properties will also be discussed.

H1.00256 Density Functional Theory Studies of Li-ion interaction with defected group 14 heteronanotubes and nanosheets. Tichakunda Pasipanodya, Prabath Wanaguru, Raymond Atta-Fynn. University of Texas at Arlington — Nanomaterials show significant promise in enhancing Lithium ion (Li-ion) battery properties. Using density functional theory, we study the binding and diffusion of Li on defected nanotubes and nanosheets of silicon carbide (SiC) and silicon germanium (SiGe). Point and extended defects are considered to fully evaluate the influence of defects on the adsorption and diffusion properties. The trends in the adsorption-induced changes in the geometric and electronic properties will be presented. Furthermore, room temperature ab initio molecular dynamics simulations will be carried out to investigate finite temperature effects on the binding mechanisms and electronic structure.

H1.00257 Ferromagnetism in SrTiO3 Single Crystals Induced by Laser irradiation. Srinivasa Rao Singamaneni, Y.F. Lee, J.T. Prater, A.I. Smirnov, J. Narayan, North Carolina State University — SrTiO3 (STO) is diamagnetic in pristine state, important in emerging field of complex oxide electronics. No attention has been paid to explore the magnetic properties of STO crystal upon laser irradiation/annealing. In this presentation, we demonstrate [1-2] that STO single crystals show ferromagnetic order up to 400 K upon KrF (248 nm) laser irradiation. The high resolution x-ray photo emission spectroscopy (XPS) measurements reveal a strong shift of Sr-, Ti- and O-related peaks. X-ray diffraction (XRD) of laser annealed STO does not reveal a signature of either secondary magnetic or amorphous phases. 300 K X-band (∼ 8.95 GHz) angle-dependent electron paramagnetic resonance (EPR) measurements showed no evidence of additional magnetic peaks up on laser irradiation. XPS and EPR data did not provide a strong evidence of Ti3+ formation upon laser annealing. No differences in the visible 300 K Raman spectra of pristine and laser annealed STO are noticed. Interestingly, the magnetic moment is decreased by almost 10-fold upon oxygen annealing of laser annealed STO, inferring that oxygen vacancies play an important role in establishing the observed ferromagnetism.

H1.00258 Cross-over from antiferromagnetic to ferromagnetic interface exchange coupling in epitaxial ferromagnetic oxides. Srinivasa Rao Singamaneni, North Carolina State University, John T. Prater, Army Research Office, Jay Narayan, North Carolina State University — Interface magnetism in La0.7Sr0.3MnO3/SrRuO3 (LSMO/SRO) bilayer (BL) has been the subject of great interest in the recent past owing to interesting physics and potential applications. Through a novel approach [1-3], LSMO (131nm)/SRO (45nm) and LSMO (33nm)/SRO (45nm) bilayers have been epitaxially integrated with Si (100). Notably, in the former sample, positive exchange bias is observed –indication of antiferromagnetic exchange coupling and is found to be absent in the later. Interestingly, in the former sample, the cross-over from antiferromagnetic to ferromagnetic interface coupling is noticed by varying the cooling field. We have verified that the coupling is of magnetic origin, not due to electrostatic interaction by inserting a thin (∼ 10nm) SrTiO3 layer between LSMO and SRO. We believe that the formation of interface domain walls and strong interplay among Zeeman, dipole and exchange energies could play a dominant role. Our results would have important implications for the physics of magnetic exchange coupled systems.

H1.00259 Exchange bias study of epitaxial LSMO/Cr2O3 thin film heterostructures integrated on Si(100) 1. SANDHYARANI PUNUGUAPATI, FRANK HUNTE, JAGDISH NARAYAN, North Carolina State University — FM/AFM exchange bias continues to be an interesting phenomenon from both a fundamental physics and an applications point of view. Recent studies of multiferroic materials have also seen a revival of interest in the magnetoelectric (ME) and antiferromagnetic (AFM) material Cr2O3. The study of exchange bias in heterostructures consisting of ferromagnet (FM) and ME thin films provides an additional mechanism of switching the magnetization of the FM by the application of an electric field. La0.75Sr0.3MnO3 (LSMO) is a FM material with TC above room temperature and shows colossal magnetoresistance. We have studied exchange bias in epitaxial thin film heterostructures of LSMO/Cr2O3 grown on C-YSZ/Si(100) by the PLD technique. We present a detailed structural characterization of the films by XRD (20 and 0) and TEM which confirm that the films were grown epitaxially. The heterostructures exhibited exchange bias as measured by SQUID magnetometry. The effects of LSMO deposition conditions, crystal orientation, temperature, and cooling field on the exchange bias will be discussed.

H1.00260 Probing defect ordering in the Curie-Weiss metallic phase of NaxCoO2 1, BEN-LI YOUNG, P.-Y. CHU, J.Y. JUANG, Dept. of Electrophysics, Natl Chiao Tung Univ., G.I. SHU, F.C. CHOU, Center for Condensed Matter Sciences, National Taiwan Univ. — Single crystals of Na2/3CoO2, Na2/9CoO3, and Na2/7CoO2, which are metallic Curie-Weiss paramagnets, have been investigated by nuclear magnetic resonance (NMR) techniques, in order to clarify the Na atomic ordering among these samples. By analyzing the 23Na and 59Co NMR spectra, we confirm that the Na vacancies arrange orderly in Na2/3CoO1.96 and Na2/7CoO2, so that a superlattice structure is formed due to such Na ordering. In addition, the oxygen vacancies in Na2/3CoO1.98 can be located by the NMR spectra. As for the Na2/3CoO2 single crystal, a long-range Na order is not observed.

H1.00261 Extended X-ray Absorption Fine Structure (EXAFS) Analysis of Vitreous Rare Earth Sodium Phosphates, CHANGHEYON OYO, KANISHKA MARASINGHE, Department of Physics and Astrophysics, University of North Dakota, Grand Forks, ND 58202, CARLO SEGREG, TOMOHIRO SHIBATA, Department of Physics & Center for Synchrotron Radiation Research and Instrumentation, Illinois Institute of Technology, Chicago, IL 60616 — The local structure around rare-earth ions (RE3+) in rare-earth ultraphosphate (REUP) glasses has been studied using RE Li/Na edge (RE = Nd, Er, Dy, and Eu) and K edge (RE = Nd, Pr, Dy, and Eu) extended X-ray absorption fine structure (EXAFS) spectroscopy. (RE2O3)1/3(Na2O)x(P2O5)1-x-y glasses in the compositional range 0<x<0.14 and y+0.3=0.4 were studied. RE-oxygen (RE-O) coordination number decreases from ~10 to ~7.5 with increasing RE-content for Nd, Pr, Eu, and Dy. For Er, RE-O coordination number increases from ~8.7 to ~10 with increasing RE-content. For the first oxygen shell, the RE-O distance ranges between 2.41-2.43 Å, 2.44-2.46 Å, 2.24-2.36 Å, 2.28-2.32 Å, and 2.32-2.36 Å for Nd, Pr, Er, Dy, and EU glasses, respectively. Second shell around RE ions consists of phosphorus atoms, with RE-P distance about 3.0-3.5 Å and coordination number ranging from 1 to 3. The third shell primarily contains oxygen and is at a distance about 4.0-4.1 Å from RE ions.

H1.00262 Extended X-ray Absorption Fine Structure (EXAFS) Analysis of Zirconium-Doped Lithium Silicate / Borate Glass-Ceramics 1, CHANGHEYON OYO, KANISHKA MARASINGHE, Department of Physics and Astrophysics, University of North Dakota, Grand Forks, ND 58202, CARLO SEGREG, Department of Physics & Center for Synchrotron Radiation Research and Instrumentation, Illinois Institute of Technology, Chicago, RICHARD K. BROWN, Materials Science & Engineering, Missouri University of Science & Technology, Rolla, MO 65409 — Results of Zr K-edge Extended X-ray Absorption Fine Structure (EXAFS) spectroscopy analysis of a series of Zr-doped (~3-10 mol% Zr and atomic ratio Li/Si ~0.8) lithium silicate glass ceramics (ZLS) and their parent glasses and a series of Zr-doped (~2-6 mol% Zr and atomic ratio Li/B ~0.25-0.18) lithium borate (ZLB) glasses are presented. Immediate coordination environment of all ZLS samples, i.e. the parent glasses and glass ceramics prepared via two different techniques, are remarkably similar. This observation suggests that zirconium ions may remain in the glass phase during nucleation and crystallization process. In contrast, immediate coordination environment of ZLB glasses appear to change markedly with the Zr concentration. These results also suggest that the structural role of Zr ions in ZLS and ZLB glasses may be significantly different. Details of analysis and results will be presented.

H1.00263 Direct Calculation of Modal Contributions to Thermal Conductivity via Green-Kubo Modal Analysis, WEI LV, ASEGUEN HENRY, Georgia Inst of Tech — In studying the physics of thermal conductivity, tremendous progress has been made over the last 20 years toward understanding lattice thermal conductivity in crystalline solids. However, most of the existing methods are based on “phonon gas model”, which is the dominant paradigm. It essentially treats vibrations as gas particles, which scatter with each other. This analogy works well for crystals, but it hinges on the assumption that particle velocity being well defined. Because amorphous materials and molecules lack periodicity, it is difficult to define the phonon velocity. We used molecular dynamics simulations and a new formalism for calculating the modal contributions to thermal conductivity to study the amorphous materials, a-Si and a-SiO2. It is the first method that is able to obtain the modal details of phonon transport in amorphous materials including full anharmonicity. This method offers a different perspective on phonon-phonon interactions and allows for direct calculation of phonon contributions to thermal conductivity, which will advance our understanding of the phonon transport mechanism and facilitate heat transfer applications in disordered solids and polymers.

H1.00264 Effect of electron-electron interaction on the conductance plateaus of a quantum wire, YONATAN ABRANYOS, GODFREY GUMBS, Hunter College of the City University of New York, MICHAEL PEPPER, Department of Electronic and Electrical Engineering, University College London, DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate, Kirtland Air Force Base — We present a model which is employed to explain recent experimental results for the conductance in a channel within GaAs/AlGaAs heterostructures.

H1.00265 Direct Calculation of Modal Contributions to Thermal Conductivity via Green-Kubo Modal Analysis
H1.00265 Study of optical properties of titania nanotube arrays by FDTD Method. OOMMAN VARGHESE1, PAWANJIIT KAUR2. University of Houston — Finite Difference Time Domain (FDTD) method is a powerful tool for understanding the propagation of electromagnetic waves through materials. The idea behind FDTD technique is to discretize both in time and space, the Maxwell equations with central difference approximations. The study of interaction between the nanostructured semiconductor materials and light is of high relevance in recent years primarily due to the applications of these materials in solar energy conversion process such as solar photovoltaics and solar photocatalysis. Titania nanotube arrays fabricated by anodic oxidation have already attracted considerable attention due to their unique properties and applications. This material has already demonstrated high light scattering and antireflection properties. To obtain a better understanding of nanotube-light interaction we used opti-FDTD software to study the influence of nanotube growth conditions on the optical properties. Simulations were carried out by defining the material properties and using the Lorenz drude model in 380-700nm range. In this presentation we will detail our findings on the correlation between the nanotube array fabrication conditions and its optical properties.

H1.00266 The magneto-optical properties of non-uniform graphene nanoribbons1, HSIEH-CHING CHUNG, MING-FA LIN, Natl Cheng Kung Univ — When synthesizing few-layer graphene nanoribbons (GNRs), non-uniform GNRs would be made simultaneously. Recently, the non-uniform GNRs, which is a stack of two GNRs with unequal widths, have been fabricated by mechanically exfoliated from bulk graphite. Some theoretical predictions have been reported, such as gap opening and transport properties. Under the influence of magnetic fields, magnetic quantization takes place and drastically changes the electronic properties. By tuning the geometric configuration, four categories of magneto-electronic spectra are exhibited. (1) The spectrum is mostly contributed by quasi-Landau levels (QLLs) of monolayer GNRs. (2) The spectrum displays two groups of QLLs, and the non-uniform GNR behaves like a bilayer one. (3) An intermediate category, the spectrum is composite disordered. (4) The spectrum presents the coexistence of monolayer and bilayer spectra. In this work, the magneto-electronic and optical properties for different geometric configurations are given, such as energy dispersions, density of states, wave functions, and magneto-antimony spectra are presented. Furthermore, the transformation between monolayer and bilayer spectra as well as the coexistence of monolayer and bilayer spectra are discussed in detail.

1One of us (Hsien-Ching Chung) thanks Ming-Hui Chung and Su-Ming Chen for financial support. This work was supported in part by the National Science Council of Taiwan under grant number 98-2112-M-006-013-MY4.

H1.00267 Resonance Raman Spectroscopy of Single-Wall Carbon Nanotubes Separated via Aqueous Two-Phase Extraction. J. R. SIMPSON, Towson University, J. A. FAGAN, A. R. HIGHT WALKER, National Institute of Standards & Technology (NIST) — We report resonance Raman Spectroscopy measurements of single-wall carbon nanotube (SWCNT) samples dispersed in aqueous solutions via surfactant wrapping and separated using aqueous two-phase extraction (ATPE) into chirality-enriched semiconducting and metallic SWCNT species. ATPE provides a rapid, robust, and remarkably tunable separation technique that allows isolation of high-purity, individual SWCNT chiralities via modification of the surfactant environment. We report RRS measurements of individual SWCNT species of various chiral index including, semiconductors, armchair and zigzag metals. Raman provides a powerful technique to quantify the metallic SWCNTs in ATPE fractions separated for metallicity. We measure Raman spectra over a wide range of excitation wavelengths from (457 to 850) nm using a series of discrete and continuously tunable laser sources coupled to a triple-grating spectrometer. The spectra reveal Raman-active vibrational modes, including the low-frequency radial breathing mode (RBM) and higher-order modes. SWCNT chiral vectors are determined from Raman spectra, specifically the RBM frequencies and corresponding energy excitation profiles, together with input from theoretical models.

H1.00268 Roles of Multi-Walled Structures in Thermal Transport Properties of Nanotubes. TOMOYUKI HATA, HIROKI KAWAI, RYOTA JONO, KOICHI YAMASHITA, Department of Chemical System Engineering, Graduate School of Engineering, the University of Tokyo — The molecular structures of carbon nanotubes are thought to be deeply related with various physical properties. Understanding the relationship is one of the challenges in designing potential materials. In the research, we theoretically investigated the thermal transport properties of carbon nanotubes, focusing the multi-walled structures. We investigated the thermal conductance of the double-walled carbon nanotubes (DWCNTs) by using the nonequilibrium Green’s function method. It is found that the inter-layer interaction causes the suppression of thermal conductance at low temperature. The analysis of the transmission coefficients revealed that this suppression was attributed to the energy shifts of the normal modes from the synchronized vibrations. The mechanism of such energy shifts is examined by the coupled vibration model with the parameters extracted from our simulations, and we grasp the multi-wall effects on the thermal transport properties of the nanotube structures.

H1.00269 Couloomb excitations for Gapped Graphene in a perpendicular magnetic field. ANDRII IUROV, University of New Mexico and Hunter College, CUNY, GODFREY GUMBS, Hunter College, CUNY and Donostia International Physics Center (DIPC), DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate — We investigate numerically the Coulomb excitations for gapped graphene and other buckled honeycomb lattices (such as silicene and germanene) in the present of a perpendicular magnetic field. The plasmons are calculated within the random phase approximation. The collective excitations in the presence of a perpendicular magnetic field for such gapped systems are shown to be different from those for both intrinsic gapless graphene as well as a standard two-dimensional electron gas. We present a theoretical description of Bernstein modes that appear due to the coupling between inter-Landau-level excitations and plasmons.

H1.00270 Calculating Observable Quantities for the Hofstadter-Type Spectrum of Graphene. LIUBOV ZHEMCHUZHA, Hunter College, CUNY, DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate, GODFREY GUMBS, Hunter College, CUNY and Donostia International Physics Center (DIPC). ANDRII IUROV, CHTM, University of New Mexico and Hunter College CUNY, SANJAY KRISHNA, CHTM, University of New Mexico — We numerically obtain density of states and the conductivity of the periodically modulated graphene in the presence of a perpendicular magnetic field. The collective excitations in the presence of a perpendicular magnetic field for such gapped systems are shown to be different from those for both intrinsic gapless graphene as well as a standard two-dimensional electron gas. We present a theoretical description of Bernstein modes that appear due to the coupling between inter-Landau-level excitations and plasmons.

H1.00271 Dielectric function for doped graphene layer with barium titanate$^1$, MANUEL MARTINEZ RAMOS, ERIC GARCES GARCIA, FERNANDO MAGANA, GERARDO JORGE VAZQUEZ FONSECA, Univ Nacl Autonoma de Mexico — The aim of our study is to calculate the dielectric function for a system formed with a graphene layer doped with barium titanate. Density functional theory, within the local density approximation, plane-waves and pseudopotentials scheme as implemented in Quantum Espresso suite of programs was used. We considered 128 carbon atoms with a barium titanate cluster of 11 molecules as unit cell with periodic conditions. The geometry optimization is achieved. Optimization of structural configuration is performed by relaxation of all atomic positions to minimize their total energies. Band structure, density of states and linear optical response (the imaginary part of dielectric tensor) were calculated.

We thank Dirección General de Asuntos del Personal Académico de la Universidad Nacional Autónoma de México, partial financial support by Grant IN-106514 and we also thank Mictl\' Super-Computing center the technical assistance.

H1.00272 Direct exfoliation of graphene in ionic liquids with aromatic groups$^1$, ROZANA BARI, GEORGE TAMAS, FAHMIHA IRIN, ADELIA AQUINO, EDWARD QUITEVIS, MICAH GREEN, Texas Tech University — The imidazolium cation of the designed and synthesized novel ionic liquids (ILs) having aromatic groups interact non-covalently with graphene. The graphene stabilized by the IL is neither covalently functionalized nor requires the presence of additive stabilizer and such process results in dispersion of pristine graphene. This graphene dispersion is stable against centrifugation and the concentration of the resulting graphene is high as well. It was observed that the ILs are less effective in dispersing graphene if the cation does not have these aromatic groups. The interaction between the cation and the graphene surface plays an important role in the final yield of graphene. The graphene dispersion was characterized by Raman spectroscopy, X-ray Diffraction, and X-ray photoelectron spectroscopy. The experimental observations were compared with the density functional theory (DFT-D3) calculations and the comparison indicated that the experimental observations and the theoretical calculations were in good agreement. These validated theoretical calculations can further be used in future to design and synthesize the ILs in order to optimize the graphene yield without the need for additional experimentation.

H1.00273 Physical Adsorption of noble gases on a monolayer graphene sheet using Grand Canonical Monte Carlo Simulation$^1$, SIDI MAIGA, Student, SILVINA GATICA, Howard University — Adsorption is defined as the attachment of atoms, or molecules of a gas, liquid or dissolved solid onto a surface. Using the Method of Grand Canonical Monte Carlo we computed the adsorption of Ar, Kr, and Xe on a monolayer graphene sheet, at various temperatures for each gas. For each temperature, we compute the adsorption isotherm, Energy-gas-surface and Energy-gas-gas, radial distribution function and structure function. We constructed the phase diagrams for 2D Ar and Kr on graphene.

1 Partial funding for this research was provided by the Partnership for Reduced Dimensional Materials (PRDM), an NSF Partnership for Research and Education in Materials (PREM) (Award Number DMR-1205608) and by the CIQM, NSF Grant No. DMR-1231319

H1.00274 Probing weak localization in chemical vapor deposition graphene with wide constriction by scanning gate microscopy$^1$, CHIASHAIN CHUANG, National Taiwan University, M. MATSUNAGA, Chiba University, FAN-HUNG LIU, TAK-PONG WOO, National Taiwan University, NOBUYUKI AOKI, Chiba University, LI-HUNG LIN, National Chiayi University, Y. OCHIAI, Chiba University, CHI-TE LIANG, National Taiwan University, NATIONAL TAIWAN UNIVERSITY COLLABORATION, CHIBA UNIVERSITY COLLABORATION, NATIONAL CHIAYI UNIVERSITY COLLABORATION — We observe weak localization effect in different wide channels on this disordered CVD graphene device. We also perform the low temperature-scanning gate microscopy experiments under weak localization regime on CVD graphene with wide constriction. The movable local gate can sensitively perturb the total conductance in the wide constriction CVD graphene under magnetic field, suggestive the advantages in the design of graphene-based spintronics.

1 The Aim for the Top University Project by National Taiwan University and Chiba University

H1.00275 Micron scale ballistic Josephson junctions in edge-contacted graphene$^1$, SRIJIT GOSWAMI, VICTOR CALADO, GAURAV NANDA, Delft University of Technology, MATHIAS DIEZ, Leiden University, ANTON AKHMEROV, Delft University of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, LIEN VANDERSYPEN, Delft University of Technology — Despite recent improvements in the electronic quality of graphene, it has remained challenging to make superconducting contacts to it while preserving its high quality. Here, we integrate monolayer graphene encapsulated in hexagonal Boron Nitride with a type-II superconductor (Molybdenum Rhenium – MoRe) via one-dimensional contacts along the edge of the graphene. We observe gate-tunable supercurrents over distances as long as 1.5 $\mu$m. Ballistic, phase coherent transport in these devices causes the switching current to oscillate periodically with the Fermi wave number, thus providing clear evidence of a ballistic Josephson junction. Furthermore, the large critical field of MoRe allows us to resolve several broken symmetry states in the quantum Hall regime, while the MoRe remains superconducting.

H1.00276 Tunable dichroism and optical absorption of graphene by strain engineering$^1$, MAURICE OLIVA-LEYVA, GERARDO G. NAUMIS, Univ Nacl Autonoma de Mexico — Recently, the concept of strain engineering has been experimentally extended to the optical domain. However, strain-induced modifications of optical absorption in graphene have been only quantified in the case of a uniaxial strain. In this sense, our work opens a more rich scenario to explore strained-graphene transparency because it is applicable to an arbitrary uniform strain (e.g., uniaxial, biaxial, and so forth). From the corresponding Dirac-like equation [1], we compute the optical conductivity of graphene under a uniform strain [2,3]. This result allowed us to study the transmittance of linearly polarized light between two media separated by a strained graphene sheet [4]. We analytically characterize the degree of dichroism and the transparency of graphene as a function of an arbitrary uniform strain and the incident polarization. Also, we discuss how measurements of dichroism and transparency for two different polarization directions can be used to determine the magnitude and direction of strain. Ours findings result in very useful tools to tune the graphene absorption by mechanical strain [4]. [1] J. Phys. Rev. B 88, 085430 (2013). [2] J. Phys.: Condens. Matter 26, 125302 (2014). [3] J. Phys.: Condens. Matter 26, 279501 (2014). [4] arXiv: 1411.1376.
H1.00277 Enhanced hot-carrier luminescence in multilayer reduced graphene oxide nanospheres1, QI CHEN, CHUNFENG ZHANG, MIN XIAO, Nanjing Univ — We report a method to promote photoluminescence emission in graphene nanospheres by enhancing carrier scattering instead of directly modifying band structure in multilayer reduced graphene oxide (rGO) nanospheres. We intentionally curl graphene layers to form nanospheres by reducing graphene oxide with spherical polymer templates to manipulate the carrier scattering. These nanospheres produce hot-carrier luminescence with more than ten-fold improvement of emission efficiency as compared to planar nanosheets. With increasing excitation power, hot-carrier luminescence from nanospheres exhibits abnormal spectral redshift with dynamic feature associated to the strengthened electron-phonon coupling. These experimental results can be well understood by considering the screened Coulomb interactions. With increasing carrier density, the reduced screening effect promotes carrier scattering which enhances hot-carrier emission from such multilayer rGO nanospheres. This carrier-scattering scenario is further confirmed by pump-probe measurements.

1This work is supported by the National Basic Research Program of China (2012CB921800, 2013CB932903), the National Science Foundation of China (91233103, 61108001, 11227406 and 11021403), and the Program of International S&T Cooperation (2011DFA01400).

H1.00278 Momentum resolved optical pump-probe spectroscopy in monolayer graphene: An analytical model and measurements1, MAXIM TRUSHIN, ALEXANDER GRUPP, GIANCARLO SOAVI, ARNE BUDWEB, University of Konstanz, Germany, DOMENICO DE FAZIO, ANTONIO LOMBARDO, UGO SASSI, ANDREA C. FERRARI, Cambridge Graphene Centre, University of Cambridge, UK, WOLFGANG BELZIG, ALFRED LEITENSTÖRFER, DANIELE BRIDA, University of Konstanz, Germany — Further development in graphene based photonics and optoelectronics requires fundamental information on the evolution of the strongly non-equilibrium charge carrier distribution created by the light-carrier interaction. Here, we report polarization and fluence dependent ultrafast optical pump-probe spectroscopy of high quality CVD-grown monolayer graphene. An analytical model has been developed and employed to describe the experiments. Graphene offers a unique opportunity to probe the photocarrier occupation, not only at different energies but also in different directions in momentum space applying linearly polarized beams. The latter approach is possible due to the pseudospin-momentum coupling which results in an optical pseudospin-selection rule. Our method allows us to quantify and control the relative contributions of both the strongly non-equilibrium anisotropic occupation and the hot Fermi-Dirac photocarrier distribution to the total differential transmission measured. We provide a conclusive and quantitative evidence for an anisotropic photocarrier occupation with a life-time of about 100 fs and claim that its relaxation towards the isotropic distribution occurs mostly due to optical phonon emission.

H1.00279 Probing the Doping level in Graphene Using Surface Plasmon Resonance,1 KAMRUL ALAM, YANG LI, JIMING BAO, University of Houston — The present work describes an investigation of the electrochemically doped large area CVD grown graphene by using surface plasmon resonance (SPR). As graphene was doped electrochemically its conductance changes based on electron and hole concentration, that have an effect on its permittivity which has influence on the refractive index. We have used SPR angle interrogation scheme, generally known as Kretschmann configuration, to detect this change in refractive index of graphene as a shift in the angle of the SPR curve. To verify our results we have use Raman spectroscopy of the graphene-Au hybrid sample that was used for SPR measurement. Shift in the G peak signifies that graphene is doped electrochemically which is also in agreement with the shift in the angle of the SPR curve.

H1.00280 Strain-Engineering of Graphene Based Topological Quantum Devices1, GINETOM S. DINIZ, MARCOS R. GUASSI, FANYAO QU, Institute of Physics, University of Brasilia, Campus Darcy Ribeiro, DF, 70910-900, Brazil — We have investigated the spin-charge transport in quantum devices based on graphene nanoribbons (GNR). Our calculation is based on the surface Green’s function technique, considering the presence of an uniform uniaxial strain, spin-orbit interactions (SOIs), exchange field and a smooth staggered potential. We propose the use of uniaxial strain as an efficient mechanism to tune the conductance profiles of GNR with different edge terminations. Our results show that distinct behaviors can be achieved: for armchair GNR there is a complete suppression of the conductance close to the Fermi level with the formation of a band gap that depends on the direction and strength of the strain deformation, while for zigzag GNR there is only a small conductance suppression. We also discuss the effects of SOIs and the appearance of spin-resolved conductance oscillations, and the local density of states of these GNR devices in the quantum anomalous Hall regime. Furthermore, we demonstrate that the local density of states show that depending on the smoothness of the staggered potential, the edge states of AGNR can either emerge or be suppressed. These emerging states can be probed by scanning tunneling microscope. Our findings can be potentially used in novel GNR based topological quantum devices.

1Supported by FAP-DF, CNPq and CAPES

H1.00281 Physisorption of Fullerenes in Graphene layers and carbon Nanoribbons1, MONICA PACHECO, PEDRO ORELLANA, Universidad Tecnica Federico Santa Maria, JULIAN CORREA, Universidad de Medellin — The study of nanostructures based on carbon allotropes has captured the interest of the scientific community in the last two decades, due to its great versatility. In such structures a simple change of geometry leads to important changes in their physicochemical properties. In this context it has been studied different carbon allotropes complexes in particular for the development of photovoltaic systems. In this paper we show a study of opto-electronic properties of fullerenes physisorbed on graphene nanoribbons. Our calculations are carried out within the framework of density functional theory (DFT) using the SIESTA package. Our results show that effectively the fullerenes bind both to the layer of graphene as well as to the nanoribbons, with binding energies of about 0.5eV. We find that when the complex is formed, the physical properties of fullerenes, graphene and nanoribbons are preserved and when graphene is functionalized with various fullerenes the electronic spectrum is composed of bands of energy which increases the intensity of the optical absorption spectrum of the complex.

H1.00282 Thermoelectric properties of a trilayer graphene nanoribbon1, PEDRO ORELLANA, NATALIA CORTES, LUIS ROSALES, MONICA PACHECO, Universidad Tecnica Federico Santa Maria, LEONOR CHICO, CSIC — In this work the electronic and thermoelectric properties of a three-layer graphene with AAA stacking type are studied. By using a tight-binding model analytical expressions for the transmission and density of states are obtained. Thermoelectric properties are analyzed by numerical integration and results for thermopower and figure of merit, electronic conductance and thermal conductance are obtained. The results show that the interference effects present in this system, like Fano effect, directly affect the behavior of these thermoelectric properties [1] as well as the Wiedemann-Franz law [2]. There is an enhancement of the thermopower of the system and a violation of the Wiedemann-Franz law in the region of energies close the Fano antiresonances and this has as a consequence an enhancement of the figure of merit of the system.

H1.00283 Polarized spin and valley transport across ferromagnetic silicene junctions V. VARGIADAMIS, P. VASILOPoulos, Concordia University, V. FEssATIDIS, Fordham University — We study ballistic transport of Dirac fermions through silicene barriers, of width d, with an exchange field M and metallic gates above them that provide tunable potentials of height U. Away from the Dirac point (DP) the spin- and valley-resolved conductances, as functions of U, exhibit resonances and close to it a pronounced dip that becomes a transport gap when an appropriate electric field E_0 is applied. The charge conductance g_e of such a junction changes from oscillatory to a monotonically decreasing function of d beyond a critical E_0. This tuning of g_e can be used to realize electric-field-controlled switching. Further, the field M splits each resonance of g_e in two split-lead peaks. The spin polarization p_y of the current near the DP increases with E_0 or M and becomes nearly perfect above certain of their values. We also show that p_y can be inverted either by varying U or by reversing the direction of M. For two barriers there is no splitting in g_e when the fields M are in opposite directions. Most of these phenomena have no analogs in graphene.

H1.00284 Graphene optical-to-thermal converter1, ALEJANDRO MANJAVacas, Rice University, SUKOSIN THONGRATTANASIRI, Kasetsart University, JEAN-JACQUES GREFFET, Institut d’Optique, Univ. Paris Sud, JAVIER GARCIA DE ABANO, ICF-CThe Institute of Photonic Sciences — Infrared plasmons in doped graphene nanostructures produce large optical absorption that can be used for narrow-band thermal light emission at tunable frequencies that strongly depend on the doping charge. By virtue of Kirchhoff’s law, thermal light emission is proportional to the absorption, thus resulting in narrow emission lines associated with the electrically controlled plasmons of heated graphene. Here [1] we show that realistic designs of graphene plasmonic structures can release over 90% of the emission through individual infrared lines with 1% bandwidth. We examine anisotropic graphene structures in which efficient heating can be produced upon optical pumping tuned to a plasmonic absorption resonance situated in the blue region relative to the thermal emission. An incoherent thermal light converter is thus achieved. Our results open a new approach for designing tunable nanoscale infrared light sources.

H1.00285 Evanescent field coupled graphene plasmon waveguide, WON JONG YOO, JAEHWAN KWEON, EUYHEON HWANG, Sungkyunkwan Univ — Surface plasmon polaritons (SPPs) is propagating electron-light coupled oscillation. There had been various methods to excite graphene plasmon such as fabricating graphene nano-ribbon and NSM micro-tip assisted methods. These methods are used for reducing wavelength of incident light and finally matching desired wavelength to propagating light. Here, we propose that evanescent field coupled graphene plasmon is using different media, evanescent field coupling and excited graphene plasmon properties are still unclear. There are severaladvantages in using this coupling method. We can control the direction of propagating plasmon and effectively find plasmon modes. Interestingly, propagating wavelength is scaled to 50 – 100 times depending on its modes and light is confined into extremely small mode size. Also its optical properties can be easily controlled by biasing voltage on its surface. To analyze graphene plasmon, we use random phase analysis (RPA) so as to figure out optical permittivity of graphene, and then we use the FDTD (finite difference time domain) and FDFD (finite difference frequency domain) computational methods so as to theoretically figure out the propagation of graphene plasmon waveguide. Also we will report various plasmon properties of graphene plasmon propagation such

H1.00286 All-Metallic Vertical Transistors Based on Stacked Dirac Materials, YANGYANG WANG1, ZEYUAN NI, School of Physics, Peking University, QIHANG LIU, University of Colorado, RUGE QUHE, School of Physics, Peking University, JIAxin ZHENG, School of Advanced Materials, Peking University, Shenzen Graduate School, MENG YE, DAPENG YU, JUNJIE SHI, JINBO YANG, School of Physics, Peking University, JU LI, Massachusetts Institute of Technology, JING LU, School of Physics, Peking University, COLLABORATIVE INNOVATION CENTER OF QUANTUM MATTER, BEIJING COLLABORATION — All metallic transistor can be fabricated from pristine semimetallic Dirac materials (such as graphene, silicene, and germanene), but the on/off current ratio is very low. In a vertical heterostructure composed by two Dirac materials, the Dirac cones of the two materials survive the weak interlayer van der Waals interaction based on density functional theory method, and electron transport from the Dirac cone of one material to the one of the other material is therefore forbidden without assistance of phonon because of momentum mismatch. First-principles quantum transport simulations of the all-metallic vertical Dirac mater heterostructure devices confirm the existence of a transport gap of over 0.4 eV, accompanied by a switching ratio of over 1014. Such a striking behavior is robust against the relative rotation between the two Dirac materials and can be extended to twisted bilayer graphene. Therefore, all-metallic junction can be a semiconductor and novel avenue is opened up for Dirac material vertical structures in high-performance model predicts. Our results provide new insight to nanoepitaxy of low dimensional structures especially quantum dots and nanoprecipitates.

H1.00287 Identification of the existence of quantum Hall edge-state in graphene field-effect transistor at high temperatures, JOONG GYU KIM, HAEYONG KANG, JEONGMIN PARK, YOOJOO YUN, THUY KIEU TRUONG, JEONG-GYUN KIM, NAHEE PARK, YOURACK LEE, CINAP, IBS, Department of Energy Science, Sungkyunkwan University, HOYEOL YUN, SANG WOOK LEE, School of Physics, Konkuk University, YOUNG HEE LEE, DONGSEOK SUH, CINAP, IBS, Department of Energy Science, Sungkyunkwan University — Quantum Hall effect (QHE) is one of the unique properties of two-dimensional electronic systems providing the universal standard of electrical resistance. Due to edge-state transport features in quantum Hall regime, the two-terminal graphene field-effect transistor (FET) is frequently examined for the study of the integer as well as the fractional QHEs of graphene. In this work, we present a simple method to identify the existence of quantum Hall state in the graphene FET especially at high temperatures. Using the monolayer graphene FET sample with fully broken degeneracy, we modified the equipotential line inside graphene and identified the existence of quantum Hall state in the graphene FET by the addition of extra electrode for the clear identification of the quantum Hall state formation at given temperature and magnetic field. We suggest a simple model to explain the difference and similarity between two-terminal and multi-terminal configurations, including the discussion about the QHE devices connected in series.

H1.00288 SUPERLATTICES, NANOSTRUCTURES AND OTHER ARTIFICIALLY STRUCTURED MATERIALS

H1.00289 Three-Dimensional Lattice Matching for Epitaxially Embedded Nanoparticles BRELON MAY, Peter ANDERSON, RObERTO MYERS, Ohio State Univ — Columbus — Since Mathews-Blakeslee developed a theory of atomic lattice matched thin films, epitaxy has been modeled using only 2D lattice matching conditions between arbitrary films. For a given degree of in-plane lattice mismatch, the theory predicts a critical film thickness above which interface defects form to relax the film strain. Here we present a three-dimensional model to predict the conditions for epitaxially encased nanoparticles, which includes not only the in-plane lattice matching, but also the out-of-plane mismatch. We find that the consideration of the out-of-plane strain, due to the Poisson effect and particle shape change, can greatly alter the critical volume compared to what the Mathews-Blakeslee model predicts. Our results provide new insight to nanoparticle/nanostructures of low dimensional structures especially quantum dots and nanoprecipitates.
H1.00290 A DFT analysis of structure and energetics of Mg/Nb multilayers, ANIL KUMAR, IRENE BEYERLEIN, JIAN WANG, Los Alamos National Laboratory — Magnesium and its alloys, the lightest structural materials, have attracted the attention of the automotive industry for reducing the vehicle’s weight to increase its fuel efficiency. The magnesium phase characterized within Mg/Nb multilayers can adopt either body-centered cubic (bcc-Mg) or hexagonal close packed (hcp-Mg) structure depending on the Mg layer thickness. The bcc-Mg has a similar weight density as the hcp-Mg, but low Young’s modulus, high shear modulus and conventional slip systems of bcc structure. In this work, using first-principles density functional theory, we studied both structural and mechanical properties of bcc-Mg and hcp-Mg in Mg/Nb multilayers as a function of Mg layer thickness and developed a simple theoretical model to predict the structural stability of the bcc-Mg/Nb and hcp-Mg/Nb multilayers. We show that the bcc-Mg/Nb multilayer is energetically favorable when the bcc-Mg layer is less than 4.2 nm. We also studied the mechanism such as inter-mixing of Mg and Nb atoms, creation of vacancies and doping of solute atoms at Mg/Nb interface to minimize the Mg/Nb interface energy. We found that solute atoms such as Zr, Cd and Zn, whose metallic radius are smaller than Mg, can easily segregate at Mg/Nb interface and lower the interface energy.

H1.00291 Layer by Layer Fabrication of 3D Photonic Crystals by Substrate Conformal Imprint Lithography (SCIL) from Titania Nanoparticle Solutions, IRENE HOWELL, University of Massachusetts-Amherst, MARC VERSCHUUREN, Philips Research, ROHIT KOTHARI, JAMES WATKINS, University of Massachusetts-Amherst — We demonstrate a method for fabricating well-aligned, large-area, log-pile 3D photonic crystals. Using 15 nm titania (anatase) nanoparticles dispersed in a mixture of propanediol and methanol, we show that these nanoparticles can be patterned to produce robust, reproducible, 1 µm pitch, 500 nm line-width gratings. By planarizing the grating with an organic UV-curable resin (Norland Optical Adhesive 60), subsequent titania layers can be patterned in the proper orientation, ending with a calcination step to remove the organic resin and create a 3D photonic crystal. This method allows for a photonic stop band in the infrared region, but the limitations in feature size and alignment capability prevent fabrications of a photonic crystal with a band gap at shorter wavelengths. By applying Substrate Conformal Imprint Lithography (SCIL) technology to this method, we can produce 3D photonic crystals with features suitable for a band gap in the visible region. SCIL utilizes a higher modulus PDMS (X-PDMS) to easily achieve sub-500 nm features. Additionally, the alignment method, involving box-in-box and Moire patterns, enables reproducible, precise alignment of sequential layers within 5 nm.

H1.00292 Phonon Scattering at Nanoparticles in LuAs:InGaAs Nanocomposites, FENG HE, RODOLFO SALAS, SETH ROBERT BANK, YAGUO WANG, University of Texas System — Nanocomposites of III-V semiconductors embedded with semi-metallic rare earth nanoparticles grown with molecular beam epitaxy (MBE) have been widely using in optoelectrics and thermoelectrics. Manipulating the growth parameters, e.g. growth rate, particle concentration and surfactant, will allow precise control of electronic and thermal transport properties for specific applications. Fundamental understanding of phonon scattering at nanoparticles in these nanocomposites under various growth conditions is not only scientifically important, but also will facilitate the material growth and device design. We have investigated the ultrafast dynamics of coherent acoustic phonons (CAP) in LuAs:InGaAs nanocomposites with standard two-color femtosecond pump-probe technique. Phonon frequency and life time have been measured in samples grown under different conditions. Our results show that CAP lifetime increases with increasing LuAs deposition, as well as pump fluences. We have also studied the influences of growth rate and surfactant on phonon lifetime.

H1.00293 Study of plasmon-polariton in 1-D photonic crystals of dielectric and magneto optical layers under the effects of external magnetic field in the polar configuration, JAIME ANDRES GIRON SEDAS, EDWIN MONCADA VILLA, Solid State Group, NELSON PORRAS MONTENEGRO, Solid State Group, Universidad del valle, Cali, Colombia — Photonic crystals (PCs) are artificial microstructures with a periodic spatial distribution of the dielectric constant, which enables us to manipulate and control the photons. In particular, the existence of photonic bands in the energy spectrum as well as photonic band gaps, forbidden frequency regions for light propagation have permitted quite a number of analogies with physical properties of semiconductor, this provides a perfect base for the construction of great varieties of photonic devices. In this case the superlattice is composed of alternating slabs of two materials, one is a dielectric, and the other is magneto-optical material. The interaction between plasma excitations and the electromagnetic radiation in the frequency region around null electric and magnetic responses in these arrangements, it gives a requisite for the existence of longitudinal waves, results in the excitation of modes that couple plasmons and optical fields. Those are known as Plasmon- Polaritons. We analyze the magneto-optic response of this PCs and the Plasmon-Polaritons behavior when an external magnetic field is placed in the growth direction of the structure using the scattering matrix approach for anisotropic layer stacks.

H1.00294 Electronic structure of palladium and gold-palladium nano clusters, both free and supported on MgO(100), CARLOS QUINTANAR, REYNA CABALLERO, RAUL ESPEJEL, ELIZABETH CHAVIRA, Universidad Autónoma de México, MAGALI UGALDE, FRANCISCO ESPINOZA, Centro de Investigación en Materiales Avanzados, SAMUEL TRICKEY, University of Florida — Ideal (or model) metal nano-clusters, both free and supported on MgO(100), have been the subject of numerous experimental studies. This work probes the characteristics of non-ideal systems. For that, palladium nano clusters first were synthesized using a sol-gel-microwave method. A mono-phase of metallic Pd was obtained as corroborated by thermo gravimetric analysis, x-ray powder diffraction, scanning electron microscopy, and high resolution transmission electron microscopy studies (HRTEM). Among the HRTEM micro-graphs we found an almost planar nano-surface (facet) with only forty six atoms (Pd_{46}). From that micro-graph we obtained the coordinates of the atoms in the Pd_{46} nano-surface. With those coordinates, we did a DFT study of the Pd_{46} nano-surface electronic structure. From the Pd_{46} nano-surface, nine and eighteen Pd atoms were chosen to build A and Pd_{18} clusters respectively. Starting from a near-planar Au8 cluster, the Au_{8} geometry was optimized over the fixed Pd_{9} and Pd_{18} nano-surfaces, charge transfer was determined with charge density difference analysis (CDDA) and Fukui analysis was done and. The Au_{8}Pd_{9} cluster was positioned on an MgO(100) surface with an O vacancy and charge transfer was determined with CDDA

H1.00295 Formation of finite layer MoS2 using ultrasonic agitation, TIM KIDD, RUI HE, ERIC CLAUSEN, University of Northern Iowa — We have developed a process in which finite layer MoS2 can be produced using ultrasonic agitation. The material shows optical properties consistent with an average layer thickness of less than five layers. The process uses ultrasonic agitation of MoS2 in an suspension using isopropanol. Interestingly, side products involving carbon nanoparticles are also produced. These side products are quite small, and become the dominant material when using a centrifuge to separate out the smallest particles. These carbon nanoparticle side products appear to include nanometer scale particles as well as materials with sizes consistent with fullerenes and graphene with nanoscale lateral dimensions. This process appears to represent a novel method for producing finite layer MoS2 and some forms of carbon nanoparticles using a relatively simple method.
**H1.00297 Bimodal Distribution of Cadmium Selenide Quantum Dots Prepared by UV-Photolithography**
AJITH DESILVA, University of West Georgia, M. KAVEH, University of Cincinnati, RAGHVEER R. GADIPALLI, SARAH G. MARTINO, University of West Georgia, H.P. WAGNER, University of Cincinnati — We employed wet chemical and UV photolithography methods to synthesize CdSe quantum dots (QDs). The dynamics of excitons in the QDs were studied using temperature-dependent photoluminescence (PL) ranging from 17 to 300 K. The inhomogeneous shape and size of the QDs led to an asymmetric PL spectrum at 17 K, which was approximately decomposed into two Gaussian emission bands, with peak energies at 2.182 and 2.299 eV and widths of 40 and 30 meV, respectively. These bands are attributed to the existence of two CdSe QDs ensembles with differently sized QDs. With increasing temperature the PL intensities of both bands weakly change, the PL yield of the larger QDs being higher at low temperatures while the smaller QDs show the stronger emission at higher temperatures. The stronger PL quenching of the larger QDs with increasing temperature is tentatively assigned to a higher density of defects at the grain boundary compared with small QDs. TEM images of the sample revealed a distribution of nanoparticles with average sizes around 10 and 15 nm supporting the existence of a bimodal QD distribution.

**H1.00298 AlN nanowire growth using InN crystalline powders by physical vapor deposition**
NAOTO KENMOCHI, HIRAKU OTA, MIKKA NISHITANI-GAMO, NOBORU WADA, Toyo University, Japan — AlN nanowires were grown by heating an evacuated quartz ampule which contained InN crystalline powders and an Al substrate at 1300 °C. Both EDX and Raman spectroscopy yielded that the nanowires should be crystalline InN. Almost all the nanowires exhibited a spherical head at the end, implying that the growth mechanism might be the vapor-liquid-solid (VLS) growth. The diameter typically varied from 30 nm to 500 nm, while the length could be several microns meters long. The nanowire growth was quite significant on the Al substrate close to the InN powder source. When the samples were kept at high temperatures for a longer time, both the spherical heads and nanowires were found to be thicker. The detailed mechanism for the growth and the growth conditions will be discussed.

**H1.00300 Metallic Nanoparticles Confined in Silica Matrices**
SHIN-HYUN KANG, MIN-JAE LEE, JEEUN LEE, JUN-KI LEE, SUNG-MIN CHOI, KAIST — Metallic nanoparticles are widely studied due to their noble properties based on the high surface area. In order to increase the practical applications, the nanoparticles should be protected from thermal damage which can cause agglomeration. A facile way of protecting metallic nanoparticles with a silica matrix is presented. Metal nanoparticles are synthesized and functionalized in aqueous solution, and are collectively confined in a silica matrix which is thermally stable enough to protect the embedded nanoparticles. The structure and morphology are investigated by small angle scattering measurements, transmission electron microscopy and scanning electron microscopy. Physical and chemical properties of the heterogeneous system would be presented, too.

**H1.00301 Synthesis, Electrical and Structural Properties of $Mg_x Pb_{(1-x)}TiO_3$ produced by mecanosynthesis**
JALDAIR NOBREGA, ARIANO DE GIOVANNI RODRIGUES, MICHELVENET ZAMBRANO, PAULO SERGIO SILVA JUNIOR, JULIO CESAR CAMILO ALBORNIZDIAZ, PAULO SERGIO PIZANI, Univ Fed de Sao Carlos, ESPETROSCOPIA RAMAN EM MATERIAIS NANOESTRUTURADOS COLLABORATION, METALURGIA FISICA E DE ESPECTROSCOPIA MECANICA COLLABORATION — Over last decades scientific studies about ceramic materials based in metallic oxides have pointed to an increasing wide range of applications. Among them, $PbTiO_3$ has been significantly applied to electronic components and optoelectronics devices. Another example can be found in the microwave dielectric $MgTiO_3$, which has been used on the production of devices. The development of a compound that combines the physical properties of these well-known materials aims the achievement of a new type of ceramics presenting distinctive applications. We report the production of $Mg_x Pb_{(1-x)}TiO_3$ by means of mecanosynthesis techniques. Electric measurements were carried out in order to verify the dielectric behavior of the system. By analyzing the signatures of characteristic phases of $PbTiO_3$ and $MgTiO_3$ in X-Ray diffractograms, we could confirm that the stoichiometry of our solid solutions could be controlled by properly adjusting the amounts of the oxides used as precursors. The Raman spectroscopy analysis showed us the behavior of the soft mode, typical of ferroelectric, which is present in all composition. By determining the dependence of its energy with temperature variation, we could estimate the temperatures of phase transition for each composition.

**H1.00302 Synthesis and Characterization of Magnetic Nanoparticle Assemblies**
MIN-JAE LEE, HO-HYUN KIM, SHIN-HYUN KANG, SUNG-MIN CHOI, KAIST — The superstructure of magnetic nanoparticles, which may provide new properties, are of great interest for various potential applications as well as its own scientific merits. Despite recent advances in the fabrication and characterization of magnetic nanoparticle structures, it remains challenges to exploit for controllable organization of magnetic nanoparticles at the nanoscale. Here, we will report the synthesis and functionalization of monodisperse magnetic nanoparticles and their self-assembled structure.
H1.00303 Microwave metal-dielectric metamaterials with magnetic inclusions, BRITTANY BATES, BRANDON ALLISON, Norfolk State Univ, NICOLE GREENE, Cornell Univ, NATALIA NOGINHOVA, Norfolk State Univ — Use of natural magnetic materials as a constituent part of metamaterials is attractive as they provide a possibility to tune material parameters at microwave range and THz frequency with external magnetic fields. Metal-dielectric multilayers and wire arrays structures were fabricated using both ferromagnetic and nonmagnetic metals. These structures were studied in free space microwave propagation experiment. We show that a cube of such a metamaterial operates as a focusing lens and a polarizer with a possibility of tuning with external magnetic field.

H1.00304 Magnetic, structural and adsorption properties for methylene blue of PAA/MnFe$_2$O$_4$ nanocomposite, WEI WANG, ZUI DING, School of Science, Beijing University of Chemical Technology, Beijing 100029, China. J. PING LIU, Department of Physics, University of Texas at Arlington, Arlington, TX 76019, USA — PAA/MnFe$_2$O$_4$ nanocomposite was fabricated by a hydrothermal procedure and ultrasonic wave-assisted method. The morphology of the synthesized MnFe$_2$O$_4$ ferronanocrystals reached 74.6 nm. FTIR spectrum confirms the coating of PAA on the surface of MnFe$_2$O$_4$ ferronanocrystals. Here, the PAA coating does not lead to a deterioration in magnetic performance. Moreover, the PAA/MnFe$_2$O$_4$ nanocomposites were applied to remove Methylene Blue (MB) from wastewater. Compared with the nanoparticles without coating, the PAA coating significantly enhanced the adsorption capacity of MB onto MnFe$_2$O$_4$ magnetic nanoparticles, where a rapid and efficient removal of MB was observed. The research suggests that as-synthesized PAA/ MnFe$_2$O$_4$ nanocomposites have promising and potential applications in water treatment for removal of dyes.

H1.00305 Synthesis and Characterization of Au@Pd@Au core-shell nanostructures, ALEJANDRA LONDONO-CALDERON, J. JESUS VELAZQUEZ-SALAZAR, MIGUEL JOSE YACAMAN, Univ of Texas, San Antonio — In this work we present a systematic study on the synthesis of (Au@Pd)@Au nanostructures by a seed mediated method in aqueous solution. In the first step, single crystal Au octahedra nanoparticles are used as seeds to promote a metallic Au core-shell nanocube of 40 nm in size. The growth mechanism of successive Au layers on the Au@Pd nanocube and the crystallinity on the Au/Pd and Pd/Au interfaces are studied by the use of Scanning Electron Microscopy (SEM), High Resolution Transmission Electron Microscopy (HTEM) and Scanning Transmission Electron Microscopy (STEM). A transformation from cubes to truncated polyhedrons is observed by Electron Tomography in the reconstruction of the surface.

H1.00306 Real-space and nanoscopic observation of phase transition behaviors of VO$_2$ thin films using Kelvin probe force microscopy, DONG-WOOK KIM, AHRUM SOHN, Department of Physics, Ewha Womans University, TERUO KANKI, KOUTARO SAKAI, HIDEKAZU TANAKA, The Institute of Scientific and Industrial Research, Osaka University — VO$_2$ undergoes a metal-insulator transition (MIT) and a tetragonal-monoclinic structural phase transition (SPT) near room temperature. We carry out transport and KPFM (Kelvin probe force microscopy) measurements on epitaxial VO$_2$/TiO$_2$ thin films simultaneously in the temperature range of 285-330 K. The samples have large grains due to very small lattice mismatch, which allows us to study inherent nature of the phase transition in quasi-2D VO$_2$ system. The sample’s work function decreases from 5.1 eV to 4.9 eV, while spanning the transition temperature. The work function maps can clearly reveal coexistence of the two distinct states at the intermediate temperature range, well explained by the 2D percolation theory.

H1.00307 Plasmon Excitations for a Coulomb-coupled Graphene Layer and a Thick Conductor, GODFREY GUMBS, Hunter College, CUNY and Donostia International Physics Center (DIPC), ANDRII IUROV, University of New Mexico and Hunter college, CUNY, NORMAN HORNING, Stevens Institute of Technology — Self-consistent field theory is used to obtain the plasmon dispersion relation of monolayer graphene which is Coulomb coupled to a thick conductor. We calculate numerically the undamped plasmon excitation spectrum for arbitrary wave number. For gapped graphene, both the low-frequency (acoustic) and high frequency (surface) plasmons may lie within the opening within the particle-hole region. Additionally, we obtain plasmon excitations in a region of the frequency-wave vector space which does not exist for free standing gapped graphene.

H1.00308 One and two dimensional shock waves of light, RICARDO FERRO, HASANUZZAMAN RAHMAN, GERMAN KOLMAKOV, MANAS KULKARNI, New York City College of Technology, City University of New York — By using numerical simulations for the dynamics of an exciton polaron condensate in an optical microcavity, we demonstrate that strongly nonlinear, spatially localized waves can be formed during the propagation of the condensate perturbations. We show that at the terminal stage of their evolution, the condensate density waves acquire the universal shape of a shock wave, which is similar to that known from a classical rarefied interacting gas dynamics. Since the exciton-polaritons in the condensate include photons as their constituents, this allows new possibilities for multiphoton quantum imaging and measuring the phase coherence of a two-dimensional condensate. We also discuss the effects of the scattering of the photon on the shock structure of the defects in the cavity, and the effects of the phase coherence during mutual scattering of two and more shock waves.

H1.00309 A quantum interferometer for studies of the exciton and polaron drag effects, ANDY HE, ROMAN YA. KEZERASHVILI, GERMAN V. KOLMAKOV, New York City College of Technology CUNY — Recently, the drag effects of excitons and cavity polaron condensates by an electric current running in a quantum well embedded in a cavity were theoretically predicted. These effects provide one with a useful tool to control the exciton and photons propagation in optical integrated circuits by external electric signals. Applications of such the drag effects in the design of semiconductor- and graphene-based devices for optical computing have recently been discussed in the literature. In our report, we propose a setup suitable for the studies of the exciton and polaronate condensate drag effects based on self-interference of a split condensate in the presence of the driving current. By numerically simulating an output signal of a ring-shaped interferometer, we determine the range of parameters, at which the exciton and polaron drag effects in a microcavity can be observed and utilized in optical nanodevices.

H1.00310 Dynamics of self-trapped excitons in layered Pb$_1$−$X$Cd$_X$I$_2$ semiconductors, YURIY GNATENKO, ANATOLII BUKIVSKII, YURIY PIYATINSKI, Institute of Physics of National Academy of Science of Ukraine — The dynamics of self-trapped excitons, localized on stretched Pb-I chemical bonds which are formed on PbI$_2$ nanocluster surface was investigated. It should be noted that these nanoclusters are naturally formed in Pb$_2$I$_4$ nanocrystals. To study the excited state properties and the excited state lifetime of Pb$_2$I$_4$ nanocrystals, the measurements of photoluminescence (PL) spectra and kinetics of PL intensity decay for those materials were performed at T=300 K. The kinetic dependences were obtained for the maximum of PL band (600 nm) and for its short-wave shoulder (550 nm). It was shown that PL decay kinetics is well approximated by stretched exponential function $I(t) = I_0 \exp(-t/\tau_d)$. Obtained values of $\tau_d$ and $\beta$ for $X = 0.5$ are equal about 800 ns and 0.76 at 600 nm. At 550 nm these values are 700 ns and 0.74, respectively. Similarly for $X = 0.7$ these values correspond about 800 ns and 0.80 at 600 nm. At 550 nm they are 800 ns and 0.82. Application of the Inverse Laplace Transformation (ILT) to our experimental data gave us an opportunity to estimate the probability density function of self-trapped exciton state lifetimes for Pb$_2$I$_4$ nanocrystals ($X = 0.3, 0.5$ and $0.7$). The position of the maximum of $F(\tau)$ gives us the average decay time $<\tau>$ which is about 1250 ns which significantly differs from $\tau_d$ which is about 800 ns (for $X = 0.5$ nm). This complex dynamics of excitons is associated with strong heterogeneity of the investigated system.
Half-metallicity in a BiFeO$_3$/La$_2$Sr$_{1/3}$MnO$_3$ heterostructure: A first-principles study

JILILI JIUWER, KAUST, PSE Division, Thuwal 23955-6900, Kingdom of Saudi Arabia, ULRICH ECKERN, Institut für Physik, Universität Augsburg, 86135 Augsburg, Germany, UDO SCHWINGENSCHLOGL, KAUST, PSE Division, Thuwal 23955-6900, Kingdom of Saudi Arabia — We present first principles results for the electronic, magnetic, and optical properties of the BiFeO$_3$/La$_2$Sr$_{1/3}$MnO$_3$ heterostructure as obtained by spin polarized calculations using density functional theory. The electronic states of the heterostructure are compared to those of the bulk compounds. Structural relaxation turns out to have only a minor impact on the chemical bonding, even though the oxygen octahedra in La$_2$Sr$_{1/3}$MnO$_3$ develop some distortions due to the interface strain. While a small charge transfer affects the heterointerfaces, our results demonstrate that the half-metallic character of La$_2$Sr$_{1/3}$MnO$_3$ is fully maintained. (Reference: EPL, 102, 67009, 2013)

Magnetoresistance Anomalies in LaAlO$_3$/SrTiO$_3$(110): Fingerprints of Flat $d_{yz}/d_{xz}$ Band along [1-10] zigzag chain

HAIJJIAO MA, NUSNNI-NanoCore and Physics Department, NUS, QINFANG ZHANG, Yancheng Institute of Technology, YANG LIU, Laboratoire SPMS, Ecole Centrale Paris, ANIL ANNADI, NUSNNI-NanoCore, NUS, WENXIONG ZHOU, NUSNNI-NanoCore and Physics Department, NUS, THIRUMALAI VENKY VENKATESAN, ARIANDO ARIANDO, NUSNNI-NanoCore and Physics Department, NUS, ARIANDO RESEARCH GROUP COLLABORATION$^1$. Q. F. ZHANG TEAM, Y. LIU TEAM — We report novel features in the in-plane magnetoresistance (MR) of anisotropic two-dimensional electron gas (2DEG) at LaAlO$_3$/SrTiO$_3$(110) heterostructures, which unveil the existence of a flat band in this system. One of the striking features is an anisotropy of the MR with a "$d_{yz}/d_{xz}$"-wave"-like symmetry upon rotating the magnetic field $H$ within [110] plane at low temperature, which is caused by the existence of flat $d_{yz}/d_{xz}$ band. Combining with theoretical and experimental results, we confirm that a flat $d_{yz}/d_{xz}$ band formed along [1-10] Ti-O-Ti zigzag chain direction which might be very interesting for searching for topological state such as in superconducting regime.

Double perovskites nanoparticles: synthesis and magnetic properties (La$_2$NiMnO$_6$ vs La$_3$CoMnO$_6$)

YUANBING MAO, University of Texas-Pan American — Nanoparticles of double perovskite La$_2$BMnO$_6$ (B = Ni and Co) with average particle size of about 50 nm were successfully prepared using a facile, environmentally friendly, scalable molten-salt synthesis method at 700 °C in air. Their structural and morphological properties were characterized by X-ray diffraction and transmission electron microscopy. Their magnetic properties were evaluated using dc magnetic M–T and M–H, and ac magnetic susceptibility versus frequency, temperature, and field for the first time. The magnetic properties of these double perovskite nanoparticles indicate that they possess very different magnetic behaviors. The following results will be discussed: (i) field-cooled and zero-field-cooled magnetization curves become divergent at their Curie temperature, i.e. 275 K and 210 K for La$_2$NiMnO$_6$(LNMO) and La$_2$CoMnO$_6$(LCMO) nanoparticles, respectively, which are almost unchanged from their bulk and thin film counterparts. (ii) ac susceptibility indicates that the LNMO particles are much more complex structurally and may have anti-site defects or a second-phase with a different transition temperature. For a better understanding of the nature of the magnetic state and dynamic characteristics observed here for these LNMO and LCMO nanoparticles, further detailed studies are needed.

Possible Mechanisms in Atomic Force Microscope-Induced Nano-Oxidation Lithography (negative AFM tip case) in La$_{0.67}$Ba$_{0.33}$MnO$_{3-\delta}$ Thin Films on SrTiO$_3$(001)

GRACE YONG, Towson University, WILLIAM VANDERLINDE, Laboratory for Physical Sciences, E. KEVIN TANYI, Norfolk University, DAVID SCHAEPFER, CHRISTOPHER STUMPF, RAJESWARI M. KOLAGANI, Towson University — In this paper, we present possible microscopic mechanisms for La$_{0.67}$Ba$_{0.33}$MnO$_{3-\delta}$ films that have been nano-oxidized by an AFM tip that is negatively biased with respect the sample. Further analysis of comparative EDS elemental profile for unmodified film versus AFM negative tip-modified films yield fresh insights. We can qualitatively explain many of the observations with electrochemical half reactions, electrochemical migration and electromigration.

Heat flow and $\delta$-layers in Si nanowires

MEHMET B. BEBEK, T. MICHAEL GIBBONS, STEFAN K. ESTREICHER, Texas Tech — Modern semiconductor growth techniques allow the use of heterostructures in semiconductor devices such as $\delta$-layers or superlattices, and their behavior regarding heat flow is generating considerable interest. However, there is no fully 'first-principles' theoretical description of the interactions between heat flow and the interface between two dissimilar materials. In this contribution, we present the result of ongoing ab-initio, microcanonical, non-equilibrium MD simulations on Si/Ge or Si/C interfaces in a Si nanowire. We show that the 'spatially-localized vibrational modes' (SLMs) associated with the interface trap incoming bulk phonons for lengths of time ranging from dozens of hundreds of periods of oscillation. Then, the trapped phonons decay into lower frequency bulk phonons. This decay depends on the availability of receiving modes on either side of the interface rather than on the origin of the incoming flow of heat.

Local electrical imaging of tetragonal domains and field-induced ferroelectric domains in conducting SrTiO$_3$

HAIJJIAO MA, Nanocore and Physics D. NUS, S. SCHARINGER, U. Tuebingen, S.W. ZENG, Nanocore, M. LANGE, A. STHR, U. Tuebingen, Z. HUANG, T. VENKATESAN, Nanocore, R. KLEINER, U. Tuebingen, M. COEY, Nanocore, D. KOELLE, U. Tuebingen, A. ARIANDO, Nanocore and Physics D., NUS, NANO CORE TEAM, DIETER TEAM — We report intrinsic electric mapping of local conductivity due to tetragonal domains and twin boundaries in conducting STO. Multidomains and stripe monodomains were observed in different samples at low temperatures. The distribution of these domains changes on thermal cycling above the STO cubic-to-tetragonal structural transition temperature and on electric field gating. The domains split into narrower domains when we applied side gating and we attributed this to field-induced ferroelectric domain. Twin boundaries with different orientations were observed. Angles of these domain boundaries in (110) plane are 0, 55, 125 and 145 degrees. These angles were calculated from the intersection of twin planes and substrate cutting orientation. The domains split into narrower domain segments when T decreases below 30 K.

H1.00317 Probing the mechanical properties and microstructure of WS$_2$/Si$_x$Ge$_{1-x}$ multiphase thermoelectric material by nanoindentation, electron and focused ion beam microscopy methods

, FRANCISCO SOLA, FREDERICK DYNYS, NASA Glenn Res Ctr — Silicon germanium (SiGe) thermoelectric (TE) alloys have been traditionally used in radioisotope thermoelectric generators (RTG) NASA applications. While RTG applications is the main driver of our current research, we are exploring other applications in the energy harvesting arena. There is still a need to improve the TE figure of merit (ZT) of SiGe based TE alloys and we have been working on ways to improve it by incorporating tungsten di-silicide (WS$_2$) phases in to the matrix by directional solidification process. Considerable efforts have been focused until now in microstructural engineering methods that can lead to ZT improvement by microstructure optimization. Although critical for the previous mentioned applications, work pertinent to the mechanical integrity of WS$_2$/SiGe based TE materials is lacking. In this presentation, we report local mechanical properties (hardness, modulus and fracture toughness) and microstructure of WS$_2$/SiGe multiphase thermoelectric material by nanoindentation, scanning electron microscopy, focused ion beam and transmission electron microscopy methods.

H1.00318 Nanophononic metamaterial: Thermal conductivity reduction by dispersion-resonance hybridization

, MAHMOUD I. HUSSEIN, HOSSEIN HONARVAR, LINA YANG, University of Colorado Boulder — Engineered manipulation of phonons can yield beneficial thermal properties in semiconducting materials. One pivotal application relates to thermoelectric materials, or the concept of converting energy in the form of heat into electricity and vice-versa. The ability to use nanostructuring to reduce the thermal conductivity without negatively impacting the power factor provides a promising avenue for achieving high values of the thermoelectric energy conversion figure-of-merit, ZT. In this work, we propose a novel nanostructured material configuration that seeks to achieve this goal. Termed “nanophononic metamaterial,” the configuration is based on a silicon thin-film with a periodic array of pillars erected on one or two of the free surfaces. The pillars qualitatively alter the base thin-film phonon spectrum due to a hybridization mechanism between their local resonances and the underlying atomic lattice dispersion. Using lattice dynamics calculations and molecular dynamics simulations, we predict a drop in the thermal conductivity to as low as 50% of the corresponding uniform thin-film value despite the fact that the pillars add more phonon modes to the spectrum.

H1.00319 Magneto-thermoelectric effects in the two-dimensional electron gas of a HgTe quantum well due to THz laser heating by cyclotron resonance absorption

, MEHDI PAKMEHR, University at Buffalo, the State University of New York, CHRISTOPH BRUJÈNE, HARTMUT BUHMANN, LAURENS MOLENKAMP, University of Wuerzburg, BRUCE MCCOMBE, University at Buffalo, the State University of New York — HgTe quantum wells (QWs) have shown a number of interesting phenomena over the past 20 years, most recently the first two-dimensional topological insulating state. We have studied thermoelectric photovoltages of 2D electrons in a 6.1 nm wide HgTe quantum well induced by cyclotron resonance absorption (B = 2 - 5 T) of a focused THz laser beam. We have estimated thermo-power coefficients by detailed analysis of the beam profile at the sample surface and the photovoltage signals developed across various contacts of a large Hall bar structure at a bath temperature of 1.6 K. We obtain reasonable values of the magneto-thermopower coefficients.

1Work at UB was supported by NSF DMR 1008138 and the Office of the Provost, and at the University of Wuerzburg by DARPA MESO contract N6001-11-1-4105, by DFG grant HA5893/4-1 within SPP 1666 and the Leibnitz Program, and the EU ERC-AG Program (Project 3-TOP.

H1.00320 The concept of position-dependent mass and its consideration in the study of a particle subjected to different types of potential

, MARTIN MOLINAR-TABARES, Organismo de Cuenca Noroeste, Comisión Nacional del Agua, LAMBERTO CASTRO-ARCE, CARLOS FIGUEROA-NAVARRO, Departamento de Física e Ingeniería, Unidad Regional Sur, Universidad de Sonora, JULIO CAMPOS-GARCÍA, Departamento de Ciencias de la Salud, Departamento Cajeme, Universidad de Sonora — We present a study where is used the concept of position-dependent mass for a particle subjected to three kind of potential: infinite quantum potential well, harmonic oscillator potential and step potential. We solve the time-independent Schrödinger equation for each potential, considering different forms for the functional dependence of the mass respect the position. We obtain the ground state energy, the energies of some excited states and the corresponding probability densities. We make a comparison of the results with those that we would obtain if we consider an average mass for the particle.

H1.00321 Investigation of insulator-sandwich MCBJ device for single molecule detection

, AKIHIDE ARIMA, MAKUSU TSUTSUI, MASATERU TANIGUCHI, The Institute of Scientific and Industrial Research, Osaka University — Mechanically controllable break junction (MCBJ) is one of the most excellent methods for accurate measurements of electron transport through single molecules because of its stability and repeatability of nanometer-scale gap distance. This method has been recently used to investigate electric conductivity of individual nucleotides in an aqueous solution. However, traditional bare electrodes of MCBJ substrate generates unexpected ionic current, which deteriorates S/N ratio and distorts accurate control of the gap distance. To solve this problem, we report the novel MCBJ device architecture. Briefly, we covered whole junctions with insulating material. This insulator-sandwich architecture enables us to suppress such ionic current and flesh electrode surface can be used in measurement because the gap distance is controlled with a high accuracy. To solve this problem, we report the novel MCBJ device architecture. Briefly, we covered whole junctions with insulating material. This insulator-sandwich architecture enables us to suppress such ionic current and flesh electrode surface can be used in measurement because the gap distance is controlled with a high accuracy.

H1.00322 Sheared graphene: Electronic properties shaped by a mechanical instability

, ANDRES CONCHA, School of Engineering and Sciences, Adolfo Ibáñez University, Santiago, Chile., SHENGFENG CHENG, Department of Physics, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, USA, LUCIAN COVACI, Department Fysica, Universiteit Antwerpen, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium, L. MAHADEVAN, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138,USA. — We explore the effects of shearing graphene ribbons on its geometry, and electronic properties. Inspired by macroscopic experiments, we show that spontaneous patterns appear when their local resonances and the underlying atomic lattice dispersion. Using lattice dynamics calculations and molecular dynamics simulations, we predict a drop in the thermal conductivity to as low as 50% of the corresponding uniform thin-film value despite the fact that the pillars add more phonon modes to the spectrum.

H1.00323 Ultrafast optical measurements of surface waves on a patterned layered nanostructure

BRIAN DALY, MATTEO BJORNSSON, AINE CONNOLLY, SUSHANT MAHAT, BRYAN RACHMILOWITZ, Vassar College, GEORGE ANTONELLI, Antonelli Research & Technology LLC, ALAN MYERS, HUI-JAE YOO, KANWAL SINGH, SEAN KING, Illinois Corporate — We report ultrafast optical pump-probe measurements of 12 – 54 GHz surface acoustic waves (SAWs) on patterned layered nanostructures. These very high frequency SAWs were generated and detected on the following patterned film stack: 25 nm physically vapor deposited TiN / 180 nm porous PECVD-grown a-SiO\(_2\)C:H dielectric / 12 nm non-porous PECVD-grown a-SiO\(_2\)C:H etch-stop / 100 nm CVD-grown a-SiO\(_2\) / Si (100) substrate. The TiN layer was dry plasma etched to form lines of rectangular cross section with pitches of 420 nm, 250 nm, 180 nm, and 168 nm and the lines were oriented parallel to the [110] direction on the wafer surface. The absorption of ultrafast pulses from a Ti:sapphire oscillator operating at 800 nm generated SAWs that were detected by time-delayed probe pulses from the same oscillator via a reflectivity change (ΔR). In each of the four cases the SAW frequency increased with decreasing pitch, but not in a linear way as had been seen in previous experiments of this sort. By comparing the results with mechanical simulations, we present evidence for the detection of different types of SAWs in each case, including Rayleigh-like waves, Sezawa waves, and leaky or radiative waves.

H1.00324 Molecular Dynamics Simulations of Surface Acoustic Waves on Patterned Layered Nanostructures

MATTEO BJORNSSON, AINE CONNOLLY, SUSHANT MAHAT, BRYAN RACHMILOWITZ, BRIAN DALY, Vassar College, GEORGE ANTONELLI, Antonelli Research & Technology LLC, ALAN MYERS, KANWAL SINGH, MIU-JAE YOO, SEAN KING, Illinois Corporation — We report coarse-grained molecular dynamics (MD) simulations of surface acoustic waves on patterned layered nanostructures. The simulations were designed for comparison with samples consisting of the following patterned film stack: 25 nm physically vapor deposited TiN / 180 nm porous PECVD-grown a-SiO\(_2\)C:H / 12 nm non-porous PECVD-grown a-SiO\(_2\)C:H etch-stop / 100 nm CVD-grown a-SiO\(_2\) / Si (100) substrate. Ultrafast optical experiments on these samples have detected high frequency surface waves in the range of 10s of GHz. The MD simulation demonstrates the presence of strongly excited modes at frequencies that closely match those found in the experiments. Moreover, the simulation predicts that the type of surface wave mode detected should change depending on the pitch. For larger pitch, Rayleigh-like waves are predicted, but for smaller pitch, Sezawa waves (surface waves with properties similar to free plate modes of the thin films) are predicted. The MD simulation also demonstrates the cutoff wavelength for the Sezawa modes, as is reflected in the experimental results and as is also predicted by isotropic elastic calculations of the surface modes of a thin film on an infinite substrate.

H1.00325 Evolution of interface and surface structures of ZnO/Al2O3 multilayers upon rapid thermal annealing

H.H. LIU, Q.Y. CHEN, C.F. CHANG, W.C. HSIEH, National Sun Yat-Sen University, Taiwan, P.V. WADEKAR, University of Liverpool, UK, H.C. HUANG, National Sun Yat-Sen University, Taiwan, H.H. LIAO, Enli Technology Inc., Taiwan, H.W. SEO, University of Arkansas, USA, W.K. CHU, University of Houston, USA — ZnO/Al2O3 multilayers were deposited on sapphires by atomic layer deposition at 85°C. This low substrate temperature ensures good interface smoothness useful for study of interfacial reaction or interdiffusion. Our study aimed at the effects of rapid thermal annealing at different annealing temperatures and times and P\(_{O_2}\)/P\(_{N_2}\). RHEED patterns during and post deposition of Ag thin films on MgO, Al2O3, STO and Si. HR-TEM and electron diffraction were carried out to correlate the microstructures and interfacial alignments as a result of the reactions.

H1.00326 Pulsed Laser Deposition and Reflection High-Energy Electron Diffraction studies of epitaxial long range order, nano- and microstructured Ag thin films grown on MgO, Al2O3, STO and Si

DANIEL VELAZQUEZ, RACHEL SEIBERT, HAMDI MAN, LINDA SPENTZOURIS, JEFF TERRY, Illinois Institute of Technology — Pulsed Laser Deposition is a state-of-the-art technique that allows for the fine tunability of the deposition rate, highly uniform and epitaxial sample growth, the ability to introduce partial pressures of gases into the experimental chamber for growth of complex materials without interfering with the energy source (laser). Pulsed Laser Deposition is a state-of-the-art technique that allows for the fine tunability of the deposition rate, highly uniform and epitaxial sample growth, the ability to introduce partial pressures of gases into the experimental chamber for growth of complex materials without interfering with the energy source (laser). An auxiliary in situ technique for growth monitoring, Reflection High-Energy Electron Diffraction, is a powerful characterization tool for predictability of the surface physical structure both, qualitatively and quantitatively. RHEED patterns during and post deposition of Ag thin films on MgO, Al2O3, Si and STO substrates are presented and their interpretations are compared with surface imaging techniques (SEM, STM) to evidence the usefulness of the technique.

H1.00327 Indeterminate form 0/0 and tunneling in double quantum wells

IGOR FILIKHIN, BRANISLAV VL AHOC, North Carolina Central University — We study single electron tunneling between localized and delocalized states in double InAs/GaAs quantum wells (DQWs). Spectral distribution of localized (or delocalized) states demonstrates high sensitivity on inter-dot distance. The tunneling goes consecutively from the higher energy levels to the ground state when the inter-dot distance decreases. The spectrum is presented by set of quasi-doublets and may be described by three parts: localized states, delocalized states, and states with different probability for localization in each QW of DQW. For the last states, the ratio W/ ΔE of the wave functions overlapping integral W and the electron energy difference ΔE of isolated left and right QWs is a weight coefficient in the expansion of wave function on the basis of the wave functions of isolated QWs. In case of weakly coupled QWs in DQW the indeterminate form 0/0 takes a place for the electron wave function. It is found that a small violation of the DQW shape symmetry drastically affects tunneling. This effect also appears as a numerical instability calculations for small variations of input parameters of numerical procedure.

H1.00328 Emission energy control of semiconductor quantum dots using phase change material

SHOHEI KANAZAWA, YU SATO, ARIYOSHI YAMAMURA, TOSHIHARU SAIIK, Keio Univ — Semiconductor quantum dots have paid much attention as it is a promising candidate for quantum, optical devices, such as quantum computer and quantum dot laser. We propose a local emission energy control method of semiconductor quantum dots using applying strain by volume expansion of phase change material. Phase change material can change its phase crystalline to amorphous, and the volume expand by its phase change. This method can control energy shift direction and amount by amorphous religion and depth. Using this method, we matched emission energy of two InAs/InP quantum dots. This achievement can connect to observing superradiance phenomenon and quantum dot coupling effect.
H1.00320 Magnetic field effects and nodal ground states in InP nanowire. TIAGO DE CAMPOS, PAULO EDUARDO DE FARIÁ JÚNIOR, Universidade de São Paulo, State University of New York at Buffalo, IGOR ZUTIC, State University of New York at Buffalo, GUILHERME SIPAHNI, Universidade de São Paulo, State University of New York at Buffalo — Semiconductor nanowires (NWs) have attracted great interest in the last decade because of their unique optical, electronic, and spin-dependent properties. They are among the leading candidates to observe exotic states, such as Majorana Fermions [1]. In asynnealing situation of a single particle confined in a quantum dot, it was predicted that the valence band ground state with a node is possible and was attributed to the formation of orbital textures [2]. This peculiar behavior may also be present in wurtzite InP NWs with a diameter less than 10 nm [3]. The presence of nodal state modifies its basic optical properties, such as the degree of off-linear polarization. Here we study the change in these states when an external magnetic field is applied along nanowire axis. We studied wurtzite InP [0001] and zincblende InP NWs calculated within a k.p method formulation that describes both crystal phases in a single-particle Hamiltonian [4] and account for the applied magnetic field.

H1.00330 Polarization dependent Optical Reflectance and Electroreflectance measurements of GaAs/AlGaAs multiple quantum well Bragg structure. MIM NAKARMI, Department of Physics, Brooklyn College-CUNY, NARESH SHAKYA, Department of Applied Physics, NYU-Polytechnic School of Engineering, VLADIMIR CHALDYSHEV, Ioffe Physico-Technical Institute, Russia. — Electoreflectance spectroscopy provides sharp and derivative-like spectral features in the energy region of excitonic transitions, while suppressing uninteresting background effects due to electro-modulation. We employed both electroreflectance and optical reflectance spectroscopy to probe excitonic transitions in a GaAs/AlGaAs multiple quantum well (MQW) Bragg structure. The sample used in this experiment consists of 60 periods of quantum well structures with GaAs well layer (13 nm) and AlGaAs barrier layer (94 nm), grown by molecular beam epitaxy on a semi-insulating GaAs substrate. We observed a significant enhancement of excitonic features at the x(e2-hh2) exciton transitions due to double resonance along with sharp features of heavy-hole and light-hole ground state x(e1-hh1) and x(e1-lh1) exciton transitions around incident angle of 23 degree. We will present results on polarization dependent optical reflectance and electroreflectance measurements of this structure and discuss the effect of polarization in the first and second energy states.

1This work was partially supported by PSC-CUNY research grant.

H1.00331 Effective masses of Quasi-2D electrons in InGaAs/GaAsSb modulation-doped heterostructures. IMTIAZ TANVEER, BRUCE MCCOMBE, University at Buffalo, The State University of New York, HERMANN DETZ, GOTTFRIED STRASSER, Vienna University of Technology, Vienna, Austria — The electronic properties of In0.53Ga0.47As/GaAsSb.0.5Sb.0.52 2D electron gas (2DEG) systems, in spite of their use in high power electronics, have not been extensively investigated. Recently, they have been suggested as potential materials for IR quantum devices such as quantum cascade lasers (QCL), and they also show a strong Rashba effect. Here accurate values of the effective masses are important. Two remotely donor (Si)-doped samples grown by MBE with a 2DEG at the single heterostructure interface were studied by FIR magneto-transmission spectroscopy with a BOMEM FTIR spectrometer. The maximum mobilities (near 70 K) are 43,000 cm2/Vs and 36,000 cm2/Vs with corresponding carrier densities of 1.07 × 10^{12} cm^{-2} and 2.13 × 10^{12} cm^{-2}, respectively. Cyclotron resonance measurements between 4T and 9T yielded m* = 0.0495 m0 for the more heavily doped sample. Individual transmission profiles in this case showed broadening toward high-energy, which may be due to contributions to the overall absorption profile from higher occupied subbands. The lower density sample shows an energy vs B dependence that does not extrapolate to zero at B = 0. The origin of this behavior will be discussed.

H1.00332 Carrier thermalization dynamics in single Zincblende and Wurtzite InP nanowires. YUDA WANG, HOWARD JACKSON, LEIGH SMITH, Dept. of Physics, Univ. of Cincinnati, TIM BURGESS, SURIATI PAINAM, PHILIPPE CAROFF, HOE TAN, CHENNUPATI JAGADISH, Dept. of Electronic and Materials Engineering — Using transient Rayleigh scattering (TRS) measurements, we obtain photoexcited carrier thermalization dynamics for both zincblende (ZB) and wurtzite (WZ) InP single nanowires (NW) with picosecond resolution. A phenomenological fitting model based on direct band to band transition theory is developed to extract the electron-hole plasma density and temperature as a function of time from TRS measurements of single nanowires which have complex valence band structures. We find that the thermalization dynamics of hot carriers depends strongly on material (GaAs NW vs. InP NW) and less strongly on crystal structure (ZB vs. WZ). The thermalization dynamics of ZB and WZ InP NWs are similar. But a comparison of the thermalization dynamics in ZB and WZ InP NWs with ZB GaAs NW reveals more than an order of magnitude slower relaxation for the InP NWs. We interpret these results as reflecting their distinctive phonon band structures which lead to different hot phonon effects. Knowledge of hot carrier thermalization dynamics is an essential component for effective incorporation of nanowire materials into electronic devices. We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, and the Australian Research Council.

H1.00333 Fluorescent DNA-templated silver nanoclusters. DAMYTO NYKYPANCHUK, Brookhaven National Laboratory, RUOQIAN LIN, YOLANDA SMALL, CUNY — Silver nanoclusters synthesized in the presence of templating DNA molecules show tunable optical properties that depend on cluster size and structure as well as on templating DNA sequence. In this paper we study the effect of DNA sequence and temperature on the cluster photoluminescence and discuss the results in the context of thermodynamics of DNA bases binding to the silver atoms in the clusters.

H1.00334 Plasmon Enhanced Ultrathin Film Broad-Band Nanoporous Absorber. JIN-YOU LU, Masdar Institute of Science and Technology, LONG LIU, Tsinghua University, KYLIE WILKE, MIT, SUMAYA NOORULLA, Masdar Institute of Science and Technology. — Ultra-thin absorbing films have attracted much attention due to their strong interference persisted inside the lossy dielectric film, which has much smaller thickness compared with conventional resonators. The absorber was realized by coating a lossy dielectric film with tens of nanometers in thickness on a metallic substrate. The ultrathin absorber was further developed to achieve broad-band absorption. This concept is realized by coating ultrathin absorbing Ge/Au films on nanoporous substrate, where the LSP mode is supported by pore-shape cavities. The near-field optical properties of ultrathin film on nanoporous substrate are analyzed by using the finite difference time domain method to study the spectroscopy and energy flow patterns. Simulation shows the absorption increases with the pore radius until the pore is too large to sustain LSP. Light is trapped in nanopores and penetrated into the lossy dielectric film around the pore entrance.

1Supported by cooperative agreement between Masdar Inst and MIT.
H1.00335 Optical Properties of CdSe Nanocrystalline Photoanodes AMANDA LESAR, ROHANA GARUTHARA, Hofstra University — Cadmium selenide (CdSe) nanocrystalline photoanodes were prepared by chemical solution deposition, with deposition time varied from 24 hours to 120 hours. Photoluminescence (PL) spectroscopy, reflectance and transmittance spectra, and photoelectric current were measured to optically characterize each sample. Photoelectric current was measured in a liquid junction configuration, with sodium sulfide as the electrolyte and platinum foil as the electrode. The PL, reflectance, and transmittance spectra were measured for each sample from 79 K to room temperature. Chemical solution deposition should lead to quantum size effects, as longer deposition times form larger size nanocrystals. Quantum size effects were observed, as longer depositions times led to a shift towards lower energy in the peak of the PL spectra. The temperature dependence of the PL peak energy position was also analyzed; as the temperature increased, the peak shifted towards higher energy. Using the reflectance and transmittance spectra, the absorption coefficient $\alpha$ was calculated, and the Tauc’s plot of $(\alpha h\nu)^2$ versus $(h\nu)$ was graphed. A correlation between the observed absorption edge and the PL spectra was seen, as the absorption edge energy was approximately equal to the PL energy peak.

H1.00336 Plasmon excitations of multi-layer graphene interacting with a conducting substrate , PAULA FEKETE, US Military Academy at West Point, NY, GODFREY GUMBS, Hunter College, City University of New York — We generalize the procedure for calculating the plasmon excitations of a 2D layer that is Coulo-coupled to a thick conducting substrate to the case when there is an arbitrary number of layers. In this work, we will present results for the plasmon excitations for up to five layers with arbitrary separation, energy gap between the valence and conduction bands for graphene and doping concentrations. Our procedure involves determining the inverse dielectric function for the composite hybrid system in the random-phase approximation (RPA). Effects due to nonlocality will be investigated.

H1.00337 Invisibility’s Flicker: Detecting Thermal Cloaks via Transient Effects1, SOPHIA SKLAN, Massachusetts Inst of Tech-MIT, XUE BAI, BAOWEN LI, National University of Singapore, XIANG ZHANG, University of California, Berkeley — Recent research on the development of a thermal cloak has concentrated on engineering an inhomogeneous thermal conductivity and homogeneous volumetric heat capacity. While the perfect cloak of inhomogeneous $\kappa$ and $\rho_c$ is known to be exact (no signals scattering or penetrating to the cloak’s interior), no such analysis has been considered for this case. Using analytic, computational, and experimental techniques, we demonstrate that these approximate cloaks are detectable. Although they work as perfect cloaks in the steady-state, their transient (time-dependent) response is imperfect and a detectable amount of heat is scattered. This is sufficient to determine the presence of a cloak and any heat source it contains, but the material composition hidden within the cloak is not detectable in practice.

H1.00338 Generating Steep Phase Anisotropy With Zero-Backscattering By Arrays of Coupled High Permittivity Dielectric Nanoresonators , FENG WANG, CINT, Los Alamos National Lab, QI-HUO WEI, Liquid Crystal Institute, Kent State University, HAN HTOON, CINT, Los Alamos National Lab — Simultaneous excitation of electric and magnetic dipolar modes in high-permittivity dielectric nano-resonators can lead to zero-backscattering, i.e. full transmission. Here, we numerically demonstrate that stable or unstable zero-backscattering by 2-dimensional (2D) arrays of Si nano-resonators can be realized. We also show that this Si nano-resonator array with anisotropic periodicity can generate approximate 2π optical phase anisotropy for the transmitted light at the wavelength of zero-backscattering. By introducing strong Fano-type coupling into unit cells of the array, ultra-steep phase anisotropy can be achieved. These special optical properties promise applications in various transmissive photonic devices, and we show their potential applications in transmissive polarization conversion and sensing.

H1.00339 Calculus of bands and profiles of study the system mirror - resonance of the Fibonacci Pt/Zn, LAMBERTO CASTRO-ARCE, Departamento de Fisica e Ingenieria, Unidad Regional Sur, Universidad de Sonora, CARLOS FIGUEROA-NAVARRO, Departamento de Ingenieria Industrial, Universidad Regional Centro, Universidad de Sonora, JULIO CAMPOS-GARCIA, Departamento de Ciencias de la Salud, Unidad Cajeme, Universidad de Sonora, MARTIN MOLINAR-TABARES, Organismo de Cuenca Noroeste, Comision Nacional del Agua, FELIPE RAMOS-MENDIETA, Departamento de Investigacion en Fisica, Universidad Regional Centro, Universidad de Sonora, BETZABE MANZANARES-MARTINEZ, Departamento de Fisica, Universidad Regional Centro, Universidad de Sonora — In order to analyze the behavior of a mirror — located resonance of 2pi, in a given system and with a given filling factor equal to 0.4 a study has been realized in an arrangement fibonacci, also in periodic slabs jobs. It is observed how in a study of profile that some waves are annulled giving birth to the mirror placed in 2pi. With regard to the resonance in a profile study the maxima are in certain structure Pt Pt Zn Pt Pt. Even if we increase the number of repetitions these are preserved, that means that they are related to effects of segments isolated inside the multilayer.

H1.00340 Atomic structure prediction of metal clusters using the evolutionary algorithm , NABIL AL-AQTASH, University of Nebraska- Omaha, KHALDOUN TARAWNEH, Princess Sumaya University for Technology, RENAT SABIRIANOV, University of Nebraska- Omaha — The evolutionary algorithm coupled with density functional (DFT) method is used to identify the global energy minimum atomic structure of metal clusters. Using evolutionary crystal structure optimization algorithm, as implemented in USPEX, we studied the atomic structure, binding energies, and magnetic properties of 13-atom Cu, Co and Cr clusters. A set of metastable and global minimum atomic structures are identified. Several new lower energy configurations were identified for 13-atom Cu, Co and Cr clusters and previous known atomic structures were confirmed by our calculations. We found that the Cu13 cluster has a distorted hexagonal bilayer (HBL) –like structure, which is composed by two layers as in the ideal HBL structure. The distorted HBL Cu13 is 1.17 eV lower in total energy compared to close-packed icosahedral (ICO) configuration, which reported as the lowest-energy structure for Cu13 in previous studies. Our calculations show that Cu13 has an ideal HBL structure and Cr13 cluster has distorted ICO structure, which are consistent with the previous studies. Moreover, our calculations show that Cr13 has another lower energy atomic configuration with 0.003 eV difference form ICO. Cr13 has ferrimagnetic (FIM) interaction which plays an important role in finding the lowest energy structure. We discuss the predictive capabilities of evolutionary algorithms for nanoclusters.

H1.00341 Electron with position-dependent mass confined in a two-dimensional infinite square well , MARTIN MOLINAR-TABARES, Organismo de Cuenca Noroeste, Comision Nacional del Agua, CARLOS RUVALCABA-CORNEJO, Departamento de Matematicas, Unidad Regional Centro, Universidad de Sonora — In order to have a case of study for introduce the concept of position-dependent mass, we propose to analyze the following case. Creating a rectangular crystal structure from the two-dimensional deposit of GaAs and Al0.35Ga0.65As on a substrate, we study the confinement of an electron with position-dependent effective mass. Knowing how the electron mass of the electron and its potential energy varies with the concentration of the semiconductor, we solve the time-independent Schrödinger equation using a linear combination of wave functions of a particle enclosed inside a two-dimensional square well with infinite potential walls. The ground state energy and the energies of some excited states with the probability density of these states are found. Making a two-dimensional growth of the structure we analyze if appears sub-bands energy and if the Bloch theorem manifests. We compare our results with those that we would obtain if we consider and constant effective mass inside the crystal.
Conformational electroresistance and hysteresis in nanoclusters

H1.00344

Conformational electroresistance and hysteresis in nanoclusters

ZHANG, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — Abstract: Existence of multiple thermodynamically stable isomer states is one of the most fundamental properties of small clusters. We show that the conformational dependence of the Coulomb charging energy of a nanocluster leads to a giant electroresistance, where charging induced conformational distortion changes the blockade voltage. The intricate interplay between charging and conformation change is demonstrated in a nanocluster Zn$_3$O$_4$ by combining a first-principles calculation with a temperature-dependent transport model. The predicted hysteretic Coulomb blockade staircase in the current-voltage curve adds another dimension to the rich phenomena of tunneling electroresistance. The new mechanism provides a better controlled and repeatable platform to study conformational electroresistance.

Finite-size scaling study of the one-dimensional Bose-Hubbard model via matrix product state representations

SUNG-BEEN PARK, MIN-CHUL CHA, Hanyang University — The Bose-Hubbard model is a prototypical simple model showing quantum phase transition with a continuous symmetry. In one dimension, the quantum critical properties of the model has been studied via various methods, but still some basic properties remain unknown, such as the exact location of the critical point. It is a computational challenge to study this model with more elaborated numerical methods. The matrix product state (MPS) representations are new variational solutions to one-dimensional quantum systems. By using this method to find the ground state, we study the critical properties of the one-dimensional Bose-Hubbard model with a periodic boundary condition. Finite-size scaling analysis provides the phase diagram and the critical exponents.

H1.00345

Solution of the homogeneous electromagnetic wave equation with velocity time depending on the discrete space-time

JULIO CAMPOS-GARCIA, Departamento de Ciencias de la Salud, Universidad Caxem, Universidad de Sonora, MARTIN MOLINAR-TABARES, Organismo de Cuenca Noroeste, Comision Nacional del Agua, LAMBERTO CASTRO-ARCE, Departamento de Fisica e Ingenieria, Universidad Regional Sur, Universidad de Sonora, CARLOS FIGUEROA-NAVARRO, Departamento de Ingenieria Industrial, Universidad Regional Centro, Universidad de Sonora, RODRIGO ROSAS-BURGOS, Departamento de Fisica, Universidad Regional Centro, Universidad de Sonora — We present in this meeting the solution of the homogeneous electromagnetic wave equation with a speed of light time depending on the discrete space-time. The solutions are compared with those that are obtained for a standard case, where the speed of light is constant. In addition, the limiting cases of the discrete and continuum space-time are analyzed.

H1.00346

Fabrication and In-situ TEM Characterization of Freestanding Graphene Nanoribbons Devices

QING WANG, RYO KITAURA, SHOJI SUZUKI, HISANORI SHINOHARA, Department of Chemistry, Nagoya University, SHINOHARA TEAM — Edge-dependent electronic properties of graphene nanoribbons (GNRs) have attracted intensive interests. To fully understand the electronic properties of GNRs, the combination of precise structural characterization and electronic property measurement is essential. For this purpose, a new experimental technique using freestanding GNR devices has been developed, leading to the simultaneous characterization of electronic properties and edge structure of GNRs. To prepare freestanding GNR devices, graphene was first transferred on a Si substrate with an open slit covered by a silicon dioxide layer, and then silicon dioxide membrane underneath the graphene was etched away by buffered hydrogen fluoride acid. The so-prepared freestanding graphene device was assembled to a home-made TEM holder for in-situ characterization. The freestanding graphene was sculpted by a focused electron beam in TEM, purified and narrowed by Joule heating down to several nanometers width. Structure-dependent electronic properties were performed in TEM. We have observed significant increase in resistance and semiconductive behavior became more dominant with decreasing width of GNR.

Surface Premelting Coupled with Bulk Phase Transitions in Colloidal Crystals

BO LI, FENG WANG, DI ZHOU, XIN CAO, YI PENG, The Hong Kong University of Science and Technology, RAN NI, Universiteit van Amsterdam, MALJIA LIAO, YILONG HAN, The Hong Kong University of Science and Technology — Colloids have been used as outstanding model systems for the studies of various phase transitions in bulk, but not at interface yet. Here we obtained equilibrium crystal-vapor interfaces using tunable attractive colloidal spheres and studied the surface premelting at the single-particle level by video microscopy. We found that monolayer crystals exhibit a bulk isostructural solid-solid transition which triggers the surface premelting. The premelting is incomplete due to the interruption of a mechanical-instability-induced bulk melting. By contrast, two- or multilayer crystals do not have the solid-solid transition and the mechanical instability, hence they exhibit complete premelting with divergent surface-liquid thickness. These novel interplays between bulk and surface phase transitions cast new lights for both types of transitions.

Entrance Pressure Fluctuation of LLDPE in Capillary Flow

HAIQING HU, SHUAI LI, LUYAO YAN, TONGJIE SUN, LINLIN LIU, Ministry of Education/Shandong Provincial Key Laboratory of Rubber-plastics; Qingdao University of Science and Technology, HE CHENG, Dongguan Institute of Neutron Physics, China; China Spallation Neutron Source, Institute of High Energy Physics CAS, Dongguan — Oscillating flow, which usually refers to the whole capillary pressure oscillation under constant piston speed, has been widely studied as an important instability phenomenon in capillary flow. The coil-stretch transition of entangled polymer molecules can be considered as a critical factor resulting in oscillating flow, which is only observed under controlled piston speed. It has been theorized by Weill since 1980 that the appearance of surface distortions may originate from a high-frequency oscillatory flow created at the die entry, but no experimental evidence has been found to prove it over 30 years. Wall slippage plays an important role in capillary extrusion flow instability for LLDPE melt. Local stick-slip transition leads to perturbations on the exit stress and sharkskin distortion, while global stick-slip transition perturbations on the exit pressure flow. This article has revealed the correspondence relationship between entrance pressure fluctuation and exit stress perturbation experimentally and illuminated it by Uhland model. We have further confirmed the idea that local wall-slip transition can induce the entrance pressure fluctuation. In brief, the molecular disentanglement in die exit determines the critical shear stress of entrance pressure fluctuation.

Superconductivity and Magnetism from First Principles

ANDREAS LINSCHEID, ANTONIO SANNA, FRANK ESSENBERGER, E.K.U. GROSS, Max Planck Institute of Microstructure Physics — Magnetism has intriguing effects in superconductors. On the one hand static magnetic fields are known to suppress the superconducting state while dynamic spin-fluctuations are the probable candidate to explain the pairing in the Fe-based Superconductors. Achieving an ab-initio description is important. First, because this allows to compute the critical field and whether a local coexistence of magnetic and superconducting phases exist. Second, the critical temperature of a material is among the predicted properties which allows to search yet unknown superconductors on a computer. The Density Functional Theory for Superconductors (SCDFT) has been very successful in predicting Tc of phonon mediated superconductors. We include the magnetic density into SCDFT so that the electronic Kohn-Sham system now reproduces the electronic density ρ(r), the order parameter of superconductivity Δ(r, y) and the magnetic density n(r). We derive the xc-potential and discuss some first results. Furthermore, we discuss an effective electron interaction mediated by spin-flip processes based on the exact spin susceptibility. We drive a xc-functional for SCDFT that includes this effective interaction and present some results.
H1.00350 Iterative backflow renormalization procedure for many-body ground state wave functions of strongly interacting normal Fermi liquids. MICHELE RUGGERI, DEMOCRITOS National Simulation Center, Istituto Officina dei Materiali del CNR and SISSA, Via Bonomea 265, I-34136 Trieste, Italy, MICHELE TADDEI, Dipartimento di Fisica, Sapienza Universita' di Roma Piazzale A. Moro 2, I-00185, Roma, Italy, SAVERIO MORONI, DEMOCRITOS National Simulation Center, Istituto Officina dei Materiali del CNR and SISSA, Via Bonomea 265, I-34136 Trieste, Italy, MARKUS HOLZMANN, LPMC, UMR 5493 of CNRS, Universite’ Grenoble Alpes, F-38100 Grenoble, France — We propose a novel trial wavefunction for the ground state of a normal Fermi liquid. We apply iterative backflow transformations to obtain a sequence of renormalized coordinates. At each iteration two and three body correlations between quasiparticles are taken into account. We use these wavefunctions to compute the ground state energy of liquid 3He at freezing density in two dimensions with Variational and Diffusion - Fixed Node Monte Carlo simulations. Comparing with exact transient estimate results for systems with small number of particles, we find that variance extrapolations provide accurate results for the true ground state together with stringent lower bounds. For larger systems these bounds can in turn be used to quantify the systematic bias of fixed-node calculations. These wave functions are size consistent and the scaling of their computational complexity with the number of particles is the same as for standard backflow wave functions.

H1.00351 Comparative Study Between GGA and LDA Approximation Using First-Principles Calculations of Structural, Electronic, Optical and Vibrational Properties of CaTiO3 Crystal , SUBENIA MEDEIROS, MAEVA ARAUJO, Universidade Federal Rural do Semi-Árido — The structural, electronic, vibrational, and optical properties of perovskite CaTiO3 in the cubic, orthorhombic, and tetragonal phase are calculated in the framework of density functional theory (DFT) with different exchange-correlation potentials by CASTEP package. The calculated band structure shows an indirect band gap of 1.88 eV at the Γ - H points in the Brillouin zone to the cubic structure, a direct band gap of 2.41 eV at the Γ - I points to the orthorhombic structure, and an indirect band gap of 2.31 eV at the M – I’ points to the tetragonal phase. It is still known that the CaTiO3 has a static dielectric constant that extrapolates to a value greater than 300 at zero temperature, and the dielectric response is dominated by low frequency (ν ≈ 90cm⁻¹) polar optical modes in which cation motion opposes oxygen motion. Our calculated lattice parameters, elastic constants, optical properties, and vibrational frequencies are found to be in good agreement with the available theoretical and experimental values. The results for the effective mass in the electron and hole carriers are also presented in this work.

H1.00352 Electron relaxation of DNP free radicals BDPA and DPPH at W-band , ARMIN KHAMOSHI, UT Dallas, PAVANEET KAUR, LKAI SONG, NHMF, LLOYD LUMATA, UT Dallas — The stable, spin-1/2 organic free radicals BDPA and DPPH are efficient polarizing agents for dissolution dynamic nuclear polarization (DNP). Despite the hydrophobic nature of these two free radicals, BDPA and DPPH can be dissolved in specialized solvents such as sulfurane or dimethyl sulfoxide. In this work, we have investigated the temperature dependence of the spin-lattice relaxation rate 1/T1 of these two DNP free radicals at W-band from 250 K down to 4 K. We have found that at high temperature above 40 K the relaxation rates of these free radicals (at optimum DNP concentration) behave closely according to the Raman process prediction. At lower temperature below 40 K, the relaxation rate slows down according to the direct process behavior. The results obtained here may elucidate the correlation between the relaxation of electrons and the efficiency of these free radicals in DNP.

H1.00353 Power laws and extreme values in antibody repertoires , SEBATIEN BOYER, DIPANWITA BISWAS, NATALA SCARAMOZZINO, ANANDA SOSHEE KUMAR, Laboratoire Interdisciplinaire de Physique - CNRS & Universite Grenoble Alpes, CLEMENT NIZAK, ESPCI ParisTech/CNRS, OLIVIER RIVOIRE, Laboratoire Interdisciplinaire de Physique - CNRS & Universite Grenoble Alpes — Evolution by natural selection involves the succession of three steps: mutations, selection, and proliferation. We are interested in describing and characterizing the result of selection over a population of many variants. After selection, this population will be dominated by the few best variants, with highest propensity to be selected, or highest “selectivity.” We ask the following question: how is the selectivity of the best variants distributed in the population? Extreme value theory, which characterizes the extreme tail of probability distributions in terms of a few universality class, has been proposed to describe it. To test this proposition and identify the relevant universality class, we performed quantitative in vitro experimental selections of libraries of > 10⁶ antibodies using the technique of phage display. Data obtained by high-throughput sequencing allows us to fit the selectivity distribution over more than two decades. In most experiments, the results show a striking power law for the selectivity distribution of the top antibodies, consistent with extreme value theory.

H1.00354 Single Crystal Diffuse X-ray Scattering Using Continuous Rotation1, MATTHEW KROGSTAD, OMAR CHMAISSEM, KEITß TÁDEDEI, Northern Illinois University, Argonne National Laboratory, JARED ALLRED, RAYMOND OSBORN, STEPHAN ROSENKRANZ, JUSTIN WOZNIAK, Argonne National Laboratory — Single crystal diffuse scattering provides a measure of the 3D pair distribution function and is thus useful for investigating short-range order in materials. Using very bright synchrotron X-ray sources and fast area detectors, large volumes of reciprocal space can be mapped quickly with a dynamic range large enough to measure both Bragg peaks and the much weaker diffuse scattering. With the appropriate tools for processing and analyzing large data sets (10 to 30GB), this technique can be used to track changes in the defect structures of a material as a function of different parameters, providing a sensitive and efficient method for investigating phenomena associated with disorder. We have been developing methods of measuring diffuse scattering using continuous sample rotations (shutterless mode) at the Advanced Photon Source, and will show data from several systems, including iron nitrides, for a range of temperatures and doping levels.

H1.00355 Chemical Bonding Forces and Metalization of Hydrogen , IVAN NAUMOV, RUSSELL HEMLEY, Carnegie Inst of Washington, CARNEGIE INST OF WASHINGTON COLLABORATION — Recent theoretical and experimental studies reveal that compressed molecular hydrogen at 200-350 GPa transforms to layered structures consisting of distorted graphene sheets. The new phases of dense solid hydrogen contrast with the long-held view that symmetric close-packed, ambient alkali-metal-like structures form at these high pressures — this raises the question about the nature and fate of molecular bonding in hydrogen on compression. The realization of such unexpected structures can be explained by consideration of simple low-dimensional model systems— H6 rings and graphene-like monolayers. Both molecular quantum chemistry and well-tested solid state approaches show that these model systems like aromatic hydrocarbons exhibit a special stability, associated with the completely filled set of bonding orbitals or valence bands. This close-shell effect persists in progressing to the real layered structures where it prevents the dielectric energy gap from closing, thus delaying the pressure-induced metalization. The latter nevertheless can occur upon further compression via destroying the closed shell electronic structure which is mainly determined by the 1S electrons. The most likely scenario is the lowering of the bonding bands (their bottoms) stemming from the unoccupied atomic 2s and 2p orbitals [1]. This research was supported by EFRee, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award DESC0001057. [1] I. Naumov and R. J. Hemley, Acc. Chem. Res. 47, 3551-3559 (2014).
H1.00356 Generation of internal gravity waves by tidal flow over random oceanic topography

JIAJUN ZHAO, Natl Univ of Singapore, LIKUN ZHANG, HARRY SWINNEY, University of Texas at Austin — Internal waves (IW) are gravity waves that propagate within density-stratified fluids such as the ocean, atmosphere, and protoplanetary disks. IWs generated by tidal flow over oceanic topography provide much of the energy needed to sustain vertical mixing, which plays a critical role in ocean circulation and global climate. Therefore, it is important to determine the amount of energy that is extracted from tidal flow over topography and radiated into IWs. We conduct 2D numerical simulations to determine the IW power generated by tidal flow over random topographies that have the seafloor spectrum. The power is found to saturate with increasing topographic roughness, and to scale linearly with the characteristic height of the topography. The linear dependence on the topographic height is, surprisingly, nearly independent of the value of the exponent characterizing the topographic spectrum. Our results should lead to improved predictions of the IW power generated by tidal flow over global ocean topography.

H1.00357 Photoresponse of Single Mn doped ZnO nanowires in UV application

MON-SHU HO, Department of Physics, National Chung Hsing University — This paper reports the fabrication of Mn doped ZnO nanowires (NWs) using a low temperature hydrothermal method. The resulting nanowires were characterized using field emission scanning electron microscopy, energy dispersive spectroscopy, X-ray diffraction analysis, transmission electron microscopy and photoluminescence spectroscopy. A single Mn doped ZnO NW UV sensor with high performance sensing capabilities was then assembled using a focused ion beam technique. The photoresponse of the ZnO NW sensors was investigated under irradiation from 365 nm and 400 nm ultra-violet lamps. The proposed sensor exhibited rapid photoresponse speeds and short recovery times with a photocurrent ratio (ΔI = I_{light} / I_{dark}) superior to that of pure ZnO NW sensor. A possible mechanism to account for adsorption-desorption of oxygen and water molecules on Mn/ZnO NW surfaces was finally proposed to give the expression.

Photoresponse of Single Mn doped ZnO nanowires in UV application

H1.00358 Power-law-like correlation between condensation energy and superconducting transition temperatures in iron pnictide/chalcogenide superconductors: Beyond the BCS understanding

JIE XING, SHENG LI, Center for Superconducting Physics and Materials, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, BING MU, BING SHEN, National Laboratory for Superconductivity, Institute of Physics and National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, J. SCHNEELOCH, R.D. ZHONG, T.S. LIU, G.D. GU, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, HAI-HU WEN, Center for Superconducting Physics and Materials, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University — Superconducting condensation energy \( U_{0}^{\alpha} \) has been determined by integrating the electronic entropy in various iron pnictide/chalcogenide superconducting systems. It is found that \( U_{0}^{\alpha} \propto T_{c}^{n} \) with \( n = 3 \) to 4, which is in sharp contrast to the simple BCS prediction \( U_{0}^{\alpha,BCS} = 1/2N_{P} \Delta_{P}^{2} \), with \( N_{P} \) the quasiparticle density of states at the Fermi energy and \( \Delta_{P} \), the superconducting gap. A similar correlation holds if we compute the condensation energy through \( U_{0}^{\alpha,eff} = 3\gamma_{n} \Delta_{P}^{2}/4n_{eff}^{2}k_{B}^{2} \), with \( \gamma_{n} \) the effective normal state electronic specific heat coefficient. This indicates a general relationship \( \gamma_{n} \propto T_{c}^{m} \) with \( m = 1 \) to 2, which is not predicted by the BCS scheme. A picture based on quantum criticality is proposed to explain this phenomenon.
is high enough to generate a distinct NEXAFS resonance at 286.2 eV (1s → π\(^+\)) the electronic states of chlorinated graphene on different substrates, including surface binding energy, dopant concentration and work function shift by use of X-ray spectroscopy provides us a sensitive probe to investigate the surface states of functionalizing dopants in graphene. Here, we systematically studied KONG, MILDRED DRESSELHAUS, TOMAS PALACIOS, Massachusetts Institute of Technology, THEANNE SCHIROS, Columbia University, DENNIS NORDLUND, SLAC National Accelerator Laboratory, YONG CHEOL SHIN, JING XU ZHANG, Massachusetts Institute of Technology, MIT/COLUMBIA UNIVERSITY/SLAC COLLABORATION.

Institute of Technology, THEANNE SCHIROS, Columbia University, DENNIS NORDLUND, SLAC National Accelerator Laboratory, YONG CHEOL SHIN, JING XU ZHANG, Massachusetts Institute of Technology, MIT/COLUMBIA UNIVERSITY/SLAC COLLABORATION — Plasma-based chlorination is a promising technique to realize controllable doping in graphene, while maintaining its high mobility. Meanwhile, synchrotron-based X-ray spectroscopy provides us a sensitive probe to investigate the surface states of functionalizing dopants in graphene. Here, we systematically studied the electronic states of chlorinated graphene on different substrates, including surface binding energy, dopant concentration and work function shift by use of Near Edge X-ray Absorption Fine Structure (NEXAFS) spectroscopy, XPS and photoemission threshold measurements. The concentration of absorbed chlorine is high enough to generate a distinct NEXAFS resonance at 286.2 eV (1s → π\(^+\) transition for C-Cl bonds). It is remarkable that the sp2 core carbon-hole exciton (291.85eV) retained its sharpness even after treatment, indicating the long-range periodicity in graphene is largely preserved. This distinguishes our approach as a noninvasive and effective doping method. The interaction between Cl and graphene also exhibits strong substrate effects: for Cu, graphene’s Fermi level is shifted downwards by 0.35eV, while for graphene on SiO2, the much (4-5 times) higher chlorine concentration causes EF to shift by 0.9eV.

3:18PM J1.00003 Near-edge X-ray Absorption Fine Structure (NEXAFS) Spectroscopy study on Chlorinated Graphene through Plasma-based Surface Functionalization. XU ZHANG, Massachusetts Institute of Technology, THEANNE SCHIROS, Columbia University, DENNIS NORDLUND, SLAC National Accelerator Laboratory, YONG CHEOL SHIN, JING XU ZHANG, Massachusetts Institute of Technology, MIT/COLUMBIA UNIVERSITY/SLAC COLLABORATION — Plasma-based chlorination is a promising technique to realize controllable doping in graphene, while maintaining its high mobility. Meanwhile, synchrotron-based X-ray spectroscopy provides us a sensitive probe to investigate the surface states of functionalizing dopants in graphene. Here, we systematically studied the electronic states of chlorinated graphene on different substrates, including surface binding energy, dopant concentration and work function shift by use of Near Edge X-ray Absorption Fine Structure (NEXAFS) spectroscopy, XPS and photoemission threshold measurements. The concentration of absorbed chlorine is high enough to generate a distinct NEXAFS resonance at 286.2 eV (1s → π\(^+\) transition for C-Cl bonds). It is remarkable that the sp2 core carbon-hole exciton (291.85eV) retained its sharpness even after treatment, indicating the long-range periodicity in graphene is largely preserved. This distinguishes our approach as a noninvasive and effective doping method. The interaction between Cl and graphene also exhibits strong substrate effects: for Cu, graphene’s Fermi level is shifted downwards by 0.35eV, while for graphene on SiO2, the much (4-5 times) higher chlorine concentration causes EF to shift by 0.9eV.

3:30PM J1.00004 First Principles Study of Chemically Functionalized Graphene1, SANJIV JHA, IGOR VASILIEV, New Mexico State University — The electronic, structural and vibrational properties of carbon nanomaterials can be affected by chemical functionalization. We applied ab initio computational methods based on density functional theory to study the covalent functionalization of graphene with benzene, carboxyl groups and tetracyanoethylene oxide (TCNEO). Our calculations were carried out using the SIESTA and Quantum-ESPRESSO electronic structure codes combined with the local density and generalized gradient approximations for the exchange correlation functional and norm-conserving Troullier-Martins pseudopotentials. The simulated Raman and infrared spectra of graphene functionalized with carboxyl groups and TCNEO were consistent with the available experimental results. The computed vibrational spectra of graphene with carboxyl groups showed that the presence of point defects near the functionalization site affects the Raman and infrared spectroscopic signatures of functionalized graphene.

3:42PM J1.00005 The influence of selective chemical doping on clean, low-carrier density SiC epitaxial graphene1. CHIASHAIN CHUANG, YANFEI YANG, National Institute of Standard and Technology, LUNG-I HUANG, CHI-TE LIANG, National Taiwan University, RANDOLPH E. ELQUIST, National Institute of Technology, NATIONAL INSTITUTE OF OF STANDARDS AND TECHNOLOGY COLLABORATION, NATIONAL TAIWAN UNIVERSITY, DEPARTMENT OF PHYSICS COLLABORATION — The charge-transfer effect of ambient air on magneto-transport in polymer-free SiC graphene was investigated. Interestingly, adsorption of atmospheric gas molecules on clean epitaxial graphene can reduce the carrier density to near charge neutrality, allowing observation of highly precise v = 2 quantum Hall plateaus. The atmospheric adsorbates were reproducibly removed and pure gases (N\(_2\), O\(_2\), CO\(_2\), H\(_2\)O) were used to form new individual adsorbates on SiC graphene. Our experimental results (v = 2) support the theoretical prediction that the ratio of transport relaxation time \(\tau_r\) to quantum lifetime \(\tau_q\) in clean graphene. The analysis of the Shubnikov-de Haas oscillations at intermediate doping levels indicates that the carrier scattering is reduced by water and oxygen so as to increase both the classical and quantum mobility. This study points to the key dopant gases in ambient air and also paves the way towards extremely precise quantized Hall resistance standards in epitaxial graphene systems with carrier density tuned by exposure to highly pure gases and vacuum annealing treatment.

3:54PM J1.00006 ABSTRACT WITHDRAWN —

4:06PM J1.00007 Electroless deposition of metal nanoparticles on graphene with substrate-assisted techniques1. ANNA M. ZANIEWSKI, CHRISTIE J. TRIMBLE, VERONICA MEEKS, ROBERT J. NEMANICH, Arizona State University — We present the electroless reduction of solution-based metal ions for nanoparticle deposition on a variety of substrates. The substrates include graphene-coated metals, insulators, doped semiconductors, and patterned ferroelectrics. We find that the metal ions are spontaneously reduced on a wide variety of graphene substrates, and the substrates play a large role in the nanoparticle coverage. For example, the reduction of gold chloride to gold nanoparticles on graphene/lithium niobate results in 3% nanoparticle coverage compared to 20% coverage on graphene/silicon and 60% on graphene/copper. Given that the work function of graphene is approximately 4.4eV, the Fermi level is ~0.1 V vs the normal hydrogen electrode (NHE). Since the reduction potential of gold chloride is +1.02 V, the spontaneous transfer of electrons from the graphene to the metal ion is energetically favorable. However, we find substrates with similar work functions nevertheless result in varied deposition rates, which we attribute to electron availability. We also find that patterned ferroelectrics can be used as a template for patterned nanoparticle deposition, with and without graphene.

4:18PM J1.00008 Quantum Transport in Few-Layer Graphene and Phosphorene Devices. CHUN NING (JEANIE) LAU, University of California, Riverside — I will present our results on transport measurements in bilayer and trilayer graphene devices with mobility as high as 400,000 cm\(^2\)/Vs. We demonstrate the presence of an intrinsic gapped state in bilayer and trilayer graphene at the charge neutrality point, a “new” spectroscopy technique for measuring the Landau level gaps, the distinct competing states at filling factor 2 and crossing between symmetry-broken Landau levels. Our results underscore the fascinating many-body physics in these 2D membranes. Finally, I will present our recent results on fabrication of air-stable few-layer phosphorene heterostructures and observation of quantum oscillations in these devices.
5:4PM J1.00009 Multi-mode Fabry-Pérot Interferences in SiO₂-supported Single Layer Graphene, in Large Aspect Ratio 2-terminal Devices¹. JOSEPH LAMBERT, Drexel University; STEVEN CARABELLO, Penn State Harrisburg and Drexel University; ROBERTO RAMOS, Indiana Wesleyan University — The Fabry-Pérot (F-P) interference of charge carriers in graphene occurs in 2-dimensional cavities defined by p-n interfaces. Typically, p-n interfaces form by local doping of metallic contacts, and serve as partially reflecting mirrors for ballistic charge carriers. Here, we report on observed F-P resonances in very large aspect ratio devices. For all devices studied, the inter-lead distance is L ≈ 0.2 μm, and the graphene channel widths range from W ≈ 5 to 17 μm, resulting in aspect ratios up to W/L ≈ 74. In maps of conductance versus source-drain and gate voltages, we observe long-range tapestry patterns, extending over the gate voltage range from Vgs = –60 V to 20 V. These features are observed at a temperature of T = 20 K. Upon lowering the temperature, an additional mode appears around T ≈ 3 K, and remains fairly unchanged down to T ≈ 30 mK. From the lowest energy features, we estimate the phase coherence length to be on the order of 1 to 2 μm. Using FFT, we have identified two modes: the fundamental longitudinal, and one of the transverse modes, which we propose is a result of smaller cavities formed by the disorder-induced charge puddles.

¹We gratefully acknowledge Prof. Fred Wellstood, University of Maryland, for access to fabrication facilities.

5:06PM J1.00010 Graphene Transport Under the Influence of Polar Molecules¹. BARRETT WORLEY, SEOHEE KIM, SAUNGEUN PARK, Univ of Texas, Austin; PETER ROSSKY, Rice University; DEJI AKINWANDE, ANANTH DODABALAPUR, Univ of Texas, Austin — Charged defects and impurities play a very important role in charge transport in graphene field-effect transistors (FETs). They influence the mobility, residual doping, and the Dirac voltage. Long-range scattering by charged impurities in fabricated graphene FETs lowers the mobility of charge carriers, while short range scattering affects the value of residual carrier concentration. Our group has shown that the electrical properties of graphene FETs are significantly improved upon exposure to fluoropolymers or polar organic vapors. We have demonstrated favorable Dirac voltage shifts, increases in mobility, and reduction in residual carrier concentration as a result of polar molecules altering the dielectric environment surrounding the graphene/substrate interface of a graphene FET. Screening of charged impurity scattering is hypothesized to be the principal effect by which the polar molecules of the altered dielectric layer bring about improvements. We employ computational chemistry to model polar organic molecule-graphene systems. Such modeling will help explain experimental results.

¹We acknowledge support from NASCENT NSF EEC-1160494 and NSF CHE-1362381.

5:18PM J1.00011 Theory of anharmonic phonons in graphene. SEBASTIAN COSTAMAGNA, Instituto de Fisica de Rosario (IFIR-CONICET); FRANCOIS M. FEETERS, KARL H. MICHEL, University of Antwerp — Anharmonic effects in an atomic monolayer thin crystal with honeycomb lattice structure are studied by analytical and numerical lattice dynamical methods. Starting from a semi-empirical model for anharmonic couplings of third and fourth order, we study the in-plane and out-of-plane (flexural) mode components of the generalized wave vector dependent Gruneisen parameters, the thermal tension and the thermal expansion coefficients as function of temperature and crystal size. From the resonances of the displacement-displacement correlation functions we study the renormalization and decay rate of in-plane and flexural phonons as function of temperature, wave vector and crystal size. Numerical evaluations are made with graphene as a specific model. The work is complementary to crystalline membrane theory and computational studies of anharmonic effects in two-dimensional crystals.

Session J2 DMP: Focus Session: Beyond Graphene - Strongly Correlated Phenomena 001B - Kin Fai Mak, Pennsylvania State University

2:30PM J2.00001 Control of Metastable Charge Density Wave Phases in Ultrathin 1T-TaS₂. ADAM TSEN, Columbia University; ROBERT ROVDEN, Cornell University; DEENNIS WANG, YOUNG DUCK KIM, Columbia University; YU LIU, WENJIAN LU, YUPING SUN, Chinese Academy of Sciences, JAMES HONE, Columbia University; LENAFITTINGKOURKOUTIS, Cornell University; PHILIP KIM, Harvard University; ABHAY PASUPATHY, Columbia University — Among the most intriguing aspects of reduced dimensionality in condensed matter systems is the enhancement of various correlation effects (electron-electron, electron-phonon, etc.). In quasi-2D metallic chalcogenides, they lead to electronic instabilities that give rise to a wealth of exotic ground states such as charge density waves (CDWs), spin density waves, and superconductivity. 1T-TaS₂ is a unique layered material which exhibits a number of different CDW states as well as a Mott phase at low temperatures. Although its electronic structure is largely two dimensional, the CDWs are stabilized by an out-of-plane stacking. By combining low temperature transmission electron microscopy with electrical transport measurements, we investigate how the various CDW phases in 1T-TaS₂ change as it approaches the physical 2D limit. We find that in well-controlled samples, the lock-in transition from a nearly commensurate CDW to a fully commensurate CDW gradually disappears with reduced thickness as both phases become increasingly metastable. I will discuss the physical reasons underlying this behavior as well as demonstrate how to manipulate this phase transition in few-layer samples by application of an in-plane electric field.

2:42PM J2.00002 Tantalum Disulfide Ionic Field-Effect Transistors. YUAN YU, FANGYUAN YANG, Fudan University, XIU FANG LU, YA JUN YAN, University of Science and Technology of China; Y. H. CHO, Rutgers University; LIGUO MA, XIAOHAI NIU, Fudan University, SEJOONG KIM, YONG-WOO SON, Korea Institute for Advanced Study, DONGLAI FENG, SHIYAN LI, Fudan University, SANG-WOOK CHEONG, Rutgers University, XIAN HUI CHEN, University of Science and Technology of China; YUANBO ZHANG, Fudan University — The ability to tune material properties using gate electric field is at the heart of the modern electronic technology. Electrolyte gating has recently emerged as an important technique to reach extremely high surface charge carrier concentration in a variety of materials through the formation of electric double layer (EDL) at the sample surface. Here we demonstrate a new mechanism of electrolyte gating that modulates the volumetric carrier density by gate-controlled intercalation in layered materials. We fabricate field-effect transistors (referred to as ionic field-effect transistor, iFET) based on transition metal dichalcogenides 1T-TaS₂ and 2H-TaS₂. The unprecedented large doping induces dramatic changes in the transport properties of the sample, including CDW phase transitions, superconductivity and metal-to-insulator transitions. The controllable and reversible intercalation of different ion species into layered materials opens up new possibilities in searching for novel states of matter in the extreme charge-carrier-concentration limit.

2:54PM J2.00003 Scanning Tunneling Microscopy and Spectroscopy of the commensurate charge density wave phase of 1T-TaS₂. ADINA LUCIAN-MAYER, ANDREW DILULLO, YANG LI, SAW WAH-HLA, Argonne National Laboratory — The 1T polymorph of TaS₂, 1T-TaS₂, has one of the richest phase diagrams among the transition metal dichalcogenides: It is metallic at higher temperatures; it has four temperature-dependent charge density wave (CDW) phases with different structures; at low temperatures it shows Mott insulator behavior and under pressure and doping it becomes superconducting. In this talk, we focus on the low temperature commensurate charge density wave phase. Using scanning tunneling microscopy and spectroscopy, we explore the spatial variation of the electronic properties of the commensurate CDW phase at the atomic level. The role that defects play in the formation of this phase will also be discussed.
3:42PM J2.0005 New STM Tip-induced Phases in 1T-TaS_2
LIGUO MA, YIJUN YU, State Key Laboratory of Surface Physics, Department of Physics, Fudan University, XIU FANG LU, YA JUN YAN, Heifei National Laboratory for Physical Science at Microscale and Department of Physics, University of the Science and Technology of China, YUANBO ZHANG, State Key Laboratory of Surface Physics and Department of Physics, Fudan University — Transition metal dichalcogenide 1T-TaS_2 is a layered material featuring a unique set of charge density wave (CDW) phases. The close proximity of the CDW phases in energy makes the material prone to external perturbation, and the intricate electron-phonon and electron-electron interactions often lead to electronic/structural phase transitions in 1T-TaS_2. Here we report a new phase transition from the insulating commensurate CDW (also known as a Mott state) to a new metallic CDW state that is induced in 1T-TaS_2 by voltage pulses from an STM tip at low temperatures. We study the topographic and spectroscopic properties of the metallic CDW phase in detail with STM and Scanning Tunneling Spectroscopy (STS).

3:54PM J2.0006 Controlling non-equilibrium CDW states in 1T-TaS_2 nano-thick crystals
MASARO YOSHIDA, YIJIN ZHANG, RYUJI SUZUKI. Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, The University of Tokyo, Japan, JIANTING YE, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands, YOSHIIRO IWASA, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, The University of Tokyo, Japan — Two-dimensional (2D) crystals provide an ideal platform for exotic electronic band structures in mono- or multi-layer form. The thinning to nano-scale may also affect collective phenomena in interacting electron systems and can lead to unconventional states that are dramatically different from those in bulk. In this presentation, we report the systematic control of charge-density-wave (CDW) transitions by changing thickness and cooling rate in nano-thick crystals of 1T-type tantalum disulfide (1T-TaS_2). First, we discovered a new super-cooled nearly-commensurate CDW state, which shows metallic behavior at low temperatures. Furthermore, we achieved current-induced switching between various CDW states. The glassy behavior and non-linear response, possibly due to the reduced dimensionality, manifest the emergent complex nature of correlated electrons in 2D crystals with nanometer thickness.

4:06PM J2.0007 Effects of Dimensionality on the Charge-Density Wave Phases of Transition-Metal Dichalcogenides
DANilo ROMERO, ECE Department, University of Maryland, College Park, MD 20740 and NIST Gaithersburg, MD 20899, JEFFREY SIMPSON, Towson University and NIST Gaithersburg, MD 20899, HELMUTH BERGER, EPSL, Lausanne, Switzerland, ANGELA HIGHT-WALKER, NIST Gaithersburg, MD 20899 — We investigate the effects of dimensionality on the electronic properties of the transition-metal dichalcogenides (TMDCs). We observe phase transitions between commensurate and incommensurate CDW phases in thin films of 1T-TaS_2 and 1T-TaSe_2. These effects are attributed to the reduced electron-phonon coupling and the reduced electron-electron interactions.

4:18PM J2.0008 Ultrafast Two-Pulse Photocurrent Correlation Measurements of Single Atomic Layer MoS_2 Photodetectors
HAINING WANG, CHANGJIAN ZHANG, WEI-MIN CHAN, OKAN KOKSAL, SANDIP TIVITY, FARHAN RANA, Cornell Univ — We present, for the first time, results from ultrafast measurements of carrier transport and carrier dynamics in monolayer MoS_2 photodetectors by time resolved two-pulse photocurrent correlation technique [1]. The photocurrent transient contains information on the recombination dynamics and transport physics of the photoexcited carriers and excitons. The measured photocurrent correlation data shows two distinct decay time constants: one fast around 5 ps and one much slower around 100 ps. The observed dynamics are largely independent of temperature (10K to 300K) and pump fluence (1 to 16 μJ/cm²). The fast decay is attributed to the fast recombination of the photoexcited carriers rather than to the transport and extraction of the photoexcited carriers from the device. The decay time scales, the temperature and the pump fluence dependence of the observed dynamics are in good agreement with defect-assisted carrier recombination model via Auger scattering. The observed time scales also agree well with our all-optical pump-probe studies. The strong Coulomb interactions and resulting strong electron-hole correlations in monolayer MoS_2, make carrier and exciton capture by defects the dominant carrier recombination mechanism.

4:30PM J2.0009 Proximity-induced superconductivity in transition metal dichalcogenides
DRISS M. BADIANE, William & Mary Coll, CHRISTOPHER TRIOLA, E. ROSSI, Department of Physics, College of William and Mary, Williamsburg, Virginia 23187, USA — In this work we study the proximity-induced superconductivity in a monolayer of the transition metal MoS_2 placed on top of a superconducting substrate. We investigate the symmetries of the proximity-induced superconducting pairing amplitude and we find that superconducting substrates with spin-orbit coupling can induce odd-frequency pairing in the MoS_2 monolayer. We discuss the relevant experimental signatures of the proximity-induced superconducting phase in the MoS_2 monolayer.

4:42PM J2.0010 In search of single layer superconductivity in semiconducting transition metal dichalcogenides
EFREn NAVARRO-MORATALLA, YAFANG YANG, HUGH CHURCHILL, PABLO JARILLO-HERRERO, Department of Physics, Massachusetts Institute of Technology — Charge carrier density control is a keystone in the study of 2D semiconductors. The use of ionic liquids as gate electrodes gives rise to the formation of high capacitance electrical double layers (EDLs) that permit exploring very high carrier density regimes (n ≈ 10^{15} cm^{-2}), opening the door for the study of field-induced correlated states, such as ferromagnetism or superconductivity. Though pioneering works on transition metal dichalcogenides have provided proof of the use of EDLs for the induction of superconductivity in bulk crystals or in the surface of thick flakes, no reports of single layer superconductivity have been put forward. We take advantage of crystal growth techniques, the EDL approach, the wide range of metal dichalcogenides and the van der Waals stacking to fabricate ultraflat samples that will permit exploring the high carrier density regime in search for switchable single layer superconductivity. The use of a liquid gate opens the possibility of studying the effect that strain or even the presence of molecular species may have in the superconducting state.
4:54PM J2.00011 Electronic and magnetic properties of NbSe$_2$ monolayer doped vacancy and transition metal atoms$^{1}$. PRIYANKA MANCHANDA, DAVID SELLMYER, RALPH SKOMSKI, Univ of Nebraska - Lincoln — Two-dimensional transition-metal dichalcogenides (2D TMDs) have attracted much attention recently due to potential applications including optoelectronic devices. Atomically thin layers of materials such as MoS$_2$, WS$_2$, NbS$_2$, NbSe$_2$, TaTe$_2$ can easily be synthesized by exfoliation techniques and exhibit variety electronic phases such as metal, semiconductor, superconductor depending on the choice of metal. Most of the TMDs are nonmagnetic and various techniques have been proposed to induce or modulate magnetic properties that are essential for nanoelectronic device applications. We use DFT calculations to analyze the effect of strain, hydrogen adsorption, and doping. Emphasis is on the magnetic properties of NbSe$_2$ monolayers containing vacancies and 3d transition metal atoms. We find that magnetism can be induced by vacancy creation and transition metal-substitution in NbSe$_2$, with effects similar to strain and hydrogen adsorption. The moment mainly arises from the localized nonbonding 3d electrons of the transition-metal atoms. Our findings contribute to the ongoing search for “better-than-graphene” thin-film materials for novel electronic devices.

$^1$This research is partially supported by DOE BES (DE-FG02-04ER46152).

5:06PM J2.00012 Superconductivity Series of Ion-gated Transition Metal Dichalcogenides. WU SHI, JIANTING YE$^1$, YIJING ZHANG, RYUJI SUZUKI, MASARO YOSHIDA, NAOKO INOUE, YU SAITO, YOSHIHIRO IWASA, Univ of Tokyo — Semiconducting transition metal dichalcogenides (TMDs) have attracted considerable interest as typical two-dimensional (2D) materials. By mechanical cleavage, atomically flat and chemically stable thin flakes of TMDs can be readily obtained from bulk crystals. Recently, coupling with high efficient ionic media, TMD thin flakes have exhibited extraordinary electronic and opto-vascular properties in the form of electrical double layer transistors (EDLTs). The introduction of high-density carriers have also induced metal-insulator transition and superconductivity in MoS$_2$, revealing an enhanced Tc and a dome-like phase diagram that is inaccessible through conventional chemically doping. In this work, we report the discovery of a superconductivity series based on a further exploration of high-density carriers and both magnetic and transport measurements of this materials physical properties.

Tuesday, March 3, 2015 2:30PM - 4:54PM — Session J3 COM FIAP: Invited Session: Research and Opportunities in Nanoscience: An Industrial Perspective 002AB - Alfredo Alexander-Katz, Massachusetts Institute of Technology

2:30PM J3.00001 Nanofabrication in the Magnetic Recording Industry: Past, Present and Future. RICARDO RUIZ, HGST, a Western Digital Company — The magnetic recording industry stands out as an example of multidisciplinary nanotechnology that keeps pushing the envelope in terms of controlling matter and events at the nanometer length scale. From magnetic media composed of sub-10 nm grains, to overcoat protecting layers that are only 2-3 nm thick, to read sensors that are ~ 30 nm wide, to recording heads that fly at ~ 5 nm heights with speeds up to 100 mi/hr, nanotechnology and nanofabrication have been inseparable to the success and extendibility of hard disk drives. Looking into the future, as the demand for data storage continues to increase in a data-centric, cloud-connected environment, future magnetic recording will need to scale accordingly to accommodate ever increasing demands for areal density gains. Future storage technologies such as heat assisted magnetic recording that employs plasmonic antennas or magnetic bit patterned media that requires self-assembly of block copolymers, also stake their success in the advances of nanoscience. I will review research opportunities in this industry with a personal perspective of a decade’s worth in self-assembly for lithographic applications.

3:06PM J3.00002 From silicon nanowire sensors to making living safer. MONIKA WEBER, Yale University

3:42PM J3.00003 Control of crystal morphology and orientation in nano-confined semi-crystalline polymer films to obtain superior barrier performance. BERNARD OBI, The Dow Chemical Company — Several global megatrends are driving the need for packaging films that offer much more superior barrier to oxygen and water vapor transmission than have been traditionally achieved, whilst maintaining high levels of transparency. For food packaging applications targeting aluminum foil barrier performance, OTR and WVTR of approximately 10$^{-4}$ cc/m$^2$/day-atm are typically required. The U.S. flexible packaging market was predicted to exceed $26.5$ billion by 2010 with an annual growth rate of over 67 wt %. We have worked at understanding the parameters that control the transmission of small penetrating molecules through these thin transparent polymeric flexible barrier films, and how to design for high barrier performance. The dispersion of large aspect ratio impervious inclusions in an In-plane oriented morphology into these films lead to very high tortuosity and correspondingly very high barrier performance. A physical model that describes mechanistically the spatial control of crystallization kinetics in a nano-confined geometry using micro-layer technology to obtain predominantly “In-plane” lamellae orientation in semi-crystalline barrier polymer films was validated for providing up to 200X improvement in barrier performance.

4:18PM J3.00004 Integrated Ge laser for silicon photonics platform. RODOLFO CAMACHO, Intel Corporation — The exponential increase of data transfers and requirements have produced difficult constraints that silicon photonics is posed to solved. The integrated platform of silicon photonics. In this ecosystem one of the main barriers is the fabrication of integrated transceivers, which translates into lasers on Si. A material proposed is germanium. Growth techniques, laser design and theory are demonstrated concluding in the creation of a 0.2% biaxial strain and highly n-type doped Ge laser exhibiting gain > 1000 cm$^{-1}$.

Tuesday, March 3, 2015 2:30PM - 5:30PM — Session J4 FOEP: Invited Session: Forum on Outreach and Engaging the Public Mayor Cockrell Room 004 - R. Micahael Barnett, Lawrence Berkeley National Laboratory
Room 005 - Anderson Janotti, University of California, Santa Barbara

and disseminate the results of efforts that are enhancing the quality and visibility of broader impacts activities in whatever form they take. As access to a community of colleagues working at the nexus of scientific research and informal education for further exploration. Through heightened awareness, (STEM) education professionals provide researchers, graduate students and staff resources to tap into as they consider their broader impacts directions. Web conditions in fostering science learning and literacy in informal settings, as well as an expanding network of informal science, technology, engineering and math (STEM) education opportunities. By creating exhibits, media or programming that will convey the scientific concepts and processes involved in research and engage students and learning goals or other intended impacts. One approach to developing such plans is to partner with an informal science education institution, program, project or individual to create exhibits, media or programming that will convey the scientific concepts and processes involved in research and engage students and public audiences in appreciation for, and understanding of. A growing body of evidence-based knowledge about what works for whom and under what conditions in fostering science learning and literacy in informal settings, as well as an expanding network of informal science, technology, engineering and math (STEM) education professionals provide researchers, graduate students and staff resources to tap into as they consider their broader impacts directions. Web infrastructure like the informalscience.org website and others offer aggregated, vetted, and searchable examples of successful partnerships and strategies, as well as access to a community of colleagues working at the nexus of scientific research and informal education for further exploration. Through heightened awareness, stronger connectivity and a growing repository of knowledge, projects like the Center for Advancement of Informal Science Education (CAISE) hope to support and disseminate the results of efforts that are enhancing the quality and visibility of broader impacts activities in whatever form they take.

3:06PM J4.00002 Quantum physics reimagined for the general public, JULIEN BOBROFF, LPS, Université Paris Sud — Quantum Physics has always been a challenging issue for outreach. It is invisible, non-intuitive and written in sophisticated mathematics. In our “Physics Reimagined” research group, we explore new ways to present that field to the general public. Our approach is to develop close collaborations between physicists and designers or graphic artists. By developing this new kind of dialogue, we seek to find new ways to present complex phenomena and recent research topics to the public at large. For example, we created with web-illustrators a series of 3D animations about basic quantum laws and research topics (graphene, Bose-Einstein condensation, decoherence, pump-probe techniques, ARPES...). We collaborated with designers to develop original setups, from quantum wave animated models or foldings to a superconducting circus with levitating animals. With illustrators, we produced exhibits, comic strips or postcards displaying the physicists in their labs, either famous ones or even our own colleagues in their daily life as researchers. With artists, we recently made a stop-motion picture to explain in an esthetic way the process of discovery and scientific publication. We will discuss how these new types of outreach projects allowed us to engage the public with modern physics both on a scientific and cultural level and how the concepts and process can easily be replicated and expanded by other physicists. We are at the precise time when creative tools, interfaces, and ways of sharing and learning are rapidly evolving (wikipedia, MOOCs, smartphones...). If scientists don’t step forward to employ these tools and develop new resources, other people will, and the integrity of the science and underlying character of research risks being compromised. All our productions are free to use and can be downloaded at www.PhysicsReimagined.com (for 3D quantum videos, specific link: www.QuantumMadeSimple.com)

3:42PM J4.00003 Developing a Global Science and Math Education System Based on Real Astronomy Data, CARLTON PENNYPACKER, Lawrence Berkeley National Lab and UC Berkeley — Global Hands-On Universe (GHOU) is an educational system where students use real astronomy data from (largely optical) telescopes to learn fundamental physics, math, astronomy, and technology. GHOU is a good example of a collaborative global education project, where data, software, teacher training methods, curriculum, activities, telescopes, and human resources are developed by many members of GHOU and then shared internationally. Assessments show that in this program students learn more science and math than in conventional classroom teaching, and students change their attitudes towards choosing careers in science and technology. GHOU is an exemplar of appropriate use of computers in the classroom for real data analysis. The International Asteroid Search program of GHOU has helped students discover over 700 asteroids. Half a dozen high schools have named the asteroids they have found after their high school (some from here in Texas)!

4:18PM J4.00004 The Role of Outreach in NSF Proposals, RANDAL C. RUCHTI, University of Notre Dame — The NSF has two merit criteria that must be addressed in proposals, intellectual merit and broader impacts. While the former is generally well understood, that latter less so. This presentation will review the issues of broader impacts, of which outreach is but one possible approach, and give a view from the perspective of a research scientist who recently served as a program director in the NSF Division of Physics.

4:54PM J4.00005 Developing Broader Impacts Activities through Informal STEM Education Collaborations and Strategies, JAMES BELL, Center for Advancement of Informal Science Education — With the National Science Foundation and other funding agencies’ renewed emphasis on broader impacts merit criterion in proposals, investigators and directors of education, outreach and engagement are challenged to identify, plan and implement innovative and transformative activities that engage a variety of audiences in the broader impacts of scientific research. These activities are also often required to have an evaluation plan for assessing the effectiveness of the strategies employed to achieve learning goals or other intended impacts. One approach to developing such plans is to partner with an informal science education institution, program, project or individual to create exhibits, media or programming that will convey the scientific concepts and processes involved in research and engage students and public audiences in appreciation for, and understanding of. A growing body of evidence-based knowledge about what works for whom and under what conditions in fostering science learning and literacy in informal settings, as well as an expanding network of informal science, technology, engineering and math (STEM) education professionals provide researchers, graduate students and staff resources to tap into as they consider their broader impacts directions. Web infrastructure like the informalscience.org website and others offer aggregated, vetted, and searchable examples of successful partnerships and strategies, as well as access to a community of colleagues working at the nexus of scientific research and informal education for further exploration. Through heightened awareness, stronger connectivity and a growing repository of knowledge, projects like the Center for Advancement of Informal Science Education (CAISE) hope to support and disseminate the results of efforts that are enhancing the quality and visibility of broader impacts activities in whatever form they take.

Tuesday, March 3, 2015 2:30PM - 5:30PM
Session J5 FIAP GERA DMP: Electricity to Light Conversion: Solid State Lighting, Juan Gorman
Room 005 - Anderson Janotti, University of California, Santa Barbara
2:30PM J5.00001 Accurate treatment of spontaneous polarization in III-nitrides1, CURTIS E. DREYER, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — The III-nitride compounds assume the wurtzite crystal structure in the ground state and therefore exhibit spontaneous and piezoelectric dipole moments in the c direction. Discontinuities in these moments at heterostructure interfaces result in electric fields in the layers, which can be detrimental because they separate electrons and holes in quantum wells. Accurate values for polarization differences are critical for understanding and engineering III-nitride heterostructures. Direct experimental measurement of spontaneous polarization has not been possible to date, and calculations are complicated by the necessity to choose a reference structure. The universal choice of reference structure for wurtzite has been zincblende; we demonstrate that this choice does not allow consistent determination of the differences of spontaneous polarizations between materials, which determine their physical manifestation. Using first-principles techniques based on hybrid density functional theory, we have determined polarization discontinuities using a consistent reference based on the hexagonal layered structure of these materials. We will discuss the results in light of available experimental data, and outline consequences for device simulations.

1Work supported by DOE.

2:42PM J5.00002 Electronic and optical properties of AlN/GaN superlattices from first-principles calculations, DYLAN BAYERL, EMMANOUIL KIOUPAKIS, University of Michigan — Group-III-nitrides are important materials for efficient light emitters in the ultraviolet and visible range. Superlattices of AlN/GaN quantum wells are especially promising for ultraviolet light emission. We use first-principles calculations to investigate the electronic and optical properties of AlN/GaN quantum well superlattices. Density functional theory with quasiparticle corrections from the GW method provides accurate electronic band structures. We then solve the Bethe-Salpeter equation to predict exciton binding energies and fundamental optical emission energies from first principles, yielding good agreement with available experimental measurements. Ultimately, we elucidate the relationship between optical emission energy and well/barrier thickness, as well as demonstrate mitigation of the quantum confined Stark effect in ultra-narrow wells for enhanced radiative recombination efficiency. This research was supported by the J. Robert Byaster Computational Innovation Graduate Fellowship and in part by C3S, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science. Computational resources were provided by the DOE NERSC facility.

2:54PM J5.00003 Correlation between optical properties and strain relaxation in thick InGaN epitaxial films,2, WEN-CHE TSAI2, Chung Yuan Christian University in Taiwan, CHIA-HE HSU, SHAO-FU FU, FANG-WEI LEE, CHIN-YU CHEN, WU-CHING CHOU, WEI-KUO CHEN, WEN-HAO CHANG1, Department of Electrophysics, National Chiao Tung University — The alloy compositions, strain distributions and emission properties of thick In$_x$Ga$_{1-x}$N layers with x ranging from 0.13 to 0.38 are investigated. High resolution x-ray diffractions (XRD) and reciprocal space mapping (RSM) along an asymmetric axis reveal that the In composition inhomogeneity is accompanied by strain relaxations during the growth of thick InGaN layers. Photoluminescence (PL) results together with RSMs indicate that the observed double PL peaks are associated with the strained and relaxed phase in the InGaN films. It is further indicated that the relaxed phase in InGaN films exhibits better emission efficiency than the strained phase from the temperature-dependent PL measurements. Recombination dynamics from time-resolved PL measurements reveal that the carrier localization effect is more pronounced in the relaxed phase. According to the optical properties, the emission efficiency is strongly correlated with the localization effect in thick InGaN films.

2This work was supported in part by the program of MOEATU and the National Science Council of Taiwan under Grant No. NSC-101-2628-M-009-002-MY3.

2:56PM J5.00004 Characterization of M-plane InGaN/GaN Quantum Wells Grown on Mis-oriented γ-LiAlO$_2$ by Plasma-Assisted Molecular Beam Epitaxy, YU-CHIAO LIN, IKAI LO, CHENG-HUNG SHIH, ZHANG WEI XIANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan, MING-CHI CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Kaohsiung, Taiwan — We have grown a series of InGaN/GaN quantum wells on misoriented LiAlO$_2$ (LAO) substrate with different growth parameters by plasma-assisted molecular beam epitaxy (PAMBE). The sample structure consists of M-plane InGaN/GaN quantum wells with 25nm GaN barrier/5nm InGaN well) with a ~225nm GaN buffer layer between the quantum wells and LAO substrate. The mis-cut angle of LAO substrate was tilted 11° off [011] direction to match the atoms of GaN lattice. From the X-ray diffraction (XRD) measurement, we found two peaks of 34.6° and 32.2°, indicating the LAO(100) substrate and [110] oriented (M-plane) for the InGaN thin films, respectively. The surface morphology, optical property and microstructure of the samples were investigated by scanning electron microscope (SEM), photoluminescence (PL) and transmission electron microscope (TEM) measurements, as well.

3:18PM J5.00005 Growth of high-quality InN thin films on InGaN buffer layer by plasma-assisted molecular beam epitaxy, CHE-NCHI CHAO, IKAI LO, CHENG-HUNG SHIH, CHIA-HSUAN HY, YING-CHIEH WANG, YU-CHIAO LIN, CHENG-DA TASI, SHOU-TING YOU, Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan, R. O. C. — Four samples were grown on 2 inch c-plane (0001) sapphire substrates with 4μm-thick GaN template. The InN thin films were grown on InGaN buffer layer by low-temperature plasma-assisted molecular beam epitaxy (PAMBE) system. These samples were grown under a varied temperature of InGaN buffer layers: 500°C, 540°C, 570°C, and 600°C. The structure properties of these samples were analyzed by X-ray diffraction (XRD). The interference fringes of InN grown on the sample 1 (the growth temperature of InGaN buffer layer at 500°C) exhibit prominent oscillations, which indicates that the sample has a high quality and layer by layer epitaxial structure. The surface morphology and microstructure of samples were investigated by scanning electron microscopy (SEM), atomic force microscopy (AFM), and transmission electron microscopy (TEM). We confirmed the smooth surface and high quality crystalline for the sample.

3:30PM J5.00006 Microstructure of Er optical centers in the large-bandgap semiconductor GaN, DEEPU GEORGE, ALI CHARKHESHT, Virginia Tech, STEPHEN MCGILL, National High Magnetic Field Laboratory, HONGXING JIANG, Texas Tech University, JOHN ZAVADA, NYU Polytechnic, NGUYEN VINH, Virginia Tech — Photoluminescence properties of Er optical centers in GaN epi-layers grown by metal-organic chemical vapor deposition are investigated in magnetic fields up to 17 T and high-resolution time-resolved PL spectroscopy. The magnetic field induced splitting is observed for all the main lines of the Er-related photoluminescence spectrum. For the most intense emission line, angular dependence of the splitting is measured in the (1120) crystallographic plane of the sample. The effective g-tensor, corresponding to the difference between individual g-tensors of the lowest multiplets of the ground and the first excited states, is experimentally determined. The neto-mageto-optical measurements, the time-resolved photoluminescence and the temperature dependence of the photoluminescence spectroscopy show that the samples have two main optical centers and they can be excited selectively under band-to-band and resonance excitations.
3:42PM J5.00007 Effect of Dopant Activation on Device Characteristics of InGaN-based Light Emitting Diodes — NICHOLAS LACROCE, GUANYU LIU, CHEE-KEONG TAN, Center for Photonics and Nanoelectronics, Department of Electrical and Computer Engineering, Lehigh University; RONALD A. ARIF, SOO MIN LEE, Veeco Instruments, Inc.; NELSON TANSU, Center for Photonics and Nanoelectronics, Department of Electrical and Computer Engineering, Lehigh University — Achieving high uniformity in growths and device characteristics of InGaN-based light-emitting diodes (LEDs) is important for large scale manufacturing. Dopant activation and maintaining control of variables affecting dopant activation are critical steps in the InGaN-based light-emitting diodes (LEDs) fabrication process. In the epitaxy of large scale production LEDs, in-situ post-growth annealing is used for activating the Mg acceptor dopant in the p-AlGaN and p-GaN of the LEDs. However, the annealing temperature varies with respect to position in the reactor chamber, leading to severe uniform dopant activation issue across the devices. Thus, it is important to understand how the temperature gradient and the resulting variance in Mg acceptor activation will alter the device properties. In this work, we examine the effect of varying p-type doping levels in the p-GaN layers and AlGaN electron blocking layer of the GaN LEDs on the optoelectronic properties including the band profile, carrier concentration, current density, output power and quantum efficiency. By understanding the variations and its effect, the identification of the most critical p-type doping layer strategies to address this variation will be clarified.

3:54PM J5.00008 Electrical contact of wurtzite GaN microdisks on p-type GaN template — CHENG-DA TSAI, IKAI LO, YING-CHIEH WANG, YU-CHI HSU, CHIA-HSUAN HU, MITCH M.C. CHOU, CHEN-CHI YANG, YU-CHIAO LIN, Department of Physics, Department of Materials and Optoelectronic Science, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University — We developed a back processing to fabricate a secure electrical contact of wurtzite GaN microdisk on a p-type GaN template with the orientation, [10-10]_disk // [10-10]_template. GaN microdisks were grown on LiAlO_2 substrate by using plasma-assisted molecular beam epitaxy [1]. In the further study, we analyzed the TEM specimen of a sample with annealed GaN microdisk/p-typed GaN template by selection area diffraction (SAD) to confirm the alignment of the microdisks with the template at the interface. From the I-V measurements performed on the samples, we obtained a threshold voltage of ∼ 5.9 V for the current passing through the GaN microdisks with a resistance of ∼ 45 KΩ. The electrical contact can be applied to the nanometer-scaled GaN light-emitting diode.

4:06PM J5.00009 Spatially resolved visible broad band multi-photon luminescence in GaN micro-pyramids — SWEEN BUTLER, Univ of North Texas, MOHAMED FIKRY, KLAUS THONKE, Ulm University, ARUP NEOGI, Univ of North Texas, ULM UNIVERSITY COLLABORATION — Multi-photon induced visible broad band luminescence was observed in position controlled m-polar GaN hexagonal micro-pyramids using a tunable near-infrared femtosecond laser source at room temperature. The GaN micro-pyramids were grown by molecular beam epitaxy on the high quality GaN template by using the epitaxial lateral overgrowth method. Excitation wavelengths corresponding to near band gap and below band gap energies were used. Spatially resolved optical characterization from a single micro-structure was achieved using multi-photon microscopy and spectroscopy. We observed broad band luminescence in the range of 400 nm to 600 nm for both near band gap and below band gap excitations. Power dependent excitation dependence confirms the origin of broad band visible emission as multi-photon induced luminescence (MPL). Band width of broadband light emission due to MPL can be controlled by selective spatial excitation of the GaN micro-pyramid.

4:18PM J5.00010 High Efficiency Alternating Current Driven Organic Light Emitting Devices Employing Active Semiconductor Gate Layers — GREGORY SMITH, JUNWEI XU, DAVID CARROLL, Wake Forest University — In this work, we describe the role of semiconductor-polymer interfaces in alternating current (AC) driven organic electroluminescent (EL) devices. We implement inorganic semiconductor materials between the external contact and the active layers in organic light EL devices. Precise control of capacitance and charge injection is required to realize bright and efficient large area AC driven devices. We show how this architecture results in active gating to the polymer layers, resulting in the novel ability to control the capacitance and charge injection characteristics. We propose a model based on band bending at the semiconductor-polymer interface. Furthermore, we elucidate the influence of the semiconductor-polymer interface on the internally coupled magnetic field generated in an alternating current driven organic light emitting device configuration. Magnetic fields can alter the ratios of singlet and triplet populations, and we show that internal generation of a magnetic field can dramatically alter the efficiency of light emission in organic EL devices.

4:30PM J5.00011 Elasto-optic effect in semiconductors: a first principle approach using Maximally Localized Wannier Functions — XIN LIANG, SOHRAB ISMAIL-BEIJI, Applied Physics, Yale University — Strain-induced changes of optical properties are of use in the design and functioning of devices that couple photons and phonons. The elasto-optic (or photo-elastic) effect describes a general materials property where strain induces a change in the dielectric tensor. Despite a number of experimental and computational works on this area, it is fair to say that a basic understanding of the effect and its materials dependence is lacking: for example, we know of no materials design rules for enhancing (or suppressing) elasto-optic response. Here, we begin by computing the elasto-optic tensor of silicon using Density Functional Theory (DFT). By analyzing the longitudinal dielectric response to uniaxial strain, we find that a promising avenue to physical understanding of the basis of the effect is to work in a real space representation and to employ Maximally Localized Wannier Functions (MLWFs). We describe our results based on this approach. This work is supported by the National Science Foundation through grant NSF DMR-0808665.

4:42PM J5.0012 Directional Control of Plasmon-Exciton interaction with Plexcitonic Crystals — SINAN BALCI, Department of Astronautical Engineering, University of Turkish Aeronautical Association, 06790 Ankara, Turkey, ERTU-GRUL KARADEMIR, COSKUN KOCABAS, ATILLA AYDINLI, Department of Physics, Bilkent University, 06800 Ankara, Turkey — Plexcitons [1] are strongly coupled plasmon excitons. In this work, we developed a platform, consisting of one and two dimensional corrugated surface patterns coated with a thin metal film and a dye solution. This system shows a controlled coupling action based on the excitation direction of SPP modes [2]. Our scheme is based on the control of wavelengths of the forbidden SPP modes. Three kinds of patterns have been tested: a one dimensional uniform, a triangular, and a square lattice type crystals. For all three cases, lowest wavelength of the band gap is observed in $\Gamma$ to M direction. For triangular and square lattice cases, band gap center oscillates between two finite values for every $60^\circ$ and $90^\circ$, respectively. We utilized this behavior to control SPP and J-aggregate coupling. We observe directional dependence of Rabi splitting energy varying between 0 meV and 60 meV. Square lattice gives the ability to tune a larger band gap, whereas triangular lattice gives higher number of symmetry points. Simulations show that, an 80 nm deep triangular lattice with 280 nm periodicity can result in omnidirectional decoupling of plexcitons.

4:54PM J5.00013  Thermochemical and electronic properties of amorphous oxides, nitrides and sulfides, PAWEŁ ZAWADZKI, STEPHAN LANY, National Renewable Energy Laboratory — Amorphous thin films materials become increasingly important components of many functional devices such as thin film displays, photovoltaic cells or thin film transistors. Due to lack of grain boundaries, they have superior uniformity and smoothest, flexibility and corrosion resistance. Amorphous thin films are typically prepared using physical vapor deposition (PVD) techniques at temperatures well below the melting point of deposited material (\(<0.2Tm\)). Computational models of amorphous structures, however, are almost elusively constructed from a high temperature equilibrated crystal melt using simulated annealing (SA) protocol. To account for low temperature growth conditions of amorphous thin films we recently developed a new simulation technique [1]. The method, kinetically limited minimization (KLM), starts from a randomly initialized structure and minimizes the total energy in a number of local structural perturbation-relaxation events. We apply KLM to model amorphous structures of 20 binary oxides, nitrides and sulfides and compare their thermochemical, structural and electronic properties.

5:06PM J5.00014 Colossal photoconductivity in transparent perovskite semiconductor BaSnO$_3$, JISUNG PARK, USEONG KIM, KOOKRIN CHAR, Seoul Natl Univ — We compare photoconductivities of BaSnO$_3$ (BSO) and SrTiO$_3$ (STO). Photoconductivity of STO has been intensively studied for its high potential for UV detector and optical devices. On the other hand, BSO has recently started to draw a large attention for its high electron mobility and thermal stability. BSO and STO have the same perovskite structure and similar band gap. Epitaxial thin films of BSO and STO were grown by pulsed laser ablation. The spectral responses measured by the monochromatic light showed peaks around the band gap of each film, an evidence that the electron-hole pair generation is the main mechanism for the photoconductivity in both materials. We have found the photoconductivity of BSO to be several orders of magnitude higher than that of STO. In addition, there exists a larger “persistent” photoconductivity in BSO. The high mobility of BSO, which is two orders of magnitude larger than that of STO at room temperature, should be partially responsible for the higher photoconductivity. The small difference between the direct gap and indirect gap of BSO may make band to band transition easier. We are also investigating the effect of dislocations on the “persistent” photoconductivity.

5:18PM J5.00015 $m$-Plane GaN Growth on “Double Miscut” Bulk Substrates for Blue Diode Applications, LEAH KURITZKY, DANIEL MYERS, KATHRYN KELCHNER, SHUJI NAKAMURA, STEVE DENBAARS, CLAUDE WEISBUCH, JAMES SPECK, Univ of California — Santa Barbara — Although nearly 100% of today’s commercial GaN devices are grown on the c-plane, the nonpolar $m$-plane is an alternative orientation that is free from polarization-induced electric fields, which separate carrier wavefunctions in c-plane InGaN quantum wells (QWs) and reduce carrier combination rates compared to m-plane. Performance of m-plane blue laser diodes is currently limited by low In uptake and broad linewidth in the blue spectrum compared to c-plane. This work examines the impact of m-plane surface miscut on these performance aspects. The morphology was examined by atomic force microscopy for homoepitaxy on co-loaded substrates: on-axis, $1^\circ$ c−miscut, $1^\circ$ a−miscut. All three films showed regions of diagonal a−c step direction where pure a− or c−direction steps were expected. These a+c regions also emitted longer wavelength in fluorescence and cathodoluminescence than other step directions. “Double miscut” substrates in the combined a− and c−directions take advantage of the observed stable a+c step direction and redshift. Multi-QWs on double miscut substrates exhibited <30 nm linewidth in the blue spectrum and higher In uptake than ever achieved for standard miscut m−plane.

Tuesday, March 3, 2015 2:30PM - 5:18PM - Session J6 DMP, DCOMP: Focus Session: Phonons, Spins, Charge and Orbital ordering in Complex Oxides 006A - Roman Engel-Herbert, Pennsylvania State University

2:30PM J6.00001 Nonlinear phononics and ultrafast control at complex interfaces, ANDREA CAVALLERI, Max-Planck Research Group for Structural Dynamics, Univ. Hamburg — No abstract available.

3:06PM J6.00002 Capturing photoinduced structural distortion within a unit cell of BiFeO$_3$, HAIDAN WEN, Argonne Natl Lab, MICHEL SASSI, Pacific Northwest National Laboratory, ZHENLIN LUO, University of Science and Technology of China, CAROLINA ADAMO, Stanford University, DARRELL SCHLOM, Cornell University, ROSSO KEVIN, Pacific Northwest National Laboratory, XIAOYI ZHANG, Argonne Natl Lab — The interaction of light with correlated materials has been an intensively studied research forefront in which the coupling of radiation energy to selective degrees of freedom offers a novel contact-free control knob to tune functionalities on ultrafast time scales. We studied a photoexcited multiferroic BiFeO$_3$ thin film using time-resolved x-ray absorption spectroscopy aided by density functional theory calculations. The study revealed a uniaxial deformation of the unit cell at a constant volume with a minimal oxygen octahedron rotation, consistent with the influence of photoinduced carriers to the ferroelectric polarization. These important findings illustrate a microscopic picture of local structural reconfiguration around iron atoms at atomistic length scales during a photocarrier-mediated nonequilibrium process in polar materials.

3:18PM J6.00003 Neutron Scattering Study of Low Energy Phonons and Spin Waves in Multiferroic BiFeO$_3$, ZHIJUN XU, UC Berkeley, GUANGYONG XU, JOHN SHNEELOCK, Brookhaven National Lab, JINSHEANG WEN, Nanjing University, PETER GEHRING, NIST, CHRIS STOCK, The University of Edinburgh, BARRY WINN, MASAAKI MATSUUDA, MA JIE, Oak Ridge National Lab, GENDA GU, Brookhaven National Lab, TOSHIMITSU ITO, AIST, STEPHEN SHAPIRO, Brookhaven National Lab, ROBERT BIRGENEAU, UC Berkeley — We have performed inelastic neutron scattering studies of the low-energy phonon and spin-wave modes in the multiferroic BiFeO$_3$. The low-energy phonon and spin wave dispersion relations along different directions have been mapped out over a broad temperature range from 100K to 750K. The temperature dependence of the intensities, dispersion relations, and lifetimes (inverse energy width) of these phonon and spin wave modes will be presented. Possible interactions between the lattice and spin dynamics will also be discussed. This work is supported by the Office of Basic Energy Sciences, DOE.

3:30PM J6.00004 Engineering orbital polarization in three-component nickelate heterostructures, CHARLES AHN, Yale University — The interplay between the structural and physical properties of transition metal complex oxides allows for the engineering of their functional properties by tuning atomic-scale structure using interfacial coupling. We show how this principle can be used to achieve orbital polarization and two-dimensional electronic conductivity in nickelate heterostructures [1, 2]. Using a combination of first principles theory and synchrotron-based experiments, we identify key structural features in LaNiO$_3$ thin films grown using molecular beam epitaxy, allowing one to correlate differences in physical structure with electronic transport properties and x-ray absorption spectroscopy measurements. By using general design principles, such as charge transfer and inversion symmetry breaking, which lead to degeneracy breaking of the Ni 3d orbitals, one can design and fabricate tri-component superlattices to engineer the electronic and orbital properties of rare-earth nickelate compounds, achieving a two-dimensional single band electronic surface at the Fermi energy.

4:06PM J6.00005 Time-resolved hard X-ray nano-diffraction study on the long-lived strain in BiFeO₃, induced by optical transient grating

YI ZHU, Argonne National Lab, QINGTENG ZHANG, PICE CHEN, University of Wisconsin, Madison, CAROLINA ADAMO, Cornell University, ZHONGSHOU CAI, DONALD WALKO, ERIC DUFRESNE, Argonne National Lab, DARRELL SCHLOM, Cornell University, PAUL EVANS, University of Wisconsin, Madison, HAIDAN WEN, Argonne National Lab, ARGONNE NATIONAL LAB TEAM, UNIVERSITY OF WISCONSIN, MADISON TEAM, CORNELL UNIVERSITY TEAM — Optical transient grating excitation was applied to induce spatially modulated strain in a BiFeO₃ thin film. The spatial profile and the dynamics of the photo-induced strain were measured by time-resolved hard X-ray nano-diffraction at beamline 7-ID of the Advanced Photon Source. By interfering two ultrafast laser beams at 400nm wavelength and ~ 100fs pulse duration, an optical transient grating with ~ 5 micron period sinusoidal profile was created and used to excite the BiFeO₃ sample. By using the nano-focused ultrafast X-ray pulses, both the strain profile and the dynamics induced by the photo-generated carriers were mapped out. We found the out-of-plane strain profile remained sinusoidal while the strain amplitude modulation lasted tens of microseconds, indicating the non-thermal nature of this photo-induced strain in BiFeO₃.

4:18PM J6.00006 Phonon dispersion relation in cubic BaTiO₃

IZUMI TOMENO, Akitu University, JAIME FERNANDEZ-BACA, RIKI KOBAYASHI, SONGKUE CHI, Oak Ridge National Laboratory, KUNIHIKO OKA, National Institute of Advanced Industrial Science and Technology, YORIHIKO TSUNODA, Waseda University — The lattice dynamics of cubic BaTiO₃ (Tc = 405 K) has been investigated along the [100], [110], and [111] directions at T = 453, 700 and 890 K using inelastic neutron scattering. The transverse acoustic (TA) phonon dispersion is relatively isotropic. This indicates that all the measured TA branches are mainly governed by the Ba atom motion against the O atoms. The zone-boundary TA phonon energies for BaTiO₃ are approximately twice as large as those for cubic PbTiO₃. These differences cannot be explained by the A-site atomic mass alone. The large Ba-O force-constant reflects the ionic nature of Ba atom in BaTiO₃. The softening of the transverse optical (TO) ΔΣ and Σ branches in a wide q range at T = 453 K is in contrast to the steep softening of the TO Σ1 branch toward the zone center. The TO Σ1 mode is heavily damped in the range q ≤ 0.25 at 453 K, whereas the well-defined TO Σ1 peak for q = 0.25 is observed at 890 K. The low-lying TO ΔΣ1 and Σ1 branches are primary due to the low-frequency Ti-O-Ti chain-like motion along [001]. The soft mode behavior in BaTiO₃ is discussed in comparison with the previous study on PbTiO₃.

4:30PM J6.0007 [001] electric field effect on phonons in PMN-32PT

JOHN SCHNEELOCH, Brookhaven National Laboratory, ZHUJUN XU, University of California, Berkeley, BARRY WINN, Oak Ridge National Laboratory, CHRIS STOCK, University of Edinburgh, PETER GEHRING, National Institute of Standards and Technology, GUANGYONG XU, Brookhaven National Laboratory — We report inelastic neutron scattering measurements on a single crystal of the relaxor ferroelectric 68%Pb(Mg₁₋ₓTiₓ)O₃-32%PbTiO₃ (PMN-32PT) under an external [001] electric field (0.5 kV/cm). In addition to the partial suppression of diffuse scattering intensities, as previously reported, we also see a field-induced change in acoustic phonon intensities and energies. The change is anisotropic, with clear differences between the [100] and [011] directions. We will discuss these results and their relation to possible changes in the domain structure under field and coupling between diffuse scattering and phonon modes.

4:42PM J6.0008 Magnetic field induced directed dichroism of spin waves in multiferroic BiFeO₃ at THz frequencies

URMAS NAGEL, T. RÖÖM, Nat.-I. Inst. of Chem. Phys. & Biophys., Tallinn, Estonia, S. BORDÁCS, I. KÉSZMÁRKI, Budapest University of Technology and Economics, Hungary, H.T. YI, S.-W. CHEONG, Rutgers Univ., New Jersey, JUN HEE LEE, RANDY S. FISHMAN, Oak Ridge National Laboratory, Tennessee — Using far infrared spectroscopy in high magnetic fields we show that spin excitations in BiFeO₃ simultaneously interact with the electric and magnetic field components of light resulting in directional dichroism (DD) of absorption. DD in BiFeO₃ arises because an applied static magnetic field induces a toroidal moment in the cycloidal spin structure. Strong DD is observed even in the room-temperature state of the material. The results are explained on the microscopic level as an interplay of five different interactions: isotropic exchange couplings between nearest and next nearest neighbors, an easy-axis anisotropy along the ferroelectric polarization, Dzyaloshinskii-Moriya (DM) interaction that creates the cycloid and DM interaction that causes spin canting.

4:54PM J6.0019 Charge Density Behavior of Ionic Liquid Gated Strontium Titanate Nanowires

TERENCE BRETZ-SULLIVAN, ALLEN GOLDMAN, University of Minnesota — Measurements of the current-voltage characteristics of ionic liquid gated nanometer scale channels of strontium titanate have been carried out. These characteristics exhibit a high voltage threshold for conduction and a nonlinear power law behavior at all temperatures measured. The source-drain current of these nanowires scales as a power law of the difference between the source-drain voltage and the threshold voltage. The temperature dependence of the threshold voltage appears to be related to the inverse of the temperature dependent dielectric constant of strontium titanate in qualitative agreement with a simple model of charge density wave depinning. These observations, when taken together, are evidence that a gate induced charge density wave has been induced, and is depinned by strong electric fields. * This work was supported by DOE Basic Energy Sciences Grant DE-FG02-02ER44004. Samples were fabricated at the Minnesota Nanofabrication Center. Parts of this work were carried out in the University of Minnesota Characterization Facility, a member of the Materials Research Facilities Network (www.mrfn.org) funded via the NSF MRSEC program.

5:06PM J6.0010 Neutron and X-ray studies in suppressing orbital order in FeV2O4 with Cr doping

DALMAU REIG-I-PLESSIS, ZHANGSU WEN, ALEXANDER THALER, U. of Illinois, VIASEL O. GARLEA, Oak Ridge National Lab, HAIDONG ZHOU, U. of Tennessee, JACOB RUFF, Cornell U., GREGORY MACDOUGALL, U. of Illinois — Fe₂V₂O₇ is a spinel compound with an orbitally active V⁵⁺ cation on a frustrated pyroclore sublattice and Jahn-Teller active Fe³⁺ on a diamond sublattice. Previous studies show that this material has three structural and two magnetic transitions, and that orbital order leads to coupling between the spin and lattice degrees-of-freedom. The opposite end of the doping series is the multiferroic, FeCr₂O₇, which has spin, but no orbital degree of freedom on the Cr⁴⁺ and only two structural transitions. Although both materials show a higher temperature collinear ferrimagnetic state and a non-collinear phase at lower temperature, the physics must be different since the canting transition in Fe₂V₂O₇ is associated with the orbital order at the lowest temperature. In this talk, I will present the results of synchrotron X-ray and neutron powder diffraction studies of the structural and magnetic transitions in the doping series Fe₂₋ₓCrₓO₇. Specifically, I will comment on the doping-temperature phase diagram we extract from these measurements, and the region of co-existence between distinct non-collinear spin orders which exist at finite doping.

1This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under award number DE-FG02-07ER46453.

2:30PM J7.00001 Spin-Polarized Tunneling Study on Spin-Momentum Locking in Topological Insulators Bismuth Selenide, CHING-TZU CHEN, LUQIAO LIU, IBM TJ Watson Research Center, ANTHONY RICHARDELLA, Department of Physics, Penn State University, ION GARATE, Department of Physics, University of Sherbrooke, YU ZHU, IBM TJ Watson Research Center, NITIN SAMARTH, Department of Physics, Penn State University — In this talk, we will demonstrate that the helical spin texture on topological insulator (TI) surfaces can be electrically detected using four-terminal tunnel junction devices with ferromagnetic top electrodes. Consistent results are obtained in both the Edelstein and spin-galvanic effect configurations, allowing a quantitative determination of the charge-spin conversion efficiency in bismuth selenide. By applying finite DC biases at the junction, we further extract the energy dependence of the effective spin polarization in bismuth selenide. The observed temperature stability up to 200K suggests that TIs can be highly promising for room-temperature spintronics applications.

2:42PM J7.00002 Tunable Intrinsic Spin Hall Conductivities in Bi$_2$(Se,Te)$_3$ Topological Insulators$^1$, CUÑEYT ŞAHIN, MICHAEL E. FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA — It has been recently shown by spin-transfer torque measurements that Bi$_2$Se$_3$ exhibits a very large spin Hall conductivity (SHC)$^1$. It is expected that Bi$_2$Te$_3$, a topological insulator with similar crystal and band structures as well as large spin-orbit coupling, would also exhibit a giant SHC. In this study we have calculated intrinsic spin Hall conductivities of Bi$_2$Se$_3$ and Bi$_2$Te$_3$ topological insulators from a tight-binding Hamiltonian including two nearest-neighbor interactions. We have calculated the Berry curvature, used the Kubo formula in the static, clean limit and shown that both materials exhibit giant spin Hall conductivities, consistent with the results of Ref. 1 and larger than previously reported Bi$_{1-x}$Sb$_x$ alloys$^2$. The density of Berry curvature has also been computed from the full Brillouin zone in order to compute the dependence of the SHC in these materials on the Fermi energy. Finally we report the intrinsic SHC for Bi$_2$(Se,Te)$_3$ topological insulators, which changes dramatically with doping or gate voltage. [1] A.R. Mellnik et al., Nature 511, 449 - 451 (2014) [2] C.Şahin and M.E.Flatté, arXiv:1410.7319

2:54PM J7.00003 Inverse spin galvanic effect in topological-insulator based heterostructures$^1$, MARTIN RODRIGUEZ-VEGA, Department of Physics, College of William and Mary, Williamsburg, VA 23187, USA, GEORG SCHWIETE, JAIRO SINOA, Institut für Physik, Johannes Gutenberg Universität Mainz, Mainz, Germany, ENRICO ROSSI, Department of Physics, College of William and Mary, Williamsburg, VA 23187, USA — We study the inverse spin galvanic effect in heterostructures formed by a layer of a three dimensional strong topological insulator (TI) and a magnetic material. We consider different configurations for the heterostructure and for the contacts. We carefully treat the effect on the TI bands of the proximity of a magnetic material and take into account both intra-band and inter-band contributions to the current-induced spin polarization of the TI surface states. Finally, we discuss the relevance of our results for recent experiments.

3:06PM J7.00004 Low energy electrodynamics of topological insulator thin films, N. PETER ARMITAGE, Johns Hopkins University — Topological insulators are recently discovered states of matter with robust metallic surface states protected by the topological properties of their bulk wavefunctions. A quantum phase transition from a topological insulator to a conventional insulator and a change in topological class can occur only when the bulk bandgap closes. In this work, we have used time-domain terahertz spectroscopy to investigate the low-frequency conductance in (Bi$_{1-x}$In$_x$)$_2$Se$_3$ as we tune through this transition by In substitution. Above certain substitution levels we observe a collapse in the transport lifetime that indicates the destruction of the topological phase. We associate this effect with the threshold where states from opposite surfaces hybridize. The substitution level of the threshold is thickness dependent and only asymptotically approaches the bulk limit $x \sim 0.06$ where a maximum in the mid-infrared absorption is exhibited. This absorption can be identified with the bulk bandgap closing and change in topological class. The correlation ength associated with the quantum phase transition appears as the evanescent length of the surface states. The observation of the thickness-dependent collapse of the transport lifetime shows the unusual role that finite-size effects play in this topological quantum phase transition. In even more recent work on bulk insulating films, we have identified a cyclotron resonance feature. At high magnetic fields we identify an anomalous increase of the scattering rate. I will discuss the reasons for this increase and put it in the context of existing theories for charge transport in topological insulators.

3:42PM J7.00005 Evidence for surface-generated photocurrent in (Bi,Sb)$_2$Se$_3$ and (Bi,Sb)$_2$Te$_3$ thin films$^1$, YU PAN, ANTHONY RICHARDELLA, BING YAO, JOON SUE LEE, THOMAS FLANAGAN, ABHINAV KANDALA, NITIN SAMARTH, the Pennsylvania State University, ANDREW YEATS, PETER MINTUN, DAVID AWSCHALOM, University of Chicago — Illumination with circularly polarized light can produce a helicity-dependent photocurrent in topological insulators such as Bi$_2$Se$_3$. However, the exact origin of this effect is still unclear since it is observed with photons well above the bulk band gap. We report measurements of the polarization-dependent photocurrent in a series of (Bi,Sb)$_2$Se$_3$ thin films with different carrier densities and find that the photocurrent is enhanced as we increase the population of the surface states. This finding is supported by a study of helicity-dependent photocurrents in back-gated (Bi,Sb)$_2$Te$_3$ thin films, where the chemical potential is varied electrostatically. By illuminating our samples at different wavelengths, we show that the helicity-dependent photocurrent is enhanced when the photon energy approaches the energy difference between the lowest and first excited (unoccupied) topological surface states. This leads us to attribute the helicity-dependent photocurrent in topological insulators to optical excitations between these two spin-textured surface states. We will also discuss experiments imaging the spatial variation of these helicity-dependent photocurrents.

$^1$This work is supported by ONR.

Session J8 GSOFT: Colloids: Crystals and Other Phases 006C - Cynthia Olson-Reichhardt, Los Alamos National Laboratory

2:30PM J8.00001 Transitions from hard-sphere colloidal crystals to colloidal crystals with strong attractive interactions1, MATTHEW GRATALE, YE XU, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — Recently, colloid experiments have probed and found interesting differences in the properties of disordered glassy media as a function of the sign of the interparticle interaction [1-3]. Here, we report a similar kind of experiment, this time involving colloidal crystals wherein the interparticle interaction between constituent particles evolves from hard-sphere repulsive to attractive. This change in sign of the interparticle interaction is achieved through use of temperature-tunable depletion agents assembled from surfactants. The depletion-driven entropic attraction between particles in suspension grows with increasing temperature. Increasing temperature changes particle interactions in a dense crystal from repulsive to attractive, and accompanying variations in structure and dynamics of the crystal can be tracked. The increase in attractive interaction can also be turned on slowly and rapidly. Preliminary experiments on polycrystalline hard-sphere samples show accompanying decreases the lattice constant and a fluid-crystal coexistance phase consisting of small, dense “attractive” crystalline domains separated by “voids” filled with dilute colloidal fluid. These voids appear to originate at grain boundaries and near lattice defects in the original hard-sphere polycrystal. Further work explores the dense parts of the colloidal phase diagram with depletion interactions. [1] Eckert et al., PRL 89, 125701 (2002). [2] Pham et al., Science 296, 5565 (2002). 2:42PM J8.00002 Melting of colloidal crystals in small cavities1, YAFEI YANG, Hong Kong University of Science & Tech — We studied the melting behaviors of small colloidal crystals in different sized and shaped small cavities by video microscopy. The crystals were composed of temperature-sensitive N-isopropyl acrylamide (NIPA) microgel spheres. The cavity shape and defects can dramatically alter the melting kinetics and the vibration modes. The melting point can increase or decrease with size of colloid crystal, depending on the shape of the cavity. Single defect-free crystals melt from edges via nucleation mechanism in large hexagonal cavities, but melt catastrophically without nucleation when the cavity is smaller than a threshold. The smaller-angled cavity better promotes the melting.

5:06PM J7.00012 Quantum Spin Hall Effect in Ultrasonic Metamaterials, S. HOSSEIN MOUSAVI, University of Texas at Austin, ALEXANDER B. KHANIKAEV, City University of New York, ZHENG WANG, University of Texas at Austin — The discovery of topological order without breaking time-reversal symmetry, such as that in Quantum Spin Hall (QSH) effect and Topological Insulators, is one of the most groundbreaking advancements of recent years in condensed matters physics. The approach to topological order without breaking time-reversal symmetry is particularly important in elastics because no natural elastic materials show linear nonreciprocal response. Here we illustrate the first elastic-wave system emulating QSH effect and demonstrate existence of topologically protected elastic edge states. The system represents an elastic metamaterial-based phononic crystal. In this crystal, we achieved degenerate linear dispersion for two sets of modes, classified by one of the system’s symmetries. Then, by relaxing and removing that symmetry by deliberately engineering a gauge field emulating a strong spin-orbit coupling of QSH, we observe opening a complete topological bandgap. Finally, the hallmark of the topological order, namely the presence of one-way chiral edge waves insensitive to nonmagnetic defects and disorders, is demonstrated in such elastic metacrystals. We illustrate property of these elastic edge waves to flow around sharp corners without back-reflection or localization.

5:18PM J7.00013 Thickness tunable quantum interference between surface phonon and Dirac plasmon states in thin-films of the topological insulator Bi$_2$Se$_3$1, YURI GLINKA, SERCAN BABAKIRAY, TRENT JOHNSON, DAVID LEDERMAN, Department of Physics and Astronomy, West Virginia University — Raman scattering has been applied to study thin films of the topological insulator Bi$_2$Se$_3$. We observed a more than 100-fold enhancement of Raman responses as laser photon energy switches from 2.33 eV (532 nm) to 1.58 eV (785 nm), which is due to direct optical coupling to Dirac surface states (SS) at the resonance energy of about 1.5 eV (a thickness-independent enhancement) and due to nonlinearly excited Dirac plasmon (a thickness-dependent enhancement). Owing to the direct optical coupling, we were able to monitor an in-plane phonon mode of hexagonally arranged Se-atoms associated with a continuous network of Dirac SS. This mode revealed a Fano lineshape for films below 15 nm thick, resulting from quantum interference between surface phonon and Dirac plasmon states.

2:54PM J8.00003 Born melting of three dimensional crystals, JORIS SPRAKEL, Wageningen University, ALESSIO ZACCONI, Technical University Munich, PETER SCHALL, University of Amsterdam, DAVID A. WEITZ, Harvard University — While the microscopic nature of melting in 1 and 2 dimensions has been elucidated both theoretically and experimentally, this has proven elusive for three-dimensional crystalline solids. Max Born hypothesized that melting can be described as a rigidity catastrophe where the crystal’s shear elastic constant vanishes at melting. Here we show experimental evidence, using three-dimensional imaging of soft colloidal crystals, for such a mechanical instability underlying melting. Our results reveal how non-affine fluctuations govern the mechanical instability which precipitates melting; modification of Born’s theory to take non-affinity into account accurately describes our experimental data. Moreover, we show how the continuous weakening of the crystal’s resistance to shear leads to the emergence of collective fluctuations who’s size diverges at the melting point.

3:06PM J8.00004 Grain Boundary Roughening in Colloidal Crystals1, YILONG HAN, MALIJA LIAO, XIAO XIAO, Hong Kong University of Science and Technology, TOM LUBENSKY, University of Pennsylvania — We studied the grain-boundary roughening transition inside the bulk of thermal-sensitive thin-film colloidal crystals by video microscopy and phase-field simulations. As the volume fraction of the microgel colloidal polycrystals decrease, we observed that the large-angle grain boundaries become rough with the strongest shape fluctuations at the roughening transition point below the premelting point. The roughening transition exhibits critical behaviors. We discovered the structural change responsible to the exotic decrease of the shape fluctuation and the mobility change of the grain boundary as approaching the premelting point. Small-angle grain boundaries do not have the roughening transition and exhibit different melting behaviors.

3:30PM J8.00006 Quantifying Stress Fields of Defects in 3D Colloidal Crystals. MATTHEW BIERBAUM, NEIL Y.C. LIN, CORNELL UNIVERSITY, PETER SCHALL, UNIVERSITY OF AMSTERDAM, JAMES P. SETHNA, ITAI COHEN, CORNELL UNIVERSITY — We introduce the “Stress Assessment from Local Anisotropy” (SALSA) method and use it to directly measure the local stress fields of defects including vacancies, dislocations, and polycrystals in 3D colloidal suspensions. In this technique, we extract a time-series of particle positions from confocal images from which we determine stresses on the particle scale. In the case of both bulk voids and the particle scale, we find a nonlinear pressure ring which is well described by linear elastic theory with a geometric nonlinearity. We next measure the stress fields in a polycrystal before and after cyclic shear. We find that the normal stresses in the grain boundaries are about 10%-20% lower than in the grains. This provides a more detailed, particle level measurement of polycrystalline stresses that is consistent with analogous X-ray experiments as well as previous simulations.

3:42PM J8.00007 Stripe Systems with Competing Interactions on Quasi-One Dimensional Periodic Substrates, DANIELLE MCDERMOTT, WABASH COLLEGE, CYNTHIA J. OLSON REICHHARDT, CHARLES REICHHARDT, THEORETICAL DIVISION, LOS ALAMOS NATIONAL LABORATORY — We numerically examine the two-dimensional ordering of a stripe forming system of particles with competing long-range repulsion and short-range attraction in the presence of a quasi-one-dimensional corrugated substrate. As a function of increasing substrate strength or the ratio of the number of particles to the number of substrate minima, we show that a remarkable variety of distinct orderings can be realized, including modulated stripes, prolate clump phases, two dimensional ordered kink structures, crystalline void phases, and smectic phases. Additionally in some cases the stripes align perpendicular to the substrate troughs. Our results suggest that a new route to self assembly for systems with competing interactions can be achieved through the addition of a simple periodic modulated substrate.

3:54PM J8.00008 Conformal Crystals, VISHAL SONI, UNIVERSITY OF CHICAGO, LEOPOLDO GOMEZ, UNIVERSIDAD DEL SUR - CONICET, WILLIAM IRVINE, UNIVERSITY OF CHICAGO — Interacting particles which would otherwise form a perfect crystal arrange into fascinating structures when immersed in spatially varying potentials. Using colloidal experiments and molecular dynamics simulations, we explore the two dimensional ordering of repulsive particles confined by external potentials. By relating the resulting inhomogeneous structures to a lattice frustrated by Gaussian curvature, we investigate the role of topological defects in organizing the conformal crystal-like ground states.

4:06PM J8.00009 Self-Healing Colloidal Crystals: Why Soft Particles Feel the Squeeze, ANDREA SCOTTI, URS Gasser, LNS, Paul Scherrer Institut, EMILY HERMAN, Ultraink Inc., MIGUEL PELAEZ-FERNANDEZ, SCHOOL OF PHYSICS, GEORGIA INSTITUTE OF TECHNOLOGY, ANDREW LYON, SCHMID COLLEGE OF SCIENCE AND TECHNOLOGY, ALBERTO FERNANDEZ-NIEVES, SCHOOL OF PHYSICS, GEORGIA INSTITUTE OF TECHNOLOGY — Point defects in crystalline materials disturb the crystal structure and often prevent crystallization. In particular, this is the case for too big particles that are put into a crystal. In metal melts, a size mismatch of 15% of the atoms in the melt suppresses crystallization. Furthermore, hard spheres with a polydispersity greater than 12% do not form crystals, and the polydispersity in the crystal state does not exceed 5.7%, as local segregation occurs. These restrictions do not necessarily apply for soft microgels. Lyon et al. (A. St. J. Iyer and L. A. Lyon, Angew. Chem. Int. Ed., 48, 2009) find bigger microgels to shrink and fit into the lattice formed by smaller ones. We find that charged groups in the microgel and their counter-ions are the key to explain this remarkable spontaneous deswelling of microgels. Using small-angle neutron and X-ray scattering, we directly observe the deswelling of bigger particles with increasing volume fraction and the effect of the bigger particles on the phase behavior of the suspension. Furthermore, we determine the osmotic pressure using osmometry and present a model for the selective deswelling of the big particles.

4:18PM J8.00010 Self-Assembly of an Icosahedral Quasicrystal Network, MICHAEL ENGEL, PABLO F. DAMASCENO, UNIVERSITY OF MICHIGAN, CAROLYN L. PHILLIPS, ARgonne national laboratory, SHARON C. GLOTZER, UNIVERSITY OF MICHIGAN — Icosahedral quasicrystals (IQC) are a form of matter that is ordered but not periodic in any direction. IQCs have the highest symmetry of all crystals and therefore exhibit orientationally highly uniform properties. This makes them candidates for materials with a complete photonic bandgap or as specialized alloys. Unlike axially-symmetric quasicrystals, which have been reported experimentally in micellar or nanoparticle systems and suggested in bi-layer water, silicon, and mesoporous silica, IQCs have not been observed in the context of non-intermetallic systems. Here, we demonstrate the self-assembly of an IQC by means of molecular dynamics simulations. The IQC is a predominantly tetrahedral, body-centered-icosahedral network and is structurally related to clathrates and other tetrahedrally coordinated crystalline networks. The IQC self-assembles rapidly and reproducibly from a fluid phase in a one-component system of particles. We provide a crystallographic structure model and show the presence of a diffusion mechanism not available in periodically ordered solids. [1] M. Engel, P.F. Damasceno, P.L. Phillips, S.C. Glotzer, Nature Materials, in press (2014).

4:30PM J8.00011 Particle dynamics in dense colloidal suspensions with short-range attraction, PIOTR HABDAS, ZACHERY BROWN, DEPARTMENT OF PHYSICS, SAINT JOSEPH’S UNIVERSITY, MATTHEW GRATALE, ARJUN G. YODH, DEPARTMENT OF PHYSICS AND ASTRONOMY, UNIVERSITY OF PENNSYLVANIA — We study single particle dynamics and dynamical heterogeneity in colloidal suspensions with tunable short-range attraction as a model for particles confined near an attractive glass. Short-range (MSD) forces induce the transition. Using direct optical microscopy, we identify colloidal particles that exhibit substantial motional events. We observe that these particles demonstrate heterogeneous dynamics which is manifested by non-Gaussian distribution of the particle displacements. Maximum dynamical susceptibility is determined systematically over a range of probe length and time scales. Preliminary results show that at volume fractions just above the colloidal glass transition the intensity of spatial heterogeneities decreases as the interparticle attraction strength is increased suggesting the system enters the ergodic fluid state.

2 School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA, FRANS SPAEPEN, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA. — A comparative study has been made to explore melt transition for two different types of soft colloids: sterically stabilized aqueous core-shell (CS) microgels and charge stabilized PMMA particles. The shell component made of polymer network stabilize the CS suspension whereas the PMMA particle suspension is stabilized by the surface charge on each particle. Both types of particles form stable three dimensional crystal structures at higher volume fractions. We locate individual particles to construct 3D pair-correlation function and mean-square-displacements (MSD). We explore the melting transition in equilibrium for both the systems by changing the inter-particle separation i.e by changing volume fraction. Different melting criterions have been used to identify melting point. The result shows that melting transition for sterically stabilized CS microgel is fundamentally different from that of charge stabilized PMMA particles.

4:42PM J8.00012 Jamming and Phase Transition in Binary Soft Colloids

AKANKSHA AGRAWAL, School of Chemical and Biomolecular Engineering, Cornell University, HSU-YU YU, School of Chemical and Biomolecular Engineering, University of Pennsylvania, SAMANVAYA SRIVASTAVA, LYNDEN A. ARCHER, School of Chemical and Biomolecular Engineering, Cornell University, SURESH NARAYANAN, Advanced Photon Source, Argonne National Laboratory — We report on jamming, yielding, and flow of binary mixtures of self-suspended silica nanoparticles densely grafted with Polyethylene glycol (PEG)(MW ~ 5000g/mol). The ratio of volume fraction of the larger particles to the total volume fraction of the silica cores, \( x_c \), is shown to sensitively affect both the yielding and jamming transitions of these systems. For all the binary systems a two-step yielding is observed in oscillatory shear measurements, which we discuss in terms of the breaking of small and big particle cages. We find that addition of larger particles to a suspension of smaller ones softens the suspensions and, for small values of the particle radius ratio \( r = R_1 / R_2 \), the larger particles produce complete fluidization of their smaller counterparts. We show that these behaviors coincide with a speeding-up of de-correlation dynamics of all particles in the suspensions using XPCS measurements and are preceded by an abrupt transition in the average inter-particle spacing, similar to behavior predicted for a semi-dilute binary hard sphere suspension model as observed from SAXS experiment.

4:54PM J8.00013 Anisotropic stress correlations in 2D liquids

BIN WU, TAKUYA IWASHITA, TAKESHI EGAMI, Univ of Tennessee, Knoxville — We demonstrate the presence of anisotropic stress correlations in the simulated 2D liquids. Whereas the temporal correlation of macroscopic shear stress is known to contribute to viscosity via the Green-Kubo formula, the general question regarding angular dependency of the spatial correlation among atomic level stresses in liquids without external shear has not been explored. Besides the apparent anisotropy with well-defined symmetry, we found that the characteristic length of shear stress correlation depends on temperature and follows the power law, suggesting divergence around the glass transition temperature. The anisotropy of the stress correlations can be explained in terms of the inclusion model by Eshelby, based upon which we suggest that the mismatch between the atom and its nearest neighbor cage produces the atomic level stress as well as the long-range stress fields.

5:06PM J8.00014 Frustrated packing of monodisperse spheres in a flat container

RALF STANNIARIUS, KIRSTEN HARTH, Otto von Guericke University, Magdeburg — We study the packing of monodisperse spheres in a flat vertical box with cell gap slightly larger than the particle diameter, and evaluate the statistics of the particle arrangements. After ‘gravitational’ filling of the container and appropriate agitation, the particles form a nearly regular triangular lattice in the cell plane. The additional freedom of a displacement normal to the cell plane places the particles either at the front or rear cell plate. This leads to a denser arrangement in the cell plane, but at the same time causes frustrated states. Two of three neighboring beads in a local triangle have to occupy the same cell wall. Analogies to order in antiferroelectric Ising spin systems on a triangular lattice and to colloidal assemblies in thin layers are evident. We analyse experimental packings statistically and compare them to the predictions of models and Monte Carlo simulations. When the container is tilted from the vertical, the gravitational field mimics an external force similar to a magnetic field in spin systems. The experiment both offers insights into the influence of geometrical constraints on random packing, and provides a descriptive example of frustrated ordering.

Tuesday, March 3, 2015 2:30PM - 5:30PM —
Session J9 DMP: Focus Session: van der Waals Bonding in Advanced Materials: Layered Materials

2:30PM J9.00001 Hexagonal Boron Nitride-Water Non-bonded Interaction from First Principles

YANBIN WU, LUCAS K. WAGNER, NARAYANA R. ALURU, Univ of Illinois - Urbana — The interaction between water and h-BN is estimated using the Muller-Plesset perturbation theory of the second order (MP2) and diffusion Monte Carlo (DMC) method. The MP2 and DMC results are verified using coupled cluster treatment with single and double excitations and perturbative triples at the complete basis set limit (CCSD(T)/CBS) using B3N3H6-water as a proxy. The water-h-BN binding energy is estimated as 1.9 \( \pm \) 0.2 kcal/mol. Boron/nitride (BN)-water non-bonded interaction parameters are developed based on the MP2 energies. The B/N-water parameters predict the water contact angle on bulk h-BN surface that is in good agreement with experimental measurements.

2:42PM J9.00002 Role of weak interactions in phase transitions of layered transition metal dichalcogenides: An ab initio study

NILADRI SENGUPTA, ADRIENN RUZSINSZKY, JOHN P. PERDEW, Temple Univ — Phase transitions of layered materials are not often clearly explained and captured by the GGA level density functional calculations. Weak interactions might play an important role in these phase transitions. Now GGA can not describe well weak interactions. So we intend to use several new meta GGAs (TPSS, RevTPSS, MS family etc.), many body VDW corrected meta GGAs and RPA to study phase transitions of layered transition metal dichalcogenides (ME\( _2 \); M = Ti, V, Cr, Ta, Mo, W ; E = Se, S, Te) and investigate the role of weak interactions in those cases.

2:54PM J9.00003 Dispersion Forces of Adatoms on Deformed Graphene

VALERI KOTOV, University of Vermont — van der Waals (vdW) forces are especially important near atomically-thin materials, such as graphene, boron nitride (h-BN) and transition metal dichalcogenides (e.g. MoSe2), which form the building blocks of the so-called van der Waals heterostructures. These systems can also exhibit strong deformations in their structure due to stress, either applied externally, or induced by the presence of a substrate. A problem of fundamental and technological importance is how the vDW forces, which reflect Coulomb interactions and polarization effects, depend on electronic and mechanical material properties. I will show that strain fields can greatly enhance the vDw interactions of neutral adatoms near graphene and structurally similar surfaces, thus substantially affecting adsorption properties and altering the dissipative dynamics associated with atomic motion. For the case of two strained graphene sheets similar enhancement was predicted by A. Sharma et.al., PRB 89, 235425 (2014). I will consider several aspects of the adatom-graphene problem: (1) Variation of the vDw force as a function of uniaxial and more general strain fields, (2) Dependence on electron-electron interactions, including renormalization effects near the Dirac point, (3) Implications for dissipative atom dynamics.
3:06PM J9.00004 RPA and beyond-RPA total energy methods for strongly and weakly bonded materials, KRISTIAN THYGESEN, Center for Atomic-scale Materials Design (CAMD), Technical University of Denmark — The random phase approximation (RPA) is attracting renewed interest as a universal and accurate method for first-principles total energy calculations. The RPA naturally accounts for long-range dispersive forces making the RPA superior to density and hybrid functionals in systems dominated by weak van der Waals or mixed covalent-dispersive interactions. We have applied the RPA to calculate the potential energy surfaces of graphene on various metal surfaces. For some of the metals, the RPA binding energy curve shows two distinct minima which arise from a delicate balance between covalent and dispersive forces that are not captured by standard semilocal or van der Waals density functionals [1]. We benchmark the RPA by calculating cohesive energies of graphite and a range of covalently bonded solids and molecules as well as the dissociation energies of H2 and H2+—The results show that the RPA with orbitals from the local density approximation suffers from delocalization errors and systematically understimates covalent bond energies yielding similar or lower accuracy than the Perdew-Burke-Ernzerhof (PBE) functional for molecules and solids [1]. Inclusion of an adiabatic xc-kernel defined through a renormalization of the LDA kernel is found to significantly improve the RPA description of short range correlations yielding essentially exact results for the homogeneous electron gas [2]. By generalizing this renormalized LDA xc-kernel to inhomogeneous systems we find a fourfold improvement of RPA binding energies in both molecules and solids. We also consider examples of barrier heights in chemical reactions, molecular adsorption, and graphene interacting with metal surfaces, which are three examples where the RPA has been successful. In these cases, the renormalized kernel provides results that are of equal quality or even slightly better than the RPA, with a similar computational cost [3].

3:42PM J9.00005 The Quantum Monte Carlo studies of Van der Waals interaction in bilayer systems, CHING-MING WEI, CHENG-RONG HSING, Institute of Atomic and Molecular Sciences, Academia Sinica, CHING CHENG, Department of Physics, National Cheng Kung University, CHUN-MING CHANG, Department of Physics, National Dong Hwa University — Van der Waals (vdW) interaction is one of the most fundamental physical quantities resulted from the quantum fluctuation of charges. However, it remains a challenge to account for this interaction quantitatively in both theory and experiment. For example, vdW interaction is one of the physical properties that the LDA and GGA of Density Functional Theory (DFT) fail to describe correctly. In recent years, there have been many proposals of DFT-vdW to overcome this deficiency. However, discrepancies in binding energy among these DFT-vdW results are usually apparent. In this talk, we present the Quantum Monte Carlo (QMC) and DFT studies of various bilayer systems: BN/BN [New. J. Phys. 16, 113015 (2014)], Silicene/Graphene, Silicene/BN and MoS2/Graphene. The calculations show large discrepancies among various DFT functionals. The QMC calculated binding energy was found to be larger than that obtained by the LDA calculation and smaller than those using DFT-vdW correction. Moreover, the QMC calculated interlayer interaction was found to have a longer-range behavior than all the available DFT schemes. The outcome of the present QMC study would provide a benchmark for future generation of various DFT xc-functionals and guidance for prospective experiments.

In these cases, the renormalized kernel provides results that are of equal quality or even slightly better than the RPA, with a similar computational cost [3].

3:54PM J9.00006 Ni(111)-graphene interface: the importance of screened van der Waals interactions, PIER LUIGI SILVESTRELLI, ALBERTO AMBROSETTI, Università degli Studi di Padova — Due to the direct applicability of Ni(111) surfaces in high-quality graphene production, the Ni(111)-graphene interface has recently been the object of extensive experimental and theoretical investigations. Achieving an accurate and efficient theoretical description of the Ni(111)-graphene interaction, however, still represents a major theoretical challenge, due to the complex interplay between van der Waals (vdW) and hybridization effects. Here we apply the DFT/vdW-WF2s method [1], augmenting semi-local Density Functional Theory with the inclusion of screened vdw interactions. Interestingly, we show that a reliable description of the vdw energy in Ni(111)-graphene requires an appropriate modeling of the metal-screening, which should not only account for the p- and s-like quasi-free electrons, but should further include the effect of the more localized d-like states. Good agreement is found with experiment and highly accurate theoretical predictions. Moreover, being the DFT/vdW-WF2s method based on Maximally Localized Wannier Functions, it permits an intuitive understanding of the complex physics underlying transition metals-graphene interactions.

4:06PM J9.00007 ZnO-Graphene Interfacial Binding Strength: Dependence on Surface Orientation, HAIYING HE, KELSEY LARSON, ADAM CLARK, ALLYSE APPEL, STAN ZYGMUNT, Valparaiso University — There is an increasing interest of hybridized materials with impacts such as improving structural integrity of known and commonly used materials. Recent experiments have suggested that the adhesion of zinc oxide (ZnO) nanowires with carbon fibers can significantly improve interfacial shear strength of fiber reinforced composites. We have carried out a systematic study of the interaction between ZnO and graphene based on density functional theory, through the inclusion of screened vdw interactions. Interestingly, we show that a reliable description of the vdw energy in Ni(111)-graphene requires an appropriate modeling of the metal-screening, which should not only account for the p- and s-like quasi-free electrons, but should further include the effect of the more localized d-like states. Good agreement is found with experiment and highly accurate theoretical predictions. Moreover, being the DFT/vdW-WF2s method based on Maximally Localized Wannier Functions, it permits an intuitive understanding of the complex physics underlying transition metals-graphene interactions.

4:18PM J9.00008 Structural and Electronic Properties of BC 3 with Van der Waals Density Functional Theory, BURAK OZDEMIR, VERONICA BARONE, Central Michigan Univ — Layered materials have attracted a lot of attention recently due to their unique properties that can be optimized for technological applications such as energy storage and transparent conductors. Among these materials, a graphite-like BC3 (g-BC3) structure has been recently under investigation as it provides a similar morphology than graphite but with a large concentration of electron deficient B atoms. Despite the recent experimental and theoretical works, the morphology of this materials is still not well understood. In this work, stable stacking configurations of g-BC3 has been determined using different exchange-correlation functionals that include dispersion corrections. We identify the most stable structures and characterize their electronic properties.

4:30PM J9.00009 Measurement of the long range van der Waals force in graphene, JUN XU, University of California, Riverside, ALEXANDR BANISHEV, University of Illinois at Urbana-Champaign, UMAR MOHIDEEN, University of California, Riverside — The gradient of the long range van der Waals force between a Si-SiO2-graphene substrate and an Au-coated sphere is measured by means of a dynamic atomic force microscope operated in the frequency shift technique. It is shown that the presence of graphene leads to up to a 9% increase in the force gradient at the shortest separation considered. The experimental results are compared to a theory of the long range thermal van der Waals interaction for multilayered test bodies coated with a graphene sheet and found to be in good agreement. References: [1] A.A. Banishev, H. Wen, J. Xu, R.K. Kawakami, G.L. Klimchitskaya, V.M. Mostepanenko, U. Mohideen, Measuring the Casimir force gradient from graphene on a SiO2 substrate, Phys. Rev. B, 87 (2013) 5. [2] G.L. Klimchitskaya, U. Mohideen, V.M. Mostepanenko, Theory of the Casimir interaction from graphene-coated substrates using the polarization tensor and comparison with experiment, Phys. Rev. B, 89 (2014) 8.

The authors thank G.L. Klimchitskaya and V.M. Mostepanenko for help with the theory and the US Department of Energy for funding the research.
Ab-stacking mode is slightly favored than the AB mode but the binding energy difference is very small, only about 0.3 meV/atom. It is also found that vdW interactions allow accurate description of the van der Waals interaction between two graphyne layers. The QMC results for the interlayer binding energies have revealed that the multiplet structure of SmB$_6$ samarium hexaboride (SmB$_6$) without Kondo physics substrates, in good agreement with recent experimental measurements by quartz crystal microbalance technique. The calculated activation energies indicate that Xe becomes movable on pure Au(111) surface at a temperature of around 30 K, whereas its motion can be activated only at a high temperature of 50 K on graphene and on graphene-coated Au(111) substrate. The van der Waals force from graphene determined per layer was found to decrease with the number of layers. In addition, increased hole doping of graphene enhanced the force. The screening was lifted in the single-layer graphene upon its fluorination, which rendered it electrically insulating. Finally, we also demonstrated strong screening of the van der Waals forces of the silicon oxide substrate by single- and double-layer molybdenum disulfide. Analysis of the experimental results was aided by density functional theory calculations.

4:54PM J9.00011 Interlayer Binding of Bilayer $\alpha$-graphyne : Quantum Monte Carlo Study
YONGKUN H Kwon, HYEONDEOK SHIN, HOONKYUNG LEE, Konkuk University, JEONGNIM KIM, Oak Ridge National Laboratory — Graphynes have recently received considerable attention because of their intriguing potential as new Dirac materials. Recent DFT calculations of Leenaerts et al. [1] predicted two stable stacking modes of bilayer $\alpha$-graphyne, while a AB-stacked configuration was found to possess a gapless parabolic band structure, the other stable mode of Ab-stacked graphyne exhibits a double Dirac cone spectrum. On the other hand, more accurate DFT calculations predicted different ground-state configurations for bilayer $\alpha$-graphyne, depending on the van der Waals (vdW)-corrected exchange-correlation functional used. In order to determine the most stable configuration of bilayer $\alpha$-graphyne along with accurate computation of its interlayer binding energy, we here employ quantum Monte Carlo method which allows accurate description of the vdW interaction between two graphyne layers. The QMC results for the interlayer binding energies have revealed that the Ab-stacking mode is slightly favored than the AB mode but the binding energy difference is very small, only about 0.3 meV/atom. It is also found that the DFT results with vdW-DF2, based on the non-local vdW functional proposed by Lee et al. [2], are in good agreement with the QMC results. This leads us to conclude that within the DFT formalism the interlayer binding of the graphyne structures is best described by the vdW-DF2 functional. [1] O. Leenaerts et al., Appl. Phys. Lett. 103, 013105 (2013). [2] K. Lee et al., Phys. Rev. B 82, 081101R (2010).

5:06PM J9.00012 Adapting DFT C6-corrections for modeling graphene on metal surfaces
PETER SCHULTZ, Sandia National Laboratories, Albuquerque, NM, USA, MICHAEL FOSTER, Sandia National Laboratories, Livermore, CA, USA — Modeling graphene on metals accurately presents a challenge for first principles due to difficulties modeling non-local electron correlation. An effective model must resolve small van der Waals (vdW) binding of graphene to the surface from the large cohesive energy in the metal and chemical bond energies in the graphene. Conventional density functional theory (DFT) such as GGA/PBE fails to describe vdW effects accurately. More sophisticated non-local vdW functionals, still in their infancy, produce inconsistent results, and there is a shortage of experimental data to assess which of these is more reliable. Moreover, computational expense limits their general application. We adopt DFT plus C6-corrected methods in concert with non-local vdW functionals to study graphene on Cu(111), Ni(111), and Ir(111). The known strengths of vdW-functionals and limited experimental data are used to constrain the definition of the C6-corrections (which in turn provides guidance as to which vdW-enhanced functionals are most suitable for accurate simulations of graphene adsorption on metals). The less expensive DFT+C6 and vdW-DFT are shown to give consistent results, and agree with known experimental data for these three metal surfaces.

Tuesday, March 3, 2015 2:30PM - 5:30PM — Session J10 DCMP: Topological Kondo Insulators
007A - Nicholas Butch, National Institute of Standards and Technology

2:30PM J10.00001 A new theoretical approach to SmB$_6$ and related mixed valence compounds without Kondo physics
ALFRED CHEUNG, MONA BERCIU, ILYA ELFIMOY, GEORGE SAWATZKY, Univ of British Columbia — Currently, samarium hexaboride (SmB$_6$) is widely thought of as a Kondo insulator with the formation of its hybridization gap being attributed to Kondo physics. This is in spite of the fact that Sm is strongly mixed valent and is hence incompatible with the Kondo scenario of fixed spins undergoing spin fluctuations. In this talk, we summarize arguments for why Kondo physics is inappropriate for the case of SmB$_6$. We then present a new model in which the low energy scale atomic multiplet structure of SmB$_6$ and the strong Sm 4f valence fluctuations are properly taken into account, replacing Kondo lattice physics as the principal player in SmB$_6$.

2:42PM J10.00002 30 MHz Self Oscillator using Topological Kondo Insulator SmB$_6$
ALEXANDER STERN, DAEJEONG KIM, SEAN THOMAS, ZACHARY FISK, JING XIA, University of California, Irvine, Department of Physics and Astronomy — We are studying electrical properties of SmB$_6$ (or Samarium Hexaboride), which is a topological insulator material. By applying a DC current to a tiny crystal of SmB$_6$ and a capacitor, we were able to generate 30 MHz oscillation voltage across the crystal. The frequency range is set by the crystal size and quality and the frequency can be fine-tuned by the amount of DC current. With varying crystal size, we have achieved the frequencies from 20Hz to 30MHz with amplitudes up to 50mV. The DC current driven oscillation is induced by thermal oscillation between topological surface and the bulk states. We will present a theoretical model for this intriguing behavior. This work is supported by DARPA/Air force grant FA 8650-14-1-7407.

Emergent photovoltage on SmB$_6$ surface upon bulk-gap evolution revealed by pump-and-probe photoemission spectroscopy

YUKI AKIMURA, TOSHIO OTSU, TOMOKO SHIMADA, MARIO OKAWA, YOHEI KOBAYASHI, ISSP, University of Tokyo, FUMITOSHI IGA, Ibaraki University, TOSHIRO TAKABATAKE, Hiroshima University, SHIK SHIN, ISSP, University of Tokyo — Recent studies suggest that an exemplary Kondo insulator SmB$_6$ belongs to a new class of topological insulators (TIs), in which non-trivial spin-polarized metallic states emerge on surface upon the formation of Kondo hybridization gap in the bulk. Remarkably, the bulk resistivity reaches more than 20 $\Omega$ cm at 4 K, making SmB$_6$ a candidate for a so-called bulk-insulating TI. We here investigate optical-pulse responses of SmB$_6$ by pump-and-probe photoemission spectroscopy. Surface photovoltage effect is observed across $\sim$ 90 K. This indicates that an optically-active band bending region develops beneath the novel metallic surface upon the bulk-gap evolution. The photovoltaic effect persists for $>200 \mu$s, which is long enough to be detected by electronics devices, and could be utilized for optical gating of the novel metallic surface.

Surface damage of SmB$_6$ through ion-irradiation

NICHOLAS WAKEHAM, YONGQIANG WANG, Los Alamos National Laboratory, ZACHARY FISK, University of California, Irvine, FILIP RONNING, JOE THOMPSON, Los Alamos National Laboratory — SmB$_6$ is a Kondo insulator, but there is strong evidence for an intrinsic conductive surface state at low temperatures. Theoretical work indicates that SmB$_6$ may be a topological Kondo insulator with a topologically protected surface state that is robust against time-reversal invariant perturbations. To investigate this robustness, we have used non-magnetic ion-irradiation to damage the (001) surfaces of SmB$_6$ single crystals to varying depths, and have measured the resistivity as a function of temperature for each depth of damage. We observe a reduction in the residual resistivity with increasing depth of damage. Our data are consistent with a model in which the surface state is not destroyed by the ion-irradiation, but instead the damaged layer is poorly conducting and the initial surface state is reconstructed below the damage. This behavior is consistent with a surface state that is topologically protected. Investigations of time-reversal symmetry breaking perturbations of the surface layer, with magnetic ion-irradiation, will also be discussed.

Ultrafast quasiparticle dynamics of Kondo insulator SmB$_6$ using THz spectroscopy

JINGDI ZHANG, Department of Physics, University of California, San Diego, JIE YONG, Department of Physics, University of Maryland, College Park, ICHIRO TAKEUCHI, Department of Materials Science & Engineering, University of Maryland, College Park, RICHARD GREENE, Department of Physics, University of California, San Diego, RICHARD AVERITT, Department of Physics, University of California, San Diego — Samarium Hex boride (SmB$_6$) is a prototype Kondo insulator with a hybridization gap of 19 meV at low temperatures. It has been theoretically predicted to be the first topological insulator involving electron-electron correlations that are truly insulating in bulk. Recent progress in fabricating thin film SmB$_6$ [1] enables using terahertz spectroscopic methods to investigate topological surface states and carriers adjacent to the hybridization gap, potentially distinguishing these distinct contributions to the optical conductivity. We report on the photo-excited quasi-particle (QP) dynamics of the Kondo insulator SmB$_6$, using ultrafast terahertz spectroscopy. The amplitude of the transient change in transmission increases with decreasing temperature, exhibiting a single-exponential decay that significantly decreases below the damage temperature. This phonon bottleneck originates from competition between QP recombination and re-excitation of QP across the hybridization gap by phonons.

Thin films synthesis and transport properties of the topological Kondo insulator candidate SmB$_6$

CHRISTOPHER M. MORRIS, N.J. LAURITA, S. KOOPAYEH, P. COTTINGHAM, W.A. PHELAN, L. SCHOOP, T.M. MCQUEEN, N.P. ARMITAGE, The Institute for Quantum Matter, Department of Physics & Astronomy, The Johns Hopkins University, Baltimore, MD 21218 — The Kondo insulator SmB$_6$ has long been known to display anomalous transport behavior at low temperatures (T < 10 K) and high pressures. At low temperatures, a plateau is observed in the resistivity, contrary to the logarithmic divergence expected for a normal Kondo insulator. Recent theoretical calculations suggest that SmB$_6$ may be the first topological Kondo insulator, a material with a Kondo insulating bulk, but topologically protected metallic surface states. Here, time domain terahertz spectroscopy (TDS) is used to investigate the temperature dependent optical conductivity of single crystals of SmB$_6$. A secondary bulk conduction mechanism is observed associated with the resistance plateau as the bulk becomes insulating. A secondary bulk conduction mechanism remains down to the lowest measured temperature, 1.6 K. Additionally, FTIR measurements have been performed that show the Kondo gap of SmB$_6$ opening at low temperatures.

Thin films synthesis and transport properties of the topological Kondo insulator SmB$_6$

YUFAN LI, SUNXIANG HUANG, C.-L. CHIEN, Department of Physics and Astronomy, Johns Hopkins University — SmB$_6$, the candidate of the newly proposed topological Kondo insulator, has attracted great research interest in its physical properties. Evidence supports the presence of the topologically protected surface state that was obtained from several experimental studies. However, recently, many researchers have focused on the bulk SmB$_6$ rather than the surface. Here, we report on the synthesis and transport properties of thin films of SmB$_6$. SmB$_6$ thin films are deposited on Si (100) substrates by RF magnetron sputtering. The resistivity decreases below 10 K and forms a plateau, while at higher temperatures the insulating behavior manifests a band gap $\sim$ 3 meV consistent with the reported value of bulk samples. A sign change of the normal Hall coefficient may indicate the formation of the hybridization energy gap.

Thin films synthesis and transport properties of the topological Kondo insulator SmB$_6$

W. K. PARK, L. SUN, L. H. GREENE, University of Illinois at Urbana-Champaign, D. J. KIM, Z. FISK, University of California, Irvine — Topological insulators are a new class of materials harboring topologically protected surface states. SmB$_6$, a well-known Kondo insulator, has attracted much interest recently due to its possibility to be topological as a system with strong interaction. Despite intensive investigations in recent years, the nature of the surface states in SmB$_6$ still remains intriguing. We adopt planar tunneling spectroscopy to study the electronic density of states in topological insulators and superconductors. As a surface-sensitive technique, it should be able to detect the surface states in SmB$_6$. Planar tunnel junctions are made on both (100) and (110) surfaces of high-quality single crystals. Crystal surfaces are prepared by polishing (with sub-nm scale smoothness) and ion-beam cleaning/etching. AlO$_x$ tunnel barrier of varying thickness is formed by sputter deposition of Al and subsequent oxidation. Differential conductance is measured as a function of temperature down to 1.7 K and magnetic field up to 9 T. Our tunneling conductance spectra show asymmetric gap-like features, reminiscent of a Fano resonance in a Kondo lattice, up to 40–50 K, close to the temperature below which the band renormalization and hybridization is known to occur. We’ll discuss how the contributions from the bulk and the surface states can be identified in our conductance data. * The work at UIUC is supported by the NSF DMR 12-06766.

4:06PM J10.00009 Effects of Surface Morphology on the 3D Topological Insulator Samarium Hexaboride

Steven Wolgast, Yun Su Kwon, Cagliyan Kurda, Dept. of Physics, University of Michigan, Dae-Jeong Kim, Zachary Fisk, Dept. of Physics and Astronomy, University of California, Irvine

The recent verification of a topologically-protected surface state in SmB₆ at low temperatures has led to several transport studies of the surface states. This task is complicated because current can flow on all surfaces of a topological insulator, each of which can have different transport characteristics. Our own measurements using a Corbino disk geometry overcome this difficulty, limiting the conduction to individual surfaces. However, the sheet conductivities of our samples counter-intuitively decrease with finer surface polishing. We therefore investigate surface and sub-surface morphology as a factor affecting the surface conductivity. Specifically, surface cracks may themselves harbor surface states and contribute to the total electrical conduction, yielding a higher measured sheet conductivity than that of a flat surface. This situation may contribute to the (sometimes unphysically) large surface conductivities already observed in SmB₆.

4:18PM J10.00010 Ultrafast carrier dynamics of SmB₆

Sanjay Adhkari, West Virginia University, Yanjun Ma, Chang-Beom Eom, UWM, Jing XIA, UCI, Cheng Cen, West Virginia University

We report femtosecond pump-probe experiment performed in SmB₆ single crystals and epitaxial thin films at variable temperatures. The observed carrier relaxations as well as different collective oscillation modes in GHz - THz range allow us to study the hybridization gap and the carrier coherence in different samples.

4:30PM J10.00011 ARPES investigation on the surface vs bulk electronic structures of correlated topological insulators YbB₆ and other rare earth hexaborides

Using ARPES performed in wide photon energy range we systematically studied the bulk and surface electronic structures of a topological mixed-valence insulator candidate, YbB₆. The bulk B-2p states are probed with bulk-sensitive soft X-ray ARPES, exhibiting strong three-dimensionality with the band top locating 80 meV below the EF at the X point. The measured bulk Yb-4f states are located at 1 and 2.3 eV below EF, which hybridize with the dispersive B-2p states. The bulk band structures obtained by experiments are substantially different from the first principle calculations, but it can be better described by adding a correlation parameter U = 7 eV, indicating YbB₆ is a correlated system. Using surface-sensitive VUV ARPES, we revealed two-dimensional surface states which form three-electron-like FSs with Dirac-cone-like dispersions. The odd number of surface FSs gives the first indication that the surface states are topological non-trivial. The spin-resolved ARPES measurements provide further evidence that these surface states are spin polarized with spin locked to the crystal momentum. Recent results on the TI phase in other rare earth hexaborides will also be shown.

4:42PM J10.00012 Observation of a non-Kondo-like topological insulator state in the correlated rare-earth hexaboride YbB₆

Madhab Neupane, S.-Y. Xu, N. Alidoust, G. Bian, C. Liu, I. Belopolski, Princeton University, USA, T.-R. Chang, National Tsing Hua University, Taiwan, H.T. Jeng, National Tsing Hua University & Institute of Physics, Academia Sinica, Taiwan, T. Durakiewicz, Los Alamos National Laboratory, USA, H. Lin, National University of Singapore, Singapore, A. Bansil, Northeastern University, USA, D.J. Kim, Z. Fisk, University of California at Irvine, USA, M.Z. Hasan, Princeton University, USA

We present angle-resolved photoemission study on the rare-earth hexaboride YbB₆, which has recently been predicted to be a topological Kondo insulator. Our data do not agree with the prediction and instead show that YbB₆ exhibits a novel topological insulator state in the absence of a Kondo mechanism. We find that the Fermi level electronic structure of YbB₆ has three 2D Dirac cone surface states enclosing the Kramers’ points, while the f-σ orbital which would be relevant for the Kondo mechanism is about 1 eV below the Fermi level. Our first-principles calculation shows that the topological state which we observe in YbB₆ is due to an inversion between Yb d and B p bands. I will also present some of our recent results on other member of hexaborides. These experimental and theoretical results provide a new approach for realizing novel correlated topological insulator states in rare-earth materials.

4:54PM J10.00013 Non-topological 2DEG at the surface of YbB₆ and Divalent Hexaborides

J.D. Denlinger, Lawrence Berkeley Nat’l Lab, C.H. Min, F. Reinert, U. Wuerzburg, Boyoun Kang, D.J. Kim, Z. Fisk, UC Irvine, K. Gottlieb, A. LANZARA, UC Berkeley, C.-J. Kang, B.I. Min, Postech, J.W. Allen, U. of Michigan—A recent theoretical prediction of YbB₆ being an f-d band-inverted mixed-valent topological insulator very similar to SmB₆ [1] and subsequent angle-resolved photoemission studies of the rare-earth hexaboride YbB₆, which has recently been predicted to be a topological Kondo insulator due to an orbital which would be relevant for the Kondo mechanism is about 1 eV below the Fermi level. Our first-principles calculation shows that the topological state which we observe in YbB₆ is due to an inversion between Yb d and B p bands. I will also present some of our recent results on other member of hexaborides. These experimental and theoretical results provide a new approach for realizing novel correlated topological insulator states in rare-earth materials.

5:06PM J10.00014 Scanning Tunneling Microscopy Studies of the Topological Insulator Candidate YbB₆

Zhihua Zhu, Y. He, Department of Physics, Harvard University, Cambridge, MA 02138, USA, D.-J. Kim, Z. Fisk, Department of Physics and Astronomy, University of California, Irvine, California 92697, USA, J. E. Hoffmann, Department of Physics, Harvard University, Cambridge, MA 02138, USA

We report scanning tunneling microscopy studies of YbB₆, a proposed topological insulator candidate with moderate correlation. The in-situ cleaved sample surface has two dominant morphologies: atomic scale terraces and disordered rows, which likely correspond to Yb and B terminations, respectively. Spatially resolved dI/dV maps show enhanced tunneling due to the local perturbation of the tip-induced band bending. The dI/dV spectra reveal a bulk gap with distinct in-gap features near the Fermi level on different terminations. Our study presents nanoscale evidence for the interplay between surface structure, correlation and topological properties.

The work at Harvard was supported by NSF-DMR-1410480 and NSERC (ZHZ).
5:18PM J10.00015 Is the black phase of SmS a topological Kondo insulator? — ERIC BAUER, N. J. GHIMIRE, F. RONNING, C. BATISTA, D. BYLER, J. D. THOMPSON, Los Alamos National Laboratory, A. RAHMANISIAN, University of British Columbia, Z. FISK, University of California, Irvine — SmS is a prototypical Kondo insulator where electronic correlations drive a system insulating that would otherwise be metallic. Whether or not such a system is also a topological insulator that hosts a protected metallic surface state, depends on the parity of the wavefunction of the occupied states. However, unlike weakly correlated materials, it is unclear whether state-of-the-art electronic structure calculations accurately predict the parity of the occupied wavefunctions of correlated insulators. Nevertheless, Dzero and collaborators suggest that Kondo insulators such as SmB6 can be topological. Like SmB6, Cubic SmS is a non-magnetic semiconductor with an insulating behavior at ambient pressure and low temperatures driven by hybridization with the Sm f-electrons. At 6 kbar, SmS undergoes a phase transition into a valance fluctuating phase accompanied by a visible color change from black to gold. It then undergoes a second phase transition at about 20 kbar to an antiferromagnetic order at low temperatures. We will discuss whether electronic structure calculations indicate a topological state of SmS at P = 0. We will also discuss whether or not the magnetic, thermal and transport properties of the black phase of SmS are consistent with the existence of a topologically protected surface state.

Tuesday, March 3, 2015 2:30PM - 5:30PM —
Session J11 DMP: Focus Session: Engineering Vortex Matter in Superconductors

2:30PM J11.00001 Observing real time motion of nano-scale objects — JORIS VAN DE VONDEL, MATIAS TIMMERMANS, KU Leuven, Belgium, TOMÁS SAMUELY, P. J. Šafářík University, BART RAES, Catalan Institute of Nanotechnology, LISE SERRIER-GARCIA, VICTOR MOSHCHELKOV, KU Leuven, Belgium — The dynamics of nanoscale objects is a very interesting field of research with a strong technological impact. Still, the combination of a technique resolving (sub)nanometer particles within a time frame relevant to observe dynamics is a very challenging task. Due to the inherent atomic-scale resolution, scanning tunneling microscopy (STM) is an ideal candidate to achieve this goal. Nevertheless, in most physical systems the dynamic events of the objects under investigation cannot be resolved by conventional STM image acquisition and will only reveal an average trace of the moving object. This is why a strong drive exists to develop new functionalities of STM, which allow studying dynamic events at the nanoscale. We address this issue, for vortex matter in NbSe2, by driving the vortices using an ac magnetic field and probing the induced periodic current modulations [1]. Our results reveal different dynamical modes of the driven vortex lattice. In addition, by extending a known functionality of STM, (i.e. the ‘Lazy Fisherman’ technique) we can use single pixel information to obtain the overall dynamics of the vortex lattice with submillisecond time resolution and subnanometer spatial resolution.

This work is supported by the FWO and the Methusalem funding of the Flemish government.

2:42PM J11.00002 Vortex cutting in superconductors — VITALII K. VLASKO-VLASOV, ALEXEI E. KOSHELEV, ANDREAS GLATZ, ULRICH WELP, WAI-K. KWOK, Argonne National Laboratory — Unlike illusive magnetic field lines in vacuum, magnetic vortices in superconductors are real physical strings, which interact with the sample surface, crystal structure defects, and with each other. We address the complex and poorly understood process of vortex cutting via a comprehensive set of magneto-optic experiments which allow us to visualize vortex patterns at magnetization of a nearly twin-free YBCO crystal by crossing magnetic fields of different orientations. We observe a pronounced anisotropy in the flux dynamics under crossing fields and the filamentation of induced supercurrents associated with the staircase vortex structure expected in layered cuprates, flux cutting effects, and angular vortex instabilities predicted for anisotropic superconductors. At some field angles, we find formation of the vortex domains following a type-I phase transition in the vortex state accompanied by an abrupt change in the vortex orientation. To clarify the vortex cutting scenario we performed time-dependent Ginzburg-Landau simulations, which confirmed formation of sharp vortex fronts observed in the experiment and revealed a left-handed helical instability responsible for the rotation of vortices.

2:54PM J11.00003 Detecting vortices in superconductors: Extracting one-dimensional topological singularities from a discretized complex scalar field — CAROLYN PHILLIPS, TOM PETERKA, DMITRY KARPEYEV, Mathematics and Computer Science Division, Argonne National Laboratory, ANDREAS GLATZ, Materials Science Division, Argonne National Laboratory — In type-II superconducting material, the dynamics of the vortices play a critical role in determining the performance of the material. In Ginzburg-Landau simulations of superconducting materials, vortices correspond to topological singularities in a discretized complex scalar field. Visualizing the vortices to understand their behavior is a key step in using simulations to engineer optimized pinning landscapes. In the past, vortices have been visualized by examining contour plots and isosurfaces of the magnitude of the field. However, these methods, primarily used for small-scale simulations, blur the fine details of the vortices, scale poorly to large-scale simulations, and do not easily enable isolating and tracking individual vortices. We present a method for exactly finding the vortex core lines from a complex order parameter field. With this method, the vortices can be easily described at a resolution even finer than the mesh itself. The precise determination of the vortex cores allows the interplay of the vortices inside a model superconductor to be visualized in higher resolution than has previously been possible.

3:06PM J11.00004 Improved critical current in confined superconductors in parallel field configuration — ANDREAS GLATZ, IGOR ARONSON, YONGLEI WANG, ZHILI XIAO, Argonne National Laboratory — We present results on the re-entrance of the superconducting state in systems placed into a magnetic field parallel to the applied current. In experiments it was observed that the magneto-resistance first increases with magnetic field, but at higher field drops again such that superconductivity is recovered. This effect is strongly temperature dependent and can lead to a suppression of resistance below the measurable threshold over a range of a few K. We study the vortex dynamics and magneto-resistance in this situation in the framework of a large-scale time-dependent Ginzburg-Landau simulation. A small external current as well as the magnetic field are applied in the x-direction, the latter is then ramped up. Our simulations reproduce this effect and reveal the mechanism for the observed behavior: the intermediate resistive state is due to a vortex instability leading to an unwinding of twisted vortex configurations. This leads to a periodic dynamic resistive state. When the field increases these instabilities get stabilized due to a higher vortex density and the resistance drops upon increasing the magnetic field.

3:18PM J11.00005 Interplay between vortex matter phases and arrays of pinning centers in low temperature superconductors \(^1\). JOSE L. VICENT, JAVIER DEL VALLE, ALICIA GOMEZ, Universidad Complutense Madrid, MANUEL RODR\'\'GUEZ, DANIEL GRANADOS, IMDEA-Nanociencia, Madrid. FERNANDO GALVEZ, ELYRVA M. GONZALEZ, Universidad Complutense Madrid. We have studied vortex matter phases in Nb films grown on Si substrates with arrays of Cu nanodots. The symmetry of the pinning arrays rules the presence of vortex matter phases. Four-fold symmetry arrays enhance the vortex glass transition temperature, at matching fields, in comparison with plain Nb films. This is a similar effect that obtained using arrays of magnetic pinning centers (Villegas et al. PRB72, 174512). Breaking the symmetry of the pinning array, such that the array mimic a smectic crystal, leads to a new phase, in a very narrow temperature window between the liquid and glassy phases, which can be identified with a vortex smectic phase. Remarkably, the smectic vortex phase is enhanced increasing the array symmetry. Increasing the number of vortices vanishes this smectic phase. (H,T) phase diagrams will be presented for different types of arrays.

\(^1\)We thank Spanish MINECO and CM.

3:30PM J11.00006 Vortex-Antivortex coexistence in Nb based Superconductor/Ferromagnet heterostructures. C. DI GIORGIO, E.R. Caianiello Physics Department, University of Salerno, IT; Physics Department, Temple University, Philadelphia, PA; F. BOBBA, E.R. Caianiello Physics Department, University of Salerno, IT; A. SCARPATI, M. LONGOBAIRD, Department of Condensed Matter Physics, University of Geneva, CH. M. IAVARONE, S.A. MOORE, Physics Department, Temple University, Philadelphia, PA. G. KARAPETROV, Physics Department, Drexel University, Philadelphia, PA; V. NOVOSAD, V. YEFREMEMKO, Materials Science Division, Argonne National Laboratory, Argonne, IL, A.M. CUCULO, E.R. Caianiello Physics Department, University of Salerno, IT. Superconductor/Ferromagnet thin film heterostructures, based on Niobium/Permalloy (Nb/Pt), have been studied by low temperature Magnetic Force Microscopy. The experimental observation of spontaneous Vortex-Antivortex in these systems depends on the Nb penetration depth and thickness, on the intensity of the Py stray field induced by the small, alternating up-and-down, out-of-plane component of the magnetic moment. Comparison with the available theoretical models allows to estimate the threshold of the local \(M_s\) for different Py thicknesses.

3:42PM J11.00007 Development of strong vortex pinning and very high \(J_c\) in iron based superconductors. CHIARA TARANTINI, National High Magnetic Field Laboratory - Florida State University — Ba(Fe\(_{1-x}\)Co\(_x\))\(_2\)As\(_2\) (Ba122) is the most tunable of the Fe-based superconductors (FBS) in terms of its acceptance of high densities of secondary phases capable of acting as effective pinning centers without depressing the properties of the superconducting matrix. It has been demonstrated that self-assembled nanorods made of Ba-Fe-O generate a strong correlated pinning along the c-axis, enhancing the critical current density, \(J_c\), in this direction and reducing the \(J_c\) anisotropy \([1, 2]\). However, when 20% of secondary phases are introduced, the reduction of the cross-section becomes significant, decreasing the low field performance. In order to overcome this issue, artificially introduced pinning centers can be added by multilayer deposition producing an anisotropy increase of \(J_c\) \([2]\). Moreover, FBS are especially sensitive to strain, allowing an important enhancement in the critical temperature, \(T_c\), of the material. It will be shown that strain induced by the substrate can further improve \(J_c\) of both single and multilayer films by more than expected because of the \(T_c\) increase. The multilayer deposition of Ba122 on CaF\(_2\) increases the pinning force density, \(F_p\), by more than 60% compared to a single layer film, reaching a maximum of 84 GN/m\(^2\) at 22.5T and 4.2 K, the highest value ever reported in any 122 phase. This work shows that the in-field performance of Ba122 widely exceeds that of Nb3Sn above 10T, attracting attention for possible applications.\[1\] C. Tarantini, S. Lee, Y. Zhang, J. Jiang, C.W. 4:18PM J11.00008 Defects and critical current in REBCO films by ion irradiation. QIANG LI, TOSHINORI OZAKI, CHENG ZHANG, Brookhaven National Lab, BROOKHAVEN NATIONAL LAB TEAM — We will present our recent studies on the defects and critical current density \(J_c\) in superconducting ReBa\(_2\)Cu\(_3\)O\(_7\) films (Re = Y, or rare earth element) irradiated by several types of ions at energy level between hundreds of KeV and tens of MeV. We observed remarkable enhancement of \(J_c\) in some of the irradiated films at low temperature and at high magnetic fields up to 35T. We examined the ion irradiation induced defects by using advanced transmission electron microscopy. It was found that the ion irradiation at this kinetic energy range produces defects that are rather small (~ a few nanometers) in physical size. However, these defects were found to create a substantially large strain field in the vicinity that depresses the pair potential and produce effective flux pinning at low temperatures. As the temperature approaching \(T_c\), the irradiation induced pinning was found less effective, presumably due to the softening of vortex line. A correlation between the nano-structures of the defects and critical current will be discussed.

4:30PM J11.00009 Enhanced critical currents of commercial 2G superconducting coated conductors through proton irradiation. ULRICH WELP, M. LEROUX, K.J. KIHLSTROM, W.-K. KWOK, A.E. KOSELEV, D.J. MILLER, Argonne National Laboratory, M.W. RUPICH, S. FLESHLER, A.P. MALOZEMOFF, American Superconductor Corp., A. KAYANI, Western Michigan University — We report on magnetization and transport measurements of the critical current density, \(J_c\), of commercial 2G-YBCO coated conductors before and after proton irradiation. The samples were irradiated along the c-axis with 4 MeV protons. Proton irradiation produces a mixed pinning landscape composed of pre-existing rare earth particles and a uniform distribution of irradiation induced nm-sized defects. This pinning landscape strongly reduces the suppression of \(J_c\) in magnetic fields resulting in a doubling of \(J_c\) in a field of ~ 4T. The irradiation dose-dependence of \(J_c\) is characterized by a temperature and field dependent threshold of the local \(M_s\) for different Py thicknesses.

4:42PM J11.00010 Optimization of vortex pinning by nanoparticles using numerical simulations. ALEXEI KOSHELEV, IVAN SADOVSKYY, Materials Science Division, Argonne National Laboratory, CAROLYN PHILLIPS, Mathematics and Computer Science Division, Argonne National Laboratory, ANDREAS GLATZ, Materials Science Division, Argonne National Laboratory and Northern Illinois University — Vortex pinning by self-assembled nanoparticles has been established as an efficient route to enhance current-carrying capability of practical superconductors. We explore vortex pinning by randomly distributed metallic spherical nanoparticles using large-scale numerical simulations of time-dependent Ginzburg-Landau equations. We found optimal size and density of particles at which the highest critical current realizes for fixed magnetic field. For every particle size the critical current reaches maximum value of 15-22% of the volume fraction filled by the particles, which is close to the percolation concentration. This optimal particle density increases with the magnetic field. We also found that the optimal particle diameter is close to 4 coherence lengths. Our results provide guidance for pinning optimization in practical superconductors.\[1\] ALEXEI KOSHELEV, IVAN SADOVSKYY, Materials Science Division, Argonne National Laboratory, CAROLYN PHILLIPS, Mathematics and Computer Science Division, Argonne National Laboratory, ANDREAS GLATZ, Materials Science Division, Argonne National Laboratory. RODRIGUEZ, DANIEL GRANADOS, IMDEA-Nanociencia, Madrid. FERNANDO GALVEZ, ELYRVA M. GONZALEZ, Universidad Complutense Madrid. We have studied vortex matter phases in Nb films grown on Si substrates with arrays of Cu nanodots. The symmetry of the pinning arrays rules the presence of vortex matter phases. Four-fold symmetry arrays enhance the vortex glass transition temperature, at matching fields, in comparison with plain Nb films. This is a similar effect that obtained using arrays of magnetic pinning centers (Villegas et al. PRB72, 174512). Breaking the symmetry of the pinning array, such that the array mimic a smectic crystal, leads to a new phase, in a very narrow temperature window between the liquid and glassy phases, which can be identified with a vortex smectic phase. Remarkably, the smectic vortex phase is enhanced increasing the array symmetry. Increasing the number of vortices vanishes this smectic phase. (H,T) phase diagrams will be presented for different types of arrays.\[2\] The work supported by the SciDAC program funded by U.S. DOE, Office of Science, Advanced Scientific Computing Research and Basic Energy Science.

This effect by measuring the transport properties of three samples with cross sections ranging from 250 µm². H. Takahashi et al., 054708 (2011). H. Takahashi, S. Inoue, and the colossally large 17008 (2007). This compound has a small energy gap of S, HIDEFUMI TAKAHASHI, RYUJI OKAZAKI, HIROKI TANIGUCHI, ICHIRO TERASAKI, Nagoya University — An unusually large - Anindya Roy, John Hopkins University and heavy-ion irradiations in commercial coated conductors. This work well for Bi2Te3, and can be used to guide strategies for suppression of bipolar effects to increase the maximum zT.

The greater mobility of the conduction band compared to the valence band suppresses the bipolar effect of the holes that enables the n-type material to retain high zT for the n-type material but the p-type is not useful. We have explained this phenomena using optical band gap measurements and transport modeling.
