8:00AM A0.00001 Beyond nematicity: emergent chirality in iron-based superconductors RAFAEL M. FERNANDES, University of Minnesota, STEVEN A. KIVELSON, Stanford University, ÉREZ BERG, Weizmann Institute of Science — In most iron superconductors, the magnetically ordered state is of stripe-type, with an ordering vector \( \mathbf{Q}_1 = (\pi, 0) \) or \( \mathbf{Q}_2 = (0, \pi) \). One of its hallmarks is the emergence of an Ising-nematic symmetry, whose breaking triggers a vestigial nematic phase that lowers the tetragonal symmetry of the system to orthorhombic. Recent experiments have observed a magnetic state that remains tetragonal, which can be understood only as a double-\( Q \) configuration (i.e. simultaneous order at \( Q_1 \) and \( Q_2 \)) that is either non-uniform or non-collinear. Here we show that these magnetic states also display emergent Ising degrees of freedom that are related not to a rotational, but to a translational symmetry breaking in real space. While in the non-uniform state the Ising symmetry is related to a charge-density wave with ordering vector \( \mathbf{Q}_1 + \mathbf{Q}_2 = (\pi, \pi) \), in the non-collinear state it is related to a chiral symmetry arising from a spin-current density-wave with the same ordering vector. We show that, in the presence of a magnetic field, the former becomes a Neel-like magnetic state, while the latter is converted into a staggered charge-current pattern. We discuss the experimental manifestations of these emergent phases and their impact in the phase diagram of the iron superconductors.

8:12AM A0.00002 Nematic-driven anisotropic electronic properties of underdoped detwinned \( \text{Ba(Fe}_{1-x}\text{Co}_x\text{)}_{2}\text{As}_2 \) revealed by optical spectroscopy\(^1\), L. DEGIOIRGI, ETH Zurich — We collect optical reflectivity data as a function of temperature across the structural tetragonal-to-orthorhombic phase transition at \( T_s \) on \( \text{Ba(Fe}_{1-x}\text{Co}_x\text{)}_{2}\text{As}_2 \) for \( x = 0 \), 2.5\% and 4.5\%, with uniaxial and in-situ tunable applied pressure in order to detwin the sample and to exert on it an external symmetry breaking field. At \( T < T_s \), we discover a remarkable optical anisotropy as a function of the applied pressure at energies far away from the Fermi level and very much reminiscent of a hysteretic-like behavior. Such an anisotropy turns into a reversible linear pressure dependence at \( T \gtrsim T_s \). Moreover, the optical anisotropy gets progressively depleted with increasing Co-content in the underdoped regime, consistent with the doping dependence of the orthorhombicity but contrary to the non-monotonic behavior observed for the dc anisotropy. Our findings bear testimony for an important anisotropy of the electronic structure and thus underscore an electronic polarization upon (pressure) inducing and entering the nematic phase.

8:24AM A0.00003 Anisotropic transient reflectivity across optimal doping in the isovalent-doped superconductor \( \text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_{2} \), ERIC THEWALT, JAMES HINTON, JOSEPH ORENSTEIN, UC Berkeley, LBNL, IAN HAYES, UC Berkeley, TONI HELM, JAMES ANALYTIS, UC Berkeley, LBNL — The isovalent-doped high-\( T_c \) superconductor \( \text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_{2} \) is characterized by a rich temperature-doping phase diagram, which includes structural, antiferromagnetic, electron nematic, and superconducting phase transitions. Of particular note is the proposed existence of a quantum critical point at optimal doping. In this work, we use 1.5 eV pump-probe reflectivity measurements to study the recombination dynamics of photoexcited quasiparticles as a function of temperature, doping, and polarization. We find that the low-temperature response is strongly anisotropic across a wide range of dopings, both above and below optimal. This indicates that the anisotropy arises independently of the orthorhombic-tetragonal and antiferromagnetic phase transitions, which occur only on the underdoped side of the phase diagram.

8:36AM A0.00004 Divergent nematic susceptibility of optimally doped Fe-based superconductors. JIUN-HAW CHU, HSUEH-HUI KUO, IAN FISHER, Stanford University — By performing differential elastoresistivity measurements on a wider range of iron based superconductors, including electron doped \( \text{Ba(Fe}_{1-x}\text{Co}_x\text{)}_{2}\text{As}_2 \), hole doped \( \text{Ba}_{1-x}\text{K}_x\text{Fe}_{2}\text{As}_2 \), and chalcogenides, we show that a divergent nematic susceptibility in the \( B_{1g} \) symmetry channel appears to be a generic feature of optimally doped compositions. For the specific case of optimally “doped” \( \text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_{2} \), the nematic susceptibility can be well fitted by a Curie-Weiss temperature dependence with critical temperature close to zero, consistent with expectations of quantum critical behavior in the absence of disorder. For however all the other optimal doped iron based superconductors, the nematic susceptibility exhibits a downward deviation from Curie-Weiss behavior, suggestive of an important role played by disorder.

8:48AM A0.00005 Orbital Nematic Order and Interplay with Magnetism in the Two-Orbital Model for Iron Pnictides, ANDRIY NEVIDOMSKYY, ZHENTAO WANG, Department of Physics and Astronomy, Rice University — Motivated by recent ARPES measurements on FeSe [1] and LiFeAs [2] families of iron-based superconductors, we have studied the orbital nematic order and its interplay with magnetism within random phase approximation, as well as using a non-perturbative variational cluster approximation (VCA). We found that the electron and hole doping affect the two orders differently within the two-orbital Hubbard model. While hole doping tends to suppress both antiferromagnetism and orbital ordering, the electron doping suppresses magnetism faster, so that orbital nematicity is stabilized in the absence of long-range magnetic order for moderately high electron doping. This is reminiscent of the orbital nematic phase observed in FeSe in the absence of magnetism [1,3], as well as in overdoped \( \text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_{2} \) where ARPES finds splitting of \( d_{xz} \) and \( d_{yz} \) orbitals inside the superconducting phase [4]. This raises the possibility that at least in some cases, the observed electronic nematicity may be primarily due to orbital rather than magnetic fluctuations.

9:48AM A0.00008 New tetragonal magnetic phase in (Ba,K)Fe2As2, ANNA BÖHMER1, FRÉDÉRIC HARDY, LIRAN WANG, PETER SCHWEISS, THOMAS WOLF, CHRISTOPH MEINGAST, Institut für Festkörperphysik, Karlsruhe Institute of Technology, Germany — The recently discovered C4-symmetric magnetic phase in (Ba,Na)Fe2As2 [2] is a rare exception among iron-based superconductors, which usually display a stripe-type spin-density wave (SDW) ground state at low doping. We re-examine the phase diagram of the closely related (Ba,K)Fe2As2 in great detail, using high-quality single crystals and thermodynamic (thermal-expansion and specific-heat) measurements. We find a small region of a, previously missed, C4-symmetric phase in the ambient-pressure phase diagram, likely related to an unidentified phase transition observed under hydrostatic pressure [4]. We investigate the remarkable interplay of the new C4 phase with superconductivity and with the SDW phase by studying the electronic entropy and the effect of uniaxial pressure on the phase diagram.

10:00AM A0.00009 Electronic correlations in hole- and electron-doped Fe-based superconductors , FREDERICK HARDY, ANNA BOEHMER, PETER SCHWEISS, THOMAS WOLF, ROLF HEID, ROBERT EDER, IFP, Karlsruhe Institute of Technology, ROBERT A. FISHER, Lawrence Berkeley National Laboratory, CHRISTOPH MEINGAST, IFP, Karlsruhe Institute of Technology — High-temperature superconductivity in the cuprates occurs at the crossover from a highly-correlated Mott insulating state to a weaker correlated Fermi liquid as a function of hole doping. The iron pnictides were initially thought to be fairly weakly correlated. However, we have recently shown using transport and thermodynamic measurements that KFe2As2 is strongly correlated. Both the Sommerfeld coefficient and the Pauli susceptibility are strongly enhanced with respect to their bare DFT values. These correlations are even further enhanced in RFe2As2 and CsFe2As2. The temperature dependence of both the susceptibility and the magnetic field dependence of the Fe spin dynamics are significantly different from the highly correlated cuprates in the metallic regime. We now have good thermodynamic data covering both the hole and electron sides of the BaFe2As2 system and we will discuss how these correlations are modified by doping.

10:12AM A0.00010 Preformed pairing in superconducting FeSe in the BCS-BEC cross-over regime, SHIGERU KASAHARA, Y. SHIMOYAMA, R. KOBAYASHI, T. YAMASHITA, T. WATASHIGE, Y. MATSUDA, Kyoto University, T. SHIBAUCHI, The Univ. of Tokyo, T. WOLF, A. E. BÖHMER, F. HARDY, C. MEINGAST, H. V. LÖHNEYSEN, Karlsruhe Institute of Technology — The BCS-BEC cross-over bridges the two important theories of bound particles (Bardeen-Cooper-Schrieffer theory and Bose-Einstein condensation) in a unified picture with the ratio of the attractive interaction to the Fermi energy as a tuning parameter. A key issue is to understand the intermediate regime, where new states of matter may emerge. It has been shown that the Fermi energy of FeSe (Tc ~ 10 K) is extremely small, with the result that this system is located at the verge of a BCS-BEC cross-over [1]. Here we show that resistivity, Hall effect, Seebeck and Nernst coefficients all exhibit anomalies at T ~ Tc, well above the superconducting transition temperature. Moreover, our highly sensitive torque magnetometry shows a suppression of the Pauli susceptibility in the same regime. These anomalies appear to suggest a reduction of the density of states ( pseudogap) caused by the onset of pair formation. Based on these results, a new phase diagram of FeSe above Tc is proposed.

10:24AM A0.00011 Impacts of Co-doping on the superconductivity and the orbital ordering state in Fe1−xCoSe single crystal studied by the electrical transport, TAKAHIRO URATA, YOICHI TANABE, Department of Physics, Graduate School of Science, Tohoku University, SATOSHI HEGURI, WPI-Advanced Institutes of Materials Research, Tohoku University, KATSUHIKO TAMAGI, WPI-Advanced Institutes of Materials Research, Tohoku University and Department of Physics, Graduate School of Science, Tohoku University — In the FeSe with the simplest crystal structure in the Fe-based superconductor families, although both the superconductivity and the orbital ordering states are investigated, the relation between them is still unclear[1-4]. Here, we report Co doping effects on the superconductivity and the orbital ordering state in Fe1−xCoSe single crystals. The electrical transport measurements demonstrated that the superconductivity vanishes at 4% Co doping while the orbital ordering state may be robust against Co doping. Present results suggest that the orbital ordering state is not related to the emergence of the superconductivity in FeSe. [1] F. C. Hsu et al., Proc. Nat. Aca. Sci. 105, 14262 (2008). [2] K. Nakayama et al., arXiv:1404.0857v1 [3] T. Shimojima et al., Phys. Rev. B 90, 121111(R) (2014). [4] K. K. Huynh et al., Phys. Rev. B 90, 144516 (2014).

10:36AM A0.00012 Relationship between structure anisotropy and Tc and phase diagram of AFe2(As1−xP)x2 (A=Ba, Sr, Ca), TORU ADACHI, TATSUYA KOBAYASHI, SHIGEKI MIYASAKA, SETSUKO TAJIMA, MASAYOSHI HICHIKAMI, MASAKI SHIDA, Osaka Univ., REIKI KUMAI, HIRONORI NAKAO, YOUICHI MURAKAMI, KEIK PF/CMRC — We investigated how the electronic phase diagram changes when the crystal structure changes in AFe2(As1−xP)x2 where A =Ba/Sr or Sr/Ca. In this study, we synthesized the single crystals of Ba0.8Sr0.2Fe2(As1−xP)x2, Sr0.92Ca0.08Fe2(As1−xP)x2, and Sr0.8Ca0.2Fe2(As1−xP)x2, measured the resistivity and determined precise structure parameters using synchrotron X-ray, then elucidated their phase diagrams and detailed crystal structures. The phase diagram of A =Ba0.8Sr0.2,Fe2(As1−xP)x2 is similar to those for A =Ba and Sr, while for A =Sr/Ca systems the superconducting phase appears at a smaller P content than the case for A =Ba and Sr. The important finding is that the maximum Tc values are almost the same in all AFe2(As1−xP)x2 systems. From the X-ray structural analysis, it has been revealed that in the optimally doped crystals, the local structures of FeAs4 tetrahedra such as pnictogen heights or bond angles of As-Fe-As are almost the same, whereas the anisotropy of the crystal structures, c/a, systematically changes. We conclude that Tc is not affected by the anisotropy (c/a) but strongly depends on the local structure such as the pnictogen height.
10:48AM A0.00013 Electronically driven nematicity in multilayer FeSe Film on SrTiO3, WEI LI, YAN ZHANG, J.J. LEE, Stanford University, HAO DING, Tsinghua University, MING YI, Stanford University, ZHI LI, Tsinghua University, SUNG-KWAN MO, Lawrence Berkeley National Lab, MAKOTO HASHIMOTO, DONGHUI LU, R.G. MOORE, SLAC National Accelerator Laboratory, XI CHEN, QI-KUN XUE, Tsinghua University, ZHI-XUN SHEN, Stanford University; SLAC National Accelerator Laboratory — Nematicity in iron-based superconductors is an intensely investigated contemporary subject. Although it is closely connected to the structural transition, it is unclear whether the lattice degree of freedom is responsible for the nematicity. Here we combine molecular beam epitaxy, angle-resolved photoemission spectroscopy and scanning tunneling microscopy together to study the nematicity in multilayer FeSe films on SrTiO3. Our results demonstrate direct connection between electronic anisotropy in momentum space and standing waves in real space. The lifting of orbital degeneracy of dxz/dyz bands causes the unidirectional interference fringes, observed in real space as standing waves produced by scattering electrons off C2 domain walls and Se-defects. On the other hand, the formation of C2 nematic domain walls unexpectedly shows no correlation with lattice strain pattern. Our results establish a clean case that the nematicity is driven by electronic rather than lattice degrees of freedom in FeSe films.

Monday, March 2, 2015 8:00AM - 11:00AM —
Session A1 DMP: Focus Session: Graphene, Adsorbates, and Electronic Structure 001A - Jeremy Robinson, Naval Research Laboratory

8:00AM A1.00001 Electronic and Structural Properties of Vacancies and Hydrogen Adsorbates on Trilayer Graphene, MARCOS MENEZES, RODRIGO CAPAZ, Universidade Federal do Rio de Janeiro — Using ab initio calculations, we study the electronic and structural properties of vacancies and hydrogen adsorbates on trilayer graphene. Those defects are found to share similar low-energy electronic features, since they both remove a pz electron from the honeycomb lattice and induce a defect level near the Fermi energy. However, a vacancy also leaves unpaired pz electrons on the lattice, which lead to important structural differences and also contribute to magnetism. We explore both ABA and ABC stackings and compare properties such as formation energies, magnetic moments, spin density and the local density of states (LDOS) of the defect levels. These properties show a strong sensitivity to the layer in which the defect is placed and smaller sensitivities to sublattice placing and stacking type. Finally, for the ABA trilayer, we also study how these states behave in the presence of an external electrical field, which opens a tunable gap in the band structure of the non-defective system. The pz defect states show a strong hybridization with band states as the field increases, with reduction and eventually loss of magnetization, and a non-magnetic, midgap-like state is found when the defect is at the middle layer.

8:12AM A1.00002 Hidden Kekule Order of Ghost Atoms on Monolayer Graphene, CHRISTOPHER GUTIERREZ, Columbia University, LOLA BROWN, EDWARD LOCHOCKI, Cornell University, ETHAN ROSENTHAL, Columbia University, CHEOL-JOO KIM, YUI OGAWA, KYLE SHEN, JIWOONG PARK, Cornell University, ABHAY PASUPATHY, Columbia University — Various charge and spin ordered phases have been predicted to exist when the lattice symmetry is broken on the atomic scale. One such phase is the Kekule distortion, whereby the C-C bond symmetry is broken and the graphene unit cell is tripled. It has been proposed that when certain adatoms are placed on monolayer graphene, strong interactions can exist between them mediated by the graphene lattice. The graphene-adatom interaction can induce Kekule order in the graphene itself, and move the adatoms to produce a hidden Kekule ordering. In this talk I will discuss evidence from scanning tunneling microscopy, electron diffraction and angle resolved photoemission spectroscopy that shows the existence of this unique ordering in epitaxial graphene on copper. Interestingly, we find in this case that the Kekule order is induced by a dilute number of “ghost atoms” — unidentified atomic features — in the otherwise perfect copper lattice underneath monolayer graphene.

8:24AM A1.00003 Ytterbiun-driven strong enhancement of electron-phonon coupling in graphene, CHOONGYU HWANG, Pusan Natl Univ, DUCK YOUNG KIM, Carnegie Institution of Washington, DAVID A. SIEGEL, KEVIN T. CHAN, JESSE NOFFSINGER, University of California, Berkeley, ALEXEI V. FEDOROV, Lawrence Berkeley Natl Lab, MARVIN L. COHEN, University of California, Berkeley, BORJE JOHANSSON, Royal Institute of Technology, JEFFREY B. NEATON, ALESSANDRA LANZARA, University of California, Berkeley — The interactions between electrons and phonons attract practical and fundamental interests in graphene, as they can not only govern transport properties, but also realize novel phenomena, such as superconductivity. By using angle-resolved photoemission spectroscopy in conjunction with first principles calculations, we provide an experimental evidence for the strong enhancement of electron-phonon coupling in graphene. Ytterbiun adsorption leads to the enhancement of electron-phonon coupling as much as a factor of 10 with respect to as-grown graphene, resulting in the highest strength ever measured for graphene and suggesting a viable route to the realization of superconducting graphene.

8:36AM A1.00004 Molecular Bound States of Supercritical Charged Impurities on Graphene1, KIRILL VEILZIHANIN, LYUDMYLA ADAMSKA, Los Alamos National Laboratory, DMITRY SOLENOV, Saint Louis University — Functionalization of graphene by chemical groups/atoms allows one to tune its electronic, chemical and mechanical properties. For example, metallic adatoms (e.g., Li, Ca, Y) can be important in applications ranging from hydrogen storage to superconductivity. Such adatoms bind ionically to graphene and the resulting positive ions move along graphene relatively freely, so understanding the energetics of their interaction with graphene and between each other becomes critical for assessing stability of resulting materials in practical applications. It has recently been demonstrated that ions with charge greater than Z ∼ 1 induce a very peculiar non-linear electronic polarization of graphene, which is reminiscent to the Dirac vacuum reconstruction around superheavy nuclei. In our work we demonstrate that such non-linear polarization quantitatively changes not only graphene electronic structure but also the energetics of the effective graphene-mediated interaction between such ions. In my talk, I will discuss the properties of such effective interaction and its dependence on various parameters of the system. In particular, I will report on our findings that molecular bound states of supercritically charged ions can be formed on graphene at certain conditions.

1This work was performed under the NNSA of the U.S. DOE at LANL under Contract No. DE-AC52-06NA25396.

8:48AM A1.00005 Doping, adsorption, and polarity of atomic-layer materials: A predictive theory from systematic first-principles study1, SUSUMU SAITO, YOSHITAKA FUJIMOTO, Department of Physics, Tokyo Institute of Technology, TAKASHI KORETSUNE, RIKEN Center for Emergent Matter Science — Based on the extensive first-principles electronic-structure study of various doped hexagonal boron-nitride (h-BN) atomic layers as well as that of various doped graphene and carbon nanotubes, we propose a simple but predictive theory of polarity in doped atomic-layer materials. We first report the electronic structure of the pristine h-BN, h-BN layers with B and B2N vacancies which have been experimentally produced and observed frequently, and doped h-BN layers, and show that both p-type and n-type h-BN layers can be produced in a variety of ways. We next review the electronic structure of doped graphene and carbon nanotubes and the effect of the H adsorption which can even change the polarity of the system. Finally we propose a simple but predictive theory which is based on the number of valence electrons of each system, and can explain the polarities of all the h-BN, graphene, and nanotube-based systems studied so far.

9:00AM A1.00006 Screening properties of graphene layers studied by Kelvin Probe Force Microscopy and Landau Level Spectroscopy1. JOHN VETICK, CHIH-PIN LU, MICHAEL ALTWATER, JUNXU DUAN, GUOHONG LI, EVA Y. ANDREI, Rutgers University, Department of Physics and Astronomy, 136 Frelinghuysen Road, Piscataway, NJ 08855 USA — Graphene is one of the best conductors known, but due to its two dimensional structure and the need to support it on insulating substrates, its electronic properties are often masked by substrate-induced random potential fluctuations. In order to realize graphene’s full potential for electronic application it is therefore important to understand its screening properties and to find ways to minimize substrate invasiveness. We employed Kelvin Probe Force microscopy (KPFM) to investigate the screening properties of CVD grown graphene crystals as a function of layer number and substrate material using a gated device geometry. The KPFM study was complemented by low temperature scanning tunneling microscopy and Landau level spectroscopy in similar samples and device configurations. Measurements were carried out on single layer, bilayer, trilayer and twisted bilayer samples deposited on SiO2 and hBN substrates. Our findings show that twisted graphene layers provide superior screening of charged impurities and random potentials while at the same time preserving the unique electronic band structure of single layer graphene.

3Work Supported by DOE-FG02-99ER45742 and NSF DMR 1207108.

9:12AM A1.00007 Adsorption of monovalent aluminum halides on graphene defects. SUFIAN ALNEMRAT, JOSEPH HOOPER, Naval Postgraduate School — Density functional theory is used to study the adsorption of the monovalent aluminum halide AlCl on pristine and defective graphene (GR). Recent experimental efforts have shown that monovalent aluminum halide solutions can nucleate and grow small Al nanoparticles on a graphene surface. This nucleation and growth process may also shed light on how similar monovalent AlCl and AlBr solutions assemble into ligand-stabilized metalloid clusters. In this study we examined several point-type defects on GR to determine favorable sites for cluster nucleation. We found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond found that the AlCl weakly physisors on pure GR, Stone-Wales point defects, and N-, B- doped-GR. On the other hand, the AlCl monomer chemisorbs on monovacancies, divacancies, and pyridine-like N, B, and O doped monovacancies. The binding energy is on the order of 5.0 eV and a strong covalent bond.

9:24AM A1.00008 Absence of a transp ort signature of spin-orbit coupling in graphene with indium adatoms. JIA ZHENZHAO, YAN BAOMING, NIU JINGJING, HAN QI, ZHU RUI, WU XIAOSONG, YU DAPENG, Peking Univ. — Enhancement of the spin-orbit coupling in graphene may lead to various topological phenomena and also find applications in spintronics. Adatom absorption has been proposed as an effective way to achieve the goal. In particular, great hope has been held for indium in strengthening the spin-orbit coupling and realizing the quantum spin Hall effect. To search for evidence of the spin-orbit coupling in graphene absorbed with indium adatoms, we carry out extensive transport measurements, i.e., weak localization magnetoresistance, quantum Hall effect and non-local spin Hall effect. No signature of the spin-orbit coupling is found. Possible explanations are discussed.

9:36AM A1.00009 Direct observation of ordered configurations of hydrogen adatoms on graphene. CHENFANG LIN, YEXIN FENG, YINGDONG XIAO, Peking Univ., MICHAEL DUERR, Justus Liebig University Giessen, XIANGQIAN HUANG, XIAOZHI XU, RUGUANG ZHAO, ENGE WANG, XIN-ZHENG LI, ZONGHAI HU, Peking Univ. — Ordered configurations of hydrogen adatoms on graphene have received great attention because they are closely tied to tuning of graphene properties including large band gap opening and formation of specific magnetic orders, both of which are highly desirable in potential applications. Many ordered structures of hydrogenated graphene have been proposed, including double sided and single sided ones, with the calculated band gap width depending on the respective H coverage. However, none of these ordered structures has been observed directly. Here we report direct imaging of several ordered configurations of H adatoms on graphene by scanning tunneling microscopy. The H atoms in the configurations exhibit apparent sublattice selectivity and tiny deviations from the exact atop-of-carbon positions. Scanning tunneling spectroscopy measurements of the configurations showed a larger than 0.6 eV gap in the local density of states. These findings can be well explained by our density functional theory simulations based on models of double sided H configurations.

Z. H. thanks the NBRP of China (Grant 2012CB921330) and the Chinese Ministry of Education for financial supports. E. W., X. Z. L. and Z. H. thank the National Natural Science Foundation of China (Grant 11074005, 91021007 and 11275008) for financial supports.

9:48AM A1.00010 Disorder induced topological transition in graphene with random adatoms1, EDUARDO CASTRO, CeFEMA, Instituto Superior Técnico, Universidade de Lisboa, Av. Rovisco Pais, 1049-001 Lisboa, Portugal, MARIA LÓPEZ-SANCHO, MARÍA VOZMEDIANO, Instituto de Ciencia de Materiales de Madrid, CSIC, Cantoblanco, E-28049 Madrid, Spain — Abstract One of the first proposals for a two-dimensional topological insulator was made for graphene, the so called Kane-Mele model, but the very low spin-orbit coupling makes this phase undetectable. It has been suggested that randomly depositing certain heavy adatoms can amplify the effect by many orders, and that a dilute concentration should be enough to open a detectable topological gap. Still lacking, however, is a precise determination of the critical density of random adatoms based in the evolution of the topological index. Based in a finite size analysis of the topological index as a function of the density of randomly distributed adatoms, and also on the localization properties of the system accessed through the Lyapunov exponent, we not only determine the critical density but also establish the nature of this peculiar topological transition.

1EC acknowledge the financial support of FCT-Portugal through grant No. EXPL/FIS-NAN/1720/2013.

10:00AM A1.00011 Electronic Structure of Iridium Clusters on Graphene1. BRADFORD A. BARKER, University of California - Berkeley, Lawrence Berkeley National Laboratory, AARON J. BRADLEY, Univ of California - Berkeley, MIGUEL M. UGEDA, University of California - Berkeley, SINISA COH, ALEX ZETTL, MICHAEL F. CROMMIE, MARVIN L. COHEN, STEVEN G. LOUIE, University of California - Berkeley, Lawrence Berkeley National Laboratory — Graphene was predicted to exhibit non-trivial Z2 topology, but its exceedingly weak spin-orbit coupling prevented this from being observed. Previous theoretical work has proposed enhancing the spin-orbit coupling strength by depositing individual adatoms adsorbed onto the surface of graphene. We show experimental evidence that the iridium adatoms cluster, with a cluster size of at least two atoms. We investigate through theoretical calculations the orientation of the iridium dimers on graphene, contrast the electronic structure of iridium dimers with iridium monomers, and compare the theoretical results with scanning tunneling spectroscopy of the experimental results determined via scanning tunneling spectroscopy.

but also the lattice thermal conductance is anisotropic, making this material a promising candidate for thermoelectric applications.

Using first-principles calculations and models, we study several fundamental properties of few-layer black phosphorus. We predict the quasiparticle band gap, energy positions of these edge states. The reconstructions self-passivate most edge dangling bonds by switching the coordination number of phosphorus from 3 to 4 or 5.

Extensive density functional theory calculations show that edge reconstructions are responsible for multiple edge states located inside the 2 eV gap and below the Fermi level. To understand these edge states, we have modeled a series of 1D phosphorene and its edges [Liang et al., Nano Letters, 2014, 14, 6400]. A detailed scanning tunneling microscopy/spectroscopy (STM/S) study with first-principles calculations reveals the presence of a semiconducting 2 eV gap, the direct bandgap for phosphorene. More importantly, we were able to identify a magnetic moment. We investigate the electronic properties of graphene nanoislands grown on Ni(111), using local tunneling spectroscopy measurements performed the first-principles based Density Functional Theory (DFT) calculations to study the stability, geometrical structures, and electronic properties of a (Pd/Pt) atom adsorbed graphene to investigate the possibility of using Pd/Pt decorated graphene as energy storage materials with reference to pristine graphene. The London dispersion forces have been incorporated by the DFT-D2 levels of calculations implemented in Quantum Espresso packages. Our findings show that Pd and Pt both adsorb on graphene at Bridge site. The electronic structures of Pd(Pt) adsorbed graphene possess band gap opening due to breaking of the symmetry of graphene. Further we have studied the adsorption of molecular hydrogen ((H 2 ) n , n = 1-7) on the Pd(Pt)-graphene system. The adatom Pd(Pt) enhances the binding energy per hydrogen molecule in Pd(Pt)-graphene system in comparison to that in the pristine graphene. The binding energy per hydrogen molecule of the adatom-graphene system decreases as the number of H 2 molecules increases and finally it saturates to 0.15 eV (0.16 eV) per hydrogen molecule for Pd-graphene (P-graphene) systems respectively.
8:24AM A2.00003 Tuning the exciton energy in single and multi-layer black phosphorus by strain and electric field. FRANCOIS PEETERS, DENIZ CAKIR, Universiteit Antwerpen, Dept. Physics, B-2020 Antwerpen, ANDRE CHAVES, UFP, Fortaleza, Brazil, HASAN SAHIN, Universiteit Antwerpen, Dept. Physics, B-2020 Antwerpen, CMT COLLABORATION — The effect of strain on the electronic and optical properties of single layer black phosphorus is investigated using first principles calculations. Biaxial strain is able to tune the optical band gap from 0.38 eV (at -8% strain) to 2.07 eV (at 5.5%). The exciton binding energy is found to be 0.40 eV for compressive biaxial strain of -8% and becomes 0.83 eV for tensile strain of 4%. The stack effect in the exciton energy is obtained by direct diagonalization of the effective mass Hamiltonian. The dependence on the number of phosphorus layers and the strength of the electric field is investigated. Band anisotropy becomes evident in the direction dependent field induced polarizability of the exciton.

8:36AM A2.00004 Anisotropic polarization dependence of light scattering in black phosphorus . JAE-UNG LEE, JUNGCHEOL KIM, Department of Physics, Sogang University, JINHWAN LEE, CHANGGU LEE1, Department of Mechanical Engineering and Center for Humann Interface Nanotechnology (HINT), Sungkyunkwan University, HYEONSIK CHEONG, Department of Physics, Sogang University — We investigated anisotropic polarization dependence of light scattering in black phosphorus by optical microscopy and Raman spectroscopy. Due to a high carrier mobility (~ 300 V cm$^{-2}$s$^{-1}$) and a high on/off ratio (~ $10^3$), black phosphorus is attracting interest as a promising candidate for a field effect transistor. Black phosphorus has an anisotropic crystal structure, which leads to directional dependence of the mobility and infrared light absorption. We prepared samples on SiO$_2$/Si substrates by mechanical exfoliation. We chose a few-hundred-nanometer thick sample with well-defined edges. By using a polarized optical microscope, we found that the optical contrast depends on the crystal direction. By comparing results with TEM measurements, we can determine the crystallographic orientation of the sample. We also performed polarized Raman measurements with several excitation energies. The intensity of each mode is largely dependent on the incident polarization direction. Furthermore, these polarization dependences vary with the excitation energy. From the polarization dependence of the Raman intensity one can determine the crystallographic orientation of the sample.

8:48AM A2.00005 Symmetry analysis of phosphorene: electronic structure with spin-orbit interaction , PENGKE LI, IAN APPELBAUM, Univ of Maryland-College Park, APPELBAUM’S GROUP TEAM — We present a symmetry analysis of electronic band structure including spin-orbit interaction close to the insulating gap edge in monolayer black phosphorus (“phosphorene”). Expressions for energy dispersion relation and spin-dependent eigenstates for electrons and holes are found via simplification of a perturbative expansion in wave vector $k$ away from the zone center using elementary group theory. Importantly, we expose the underlying symmetries giving rise to substantial anisotropy in optical absorption, charge, and spin transport properties, and reveal the mechanism responsible for valence band distortion and possible lack of a true direct gap. We discovered that, spin flip processes are decoupled by symmetry from flexural phonons, allowing us to predict a spin lifetime comparable to bulk Si, vastly greater than graphene.

9:00AM A2.00006 Tuning Electronic and magnetic properties of phosphorene by vacancies and adatoms1, POOJA SRIVASTAVA, K.P.S.S. HEMBRAM, HIROSHI MIZUSEKI, KWANG-RYEOL LEE, SANG SOO HAN, SEUNGCHUL KIM, Korea Institute of Science and Technology — In the search of novel materials, phosphorene (2D layers of black phosphorus) has been synthesized recently. Intrinsic bandgap, hydrophilicity and anisotropic electron mobility make phosphorene different from graphene and also, its hole mobility is higher than that in MoS$_2$. All these properties make it a very promising material for electronics and optoelectronics applications. As with other as-synthesized materials, phosphorene exhibits defects such as vacancies, and these defects can affect the properties of the material significantly. The present work provides a detailed understanding of various vacancy defects (mono- and di-vacancies) and their effect on the electronic and magnetic properties of phosphorene. We have also studied the effects of omnipresent non-metallic C/N/O and transition metal (TM) Fe/Co/Ni on the electronic and magnetic properties of phosphorene. We show that, for various adatom adsorbed pristine/defective phosphorene structures the magnetic moment can be tuned via the control of Fermi level. The magnetism for non-metallic adatom adsorbed pristine/defective phosphorene systems can be switch ON/OFF. TM adatoms provide extra flexibility by tuning the magnitude as well.

9:12AM A2.00007 Quantum Monte Carlo Studies of Bulk and Few- or Single-Layer Black Phosphorus1, LUKE SHULENBURGER, ANDREW BACZEWSKI, Sandia National Laboratories, ZHEN ZHU, JIE GUAN, DAVID TOMANEK, Michigan State University — The electronic and optical properties of phosphorus depend strongly on the structural properties of the material. Given the limited experimental information on the structure of phosphorene, it is natural to turn to electronic structure calculations to provide this information. Unfortunately, given phosphorus’ propensity to form layered structures bound by van der Waals interactions, standard density functional theory methods provide results of uncertain accuracy. Recently, it has been demonstrated that Quantum Monte Carlo (QMC) methods achieve high accuracy when applied to solids in which van der Waals forces play a significant role. In this talk, we will present QMC results from our recent calculations on black phosphorus, focusing on the structural and energetic properties of monolayers, bilayers and bulk structures.

9:24AM A2.00008 Atoms dictating shape: The discrete geometry of conformal two-dimensional materials, MEHRSHAD MEHBOUDI, KAINEN UTT, Univ of Arkansas-Fayetteville, HUMBERGE TERRONES, Rensselaer Polytechnic Institute, ALEJANDRO PACHECO, Universidad del Norte, EDMUND HARRISS, SALVADOR BARRAZA-LOPEZ, Univ of Arkansas-Fayetteville — The electronic, optical, thermal, mechanical and chemical behavior of two-dimensional (2D) materials depends on their shape (geometry). 2D materials are nets [1], with covalent bonds representing edges, and where atoms are vertices. Here we use a mathematical language to tell the shape of meshes and discuss the geometry of 2D materials of varied lattice structures, such as: hexagonal boron nitride, black phosphorus monolayers, low-buckled silicene, germanene, blue phosphorus, newly predicted III-V buckled 2D compounds such as AlP, conformal “thicker” layered materials such as 2D tin, “single-layer” transition metal dichalcogenides (MX$_2$’s), and a single-quintuple-layer of the topological insulator Bi$_2$Se$_3$. We characterize the geometry of each atom position without recourse to a continuum parametric model. The new framework generalizes the discrete geometry we introduced recently for graphene [2,3]. 9:36AM A2.00009 Raman modes of exfoliated black phosphorus down to the monolayer. ANNE- LAURENCE PHANEUF-L’HEUREUX, Polytechnique Montreal, ALEXANDRE FAVRON, ETIENNE GAUFRES, RICHARD MARTEL, Universite de Montreal, SEBASTIEN FRANCECOEUR, Polytechnique Montreal — Exfoliated black phosphorus layers, or 2D-phosphane, are a lamellar direct-gap semiconductor providing high mobilities and enabling a thickness-controlled band gap tunability ranging from 0.3 up to about 2 eV. Using Raman spectroscopy, we have studied vibrational modes of pristine and non-oxidized 2D-phosphane as a function of the number of layers involved (n), and also as a function of temperature, polarization, and excitation wavelength. The evolution of the width and of the frequency of A$_1^g$ as a function of n presents a clear non-monotonic dependence. This can be explained by the presence of new nearly-degenerate Raman-allowed modes that are symmetry-forbidden in both bulk and monolayer samples. We also present Raman spectra of few-layer samples for excitation wavelengths in the vicinity of the expected band gap.

9:48AM A2.00010 Raman signatures of degradation in mono-, bi- and trilayers of exfoliated black phosphorus$^1$. ALEXANDRE FAVRON, ETIENNE GAUFRES, Universite de Montreal, FREDERIC FOSSARD, Laboratoire d’Etude de Microstructure, ANNE-LAURENCE PHANEUF-L’HEUREUX, Polytechnique Montreal, ANNICK LOISEAU, Laboratoire d’Etude de Microstructure, RICHARD LEONELLI, Universite de Montreal, SEBASTIEN FRANCECOEUR, Polytechnique Montreal, RICHARD MARTEL, Universite de Montreal — Thin layers of black phosphorus have recently raised interest for their two-dimensional (2D) semiconducting properties, such as tunable bandgap with layer thickness and high carrier mobilities. This lamellar crystal of P atoms can be exfoliated down to monolayer 2D-phosphate (also called phosphorene) using procedures similar to that for monolayer graphene. The devices are however challenging to fabricate due to fast degradation of the thin layers upon exposure to light in air. We investigated this degradation process using in-situ Raman and transmission electron spectroscopies and reported on a thickness dependent reactivity of the layers. Moreover, the degradation process was identified to be due to an ubiquitous photo-induced oxidation of the layers by adsorbed oxygen in water. Optimum experimental conditions to prepare n-layer 2D-phosphate in their pristine states were applied to determine the Raman signatures of degradation. Here, we report on the use of the ratio of intensity of the A1g over A2g modes as an assessment of the crystal quality.

10:12AM A2.00012 First-principles study of atomic adsorptions on phosphorene. JUN-HO LEE, YOUNG-WOO SON, Korea Inst for Advanced Study — Phosphorene with a moderate intrinsic band gap around 1eV and appropriate carrier mobility merits a next-generation electronic devices. One of the interesting characters of phosphorene is anisotropic electronic and optical properties due to its puckered atomic structures, providing an interesting realization of self-assembled low-dimensional nanostructure on it. In this study, we investigated electronic and magnetic properties of two-dimensional atomic layer formed on phosphorene by using density-functional theory calculations. We explored adsorption properties of various atoms on phosphorene and calculated energetics to predict two-dimensional atomic arrangements on top of phosphorene. In a strong spin-orbit system, we also found anisotropic spin splitting owing to its structural anisotropic.

10:24AM A2.00013 Electronic band structure of surface-doped black phosphorus$^1$. JIMIN KIM, Pohang University of Science and Technology, SAE HEE RYU, YEONGSUP SOHN, KEUN SU KIM, Pohang University of Science and Technology, Institute for Basic Science — There are rapidly growing interests in the study of few-layer black phosphorus owing to its promising device characteristics that may impact our future electronics technology. The low-energy band structure of black phosphorus has been widely predicted to be controllable by external perturbations, such as strain and doping. In this work, we attempt to control the electronic band structure of black phosphorus by in-situ surface deposition of alkali-metal atoms. We found that surface doping induces steep band bending towards the bulk, leading to the emergence of new 2D electronic states on top of phosphorene. In a strong spin-orbit system, we also found anisotropic spin splitting owing to its structural anisotropic.

10:36AM A2.00014 Van der waals heterostructure of phosphorene and graphene: Tuning the Shottky barrier and doping by electrostatic gating$^1$. JOSE EDUARDO PADILHA DE SOUSA, ADALBERTO FAZZIO, Universidade de Sao Paulo, ANTONIO JOSE ROQUE DA SILVA, Universidade de Sao Paulo/Laboratorio Nacional de Luz Sincrotron — Van der Waals heterostructures of 2D materials is one of the most promising approaches in terms of the new nanodevices. One of these 2D materials that have attracted a lot of attention from a broad community is the phosphorene, an elemental material composed only of phosphorus. If one wishes to build devices, two important points must always be addressed: how to make contacts - and the value of the resulting Schottky Barrier Height (SBH) - and how to control the charge doping level. In the present work we study the structural and electronic properties of single and bilayer phosphorene with graphene. We show that both the properties of graphene and phosphorene are preserved upon its contact, and we also show that via the application of a perpendicular electric field it is possible to tune the position of the band structure of phosphorene with respect to that of graphene. This leads to a great control of the Schottky barrier height and doping of phosphorene, which are important features in the design of new devices based on this kind of structure.

10:48AM A2.00015 Low-frequency interlayer breathing mode in few-layer black phosphorus. XI LING, SHENQI HUANG, MIT, LIANGBO LIANG, VINCENT MEUNIER, RPI, MILDRED DRESSELHAUS, MIT — Black phosphorus (BP), as a layered material, has attracted intense interest recently. Many interesting electronic and optoelectronic properties are being explored based on its unique anisotropic structure. In this work, we studied the Raman spectra in few-layer BP, including the intralayer and interlayer vibrational modes. Besides the three typical Raman modes A$_1^g$ (~ 359 cm$^{-1}$), B$_{2g}$ (~ 437 cm$^{-1}$), and A$_2^g$ (~ 466 cm$^{-1}$), low-frequency modes were observed in few-layer BP, as predicted by the first-principles density functional theory (DFT) calculation. The interlayer breathing mode at around 87 cm$^{-1}$ was assigned as A$_0^g$, since the DFT calculation result showed it has the symmetry of A$_0^g$. In addition, the polarization dependence of the Raman modes in BP is studied systematically. Both the DFT calculation and the experimental results show that the polarization dependence profiles are sensitive to the crystal orientation of BP. In addition, the temperature dependence of the modes is studied in the range of -150 °C to room temperature. It is found that the A$_0^g$ mode has almost no dependence on the temperature change, and the out-of-plane mode (A$_2^g$) has weaker dependence than the in-plane modes (B$_{2g}$ and A$_1^g$).
Data to increase the understanding of the protein's structure. Regulate the kinetics of pore formation in a model bilayer lipid membrane. The FOS-14 Detergent was tested under various conditions to understand its impact.

Detergent Stabilized Nanopore Formation Kinetics of an Anthrax Protein

KELBY PETERSON, Utah State University — This summer research project funded through the Society of Physics Students Internship Program and The National Institute of Standards and Technology focused on optimization of pore formation of Protective Antigen protein secreted by Bacillus Anthraces. This experiment analyzes the use of N-tetradecylphosphocholine (FOS-14 Detergent) to stabilize the water soluble protein, protective antigen protein (PA63) to regulate the kinetics of pore formation in a model bilayer lipid membrane. The FOS-14 Detergent was tested under various conditions to understand its impact on the protein pore formation. The optimization of this channel insertion is critical in preparing samples of oriented for neutron reflectometry that provide new data to increase the understanding of the protein's structure.
Protein Unfolding reveals the effects of diatom geometry on their optical properties. Finally, the dimensions of the photonic crystal are parametrically swept, allowing for further average geometries of the diatom frustules are used to recreate a 2-dimensional photonic crystal, after which the electric field distribution and optical transmission frustules, a biomimetic photonic crystal derived from diatom frustules can be recreated and modeled with the finite element method. In this approach, the photonic crystals. Through the examination and measurement of the physical characteristics of many scanning electron microscope (SEM) images of diatom frustules, a biomimetic photonic crystal derived from diatom frustules can be recreated and modeled with the finite element method. In this approach, the average geometries of the diatom frustules are used to recreate a 2-dimensional photonic crystal, after which the electric field distribution and optical transmission through the photonic crystal are both measured. The optical transmission is then compared to the transmission spectra of a regular hexagonal photonic crystal, revealing the effects of diatom geometry on their optical properties. Finally, the dimensions of the photonic crystal are parametrically swept, allowing for further control over the transmission of light through the photonic crystal.

Fayetteville, JOSEPH HERZOG, Department of Physics, University of Arkansas Fayetteville — Diatom algae are unicellular, photosynthetic microorganisms. MISHLER, Department of Physics, University of Arkansas, Fayetteville, ANDREW ALVERSON, Department of Biological Sciences, University of Arkansas, Fayetteville, JOSEPH HERZOG, Department of Physics, University of Arkansas Fayetteville — Diatom algae are unicellular, photosynthetic microorganisms with a unique external shell known as a frustule. Frustules, which are composed of amorphous silica, exhibit a unique periodic nano-patterning, distinguishing diatoms from other types of phytoplankton. Diatoms have been studied for their distinctive optical properties due to their resemblance of photonic crystals. In this regard, diatoms are not only considered for their applications as photonic crystals, but also for their use as biomimetic templates for artificially fabricated photonic crystals. Through the examination and measurement of the physical characteristics of many scanning electron microscope (SEM) images of diatom frustules, a biomimetic photonic crystal derived from diatom frustules can be recreated and modeled with the finite element method. In this approach, the average geometries of the diatom frustules are used to recreate a 2-dimensional photonic crystal, after which the electric field distribution and optical transmission through the photonic crystal are both measured. The optical transmission is then compared to the transmission spectra of a regular hexagonal photonic crystal, revealing the effects of diatom geometry on their optical properties. Lipids are organic molecules composed of hydrophobic fatty acid tails and hydrophilic head groups that can form a multitude of structures, including lipid vesicles which provides an excellent model representing cell membranes. In this study, we examine the effects of antimicrobial peptides and drugs on lipid vesicles. Fourier transform infrared spectroscopy measurements are performed with and without the antimicrobial peptide. A change in absorbance corresponding to the wavenumber regimes associated with the stretching of the carbonyl and phosphate groups is observed. Also, a dye leakage assay is performed with vesicles composed of neutral and charged lipids. Calcein dye is enclosed within these vesicles in solution. Different concentrations of the active and inactive antimicrobial peptides, and tamoxifen are incubated with the vesicles. Concentration dependent dye leakage is determined by measuring fluorescence intensity before and after the addition of the peptides and tamoxifen. Different leakage behavior is observed for the active and inactive peptides, and the lipid composition of the vesicle is found to have a large effect.

8:24AM A4.00003 Amphiplex Formation, SHANON PETERSEN, Allegheny College, JENNIFER LAAER, TIMOTHY LODGE, University of Minnesota — Polymer-micelle complexes are currently under heavy investigation due to their potential applications in targeted drug delivery and gene therapy, yet the dynamics of the complex formation is still relatively unstudied. By varying the ratios of poly(styrene sulfonate) chains and cationic poly(dimethylaminoethyl methacrylate)-b-poly(styrene) micelles and the ionic strength of the system, we created a variety of complex configurations of different sizes and charges. The complexes were characterized dynamic light scattering and zeta potential measurements which provided information regarding the hydrodynamic radius, distribution of sizes, and effective charge.

8:36AM A4.00004 Biomimetic Photonic Crystals based on Diatom Algae Frustules, JONATHAN MISHLER, Department of Physics, University of Arkansas, Fayetteville, ANDREW ALVERSON, Department of Biological Sciences, University of Arkansas, Fayetteville, JOSEPH HERZOG, Department of Physics, University of Arkansas Fayetteville — Diatom algae are unicellular, photosynthetic microorganisms with a unique external shell known as a frustule. Frustules, which are composed of amorphous silica, exhibit a unique periodic nano-patterning, distinguishing diatoms from other types of phytoplankton. Diatoms have been studied for their distinctive optical properties due to their resemblance of photonic crystals. Finally, the dimensions of the photonic crystal are parametrically swept, allowing for further control over the transmission of light through the photonic crystal.

8:48AM A4.00005 Employing Multiple Spectroscopic Techniques Simultaneously to Observe Protein Unfolding, MICHAEL CROWE, BEN KELTY, JUSTIN LINK, Xavier University — A protein’s function is directly related to its native, folded structure. In order to study the structure of proteins, the unfolding process may be characterized. In our study, by using the spectroscopic techniques of circular dichroism (CD), absorption, and fluorescence simultaneously, we examined the unfolding of horse heart cytochrome c, a well-studied, model protein by gradually increasing the concentration of the chemical denaturant, guanidine hydrochloride. The signal changes from these modalities over the course of the unfolding reaction provides some of the thermodynamic properties like Gibbs free energy for insight into the stability of the protein. This allows us to compare the three techniques under the exact same conditions. The objective of this session is to present recent work in developing a protocol to observe the unfolding of cytochrome c using fluorescence, absorbance, and CD simultaneously.

9:00AM A4.00006 The Effect of Magnetic Fields on the Quorum Sensing-Regulated Luminescence of Vibrio fischeri, ADDIE BARRON, STEVE HAGEN, MINJUN SON. None — Quorum sensing (QS) is a mechanism by which bacteria communicate through the secretion and detection of extracellular signaling molecules known as autoinducers. This research focuses on the quorum sensing regulated bioluminescence of Vibrio fischeri, a marine bacterium that lives in symbiosis with certain fish and squid species. Previous studies of V. harveyi, a close relative of V. fischeri, indicate that a strong magnetic field has a positive effect on V.harveyi bioluminescence. However the effect of magnetic fields on quorum sensing-regulated luminescence is in general poorly understood. We grew V. fischeri in solid and liquid growth media, subject to strong static magnetic fields, and imaged the bioluminescence over a period of forty-eight hours. Luminescence patterns were analyzed in both the spatial and time dimensions. We find no indication that a magnetic field influences Vibrio fischeri luminescence either positively or negatively.

This research was funded by the grant number NSF DMR-1156737.

9:12AM A4.00007 Electron mobility in liquid-gated graphene biosensors, CHRISTINA HARMON, Linfield College, MORGAN BROWN, ETHAN MINOT, Oregon State University, MICHAEL CROSSER, Linfield College — We report measurements of the electron mobility in liquid-gated graphene. Graphene field-effect transistor (GFET) biosensors are more sensitive to changes in external fields when the mobility is high; therefore, increasing mobility will improve sensitivity. Mobility can be calculated from the ratio of sheet conductivity to carrier density. Sheet conductivity was measured using a van der Pauw geometry and carrier density was determined from measurements of the liquid-gate capacitance. We show that mobility improves after the graphene surface is cleaned by an annealing process.

9:24AM A4.00008 Detecting a Protein in its Natural Environment with a MOSFET Transistor, BENJAMIN PEREZ, The Society of Physics Students/ NIST, ARVIND BALLEIPALLI, NIST — Our group’s goal is to make a MOSFET transistor that has a nanopore through it. We want to have proteins flow through this device and examine their structure based on the modulation they cause on the current. This process does not harm the protein and allows the protein to be studied in its natural environment. The electric field and electric potential of a point charge were computed within a nano-transistor. The simulations were used to see if the point charge had enough influence on the current to cause a modulation. The point charge did cause a rise in the current making the modulation concept a viable one for medical applications. COMSOL multiphysics software was used to perform all simulations.

9:36AM A4.00009 Topological Properties of Some Integrated Circuits for Very Large Scale Integration Chip Designs¹, S. SWANSON, M. LANZEROTTI, Augsburg College, G. VERNIZZI, J. KUJAWSKI, A. WEATHERWAX, Siena College — This talk presents topological properties of integrated circuits for Very Large Scale Integration chip designs. These circuits can be implemented in very large scale integrated circuits, such as those in high performance microprocessors. Prior work considered basic combinational logic functions [1] and produced a mathematical framework based on algebraic topology for integrated circuits composed of logic gates [2]. Prior work also produced an historically-equivalent interpretation of Mr. E. F. Rent’s work for today’s complex circuitry in modern high performance microprocessors, where a heuristic linear relationship was observed between the number of connections and number of logic gates [3]. This talk will examine topological properties and connectivity of more complex functionally-equivalent integrated circuits. References: [1] E. Hitesue, K. Irvin, M. Lanzerotti, G. Vernizzi, J. Kujawski, A. Weatherwax, “Topological Properties of Basic Combinational Logic Functions for Very Large Scale Integrated Circuits,” in 2014 Proc. APS Mtg., Denver, CO, 2014. [2] C. Vernizzi, M. Y. Lanzerotti, J. Kujawski, A. Weatherwax, “Topological Constraints for E. F. Rent’s Work on Microminiature Packaging and Circuitry,” IBM Jnl. Res. Dev., vol. 58, no. 2/3, pp. 13:1-17, Mar/May 2014. ¹The views expressed in this article are those of the author and do not reflect the official policy or position of the United States Air Force, Department of Defense or the U.S. Government.

9:48AM A4.00010 Exploration of Whispering Gallery Modes in an Optically Trapped Aerosol Droplet, ANGELA LUDVIGSEN, LOWELL MCCANN, University of Wisconsin - River Falls — Optical traps use a laser beam to catch and hold small transparent objects. Past observations of optically trapped aqueous aerosol droplets have shown that the droplet moves between two or more stable positions depending upon the power of the trapping laser. It is hypothesized that this movement coincides with a resonance of the light with the droplet called a Whispering Gallery Mode. When the resonance occurs, additional forces act on the droplet. To investigate this behavior, Raman scattered light from the droplet is measured using a spectrometer while simultaneously recording the droplet’s position. The Raman spectrum exhibits a series of peaks that appear due to the very spherical shape of the droplet called Cavity Enhanced Raman Spectroscopy. The location and spacing of the peaks are related to the diameter and the optical properties of the droplet. In order to achieve an accurate determination of the radius from this spectrum, the magnitude of the electric and magnetic fields of the light scattered off the droplet are calculated. This allows for a precise measurement of the droplet’s radius at the moment that the droplet moves between stable positions.

10:00AM A4.00011 Measuring the Temperature of the Ithaca College MOT Cloud using a CMOS Camera, JONATHAN SMUCKER, BRUCE THOMPSON, Ithaca College — We present our work on measuring the temperature of Rubidium atoms cooled using a magneto-optical trap (MOT). The MOT uses laser trapping methods and Doppler cooling to trap and cool Rubidium atoms to form a cloud that is visible to a CMOS Camera. The Rubidium atoms are cooled (by removing the magnetic field). In order to measure the temperature of the MOT we take pictures of the cloud using a CMOS camera as it expands and calculate the temperature based on the free expansion of the cloud. Results from the experiment will be presented along with a summary of the method used.

10:12AM A4.00012 Investigation of Nanowire Thickness and Enhancement Characteristics, CAMERON SAYLOR, DESALEGN DEBU, University of Arkansas Fayetteville, ERIC NOVAK, Shippensburg University, JOSEPH HERZOG, University of Arkansas Fayetteville — This work investigates the effect of nanowire thickness on the optical enhancement of nanowire. We present a study that shows there is potential in altering the thickness of plasmonic structures to improve their optical field enhancement. The study was performed using a finite element method.

10:24AM A4.00013 Nonlinear Interactions between Slender Structures and Axial Flow, LI DU, Nanjing University — For decades, dynamic behaviors of a slender structure with axial flow have been extensively studied. However, the governing equation based on expansions of small quantities is complicatedly-expressed and can be inappropriate as amplitude becomes considerably large. In this research, we are dedicated to finding an approach to study the nonlinear dynamics of a fluid-conveying slender structure with arbitrary amplitude. By introducing the Intrinsic Coordinate, we find a concise way to describe the configuration of the system. Differential relations of such coordinate are studied and the rigorous nonlinear equation of motion is derived. Then rather than small-deflection approximation, linear dynamics are studied using Argand Diagram under a weaker condition named low-varying approximation. Nonlinear properties including Hopf bifurcation, limit-cycle motion and vibration frequencies are studied theoretically and experimentally.

10:36AM A4.00014 ABSTRACT WITHDRAWN —

10:48AM A4.00015 The Importance of Science Policy and its Challenges¹, BENJAMIN PREIS, Tufts University — I worked for physicist and Congressman Bill Foster (D-IL) as the Mather Public Policy Intern through the American Institute of Physics and the Society of Physics Students during the summer of 2014. This internship is meant to connect undergraduate physics students with the policy process in Washington DC. As a Mather Public Policy Intern, I worked for Congressman Foster researching policy initiatives such as science funding, STEM education, and environmental regulations. This talk will discuss my experience and many of the things that I learned as an undergraduate physicist working on Capitol Hill. For example, through my experience with the internship, I attended lectures and hearings that illuminated for me how members of Congress conceive of scientific research. I also met with many physicists on Capitol Hill working to improve government interest in physics research — AAAS Fellows, Members of Congress, and Government Relations Specialists — and I will talk about how I saw physicists impacting governmental policies relating to scientific research and development. This internship is part of the Society of Physics Students internship program and was funded by the John and Jane Mather Foundation for Science and the Arts.

Monday, March 2, 2015 8:00AM - 10:48AM —
Session A5 FIAP: Fractional Quantum Hall Effect I
Juan Gorman Room 005 - John Watson, Purdue University
8:00AM A5.00001 Properties of in-situ back-gated two-dimensional electron gases in GaAs/AlGaAs for the study of electron correlations in the 2d Landau level, JOHN WATSON, Department of Physics and Birck Nanotechnology Center, Purdue University, MICHAEL MANFRA, Department of Physics, Birck Nanotechnology Center, Schools of Electrical and Computer Engineering and Materials Engineering, Purdue University — We report on growth and processing optimization of in-situ back-gated two-dimensional electron gases in GaAs/AlGaAs quantum wells. We find that gate leakage currents as small as 4 pA can cause noticeable heating of the electrons if the lattice is not properly thermally anchored to the cryostat. However, we also show that when the devices are properly optimized gate voltages as large as 4V can be applied before leakage turns on, allowing the density to be tuned over a large range from near depletion to over \( 4 \times 10^{11} \text{ cm}^{-2} \). In these optimized devices heating effects at dilution refrigerator temperatures are negligible and the gap at \( \nu = 5/2 \) can be tuned continuously with density to a maximum >400 mK. Such devices should prove useful for the study of electron transport in nanostructures in the 2d Landau level.

8:12AM A5.00002 Analyzing the Disorder Broadening of the Even Denominator Fractional Quantum Hall States in the Presence of Alloy Disorder, ETHAN KLEINBAUM, NIANPEI DENG, GEOFFREY GARDNER, MICHAEL MANFRA, GABOR CSATHY, Purdue University — The unique character and potential application of the even denominator \( \nu=5/2 \) fractional quantum hall state has elicited significant interest. Yet, the most basic properties of this ground state remain unexplained. One poorly understood effect is that of the various types of disorder. We report energy gaps at the filling factor \( \nu=7/2 \) in a series of samples into which we intentionally added aluminum impurities during the MBE growth. These data, together with the availability of energy gaps at \( \nu=5/2 \) in the same samples, allows us to quantify the disorder broadening and the intrinsic gap of the even denominator fractional quantum Hall states. This work was supported by DOE DE-SC000671.

8:24AM A5.00003 Experimental constraints and a possible quantum Hall state at \( \nu=5/2 \), DIMA FELDMAN, Brown Univ, GUANG YANG, RIKEN — Several topological orders have been proposed to explain the quantum Hall plateau at \( \nu=5/2 \). The observation of an upstream neutral mode on the sample edge [Bid et al., Nature (London) 466, 585 (2010)] supports the non-Abelian anti-Pfaffian state. On the other hand, the tunneling experiments [Radu et al., Science 320, 899 (2008); Lin et al., Phys. Rev. B 85, 165321 (2012); Baer et al., Phys. Rev. B 90, 075403 (2014)] favor the 331 state which exhibits no upstream modes. We find a topological order, compatible with the results of both types of experiments. That order allows both finite and zero spin polarizations. It is Abelian but its signatures in Aharonov-Bohm interferometry can be similar to those of the Pfaffian and anti-Pfaffian states.

8:36AM A5.00004 Entanglement Entropy of Quantum Hall Systems with Short Range Disorder, BARRY FRIEDMAN, Department of Physics, Sam Houston State University, GREG LEVINE, Department of Physics and Astronomy, Hofstra University — The critical value of the mobility for which the filling 5/2 quantum Hall effect is destroyed by short range disorder is determined from an earlier calculation of the entanglement entropy. The value agrees well with experiment; this agreement is particularly significant in that there are no adjustable parameters. Entanglement entropy vs. disorder strength for filling 1/2, filling 9/2 and filling 7/3 is calculated. For filling 1/2 there is no evidence for a transition for the disorder strengths considered; for filling 9/2 there appears to be a stripe-liquid transition. For filling 7/3 there again appears to be a transition at similar value of the disorder strength as the 5/2 transition but there are stronger finite size effects.

8:48AM A5.00005 Hall viscosity of hierarchical quantum Hall states, MIKAEL FREMLING, THORS HANS HANSSON, Stockholm University, JUHA SUORSA, Nordita — We construct model wave functions on a torus for all chiral states in the abelian quantum Hall hierarchy. These functions have no variational parameters, and they transform under the modular group in the same way as the multicomponent generalizations of the Laughlin wave functions. Assuming the absence of Berry phases upon adiabatic variations of the modular parameter \( \tau \), we calculate the quantum Hall viscosity and find it to be in agreement with the formula, given by Read, which relates the viscosity to the average orbital spin of the electrons. For the filling factor \( \nu = 2/5 \) Jain state, which is at the second level in the hierarchy, we compare our model wave function with the numerically obtained ground state of the Coulomb interaction Hamiltonian in the lowest Landau level, and find very good agreement in a large region of the complex \( \tau \)-plane. For the same example, we also numerically compute the Hall viscosity and find good agreement with the analytical result for both the model wave function and the numerically obtained Coulomb wave function. We argue that this supports the notion of a generalized plasma analogy that would ensure that wave functions obtained using conformal field theory methods do not acquire Berry phases upon adiabatic evolution.

9:00AM A5.00006 High-mobility hydrogen-terminated Si(111) transistors for measurement of six-fold valley degenerate two-dimensional electron systems in fractional quantum Hall regime, BINHUI HU, MOHAMAD MEQAD YAZDANPANAH, BRUCE E. KANE, Univ of Maryland-College Park — The quality of hydrogen-terminated Si(111)-(H-Si(111)) transistors has improved significantly. Peak electron mobility of 325,000 cm²/Vs was achieved at 90 mK, and the fractional quantum Hall effect (FQHE) at \( 1 < \nu < 2 \) was studied extensively [1]. We have further improved the device by solving gate leakage and contact problems with an updated design, in which a Si piece with thermal oxide acts as a gate through a vacuum cavity, and PN junctions are used to define a hexagonal two-dimensional (2D) region on a H-Si(111) piece. The device operates as an ambipolar transistor, in which a 2D electron system (2DES) and a 2D hole system can be induced at the same \( \nu=5/2 \). The \( \nu=5/2 \) fraction of the various types of disorder. We report energy gaps at the filling factor \( \nu=5/2 \) in a series of samples into which we intentionally added aluminum impurities during the MBE growth. These data, together with the availability of energy gaps at \( \nu=5/2 \) in the same samples, allows us to quantify the disorder broadening and the intrinsic gap of the even denominator fractional quantum Hall states. This work was supported by DOE DE-SC000671.

9:00AM A5.00006 High-mobility hydrogen-terminated Si(111) transistors for measurement of six-fold valley degenerate two-dimensional electron systems in fractional quantum Hall regime, BINHUI HU, MOHAMAD MEQAD YAZDANPANAH, BRUCE E. KANE, Univ of Maryland-College Park — The quality of hydrogen-terminated Si(111)-(H-Si(111)) transistors has improved significantly. Peak electron mobility of 325,000 cm²/Vs was achieved at 90 mK, and the fractional quantum Hall effect (FQHE) at \( 1 < \nu < 2 \) was studied extensively [1]. We have further improved the device by solving gate leakage and contact problems with an updated design, in which a Si piece with thermal oxide acts as a gate through a vacuum cavity, and PN junctions are used to define a hexagonal two-dimensional (2D) region on a H-Si(111) piece. The device operates as an ambipolar transistor, in which a 2D electron system (2DES) and a 2D hole system can be induced at the same \( \nu=5/2 \) surface. Peak electron mobility of more than 200,000 cm²/Vs is routinely achieved at 300 mK. The Si(111) surface has a six-fold valley degeneracy. The hexagonal device is designed to investigate the symmetry of the 2DES. Preliminary data show that the transport anisotropy at \( \nu < 6 \) can be explained by the valley occupancy. The details of the valley occupancy can be caused by several mechanisms, such as miscut, magnetic field, pseudospin quantum Hall ferromagnetism (QHFM), and nematic valley polarization phases [2]. The FQHE is investigated in magnetic fields up to 35T, and the properties of composite fermions will be discussed. [1] T.M. Koti, B.H. Hu, S.H. Brown, B.E. Kane, Phys. Rev. B 89, 041107(R) (2014) [2] D. A. Abanin, S. A. Parameswaran, S. A. Kivelson, and S. L. Sondhi. Phys. Rev. B, 82, 035428 (2010)

9:12AM A5.00007 Quantum Hall Systems on Toroidal Geometries, NIALL MORAN, JOOST SLINGERLAND, Natl Univ of Ireland Maynooth — We present results of recent numerical calculations of second Landau level (LL) states on toroidal geometries. Calculations on the torus generally allow for smaller particle numbers than those on the sphere, due to less powerful symmetries. However, on the torus, different candidate states for particular quantum Hall plateaus appear at equal flux, in contrast to the situation on the sphere or plane. This means that working on the torus allows for more direct comparisons of trial states and reduces the problem of aliasing. Moreover, the torus brings interesting geometry, described by a modular parameter \( \tau \). This potentially allows for a larger variety of phases as well as some interesting limits which can be treated analytically. It also allows for the calculation of the Hall viscosity, a quantity which corresponds to the shift on the sphere. Among fillings considered are \( \nu = 12/5 \) and \( \nu = 3/2 \) where states hosting non-Abelian anyons have been conjectured.
9:24AM A5.00008 Disc configuration exact diagonalization studies of the phase diagram and edge states of the $\nu = 5/2$ fractional quantum Hall state with Landau level mixing and finite well thickness¹, ANTHONY TYLAN-TYLER, YULI LYANDA-GELLER, Department of Physics and Astronomy, Purdue University, West Lafayette, IN 47907 USA — The $\nu = 5/2$ fractional quantum Hall effect is of experimental and theoretical interest as a possible manifestation of non-Abelian statistics. The nature of this state has yet to be fully determined. The leading candidates are the Moore-Read Pfaffian state and its particle-hole conjugate, the anti-Pfaffian. When effects which break particle-hole symmetry are not included, these states are degenerate. We carry out an exact diagonalization calculation in a disk of neutralizing charge configuration, which breaks this degeneracy, and include Landau level mixing interactions arising from a diagrammatic expansion of the Coulomb potential and the effects of finite thickness. The Pfaffian sector is shown to favor strong interactions with the neutralizing background and strong Landau level(LL) mixing, while the anti-Pfaffian state occurs at weak LL mixing and background interactions. We find that there is a phase transition from the anti-Pfaffian to the Pfaffian state through a series of compressible stripe states as LL mixing is turned on. Furthermore, LL mixing interactions lead to an increased quasihole size and can overcome the effects of edge reconstruction. When the effects of the finite thickness of the confining quantum well are included, we observe enhancement these properties.

9:36AM A5.00009 Non-Abelian statistics of Luttinger holes in quantum wells², GEORGE SIMION, Purdue University, YULI LYANDA-GELLER, Department of Physics, Purdue University, West Lafayette, IN 47907 USA — Non-Abelian quasi-particle excitations represent a key element of topologically protected quantum computing. Such exotic states appear in fractional quantum Hall (FQH) effect as eigenstates of N-body interaction potential. These potentials can be obtained by renormalization of electron-electron interactions in the presence of Landau level (LL) mixing. The properties of valence band holes makes them fundamentally different from electrons. In the presence of magnetic field, low-lying states do not exhibit fan-like diagram and several of the levels cross. Variation of magnetic field in the vicinity of level crossings serves as a knob that tunes LL mixing and enhances the 3-body interaction. 1/2 filling factor FQH is a state that was not observed in electron liquid, but has been observed for holes. The properties of the two dimensional charged quantum hole liquid in the presence of magnetic field are studied using the spherical geometry. The properties of the novel 1/2 state are discussed.

²Research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-SC0010544.

9:48AM A5.00010 Competing quantum Hall phases in the second Landau level in low density limit³, WEI PAN, Sandia National Labs, A. SERAFIN, J.S. XIA, L. YIN, N.S. SULLIVAN, University of Florida and NHMFL, K.W. BALDWIN, K.W. WEST, L.N. PFEIFFER, D.C. TSUI, Princeton University — We present here the results from two high quality, low density GaAs quantum wells. In sample A of electron density $n = 5.0 \times 10^{10}$ cm$^{-2}$, anisotropic electronic transport behavior was observed at $\nu = 7/2$ in the second Landau level. We believe that the anisotropy is due to the large Landau level mixing effect in sample A. In sample B of density $4.1 \times 10^{10}$ cm$^{-2}$, strong $8/3$, $5/2$, and $7/3$ fractional quantum Hall states were observed. Furthermore, our energy gap data obtained in various samples of different densities suggest that the $5/2$ state may be spin unpolariized in the low density limit. The results from both samples show that the strong electron-electron interactions and a large Landau level mixing play an import role in the competing ground states in the second landau level. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

10:00AM A5.00011 Heterostructure design and growth conditions necessary for electron mobility exceeding $30\times10^6$ cm$^2$/Vs in GaAs quantum wells, SAEED FALLAH, Department of Physics and Birck Nanotechnology Center, Purdue University, GEOFFREY GARDNER, Schools of Materials Engineering and Birck Nanotechnology Center, Purdue University, JOHN WATSON, Department of Physics and Birck Nanotechnology Center, Purdue University, MICHAEL MANFRA, Department of Physics, Birck Nanotechnology Center and Schools of Materials Engineering and Electrical and Computer Engineering, Purdue University — Ultra-high purity GaAs/AlGaAs heterostructures remain the material purity for the achievement of high mobility. In our work high mobility has been achieved primarily through improvements in starting source materials and heterostructure design rather than improvements in vacuum quality, it does not encode all information necessary to quantify disorder relevant to the fractional quantum Hall effect. Here we describe the heterostructure design considerations and molecular-beam-epitaxy growth conditions needed to achieve an electron mobility $>30\times10^6$ cm$^2$/Vs. In particular, we report on the impact of several modulation doping schemes on mobility and the quality of transport in the 2nd Landau level. We also detail constraints on starting source material purity for the achievement of high mobility. In our work high mobility has been achieved primarily through improvements in starting source materials and heterostructure design rather than improvements in vacuum quality.

10:12AM A5.00012 Phase Diagram of Fractional Quantum Hall Effect of Composite Fermions in Multi-Component Systems¹, AJIT COIMBATORE BALRAM, Pennsylvania State University, CSABA TŐKE, Budapest University of Technology and Economics, ARKKADIUSZ WOJŚ, Wrocław University of Technology, JAINENDRA JAIN, Pennsylvania State University — The fractional quantum Hall effect (FQHE) of composite fermions (CFs) produces delicate states arising from a weak residual interaction between CFs. We study the spin phase diagram of these states, motivated by the recent experimental observation by Liu et al. [1] of several spin-polarization transitions at 4/5, 5/7, 6/5, 9/7, 7/9, 8/11 and 10/13 in GaAs systems. We show [2] that the FQHE of CFs is much more prevalent in multicomponent systems, and consider the feasibility of such systems for states with N components for an SU(N) symmetric interaction. Our results apply to GaAs quantum wells, wherein electrons have two components, to AlAs quantum wells and graphene, wherein electrons have four components (two spins and two valleys), and to an H-terminated Si(111) surface, which can have six components. We provide a fairly comprehensive list of possible incompressible FQH states of CFs, their SU(N) spin content, their energies, and their phase diagram as a function of the generalized “Zeeman” energy. The results are in good agreement with available experiments.

¹DOE Grant No. DE-SC0005042, Hungarian Scientific Research Funds No. K105149 (CT), the Polish NCN grant 2011/01/B/ST3/04504 and the EU Marie Curie Grant PCIG09-GA-2011-294186
The Phase Diagram of the $\nu = 5/2$ Fractional Quantum Hall Effect: Effects of Landau Level Mixing and Non-Zero Width$^1$. MICHAEL PETERSON, Cal State Univ- Long Beach, KIRYL PAKROUSKI, ETH Zurich, THIERRY JOLICOUR, CNRS and Universite Paris-Sud, VITO SCAROLA, VA Tech, CHETAN NAYAK, Microsoft, University of California Santa Barbara, MATTHIAS TROYER, ETH Zurich — We study the phase diagram of the $\nu = 5/2$ state by exactly diagonalizing an effective Hamiltonian describing the fractional quantum Hall effect of electrons under realistic conditions in GaAs semiconductors. The effective Hamiltonian takes Landau level mixing into account to lowest-order perturbatively in $\kappa$, the ratio of the Coulomb energy scale to the cyclotron gap and we incorporate non-zero width $\omega$ of the quantum well and sub-band mixing. Using the torus and sphere, we analyze the non-trivial competition between candidate ground states with 4 criteria: overlaps with trial wave functions; the size of energy gaps; the sign of an order parameter for particle-hole symmetry breaking; and entanglement spectrum. We find the ground state is in the universality class of the Moore-Read Pfaffian state, rather than anti-Pfaffian, for $\kappa < \kappa_c(\omega)$, where $0.6 < \kappa_c(\omega) < 1$. Landau level mixing and non-zero width suppress the excitation gap with Landau level mixing having a larger effect. Our findings have important implications for the identification of non-Abelian fractional quantum Hall states.

9:00AM A6.00004 Standing wave plasmon modes interact in an antenna-coupled nanowire \(^1\). JARED DAY, NICOLAS LARGE \(^2\), PETER NORDLANDER, NAOMI HALAS, Rice University — In a standing wave optical cavity, the coupling of cavity modes, e.g. through a nonlinear medium, results in a rich variety of nonlinear dynamical phenomena, such as frequency pushing and pulling, mode-locking and pulsing, and modal instabilities. Metallic nanowires of finite length support a hierarchy of longitudinal surface plasmon modes with standing wave properties: the plasmonic analog of a Fabry-Perot cavity. Here we show that positioning the nanowire within the gap of a plasmonic nanoantenna introduces a passive, hybridization-based coupling of the standing-wave plasmonic modes with the antenna structure, mediating an interaction between the nanowire plasmon modes themselves. Frequency pushing and pulling, and the enhancement and suppression of specific plasmon modes, can be controlled and manipulated by nanoantenna position and shape. Dark-field spectroscopy, CL spectroscopy and imaging, and finite-difference time-domain calculations are performed to investigate these surface plasmon “drift.” Near-field coupling of nanoantennas to nanowire optical cavities shows that plasmon hybridization is a powerful strategy for controlling the radiative LDOS of nanowires, and could ultimately enable strategies for active control of emission properties in nanowire-based devices.

\(^1\)Work funded by the Welch Foundation (C-1220, C-1222), the NSSEFF (N00244-09-1-0067), the ONR (N00014-10-1-0989), and the NSF (ECCS-1040478, CNS-0821727).

9:12AM A6.00005 Accurate modeling of photodynamic processes enhanced by plasmonic nanoantennas \(^3\). CHRISTOS ARGYROPOULOS, University of Nebraska-Lincoln, GLEB AKSELROD, Duke University, CRISTIAN CIRACI, Istituto Italiano di Tecnologia, THANG HOANG, MAIKEN MIKKELSEN, DAVID SMITH, Duke University — Plasmonic nanoantennas are powerful platforms to enhance fluorescence and spontaneous emission rates leading to exciting nanophotonic applications. Strong fields confined in highly subwavelength regions in the nanoantenna geometry are ideal conditions to increase the Purcell factor. However, the accurate modeling of the interaction between fluorescence molecules or quantum-dots and plasmonic nanoantennas is a complicated task. In our talk, we will demonstrate efficient numerical techniques to accurately compute the total spontaneous emission rate and radiation efficiency by multiple fluorescence molecules and quantum-dots randomly positioned nearby the plasmonic nanoantennas [G. Akselrod, C. Argyropoulos et al., Nat. Phot. 8, 835-840 (2014)]. This is a complex problem because in plasmonic systems the Purcell factor has contributions from an increased radiative rate and from an increased nonradiative rate due to the inherent metallic losses. We will demonstrate ways to accurately compute the useful fraction of energy emitted as radiation, known as the radiative quantum yield. When we combine the knowledge of the Purcell factor and the quantum yield, the enhancement in the emitters’ radiative rate can be computed, which consists the key property to obtain efficient ultrafast nanophotonic communication systems. The presented numerical results are in excellent agreement with experimental results obtained by similar nanoantenna systems.

9:24AM A6.00006 Surface Plasmon Propagation in Nanostructured Metallic Waveguides \(^4\), Y.M. CALM, J.M. MERLO, A.H. ROSE, N.T. Nesbitt, A.M. BOYCE, G. McMahan, M.J. BURNS, K. KEMP, M.J. NAUGHTON \(^1\), Boston College — Visible frequencies of light can be routed on subwavelength scales with nanostructured, metallic waveguides by coupling optical energy to surface plasmon (SP) modes at a metal-insulator interface. Epitaxially-grown Ag nanowires and nanocables provide a low-loss, “model” system to characterize the propagation of SP waves. We have studied these structures by electron, focused ion, scanning probe, and optical microscopies, and have observed propagation lengths exceeding 15 \(\lambda\), which extracts near-field (evanescent) information and propagates it into the far-field, is presented.

\(^4\)Supported by the W.M. Keck Foundation

9:36AM A6.00007 Investigation of nanogap localized field enhancement in gold plasmonic structures \(^5\). DESALEGN TADESE DEBU, STEPHEN BAUMAN, CAMERON SAYLOR, University of Arkansas, ERIC NOVAK, Shippensburg University, DAVID FRENCH, JOSEPH HERZOG, University of Arkansas — Nanogaps between plasmonic structures allow confining the localized electric field with more enhancements. Based on previously implemented two-step lithography process, we introduce a nano-masking technique to fabricate nanostructures and nanogaps for various geometrical patterns. This new method can fabricate gold nanostructures as well as nanogaps that are less than 10nm, below the limiting scale of lithography. Simulation from finite element method (FEM) shows strong gap dependence of optical properties and peak enhancement of these devices. The fabricated plasmonic nanostructure provides wide range of potential future application including highly sensitive optical antenna, surface enhanced Raman spectroscopy and biosensing.

\(^5\)Current affiliation: Northwestern University

9:48AM A6.00008 Purcell factors exceeding 1,000 in directional and efficient plasmonic nanoantennas \(^6\). GLEB AKSELROD, CHRISTOS ARGYROPoulos, THANG HOAng, CRISTIAN CIRACi, CHAO FANG, JIANI HUANG, DAVID SMith, MAIKEN MIKKELSEN, Center for Metamaterials and Integrated Plasmonics, Duke University — To move nanophotonic devices such as nano-lasers, ultrafast LEDs, and single photon sources into the practical realm, a challenging list of requirements must be met, including directional emission, room temperature and broadband operation, and high radiative quantum yield, while having a large spontaneous emission rate. To achieve these features simultaneously, a platform is needed in which the various decay channels of embedded emitters can be fully understood and controlled. In this work we show that all these device requirements can be satisfied by a plasmonic nanoantenna with emitters embedded in the nanoscale gap (\(\sim 10 \text{ nm}\)) between a metal film and a silver nanocube. Fluorescence lifetime measurements on ensembles of emitters reveal Purcell factors exceeding 1000 while maintaining high quantum yield (\(> 0.5\)) and directional emission (84% collection efficiency). Using angle resolved fluorescence measurements, we independently determine the orientations of emission dipoles in the nanoscale gap. By incorporating this information along with the three-dimensional spatial distribution of dipoles into simulations, we predict the emission dynamics in excellent agreement with experiment.

Nanoparticles on Au Nano-cavity Arrays

Our analysis shows the power dependent enhancement in upconversion luminescence can almost entirely be accounted for by a constant shift in the effective excitation intensity, which is maintained over five orders of magnitude variation in excitation intensities in the spectroscopic images on and off the nano-cavity arrays provides an estimate of the average enhancement factor independent of fluctuations in intensity. The variations in upconversion luminescence enhancement with power are modeled by a 3-level-system near the saturation limit, and by simultaneous off-resonance scattering from Au nanoparticles. Our hybrid nanostructures with tunable optical properties can be useful for various optoelectronic applications such as photothermal nanoreactors and ultrafast optical switches.

This work has been supported under the grant from Volkswagen Foundation

We use spectroscopic imaging to assess the spatial variations in upconversion luminescence from NaYF4:Er3+, Yb3+ nanoparticles embedded in PMMA on Au nano-cavity arrays. The nano-cavity arrays support a surface plasmon (SP) resonance at 980nm, coincident with the peak absorption of the Yb3+ sensitizer. Spatially-resolved upconversion spectra show a 30X to 3X luminescence intensity enhancement on the nano-cavity array compared to the nearby smooth Au surface, corresponding to excitation intensities from 1 W/cm2 to 300kW/cm2. Our analysis shows the power dependent enhancement in upconversion luminescence can be almost entirely accounted for by a constant shift in the effective excitation intensity, which is maintained over five orders of magnitude variation in excitation intensity. The variations in upconversion luminescence enhancement with power are modeled by a 3-level-system near the saturation limit, and by simultaneous solution of a system of coupled nonlinear differential equations, both analyses agree well with the experiments. Analysis of the statistical distribution of emission intensities in the spectroscopic images on and off the nano-cavity arrays provides an estimate of the average enhancement factor independent of fluctuations in nanoparticle density.

8:00AM A7.00001 Realization of high-precision and more robust quantum anomalous Hall state in a hard ferromagnetic topological insulator. CUI-ZU CHANG, Massachusetts Institute of Technology. The discovery of the integer quantum Hall (QH) effect in 1980 led to the realization of a topological electronic state with dissipationless currents circulating in one direction along the edge of a two-dimensional electron layer under a strong magnetic field. The quantum anomalous Hall (QAH) effect shares a similar physical phenomenon as the QH effect, whereas its physical origin is a result of intrinsic spin-orbit coupling of the topological insulator (TI) and when it is in ferromagnetic state. Since the QAH effect does not require an external field and the associated Landau levels, it is believed that this effect has unique potential for applications in electronic devices with low-power consumption. In this talk, we shall describe the experimental observation of the QAH state in V-doped (Bi$_2$Sb)$_2$Te$_3$ TI films. We find that in zero-field longitudinal resistance decreases to 0.00013 ± 0.00007 $\Omega^{-2}$ at $T=25$mK, thus realizing the anomalous Hall transport with negligible dissipation in the absence of any initial magnetic field. The advantage of this system comes from the fact that it is a hard ferromagnet with a large coercive field ($H_c=1$Oe) and a relative high Curie temperature. These results were unexpected from the theoretical calculations. This high-precision realization of a more robust QAH state in hard FMTIs is a major step towards dissipationless electronic applications without external applied fields.

Supported by funding from NSF (DMR-1207469), NSF (DMR-0907007), ONR (N00014-13-1-0301), NSF (DMR-0820404, Penn State MRSEC), and the STC Center for Integrated Quantum Materials under NSF grant DMR-1231319.

8:36AM A7.00002 Transport studies on Cr-doped (Bi,Sb)$_2$Te$_3$ thin films with nearly quantized anomalous Hall effect. MINHAO LIU, Physics Department, Princeton University, ANTHONY RICHARDELLA, ABHINAV KANDALDA, Physics Department, Pennsylvania State University, WUDI WANG, ALI YAZDANIB, Physics Department, Princeton University, NITIN SAMARTH, Physics Department, Pennsylvania State University, N. PHUAN ONG, Physics Department, Princeton University. We describe measurements of the quantum anomalous Hall effect in ferromagnetic Cr-doped (Bi,Sb)$_2$Te$_3$ thin films (6-8 QL thickness) grown on (111) SrTiO$_3$ (STO) substrates by molecular beam epitaxy. The Fermi level is tuned close to the neutrality point by tuning the growth flux ratios of Cr, Bi and Sb. Transport measurements were carried out in a dilution fridge at a base temperature of 20 mK. By tuning the chemical potential with a back gate on the STO substrate, we observed an anomalous Hall effect as high as 0.95 $\Omega^{-2}$/s, with a coercive field ~ 0.15 T and a narrow transition between positive/negative Hall plateaus. Transport measurements in a non-local configuration showed a Hall-effect-like non-local resistance with a systematic dependence on the back gate voltage and with pronounced peaks which resembled the non-local resistance of the quantum Hall effect. The non-local signal has a maximum that coincides with the maximum in Hall conductivity, indicating the edge channel as its origin. Our results show that the edge channel manifests itself in various transport properties even though the Hall resistance is not perfectly quantized.

8:48AM A7.00003 Spin-Orbital texture and magnetic proximity effect of Bi$_2$Se$_3$/EuS heterostructure. ALEX TAEKYUNG LEE, Columbia Univ, MYUNG JOON HAN, Department of Physics, KAIST, KYUNGWHA PARK, Department of Physics, Virginia Tech. A topological insulator Bi$_2$Se$_3$ has gapless Dirac surface states topologically protected by time reversal symmetry with the helical spin texture. The spin texture has a unique orbital dependence and it allows topological insulator hybrid structures to be used for spintronics or spin transfer torque devices. Recently, an interface between a topological insulator Bi$_2$Se$_3$ and a ferromagnetic insulator EuS, has been experimentally realized, which provides an opportunity to study effects of magnetic interface on Dirac surface states of Bi$_2$Se$_3$. In this talk, we present our study of magnetic proximity effects and spin-orbital texture of the topological surface states of Bi$_2$Se$_3$ at the Bi$_2$Se$_3$/EuS interface, by using first-principles calculations and an low-energy effective model [A. T. Lee et al., Phys. Rev. B. 90, 155103 (2014)]. We discuss an energy gap opening due to the out-of-plane magnetic moment induced by the EuS, and a new Dirac cone occurring for thick Bi$_2$Se$_3$ slabs. Furthermore, we show an interesting coupling between the out-of-plane spin moment and the orbitals caused by broken time reversal symmetry.

9:00AM A7.00004 Giant anisotropic magneto-resistance in the magnetic topological insulator Cr$_y$(Bi$_{1-x}$Sb$_x$)$_2$I$_2$Te$_3$. ABHINAV KANDALDA, ANTHONY RICHARDELLA, CHAOXING LIU, NITIN SAMARTH, Penn State University. We demonstrate magnetization control of edge state transport and report the observation of a gate-tunable giant anisotropic magneto-resistance (GAMR) effect in the magnetic topological insulator Cr$_y$(Bi$_{1-x}$Sb$_x$)$_2$I$_2$Te$_3$ as an external field (and the magnetization $M$) is rotated from out-of-plane (polar angle $\theta = 0^\circ$) to in-plane ($\theta = 90^\circ$). The angular dependence of the GAMR deviates from the standard $\cos^2 \phi$ form (where $\phi$ is the angle between $M$ and the current density $J$), and is instead explained by a Landauer-Büttiker formalism that accounts for bulk-edge mixing. However, the rotation of the magnetization in-plane produces a weak, conventional AMR. These results serve as evidence for a field tilt-tuned crossover between an “imperfect” quantum anomalous Hall insulator (QAH) and a gapless, ferromagnetic topological insulator. We expect the GAMR to become stronger in the ideal QAH regime where edge state conduction dominates over bulk conduction, thus providing a route toward proof-of-concept ferromagnetic topological insulator transistors and magnetic field sensors. Funded by DARPA.

9:12AM A7.00005 Magnetization in Intrinsic Topological Insulators Induced by Exchange Interaction with Ferromagnetic Insulator. VALERIA LAUTER, Oak Ridge National Laboratory, Oak Ridge, USA, FERHAT KATMIS, Francis Bitter Magnet Laboratory, MIT, Cambridge, USA, BADIH ASSAF. Ecole Normale Supérieure, Paris France, DON HEIMAN, Department of Physics, Northeastern University, Boston, USA, JAGADEESH MOODERA, Department of Physics, MIT, Cambridge, MA-02139, USA. — We examine the magnetic proximity-induced symmetry breaking via the exchange interaction in heterostructures of the topological insulator (TI) Bi$_2$Se$_3$ and the ferromagnetic insulator (FMI) EuS [1]. We observed the emergence of a ferromagnetic phase in TI with the excess of magnetic moment at the interface using depth and element sensitive Polarized Neutron Reflectometry (PNR). We find that the magnetization, penetrating into the TI originates through exchange interaction, without structural perturbation at the interface. Due to the different interlayer exchange coupling as well as the properties of the bulk and surface magnetizations, we investigated several different heterostructures after cooling in zero field (ZFC) and in an external magnetic field (FC). The significantly enhanced magnetic properties of the heterostructures as revealed by the PNR studies, as well as the temperature and external magnetic field dependence will be presented.

9:24AM A7.00006 Observation of ferromagnetic domains in magnetic topological insulator1, WENBO WANG, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854 USA, FANG YANG, CHUNLIE GAO, JINFENG JIA, Department of Physics and Astronomy, Shanghai Jiao Tong University, 800 Dongchuan Road, Shanghai 200240, China, WEIDA WU, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854 USA — The breaking of time reversal symmetries in a topological insulator can lead to exotic quantum effects, such as magnetic monopoles, quantum anomalous Hall effect (QAHE), and so on. Recently QAHE has been experimentally observed in a ferromagnetic topological insulator Cr doped Bi$_{1-y}$Sb$_y$Te$_3$[1]. Although a lot of studies have conducted on characterizing the ferromagnetic properties in these fascinating materials, direct observation of ferromagnetic ordering is still lacking. Here, we report variable temperature magnetic force microscopy (VT-MFM) studies on thin film of Cr doped Bi$_{1-y}$Sb$_y$Te$_3$ synthesized by molecular beam epitaxy (MBE). Small bubble-like ferromagnetic domains were observed below Tc $\sim$ 30 K. The evolution of these domains at various temperatures and magnetic fields will be presented.

9:36AM A7.00007 Study of magnetism in Cr doped (Bi$_{1-y}$Sb$_y$)$_2$Te$_3$ — ANTHONY RICHARDELLA, ABHINAV KANDALA, SUSAN KEMPINGER, NITIN SAMARTH, Pennsylvania State Univ., University Park PA, ALEX GRUTTER, JULIE BORCHERS, NCNR, NIST Gaithersburg MD — The quantum anomalous Hall (QAH) effect was first observed in Cr doped films of the topological insulator (TI) (Bi$_{1-y}$Sb$_y$)$_2$Te$_3$. This ferromagnetic T-I opens a gap at the Dirac point and, when the Fermi energy lies inside this gap, a quantized QAH conductance can be observed. The origin of ferromagnetism in this material is still not well understood with the mechanism typically attributed to either a high van-Vleck susceptibility or a carrier mediated RKKY like interaction. To elucidate this we have studied Cr$_x$(Bi$_{1-y}$Sb$_y$)$_2$Te$_3$ thin films grown by MBE on SrTiO$_3$ (STO) substrates using polarized neutron reflectivity (PNR) while in-situ backgating the film to change the position of the Fermi energy. The films are also characterized by XRD, AFM, TEM and low temperature transport measurements. PNR measurements provide a direct measure of the depth dependent magnetization of a sample. We use this to study how the magnetization changes as the Fermi energy is moved towards the Dirac point. Funded by DARPA and ARO-MURI.

9:48AM A7.00008 Electrical Transport Properties of Mn doped Bi$_2$Se$_3$ Thin Films — SERCAN BABAKIRAY, TRENT JOHNSON, PAVEL BORISOV, DAVID LEDERMAN, West Virginia University — Magnetic impurity doping in topological insulators manifest itself with a gap opening in the Dirac cone as a result of breaking the time reversal symmetry. Moreover, the magnetic impurities affect the structural and quantum transport properties of topological insulators by increasing the disorder and by changing the bulk charge carrier type, charge carrier density and Hall mobility. Here, we report magnetotransport properties of Bi$_2$-xMnxSe$_3$ thin films which are 12 quintuple layers thick and grown on Au(001) single crystal substrates via molecular beam epitaxy (MBE). Hikami-Larkin-Nagaoka (HLN) formalism was used to study the weak antilocalization (WAL). Increasing Mn doping concentration was found to increase the bulk charge carrier density and to decrease the Hall mobility. A decrease was also observed in the phase coherence length related to WAL as a function of Mn content $x$. Values of another WAL parameter, the pre-factor alpha, showed that the top and bottom surfaces were coupled through the bulk conducting channels. The temperature dependence of phase coherence length indicated the electrical transport was dominated by 2D electron-electron scattering for the undoped, and by bulk weak localization effects for the Mn doped samples, respectively.

10:00AM A7.00009 Probing interface ferromagnetism of EuS/Bi$_2$Se$_3$ heterostructures with magnetic second harmonic generation1, CHANGMIN LEE, Department of Physics, MIT, FERHAT KATMIS, Francis Bitter Magnet Lab, MIT, PABLO JARILLO-HERRERO, Department of Physics, MIT, JAGADEESH S. MOODERA, Francis Bitter Magnet Lab and Department of Physics, MIT, NUH GEDIK, Department of Physics, MIT — Ferromagnet / topological insulator interfaces are novel heterostructures that can host various interesting physical phenomena, such as massive Dirac fermions, the quantum anomalous Hall effect, and the topological magneto-electric effect. By using magnetic second harmonic generation (MSHG), we separately measure the in-plane and the out-of-plane magnetization at the interface between a ferromagnetic insulator EuS and Bi$_2$Se$_3$. In contrast to bulk-sensitive linear magneto-optics, such as the Faraday and Kerr effects, MSHG allows a selective measurement of ferromagnetism and crystal symmetry of the interface, at which inversion symmetry is broken. Our technique can thus be used to study magnetism and crystal structure of such “buried” interfaces to which other conventional probes do not have direct access.

10:12AM A7.00010 Investigation of the structural and magnetic properties of MBE-grown Cr-doped Bi$_2$Se$_3$ thin films — LIAM COLLINS-MCINTYRE, PIET SCHOENHERR, SHILEI ZHANG, ALEXANDER BAKER, University of Oxford, ADRIANA FIGUEROA, GIANNANTONIO CIBIN, GERRIT VAN DER LAAN, Diamond Light Source, NINA-JULIANA STEINKE, CHRISTY KINANE, TIMOTHY CHARLTON, DIEGO ALBA-VENERO, SEAN LANGRIDGE, ISIS Neutron Source, AKASH PUSHP, ANDY KELLOCK, STUART PARKIN, IBM Almaden Research Center, SARA HARRISON, JAMES HARRIS, Stanford University, THORSTEN HESJEDAL, University of Oxford — We report a study of the structural and magnetic properties of Cr-doped Bi$_2$Se$_3$ films grown by MBE. We present a thorough exposition of the electronic character of the magnetic ground state of this material as determined by x-ray magnetic circular dichroism (XMCD) as well as complementary measurements by polarised neutron reflectometry, X-ray diffraction and SQUID magnetometry. We observe the formation of a ferromagnetic ground state (via SQUID), below a measured Tc $\sim$ 8.5 K with a saturation magnetization of 2.1 $\mu_B$/Cr. By XRD we observe a reduction in c-axis lattice parameter with increasing Cr concentration up to 12 at.% of dopant. XMCD and EXAFS studies indicate that, contrary to expectations, the Cr dopes into the system as Cr$_2$Te$_3$. This material demonstrates ferromagnetic proximity coupling.

10:24AM A7.00011 ABSTRACT MOVED TO M31.00008 —

10:36AM A7.00012 Critical Mechanism of Magnetic Doped Cr$_x$Bi$_{2-x}$Te$_3$ Topological Insulator Thin Films1, ZHEN ZHANG, YAN NI, RAVI HADIMANI, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University, CAJETAN NLEBEDIM, Ames Laboratory, US Department of Energy — Introducing magnetic dopants into topological insulators can lead to the opening of the surface band gap which can induce interesting phenomena such as the quantized anomalous Hall effect (QAHE) and magnetoelectric effect. However, the critical properties of ferromagnetism in magnetic doped TIs are not well studied. In this work, we investigated the effect of magnetic doping on magnetic and transport response in Bi$_2$Te$_3$ thin films. Cr$_x$Bi$_{2-x}$Te$_3$ thin films with x = 0.03, 0.14, and 0.29 were grown with low surface roughness ($\sim$ 0.4 nm). It is found that Cr is an n-type doping element, which reduces the carrier density of p-type Bi$_2$Te$_3$. Moreover, doping Cr induces long range ferromagnetism when x = 0.14 and 0.29, where anomalous Hall effect and weak localization of magnetoconductance were observed. The Arrrott-Noakes plot for Cr$_x$Bi$_{2-x}$Te$_3$ demonstrates that the critical mechanism of the ferromagnetism can be described well with 3D-Heisenberg model. Our work may benefit for the practical applications of ferromagnetic TIs with opened surface band gap in spintronics and magnetoelectric devices.

10:48AM A7.00013 Electrostatic control of spin polarization in a quantum Hall ferromagnet: a new platform to realize non-Abelian excitations. ALEXANDER KAZAKOV, Purdue University, V. KOLKOVSKY, Z. ADAMUS, G. KARCZEWSKI, T. WOJTOWICZ, Institute of Physics, Polish Academy of Sciences. LEONID ROKHINSON, Purdue University — Several experiments detected signatures of Majorana fermions in nanowires, and the focus of current research is shifting toward systems where non-Abelian statistics of excitations can be demonstrated. To achieve this goal we are developing a new platform where non-Abelian excitations can be created and manipulated in a two-dimensional plane, with support for Majorana and higher order non-Abelian excitations. The system is based on CdTe quantum wells non-uniformly doped with paramagnetic impurities, which result in a complex field-dependence of Zeeman splitting. A unique property of the system is that at high fields we can form a quantum Hall ferromagnet with gate-controllable spin polarization. Helical 1D edge channels formed along the edges of electrostatic gates may support generalized non-Abelian excitations in the fractional quantun Hall regime, and Majorana and parafermion excitations in the presence of induced superconductivity. We will present results on the gate control of s-d exchange in specially designed heterostructures, demonstrate gate control of spin polarization at filling factor $\nu = 2$, and show spatially separated design of quantum Hall states with different spin polarization using lithographically defined gates.

Monday, March 2, 2015 8:00AM - 11:00AM — Session A8 DCMP: Semiconductor Surfaces and Interfaces 006C - Francesca Cavallo, University of New Mexico

8:00AM A8.00001 Unusual Dramatic Surface Restructuring of Silicon Substrate during Epitaxy1. TANYA GUPTA, DANIEL STEINGART, Princeton University. JAMES HANNON, IBM, PRINCETON UNIVERSITY COLLABORATION, IBM COLLABORATION — Interfacial strain is unavoidable in heteroepitaxial growth and can have a profound impact on the morphology and properties of thin films. In fact, "engineering" thin-film strain is a critical component in many advanced technologies. For example, straining the silicon in advanced CMOS devices can increase the device speed by as much as 90 percent. In order to control interfacial strain, its effects on growth must be understood. The common picture is that the growth substrate is essentially passive: its role is to provide the lattice mismatch that the growing film must respond to. As the film grows thicker, the stress in the film evolves, which can lead to morphological changes in the film, e.g., dislocations, or a change in growth mode from 2D, planar growth to 3D, quantum dot growth. In both of these examples, the action is in the growing film. In this work we describe a growth system that behaves in a completely unexpected manner that does not fit into this conventional picture. Interfacial strain that accompanies the growth of SiC nanoparticles is relieved by a dramatic 3D, quantum dot growth. In fact, "engineering" thin-film strain is a critical component in many advanced technologies. For example, straining the silicon in advanced CMOS devices can increase the device speed by as much as 90 percent.  

8:12AM A8.00002 A joint first principles and Kelvin probe force microscopy study of stepped silicon surfaces with unprecedented resolution1. STEFAN WIPPERMANN, Max-Planck-Institute for Iron Research, CARMEN PEREZ LEON, HOLGER DREES, MICHAEL MARZ, REGINA HOFFMANN-VOGEL, Karlsruhe Institute of Technology — Stepped well-ordered surfaces are important model systems of this kind. It contains (7x7) reconstructed areas equivalent to the well characterized and understood Si(111)-(7x7) surface. Thereby this system essentially contains its own calibration, providing an ideal testbed for surface characterization techniques and understanding in depth the rich morphology of the structural features present in this system. Here we present a joint experimental and theoretical investigation of the structural properties of the vicinal Si(7710) surface. We carried out Kelvin probe force microscopy (KPFM) measurements with unprecedented atomic resolution, and first principles calculations of the local work function as a function of the lateral position of the tip above the surface. These calculations allowed us to interpret the experimental KPFM data in terms of specific structural features and electronic properties of surface states, such as e.g., defects, dangling bond angles and occupations of dangling bonds.

8:24AM A8.00003 A novel ground state of the (2√3x2√3)/R30° Sn double layer on Si(111) induced by modulation hole-doping. FANGFEI MING, DANIEL MULUGETA, PAOLO VILMERCATI, University of Tennessee, Knoxville, HANNO H. WEITERING, University of Tennessee, Knoxville and Oak Ridge National Laboratory, PAUL C. SNIJ德ERS, Oak Ridge National Laboratory — Charge doping provides a tuning knob of the delicate interactions between spin, orbital, charge and lattice degrees of freedom in low-dimensional systems, which dictate many intriguing quantum phenomena. Using scanning tunneling microscopy/spectroscopy, we characterize the (2√3x2√3)/R30° Sn double layer grown on a (√3x√3)-B reconstructed Si(111) surface, where 1/3 monolayer B dopants resides in the subsurface layer without forming direct chemical bonds with the Sn layer. The B atoms donate holes to the Sn double layer and shift the Fermi level toward the valence band edge. Surprisingly, it further induces a fraction of the 2√3x2√3 phase to gradually transform to a new 4√3x2√3 phase below 80 K. The two phases coexist down to 2.5 K, indicating a phase-separated ground state for the hole doped Sn double layer, in contrast to a homogeneous 2√3x2√3 phase for the undoped one. The new 4√3x2√3 phase has a larger band gap than the 2√3x2√3 phase and the valence band edge shifts a few tens meV away from the Fermi level to higher binding energy, suggesting that the transition to the 4√3x2√3 structure is accompanied by an electronic structure rearrangement.

8:36AM A8.00004 Structure of the modulation hole doped (2√3x2√3)/R30° Sn double layer on Si(111)1. PAUL C. SNIJ德ERS, Oak Ridge National Lab, YING-TZU HUANG, University of Pennsylvania, State College, FANGFEI MING, DANIEL MULUGETA, WEISONG TU, University of Tennessee, Knoxville, PAUL R.C. KENT, Oak Ridge National Lab, RENEE D. DIEHL, University of Pennsylvania, State College, HANNO H. WEITERING, University of Tennessee, Knoxville — Over the years, a large collection of temperature dependent phase transitions has been identified in atomically thin metal overlayers on semiconductor surfaces. However, studying their doping dependence remains difficult due to the symmetry breaking nature of dopant atoms located on top of these structures, and the associated local lattice deformations localizing the doped carriers. Here we have used a subsurface modulation doping approach using B on Si(111) to hole-dope an overlaying Sn double layer. STM, LEED-I(E), and XPS were used to characterize the structure of a (2√3x2√3)/R30° Sn double layer on a Si(111) (√3x√3)-B surface. STM images 4 atoms in the top Sn layer. Using the tip to remove this top layer, a second layer consisting of 3 triangular structures becomes visible, resulting in a total of 13 Sn atoms per unit cell, consistent with an XPS core level intensity analysis. An extensive LEED-I(E) analysis using 20 independent beams with an energy range of 7126 eV points to a structural model consistent with the STM and XPS data and having a Pendry R-factor of 0.34.

9:00AM A8.00006 The effect of Al content on the work function engineering at TiAlN/HfO$_2$ interface$^1$, GEUN-MYEONG KIM, YOUNG JUN OH, KEE JOO CHANG, Department of Physics, KAIST — In high-k/metal gate stacks of metal-oxide-semiconductor field-effect transistors, it is important to control the metal work function such that it should be close to the valence and conduction band edges of Si in p- and n-channel devices. It was reported that depositing TiAl on top of TiN/HfO$_2$ stack in gate-last process can effectively induce the n-type shift of work function, while the work function is of p-type at TiN/HfO$_2$ stack. In this work, we perform first-principles density functional calculations to investigate the Schottky barrier height at TiAl/HfO$_2$. In bulk TiN, it is found that a substitutional Al is the most stable form of Al impurity. When substitutional Al atoms are introduced at TiN/HfO$_2$ interface, the effective work function tends to decrease. At TiAIN/HfO$_2$ interface, the n-type shift of the work function increases almost linearly with the Al content. This is attributed to the change of interface bonds by Al incorporation and the dipole field induced at the interface. On the other hand, relative thicknesses of TiAl and Ti on abrupt TiAl/TiN/HfO$_2$ interface do not significantly affect the effective work function.

9:24AM A8.00008 Reversible hydrogenation of silicene, JINGLAN QIU, HUIXIA FU, LAN CHEN, KEHUI WU, Institute of Physics, Chinese Academy of Sciences — The hydrogenation of monoatomic silicene sheet on Ag$(111)$ was studied by scanning tunneling microscopy and density functional theory calculations. It was observed that hydrogenation of silicene-4×4 structure at room temperature results in a perfectly ordered γ-4×4 superstructure. A theoretical model, which involves 7 H atoms and rearranged buckling of Si atoms, was proposed and agrees with experiments very well. Unlike silicene-4×4, the hydrogenation of $(\sqrt{7}\times\sqrt{7})$silicene/(2×3) was found to be reversible at room temperature. This separation (lack of intermixing) between Ba and Ge layers is retained through successive annealing experiments up to 770 K with a gradual ordering of the Ba layer at 570 K and above and a decrease in Ba layer density. Annealing above 770 K produces the 2-D surface alloy phase accompanied by strain relief through monolayer height trench formation. At 1070 K the surface morphology changes again but remains a 2-D surface alloy phase.

9:36AM A8.00009 The STM investigations of hydrogenation on monolayer silicene with r7x7 superstructure, LAN CHEN, Institute of Physics, The Chinese Academy of Sciences — The early investigations revealed the monolayer silicene with r7x7 superstructure on Ag$(111)$ can extend over the whole substrate. But this phase was considered to be highly defective due to the strong strain, which limit the applications of this phase. In this presentation, I will report our works about the hydrogenations on the monolayer silicene with r7x7 superstructure on Ag$(111)$ by scanning tunneling microscopy (STM). The STM images show the ordered structures with lattice identical to silicene-1×1 unit cell after hydrogenation on silicene at room temperature, which reveals that the original silicene with r7x7 superstructure is an ideal defectless single-crystal monolayer film. Combined with density functional theory calculations, the structures of hydrogenation can be explained by the “sub-lattice adsorption-picture,” in which H atoms only adsorb on Si atoms in one sub-lattice of silicene. Moreover, by annealing to a moderate temperature, about 450 K, de-hydrogenation process occurs and the clean silicene surface can be fully recovered. Such reversible hydrogenation suggests that silicene may be a potential candidate as hydrogen storage materials.

9:48AM A8.00010 The Role of a Buried Interface in the Growth of Metallic Nanocrystals: Quantum Size Effects in Ag/Si$(111)$7x7, YIYAO CHEN, MICHAEL GRAMLICH, SHAWN HAYDEN, PAUL MICELI, University of Missouri-Columbia — It is shown that the buried interface between a metallic nanocrystal and its supporting substrate plays an essential role in understanding the stability of nanomaterials that grow on a wetting layer in the Stranski-Krastanov growth mode. These in situ x-ray scattering studies reveal a minimum tri-layer height for stable commensurate FCC Ag islands that are in coexistence with a commensurate Ag wetting layer. The minimum height without an oscillating height preference is explained by electron quantum confinement effects, which is manifested differently for Ag$(111)$ than for other metals, such as Pb$(111)$, that can exhibit oscillations of height preference with thickness. The results suggest that quantum size-effects are broadly important for the growth of metallic nanocrystals. Support is gratefully acknowledged from NSF DMR-0706278 and DGE-1069091. The Advanced Photon Source at Argonne National Laboratory is supported by the US-DOE W-31-109-Eng-38.
10:00AM A8.00011 A multi-scale approach to the electronic structure of doped semiconductor surfaces, OFER SINAi, Weizmann Institute of Science, Rehovoth, IL, OLIVER T. HOFMANN, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, DE, PATRICK RINKE, Aalto University School of Science, Aalto, FI, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, DE, GEORG HEIMEL, Humboldt-Universität zu Berlin, Berlin, DE, LEEOR KRONIK, Weizmann Institute of Science, Rehovoth, IL — The inclusion of the global effects of semiconductor doping poses a unique challenge for first-principles simulations, because the typically low concentration of dopants renders an explicit treatment intractable. Furthermore, the width of the space-charge region (SCR) at charged surfaces often exceeds realistic supercell dimensions. We present a multi-scale technique that addresses these difficulties. It is based on the introduction of excess charge, mimicking free charge carriers from the SCR, along with a fixed sheet of counter-charge mimicking the SCR-related field. Self-consistency is obtained by imposing charge conservation and Fermi level equilibration between the bulk, treated semi-classically, and the electronic states of the slab/surface, which are treated quantum-mechanically. The method, called CREST - the Charge-Reservoir Electrostatic Sheet Technique - can be used with standard electronic structure codes. We validate CREST using a simple tight-binding model, which allows for comparison of its results with calculations encompassing the full SCR explicitly. We then employ it with density functional theory, obtaining insight into the doping dependence of the electronic structures of the metallic clean-cleaned Si(111) surface and its semiconducting (2x1) reconstructions.

10:12AM A8.00012 First principles studies of the stability and Shottky barriers of metal/CdTe(111) interfaces, ODKHU-DORJ, M.S. MIAO, N. KIOUSSIS, California State University Northridge, S. TARI, F. AQUARIA, Y. CHANG, Sivananthan Laboratories, C. GREIN, University of Illinois at Chicago — CdZnTe and CdTe based semiconductor X-Ray and Gamma-Ray detectors have been intensively studied recently due to their promising potentials for achieving high-resolution, high signal-to-noise ratios and low leakage current, all are desirable features in applications ranging from medical diagnostics to homeland security. Understanding the atomic and electronic structures of the metal/semiconductor interfaces is essential for the further improvements of performance. Using density functional calculations, we systematically studied the stability, the atomic and electronic structures of the interfaces between Cd-terminated CdTe (111) surface and the selected metals. We also calculated the Shottky barrier height (SBH) by aligning the electrostatic potentials in semiconductor and metal regions. Our calculations revealed the importance of intermixing between semiconductor and metal layers and the formation of Te-metal alloys at the interface. The obtained SBH does not depend much on the choice of metals despite the large variation of the work functions. On the other hand, the interface structure is found to have large effect to the SBH, which is attributed to the metal induced states in the gap. The position of such states is insensitive to the metal work functions, as revealed by the analysis of the electronic structures.

10:24AM A8.00013 Band offsets at the crystalline / hydrogenated amorphous silicon interface from first-principles, EBRAHIM HAZRATI, KAROL JAROLIMEK, GILLES A. DE WIJJS, Roadbed University, Nijmegen, The Netherlands, INSTITUTE FOR MOLECULES AND MATERIALS TEAM — The heterojunction formed between crystalline silicon (c-Si) and hydrogenated amorphous silicon (a-Si:H) is a key component of a new type of high-efficiency silicon solar cell. Since a-Si:H has a larger band gap than c-Si, band offsets are formed at the interface. A band offset at the minority carrier band will mitigate recombination and lead to an increased efficiency. Experimental values of band offsets scatter in a broad range. However, a recent meta-analysis of the results (W. van Sark et al. pp. 405, Springer 2012) gives a larger valence offset (0.40 eV) than the conduction offset (0.15 eV). In light of the conflicting reports our goal is to calculate the band offsets at the c-Si/a-Si:H interface from first-principles. We have prepared several atomistic models of the interface. The crystalline part is terminated with (111) surfaces on both sides. The amorphous structure is generated by simulating an annealing process at 1100 K, with DFT molecular dynamics. Once the atomicistic model is ready it can be used to calculate the electronic structure of the interface. Our preliminary results show that the valence offset is larger than the conduction band offset.

10:36AM A8.00014 Interface Formation for a Ferromagnetic/Antiferromagnetic Bi-layer System Studied by Scanning Tunneling Microscopy and First Principles Theory, ANDRADA-OANA MANDRU, JONATHAN GUERRERO-SANCHEZ, JEONGHIM PAK, NOBORU TAKEUCHI, ARTHUR SMITH, Nanoscale and Quantum Phenomena Institute, Department of Physics and Astronomy, Ohio University, Athens, Ohio 45701, USA — We investigate the initial stages of interface formation for Fe/Mn$_2$N$_2$(001) ferromagnet/antiferromagnet bi-layer system down to the atomic scale using a combination of molecular beam epitaxy, scanning tunneling microscopy and first principles theoretical calculations. Sub-monolayer iron deposits on onto manganese nitride nanoparticle surfaces induce the formation of one monolayer high islands that are present on all terraces. Unexpectedly, the chemical composition of the observed islands does not consist of Fe, as determined using Auger electron spectroscopy, conductance imaging and theoretical models. Further theoretical calculations reveal how Fe atoms incorporate into specific subsurface layers. In addition, theory finds the magnetic alignment of the Fe atoms within a particular layer and with adjacent Mn$_2$N$_2$(001) layers. This study suggest that these complex structural rearrangements at the interfaces between such magnetic bi-layer systems are important to take into account when considering the exchange coupling between the layers.

10:48AM A8.00015 ABSTRACT WITHDRAWN —

Monday, March 2, 2015 8:00AM - 11:00AM — Session A9 DCMP: Majorana Fermions and Superconductivity 006D - Christian Platt, Stanford University

8:00AM A9.00001 Topological Shiba chain in a spin-orbit coupled superconductor, PHILIP BRYDON, HOI-YIN HUI, JAY SAU, Condensed Matter Theory Center, University of Maryland, College Park — The impurity band formed from a chain of classical spins embedded in a superconductor can be topological, depending on the magnetic texture of the spins. Previous proposals require a helical texture [1] which is, however, unstable towards a ferromagnetic or antiferromagnetic configuration [2]. We show that including surface spin-orbit coupling permits a topological gap in a broad range. However, a recent meta-analysis of the results (W. van Sark et al. pp. 405, Springer 2012) gives a larger valence offset (0.40 eV) than the conduction offset (0.15 eV). In light of the conflicting reports our goal is to calculate the band offsets at the c-Si/a-Si:H interface from first-principles. We have prepared several atomistic models of the interface. The crystalline part is terminated with (111) surfaces on both sides. The amorphous structure is generated by simulating an annealing process at 1100 K, with DFT molecular dynamics. Once the atomicistic model is ready it can be used to calculate the electronic structure of the interface. Our preliminary results show that the valence offset is larger than the conduction band offset.

1. We acknowledge support from JQI-NSF-PFC and LPS-CMTC.

8:12AM A9.00002 Zero-bias peak splitting in InSb nanowires , JUN CHEN, PENG YU, University of Pittsburgh, Pittsburgh, PA, 15260, USA, MOIRA HOCEVAR, Institut Niel CNRS, Grenoble, France, SEBASTIEN PLISSARD, CNRS, LAAS, Toulouse, France, DIANA CAR, ERIK BAKKERS, Eindhoven University of Technology, 5600 MB Eindhoven, The Netherlands, SERGEY FROLOV, University of Pittsburgh, Pittsburgh, PA, 15260, USA — Zero-bias conductance peak (ZBP) has been reported as a signature of Majorana fermions in InSb nanowires. Other features like ZBP phase diagram in chemical potential vs. magnetic field and peak splitting are proposed as additional evidences of Majorana fermions. We make superconductor-InSb nanowire hybrid devices with the aim of exploring these features and beyond. By means of high-k HfOx as the dielectric layer, we obtain large gate-tunability of magnetic properties and use it to map out ZBP phase diagram. Here we report observation of ZBP at finite magnetic field. Such peak is tunable with gates underneath the superconductor. In particular, it splits and merges again as a function of the center gate. We study such splitting in the context of a pair of coupled Majorana bound states.

8:24AM A9.00003 Electrostatic effects in Majorana hybrid structures , PIYAPONG SITHSONN, TUDOR STANESCU, West Virginia University — We study the electrostatic effects that emerge in proximity-coupled semiconductor (SM-SC) structures due to the charge transfer induced by the work function difference between the two materials. The effects are described theoretically using a tight-binding model of the heterostructure solved within a self-consistent Poisson-Schrödinger scheme. We find that these effects are responsible for i) generating an effective Rashba-type spin-orbit coupling and ii) modifying the spatial dependence of the low-energy wave functions near the SM-SC interface. This change in the wave-function amplitude at the interface strongly affects the proximity-induced superconducting gap. Both effects have critical consequences on the stability of the Majorana-hosting topological superconducting phase that is predicted to emerge in this type of structures. For a thin-film geometry, we determine the dependence of the effective spin-orbit coupling and induced superconducting gap on the film thickness and on the strength of the SM-SC coupling.

8:36AM A9.00004 Majorana bound states on a self-organizing helical magnonic wire on the surface of a superconductor with spin-orbit coupling , MORTEN HOLM CHRISTENSEN, JENS PAAESKE, BRIAN M. ANDERSEN, Niels Bohr Institute, University of Copenhagen — Recent STM experiments [1] have observed zero-energy modes consistent with Majorana bound states at the ends of ferromagnetically aligned Fe-chains grown on the surface of lead. We consider a chain of magnetic moments on top of an s-wave superconductor with spin-orbit coupling and study their magnetic ordering self-consistently. In the absence of spin-orbit coupling we find that a topologically non-trivial helical state appears for sufficiently high values of the chemical potential, in agreement with Ref. [2], while including spin-orbit coupling and imposing ferromagnetic order we find a non-trivial phase with Majorana bound states in agreement with Ref. [3]. We report numerical results for the general case, with non-zero spin-orbit coupling and self-organized magnetic order, allowing the moments to minimize the free energy. A range of different magnetic orders are identified and topologically non-trivial regions are found to prevail in a large parameter region. [1] Yazdani et. al Science, 6209 (2014) [2] I. Reis et. al. Phys. Rev. B. 90, 085124 2014 [3] Brydon et. al. arXiv:1407.6345 (2014)

8:48AM A9.00005 Majorana modes and transport across junctions of superconductors and normal metals1 , DIPTIMAN SEN, MANISHA THAKURATHI, OINDRILA DEB, Indian Institute of Science, Bengaluru, India — We study Majorana modes and transport in one-dimensional systems with junctions of p-wave superconductors (SCs) and normal metal (NM) leads. For a system with a SC lying between two NM leads, it is known that there exists a Majorana mode at the junction between the SC and each NM. If an impurity is present or the p-wave pairing amplitude changes sign at some point in the superconductor, two additional Majorana modes appear near that point. We study the effects of all these modes on the normal and Cooper pair conductances. The main effect is to shift the conductance peaks away from zero bias due to hybridization between the Majoranas, the shift oscillates and also decays exponentially as the length of the SC is increased. Using bosonization and the renormalization group (RG) method, we study the effect of interactions between the electrons on the Majorana modes and the conductances. We then consider a system with a junction of three SC regions connected to NM leads. The junction is parameterized by a scattering matrix. Depending on the relative signs of the pairing amplitudes in the three SCs, there may be one or three Majorana modes at the junction. We study the effect of interactions on these modes using an RG analysis which is valid for weak interactions.

1 We thank DST, India and CSIR, India for financial support.

9:00AM A9.00006 Majorana Correlation as a Signature of a Topological Phase Transition1 , AMIT NAG, JAY D. SAU, Condensed matter theory center, University of Maryland- College Park — Spin orbit coupled semiconductor nanowires in proximity to ordinary s-wave superconductor exhibit a topological phase which supports Majorana fermions at the two ends of the nanowire. A signature of Majorana fermions would be a zero bias conductance peak. Indeed such a peak has been observed in recent experiments but at the same time alternate non topological mechanisms have been suggested to explain appearance of the zero bias peak. Here we demonstrate that the zero bias conductance peak from Majorana fermions must appear in a correlated way between the two ends. We analyze how this peculiarity can be used as a signature of the topological phase transition linked to the appearance of Majorana modes and thus can be used to experimentally distinguish between competing theoretical mechanisms.

1 We acknowledge support from Physics Frontier Center and Maryland Startup Fund.

9:12AM A9.00007 Topological Kondo effect in transport through superconducting wire with multiple Majorana end states , OLEKSII KASHUBA, CARSTEN TIMM, Institute of Theoretical Physics, TU Dresden — The transport through the interface between normal metal and topological superconducting wire can be affected by the interaction of the lead electrons and edge states in the wire. For a minimum of three Majorana fermions at the interface, we find nontrivial renormalization physics. Classification of the tunneling processes by spin-1/2 and spin-3/2 irreducible representations of the SU(2) group allows to identify two different renormalization behaviors associated with the representations. Renormalization triggered by the interaction enhances one group of the tunneling amplitudes and suppresses another one, depending on whether the coupling is ferro- or antiferromagnetic. The nontrivial RG processes manifest themselves in distinct temperature dependencies and different spin polarizations of the current through the interface depending on the sign of the interaction.

9:24AM A9.00008 Modulation of the phase in SC order parameter in Kitaev chain and its consequences , SHO NAKOSAI, Univ of Tokyo, YUKIO TANAKA, Nagoya Univ, NAOTO NAGAOSA, RIKEN — Kitaev’s superconducting chain model, one dimensional spinless p-wave superconductor, is a prototype of topological superconductors and supports Majorana modes at the ends of the system. There have been intensive researches on the model since the role of topology in condensed matter physics is highlighted, and recently not a few experimental results show the model can be effectively generated in designed systems. Anytime soon, we will arrange it as we like. A simple extension of the model is two-parallel-aligned chains. It possesses four Majorana states in total. When we take into account the modulation of the phase in the superconducting order parameter, however, the degeneracy of the energy levels is resolved. We investigate the physical consequence of it. The phase should change along the chain to reduce the total energy of the system, and the deterministic equation for it is in the form of sine-Gordon equation. The distribution of the supercurrent due to the modulation leaves the degeneracy in the ground states. Then we can regard the system as a flux qubit. In the presence of external magnetic field, these modulations will couple with the spontaneous field associated with the phase modulation, and result in control of states and an unusual Josephson effect.
Topological Superconductivity in Ferromagnetic Metal Chains: Part I

JIAN LI, Princeton University, HUA CHEN, University of Texas at Austin, Ilya Drozdov, Ali Yazdani, Bogdan Bernevig, Princeton University, Alllan MacDonald, University of Texas at Austin — Recent experiments have demonstrated superconductivity induced in ferromagnetic atomic chains as a new route to the research of Majorana physics. In this talk we discuss the theory behind these experiments. We will present a generic picture for how superconductivity is induced in ferromagnetic metal chains through coupling to a superconductor with strong spin-orbit coupling, and explain why this hybrid system is a plausible new platform in searching for topological superconductivity. We will then present a tight-binding model associated with the existing experiments. We reveal a new chain magnetic symmetry that is able to stabilize multiple Majorana end modes in the absence of disorder, resulting in a one-dimensional crystalline topological superconductor. We show phase diagrams in terms of such topological phases and point out their relevance to the existing experiments. In the last part of this talk we will briefly discuss some other directions of research based on the new platform, including braiding Majorana quasi-particles in ferromagnetic chains, as well as realizing topological superconductivity in two-dimensional ferromagnetic thin films.

Impurity-induced bound states in superconductors with spin-orbit coupling1

YOUNGHYUN KIM, University of California - Santa Barbara, JUN HUA ZHANG, E. ROSSI, College of William and Mary, ROMAN LUTCHYN, Microsoft Research Station Q — We study the effect of strong spin-orbit coupling on bound states induced by impurities in superconductors. The presence of spin-orbit coupling breaks the SU(2)-spin symmetry and causes the superconducting order parameter to have generically both singlet (s-wave) and triplet (p-wave) components. As a result, impurity-bound states corresponding to different angular momentum channels hybridize and display a number of qualitatively different features from that of the well-known Yu-Shiba-Rusinov states in conventional s-wave superconductors. In particular, we find that in the presence of spin-orbit coupling the spectrum of the impurity-bound states depends on the orientation of the magnetic moment of the impurity. Our predictions can be used to distinguish the order parameter and have implications for the Majorana proposals based on chains of magnetic atoms placed on the surface of superconductors with strong spin-orbit coupling [1].

Effect of spin-orbit coupling on the topological phase diagram of a Shiba chain1

TEEMU OJANEN, JOEL RONTYNEN, ALEX WESTSTROM, KIM POYHONEN, School of Science, Aalto University, O. V. LOUNASMAA LABORATORY TEAM — Topological superconductivity was recently observed in a system consisting of a 1D magnetic adatoms on top of a superconducting surface. Anticipating further developments, we show that a 2D array of magnetic atoms support a variant of px +ipy superconductivity and exhibit very complex phase diagram with high Chern numbers. We also present a detailed study of Majorana bound states in 1D chains.

1 The authors acknowledge the Academy of Finland for support.

Weak and strong coupling regimes in Majorana hybrid structures1

JOHN STENGTER, TUDOR STANESCU, West Virginia University — We study the proximity-induced low-energy physics that emerges in semiconductor - superconductor hybrid structures. We find that the proximity-induced gap has a non-monotonic dependence on the effective semiconductor - superconductor coupling strength. To identify the qualitative difference between weak and strong coupled regimes characterized by similar values of the induced gap, we determine the dependence of the differential conductance of a metal - semiconductor - superconductor structure capable of hosting zero-energy Majorana bound states on the heterostructure parameters (semiconductor wire thickness, semiconductor - superconductor coupling strength, etc.) and apply an effective energy theory. We apply this effective theory by properly integrating out the high-energy degrees of freedom (rather than simply ignoring them), which results in a strong renormalization of the low-energy sector. Using this effective theory, we describe the qualitative differences between the Majorana signatures emerging in the weak and strong coupling regimes.

Universal Nonequilibrium Signatures of Majorana Zero Modes in Quench Dynamics1

ROMAIN VASSEUR, JAN DAHLHAUS, JOEL MOORE, UC Berkeley — The quantum evolution after a metallic lead is suddenly connected to an electron system contains information about the excitation spectrum of the combined system. We exploit this type of “quantum quench” to probe the presence of Majorana fermions at the ends of a topological superconducting wire. We obtain an algebraically decaying overlap (Loschmidt echo) Ζ(t) = (|ψ(0)|ψ(t))² ∼ t^−α for large times after the quench, with a universal critical exponent α = 1/4 that is found to be remarkably robust against details of the setup, such as interactions in the normal lead, the existence of additional lead channels or the presence of bound levels between the lead and the superconductor. As in recent quantum dot experiments, this exponent could be measured by optical absorption, offering a new signature of Majorana zero modes that is distinct from interferometry and tunneling spectroscopy.

New Topological Superconducting phase in Superconductor/2D Topological Insulator/Superconductor Junction

YAO LU, KAM TUEN LAW, The Hong Kong University of Science and Technology — It is well known that a Josephson junction built on top of helical edge states of the topological insulator traps two Majorana fermions when the phase difference between the two superconductors is π and the system can be considered as a DIII class topological superconductor. In this work, we show that a narrow strip of two dimensional topological insulator coupled to two superconductors, forming a Josephson junction, can support a new topological phase in the presence of an in-plane magnetic field. In this phase, each end of the strip of the topological insulator supports a single Majorana fermion for a wide range of phase difference between the two superconductors. This topological phase can be revealed by Josephson current measurements and tunneling spectroscopy experiments.
Monday, March 2, 2015 8:00AM - 11:00AM — Session A10 DCMP: Topological Matters 007A - Jason Alicea, California Polytechnic Institute

8:00AM A10.00001 Composite Dirac liquids: parent states of symmetric surface topological orders

ANDREW ESSIN, DAVID MROSS, IQIM, Caltech, JASON ALICEA, Caltech — In the absence of interactions, topological insulators surfaces must be gapless or break symmetry. With the addition of strong interactions at the surface, a third possibility is a gapped, symmetric surface that supports anyons, as has been recognized in a number of recent developments. The composite Dirac liquid (CDL) provides a natural stepping stone to identifying such states. The CDL consists of neutral, fractional Dirac fermions coupled to gapped charges, and the addition of pairing to the neutral sector produces a gap for all excitations without breaking any symmetry. The quasi-1D technology we have used in the study of the CDL also allows us to construct and characterize such gapped surface phases, and generalizes naturally to (bosonic) symmetry protected topological phases as well.

1 This work was supported by the Institute for Quantum Information and Matter, an NSF Physics Frontiers Center with support of the Gordon and Betty Moore Foundation through Grant GBMF1250

8:12AM A10.00002 Composite Dirac liquids: exotic gapless states at an electronic topological insulator surface

DAVID MROSS, ANDREW ESSIN, JASON ALICEA, Caltech — We introduce exotic gapless states 'composite Dirac liquids' that can appear at a strongly interacting surface of a three-dimensional electronic topological insulator. Composite Dirac liquids exhibit a gap to all charge excitations but nevertheless feature a single massless Dirac cone built from emergent electrically neutral fermions. These states thus comprise electronic insulators that preserve all symmetries and, interestingly, retain thermal properties similar to those of the non-interacting topological insulator surface. To controllably access the composite Dirac liquid we exploit a quasi-1D deformation of the original electronic Dirac cone that enables us to analytically address the fate of the strongly interacting surface.

8:24AM A10.00003 Axion field theory and \( Z_{16} \) classification of time reversal invariant topological superconductors

YINGFEI GU, XIAOLIANG QI, Stanford Univ — Time-reversal invariant topological superconductors (TRI TSC) are gapped superconductors with topologically robust gapless modes on the boundary. In the work by X. L. Qi et al, [PRB, 87, 134519(2013)], a topological field theory description was proposed for 3+1-dimensional TRI TSC, which contains an axionic coupling between superconducting phase and electromagnetic field. In my talk, I will describe a generalization of this theory to include interaction effects which provides a physical explanation why the integer classification is reduced to \( Z_{16} \). I will also attempt to generalize our results to higher dimensions and give constraints on the possible collapsing of topological classification induced by interaction effects.

8:36AM A10.00004 Possible realization of interacting symmetry-protected topological phases in topological crystalline insulators

HIROKI ISOBE, University of Tokyo, LIANG FU, Massachusetts Institute of Technology — The effects of electron-electron interaction in edge states of mirror-symmetry protected topological crystalline insulators (TCIs) are discussed. The analysis is performed by using bosonized Hamiltonian following the Tomonaga-Luttinger liquid theory. When two pairs of helical edge states exist, electron-electron interaction could gap out one edge mode, which is a possible realization of interacting symmetry-protected topological (SPT) phases. This type of SPT phase is closely related to a Luther-Emery liquid in spinful 1D system. We also propose a method of detecting the SPT phases by STM. The other focus of the study is the classification of SPT phases in mirror-symmetry protected TCIs. By adopting the Chern-Simons theory, we find that electron-electron interaction reduces the classification from \( Z \) to \( Z_{16} \). It means that the edge states can be gapped out when four pairs of edge states exist. In other cases, the edge modes cannot be fully gapped. Each of these states corresponds to a different SPT phase depending on the relevant interaction process.

8:48AM A10.00005 Topological crystalline insulators from crystal field effect in monolayer IV-VI semiconductors

JUNWEI LIU, XIAOFENG QIAN, LIANG FU, MIT — Two-dimensional (2D) topological crystalline insulators (TCIs) were recently predicted in thin films of the SnTe class of IV-VI semiconductors, which can host metallic edge states protected by mirror symmetry. As thickness decreases, quantum confinement effect will increase and surpass the inverted gap at a critical thickness, turning 2D TCIs into normal insulators. Surprisingly, based on first-principles calculation, here we demonstrate that (001) monolayers of rocksalt IV-VI semiconductors XY (X=Ge, Sn, Pb and Y= S, Se, Te) are 2D TCIs with the fundamental band gap as large as 260 meV in monolayer PbTe. This unexpected nontrivial topological phase stems from the strong crystal field effect in the monolayer, which lifts the degeneracy between \( p_x \) and \( p_y \) orbitals and leads to band inversion between cation and anion \( p_z \) orbitals. Our work offers a new strategy to find atomically thin 2D topological materials.

9:00AM A10.00006 ABSTRACT WITHDRAWN —

9:12AM A10.00007 Probing Topological Superconductors

DAVID SCHMELTZER, C.C.N.Y. — The presence of attractive interaction on the surface of a 3D topological insulator which is characterized by spinors carrying a Berry phase of \( \pi \) stabilizes gapped symmetric surface topological superconductors with topologically robust gapless modes on the boundary. We construct the effective dual action for the superconductor with the vortices, and show that the \( 2n \) Majorana fermions are localized and can be replaced with \( n \) spinless fermions. The effect of the Majorana zero modes can be observed through the Andreev cross reflection when metallic leads are attached to the superconductor. The presence of the Majorana fermions can be detected with transverse sound waves. We have computed the effect of elastic strain fields and obtain an anomalous response indicating the presence of the Majorana fermions.

9:24AM A10.00008 Time-reversal invariant topological superconductivity in doped Weyl semimetals

PAVAN HOSUR, Stanford Univ, XI DAI, ZHONG FANG, Institute of Physics, Chinese Academy of Sciences, XIAO-LIANG QI, Stanford Univ — Time-reversal invariant topological superconductors are a new state of matter which have a bulk superconducting gap and robust Majorana fermion surface states. These have not yet been realized in solid state systems. In this paper, we propose that this state can be realized in doped Weyl semimetals or Weyl metals. The Fermi surfaces of a Weyl metal carry Chern numbers, which is a required ingredient for such a topological superconductor. By applying the fluctuation-exchange approach to a generic model of time-reversal invariant Dirac and Weyl semimetals, we investigate what microscopic interactions can supply the other ingredient, viz., sign changing of the superconducting gap function between Fermi surfaces with opposite Chern numbers. We find that if the normal state is inversion symmetric, onsite repulsive and exchange interactions induce various nodal phases as well as a small region of topological superconductivity on the phase diagram. Unlike the 3D Dirac topological superconductor, the phase here does not rely on any special momentum dependence of the pairing amplitude. Breaking inversion symmetry precludes some of the nodal phases and the topological superconductor becomes much more prominent, especially at large ferromagnetic interaction.

1 We acknowledge support from the David and Lucile Packard Foundation, the Department of Energy Office of Basic Sciences, National Science Foundation, National Science Foundation of China and 973 Program of China for financial support
9:36AM A10.00009 Topological Crystalline Metal in Orthorhombic Perovskite Iridates, YIGE CHEN, University of Toronto, YUAN-MING LU, University of California, Berkeley, HAE-YOUNG KEE, University of Toronto — Since topological insulators were theoretically predicted and experimentally observed in semiconductors with strong spin-orbit coupling, more and more attention has been drawn to topological materials which host exotic surface states. These surface excitations are stable against perturbations since they are protected by global or spatial/lattice symmetries. Succeeded in achieving various topological insulators, a tempting challenge now is to search for metallic materials with novel topological properties. Here we predict that orthorhombic perovskite iridates realize a new class of metals dubbed topological crystalline metals, which support zero-energy surface states protected by certain lattice symmetry. These surface states can be probed by photoemission and tunneling experiments. Furthermore, we show that by applying magnetic fields, the topological crystalline metal can be driven into other topological metallic phases, with different topological properties and surface states.  

9:48AM A10.00010 Crystalline Topological Insulators and Superconductors – The Role of Nonsymmetric Symmetries, DANIEL VARJAS, FERNANDO DE JUAN, YUAN-MING LU, Univ of California - Berkeley — We investigate how the presence of nonsymmetric lattice symmetries affects the classification of topological insulators and superconductors in 2 and 3 dimensions. We use the representation theory of space groups, the classification of 1D fermionic symmetry protected topological phases and analyze tight binding models that exhibit gapless surface modes protected by unitary or antiunitary space group symmetries.

10:00AM A10.00011 New classes of three-dimensional topological crystalline insulators with unpinned surface Dirac cones, CHEN FANG, TIMOTHY HSIEH, LIANG FU, Massachusetts Institute of Technology — We theoretically predict two new classes of 3D topological crystalline insulators (TCI) that have protected, robust surface states. In first class, the surface states are protected by a single glide mirror symmetry. On a symmetry-preserving surface, a single Dirac point can appear at any position along either one of the two mirror symmetric lines inside the surface Brillouin zone (SBZ). In the second class, the surface Dirac point is protected by a combination of twofold rotation and time-reversal symmetry, and appears on the crystal surface perpendicular to the rotation axis. Its position in the SBZ is completely free to move by symmetry-preserving perturbations. In each class, we prove the existence of a $Z_2$ bulk invariant and find its explicit analytic expression. These new classes of TCI do not presume the presence or the absence of spin-orbital coupling.

10:12AM A10.00012 Topological phase transition in thin-film topological crystalline insulators, AI YAMAKAGE, HIDEYUKI OZAWA, MASATOSHI SATO, YUKIO TANAKA, Department of Applied Physics, Nagoya University — Topological crystalline insulator is one of the recent breakthrough ideas [1], in which Dirac fermions on the surface protected by crystalline symmetry, not by time-reversal symmetry. Another direction of the topological expansion is nanofabrication. In this work, we reveal the topological phase diagram of a thin-film topological crystalline insulator Pb$_x$Sn$_{1-x}$Te. Odd numbers of layers of Pb$_x$Sn$_{1-x}$Te exhibit the topological phase transition between two-dimensional trivial and topological crystalline insulators protected by the mirror-Chern number, which is consistent with the previous work [2]. In addition, we have found a new topological phase in the even numbers of layers, which is protected by the glide symmetry [3]. This glide topological phase can be realized in the thin film not in the bulk system.

10:24AM A10.00013 Interface gapless states from interfacial symmetries, RYUJI TAKAHASHI, University of Applied Physics, Tokyo, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology — Previously we have shown that at an interface between two topological insulators with opposite Dirac velocities, gapless interface states protected by mirror symmetry appear [1]. We can calculate the interface dispersion using the Fu-Kane-Mele (FKM) tight-binding model, and it typically consists of Dirac cones. In this presentation, we report another kind of interface metallic states; the Fermi surface forms loops (‘Fermi loop’) [2], rather than isolated Dirac points, sometimes seen in the interface of the FKM models. Such a degeneracy along a loop is unexpected. This Fermi loop appears when the whole junction system preserves particle-hole symmetry, while each system breaks particle-hole symmetry. We call this symmetry “interfacial particle-hole symmetry” (IPHS). We discuss the IPHS in general systems and show that the Fermi loop results from a sign change of a Pfaffian of some matrix, defined only in junctions with IPHS symmetry [2].

10:36AM A10.00014 Quantum anomalous Hall insulators and transitions in spin-orbit coupled double perovskites, ARUN PARAMEKANTI, ASHLEY COOK, CIARAN HICKEY, University of Toronto — Motivated by the interest with strong spin-orbit coupling and ferromagnetism, we study quantum anomalous Hall insulators and their quantum phase transitions in clean systems. We show that certain quantum anomalous Hall critical points support quadratic band touching points, which can lead to interaction induced emergent phases which form a domino around the critical point. This yields the simplest example of the ubiquitously observed formation of novel phases around an underlying metallic quantum critical point. We explore double perovskites with high Tc ferromagnetism and strong spin-orbit coupling, including Sr$_2$FeMoO$_6$, as possible candidate materials in which to explore this physics.

3We acknowledge funding from NSERC and CIFAR.

10:48AM A10.00015 Transport Signatures of Fermi Surface Topology in BiTeI, LINDA YE, University of Tokyo, JOSEPH CHECKELSKY, Massachusetts Institute of Technology, FUMITAKA KAGAWA, YOSHINORI TOKURA, RIKEN Center for Emergent Matter Science — The giant bulk Rashba spin-orbit coupling in BiTeI makes it not only an interesting spintronics system but also a host of an effect Dirac-like electronic structure of fundamental interest. As a function of lowering the Fermi level $E_F$ across the associated Dirac point ($E_F = 0$), the Fermi surface of BiTeI changes its topology: from a spindle-torus ($E_F > 0$) through a horn-torus ($E_F = 0$) to a ring-torus ($E_F < 0$). Here we report a systematic evolution of the magnetoresistance across these energy boundaries in high quality single crystals exhibiting Shubnikov-de Haas oscillations. We further discuss the physical origin of the detailed $E_F/field$/temperature dependencies and remark on the relevance of this study to band crossings generally occurring in 3D systems.
8:00AM A11.00001 Origin of charge density wave instability in the underdoped cuprates\textsuperscript{1}. VIVEK MISHRA, M. R. NORMAN, Materials Science Division, Argonne National Laboratory, Lemont, IL 60439. — The exact nature of the normal state in the underdoped cuprates is still debatable. Recent experimental results favor the existence of an unconventional charge density wave with d-wave form factor above the superconducting transition. Here we study the charge density wave instability within the Eliashberg framework. We find the full momentum structure of the leading charge density wave order and compare its strength to the superconductivity driven by spin-fluctuation mediated pairing interaction.

8:12AM A11.00002 ABSTRACT WITHDRAWN

8:24AM A11.00003 Interplay between pair-density-wave and charge-density-wave orders in underdoped cuprates. DANIEL AGTERBERG, University of Wisconsin-Milwaukee, YUXUAN WANG, Univ of Wisconsin, Madison, ANDREY CHUBUKOV, University of Minnesota — We analyze the interplay between charge-density-wave (CDW) and pair-density-wave (PDW) orders within the spin-fermion model for the cuprates. We show that both orders do emerge in the spin-fermion model as preemptive orders to antiferromagnetism, and are constructed out of pairs of “hot” fermions on the Fermi surface. We that the two orders are nearly degenerate and are related by an approximate SU(2) particle-hole symmetry of the spin-fermion model. The SU(2) symmetry is exact if one neglects the curvature of the Fermi surface in hot regions, in which case the CDW and PDW, each breaking translational U(1) symmetry, become components of an O(4)-symmetric super-vector. We show that the curvature of the Fermi surface breaks this degeneracy and that the mean-field transition temperature is higher for the PDW order. However, we also argue that both CDW and PDW order break additional discrete $Z_2$ symmetries and show that the feedback from the $Z_2$ order on the CDW order is stronger. This feedback increases the critical temperature for CDW order compared to that for PDW order. Which state develops first depends on system parameters. We also consider the case when both orders are present at low $T$ and argue that simultaneous presence of CDW and PDW orders induce a variety of states.

8:36AM A11.00004 Composite Charge Order In Cuprate Superconductors. ANDREY CHUBUKOV, University of Minnesota, YUXUAN WANG, Univ of Wisconsin, Madison — We analyze charge order in hole-doped cuprates. We argue that magnetically-mediated-interaction, which is known to give rise to d-wave superconductivity, also gives rise to charge-density-wave instabilities with momenta $Q_x = (Q, 0)$ and $Q_y = (0, Q)$, as seen in the experiments. We show that the emerging charge order with $Q_x/Q_y$ is of stripe type and that a stripe charge order parameter by itself has two components: one is incommensurate density variation, another is incommensurate current. Both components are non-zero in the CDW-ordered state, with the relative phase $\pm \pi/2$. Such an order breaks time reversal symmetry. We further show that, before a true incommensurate CDW order sets in, the system develops a pre-emptive composite order which breaks lattice rotational symmetry and time-reversal symmetry but preserves a translational $U(1)$ symmetry. We discuss the interplay between our CDW order and superconductivity and the spin-fluctuation scenario for the pseudogap phase.

8:48AM A11.00005 Ginzburg-Landau Theory of multi-component order parameter in the cuprate pseudo-gap regime. LAIMEI NIE, Stanford University, SUBIR SACHDEV, Harvard University, STEVEN KIVELSON, Stanford University — We study a Landau-Ginzburg-Wilson effective field theory of a quasi-2D system with potential disorder in which incommensurate charge-density-wave and superconducting orders are intertwined. The model is shown to exhibit a rich phase diagram at a large-N mean-field level, where both superconducting and nematic, but not charge-density-wave order, can persist in the presence of the quenched disorder. We select three representative sets of input parameters and compute the corresponding CDW structure factors. Where nematicity and SC coexist, the peak height of the CDW structure factor decreases monotonically as a function of increasing $T$, unlike what is seen in X-ray experiments in YBCO. In the parameter regime where no nematic phase occurs, we compute to one-loop order the nematic correlation length, which is shown to be much shorter than CDW correlation length.

9:00AM A11.00006 Quasiparticle transport coefficients from a mean field bond density wave state in high-Tc cuprates. GIRISH SHARMA, Clemson University, Clemson, SC 29634, USA, KANGJUN SEO, School of Natural Sciences, University of California at Merced, Merced, California 95343, USA, SUMANTA TEWARI, Clemson University, Clemson, SC 29634, USA, COLLABORATION WITH K.SEO COLLABORATION — The pseudogap regime in low hole doped high Tc cuprate superconductors exhibits peculiar experimental signatures like the detection of enhanced negative signals for Hall, Seebeck and Nernst coefficients. This has been ascribed to a competing density wave order near 1/8 hold doping and low temperature regimes. Starting with a mean field quasiparticle model describing a bi-axial bond density wave (BDW) state with $Q_1 = (0, 2\pi/3)$ and $Q_2 = (2\pi/3, 0)$, we show that the Fermi surface is reconstructed with the emergence of electron and hole-like pockets in the Brillouin zone. Employing semi-classical Boltzmann dynamics, the emergence of an enhanced negative Hall, Seebeck and Nernst coefficients is shown which is consistent with experimental data. This type of response is not seen for a uni-axial BDW order of type Q1 or Q2.

9:12AM A11.00007 Monte Carlo studies of diamagnetism and charge density wave order in the cuprate pseudogap regime. LAUREN HAYWARD SIERENS, ANDREW ACHKAR, DAVID HAWTHORN, University of Waterloo, ROGER MEIKO, University of Waterloo / Perimeter Institute for Theoretical Physics, SUBIR SACHDEV, Harvard University / Perimeter Institute for Theoretical Physics — The pseudogap regime of the hole-doped cuprate superconductors is often characterized experimentally in terms of a substantial diamagnetic response and, from another point of view, in terms of strong charge density wave (CDW) order. We introduce a dimensionless ratio, $R$, that incorporates both diamagnetic susceptibility and the correlation length of CDW order, and therefore reconciles these two fundamental characteristics of the pseudogap [PRB 90, 094515 (2014)]. We perform Monte Carlo simulations on a classical model that considers angular fluctuations of a six-dimensional order parameter [Science 343, 1336 (2014)], and compare our Monte Carlo results for $R$ with existing data from torque magnetometry and x-ray scattering experiments on YBa$_2$Cu$_3$O$_{6+x}$. We achieve qualitative agreement, and also propose future experiments to further investigate the behaviour of this dimensionless ratio.

9:24AM A11.00008 The charge susceptibility in the cuprate pseudogap phase: Similarieties and differences between Fermi pockets and Fermi arcs scenarios. PETER SCHERPELZ, ADAM RANCON, James Franck Institute, University of Chicago, YAN HE, College of Physical Science and Technology, Sichuan University, K. LEVIN, James Franck Institute, University of Chicago — Recent experimental results have provided a variety of evidence for incommensurate charge ordering in underdoped cuprates. To understand these experimental findings, here we address the calculation of charge response functions. We perform these calculations for both the Fermi arcs approach, and the Fermi pockets scenario of Yang, Rice, and Zhang. Critically, we include vertex corrections that have previously been omitted, and which are shown to exactly satisfy the sum rules. We show that these corrections lead to a double-peak structure in the susceptibility, as well as significant suppression of the susceptibility for low $q$. These effects have a straightforward physical interpretation: They represent the inclusion of charged bosonic, spin singlet degrees of freedom. See also Scherpelz et al., PRB 90 060506(R) (2014).
9:36AM A11.00009 Fully consistent theory of response functions in the cuprate pseudogap phase: Implementing the Ward Takahashi identity

CHIEN-TE WU, RUFUS BOYACK, PETER SCHERPELZ, KATHRYN LEVIN, James Franck Institute, University of Chicago — There is a multiplicity of pairing-based theories of the cuprate pseudogap associated with Fermi surface reconstruction or charge ordering, which have a simple mean-field-like self energy. These include the scenario of Yang, Rice and Zhang and the recent Amperian pairing scenario of Lee. We demonstrate here how to arrive at precise response functions for this class of theories which include vertex corrections, where necessary. Thus one can address two body physics experiments at the same level of accuracy that one addresses the one body physics of photoemission spectroscopy. We do so by exploiting the Ward Takahashi identity. As an illustration, we present the spin dynamical response functions of neutron scattering for three different scenarios, finding that a recently proposed pair Amperian pairing scheme is readily distinguishable from other related scenarios.

9:48AM A11.00010 Emergent loop current order from pair density wave superconductivity

MANOJ KASHYAP, Univ of Wisconsin, Milwaukee, DREW MELCHERT, Univ of Chicago, Chicago, DANIEL AGTERBERG, Univ of Wisconsin, Milwaukee — In addition to charge density wave (CDW) order, it is clear that the pseudogap phase in the cuprates breaks time reversal symmetry. Here we show that pair density wave (PDW) states give rise to a translational invariant non-superconducting order parameter that breaks time reversal and parity symmetries, but preserves their product. This secondary order parameter has a different origin, but shares the same symmetry properties as a magnetoelectric loop current order that has been proposed earlier in the context of the cuprates to explain the appearance of intra-cell magnetic order. We further show that, due to fluctuations, this secondary loop current order, which represents the breaking of discrete symmetries, can preempt PDW order, which breaks both continuous and discrete symmetries. In such a phase, the emergent loop current order coexists with spatial short range CDW and short range superconducting order. Finally, we propose a PDW phase that accounts for intra-cell magnetic order and the Kerr effect, has CDW order consistent with x-ray scattering and nuclear magnetic resonance observations, and quasi-particle properties consistent with resolved photoemission scattering.

10:00AM A11.00011 Vortices and charge order in high-Tc superconductors

MATTHIAS EINENKEL, Ruhr-Universität Bochum, National University of Science and Technology “MISIS,” Moscow, HENDRIK MEIER, Yale University, CATHERINE PÉPIN, CEASaclay, KONSTANTIN B. EFETOV, Ruhr-Universität Bochum, National University of Science and Technology “MISIS,” Moscow — We theoretically investigate the vortex state of the cuprate high-temperature superconductors in the presence of magnetic fields. Assuming the recently derived nonlinear σ-model for fluctuations in the pseudogap phase, we find that the vortex cores consist of two crossed regions of elliptic shape, in which a static charge order emerges. Charge density wave order manifests itself as satellites to the ordinary Bragg peaks directed along the axes of the reciprocal copper lattice. Quadrupole density wave (bond order) satellites, if seen, are predicted to be along the diagonals. The intensity of the satellites should grow linearly with the magnetic field, in agreement with the result of recent experiments.

10:12AM A11.00012 Orbital symmetry of charge density wave order in La1.875Ba0.125CuO4 and YBa2Cu3O6.67

DAVID HAWTHORN, ANDREW ACHKAR, University of Waterloo, FEIZHUO HE, RONNY SUTARTO, Canadian Light Source, CHRISTOPHER MCMAHON, University of Waterloo, MARTIN ZWIEBLER, Leibniz Institute for Solid State and Materials Research IFW Dresden, MARKUS HÜCKER, GENDA GU, Brookhaven National Laboratory, RUXING LIANG, DOUG BONN, WALTER HARDY, University of British Columbia, JOCHEN GETK, Leibniz Institute for Solid State and Materials Research IFW Dresden — Recent theories of charge density wave (CDW) order in high-temperature superconductors have predicted a primarily d CDW orbital symmetry. Here, we report on the orbital symmetry of CDW order in the canonical cuprate superconductors La1.875Ba0.125CuO4 (LBCO) and YBa2Cu3O6.67 (YBCO), using resonant soft x-ray scattering and a model mapped to the CDW orbital symmetry. From measurements sensitive to the O sublattice, we conclude that LBCO has predominantly s′ CDW orbital symmetry, in contrast to the d orbital symmetry recently reported in other cuprates. Additionally, we find that the C2 orbital symmetry of the Cu sublattice scattering is approximately preserved in LBCO and broken in YBCO. This work highlights orbital symmetry as an additional key property of CDW order that distinguishes the different cuprate families. We discuss how the CDW symmetry may be related to the “1/8-anomaly” and to static spin ordering.

WEI-LIN TU, Doctoral Candidate, Department of Physics, National Taiwan University, TING-KUO LEE, Director, Institute of Physics, Academia Sinica — One of the most puzzling facts about the cuprate high temperature superconductors is the observation of a variety of low-energy states in coexistence with the superconductivity and/or antiferromagnetism in the underdoped regime. These states could have a unidirectional charge density wave like structure or a bidirectional checkerboard structure. Some of them like the stripe state could also have an intertwined charge density and spin density waves together. Can all these different states caused by different mechanisms and competing with the superconducting state? Can these states also be consistent with the recently observed d-form factor density wave in cuprates? In this talk we will present reasons to show that these states are all originated from the same strong correlation inherent in the cuprates.

10:36AM A11.00014 Spin-Fluctuation-Driven Nematic Charge-Density-Wave in Cuprate Superconductors: Charge-Orbital-Spin Multimode Fluctuations Caused by Vertex Corrections

YOSUKE YAMAKAWA, MASASHI TSUCHIIZU, HIROSHI KONTANI, Department of Physics, Nagoya University — We explain the recently discovered nematic charge-density-wave (CDW) state in cuprate superconductors on the basis of the three-orbital d-Γ Hubbard model, by including the vertex correction (VC) [1]. Due to the strong charge-spin interference given by the VC, the CDW instability at $q = (\Delta_{FS} \cdot 0, 0, \Delta_{FS})$ is strongly promoted near the magnetic critical point. Here, $\Delta_{FS}$ is the wavenumber connected by the neighboring hot spots. The obtained spin-fluctuation-driven CDW is described as the “intra-unit-cell orbital order” accompanied by the charge transfer between the neighboring atomic orbitals. The obtained nematic-type charge pattern is similar to the STM results. The CDW in cuprates has a close relation to the nematic orbital order in Fe-based superconductors. [1] Y. Yamakawa and H. Kontani, arXiv:1406.7520.
10:48AM A11.00015 Charge Order Instability in Doped Resonating Valence Bond State and Magnetic Orbits from Reconstructed Fermi Surface in Underdoped Cuprates1, LONG ZHANG, Tsinghua Univ, JIA-WEI MEI, Perimeter Institute for Theoretical Physics — Recent experiments reveal incommensurate charge density wave (CDW) and quantum oscillations (QO) in the pseudogap phase of underdoped cuprates. In this work, we take a phenomenological synthesis of the resonating valence bond (RVB) state and the CDW order. Starting from the Yang-Rice-Zhang (YRZ) ansatz for the Green’s function of the RVB state, we show that the CDW instability at wavevectors connecting the tips of the Fermi arcs can induce Fermi surface reconstruction. We find three primary magnetic orbits in the QO spectrum, the CDW-induced electron-like \( \alpha \) and hole-like \( \beta \) orbits and the \( \gamma \) orbit enclosing the initial nodal YRZ hole pockets due to magnetic breakdown. Their combinations naturally explain the multi-component QO pattern observed in experiments. The \( \gamma \) orbit encloses an area satisfying the generalized Luttinger theorem. The cyclotron mass of the \( \gamma \) orbit increases monotonically with doping in agreement with the optical Hall angle measurements, while that of the \( \alpha \) orbit is enhanced as the CDW order vanishes on approaching two critical dopings. However, we find that the enhancement of \( m_{\gamma}^* \) is overestimated in QO experiments due to the ignorance of the impact of the CDW order suppression with increasing temperature.

---

Monday, March 2, 2015 8:00AM - 11:00AM — Session A12 DMP: Focus Session: Iridates and Ruthenates 007C - Gang Cao, University of Kentucky

8:00AM A12.00001 X-ray scattering and spectroscopy studies of strongly correlated iridates, YOUNG-JUNE KIM, University of Toronto — Due to strong spin-orbit coupling and electronic correlation, iridates host a number of interesting quantum phases of matter. A broad overview of recent x-ray scattering and spectroscopy studies of iridates on honeycomb, pyrochlore, and square lattice will be given. In particular, we will focus on square lattice iridates, which exhibit physical and magnetic properties remarkably similar to those of cuprates, such as quasi-two-dimensional magnetism and very large magnetic exchange. Various studies found unusual metallic phases in \( \text{Sr}_2\text{IrO}_4 \) doped with charge carriers [1-3]. We examine the case of partially replacing \( \text{Ir}^{4+} \) ions with \( \text{Rh}^{3+} \) ions, which corresponds to a hole-doping. Our magnetic x-ray scattering and x-ray absorption spectroscopy investigation reveal that the suppression of magnetic order and the rise of metallicity is described by a percolation picture [3]. We also obtained magnetic excitation spectra using resonant inelastic x-ray scattering (RIXS), which will be compared with those of cuprates and possible routes to high temperature superconductivity will be discussed [4].

1-3. We examine the case of partially replacing \( \text{Ir}^{4+} \) ions with \( \text{Rh}^{3+} \) ions, which corresponds to a hole-doping. Our magnetic x-ray scattering and x-ray absorption spectroscopy investigation reveal that the suppression of magnetic order and the rise of metallicity is described by a percolation picture [3]. We also obtained magnetic excitation spectra using resonant inelastic x-ray scattering (RIXS), which will be compared with those of cuprates and possible routes to high temperature superconductivity will be discussed [4].

8:36AM A12.00002 High-energy electronic excitations in \( \text{Sr}_2\text{IrO}_4 \) observed by Raman scattering1, JHIH-ANG YANG, YI-PING HUANG, MICHAEL HERMELE, Univ of Colorado - Boulder, TONGFEI QI, GANG CAO, University of Kentucky, DMITRY REZNIK, Univ of Colorado - Boulder — The interplay between spin-orbit interaction, on-site coulomb correlation, crystal field splitting, and inter-site hopping leads to a novel insulating behavior in \( \text{Sr}_2\text{IrO}_4 \) as the realization of the \( J_{\text{eff}} = 1/2 \) state. We report results of a large-shift Raman scattering investigation of electronic excitations in \( \text{Sr}_2\text{IrO}_4 \). We found two high-energy excitations at 690 meV and 680 meV with \( A_{1y} \) and \( B_{1y} \) symmetry respectively. The two peaks have different temperature and Rh-doping dependences. Symmetry analysis of the dd transitions that contribute to Raman signals will also be presented. The observed peaks are consistent with the scenario of excitons associated with inter-site dd transitions without pseudospin-flip.

8:48AM A12.00003 Evolution of Magnetism in Single-Crystal \( \text{Ca}_2\text{Ru}_1-x\text{Ir}_x\text{O}_4 \) \( (0 \leq x \leq 0.65) \), S.J. YUAN, J. TERZIC, J.C. WANG, L. LI, T.F. QI, W.H. SONG, S. ASWARTHAM, G. CAO, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506, USA — We report structural, magnetic, transport and thermal properties of single-crystal \( \text{Ca}_2\text{Ru}_1-x\text{Ir}_x\text{O}_4 \) \( (0 \leq x \leq 0.65) \). \( \text{Ca}_2\text{Ru}_1-x\text{Ir}_x\text{O}_4 \) is a structurally-driven Mott insulator with a metal-insulator transition at \( T_{\text{MI}} = 357 \) K, followed by a well-separated antiferromagnetic order at \( T_N = 110 \) K. Substituting Ru with Ir enhances the spin-orbit coupling (SOC) and causes further orthorhombic distortions. As a result, a pronounced weak ferromagnetic behavior occurs, which enhances dramatically with increasing Ir concentration. The magnetic ordering temperature \( T_N \) increases from 110 K at \( x = 0 \) to 215 K at \( x = 0.65 \), along with enhanced magnetic anisotropy due to SOC. In addition, with increasing \( x \), the metal-insulator transition \( T_{\text{MI}} \) increases initially and vanishes eventually.

9:00AM A12.00004 Ground State Tuning by Spin-Orbit Coupling and Lattice Degrees of Freedom in Single-Crystal \( \text{Ba}_x\text{Ru}_{1-x}\text{O}_3 \) \( (0 \leq x \leq 1) \), K. BUTROUNA, S.J. YUAN, T.F. QI, J. TERZIC, S. ASWARTHAM, L.E. DELONG, G. CAO, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506, USA — \( \text{Ba}_x\text{Ru}_{1-x}\text{O}_3 \) is a magnetic insulator driven by spin-orbit coupling (SOC) whereas \( \text{Ba}_2\text{RuO}_3 \) is a paramagnetic metal. The contrasting ground states provide a unique opportunity to study the role of the SOC and the lattice degrees freedom. Our investigation reveals that substitution of Ru\(^{4+}\) \( (4d^5) \) ions for Ir\(^{5+}\) \( (5d^2) \) ions in \( \text{Ba}_2\text{RuO}_3 \) reduces the magnitude of the SOC and the structural distortion. There are two major effects of Ru additions: (1) Light Ru doping \( (0 \leq x \leq 0.15) \) prompts a simultaneous, precipitous drop in both the magnetic ordering temperature \( T_C \) and the electrical resistivity, which exhibits a crossover behavior from a metallic to an insulating state near \( T_C \). (2) Heavier Ru doping \( (0.41 \leq x \leq 0.9) \) induces a robust metallic state with a strong spin frustration.

9:12 AM A12.00005 Surface Bilateral Symmetry on Orthorhombic Double-layer Sr$_3$(Ru$_{1-x}$Mn$_x$)$_2$O$_7$\(^1\) — CHEN CHEN, JIANDI ZHANG, RONGYING JIN, WARD PLUMMER, Louisiana State University — The double-layered ruthenate Sr$_3$Ru$_2$O$_7$ exhibits very interesting properties especially on the surface because of the broken symmetry (G. Li et al., Scientific Reports 3 2882 (2013)). Compared to the bulk, the surface not only enhances the octahedral rotation but also introduces tilt (not in the bulk). Partial substitution of Mn for Ru reduces the tilt distortion while keeps the rotation angle constant up to ~20% doping. Tilt distortion as expected removes one of the glidelines (associated with rotation) and breaks the mirror symmetry along this broken glideline in the LEED pattern, resulting in a “bilayer symmetry” as a prefect human has. It is surprising that the surface has lost much of the symmetry present in the bulk. When the tilt is removed by increased Mn doping (z) in Sr$_3$(Ru$_{1-z}$Mn$_z$)$_2$O$_7$ the LEED pattern returns to the expected one with two glide planes. In comparison, the LEED pattern of single layer Ca$_1.9$Sr$_0.1$Ru$_2$O$_4$ which has tilt still preserves the mirror symmetry. We assign this difference to the different structures in the first and second octahedral layers.

9:24 AM A12.00006 STM study of lattice distortion effect on Sr$_3$(Ru$_{1-x}$Mn$_x$)$_2$O$_7$ surfaces\(^1\) — JISUN KIM, ZHENGYU DIAO, JIANDI ZHANG, RONGYING JIN, E.W. PLUMMER, Department of Physics and Astronomy, Louisiana State University, Baton Rouge — The Ruddlesden-Popper ruthenates Sr$_{n+1}$Ru$_n$O$_{3n+1}$ (n = 1 to ∞) exhibit a wide range of distinct electronic and magnetic properties due to strong coupling between charge, spin, lattice, and orbital degrees of freedom. For example, substituting Ru with Mn in Sr$_3$Ru$_2$O$_7$ (Sr327) leads to a metal-insulator transition (MIT) at $T_{MIT}$, as well as a magnetic phase transition from paramagnetic at high temperatures to long-range AFM ordering at $T_M$. In the parent compound (x=0), RuO$_2$ octahedra are rotated by ~8° in the bulk and the distortion is enhanced at the surface (12°) with the addition of tilt (~5°). With Mn doping, the rotation of octahedra at the surface does not change but tilt is eliminated. Our recent study of Mn doped Sr327 shows that the surface symmetry and Mn-induced local disturbance observed by scanning tunneling microscope (STM) changes with increasing Mn doping (6 to 16 %), suggesting that the surface electronic properties change with the concentration of Mn doping, driven by the structural change. By studying lower Mn doped Sr327 using STM/STS we delineate the relationship of size of the disturbance induced by Mn to surface metallicity. The result is also compared to 1 % Ti doped Sr327 case.

9:36 AM A12.00007 Novel magnetic states in insulating d$^4$ oxides with strong spin-orbit coupling\(^2\) — CHRISTOPHER SVOBODA, NANDINI TRIVEDI, The Ohio State University — The comparable energy scales in 4d and 5d transition metal oxides, arising from Coulomb correlations, spin-orbit coupling and bandwidth, can lead to new phases and phenomena. With this motivation we examine an isovalent substitution of Ti by Zr in the double perovskite Cu$_2$Ir$_2$O$_6$ in order to explore the nature of the ground state, by crystal field splitting. Upon including spin-orbit coupling, the completely filled $d^4$ manifold is nonmagnetic but with a nonzero magnetic susceptibility. Upon introducing hopping between two $d^4$ atoms, we find novel entangled ferromagnetism generated by the superexchange interaction in a significant part of the phase diagram [1]. We further present results for the temperature dependent susceptibility calculated using exact diagonalization to illustrate this novel magnetic behavior and the role Hund’s coupling plays in producing these phases. We make predictions for resonant X-ray scattering and magnetic measurements in pyrochlore osmates.

\(^2\)We acknowledge the support of the CEM, and NSF MRSEC, under grant DMR-1420451.

9:48 AM A12.00008 Electronic, magnetic and optical properties of Sr$_{n+1}$Ir$_n$O$_{3n+1}$ (n = 1, 2, and ∞)\(^1\) — PEITAO LIU, Faculty of Physics, University of Vienna, Vienna, Austria, SERGII KUMELEVSKYI, Department of Applied Physics, Vienna University of Technology, Vienna, Austria, BONGJAE KIM, Faculty of Physics, University of Vienna, Vienna, Austria, XING-QIU CHEN, DIANZHONG LI, Institute of Metal Research, Chinese Academy of Sciences, Shenyang, China, CESARE FRANCHINI, Faculty of Physics, University of Vienna, Vienna, Austria — We have studied the crossover between metallic/insulating and non-magnetic/magnetic phases in Ruddlesden-Popper series of iridates Sr$_{n+1}$Ir$_n$O$_{3n+1}$ (n = 1, 2, and ∞) by means of density functional theory including an on-site Hubbard U correction and many-body first principles methods. By systematically investigating the evolution of the orbital and spin properties as a function of U, spin-orbit coupling (SOC) strength, and n we have constructed detailed phase diagrams of the metal-insulator transition (MIT) which provide clear evidence for the crucial role played by SOC and U in establishing a relativistic Mott-Hubbard insulating state in the n = 1 and 2 compounds. Optical spectra computed within a model Bethe-Salpeter scheme show the typical double peak structure observed in experiments and capture well the progressive shrinkage of the band-gap and the widening of the bandwidth going from n = 1 to n = ∞. Finally, we clarify the origin of the canted magnetic ground state of Sr$_2$IrO$_3$ as due to the the synergistic effect of structural distortions (rotation and tetragonal distortion of IrO$_6$ octahedral) and to the competition between exchange and Dzyaloshinskii-Moriya interactions.

\(^1\)This work is supported by the China Scholarship Council and Austria Science fund.

10:00 AM A12.00009 Coherent quasiparticles with a small Fermi Surface in lightly doped Sr$_3$Ir$_2$O$_7$. ALBERTO DE LA TORRE, SIOBHAN MCEWOWN WALKER, ANNA TAMAI, University of Geneva, EMILY HUNTER, University of Edinburgh, ALASKA SUBEDI, Ecole Polytechnique, TIMUR KIM, MORITZ HOESCH, Diamond Light Source, ROBIN PERRY, University College London, ANTOINE GAGNÉS, College de France, FELIX BAUMBERGER, University of Geneva — We characterize the electron doping evolution of Sr$_{2n+1}$Ir$_n$O$_{3n+1}$ by means of angle-resolved photoemission. Concomitant with the metal insulator transition around $x \approx 0.05$ we find the emergence of coherent quasiparticle states forming a closed small Fermi surface of volume $3\pi/2$, where $x$ is the independently measured La concentration. The quasiparticle weight $Z$ remains large along the entire Fermi surface, consistent with the moderate renormalization of the low-energy dispersion and no pseudogap is observed. This indicates a conventional, weakly correlated Fermi liquid state with a momentum independent residue $Z \approx 0.5$ in lightly doped Sr$_3$Ir$_2$O$_7$, in stark contrast with underdoped cuprates.

10:12 AM A12.00010 Experimental bandstructure of the 5d transition metal oxide IrO$_2$. JASON KAWASAKI, YUEFENG NIE, Cornell University, MASAKI UCHIDA, University of Tokyo, DARRELL SCHLOM, KYLE SHEN, Cornell University — In the 5d iridium oxides the close energy scales of spin-orbit coupling and electron-electron correlations lead to emergent quantum phenomena. Much research has focused on the ternary iridium oxides, e.g. the Ruddlesden-Poppers A$_{n+1}$B$_n$O$_{3n+1}$, which exhibit behavior from metal to antiferromagnetic insulator ground states, share common features with the cuprates, and may host a number of topological phases. The binary rutile IrO$_2$ is another important 5d oxide, which has technological importance for spintronics due to its large spin Hall effect and also applications in catalysis. IrO$_2$ is expected to share similar physics as its perovskite-based cousins; however, due to bond-length distortions of the IrO$_6$ octahedra in the rutile structure, the extent of similarities remains an open question. Here we use angle-resolved photoemission spectroscopy to perform momentum-resolved measurements of the electronic structure of IrO$_2$. IrO$_2$ thin films were grown by molecular beam epitaxy on TiO$_2$ (110) substrates using an Ir e-beam source and distilled ozone. Films were subsequently transferred through ultrahigh vacuum to a connected ARPES system. Combined with first-principles calculations we explore the interplay of spin-orbit coupling and correlations in IrO$_2$.

10:24AM A12.00011 Magnetic fluctuations induced insulator-to-metal transition in Ca(Ir,Ru)_{1-x}O_3. DEEPAK SINGH, JAGATH GUNASEKERA, ASHUTOSH DAHAL, University of Missouri, Columbia, LELAND HARRIGER, National Institute of Standards and Technology, Gaithersburg, THOMAS HEITMANN, University of Missouri Research Reactor, Columbia — The Fermi liquid theory dictates the metal-insulator transition in a continuous fashion via the divergence of the quasiparticle mass m*. However, the metallic phase near the Mott insulator in the metal-insulator phase diagram based on the Hubbard model is dominated by the fluctuations of spin, charge and orbital correlations; often termed as the anomalous metallic phase. In this presentation, experimental results manifesting the magnetic fluctuations induced insulator-to-metal transition in Ca(Ir,Ru)_{1-x}O_3 will be discussed in the framework of the Hubbard model. For x = 1, the compound CaIrO_3 is a Mott insulator with antiferromagnetic order below T ~ 110 K. A gradual substitution of Ir by Ru results in the onset of anomalous metallic behavior as a function of the tuning parameter x. At x = 0, the compound CaRuO_3 is a non-Fermi liquid metal with no apparent magnetic order. While the orthorhombic structural integrity is maintained throughout the group, strong magnetic fluctuations is detected below x = 0.8. The role of magnetic fluctuations in the metallic transition is further confirmed by first principle theoretical calculation.

10:36AM A12.00012 Magneto-optical transmission of Bi_2Se_3 at the fundamental absorption edge. GERARD MARTINEZ, MILAN ORLITA, BENJAMIN PIOT, MAREK POTEMSKI, LNCMI, CNRS, France, YEW SAN HOR, Missouri University of Science and Technology, MO, USA, G. STRZELECKA, A. HRUBAN, Institute of Electronic Materials, Warsaw, Poland — Magneto-optical transmission spectroscopy of a series of n-type Bi_2Se_3 samples have been performed, around the fundamental absorption edge, up to 32 T. The absorption edge splits in two components, offset by about 0.2 eV. The first component is associated with the spin splitting of the 3d states of Se_2p. The second component, corresponding to the spin splitting of the 5d states of Bi_5s. The splitting increases linearly with the magnetic field up to a critical value B_c depending on the carrier density, beyond which it remains constant. This corresponds to a complete spin polarization of the compound. The consequences of this specific property put some constrains on the parameters of the Hamiltonian describing the system.

10:48AM A12.00013 Quasi-local critical nature of cooperative paramagnetic fluctuations in CaRuO_3 metal. JAGATH GUNASEKERA, Univ of Missouri - Columbia, LELAND HARRIGER, NIST, THOMAS HEITMANN, MURR, DEEPAK SINGH, Univ of Missouri - Columbia — Ruthenate perovskites of the form ARuO_3, where A is an alkaline earth metal, hold strong promises in developing new paradigm of the quantum magnetism. CaRuO_3 is of special interest among this group. The unusual combination of the absence of magnetic order and the anomalous non-Fermi liquid properties makes it an archetypal perovskite for the exploration of the quantum magnetism. Recently, we performed detailed electric, magnetic and neutron scattering measurements on high quality polycrystalline sample of CaRuO_3. The experimental results suggest that the underlying magnetism is depicted by the quantum mechanical fluctuations of Ru^{4+} spins, confined to field-independent random domains that form a cooperative paramagnetic state at low temperature. The dynamic structure factor, which increases significantly below T ~ 22 K, manifests a linear (E^2T) scaling, implying the Curie-Weiss type fluctuations with temperature as the most relevant parameter. Moreover, the linear dynamic scaling in conjunction with the divergence of the spin fluctuations mean relaxation time as T ~ 0 K suggest the existence of a quasi-local critical behavior in the system.

Monday, March 2, 2015 8:00AM - 11:00AM — Session A13 DMP: Focus Session: Titania Interfaces and Heterostructures 007D - Roman Engel-Herbert, Pennsylvania State University

8:00AM A13.00001 Thermal and photoconductivity at the La_{1-x}Sr_{x}CrO_{3}/SrTiO_{3}(001) interface. SCOTT CHAMBERS, Pacific Northwest National Laboratory — We have investigated the electronic and photophysical properties of interfaces between La_{1-x}Sr_{x}CrO_{3} and SrTiO_{3}(001) as prepared by molecular beam epitaxy. LaCrO_3 is a III-II antiferromagnetic insulator whereas SrCrO_3 is a II-IV metallic oxide. Substituting Sr^{2+} for La^{3+} in LaCrO_3 effectively dopes holes into the top of valence band, reducing the band gap and the resistivity, and generating a p-type oxide semiconductor. In contrast, SrTiO_3 is a wide-gap II-IV semiconductor that is readily made n-type by La doping. Therefore, the La_{1-x}Sr_{x}CrO_{3}/SrTiO_{3}(001) system has much potential for interesting interface physics with regard to studying intrinsic conductivity via electronic reconstruction and electron-hole pair separation under light irradiation. However, there are inherent physical and chemical complexities at these interfaces and within the bulk of the La_{1-x}Sr_{x}CrO_{3} films which can have profound effects on the associated functional properties. In this talk, we present some of our most recent results from this ongoing investigation.

In collaboration with Kelvin Zhang, Du Yingge, Sushko Peter, Bowden Mark, Shuttanandan V, Pacific Northwest National Laboratory; and Shawn Sallis, Louis Piper, Binghamton University.

8:36AM A13.00002 ABSTRACT WITHDRAWN —

8:48AM A13.00004 Extreme high-density electron gas using band engineered complex oxide interfaces. PENG ANDREW XU, Univ of Minn - Minneapolis, TIMOTHY C. DROUBAY, Pacific Northwest National Laboratory, JONG SEOK JEONG, Univ of Minn - Minneapolis, SCOTT A. CHAMBERS, Pacific Northwest National Laboratory, ANDRE K. MKHOYAN, BHARAT JALAN, Univ of Minn - Minneapolis — The study of interfaces between polar and non-polar complex oxides has seen unprecedented growth due to their unique ability to display interface-stabilized ground states including high-density two-dimensional electron gas (equivalent to 0.5 electron/u.c./interface). In this talk, we will present thickness dependent structural and electronic transport study of the MBE-grown NdTiO_3/SrTiO_3 heterostructures. High-resolution x-ray diffraction, atomic force microscopy, reflection high-energy electron diffraction, scanning transmission electron microscopy and different spectroscopy techniques reveal nearly stoichiometric composition and abrupt interfaces. We will review the long-standing question on the origin of carriers at oxide semiconductor interface and present an approach to combine the high carrier density of 2DEG oxides with a higher mobility medium in order to realize the combined benefits of higher mobility and carrier density.

1This work is supported partially by NSF through UMN MRSEC and the office of vice president for research, UMN.

9:00AM A13.00004 Band offset engineering of 2DEG oxide systems on Si. ERIC JIN, LIOR KORNBLUM, DIVINE KUMAH, KE ZOU, Yale Univ, CHRISTINE BROADBRIDGE, Southern Connecticut State Univ, JOSEPH NGAI, Univ of Texas at Arlington, CHARLES AHN, FRED WALKER, Yale Univ — The discovery of 2-dimensional electron gases (2DEGs) at perovskite oxide interfaces has sparked much interest in recent years due to their large carrier densities when compared with semiconductor heterostructures. For device applications, these oxide systems are plagued by low room temperature electrical densities. We present an approach to combine the high carrier density of 2DEGs with a higher mobility medium in order to realize the combined benefits of higher mobility and carrier density. We grow epitaxial films of the interfacial oxide system LaTiO_3/SrTiO_3 (LTO/STO) on silicon by molecular beam epitaxy. Magnetotransport measurements show the sheet carrier densities of the heterostructures scale with the number of LTO/STO interfaces, consistent with the presence of a 2DEG at each interface. Sheet carrier densities of 8.9 x 10^{14} cm^{-2} per interface are measured. Band offsets between the STO and Si are obtained, showing that the conduction band edge of the STO is close in energy to that of silicon, but in a direction that hinders carrier transfer to the silicon substrate. Through modification of the STO/Si interface, we suggest an approach to raise the band offset in order to move the 2DEG from the oxide into the silicon.
9:12AM A13.00005 High-carrier-density phase in LaTiO$_3$/SrTiO$_3$ superlattices$^1$. SE YOUNG PARK, KARIN RABE, Rutgers University, ANDREW MILLIS, Columbia University — We investigate superlattices composed of alternating layers of Mott insulating LaTiO$_3$ and band insulating SrTiO$_3$ from first principles, using the density functional theory plus U (DFT+U) method. For values of U above a critical threshold, we find that melting of the Mott-insulating phase can extend from the interface into the LaTiO$_3$ layer, resulting in a sheet carrier density exceeding the density of 0.5 electrons per in-plane unit cell found in previous studies. The critical U for the melting transition is larger than the critical Coulomb correlation required for the insulating LaTiO$_3$, suggesting the existence of a high sheet carrier density phase in LaTiO$_3$/SrTiO$_3$ superlattices. The effects of in-plane strain and varying layer thickness on the melting transition are discussed. For insulating superlattices, we study the strain and thickness dependence of the polarization and its relation to near-interface local atomic distortions.

1Support: DOE ER 041669, ONR N00014-11-0666

9:24AM A13.00006 Phase diagram and high density two-dimensional electron gas at the LaAlO$_3$/La$_{0.5}$Sr$_{0.5}$TiO$_3$/SrTiO$_3$ heterostructures. HAILIAO MA, NUSNNI-Nanocore and Physics Department, NUS, ZHEN HUANG, SHENGWEI ZENG, ANIL ANNADI, NUSNNI-Nanocore, NUS. THIRUMALAI VENKY VENKATESAN, ARIANDO ARIANDO, NUSNNI-Nanocore and Physics Department, NUS, ARIANDO RESEARCH GROUP TEAM$^1$ — We report a two dimensional electron gas with a high carrier density at the LaAlO$_3$/La$_{0.5}$Sr$_{0.5}$TiO$_3$/SrTiO$_3$ heterostructures, reaching a value of about five times higher than that observed at the LaAlO$_3$/SrTiO$_3$ interface. The La$_{0.5}$Sr$_{0.5}$TiO$_3$ polar layer is introduced to preserve the degeneracy of the Ti $t_{2g}$ orbitals and minimize the disorder at the LaAlO$_3$/La$_{0.5}$Sr$_{0.5}$TiO$_3$/SrTiO$_3$ interface. Various thickness combinations of La$_{0.5}$Sr$_{0.5}$TiO$_3$ and LaAlO$_3$ layers are used for tuning the total internal potential of the polar layer responsible for the charge transfer. Experimental data showed that the carrier density increases by raising the total internal potential, and this is in a good agreement with a simple electrostatic model. A complete metal-insulator phase diagram is obtained, which shows that at least 3.15 eV polar potential is needed to form the metallic interface at the SrTiO$_3$, providing an estimate for the critical thickness needed for the metallic phase. Nonlinear Hall effect was observed below 60 K which can be understood by multiple filling of the degenerated orbitals responsible for multiple band electronic conductions.

9:36AM A13.00007 Induced Itinerant Antiferromagnetism in SrTiO$_3$. BRANDON ISAAC, EVGENY MIKHEEV, CHRIS FREEZE, SUSANNE STEMMER, University of California, Santa Barbara — Interfaces between RTiO$_3$ (R = Gd or Sm) and SrTiO$_3$ grown by molecular beam epitaxy induce a high-density two-dimensional electron gas (2DEG). Such 2DEGs show evidence of strong electron correlation effects, including non-Fermi liquid behavior, and a non-trivial magnetoresistance. Here we present magneto-transport measurements of SmTiO$_3$/SrTiO$_3$/SmTiO$_3$ quantum well structures to investigate induced, itinerant, antiferromagnetic ordering in the SrTiO$_3$ through proximity to the SmTiO$_3$. At low temperatures, the Hall effect, the longitudinal resistance, and the magnetoresistance all show evidence of itinerant antiferromagnetism. For example, the longitudinal resistance shows deviations from the logarithmic correction of weak localization, and the Hall effect indicates opening of a gap and loss of carriers. The results will be discussed in terms of a possible spin-density wave formation and gap opening on the Fermi surface.

9:48AM A13.00008 Pseudogaps in SrTiO$_3$. Quantum Wells. PATRICK MARSHALL, SANTOSH RAGHAVAN, EVGENY MIKHEEV, SUSANNE STEMMER, Univ of California - Santa Barbara — A departure from Fermi liquid behavior appears in molecular beam epitaxy grown SrTiO$_3$ quantum wells embedded in the antiferromagnetic insulator SmTiO$_3$, suggesting proximity to a quantum critical point. We will report on the observation of pseudogap behavior in SmTiO$_3$/SrTiO$_3$/SmTiO$_3$ quantum wells via tunneling spectroscopy measurements. Tunnel junction devices with SrZrO$_3$ barriers grown in-situ were fabricated from quantum wells of varying thickness. The tunneling conductance spectra of these devices revealed the formation of a pseudogap in the density of states upon cooling, indicating the onset of non-Fermi liquid behavior. The pseudogap state was most pronounced in thin quantum wells, persisting up to nearly 200 K in the well containing only 2 SrO layers. The pseudogap was absent in the thickest wells, which showed only a small suppression of the density of states with a logarithmic dependence on bias resulting from disorder. The results are compared to tunneling spectra of GdTiO$_3$/SrTiO$_3$/GdTiO$_3$ quantum wells, providing insight into the role of structural distortion and octahedral tilts on the electronic structure and quantum critical behavior in oxide heterostructures.

10:00AM A13.00009 Tunable Orbital-Selective Magnetic Interaction in Tricolor Oxide Interfaces. YANWEI CAO, MICHAEL KAREEV, XIAORAN LIU, DEBRAJ CHOUHDURY, SRIMANTA MIDDEY, DEREK MEYERS, JAK CHAKHALIAN, University of Arkansas — Several recent theoretical scenarios of orbital-selective magnetic interactions were proposed to understand the emergence of the unexpected interfacial magnetism in the archetypal SrTiO$_3$-based two-dimensional electron gas systems, the origin of which is still intriguing and not an entirely understood phenomenon in oxide interface physics. Experimentally, however, there thus far lacks a material system to directly demonstrate the magnetic interaction with orbital-selection (dxy vs. dxz/dyz) and eventually manipulate this magnetic interaction. To address this, here we induced 2DEG and localized magnetism in the same SrTiO$_3$ layer by devising the heterostructure LaTiO$_3$/SrTiO$_3$/YTiO$_3$. Combined electrical transport and atomic-resolved scanning transmission electron microscope with electron energy loss spectroscopy revealed that the magnetic localized electrons are formed by the spin transfer from the YTiO$_3$ layer into 2DEG formed at the LaTiO$_3$/SrTiO$_3$ interface, with the orbital occupancy and strength of the magnetic interaction controlled by the SrTiO$_3$ layer thickness. Our work provides an ideal platform to explore the orbital physics driven by the interfacial magnetism with prospects for exciting spintronic applications.

10:12AM A13.00010 High electron density 2DEGs at 111 SrTiO$_3$/SmTiO$_3$ interfaces. SANTOSH RAGHAVAN, SUSANNE STEMMER, University of California Santa Barbara, STEMMER RESEARCH GROUP TEAM — (001) SrTiO$_3$ quantum wells formed in structures such as RTiO$_3$/SrTiO$_3$/RTiO$_3$ (R = Gd or Sm) exhibit two dimensional electron gases (2DEGs) that exhibit ferromagnetism and non-Fermi-liquid behavior. 2DEGs are also expected for (111) quantum wells, which furthermore form a honeycomb lattice that is susceptible to geometric frustration and nontrivial band structures. In this work, we present the growth of high quality SrTiO$_3$ and SmTiO$_3$ layers on (111) LSAT substrates using a hybrid molecular beam epitaxy technique. Structural and electrical characterization show atomically sharp (111) interfaces between SrTiO$_3$ and SmTiO$_3$, and the presence of a high charge carrier density of $\sim 3 \times 10^{13}$ cm$^{-2}$. We will discuss results of magneto-transport studies in highly confined quantum wells that are only a few atomic planes thick and compare them with results from (001) interfaces.

10:24AM A13.00011 ABSTRACT WITHDRAWN —
10:36AM A13.00012 Thickness dependent metal-insulator transition in GdTiO$_3$/SrTiO$_3$ superlattices$^1$, ANDERSON JANOTTI, LARS BJAALIE, BURAK HIMMETOGLU, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — SrTiO$_3$ (STO) is at the core of recent discoveries of two-dimensional electron gas (2DEG) formation at complex oxide interfaces, with the 2DEG residing on the STO side. Experimental results for ultrathin STO layers inserted in GdTiO$_3$ reveal a transition from metallic to insulating behavior, and suggest a strong interplay between electron-electron interaction and lattice distortions. Using first-principles calculations we investigate the evolution of the electronic structure of STO/STO superlattices as a function of the thickness of the STO layer. We show that the metal-to-insulator transition is a bulk property of STO that emerges at extreme doping levels [1]. For thick STO layers, we find a two-dimensional electron gas with a density of 1/2 electron per unit-cell area per interface within the STO. However, once the STO layer thickness is reduced below three layers, we find that the electrons localize on every second interface Ti atom, giving a charge-ordered Mott-insulating phase. This onset of localization is analyzed in terms of the electron density in the STO layer and octahedral distortions at the interface. The Mott-insulator phase is shown to occur both in STO/LaAlO$_3$ and STO/GdTiO$_3$ heterostructures with ultrathin STO layers.

10:48AM A13.00013 Mixed-valence magnetism in TiO$_2$/Ti$_2$O$_3$ superlattices, W.C. HSIEH, National Sun-Yat Sen University, Taiwan, P.V. WADEKAR, University of Liverpool, UK, H.C. HUANG, C.F. CHANG, National Sun-Yat Sen University, Taiwan, M.S. WONG, National Dong Hua University, Taiwan, H.W. SEO, University of Arkansas, USA, F.C. CHUANG, Q.Y. CHEN, National Sun-Yat Sen University, Taiwan — Epitaxial TiO$_2$ and Ti$_2$O$_3$ superlattices, ~ 1-nm thick per layer by sputtering at 570°C using pure argon on sapphire substrates. From HR-TEM, the periodically alternating layers are well-defined. XPS analyses based on the binding energy of Ti 2p$_{3/2}$ peaks suggest the co-existence of Ti$^{3+}$ and Ti$^{4+}$, thus verifying the mixed-valence nature. The M(H) curves measured at room temperature using SQUID showed hysteretic loops typical of ferromagnetism. Electrical transport measurements were done at zero field demonstrate transition of charge ordering at low temperatures, reminiscent of what was found in Ti-rich Ti$_{1+x}$O$_2$ single-layer thin films, made by Ti ion implantation into TiO$_2$ crystals, in which randomly distributed TiO$_2$, Ti$_2$O$_3$ and TiO were found to coexist. Preliminary First-principle (ab initio) calculations to understand the roles of oxygen vacancies in various TiO$_2$ super-cells could indeed lead to spontaneous magnetizations. We thus argue that mixed-valence titanium ions are responsible for the magnetism.

Monday, March 2, 2015 8:00AM - 11:00AM – 
Session A14 DMP: Focus Session: Quantum Phase Transitions And Quantum Criticality 008A
- Vivien Zapf, Los Alamos National Laboratory

8:00AM A14.00001 Transport signatures of Majorana ferromagnetism realized by dissipative resonant tunneling, HUAIXIU ZHENG, Departments of Physics and Applied Physics, Yale University, New Haven, Connecticut 06511, USA, SERGE FLORENS, Institut Neel, CNRS and UJF, 25 avenue des Martyrs, BP 166, 38042 Grenoble, France, HAROLD BARANGER, Department of Physics, Duke University, P. O. Box 93055, Durham, North Carolina 27708, USA — We consider theoretically the transport properties of a spinless resonant electronic level coupled to strongly dissipative leads, in the regime of circuit impedance near the resistance quantum [1]. Using the Luttinger liquid analogy, one obtains an effective Hamiltonian expressed in terms of interacting Majorana fermions, in which all environmental degrees of freedom (leads and electromagnetic modes) are encapsulated in a single fermionic bath. A perturbative treatment of the Majorana interaction term yields the appearance of a marginal, linear dependence of the conductance on temperature when the system is tuned to its quantum critical point, in agreement with recent experimental observations [2].

8:12AM A14.00002 Metallic transport near a quantum critical point in organic superconductors from a renormalized Boltzmann theory, MARYAM SHAHBAZI, CLAUDE BOURBONNAIS, Regroupement Québécois des Matériaux de pointe, Département de Physique, Université de Sherbrooke, Sherbrooke, QC, Canada J1K 2R1 — The electrical and thermal transport properties of the normal state of quasi-1D superconductors like Bechgaard salts are investigated by combining the linearised Boltzmann equation and the renormalisation group (RG) method. The collision integral operator is calculated using the Umklapp scattering amplitudes obtained by the RG method yielding the electrical resistivity($\rho$) and Seebeck coefficient ($S$). The power law dependence, $\rho(T) \sim T^\alpha$, for resistivity is obtained by changing the antining parameter $t'_r$, simulating the pressure distance from the quantum critical point (QCP) between spin-density-wave (SDW) and d-wave SC (SCd) in the phase diagram. The resistivity evolves from a linear component ($\alpha \approx 1$) to the QCP towards a Fermi liquid component ($\alpha \approx 2$) with increasing $t'_r$, which confirms an extended region of quantum criticality as a result of interference between SCd and SDW causing an anomalous growth of Umklapp scattering. Its anisotropy is also tied to the $k_z$-dependence of hot/cold scattering regions along the Fermi surface. Similar calculations for the Seebeck coefficient show deviations from the usual linear temperature dependence and also a change of sign near a SDW instability.

8:36AM A14.00004 Higgs criticality in a two-dimensional metal, SUBIR SACHDEV, DEBANJAN CHOWDHURY, Harvard Univ — We analyze a candidate theory for the strange metal near optimal hole-doping in the cuprate superconductors. The theory contains a quantum phase transition between metals with ‘large’ and ‘small’ Fermi surfaces, but the transition does not directly involve any broken global symmetries. The two metals have emergent SU(2) and U(1) gauge fields respectively, and the transition is driven by the condensation of a real Higgs field which carries an adjoint SU(2) charge. We propose a global phase diagram around this Higgs transition, and describe its relationship to a variety of recent experiments on the cuprate superconductors.
Quantum Criticality In Layered YFe<sub>2</sub>Al<sub>10</sub>

Quantum critical point of Dirac fermions studied using efficient continuous-time projector quantum Monte Carlo method  
Lei Wang, Mauro Iazzì, ETH - Zurich, Philippe Corboz, University of Amsterdam, Matthias Troyer, ETH - Zurich — Quantum phase transition (QPT) of Dirac fermions is a fascinating topic both in condensed matter and in high energy physics. Besides its immediate connection to fundamental problems like mass generation and exotic phases of matter, it provides a common playground where the state of the art numerical simulations can be crosschecked with various effective field theory predictions, thus deepen our understanding of both fields. The universality class of the QPT is fundamentally different from the usual bosonic field theory because of the coupling to the gapless fermionic mode at the critical point. We study lattice models with spinless and multi-flavor Dirac fermions using the newly developed efficient continuous-time projector quantum Monte Carlo method. Besides eliminating the Trotter error, the method also enables us to directly calculate derivative observables in a continuous range of interaction strengths, thus greatly enhancing the resolution of the quantum critical region. Compatible results are also obtained from infinite projected entangled-pair states calculations. We compare these numerical results with predictions of the Gross-Neveu theory and discuss their physical implications.

Quantum phase transitions in the Kondo-necklace model  
Nader Ghassemi, Shayan Hemmatiyan, Department of Physics, Texas A&M University, College Station, TX 77843-4242, Mahsa Rahimi Movassagh, Department of Physics, McMaster University, ON L8S 4L8, Canada, Mahdi Kargarian, Department of Physics, University of Texas at Austin, Austin, Texas 78712-1081, USA, Ali T. Rezakhani, Abdollah Langari, Department of Physics, Sharif University of Technology, Tehran 11155-9161, Iran — Kondo-necklace model, which includes an additional spin degree of freedom, exhibits unique quantum phase transitions due to the strong quantum correlations. We study these phase transitions using the time projector quantum Monte Carlo method. Besides eliminating the Trotter error, the method also enables us to directly calculate derivative observables in a continuous range of interaction strengths, thus greatly enhancing the resolution of the quantum critical region. Compatible results are also obtained from infinite projected entangled-pair states calculations. We compare these numerical results with predictions of the Gross-Neveu theory and discuss their physical implications.

Emergent space-time supersymmetry in 3D Weyl semimetals and 2D Dirac semimetals  
Shao-Kai Jian, Yi-Fan Jiang, Hong Yao, Institute for Advanced Study, Tsinghua University — Supersymmetry (SUSY) interchanges bosons and fermions but no direct evidences of it have been revealed in nature yet. In this paper, we observe that fluctuating pair density waves (PDW) phase of the spinless honeycomb model with nearest neighbor attractions by doing fermionic projected entangled pairing state (PEPS) algorithm for infinite lattices. It was recently shown by renormalization group (RG) analysis that space-time supersymmetry (SUSY) emerges in Dirac fermions at their PDW transition. The connection of our present PEPS studies with the emergent space-time SUSY at the PDW transition shown by RG will be discussed.

10:00AM A14.00011 How Ubiquitous is Total Electron Transmission through Nanostructures (Quantum Dragons)?¹, MARK NOVOTNY, Mississippi State University — In transport through nanostructures connected to two semi-infinite leads, the transmission probability \( T(E) \) as a function of the energy \( E \) of the incoming electron plays a central role in the Landauer calculation of the electrical conductance \( G \). A quantum dragon nanostructure [1] is one which when connected to appropriate leads has total electron transmission for all energies, \( T(E)=1 \).

In two-terminal measurements of single-channel quantum dragons, the quantum of conductance, \( G_0=2e^2/h \), should be observed. A quantum dragon may have strong scattering. In [1] the disorder was along the axis of electron propagation, the \( z \) axis. We show that quantum dragon nanostructures can be found for strong disorder perpendicular to the \( z \) axis. In select types of nanostuctures, we find the ratio of the dimension of the parameter space where quantum dragons exist to that of the complete parameter space. The results use the single-band tight-binding model, and are for the case with only one open channel and homogeneous leads. One type of nanostructure with \( T(E)=1 \) has completely disordered slices perpendicular to the \( z \) axis, but identical slices along the \( z \) direction. [1] M.A. Novotny, Phys. Rev. B 90, 165103 [14 pages] (2014)

¹Supported in part by NSF grant DMR-1206233.

10:12AM A14.00012 Single and Multi-channel Quantum Dragons from Rectangular Nanotubes, ZHOU LI, MARK NOVOTNY, Mississippi State University — Recently quantum dragons have been discovered theoretically [1]. Quantum dragons are nanostructures with correlated disorder that permit energy-independent total quantum transmission of electrons. Hence the electrical conductance \( G \) in a two-terminal measurement should be the conductance quantum \( G_0=2e^2/h \). The single-band tight binding model is used.

An example of a single-channel quantum dragon is a rectangular nanotube with disorder along the direction \( z \) of the electron propagation [1]. Quantum dragons are obtained by solving the time-independent Schrödinger equation to obtain the electrical transmission \( T \) as a function of the incoming electron energy \( E \). A quantum dragon has \( T(E)=1 \) for all energies. This work generalizes the solution of the time-independent Schrödinger equation to the case of more than one open channel, and applies the method to nanotubes formed from rectangular lattices. One can envision such single-walled rectangular nanotubes for iron starting from free-standing single-atom-thick Fe membranes which have recently been obtained experimentally [2].

¹Supported in part by NSF grant DMR-1206233

10:24AM A14.00013 Single and Multi-Channel Carbon-based Quantum Dragons¹, GODFRED INKoom, Mississippi State University, OMADILLO ABDURAZAKOV, NCSU, MARK NOVOTNY, Mississippi State University — In the coherent regime for electrical conductance measurements, two semi-infinite leads are connected to a finite nanostructure, and the nano-device conductance is calculated using the Landauer formula. Any channel \( k \) that has transmission for electrons with energy \( E \), \( T_k(E)=1 \) contributes the conductance quantum \( G_0=2e^2/h \). Any nano-device with at least one \( T_k(E)=1 \) is called a quantum dragon [1]. The transmission probability \( T_k(E) \) can be obtained from the solution of the time-independent Schrödinger equation. Uniform leads connected to armchair single-walled carbon nanotubes (SWCNTs) have \( T(E)=1 \), while when connected to zigzag SWCNTs the \( T(E) \) is less than unity. Appropriately dimerized leads connected to zigzag SWCNTs are quantum dragons, while when connected to armchair SWCNTs \( T(E) \) is less than unity [1]. We have generalized the matrix method and mapping methods of [1] in order to investigate SWCNTs that can be multi-channel quantum dragons. For example, one can use armchair SWCNT leads to connect to an armchair SWCNT to try to produce a multi-channel quantum dragon.

¹Supported in part by NSF grant DMR-1206233

10:36AM A14.00014 Quantum degradation of the second order phase transitions, SERGEI STISHOV, ALLA PETROVA, Institute for High Pressure Physics of RAS, Troitsk, Russia, SERGEY GAVRILKIN, P. N. Lebedev Physical Institute of RAS, Leninsky pr., 53, 119991 Moscow, Russia, LUBOV KLINKOVA, Institute of Solid State Physics of RAS, Chernogolovka, Moscow District, Russia — The specific heat, magnetization and thermal expansion of single crystals of antiferromagnetic insulator EuTe were measured at temperatures down to 2 K and in magnetic fields up to 90 kOe. The Neel temperature, being \(~9.8\) K at \( H=0 \), decreases with magnetic field and tends to zero at \(~76\) kOe, therefore forming the quantum critical point. The heat capacity and thermal expansion coefficient reveal \( \lambda \)-type anomalies at the second order magnetic phase transition at low magnetic fields, evolving to simple jumps at high magnetic fields and low temperatures, well described in a fluctuation free mean - field theory. The experimental data and the corresponding analysis favor the quantum concept of effective increasing space dimensionality at low temperatures that suppresses a fluctuation divergence at a second order phase transition.

10:48AM A14.00015 Dynamic spin susceptibility of interacting electron systems¹, VLADIMIR ZYUZIN, DMITRII MASLOV, University of Florida — We study the dynamic spin susceptibility of interacting electrons in spatial dimensions from one to three. In all cases, backscattering processes result in non-zero imaginary part of the spin susceptibility above the particle-hole continuum of non-interacting electrons. In one dimension, we employ the renormalization group to go beyond the second order and obtain a general expression for the spin susceptibility. In higher dimensions, we show that the imaginary part of the spin susceptibility arises from the same mechanism as non-analytic corrections to the Fermi-liquid theory. We relate the obtained results to the lifetime of collective spin modes.

8:00AM A15.00001 First-principles interpretation of attosecond time-resolved XUV absorption spectroscopy of laser excited Silicon, SRI CHAITANYA DAS PEMMARAJU, Lawrence Berkeley Natl Lab, SHUNSUKE SATO, KAZUHIRU YABANA, University of Tsukuba, KRUPA RAMASESHA, University of California, Berkeley, MARTIN SCHULTZE, Ludwig-Maximilians-Universitat, STEPHEN R. LEONE, University of California, Berkeley, DAVID PRENDERGAST, Lawrence Berkeley Natl Lab — The availability of ultrafast x-ray pulses both from powerful free electron laser light-sources as well as table top high-harmonic generation, has significantly enhanced the utility of core-level spectroscopies as probes for investigating dynamical processes in functional materials. Theoretical approaches to complement these time-domain experiments are therefore actively being developed. In this study we employ a combination of real-time time-dependent density functional theory (TDDFT), occupancy-constrained density functional theory and many-body perturbation theory approaches to help interpret spectral signatures observed in attosecond time-resolved core-level spectroscopic measurements on laser-excited silicon. Using non-equilibrium electron-hole densities obtained from real-time TDDFT simulations of the valence electronic structure we estimate the transient modulation of L-edge absorption in femtosecond infrared pump - attosecond XUV probe experiments. We further estimate the contribution of electron-phonon and electron-electron scattering mechanisms to the lifetime broadening observed in measured L-edge spectra using occupation-constrained density functional theory and GW calculations respectively.

8:12AM A15.00002 First-principles calculation of electronic structure and optical absorption of BN ZnO, XIAO ZHANG, ANDRE SCHLIEFE, Univ of Illinois - Urbana — The α-BN structure of ZnO, a nonequilibrium phase with a transition pressure of 25 GPa, has been found in nano structures of ZnO. The structural difference between the BN structure and the equilibrium wurtzite structure can play an important role for applications of nanostructured ZnO. In order to understand the difference, first principles calculations have been performed on both phases. The electronic structure is computed using the GW method based on Density Functional Theory and HSE hybrid functional calculations. The GW method includes the quasiparticle effects due to the screened electron-electron interaction which gives an accurate description of the electronic band structure and density of states. After that, by solving the Bethe-Salpeter Equation for the optical polarization function, which take excitonic effects into account, we have achieved an accurate description of optical absorption spectra for both structures. We find a good agreement with experimental and previous computational results for WZ structure, and predict the absorption for the BN structure. The BN structure shows a larger band gap and we found a very large optical anisotropy: The gap for extraordinary light polarization is almost 0.7eV larger than that for ordinary light polarization.

8:24AM A15.00003 Wannier function analysis of charge states in transition metal oxides1, YUNDI QUAN, WARREN PICKETT, Univ of California - Davis — The charge (or oxidation) state of a cation has been a crucial concept in analyzing the electronic and magnetic properties of oxides as well as interpreting “charge ordering” metal-insulator transitions. In recent years a few methods have been proposed for the objective identification of charge states, beyond the conventional (and occasionally subjective) use of projected densities of states, weighted band structures (fatbands), and Born effective charges. In the past two decades Wannier functions (WFs) and particularly maximally localized WFs (MLWFs), have become an indispensable tool for several different purposes in electronic structure studies. These developments have motivated us to explore the charge state picture from the perspective of MLWFs. We will illustrate with a few transition metal oxide examples such as AgO and YNiO3 that the shape, extent, and location of the charge centers of the MLWFs provide insights into how cation-oxygen hybridization determines chemical bonding, charge distribution, and “charge ordering.”

8:36AM A15.00004 DFT+U invsitgation of doped-PbPdO2 spin gapless semiconductors, HAN HSU, SHENG-CHIEH HUANG, National Central University — Spin gapless semiconductors (SGSs), with a zero gap in one spin channel and a finite gap in the other, have attracted considerable attention due to their potential in spintronics. Ever since PbPdO2 was predicted a gapless semiconductor by local density approximation (LDA) calculations and confirmed by experiments afterward, it is anticipated to be a backbone material for SGS. Using density functional theory + self-consistent Hubbard U (DFT+U) calculations, we investigate doped PbPdO2 with different kinds of transition-metal dopants, including V, Cr, Mn, Fe, Co, and Ni, at different dopant concentration. We show that doped PbPdO2 can be a SGS with a proper choice of dopant and dopant concentration. Furthermore, different dopant and dopant concentration can lead to different types of SGS.

8:48AM A15.00005 Final-state effect on X-ray photoelectron spectrum of n-doped SrTiO3, CHUNGHWEI LIN, AGHAM POSADAS, ALEXANDER DEMKOV, UT Austin, Physics Department, DEMKOV TEAM — X-ray photoelectron spectroscopy (XPS) is a widely used technique to determine the oxidation states of chemical elements. In stoichiometric SrTiO3, the Ti4+ peak appears at a binding energy of about 459.0 eV for photoelectrons ejected from the Ti 2p core level. In lightly n-doped SrTiO3, a weak shoulder at a binding energy of about 1.5 eV lower than the Ti4+ peak appears in the XPS spectrum which has been conventionally interpreted as a Ti3+ signal. By taking the final-state effect into account, i.e. by considering the response of the valence electrons in the presence of a core hole, we argue that such a Ti3+ peak does not necessarily imply the existence of spatially localized Ti3+ ions, and explicitly show that a spatially uniform Ti(4−z)+ distribution also leads to the multi-peak structure. Spectra from metallic n-doped SrTiO3 (e.g. La replacing Sr, Nb replacing Ti, or even oxygen vacancy doping) should be interpreted as the latter case. Several experiments based on this interpretation are discussed.

9:00AM A15.00006 Test set for materials science and engineering, TOKTAM MORSHEDLOO, Fritz-Haber-Institut der MPG, Berlin, DE; Ferdowsi University of Mashhad, IR, NORINA A. RICHTER, FAWZI MOHAMED, Fritz-Haber-Institut der MPG, Berlin, DE, XINGUO REN, Fritz-Haber-Institut der MPG, Berlin, DE; University of Science and Technology of China, China, SERGEO V. LEVCHENKO, LUCA M. GHIRINGHELLI, ICOR YING ZHANG, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, DE — Understanding of the applicability and limitations of electronic-structure methods needs detailed comparison with highly accurate data of representative test sets. A variety of highly valuable test sets have been established in quantum chemistry for small molecules. However, for crystalline solids they are still lacking. We present a representative test set for materials science and engineering (MSE) which includes first and second row elements and their binaries, comprising various crystal structures. This test set allows for unbiased benchmarking for various chemical interactions. In the MSE test set, we consider cohesive energy, lattice constant, bulk modulus, electronic, band structures and phonons etc. A big effort is made to produce systematically converged results with respect to basis set[1] and k mesh for a hierarchy of electronic-structure methods, ranging from the local-density approximation to advanced orbital-dependent functionals implemented in the all-electron, full-potential FHI-aims code. Furthermore, we use incremental schemes to obtain benchmark values calculated with coupled-cluster approaches.

Berkeley National Laboratory, ARUN BANSIL, Northeastern University, ALESSANDRA LANZARA, University of California, Berkeley and Lawrence National Tsing Hua University and Academia Sinica, ASLIHAN SUSLU, Arizona State University, JUNQIAO WU, University of California, Berkeley and Lawrence TONGAY, Arizona State University, TAY-RONG CHANG, National Tsing Hua University, HSIN LIN, National University of Singapore, HORNG-TAY JENG, calculated electron and hole effective masses. Funded in part by the NSF and the Louisiana Board of Regents, through LASiGMA [Award Nos. EPS-1003897, Γ at the other ionic inputs; hence, the description of w-AlN is provided by a calculation with these ionic species as input. Our calculated, direct band gap for w-AlN, of the calculation leading to the lowest, occupied energies. With Al \( ^{3+} \) states of Al and N, the method led to several sets of calculations with different ionic species as input. LDA requires, for the description of w-AlN, the results of Gaussian orbitals (LCGO), and the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF). With multiple oxidation states of Al and N, the method led to several sets of calculations with different ionic species as input. LDA requires, for the description of w-AlN, the results of Gaussian orbitals (LCGO), and the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF), in our implementation of the LCGO. We discuss electronic energy bands, total (DOS) and partial (pDOS) densities of states, effective masses that are pertinent to transport properties, and the bulk modulus. For a room temperature lattice constant of 6.539 Å, our calculated, direct band gap of the material, at \( \Gamma \), is 2.83 eV. We predict a direct band gap of 3.05 eV for the calculated equilibrium lattice constant of 6.395 Å. The significant decrease of the lattice constant, for a drop in temperature from 300 to 0 K, is understandable with the relatively small, predicted bulk modulus of 43.9 GPa. Acknowledgments: This work was funded in part by the NSF and the Louisiana Board of Regents, through LASiGMA [Award Nos. EPS-1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – NNSA (Award Nos. DE-NA0001861 and DE-NA0002630). LaSPACE, and LONI-SUBR.

9:24AM 15.00008 Electronic structure, spin–orbit coupling, and interlayer interaction in bulk MoS\(_2\) and WS\(_2\). DREW LATZKE, WENTAO ZHANG, University of California, Berkeley and Lawrence Berkeley National Laboratory, SEFAATTIN TONGAY, Arizona State University, TAY-RONG CHANG, National Tsing Hua University and Academy Sinica, ASLIHAN SUSLU, Arizona State University, JUNQIAO WU, University of California, Berkeley and Lawrence Berkeley National Laboratory, ARUN BANSIL, Northeastern University, ALESSANDRA LANZARA, University of California, Berkeley and Lawrence Berkeley National Laboratory — Transition metal dichalcogenides (TMDs) (MX\(_2\) where M = Mo or W and X = S, Se, or Te) are theorized to possess unique spin-split valence bands along with rare spin–valley coupling, making them attractive for applications within the growing fields of spintronics and valleytronics. Despite the importance of the spin valence band that governs the unique spin- and valley-physics of TMDs, there remain many questions regarding its origin and properties in bulk TMDs. In this talk, I will present high-resolution angle resolved photoemission spectroscopy (ARPES) measurements of the electronic band structure of bulk TMDs MoS\(_2\) and WS\(_2\). Detailed comparison with first principle calculations will be shown. The role of the valence band splitting and how it can be controlled will be discussed.

9:36AM 15.00009 Barium disilicides (BaSi\(_2\)) a low-cost, earth-abundant material for thin-film solar cells. MUKESH KUMAR, NAOTO UMEZAWA, MOTOHARU IMAI, Natl Inst for Materials Sci — In order to meet the clean energy requirement, materials consisting of abundant, eco-friendly, and low-cost elements are of great interest. Therefore in this study, we discussed the importance of BaSi\(_2\) and other similar semiconductor compounds which contain inexpensive and earth abundant elements, for solar cell applications. Employing first-principles modeling within the density functional theory, we analyze the structural, electronic and optical properties and find that these compounds have fundamental indirect band gaps and the gap energies are in the region of 0.9–1.3 eV, which is suitable for solar cell applications. Furthermore, a lower energy dispersion of the conduction band (CB), which results in a flat shape of the CB minimum, implies a large optical absorption. In fact, our calculations reveal that the photoabsorption of these compounds is stronger than other common PV materials like Si and Cu(Ga,In)Se\(_2\).

9:48AM 15.00010 Quantifying defect levels in hexagonal boron nitride from simulated x-ray absorption spectroscopy \(^1\). SEBASTIAAN HUBER, Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, United States, ROBBERT VAN DE KRUJIS, FRED BIJKERK, Industrial Focus Group XUV Optics, MESA+ Research Institute for Nanotechnology, University of Twente, The Netherlands, ERC GULLIKSON, Center for X-Ray Optics, Lawrence Berkeley National Laboratory, Berkeley, United States, DAVID PRENDERGAST, Molecular Foundry, Lawrence Berkeley National Laboratory, United States — X-Ray Absorption Spectroscopy is a technique that is highly sensitive to the local structural and chemical environment of the probed species. This quality can be exploited to investigate the characteristics of localized structural imperfections such as point defects and grain boundaries. In this study, we simulated X-ray absorption spectra for several hexagonal (h-BN) and amorphous boron nitride (a-BN) samples were recorded. Simulation of X-ray absorption spectra from first principles allows for characteristic features in the measured spectra to be attributed to local defects of the planar hexagonal structure of the material. Analysis of the relative intensities of these features can subsequently provide a quantitative analysis of the levels of various defects in the analyzed structure.

10:00AM 15.00011 Accurate, Electronic and Transport Properties of Wurtzite Aluminum Nitride (w-AIN). IFEANYI NWIGBOJI, YURIY MALOZOVSKY, LASHOUNDA FRANKLIN, Southern University and A&M College, CHINEDU EKUMA, Louisiana State University, DIOLA BAGAYOKO, Southern University and A&M College — We present results from ab-initio, self-consistent calculations of electronic and transport properties of wurtzite aluminum nitride (w-AIN). We utilized a local density approximation (LDA) potential, the linear combination of Gaussian orbitals (LCGO) potential and the linear combination of Gaussian orbitals (LCGO) formalism. We followed the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF). With multiple oxidation states of Al and N, the method led to several sets of calculations with different ionic species as input. LDA requires, for the description of w-AIN, the results of the calculation leading to the lowest, occupied energies. With Al\(^{3+}\) and N\(^{3+}\) as input, the binding energy was 1.5 eV larger, in magnitude, than those for other ionic inputs; hence, the description of w-AIN is provided by a calculation with these ionic species as input. Our calculated, direct band gap for w-AIN, at the \( \Gamma \) point, is 6.28 eV, in excellent agreement with the 6.28 eV experimental value at 5 K. We discuss the bands, total and partial densities of states, and calculated electron and hole effective masses. Funded in part by the NSF and the Louisiana Board of Regents, through LASiGMA [Award Nos. EPS-1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – NNSA (Award No. DE-NA0001861), LaSPACE, and LONI-SUBR.

10:12AM 15.00012 Electronic properties of perovskite absorbers for solar cell applications\(^1\). MARINA FILIP, FELICIANO GIUSTINO, University of Oxford, Department of Materials — Metal halide perovskite absorbers have captured the attention of the photovoltaics community in the past 3 years, reaching efficiencies over 19%. Despite this unprecedented progress, the remarkable physical properties of these materials are not yet fully understood. In this work we show an exhaustive computational study of CH\(_3\)NH\(_3\)PbI\(_3\) within density functional theory and the GW approximation. We show the effect of semicore states and spin-orbit coupling on the quasiparticle band gap of CH\(_3\)NH\(_3\)PbI\(_3\) and describe a straightforward "self-consistent scissor" method to correct the underestimated dielectric screening in the G0W0 approach [1]. Finally, we model the interplay between the structural and electronic properties of lead-iodide perovskites and propose novel lead-iodide perovskite absorbers with different cations at the center of the cuboctahedra cavity facilitating the tuning of the fundamental band gap [2].

10:24AM A15.00013 Chemical trends in halide perovskite electronic properties¹. WALTER LAM-BRECHT, LING-YI HUANG, Case Western Reserve University — The halide perovskites ABX₃ with B = Pb or Sn, X = I, and A = Cs or methylammonium (MA), have recently attracted attention as solar cell materials. We discuss the basic bonding, stability and electronic band structure of these materials for different chemical substitutions using first-principles calculations. An important feature of the Pb and Sn based halides is that these element’s 6-electrons strongly hybridize with the halogen p-orbitals leading to a valence band maximum with strong Sn or Pb-p character and small effective mass. The conduction band minimum is Sn or Pb-p-like. We present trends in the electronic band structure with the halogen X = I, Br, Cl and the B cation Pb, Sn, Ge, Si. The gap is remarkably insensitive because of the opposing trends of the increased spin-orbit coupling for heavier elements (reducing the gap) and the decreased valence band width for heavier elements due to the larger B-X distance, which increases the gap. The stability of the perovskite structure vs. competing structures is influenced by the tolerance factor t = RₓA₃/VγBₓC₃. The smaller this factor, the least stable is the perovskite structure. CsSnI₃ is found to be a topological insulator. Its stability with respect to CsI and SnI₂ is discussed.

10:36AM A15.00014 Electronic structure studies of MX₂ (M=Mo, W; X=S, Se) by ARPES and the band evolution of hydrogen gas exposed MoS₂. BEOM SEO KIM, SOOHYUN CHO, BEOMYOUNG KIM, Yonsei Univ; JONATHAN DENLINGER, Advanced Light Source, BYUNG HOON KIM, SEUNG RYONG PARK, Incheon National Univ, CHANGYOUNG KIM, Yonsei Univ — The physics associated with transition metal dichalcogenides (TMDs) is one of the most intriguing issues in condensed matter physics. These materials have several interesting aspects inter physical properties, especially the direct to indirect band gap transition and spin-orbit coupling induced spin band splitting at the K-point. However, thorough systematic studies on the electronic structures of TMDs regarding those issues have not been done. We present the electronic structure studies of MoS₂ using angle resolved photoemission spectroscopy (ARPES). We investigated the indirect band gap and spin-band splitting sizes of MoS₂. In addition, we present ARPES results from MoS₂+H₂(10h), performed to investigate the evolution of the band structure as a function of hydrogen exposure (from MoS₂ to MoS₂+H₂(10h)). Photon energy dependence and potassium dosing were performed for each system. The results from MX₂ are quite consistent with the published band calculation results. In the MoS₂+H₂ (10h) case, there are two interesting observations from the results. The first is that the indirect band gap size decreases upon exposure to hydrogen. The other observation is that the Γ band appears to have quantized confinement effect.

10:48AM A15.00015 Discrete energy bands in bulk semiconductors. MAOHUA DU, HONGLIANG SHI, Oak Ridge National Lab — Bulk semiconductors typically have continuous valence and conduction bands. Discrete energy levels and bands have been sought after for various applications. For instance, discrete energy levels existing in semiconductor nanocrystals, or quantum dots (QDs) have been proposed as a mechanism to suppress hot carrier thermalization and to enhance carrier multiplication in QD solar cells. Impurity bands in the band gap have been proposed for intermediate-band solar cells and for efficient visible light absorption and photocatalysis. In this talk, we show by first principles calculations that, in a multinary compound, a combination of large electronegativity difference between different cations (anions) and large nearest-neighbor distances in cation (anion) sublattices can lead to the splitting of the conduction (valence) band, resulting in several discrete and narrow energy bands separated by large energy gaps. We also discuss applications that may benefit from such electronic structure.

Session A16 DMP DCOMP: Focus Session: Materials by Theoretical Design

8:00AM A16.00001 Theory-guided discovery of new superconducting materials¹. ALEKSEY KOLMOGOROV, Binghamton University, SUNY — Extensive theoretical effort to predict new superconductors has resulted in remarkably few discoveries. Successful examples so far have been restricted primarily to pressure- or doping-driven superconducting transformations in existing materials. In this talk I will describe our work that has led to the prediction [1] and discovery [2] of a brand-new superconducting FeB₄ compound with a previously unknown crystal structure. First measurements supported the predicted phonon-mediated pairing mechanism, rare for an iron-based superconductor. The identification of FeB₄ candidate material was a result of combined high-throughput screening, targeted evolutionary search [3], and rational design. The systematic study of more than 12,000 metal boride phases has identified dozens of synthetizable materials with unusual structural motifs, some of which have been confirmed experimentally [4]. I will overview employed strategies for selecting promising superconducting compounds and describe our ongoing work on accelerating the search for stable materials.

8:36AM A16.00002 Guided design of copper oxyxulfide superconductors. CHUCK-HOU YEE, TURAN BIROL, GABRIEL KOTLIAR, Rutgers University — Using the framework of chemical intuition introduced by Antipov, et. al., in his synthesis of the Hg-based high-temperature superconductors, supplemented with modern first-principles electronic structure tools, materials databases, and evolutionary algorithms capable of exploring large configurational spaces, we design a novel family of copper oxyxulfides. We explore the predictions of theories based on charge-transfer energies, orbital distillation and uniaxial strain on the superconducting transition temperatures of these oxyxulfides.

8:48AM A16.00003 Conformational space annealing scheme in the inverse design of functional materials¹. SUNGHYUN KIM, KAIST; IN-HO LEE, Korea Research Institute of Standards and Science. JOOYOUNG LEE, Center for In Silico Protein Science, School of Computational Science, YOUNG JUN OH, KEE JOO CHANG, KAIST — Recently, the so-called inverse method has drawn much attention, in which specific electronic properties are initially assigned and target materials are subsequently searched. In this work, we develop a new scheme for the inverse design of functional materials, in which the conformational space annealing (CSA) algorithm for global optimization is combined with first-principles density functional calculations. To implement the CSA, we need a series of ingredients, (i) an objective function to minimize, (ii) a ‘distance’ measure between two conformations, (iii) a local enthalpy minimizer of a given conformation, (iv) ways to combine two parent conformations to generate a daughter one, (v) a special conformation update scheme, and (vi) an annealing method in the ‘distance’ parameter axis. We show the results of applications for searching for Si crystals with direct band gaps and the lowest-enthalpy phase of boron at a finite pressure and discuss the efficiency of the present scheme.

9:00AM A16.00004 Computational materials design of negative effective $U$ system in the hole-doped Delafosseite of CuAlO$_2$, AgAlO$_2$ and AuAlO$_2$. AKITAKA NAKANISHI, TETSUYA FUKUSHIMA, HIROKI UEDE, HIROSHI KATAYAMA-YOSHIDA, Osaka University — In order to realize the super-high-$T_c$ superconductors ($T_c$(0)>1.00K) based on the general design rules [1] for the negative $U_{eff}$ system, we have performed computational materials design for the hole-doped one-dimensional (1D) Delafosseite CuAlO$_2$, AgAlO$_2$ and AuAlO$_2$ from the first principles. We find the interesting chemical trend of $T_c$ in 2D and 3D systems; where the $T_c$ increases exponentially in the weak coupling regime ($|U_{eff}|=0.44 eV$) for the band width $W$ (1.7 eV) for hole-doped CuAlO$_2$. [1] H. Katayama-Yoshida et al., Appl. Phys. Express 1 081703, 2008.

9:12AM A16.00005 How to design negative effective $U$ Fermion system in hole doped chalcopryte CuFeSe$_2$? HIROSHI KATAYAMA-YOSHIDA, TETSUYA FUKUSHIMA, HIROKI UEDE, YUKI TAKAWASHI, AKITAKA NAKANISHI, Graduate School of Engineering Science, Osaka University, KAZUNORI SATO, Graduate School of Engineering, Osaka University — Here, we have proposed a general rule of the attractive Fermion system in the purely electronic origin, which is called negative effective $U$ ($U_{eff}<0$) system. Purely electronic-originated $U_{eff}<0$ is caused by (i) the exchange-correlation-induced energy gain in the Hund’s rules, and (ii) the charge-excitation-induced energy gain. Based on the general design rules, we perform ab initio electronic structure calculations for hole-doped Chalcopryte CuFeSe$_2$. It is found that the hole-doped CuFeSe$_2$ has the $U_{eff}<0$ is originated by the charge-excitation- induced mechanism in the hole-doped Cu$^{3+}$ ($d^9$) and $S^2- (e^2p^2)$, and also originated by the exchange-correlation- induced mechanism in the hole-doped Fe$^{4+}$ ($d^5$). The hole-doped paramagnetic and metallic CuFeSe$_2$ with $U_{eff}<0$ may cause a possible super-high-$T_c$ superconductor ($T_c$ $\approx$ 1000 K, if $\Delta/|U_{eff}| \approx 10$ by assuming a strong coupling regime.) because of the strong attractive electron-electron interactions (superconducting gap $\Delta \approx |U_{eff}| \approx 5000$ K). We propose a new computational materials design methodology to design super-high-$T_c$ superconductors starting from the atomic number only. [1] T. Fukushima et al., J. Phys. Condens. Matter, 26 355502, 2014.

9:24AM A16.00006 Direct band gap silicon crystals predicted by an inverse design method. YOUNG JUN OH, Korea Advanced Institute of Science and Technology, IN-HO LEE, Korea Research Institute of Standards and Science. JOOYOUNG LEE, Korea Institute for Advanced Study, SUNGYUN KIM, KEE JONG CHANG, Korea Advanced Institute of Science and Technology — Cubic diamond silicon has an indirect band gap and does not absorb or emit light as efficiently as other semiconductors with direct band bands. Thus, searching for Si crystals with direct band gaps is important to realize efficient thin-film solar cells. In this work, we report various crystalline silicon allotropes with direct and quasi-direct band gaps, which are predicted by the inverse design method which combines a conformation space annealing algorithm for global optimization and first-principles density functional calculations. The predicted allotropes exhibit energies less than 0.3 eV per atom and good lattice matches, compared with the diamond structure. The structural stability is examined by performing finite-temperature ab initio molecular dynamics simulations and calculating the phonon spectra. The absorption spectra are obtained by solving the Bethe-Salpeter equation together with the quasiparticle phonon spectra. The absorption spectra are obtained by solving the Bethe-Salpeter equation together with the quasiparticle phonon spectra.

9:36AM A16.00007 Design of I$_2$-II-IV-VI$_4$ Semiconductors through Element-substitution: the Thermodynamic Stability Limit and Chemical Trend. SHIYOU CHEN, East China Normal University, CONGCONG WANG, Fudan University, HONGKUN XIANG, XIN-GAO GONG, Fudan University, ARON WALSH, University of Bath, SU-HUAI WEI, National Renewable Energy Laboratory — Through element substitution in kesterite Cu$_2$ZnSnS$_4$ or Cu$_2$ZnSnSe$_4$, a class of I$_2$-II-IV-VI$_4$ semiconductors can be designed as novel functional materials. Using the first-principles calculations, we show that this element-substitution design is thermodynamically limited, i.e., although I$_2$-II-IV-VI$_4$ with I=Cu, Ag, II=Zn, Cd, Hg, IV=Si, Ge, Sn and VI=5, 6, Se, Te are stable quaternary compounds, those with I=Mg, Ca, Sr, Ba, IV=Ti, Zr, Hf, and VI=O are unstable against the phase-separation into the competing binary and ternary compounds. Three main phase-separation pathways are revealed. We show that if the secondary II-VI or I-IV-VI$_4$ phases prefer to have non-tetrahedral structures, then the I$_2$-II-IV-VI$_4$ semiconductors tend to phase separate. This finding can be used as a guideline for future design of new quaternary semiconductors.

9:48AM A16.00008 Materials predicted to be topological insulators in hypothetical structures assumed by theorists might be trivial insulators in their stable phases. GIANCARLO TRIMARCHI, Northwestern U., Evanston, IL, XIUWEN ZHANG, ALEX ZUNGER, U. of Colorado, Boulder, CO — The quest for new topological insulators (TIs) has motivated numerous ab initio calculations of the topological metric $Z_2$ of candidate compounds in hypothetical crystal structures, or in assumed pressure or doping conditions. However, TI-ness might destabilize certain crystal structures that would be replaced by other structures, which might not be TIs. Here, we discuss such false-positive predictions in the ab initio search for new TIs. (i) Various ABX compounds, predicted to be TIs in the assumed ZrBeSi-type structure that turns out to be unstable, become trivial insulators in their stable structures. (ii) Band-inversion-inducing structure perturbations destabilize the system which is instead trivial at equilibrium: examples of this scenario are the cubic $\text{Al}_{13}\text{Bi}_3\text{O}_{34}$ perovskites that transform from topological to trivial when they relax to their equilibrium structures. (iii) Doping destabilizes the band-inverted system that relaxes to a trivial atomic configuration (orthorhombic band-inverted $\text{BaBiO}_3$) is a shallow acceptor producing holes yet the hole-killer donor of B-interstitial is unfavorable. (4) When B=N or Co, the compound favors $n$-type due to the dominance of B-interstitial defects (e.g., TiCoSb). We will show the calculated leading defect types and the dependence of carrier concentrations on chemical conditions for newly predicted half-Heusler insulators. This study is supported by DOE, Office of Science, Basic Energy Science, MSE division grant to CU Boulder.

1Work at CU, Boulder supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Grant DE-FG02-13ER46959.

10:00AM A16.00009 Doping designed half-Heusler insulators. YONGGANG YU, XIUWEN ZHANG, LIPING YU, University of Colorado, Boulder, CO, FENG YAN, A. NAGARAJA, T. O. MASON, Northwestern University, Evanston, IL, ALEX ZUNGER, University of Colorado, Boulder, CO — The 18-valence electron 1:1:1 compounds of the type III-X-V, IV-X-IV, IV-IX-V and V-IX-IV include thermoelectric materials, topological insulators, and recently a high mobility $p$-type transparent conductor TaRbGe (arXiv:1406.0872), yet their intrinsic doping trends are poorly known or understood. Using the “modern theory of doping” that addresses via DFT and HSE the thermodynamic formation energies and the DFT-corrected transition levels in the gap, we find the following interesting trends: (1) High atomic number compounds such as TaRbGe made of metallic elements can surprisingly have a large band gap (direct) of $\sim$ 2.5 eV. (2) Half-Heusler such as $\text{A}^{(IV)}\text{B}^{(II)}\text{C}^{(IV)}$ is naturally n-type if its DFT calculated chemical stability field resides within the A-rich or B-rich domain of the stability triangle, while it is n-type within the C-rich domain. Such calculations provide a good metric. (3) When the B atom $[1, 4, 1, 4, 1, 4]$ is as large as Ir or Pt, the compound prefers p-type because the C-on-A antisite [such as Ge$_3$Zn$_{13}$] is a shallow acceptor producing holes yet the hole-killer donor of B-interstitial is unfavorable. (4) When B=N or Co, the compound favors n-type due to the dominance of B-interstitial defects (e.g., TiCoSb). We will show the calculated leading defect types and the dependence of carrier concentrations on chemical conditions for newly predicted half-Heusler insulators. This study is supported by DOE, Office of Science, Basic Energy Science, MSE division grant to CU Boulder.
Trends of semiconductivity in 3d oxides^1. STEPHAN LANY, NREL — Open shell transition metal oxides are usually described as Mott insulators, which are often viewed as being disparate from semiconductors. Based on the premise that the presence of a Mott gap and semiconductivity are not mutually exclusive, this work reviews electronic structure calculations on the binary 3d oxides, so to distill trends and design principles for semiconducting transition metal oxides. This class of materials possesses the potential for discovery, design, and development of novel functional semiconducting compounds, e.g., for energy applications. This presentation gives an overview for the band-structure trends of 3d oxides with special attention on the hybridization between the 3d crystal field symmetries with the sp bands, and on how this interactions affect the effective masses and the likelihood of self-trapping of electrons or holes.

^1Supported by DOE-SC-BES as part on an Energy Frontier Research Center.

Discovery of earth abundant light absorbers for solar water splitting: Mn,V₂O₇ and beyond^1. QIMIN YAN, Molecular Foundry, Lawrence Berkeley National Laboratory, PAWL F. NEWHOUSE, California Institute of Technology, GUO LI, JIE YU, WEI CHEN, KRISTIN PERSSON, Lawrence Berkeley National Laboratory, JOHN GREGOIRE, California Institute of Technology, JEFFREY NEATON, Lawrence Berkeley National Laboratory — Utilizing a first-principles data driven discovery approach with high-throughput computations and machine learning techniques, we screen for transition metal oxide (TMO) compounds with low band gaps and optimal band edges for solar water splitting applications. Combining the computational screening with the high-throughput experimental synthesis efforts, we identify the complex oxide β-Mn₂V₂O₇ as exhibiting a band gap and band edges that are near optimal for photocatalytic water splitting. Experiments, corroborated by theory, indicate that β-Mn₂V₂O₇ has a near-direct band gap near 1.8 eV. Our calculations further reveal a valence band maximum composed of mixed O-p/Mn-d states, and a conduction band maximum of V d-character, leading to dipole-allowed direct transitions at the band edges. Photoelectrochemical measurements indicate appreciable photocurrent from Mn₂V₂O₇ samples, corroborating our predictions. We further discuss design principles for guiding the discovery of more promising metal oxides with optimal band energetics for solar fuels applications.

Theoretical prediction of stable tin oxides: stoichiometry, electronic structure and possible applications. JUNJIE WANG, NAOITO UMEZAWA, National Institute for Materials Science, THEORETICAL DESIGN OF ENVIRONMENTAL REMEDIATION MATERIALS TEAM — We have carried out a computational materials search for stable crystal phases of tin oxides in different composition ratios under ambient pressure condition. By employing density-functional theory calculations combined with evolutionary algorithm, we have identified several thermodynamically stable phases of tin oxides and investigated their dynamical stabilities by computing phonon vibration frequencies. We revealed the mechanism of determining the electronic structures of tin oxide crystals/van der Waals heterostructures through a systematic computational study of chemical bonding, band structure and Bader charges. Based on our theoretical analysis, we demonstrated that the predicted structures can lead to a desirable band structure for photocatalytic hydrogen evolution from water solution. Therefore, the tin oxides proposed in the present work have great potential as an abundant, cheap and environmentally-benign solar-energy conversion catalyst.

Pentahexoctite: A New Two-dimensional Allotrope of Carbon. ADITYA MANJANATH, Centre for Nano Science and Engineering/Materials Research Centre, Indian Institute of Science, BABU RAM SHARMA, ABHISHEK K. SINGH, Materials Research Centre, Indian Institute of Science — Structures with carbon atoms can be arranged in various shapes (polygons) that exhibit unique properties. This has spawned search in exploring such newer allotropes across dimensions. Although research has been extensive in bulk graphitic structures, there are several 2D allotropes that are yet to be unearthed. Here, we report a new allotrope consisting of 5-6-8 rings of carbon atoms, named as “pentahexoctite.” This sp² hybridized 2D allotrope has mechanical strength comparable to graphene. Electronically, the sheet is metallic with direction-dependent flat and dispersive bands at the Fermi level. It serves as a precursor for a stable 1D nanotubes with chirality-dependent electronic and mechanical properties. With these unique properties, the pentahexoctite sheet is another exciting addition to the family of robust novel 2D allotropes of carbon.

Monday, March 2, 2015 8:00AM - 11:00AM — Session A17 DMP: Focus Session: Carbon Nanotubes & Related Materials: Growth, Separation, and Assembly 102AB — Andrew Rinzler, University of Florida

Modulating diameter of single-walled carbon nanotubes in alcohol catalytic chemical vapor deposition. RONG XIANG, KEHANG CUI, JIE YU, HUA AN, XIAO CHEN, SHOHEI CHIASHI, SHIGEO MARUYAMA, Department of Mechanical Engineering, the University of Tokyo — Modulating the diameter of a single walled carbon nanotube (SWNT) is essential for its applications in optical and electronic devices. We demonstrate that the average diameter of vertically aligned SWNTs can be successfully reduced from 2.5 to 1.2 nm by changing catalyst component ratio in a Co/Mo bimetallic system, no matter the catalyst is dip-coated or spray-coated onto a substrate. Meanwhile, the diameter can be further reduced after replacing the conventional ethanol carbon source by acetonitrile. Recently, Cu is found to be effective in reducing diameter of mechanical and dispersive bands at the Fermi level. It serves as a precursor for a stable 1D nanotubes with chirality-dependent electronic and mechanical properties.

Ethanol decomposition on transition metal nanoparticles during carbon nanotube growth: ab initio molecular dynamics study. YASUSHI SHIBUTA, The University of Tokyo, KOHEI SHIMAMURA, Kumamoto University, TOMOYA OGURI, The University of Tokyo, RIZAL ARIFIN, FUUYUKI SHIMOJO, Kumamoto University, SHU YAMAGUCHI, The University of Tokyo — The growth mechanism of carbon nanotubes (CNT) has been widely discussed both from experimental and computational studies. Regarding the computational studies, most of the studies focuses on the aggregation of isolate carbon atoms on the catalytic metal nanoparticle, whereas the initial dissociation of carbon source molecules should affect the yield and quality of the products [1]. On the other hand, we have studied the dissociation process of carbon source molecules on the metal surface by the ab initio molecular dynamics simulation [2,3]. In the study, we investigate the ethanol dissociation on Pt and Ni clusters by ab initio MD simulations to discuss the initial stage of CNT growth by alcohol CVD technique. [1] Y. Shibuta, Diamond and Related Materials, 20 (2011) 334-338. [2] T. Oguri, K. Shimamuray, Y. Shibuta, F. Shimojo, S. Yamaguchi, J. Phys. Chem. C 117 (2013) 9983. [3] T. Oguri, K. Shimamuray, Y. Shibuta, F. Shimojo, S. Yamaguchi, Chem. Phys. Lett., 595-596 (2014) 185.
variety of feedstock materials. Conditions, collapsed BN nanotubes (i.e., nanoribbons), and closed shell BN capsules (i.e., nanococoons) are also obtained. The process is adaptable to a large system has been developed and used to produce high-quality boron nitride nanotubes (BNNTs) at continuous production rates of 35 g/h. Under suitable conditions, the graphene is tuned through precise feedstock application. Through careful materials synthesis, the interfaces of these hybrid carbon nanotube – graphene systems are investigated through ultra-high resolution electron microscopy. As a result the graphene embryos incorporate in their hexagonal network various polygons to accommodate the curved 3D geometry that initiates cap formation following by elongation of the circumferential rims. Based on these results, also on the census of nanotube caps and the fact that given cap fit only one nanotube wall, we consider carbon cap responsible for the helicity of carbon nanotube. This understanding could provide new avenues towards engineering particles to explicitly accommodate certain helicities via exploitation of the angular distribution of catalyst adjacent facets. Our recent progresses in production of carbon nanotubes, nanotube reinforced composites and their potential applications also will be presented.

9:36 AM A17.00007 Crystallographic growth and alignment of carbon nanotubes on few-layer graphene, ARAM ARASH, PATRICK D. HUNLEY, MOHSEN NASSERI, MATTHIAS J. BOLAND, ABHISHEK SUNDARARAJAN, BETHANY M. HUDAK, BETH S. GUITON, DOUGLAS R. STRACHAN, Univ of Kentucky — Hybrid carbon nanotube and graphene structures are emerging as an exciting material system built from a common sp2 carbon backbone. Such hybrid systems have promise for use in improving the performance of energy storage and high-speed electronic applications. Towards the attainment of such hybrid materials, the catalytic growth and crystallographic alignment of these integrated structures are investigated along with the atomic-scale features of their interfaces. The catalytic activity of nanoparticles to form carbon nanotubes on the surface of few-layer graphene is tuned through precise feedstock application. Through careful materials synthesis, the interfaces of these hybrid carbon nanotube – graphene systems are investigated through ultra-high resolution electron microscopy.

9:48 AM A17.00008 Sealed Synthesis of Boron Nitride Nanotubes, Nanoribbons, and Nanococones Using Direct Injection into an Extended-Pressure, Inductively-Coupled Thermal Plasma, AIDIN FATHALIZADEH, THANG PHAM, WILLIAM MICKELSON, ALEX ZETTL, Department of Physics, University of California at Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — A variable pressure (up to 10 atm) powder or gas injection inductively coupled plasma system has been developed and used to produce high-quality boron nitride nanotubes (BNNTs) at continuous production rates of 35 g/h. Under suitable conditions, collapsed BN nanotubes (i.e., nanoribbons), and closed shell BN capsules (i.e., nanococones) are also obtained. The process is adaptable to a large variety of feedstock materials.
10:00AM A17.00009 Electronic and optoelectronic devices based on chirality-enriched wafer-scale single-wall carbon nanotube thin films, WEILU GAO, XIAOWEI HE, LIJUAN XIE, QI ZHANG, ECE Department, Rice University, ERIK HAROZ, STEPHEN K. DOORN, Los Alamos National Laboratory, JUNICHIRO KONO, ECE Department, Rice University — The unique and rich material properties of single-wall carbon nanotubes (SWCNTs) make them attractive for nano-electronic and optoelectronic applications. Slight changes in tube diameter and wrapping angle, defined by the chirality indices \((n,m)\), can dramatically modify the bandstructure, which can be utilized for designing devices with tailored properties. However, it remains to be a challenge to fabricate macroscopic, single-chirality devices. Here, we introduce a simple way of producing chirality-enriched wafer-scale SWCNT films by combining recently developed solution-based polymer-modified sorting method\(^1\) and vacuum filtration. The produced thin films can be easily transferred onto any substrate to have a CMOS compatible wafer. We fabricated a transistor of \((6,5)\)-enriched SWCNTs with an on/off ratio \(>10^{11}\). Large-scale photothermoelectric-effect-based and photovoltaic-effect-based photodetectors made of \((6,6)\)- and \((6,5)\)-enriched films, respectively, will also be discussed.

10:12AM A17.00010 Single Chirality Resolution Separation of Single-Wall Carbon Nanotubes up to 1.7+ nm in Diameter using Aqueous Two-Phase Extraction, JEFFREY FAGAN, National Institute of Standards and Technology — The recent development of aqueous two-phase extraction (ATPE) as a method for separating single-wall carbon nanotubes (SWCNTs) provides a scalable method for isolating many individual species of SWCNT via solution processing. In this presentation I will demonstrate that the ability of ATPE is not limited to the separation of small diameter SWCNTs \(<1\text{nm}\), but enables the extraction of single metallic and semiconducting SWCNT species from plasma torch, laser ablation, electric arc and even large diameter CVD grown SWCNTs. The separation range of the technique thus extends to the isolation of individual species of nanotubes up to at least 1.7 nm in diameter, a dramatic improvement beyond previous SWCNT separation methods. Optical characterization of the refined populations, and analysis of the order of \((n,m)\) extraction with respect to the mechanism underlying the ATPE method will be presented.

10:24AM A17.00011 Molecular Dynamics Study of Surfactant Self-Assembly on Single-Walled Carbon Nanotubes (SWCNTs), FREDERICK PHELAN JR., NIST - Natl Inst of Stds & Tech — Single-walled carbon nanotubes (SWCNTs) are materials with structural, electronic and optical properties that make them attractive for a myriad of advanced technology applications. Increased adaptation of these materials requires advancement in separation techniques which enable them to be sorted with increased reliability into monodisperser fractions with respect to length and chirality. Most separation techniques currently in use rely on dispersion of tubes in aqueous solution using surfactants. This results in a colloidal mixture in which tubes are packed and individually dispersed in a surfactant shell. Understanding the structure and properties of the SWCNT-surfactant complex at the molecular level, and how this is affected by chirality, will help to improve separations processes. In this work, we study the structure and properties of SWCNT-surfactant colloidal complexes using all-atom molecular dynamics. Self-assembled structures are computed for a number of combinations SWCNT/surfactant, and also, co-surfactant mixtures for the bile salt surfactant sodium deoxycholate (DOC) and the anionic surfactant sodium dodecyl sulfate (SDS). From the radial distribution function we estimate the size of the SWCNT hydration layer, and use that information to compute the buoyant densities of unfilled tubes for a number of concentrations. Estimates of the change in hydrodynamic radius with increased surfactant packing and the binding energies of the individual surfactants are also obtained.

10:36AM A17.00012 Integration of Nanotubes, Etch Tracks, and Nanoribbons in Crystallographic Alignment, MATHIAS J. BOLAND, D. PATRICK HUNLEY, ABHISHEK SUNDRARAJAN, MOHSEN NASSERI, DOUGLAS R. STRACHAN, Univ of Kentucky — Three nanomaterial components, carbon nanotubes (CNTs), few-layer graphene (FLG), and etch tracks exposing insulating SiO\(_2\) regions, are integrated to form crystallographically-aligned nanoscale systems. These integrated systems consist of CNTs grown across nanogap etch tracks and nanoribbons formed within the FLG films as a result of chemical vapor deposition (CVD) processing. Each nanoscale component is aligned along the underlying graphene lattice, resulting in their orientations being locked into precise values, with CNTs maintaining alignment even after crossing etch tracks. The growth of aligned CNTs across nanogap etch tracks and nanoribbons suggests that integrated formations can be achieved by growing CNTs directly over nanogap etch tracks and nanoribbons. This is supported by calculations of the vibrational energy of CNTs indicating that they should be capable of maintaining atomic registry with an underlying graphene lattice as they grow across a typical etch track, in agreement with our experimental results. Thus, this work is relevant to the integration of semiconducting, conducting, and insulating nano-materials all together into precise nano-electronic systems.

10:48AM A17.00013 High stability of faceted nanotubes and fullerenes of multi-phase layered phosphorus: A computational study, JIE GUAN, ZHEN ZHU, DAVID TOMANEK, Michigan State University — We present a paradigm in constructing very stable, faceted nanotube and fullerene structures by laterally joining nanoribbons or patches of different planar phosphorene phases. Our \textit{ab initio} density functional calculations indicate that these phases may form very stable, non-planar joints. Unlike fullerenes and nanotubes obtained by deforming a single-phase planar monolayer at substantial energy penalty, we find faceted fullerenes and nanotubes to be nearly as stable as the planar single-phase monolayers. The resulting rich variety of polymorphs allows to tune the electronic properties of phosphorene nanotubes (PNTs) and fullerenes not only by the chiral index, but also by the combination of different phosphorene phases. In selected PNTs, a metal-insulator transition may be induced by strain or changing the number of walls.

oxide-metal interfaces. They are also used to address key questions associated with corrosion, thin film growth, and heterogeneous catalysis.

...becomes routine. The recently developed charge optimized many body potential (COMB) potentials have significantly enhanced our

...computational simulations of multi-phase systems is increasingly important as our ability to simulate atomic and electronic structure evolution unravels the elementary steps that constitute a chemical reaction. This approach cannot capture many interesting processes that involved excitation of electrons and its effects on the coupled electron-ion dynamics. The time scale needed to accurately resolve the evolution of electron dynamics is atto-seconds. This poses a challenge to the simulation of important chemical processes that typically take place on time scales of pico-seconds and beyond, such as reactions at surfaces and charge transport in macromolecules. We will present a methodology based on time-dependent density functional theory for electrons, and classical (Ehrenfest) dynamics for the ions, that successfully captures such processes. We will give a review of key features of the method and several applications. These illustrate how the quantum information-theoretic lower bound on the number of particles needed for the approximation to hold, asymptotically. This is joint work with Tom Wong.

8:36AM A18.00002 Quantum algorithms for quantum field theories1 — STEPHEN JORDAN, NIST — Ever since Feynman’s original proposal for quantum computers, one of the primary applications envisioned has been efficient simulation of other quantum systems. In fact, it has been conjectured that quantum computers would be universal simulators, which can simulate all physical systems using computational resources that scale polynomially with the system’s number of degrees of freedom. Quantum field theories have posed a challenge in that the set of degrees of freedom is formally infinite. We show how quantum computers, if built, could nevertheless efficiently simulate certain quantum field theories at bounded energy scales. Our algorithm includes a new state preparation technique which we believe may find additional applications in quantum algorithms.

9:12AM A18.00003 Boson Sampling for Molecular Vibronic Spectra — GIAN GIACOMO GUERRESCHI, Harvard University — Quantum computers are expected to be more efficient in performing certain computations than any classical machine. Unfortunately, the technological challenges associated with building a fullscale quantum computer have not yet allowed the experimental verification of such an expectation. Recently, boson sampling has emerged as a problem that is suspected to be intractable on any classical computer, but efficiently implementable with a linear quantum optical setup. Therefore, boson sampling may offer an experimentally realizable challenge to the Extended Church-Turing thesis and this remarkable possibility motivated much of the interest around boson sampling, at least in relation to complexity-theoretic questions. In this work, we show that the successful development of a boson sampling apparatus would not only answer such inquiries, but also yield a practical tool for difficult molecular computations. Specifically, we show that a boson sampling device with a modified input state can be used to generate molecular vibronic spectra, including complicated effects such as Duschinsky rotations.

9:48AM A18.00004 ABSTRACT WITHDRAWN —

10:24AM A18.00005 Hidden subgroups and hidden polynomials — MIKLOS SANDTA, CNRS, Université Paris Diderot and CQT, National University of Singapore — Efficient solutions for the abelian hidden subgroup problem (HSP) constitute probably the greatest success of quantum computing. As a sequel to these results, various generalizations of the abelian HSP have been investigated, such as the non abelian HSP, hidden symmetry problems, and hidden structures of higher degree. In this talk we review an interesting connection between the HSP in certain semidirect product p-groups of constant nilpotency class and the multi-dimensional univariate hidden polynomial graph problem when the degree of the polynomials is constant. Using that connection, we present an efficient quantum solution for both, based on a new randomized algorithm for solving systems of diagonal polynomial equations in finite fields.

Joint work with Gábor Ivanyos.

Monday, March 2, 2015 8:00AM - 11:00AM —

Session A19.00001 Recent advances in Ab initio Molecular Dynamics — ROBERTO CAR, Princeton University — No abstract available.

8:36AM A19.00002 Combining Molecular Dynamics and Density Functional Theory — EFTHIMIOS KAXIRAS1, Harvard University — The time evolution of a system consisting of electrons and ions is often treated in the Born-Oppenheimer approximation, with electrons in their instantaneous ground state. This approach cannot capture many interesting processes that involved excitation of electrons and its effects on the coupled electron-ion dynamics. The time scale needed to accurately resolve the evolution of electron dynamics is atto-seconds. This poses a challenge to the simulation of important chemical processes that typically take place on time scales of pico-seconds and beyond, such as reactions at surfaces and charge transport in macromolecules. We will present a methodology based on time-dependent density functional theory for electrons, and classical (Ehrenfest) dynamics for the ions, that successfully captures such processes. We will give a review of key features of the method and several applications. These illustrate how the atomic and electronic structure evolution unravels the elementary steps that constitute a chemical reaction.

9:12AM A19.00003 Material Discovery and Design with Dynamic Charge Reactive Potentials — SUSAN SINNOTT, University of Florida — Atomic scale computational simulations of multi-phase systems is increasingly important as our ability to simulate nanometer-sized systems becomes routine. The recently developed charge optimized many body potential (COMB) potentials have significantly enhanced our ability to carry out atomic-scale simulations of heterogeneous material systems. The formalism of this potential combines variable charge electrostatic interactions with a classical analytical bond-order potential. It therefore has the capacity to adaptively model metallic, covalent, ionic, and van der Waals bonding within the same simulation cell and dynamically determine the charges on individual atoms according to the local environment. The utility of the COMB potentials is illustrated for materials design and discovery by exploring the structure, stability, mechanical properties, and thermal properties of intermetallic systems and oxide-metal interfaces. They are also used to address key questions associated with corrosion, thin film growth, and heterogeneous catalysis.
Small is Different: Nanoscale Computational Microscopy, UZI LANDMAN, School of Physics, Georgia Institute of technology — Finite materials systems of reduced sizes exhibit discrete quantized energy level spectra and specific structures and morphologies, which are manifested in unique, noncalable, size-dependent physical and chemical properties. Indeed, when the scale of materials structures is reduced to the nanoscale, emergent phenomena often occurs, that is not commonly expected, or deduced, from knowledge learned at larger sizes. Characterization and understanding of the size-dependent evolution of the properties of materials aggregates are among the major challenges of modern materials science. Computer-based classical and quantum computations and simulations are tools of discovery of nanoscale emergent behavior [1]. We highlight such behavior in diverse systems, including: (i) Atomistic simulations of nanoscale liquid jets and bridges and the stochastic hydrodynamic description of their properties [2]; (ii) Metal nanoclusters and their self-assembled superlattices exhibiting stabilities and properties originating from superatom electronic shell-closing, atom packing, and interactions between protecting ligands [3]; (iii) Electric-field-induced shape-transitions and electrorcrystalization of liquid droplets [4]; and (iv) Symmetry-breaking and formation of highly-correlated Wigner molecules between electrons in 2D quantum dots and bosons in traps [5].

Monday, March 2, 2015 8:00AM - 11:00AM
Session A20 DPOLY: Invited Session: Interfacing Experiment and Theory in Polymer Physics
Ballroom B - Bryan Boudouris, Purdue University

8:00AM A20.00001 Order and Disorder in Short Block Polymers1, FRANK S. BATES, University of Minnesota — Block polymers have captivated the interest of scientists and engineers for more than half a century. The phase behavior of this class of self-assembling soft material is well understood in the limit of infinite molecular weight, based on the self-consistent mean-field theory pioneered by Leibler. At practical molecular sizes, typically around N ≈ 1000 repeat units, fluctuation effects become highly significant in the vicinity of the order disorder transition. One-loop corrections to mean-field theory, first described by Brazovski and applied to block polymers by Fredrickson and Helfand, are not expected to be applicable in this limit. Moreover, the drive towards ever smaller domain dimensions, and the opportunity to circumvent transport limitations associated with entanglements, have motivated experiments with yet lower molecular weight block polymers, N less than 100. This presentation will describe the consequences of fluctuations and the equilibrium structural properties of short model AB diblock polymers in the symmetric (f = 1/2) and asymmetric (f → 0) regimes above and below the order-disorder transition. The consequences of fluctuations and access to equilibrium states will be described in the 1-dimensional striped (lamellar) phase and the ordering in reduced dimensions. A computer simulation with realistic molecular detail becomes feasible presenting exciting opportunities to compliment the associated theoretical challenges.

8:36AM A20.00002 Nanocomposites with Crystalline Polymers, SANAT KUMAR, Columbia University — The creation of ordered (layered) biomimetic materials typically follows a series of steps: first mix nanoparticles with water, organize the NPs by ice templating, evaporate the ice and then back fill with metal or polymer. We propose a simple method exploiting the in situ self-assembly of a crystalline polymer in the presence of nanoparticles to facilitate this process, and provide a completely new pathway for the synthesis of biomimetic materials. A suite of complementary experimental tools are used in this analysis. In parallel, we are developing theoretical tools to a priori predict the morphologies adopted by semicrystalline polymers. The convergence of these novel experimental and theoretical developments in the venerable field of semicrystalline polymers could lead to new applications for this largest class of commercially relevant polymeric materials. With Jacques Jestin, Brian Benicewicz, Dan Zhao, Longxi Zhao

9:12AM A20.00003 Segmental Interactions between Polymers and Small Molecules in Batteries and Biofuel Purification, NITASH BALSARA, UC Berkeley — Polymers such as poly(ethylene oxide) (PEO) and poly(dimethyl siloxane) (PDMS) have the potential to play an important role in the emerging clean energy landscape. Mixtures of PEO and lithium salts are the most widely studied non-flammable electrolyte for rechargeable lithium batteries. PDMS membranes are ideally suited for purifying bioethanol and biobutanol from fermentation broths. The ability of PEO and PDMS to function in these applications depends on segmental interactions between the polymeric host and small molecule guests. One experimental approach for studying these interactions is X-ray absorption spectroscopy (XAS). Models for interpreting XAS spectra of amorphous mixtures and charged species such as salts must quantify the effect of segmental interactions on the electronic structure of the atoms of interest (e.g. sulfur). This combination of experiment and theory is used to determine the species formed in during charging and discharging lithium-sulfur batteries; the theoretical specific energy of lithium-sulfur batteries is a factor of four larger than that of current lithium-ion batteries. Selective transport of alcohols in PDMS-containing membranes is controlled by the size, shape, and connectivity of sub-nanometer cavities or free volume that form and disappear spontaneously as the chain segments undergo Brownian motion. We demonstrate that self-assembly of PDMS-containing block copolymers can be used to realistic molecular detail becomes feasible presenting exciting opportunities to compliment the associated theoretical challenges.
9:48AM A20.00004 Using multi-scale molecular simulations to guide experimental design of biomaterials for drug and DNA delivery. ARTHI JAYARAMAN, University of Delaware — In this talk I will present molecular simulations studies that guide experimental synthesis of polymers for efficient DNA delivery. Viruses, while effective at delivery and transfection of DNA, can elicit harmful immunogenic responses, thus motivating design of non-viral transfection agents. Polycations are a promising class of non-viral vectors that bind to the negatively charged DNA backbone to form a complex (polyplex) that is then internalized into the target cell. Combinatorial approaches have generated various polycations with differing DNA transfection efficiencies, but there is a need for general design guidelines that can relate the molecular features of the polycation to its DNA transfection efficiency. Using atomistic and coarse-grained molecular dynamics simulations we connect the thermodynamics of polycation-DNA binding and polyplex structure to experimentally observed transfection efficiency as a function of polycation chemistry and architecture.

10:24AM A20.00005 Ion Containing Polymers for Battery Technology. JANNA K. MARANAS, Departments of Chemical Engineering and Materials Science and Engineering, The Pennsylvania State University — Polymer electrolytes have potential for use in next generation lithium and sodium batteries. Replacing the liquid electrolyte currently used has several advantages: it allows use of high energy density solid lithium as the anode, removes toxic solvents, improves safety, and eliminates the need for heavy casings. Despite their advantages, the conductivity of solid polymer electrolytes is not sufficient for use in batteries. As a result, considerable effort towards improving conductivity and understanding mechanisms of lithium transport has taken place over the last 30 years. This talk considers the interplay of conductivity, crystallinity, local coordination and polymer dynamics in solid polymer electrolytes. Using a combination of experimental and computational technique, we propose the possibility of high charge mobility using ion aggregates and percolated nanofiller networks.

Monday, March 2, 2015 8:00AM - 11:00AM —
Session A21 GIMS: Focus Session: Advances in Scanned Probe Microscopy I: Novel Approaches and Ultrasensitive Detection
201 - Nikolai Zhitenev, National Institute of Standards and Technology

8:00AM A21.00001 Cryogen-free low temperature STM/AFM based on a closed cycle cryostat . BYOUNG CHOI, STEFEN ULRICH, RYAN MURDICK, RHK Technology, Inc, RHK TECHNOLOGY, INC. TEAM — Closed cycle cryogenic scanning tunneling microscope (CCC-STM) and atomic force microscope (AFM) will be presented. By using He heat exchange gas, thermally linked and mechanically decoupled CCC-STM/AFM enables atomically resolved microscopy and spectroscopy on various surfaces. We will present the noise measurement of the tunneling current and the thermal drift analysis. Temperature as low as 14K on the sample and the tip-sample distance fluctuation as low as 2 picometer have been achieved.

8:12AM A21.00002 Construction of a 3He Magnetic Force Microscope with a Vector Magnet . JINHO YANG, YUNWON KIM, ILKYU YANG, JUYOUNG JEOUNG, DONGWOO SHIN, DIRK WULFERDING, YOONHEE JEOUNG, HANWOONG YEOM, JEEHOON KIM, CALDES, IBS, POSTECH, Pohang, Korea — We have built a 3He magnetic force microscope (MFM) with a base temperature of 300 mK, operating in a vector magnet with the field of Z=9 T, X=2 T, Y=2 T for each axis. We employed a fiber interferometer system for detection of a cantilever motion that includes two autotcobe types of walkers for alignment between the fiber end and a cantilever tip. We apply our novel microscope to investigate unconventional magnetic materials and superconductors such as centrosymmetric skyrmmion crystals and Heavy Fermion Superconductors. We will show some preliminary MFM images in these systems.

8:24AM A21.00003 Mapping surface charge density with a scanning nanopipette . LASSE HYLDGAARD KLAUSEN, THOMAS FUHLS, FLEMMING BESENBACKER, MINGDONG DONG, Interdisciplinary Nanoscience Center, Aarhus University, Denmark — Characterisation of the surface charge density (SCD) is important in interface and colloid science, and especially local variations in SCD of biological samples are of keen interest. The surface charge of lipid bilayers governs the uptake of charged particles and guides cell-cell interactions. As the electrostatic potential is screened by high physiological salt concentrations, direct probing of the potential can only be performed at a sub nanometer distance; therefore it was impossible to directly measure the SCD under physiological conditions. Yet the charged surface attracts counter ions leading to an enhanced ionic concentration near the surface, creating a measurable surface conductivity. In this study we measure SCD using a scanning ion-conductance microscope (SICM) setup, where the electrolyte current through a nanopipette is monitored as the pipette is positioned in the vicinity of the sample. We investigate the current dependency of SCD and pipette potential using numerical solutions to Poisson and Nernst-Planck equations and characterise a complex system governed by a multitude of factors such as pipette size, geometry and charge. We then propose an imaging method and prove its feasibility by mapping the surface charge density of phase separated lipid bilayers.

8:36AM A21.00004 The SQCRMscope: Probing exotic materials with quantum gases1 . SHENGLAN QIAO, RICHARD TURNER, JACK DISCIACCA, BENJAMIN LEV, Stanford University — Microscopy techniques co-opted from nonlinear optics and high energy physics have complemented solid-state probes in elucidating exotic order manifest in condensed matter materials. Up until now, however, no attempts have been made to use modern techniques of ultracold atomic physics to directly explore properties of strongly correlated or topologically protected materials. Our talk will present the SQCRMscope, a novel Scanning Quantum Cryogenic Atom Microscope technique for imaging magnetic and electric fields near cryogenically cooled materials. With our SQCRMscope, we aim to image inhomogeneous transport and domain percolation in technologically relevant materials whose order has evaded elucidation.

1We are grateful to the Moore Foundation and the Department of Energy for their generous support.

8:48AM A21.00005 Simulated imaging of intermolecular bonds using high throughput real-space density functional calculations . ALEX LEE, The University of Texas at Austin, MINJUNG KIM, Yale University, JAMES CHELIKOWSKY, The University of Texas at Austin — Recent experimental noncontact atomic force microscopy (AFM) studies on 8-hydroxyquinoline (8-hq) assemblies have imaged distinct lines between molecules that are thought to represent intermolecular bonding. To aid the interpretation of these images, we calculate simulated AFM images of an 8-hq dimer with a CO functionalized tip using a real-space pseudopotential formalism. We examine the effects of Pauli repulsion and tip probe relaxation as explanations for the enhanced resolution that resolves these intermolecular force lines. Our study aims to compute ab initio real-space images of intermolecular interactions.
Maps are important to engineer nanomaterials in applications ranging from photovoltaics to sensing and therapeutics. Wavelengths (\(\lambda\)) near-IR probe electronic transitions in materials, providing information regarding band gap and defects while light in mid-IR probes vibrational transitions and processes.

Forces between the nc-AFM tip and specimen. We simulate images of planar organic molecules with two different approaches: 1) with a chemically inert tip and 2) with a CO functionalized tip. We find dramatic differences in the resulting images, which are consistent with recent experimental work.

Our work is supported by the DOE under DOE/DE-FG02-06ER46286 and by the Welch Foundation under grant F-1837. Computational resources were provided by NERSC and XSEDE.

Photo Thermal Induced Resonance (PTIR) is a novel technique that circumvents light diffraction by employing an AFM tip as a local detector for measuring light absorption with \(\lambda\)-independent nanoscale resolution. Our PTIR setup combines an AFM microscope with three lasers providing \(\lambda\)-tunability from 500 nm to 1600 nm continuously. The AFM tip transduces locally the sample thermal expansion induced by light absorption into large cantilever oscillations. Local absorption spectra (for electronic, vibrational, or functional) and maps are obtained recording the amplitude of the tip deflection as a function of \(\lambda\) and position, respectively. The working principles of the PTIR technique will be described first, and nano-patterned polymer samples will be used to evaluate its lateral resolution, sensitivity, and linearity. Results show that the PTIR signal intensity is proportional to the local absorbed energy suggesting applicability of this technique for quantitative chemical analysis at nanoscale, at least for thin (less than 1000 nm thick) samples. Additionally, a \(\lambda\)-independent resolution of 20 nm is demonstrated through the work of the talk. In the second part of the talk, PTIR will be applied to image the dark plasmonic resonance of gold asymmetric split ring resonators (A-SRRs) in the mid-IR. Additionally, the chemically-specific PTIR signal will be used to map the near-field absorption enhancement of PMMA coated A-SRRs, revealing hot-spots with enhancement factors up to \(\approx 30\). PTIR has broad applicability; recent examples from my lab include the characterization of chemically heterogeneous domains in metal-organic frameworks crystals and solar cells materials.

Connecting the Tips of a Millikelvin Dual-Tip STM was supported by National Basic Research Programs of China, National Science Foundation of China.

Asymmetric superconducting quantum interference devices for suppression of phase diffusion in small Josephson junctions was supported by National Basic Research Programs of China, National Science Foundation of China.

Connecting the Tips of a Millikelvin Dual-Tip STM is a novel technique that recombinates, spectrally-separated, local electron tunneling and thermal expansion to measure the sample chemical potential with \(\lambda\)-independent nanoscale resolution. Our PTIR setup combines an AFM microscope with three lasers providing \(\lambda\)-tunability from 500 nm to 1600 nm continuously. The AFM tip transduces locally the sample thermal expansion induced by light absorption into large cantilever oscillations. Local absorption spectra (for electronic, vibrational, or functional) and maps are obtained recording the amplitude of the tip deflection as a function of \(\lambda\) and position, respectively. The working principles of the PTIR technique will be described first, and nano-patterned polymer samples will be used to evaluate its lateral resolution, sensitivity, and linearity. Results show that the PTIR signal intensity is proportional to the local absorbed energy suggesting applicability of this technique for quantitative chemical analysis at nanoscale, at least for thin (less than 1000 nm thick) samples. Additionally, a \(\lambda\)-independent resolution of 20 nm is demonstrated through the work of the talk. In the second part of the talk, PTIR will be applied to image the dark plasmonic resonance of gold asymmetric split ring resonators (A-SRRs) in the mid-IR. 10:36AM A21.00012 Kelvin probe force microscopy: imaging open-circuit voltage in optoelectronic devices. ELIZABETH TENNYSON, Materials Science and Engineering, Univ. of Maryland, JOSEPH GARRETT, Physics, Univ. of Maryland, JESSE FRANTZ, JASON MYERS, U.S. Naval Research Laboratory, ROBEL BEKELE, University Research Foundation, JASBINDER SANGHERA, U.S. Naval Research Laboratory, JEREMY MUNDAY, Electrical and Computer Engineering, Univ. of Maryland, MARINA LEITE, Materials Science and Engineering, Univ. of Maryland — Scanning probe microscopy has been successfully implemented to probe the electrical characteristics of optoelectronic devices. Currently, a method that directly correlates measured signals to device performance is missing. We implement illuminated Kelvin probe force microscopy (KPFM) to spatially resolve the open-circuit voltage of optoelectronics with nanoscale resolution, 5 orders of magnitude better than previous methods. In illuminated-KPFM, the surface photovoltage, is the difference between the contact potential difference under illumination and in the dark, and proportional to the Fermi level splitting. We apply our imaging method to a variety of solar cells and find that the open-circuit voltage in some materials varies locally by >0.2 V, suggesting the spatial variation of non-radiative recombination strongly affects performance. A detailed examination of possible topography pick-up was excluded by measuring samples with modified surface morphology and considering the tip-sample separation dependence of the signal. This novel metrology enables new insights into the loss mechanisms that hinder solar cells and provides a new platform to image device performance with nanoscale resolution.

10:48AM A21.00013 A method for correcting out-of-plane, fast time scale positional drift in atomic force microscopy1 . JOHN P. WHEELER, PARDEEP S. BANWAIT, ISAAC D. ROHRER, GREG A. HAMILTON, KELLY A. SHAW, MICHAEL C. LEOPOLD, MATTHEW L. TRAWICK, University of Richmond — We describe a method for correcting atomic force microscopy images that have been affected by random fluctuations (fast time scale positional drift) in measurements along the axis perpendicular to the sample plane. These fluctuations, typically manifested as random horizontal streaks or bands across the image, have several sources, including electrostatic charging and the transfer of material between the sample and the tip. Our correction method involves scanning a second, partial image after each full image scan, and applying an offset correction to each individual scan line in both images in order to minimize the statistical discrepancy between them. This method supersedes the widely used “flattening” algorithm, which can destroy valid height information and can create additional image artifacts.

8:00AM A22.00001 Gapped collective modes in quantum solids, DANIEL AROVAS, University of California - San Diego, SNIR GAZIT, ASSA AUERBACH, HELOISE NONNE, DANIEL PODOLSKY, Technion - Israel Institute of Technology — The harmonic theory of crystals predicts that the excitation spectrum of a Bravais lattice, i.e. a mono-atomic crystal structure, consists solely of gapless acoustic phonons. Surprisingly, an inelastic Neutron scattering experiment of solid He4 BCC phase has uncovered a zero momentum gapped excitation [1]. Motivated by the large zero point motion in the BCC phase, we describe the crystal through a phenomenological effective Ginzburg-Landau field theory of a charge density wave order parameter. We find that the excitation spectrum contains gapped modes which correspond to fluctuations of the charge density wave order parameter amplitude. We characterize the modes according to their symmetry and compute their visibility in Neutron scattering experiments. To further validate our results, we calculate the scalar susceptibility by means of an ab-initio quantum Monte Carlo simulation. We find a gapped resonance in good agreement with the experimental measurements. Our results motivate future studies of the excitation spectrum of quantum solids. [1] T. Markovich, E. Polturak, J. Bossy, and E. Farhi, Phys. Rev. Lett. 88, 195301 (2002)

8:12AM A22.00002 Strong-coupling and the stability of crystalline order in superfluid 3He films1 . JOSHUA WIMAN, J. A. SAULS, Northwestern University — In a film of thickness D, weak-coupling theory for p-wave, spin-triplet pairing predicts a “stripe” phase that spontaneously breaks translational symmetry in the plane of the film[2]. NMR on superfluid 3He confined in a slab has so far failed to detect any signature of the stripe phase, and the A-B transition is observed at lower temperatures than predicted by weak-coupling theory[2]. We report calculations of the phase diagram for 3He films based on Ginzburg-Landau (GL) theory that includes strong-coupling effects via experimentally estimated β parameters[3]. At low pressures GL theory predicts the A-stripe phase transition, for small D, to be significantly suppressed compared to weak-coupling. For large D, the stripe transition is eliminated in favor of an A-B transition at lower temperatures than in weak-coupling. At higher pressures the stripe phase is predicted to be stable only at very low temperatures, outside the expected applicability of the strong-coupling GL theory. Our results suggest that the discrepancy between experiment and weak-coupling theory likely results from strong-coupling effects.

8:24AM A22.00003 Is there a stable commensurate solid phase in the second 4He layer on graphite? — path integral Monte Carlo study, JEONGHWAN AHN, HOOKYUNG LEE, YONGKYUNG KWON, KonKuk Univ — Existence of a stable commensurate structure in the second 4He layer on graphite has been a subject of intensive experimental and theoretical studies because of its implication in the possible realization of two-dimensional supersolidity. Earlier path-integral Monte Carlo (PIMC) calculations of Pierce and Manousakis predicted a stable C_{17} commensurate structure above the first-layer 4He atoms fixed at triangular lattice sites [1], but Corboz et al. later showed that no commensurate phase was stable when quantum dynamics of the first-layer 4He atoms was incorporated in the PIMC calculations [2]. On the other hand, recent heat capacity measurements of Nakamura et al. provided a strong evidence for a commensurate solid in the second 4He layer over an extended density range [3]. Motivated by this, we have performed new PIMC calculations for the second helium layer on graphite. Unlike previous PIMC calculations where a laterally-averaged one-dimensional substrate potential was used, we here employ an anisotropic 4He-graphite potential described by a sum of the 4He-C pair potentials. With this fully-corrected substrate potential we make more accurate description of quantum dynamics of the first-layer 4He atoms and analyze its effects on the phase diagram of the second layer.

1Supported by NSF Grant DMR-1106315.

8:36AM A22.00004 High temperature superfluidity in a commensurate phase of adsorbed \(^{4}\text{He}\)

RAINIA OLSEN, Oak Ridge National Laboratory — It is well known that a substrate can have a significant effect on the phase diagram of adsorbed atoms. For instance, \(^{4}\text{He}\) adsorbed on graphene forms a solid structure commensurate (aligned) with the substrate which has a density much smaller than the density of bulk \(^{4}\text{He}\). This occurs because the underlying periodic potential stabilizes the solid by opening an energy gap between the commensurate solid and the longest wavelength lattice excitations which would otherwise change the structure. Here we report calculations of superfluidity for \(^{4}\text{He}\) in a periodic potential with variable lattice spacing, using a Bogoliubov transformation to calculate the energy spectrum of the excitations. We find a gap in energy between the superfluid state and the longest wavelength excitations. When this superfluid energy gap is large enough, there should be few excitations even at temperatures above the lambda point, where superfluidity is not observed in the bulk. This occurs only when the lattice spacing of the substrate corresponds to the lattice spacing of bulk \(^{4}\text{He}\). In contrast, when the substrate periodicity is too large, as is the case with graphene, a classical commensurate solid is expected instead. We discuss other possible materials.

8:48AM A22.00005 Dislocation structure and mobility in hcp \(^{4}\text{He}\)

MAURICE DE KONING, EDGAR JOSUÉ LANDINEZ BORDA, UNICAMP-Univ de Campinas, WEI CAI, Stanford University — We present results of Path-integral Monte Carlo simulations of the basal-plane screw dislocation in hcp \(^{4}\text{He}\) at temperatures below 1K. First, our results show that, due to the extremely low stacking-fault energy, its core is widely extended, dissociating into a pair of Shockley partials separated by a ribbon of stacking-fault. Second, our findings suggest that the stress required to initiate dislocation motion is different from zero and of the order of 0.1 bar. Finally, we discuss the role of \(^{3}\text{He}\) impurities.

9:00AM A22.00006 Shear modulus of solid \(^{3}\text{He}\) in the bcc and hcp phases

JOHN BEAMISH, ZHIGANG CHENG, FABIEN SOURIS, University of Alberta — The shear modulus of solid hcp \(^{4}\text{He}\) decreases significantly at temperatures above 100 mK [1, 2]. This is due to dislocations which are localized when pinned by \(^{4}\text{He}\) impurities at low temperature but become mobile when \(^{3}\text{He}\) impurities “evaporate” at high temperature. The unpinned dislocations move freely in the basal plane of the hcp structure. This produces anisotropic and extraordinarily large softening of the shear elastic constant C_{44}, an effect referred to as “giant plasticity” [2]. Previous measurements [3] on solid \(^{3}\text{He}\) showed similar shear modulus changes in the hcp phase but not in the bcc phase. Here, we report new shear modulus measurements in both the bcc and hcp phases. These show a similar shear modulus anomaly in the bcc phase, indicating that dislocation softening is not unique to hcp phase of helium. We compare our results for bcc and hcp \(^{4}\text{He}\) to those \(^{4}\text{He}\), and discuss the roles that lattice structure and quantum statistics play in dislocation motion and impurity pinning.

Research supported by NSERC Canada

9:12AM A22.00007 Impact of dislocations on the structure of solid helium

HANS LAUTER, Oak Ridge National Lab, JOHN GOODKIND, USCD San Diego, KENNETH HERWIG, Oak Ridge National Lab, ECKHARD KROTSCHECK, University at Buffalo, EFIM KATS, Institut Laue Langevin, ANDREY PODLEŞNYAK, ANDREI SAVICI, DIALLO SOULEYMANE, JUSTIN CAREMICHAEL, Oak Ridge National Lab — Uncommon phonon spectra were obtained from solid helium below 1.3K and at pressures near 30 bar. Rapid cooling using the blocked capillary method created stressed solid helium in non-equilibrium state. Using inelastic neutron scattering, we disclosed the absence of Bragg-scattering combined with the presence of a phonon-gap, a phenomenon revealing the absence of long-range crystalline order. The energy of the gap is close to the value of a thermal activation energy measured by ultrasonic attenuation in unstrained solid \(^{4}\text{He}\) crystals. The dispersion of the phonons shows point-like intensities interpreted as signature of finite-edge length dislocations. The range and shape of the strain field perpendicular to the dislocation line was identified discerning excitations related to the fluttering mechanism [2]. These findings give new input to the discussion of a dislocation network in view of the shear modulus in distorted solid \(^{4}\text{He}\) [3, 4].

9:24AM A22.00008 Interaction of ultrasound and torsional oscillation in solid \(^{4}\text{He}\)

IZUMI IWASA, Kanagawa University, Kanagawa Japan, JOHN GOODKIND. Department of Physics, University of California San Diego, La Jolla, CA 92093, HARRY KOJIMA, Serin Physics Laboratory, Rutgers University, Piscataway, NJ — A new cell for studying ultrasound (10 MHz) propagation and torsional oscillation (1013 Hz) in solid \(^{4}\text{He}\) was constructed. Improvements were made in the design of the spacer for the quartz transducers and the diameter of the torsion rod containing helium fill hole to reduce the effects of the shear modulus of the solid \(^{4}\text{He}\) sample on the torsional oscillator response. Sudden shifts in both the sound propagation velocity and attenuation are observed below 100 mK. The detailed response depends on the ultrasound excitation level and thermal history. Increase in torsional oscillator frequency is observed at nearly the same temperature as where the sound propagation velocity shifts occur. At temperatures below 50 mK, changes in the ultrasound excitation level induce changes in the torsional oscillator frequency. Interpretation of these results in terms of He-3 impurity being trapped on dislocation lines will be discussed.

NSF grant DMR-1005325.

9:36AM A22.00009 Frequency-dependent Study of Ultrapure Solid \(^{4}\text{He}\) by Using Rigid Double-pendulum Torsional Oscillator

JAEWON CHOI, JAEHO SHIN, EUNSEONG KIM, Korea Advanced Institute of Science and Technology — The physical origin of the period drop found in the torsional oscillator (TO) containing solid \(^{4}\text{He}\) was previously interpreted as the appearance of supersolidity[4]. The current consensus is that the increase in the shear modulus leads to the period anomaly. Further studies show that the stiffening effect in TO can be simplified if a TO is not properly design in TO. High purity solid \(^{4}\text{He}\) sample (0.6ppb) was grown by the blocked capillary method. The resonant period of TO starts to decrease from the empty cell data at 80mK. The ratio of the resonant period changes to the total mass loading are \(3.8 \times 10^{-5}\) and \(2.6 \times 10^{-4}\) for 1st and 2nd mode, respectively. Unlike recent experiment[1] we could not found a frequency-independent period drop. The upper bound for the putative supersolid fraction is less than \(4 \times 10^{-6}\). The dissipation peak accompanied with the period drop was also analyzed with Cole-Cole plot and \(\omega \tau\) plot. We conclude that major contribution for the anomalous TO responses comes from the elastic effect.

10:00AM A22.00011 Mass Superflux in Solid Helium: Dependence on Temperature, Density and $^3$He Impurity Concentration, YEGOR VEKHOV, ROBERT HALLOCK, Univ. of Mass. - Amherst — The mass flux, $F$, induced to flow through solid $^4$He by means chemical potential differences imposed by the fountain effect in the range $25.6 < \rho < 26.4$ bar rises with falling temperature below 650 mK. At a lower temperature, $T_\text{d}$, the flux drops sharply. The behavior of the flux above $T_\text{d}$ is consistent with the presence of a bosonic Luttinger liquid. We report a study $F$ as a function of $^3$He concentration, $\chi$ (0.17 – 220) ppm, and explore the effect of level of $^3$He impurities on $T_\text{d}$. We find a strong reversible reduction of the flux, typically complete within a few mK. We find that $T_\text{d}$ is an increasing function of $\chi$ and the $T_\text{d}(\chi)$ dependence differs somewhat from the predictions for bulk phase separation. It is possible that the cores of edge dislocations carry the flux. In such a case the flux may be extinguished by the decoration of the cores or dislocation intersections by $^4$He.

1Work supported by NSF DMR 12-05217.

10:12AM A22.00012 Mass Superflux in Solid Helium: What Limits the Flux? $^1$, ROBERT HALLOCK, YEGOR VEKHOV, Univ. of Mass. - Amherst — The thermo-mechanical effect in superfluid helium is used to create a chemical potential difference, $\Delta \mu$, across a superfluid-filled vertical Vycor rod. This rod separates a bulk liquid superfluid helium reservoir, $R_1$, on the top of the Vycor at $T_1 = 1.46 – 1.51$ K and solid hcp $^4$He on the bottom at $T_\text{C} = 0.1 – 0.8$ K. Two in situ capacitance pressure gauges, $C_1$ and $C_2$, are placed at the ends of the horizontal cylindrical solid helium sample (1.84 cm$^3$, 25.9 – 26.4 bar) and located at different distances from the position of the Vycor rod in the solid helium, 10 and 31 mm, respectively. A $T_\text{d}$ decrease/increase changes $\Delta \mu$ and leads to a solid helium pressure increase/decrease detected by both $C_1$s. The rate of pressure change is slower at the further gauge, $C_2$, than at the nearer one, $C_1$. This behavior is interpreted as due to the presence of a mass flux bottleneck inside the solid helium sample. We believe, e.g. in the case of a $T_\text{d}$ decrease, that helium atoms emerge from the Vycor rod, perhaps migrate along the superfluid core of edge dislocations in solid helium and adsorb on them. This is the so-called "syringe-effect" or superclimb of edge dislocations. The dependence on temperature will be discussed.

1Work supported by NSF DMR 12-05217.

10:24AM A22.00013 Quantum Plasticity and Supersolid Response in Helium-4$^1$, ANATOLY KUKLOV, Department of Physics & Engineering, College of Staten Island, CUÑY, LODE POLLET, Department of Physics, Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, University of Munich, NIKOLAY PROKOF'EV, BORIS SVISTUNOV, Department of Physics, University of Massachusetts, Amherst — We argue that the three key phenomena recently observed in solid $^4$He — mass supertransport, anomalous isochoric compressibility (syringe effect), and giant plasticity—are closely related to each other: 1) the characteristics of an interconnected network of tilted quantum-rough gliding and superclimbing dislocations. Such roughness is guaranteed, on one hand, by tilting of dislocations in Peierls barrier, and, on the other, by fast tunneling of kinks and jogs. Quantum rough gliding or superclimbing dislocation features 1D quantum liquid of kinks or jogs, respectively. As immediate implications of this connection several predictions follow: In the absence of $^3$He impurities, the syringe effect and giant plasticity persist down to $T = 0$; the dynamical low-frequency syringe and giant-plasticity responses are dispersionless; and similarly to giant plasticity but without direct relationship to the supertransport along the dislocation cores, $^3$He impurities should suppress the syringe effect partially or completely at appropriately low temperatures.

1This work was supported by the National Science Foundation under the grants PHY-1314469 and PHY-1314735, and by FP7/ Marie-Curie Grant No. 621918 and FP7/ERC Starting Grant No. 306897.

10:36AM A22.00014 Helium-4 superfluid density; action-at-a-distance effects $^1$, STEPHEN R.D. THOMSON, FRANCIS M. GASPARINI, The State University of New York at Buffalo — We report results from experiments with $^4$He confined in two concentric 277 nm thick planar regions that are connected across a ring which forms a thin film weak link 33 nm thick. Measurements of the superfluid fraction within rings of varying widths have shown that the planar regions affect the film in the ring over distances much longer than the correlation length $\xi$. These results are analogous to those reported for a different geometry of both the specific heat and superfluid fraction [1]. To investigate the wide dependence of this proximity effect we have performed measurements with rings that are 8, 17, 40 and 100 $\mu$m wide. We will discuss our method of measurement and a possible mechanism for the long range action-at-a-distance effect suggested in [2] for the 2D Ising system.

10:48AM A22.00015 Mass transport in micrometer size solid $^4$He $^1$, ARIEL HAZIOT, DUK YOUNG KIM, MOSES CHAN, The Pennsylvania State University — We have studied the transport of $^4$He atoms through a thin solid $^4$He slab of $\sim$50 $\mu$m thick sandwiched between two superfluid ‘electrodes’ of liquid helium filled Vycor rods. The geometry of the experiment is similar to the configuration used by Hallock and collaborators at the University of Mass [1,2] however the thickness of our solid sample is about 8000 times thinner than the UMmass solid sample. The observed mass flow through the solid slab shows the characteristic of a superflow and the rate is more than a 1000 times higher than the UMass experiment. The mass flow rate decreases strongly with the pressure to vanish around 31 bar and it shows an hysteresis loop as a function of pressure. In contrast to the UMass experiment, the mass flow rate in our experiment decreases weakly and smoothly with increasing temperature between 30 mK and 1.2 K. In addition, we found no dependence on the $^3$He concentration from 3 ppm to 1%.

8:00AM A23.00001 Vertical Transport in Ferroelectric/Superconductor Heterostructures\(^1\),
LAURA BEGON-LOURS, JUAN TRASTOY, ROZENN BERNARD, ERIC JACQUET, CECILE CARRETERO, KARIM BOUZEHOUANE, STEPHANE FUSIL, VINCENT GARCIA, STEPHANE XAVIER, STEPHANIE GIROD, CYRILE DERANLOT, MANUEL BIBES, AGNES BARTHELEMY, JAVIER E. VILLEGAS, Unite Mixte de Physique CNRS/Thales, France — We study electric field-effects in superconducting films by measuring vertical transport in ferroelectric/superconductor heterostructures. These are based on ultrathin (4 to 8 nm thick) BiFeO\(_3\)-Mn grown on YBa\(_2\)Cu\(_3\)O\(_7\) by pulsed laser deposition. Nanoscale contacts are defined on the BiFeO\(_3\) via a series of nanofabrication steps which include e-beam lithography, metal deposition (Nb or Co capped with Pt) and lift-off. Conductive-tip atomic force microscopy and piezoresponse force microscopy are used to characterize the transport across the ferroelectric barrier as a function of its polarization (up/down). The observed electro-resistance, measured at various temperatures, allows studying the different electric-field screening in the normal and superconducting states.

8:12AM A23.00002 Two-dimensional simulations of the superconducting proximity in superconductor-semiconductor junctions, VICTOR CHUA, University of Illinois at Urbana-Champaign, MICHAEL VISSERS, The National Institute of Standards and Technology (NIST), STEPHANIE A. LAW, University of Delaware, SMITHA VISHVESHWARA, JAMES N. ECKSTEIN, University of Illinois at Urbana-Champaign — We simulate the consequences of the superconducting proximity effect on the DC current response of a semiconductor-superconductor proximity device within the quasiclassical formalism in the diffusively disordered limit. The device is modeled on in-situ fabricated NS junctions of superconducting Nb films on metallic doped InAs films, with electrical terminals placed in an N-S-N T-junction configuration. Due to the non-collinear configuration of this three terminal device, a theoretical model based on coupled two dimensional spectral and distributional Usadel equations was constructed and numerically solved using Finite-Elements methods. In the regime of high junction conductance, our numerical results demonstrate strong temperature and spatial dependencies of the proximity induced modifications to spectral and transport properties. Such characteristics deviate strongly from usual tunnel junction behavior and aspects of this have been observed in prior experiments[arXiv:1402.6055].

8:24AM A23.00003 STM/STS on proximity-coupled superconducting graphene\(^1\), MAOZ OVADIA, YU JI, JENNIFER HOFFMAN, Harvard University, JOEL I-JAN WANG, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Graphene in good electrical contact with a superconductor has been observed to have an enhanced proximity effect. Application of a magnetic field is expected to generate an Abrikosov lattice of superconducting vortices, each containing Andreev bound states in its core. With our versatile, homebuilt, low temperature scanning tunneling force microscope (STM/SFM), we investigate the electronic properties of graphene on superconducting NbSe\(_2\) in a magnetic field and search for signatures of these vortex core states.

8:36AM A23.00004 Closing the gap in the Andreev spectrum in a three-terminal superconducting junction, CIPRIAN PADURARIU, RÉGIS MELIN, Institut Néel CNRS, Grenoble, France, THIBAULT JONCKHEERE, JÉRÔME RECH, THIERRY MARTIN, Centre de Physique Théorique CNRS, Marseille, France, DENIS FEINBERG, Institut Néel CNRS, Grenoble, France, BENOÎT DOUCOT, Laboratoire de Physique Théorique et Hautes Energies CNRS. Paris, France, YULI NAZAROV, Kavli Institute of Nanoscience, TU Delft, The Netherlands — Quasiclassical circuit theory \(^1\) is used to investigate transport in a mesoscopic junction with three superconducting terminals. Our study reveals the closing of the gap in the Andreev spectrum for a wide range of phase-biases and transparencies, in agreement with previous work \(^2\). In this regime a superconducting current flows in the junction, while the proximity mini-gap is closed. The corresponding parameter region is studied systematically, both analytically in the low transparency limit and numerically. We provide a microscopic explanation for the closing of the gap in terms of multiple pair processes that correlate the superconducting currents flowing between different pairs of terminals \(^3\). We show that multi-terminal superconducting junctions provide unique opportunities for applications in quantum devices based on Josephson and/or Majorana physics.

8:48AM A23.00005 Proximity Effects in Superconductor–Graphene Junctions\(^1\), FABIAN A. CUEL-LAR, DAVID PERCONE, MARIE-BLANDINE MARTIN, BRUNO DLIBAK, MAELIS PIQUEMAIL, ROZENN BERNARD, JUAN TRASTOY, CONSTANCE MOREAU-LUCHAIRE, PIERRE SENEOR, JAVIER E. VILLEGAS, Unite Mixte de Physique and Universite Paris-Sud, Palaiseau, France, PIRAN KIDAMBI, STEPHAN HOFMANN, JOHN ROBERTSON, Department of Engineering, University of Cambridge, Cambridge, United Kingdom — Superconducting proximity effects are of particular interest in graphene: because of its band structure, an unconventional (specular) Andreev reflection is expected \(^1\). In this context, high-Tc superconductor-graphene junctions are especially attractive. In these, the size of the superconducting energy-gap may exceed the graphene doping inhomogeneities around the Dirac point, which should favor the observation of the specular Andreev reflection. Yet, the fabrication of high-Tc superconductor-graphene junctions is challenging: the usual growth and lithography processes in both materials are incompatible. We report here on a fabrication method that allow us to fabricate planar cuprate superconductor-graphene junctions, which we characterize via conductance spectroscopy. We analyze the features in the conductance spectra as a function of graphene doping, and discuss them in the framework of the Andreev reflection. \(^1\)C. W. J. Beenakker. Phys. Rev. Lett. 97, 067007 (2006)

9:00AM A23.00006 ABSTRACT WITHDRAWN —

9:12AM A23.00007 ABSTRACT WITHDRAWN —
9:24AM A23.00008 AC measurements of the superconducting proximity effect in metal nanowires, RUSSELL LKKE, JOONAS GOVENIUS, KUAN YEN TAN, MIKKO MÖTTÖNEN, QCD Labs, COMP Centre of Excellence, Department of Applied Physics, Aalto University School of Science, PO Box 13500, FI-00076 Aalto, Finland — We quantitatively probe the admittance of diffusive superconductor/nanowire/superconductor (SNS) weak links. Measurements are performed from 0.4 GHz to 12.8 GHz which includes regimes above and below the predicted characteristic energy scale for the superconducting proximity effect. Each device consists of a flux-biased SNS SQUID chain where N is a gold-palladium nanowire. The chain has strong capacitive coupling to a multimode microwave resonator. Measurements of the resonance frequency and quality factor for each resonator mode reveal the dissipative and reactive parts of the admittance of the SNS SQUID chain. The measurement results are valuable because they provide a direct test for theories of non-equilibrium superconductivity in SNS weak links and because AC measurements have only recently been reported in the literature. The data presented is also crucial for understanding losses in microwave circuits that employ SNS weak links, including nanobolometers. References: [1] P. Virtanen et al. Phys. Rev. B 83, 144514 (2011), [2] F. Kos et al. Phys. Rev. B 87, 174521 (2013), [3] B. Dassonville et al. Phys. Rev. Lett. 110, 217001 (2013). [4] J. Govenius et al. Phys. Rev. B 90, 064505 (2014)

9:36AM A23.00009 Cascading Proximity Effect and Singlet-Triplet Mixing in Rotating Magnetization Junctions, ANDREAS BILL, California State University Long Beach, CA 90840-9505, THOMAS E. BAKER, University of California, Irvine, CA 92697, ADAM RICHE-HALFORD, University of Washington, Seattle, WA 98195 — The proximity of a superconductor to an inhomogeneous magnetic material induces singlet and triplet pair correlations in the hybrid structure. The amount of each component and their presence deep in the magnetic material strongly depends on the magnetic inhomogeneity. We present a comparative study of pair correlations in a diffusive magnetic Josephson junction involving a multilayer with misaligned magnetization, a cosine-type helical structure and a more flexible and realistic domain wall of an exchange spring. Using the cascading effect we demonstrate that the three systems induce qualitatively different mixtures of correlations. In particular, we show that misaligned and continuously rotating magnetizations do not display the same physical state. Analyzing the Gor’kov functions we find that so-called short range singlet correlations can be found deep in the magnetic material and compete with triplet correlations giving rise to the so-called singlet-triplet 0 – π transition.

9:48AM A23.00010 Spin-transfer torque effect in nanopillar superconducting-magnetic hybrid Josephson junctions, BURM BAEK, WILLIAM RIPPARD, MATTHEW PUFALL, SAMUEL BENZ, STEPHEN RUSSEK, HORST ROGALLA, PAUL DRESSELHAUS, National Institute of Standards and Technology, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY TEAM — We have developed single nanopillar Josephson junctions with pseudo-spin-valve barriers with a feature size 50 nm or larger. We observed changes in Josephson critical current depending on the magnetization state of the barrier (parallel or anti-parallel) through the superconductor-ferromagnet proximity effect. The magnetization states of the pseudo-spin-valve barriers could also be switched with applied bias currents which is consistent with the spin-transfer torque effect in room-temperature spin valve devices. Our results demonstrate devices that combine superconducting and spintronic functions promising for a nanoscale cryogenic memory technology.

10:00AM A23.00011 Josephson Interference due to Orbital States in Nanowire Proximity Effect Junctions, KAVEH GHARAVI, GREGORY HOLLOWAY, JONATHAN BAUGH, Institute for Quantum Computing, University of Waterloo — The Josephson effect in a nanowire-based superconductor-normal-superconductor (SNS) junction is studied theoretically and experimentally, focusing on the effects of nanoscale confinement on the current-phase relationship of the junction. An axial external magnetic field is applied. The theory of a previously unstudied type of Josephson interference is described, based on the coupling between the axial flux and N-section Andreev quasiparticles (continuum states or bound states) occupying subbands of non-zero orbital angular momentum. The Bogoliubov-de Gennes equations are solved while considering the transverse subbands in the N-section, yielding energy-versus-phase curves that are shifted in phase in the presence of the flux. A similar phase shift is observed in the continuum current of the junction. An intuitive, semi-classical version of the theory is presented. The critical current $I_c$ of the junction is numerically calculated, and shown to oscillate versus the axial flux. Experimental observations of the oscillations of $I_c$ in an Nb-InAs nanowire-Nb junction are reported. It is shown that the observed oscillations can be described by the semi-classical picture. The scope and applicability of the theory to experimental devices is discussed.

Monday, March 2, 2015 8:00AM - 10:36AM – Session A26 DCP: Focus Session: Non-Adiabatic Dynamics: New Insights from Experiment and Theory –

8:00AM A26.00001 Representing Adiabatic Potential Energy Surfaces Coupled by Conical Intersections in their Full Dimensionality Using Coupled Quasi-Diabatic States, DAVID YARKONY, Johns Hopkins University — The construction of fit single state potential energy surfaces (PESs), analytic representations of ab initio electronic energies and energy gradients, is now well established. These single state PESs, which are essential for accurate quantum dynamics and have found wide application in more approximate quasi-classical treatments, have revolutionized adiabatic dynamics. The situation for nonadiabatic processes involving dissociative and large amplitude motion is less sanguine. In these cases, compared to single electronic state dynamics, both the electronic structure data and the representation are more challenging to determine. We describe the recent development and applications of algorithms that enable description of multiple adiabatic electronic potential energy surfaces coupled by conical intersections in their full dimensionality using coupled quasi-diabatic states. These representations are demonstrably quasi-diabatic, provide accurate representations of conical intersection seams and can smooth out the discontinuities in electronic structure energies due to changing active orbital spaces that routinely afflict global multistate representations.

8:48AM A26.00003 Non-adiabatic dynamics of reactions of O(1D) with Xe, CO, NO2, and CO2 from crossed atomic and molecular beam experiments. KRISTIE BOERING, University of California, Berkeley — Reactions of the first excited state of atomic oxygen, O(1D), with small molecules such as CO, NO2, and CO2 continue to be of interest in aeronomy and atmospheric chemistry, thus providing additional motivation to understand the dynamics of these reactions and how well they are predicted by theory. In collaboration with Prof. Jim Lin of the Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan, we have studied the dynamics of quenching and non-quenching reactions between O(1D) and various small molecules using a universal crossed atomic and molecular beam apparatus. New experimental results for the dynamics of quenching of O(1D) by Xe and CO will be presented and compared with previous results for NO2 (K.A. Mar, A.L. Van Wynyarden, C.-W. Liang, Y.T. Lee, J.J. Lin, K.A. Boering, J. Chem. Phys., 137, 044302, doi: 10.1063/1.4736567, 2012) and CO2 (M.J. Perri, A.L. Van Wynyarden, K.A. Boering, J.J. Lin, and Y.T. Lee, J. Chem. Phys., 119(16), 8213-8216, 2003; M.J. Perri, A.L. Van Wynyarden, J.J. Lin, Y.T. Lee, and K.A. Boering, J. Phys. Chem. A, 108(39), 7995-8001, doi: 10.1021/jp0458545, 2004). Among the most intriguing of the new results are for quenching of O(1D) by Xe, for which marked oscillations in the differential cross sections were observed for the O(1P) and Xe products. The shape and relative phase of the oscillatory structure depended strongly on collision energy. This behavior is likely due to the quantum nature of the collision dynamics, caused by interferences among multiple curve crossing pathways accessible during electronic quenching, known as Stueckelberg oscillations.

9:24AM A26.00004 Light, Molecules, Action: Broadband UV-visible transient absorption studies of excited state dynamics in photoactive molecules. ROSEANNE SENSION, Departments of Chemistry and Physics, Univ of Michigan - Ann Arbor — Broadband UV-visible transient absorption spectroscopy provides a powerful tool for the investigation of the dynamics of electronically excited molecules in the condensed phase. It is now possible to obtain transient spectra on a routine basis spanning the range from <300 nm to >800 nm with femtosecond time resolution. We have used this method to study the excited state dynamics and internal conversion of a range of molecular systems with potential application as optically powered molecular devices. The cyclohexadiene ring-opening reaction is the basis of a class of important optical switches and of the biological synthesis of vitamin D3. The ring-opening reaction is ultrafast, occurring on a picosecond to subpicosecond timescale depending on the substituents around the ring. These have a significant influence on the dynamics and electronic structure of the electronically excited molecule. The results of a series of transient absorption studies as a function of chromophore substitution and environment will be presented. The cis-trans isomerization of polynene molecules, especially substituted stilbenes, provides another important class of functional molecular transformations. Again the excited state dynamics can be ultrafast with photochemistry controlled by details of the curve crossings and conical intersections. Finally the photochemistry of the even more complex set of cobalamin chromophores with a photoactivable C-Co bond has been proposed as a tool for spatio-temporal control of molecule delivery including drug delivery. Broadband transient absorption spectroscopy has been used to investigate the ultrafast electronic dynamics of a range of cobalamin compounds with comparison to detailed theoretical calculations. The results of these studies will be presented.

10:00AM A26.00005 Long-lived complexes in the F + H2O and F + CH3OH Hydrogen Abstraction Reactions. ROBERT CONTINETTI, Univ of California - San Diego — Extending our recent study of the benchmark four-atom F·H2O system [1], we have now studied the dissociative photodetachment (DPD) of the seven-atom F·(CH3OH) cluster as well. The energetics of this system dictate that DPD only occurs to the HF + OCH3+ e− product channel on the neutral potential energy surface resulting in diagonal banding in the photoelectron-photofragment coincidence spectrum consistent with resolved HF vibrational excitation in the products. Evidence for photodetachment to long-lived (μs) van der Waals complexes (FH···OCH3) was also observed, as in the F·H2O system. The metastable states involved in F·H2O are best described as vibrational Feshbach resonances, and the energetics and dynamics of the metastable complexes in the two systems will be examined. This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under award number DE-FG03-98ER14679.

10:12AM A26.00006 Non-adiabatic dynamics in the detachment continuum of radical anions. JAN VERLET, Durham University — Using photoelectron (PE) spectroscopy at a range of photon energies above the detachment threshold of a radical anion, the dynamics of resonances can be identified by the appearance of various channels. These include: (i) direct and prompt autodetachment, which appears in the PE spectrum as a peak that increases in intensity as the photon energy is shifted to lower kinetic energy and typically does not shift with photon energy; and (ii) thermionic emission from the radical anion ground state which appears as an exponential decay at low very low kinetic energy. Using time-resolved PE spectroscopy, the non-adiabatic dynamics leading to the formation of the ground state anion can be monitored in real time. In some cases, these dynamics occur on timescales that vastly out-compete autodetachment, even at energies of 3 eV above the neutral. The methodology has been applied to a number of quinone-related molecules and provides insights into how electron capture can lead to stable anions, which is of relevance in switches and of the biological synthesis of previtamin D3. The ring-opening reaction is ultrafast, occurring on a picosecond to subpicosecond timescale depending on the substituents around the ring. These have a significant influence on the dynamics and electronic structure of the electronically excited molecule. The results of a series of transient absorption studies as a function of chromophore substitution and environment will be presented. The cis-trans isomerization of polynene molecules, especially substituted stilbenes, provides another important class of functional molecular transformations. Again the excited state dynamics can be ultrafast with photochemistry controlled by details of the curve crossings and conical intersections. Finally the photochemistry of the even more complex set of cobalamin chromophores with a photoactivable C-Co bond has been proposed as a tool for spatio-temporal control of molecule delivery including drug delivery. Broadband transient absorption spectroscopy has been used to investigate the ultrafast electronic dynamics of a range of cobalamin compounds with comparison to detailed theoretical calculations. The results of these studies will be presented.

10:24AM A26.00007 Photofragment vector correlations and rotational distributions from ozone dissociation at 266 and 248 nm. MICHELLE WARTER, WEI WEI, SIMON NORTH, Texas A&M University — Ozone photolysis is very important in the atmosphere and has been studied by many people, but there are still mysteries involved in O3 dissociation. Velocity-Max-Planck imaging experiments on O3 dissociation at 266 and 248 nm have been performed to reveal these mysteries. The even odd population alternations of the O2 rotational distribution and the vector correlations have been studied to determine if there is a dynamical effect on the odd state depletion.

Monday, March 2, 2015 8:00AM - 10:48AM
Session A27 DCP: Focus Session: Emerging Ultrafast Technologies

204B - Andrei Tokmakoff, University of Chicago
these features, we investigate the quantum-coherent interaction between the ultrashort electron pulse and the optical near-field of an illuminated nanostructure.

Finally, further applications and prospects of ultrafast electron imaging, diffraction and spectroscopy using nanoscale field emitters will be discussed. Finally, an update on our new results in coupling ultrafast lasers with TERS. This last topic illuminates a path forward toward the goal of understanding chemistry at the space-time limit.

8:36AM A27.00002 Coherent two-dimensional infrared microscopy, CARLOS BAIZ, DENISE SCHACH, ANDREI TOKMAKOFF, Univ of Chicago — We developed ultrafast 2D IR spectral microscopy, a new technique to measure spatially-resolved 2D infrared spectra and vibrational dynamics with diffraction-limited spatial resolution and femtosecond time resolution. The key enabling development consists of a new geometry where all three IR pulses propagate fully collinearly through an all-reflective IR microscope. A combination of polarization, chopping, and phase-cycling isolates the 2D IR signal by removing all unwanted signal and interference contributions. The single-beam collinear geometry enables us to implement 2D IR in three configurations: transmission, reflectance, and ATR. In terms of sensitivity, the 6 micron focus size produces an 8-fold enhancement of the signal compared to focusing with standard parabolic mirrors. These methods open up new possibilities for imaging proteins in cells, lipid membranes, or vesicles, as well as performing surface-sensitive studies on biological systems.

8:48AM A27.00003 Mapping the nanoscale energetic landscape in conductive polymer films with spatially super-resolved exciton dynamics, NAOMI GINSBERG, Univ of California - Berkeley — The migration of Frenkel excitons, tightly-bound electron-hole pairs, in polymeric organic semiconducting films is critical to the efficiency of bulk heterojunction solar cells. While these materials exhibit a high degree of structural heterogeneity on the nanoscale, traditional measurements of exciton diffusion lengths are performed on bulk samples. Since both the characteristic length scales of structural heterogeneity and the reported bulk diffusion lengths are smaller than the optical diffraction limit, we adapt far-field super-resolution fluorescence imaging to uncover the correlations between the structural and energetic landscapes that the excitons explore.

9:24AM A27.00004 Ultrafast electron microscopy and diffraction with laser-driven field emitters, CLAUS ROPERS, University of Goettingen — Ultrafast structural dynamics in solids and nanostructures can be investigated by an increasing number of sophisticated electron and x-ray diffraction techniques. Electrons are particularly suited for this purpose, exhibiting high scattering cross-sections and allowing for beam control by versatile electrostatic or magnetic lens systems. The capabilities of time-resolved electron imaging techniques critically depend on the employed source of laser-driven ultrashort electron pulses. Nanoscopic sources offer exceptional possibilities for the generation of electron probe pulses with very short durations and high spatial beam coherence. In this talk, I will discuss recent progress in the development of ultrafast electron microscopy and diffraction based on nanoscopic photocathodes. In particular, we implemented ultrafast low-energy electron diffraction (ULEED) and ultrafast transmission electron microscopy (UTEM) driven by nonlinear photoemission from field emission tips. ULEED enables the study of structural changes with high temporal resolution and ultimate surface sensitivity, at sub-keV electron energies. As a first application of this technique, we studied the structural phase transition in a stripe-like polymer superstructure on freestanding monolayer graphene. An advanced UTEM instrument was realized by custom modifications of a standard transmission electron microscope, leading to electron focal spot sizes in the microscope's sample plane of about 10 nm and electron pulse durations of less than 700 fs. Utilizing these features, we investigate the quantum-coherent interaction between the ultrashort electron pulse and the optical near-field of an illuminated nanostructure. Finally, further applications and prospects of ultrafast electron imaging, diffraction and spectroscopy using nanoscale field emitters will be discussed.
8:00AM A28.00001 Magnetic droplets and dynamical skyrmions, JOHAN AKERMAN, University of Gothenburg — Nanocontact spin-torque oscillators (NC-STOs) provide an excellent environment for studying nano-magnetic phenomena such as localized and propagating auto-oscillatory spin wave (SW) modes. The recent experimental observation of magnetic droplet solitons in NC-STOs with perpendicular magnetic anisotropy (PMA) free layers [1], and the numerical [2] and experimental [3] demonstrations of spin transfer torque (STT) nucleated skyrmions in similar magnetic thin films add two interesting and useful nanoscale magnetic objects. Due to the competition between exchange, anisotropy, and, in the case of skyrmions, the Dzyaloshinskii-Moriya interaction (DMI), the droplet and the skyrmion are extremely compact, on the order of 10-100 nm. One of the main differences between a magnetic dissipative droplet soliton and a skyrmion is that the former is a dynamical object with all its spins precessing around an effective field and stabilized by STT, exchange, and PMA, while the latter has static spins and an internal structure stabilized by DMI, exchange, and PMA. The dissipative droplet is furthermore a non-topological soliton, while the skyrmion is topologically protected. In this work I will report on our most recent droplet experiments, including droplet collapse at very high fields, droplets excited in nano-wire based NC-STOs, and studies of the field-current droplet nucleation boundary. I will also demonstrate numerically and analytically that STT driven precession can stabilize so-called dynamical skyrmions even in the absence of DMI, and I will describe their very promising properties in detail. From a more fundamental perspective, precession is hence a third independent possibility to stabilize a skyrmion, without the need for the conventional stabilization from either dipolar energy or DMI.

8:36AM A28.00002 Physical Mechanisms and Limits of Skyrmions for Information Processing and Storage, GEN YIN, ROGER LAKE, Department of Electrical Engineering, UC Riverside, CHIA-LING CHIEN, JIADONG ZANG, Department of Physics and Astronomy, Johns Hopkins University — Magnetic Skyrmions have been proposed for applications in future information storage because of their small size, their stability and their facial movement with low current. For such purposes the ability to create single Skyrmions is required and an understanding of the process of Skyrmion creation and decay is highly desirable. Here we numerically show that the location and the moment of Skyrmion creation or annihilation can be precisely controlled by a nano second unpolarized current pulse. To analyze the microscopic process we employ a lattice version of the topological charge on a tight-binding 2D plate. It provides a clear picture of the spin trajectories and orientations that locally trigger a topological transition, and it reviews the topological origin of a Skyrmion’s stability at finite temperatures. The robustness and experimental feasibility of the proposed mechanism are numerically examined.

8:48AM A28.00003 Electrical transport in three-dimensional cubic Skyrmion crystal, XIAO-XIAO ZHANG, Univ of Tokyo, NAOTO NAGAOSA, Univ of Tokyo and RIKEN CEMS — Two-dimensional magnetic Skyrmions have been well confirmed via various experimental techniques in the bulk or on epitaxial thin films. Besides, a topologically nontrivial three-dimensional cubic Skyrmion crystal in the bulk, which is essentially a hedgehog-antihedgehog pair texture predicted theoretically, has also been tentatively observed. Equipped with a sophisticated spectral analysis program, we adopt Matsubara Green’s function technique to study electrical transport, especially diagonal conductivity, in such system. We consider conduction electrons interacting with spinwaves via the strong Hund’s rule coupling, wherein fluctuation of monopolar emergent electromagnetic field exits within adiabatic approximation. We describe in detail the influence of temperature and Skyrmion number on both dc and ac conductivities. Possible deviation from Fermi liquid behavior will also be discussed.

9:00AM A28.00004 Statics and dynamics of zero field stable skyrmions in magnetic thin layers, NIKOLAI S. KISELEV, IAS1, Forschungszentrum Jülich, Germany, CHANGHOON HEO, IMM, Radboud University Nijmegen, Netherlands, ASHIS KUMAR NANDY, IAS1, Forschungszentrum Jülich, Germany, THEO RASING, IMM, Radboud University Nijmegen, Netherlands, STEFAN BLÜGEL, IAS1, PG1, Forschungszentrum Jülich, Germany — We present a comprehensive theoretical study of the statics and dynamics of magnetic skyrmions stabilized in zero magnetic field. The essential energy contributions for the stability of such magnetic skyrmions are the Dzyaloshinskii-Moriya interaction (DMI) and the uniaxial anisotropy. We define a finite range of the strength of these parameters corresponding to the stability of isolated skyrmions at zero magnetic field. Within this range there are two metastable Skyrmion solutions characterized by opposite polarity and opposite topological charge. Such skyrmions can lead to conceptually new approaches in data storage provided by field or current induced switching between two of such skyrmion states. We discuss in detail various aspects of the problem connected with the switching between two skyrmion states driven by an applied magnetic field pulse, including the role of magnetic pulse width, intensity and direction. The role of damping and dependencies on magnetic layer thickness, size and shape are also discussed. Presented results are obtained by the method of stochastic spin dynamics simulation applied to an extended Heisenberg model for localized magnetic spins.

9:12AM A28.00005 Collective Transport Properties of Driven Skyrmions with Random Disorder, DIPANJAN RAY, CYNTHIA OLSON REICHHARDT, CHARLES REICHHARDT, Los Alamos National Laboratory — We use particle-based simulations to examine the static and driven collective phases of skyrmions interacting with random quenched disorder. We show that non-dissipative effects due to the Magnus term reduce the depinning threshold and strongly affect the skyrmion motion and the nature of the dynamic phases. The quenched disorder causes the Hall angle to become drive-dependent in the moving skyrmion phase, while different flow regimes produce distinct signatures in the transport curves. For weak disorder, the skyrmions form a pinned crystal and depin elastically, while for strong disorder the system forms a pinned amorphous state that depins plastically. We discuss in detail the influence of temperature and Skyrmion number on both dc and ac conductivities. Possible deviation from Fermi liquid behavior will also be discussed.

9:24AM A28.00006 Dynamics of monopole-like excitation in chiral magnets under a current drive, SHI-ZENG LIN, AVADH SAXENA, Theoretical Division, Los Alamos National Laboratory — Skyrmions in chiral magnets are hedgehog-like spin textures, which wrap the sphere once. Skyrmion lines in metallic chiral magnets produce an emergent magnetic field that couples to the orbital motion of the conduction electrons. The inflow and outflow of this field around a closed surface is not necessary equal, i.e. the divergence of this field is not necessary zero, and thus it allows for the existence of emergent monopoles. One example is a finite segment of a skyrmion line inside crystal. The two ends of the segment produce a monopole and antimonopole, which are connected by lines of the emergent magnetic flux. Here we study the monopole dynamics induced by an electric current injected in the chiral magnet. We reveal that skyrmion segments are nucleated via the creation of monopoles and antimonopoles. Then these segments merge to form longer skyrmion lines via annihilation of monopoles and antimonopoles. Finally these skyrmion lines span the whole system, where all monopoles and antimonopoles disappear. The skyrmion lines are destroyed via the proliferation of monopoles and antimonopoles. We also propose to create the monopoles in a controlled way by applying current to surfaces. The existence of monopoles can be inferred from transport or imaging measurements.

This work was carried out under the auspices of the NNSA of the US DOE at LANL under Contract No. DE-AC52-06NA25396, and was supported by the US Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering.
9:36AM A28.00007 Detection of helical spin structures by magnetotransport 1, ALI C. BASARAN, Univ of California - San Diego, RAFAEL MORALES, Univ of the Basque Country, STEFAN GUENON, Eberhard-Karls-Universitat Tubingen, IVAN K. SCHULLER, Univ of California - San Diego — We have developed a method which allows determining the magnetic helicity in thin films by magnetotransport measurements. A helical spin configuration occurs during magnetization reversal in exchange coupled Ni/FeF 2 heterostructures. Both longitudinal and transverse components of the magnetization are concurrently detected using magnetotransport through a lithographically patterned cross junction. Small angle deviations around the well-defined unidirectional anisotropy axis reveal the change in the helicity of in-depth spin configuration. The simulations obtained using an incomplete domain wall model are in excellent agreement with the experimental data. Thus, we show that the complex spin formations in nanomagnetic systems can be studied with a lab based, well known, and rather simple experimental technique.

9:48AM A28.00008 Micromagnetic modeling of skyrmion injection in an inhomogeneous geometry 1. OLLE HEINONEN, WANJUN JIANG, SUZANNE TE VELTHUIS, AXEL HOFFMANN, Argonne Natl Lab — Magnetic systems with broken inversion symmetry can support skyrmion structures stabilized by the Dzyaloshinskii-Moriya interaction (DMI). This can be realized in thin magnetic films, such as CoFe, on a substrate with appreciable spin-orbit interactions, e.g., Ta or Pt. Recent works have explored the creation and manipulations in such thin films using spin transfer torque or domain wall injection, which is challenging. We recently demonstrated that an inhomogeneous spin-Hall current can efficiently create and inject skyrmions, which can then be manipulated and transported. Based on this observation we will here present micromagnetic modeling of the injection dynamics of skyrmions in a geometry similar to the ones used experimentally. For small current densities, the system will inject meandering stripes that will arrange themselves along equipotential lines. For large enough current densities, a domain wall forms in the narrow part of the system and much complicated dynamical structures are sprayed into the wider part of the system. When the driving current is subsequently turned off, these structures coalesce into skyrmions. A key ingredient here is the inhomogeneous spin-Hall torque resulting from the geometry of the system.

10:00AM A28.00009 Annihilation of skyrmions by spin wave in crossbar geometry 1, YIZHOU LIU, Department of Electrical and Computer Engineering, University of California Riverside, JIAODONG ZANG, Department of Physics and Astronomy, Johns Hopkins University, ROGER LAKE, Department of Electrical and Computer Engineering, University of California Riverside — Magnetic Skyrmions are possible candidates for future information storage applications due to their small size and topological protection. Understanding of the creation and annihilation process is necessary for developing a Skyrmion-based technology. We theoretically study the annihilation process within a crossbar geometry. By micromagnetic simulation, we find the annihilation of a single Skyrmion can be achieved by injecting a spin wave. The influence of a defect in this system is also discussed. Our method could be applied to individually address arrays of Skyrmions in a memory architecture.

10:12AM A28.00010 Magnetization pumping and dynamics in a uniform Dzyaloshinskii-Moriya magnet, ALEXEY KOVALEV, UTKAN GÜNÖRDÜ, University of Nebraska-Lincoln — We formulate a phenomenological description of thin ferromagnetic layers with inversion asymmetry where the long-wavelength magnetic dynamics experiences magnon current-induced torques and leads to magnon-motive forces. We first construct a phenomenological theory based on irreversible thermodynamics, taking into account the symmetries of the system. Furthermore, we confirm that these effects originate from Dzyaloshinskii-Moriya interactions from the analysis based on the stochastic Landau-Lifshitz-Gilbert equation. Our phenomenological results can be generalized to other systems such as pyrochlore crystals and chiral magnets. Possible applications include spin current generation, magnetization reversal and magnonic cooling.

10:24AM A28.00011 Current-Driven Dynamics of Skyrmions Stabilized in MnSi Nanowires Revealed by Topological Hall Effect 1, DONG LIANG, JOHN DEGRAVE, MATTHEW STOLT, Department of Chemistry, University of Wisconsin-Madison, YOSHINORI TOKURA, RIKEN Center for Emergent Matter Science, SONG JIN, Department of Chemistry, University of Wisconsin-Madison — Skyrmions, novel topologically stable spin vortices, hold promise for next-generation high-density magnetic storage technologies due to their nanoscale domains and ultralow energy consumption. One-dimensional (1D) nanowires are ideal hosts for skyrmions since they not only serve as a natural platform for magnetic racetrack memory devices but also can potentially stabilize skyrmions. We use the topological Hall effect (THE) to study the phase stability and current-driven dynamics of the skyrmions in MnSi nanowires. The THE was observed in an extended magnetic field-temperature window (15 to 30 K), suggesting stabilization of skyrmion phase in nanowires compared with the bulk (27 to 29.5 K). Furthermore, we study skyrmion dynamics in this extended skyrmion phase region and found that under the high current-density of 10 10−10 10−9 Am−2 enabled by nanowire geometry, the THE decreases with increasing current densities, which demonstrates the current-driven motion of skyrmions generating the emergent electric field. These results open up the exploration of nanowires as an attractive platform for investigating skyrmion physics in 1D systems and exploiting skyrmions in magnetic storage concepts.

10:36AM A28.00012 Towards Skyrmions: Magnetic and electrical properties of Mn 2−xRh xSn Heusler compounds, KUMARI GAURAV RANA, MPI for Chemical Physics of Solids, Dresden, Germany and MPI of Microstructure Physics, Halle, Germany, E. BENEDIKT, MPI for Chemical Physics of Solids, Dresden, Germany, O. MESHCHERIAKOVA, MPI for Chemical Physics of Solids, Dresden, Germany and MPI of Microstructure Physics, Halle, Germany. A. KÖHLER, D. EBKE, C. FELSER, MPI for Chemical Physics of Solids, Dresden, Germany — A variety of possible ground states and tunable magnetic and electronic properties makes Mn 2−xRh xSn one of the most relevant materials for spintronic devices. Mn 2−xRh xSn, a non-centrosymmetric tetragonal Heusler with enhanced spin-orbit coupling, is recently found to possess a strong spin canting of its magnetic sublattices and the found strong Dzyaloshinskii-Moriya exchange encourages studies of Skyrmions in this promising Heusler compound. We report on the evolution of magnetic and electronic properties of ordered Mn 2−xRh xSn films grown on single crystalline MgO (100) substrates using DC co-sputtering. For tetragonally ordered films, a curie temperature of up to 281 K and coercive field of up to 630 Oe (out of plane) is obtained. However, an in-plane component sets in for temperatures below 100 K. The structural ordering for the films grown at different substrate temperatures influences the magnetic as well as the electronic properties. The exchange energies, magneto-transport properties, Hall effect will be discussed. Our work gives an insight to tailor the properties of Mn 2−xRh xSn films and highlights it as a potential candidate for future spintronic devices.

10:48AM A28.00013 Large non-collinearity and spin-reorientation in the novel Mn$_2$RhSn Heusler magnet. — O. MESHCHERIUKOVA, S. CHADOV, A. NAYAK, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, U.K. ROESSLE, Institute for Theoretical Solid State Physics, Leibniz Institute for Solid State and Materials Research, Dresden, Germany, J. KUEBELER, Institute of Solid State Physics, Technical University of Darmstadt, Darmstadt, Germany, G. ANDRE, Laboratoire Leon Brillouin, CEA-CNRS Saclay, Gif-sur-Yvette, France, A.A. TSIRLIN, National Institute of Chemical Physics and Biophysics, Akadeemia tee 23, 12618 Tallinn, Estonia, C. FELSER, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — Heusler compounds is a large class of materials, which exhibits diverse fundamental phenomena, together with the possibility of the specific tailoring for various engineering tasks. Present work discusses the magnetic noncollinearity in the family of noncentrosymmetric Mn$_2$-based Heusler compounds. According to the experimental and theoretical results, Mn$_2$YZ Heusler family is suspected to provide promising candidates for the formation of the skyrmion lattice. The work is focused on Mn$_2$RhSn bulk polycrystalline sample, which serves as a prototype. It crystallizes in the tetragonal noncentrosymmetric structure (No. 119 I4/mcm), which enables the anisotropic DM coupling. Additional short-range modulation, induced by the competing nearest and next-nearest interplane Heisenberg exchange, is suppressed above the 80 K. This allows to develop the long-range modulations in the ideal ferrimagnetic structure within the $ab$ crystallographic planes.

Session A29 GMAG DMP: Focus Session: Antiferromagnets on Triangular Lattices 206A -
Alexander Chernyshev, University of California, Irvine

8:00AM A29.00001 Magnetostriiction to 100T in SrCu$_2$(BO$_3$)$_2$: magnetic pantograph effect and tuning of $J'/J$ ratio. — M. JAIME, NHMF-LLNL, A. SAUL, CINaM/CNRS, CEE/MIT, G. RADTKE, IMPMC/CNRS, M.B. SALAMON, Physics, UT Dallas, H.A. DABKOWSKA, McMaster Univ. — The magnetostriiction of the frustrated spin dimer system SrCu$_2$(BO$_3$)$_2$ was measured in pulsed high magnetic fields with an optical fiber Bragg grating technique. Both longitudinal (c-axis) and transverse (ab-plane) magnetostriiction were obtained to be $H = 60T$ for $H // c$-axis, observing a reduction of the unit cell volume as the sample is magnetized past the 1/3 saturation magnetization plateau. Modest changes in the lattice parameters, when combined with existing elastic neutron scattering data, suggest significant changes in the Cu-O-Cu bond angles (superexchange) through a pantograph effect as the sample is driven into highly polarized magnetic states. Supportive computations reveal an increase of the ratio of intra- to inter-dimer exchange integrals ($J'/J$) with a decrease in the Cu-O-Cu angle, and the concomitant drop in unit cell volume. These results impact our reading of existing predictions for the (H,T) phase diagram, and predictions for the effect of hydrostatic pressures on the ground state.

8:12AM A29.00002 Theory of lattice response to external magnetic field in SrCu$_2$(BO$_3$)$_2$: magnetostriiction driven by pantograph effect. — ANDRES SAUL, CINaM/CNRS, CEE/MIT and UMI/CNRS-MIT, GUILLAUME RADTKE, IMPMC/CNRS and Univ Paris 06, MARCELO JAIME, National High Magnetic Field Laboratory, Los Alamos National Laboratory, MYRON SALAMON, Department of Physics, The University of Texas at Dallas, HANNA DABKOWSKA, McMaster Univ. — Recent magnetostriiction experiments have shown that the macroscopic physical dimensions of the Shastry-Sutherland compound SrCu$_2$(BO$_3$)$_2$ change with the applied magnetic field mimicking the same complex behavior observed in the magnetization. Using Density Functional based methods we find that the driving force behind the magnetostriiction coupling is the Cu-O-Cu superexchange angle which, thanks to the orthogonal Cu$^{2+}$ dimers acting as pantographs, can shrink significantly (0.44%) with minute (0.01%) variations in the lattice parameters. The consequence is a reduction of the order of ~10% in the antiferromagnetic intra-dimer exchange integral J, sufficient to compensate the elastic energy loss in the deformation.

8:24AM A29.00003 NMR in Pulsed Magnetic Fields on the Orthogonal Shastry-Sutherland spin system SrCu$_2$(BO$_3$)$_2$: magnetostriiction driven by pantograph effect. — RAIVO STERN, NICPB, JONAS KOHLRAUTZ, Uni-Leipzig, HANNES KÜHNE, LIZ GREENE, JOCHEN WOSNITZA, EMFL-HLD, JÜGEN HAASE, Uni-Leipzig — SrCu$_2$(BO$_3$)$_2$ is a quasi-two-dimensional spin system consisting of Cu$^{2+}$ ions which form orthogonal spin singlet dimers, also known as the Shastry-Sutherland lattice, in the ground state. Though this system has been studied extensively using a variety of techniques to probe the spin triplet excitations, including recent magnetostriiction measurements over 100T, microscopic techniques, such as nuclear magnetic resonance (NMR), could provide further insight into the spin excitations and spin-coupling mechanisms. We demonstrate the feasibility of performing NMR on real physical system in pulsed magnets. We present $^{11}$B NMR spectra measured in pulsed magnetic fields up to 53 T, and compare those with prior results obtained in static magnetic fields. Herewith we prove the efficacy of this technique and then extend to higher fields to fully explore the spin structure of the 1/3 plateau.

8:36AM A29.00004 Identifying topological order in the Shastry-Sutherland model via entanglement entropy. — DAVID RONQULLIO, MICHAEL PETERSON, Cal State Univ- Long Beach — It is known that for a topologically ordered state the area law for the entanglement entropy shows a negative universal additive constant contribution, $-\gamma$, called the topological entanglement entropy. We theoretically study the entanglement entropy of the two-dimensional Shastry-Sutherland quantum antiferromagnet using exact diagonalization on clusters of 16 and 24 spins, utilizing the Kitaev-Preskill construction [A. Kitaev and J. Preskill, Phys. Rev. Lett. 96, 110404 (2006)]. We extract a finite topological term, $-\gamma$, in the region of bond-strength parameter space corresponding to high geometrical frustration. Thus, we provide strong evidence for the existence of an exotic topological ordered state and shed light on the nature of this model’s strongly frustrated, and long controversial, intermediate phase.

8:48AM A29.00005 Magnetic vortex crystals in frustrated 3D Mott insulators. — ZHENTAO WANG, Department of Physics and Astronomy, Rice University, YOSHITOMO KAMIYA, ITHIS Research Group and Condensed Matter Theory Laboratory, RIKEN, ANDRIY NEVIDOMSKYY, Department of Physics and Astronomy, Rice University, CRISTIAN BATISTA, Theoretical Division, T-4 and CNSL, Los Alamos National Laboratory — Topological spin textures, such as skyrmions, are of great interest to the field of spintronics and usually arise due to the interplay of Dzyaloshinskii-Moriya and exchange couplings. By contrast, using the BCC and FCC lattices as examples, here we demonstrate that frustrated spin exchange interactions alone can produce topological vortex crystals near the magnetic field-induced saturation transition of 3D bulk Mott insulators. Because of the magnetic frustration, the magnon spectrum of the high-field fully polarized state has multiple degenerate minima at different Q-vectors. This quantum paramagnet becomes gapless and goes through a Bose-Einstein condensation at the saturation field (quantum critical point). In this limit, we apply the dilute boson gas approximation to study the rich topological structures produced due to multi-Q condensation. We find that the vortex crystal phases span sizable regions in the phase diagrams of frustrated 3D Mott insulators with isotropic Heisenberg interactions, and are further stabilized by exchange anisotropies. Vortex strings emerge in the direction of the magnetic field and, depending on the distributions of the condensed modes, can form different exotic patterns.
9:00AM A29.00006 Magnetic phase diagram of the S=1/2 triangular-lattice antiferromagnet Ba$_3$CoSb$_2$O$_9$\cite{1}, YOSHITOMO KAMIYA, RIKEN, CRISTIAN BATISTA, Los Alamos National Laboratory — To explain the recently reported magnetic phase diagram of the spin-1/2 triangular-lattice compound Ba$_3$CoSb$_2$O$_9$ [1-3], we present a semiclassical mean-field theory for the easy-plane XXZ model on the stacked (pentagonal-lattice with a small inter-layer coupling. Quantum effects are incorporated by deriving effective interactions from the linear spin-wave analysis of the two-dimensional model. This analysis reproduces the main experimental observations, such as the 1/3-magnetization plateau (B |c/3, a cusp near 1/3 of the saturated moment (B |c), and a small step anomaly in the high field regime. The predicted spin configurations are compared against the NMR measurements on this compound. This work was done in collaboration with G. Koutroulakis (Los Alamos), T. Zhou (UCLA), J. D. Thompson (Los Alamos), H. D. Zhou (Univ. of Tennessee), and S. E. Brown (UCLA).

9:12AM A29.00007 Exotic magnetism on the quasi-FCC lattices of the d$^3$ double perovskites La$_2$NaBO$_6$ (B' = Ru, Os)\cite{2}, ADAM ACZEL, Quantum Condensed Matter Division, Oak Ridge National Laboratory — B-site ordered double perovskites with quantum spins S = 1/2 (d$^3$) and S = 1 (d$^4$) on the B' site have attracted a great deal of recent interest, due to the possibility of studying 4d and 5d magnetism combined with magnetic frustration on the face-centered-cubic (FCC) lattice. There has been less focus on d$^3$ systems, as they are generally expected to behave more classically and yield simple, commensurate magnetic ground states. In contrast, we find evidence for long-range and short-range (ξ = 70 A at 4 K) incommensurate magnetic order on the quasi-FCC lattices of the monoclinic double perovskites La$_2$NaRuO$_6$ and La$_2$NaOsO$_6$, respectively. Incommensurate magnetic order on the FCC lattice has not been predicted by mean field theory, but may arise via a delicate balance of inequivalent nearest neighbor and next nearest neighbor exchange interactions. Furthermore, in the Ru system with long-range order, inelastic neutron scattering reveals a spin gap Δ = 2.75 meV. Magnetic anisotropy is generally minimized in the more familiar octahedrally-coordinated 3d$^3$ systems, so the large gap observed for La$_2$NaRuO$_6$ may result from the significantly enhanced value of spin-orbit coupling in this 4d$^3$ material.

9:48AM A29.00008 The incommensurate-commensurate phase transition of anisotropic XXZ model on the triangular lattice, XUEFENG ZHANG, SHI-JIE HU, AXEL PELSTER, SEBASTIAN EGGERT, Univ Kaiserslautern — We investigate the XXZ model on the triangular lattice with anisotropic ferromagnetic xy coupling and antiferromagnetic z coupling. In previous studies, an incommensurate supersolid phase was found when introducing anisotropy of interactions in different directions. However, the mechanism of the incommensurate phase is still unknown. In the strong coupling regime where interactions in the z direction are larger than in the xy plane, we found that quantum fluctuation of domain wall excitations can reduce the energy and cause the incommensurate order. By using quantum Monte Carlo simulations, we confirmed our theoretical analysis and found that the number of domain walls and the incommensurate k-vector monotonically increase with the anisotropy. The physics is dimensionally reduced to 1d.

10:00AM A29.00009 Spin phonon induced magnetic soft mode in triangular antiferromagnet h-RMnO$_3$, JOOSUNG OH, MANH DUC LE, HASUNG SIM, JE-GEUN PARK, Center for Correlated Electron Systems, Institute for Basic Science & Department of Physics and Astronomy, Seoul National University, T.G. PERRING, ISIS Facility, STFC Rutherford Appleton Laboratory — The relief of geometrical magnetic frustration by spin-lattice coupling is an extensively studied subject: For example, theory shows that in triangular lattice antiferromagnets, the spin-phonon coupling can stabilize a collinear magnet order over the non-collinear 120° order. We report inelastic neutron scattering measurements on the triangular lattice antiferromagnets (Y/Lu)MnO$_3$, showing evidence of magnon-phonon hybridization at the Brillouin zone boundary. Furthermore, a magnetic soft mode is observed at lower energy at the same momentum transfer. The exchange striction model within the linear approximation qualitatively explains the observed features while the 1/S expansion calculation shows that a third of the observed softening is caused by magnon-magnon interactions. Our results demonstrate how the spin-phonon coupling and quantum effect cooperatively develops the roton-like minimum in triangular lattice antiferromagnets with a 120° structure.

10:12AM A29.00010 Magnetic phase diagram and multiferroicity of Ba$_3$MnNb$_2$O$_9$: A spin-triangular lattice antiferromagnet with weak easy-axis anisotropy\cite{3}, M. LEE, E.S. CHOI, Natl High Magnetic Field Lab, X. HUANG, Southeast University, Nanjing, China, J. MA, C.R. DELA CRUZ, M. MATSUDA, W. TIAN, Oak Ridge Natl Lab, TN, USA, Z.L. DUN, University of Tennessee, TN, USA, S. DONG, Southeast University, Nanjing, China, H.D. ZHOU, University of Tennessee, TN, USA — We have performed magnetic, electric, thermal, and neutron powder diffraction (NPD) experiments as well as density functional theory (DFT) calculations on Ba$_3$MnNb$_2$O$_9$. All results suggest that Ba$_3$MnNb$_2$O$_9$ is a spin-1/2 triangular lattice antiferromagnet (TLAF) with weak easy-axis anisotropy. At zero field, we observed a narrow two-step transition at $T_{k1} = 3.4$ K and $T_{k2} = 3.0$ K. The neutron diffraction measurement and the DFT calculation indicate a 120° spin structure in the ab plane with out-of-plane canting at low temperatures. With increasing magnetic field, the 120° spin structure evolves into up-up-down (udd) and oblique phase showing successive magnetic phase transitions, which fits well to the theoretical prediction for the 2D Heisenberg TLAF with classical spins. Multiferroicity is observed when the spins are not collinear but suppressed in the udd and the oblique phase. We discuss the results in comparison with our previous works on its sister compounds with small spins, Ba$_3$NiNb$_2$O$_9$ ($S = 1$) (J. Hwang et al., Phys. Rev. Lett. 109, 257205 (2012) and Ba$_3$CoNb$_2$O$_9$ ($S = \frac{3}{2}$) (M. Lee et al., Phys. Rev. B 89, 104420 (2014)).

10:24AM A29.00011 Indirect RIXS study of bimagnon excitations in triangular-lattice quantum Heisenberg antiferromagnet\cite{4}, TRINANJAN DATTA, Georgia Regents University, CHENG LUO, ZHENGE HUANG, DAO-XIN YAO, Sun Yat-Sen University — Bimagnon correlations in triangular-lattice quantum Heisenberg antiferromagnet can be probed by the resonant inelastic X-ray scattering (RIXS) technique. Utilizing an interacting spin wave theory within the Bethe-Salpeter approximation scheme, we compute the K-edge indirect RIXS spectra for the nearest neighbor Heisenberg model with a general S for the entire magnetic Brillouin zone. The non-collinear spin arrangement in the triangular lattice geometry supports the intrinsic spontaneous single-magnon decay or recombination. Based on our calculation, we find that the RIXS spectra display a peak at the antiferromagnetic wave vector (4π/3, 0) corresponding to the triangular lattice, which is in contrast to the square lattice case. The major contribution to the RIXS spectra originates from the decay vertices arising from the three-magnon interaction terms, with the quartic interaction contributions subduced. Our results indicate that the spontaneous decay and recombination of magnons inherent to the triangular lattice model can be observed in the RIXS spectra without a disintegration.

10:36AM A29.00012 Stripes and antiphase boundaries in CaFe$_2$O$_4$\(^1\), CHRIS STOCK, Univ of Edinburgh, EFRAIN RODRIGUEZ, University of Maryland, MARK GREEN, Kent University, NARA LEE, S.-W. CHEONG, Rutgers University — We report on the magnetic structure and spin dynamics in CaFe$_2$O$_4$ based upon an orthorhombic structure \[1\]. The magnetic structure consists of two competing magnetic phases based upon stripes of S=5/2 Fe$^{3+}$ ions. The magnetic dynamics illustrate that the coupling is primarily two dimensional. On application of a magnetic field, antiphase magnetic boundaries can be introduced into the lattice and frozen in at low temperatures. We investigate the structure and dynamics of these domains using polarized and unpolarized neutron scattering and discuss how the triangular geometry allow these localized defects to be energetically favorable.

10:48AM A29.00013 Anomalous weak ferromagnetism in \(R_{1-x}Y_xB_4\) \((R=\text{Sm, Gd, Tb, Dy, Ho, Er})\), B.Y. KANG, MYUNGUK SONG, B.K. CHO, School of Materials Science and Engineering, Gwangju Institute of Science and Technology (GIST), Korea, J.Y. KIM, Research Institute of Industrial Science & Technology, Korea — Since the report of magnetic properties of rare earth tetraborides, \(R_{1-x}Y_xB_4\) compounds have received a great attention over last decades because it shows various interesting magnetic ground states depending on rare-earth elements. \(R_{1-x}Y_xB_4\) exhibits antiferromagnetic ordering at low temperature and is classified as the Shastry-Sutherland lattice, which is a geometrically frustrated system. In this system, the disturbance of a delicate balance can lead to new electronic and magnetic states. In this study, single crystals of \(R_{1-x}Y_xB_4\) \((R=\text{Sm, Gd, Tb, Dy, Ho, Er})\), \((x=0, 0.1, 0.2, 0.3, 0.35, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1)\) were synthesized using the high-temperature AI solution growth method. Interestingly, weak ferromagnetism was found to emerge at the Neel temperature for the Y-doped single crystals of \(R_{1-x}Y_xB_4\). The magnitude of spontaneous magnetic moment was found to be correlated with the Y substitution ratio, which have maximum value at about 30% of Y-concentration. The weak ferromagnetism reveals also a strong magnetic anisotropy depending on rare-earth elements. The observed data indicate that the weak ferromagnetism is not due to an individual atomic effect but a systematic bulk effect. The exotic antiferromagnetic properties will be discussed in detail in terms of yttrium substitution and magnetic and geometrical structures.

206B - Alexander Khitun, University of California, Riverside

8:00AM A30.00001 Magnonic Holographic Memory\(^1\), ALEXANDER KHITUN, University of California Riverside, ALEXANDER KOZHEVNIKOV, Kotel’nikov Institute of Radioengineering and Electronics of Russian Academy of Sciences, Saratov Branch, FREDERICK GERTZ, University of California Riverside, YURI FILIMONOV, Kotel’nikov Institute of Radioengineering and Electronics of Russian Academy of Sciences, Saratov Branch — Collective oscillation of spins in magnetic lattice known as spin waves (magnons) possess relatively long coherence length at room temperature, which makes it possible to build sub-micrometer scale holographic devices similar to the devices developed in optics. In this work, we present a prototype 2-bit magnonic holographic memory. The memory consists of the double-cross waveguide structure made of \(Y_{x}Fe_{2}(FeO)_{13}\) with magnets placed on the top of waveguide junctions. Information is encoded in the orientation of the magnets, while the read-out is accomplished by the spin waves generated by the micro-antennas placed on the edges of the waveguides. The interference pattern produced by multiple spin waves makes it possible to build a unique holographic image of the magnetic structure and recognize the state of the each magnet. The development of magnonic holographic devices opens a new horizon for building scalable holographic devices compatible with conventional electronic devices.

8:12AM A30.00002 Calculating a parameter space to smoothly transport magnetically-trapped suspended superparamagnetic microbeads with electric-field domain wall control\(^1\), BRENDA MCLELLAN, New York University Polytechnic School of Engineering, MARK NOWAKOWSKI, JEFFREY BOKOR, University of California, Berkeley, CHENG-YEN LIANG, JOSHUA HOCKEL, KYLE WETZLAR, SCOTT KELLER, HYUNMIN SOHN, GREGORY CARMAN, University of California, Los Angeles, ANTHONY YOUNG, ANDREW DORAN, MATTHEW MARCUS, Advanced Light Source, Lawrence Berkeley National Laboratory, MATHIAS KLAUI, Institute of Physics, University of Mainz, 55128 Mainz, Germany, ROBERT CANDLER, University of California, Los Angeles, California NanoSystems Institute, Los Angeles, CA — We demonstrate the capture and electrically-driven piecewise transport of superparamagnetic microbeads trapped in a magnetostatic potential energy well produced by the magnetic domain walls of Ni micromirrors on a [Pb(Mg$_{1/3}$Nb$_{2/3}$)O$_3$]$_{66}$-[PbTiO$_3$]$_{34}$ (PMN-PT) substrate. Here I present micromagnetic simulations that illustrate the formation of field-initialized domain walls in Ni micromirrors and calculate the approximate force of attraction experienced by superparamagnetic microbeads near the domain walls. This force is estimated as a function of the ring geometry, bead diameter, and distance from the domain wall, and provides an upper bound for the strain-mediated, electrically-induced domain wall velocity that can be implemented to smoothly transport coupled microbeads within a fluidic environment. These results provide an initial estimate for important technological parameters and set a foundation for the optimization of this microfluidic magnetic control scheme. H. Sohn, M. Nowakowski, et al. submitted, 2014.

8:24AM A30.00003 Stochastic simulations of switching error in magneto elastic and spin-Hall effect based switching of nanomagnetic devices\(^1\), MD MAMUN AL-RASHID, SUPRIYO BANDYOPADHYAY, JAYASIMHA ATULASIMHA, Virginia Commonwealth University — Switching of single domain multiferroic nanomagnets with electrically generated mechanical strain \[1\] and with spin torque due to spin current generated via the giant spin Hall effect \[2\] are two promising energy-efficient methods to switch nanomagnets in magnetic computing devices. However, switching of nanomagnets is always error-prone at room temperature owing to the effect of thermal noise. In this work, we model the strain-based and spin-Hall-effect-based switching of nanomagnetic devices using stochastic Landau-Lifshitz-Gilbert (LLG) equation and present a quantitative comparison in terms of switching time, reliability and energy dissipation.

8:36AM A30.0004 Preliminary experiments on SAW based magnetization switching of nanomagnets\textsuperscript{1}. VIMAL SAMPATH, NOEL D’SOUZA, SUPRIYOGO BANDYOPADHYAY, JAYASIMHA ATULASIMHA, Virginia Commonwealth University — Magnetization rotation in micron-sized ferromagnetic elements, using Surface Acoustic Waves (SAW), has been demonstrated experimentally \textsuperscript{1} while the use of SAW to lower the energy dissipation in switching of nanomagnets with spin transfer torque has been studied theoretically \textsuperscript{2}. Furthermore, SAW can be used to “Bennett clock” an array of nanomagnets in nanomagnetic logic without requiring lithographic contacts to individual nanomagnets \textsuperscript{3}. We report preliminary experiments on use of SAW to switch magnetostrictive Co nanomagnets grown on bulk 128 Y-cut lithium niobate. Switching is studied by imaging the nanomagnets’ magnetic states with Magnetic Force Microscopy (MFM) before and after the SAW waves interact with them. Switching of single, isolated nanomagnets of various sizes, and dipole coupled nanomagnets implementing a Boolean NOT gate, is studied.

8:48AM A30.0005 Magneto-elastic artificial neurons with extremely low energy dissipation\textsuperscript{1}. AYAN K. BISWAS, MD MAMUN AL-RASHID, JAYASIMHA ATULASIMHA, SUPRIYOGO BANDYOPADHYAY, Virginia Commonwealth University — We present a detailed analysis of artificial step transfer function neurons and binary weight synapses implemented with magneto-tunneling junctions whose soft layers are magnetostrictive nanomagnets switched with voltage generated mechanical strain. These devices are more energy-efficient than CMOS-based neurons or so-called spin neurons that are based on magnets switched with spin-polarized current \textsuperscript{1}. We studied their switching dynamics using stochastic Landau-Lifshitz-Gilbert simulations for two different geometries (elliptical and cylindrical) of the magnetostrictive nanomagnet. Our study revealed that while the step transition (firing) of the magnetic neuron is always very sharp at 0 K, the threshold is significantly broadened at room temperature, regardless of geometry and regardless of whether the magnetic neuron is switched with strain or spin-polarized current. While this could preclude some applications, the extreme energy-efficiency of these neurons makes them nearly ideal for use in certain types of neuromorphic computation. \textsuperscript{1}M. Sharad, et al., IEEE Trans. Nanotechnol., 11, 843 (2012).

This work is supported by the NSF under grant ECCS-1124714 and CCF-1216614.

9:00AM A30.0006 Three dimensional magnetic abacus memory \textsuperscript{1}. SHILEI ZHANG, Oxford University, JINGYAN ZHANG, University of Science and Technology Beijing, ALEXANDER BAKER, University of Oxford, SHOUGUO WANG, Chinese Academy of Science, GUANGHUA YU, University of Science and Technology Beijing, THORSTEN HESJEDAL, University of Oxford — Stacking nonvolatile memory cells into a three-dimensional matrix represents a powerful solution for the future of magnetic memory \textsuperscript{1,2}. However, it is technologically challenging to access the individual data in the storage medium if large numbers of bits are stacked on top of each other. Here we introduce a new type of multilevel, nonvolatile magnetic memory concept, the magnetic abacus \textsuperscript{3}. Instead of storing information in individual magnetic layers, thereby having to read out each magnetic layer separately, the magnetic abacus adopts a new encoding scheme which envisions a classical abacus with the beads operated by electron spins. It is inspired by the idea of second quantization, dealing with the memory state of the entire stack simultaneously. Direct read operations are implemented by measuring the artificially engineered 'quantized' Hall voltage \textsuperscript{4}, representing a count of the spin-up and spin-down layers in the stack. This concept of 'second quantization of memory' realizes the 3D memory architecture with superior reading and operation efficiency, thus is a promising approach for future nonvolatile magnetic random access memory. \textsuperscript{1}Parkin, S. S. P. et al. Science 320, 190 (2008). \textsuperscript{2}Lavrijsen, R. et al. Nature 493, 647 (2013). \textsuperscript{3}Zhang, S. L. et al. Sci. Rep. 4, 6109 (2014). \textsuperscript{4}Zhang, S. L. et al. Sci. Rep. 3, 2087 (2013).

9:12AM A30.0007 Controlling Magnetization using Spin Orbit Torque \textsuperscript{1}. SAYEEF SALAHUDDIN, EECS, UC Berkeley — Recently it has been shown that spin orbit coupling (SOC) and/or broken inversion symmetry in vertical heterostructures can generate accumulation of spins when a current is flowing through them. In doing so, it can exert a torque on an adjacent magnet \textsuperscript{1,2}. Indeed, high Z metals (Ta, Pt, W, etc.) with strong SOC have been used to inject spin currents into adjacent ferromagnetic layers and thereby to induce magnetic switching, oscillation, domain wall movement etc. SOC physics promises to significantly reduce the required current for current induced magnetic switching for next generation data-storage applications. In this presentation we shall discuss some of our recent work on SOC induced control of magnets with perpendicular magnetic anisotropy (PMA). A current flowing in-plane present interesting symmetry problems with respect to a PMA magnet. We shall discuss how these symmetry relations can be utilized for switching of and domain wall movement in the PMA magnets \textsuperscript{3}. In addition to storage applications, we shall also discuss possibility of exploiting SOC for spintronic logic applications \textsuperscript{4}.

9:48AM A30.0008 Bridging amount of spin-glasses over ferromagnetic/antiferromagnetic thin films and bit-cell dispersion of exchange bias in corresponding TA-MRAM devices \textsuperscript{1}. KAMIL AKMALDINOV, Spintec/Crocus Technology, CLARISSE DUCRUET, JEREMY ALVAREZ-HERAULT, Crocus Technology, VINCENT BALTZ, Spintec, SPIN-TEC TEAM\textsuperscript{2} — For thermally-assisted magnetic random access memories (TA-MRAM), lowering bit-cells dispersions of exchange bias is necessary. In this study, we prove that spin-glass-like phases (SG) spread over the ferromagnetic/antiferromagnetic (F/AF) storage layer are the main cause of such distributions once the film is nanofabricated into a device. In particular, we show that the less the SG, the lower the bit-cell dispersion. More precisely, the amount of SG was varied from sample to sample by sputtering various AFS: IrMn, FeMn and their alloys \textsuperscript{1}. Blocking temperature distributions were measured to quantify the amount of SG at the wafer level \textsuperscript{2}. The wafers were then patterned to obtain 1kb devices and all the cells were tested electrically. Finally, the resulting loop shift cumulative distribution functions accounting for the bit-cell dispersions were correlated to the initial amount of SG. In addition to bridging the gap between fundamental SG and a technological application, we also demonstrated that blocking temperature distributions are a versatile method to qualify TA-MRAM production batches before processing \textsuperscript{3}.

10:00AM A30.00009 Electromechanical Switching of the Magnetization in Nanomagnets¹.
REEM JAAFAAR, City University of New York - LaGuardia Community College, EUGENE CHUDNOVSKY, City University of New York - Lehman College — We demonstrate the possibility of switching the magnetization by a mechanical kick generated by, e.g., a pulse of the electric field applied to a multiferroic nanoparticle or to a piezoelectric coupled to a magnetic particle that is free to rotate. The effect is based upon the observation that the mechanical rotation is equivalent to the magnetic field in the coordinate frame of the particle. This removes the symmetry argument on the way of reversing the magnetic moment by the electric field as the latter is used to generate rotation which provides the effective magnetic field acting on the magnetic moment. Analytical and numerical results will be reported.

¹This research was funded by DARPA MESO.

10:12AM A30.00010 Strain-induced Electric Field Switching of Magnetic Anisotropy in Ferromagnetic/Ferroelectric Interface¹.
Milwaukee — Magnetism induced by an external electric field (e-field) has received much attention as a potential approach for controlling magnetism at the nano-scale with the promise of ultra-low energy power consumption. Here, the electric field as the latter is used to generate rotation which provides the effective magnetic field acting on the magnetic moment.

10:24AM A30.00011 Strain control of magnetization in TbFe₂.
DORJKHUU, Department of Physics, Incheon National University, South Korea, P. V. ONG, TSEVELMAA, N. KIOUSSIS, Department of Physics and Astronomy, California State University Northridge, USA — Magnetostriuctive materials change their shape upon application of strain and can be used as actuators and sensors. In this work, we perform a computational analysis of a highly magnetostriuctive compound, TbFe₂, to understand how the lattice and magnetization couple. We use Density Functional Theory (DFT) to investigate the magnitude and direction of the metallic moment as a function of pressure. The localized nature of Tb e-electrons classify this compound as “strongly-correlated” and necessitate the simultaneous use of spin-orbit coupling to treat magnetostriction and the DFT methodology to capture the physics of the e-electrons. Although, the energy scales involved in spin-lattice interactions are extremely small, we were able to correctly reproduce the correct magnetic ground state and the experimentally observed ferrimagnetic coupling between Tb and Fe atoms in TbFe₂. The easy axis in TbFe₂ points along one of its body diagonals, which makes the shape of the crystal rhombohedral. Switching of magnetization between the easy axes requires the magnetization to pass through one of the [100] directions. In our study we show that by applying isotropic strain on TbFe₂ crystal, we can decrease the energy barrier between [111] and [100] magnetization directions of the crystal.

10:36AM A30.00012 Spin Optodynamics in Magnetic Solids¹.
TIANYU LIU, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, XUFENG ZHANG, HONG X. TANG, Department of Electrical Engineering, Yale University, MICHAEL E. FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa — Coherent couplings between cavity photons and spin ensembles, such as cold atoms [1] and nanomagnets [2], have been studied theoretically before. By virtue of magneto-optic interactions, we propose here to use a photonic cavity made of magnetic crystal to study the intrinsic coupling rate (Γ) that describes the effect of a single photon on the cavity. Cavity bistability due to multistatic magnetization is identified, and with clever choosing of driving fields, one can realize coherent amplification/damping of spin-wave amplitudes, which is superior than the incoherent methods, such as the one using spin transfer torque. Our theory has great potential in developing all optical control of magnonics.

10:48AM A30.00013 Electric-field-induced modification in Curie temperature of Co monolayer on Pt (111).
KOHI NAKAMURA, MIKITO OBA, TORU AKIYAMA, TOMONORI ITO, Mie Univ, MICHAEL WEINERT, University of Wisconsin-Milwaukee — Magnetism induced by an external electric field (E-field) has received much attention as a potential approach for controlling magnetism at the nano-scale with the promise of ultra-low energy power consumption. Here, the E-field-induced modification of the Curie temperature for a prototypical transition-metal thin layer of a Co monolayer on Pt(111) is investigated by first-principles calculations by using the full-potential linearized augmented plane wave method that treats spin-spiral structures in an E-field. An applied E-field modifies the magnon (spin-spiral formation) energies by a few meV, which leads to a modification of the exchange pair interaction parameters within the classical Heisenberg model. With inclusion of the spin-orbit coupling (SOC), the magnetocrystalline anisotropy and the Dzyaloshinskii-Moriya interaction are obtained by the second variation SOC method. An E-field-induced modification of the Curie temperature is demonstrated by Monte Carlo simulations, in which a change in the exchange interaction is found to play a key role.

Monday, March 2, 2015 8:00AM - 11:00AM — Session A31 GMAG DMP: Focus Session: Molecular Magnets
207A - Christopher Landee, Clark University
8:00AM A31.00001 Photocontrol of Magnetism above 77 K in Nanoscaled Heterostructures of Cyanometallate Coordination Networks: Mechanism and Limits1. MARK W. MEISEL, Department of Physics and NHMFL, University of Florida — Using nanometer-sized heterostructures of cyanometallate coordination networks, specifically core@shell nanoparticles of CoFe@Cr2-PBA (PBA = Prussian blue analogues), irradiation by white light at 80 K modifies the magnetic response, and these changes remain intact and persist without continued irradiation to nominally 125 K. Preliminary pressure studies indicate the photoinduced changes can be maintained up to 200 K, the transition temperature of the ferromagnetic Cr2-PBA component. The effect, which we first reported up to 70 K, arises from thermally induced interface strain, which is relaxed by irradiation of the photactive constituent, CoFe-PBA. The ferromagnetic domains in the strained interface region are affected and generate the persistent changes of the magnetism. Our understanding of this photo-magnetostructural mechanism enabled us to extend the phenomenon to include photoactive spin-crossover systems2 and other ferromagnetic PBAs. The potential path to higher temperatures will be sketched.

1Presentation coauthored with Daniel R. Talham, UF Chemistry, and supported by the NSF via DMR-1405439 (DRT), DMR-1202033 (MWM), and DMR-1157490 (NHMFL), and by the UF Division of Sponsored Research.

8:36AM A31.00002 Single Crystal Neutron Diffraction Study of Organic Multiferroic (Nd1.2[FeCl3(D2)3])1. WEI TIAN, HUIBO CAO, JIAQIANG YAN, BRYAN CHAKOUMAKOS, BRIAN SALES, JAIME FERNANDEZ-BACA, Oak Ridge National Laboratory — (NH4)2[FeCl3(H2O)] is a new organic multiferroic that exhibits intriguing magnetic/multiferroic behavior as a function of temperature and applied magnetic field. Unlike its counterpart compounds where NH4 group is replaced by K, Cs, and Rb, [(NH3)2[FeCl3(H2O)] is the only system that undergoes two successive magnetic transitions accompanied by pronounced spontaneous electric polarization. Large deuterated (Nd1.2[FeCl3(D2)3]) single crystals were grown and characterized by specific heat and magnetization measurements showing no significant effects due to deuteration. Here we report single crystal neutron diffraction results that reveal an incommensurate antiferromagnetic order below Tc ∼ 7.3 K with a propagation vector of (0 0 0.77). Higher harmonic Bragg peaks were observed indicate “squaring up” behavior upon further cooling. At 1.5 K, a field induced incommensurate-to-commensurate transition was also observed by applying magnetic field along the a-axis.

8:48AM A31.00003 Slow relaxation of the magnetization in an Isostructural series of Zinc-lanthanide complexes: an integrated EPR and AC susceptibility study, ASMA AMJAD, INSTM Research Unit - LAMM Dipartimento di Chimica “U. Schiff,” Università di Firenze, Sesto Fiorentino(FI), Italy, AUGUSTIN MADALAN, MARIUS ANDRUH, University of Bucharest, Faculty of Chemistry, Inorganic Chemistry Laboratory, Bucharest, Romania, ANDREA CANESCHI, LORENZO SORACE, INSTM Research Unit - LAMM Dipartimento di Chimica “U. Schiff,” Università di Firenze, Sesto Fiorentino(FI), Italy. UNIVERSITY OF BUCHAREST, FACULTY OF CHEMISTRY, INORGANIC CHEMISTRY LABORATORY, BUCHAREST, ROMANIA COLLABORATION — Lanthanide based molecular complexes have shown potential to behave as single molecule magnets proficient to function above cryogenic temperatures. In this work we explore the dynamics of one such family, [Zn(LH)2Ln](NO3)2·6H2O – (Ln = Nd3+, Dy3+, Tb3+, Ho3+, Er3+, Yb3+). The series has a single lanthanide ion as a magnetic center in a low symmetry environment; the dynamics and energy landscape of the series is explored using X-band EPR, AC and DC susceptibility over a range of temperature, field and frequency. DC magnetic data show βX value consistent with expected behavior. EPR spectra for Er3+ and Yb3+ complexes shows EPR spectra typical for easy-plane and quasi-isotropic systems respectively, thus explaining the lack of out of phase susceptibility even in an external applied field. However, Dy3+ derivative show slow relaxation of the magnetization in zero field up to 15 K and is, accordingly EPR silent.

9:00AM A31.00004 Controlled Under Pressure: Understanding Spin Orbit Coupling and Exchange Anisotropy in Organic Magnets1. STEPHEN HILL, Florida State University and NHMFL, Tallahassee, FL32310 — The application of high pressure in the study of molecule-based materials has gained considerable interest, in part due to their high compressibilities, but also because the relevant electronic/magnetic degrees of freedom are often very sensitive to pressure. For example, small changes in the coordination environment around a magnetic transition metal ion can produce quite dramatic variations in both the on-site spin-orbit anisotropy as well as the exchange interactions between such ions when assembled into clusters or 3D networks. This has spurred the development of sophisticated spectroscopic tools that can be integrated with high-pressure instrumentation. The study of magnetic structure/property relations requires not only precise crystallographic data, but also detailed spectroscopic information concerning the unpaired electrons that give rise to the magnetic properties. This invited talk will begin with a brief description of the development and application of methods enabling EPR studies of oriented single-crystal samples subjected to hydrostatic pressures of up to 3.5 GPa. After an introductory example, the remainder of the talk will focus on a family of heavy atom organic radical ferromagnets (containing S and Se heteroatoms) that hold records for both the highest transition temperature and coercivity (for organic magnets). The latter is the result of an unexpectedly high magnetic anisotropy, attributable to spin-orbit-mediated exchange (hopping) processes. Ferromagnetic resonance (FMR) measurements reveal a continuous increase in the magnetic anisotropy with increasing pressure in the all Se compound, in excellent agreement with ab initio calculations based on the known pressure-dependence of its structure. The large value of anisotropic exchange terms in this heavy atom organic ferromagnet emphasizes the important role of spin-orbit coupling in a wide range of organic magnets where this effect is usually considered to be small.

9:36AM A31.00005 Realization of Long-Term Air Stability in the Organic Magnet Vanadium Tetracyanoethylene\textsuperscript{1}  
IAN FRONING, MEGAN HARBERTS, YU LU, HOWARD YU, ARTHUR J. EPSTEIN, EZEKIEL JOHNSTON-HALPERIN,  
Ohio State Univ - Columbus — The organic ferromagnet vanadium tetracyanoethylene (VTCNE)\textsubscript{2} has potential uses in both microwave electronics and spintronics due to the combination of high temperature magnetic ordering (TC \geq 600 K), extremely sharp ferromagnetic resonance (peak to peak linewidth of 1 G), and low-temperature conformal deposition via chemical vapor deposition (CVD; deposition temperature of 50 C), but air-sensitivity leads to the complete degradation of the films within 2 hours under ambient conditions. We have encapsulated thin films of VTCNE\textsubscript{2} using a UV-cured epoxy that increases film lifetime to over 700 hours as measured by the remanent magnetization. The saturation magnetization and Curie temperature decay more slowly than the remanence, and the coercivity is unchanged after 340 hours of air exposure. Fourier transform infrared spectroscopy (FTIR) shows that the epoxy does not react with the film, and magnetometry measurements show that the epoxy does not impact bulk magnetic properties. This encapsulation strategy enables experimental protocols and investigations that were not previously possible for air-sensitive samples and points the way toward the development of practical applications for this promising organic-based magnetic material.

9:48AM A31.00006 Photomagnetic and structural studies of Prussian blue analogue CoFe@CoCr core@shell heterostructures\textsuperscript{1}  
P.A. QUINTERO, T.V. BRINZARI, M.W. MEISEL, Dept. of Physics and NHMFL, Univ. of Florida, O.N. RISSET, M.J. ANDRUS, D.R. TALHAM, Dept. of Chemistry, Univ. of Florida, M.W. LUFASO, Dept. of Chemistry, Univ. of North Florida — The photomagnetic and structural properties of core@shell nanostructures of Prussian blue analogues, Rb\textsubscript{0.24}CoFe(CN)\textsubscript{6}O\textsubscript{0.74}K\textsubscript{0.10}CoCr(CN)\textsubscript{6}O\textsubscript{0.70} \cdot nH\textsubscript{2}O, with different shell thicknesses have been studied as a function of temperature and under white light irradiation\textsuperscript{2} The nature of the charge transfer induced spin transition (CTIST) of the core was affected by the presence of the shell. Specifically, while a continuous and hysteretic CTIST was observed in the bare cores, a discontinuous and non-hysteretic behavior was observed for the core@shell systems. In addition, the core@shell nanoparticles show light-induced magnetization changes radically different from the bare cores. These changes were modeled as a combination of the expected light-induced magnetism change in the cores and a modification of the magnetism in a region of the shell close to the interface, where the depth of the modified region was found to be about 25 nm for all shell thicknesses investigated.

\textsuperscript{1}Supported by the NSF via DMR-1202033 (MMW), DMR-1405439 (DRT), and DMR-1157490 (NHMFL).

10:00AM A31.00007 Separation of a molecular electronic configuration transition from the spin-crossover transition  
XIN ZHANG, SAU MU, University of Nebraska-Lincoln, JIA CHEN, Columbia University, GILLESCHI CHASTANET, DARO NATHALIE, JEAN-FRANCOIS LERTARD, TATIANA PALAMARCIUC, PATRICK ROSA, Université de Bordeaux, JING LIU, DARIO ARENA, GEORGE STELBINSKY, Brookhaven National Laboratory, BOHDAN KUNDYS, BERNARD DOUDIN, Université Louis Pasteur Strasbourg, PETER A. DOWBEN, University of Nebraska-Lincoln — We have investigated the unoccupied electronic structure of several molecular spin crossover systems including [Fe(H\textsubscript{2}B(pz)\textsubscript{2})\textsubscript{2}(bipy)]\textsuperscript{2+}, [Fe(H\textsubscript{2}B(pz)\textsubscript{2})\textsubscript{2}(phen)],[Fe(PM-Aza)\textsubscript{2}(NCS)\textsubscript{2} and [Fe(phen)\textsubscript{2}(NCS)\textsubscript{2}] by inverse photoemission (IPES) and X-ray absorption spectroscopy (XAS). The XAS clearly shows the change of iron L\textsubscript{2} edge spectra, typically associated with thermal induced spin crossover, occurring at temperatures well below the temperatures of the spin crossover transition. This suggests a change in the electronic structure configuration occurring separately from the spin ordering from a low spin to high spin state. These results may be significant to understand the observations that indicate that the spin crossover transition, and certainly the unoccupied electronic structure, is influenced by electric field. In some respects, these results for the molecular spin crossover transition resemble the separation of the charge ordering transition from the ferromagnetic transition in the manganites.

10:12AM A31.00008 Changes in the unoccupied electronic structure of [Fe(H\textsubscript{2}B(pz)\textsubscript{2})\textsubscript{2}(bipy)]\textsuperscript{2+} thin films  
YANG LIU, XIN ZHANG, SUMIT BENIWAL, AXEL ENDERS, Univ of Nebraska - Lincoln, PATRICK ROSA, JEAN-FRANCOIS LERTARD, TATIANA PALAMARCIUC, Université de Bordeaux, JING LIU, DARIO ARENA, National Synchrotron Light Source, BERNARD DOUDIN, Université Louis Pasteur Strasbourg, PETER A. DOWBEN, Univ of Nebraska - Lincoln, GROUPE DES SCIENCES MOLECULAIRES, UNIVERSITE DE BORDEAUX COLLABORATION, BROOKHAVEN NATIONAL LABORATORY, NATIONAL SYNCHROTRON LIGHT SOURCE COLLABORATION, INSTITUT DE PHYSIQUE APPLIQUE DU PHYSIQUE ET CHIMIE DES MATIEREAUX DE STRASBOURG, UNIVERSITE LOUIS COLLABORATION — We have investigated the unoccupied electronic structure of ultra thin films of the spin crossover [Fe(H\textsubscript{2}B(pz)\textsubscript{2})\textsubscript{2}(bipy)] complex (with H\textsubscript{2}B(pz)\textsubscript{2} =bis(hydrido)bis(1H-pyrazol-1-yl)borate and bipy = 2,2'-bipyridine) deposited on Au(111) by inverse photoemission (IPES) and X-ray absorption spectroscopy (XAS). The XAS clearly shows the changes of iron L\textsubscript{2} edge spectra typically associated with thermal induced spin crossover and found to be very consistent with the changed of the lowest unoccupied molecular orbitals seen in inverse photoemission with temperature. A band gap of 2-3 eV is deduced from combined UPS and IPES measurements of the films on Au substrates. The shift of the unoccupied density of states seen in inverse photoemission and XAS, with temperature, differs little from the molecular powder suggesting little influence of the substrate. We suggested that the ordering of this spin-crossover molecule on the gold substrate, may lead to a small anisotropy energy, for the molecular high spin state.

10:24AM A31.00009 Spin-lattice interactions as revealed by the pressure-temperature phase diagram of Co[N(CN)\textsubscript{2}]\textsubscript{2}  
JANICE MUSFELDT, Univ of Tennessee, Knoxville, T. V. BRINZARI, K. R. O’NEAL, P. CHEN, University of Tennessee, J. A. SCHLEUTER, Argonne National Laboratory, J. L. MANSON, Eastern Washington University, A. P. LITVINCHUK, University of Houston, Z. LIU, Carnegie Institute — We combined diamond anvil cell techniques, synchrotron-based infrared and Raman spectroscopies, and complementary lattice dynamics calculations to investigate spin-lattice coupling and the magnetic crossover mechanism in the molecule-based quantum magnet Co[N(CN)\textsubscript{2}]\textsubscript{2}. These findings along with prior magnetic properties work were brought together to create a pressure-temperature phase diagram in which the second-order structural boundaries converge on key areas of activity involving the spin state, exposing how the pressure-induced local lattice distortions trigger the ferromagnetic to antiferromagnetic crossover transition. Similar triggering events may take place in other materials.

\textsuperscript{1}We thank the NSF and PRF for support of this work.
10:36AM A31.00010 Observation of the interplay between Photoinduced Magnetisation and Pressure Induced Electron Transfer in Cobalt Hexacyanoferrare Prussian Blue Analogue1, M.K. PEHRAH, M.F. DUMONT, M.W. MEISEL, Dept. of Physics and NHMFL, Univ. of Florida, C.H. LI, D.R. TALHAM, Dept. of Chemistry, Univ. of Florida — The Prussian blue analogue K₃[CoFe(CN)₆]·nH₂O (CoFe-PBA) has been studied in both its light and dark states as a function of pressure up to 2.23 GPa. The material is known to undergo photoinduced magnetization (PIM) where irradiation leads to an increase in magnetization. On the other hand, application of pressure results in a pressure induced electron transfer (PIET) where a decrease in magnetization is observed. Both phenomena involve a spin transition between the low spin (S = 0) and the high spin (S = 2) states, and our work encompasses the application of both light and pressure to study the interplay between these two external stimuli. Our magnetic results indicate the suppression of the PIM at 2.23 GPa, but below this pressure, the coexistence of PIET and PIM is observed. Furthermore, in high temperature region, we observe a increase in the temperature at which the charge transfer induced spin transition (CTST) occurs.

1Supported by NSF DMR-105581 and DMR-1405439 (DRT), DMR-1202033 (WWM), and DMR-1157490 (NHMFL).

10:48AM A31.00011 A fully first-principles approach to the Molecular Kondo problem, MARIA SORIANO, Univ Autonoma de Madrid, DAVID JACKOB, Max Planck Institute of Microstructure Physics, JUAN JOSÉ PALACIOS, Univ Autonoma de Madrid, ATOMELIX TEAM — There has been a great effort in recent years to understand the emerging Kondo-like resonances in different magnetic molecules such as MnPC. Theoretical approaches based on atomic models have proven to be very useful for the study of this phenomenon when the magnetic moment is essentially localized on a magnetic atom [1,2]. Nevertheless the Kondo effect can arise in pure carbon-based systems as has been demonstrated experimentally in fullerences and carbon nanotubes [3,4]. In this communication we present a multiorbital Anderson model where the orbitals are not atomic but molecular orbitals. This model is fully obtained from Density Functional Theory calculation in combination with Green’s functions methodologies [5,6]. Standard impurity solver techniques are used to solve the model which is applied to fullerenes and other nanographene structures [7].

Monday, March 2, 2015 8:00AM - 11:00AM — Session A32 GMAG DMP: Focus Session: Magnetic Oxide Films. Surface and Interface Effects

8:00AM A32.00001 New chemical and magnetic structure at the domain walls of an epitaxial oxide, SAEDEEH FAROKHIPOOR, University of Groningen, Netherlands, C. MAGEN, Universidad de Zaragoza, Spain, S. VENKATESAN, Universitat Munchen, Germany, J. INIGUEZ, ICMAB-CSIC, Spain, C.J.M DAUMONT, D. RUBI, University of Groningen, Netherlands, E. SNOECK, CEMES - CNRS, France, M. MOSTOVOY, C. DE GRAAF, University of Groningen, Netherlands, A. MULLER, M. DOBLINGER, C. SCHEU, Universitat Munchen, Germany, B. NOHEDA, University of Groningen, Netherlands — Domain walls (DWs) in multiferroic thin films are nanoscale regions presenting different properties compared to the adjacent domains. This distinct behavior originates from the broken crystal symmetry and intense strain gradients around the walls. Therefore, engineering and controlling the properties of DWs in different types of functional materials, in particular in complex oxides, can become a promising path to design and tailor novel electronic and spintronic devices. In TbMnO₃, an antiferromagnetic orthorhombic perovskite in bulk form, ferroelastic DWs can also be achieved in a very controlled way, with densities that increase inversely proportional to the film thickness, such that for the thinnest films, the volume fraction of DWs can be as much as 25% of the total film volume. These DWs, display a net magnetic moment that originates in an unique chemical environment, a novel Mn coordination has been locally synthesized due to the local stress present at the DWs. We believe that this method can be applied more generally to obtain embedded 2D ferromagnetic sheets of interest in electronics and spintronics. S. Farokhipoor, et al., Nature (20 Nov.2014).

8:12AM A32.00002 The stoichiometry and Surface termination of La₂/₃Sr₁/₃MnO₃ film on SrTiO₃ (001) substrate *, LINA CHEN, ZHEN WANG, GAOMIN WANG, HANGWEN GUO, MOHAMMAD SAGHAYEZHIAN, E.W. PLUMMER, JIANDI ZHANG, Louisiana State Univ - Baton Rouge, JING TAO, LIJUN WU, YIMEI ZHU, Brookhaven National Laboratory — It has been observed that films of La₂/₃Sr₁/₃MnO₃ (LSMO) are insulating when the films are below a certain critical thickness. The nature of such thickness-driven metal-to-insulator transition is still under debate: is this an intrinsic (dimensional confinement) or an extrinsic (oxygen vacancies or change of stoichiometry) effect? We have investigated the thickness-dependent composition variation in the LSMO films on SrTiO₃ (001) by Low Energy Electron Diffraction (LEED), Angle-resolved XPS (ARXPS), and scanning transmission electron microscopy (STEM). Both ARXPS and STEM results show that the LSMO films prefer to terminated with (La/Sr)-O layer and exists a thickness-dependence of Sr vs La concentration ratio in the film as well as the Sr surface segregation, incorporated with the thickness, are used to solve the model which is in the Mo2O2 basal plane. These changes should have profound effect on the electronic and magnetic property, including the emergent insulating behavior in ultrathin films. * Supported by U.S. DOE under Grant No. DOE DE-SC0002136

10:48AM A32.00004 Exchange Bias and Unusual Initial Magnetization in Nanocrystalline Spinel Ferrite Thin Films¹, URUSA ALAAN, Stanford University, SREENIVASULU GOLLAPUDI, Oakland University, KIN MAN YU, Lawrence Berkeley National Laboratory, PADRAIC SIMPER, ELKE ARENHOLZ, Advanced Light Source, GOPALAN SRINIVASAN, Oakland University, YURI SUZUKI, Stanford University — We report on unconventional magnetic behavior in nanocrystalline (Mn,Zn,Fe)₂O₄ (MZO) thin films grown at room temperature. Structural studies show no secondary phases, yet these films are exchange biased, with magnetic hysteresis loops shifted by as much as ~ 200 Oe at 10 K after field-cooling. The samples can be “trained” so that successive magnetization loops exhibit reduced exchange bias. Shifts of the hysteresis loops exist even after cooling in zero field, indicating that the MZO is not externally biased. We attribute the exchange bias to disordered, grain-boundary-like regions that bias more ordered MZO. Annealing experiments that improved sample crystallinity decreased the exchange bias. Higher annealing temperatures resulted in reduced coercivities, higher magnetizations, and even the elimination of the exchange bias. Annealing also removed an unusual crossover of the initial magnetization curve outside of the saturated magnetization loop. This behavior has been seen in so-called “mictomagnetic” alloys. Using x-ray magnetic circular dichroism measurements, we have shown that cation disorder was reduced with annealing, and correlated the atypical initial magnetization with the degree of disorder.

9:12AM A32.00005 New features in electronic transport across the ferromagnetic transition in SrRuO3/Nb:STo3 devices. SAURABH ROY, Physics of Nanodevices, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands — SrRuO3 (SRO), a moderately correlated material system, exhibits unique structural and magnetoelectric properties at interfaces with other correlated oxides. Here we report on new features in electronic transport across a functional interface between SRO and Nb:STo3, a n-type semiconductor. We map the potential landscape across such an interface using a nanoscale transport probe and find it to be strongly influenced by differences in local substrate termination. A difference in Schottky barrier height of 0.19 eV for SRO grown on local TiO2 or StO substrate terminations is found. This difference is attributed to different metal-oxygen displacements of the first unit cell of SRO at the different terminations; further supported by High-Resolution Transmission-Electron-Microscopy studies and Density Functional Theory calculations. This strong correlation of structure with electronic transport at the interface is reflected in a concomitant decrease of hot electron attenuation length from 1.6 u.c. to 0.88 u.c. at -2.1 V with the onset of the ferromagnetic state. This is attributed to the increased buckling of Ru-O-Ru bonds in ferromagnetic SRO, highlighting the role of strong correlations at such interfaces.

9:24AM A32.00006 Controlling the dimensionality of the octahedra network in SrRuO3/STo3 superlattice, MINGQIANG GU, Northwestern University, QIYUN XIE, Nanjing University of Posts and Telecommunications, GUOPING ZHANG, Indiana State University, XIAOSHAN WU, Nanjing University — Two dimensional (2D) systems in perovskites have been widely investigated by designing superlattices. We propose a way to control the dimensionality of the octahedra network in perovskite superlattices by selecting different substrate orientation and superlattice periods. Lower dimensionality like one-dimension (1D) and zero-dimension (0D) can be achieved. Taking SrRuO3/STo3 as an example, we demonstrate that the 1D structure is in a 1D Ising state, which is paramagnetic, while the 0D structure is ferromagnetic insulator with fully saturated magnetic moment on the Ru sites. New phenomena in the magnetic and electronic properties are observed, including large strain response, half-metallicity, and orbital-selective quantum confinement effects.

9:36AM A32.00007 The surface study of ReFeO3 (Re=Lu, Yb) thin films by X-ray Photoemission Spectroscopy and Density Function Calculation, SHI CAO, TULA PAUDEL, KISHAN SINHA, XUANYUAN JIANG, Dept. of Physics and Astronomy, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, Nebraska 68588, USA, WENBIN WANG, Dept. of Physics, Fudan University, Shanghai, 200433, China, EVGENY TSYMBAL, XIAOSHAN XU, PETER DOWBEN, Dept. of Physics and Astronomy, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, Nebraska 68588, USA — The rare-earth ferrites, ReFeO3, may have a large magneto-electric response, with high surface/interface polarization, thus the surfaces are of considerable interest. We have characterized the surfaces of hexagonal ReFeO3 (Re= Lu, Yb) and orthorhombic LuFeO3 thin films by angle resolved X-ray photoemission spectroscopy (ARPES) and compared with density function theory (DFT). The surfaces will terminate in either Fe-O or Re-O depending on whether in the hexagonal or orthorhombic phase of the rare earth ferrite, but consistent with the expectations of DFT. The orthorhombic or hexagonal phases of these rare earth ferrites have the Fe in different crystal fields, which in turn affects the electronic properties of the Fe-O ligands. These changes in electronegativity are experimentally evident as differences in the Fe 2p core level photoemission system properties, notably leading to a decrease of the atomic magnetic moments.

10:00AM A32.00009 ABSTRACT WITHDRAWN
high-pressure shock waves into the sample, while 8 keV x-rays from LCLS was used to probe the target.

We compressed using 3 ns square pulses with total laser energy of 6 J per beam. A drive intensity of $3 \times 10^{12}$, MAXENCE GAUTHIER, LUKE FLETCHER, ALESSANDRA RAVASIO, SLAC National Accelerator Laboratory and deuterated plastic targets are very large at very early times decay occurs rapidly as propagation distance increases. Finally we will consider the prospects for using these data to obtain theoretical models of compressed matter and will discuss future plans for the study of hot and dense matter.

measure plasmons and to visualize the density and pressure evolution across melt lines by resolving correlations at distances comparable to atomic scales. Our theoretical models of compressed matter include shifts in the peak positions and changes in their crystal-field splitting, on moving from the bulk to the surface. Moreover, we observe these changes to extend several layers into the films rather than being restricted to the topmost layer. For example in a $\text{LaFeO}_3/(\text{SrFeO}_3)_m$ superlattice, we observe that the Fe oxidation state remains unchanged, a reversal in the intensity of the crystal-field split $I_{6g}$ and $I_{eg}$ peaks occurs over a length of 5 unit cells suggesting a shift from octahedral coordination in the bulk to tetrahedral coordination at the surface. Simultaneously acquired annular bright field and dark field images allow us to map the associated changes in their structure, such as cation displacements and changes in oxygen columns. We combine these results with density functional theory calculations to give a complete picture of surface reconstruction in the studied films including changes in the electronic, magnetic properties and its effect on the adsorption of $\text{CO}_2$ and $\text{H}_2\text{O}$ molecules that could point to routes to tune surface properties for water splitting and other applications.

In Extreme Conditions instrument at the Linac Coherent Light Source a world-unique experimental capability has become available to study the physics of hot and dense matter. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory — We have obtained pressure physics data from micron-thick tantalum films using our ultrafast laser shock platform. By measuring free surface velocity time histories at breakout, and shock wave arrival times at different film thicknesses, we have been able to estimate the dependence of peak and shock velocities on propagation distances and strain rates. We will show how elastic precursor shock waves depend on strain rate in the regime up to and above $10^9$ s$^{-1}$. We find that while elastic amplitudes are very large at very early times decay occurs rapidly as propagation distance increases. Finally we will consider the prospects for using these data to obtain the dynamic strength of tantalum at these very high strain rates. This work was supported by the NSF (DMR-1008791 and ECCS-1232275).

10:48AM A32.00013 Magnetic anomalies in self-assembled SrRuO3 - CoFe2O4 nanostructures studied by Raman spectroscopy . YI-CHUN CHEN, YEN-CHIN HUANG, CHIA-HSIEN CHIEN, Department of Physics, National Cheng Kung University, HENG-JUI LIU, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University — Self-assembled nanostructures with high interface-to-volume ratio usually possess interesting physical properties through the coupling between neighboring materials. In complex-oxide nanomaterials, the interplay of spin charge, orbital, and lattice degrees of freedom especially provides various functionalities. Our recent study had shown photo-induced magnetization switching in a self-assembled system, CoFe2O4 (CFO)- SrRuO3(SRO), where the CFO nanopillars were embedded in the SRO matrix. Moreover, this system also has significant magnetoresistance behaviors. In this study, we used Raman spectroscopy to investigate the magnetic coupling mechanisms in CFO-SRO nanostructures. Compared to the pure CFO films, the CFO nano-pillars under out-of-plane compressive strain show a slightly increase of $\text{Al}_2\text{O}_3$/Al(Fe) intensity ratio, which corresponds to a migration of Co ions from O-site (oxygen octahedron) to T-site (oxygen tetrahedron). This behavior can be further tuned by external stimulus, such as magnetic fields and temperatures. A strong increase of $\text{Al}_2\text{O}_3$/Al(Fe) ratio together with a discontinuous Al2 frequency shift occur at the SRO magnetic transition temperature. This result confirms that the spin-orbital interaction in CFO can be modulated by the SRO magnetic transition.

Monday, March 2, 2015 8:00AM - 11:00AM — Session A34 DMP: Focus Session: Experimental Techniques and Results: Dynamic High-Pressure Physics 210A -

8:00AM A34.00001 Studying compressed matter physics at the Linac Coherent Light Source1, SIEGFRIED GLENZER, LUKE FLETCHER, SLAC National Accelerator Laboratory, HED SCIENCE, SLAC NATIONAL ACCELERATOR LABORATORY TEAM, LAWRENCE BERKELEY LABORATORY TEAM, LAWRENCE LIVERMORE NATIONAL LABORATORY TEAM — With the advent of the Matter in Extreme Conditions instrument at the Linac Coherent Light Source a world-unique experimental capability has become available to study the physics of dynamically compressed solids. Our new high-energy-density science program at SLAC is aimed to take advantage of x-ray pulses with the highest peak brightness available today. In a single shot, the x-ray beam delivers $10^{12}$ x-ray photons in 50 fs focused to a spot of order 1 µm. This capability allows us to measure plasmons and to visualize the density and pressure evolution across melt lines by resolving correlations at distances comparable to atomic scales. Our data allow direct determination of pressure for validating theoretical models for the thermodynamics at high pressure. We will show how LCLS data test our theoretical models of compressed matter and will discuss future plans for the study of hot and dense matter.

8:12AM A34.00002 Elastic precursor shock waves in tantalum at very high strain rates. JONATHAN CROWHURST, MICHAEL ARMSTRONG, HARRY RADOUSKY. JOSEPH ZAUG, SEAN GATES, Lawrence Livermore National Laboratory — We have obtained data from micron-thick tantalum films using our ultrafast laser shock platform. By measuring free surface velocity time histories at breakout, and shock wave arrival times at different film thicknesses, we have been able to estimate the dependence of peak and shock velocities on propagation distances and strain rates. We will show how elastic precursor shock waves depend on strain rate in the regime up to and above $10^9$ s$^{-1}$. We find that while elastic amplitudes are very large at very early times decay occurs rapidly as propagation distance increases. Finally we will consider the prospects for using these data to obtain the dynamic strength of tantalum at these very high strain rates. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344 with Laboratory directed Research and Development funding (12ERD042).

8:24AM A34.00003 X-ray scattering measurements of laser-driven shock compressed plastic and deuterated plastic targets, MAXENCE GAUTHIER, LUKE FLETCHER, ALESSANDRA RAVASIO, SLAC National Accelerator Laboratory, TILO DÖPPNER, Lawrence Livermore National Laboratory, SIEGFRIED GLENZER, SLAC National Accelerator Laboratory, HED SCIENCE COLLABORATION — The study of materials under extreme conditions, i.e., high energy density, has gathered enormous scientific interest in various domains from inertial confinement fusion to planetary physics. The material response of plastic to shock and its behavior is important because of its common use as an ablative in inertial confinement fusion experiments. In this study, simultaneous measurements of spatially and x-ray temperature sensitive emission from laser-shock compressed plastic foils allow us to study the structural transition from a polymer to a liquid-like state. The 527 nm, 2 GW laser system available at the MEC station of the LCLS facility has been used to compress CH and CD foils using laser-driven shocks. 40 to 57 µm thick CH and CD targets were compressed using 3 ns square pulses with total laser energy of 6 J per beam. A drive intensity of $3 \times 10^{12}$ W/cm$^2$ on each irradiated surface was used to generate high-pressure shock waves into the sample, while 8 keV x-rays from LCLS was used to probe the target.
8:36AM A34.00004 Anguilarly resolved x-ray scattering measurements of shock and ramp compressed polycrysaalline diamond. M.J. MACDONALD, SLAC National Accelerator Lab, University of Michigan, L.B. FLETCHER, E.J. GAMBOA, M. GAUTHIER, H.J. LEE, E. GALTIER, SLAC National Accelerator Lab, A. RAVASIO, SLAC National Accelerator Lab, LULI, A. GELEON, SLAC National Accelerator Lab, Stanford University, S. HAMEL, Lawrence Livermore National Lab, J. VORBERGER, Max Plank Institute, D.O. GERICK, University of Warwick, Z. CHEN, University of Alberta, D. KRAUS, B. BARBREL, University of California Berkeley, S. FUNK, J.B. HASTINGS, S.H. GLENZER, SLAC National Accelerator Lab, HED SCIENCE COLLABORATION COLLABORATION — Direct measurements of the crystal structure of materials under shock and ramp compression has remained an interesting and at times challenging area of fundamental research, particularly in the area of high pressure matter. In this work we present the results from 102 experiments on polycrystalline diamond performed with table-top scale laser systems. Here we present results for ultrafast laser driven shock experiments using up to 500x more drive intensity than our previous experiments, as determined with XRD measurements, by Stevens et al. (Propellants Explos. Pyrotech. 33, 286 (2008)). A near perfect match between the two sets of data was observed. Moreover, we have observed the dynamic formation of hexagonal diamond by shock-compression of highly oriented graphite samples. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. This work was supported SSAA program Contract No. DEFG52- 06NA26212.

8:48AM A34.00005 Equation of state measurements of shocked ammonia gas. JOHN LANG, DANA DATTELBAUM, PETER GOODWIN, JOSHUA COE, DANIEL GARCIA, Los Alamos National Laboratory — Ammonia is one of the constituents of the liquid phases of the outer planets. We here present results from a series of gas gun-driven plate impact experiments on NH₃ gas at elevated initial density. PDV and VISAR optical diagnostics were used to directly measure shock velocities and particle velocities in the shocked gas, used in quantifying the principal Hugoniot locus, and pressure and density of the shocked gas. Emission was measured using both 5-color pyrometry and streak spectroscopy, from which we estimated the temperature of the shocked gas. The pressure and density measurements were in good agreement with results from simulations using the SESAME EOS for NH₃, however the measured temperatures were found to be consistently lower than in the simulations, and lower than shocked atom gas species such as Ar.

9:00AM A34.00006 Extreme dynamic compression with a table top laser¹, MICHAEL ARMSTRONG, JONATHAN CROWHURST, HARRY RADOUSKY, JOSEPH ZAUG, Lawrence Livermore Natl Lab — Recently, it was shown that the energy required for laser driven dynamic compression experiments varies as the third power of the compression time, where the compression time must be larger than the equilibration time of the sample. Traditional dynamic compression experiments typically have drive times greater than 10 ns, but a wide range of materials equilibrate on substantially faster time scales, which should enable such materials to be compressed on much shorter time scales. So, for materials which equilibrate on a sub-nanosecond time scale, ultrafast dynamic compression has the potential to substantially reduce the laser energy required to obtain highly compressed states of matter. This has been demonstrated for sub-Mbar pressures with <100 µJ energy laser drive pulses, where the laser drive energy per unit density change is as much as 10³ smaller than longer time scale experiments. Although these results are promising, extreme pressures (up to 10 Mbar) have not yet been observed with tabletop scale laser systems. Here we present results for ultrafast laser driven shock experiments using up to 500x more drive intensity than our previous work, which, by conventional scaling, should result in dynamic pressures previously only accessible to facility scale inarts.

9:12AM A34.00007 Dynamics of the shock-induced transition from graphite to warm dense diamond and liquid carbon¹, D. KRAUS, B. BARBREL, UC Berkeley, S. FRYDRYCH, J. HELFRICH, G. SCHAUANN, TU Darmstadt, J. VORBERGER, Max Plank Institut fuer die Physik komplexer Systeme, Dresden, D.O. GERICK, University of Warwick, L.B. FLETCHER, M. GAUTHIER, S. GOEDE, E. GRANADOS, H.J. LEE, B. NAGLER, E. GAMBOA, A. RAVASIO, W. SCHUMAKER, SLAC National Accelerator Laboratory, T. DOEPPNER, B. BACHMANN, Lawrence Livermore National Laboratory, P. NEUMAYER, GSI Helmholtzzentrum fuer Schwerionenforschung, G. GREGORI, University of Oxford, M. ROTH, TU Darmstadt, S.H. GLENZER, SLAC National Accelerator Laboratory, R.W. FALCON, UC Berkeley — We present novel experimental observations of the ion structure in warm dense carbon at pressures from 20 to 220 GPa and temperatures of several thousand Kelvins. Our experiments employ x-ray sources at kilo-joule class laser facilities and at the Linac Coherent Light Source to perform spectrally and angularly resolved x-ray scattering from shock-compressed graphite samples. Using different types of graphite and varying drive laser intensity, we were able to probe conditions below and above the melting line, resolving the shock-induced graphite-to-diamond and graphite-to-liquid transitions on nanosecond time scale. Moreover, we have observed the dynamic formation of hexagonal diamond by shock-compression of highly oriented graphite samples.

9:24AM A34.00008 Quantitative Results from Shockless Compression Experiments on Solids to Multi-Megabar Pressure. JEAN-PAUL DAVIS, JUSTIN BROWN, MARCUS KNUDSON, RAYMOND LEMKE, Sandia Natl Labs — Quasi-isentropic, shockless ramp-wave experiments promise accurate equation-of-state (EOS) data in the solid phase at relatively low temperatures and multi-megabar pressures. In this range of pressure, isothermal diamond-anvil techniques have limited pressure accuracy due to reliance on theoretical EOSs of calibration standards, thus accurate quasi-isentropic compression data would help immensely in constraining EOS models. Multi-megabar shockless compression experiments using the Z Machine at Sandia as a magnetic drive with stringent limits continue to be performed on a number of solids. New developments will be presented in the design and analysis of these experiments, including topics such as 2-D and magneto-hydrodynamic (MHD) effects and the use of LiF windows. Results will be presented for tantalum and/or gold, with comparisons to independently developed EOS. A Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:36AM A34.00009 EOS determination through microscopy- interferometry measurements: A low symmetry energetic materials case study¹, ELISSAIOS STAVROU, JOSEPH ZAUG, JONATHAN CROWHURST, SORIN BASTEA, MIKE ARMSTRONG, Lawrence Livermore National Laboratory, Material Science Division — Measuring equation of state (EOS) of solid specimens under pressure usually involves the determination of the primitive cell volume using x-ray diffraction (XRD) measurements. However, in the case of low symmetry (e.g. triclinic) materials with twinning features and large primitive cells, this can be problematic and ambiguous. In order to address this issue we examine the possibility of a direct approach which is based on measuring the surface area and thickness with microscopy and optical interferometry respectively. To test the validity of this approach applied to a crystalline material, we first compared our results from Triamino-Trinitrobenzene (TATB, SG P-1) with the published SESAME EOS for NH₃, however the measured temperatures were found to be consistently lower than in the simulations, and lower than shocked atom gas species such as Ar.

¹This work was performed by the U.S. Department of Energy jointly by Lawrence Livermore National Laboratory; Contract DE-AC52-07NA27344.
9:48AM A34.00010 Pressure-induced antiferrodistortive phase transition in SrTiO3: common scaling of soft-mode with pressure and temperature, SHIHWANG WENG, National Synchrotron Radiation Research Center, RUQING XU, Advanced Photon Source, Argonne National Laboratory, XINYUE FANG, Department of Physics, University of Illinois at Urbana-Champaign, AYMAN SAID, BOGDAN LEU, YANG DING, HAWOONG HONG, Advanced Photon Source, Argonne National Laboratory, PETER ABBAMONTE, Department of Physics, University of Illinois at Urbana-Champaign, S.-L. CHANG, National Synchrotron Radiation Research Center, T.-C. CHIANG, Department of Physics, University of Illinois at Urbana-Champaign — We report a study of the pressure-induced antiferrodistortive cubic-to-tetragonal phase transition in strontium titanate (SrTiO3) at ambient temperature. High-resolution inelastic X-ray scattering measurements reveal the softening of a phonon mode (R20) at the Brillouin zone boundary; a lattice distortion sets in at a critical pressure of 9.5 GPa, which corresponds to a critical volume reduction of 5.3%. Prior studies have shown that phonon softening and ensuing lattice distortion can be induced under ambient pressure by lowering the sample temperature through a critical temperature of 105 K. The relationship between the two phase transitions is clarified by comparing the powers laws of the pressure and temperature dependences of the softening behavior and by first-principles calculations of the energetics of the system.

10:00AM A34.00011 A new uniaxial strain measurement technique for improved strain homogeneity, MARK BARBER, University of St Andrews, CLIFFORD HICKS, Max Planck Institute for Chemical Physics of Solids, STEPHEN EDKINS, DANIEL BRODSKY, University of St Andrews, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids — Response to uniaxial distortion can be a powerful probe of the electronic properties of a solid. However, it is not a very commonly applied technique, chiefly because of the technical challenges of obtaining good strain homogeneity while applying significant pressures. In typical uniaxial pressure measurements, thin and wide samples are clamped between two anvil. Our approach uses a different, easier technique: cutting the sample into a long, narrow bar, and securing its two ends with epoxy across a vice. We have already demonstrated this technique with measurements on Sr2RuO4. Here we explain the details of this technique and by using finite element simulations present the guidelines (readily achievable in experiments) that need to be followed in order to achieve high strain homogeneity.

10:12AM A34.00012 Calorimetry at high-pressure using high-frequency Joule-heating, ZACHARY GEBALLE, VIKTOR STRUZHJKIN, Carnegie Geophysical Lab — Calorimetric measurements of materials at 1 to 100 GPa of pressure would provide intriguing tests of condensed matter theories, sensitive probes of chemical reactions during high-pressure synthesis, and useful inputs for models of the Earth’s interior. We present the design and first results of quantitative heat capacity measurements at >10 GPa of pressure. High-frequency AC voltage heats a small metal strip pressed between diamond anvils, creating temperature oscillations whose amplitudes are determined from the higher harmonics of voltage. Thermal models show that frequencies >100 kHz are required to contain heat in the ng-mass samples, while electrical models show that frequencies >100 MHz are not practical. Our experimental results show that the heat of iron and nickel can indeed be measured at high pressures in diamond anvil cells, paving the way for studies of the energetics of a wide-variety of entropy-driven phase changes at high pressure.

10:24AM A34.00013 High pressure, high magnetic field dilatometry experiment applied to strongly correlated electron systems1, AUDREY GROCKOWIAK, DAVID GRAF, WILLIAM CONIGLIO, JU-HYUN PARK, TIMOTHY MURPHY, SCOTT HANNAHS, STANLEY TOZER, NHMFL-Florida State University — Standard dilatometry techniques including capacitance measurements [1] have been developed and used for low temperature and high magnetic field measurements, but do not permit the use of high pressures. Following the experimental development of [2], we present a setup coupling Fiber Bragg Gratings (FBG) with pressure cells to map the whole magnetic field-pressure-temperature phase space of various systems as actinides and pnictides. FBG dilatometry measurements permit to achieve a resolution of ΔL/L ≈ 3.10⁻⁷ making it the most sensitive dilatometry technique. “Mini-me” piston cylinder cells developed at the NHMFL permit us to reach a pressure of 3 GPa, and their compact size allows them to be used in highly constrained sample volume of a portable dilution refrigerator, giving us the ability to do high pressure dilatometry studies in any high magnetic field facility at temperatures as low as 25 mK. We will present the setup along with preliminary results obtained on diverse test samples.

1 NSF DMR-1157490, State of Florida, DOE NNSA SSAA DE-NA00019

10:36AM A34.00014 Metallic carbon at high pressure and low temperature, KATSUYA SHIMIZU, MAEDA KOKI, MASAFUMI SAKATA, KYOKUGEN, Osaka University, MUTSUUKI MURAKAMI, KANEKA Co., KYOKUGEN TEAM, KANEKA TEAM — Graphite shows phase transition into hexagonal diamond by an application of pressure at room temperature. We have studied the pressure-induced phase transition to hexagonal or cubic diamond with Raman spectroscopy and resistance measurements using highly crystallized graphite films prepared by heat treatment of carbonized polyimide films. Inhomogeneous resistivity between current direction along ab-plane and c-axis was found to unite by squeezing at low temperature.

10:48AM A34.00015 The influence of moisture content on the shock compression responses of brittle granular materials, KUN XUE, Beijing Institute of Technology — The irreversible energy-absorbing compaction processes of shocked particle layers change with the moisture content. The shock wave interaction with dry and wet granular layers is experimentally investigated to elucidate the moisture effects on the energy distribution in the brittle granular layers. It is found that the frictional and breakage dissipation combined as the plastic dissipation of the granular layers is increasingly mitigated by the increasing moisture content. The higher strain rate in the shock loaded wet granular layer leads to an increased number of debris as predicted by the theoretical analysis. Nevertheless the inter-particle moisture effectively lubricates the enhanced particle friction arising from the intensive particle rearrangement concomitant with the greater degree of particle breakage. As a result, the efficiency of the momentum transfer in the wet granular layer is significantly improved manifested by the much larger particle kinetic energy. Meanwhile the particle breakage mode transits from the corner grinding to the shear cleavage with moisture content as revealed by the SEM image of the recovered grains from shock wave experiments.

Monday, March 2, 2015 8:00AM - 10:48AM – Session A35 DAMOP: Low-Dimensional and Non-Equilibrium Physics in Quantum Gases 210B
- David Pekker, University of Pittsburgh
8:00AM A35.00001 Non-equilibrium dynamics of an impurity in the one-dimensional Bose gas
NEIL ROBINSON, ROBERT KONIK, Brookhaven National Lab — In recent years, the out-of-equilibrium dynamics of interacting many-body quantum systems have attracted much attention. Integrable quantum models have played an important role in understanding the role of local conservation laws in the relaxation of observables, explaining unusual experimental observations in the one-component Bose gas [1]. We study the non-equilibrium dynamics of “impurity” wave packets containing a single boson propagating in the one-component Bose gas. Utilizing the integrability of the multi-component Lieb-Liniger model and recent results from the algebraic Bethe ansatz [2], we compute the time-evolution of the density profile of the “impurity” in the cases where the bosons is of the same or different species as the background gas. Our method, based upon numerically solving the Bethe ansatz equations and evaluating the Lehmann spectral representation for local observables, allows us to reach long times with high numerical precision. By comparing results from the two-component Lieb-Liniger model to the one-component Bose gas we can comment on the role of distinguishability of impurities in integrable models.

8:12AM A35.00002 Quench dynamics of one-dimensional interacting bosons in a disordered potential: Elastic dephasing and critical speeding-up of thermalization1, MARCO TAVORA, New York Univ NYU, ACHIM ROSCH, University of Cologne, ADITI MITRA, New York Univ NYU — The dynamics of interacting bosons in one dimension following the sudden switching on of a weak disordered potential is investigated. On time scales before quasiparticles scatter (prethermalized regime), the dephasing from random elastic forward scattering causes all correlations to decay exponentially fast, but the system remains far from thermal equilibrium. For longer times, the combined effect of disorder and interactions gives rise to inelastic scattering and to thermalization. A novel quantum kinetic equation accounting for both disorder and interactions is employed to study the dynamics. Thermalization turns out to be most effective close to the superfluid-Bose glass critical point where nonlinearities become more and more important. The numerically obtained thermalization times are found to agree well with analytic estimates.

8:24AM A35.00003 Thermalisation of a quantum system from first principles, GREGOIRE ITHIER, Department of Physics, Royal Holloway, FLORENT BENAYCH-GEORGES, MAP5 Université Paris Descartes — How does a quantum system reach thermodynamical equilibrium? Answering such a question from first principles is, perhaps surprisingly, still an open issue (Popescu Nat. Phys. 2006, Goldstein PRL 2006, Genway PRL 2013). We present here a new model comprising an arbitrary quantum system interacting with a large arbitrary quantum environment, both initially prepared in a quantum pure state. We then demonstrate that thermalisation is an emergent property of the unitary evolution under a Schrödinger equation of this large composite system. The key conceptual tool of our method is the phenomenon of “measure concentration” appearing with functions defined on large dimension Hilbert spaces, a phenomenon which cancels out any effect of the microscopic structure of interaction Hamiltonians. Using our model, we first characterize the transient evolution or decoherence of the system and show its universal character. We then focus on the stationary regime and recover the canonical state well known from statistical thermodynamics. This finding leads us to propose an alternative and more general definition of the canonical partition function, that includes, among other things, the possibility of describing partial thermalisation.

8:36AM A35.00004 ABSTRACT WITHDRAWN

8:48AM A35.00005 Relaxation and thermalization in the one-dimensional Bose-Hubbard model: A case study for the interaction quantum quench from the atomic limit2, FABIAN HEIDRICH-MEISSNER, LODE POLLET, STEFAN SORG, LEV VDIMAR, LMU Munich — We study the relaxation dynamics and thermalization in the one-dimensional Bose-Hubbard model induced by a global interaction quench. Specifically, we start from an initial state that has exactly one boson per site and is the ground state of a system with infinitely strong repulsive interactions at unit filling [1]. The same interaction quench was realized in a recent experiment [2]. Using exact diagonalization and the density-matrix renormalization-group method, we compute the time dependence of such observables as the multiparticle occupancy and the momentum distribution function. We discuss our numerical results in the framework of the eigenstate thermalization hypothesis and we observe that the microcanonical ensemble describes the time averages of many observables reasonably well for small and intermediate interaction strength. Moreover, the diagonal and the canonical ensembles are practically identical for our initial conditions already on the level of their respective energy distributions for small interaction strengths.

9:00AM A35.00006 Measuring time-dependent Greens Functions of strongly correlated gases in optical lattices3, ADRIAN KANTIAN, DQMP, University of Geneva, ULRICH SCHOLLWOECK, Department für Physik, LMU München, THIERRY GIAMARCHI, DQMP, University of Geneva — Recent advances in single-site addressing [1] in optical-lattice confined strongly correlated ultracold gases promise to deliver entirely new capabilities for these systems to serve as quantum simulators. We show how these advances may be employed to design in-situ measurements of both local and nonlocal time-dependent Greens functions as well as higher-order correlators. Using analytics side-by-side with time-dependent DMRG we quantify the practically available resolutions of these schemes - which can be applied for practically any 1D and 2D system of lattice-confined ultracold atoms - for several examples of interest, such as the mobile impurity problem [2] and the superfluid-Mott insulator transition.

9:12AM A35.00007 Entanglement entropy scaling laws and eigenstate thermalization in free fermion systems4, HSIN-HUA LAI, Natl High Magnetic Field Lab, KUN YANG, Natl High Magnetic Field Lab and Florida State University — We demonstrate that the entanglement entropy area law for free fermion ground states and the corresponding volume law for highly excited states are related by a position-momentum duality, thus of the same origin. For a typical excited state in the thermodynamic limit, we further show that the reduced density matrix of a subsystem approaches thermal density matrix, provided the subsystem’s linear size is small compared to that of the whole system in all directions. This provides an explicit example of eigenstate thermalization, and reveals how statistical physics emerges from a single eigenstate by tracing out a large number of degrees of freedom.

9:24AM A35.00008 Particle partition entanglement of Luttinger liquids

C.M. HERDMAN, University of Waterloo, ADRIAN DEL MAESTRO, University of Vermont — We consider the Rényi entanglement entropy of a Luttinger liquid under a particle bipartition. Using Luttinger liquid theory, we demonstrate that the leading finite-size scaling of the second Rényi particle entanglement entropy is logarithmic in the system-size with a prefactor that is the inverse Luttinger parameter. While higher order corrections depend on the short distance physics, the leading order scaling depends only on the sole dimensionless parameter that characterizes the low energy physics; this contrasts with the leading entanglement entropy scaling under a spatial bipartition, for which the scaling coefficient is universal and independent of the Luttinger parameter. Additionally, using quantum Monte Carlo calculations, we explicitly confirm the Luttinger liquid theory scaling for the Lieb-Liniger model of delta function interacting bosons in the one-dimensional spatial continuum; we find that the scaling coefficient of the 2nd Rényi particle entropy of the ground state of the Lieb-Liniger model agrees with the Luttinger parameter determined from the Bethe ansatz.

10:00AM A35.00011 2D Superexchange mediated magnetization dynamics in an optical lattice

R.C. BROWN, Joint Quantum Institute, NIST & UMD, R. WYLLIE, Joint Quantum Institute, NIST & UMD; GTRI, S.B. KOLLER, E.A. GOLDSCHMIDT, M. FOSS-FEIG, J.V. PORTO, Joint Quantum Institute, NIST & UMD — The competition of magnetic exchange interactions and tunneling underlies many complex quantum phenomena observed in real materials. We study non-equilibrium magnetization dynamics in an extended 2D system by loading effective spin-1/2 bosons into a spin-dependent optical lattice, and we use the lattice to separately control the resonance conditions for tunneling and superexchange. After preparing a non-equilibrium anti-ferromagnetically ordered state, we quench the lattice to its final configuration, and observe relaxation dynamics governed by two well-separated rates. These rates scale with the underlying Hamiltonian parameters associated with superexchange and tunneling. Remarkably, with tunneling off-resonantly suppressed, we are able to observe superexchange dominated dynamics over two orders of magnitude in magnetic coupling strength, despite the presence of vacancies. In this regime, the measured timescales are in agreement with simple theoretical estimates, but the detailed dynamics of this 2D, strongly correlated, and far-from-equilibrium quantum system remain out of reach of current computational techniques.

10:12AM A35.00012 Sound-induced vortex interactions in a zero temperature two-dimensional superfluid

PIOTR SUROWKA, ANDREW LUCAS, Harvard University — Recent experimental work on two-dimensional turbulent superfluids have increased the importance of resolving fundamental theoretical questions about the nature of superfluid turbulence in two dimensions. Crucial to this task is a proper understanding of the effective dynamics of vortices in the superfluid. We present a systematic calculation of the effective action of $N > 1$ superfluid vortices, assuming that the underlying continuum action is the Gross-Pitaevskii action. Our calculation is valid at next-to-leading order in the ratio of the vortex core size to intervortex spacing, and so takes into account the leading-order dressing of superfluid vortices by sound. We are able to exactly determine the action for a pair of vortices and we find that it demonstrates no instability to annihilation. This is suggestive that the inverse cascade picture of classical turbulence is qualitatively correct for a turbulent zero temperature superfluid.

10:24AM A35.00013 Decay of hydrodynamic modes in dilute Bose-Einstein condensates

ERICH GUST, LINDA REICHL, Univ of Texas, Austin, Center for Complex Quantum Systems — We present the results of Bogoliubov mean field theory [1] applied to the hydrodynamic modes in a dilute Bose-Einstein condensate. The condensate has six hydrodynamic modes, two of which are decaying shear modes related to the viscosity, and two pairs of sound modes which undergo an avoided crossing as the equilibrium temperature is varied [2]. The two pairs of sound modes decay at very different rates, except in the neighborhood of the avoided crossing, where the identity of the longest-lived mode switches. The predicted speed and lifetime of the longest-lived sound mode are consistent with recent experimental observations on sound in an $^87$Rb Bose-Einstein condensate. The strong dependence of the decay rates on temperature implies a possible new method for determining the temperature of Bose-Einstein condensates. [1] L. E. Reichl and Erich D. Gust, Phys. Rev. A 88, 053603 (2013) [2] Erich D. Gust and L. E. Reichl, Phys. Rev. A, 90, 043615 (2014)

10:36AM A35.00014 ABSTRACT WITHDRAWN

Monday, March 2, 2015 8:00AM - 10:48AM —
Session A36 DAMOP: Interacting Fermi Gases I

8:00AM A36.00001 Dynamical instabilities and transient short-range order in the fermionic Hubbard model

JOHANNES BAUER, Harvard University, MEHRTASH BABADI, California Institute of Technology, EUGENE DEMLER, Harvard University — We study the dynamics of magnetic correlations in the half-filled fermionic Hubbard model following a fast ramp of the repulsive interaction. We use Schwinger-Keldysh self-consistent one-loop perturbation theory to investigate the evolution of single-particle Green’s functions and solve the non-equilibrium Bethe-Salpeter equation to study the dynamics of magnetic correlations. This approach gives us new insights into the interplay between single-particle relaxation dynamics and the growth of antiferromagnetic correlations. Depending on the ramping time and the final value of the interaction, we find different dynamical behavior which we illustrate using a dynamical phase diagram. Of particular interest is the emergence of a transient short-range ordered regime characterized by the strong initial growth of antiferromagnetic correlations followed by a decay of correlations upon thermalization. The discussed phenomena can be probed in experiments with ultracold atoms in optical lattices.

8:12AM A36.00002 Polarization induced phase separation and re-entrant transition of two component lattice fermions in one dimension

THEJA DESILVA, Georgia Regents University — By investigating the compressibility of one dimensional lattice fermions at various filling factors, we study phase separation and re-entrant transition within the framework of Bethe ansatz method. We model the system by repulsive Hubbard model and calculate compressibility as functions of polarization for arbitrary values of chemical potential, temperature, and interaction strength. For filling factors $0 < n < 1$, the compressibility is a non-monotonic function of polarization at all thermodynamic parameters. The compressibility reveals phase transition into phase separated state for both low and intermediate temperatures, as well as intermediate interactions as one increases the polarization. For certain filling factors, we find re-entrant transition into the mixed phase at a higher polarization.
8:24AM A36.00003 Size and shape of Mott regions for fermionic atoms in a two-dimensional optical lattice, TIAGO MENDES SANTOS, THEREZA PAIVA, RAIMUNDO R. DOS SANTOS, Federal University of Rio de Janeiro (UFRJ) — We investigate the harmonic-trap control of size and shape of Mott regions in the Fermi Hubbard model on a square optical lattice. The use of Lanczos diagonalization on clusters with twisted boundary conditions, followed by an average over 50-80 samples, drastically reduce finite-size effects in some ground state properties; calculations in the grand canonical ensemble together with a local-density approximation (LDA) allow us to simulate the radial density distribution. We have found that as the trap closes, the atomic cloud goes from a metallic state, to a Mott core, and to a Mott ring; the coverage of Mott atoms reaches a maximum at the core-ring transition. A “phase diagram” in terms of an effective density and the on-site repulsion is proposed, as a guide to maximize the Mott coverage. We also predict that the usual experimentally accessible quantities, the global compressibility and the average double occupancy (rather, its density derivative) display detectable signatures of the core-ring transition. Some spin correlation functions are also calculated, and predict the existence Néel ordering within Mott cores and rings.

8:36AM A36.00004 Ground-state properties of spin-imbalanced Fermions in three-dimensional optical lattices, PETER ROSENBERG, SIMONE CHIESA, SHIWEI ZHANG, College of William and Mary — The past two decades have seen remarkable progress in cold atom physics. Novel experimental techniques have made it possible to simulate many condensed matter models. One system that has received considerable focus is ultra-cold atoms in an optical lattice with unequal populations of two hyperfine states. This system is an ideal candidate for the experimental realization of the elusive Fulde-Ferrell-Larkin-Ovchinnikov phase. We investigate the phase diagram of this system using Hartree-Fock-Bogoliubov theory. Detailed numerical calculations are performed to determine the ground-state properties systematically for different values of density, spin polarization and interaction strength. We first consider the high density and low polarization regime, in which the effect of the optical lattice is most evident. We then proceed to the low density and high polarization regime where the effects of the underlying lattice are less significant and the system begins to resemble a continuum Fermi gas. We explore the effects of density, polarization and interaction on the character of the phases in each regime and highlight the qualitative differences between the two regimes.

8:48AM A36.00005 Spin-balanced Fulde-Ferrell superfluids in driven fermionic optical lattices, ZHEN ZHENG, The University of Texas at Dallas; University of Science and Technology of China, CHUNLEI QU, The University of Texas at Dallas, XUBO ZOU, University of Science and Technology of China, ZOU, College of William and Mary — We study a two-leg fermionic Hubbard ladder model with a state-dependent hopping. We find that, contrarily to the case without a state-dependent hopping, for which the system has a superfluid nature regardless of the sign of the interaction at incommensurate filling, in the presence of such a hopping a spin-triplet superfluid, spin- density wave and charge-density wave phases emerge. We examine our results in the light of periodically-driven optical lattices in cold atoms, and give protocols allowing to realize the spin-triplet superfluid elusive in the cold atoms.

9:00AM A36.00006 Two-leg fermionic Hubbard model with a state-dependent hopping, SHUN UCHINO, THIERRY GIAMARCHI, DQMP, University of Geneva — We study a two-leg fermionic Hubbard ladder model with a state-dependent hopping. We find that, contrarily to the case without a state-dependent hopping, for which the system has a superfluid nature regardless of the sign of the interaction at incommensurate filling, in the presence of such a hopping a spin-triplet superfluid, spin- density wave and charge-density wave phases emerge. We examine our results in the light of periodically-driven optical lattices in cold atoms, and give protocols allowing to realize the spin-triplet superfluid elusive in the cold atoms.

9:12AM A36.00007 Attractive Hofstadter-Hubbard model with imbalanced chemical and vector potentials, MENDERES ISKIN, Koc University - Istanbul — We study the interplay between the Hofstadter butterfly, strong interactions and Zeeman field within the mean-field Bogoliubov-de Gennes theory in real space, and explore the ground states of the attractive single-band Hofstadter-Hubbard Hamiltonian on a square lattice, including the exotic possibility of imbalanced vector potentials. We find that the cooperation between the vector potential and superfluid order breaks the spatial symmetry of the system, and gives rise to stripe-ordered Fulde-Ferrell-Larkin-Ovchinnikov (FFLO)-like superfluid and supersolid phases that can be distinguished and characterised according to their coexisting pair-density (PDW), charge-density (CDW) and spin-density (SDW) wave orders. We also discuss confined systems and comment on the likelihood of observing such stripe-ordered phases by loading neutral atomic Fermi gases on laser-induced optical lattices under laser-generated artificial gauge fields.

9:24AM A36.00008 Induced p-wave Superfluidity in Imbalanced Fermi Gases in a Synthetic Gauge Field, HERON CALDAS, Universidade Federal de Sao Joao del Rei, Sao Joao del Rei, Brazil, MUCIO CONTINENTINO, Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil — We study pairing formation and the appearance of induced spin-triplet p-wave superfluidity in dilute three-dimensional imbalanced Fermi gases in the presence of a uniform non-Abelian gauge field. This gauge field generates a synthetic Rashba-type spin-orbit interaction which has remarkable consequences in the induced p-wave pairing gaps. Without the synthetic gauge field, the p-wave pairing occurs in one of the components due to the induced (second-order) interaction via an exchange of density fluctuations in the other component. We show that this p-wave superfluid gap induced by density fluctuations is greatly enhanced due to the Rashba-type spin-orbit coupling.

9:36AM A36.00009 The Realization of 3D Weyl Semimetal Phase in Optical lattice and its Detection, WEN-YU HE, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China, SHI-ZHONG ZHANG, Department of Physics and Center of Theoretical and Computational Physics, The University of Hong Kong, Hong Kong, China, KAM TUEN LAW, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China — We describe a method to realize 3D Weyl semimetal phase in multilayer-coupled honeycomb optical lattices, with energy offset between the sublattices turned on. Two Raman beams are utilized to assist coupling between neighbor sites and generate synthetic magnetic flux both vertically and horizontally. Both one and two pairs of Weyl points can be achieved by tuning the unconventional interlayer coupling strength and the detuning in the Raman processes. We demonstrate that the detection of the emergence of Weyl points can be done through measuring the Landau Zener transitions of atoms from the lower occupied bands to the upper unoccupied bands.
9:48AM A36.00010 Nambu-Goldstone modes of an ultracold $^6\text{Li} - ^{40}\text{K}$ mixture in an optical lattice. ZLATKO KOINOV, Department of Physics and Astronomy, University of Texas at San Antonio, San Antonio, TX 78249, SHANNA PAHL, RAFAEL MENDOZA, Department of Physics and Astronomy, University of Texas at San Antonio, San Antonio, USA — A low-energy theory of the Nambu-Goldstone excitation spectrum and the corresponding speed of sound of an interacting Fermi mixture of Lithium-6 and Potassium-40 atoms in a two-dimensional optical lattice at finite temperatures with the Fulde-Ferrell order parameter is presented. We assume that the interacting fermions are in a sufficiently deep periodic lattice potential described by the Hubbard Hamiltonian. The discussion is restricted to the BCS side of the Feshbach resonance where the Fermi atoms exhibit superfluidity. The quartic on-site Hubbard interaction is decoupled via a Hubbard-Stratonovich transformation. The numerical solution of the Bethe-Salpeter equation in the generalized random phase approximation shows that the two-species Fermi gas has a superfluid phase revealed by two roton-like minima in the composite collective-mode energy. At some values of polarization, interacting strength and temperature, the dispersion relation of the Nambu-Goldstone excitation $\omega(Q)$ initially bends upward as the quasimomentum $Q$ increases before bending over. Due to this anomalous dispersion one long-wavelength phonon can decay into another one by absorbing a second phonon (Landau damping), or one phonon can decay into two others (the Beliaev damping).

10:00AM A36.00011 Unusual robust phase coherence in a coupled boson-fermion system. MACIEJ MASKA, Institute of Physics, University of Silesia, NANDINI TRIVEDI, The Ohio State University — We consider a coupled boson-fermion model in two dimensions, that describes itinerant fermions hybridizing with localized bosons composed of pairs of tightly bound opposite-spin fermions. We trace out the fermionic degrees of freedom and perform a Monte Carlo simulation for the effective classical Hamiltonian of boson phases. We find that the fermions not only generate an effective long-range temperature-dependent boson-boson coupling that generates a finite phase stiffness, but remarkably the phase stiffness is considerably more robust than that described by the XY model. Our analysis further shows that the inter-vortex interaction in the effective model is a power law rather than logarithmic as in the XY model. As one of the possible explanations for this persistent phase stiffness we consider the long range Berry phases carried by the itinerant fermions. Our results are relevant for resonance superfluids in the BCS-BEC crossover regime and also certain aspects of the high temperature superconductivity.

10:12AM A36.00012 Shear viscosity to entropy density ratios and implications for (im)perfect fluidity in Fermionic and Bosonic superfluids. RUFUS BOYACK, James Franck Institute, University of Chicago, Chicago, IL, HAO GUO, Department of Physics, Southeast University, Nanjing 211189, China, K. LEVIN, James Franck Institute, University of Chicago, Chicago, IL — Recent experiments on both unitary Fermi gases and high temperature superconductors (arxiv:1410.4835 [cond-mat.quant-gas], arxiv:1409.5820 [cond-mat.str-el]) have led to renewed interest in near perfect fluidity in condensed matter systems. This is quantified by studying the ratio of shear viscosity to entropy density. In this talk we present calculations of this ratio in homogeneous bosonic and fermionic superfluids, with the latter ranging from BCS to BEC. While the shear viscosity exhibits a power law (for bosons) or exponential suppression (for fermions), a similar dependence is found for the respective entropy densities. As a result, strict BCS and (true) bosonic superfluids have an analogous viscosity to entropy density ratio, behaving linearly with temperature times the (T-dependent) dissipation rate; this is characteristic of imperfect fluidity in weakly coupled fluids. This is contrasted with the behavior of fermions at unitarity which we argue is a consequence of additional terms in the entropy density thereby leading to more perfect fluidity. (arXiv:1407.7572v1 [cond-mat.quant-gas])

10:24AM A36.00013 Odd frequency Bosonic and Fermionic condensate. ALEXANDER BALATSKY, Los Alamos Natl Lab, Nordita — We introduce the concept of the odd-frequency Bose-Einstein Condensate (BEC), characterized by the odd frequency/time two-boson expectation value. To illustrate the concept of odd frequency BEC we present simple classification of pair boson condensates that explicitly permits this state. We point qualitative differences of odd-frequency BEC with conventional BEC and introduce the order parameter and wave function for the odd-frequency BEC [1]. This step extends the classification of the odd frequency states typically discussed in the context of odd frequency fermion pairing [2].

1Work supported by US DOE BES E304 and KAW.

10:36AM A36.00014 Vortex Dynamics in Atomic BECs: Some Recent Developments. PANAYOTIS KEVREKIDIS, UMass, Amherst — In the present work, we will briefly discuss a series of recent experiments by a number of groups enabling the examination of a small number of vortices (including ones of different charges) in atomic BECs. We will use a particle method to try to understand the dynamics of these vortices, in the appropriate limits. We will also briefly demonstrate a so-called generating function method that allows to connect the problem of identifying vortex centers to the theory of classical orthogonal (such as Hermite) polynomials. This formalism will be shown to be quite useful in identifying vortex polygons and other complex vortex patterns. Time permitting, generalizations to 3D settings and vortex rings will be briefly touched upon.

Monday, March 2, 2015 8:00AM - 11:00AM — Session A37 GQI: Focus Session: Semiconductor Qubits - Single Donors 212A - Bruce Kane, Laboratory for Physical Sciences

8:00AM A37.00001 Entanglement of an Electron-Nuclear Spin Pair in $^{28}\text{Si}$. STEPHANIE SIMMONS, CQ2T, Electrical Engineering Department, UNSW, Australia — Single-shot, single spin readout allows for strong projective quantum measurements which are used for Bell inequality violations, teleportation, error correction, and many other quantum codes. Very recently, strong projective measurements have become available using a long-lived electron-nuclear donor spin pair in silicon-$^{28}$. Here we demonstrate Bell/CHSH inequality violations, a proven entanglement witness, using this two spin system. A Bell inequality violation of 2.7(1) conclusively demonstrates on-demand two-spin entanglement, and the $>99\%$ detection efficiency simultaneously closes the detection loophole for this system. Furthermore, we improve upon the destructive electron measurement approach by mapping all electron detection efficiency onto the nuclear spin for high-fidelity quantum non-demolition (QND) measurement. Lastly, we complement the Bell inequality entanglement witness with full two-qubit state tomography complete with QND measurement. Preliminary results confirm a highly entangled state, yielding a fidelity of 99(2)\%, concurrence of 0.8(0), and a partial transpose negativity result of 0.46(4). Together these results demonstrate, within a single experiment, the very high initialisation ($>97\%$), estimated control ($>98\%$) and measurement ($>99.9\%$) fidelities in this two-qubit system.
8:36AM A37.00002 Local electrical control of a single-atom spin qubit in a continuous microwave field ¹, ANDREA MORELLO, ARNE LAUCHT, JUHA MUHONEN, FAHD MOHIYADDIN, RACHPON KALRA, JUAN DEHOLLAIN, SOLOMON FREER, FAY HUDDSON, MENNO VELDHORST, ANDREW DZURAK, UNSW Australia, KOHEI ITOH, Keio University, JEFFREY MCCALLUM, DAVID JAMIESON, University of Melbourne, ANDREA MORELLO, UNSW Australia — Local coherence times and fast manipulation are two desirable qualities of a qubit that for many systems are mutually incompatible. Storing quantum information in an ancillary qubit, i.e. a ‘quantum memory’, is a strategy to address this issue. It is a advantageous property of donor impurities in silicon to have qubits of both qualities in a single lattice site. Here we demonstrate storage and retrieval of quantum information from a single donor electron spin to its host phosphorus nucleus in isotopically-enriched ²⁸Si. We show a high fidelity memory process characterised via both state and process tomography. We use dynamical decoupling sequences during the nuclear storage to extend the memory time, and demonstrate storage and retrieval of a single qubit of information multiple times before decay. These results underline the inherent versatility and high fidelity of our two qubit system.

¹Funded by the Australian Research Council (CE11E000127) and the U.S. Army Research Office (W911NF-13-1-0024)

8:48AM A37.00003 Quantum memory in a single nucleus in silicon ², SOLOMON FREER, STEPHANIE SIMMONS, ARNE LAUCHT, JUHA MUHONEN, JUAN PABLO DEHOLLAIN, RACHPON KALRA, FAY HUDDSON, ANDREW DZURAK, UNSW Australia, KOHEI ITOH, Keio University, JEFFREY MCCALLUM, DAVID JAMIESON, University of Melbourne, ANDREA MORELLO, UNSW Australia — Long coherence times and fast manipulation are two desirable qualities of a qubit that for many systems are mutually incompatible. Storing quantum information in an ancillary qubit, i.e. a ‘quantum memory’, is a strategy to address this issue. It is a advantageous property of donor impurities in silicon to have qubits of both qualities in a single lattice site. Here we demonstrate storage and retrieval of quantum information from a single donor electron spin to its host phosphorus nucleus in isotopically-enriched ²⁸Si. 9:00AM A37.00004 Optical quantum memory made from single nuclear spin in nitrogen vacancy in diamond. SEN YANG, YA WANG, THAI HIEN TRAN, S. ALI MOMENZADEH, RAINEER STOEHR, PHILIPP NEUMANN, 3rd Physics Institute, Universität Stuttgart, HIDEO KOSAKA, Department of Physics, Yokohama National University, JOERG WRACHTRUP, 3rd Physics Institute, Universität Stuttgart — Quantum repeater is one of the key elements to realize long distance quantum communication. In the heart of a quantum repeater is quantum memory. There are a few requirements for this memory: it needs to couple to flying qubits: photon; it needs to have long coherence time, so quantum error correction algorithm can be performed in the quantum repeater nodes; it needs to be stable under optical illuminations. Nitrogen nuclear spin is available for every nitrogen vacancy center(NV) in diamond. Besides it can be a robust quantum memory for spin qubit operations, nitrogen nuclear spin can couple to photon by taking advantage of optically resonant excitation of spin-selective transitions in low temperature. Here we demonstrate the coherent storage of quantum information from photon into nuclear spin. We show this quantum memory fulfills requirements as quantum memory for quantum repeater. Coherent time beyond 5 seconds is measured in ¹³C natural abundant sample. Under resonant laser excitations, the excited state quadruple and hyperfine interaction could lead to decoherence of nuclear spin. We show those interactions are low and nuclear spin can keep its coherence over 1000 times resonant laser excitation of electron spin.

9:12AM A37.00005 Electron Spin Resonance Experiments on a Single Electron in Silicon Implanted with Phosphorous, DWIGHT R. LUHMAN, K. NGUYEN, L.A. TRACY, S. CARR, J. BORCHARDT, N. BISHOP, G. TEN EYCK, T. PLUYM, J. WENDT, M.P. LILLY, M.S. CARROLL, Sandia Natl Labs — In this talk we will discuss the results of our ongoing experiments involving electron spin resonance (ESR) on single-electrons traps in a natural silicon sample. The sample consists of an SET, defined by lithographic polysilicon gates, coupled to nearby phosphorous donors. The SET is used to detect charge transitions and readout of the spin of the electron being investigated with ESR. The measurements were done with the sample at dilution refrigerator temperatures in the presence of a 1.3 T magnetic field. We will present data demonstrating Rabi oscillations of a single electron in this system as well as measurements of the coherence time, T₂. We will also discuss our results using these and various other pulsing schemes in the context of a donor-SET system. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

9:24AM A37.00006 Evaluation of strained silicon on insulator for SET based single donor spin read-out, PETER SHARMA, GREG TEN EYCK, DANIEL WARD, JASON DOMINGUEZ, KENTON CHILDS, JOEL WENDT, MICHAEL LILLY, MALCOLM CARROLL, Sandia National Laboratories — Recent successes in realizing single donor control and achieving very high fidelity gate operations has driven interest in silicon-based donor qubits. A number of proposals for donor to donor coupling rely on vertical field for Stark shift and ionization to a nearby interface. Back gaging silicon on insulator is one approach to achieving sufficient field strengths. We present low temperature measurements of back gatted SET structures and donor implanted SETs fabricated from strained silicon on insulator substrates with a low doped handle. This strained silicon system is useful for studying the effects of strain on both single donor physics and may provide insight into the behavior of strained silicon channels for quantum dots. We use SET thresholds to characterize the oxide/Si defect density. Back gaging influences the transient time response, mobility, and FET threshold. These parameters are also modified by above band gap light illumination. Two transport channels are observed, which also strongly depend on back gate voltage and illumination. This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy Office of Science. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U. S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:36AM A37.00007 Electric field control of donor pair diatomic molecules in silicon, ALEJANDRA BAENA, Instituto de Física-Universidad Federal do Rio de Janeiro, ANDRE SARAIVA, University of Wisconsin-Madison and Instituto de Física-Universidade Federal do Rio de Janeiro, MARIA J. CALDERON, Instituto de Ciencias de Materiales de Madrid ICM-M-CSIC, BÉLITA KOILLER, Instituto de Física-Universidade Federal do Rio de Janeiro — Single donors are well-established building blocks for engineering electronic properties of semiconductors, acting effectively as giant hydrogen atoms [1]. Donor pairs, analogous to effective hydrogen molecules, were recently investigated [2,3] in the strongly interacting regime in silicon. In this regime, electric field control renders titmic results. Pairs that are more distant are more susceptible to external fields, and may harbour single electron charge control. Theoretically, the molecular quantum mechanics analogy between a donor pair and the H₂ molecule in vacuum is not as straightforward as it may seem. A detailed understanding of the electronic structure of these molecular systems is a current challenge. We analyze the lowest energy states within effective mass theory, including central cell corrected donor potential effects and the conduction band multiplicity in Si. The spectrum of ionized donor pairs and its response to an external electric field will be presented. We contemplate possible advantages of heteropolar diatomic molecules, e.g. Sb—As pairs, as more efficient elements for such devices and applications.

spin-state energetics and we discuss the effect of strain fields on the defect stability. We also discuss possible initialization schemes utilizing spin-dependent

parameters were derived from first-principles. We consider five native defects: \(V_{ab-initio}\) of defect spins with similar properties. We present a systematic study aimed at searching for localized triplet spin states in \(n\) for possible applications in quantum computing and metrology. In addition, these results stimulated an active search for other materials, which may exhibit

splitting, spin-orbit coupling, spin-spin coupling, strain and Jahn-Teller interactions. We have also carried out DFT calculations that support and complement

seen in recent experiments for the 4H-SiC defect. We have included several different mechanisms involved in the mixing of its spin states, such as crystal field

10:00AM A37.00009 Robust Two-Qubit Gates for Donors in Silicon Controlled by Hyperfine Interactions

— RACHPON KALRA, ARNE LAUCHT, CHARLES D. HILL, ANDREA MORELLO, Centre for Quantum Computation and Communication Technology, Australia.

— CENTRE FOR QUANTUM COMPUTATION AND COMMUNICATION TECHNOLOGY, AUSTRALIA TEAM — The electron spin of a single atom in silicon is an excellent candidate for the building-block of a quantum computer. Recent breakthrough experiments have shown an individual phosphorus impurity atom can be used to store and elaborate one bit of quantum information. To continue along this exciting path, it is necessary to couple multiple phosphorus atoms in a controllable way and demonstrate quantum logic operations between pairs of qubits. This was thought to require exquisite control of their mutual interaction, and atomically-precise placement of the spins. Our work shows that the nuclei, to which the electrons are bound, can be exploited to realize a logic operation based on selective resonant excitation. This observation is of tremendous advantage as the inter-qubit interaction does not require any modification. Our calculations show that high-fidelity operations can be performed while tolerating a rather wide range of distances between atoms. This drastically reduces the demands posed on device fabrication, paving the way forward for large-scale quantum-information processing in silicon.

— Funded by the Australian Research Council (CE11E000127) and the U.S. Army Research Office (W911NF-13-1-0024)

10:12AM A37.00010 Triangulating the Position of Antimony Donors Implanted in Silicon

— CHLOE BUREAU-OXTON, Université de Sherbrooke, Sandia National Laboratories, ERIK NIelsen, DWIGHT LUHMAN, GREGORY TEN EYCK, TAMMY PLUYOM, JOEL WENDT, Sandia National Laboratories, MICHEL PIORO-LADRIERE, Université de Sherbrooke, MICHAEL LILLY, MALCOLM CARROLL, Sandia National Laboratories — A potential candidate for a quantum bit is a single Sb atom implanted in silicon. A single-electron-transistor (SET) situated close to an Sb donor can be used to measure the occupancy and spin of the electron on the donor while the lithographically patterned poly-silicon gates defining the SET can be used to control donor occupancy. In our samples two clusters of Sb donors have been implanted adjacent to opposite sides of the SET through a self-aligned process. In this talk, we will present experimental results that allow us to determine the approximate position of different donors by determining their relative capacitance to pairs of the SET’s poly-silicon gates. We will present the results of capacitive-based modeling calculations that allow us to further locate the position of the donors. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

10:24AM A37.00011 Atomic configuration interaction interaction simulations of two-electron states of donors in silicon

— ARCHANA TANKASALA, YU WANG, GERHARD KLIMECK, RAJIB RAHMAN, Purdue University — Two-electron states bound to donors in silicon are important for both two qubit gates and spin readout. We present a full configuration interaction technique in the atomistic tight-binding basis to capture multi-electron exchange and correlation effects taking into account the full bandstructure of silicon and the atomic scale inhomogeneity of a nanoscale device. The negatively charged two-electron \(D^-\) state of a single donor is solved as a function of a vertical field and depth from the silicon surface. Excited \(s\)-like states are found to strongly influence the charging energy. The same technique is used to solve the two-electron states of two donors as a function of separation, showing the transition from a Heitler-London like regime to a molecular regime. Excited valley states are found to affect the exchange energy for small donor separations.

10:36AM A37.0012 Electronic structure of Si vacancy centers in SiC

— ONEY SOYKAL, PRATIBHA DEV, SOPHIA ECONOMOU, Naval Research Laboratory (NRL) — The spin state of silicon vacancies in SiC is a promising candidate for applications in solid state quantum information technologies due to its long coherence time at room temperature, its technological availability and wide range of polytypism. Until recently, the electronic structure of this vacancy was not well understood. We have developed a group theoretical model that correctly predicts the spin \(3/2\) structure seen in recent experiments for the 4H-SiC defect. We have included several different mechanisms involved in the mixing of its spin states, such as crystal field splitting, spin-orbit coupling, spin-spin coupling, strain and Jahn-Teller interactions. We have also carried out DFT calculations that support and complement our analytical results.

10:48AM A37.0013 First-principles theory of defect spins in w-AlN for quantum information and sensing technologies

1 — HOSUNG SEO, MARCO GOVONI, GIULIA GALLI, The Institute for Molecular Engineering, The University of Chicago — The detection and coherent manipulations of the single nitrogen-vacancy defect spin in diamond \[1\] attracted a tremendous amount of attention for possible applications in quantum computing and metrology. In addition, these results stimulated an active search for other materials, which may exhibit defect spins with similar properties. We present a systematic study aimed at searching for localized triplet spin states in \(n\)-type \(w\)-AlN. We use a combination of \textit{ab-initio} calculations based on density functional and many-body perturbation theory and model calculations with an extended Hubbard Hamiltonian whose parameters were derived from first-principles. We consider five native defects: \(V_N\), \(V_A\), \(O_N\), \(V_AO_N\), and \(V_A/V_N\). We investigated the defect charge and spin-state energetics and we discuss the effect of strain fields on the defect stability. We will discuss how useful information can be extracted from large datasets obtained with full configuration interaction, multivalue, central-cell corrected effective mass calculations \[3\]. As examples, we will study the successful cases of theory/experiment comparison in Refs. \[1\] and \[2\], as well as provide early predictions for other systems, such as singlet-triplet donor-based qubits. \[1\] M. Session A38 GQI: Focus Session: Topological Quantum Information

— Mohammad Hafezi, University of Maryland
8:00AM A38.00001 Protected gates for topological quantum field theories, ROBERT KOENIG, Technical University Munich — We give restrictions on the locality-preserving unitary automorphisms U, which are protected gates, for topologically ordered systems. For arbitrary anyon models, we show that such unitaries only generate a finite group, and hence do not provide universality. For abelian anyon models, we find that the logical action of U is contained in a proper subgroup of the generalized Clifford group. In the case D(2), which describes Kitaev’s toric code, this represents a tightening of statement previously obtained within the stabilizer framework (PRL 110:170503). For non-abelian models, we find that such automorphisms are very limited: for example, there is no trivial gate for Fibonacci anyons. For Ising anyons, protected gates are elements of the Pauli group. These results are derived by relating such automorphisms to symmetries of the underlying anyon model: protected gates realize automorphisms of the Verlinde algebra. We additionally use the compatibility with basis changes to characterize the logical action. This is joint work with M. Beverland, F. Pastawski, J. Preskill and S. Sijher.

8:36AM A38.00002 Majorana Zero Modes Without Superconductivity at the Edge of Chiral Gapless Abelian Quantum Hall States, JENNIFER CANO, University of California, Santa Barbara, MENG CHENG, MAIISAM BARKESHLI, Microsoft Research, Station Q, CHETAN NAYAK, Microsoft Research, Station Q and University of California, Santa Barbara — We show that the $\nu = 8$ integer quantum Hall state can support Majorana fermion zero modes at domain walls between its two different stable chiral edge phases, even without superconductivity. This is due to the existence of an edge phase that does not support gapless fermionic excitations — all gapless excitations are bosonic in this edge phase. Majorana fermion zero modes occur at a domain wall between this edge phase and the more conventional one that does support gapless fermions. The zero modes survive the presence of gapless fermions in the conventional edge phase. Remarkably, the topological degeneracy of these zero modes has exponential protection, as a function of the relevant length scales, in spite of the presence of gapless excitations. These results are compatible with charge conservation, but do not require it. We discuss generalizations to other integer and fractional quantum Hall states.

8:48AM A38.00003 Fidelity of Majorana-based quantum operations, MOSTAFA TANHAYI AHARI, GERARDO ORTIZ, BABAK SERADJHE, Indiana Univ - Bloomington — It is well known that one-dimensional p-wave superconductor, the so-called Kitaev model, has topologically distinct phases that are distinguished by the presence of Majorana fermions. Owing to their topological protection, these Majorana fermions have emerged as candidates for fault-tolerant quantum computation. They furnish the operation of such a computation via processes that produce, braid, and annihilate them in pairs. In this work we study some of these processes from the dynamical perspective. In particular, we determine the fidelity of the Majorana fermions when they are produced or annihilated by tuning the system through the corresponding topological phase transition. For a simple linear protocol, we derive analytical expressions for fidelity and test various perturbative schemes. For more general protocols, we present exact numerics. Our results are relevant for the operation of Majorana-based quantum gates and quantum memories.

9:00AM A38.00004 Strongly interacting Majorana fermions, MARCEL FRANZ, CHING-KAI CHIU, DMITRY PIKULIN, University of British Columbia — Interesting phases of quantum matter often arise when the constituent particles — electrons in solids — interact strongly. Such strongly interacting systems are however quite rare and occur only in extreme environments of low spatial dimension, low temperatures or intense magnetic fields. Here we introduce a new system in which the fundamental electrons interact only weakly but the low energy effective theory is described by strongly interacting Majorana fermions. The system consists of an Abrikosov vortex lattice in the surface of a strong topological insulator and is accessible experimentally using presently available technology. The simplest interactions between the Majorana degrees of freedom exhibit an unusual nonlocal structure that involves four distinct Majorana sites. We formulate simple lattice models with this type of interaction and find exact solutions in certain physically relevant one- and two-dimensional geometries. In other cases we show how our construction allows for the experimental realization of interesting spin models previously only theoretically contemplated.

9:12AM A38.00005 An experimental proposal to observe non-abelian statistics of Majorana-Shockley fermions in an optical lattice, DONG-LING DENG, SHENG-TAO WANG, KAI SUN, LU-MING DUAN, Department of Physics, University of Michigan, Ann Arbor, Michigan 48109, USA — Besides the conventional bosons and fermions, in synthetic two-dimensional (2D) materials there could exist more exotic quasi-particles with non-abelian statistics, meaning that the quantum states in the system will be transformed by non-commuting unitary operators when we adiabatically braid the particles one around another. The search for such non-abelian particles is of critical significance in the current investigation on quantum physics. Despite the recent great progress, it remains technically elusive to braid the quasi-particles in materials to verify their conjectured non-abelian statistics. Here, we propose an experimental scheme to observe non-abelian statistics with cold atoms in a 2D optical lattice. We show that the Majorana-Shockley modes associated with line defects can be braided with non-abelian statistics through adiabatic shift of the local potentials. Observation of the non-abelian statistics will serve both fundamental interest and practical importance, in particular for topological quantum computation.

9:24AM A38.00006 Decoherence Patterns of Topological Qubits from Majorana Modes, SUNG PO CHAO, Academia Sinica, SHIH HA-HO, National Center for Theoretical Science, CHUNG HSIEN CHOU, National Cheng Kung University, FENG LI LIN, National Taiwan Normal University — We investigate the decoherence patterns of topological qubits in contact with the environment. Each topological qubit is made of two Majorana modes of a 1D Kitaev’s chain. These two Majorana modes weakly interact with the fermionic/bosonic environments. We find the topological qubits decohere completely in the Ohmic and sub-Ohmic environments but not in the super-Ohmic ones. Though the fermion parities of the topological qubits cannot prevent the qubit states from decoherence in the sub-Ohmic environments, it can prevent the qubits turning into Gibbs state. We also study the cases in which each Majorana mode couples to different Ohmic-like environments and the time dependence of concurrence for two topological qubits.

9:48AM A38.00007 A simple quasi-1D model of Fibonacci anyons, DAVID AASEN, ROGER MONG, DAVID CLARKE, JASON ALICEA, California Institute of Technology, PAUL FENDELEY, University of Oxford — There exist various ways of understanding the topological properties of Ising anyons—from simple free-fermion toy models to formal topological quantum field theory. For other types of anyons simple toy models rarely exist; their properties have to be obtained using formal self-consistency relations. We explore a family of gapped 1D local bosonic models that in a certain limit become trivial to solve and provide an intuitive picture for Fibonacci anyons. One can interpret this model as a quasi-1D wire that forms the building block of a 2D topological phase with Fibonacci anyons. With this interpretation all topological properties of the Fibonacci anyons become manifest including ground state degeneracy and braid relations. We conjecture that the structure of the model is protected by an emergent symmetry analogous to fermion parity.

10:00AM A38.00009 Robust quantum control using smooth pulses and topological winding
d. EDWIN BARNES, Condensed Matter Theory Center and Joint Quantum Institute, Dept. of Physics, University of Maryland, XIN WANG, Condensed Matter Theory Center, Dept. of Physics, University of Maryland — Perhaps the greatest challenge in achieving control of microscopic quantum systems is the decoherence induced by the environment, a problem which pervades experimental quantum physics and is particularly severe in the context of solid state quantum computing and nanoscale quantum devices because of the inherently strong coupling to the surrounding material. We present an analytical approach to constructing intrinsically robust driving fields which automatically cancel the leading-order noise-induced errors in a qubit’s evolution exactly. We address two of the most common types of non-Markovian noise that arise in qubits: slow fluctuations of the qubit energy splitting and fluctuations in the driving field itself. We demonstrate our method by constructing robust quantum gates for several types of spin qubits, including phosphorous donors in silicon and nitrogen-vacancy centers in diamond. Our results constitute an important step toward achieving robust generic control of quantum systems, bringing their novel applications closer to realization.

1Work supported by LPS-CMTC.

10:12AM A38.00010 Measuring second Chern number from dynamics, MICHAEL KOLODRUBETZ, Boston Univ, TIAGO SOUZA, ANATOLI POLKOVNIKOV, Boston University — By using the fact that Berry curvature acts as an effective electromagnetic field, recent work has demonstrated the direct experimental measurement of the first Chern number in systems of one and two superconducting qubits. This basic idea should extend to a number of interesting cases, including the presence of finite temperature or degenerate ground states. In this talk, I will show how in such a system one can measure the next non-trivial number in a line of topological invariants — the second Chern number. I will comment on experimental realizations of this measurement and its connection to fractionalization phenomena.

10:24AM A38.00011 Topological Phases of Sound and Light, VITTORIO PEANO CAVASOLA, CHRISTIAN BREDEL, MICHAEL SCHMIDT, FLORIAN MARQUARDT, University of Erlangen-Nuernberg — Topological states of matter are particularly robust, since they exploit global features insensitive to local perturbations. In this talk, we describe how to create a Chern insulator of phonons in the solid state. The proposed implementation is based on a simple setting, a dielectric slab with a suitable pattern of holes. Its topological properties can be wholly tuned in situ by adjusting the amplitude and frequency of a driving laser that controls the optomechanical interaction between light and sound. The resulting chiral, topologically protected phonon transport along the edges can be probed completely optically. Moreover, we identify a regime of strong mixing between photon and phonon excitations, which gives rise to a large set of different topological phases. This would be an example of a Chern insulator produced from the interaction between two physically very different particle species, photons and phonons.

10:36AM A38.00012 Topological Flux Phases of Levin-Wen String-Net Models, KAUSHAL PATEL, Univ of California - Santa Barbara, PARSA BONDERSON, Microsoft Station Q, KIRILL SHTENGEL, Univ of California - Riverside, STEVEN SIMON, Oxford — Levin-Wen string-net models provide exactly-solvable lattice models for gapped topological phases. We examine flux phases of these models, in which the lattice plaquettes contain a nontrivial flux instead of containing zero flux. In particular, we study $Z_N$ and Ising flux phases. We find that the Ising $\sigma$ flux phase is gapless, but nonetheless contains quasiparticles with topologically protected non-Abelian braiding statistics, thus providing an exactly-solvable model of a quasi-topological phase.

10:48AM A38.00013 Critical entanglement spectrum of one-dimensional symmetry protected topological phases, GUANG-MING ZHANG, Tsinghua Univ., BEIJING CHINA, XIN WAN, Zhejiang University, Hangzhou, China — Under an appropriate symmetric extensive bipartition in a one-dimensional symmetry protected topological (SPT) phase, a bulk critical entanglement spectrum can be obtained, resembling the excitation spectrum of the critical point separating the SPT phase from the trivial (vacuum) state. Such a critical point is beyond the standard Landau-Ginzburg-Wilson paradigm for symmetry breaking phase transitions. For the $S=1$ SPT (Haldane) phase with the Affleck-Kennedy-Lieb-Tasaki exact wave function, the resulting critical entanglement spectrum shows a delocalized version of the edge excitations in the SPT phase. From the wave function corresponding to the lowest entanglement energy level, the central charge of the critical point can be extracted and the critical theory can be identified as the same effective field theory as the spin-1/2 antiferromagnetic Heisenberg chain or the spin-1/2 Haldane-Shastry model with inverse square long-range interaction. Monday, March 2, 2015 8:00AM - 11:00AM — Session A39 GQI: Superconducting Qubits: Entanglement and Feedback 213AB - Leo DiCarlo, Delft University of Technology

8:00AM A39.00001 Superconducting qubits: entanglement by synchronous and asynchronous feedback, YEHAN LIU, S. SHANKAR, N. OFEK, M. HÄTRIDGE, A. NARLA, K.M. SLIWA, R.J. ŠCIOELKOPF, M.H. DEVORÉT, Department of Applied Physics, Yale University — Quantum feedback for error correction is now an important component of superconducting quantum information processing. We have implemented two feedback schemes, autonomous (AT) and measurement-based (MB), to stabilize entanglement between two transmon qubits coupled to a cavity. The two qubits are coupled with nearly equal dispersive shifts to the cavity, such that a cavity drive maps the qubits’ parity onto the cavity state. Entanglement is autonomously stabilized by applying continuous photon-number-selective Rabi drives on qubit transitions with phases conditioned on the measured signal. A synchronous protocol stabilizes entanglement for a fixed duration using either scheme resulting in a target Bell state with an unconditioned fidelity in excess of 55 % for MB and 77 % for AT. Furthermore, we have enhanced the fidelity of the entanglement by implementing an asynchronous “wait until success” protocol conditioning the tomography on a parity measurement in real time.

3Work supported by: IARPA, ARO, and ONR.
8:12AM A39.00002 Steady-state entanglement of distant transmons, stabilised against high transmission loss
FELIX MOTZOI, ELI HALPERIN, University of California, Berkeley, XIAOTING WANG, Massachusetts Institute of Technology, BIRGitta WHALEY, University of California, Berkeley, SOPHIE SCHIRMER, Swansea University — Being able to stabilise entanglement over long distances and long times provides numerous advantages over pulsed experiments (avoiding variability, synchronisation, and calibration issues) while providing an important resource on-demand, which can then be potentially distilled and used to construct a quantum network. We show how existing superconducting technologies can be entangled over distances of tens of meters providing resilient stabilisation even in the presence of high inefficiency of the transmission channel. This can be achieved both in the dispersive and non-resonant cavity regimes using simple protocols that employ correlated environmental interactions and symmetrity breaking. These require only a single-frequency drive that interacts sequentially with each cavity-qubit system. The dispersive regime protocol uses feedback while the near-resonant regime protocol is autonomous.

8:24AM A39.00003 Stochastic master equation approach for analysis of remote entanglement with Josephson parametric converter amplifier
M. SILVERI, Department of Physics, Yale University, E. ZALYS-GELLER, M. HATRIDGE, Z. LEGHTAS, M.H. DEVORET, Department of Applied Physics, Yale University, S.M. GIRVIN, Department of Physics, Yale University — In the remote entanglement process, two distant stationary qubits are entangled with separate flying qubits and the which-path information is erased from the flying qubits by interference effects. As a result, an observer cannot tell from which of the two sources a signal came and the probabilistic measurement process generates perfect heralded entanglement between the two signal sources. Notably, the two stationary qubits are spatially separated and there is no direct interaction between them. We study two transmon qubits in superconducting cavities connected to a Josephson Parametric Converter (JPC). The qubit information is encoded in the traveling wave leaking out from each cavity. Remarkably, the quantum-limited phase-preserving amplification of two traveling waves provided by the JPC can work as a which-path information eraser. By using a stochastic master approach we demonstrate the probabilistic production of heralded entangled states and that unequal qubit-cavity pairs can be made indistinguishable by simple engineering of driving fields. Additionally, we will derive measurement rates, measurement optimization strategies and discuss the effects of finite amplification gain, cavity losses, and qubit relaxations and dephasing.

8:36AM A39.00004 Optimizing JPC-based remote entanglement of transmon qubits via stochastic master equation simulations
E. ZALYS-GELLER, M. HATRIDGE, Department of Applied Physics, Yale University, M. SILVERI, Department of Physics, Yale University, A. NARLA, K.M. SLIWA, S. SHANKAR, Department of Applied Physics, Yale University, M.H. DEVORET, Department of Applied Physics, Yale University — Remote entanglement of two superconducting qubits may be accomplished by first entangling them with flying coherent microwave pulses, and then erasing the which-path information of these pulses by using a non-degenerate parametric amplifier such as the Josephson Parametric Converter (JPC). Crucially, this process requires no direct interaction between the two qubits. The JPC, however, will fail to completely erase the which-path information if the flying microwave pulses encode any difference in dynamics of the two qubit-cavity systems. This which-path information can easily arise from mismatches in the cavity linewidths and the cavity dispersive shifts from their respective qubits. Through analysis of the Stochastic Master Equation for this system, we have found a strategy for shaping the measurement pulses to eliminate the effect of these mismatches on the entangling measurement. We have then confirmed the effectiveness of this strategy by numerical simulation.

8:48AM A39.00005 Entanglement of remote transmon qubits by concurrent measurement using Fock states
A. NARLA, M. HATRIDGE, S. SHANKAR, Z. LEGHTAS, K.M. SLIWA, B. VLASTAKIS, E. ZALYS-GELLER, Department of Applied Physics, Yale University, M. MIRRAHIMI, Department of Applied Physics, Yale University and INRIA Paris Rocquencourt, M.H. DEVORET, Department of Applied Physics, Yale University — A requirement of any modular quantum computer is the ability to maintain individual qubits in isolated environments while also being able to entangle arbitrary distant qubits on demand. For superconducting qubits, such a protocol can be realized by first entangling the qubits with flying microwave coherent states which are then concurrently detected by a parametric amplifier. This protocol has a 50% success probability but is vulnerable to losses between the qubits and the amplifier which reduce the entanglement fidelity. An alternative is to use itinerant Fock states, since losses now tend to reduce the success probability of creating an entangled state but not its fidelity. Such single-photon protocols have been implemented in trapped-ion and NV-center experiments. We present such a protocol tailored for entangling two transmon qubits in the circuit QED architecture. Each qubit is entangled with a Fock state of its cavity using sideband pulses. The Fock states leak out of the cavity, interfere on a beam-splitter which erases their which-path information, and are subsequently detected using a novel photo-detector realized by another qubit-cavity system. Simulations suggest that we can realize a high-fidelity entangled state with a success probability as large as 1%.

9:00AM A39.00006 Generation of multi-qubit entanglement in a superconducting quantum circuit by parallelized parity measurements
STEFANO POLETTI, DIEGO RISTE, MENG-ZI HUANG, ALESSANDRO BRUNO, VISA VESTERINEN, OLLI-PENTTI SAIRA, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience — We present the generation of multi-qubit entanglement using parallelized ancilla-based parity measurements in a five qubit superconducting processor. Two-qubit Bell states and three-qubit GHZ-type states are generated by single and double two-qubit parity measurements on superposition states, respectively, and characterized by both witnessing and state tomography. The protocol for generation of GHZ-type states can be used as the encoding step in the three-qubit bit-flip quantum error correction code, and made deterministic by digital feedback control. We assess its performance by state tomography of the six encoded cardinal states, and compare to the traditional method of encoding by gates.

9:12AM A39.00007 Geometry of two-qubit evolution and entanglement protection via local operations
CHARLES TAHAN, RUSKO RUSKOV, Laboratory for Physical Sciences, College Park, MD — The two-qubit pure state evolution under unitary (Hamiltonian) and measurement transformations is conveniently described via a Hopf fibration map, where an S4 sphere is the two-qubit analog of the single-qubit Bloch sphere and entanglement is encoded in an S4 subspace. We show that there exist two-qubit entanglement protection protocols based only on local operations that are as efficient as in the case of a single qubit state protection. We consider several examples related to current or near future experiments in superconducting circuits. We discuss the relevance of such ideas for quantum computing.
9:24AM A39.00008 Toward Resource-Efficient Deterministic Entanglement in 3D Superconducting Qubits, M. E. SCHWARTZ, L. MARTIN, QNL, University of California, Berkeley, C. ARON, Department of Electrical Engineering, Princeton University, M. KULKARNI, New York City College of Technology, City University of New York, H.E. TURECI, Department of Electrical Engineering, Princeton University, I. SIDDIQI, QNL, University of California, Berkeley — We present progress towards deterministic entanglement in a three-dimensional, superconducting qubit architecture, using only one continuous drive to engineer steady-state entanglement [1]. Our protocol uses two (nominally) identical copper waveguide cavities that each contain a transmon qubit. The cavities are directly coupled to one another and hybridized into symmetric and antisymmetric modes. The coupling of the cavities introduces a cavity-mediated qubit coupling that splits the degeneracy between the singlet and triplet states in the odd-parity subspace. By driving the cavities symmetrically and carefully tuning the single drive amplitude and frequency to take advantage of the hybridized cavity density of states, we aim to achieve bipartite entanglement that is stable against both dephasing and finite qubit lifetime. In this talk, we present experimental progress towards this cavity-assisted, bath engineered generation of entanglement.

This work was supported by the ARO and by the Hertz Foundation.

9:36AM A39.00009 Optimal feedback for remote entanglement, LEIGH MARTIN, Whaley Research Group and QNL, University of California, Berkeley, FELIX MOTZOI, HANHAN LI, MOHAN SAROVAR, Whaley Research Group, University of California, Berkeley, IRFAN SIDDIQI, QNL, University of California, Berkeley, BIRGITTA WHALEY, Whaley Research Group, University of California, Berkeley — Recent experiments in superconducting qubits have demonstrated measurement as a resource for entanglement, even when qubits are spatially separated to a significant degree. We consider the problem of using measurement combined with feedback to deterministically entangle remote qubits. This constraint forces us to consider only local feedback, which leads us to an interesting control-theory problem. Within this constraint, we derive a series of protocols for this system which generate entanglement as quickly as possible. We find that even in the presence of expected experimental imperfections, it should be possible to achieve high-fidelity entanglement with currently accessible experimental parameters.

This work is supported by the National Science Foundation.

9:48AM A39.00010 Robust quantum state transfer using flying microwave qubits, ERIC MLINAR, EYOB A. SETE, ALEXANDER N. KOROTKOV, University of California, Riverside — We analyze the transfer of a quantum state between two superconducting microwave resonators connected by a transmission line. Nearly perfect state-transfer efficiency can be achieved by using adjustable couplers to cancel the back-reflection from the receiving coupler with destructive interference. We show that the transfer protocol is robust to parameter variations affecting the transmission amplitudes of the couplers. We also show that the effects of Gaussian filtering, pulse-shape noise, and multiple reflections on the transfer efficiency are not significant for experimentally realistic parameters. However, the transfer protocol is very sensitive to a frequency mismatch between the two resonators. Moreover, the type of coupler we consider produces a time-dependent detuning, which requires active compensation with sufficient accuracy to yield high-efficiency state transfer.

10:00AM A39.00011 Scaleable two and four qubit parity measurement with a photon counter, LUKE C.G. GOVIA, Univ des Saarlandes, EMILY J. PRITCHETT, HRL Laboratories, R. MCDERMOTT, University of Wisconsin-Madison, FRANK K. WILHELMI, Univ des Saarlandes — Multi-qubit parity readout is a central ingredient to quantum information processing, with applications ranging from quantum error correction to entanglement generation. As the physical implementation of QIP technologies grows in size, so too does the need for scalable readout protocols. Here we present a scalable, high-fidelity, quantum non-demolition readout protocol for the parity of two or four qubits using a single dispersively coupled cavity and a photon counter. By selectively populating the cavity dependent on the qubit parity, it is possible to non-destructively read out the qubit parity using a phase insensitive photon counter, without gaining any further qubit-state resolving information. We describe our protocol in the context of superconducting integrated circuits, where the cavity is a microwave resonator, and as an example photon counter we choose the Josephson photomultiplier (PRL 107, 217401 (2011)).

10:12AM A39.00012 Analytical approach to switchoff non-leaky entangling gates in superconducting qubits, SOPHIA ECONOMOU, Naval Research Laboratory, EDWIN BARNES, Condensed Matter Theory Center and Joint Quantum Institute, Dept. of Physics, University of Maryland — We develop schemes for designing pulses that implement fast and precise entangling quantum gates in superconducting qubit systems despite the presence of nearby harmful transitions. Our approach is based on purposely involving the nearest harmful transition in the quantum evolution instead of trying to avoid it. Using analytical tools, we design simple microwave control fields that implement maximally entangling gates with fidelities exceeding 99 percent in times as low as 40 ns. We demonstrate our approach in a two-qubit circuit QED system by designing the two most important quantum entangling gates: a conditional-NOT gate and a conditional-Z gate. Our results constitute an important step toward overcoming the problem of spectral crowding, one of the primary challenges in controlling multi-qubit systems.

This work was supported by LPS-CMTC (EB) and in part by ONR (SEE).

10:24AM A39.00013 3D Multimode Cavity QED, RAVI NAIK, DAVID C. MCKAY, DAVID I. SCHUSTER, Physics Department and James Franck Institute, University of Chicago — Scalable quantum computing architectures require many long-lived and highly coherent, yet easily addressable quantum states. Photonic qubits in 3D superconducting microwave cavities are a promising approach because they are highly insensitive to decoherence and single photon lifetimes exceeding 10 ms have been demonstrated[1]. However, the plurality of current 3D cavity devices are engineered to address single photon modes. In this talk, we introduce our implementation of a multimode 3D cavity that can store greater than 20 distinct, long-lived photon modes. To perform single- and two-qubit gates between photons, each of the modes are coupled to a single flux-tunable superconducting transmon qubit. We will discuss our preliminary results towards a controlled phase gate between any pair of photons modes. This multimode circuit QED architecture may also be used as a many-body bosonic system for quantum simulation, to study multimode quantum optics, and for quantum memories as part of a larger quantum network.

10:36AM A39.00014 ABSTRACT WITHDRAWN —
10:48AM A39.00015 Design and processing considerations for superconducting qubits coupled to multiple 3D cavities

8:00AM A41.00001 n-type doping through tethered functionality: a new paradigm for molecular design of solution-processed organic thermoelectrics. BORIS RUSS, UC Berkeley, Dept of ChemE; MAXWELL J. ROBB, UCSB, Chem and Materials Deps; BHOOSHAN C. POPERE, UCSB, Dept of ChemE; ERIN PERRY, UCSB, Chem and Materials Deps; JEFFREY J. URBAN, LBNL, Molecular Foundry; MICHAEL L. CHABINYC, CRAIG J. HAWKER, UCSB, Chem and Materials Deps; RACHEL A. SEGALMAN, UCSB, Dept of ChemE — A scarcity of stable n-type doping mechanisms compatible with facile processing has been a major impediment to the advancement of n-type (electron transporting) organic thermoelectric materials. We recently demonstrated that trimethylammonium functionalization with hydroxide counterions, tethered to a perylene diimide core by alkyl spacers, facilitated solution-processing and resulted in extremely high carrier concentrations (10\textsuperscript{20} carriers/cm\textsuperscript{3}) and best-in-class thermoelectric performance in thin films. In this presentation, we report our recent findings on the underlying mechanism enabling charge carrier generation in these self-doping materials and its influence on material thermoelectric behavior. To draw these conclusions, we complement thermoelectric characterization with insights into chemical, electronic, and structural properties from XPS, optical spectroscopy, EPR, and GIWAXS experiments. Furthermore, we show that doping through tethered functionality can be extended to other n-type small molecule systems of interest, including naphthalene diimides and diketopyrrolopyrroles. Our findings help shape promising molecular design strategies for future enhancements in n-type thermoelectric performance.

Monday, March 2, 2015 8:00AM - 11:00AM
Session A41 DPOLY DMP: Focus Session: Organic Electronics and Photonics - Thermoelectric, Ferroelectric, and Piezoelectric Materials 214A - Jennifer Schaefer, National Institute of Standards and Technology

8:00AM A41.00001 n-type doping through tethered functionality: a new paradigm for molecular design of solution-processed organic thermoelectrics

8:12AM A41.00002 Silver Nafion for Thermogalvanic Applications. WILLIAM CHANG, BHOOSHAN POPERE, University of California, Berkeley, CHRIS EVANS, University of California, Santa Barbara, BORIS RUSS, University of California, Berkeley, RACHEL SEGALMAN, University of California, Santa Barbara — Thermogalvanic devices typically operate on the difference between waste heat, into electrical power using a reversible electrochemical reaction. The conversion efficiency in thermogalvanics, like with thermoelectrics, are governed by the Seebeck coefficient, the carrier conductivity and the thermal conductivity of the material. We demonstrate that the material systems silver Nafion and silver poly-styrenesulfonate are air-stable, water processable materials that demonstrate extremely high Seebeck coefficients and moderate carrier conductivities. These power factors, when coupled with the low thermal conductivities inherent in polymers, results in materials with excellent thermogalvanic figure of merits. We show the dependence of these three material properties to material composition and processing. In this talk, we show how the Seebeck coefficient in silver Nafion and silver poly-styrenesulfonate are opposite in sign, allowing construction of a thermogalvanic device. With these ion conductors, we hope to open up a flexible pathway to waste heat recovery using materials typically studied for electrochemical applications.

8:24AM A41.00003 Thermoelectric properties of hole- and electron-doped ambipolar polymers. ANNE GLAULDELL, ERIN PERRY, RUTH SCHLITZ, MICHAEL CHABINYC, Univ of California - Santa Barbara — The library of possible materials, both p- and n-type, for organic thermoelectric devices has been steadily growing with the continuous improvement in electrical properties and stability. Maximizing the thermoelectric power factor in these materials requires the simultaneous optimization of both electrical conductivity and thermopower. The challenge remains that charge transport is not well understood in organic materials due to energetic disorder from crystalline and non-crystalline domains. We have performed temperature-dependent measurements of both thermopower and electrical conductivity to uncover the relationship between microstructure and thermoelectric performance. These measurements were complemented by techniques such as electronic paramagnetic resonance (EPR) that help provide the carrier concentration to give a more complete picture of the competing charge transport mechanisms and structure-property relationships. We will present results on p- and n-type doping of ambipolar polymers that reveal the difference in thermopower for electrons and holes in the same material. An ideal thermoelectric device has n- and p-type legs with similar mechanical and thermoelectric properties, a balance more easily realized using the same polymer for each leg.

8:36AM A41.00004 Conductance and Thermopower in Thiophene and Oxidized Thiophene Single-Molecule Junctions. LATHA VENKATARAMAN, Columbia Univ — Organic electronic materials have impacted the development of semiconducting, photovoltaic and thermoelectric devices. The precise control afforded over molecular design by organic synthesis allows for device properties to be readily tailored facilitating varied functionality. Measuring charge transfer characteristics and thermoelectric properties in organic devices and across metal-organic interfaces is of critical importance for understanding structure-function relations and single molecule measurements offer an ideal test bed for such measurements. Organic materials such as thiophene and its oxidation products are prime examples of self-assembled small-molecule devices focusing on molecular systems that have strong potential for application in organic and photovoltaic devices. Specifically, I will discuss measurements of thiophene and oxidized thiophene oligomers that illustrate how structure and conformations impact both the electronic characteristics and the dominant charge carrier in these systems. I will end this talk discussing results with a new class of thiophene derivatives where the charge carriers are changed from holes to electrons as the length of the oligomer is increased. With these measurements, we illustrate a new means to tune p- and n-type transport in organic materials.

9:12AM A41.00005 Thermoelectricity in Disordered Organic Semiconductors under the Premise of the Gaussian Disorder Model and its Variants. DAN MENDELS, NIR TESSLER, TECHNION, ORGANIC MATERIALS AND DEVICES TEAM — Charge transport in disordered organic systems has been in recent decades mainly discerned from the perspective of a variety of phenomenological models prominent of which those stemming from the Gaussian Disorder Model. But while the use of these models has been prevalent, uncertainty regarding the extent of their validity remains due to the large number of free parameters they consist and their frequent deficiency to consistently account for large sets of experiments while keeping model input parameters and distributions unchanged. In the presented study, we have investigated using Monte Carlo simulations the thermoelectric properties of disordered organic semiconductors under the premise of the Gaussian Disorder Model and its variants. Doing so enabled the provision of additional directional comparison between the aforementioned theoretical frameworks and real systems, beyond those based on extensively studied charge transport properties, and the provision of a frame-of-reference for rising interest in these systems for thermoelectric applications. To illustrate the potential existing in the implementation of combined transport and thermoelectric investigation, strategies will be discussed to experimentally deduce the DOS shape, infer whether a system’s activation energy originates from its energetic disorder or a polaron activation energy (while deducing the given polaron activation energy), and discerning whether a system’s energetic disorder is spatially correlated or accompanied by off-diagonal disorder.
Nanotube Based Organic Thermoelectric Matrices, THUSITHA ETAMPAWALA, Department of Chemistry, The University of Tennessee, Knoxville, TN.

understanding illustrates that FE in even n-nylons originates from the defective crystalline phase rather than the amorphous region. The conformation is smectic-like, twisted, and the hydrogen bonds are randomized. Therefore, this mesophase is abundant in defects and poorly bonded amide dipoles, which result from the defective crystalline mesophase, play an important role in the FE behavior of nylon 12. In this mesophase, the chain

nylon 6 was due to the amorphous phase, the conclusion is debatable and the understanding of the FE mechanism is still lacking. We find that poorly bonded mesomorphic crystalline structure formed via quenching and/or stretching. Although there was an earlier claim maintaining that FE behavior in melt-quenched nanocomposites were probed by small and ultra-small angle neutron scattering (SANS and USANS respectively) as a function of CNT loading (10wt%, 30wt%, and 50wt%), sonication duration to control the CNT dispersion, and presence and absence of ethylene glycol (EG) in the deposition solution of PEDOT:PSS. The morphology of these composites is currently being correlated to their thermo-electric performance. The SANS and USANS profiles were analyzed with the hierarchical Beaucage model. Further, the USANS data were fit to a two ellipsoidal form factor, which is consistent with the analysis of the USANS data by the Beaucage model and SEM results. These results reveal that the sonication duration and presence of EG effectively de-bundle the CNTs and disperse them in the PEDOT:PSS matrix.

9:36AM A41.00007 Exploiting the Different Polarity in Piezoresistive Characteristics of Conducting Polymers for Strain Gauge Applications, MELDA SEZEN, JEFFREY T. REGISTER, Dept. of Chemical and Biological Engineering, Princeton University, YAO YAO, BRANKO GLISIC, Dept. of Civil and Environmental Engineering, Princeton University, YUEH-LIN LOO, Dept. of Chemical and Biological Engineering, Princeton University — Piezoresistivity defines the change in resistance of a material in response to mechanical stress. We exploit the effects of structural modifications on the piezoresistive properties of conducting polymers, poly(2-acrylamido-2-methyl-1-propanesulfonylic acid) doped polyaniline, PANI-PAAMPSA, and poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate), PEDOT:PSS, for strain gauge applications. Under tensile deformation, the resistances of as-cast PANI-PAAMPSA and PEDOT:PSS increase due to increased separation between the electrostatically stabilized conducting polymer particles. Upon solvent annealing in dichloroacetic acid, DCA, PANI-PAAMPSA’s resistance decreases whereas PEDOT:PSS’s resistance still increases with tension. While DCA treatment reduces the electrostatic interactions between PANI and PAAMPSA, it only removes the PSS overlay in PEDOT:PSS. The change in the polarity of PANI-PAAMPSA’s piezoresistivity is attributed to the unlocking of the globular structure of the as-synthesized conducting polymer complex with DCA-treatment, which then enables strain-induced crystallization on deformation. By tuning the piezoresistive characteristics of the polymers through structural modification, we can design strain gauge circuits for monitoring the conditions of civil structures.

9:48AM A41.00008 Temperature-dependent electrical transport in ferroelectric organic field-effect transistors, AMRIT LAUDARI, SUCHISMITA GUHA, Univ of Missouri - Columbia — Ferroelectric dielectrics, permitting access to nearly an order of magnitude range of polarization with temperature as the tuning parameter, offer a great test-bed to monitor the changes in interfacial transport in organic field-effect transistors (OFETs) as the polarization strength is tuned. Temperature-dependent transport studies have been carried out from pentacene and other organic semiconductor-based OFETs using the ferroelectric copolymer poly(vinylidene fluoride-co-trifluoroethylene) (PVDF-TrFe) as a gate insulating layer. By fits to an Arrhenius-type dependence of the charge carrier mobility as a function of temperature, the activation energy in the ferroelectric phase is found to increase as the thickness of the PVDF-TrFe layer increases. For thicknesses of the dielectric layer above 100 nm, the activation energy is found to be greater than 150 meV, which greatly reduces in the paraelectric phase of the dielectric. The weak temperature-dependence of the charge carrier mobility in the ferroelectric phase of PVDF-TrFe may be attributed to a polarization fluctuation driven transport. The threshold voltage decreases upon increasing temperatures with a large change above the ferroelectric to paraelectric phase transition temperature.

10:00AM A41.00009 Ferroelectrically-driven photocurrent in P3HT-based diodes, ELENI PAVLOPOULOU, CARINE LACROIX, ANTIGONI PASPALI, GUILLAUME FLEURY, CYRIL BROCHON, ERIC CLOUTET, LCPC, CNRS/University of Bordeaux, Bordeaux/Bordeaux INP, Pessac France, FABRICE DOMINGUES DOS SANTOS, Piezotech, France, MARIO MAGLIONE, ICMCB?CNRS, University of Bordeaux, Pessac France, GEORGES HADZIOANNOU, LCPC, CNRS/University of Bordeaux/Bordeaux INP, Pessac France — Blends of ferroelectric and semiconducting polymers are known to phase separate in thin film configuration, forming semiconducting columnar structures embedded in a ferroelectric matrix. These blends have been used in the past to fabricate non-volatile bistable diodes. In this work we demonstrate that the phase separated network of poly(3-hexylthiophene), P3HT, and poly(vinylidenefluoride-co-trifluoroethylene), P(VDF-co-TrFE), can be also used for the extraction of photocurrent under illumination. Furthermore, we provide experimental proofs on the ferroelectric origin of this photocurrent and we show that its magnitude depends on the polarization characteristics of the pre-polarized P(VDF-co-TrFe) matrix. The devices we propose herein can provide an alternative to the existing organic photovoltaic devices.

10:12AM A41.00010 Ferroelectricity and Double Hysteresis Loop Behavior in Even-Numbered n-Nylons, ZHONGBO ZHANG, LEI ZHU, MORTON LITT, Case Western Reserve Univ — Ferroelectric (FE) property in odd-numbered n-nylons has been known for a long time. In comparison, even-numbered n-nylons are claimed to be non-ferroelectric due to their non-polar crystalline structure, where the direction of hydrogen bonded dipoles alternates. Nevertheless, in this presentation, FE property is discovered in even n-nylons, and it is related to the mesomorphic crystalline structure formed via quenching and/or stretching. Although there was an earlier claim maintaining that FE behavior in melt-quenched nylon 6 was due to the amorphous phase, the conclusion is debatable and the understanding of the FE mechanism is still lacking. We find that poorly bonded amide dipoles, which result from the defective crystalline mesophase, play an important role in the FE behavior of nylon 12. In this mesophase, the chain conformation is smectic-like, twisted, and the hydrogen bonds are randomized. Therefore, this mesophase is abundant in defects and poorly bonded dipoles, which can easily flip under electric field. In addition, the hydrogen-bonded amides can serve as pinning points and induce double hysteresis loop behavior. This understanding indicates that FE in even n-nylons originates from the defective crystalline phase rather than the amorphous region.

10:24AM A41.00011 Relaxor Ferroelectric Behavior from Strong Physical Pinning in a Poly(vinylidene fluoride-co-trifluoroethylene-co-chlorotrifluoroethylen) Random Terpolymer 1
LEI ZHU, LIANYUN YANG, Dept. of Macromolecular Sci. & Eng., Case Western Reserve University, Cleveland, OH 44106, BRADY TYBURSKI, Dept. of Chemistry, Central Michigan University, Mount Pleasant, Michigan 48859, FABRICE DOMINGUES DOS SANTOS, Pliezotech S.A.S, Arkema-CRAA, Rue Henri Moissan 69493 Pierre-Benite Cedex, France — Although narrow single hysteresis loop (SHL) is observed for electron beam (e-beam) irradiated poly(vinylidene fluoride-co-trifluoroethylene) [P(VDF-TrFE)] random copolymers owing to strong chemical pinning in isomorphic (or defect-modified) crystals, it has not been achieved for P(VDF-TrFE)-based random terpolymers, such as P(VDF-TrFE-CFE) (CFE is 1,1-chlorofluoroethylene), which only exhibits double hysteresis loops (DHLs). This is attributed to the weak physical pinning of CFE units in isomorphic crystals. In this work, the comonomer CFE in the terpolymer was replaced by the larger chlorotrifluoroethylene (CTFE). Intriguingly, narrow SHLs were exclusively observed for the P(VDF-TrFE-CTFE) terpolymer above room temperature. This was attributed to the stronger physical pinning force of the larger CTFE, which has a smaller dipole moment (only 0.64 Debye). This result provides further insight into the structure and behavior of relaxor ferroelectric polymers, which can help to design and develop new ferroelectric polymers with more desirable properties and enhanced performance.

10:36AM A41.00012 ABSTRACT MOVED TO M6.00013 —

10:48AM A41.00013 Enhanced Electrical Conductivity due to Morphological Changes in Polyanailine-Titania Core-Shell Nanocomposites
NELSON COATES, California Maritime Academy, JIANFENG LIU, University of California, Berkeley, RACHEL SEGALMAN, University of California, Santa Barbara, JEFFREY URBAN, Lawrence Berkeley National Laboratory — Conducting polymer-inorganic nanoparticle composites are a valuable class of advanced materials with a wide range of applications due to extensive physical and chemical tunability. Although effective medium theories are often used to predict the behavior of these materials, the actual physical properties can be distinctly different from the predictions of the effective medium interactions that they manifest. Here, we present electrical conductivity data for TiO2 nanoparticles coated with polyaniline, along with structural characterization of the conducting polymer as a function of component volume fraction. For these composites, we find that the electrical conductivity cannot be explained by a 2-component effective medium theory, but rather is correlated to a structural change in the polymer. We hypothesize that the organic-inorganic interface induces a structural change in a region of polymer surrounding the nanoparticle which improves the electrical conductivity of the composite. These results emphasize the importance of controlling interfacial interactions in organic-inorganic composites, and demonstrate the potential for using such interactions as a way to tune electrical transport.

Monday, March 2, 2015 8:00AM - 11:00AM — Session A42 DPOLY: Polymeric Elastomers and Gels 214B - Edwin Chan, National Institute of Standards and Technology

8:00AM A42.00001 Tailoring Phase Behavior and Mechanical Properties in Thermoplastic Elastomers through Block Sequence and Macromolecular Architecture
ADAM BURNS, RICHARD REGISTER, Princeton University — Block copolymers exhibit unique properties which depend not only on the identities of the constituent blocks but also the block sequence and macromolecular architecture. Thermoplastic elastomers (TPEs) are a prime example. In TPEs the arrangement of glassy end blocks flanking a long rubbery midblock gives rise to a physically cross-linked, elastic solid. Exchanging the glassy blocks for crystalline blocks can improve the processability and solvent resistance, but adversely affects the mechanical performance. The block sequence crystalline-glassy-rubber-crystalline has been developed to combine the advantages of both crystalline and glassy blocks. Careful selection of block lengths produces materials in which the order-disorder transition temperature lies below the melting point of the crystalline block, ensuring that the melt will be homogeneous above the melting point. Access to single-phase melts provides a large reduction in viscosity and elasticity over conventional TPEs, which remain microphase-separated in the melt. Inserting the glassy blocks between the crystalline and rubbery blocks produces a vitreous layer surrounding the crystalline domains, which improves the room-temperature mechanical performance. Incorporating the crystalline-glassy-rubber motif into the arms of star block copolymers adds another level of control. The star architecture introduces a permanent cross-link at the center of the star without appreciatively affecting the phase behavior.

8:12AM A42.00002 Shear Induced Morphology Evolution and Dynamic Viscoelastic Behavior of Binary and Ternary Elastomer Blends 1
XIA DONG, XIAOJIANG LIU, WEI LIU, CHARLES C. HAN, DUJIN WANG, Beijing National Laboratory for Molecular Sciences, CAS Key Laboratory of Engineering Plastics, Institute of Chemistry Chinese Academy of Sciences — The morphology evolution and rheological response of a near-critical composition polybutadiene/polyisoprene blend and solution-polymerized styrene-butadiene rubber/polyisoprene/silica ternary composites after various shear flow were in situ studied with the rheological and rheo-optical techniques. The relationship between the morphology of the blend during the relaxation after the cessation of steady shear with different shear rates and their corresponding rheological properties was successfully established. It was found that the different shear-induced morphologies under steady shear would relax to the equilibrium states via varied mechanisms after the shear cessation. The storage modulus G' increased significantly in the breakup process of the string-like phase. In long time scale, silica slowed down the succeeding breakup of the string-phase domains and simultaneous coalescence of broken droplets, and then effectively reduced the droplets size and stabilized the morphology.

8:24AM A42.00003 Structure and mechanical properties of isotactic polypropylene (iPP) gels formed at different cooling temperatures
RYUSUKE OKOSHI, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — The effects of the cooling temperature on the crystalline network formation and the mechanical properties of isotactic polypropylene (iPP) gels were evaluated. iPP-decallydroonaphthalene gels were prepared at different cooling temperatures varying from 25 degrees C to -196 degrees C. Tensile test was carried out to measure the mechanical properties of the gels. Scanning electron microscopy (SEM) and differential scanning calorimetry (DSC) analyses were conducted to observe the density and the homogeneity of the network structures. It was found that the iPP gel quenched at -196 degrees C was highly elastic, exhibiting the highest fracture strain and stress of 2500% and 230 kPa. The SEM analysis revealed that nano-crystals were formed, which acted as crosslinkers that were distributed throughout the gels by quenching below -40 degrees C. By contrast, spherulites were observed to have grown inhomogeneously by cooling above -20 degrees C. It was found by DSC that the amount of decreasing the cooling temperatures, indicating an increase in the density of the network structures. From these results, it was therefore concluded that iPP gel quenched at -196 degrees C possessed the highest mechanical property due to its dense and homogeneous network structures.
Copolymers parameters obtained from PRI with results from neutrons scattering studies of the same series of hydrogels. Applying various thermodynamic network swelling models to describe the mechanical response of these gels as measured from PRI, we are able to extract *glycol* chains. We use PRI to quantify the mechanical and transport properties of a series of "click" hydrogels with different crosslink densities. By

9:00 AM A42.00006 Wide bicontinuous compositional windows from co-networks made with telechelic macromonomers, Gregory TeW, Polymer Science and Engineering, University of Massachusetts, Amherst — Phase-separated and self-assembled co-network materials offer a simple route to bicontinuous-like morphologies, which are expected to be highly beneficial for applications such as ion, charge, and oxygen transport. Despite these potential advantages, the systematic definition of co-network structures has not been achieved, largely due to the lack of well-controlled chemistries for their preparation. Here, a thiol-ene end-linking platform enables the systematic investigation of phase-separated poly(ethylene glycol) (PEG) and polystyrene (PS) networks in terms of the molecular weight and relative volume fractions of precursor polymers. The ion conductivity and storage modulus of these materials serve as probes to demonstrate that both phases percolate over a wide range of compositions, spanning PEG volume fractions from ∼0.3 - 0.65. These findings demonstrate that this approach to thiol-ene co-networks is a versatile platform to create bicontinuous morphologies.

9:12 AM A42.00007 Squeezing a gel to establish network structure-transport property relationships, Edwin Chan, Nichole Nadermann, Material Science and Engineering Division, National Institute of Standards and Technology, Gaithersburg, MD, 20899, USA — Gels are used in many applications, ranging from drug delivery to water purification, where regulating transport of a particular permeant is crucial. The structure of the gel determines its transport properties but developing the gel structure-transport property relationships often require multiple measurement techniques. In this work, we demonstrate poroelastic relaxation indentation (PRI) as a single measurement tool to establish the relationships between the polymer network structure and the transport properties of well-defined hydrogel networks synthesized via a thiol-norbornene click reaction of poly(ethylene glycol) (PEG) chains. We use PRI to quantify the mechanical and transport properties of a series of “click” hydrogels with different crosslink densities. By applying various thermodynamic network swelling models to describe the mechanical response of these gels as measured from PRI, we are able to extract thermodynamic parameters of these hydrogels including the Flory chi parameter and the mesh size. We validate our approach by comparing the thermodynamic parameters obtained from PRI with results from neutrons scattering studies of the same series of hydrogels.

9:24 AM A42.00008 Tensile Deformation and Morphological Evolution of Precise Acid Copolymers, Luri Robert Middleton, Steve Szewczyk, Eric Schwartz, University of Pennsylvania, Jason Azoulay, Dustin Murtagh, Joseph Cordon, Sandia National Laboratory, Kenneth Wagen, University of Florida, Karen Winney, University of Pennsylvania — Acid- and ion-containing polymers have specific interactions that produce complex and hierarchical morphologies that provide tunable mechanical properties. We report tensile testing and in situ x-ray scattering measurements of a homologous series of precise poly(ethylene-co-acrylic acid) copolymers (pXAA). Upon variation of the number of backbone carbons (x = 9, 15, 21) between pendant acrylic acid groups along the linear polyethylene chain, these materials exhibit pronounced changes in both their tensile properties as well as their morphological evolution during deformation. The hierarchical layered acid aggregate structure coincides with the onset of a strain hardening mechanism and was observed in both a semi-crystalline sample (p21AA) as well as an amorphous sample (p15AA). The polymer with the shortest spacing between acid groups (p9AA) maintains a liquid-like distribution of acid aggregates during deformation, exhibiting low tensile strength which we attribute to facile acid exchange between acid aggregates during deformation. Our results indicate that the formation of the hierarchical layered structure, which coincides with polymer strain-hardening regime, originates from the associating acid groups cooperatively preventing disentanglement.

9:36 AM A42.00009 Nonlinear behavior of ionically and covalently cross-linked alginate hydrogels, Seyedmeymans Hasmemnejad, Mahla Zabet, Santanu Kundu, Dave C. Swalm School of Chemical Engineering, Mississippi State University, MS State, MS — Gels deform differently under applied load and the deformation behavior is related to their network structures and environmental conditions, such as pH and ionic strength. Conventional linear theories are not suitable to describe the mechanical behavior of both ionically and covalently cross-linked alginate hydrogel using large amplitude oscillatory shear (LAOS) and cavitation experiments. Ionically-bound alginate gels were obtained by using divalent calcium. Alginate volume fraction and alginate to calcium ratio were varied to obtain gels with different mechanical properties. Chemical gels were synthesized using adipic acid dihydrazide (AAD) as a cross-linker. The non-linear rheological parameters are estimated from the stress responses to elucidate the strain softening behavior of these gels. Fracture initiation and propagation mechanism during shear rheology and cavitation experiments will be presented. Our results provide a better understanding on the deformation mechanism of alginate gel under large-deformation.

9:48 AM A42.00010 Nonlinear Elasticity and Cavitation of a Triblock Copolymer Gel, Santanu Kundu, Seyedmeymans Hasmemnejad, Mahla Zabet, Satish Mishra, Dave C. Swalm School of chemical engineering, Mississippi State University, MS State, MS — Polymer gels are subjected to large-strain deformation during their applications. The gel deformation at large-strain is non-linear and can often lead to failure of the material. Here, we report the large-strain deformation behavior of a physically cross-linked, swollen polymer gel, which displays unique strain-stiffening response at large-strain. Investigations were performed using large amplitude oscillatory shear (LAOS) and custom designed cavitation rheology techniques. Gent constitutive model, which considers finite extensibility of midblock, was fitted with the LAOS data, therefore, linking the estimated parameters from LAOS analysis to the structure of the gel. Cavitation experiments were conducted as a function of temperature. Both analytical method and finite-element based modeling have been implemented to capture the pressure response in cavitation experiments. Our results provide a critical understanding of gel failure mechanism at large-strain.
and compared with literature data of other known glass formers. Contrary, we observed formation of highly stable glasses of ethylcyclohexane and 1-pentene. The results on ethylcyclohexane and 1-pentene will be presented.

0.2 Hz to 4 kHz. Ethylcyclohexane and 1-pentene are both strong glass formers, for which possibility of stable glass formation has been questioned. On the contrary, we observed formation of highly stable glasses of ethylcyclohexane and 1-pentene. The results on ethylcyclohexane and 1-pentene will be presented and compared with literature data of other known glass formers.

10:12AM A42.00012 On the role of geometric non-linearities in the mechanics of nematically ordered semi-flexible networks, LOUIS FOUCARD, Department of Chemistry and Biochemistry, UCLA, JORDAN KAZUO PRICE, WILLIAM KLUG, Department of Mechanical and Aerospace Engineering, UCLA, ALEX LEVINE, Department of Chemistry and Biochemistry, UCLA — Extending previous studies on the affine-nonaffine transition of nematically ordered semiflexible networks, we investigate numerically the effect of geometric non-linearities on the mechanical response of anisotropic networks of elastic filaments. We find that the strong dependence of buckling susceptibility on segment length has a pronounced effect on the nonlinear elastic behavior of anisotropic networks; contrary to isotropic networks, highly ordered ones show an important softening of the shear modulus at nonlinear (finite) strains. We compute the spatial correlation of the Conti/McKintosh buckling order parameter and show that the particularity of the nonlinear response of nematic networks resides in the cooperativity of the buckling events. We also show that dependence of the shear modulus on the nematic order parameter can be predicted using the assumption of affine deformation at small shear, and in terms of a generalized floppy mode analysis of the nonaffine mechanics at larger deformation.

10:24AM A42.00013 Using stability analyses to predict dynamic behaviour of self-oscillating polymer gels, VAIBHAV PALKAR, GAURAV SRIVASTAVA, Indian Institute of Technology Gandhinagar, OLAGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh, PRATYUSH DAYAL, Indian Institute of Technology Gandhinagar — Use of chemo-mechanical transduction to produce locomotion is one of the significant characteristics of biological systems. Polymer gels, intrinsically powered by oscillatory Belousov-Zhabotinsky (BZ) reaction, are biomimetic materials that exhibit rhythmic self-sustained mechanical oscillations by chemo-mechanical transduction. Via simulations, based on the 3D gel lattice spring model, we have successfully captured the dynamic behaviour of BZ gels. We have demonstrated that it is possible to direct the movement of BZ gels along complex paths, guiding them to bend, reorient and turn. From a mathematical perspective, the oscillations in the BZ gels occur when the gel's steady states lose stability by virtue of Hopf bifurcations (HB). Through the use of stability analyses, we predict the conditions under which gel switches from stationary to oscillatory mode and vice versa. In addition, we characterize the nature of HB and also identify other types of bifurcations that play a critical role in governing the dynamic behaviour of BZ gels. Also, we successfully predict the frequency of chemo-mechanical oscillations and characterize its dependency on the model parameters. Our approach not only allows us to establish optimal conditions for the motion of BZ gels, but also can be used to design other dynamical systems.

10:36AM A42.00014 Shape Actuation of Competitive Networks, YUAN MENG, JISU JIANG, MITCHELL ANTHAMATTEN, University of Rochester, Department of Chemical Engineering — We demonstrate a single phase, two-way shape actuator that, in the absence of an external load, elongates upon cooling and reversibly contracts upon heating. In a simple and straightforward process, a partially crosslinked, semi-crystalline PCL network is melted, stretched to several hundred percent strain, and further crosslinked. Upon removal of the applied load, the elastic ‘double network’ adopts a ‘state-of-ease’ that retains part of its former strain. When cooled, internal stress-induced crystallization causes further elongation of the configurational biased chains; and when heated, crystallites melt, and the sample returns to its equilibrium state-of-ease. Under optimized conditions, reversible actuation of over 15 percent strain can be reproducibly achieved, and samples can be cycled multiple times with highly uniform actuation with no observable creep. The mechanism behind such actuation was further confirmed via calorimetry and X-ray scattering.

1 Pump Primer Grant, Univ. of Rochester

10:48AM A43.00015 Shape Memory Polymers from Blends of Elastomers and Crystalline Small Molecules, KEVIN CAVICCHI, NICOLE BROSTOWITZ, Dept of Polymer Engineering, University of Akron, BRENT HUKILL, Dept of Chemical Engineering, Rose Hulman Institute of Technology, HEATHER FAIRBAIRN, Dept of Chemical Engineering, University of Akron — This talk will present work on the fabrication of shape memory polymers (SMPs) by swelling natural with molten fatty acids. By this method a SMP with excellent shape recovery can be obtained during free recovery after uniaxial deformation to 100% strain. Experiments to measure the shape memory properties under both stress and strain controlled conditions will be reported and compared. This fabrication method offers a number of advantages for preparing SMPs. First, it utilizes natural rubber as the base material for the SMP, which capitalizes on a high performance, commodity elastomer. Second, by blending a commercial polymer with a small molecule additive no additional chemistry is needed for the preparation of the SMP. Third, this route inverts the typically processing steps by crosslinking the permanent network prior to formation of the physically crosslinked reversible network. This offers a means to potentially generate a SMP from any preformed elastomer article.

Monday, March 2, 2015 8:00AM - 11:00AM –
Session A43 DPOLY: Focus Session: Stable Glasses and Their Properties

8:00AM A43.00001 Stable glasses from strong liquids, YEONG ZEN CHUA, MATHIAS AHRENBERG, University of Rostock, MICHAEL TYLINSKI, MARK D. EDIGER, University of Wisconsin-Madison, CHRISTOPH SCHICK, University of Rostock — To date, only several materials have been observed to form ultra-stable glasses by vapor deposition. Some authors have suggested that fragility might be a controlling factor in the ability to form stable glasses by vapor deposition, with highly stable glasses only being possible for highly fragile liquids. Glasses of ethylcyclohexane, fragility index 56.5, and 1-pentene, a very small molecule, produced by physical vapor deposition have been characterized by in situ AC chip nanocalorimetry. Since the fragility index of 1-pentene was not available, it was determined as 52 from the calorimetric glass transition temperatures measured in the frequency range from 0.2 Hz to 4 kHz. Ethylcyclohexane and 1-pentene are both strong glass formers, for which possibility of stable glass formation has been questioned. On the contrary, we observed formation of highly stable glasses of ethylcyclohexane and 1-pentene. The results on ethylcyclohexane and 1-pentene will be presented and compared with literature data of other known glass formers.
8:12AM A43.00002 Stable Glasses of a Low Fragility Organic Liquid. M. TYLINSKI, A. SEPULVEDA, Univ of Wisconsin, Madison, A. GUISEPPI-ELIE, Clemson University, R. RICHERT, Arizona State University, Y.Z. CHUA, C. SCHICK, University of Rostock, M.D. EDIGER, Univ of Wisconsin, Madison — We have created stable glasses of the low fragility liquid methyl-m-toluate (MMT, m = 60). The MMT stable glass films are prepared by physical vapor deposition and characterized in situ with AC nanocalorimetry and dielectric spectroscopy. Stable glasses of MMT have lower heat capacities and increased kinetic stability compared to the liquid-cooled glass. The films transform into the supercooled liquid via two mechanisms. A propagating front controls the transformation of thin films while a bulk mechanism dominates the transformation of thick films. This behavior is similar to other stable glass systems and shows that stable glasses can be prepared from liquids with a very wide range of fragilities (60 < m < 147). In one respect MMT stands out from previously studied systems. When a stable glass of MMT is annealed above $T_g$ the surface-initiated front propagates 5 $\mu$m into the sample before the bulk mechanism dominates the transformation. This 5 $\mu$m length scale is significantly larger than what has been observed in other stable glass systems.

8:24AM A43.00003 Synthesis and Characterization of Exceptionally Stable Glasses of 1,3-Bis(1-naphthyl),5-(2-aryl)benzene. TIANYI LIU, KEVIN CHENG, ELMIRA SALAMI, FENG GAO, CHEN LI, Department of Chemistry, University of Pennsylvania, XIAO TONG, Brookhaven National Lab, YUE ZHANG, YI-CHIH LIN, WILLIAM ZHANG, ETHAN GLOR, PATRICK WALSH, ZAHRA FAKHRAAI, Department of Chemistry, University of Pennsylvania — Stable glasses can be prepared by physical vapor deposition (PVD). Compared to ordinary glasses, stable glasses have exceptional properties such as higher density and thermal stability. Deposition temperature is one of the most important parameters that controls the properties of PVD glasses. When scaled to the glass transition temperature ($T_g$), most stable glasses are usually obtained at deposition temperatures around 0.85 $T_g$. Chemical structure, entropy of super-cooled liquid, fragility and enhanced mobility may all affect the most stable structure obtained via PVD. To examine the effect of chemical structure, specifically the molecular weight effect on the stability of PVD glasses, we synthesized and characterized stable glasses of small organic molecule 1,3-bis(1-naphthyl),5-(2-aryl)benzene ($\alpha_{10\beta\gamma}$) and its molecular analogues. With systematically changing its chemical structure, thermal expansion coefficients, fictive temperature and density of stable glasses all vary systematically. These results indicate the robust nature of stable glass formation and can elucidate the processes by which these glasses are formed.

8:36AM A43.00004 Using deposition rate as a means to alter the properties of small molecule organic glasses for OLED applications. KENNETH KEARNES, The Dow Chemical Company, PAIGE KRZYSKOWSKI, ZACHARY DEVEREAX, Department of Chemistry, Saginaw Valley State University — Organic light emitting diode (OLED) devices rely on vapor-deposited, small molecule organic glasses. Recent work has shown that deposition condition plays a critical role in altering OLED device performance. Here it will be shown that the deposition rate alters the onset and fictive temperatures measured by differential scanning calorimetry (DSC) of the deposited glass. Glasses of the common hole transport materials NPD and TPD were prepared with onset temperatures 17 and 16 K higher, respectively, than the ordinary glass prepared by cooling the supercooled liquid. The thermal stability of glasses in functioning devices can be underestimated due to increases in onset temperature relative to $T_g$. The fictive temperatures for NPD and TPD were 32 and 27 K lower, respectively, than the $T_g$ of the ordinary glass. These results are consistent with literature reports on other non-OLED glasses where enhanced mobility allows for glasses with similar properties to be made. Ellipsometry studies on NPD showed that the fictive and onset temperatures were consistent with the DSC results. Additionally, the modeled birefringence of the as-deposited NPD glass was non-zero and quickly decreased upon heating above the onset temperature, which has implications for device performance.

8:48AM A43.00005 Structural equivalence of equal-energy vapor deposited and liquid cooled films in two dimensions. DANIEL REID, IVAN LYUBIMOV, JUAN DE PABLO, Univ of Chicago — Vapor deposition has been shown to provide a means of producing supercooled liquids with exceptional structural and kinetic stability compared to samples prepared by gradual cooling of a liquid. In this work, we study two-dimensional binary glassy films formed by vapor deposition and liquid cooling. We show that distinctive local structural regimes correspond directly to the structural energy of these films. We find the path towards equilibrium to be characterized by a transition in these structural regimes from medium sized square-ordered clusters to states with significant pentagonal local order. Tracking the degree of local order over a range of structural energies using both formation strategies, we find that the structure of vapor deposited and liquid cooled films are equivalent in films with equal inherent structural energies. Previous work has found that the substrate temperature that yields minimum energy for a vapor deposited film lies near 85% of the material’s glass transition temperature. Our simulations indicate that in two dimensions, the optimal substrate temperature for stable glass formation decreases with deposition rate.

9:00AM A43.00006 Do Two-Level-Systems and Boson Peak persist or disappear in highly stable glasses? MIGUEL A. RAMOS, TOMAS PEREZ-CASTANEDA, Univ Autonoma de Madrid, RAFAEL JIMENEZ-RIOBOO, Inst Ciencia de Materiales de Madrid, CRISTIAN RODRIGUEZ-TINOCO, JAVIER RODRIGUEZ-VIEJO, Univ Autonoma de Barcelona — We have investigated how deep kinetic and thermodynamic stabilization in glasses can affect their universal properties at low temperatures. In particular, we have studied two different kinds of material which allow us to access highly-stable glassy states, as well as their corresponding conventional glasses: (i) ancient amber, which is a glass which has experienced an extremely long hyperaging process; and (ii) ultrastable thin-film glasses of indomethacin, prepared by physical vapor deposition at temperatures around 85% of its glass-transition temperature. Specifically, we have studied 110-million-year-old amber samples from El Soplao (Spain). Specific heat Cp measurements of pristine and rejuvenated samples were conducted in the temperature range 0.07K < T < 30K, as well as around its glass-transition temperature $T_g = 150^\circ C$. A modest increase of the boson-peak height (in Cp/T$^3$) with increasing rejuvenation was observed. The amount of two-level systems (TLS) was however found to decrease as the surface-initiated-front propagates 5 $\mu$m into the surface-initiated-front propagates 5 $\mu$m into the

9:12AM A43.00007 Dielectric Relaxation of Materials that Form Ultra-Stable Glasses RANKO RICHERT, Arizona State University — Physical vapor deposition of glass forming materials onto substrates at temperatures around 0.8 $T_g$ produces glasses of high density and low enthalpy. Using interdigitated electrode cells as substrates, such stable glasses can be studied by dielectric spectroscopy in situ. This technique is applied to monitor the dynamics of stable films upon their conversion to the ordinary supercooled liquid state. The dielectric loss during transformation indicates that the softening occurs by a growth front mechanism generating the ordinary liquid state without forming intermediates. The same technique is also used to assess the residual dynamics of the stable glassy state. We observe that processes such as the Johari-Goldstein beta relaxation are strongly suppressed in this stable state, consistent with the relatively low fictive temperature of these glassy glasses.

N,N-deposition temperature to generate films with moduli nearly twice that obtained for analogous films fabricated under normal vapor deposition conditions. For decreased in ultrathin films for materials deposited at low temperatures. Moreover, the thin film behavior of these small molecule glasses are altered by the and this can be used to tune the modulus of bulk-like glasses. Here, examination of ultrathin (<30 nm) films provides a route to further test hypotheses about mobile surface layers near Tg. We find that the proximity of the mechanical testing temperature to bulk Tg controls if the modulus is increased or decreased in ultrathin films for materials at low temperatures. Moreover, the thin film behavior of these small molecule glasses are altered by the deposition temperature to generate films with moduli nearly twice that obtained for analogous films fabricated under normal vapor deposition conditions. For N,N′-Di-(1-Naphthyl)-(N,N-diamine (NPD) with a bulk Tg of \sim 90\textdegree C, the modulus of the material is optimized if deposited at 70 C (0.9Tg). The stable glass deposition temperature of 0.85Tg reported originally by Ediger and coworkers results in more than 20% decrease in the elastic modulus. This suggests that the optimum deposition temperature depends on property of interest.
to the electronic behavior of 2D materials. Finally, using graphene as an example, we demonstrate that the kirigami structure may open up interesting opportunities in coupling molecular dynamics simulations that have been used almost exclusively for macroscale structures to dramatically enhance their stretchability. Specifically, we show using classical mechanics and numerical simulations that the yield and fracture strains of graphene and MoS$_2$ that have been used to improve the stretchability of elastic materials can be enhanced by about a factor of three using kirigami as compared to standard monolayers. We explore the emergence of elastic properties in smocked fabrics as functions of both fabric elasticity and smocking pattern.

8:12AM A44.00002 Miura Tubes and Assemblages: Theory and Applications, EVGENI FILIPOV, GLAUCIO PAULINO, University of Illinois at Urbana Champaign. TOMOHIRO TACHI, University of Tokyo — Origami systems inspired from the Miura-ori pattern are rigid and flat foldable meaning that they can fold completely by deforming only about prescribed fold lines. We investigate origami tubes and assemblages constructed from Miura-ori inspired sheets and use eigenvalue analyses to study their stiffness characteristics. A simplified bar model is used to model the stretching and shear of the flat panel segments and rotational hinges are used to simulate the bending stiffness of the panels and prescribed fold lines. We discuss the small to large deformation bending of thin sheets and show an improved method to estimate stiffness when modeling origami structures. The tube assemblages show interesting behaviors that make them suitable for applications in science and engineering.

8:24AM A44.00003 Multishape Origami Metasheets, SCOTT WAITUKAITIS, MARTIN VAN HECKE, Leiden University — We show how origami-based folding structures are a platform for multistable metamaterials. Our focus is the simplest building block, rigid 4-vertices, which we demonstrate can have up to six stable states. We extend our results to non-Euclidean vertices, which enables us fine-control over the number of minima. Our results lay the foundation for building designer, origami-based shape-shifting structures.

8:36AM A44.00004 Multi-stability in folded shells: non-Euclidean origami, ARTHUR EVANS, University of Massachusetts, Amherst — Both natural and man-made structures benefit from having multiple mechanically stable states, from the quick snapping motion of hummingbird beaks to micro-textured surfaces with tunable roughness. Rather than discuss special fabrication techniques for creating bi-stability through material anisotropy, in this talk I will present several examples of how folding a structure can modify the energy landscape and thus lead to multiple stable states. Using ideas from origami and differential geometry, I will discuss how deforming a non-Euclidean surface can be done either continuously or discontinuously, and explore the effects that global constraints have on the ultimate stability of the assemblings.

9:12AM A44.00005 Prediction of the force required to unwrap a thin-film origami structure, LEE WILSON, SERGIO PELLEGRINO, Caltech — We consider thin film membranes wrapped around a polygonal hub according to the origami crease pattern developed by Guest and Pellegrino [1]. The problem of unwrapping such membranes is important for applications such as space solar sails. Their deployment can be controlled by displacing four edge points radially outwards. During deployment the film buckles multiple times, creating a complex deployment force profile. We have used finite element simulations to investigate how different models of the creases affect the predicted force profile and we have compared the results of our simulations with experimental results for Kapton thin film thicknesses of 50um, 25um, 12.5um and 7.5um. The deployment force profile is also highly dependent on the initial packaged configuration of the film, which in our model is obtained by simulating the folding process from a flat state. 9:24AM A44.00006 Making the Cut: Lattice Kirigami Rules, TOEN CASTLE, YIGIL CHO, XINGTING GONG, EUIYEON JUNG, DANIEL SUSSMAN, SHU YANG, RANDALL KAMEN, University of Pennsylvania — Complex 3D structures can be built by bending and folding a flat sheet, as is done in origami. This paradigm can be extended by cutting and gluing the sheet as well as folding. The principles manifest in manipulating a piece of paper can translate across many length scales, limited only by fabrication methods. We explore and develop a simple set of rules that apply to cutting, pasting, and folding honeycomb lattices. We consider origami-like structures that are extrinsically flat away from zero-dimensional sources of Gaussian curvature and one-dimensional sources of mean curvature, and our cutting and pasting rules maintain the intrinsic bond lengths on both the lattice and its dual lattice. We find that a small set of rules is allowed, providing a framework for exploring and building kirigami - folding, cutting, and pasting the edges of paper.

9:36AM A44.00007 Kirigami for Two-Dimensional Electronic Membranes, ZENAN QI, Boston University, DARIO BAHAMON, Mackenzie Presbyterian University, DAVID CAMPBELL, HAROLD PARK, Boston University — Two-dimensional materials have recently drawn tremendous attention because of their unique properties. In this work, we introduce the notion of two-dimensional kirigami, where concepts that have been used almost exclusively for macroscale structures are applied to dramatically enhance their stretchability. Specifically, we show using classical molecular dynamics simulations that the yield and fracture strains of graphene and MoS$_2$ can be enhanced by about a factor of three using kirigami as compared to standard monolayers. Finally, using graphene as an example, we demonstrate that the kirigami structure may open up interesting opportunities in coupling to the electronic behavior of 2D materials.

10:00AM A44.00009 Optimization of Actuating Origami Networks1, PHILLIP BUSKOHL, Air Force Research Laboratory, KAZUKO FUCHI, Wright State Research Institute, GIORGIO BAZZÁN, JAMES JOO, REICH GREGORY, RICHARD VAIA, Air Force Research Laboratory – Origami structures morph between 2D and 3D conformations at predetermined fold lines that efficiently program the form, function and mobility of the structure. By leveraging design concepts from action origami, a subset of origami art focused on kinematic mechanisms, reversible folding patterns for applications such as solar array packaging, tunable antennae, and deployable sensing platforms may be designed. However, the enormity of the design space and the need to identify the requisite actuation forces within the structure places a severe limitation on design strategies based on intuition and geometry alone. The present work proposes a topology optimization method, using truss and frame element analysis, to distribute foldline mechanical properties within a reference crease pattern. Known actuating patterns are placed within a reference grid and the optimizer adjusts the fold stiffness of the network to optimally connect them. Design objectives may include a target motion, stress level, or mechanical energy distribution. Results include the validation of known action origami structures and their optimal connectivity within a larger network. This design suite offers an important step toward systematic incorporation of origami design concepts into new, novel and reconfigurable engineering devices.

10:12AM A44.00010 Origami folding of polymer sheets by inkjet printing, YING LIU, BRANDI SHAW, MICHAEL D. DICKEY, JAN GENZER, North Carolina State University — In analogy to the ancient Japanese art of paper folding (Origami), self-folding is an attractive strategy to induce the formation of three-dimensional (3D) objects with well-defined shapes and dimensions using conventional two-dimensional (2D) patterning techniques, such as lithography and inkjet printing. Self-folding can be applied in the areas of reconfigurable devices, actuators, and sensors. Here we demonstrate a simple method for self-folding of polymer sheets utilizing localized light absorption on selected areas of the pre-strained polymer sheet. The ink is patterned via a desktop printer and it defines the location of the ‘hinge’ on the sheet. The inked areas on the 2D sheet absorb light preferentially, thus causing the polymer sheet to fold locally in the inked areas. The temperature gradients through the depth of the sheet induce localized shrinkage and the sheet folds within seconds. This patterned polymer sheets act as shape memory materials which can be programmed to fold into various 3D structures based on the nature of the light source, the shape and size of the ink patterns, and ink property. By controlling the aforementioned parameters we achieve a complete control of the time and degree of folding, which ultimately govern the final 3D shape of the folded object.

10:24AM A44.00011 Actuated 3D origami-like structures with tunable volume and stiffness, JOHANNES OVERVELDE, TWAN DE JONG, JAMES WEAVER, CHUCK HOBERMAN, KATIA BERTOLDI, Harvard University — Recent years have seen an upsurge of new materials with interesting and unusual properties that result from their regular periodic microstructure. Origami-based metamaterials based on the Miura fold pattern have recently gained a lot of attention for their ability to drastically change their shape and therewith creating a programmable metamaterial. In this work, we propose a completely new class of actuated 3D foldable materials with three degrees of freedom that can drastically change their shape and volume by folding. These materials do not only change their shape, but also have a tunable stiffness that can vary two orders of magnitude by making use of contact interaction between different parts of the material. We experimentally show their effectiveness by building a metamaterial consisting of 64 unit cells and by incorporating local inflatant actuators in the material to enable large on demand changes in shape and stiffness.

10:36AM A44.00012 Stress Focusing in Creased Shells, SARAH SELDEN, ARTHUR EVANS, NAKUL BENDE, RYAN HAYWARD, CHRISTIAN SANTANGELO, Univ of Mass - Amherst — Upon indentation, thin shells react by localizing strain energy in polygonal structures as opposed to a uniform axisymmetric distribution. While the formation of these localized structures are well-characterized for perfect shells, the introduction of a crease fundamentally changes the nature of the shell deformation. We perform finite element simulations, in tandem with experiments to explore the effect of a creased shell on the energy landscape. We find that the crease induces a new symmetry-breaking localization that does not appear in perfect shells, and we explore the deformation characteristics of the creased shell over a wide range of crease sizes, shell thickness, and crease orientations.

10:48AM A44.00013 Folding and bending of self-assembled nanoparticle membranes, YIFAN WANG, The University of Chicago, JIANHUI LIAO, Peking University, SEAN MCBRIDE, EFI EFRATI, The University of Chicago, XIAO-MIN LIN, Argonne National Laboratory, HEINRICH JAEGER, The University of Chicago — We demonstrate that self-assembled nanoparticle monolayers can be folded into 3 dimensional hollow structures. Using a force-volume Atomic Force Microscope (AFM), indentation measurements were made on these nanoparticle scrolls, and the bending modulus of the nanoparticle membrane is obtained for the first time. The resulting bending modulus is two orders of magnitude larger than that predicted by classical continuum elastic theory, we show this can be explained by a micropolar theory as the material makes on these nanoparticle scrolls, and the bending modulus of the nanoparticle membrane is obtained for the first time. Monday, March 2, 2015 8:00AM - 11:00AM Session A45 DPOLY: Crystalline Polymers 216AB - Christopher Li, Drexel University 8:00AM A45.00001 Interplay Between a Strong Memory Effect of Crystallization and Liquid-Liquid Phase Separation in Melts of Broadly Distributed Ethylene 1-Alkene Copolymers, RUFINA G. ALAMO, AL MAMUN, XUEJIAN CHEN, FAMU-FSU College of Engineering, Department of Chemical and Biomedical Engineering, Tallahassee, FL 32310 — Ethylene-1-alkene copolymers with a broad, bimodal comonomer distribution display acceleration and retardation of the crystallization rate when cooling from a range of melt temperatures where narrow copolymers show a continuous acceleration of the rate. The acceleration of the rate is observed in a range of melt temperatures between 165 and 150 °C, and is due to a strong memory effect of crystallization above their equilibrium melting point. The retardation or inversion of the rate, observed in a range of 150 to 123 °C, demarcates the onset of a self-seeded assisted liquid-liquid phase separation (LLPS) between comonomer-rich and comonomer poor molecules. The interplay between number of self-seeds at the initial melt temperature and chain diffusion during LLPS causes a decrease in the crystallization rate with decreasing melt temperature. When crystallites remain in the melt at temperatures <123 °C, the crystallization rate again accelerates quickly. The crystallization rates were studied by DSC, and the effect in nucleation density and in overall crystalline morphology of crystallizations from one phase or two liquid phases was followed by polarized optical microscopy and transmission electron microscopy.
8:12AM A45.00002 Butyl Branch Partitioning to the Crystal Surface in Polyethylenes Detected by NMR. KLAUS SCHMIDT-ROHR, Brandeis University, Department of Chemistry, Waltham, MA 02453, USA, ALLISON WHITE, Iowa State University, Department of Chemistry, Ames, IA 50011, USA, KANMI MAO, DIANA SMIRNOVA, ExxonMobil Research and Engineering, 1545 Route 22 East, Annandale, NJ 08801, USA — Short-chain branches have pronounced effects on the structure and properties of semicrystalline polyethylenes. Distinct partitioning of butyl branches in high- and linear low-density polyethylenes (HDPEs and LDLDPEs) synthesized with hexene comonomers has been detected by solid-state $^{13}$C NMR. In mobility-selective $^{13}$C NMR spectra, distinct signals of mobile amorphous and of trans-rich immobilized branches are observed, the latter with longer $^{13}$C spin lattice relaxation times and limited mobility. This analysis takes advantage of double inverse filtering, which provides the signals of limited-mobility noncrystalline segments selectively. The location of the dynamically constrained branches near the crystal surface has been confirmed by $^1$H spin diffusion measurements. The fraction of immobilized butyl branches is approximately constant at about 0.5 mol% for a series of copolymers with 0.35 – 3.3 mol% hexene. It is close to the percentage expected if one surface site is freely available for each crystalline chain stem. Lower molecular weight appears to enable better ordering of branches at the crystal surface. Further, it more strongly limits a fast-relaxing component in $^{13}$C spin-lattice relaxation of the crystalline signal that can be attributed to chain diffusion. In a HDPE with 0.35 mol % hexene content, nearly all branches are at the crystal surface.

8:24AM A45.00003 Chain Trajectory of Polymer Chains in Bulk and Single Crystals: Molecular Weight Effect. TOSHIKAZU MIYOSHI, YOULEE HONG, The University of Akron, THE UNIVERSITY OF AKRON TEAM — Semicrystalline polymers are crystallized as folded chains in thin lamellae of ca. 5-20 nm from random coils in the melt and solution states. Recently, we developed a novel strategy to access chain trajectory of semi-crystalline polymers using $^{13}$C/$^{13}$C double Quantum (DQ) NMR combined with selectively isotopic labeling. This approach does not suffer from morphology (bulk vs single crystals), molecular weight distribution, and crystallization temperatures. Thereby, DQ NMR has been successfully applied to determination of chain trajectory of semi-crystalline polymer with a relatively low molecular weight in bulk as well as single crystals in wide crystallization temperatures. In this work, we will report chain-folding structure of a semicrystalline polymer with a high molecular weight in bulk as well as single crystals. Molecular weight effects on chain trajectory in different morphology will be demonstrated.

8:36AM A45.00004 SAXS/WAXS measurements of HDPE crystallization during uniaxial extensional flow.ERICA MCCREADY, WESLEY BURGHARDT, Northwestern University — We report studies of flow-induced crystallization of high density polyethylene during uniaxial extensional flow. Flow was applied using an SER extensional fixture housed in a custom built oven designed to facilitate in situ synchrotron x-ray experiments. Samples were loaded onto the fixture, heated to well above the melting temperature, and then cooled to the desired crystallization temperature. Extent of crystallization, orientation of crystallites, and extensional viscosity were determined throughout the entire uniaxial extensional flow, using simultaneous small- and wide-angle x-ray scattering (SAXS and WAXS) and torque measurements. Both temperature and extension rate were varied. SAXS patterns show distinct shapes characteristic of shish kebab morphology formation. WAXS peaks indicate high alignment of unit cell structure along the flow direction. Evolution of both SAXS and WAXS patterns can be correlated to each other and to extensional viscosity features during the crystallization process.

8:48AM A45.00005 Selective crystallization of conjugated polymer nanowires from graphene-coated surfaces. DANIEL ACEVEDO CARTAGENA, YUE ZHANG, University of Massachusetts, ELVIRA TRABANINO, None, EMILY PENTZER, Case Western Reserve University, TODD EMRICK, ALEJANDRO BRISEN0, RYAN HAYWARD, University of Massachusetts — Solution-based crystallization of conjugated polymers is a promising route to develop hierarchical structures for organic electronic devices, especially solar cells. Well-defined nucleation sites in supersaturated solutions can regulate the crystallization behavior to control the morphology of the material. We have developed an approach to tune the hysteresis between melting and crystallization of poly(3-hexylthiophene) in a marginal solvent, using temperature controlled fractionation. This process produces supersaturated solutions in a metastable state at room temperature, suppressing homogeneous nucleation of crystals but allowing for heterogeneous crystallization on nucleation sites. We show that in these metastable solutions, crystalline nanowires are selectively grown on graphene-coated surfaces and highly oriented pyrolytic graphite.

9:00AM A45.00006 Mesomorphic State in Early Stage Crystallization of Polyethylene. KALMAN MIGLER, ANGELA HIGHT WALKER, ANTHONY KOTULA, NIST — The kinetic pathway by which a molten polymer transforms into a multi-length scale, semi-crystalline structure upon cooling is an unsolved problem in polymer physics, yet it is critical to the processing, properties and ultimate performance of these materials. Here we utilize Raman spectroscopy to probe the early stage crystallization kinetics of a high-density polyethylene during low undercooling. The importance of Raman as a tool stems from its ability to measure the mass fraction of conformations that are in consecutive trans sequences (locally straight) but are not in an orthorhombic configuration, which we term non-orthorhombic continuous-trans (NOCT). We find that the Raman peaks indicative of NOCT precede the appearance of the peak which indicates orthorhombic crystallinity. We analyze the spectra within the context of a three-state conformational model to extract the mass fractions of the NOCT and the orthorhombic conformational states as crystallization proceeds. Concomitant birefringence and turbidity measurements indicate that this NOCT state can be understood as a separate mesomorphic phase which emerges from the melt state and precedes crystallization.

9:12AM A45.00007 Morphology and Crystallization Behavior of Poly(3-(2'-ethyl)hexthiophene) (P3EHT) Containing Diblock Copolymers. EMILY DAVIDSON, BRYAN BECKINGHAM, VICTOR HO, UC Berkeley, RACHEL SEGALMAN, UC Santa Barbara — Poly(3-alkylthiophene) crystallites are confined within classical diblock copolymer microphase separated domains by substituting the alkyl side chain to reduce the crystalline driving force. Previously, we determined that the P3AT chain axis is oriented perpendicular to the domain interface within crystallites. Here, we find that following block copolymer self-assembly in the melt, crystallite growth drives expansion of microdomains, indicating that chains adopt an extended conformation within confined crystallites. In addition, we demonstrate that the degree of perfection of crystallites confined within lamellae may be tuned via the degree of undercooling.
9:24AM A45.00008 Exploring Molecular Dimension and Trajectory of Polymer Chains Embedded in Single Crystals1, YOULEE HONG, TOSHIKAZU MIYOSHI. University of Akron — Semicrystalline polymers are crystallized as folded chains in thin lamellae of ca. 5-20 nm from random coils in the melt and solution states. Even though there are continuous efforts on understanding of crystallization mechanisms at molecular levels for understanding of crystallization mechanism of polymers at molecular levels, the fundamental questions - when, where, and how do semicrystalline polymers fold during crystallization? - have not been clarified due to experimental limitations. Recently, we developed a novel strategy to access chain trajectory of semi-crystalline polymers using 13C-13C double Quantum (DQ) NMR. In this work, we recently investigated determined molecular dimension as well as chain-trajectory of 13C CH3-labeled isotactic poly(1-butene) (iPB1) in form III chiral single crystals blended with nonlabeled iPB1 crystallized under low supercooling, using solid-state NMR. Comparisons of 13C-13C double quantum (DQ) NMR results at multiple sites with spin dynamics simulation revealed individual chains form the three dimensional nanoclusters via folding. This result supports proves two step process of i) cluster formation by chain-folding the prestige of crystallization, and ii) depositions of the cluster on the growth front of single crystal.

9:36AM A45.00009 On the strain-induced structural evolution upon uniaxial stretching of Poly(Vinylidene Fluoride): influence of secondary crystals and crystalline relaxation, JULIETTE DEFEBVIN, SOPHIE BARRAU, GRÉGORY STOCLET, JEAN-MARC LEFEBVRE. Umet-Université Lille1, POLYMER ENGINEERING SCIENCE TEAM — Development of more efficient piezoelectric devices tends to innovate and create materials able to combine flexibility and electro-mechanical conversion. Poly(vinylidene fluoride) (PVDF) is a semi-crystalline polymer that exhibits interesting piezoelectric properties. Besides PVDF is able to convert an electric energy and vice versa. However these physical properties are highly dependent on the polymer crystal structure. PVDF presents at least two main crystalline forms. The most common phase is the α-phase that is non-polar. On the other hand, the β phase is the most polar one and it can be obtained by a stretching of the α-phase. Knowing the influence of the drawing conditions on the strain-induced structural evolution is thus of prime interest. To assess this point the strain-induced structural evolution of PVDF, stretched under different conditions, has been followed in-situ by means of WAXS/SAXS experiments. As a main result, this study shows that drawing conditions strongly affect both the α to β phase conversion degree and the crystalline morphology. Moreover the key role played by the crystalline relaxation of PVDF on the strain-induced structural evolution is also highlighted for the first time.

9:48AM A45.00010 Quantifying tie-chain content in semicrystalline polyolefins with vapor-flow small-angle neutron scattering, AMANDA MCDERMOTT, CHAD SNYDER. National Institute of Standards and Technology (NIST), PAUL DESLAURIERS, Chevron Phillips Chemical Company, RONALD JONES. National Institute of Standards and Technology (NIST) — Tie molecules bridging adjacent crystalline lamellae in semicrystalline polymers strongly impact mechanical properties, but they remain difficult to characterize. In this work we apply equilibrium swelling theory, balancing the entropic cost of tie-chain extension against the free energy of mixing, to small-angle neutron scattering patterns from semicrystalline polyethylene films whose interlamellar amorphous regions are swollen with deuterated organic solvent. Results show that for a linear polyethylene and several ethylene-hexene copolymers, these vapor-flow SANS measurements of tie-chain content compare favorably with a primary structural parameter (PSP2) that is calculated from molecular architecture and correlates with slow crack growth behavior.

10:00AM A45.00011 Isothermal Programming Triple Shape Memory1, SERGEI SHEIKO, JING ZHOU, QIAOXI LI, SARA TURNER, VALERIE ASHBY, University of North Carolina at Chapel Hill, ANDREY DOBRYNIN, University of Connecticut — While a variety of shape memory materials have been developed for triple shape memory (TSM), different fixation temperatures are required for memorizing different shapes, with imposed limitations on materials design. We present a new strategy for TSM, where different shapes are programmed at a constant fixation temperature and can be applied to a variety of semi-crystalline elastomers. This universal strategy is based on controlling the interplay between shape-memory thermodynamics and kinetics of polymer crystallization. We have developed a composite model to study correlations between the control parameters (chemical composition, crosslinking density, crystallization rate) and TSM performance (shape fixation and recovery). Furthermore, the isothermal TSM allows one-way reversible shape memory.

10:12AM A45.00012 Flow-induced crystallinity in polyethylene as probed by time-resolved Raman spectroscopy and optical microscopy, ANTHONY KOTULA, ANGELA HIGHT WALKER, KALMAN MIGLER, National Institute of Standards and Technology — The crystallization of polymer melts under flow is critically relevant to the polymer processing industry. Optical, thermal, and mechanical properties of semi-crystalline polymer products depend on the final crystallinity of the material, which depends on the structure and orientation of the initial molecular-scale crystal nuclei formed in flow. Here, we present a combination of optical microscopy and Raman scattering techniques to analyze structure formation in high density polyethylene during steady shear at low degrees of undercooling. When low shear rates (~ 1 s-1) are imposed after a temperature quench to less than 10 °C undercooling, fibrous structures aligned parallel to the flow direction appear over a period of minutes. Raman spectra indicate that chain straightening (consecutive trans chain conformation) precedes the growth of the crystalline phase, and increased shear increases the rate of growth of the consecutive trans and crystalline fractions. Complimentary Raman scattering experiments are performed on n-alkanes to compare conformational similarities in the molecular structure during the crystallization process.

10:24AM A45.00013 Short-Range Order of Mesomorphic Phase of a Semi-crystalline Polymer by Solid-State NMR: Isotactic Polypropylene1, SHICHEN YUAN, TOSHIKAZU MIYOSHI, Univ of Akron — Mesophase is intermediate phase between crystalline and melt state. Characterization of short-range structures of disordered mesomorphic phase without long-range order is challenging issue in polymer characterization. The short range order was considered same as α or β . However, in this work, a new strategy using 13C-13C through space interactions as well as molecular dynamics based on chemical shift anisotropy (CSA) re-orientation is proposed for evaluating short-range order of mesophase of isotactic-polypropylene (iPP). 13C-13C double quantum (DQ) build up curves of 13C 15 percent CH3 selectively labeled iPP and spin dynamics simulations elucidate that local packing structures in mesophase is very close to that in β phase. Moreover, exchange NMR proves that the crystalline chains perform large amplitude motions in all α, β, and mesophase. The correlation time of overall dynamics of stems in mesophase follows the same Arrhenius line with that of β phase but is largely deviated from the Arrhenius line of the α phase. Through the obtained results, it is concluded that short-range order in mesophase is exceedingly close or same to those in β phase.

10:36AM A45.00014 Stress induced reversible crystal transition in poly(butylene succinate)\(^1\). GUOMING LIU, LIUCHUN ZHENG, XIQIN ZHANG, CHUNCHENG LI, DUJIN WANG, CAS Key Laboratory of Engineering Plastics, Institute of Chemistry, the Chinese Academy of Sciences, Beijing, 100190, China — The plastic deformation mechanism of semi-crystalline polymers is a long-studied topic, which is crucial for establishing structure/property relationships. For polymers with stress induced crystal transition, some open questions still need to be answered, such as on which stage of plastic deformation does the crystal transition take place, and more importantly, what happens on the lamellar structure during crystal transition. In this talk, stress-induced reversible crystal transition in poly(butylene succinate) was systematically investigated by in-situ WAXS and SAXS. A "lamellar thickening" phenomenon was observed during stretching, which was shown to mainly originated from the reversible crystal transition. This mechanism was shown to be valid in poly(ethylene succinate). The critical stress for the transition was measured in a series of PBS-based crystalline-amorphous multi-block copolymers. Interestingly, these PBS copolymers exhibited identical critical stress independent of amorphous blocks. The universal critical stress for crystal transition was interpreted through a single-microfibril-stretching mechanism.

10:48AM A45.00015 Crystallization of low molecular weight atactic polystyrene, YU CHAI, JAMES GILBERT, CHAD DALEY, JAMES FORREST, Univ of Waterloo — It is well known that atactic polystyrene does not crystallize. However, it is also true that even in pure atactic polystyrene, there is a small fraction of isotactic and syndiotactic moieties due to random statistics, which are crystallizable. Using small molecular weight atactic polystyrene, we are able to observe crystallization in an acceptable time window. We characterize the crystals in terms of both the morphology and dynamics by using atomic force microscopy and differential scanning calorimetry and the results are consistent with that from the bulk isotactic and syndiotactic polystyrene. As the molecular weight increases, the fraction of pure isotactic and syndiotactic components becomes smaller, and crystallization is not observed.

Session A46 DBIO: Invited Session: DNA Physics and Chromatin Organization 217A - Alexandre Morozov, Rutgers University

8:00AM A46.00001 Dynamics of the Competition Between Nucleosome Unwrapping and DNA Binding Proteins\(^1\), RALF BUNDSCHUH, Ohio State Univ - Columbus — In eukaryotic organisms DNA is tightly wrapped into nucleosomes. This bears the question how this DNA can be accessed in order to be copied, transcribed, or repaired. A process that allows access to the DNA is transient unwrapping of the DNA from the histone proteins. We have developed a quantitative model of this unwrapping process which we calibrate by comparison to nucleosome unzipping experiments by the Wang group. We then apply this model to quantitatively explain the dynamics of transcription factor binding within nucleosomal DNA. In this context, it has been well known that nucleosomes reduce the affinity for transcription factors to binding sites covered by the nucleosome. It has been assumed that this is due to a reduction in on-rate since a transcription factor can only bind when a rare thermal fluctuation of the nucleosome makes the DNA accessible. However, recent experimental data surprisingly shows that the off-rate of transcription factors is also strongly affected in the presence of a nucleosome. The application of our nucleosome unwrapping free energy landscape demonstrates that this increase in off-rate by several orders of magnitude is a consequence of a competition between partial binding events of dimeric transcription factors and the nucleosome.

8:36AM A46.00002 Hydrodynamics, ROBijn Bruinsma, Department of Physics and Astronomy, University of California, Los Angeles — The talk will present a hydrodynamic description of large-scale cooperative movement of chromatin that have been observed by particle tracking methods. The results of the hydrodynamic description will be compared with the tracking data. Passive thermal fluctuations and active "scalar" events - associated with local chromatin condensation - are found to dominate cooperative motion at shorter length scales while active "vector" events - associated with chromatin remodeling - driving transverse hydrodynamic modes dominate at large length scales.

9:12AM A46.00003 A physical analysis of nucleosome positioning, ULRICH GERLAND, Physik Department, Technische Universität München, Munich, Germany — The first level of genome packaging in eukaryotic cells involves the formation of dense nucleosome arrays, with DNA coverage near 90% in yeasts. A high nucleosome coverage is essential for cells, e.g. to prevent cryptic transcription, and the local positions of specific nucleosomes can play an important role in gene regulation. It is known that in vivo nucleosome positions are affected by a complex mix of passive and active mechanisms, including sequence-specific histone-DNA binding, nucleosome-nucleosome interactions, AT-dependent remodeling enzymes, transcription, and DNA replication. Yet, the statistical distribution of nucleosome positions is extremely well described by simple physical models that treat the chromatin fiber as an interacting one-dimensional gas. I will discuss how can we interpret this surprising observation from a mechanistic perspective. I will also discuss the kinetics of the interacting gas model, which is pertinent to the question of how cells achieve the high nucleosome coverage within a short time, e.g. after DNA replication.

9:48AM A46.00004 DNA-protein recognition and sequence-dependent variations of DNA conformational properties, ALEXANDER VOLOGODSKII, New York University — Parameters of B-DNA, the major form of the double helix, depend on its sequence. This dependence can contribute to the recognition of specific DNA sequences by proteins. Here we try to analyze this contribution quantitatively. In the first approach to this goal we used experimental data on the sequence dependence of DNA bending rigidity and its helical repeat. The solution data on these parameters of B-DNA were derived from the experiments on cyclization of short DNA fragments with specially designed sequences. The data allowed calculating the sequence variations of DNA bending energy, as well as the variations of the energy of torsional deformation of the double helix associated with a protein binding. The results show that DNA conformational parameters can have very limited influence on the sequence specificity of protein binding. In the second approach we analyzed the experimental data on the binding affinity of the nucleosome core with DNA fragments of different sequences. The conclusions derived in these two approaches are in a good agreement with one another.

10:24AM A46.00005 Polymer Models of Looping in Genome, ANIRVAN SENGUPTA, Rutgers University — Regions of the chromosome that are many thousands of bases away often have to come in contact for turning some genes on or off. To discover the specific and highly regulated contacts, we need to have a good statistical description of the strength of non-specific ones. We model the chromatin fiber as a potentially heterogeneous polymer and discuss how to use such a model in the analysis of chromatin conformation capture data.

Session A47 DBIO: Focus Session: Physics of Behavior I 217B - Greg Stephens, Vrije Universiteit Amsterdam & Okinawa Institute of Science and Technology
8:00AM A47.00001 ABSTRACT WITHDRAWN

8:12AM A47.00002 How to catch a falling fruit , ANDREW MARANTAN, LAKSHMINARAYANAN MAHADEVAN, Harvard Univ — A variety of fish engage in complex hunting behaviors involving catching airborne prey falling to the surface of the water. In principle this requires that the fish develop internal models describing both the falling prey and its own motion relative to that prey. However learning such models is complicated by the fact that the fish must also account for noise in optical measurements and the refraction occurring at the air/water interface. Inspired by experimental observations, we describe how one such species (Brycon guatemalensis) might feasibly overcome these obstacles and learn a model accurate enough to catch falling fruit. Instead of learning a model for how the fruit falls and a model for how it moves in the water and a model accounting for refraction, we argue that the fish could instead learn one approximate linear model relating a set of measured inputs to a set of measured outputs valid in a limited domain of initial conditions. The fish could then make its control decisions based on the outcome predicted by this combined linear model. We also discuss how the fish can leverage neural transformations of raw data to learn a model with a larger domain of validity and yet more sensitive to noise due to nontrivial Jacobians arising from the neural transformations.

8:24AM A47.00003 Growth behaviors of bacteria reveal the evolutionary significance of energy-efficiency1. ARJIT MAITRA, KEN DILL, Stony Brook University — Microorganisms have evolved a mosaic of gene expression changes to adapt their growth behaviors to changing environmental conditions. The subset of genes coding for the protein translation machineries, the ribosomes, however display robust linear activities with growth rates. Such patterns are considered to be the source of growth itself. There is another robust growth law, observed by Monod in the 1940s, in which bacteria are able to scale their growth with food concentration before plateauing off to a constant value. To interlink these observed growth laws we derive an analytical network model that leverages metabolic data to capture how the cell manages its exchange of energy to support costly gene expression. The model explores the limits of energy allocation for function and reveals evolutionary principles. Among others, we find, in glucose medium the fastest growing *E. coli* operate close to their maximum energy-efficiency. Optimization of energy efficiency provides a quantitative limit to how much energy is allocated for protein synthesis and it is determined by evolutionarily selected structural and biophysical constants. We conclude that energy efficiency has played a key role in bacterial evolution.

8:36AM A47.00004 Migration of amoeba cells in an electric field1. ISABELLA GUIDO, EBERHARD BODENSCHATZ, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — Exogenous and endogenous electric fields play a role in cell physiology as a guiding mechanism for the orientation and migration of cells. Electrotaxis of living cells has been observed for several cell types, e.g. neurons, fibroblasts, leukocytes, neural crest cells, cancer cells. Dictyostelium discoideum (Dd), an intensively investigated chemotactic model organism, also exhibits a strong electrotactic behavior moving toward the cathode under the influence of electric fields. Here we report experiments on the effects of DC electric fields on the directional migration of Dd cells. We apply the electric field to cells seeded into microfluidic devices equipped with agar bridges to avoid any harmful effects of the electric field on the cells (ions formation, pH changes, etc.) and a constant flow to prevent the build-up of chemical gradient that elicits chemotaxis. Our results show that the cells linearly increase their speed over time when a constant electric field is applied for a prolonged duration (2 hours). This novel phenomenon cannot be attributed to mechanotaxis as the drag force of the electroosmotic flow is too small to produce shear forces that can reorient cells. It is independent of the cellular developmental stage and to our knowledge, it was not observed in chemotaxis.

9:00AM A47.00006 Crosslink dynamics in a model of two filaments of actin under shear, ARJAN BOERMA, ERIK VAN DER GIJSEN, STEFANOS PAPANIKOLAOU, University of Groningen — We seek to elucidate the dynamic mechanisms underlying the stress dependent effects of the cellular cytoskeleton, as they are observed in the storage and loss modulus as a function of frequency and cross-linker concentration. We report on the statistical behavior of the effects originating from cross-linker dynamics in the basic constituent of a cytoskeleton network: two mutually cross-linked filaments. We model each of the filaments and the cross-linkers in terms of elastic finite elements. Unbinding of individual cross-linkers takes place through a realistic constitutive model and re-binding may occur to maintain the average cross-linker density. Our approach provides a direct analysis of the athermal interplay of the elastic filament interactions with the dynamics of the cross-linking molecules.

9:12AM A47.00007 Neuromechanics of crawling in *D. melanogaster* larvae, CENGIZ PEHLEVAN, HHMI Janelia Research Campus. PAOLO PAOLETTI, University of Liverpool, L. MAHADEVAN, Harvard University — Nervous system, body and environment interact in non-trivial ways to generate locomotion and thence behavior in an organism. Here we present a minimal integrative mathematical model to describe the simple behavior of forward crawling in *Drosophila* larvae. Our model couples the excitation-inhibition circuits in the nervous system to force production in the muscles and body movement in a frictional environment, which in turn leads to a proprioceptive signal that feeds back to the nervous system. Our results explain the basic observed phenomenology of crawling with or without proprioception, and elucidate the stabilizing role of proprioception in crawling with respect to external and internal perturbations. Our integrated approach allows us to make testable predictions on the effect of changing body-environment interactions on crawling, and serves as a substrate for the development of hierarchical models linking cellular processes to behavior.
Entropy measures of collective cell migration. ARIADNE WHITBY, Imperial College London & MRC Clinical Sciences Centre, SIMONA PARRINELLO, MRC Clinical Sciences Centre, ALDO FAISAL, Imperial College London — Collective cell migration is a critical process during tissue formation and repair. To this end there is a need to develop tools to quantitatively measure the dynamics of collective cell migration obtained from microscopy data. Drawing on statistical physics we use entropy of velocity fields derived from dense optic flow to quantitatively measure collective migration. Using peripheral nerve repair after injury as experimental system, we study how Schwann cells, guided by fibroblasts, migrate in cord-like structures across the cut, paving a highway for neurons. This process of emergence of organised behaviour is key for successful repair, yet the emergence of leader cells and transition from a random to ordered state is not understood. We find fibroblasts induce correlated directionality in migrating Schwann cells as measured by a decrease in the entropy of motion vector. We show our method is robust with respect to image resolution in time and space, giving a principled assessment of how various molecular mechanisms affect macroscopic features of collective cell migration. Finally, the generality of our method allows us to process both simulated cell movement and microscopic data, enabling principled fitting and comparison of in silico to in vitro.

9:36AM A47.00009 Sensory-motor system identification of active perception in ecologically valid environments. WILLIAM ABBOTT, ANDREAS THOMIK, A. ALDO FAISAL, Imperial College London — The brain is a dynamical system mapping sensory inputs to motor actions. This relationship has been widely characterised by reductionist controlled experiments. Here we present working models out of the lab “into the wild” to capture, rather than constrain, sensory inputs and motor outputs, by recording 90% of sensory inputs using head mounted eye-tracking, scene camera and microphone as well as recording 95% of skeletal motor outputs by motion tracking 51 degrees of freedom in the body and a total of 40 degrees of freedom from the hands. We can thus begin to systematically characterise the perception-action loop through system identification. This enables us to evaluate classical relationships in ecologically valid settings and behaviours including 3 daily scenarios: breakfast in the kitchen, evening chores and activities and in-door ambulation. This level of data richness (97 DOF, 60Hz), coupled with the extensive recordings of natural perceptual and behavioural data (total > 30 hrs, 10 subjects) enables us to answer general questions of how lab tasks and protocols will produce systematically different results from those found in daily life.

9:48AM A47.00010 Animal and robot experiments to discover principles behind the evolution of a minimal locomotor apparatus for robust legged locomotion. BENJAMIN MCMINROE, HENRY ASTLEY, Georgia Tech, SANDY KAWANO, NIMBioS, RICHARD BLOB, Clemson University, DANIEL I. GOLDMAN, Georgia Tech — In the evolutionary transition from an aquatic to a terrestrial environment, early walkers adapted to the challenges of locomotion on complex, flowable substrates (e.g. sand and mud). Our previous biological and robotic studies have demonstrated that locomotion on such substrates is sensitive to both limb morphology and kinematics. Although reconstructions of early vertebrate skeletal morphologies exist, the kinematic strategies required for successful locomotion by these organisms have not yet been explored. To gain insight into how early walkers contended with complex substrates, we developed a robotic model with appendage morphology inspired by a model analog organism, the mudskimmer. We tested mudskippers and the robot on different substrates, including rigid ground and dry granular media, varying incline angle. The mudskippers moved effectively on all level substrates using a fin-driven gait. But as incline angle increased, the animals used their tails in concert with their fins to generate propulsion. Adding an actuated tail to the robot improved robustness, making possible locomotion on otherwise inaccessible inclines. With these discoveries, we are elucidating a minimal template that may have allowed the early walkers to adapt to locomotion on land.

10:00AM A47.00011 Evolution of foraging behavior in Drosophilid larvae. MARTA RIVERA-ALBA, MAYANK KABRA, KRISTIN BRANSON, Janelia Research Campus, HHMI, CHRISTEN MIRTH, Instituto Gulbenkian de Ciencia — Drosophilids, like other insects, go through a larval phase before metamorphosing into adults. Larvae increase their body weight by several orders of magnitude in a few days. We therefore hypothesized that foraging behavior is under strong evolutionary pressure to best fit the larval environment. To test this hypothesis we used a multidisciplinary approach to analyze foraging behavior across species and larval stages. First, we recorded several videos of larvae foraging for each of 4 Drosophilid species. Then, using a supervised machine learning approach, we automatically annotated the video collection for the foraging sub-behaviors, including crawling, turning, head casting or burrowing. We also computed over 100 features to describe the posture and dynamics of each animal in each video frame. From these data, we fit models to the behavior of each species. The models each had the same parametric form, but differed in the exact parameters. By simulating larva behavior in virtual arenas we can infer which properties of the environments are better for each species. Comparisons between these inferred environments and the actual environments where these animals live will give us a deeper understanding about the evolution of foraging behavior in Drosophilid larvae.

10:12AM A47.00012 Collective workload organization in confined excavation of granular media. DARIA MONAENKOVA, VADIM LINEVICH, MICHAEL A. GOODISMAN, DANIEL I. GOLDMAN, Georgia Institute of Technology — Many social insects collectively construct large nests in complex substrates: such structures are often composed of narrow tunnels. The benefits of collective construction, including reduced construction costs per worker come with challenges of navigation in crowded, confined spaces. Here we study the workforce organization of groups of S. invicta fire ants creating tunnels in wet granular media. We monitor the activity levels of marked (painted) workers—defined as a number of tunnel visits over 12 hours—during initiation of tunnels. The activity levels are described by a Lorenz curve with a Gini coefficient of ∼0.7 indicating that a majority of the excavation is performed by a minority of workers. We hypothesize that this workload distribution is beneficial for excavation in crowded conditions, and use a 2D cellular automata (CA) model to reproduce behaviors of the excavating ants. CA simulations reveal that tunnel construction rates decrease in groups of equally active animals compared to groups with the natural workload distribution. We use predictions of the CA model to organize collective excavation of granular material by teams of digging robots, and use the robots to test hypotheses of crowded excavation in the physical world.

10:24AM A47.00013 Nociception and escape behavior in planarians. EVA-MARIA SCHOEZT COLLINS, University of California, San Diego — Planarians are famous and widely studied for their regenerative capabilities. When a moving planarian is cut through the middle, the resulting head and tail pieces instantaneously retract and exhibit a characteristic escape response that differs from normal locomotion. In asexaul animals, a similar reaction is observed when the planarian undergoes fission, suggesting that reproduction through self-tearing is a rather traumatic event for the animal. Using a multiscale approach, we unravel the dynamics, mechanics, and functional aspects of the planarian escape response. This musculature-driven gait was found to be a dominating response that supersedes the urge to feed or reproduce and quantitatively differs from other modes of planarian locomotion (gliding, peristalsis). We show that this escape gait constitutes the animal’s pain response mediated by TRP like receptors and the neurotransmitter histamine, and that it can be induced through adverse thermal, mechanical, electrical or chemical stimuli. Ultimately, we will examine the neuronal subpopulations involved in mediating escape reflexes in planarians and how they are functionally restored during regeneration, thereby gaining mechanistic insight into the neuronal circuits required for specific behaviors.

An explicitly solvated full atomicistic model of the cardiac thin filament and application on the calcium binding effects from familial hypertrophic cardiomyopathy linked mutations, MICHAEL WILLIAMS, STEVEN SCHWARTZ, Dept. of Chemistry and Biochemistry, The University of Arizona — The previous version of our cardiac thin filament (CTF) model consisted of the troponin complex (cTn), two coiled-coil dimers of tropomyosin (Tm), and 29 actin units. We now present the newest revision of the model to include explicit solvation. The model was developed to continue our study of genetic mutations in the CTF proteins which are linked to familial hypertrophic cardiomyopathies. Binding of calcium to the cTnC subunit causes subtle conformational changes to propagate through the cTnC to the cTnI subunit which then detaches from actin. Conformational changes propagate through to the cTnT subunit, which allows Tm to move into the open position along actin, leading to muscle contraction. Calcium disassociation allows for the reverse to occur, which results in muscle relaxation. The inclusion of explicit TIP3 water solvation allows for the model to get better individual local solvent to protein interactions; which are important when observing the N-lobe calcium binding pocket of the cTnC. We are able to compare in silica and in vitro experimental results to better understand the physiological effects from mutants, such as the R92L/W and F110V/I of the cTnT, on the calcium binding affinity compared to the wild type.

Proteins and Complexity, JOELLE MURRAY, DANA GIBBON, ALISSA RUNYON, ARUN BA-JRACHARYA, Linfield College — A protein’s tertiary structure determines its function in living organisms. The different functions proteins serve necessitate variety in native structures. How is variation in tertiary structure created from a common set of amino acids and molecular forces? In other words, what generates complexity in structures across all types of native proteins? To explore this question, a simple HP model of protein folding was explored for evidence of self-organized criticality, a potential generator of complexity.

Interaction and dynamics of homologous pairing protein 2 (HOP2) and DNA studied by MD simulation, HEM MOKTAN, Oklahoma State University, ROBERTO PEZZA, Oklahoma Medical Research Foundation, DONGHUA ZHOU, Oklahoma State University — The homologous pairing protein 2 (HOP2) plays an important role in meiosis and DNA repair. Together with protein Mnd1, HOP2 enhances the strand invasion activity of recombinase Dmc1 by over 30 times, facilitating proper synopsis of homologous chromosomes.

We recently determined the NMR structure of the N-terminal domain of Hop2 and proposed a model of Protein-DNA complex based on NMR chemical shift perturbations and mutagenesis studies (Moktan, J Biol Chem 2014 10.1074/jbc.M114.548180). However structure and dynamics of the complex have not been studied at the atomic level yet. Here, we used classical MD simulations to study the interactions between the N-terminal HOP2 and DNA. The simulated results indicate that helix3 (H3) interacts with DNA in major groove and wing1 (W1) interacts mostly in minor groove mainly via direct hydrogen bonds. Also it is found that binding leads to reduced fluctuations in both protein and DNA. Several water bridge interactions have been identified. The residue-wise contributions to the interaction energy were evaluated. Also the functional motion of the protein is analyzed using principal component analysis. The results confirmed the importance of H3 and W1 for the stability of the complex, which is consistent with our previous experimental studies.

Principles of allosteric mechanisms in cell signaling, RUTH NUSSINOV, National Cancer Institute — Linking cell signaling events to the fundamental physicochemical basis of the conformational behavior of single molecules and ultimately to cellular function are key challenges facing the life sciences. Specific protein function is determined by the extent to which the protein populates a distinct active state. Allostery, an inherent physical property of proteins, is a key factor governing the relative populations among accessible conformational states. Allostery can be defined as the change in the distribution of the conformational ensemble through some perturbation. Nature has co-evolved ligand-host protein interactions, optimizing them to tune the populations of the active (or inactive) states for function, either by stabilizing the active conformation and/or destabilizing the inactive conformations, or vice versa. More and more data attest to the significance of allostery in cell life under physiological conditions and in disease. We aim to delineate key challenging questions, such as can we predict a priori- and quantify changes incurred by allosteric mutations or specific binding events to increase/decrease the population of the active or inactive state to up- or down- regulate the protein? I will provide an overview of the fundamental underpinnings of allostery.

Interaction of albumin with perylene-diimides with aromatic substituents, MOHAMMED FAROOQI, MARK PENICK, JESSICA BURCH, GEORGE NEGRETE, LORENZO BRANCALON, University of Texas at San Antonio — Perylene diimide (PDI) derivatives, a class of synthetic organic dyes, serve as useful tools in biology to study fundamental aspects of protein-protein interactions, protein-ligand binding and to probe the conformational change of unliganded proteins. Using ultrafast IR spectroscopy, we have been able to track the conformational changes of a single protein-binding groove of an allosteric protein domain, a conformational change can be initiated by a laser pulse. This transition mimics the conformational change of the unmodified domain upon ligand binding. We have studied this light induced conformational change by ultrafast IR spectroscopy. So far, we have probed two IR absorption bands: First, the amide I band which arises from the carbonyl stretch vibration of all amide groups in the protein and is sensitive to overall structural changes, and second, a vibration localized on the photoswitch, which is sensitive to its local environment, namely the opening of the binding groove. We have found that the binding groove opens on a timescale of 100 ns in a non-exponential manner. Even after the binding groove has equilibrated, the protein conformation still continues to change. Currently, we are incorporating site-specific IR labels, to learn more about the response of the protein to the perturbation of the binding groove.

Probing a Conformational Change of a Photoswitchable Allosteric Protein with Ultrafast IR Spectroscopy, BRIGITTE STUCKI-BUCHLI, STEVEN A. WALDHAUER, RETO WALSER, ROLF PFISTER, PETER HAMM, Department of Chemistry, University of Zurich, Switzerland — By covalently linking an azobenzene photoswitch across the binding groove of an allosteric protein domain, a conformational transition can be initiated by a laser pulse. This transition mimics the conformational change of the unmodified domain upon ligand binding. We have studied this light induced conformational change by ultrafast IR spectroscopy. So far, we have probed two IR absorption bands: First, the amide I band which arises from the carbonyl stretch vibration of all amide groups in the protein and is sensitive to overall structural changes, and second, a vibration localized on the photoswitch, which is sensitive to its local environment, namely the opening of the binding groove. We have found that the binding groove opens on a timescale of 100 ns in a non-exponential manner. Even after the binding groove has equilibrated, the protein conformation still continues to change. Currently, we are incorporating site-specific IR labels, to learn more about the response of the protein to the perturbation of the binding groove.

Kinetic response of a photoperturbed allosteric protein, BRIGITTE STUCKI-BUCHLI, STEVEN A. WALDHAUER, RETO WALSER, ROLF PFISTER, PETER HAMM, Department of Chemistry, University of Zurich, Switzerland — By covalently linking an azobenzene photoswitch across the binding groove of an allosteric protein domain, a conformational transition can be initiated by a laser pulse. This transition mimics the conformational change of the unmodified domain upon ligand binding. We have studied this light induced conformational change by ultrafast IR spectroscopy. So far, we have probed two IR absorption bands: First, the amide I band which arises from the carbonyl stretch vibration of all amide groups in the protein and is sensitive to overall structural changes, and second, a vibration localized on the photoswitch, which is sensitive to its local environment, namely the opening of the binding groove. We have found that the binding groove opens on a timescale of 100 ns in a non-exponential manner. Even after the binding groove has equilibrated, the protein conformation still continues to change. Currently, we are incorporating site-specific IR labels, to learn more about the response of the protein to the perturbation of the binding groove.

9:36 AM A48.00007 Global Low Frequency Protein Motions in Long-Range Allosteric Signaling

The proposed model allows to combine prior knowledge with additional sources of information (likelihood) from another neural population, and to implement in dynamics and recurrent inhibitory connections, enables a neural population to learn the statistical properties of the received sensory input (prior). Moreover, resource to implement close-to-optimal inference by sampling. Specifically, we derive a synaptic plasticity rule which, coupled with integrate-and-fire neural

9:48 AM A48.00008 Modulation of Allostery by protein intrinsic Disorder

ASHOK DENIZ, The Scripps Research Institute — No abstract available.

10:24 AM A48.00009 Functionally important residues from mode coupling during short-time protein dynamics

ALKAN KABAKCIIOGLU, Koc Univ, ONUR VAROL, Indiana Univ, DENIZ YURET, BURAK ERMAN, Koc Univ — Relevance of mode coupling to energy/information transfer during protein function, particularly in the context of allosteric interactions is widely accepted. However, existing evidence in favor of this hypothesis comes essentially from model systems. We here report a novel formal analysis of the near-native dynamics for proteins, which allows us to explore the impact of the interaction between possibly non-Gaussian vibrational modes on fluctutational dynamics. We show that, an information-theoretic measure based on mode coupling alone yields a ranking of residues with a statistically significant bias favoring the functionally critical locations identified by experiments on Myosin II and AncGR1.2.

10:36 AM A48.00010 Optical observation of correlated motions in dihydrofolate reductase

MENGYANG XU, KATHERINE NIESSEN, State Univ of NY - Buffalo, JAMES PACE, VIVIAN CODY, Hauptman-Woodward Medical Research Institute, ANDREA MARKELZ, State Univ of NY - Buffalo — Enzyme function relies on its structural flexibility to make conformational changes for substrate binding and product release. An example of a metabolic enzyme where such structural changes are vital is dihydrofolate reductase (DHFR). DHFR is essential in both prokaryotes and eukaryotes for the nucleotide biosynthesis by catalyzing the reduction of dihydrofolate to tetrahydrofolate. NMR dynamical measurements found large amplitude fast dynamics that could indicate rigid-body, twisting-hinge motion for ecDHFR that may mediate flux [1]. The role of such long-range correlated motions in function was suggested by the observed sharp decrease in enzyme activity for the single point mutation G121V, which is remote from active sites [2]. This decrease in activity may be caused by the mutation interfering with the long-range intramolecular vibrations necessary for rapid access to functional configurations. We use our new technique of crystal anisotropy terahertz microscopy (CATM) [3], to observe correlated motions in ecDHFR crystals with the bonding of NADPH and methotrexate. We compare the measured intramolecular vibrational spectrum with calculations using normal mode analysis. 1. Cameron C.E. and Benkovic S.J., Biochemistry, 1997. 36(50): p. 15792-15800. 2. Bhabha G., et al., Nat Struct Mol Biol, 2013. 20(11): p. 1243-9. 3. Acbas, G., Niessen K.A., Snell E. H., and Markelz A.G., Nat Commun, 2014. 5, 3076.

10:48 AM A48.00011 Non-linear dynamics in recurrently connected neural circuits implement Bayesian inference by sampling

ALESSANDRO TICCHI, ALDO A. FAISAL, Imperial College London, BRAIN AND BEHAVIOUR LAB TEAM — Experimental evidence at the behavioural-level shows that the brains are able to make Bayes-optimal inference and decisions (Kording and Wolpert 2004, Nature: Ernst and Banks, 2002, Nature), yet at the circuit level little is known about how neural circuits may implement Bayesian learning and inference (but see Ma et al. 2006, Nat Neurosci)). Molecular sources of noise are clearly established to be powerful enough to pose limits to neural function and structure in the brain (Faisal et al. 2008, Nat Rev Neurosci; Faisal et al. 2005, Curr Biol). We propose a spiking neuron model where we exploit molecular noise as a useful resource to implement close-to-optimal inference by sampling. Specifically, we derive a synaptic plasticity rule which, coupled with integrate-and-fire neural dynamics and recurrent inhibitory connections, enables a neural population to learn the statistical properties of the received sensory input (prior). Moreover, the proposed model allows to combine prior knowledge with additional sources of information (likelihood) from another neural population, and to implement in spiking neurons a Markov Chain Monte Carlo algorithm which generates samples from the inferred posterior distribution.

Session A49 GSOFT: Focus Session: Self-Phoretic Colloids and Active Emulsions I

8:00AM A49.00001 Swarming of active colloidal Janus particles: Polar waves and vortices

Cong Xu, Jing Yan1, University of Illinois at Urbana-Champaign, Ming Han, Erik LuuTEN, Northwestern University, Steve Granick, University of Illinois at Urbana-Champaign — The synthesis of artificial “swarming” particles with tunable interaction represents a strong interest of the soft active matter community. Here, we demonstrate a straightforward design of swarming Janus colloids that exhibit transient mutual alignment within a certain frequency range of an applied AC electric field. In a dense two-dimensional suspension of these Janus colloids, we observe that coherent polar waves emerge at first, which then collide and merge into stable discrete vortices. Based upon a careful analysis of the pair interaction, we propose a simple mechanism that explains the formation of the polar waves, with agreement between experiment and simulation. A rich spectrum of phenomena, including dimer swarming, chain formation, and particle clustering, can be further achieved by changing the frequency of the AC electric field.

1Currently working as a postdoctoral researcher in Princeton University.
8:12 AM A49.00002 Confining collective motion, DENIS BARTOLO, ANTOINE BRICARD, JEAN-BAPTISTE CAUSSIN, ENS Lyon, DEBASHIS DAS, UCSD, CHARLES SAVOIE, VIJAYAKUMAR CHIKKADI, ENS Lyon, KYOEI SHITARA, Kyushu University, OLESKAR CHEP-IZHKO, Odessa National University, FERNANDO PERUANI, 61030775, DAVID SAINTILLAN, UCSD — Confined active materials are often found to display self-organization in the form of a macroscopic steadily rotating vortex, yet a unified description of the formation and structure of this pattern based on microscopic interaction rules remains lacking. We use a combination of experiments, numerical simulations and theory to address this question in the case of a confined population of colloidal rollers. We first demonstrate experimentally that upon increasing density this system undergoes a continuous phase transition from a dilute isotropic-gas phase to a heterogeneous polar-liquid phase. In the ordered phase, the entire population self-organizes into a single vortex lying at the onset of a phase separation. Numerical simulations confirm the existence of this non-equilibrium phase transition, and make it possible to single out the very ingredient responsible for the emergent-vortex structures: the competition between alignment and repulsive interactions. Building on this observation, we also establish a continuum theory and lay out a strong foundation for the description of emergent collective behavior in a broad class of motile populations constrained by geometrical boundaries.

8:24 AM A49.00003 Flocking at a distance in granular matter, HARSH SONI, Indian Institute of Science, SRIRAM RAMASWAMY, TIFR Hyderabad — A mixture of polar granular rods and spherical beads on a vibrated plate undergoes a phase transition to an orientationally ordered state above a critical bead concentration. We study this system using large scale numerical simulations with periodic boundary conditions. We find an intermediate state with banded structures between the disordered and the globally ordered state. We observe a single band whose width increases with rod concentration. We find that at high densities the rods and the beads phase separate. We also test the various theoretical predictions of the hydrodynamic theory in the ordered state. Our results, which are in good agreement with the theory, are following: We see a highly anisotropic dispersion relation are exhibited with geometrical boundaries.

8:36 AM A49.00004 Exploring flocking via quantum many-body physics techniques, ANTON SOUSLOV, BENJAMIN LOEWE, PAUL M. GOLDBART, Georgia Institute of Technology — Flocking refers to the spontaneous breaking of spatial isotropy and time-reversal symmetries in collections of bodies such as birds, fish, locusts, bacteria, and artificial active systems. The transport of matter along biopolymers using molecular motors also involves the breaking of these symmetries, which in some cases are known to be broken explicitly. We study these classical nonequilibrium symmetry-breaking phenomena by means of models of many strongly interacting particles that hop on a periodic lattice. We employ a mapping between the classical and quantum dynamics of many-body systems, combined with tools from many-body theory. In particular, we examine the formation and properties of nematic and polar order in low-dimensional, strongly-interacting active systems using techniques familiar from fermionic systems, such as self-consistent field theory and bosonization. Thus, we find that classical active systems can exhibit analogs of quantum phenomena such as spin-orbit coupling, magnetism, and superconductivity. The models we study connect the physics of asymmetric exclusion processes to the spontaneous emergence of transport and flow, and also provide a soluble cousin of Vicsek’s model system of self-propelled particles.

8:48 AM A49.00005 Dynamics of cluster growth in a system of self-propelled particles, MICHELLE DRISCOLL, MELISSA FERRARI, JEREMIE PALACCI, PAUL CHAIKIN, New York Univ NYU — Self-propelled particles are a simple realization of an active-matter system; particles are continuously driven and thus inherently out of equilibrium. It has recently been shown that this leads to a rich variety of behaviors, including self-organization into dynamic clusters. Particles aggregate into clusters which are not static, but are constantly growing and shrinking by exchanging particles, coalescing, and breaking apart. Here we study in detail the dynamics of this process in a system of photo-activated colloidal swimmers. Soon after the self-propulsion mechanism is activated, a large fraction of the swimmers quickly incorporate into clusters. We measure the distributions of cluster size, and show that a substantial population of small clusters can persist even at late times. Additionally, we examine how geometric confinement of the system can alter cluster growth dynamics.

9:00 AM A49.00006 Transitions between homogeneous phases of polar active liquids, OLIVIER DAUCHOT, CNRS, UMR Gulliver, PSL University, KHANH DANG NGUYEN THU LAM, ESPCI-Paris Tech, PSL University, MICHAEL SCHINDLER, CNRS, UMR Gulliver, PSL University, EC2M TEAM, PCT TEAM — Polar active liquids, composed of aligning self-propelled particles, exhibit large scale collective motion. Simulations of Vicsek-like models of constant-speed point particles, aligning with their neighbors in the presence of noise, have revealed the existence of a transition towards a true long range order polar-motion phase. Generically, the homogeneous polar state is unstable; non-linear propagative structures develop; and the transition is discontinuous. The long range dynamics of these systems has been successfully captured using various scheme of kinetic theories. However the complexity of the dynamics close to the transition has somewhat hindered more basics questions. Is there a simple way to predict the existence and the order of a transition to collective motion for a given microscopic dynamics? What would be the physically meaningful and relevant quantity to answer this question? Here, we tackle these questions, restricting ourselves to the study of the homogeneous phases of polar active liquids in the low density limit and obtain a very intuitive understanding of the conditions which particle interaction must satisfy to induce a transition towards collective motion.

9:12 AM A49.00007 Active self-assembly and collective chemotaxis of catalytic colloids, RAMIN GOLESTANIAN, Rudolf Peierls Centre for Theoretical Physics, University of Oxford — The equilibrium dynamics of phoretically active colloids could lead to spontaneous formation of interesting structures and patterns due to the presence of long-range Coulomb-like interactions. We examine theoretically the consequences of this interaction, and present some results that exemplify the type of emergent properties that could result from them. In particular, we discuss the following: (1) spontaneous formation of small stable clusters or “molecules” that can exhibit functionality that depends on geometry (2) collective chemotaxis in a solution of catalytically active colloids that could lead to cluster formation, aster condensation, and spontaneous oscillations, and (3) swarming in the form of a comet - of light-induced thermally active colloids with negative Soret coefficient due to a shadowing interaction.

9:48 AM A49.00008 Hydrodynamics of Turning Flocks1, XINGBO YANG, M. CRISTINA MARCHETTI, Syracuse University — We present a hydrodynamic model of flocking that generalizes the familiar Toner-Tu equations to incorporate turning inertia of well polarized flocks. The continuum equations are derived by coarse graining the inertial spin model recently proposed by Cavagna et al. The interplay between orientational inertia and bend elasticity of the flock yields spin waves that mediate the propagation of turning information throughout the flock. When the inertia is large, we find a novel instability that signals the transition to complex spatio-temporal patterns of continuously turning and swirling flocks.

10:00 AM A49.00009 Interactions and Collective Behaviour of Chemotactic Active Colloids, SUROPRIYA SAHA, Indian Institute of Science, SURBHI HABLANI, TIFR Centre for Interdisciplinary Sciences, 21 Brundavan Colony, Narsingi, Hyderabad 500075, RAMAN RAGHUPATI, ESRIIRAM, Rudolf Peierls Center for Theoretical Physics, University of Oxford, 1 Keble Road, Oxford OX1 3NP, United Kingdom, SRIRAM RAMASWAMY, TIFR Centre for Interdisciplinary Sciences, 21 Brundavan Colony, Narsingi, Hyderabad 500075 — Artificial realizations of motility in the ordered state. Our results, which are in good agreement with the theory, are following: We see a highly anisotropic dispersion relation are exhibited with two sound modes in all directions except along the flock. Further the rods are super diffusive in the transverse direction and exhibit large number fluctuations.
10:12AM A49.00010 The Swim Pressure of Active Matter. JOHN BRADY, SHO TAKATORI, WEN YAN. California Institute of Technology — Through their self-motion, active matter systems generate a unique "swim pressure" that is entirely athermal in origin. This new source for the active stress exists at all scales in both living and nonliving active systems, and also applies to larger organisms where inertia is important. Here we explain the origin of the swim stress and develop a simple thermodynamic model to study the self-assembly and phase separation in active soft matter. Our new swim stress perspective may help analyze and exploit a wide class of active soft matter, from swimming bacteria and catalytic nanobots, schools of fish and birds, and molecular motors that activate the cellular cytoskeleton.

10:24AM A49.00011 Diffusive properties of Brownian agents interacting via metric-free aligning-forces1. FRANCISCO J. SEVILLA, LUIS ALBERTO GÓMEZ NAVA, JOSÉ LUIS MIRADA OLVERA, MIGUEL ALEJANDRO PÉREZ CONTRERAS. Instituto de Física, Universidad Nacional Autónoma de México — The diffusive properties of active particles moving at constant speed in two dimensions and interacting through metric-free aligning-forces are studied. Exponential and scale free networks are used as the backbone for the interactions among agents. Averages over the trajectories of hundred thousand agents are performed to compute the single particle mean-square displacement, and the Kurtosis of the spatial distribution, as a function of time. These quantities provide a mean to evaluate the effects of interaction. In contrast to what one would expect, the diffusion constant, increases with the intensity of the alignment.

10:36AM A49.00012 Self-consistent nonlocal feedback theory for electrocatalytic swimmers2. AMIR NOURHANI, VINCENT H. CRESPI, PAUL E. LAMMERT. Department of Physics, The Pennsylvania State University — The phoretic propulsion mechanisms of electrocatalytic micro/nano-motors has received considerably more theoretical attention than the heterogeneous electrochemical processes underlying their operation. We present a flexible approach to such heterogeneous electrochemistry with nonlocal feedback using a surface bias potential field as a control parameter field with a locally open-circuit reference state. The framing in operational terms permits both convenient contact to experiment and potential for implementation in Frumkin-Butler-Volmer kinetics. Previous results are recovered in a simple approximation, and an approximate scaling form is deduced for motor speed as function of fuel concentration and swimmer size which is more consistent with data from the literature than the original linear fits.

8:00AM A50.00001 Multiple networks in soft materials: polycontinuity. STEPHEN HYDE, Australian National University — Bicontinuous network phases contain a pair of interwoven labyrinths. Analogous patterns with 3, 4, ..., 8, ..., 54,... labyrinths are readily constructed via 2d hyperbolic geometry. Some of these have been realised in synthetic materials, from mesoporous silicates and lyotropic liquid crystals to metal-organic frameworks. We stumbled on polycontinuous forms while exploring 2d hyperbolic geometry. The only known tricontinuous phase found to date in mesoscale self-assembled materials was described via 2d non-euclidean geometry many years before its discovery. This example demonstrates the relevance of regular patterns in non-euclidean spaces to self-assembled morphologies in actual materials. One route to explicit ground-up design of mesoscale polycontinuous phases is via star-shaped molecules with immiscible arms, such as Y-shaped “polyphiles.” Some results of theoretical geometric modelling and experimental formulation of lyotropic LC mesophases with polyphile will be discussed.

8:36AM A50.00002 Hard Spheres on the Primitive Surface. TOMONARI DOTERA, YUSUKE TAKAHASHI, Dept. of Physics, Kinki Univ. — Recently hierarchical structures associated with the gyroid in several soft-matter systems have been reported [1,2]. One of fundamental questions is regular arrangement or tiling on minimal surfaces [3]. We have found certain numbers of hard spheres per unit cell on the gyroid surface are entropically self-organized [4,5]. Here, new results for the primitive surface are presented. 56/64/72 per unit cell on the primitive minimal surface are entropically self-organized. Numerical evidences for the fluid-solid transition as a function of hard sphere radius are obtained in terms of the acceptance ratio of Monte Carlo moves and order parameters. These arrangements, which are the extensions of the hexagonal arrangement on a flat surface, can be viewed as hyperbolic tiling on the Poincaré disk with a negative Gaussian curvature.

Real time SANS studies on the transformation between the hexagonal cylinder phase and the bi-continuous gyroid structure: transient structures\textsuperscript{1}.

KELL MORTENSEN, Univ of Copenhagen, MARTIN VIGILD, Technical University of Denmark, RUYA ESKIMERGEN, Leo Pharma, Denmark — Combined application of SANS and oscillatory shear is effective tools for studying structure and real-time dynamics of soft matter materials. Large-amplitude oscillatory shear can be used to effectively control the texture of soft materials in the ordered states. We will show experimental data proving that the 10-spot pattern often characterizing the gyroid phase of block copolymer melts as well as surfactant systems is a 2D powder-pattern, originating from the dominating structure of the cylinder axis when grown from single-domain hexagonal structures. We show that the gyroid state is unstable when exposed to large amplitude / large frequency shear, transforming into the a hexagonal cylinder phase: the transformation is completely reversible. With the slow kinetics, it is possible in detail to follow the complex materials transformation from one-dimension cylinders to the complex three-dimensional gyroid phase of block copolymers. The transformation kinetics is different within the various crystallographic directions, and shows the transformation through a transient structure rather similar to that found in SCFT-studies\textsuperscript{2}.

Towards complex network droplets — a computational study of bicontinuous network regions in star polymer droplets, RYAN MARSON, SHARON GLOTZER, Univ of Michigan - Ann Arbor — The complexity and functionality of network phases in soft matter systems offer a wealth of possible technological applications ranging from photonics to medicine. Through Dissipative Particle Dynamics (DPD) simulations, with explicit solvent, of over 1 million particles we demonstrate control of nano- and micro-scale ordering in star polymer droplets. By tuning the building block geometry and interactions between star polymer components we produce a droplet phase diagram. In particular we highlight regions of the structure that contain phase separated bicontinuous network domains. This system demonstrates the possibility of functional droplets composed of complex networks, with a hierarchy of scales that can be tuned for specific applications.

Free Energy-Based Monte Carlo Determination of a Model Microphase Former, YUAN ZHUANG, Duke Univ, KAI ZHANG, Yale Univ, PATRICK CHARBONNEAU, Duke Univ — Determining the equilibrium phase behavior of microphase formers from particle-based simulations is particularly challenging because the occupancy of the various microphase features (clusters, layers, cylinders, etc.) fluctuates and varies from one state point to the next. Here, we compute the phase diagram of a schematic microphase former, the square well-linear model, using a novel free energy-based Monte Carlo simulation methodology. Our approach surmounts traditional equilibration difficulties by including modulated reference fields and developing the expanded isothermal-isobaric [N]PT ensemble. Our results for the square-well-linear model goes beyond other descriptions of the equilibrium phase behavior of simple microphase formers by revealing the complex thermodynamic interplay of various microphases with micelle formation and percolation.

Structural Diversity of Self-Assembled Iridescen Arthropod Biophotonic Nanostructures, VINOD KUMAR SARANATHAN, Division of Physics and Applied Physics, Nanyang Technological University, RICHARD O. PRUM, Department of Ecology and Evolutionary Biology, Yale University — Many organisms, especially arthropods, produce vivid interference colors using diverse mesoscopic (100-350 nm) integumentary biophotonic nanostructures that are increasingly being investigated for technological applications. Despite a century of interest, we lack precise structural knowledge of many biophotonic nanostructures and mechanisms controlling their development, when such knowledge can open novel biomimetic routes to facilely self-assemble tunable, multi-functional materials. Here, we use synchrotron small angle X-ray scattering and electron microscopy to characterize the photonic nanostructure of 140 iridescent integumentary scales and setae from 127 species of terrestrial arthropods in 85 genera from 5 orders. We report a rich nanostructural diversity, including triply-periodic bicontinuous networks, close-packed spheres, inverse columnar, perforated lamellar, and disordered sponge-like morphologies, commonly observed as stable phases of amphiphilic surfactants, block copolymer, and lyotropic lipid-water systems. Diverse arthropod lineages appear to have independently evolved to utilize the self-assembly of infolding bilayer membranes to develop biophotonic nanostructures that span the phase-space of amphiphilic morphologies, but at optical length scales.

The Tricontinuous 3ths(5) Phase: A New Morphology in Copolymer Melts, MICHAEL FISCHER, Adolphe Merkle Institute, Chemin des Verdiers 4, CH-1700 Fribourg, Switzerland, LILIANA DE CAMPO, Australian National Science and Technology Organisation, Bragg Institute, New Illawarra Road, Lucas Heights NSW 2234, Australia; JACOB KIRKENSGAARD, Niels Bohr Institute, University of Copenhagen, Universitetsparken 5, 2100 København Ø, Denmark, STEPHEN HYDE, Applied Maths, Research School of Physics & Engineering, The Australian National University, Canberra ACT 0200, Australia, GERD SCHROEDER-TURK, Institut für Theoretische Physik, Friedrich-Alexander Universität Erlangen-Nürnberg, Staudtstr. 7B, 91058 Erlangen, Germany — Self-assembly remains one of the most efficient routes to the formation of ordered nanostructures, but at optical length scales. Here, we demonstrate the existence of a tricontinuous morphology, called 3ths(5), based on the intergrowth of three distorted nths nets, in an equilibrium phase of triblock star-copolymer melts when an extended molecular core is introduced. The introduction of the core enhances the role of chain stretching by enforcing larger structural length scales, thus destabilizing the hexagonal columnar phase in favor of morphologies with less packing frustration. This study further demonstrates that the introduction of molecular cores is a general concept for tuning the relative importance of entropic and enthalpic free energy contributions, hence providing a tool to stabilize an extended repertoire of self-assembled nanostructured materials.

Group Theory of Circular-Polarisation Effects in Chiral Photonic Crystals with Four-Fold Rotation Axes, Applied to the Eight-Fold Intergrowth of Gyroid Nets, MATTHIAS SABA, Theoretische Physik, FAU Erlangen-Nuremberg, MARK D. TURNER, CUDOS & Centre for Micro-Photonics, Swinburne University of Technology, KLAUS MECKE, Theoretische Physik, FAU Erlangen-Nuremberg, MIN GU, CUDOS & Centre for Micro-Photonics, Swinburne University of Technology, GERD E. SCHRODER-TURK, Theoretische Physik, FAU Erlangen-Nuremberg — The 8-srs PhC of body-centered cubic f\textit{\textalpha}3 symmetry consists of eight interwoven equal-handed dielectric Gyroid networks. The complete resolution of the scattering matrix parameters to derive analytical results for the band structure topology and the circular polarization scattering parameters of the 8-srs PhC and any other lossless f\textit{\textalpha}3 photonic crystal. All results are supported by numerical. We demonstrate in particular that all bands along the cubic [100] direction can be identified with the irreducible representations \textit{E}±, \textit{A} and \textit{B} of the \textit{C}4 point group. The \textit{E}± (\textit{E}) representation can be identified as the only transmission channel for right(left)-circularly polarized light. We derive explicit relationships for the (zero Bragg order) transmission and reflectance amplitudes which guarantee equal transmission rates for both polarizations and vanishing ellipticity below a critical frequency, yet allowing for finite rotation of the polarization plane. The combination of vanishing losses, vanishing ellipticity, near-perfect transmission and optical activity comparable to that of metallic meta-materials makes this geometry an attractive design for nanofabricated photonic materials.
non-Hermitian systems, and show new experiments exploring their properties. Time permitting, I will discuss the question of what it means to have topological interface states in an anomalous Hall effect. I will also present experimental results on the first realization of a “topological Anderson insulator” (in a similar setting), where the symmetry. This leads to bands with non-zero Chern number, and thus topologically-protected edge states (protected in the quantum Hall sense – not by any materials that are insulators in the bulk, but conduct electricity along their surfaces - and are intrinsically robust to disorder. In particular, when a surface

8:36 AM A51.00002 Proposed Realization and Signatures of Floquet Topological Superconductors and Insulators\(^1\), BABAK SERADJEH, Indiana Univ.-Bloomington — As understood recently, a topological state may be generated dynamically in an otherwise normal combination of materials by a periodic driving force. These states can only occur when the system is driven out of equilibrium. A Floquet topological insulator can be realized, for example, in a two-dimensional system of Dirac fermions, such as graphene, irradiated by a circularly polarized laser [1]. It is characterized by steady state edge modes and two separate integer-valued topological invariants. A Floquet topological superconductor, on the other hand, is characterized by two types of Floquet Majorana fermions—steady states of equal superposition of electrons and holes—with a period that is the same or twice that of the drive [2]. I introduce these concepts and present our recent theoretical work on the realization and detection of these Floquet topological states. First, I discuss how Floquet Majorana fermions can be realized in a highly tunable setup consisting of two coupled quantum dots and detected by a third probe dot [3]. More generally, Floquet Majorana fermions can be detected by measuring a quantized conductance sum rule over discrete values of lead bias differing by multiples of drive frequency [4]. This quantized sum rule is robust against weak disorder. Finally, I present an effective theory of Floquet topological insulators and use it to study their transport signature [5]. Remarkably, we find that disorder can enhance transport at certain Floquet topological transitions by several orders of magnitude.\(^1\)

9:12 AM A51.00003 Interactions and dissipation in Floquet-Bloch systems\(^1\), NETANEL LINDNER, Technion - Israel Institute of Technology — Time periodic driving fields provide a versatile route for dynamically altering band structures. Particular excitement surrounds the possibility of controlling the topology of the resulting “Floquet bands,” whose topological classification is even richer than the one describing their static counterparts. While many schemes have been proposed for realizing interesting Floquet band structures, crucial questions remain regarding the many-body steady states of these systems. In this work we study the roles of interactions, heating, and dissipation in the population kinetics of many-particle Floquet systems. While a naive picture might lead one to expect rapid heating of any strongly driven interacting system, we find wide parameter regimes in which non-trivial Floquet steady states are obtained at intermediate and long times. Prospects for obtaining and probing the physics of these many-body Floquet systems will be discussed.

\(^1\)In collaboration with: Karthik Seetharam (Caltech), Charles-Edouard Bardyn (Caltech), Mark Rudner (Copenhagen), and Gil Refael (Caltech).

9:48 AM A51.00004 Topology in Floquet-Bloch systems: physics beyond the topological insulators\(^1\), MARK RUDNER, Copenhagen University — Floquet theory provides a powerful framework for understanding the dynamics of periodically-driven quantum systems. When applied to systems with spatially periodic potentials, the emergence of Floquet-Bloch quasiequation bands suggests many exciting opportunities to explore topological phenomena through analogies to those known in equilibrium. Due to the periodicity of quasienergy, however, the topological classification of the resulting Floquet states is richer than that of static systems. This opens the way for discovering truly new, non-equilibrium topological phenomena. For example, a one dimensional Floquet system may host chiral bands, while in two dimensions a system whose Floquet bands all have zero Chern numbers may support robust chiral edge states. In this talk I will address the question: when is a Floquet-Bloch system not like a static system? I will discuss both general considerations, based on the structure of the time-dependent Floquet-Bloch evolution operator, and specific examples which highlight the possibilities available in both non-interacting and interacting systems.

\(^1\)In collaboration with: Frederik Nathan (Copenhagen), Erez Berg (Weizmann), Netanel Lindner (Technion), Michael Levin (Chicago).

10:24 AM A51.00005 Observation of topological transitions in interacting quantum circuits\(^1\), PEDRAM ROUSHAN, Google Inc., Santa Barbara, CA — Topology, despite its mathematical abstractness, often manifests itself in physics and plays a pivotal role in our understanding of natural phenomena. Notable examples include the discoveries of topological phases in condensed matter systems which have changed the modern conception of phases of matter. The global nature of topological ordering, however, makes direct experimental probing an outstanding challenge. Present experimental tools are mainly indirect and inadequate for studying such properties at a fundamental level. Here, we employ the exquisite control afforded by superconducting quantum circuits to directly investigate topological properties of quantum spin systems. The essence of our approach is to infer local curvature by measuring the deflection of quantum trajectories topological properties are then revealed from a quantum analog of the Gauss-Bonnet theorem. We benchmark our technique by constructing the topological phase diagram of the celebrated Haldane model. The nature of the individual phases is revealed by visualizing their microscopic spin texture and evolution across the transition. Furthermore, we demonstrate the power of our method in studying the topology of interacting quantum systems, utilizing a novel qubit architecture which enables control over every term in a two-qubit Hamiltonian. We discovered an interaction-driven topological phase, whose emergence is understood by fully exploring the parameter-space of the Hamiltonian. Our work establishes a generalizable experimental platform to study fundamental aspects of topological phenomena in quantum systems.

Monday, March 2, 2015 8:00AM - 11:00AM – Session A52 DCMP: Invited Session: Coherent Flow and Vortices in Polariton Condensates

8:00 AM A52.00001 Quantum features in the hydrodynamic flow of a superfluid of light, IACOPO CARUSOTTO, INO-CNR BEC Center — After a number of experiments showing the power of fluids of light in semiconductor microcavity devices for superfluid hydrodynamic studies, a growing activity is being devoted to quantum hydrodynamic features, where hydrodynamic quantities such as density, current, etc. must be described by quantum operators. As a concrete example, we shall consider the emission of phonon pairs from a sonic horizon via analog Hawking radiation processes. The robustness of entanglement against the driven-dissipative nature of the microcavity photon fluid will be discussed and perspectives to detect it will be sketched. In the last part, I will discuss the potential of a different, propagating architecture in view of studies of the conservative quantum dynamics of a photon fluid. After a brief summary of the general theoretical framework, our attention will be focused to a slab geometry able to exploit the power of quantum fluids of light to study the physics of quantum quenches.
8:36AM A52.00002 Half-quantum flow of a polariton spinor condensate in a ring geometry¹. DAVID SNOKE, University of Pittsburgh — We have created a macroscopic ring trap for exciton-polaritons with long lifetime, about 200 ps at resonance. In this trap we have observed Bose condensation of the polaritons, as seen in the strongly peaked energy spectrum and in the phase coherence across the trap, with coherence length of at least 50 microns. Studies of the phase gradient of the ring condensate show that it spontaneously goes into a quantized circulation state, sometimes circulating one way, sometimes the opposite way. Because this is a spinor condensate, states with only a half quantum of angular momentum are possible, accompanied by a 180-degree rotation of the polarization angle between the two spinor states. The circulating states with lowest energy in our experiments have this property, and in addition, the sign of the spin flips from one side of the ring to the other, unlike the case of a standard “half-quantum vortex.”

¹Supported by the National Science Foundation under Grant No. DMR-1104383.

9:12AM A52.00003 Hydrodynamics and coherence properties of polaritons in lattices, FLORENT BABOUX, Laboratoire de Photonique et Nanostructures, LPN/CNRS — At the frontier between non-linear optics and the physics of Bose-Einstein condensation, microcavity polaritons opened a new research field, both for fundamental studies of bosonic quantum fluids in a driven dissipative system, and for the development of new devices for all optical information processing. In this talk, I will review how semiconductor microcavities can be engineered into 1D and 2D lattices, allowing to implement complex hamiltonians and to study the hydrodynamics and coherence properties of polaritons in a novel and controlled environment. I will first show how we could generate polaritons in a 1D quasi-periodic Fibonacci potential and reveal features characteristic for a fractal energy spectrum, opening the way to the investigation of the anomalous propagation (neither ballistic nor diffusive) predicted in such structures. Then I will present a 2D honeycomb lattice for polaritons, which allows direct imaging of Dirac cones, paving the way for studies of the hydrodynamics of massless Dirac polaritons. Finally 1D lattices sustaining a non-dispersive band or “flat band” will be presented: here reduced spatial coherence is evidenced as a consequence of phase frustration.

9:48AM A52.00004 Pattern formation in interacting exciton-polariton condensates, PAVLOS SAVVIDIS, Nanophotonics Centre, Cavendish Lab, University of Cambridge, UK FORTH-IESL and Dept. of Materials S — Strongly coupled semiconductor microcavities support the formation of the exciton-polaritons, which can condense into macroscopically occupied quantum states or quantum liquids. The investigation of such systems revealed a number of effects commonly associated with the formation of a macroscopic phase, for instance superfluid-like behavior [1] or the appearance of quantized vortices. One of the focal points of current research regards the possibility of optically manipulating polariton condensates to realize new experiments and potential applications like all-optical polariton circuits. We develop this vision by employing a spatial light modulator to create arbitrary excitation patterns, where nonresonant excitation of polariton condensates allows us to define the potential landscape experienced by the condensates. Novel effects regarding the interaction of multiple polaritonic quantum liquids are revealed, in particular phase-locking between freely-flowing condensates [2], the formation of vortex lattices for multiple pump spots at large separations and the transition to a trapped configuration as the pump spots are moved closer together [3,4]. These results enhance our ability to explore new features in macroscopic coherent systems and bring us closer to practical applications with polariton condensates such as creating all-optical coherent circuits [5].

10:24AM A52.00005 Vortex-lattice phase order in a microcavity exciton-polariton lattice system, NA YOUNG KIM, Stanford University — Microcavity exciton-polaritons are bosonic quasi-particles in microcavity-quantum-well structures, exhibiting spontaneous coherence to form condensates. We have engineered two-dimensional polariton-lattice systems for investigating quantum phase order associated with high-ordinal symmetry. In particular, we have observed two-degenerate vortex-antivortex lattice order at the inequivalent K and K' points in the honeycomb lattice. Under the inversion symmetry, we identify the handedness of the vortex-antivortex phase order via an interferometry technique, which leads the quest for the nature of degenerate condensates at zero-momentum values. We envision that the polariton-lattice systems will provide exciting opportunities to explore new quantum order arising from the interplay of topology, spin, orbital and various symmetry properties. We embark on a journey to deepen our understandings in quantum nature and to develop its novel applications.

Monday, March 2, 2015 8:00AM - 11:00AM –
Session A53 DCMP: Invited Session: Optoelectronic Response of Low Dimensional Materials
Grand Ballroom C3 - Nathaniel Gabor, University of California, Riverside

8:00AM A53.00001 Electrical control and detection of nanoscale optical fields with 2d materials, FRANK KOPPENS, ICFO, the Institute of Photonic Sciences — No abstract available.

8:36AM A53.00002 Hot Carriers and Photoresponse in Graphene, QIONG MA, Massachusetts Institute of Technology — The photoresponse of materials, which determines the performance of optoelectronic devices, is governed by energy relaxation pathways of photo-excited electron-hole pairs. In graphene, with the electron-lattice coupling strongly quenched by the vanishing electronic density of states, a novel transport regime is reached in which the photo-generated carrier population can remain hot while the lattice stays cool. In this talk, I will review how semiconductor microcavities can be engineered into 1D and 2D lattices, allowing to implement complex hamiltonians and to study the hydrodynamics and coherence properties of polaritons in a novel and controlled environment. I will first show how we could generate polaritons in a 1D quasi-periodic Fibonacci potential and reveal features characteristic for a fractal energy spectrum, opening the way to the investigation of the anomalous propagation (neither ballistic nor diffusive) predicted in such structures. Then I will present a 2D honeycomb lattice for polaritons, which allows direct imaging of Dirac cones, paving the way for studies of the hydrodynamics of massless Dirac polaritons. Finally 1D lattices sustaining a non-dispersive band or “flat band” will be presented: here reduced spatial coherence is evidenced as a consequence of phase frustration.
survives to temperatures well above the Neel ordering $T_x$, liquid-like state with local order in the form of weakly correlated, co-aligned four-spin plaquettes. Additionally, this dynamical magnetism is extremely robust. It exhibits a small but measurable response, suggesting dynamical correlation length of only 1-2 lattice repeats. The wave-vector structure of magnetic fluctuations can be best described by a

9:48AM A53.00004 Single carbon-nanotube photonics and optoelectronics1, YUICHIRO K. KATO, The University of Tokyo — Single-walled carbon nanotubes have unique optical properties as a result of their one-dimensional structure. Not only do they exhibit strong polarization for both absorption and emission, large exciton binding energies allow for room-temperature excitonic luminescence. Furthermore, their emission is in the telecom-wavelengths and they can be directly synthesized on silicon substrates, providing new opportunities for nanoscale photonics and optoelectronics. Here we discuss the use of individual single-walled carbon nanotubes for generation, manipulation, and detection of light on a chip. Their emission properties can be controlled by coupling to silicon photonic structures such as photonic crystal microcavities [1] and microdisk resonators [2]. Simultaneous photoluminescence and photocurrent measurements show that excitons can dissociate spontaneously [3], enabling photodetection at low bias voltages despite the large binding energies. More recently, we have found that alternating gate-voltages can generate optical pulse trains from individual nanotubes [4]. Ultimately, these results may be combined to achieve further control over photons at the nanoscale.

10:24AM A53.00005 Many-body interactions in atomically thin 2D materials, ALEXEY CHERNIKOV, Columbia University — Since the discovery of graphene, a single sheet of carbon atoms, research focused on two-dimensional (2D) materials evolved rapidly due to the availability of atomically thin, thermally stable crystals with intriguing physical properties. The 2D materials naturally inherit major traits associated with systems of reduced dimensionality: strongly enhanced Coulomb interactions, efficient light-matter coupling, and sensitivity to the environment. In particular, the considerable strength of the Coulomb coupling between the charge carriers introduces a rich variety of many-body phenomena. In the class of 2D semiconductors, e.g., this leads to the emergence of strongly bound electron-hole quasi-particles, such as excitons, tripons, and biexcitons, with unusually high binding energies and efficient light absorption. In this talk, I will present a study of the excitonic properties of 2D semiconductors, as exemplified in recent works on atomically thin transition metal dichalcogenides [1-4]. The observation of exciton binding energies on the order of 0.5 eV and the marked deviation of the exciton Rydberg series from the hydrogenic model will be discussed. The results reflect both strong carrier confinement and the distinctive nature of dielectric screening in atomically thin materials. I will further describe how carrier doping and strong photo-excitation can profoundly alter the many-body interactions in these 2D systems.

11:15AM B0.00001 Nematic spin correlations in the tetragonal state of uniaxial-strained BaFe$_{2-x}$Ni$_x$As$_2$1, PENGCHENG DAI, Rice Univ — Understanding the microscopic origins of electronic phases in high-transition temperature (high-$T_c$) superconductors is important for elucidating the mechanism of superconductivity. In the paramagnetic tetragonal phase of BaFe$_{2-x}$Ni$_x$As$_2$ (where $T_c$ is $\sim$ 60 K, and even exhibits unusual temperature-induced enhancement. More surprisingly, no coherent excitation was seen to emerge when system is cooled into magnetically ordered state. Nevertheless, spin-wave theory has been applied to interpret the measured spectra, but the agreement of its predictions with the experiment was found to be marginal at best. Here we report the discovery of a coherent magnetic excitation in the magnetically ordered state at low temperature, which coexists with the diffuse, liquid-like magnetic response. This resolves puzzle of surprising absence of coherent excitations associated with magnetic order in FeTe, where emergence of sharp electronic resonance near the Fermi energy has been observed by ARPES. This work was supported by the US DOE under Contract DE-AC02-98CH10886.

1This work is supported by MOST of China, US NSF, and Welch foundation grants.

11:51AM B0.00002 Coexistence of diffuse liquid-like scattering and emergent coherent mode in Fe$_{1+y}$Te, IGOR ZALIZNYAK, DAVID FOBES, ZHIJUN XU, GENDA GU, JOHN TRANQUADA, Brookhaven Natl Lab, ANDREI SAVICI, OVIDIU GARLEAN, DOUGLAS ABERNATHY, Oak Ridge National Lab — Neutron scattering in the chalcogenide parent material FeTe reveals diffuse dynamical magnetic response, suggesting dynamical correlation of the form of only 1-2 lattice repeats. The wave-vector structure of magnetic fluctuations can be best described by a liquid-like state with local order in the form of weakly correlated, co-aligned four-spin plaquettes. Additionally, this dynamical magnetism is extremely robust. It survives to temperatures well above the Neel ordering $T_N$ ~ 60 K, and even exhibits unusual temperature-induced enhancement. More surprisingly, no coherent excitation was seen to emerge when system is cooled into magnetically ordered state. Nevertheless, spin-wave theory has been applied to interpret the measured spectra, but the agreement of its predictions with the experiment was found to be marginal at best. Here we report the discovery of a coherent magnetic excitation in the magnetically ordered state at low temperature, which coexists with the diffuse, liquid-like magnetic response. This resolves puzzle of surprising absence of coherent excitations associated with magnetic order in FeTe, where emergence of sharp electronic resonance near the Fermi energy has been observed by ARPES. This work was supported by the US DOE under Contract DE-AC02-98CH10886.
12:03PM B0.00003 Decoupling neutron resonances from superconducting transition temperatures in NaFe$_{1-x}$Co$_x$As. CHENGLIN ZHANG, Rice University, EGAMI TAKEISHI, University of Tennessee, PENGCHENG DAI, Rice University, RICE UNIVERSITY TEAM, UNIVERSITY OF TENNESSEE TEAM — We report a comprehensive study of the evolution of neutron resonance modes in wide doping range of NaFe$_{1-x}$Co$_x$As. Double resonances, a sharp followed by a broad one, are observed in certain underdoped region. Surprisingly, the sharp resonance energy is nearly unchanged with variation of doping concentrations and therefore $T_c$. In overdoped region without competing phases, single resonance present and is gradually broadening with further increasing doping. Nevertheless, the resonances peak at the same energy while $T_c$ falls half from slightly overdoped one ($T_c=18$ K) to heavily overdoped one ($T_c=9$ K). The decoupling between $E_r$ and $T_c$ indicates unappreciated cooperation which had not been predicted by any theoretical model. Our results manifest the distinct multibarital character in FeSeC, guiding a new direction in the pursuit of a generic connection in diversified unconventional superconductors.

12:15PM B0.00004 Elastic and Inelastic neutron scattering results in heavily Cu doped NaFe$_{1-x}$Cu$_x$As with $x$ approaching 0.5. YU SONG, Rice University, DAVID TAM, Rice Univ, MENG WANG, UC Berkeley, RICE UNIVERSITY TEAM — We performed inelastic neutron scattering on Co-doped LiFeAs material. In 12% Co doped LiFeAs, where $T_c$ is dramatically suppressed, the low energy spin excitation is commensurate at $(p,0)$ point which is different from pure LiFeAs case. Based on the fact that in the material the perfect nesting exists between outer hole pocket and electron pocket and is dominated by $d_{xy}$ orbital, we argue that the superconductivity is actually associated with electron scattering from $d_{xz}/d_{yz}$ orbital and $d_{xy}$ orbital bare contributes to the superconducting pairing.

12:27PM B0.00005 Inelastic neutron scattering study on Co-doped LiFeAs, YU LI, Rice University, DAVID TAM, Rice Univ, Ming WANG, UC Berkeley, Rice University — We performed inelastic neutron scattering on Co-doped LiFeAs. In 12% Co doped LiFeAs, where $T_c$ is dramatically suppressed, the low energy spin excitation is commensurate at $(p,0)$ point which is different from pure LiFeAs case. Based on the fact that in the material the perfect nesting exists between outer hole pocket and electron pocket and is dominated by $d_{xy}$ orbital, a wave that the superconductivity is actually associated with electron scattering from $d_{xz}/d_{yz}$ orbital and $d_{xy}$ orbital bare contributes to the superconducting pairing.

12:39PM B0.00006 Phase diagram of BaFe$_2$(As$_{1-x}$P$_x$)$_2$. DING HU, SHILIANG LI, HUIQIAN LUO, Chinese Academy of Sci (CAS), PENGCHENG DAI, Chinese Academy of Sci (CAS):Rice University — As a unique system of high temperature Iron-based superconductors, recent experimental results indicate that there is a quantum critical point (QCP) around the optimal level in BaFe$_2$(As$_{1-x}$P$_x$)$_2$. We use neutron diffraction, high resolution X-ray scattering and NMR techniques to map out the detailed phase diagram. It is found that the long-range antiferromagnetic (AF) order survives up to the optimal doping level within the instrument resolution. Our results suggest that the evolution of the AF order upon doping in BaFe$_2$(As$_{1-x}$P$_x$)$_2$ is different from that in the electron-doped Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ or Ba(Fe$_{1-x}$Ni$_x$)$_2$As$_2$.

12:51PM B0.00007 Magneto-elastic coupling in detwinned Sr(Fe$_{1-x}$Co$_x$)$_2$As$_2$ by inelastic x-ray scattering. NAOKI MURAI, RIKEN SPing-8 Center and Osaka University, TATSUO FUKUDA, RIKEN SPing-8 Center and JAEA, MASAMICHI NAKAJIMA, TATSUYA KOBAYASHI, Osaka University, HIROSHI UCHIYAMA, RIKEN SPing-8 Center and JASRI, SATOSHI TSUTSUI, JASRI, DAISUKU ISHIKAWA, RIKEN SPing-8 Center and JASRI, HIROKI NAKAMURA, MASAKI MACHIDA, JASRI, SHIGEKI MIYASAKA, SETSUKO TAJIMA, Oska University, ALFRED BARON, RIKEN SPing-8 Center and JASRI — We measured magneto-elastic coupling in Sr(Fe$_{1-x}$Co$_x$)$_2$As$_2$ with different doping levels ($x=0$ and 0.08) using inelastic x-ray scattering with 1.5 meV resolution at SPing-8. The crystals were detwinned by application of in-plane uniaxial stress. This allowed us to measure single domain phonon structure in the magnetically ordered state. We clearly identified the change in the phonon dispersion induced by the onset of magnetic order, with phonon energies depending on orientation of the phonon wave vector relative to the Fe moment. We compare our results to ab-initio pseudo potential calculations: Magnetic calculations give better agreement than non-magnetic calculations, in but in most parts of the Brillouin zone investigated, they overestimate the magnitude of the mode splitting and in fact often fail to predict even the correct sign of the splitting. 1

1:03PM B0.00008 Magnetic phase diagram of Ca(1-x)Co$_x$Fe$_2$As$_2$ ($x \leq 0.1$) single crystals. W.T. JAYASEKARA, B.G. UELAND, ABHISHEK PANDEY, V.K. ANAND, N.S. SANGEETHA, Ames Laboratory U.S. DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA, W. TIAN, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, D.C. JOHNSTON, A. KREYSSIG, A.I. GOLDMAN, Ames Laboratory U.S. DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA. Both CaCo$_2$As$_2$ and CaFe$_2$As$_2$ possess the tetragonal ThCr$_2$Si$_2$ crystal structure and are paramagnetic at room temperature and ambient pressure. Upon cooling, CaCo$_2$As$_2$ shows A-type antiferromagnetic (AFM) order below a Neel temperature of $T_N = 50-70$ K, while CaFe$_2$As$_2$ transitions to an orthorhombic lattice with stripe-type AFM order below $T_N \approx 170$ K. Here, we present results from neutron diffraction experiments on a series of Ca(1-x)Co$_x$Fe$_2$As$_2$ single crystals ($x = 0$ to 0.1) studying the evolution of CaCo$_2$As$_2$'s low-temperature state upon substituting Fe for Co. We find that A-type magnetic order persists for all of the values of $x$ studied with suppressed $T_N$ and ordered moment for increasing Co concentration and present the magnetic phase diagram for the Co rich region.

Work at Ames Laboratory was supported by US DOE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Contract No. DE-AC02-07CH11358. Research conducted at ORNL’s High Flux Isotope Reactor was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, US DOE.

1:15PM B0.00009 Study of lattice distortion in Sr(Fe$_{1-x}$Co$_x$)$_2$As$_2$ single crystals employing high-energy x-ray diffraction. A. SAPKOTA, W.T. JAYASEKARA, ABHISHEK PANDEY, SHREE R. BANJARA, P. DAS, N.S. SANGEETHA, D.C. JOHNSTON, A. KREYSSIG, A.I. GOLDMAN, Ames Laboratory U.S. DOE, Department of Physics and Astronomy, Iowa State University — For the iron arsenide family of superconductors, the interplay between structure, magnetism, and superconductivity is a major theme of research. Among $A$Fe$_2$As$_2$ ($A =$ Ca, Sr, Ba), a difference lies in the strength of magnetoelectric coupling: it is strongest in CaFe$_2$As$_2$ as indicated by strongly coupled first order phase transitions (structural and magnetic) and modest in BaFe$_2$As$_2$ in which the two phase transitions split with Co-substitution. Moreover, similar to the structural transition, the magnetic transition becomes second order with higher Co-concentration. SrFe$_2$As$_2$ shows intermediate behavior. Here we present a temperature-dependent study of the lattice distortion from tetragonal to orthorhombic in Sr(Fe$_{1-x}$Co$_x$)$_2$As$_2$ single crystals through diffraction measurements using x-ray radiation of two energies: 8.047 keV and 100 keV. The lower energy probes a few micrometers down from the surface of the sample whereas the higher energy characterizes the bulk. Details of the lattice distortion obtained with these two probes will be discussed.

The work at Ames Laboratory was supported by US DOE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Contract DE-AC02-07CH11358. This research used resources of Advanced Photon Source, a US DOE, Office of Science User Facility.
Tetragonal-to-orthorhombic lattice distortion and domains in Ca\(\text{Fe}_{1-x}\text{Co}_x\)\_2As\_2 single crystals, A. KREYSSIG, E.C. BLOMBERG, G.S. TUCKER, A. SAPKOTA, S. RAN, S.L. BUD’KO, P.C. CANFIELD, M.A. TANATAR, R. PROZOROV, A.I. GOLDMAN, Ames Laboratory US DOE, Department of Physics and Astronomy, Iowa State University — Similarly to other Fe-based pnictide superconductors, Ca\(\text{Fe}_{1-x}\text{Co}_x\)\_2As\_2 single crystals show a tetragonal-to-orthorhombic lattice distortion that is suppressed with increasing Co concentration. However, in contrast to other Fe-based pnictide superconductors, an unprecedented 45° rotation of the domain patterns in polarized-light microscopic studies has been observed for Co concentrations \(x \approx 0.2\) at temperatures around the onset of antiferromagnetic order and lattice distortion. We present a high-resolution high-energy x-ray diffraction study demonstrating that the observed change in domain arrangement is related to the coexistence of the tetragonal and orthorhombic phases in a well-defined geometric configuration allowed by a special relationship between the lattice parameters of both phases in these compounds.

The work at the Ames Laboratory was supported by US DOE, Office of Basic Energy Sciences, Department of Materials Sciences and Engineering under contract DE-AC02-07CH11358. This research used resources of the Advanced Photon Source, a US DOE, Office of Science User Facility.

Competing magnetic and superconducting order and the role of vortices in iron-based superconductors, B. MENCIA URANGA, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark, J. LARSEN, Department of Physics, Technical University of Denmark. 2800 Kgs. Lyngby, Denmark, G. STIEBER, S.L. HOLM, K. LEFFMANN, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark, C. NIEDERMAYER, Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institute, CH-5232 Villigen, Switzerland, T. WOLF, Karlsruher Institut fuer Technologie, Institut fuer Festkoerperfysik, D-76021 Karlsruhe, Germany, B.M. ANDERSEN, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark — We discuss recent neutron and muSR measurements of the magnetic and superconducting (SC) properties of Co-doped Ba-122 as a function of temperature and external magnetic field \([1]\). Below the \(T_c\), the magnetic and SC order parameters coexist and compete. A magnetic field can significantly enhance the magnetic scattering in the SC state \([1]\). We perform a microscopic modeling of the data by use of a five-band Hamiltonian relevant to iron pnictides. In the SC state, vortices can slow down and freeze spin fluctuations locally. When such regions couple they result in a long-range ordered antiferromagnetic phase producing the enhanced magnetic elastic scattering in agreement with experiments \([1]\). Lastly, we also study the low energy bound states in the vortex core of LiFeAs, where the quasiparticle states in the vortex core can provide useful information about the gap structure \([2]\).

Itinerant ferromagnetism in the As \(4p\) conduction band of Ba\(0_x\)K\(0.4\)Mn\(2As_2\) identified by x-ray magnetic circular dichroism, B. G. UELAND, ABHISHEK PANDEY, A. SAPKOTA, Y. LEE, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, Y. CHOI, D. HASKEL, R. A. ROSENBERG, J. C. LANG, Advanced Photon Source, Argonne National Laboratory, B. N. HARMON, D. C. JOHNSTON, A. KREYSSIG, A. I. GOLDMAN, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University — X-ray magnetic circular dichroism (XMCD) measurements on single-crystal and powder samples of Ba\(0_x\)K\(0.4\)Mn\(2As_2\) show that the ferromagnetism (FM) below \(T_c\) \(\approx 100\) K arises in the As \(4p\) conduction band. No XMCD signal is observed at the Mn \(x\)-ray absorption edges, however, a clear XMCD signal is found below \(T_c\) at the As \(K\) edge which increases with decreasing temperature. The XMCD signal is absent with the beam directed parallel to the crystalline c-axis, indicating that the ordered orbital moment lies in the basal plane of the tetragonal lattice. These results show that the previously reported itinerant FM is associated with the As \(4p\) conduction band and that distinct local-moment antiferromagnetism and itinerant FM coexist at low temperature.

Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences, Division of Materials Sciences & Engineering, under Contract No. DE-AC02-07CH11358. This research used resources of the Advanced Photon Source, a U.S. Department of Energy Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory under Contract No. DE-AC02-06CH11357.

Collapsed tetragonal phase in SrCo\(_2\)As\(_2\) under high pressure, W.T. JAYASEKARA, B.G. UELAND, A. KREYSSIG, ABHISHEK PANDEY, N.S. SANGEETHA, Ames Laboratory U.S. DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA, G. FABBRI, YEJUN FENG, D. HASKEL, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, D.C. JOHNSTON, A.I. GOLDMAN, Ames Laboratory U.S. DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA — SrCo\(_2\)As\(_2\) possesses the same tetragonal ThCr\(_2\)Si\(_2\) structure as the \(\text{AFe}_2\text{As}_2\) (\(A = \text{Ca, Sr, Ba}\)) family of high-temperature superconductors but does not manifest magnetic order or superconductivity down to a temperature of 1.8 K. Nevertheless, inelastic neutron scattering data show the presence of magnetic fluctuations peaked at a wavevector of \((1/2 1/2 1)\), which corresponds to the stripe antiferromagnetic propagation vector found for \(\text{AFe}_2\text{As}_2\). Here, we present evidence from high-energy x-ray diffraction experiments which show that SrCo\(_2\)As\(_2\) undergoes a transition to a collapsed-tetragonal phase characterized by a 10% reduction of the \(c\)-lattice parameter for an applied pressure of 5 GPa at 7 K. This fascinating result opens another path for studying the role of magnetic ordering, spin fluctuations, and magnetoelastic coupling in the development of superconductivity in the Fe-pnictides and related materials.

Monday, March 2, 2015 11:15AM - 2:15PM —
Session B1 DMP: Focus Session: Graphene - Point Defects and Structural Defects 001A - Benjamin Butz, Friedrich Alexander Universitaet Erlangen

Spontaneous Boron-doping of Graphene at Room Temperature, LIDA PAN, Vanderbilt Univ, YANDE QUE, SHIXUAN DU, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, SOKRATES T. PANTELIDES, Vanderbilt Univ — Doping graphene with boron or nitrogen is an effective way to modify its electronic properties. However, the reaction barrier for introducing these impurities is quite high, making the doping process difficult. In this work, we propose a low-energy reaction route derived from first-principles calculations and subsequently validated by experiments. The calculations show that, when graphene is placed on a ruthenium substrate and exposed to atomic boron, boron atoms can incorporate substitutionally into the graphene sheet with an energy barrier about 0.1 eV, displacing carbon atoms below the graphene sheet where they migrates away. This result suggests that spontaneous doping by boron can take place at room temperature. Following the prediction, we grew high-quality graphene on the Ru(001) surface and then expose it to B\(_2\)H\(_6\) which decomposes into atomic boron. XPS and STM results indicate that boron dopes graphene substantially without disturbing the graphene lattice, confirming the theoretical predictions. Doping by nitrogen and co-doping by B and N will also be discussed.
11:27AM B1.00002 Boron Substitution in Disordered Graphene-like Carbon. JOE SCHAEPPERKOETTER, ANDREW GILLESPIE, CARLOS WEXLER, PETER PFEIFER, University of Missouri, MATERIALS RESEARCH INSTITUTE—MISSOURI S&T COLLABORATION—X-ray photoelectron spectroscopy was used to determine both the elemental composition of boron doped carbons as well as gain insight into the arrangement of atoms in the material. The hypothesized arrangement of atoms is a direct substitution of boron for carbon into a graphene like sheet, maintaining the hexagonal honeycomb lattice of sp² sigma bonds. Such a boron atom would have an electronic configuration of 1s²(sp³)². With a graphitic carbon atom, the p_st orbitals are maintained and participate in mobile pi bonds with neighboring carbon atoms, as understood in the aromatic model. Boron, however, would require a charge donation to fill its p_z orbital. Thus, three possible models are proposed for the out of plane electron density: (1) the orbital remains unoccupied and the boron is a free radical, (2) charge is donated from a neighboring atom and the boron atom is ionic, (3) the delocalization of charge in the aromatic system results in a partial charge transfer with an effective charge somewhere between neutral and anionic. Our results suggest that boron is not in an anionic state, and, by doing a quantitative and simultaneous analysis from multiple elemental spectra, we conclude that no more than 2 wt% of boron is being substitutionally doped into the system.

11:39AM B1.00003 Stabilities and electronic structures of B and N defects in bilayer graphene. YOSHITAKA FUJIMOTO, SUSUMU SAITO, Department of Physics, Tokyo Institute of Technology — Since its discovery, atomically thin monolayer of graphene has attracted great attention both scientifically and technologically since they exhibit different electronic structures from monolayer graphene. One of the effective ways to tune the electronic properties of carbon-based nanomaterials is to dope them with B and N atoms. Here, we study energetics and electronic properties of B and N defects in bilayer graphene, based on the first-principles density-functional theory. All kinds of dopant sites and stacking patterns (AA and AB) of bilayer sheets are studied and the site-dependent and independent behaviors of the dopants are found. We also report the electronic structures and study the STM images of doped bilayer graphene. While B-doped and N-doped defects show different STM images, the STM images are shown to be similar for AA and AB stacking patterns in both B- and N-doped defect cases.

11:51AM B1.00004 Imaging the Individual Nitrogen Dopant Atoms in Graphene with Thermoelectric Measurements. HO-KI LYEO, SANGHEE CHO, Korea Research Institute of Standards and Science, EUI-SUB LEE, YONG-HYUN KIM, Korea Advanced Institute of Science and Technology, JUNSTIN BULT, JEFFREY BLACKBURN, National Renewable Energy Laboratory — Chemical doping of nitrogen has been known as a means of modifying the electronic structure of graphene grown on a Cu substrate. We used scanning thermoelectric microscope to investigate the influence of individual nitrogen dopant atoms in monolayer graphene. Nitrogen-doped graphene was grown on a single crystal Cu substrate by using the chemical vapor deposition of pyridine molecules that contain a nitrogen atom substituting a carbon atom in the carbon hexagon. Thermoelectric voltage measurements, which have been shown to be differentially sensitive to the Fermi energy state, can produce two-dimensional images of electronic signature near the individual nitrogen dopants on the atomic scale. The measurements yielded a more complicated and extended modification of electronic structure than previously measured by using tunneling spectroscopy, which can be accounted for by the theoretical simulation and experimental evidences of nitrogen inclusion obtained from Raman and XPS measurements.

12:03PM B1.00005 Manipulate the Doping of Graphene at Nanoscale with Intercalated Oxygen. XIN ZHANG, HONG LUO, Department of Physics, University at Buffalo, the State University of New York, LEI LIU, GONG GU, Department of Electrical Engineering and Computer Science, the University of Tennessee, DANIELE STRADI, MADS BRANDBYGE, Department of Micro- and Nanotechnology, Center for Nanostructured Graphene, Technical University of Denmark — We have created nanoscale p- and n-doped graphene regions side by side, by partially removing the oxygen between the graphene and the Cu foil growth substrate intercalated upon elongated air exposure. The Cu foil surface is almost exclusively (100) oriented, and the removal of intercalated oxygen is by thermal annealing. Scanning tunneling microscopy (STM) reveals a 0.72 × 0.72 nm square superlattice in the single layer (1L) graphene/O/Cu(100) structure, assigned to be Cu(2√2 × 2√2)R45°-O, which has not been reported so far. Graphene with intercalated oxygen underneath is p-doped while the surrounding graphene areas, directly in contact with the copper surface, are n-doped. Comparing the scanning tunneling spectra (STS) of the two types of regions, we show a charge transfer-induced shift of the electronic structure. Such a shift is also observed between p- and n-doped twisted bilayer (2L) graphene regions, where the van Hove singularity (vHS) peaks are used as markers to precisely determine the energy shift. Across the boundaries between the p- and n-doped regions, the shift of the electronic structure is spatially resolved, showing the vanishing and reappearance of the vHS peaks. The experimental observations are consistent with first-principles calculations.

12:15PM B1.00006 Symmetry protected zero modes in graphene grain boundaries. MADELEINE PHILLIPS, E.J. MELE, University of Pennsylvania — We study electronic states in graphene grain boundaries using topological band theoretic arguments. Using bulk eigenstates, we calculate a geometric phase that counts the number of zero modes in projected bulk gaps. We argue that these localized zero modes are protected by a hidden chiral symmetry. We apply our topological theory to various grain boundary geometries and corroborate our results using numerical calculations on a tight binding lattice.

12:27PM B1.00007 Conserved Bonding Sequences and Atomic Strain Fields of Graphene Grain Boundaries. HAIDER RASOOL, UC Berkeley, COLIN OPHUS, Lawrence Berkeley National Laboratory, ZIANG ZHANG, Rice University, MICHAEL CROMMIE, UC Berkeley, BORIS YAKOBSON, Rice University, ALEX ZETTLUC Berkeley — Grain boundaries in polycrystalline materials have significant impact on their bulk mechanical properties. The detailed arrangement of atoms and bonding at the boundary dictate these properties and their differences from bulk single crystal behavior. In this work, we use aberration corrected high resolution transmission electron microscopy imaging to study the structure of graphene grain boundaries. By mapping the exact atomic positions of the carbon lattice, we visualize atomic scale strain organization in the material. We find that grain boundaries are comprised of conserved bonding sequences that can appear as periodic or aperiodic building blocks that give rise to similar strain behavior at the boundary. Using molecular dynamics fracture simulations, we predict that experimentally observed grain boundary structures will maintain strengths that are comparable to ideal theoretical grain boundaries.

12:39PM B1.00008 Scattering properties of extended structural defects in graphene. DANIEL GUNLYCZE, CARTER WHITE, Naval Research Laboratory — A challenge preventing widespread use of graphene in nanoelectronic devices is the absence of a band gap at the Fermi level. Without a practical band gap, other ways to make electronic transport switchable are needed. One promising possibility is to use parallel graphene transport barriers to generate a transport gap. This approach requires transport barriers that are penetrable and fairly reflective. Such barriers could be formed by extended structural defects such as grain boundaries or line defects. Herein, we present scattering properties in the specular regime of a generic transport barrier described by an effective barrier coupling, an effective barrier potential, and an asymmetry parameter. We also show that these scattering properties could be probed without the need for lateral transport measurements. Instead, we suggest the use of scanning probe techniques measuring the undulations in the local density of states. That the transmissivity could be probed in equilibrium when no current flows through the barrier is a manifestation of quantum interference at the barrier.

12:51PM B1.00009 Effect of defects produced by electron irradiation on the electrical properties of graphene

**ADRIAN BALAN, JULIO ALEJANDRO RODRIGUEZ-MANZO, MATTHEW PUSTER, MARUA DRNDIC**, Univ of Pennsylvania — We present a study of the effects of the defects produced by electron irradiation on the electrical and crystalline properties of graphene. We realized back or side gated electrical devices from monolayer graphene crystals suspended on a 50nm SiNx. The devices are exposed to electron irradiation inside a 200kV transmission electron microscope (TEM) and we perform in situ conductance measurements. The number of defects and the quality of the crystalline network obtained by diffraction are correlated with the observed decrease in mobility and conductivity of the devices. We observe a different behavior between type of monolayer materials, and try to associate with different conduction with defect models. [1] Towards sensitive graphene nanoribbon-nanopore devices by preventing electron beam induced damage. M. Puster, J. A. Rodriguez-Manzo, A. Balan, M. Drndic. ACS Nano,10.1021/nn405112m.

1:03PM B1.00010 Magnetic Defects in Graphene Quantum Dots

**SRINIVASA RAO SINGAMANENI**, North Carolina State University, JOHAN VAN TOL, National High Magnetic Field Laboratory, Florida State University, 1800 E. Paul Dirac Drive, Tallahassee, Florida 32310, USA, RUQUAN YE, JAMES M. TOUR, Department of Chemical Engineering and Materials Science, 65malley Institute for Nanoscale Science and Technology, Rice U — Spin-coherence time in graphene quantum dots (GQDs), which are highly sought-after spintronics materials is controlled by defects. To that end, the nature of the (spin) defect centers in these GQDs is important. Electron spin resonance (ESR) spectroscopy is an ideal local probe to investigate the spin properties of GQDs. ESR investigations are carried out on GQDs [1] as a function of temperature (6-290 K) at two distinct microwave high frequencies 292.2 and 336 GHz. The ESR signal does not show power dependence at 292.2 GHz, 6K, could be adequately described with three distinct components using Lorentzian line shape. From the experimental findings together with computer-aided simulations, we have identified them as one broad (700 Gauss) and narrow (60 Gauss) carbon-centered paramagnetic defect centers and the third one as Mn$^{2+}$ signal, which is an extrinsic impurity. The temperature dependence of carbon-derived spin centers in GQDs resembles to that of conduction electrons, in contrast to the localized spins observed by us earlier [2-5] in graphene nanoribbons.

**BI RU WU**, Department of Natural science, Center for General Education, Chang Gung University, CHIH-KAI YANG, Graduate Institute of Applied Physics, National Chengchi University — We investigated a variety of configurations of hydrogen-vacancy (HV) chains in graphane with density functional theory. We found the configurations that each of zigzagged HV chains separated by one or more H chains exhibit nonmagnetic conductor or has a tiny gap. Once as the neighbored zigzag HV chains blocked by isolated H atoms, the structure transformed from a nonmagnetic conductor into a magnetic semiconductor. If the HV chains are continuously distributed, it looks like a graphene nanoribbon embedded in graphane. The zigzag edged embedded graphene nanoribbons also show antiferromagnetic. An additional H atom on the ribbon can tune the band gap and generate magnetic moment; moreover, if bare C atoms are present outside the nanoribbon also have similar effect. The results will be helpful for designing graphane-based nanoelectronic devices.

1:27PM B1.00012 Characterizing Defects Generated in Graphene by Scanning Probe Microscopy

**JONATHON DAVID WHITE**, Yuan Ze University, Taiwan, HSIAO-MEI CHIEN, MIN-CHIANG CHUANG, HUNG-CHIEH TSAI, National Central University, Taiwan, HUNG-WEI SHUI, LO-YUEH CHANG, CHIA-HAO CHEN, National Synchrotron Radiation Research Center, Taiwan, SHENG-WEI LEE, WEI-YEN WOON, National Central University, Taiwan — Graphene was prepared by chemical vapor deposition (CVD). Defects with differing topographical and tribological properties were then created by scanning probe lithography (SPL) under ambient conditions. The nature of these defect structures was then investigated by micro-Raman ($\mu$-RS) and micro-X-ray photoelectron ($\mu$-XPS) spectroscopy. Investigation of these structures suggests that, despite their physical differences, similar defects are present in both structures. In particular, $\mu$-RS indicated that the ratio of the defect Raman peaks and the effective $\alpha_g$, in stark contrast to the atomic case where $\alpha_g \approx 170$ is experimentally inaccessible. However due to the significant screening in graphane, attaining the supercritical regime is challenging. We will report on a new method to create charge centers within the graphene layer whose charge, Z, can be tuned to exceed the critical value. Using low temperature scanning tunneling microscopy and spectroscopy we study the evolution in the local electronic structure of graphene as a function of Z, from charge neutrality to the supercritical regime, which is identified by comparing to numerical simulations.

1:39PM B1.00013 Supercriticality of charge centers in graphene probed with scanning tunneling microscopy

**YUHANG JIANG, JINHAI MAO, GUOHONG LI, Rutgers University, Department of Physics and Astronomy, 136 Frelinghuysen Road, Picataway, NJ 08855 USA, D. MOLDOVAN, M. RAMEZANI MASIR, F. M. PEETERS, Departement Fysica, Universiteit Antwerpen Groenenborgerlaan 171, B-2020 Antwerpen, Belgium, EVA Y. ANDREI, Rutgers University, Department of Physics and Astronomy, 136 Frelinghuysen Road, Picataway, NJ 08855 USA — The massless Dirac fermion carriers in graphene, with their effective fine structure constant, $\alpha_g$, being of order unity, provide fertile ground for exploring the physics of ultra-relativistic particles in the strong coupling limit.In particula, positive charge $Z$ embedded in graphene is expected to exhibit supercricital behavior already for $Z>Z_c=-5/\alpha_g$, in stark contrast to the atomic case where $Z_c \approx 170$ is experimentally inaccessible. However due to the significant screening in graphane, attaining the supercritical regime is challenging. We will report on a new method to create charge centers within the graphene layer whose charge, Z, can be tuned to exceed the critical value. Using low temperature scanning tunneling microscopy and spectroscopy we study the evolution in the local electronic structure of graphene as a function of Z, from charge neutrality to the supercritical regime, which is identified by comparing to numerical simulations.

1:51PM B1.00014 Supercriticality and screening effects in graphene. JINHAI MAO, YUHANG JIANG, GUO-HONG LI, Rutgers University, Department of Physics and Astronomy, 136 Frelinghuysen Road, Piscataway, NJ 08855 USA, D. MOLDOVAN, M. RAMEZANI MASIRI, F.M. PEETERS, Departement Fysica, Universiteit Antwerpen, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium, EVA Y. ANDREI, Rutgers University, Department of Physics and Astronomy, 136 Frelinghuysen Road, Piscataway, NJ 08855 USA — The chiral nature of charge carriers in graphene prohibits backscattering and prevents confinement by electrostatic potentials, resulting in high electronic mobility and unusual phenomena such as Klein tunneling. This picture breaks down in the presence of charge impurities exceeding a critical value $Z_{c}$, whereas qualitative change in behavior leads to the capture of electrons akin to atomic collapse in 3D atoms. Although in graphene $Z_{c}$ is substantially lower than in 3D atoms, attaining the supercritical regime is difficult because screening can significantly reduce the effective charge of the impurity. We have devised a method of inducing a controllable amount of localized charge whose strength can be tuned by adjusting screening through a gate voltage or a magnetic field. The effect of the impurity on the local electronic structure was monitored with low temperature scanning tunneling microscopy and spectroscopy and with Landau level spectroscopy. By following the evolution of the spectra as a function of the induced charge and comparing with numerical simulations, we are able to pinpoint the onset of atomic collapse and beyond, providing new insights into the physics of supercriticality.

2:03PM B1.00015 Observation of vacancy-induced suppression of electronic cooling in defected graphene. XIAOSONG WU, QI HAN, YI CHEN, GERUI LIU, DAPENG YU, Peking Univ — Previous studies of electron-phonon interaction in impure graphene have found that static disorder can give rise to an enhancement of electronic cooling. We investigate the effect of dynamic disorder and observe over an order of magnitude suppression of electronic cooling compared with clean graphene. The effect is stronger in graphene with more vacancies, confirming its vacancy-induced nature. The dependence of the coupling constant on the phonon temperature implies its link to the dynamics of disorder. Our study highlights the effect of disorder on electron-phonon interaction in graphene. In addition, the suppression of electronic cooling holds great promise for improving the performance of graphene-based bolometer and photo-detector devices.

11:15AM B2.00001 Improved Performance in MoS$_2$ Field-Effect Transistors Contacted by Highly Doped Graphene Electrodes and Passivated by Hexagonal Boron Nitride. HSUN-JEN CHUANG, ZHIXIAN ZHOU, Wayne State University — A major challenge for developing semiconducting transition-metal-dichalcogenide (TMD)-based electronic devices is that TMDs tend to form a substantial tunneling or Schottky barrier (SB) with most metals commonly used for making electrical contacts, while low resistance Ohmic contacts are needed for exploring intrinsic transport properties of the channel material, and performance limits of realistic devices. We have fabricated low-resistance contacts to MoS$_2$ field-effect transistors by using graphene as work function tunable electrode material. To minimize the Schottky barrier height at the MoS$_2$/graphene junction and the contact resistance, both electrostatic and surface charge transfer doping methods were used to selectively dope the graphene electrodes. Substantial improvement of device performance was observed in devices with highly n-doped graphene electrodes. Four-probe electrical transport measurement was performed on MoS$_2$ devices with the active channel stacked between atomically flat hexagonal boron nitride (hBN) to further investigate the intrinsic performance limit of MoS$_2$ as a channel material.

1This work was supported by NSF (DMR-1308436).

11:27AM B2.00002 Electrical and optical properties of chemically doped p-type MoS$_2$. JOONKI SUH, University of California, Berkeley, TAE-EON PARK, Korea Institute of Science and Technology, DER-YUH LIN, National Chianghua University of Education, SEFAATTIN TONGAY, Arizona State University, JUNQIAO WU, University of California, Berkeley — Molybdenum disulfide is a model example of two-dimensional semiconductors, holding promise for applications in optoelectronic devices and field-effect transistors. So far, however, its practical use has been exclusively restricted to native, n-type doping. Here we experimentally demonstrate stable p-type conduction in molybdenum disulfide substitutionally doped with niobium. This chemical doping leads to a degenerate hole density of $\sim 1.8 \times 10^{14}$ cm$^{-2}$ and enables gate-tunable van der Waals p-n homojunctions. Also, the p-type monolayer molybdenum disulfide exhibits a greatly enhanced and broadened photoluminescence compared to that acquired from undoped monolayers. Our study demonstrates the stable p-type doping in molybdenum disulfide, and also reveals an effective way to tailor optical and electrical properties of two-dimensional semiconductors with extrinsic dopants.

11:39AM B2.00003 Electrostatic control of polarity of $\alpha$-MoTe$_2$ transistors with dual top gates. SHU NAKAHARAI, MAHITO YAMAMOTO, Natl Inst for Materials Sci, KEIJI UENO, Saitama Univ, YEN-FU LIN, SONG-LIN LI, KAZUHITO TSUKAGOSHI, Natl Inst for Materials Sci — Transition metal dichalcogenides have been expected for future applications in nanoelectronics due to their unique features of the atomically-thin structure. Using semiconducting $\alpha$-molybdenum ditelluride ($\alpha$-MoTe$_2$), we realized field effect transistors (FETs) in which the polarity (n- or p-type) can be electrostatically controlled without impurity doping. The fabricated device had a pair of top gates (aluminum electrode on silicon dioxide) attached in series with a gap length of 100 nm in between. We experimentally performed transistor operations in both n-FET and p-FET modes in a single device by changing the voltage applied to one of the two top gates, which determined the transistor polarity, and sweeping the bias of the other gate. The demonstrated reversibility of the transistor polarity will contribute to the renovated architecture of logic circuits with lower numbers of transistors and hence the lower power consumption than the conventional technology.
11:51AM B2.00004 Field-Effect Transistors Based on Few-Layered Ambipolar MoSe$_2$ and α-MoTe$_2$. DANIEL RHODES, Florida State University, NIHAR PRADHAN, NHMFL, SIMIN FENG, Pennsylvania State University, BYOUNG-HEE MOON, VAN XIN, NHMFL, SHARHRIAR MEMANDAN, MUNANDIS NCHIDUMA, LAKSHMI BHASKARAN, PSU, STEPHEN HILL, NHMFL, HUMBERTO TERRONES, Rensselaer Polytechnic Institute, MAURICIO TERRONES, PSU, AJAYAN PULICKEL, Rice University, LUIS BALICAS, NHMFL. We report a room temperature study on the electrical responses of field-effect transistors (FETs) based on few-layered MoSe$_2$ and MoTe$_2$, grown by chemical vapor transport, mechanically exfoliated onto SiO$_2$. MoSe$_2$ FETs electrically contacted with Ti display ambipolar behavior with current on/off ratios up to $10^6$ for both hole and electron channels. For both channels the Hall effect indicates Hall mobilities $\mu_H \approx 250$ cm$^2$/Vs, which are comparable to the corresponding field-effect mobilities, $\mu_{FE} \sim 175$ cm$^2$/Vs, evaluated through two-terminal field-effect configuration. MoTe$_2$ field-effect transistors are observed to be hole-doped, displaying on/off ratios of $\sim 10^8$ and subthreshold swings of $\sim 140$ mV per decade. Our results suggest that MoSe$_2$ is a good candidate for single atomic layer p-n junctions and for low-power, complementary logic applications, with MoTe$_2$ having similar properties. However, in MoTe$_2$ we observe a field-effect mobility of only $\mu_{FE} \sim 20$ cm$^2$/Vs in a bilayer device and $\sim 27$ cm$^2$/Vs in seven layers.

12:03PM B2.00005 ABSTRACT WITHDRAWN

12:15PM B2.00006 Conduction and Valence Band Offsets in WSe$_2$-Graphene Heterostructures. KOYOUNGHWA KIM, STEFANO LARENTIS, BABAK FALLAHAZAD, KAYOUNG LEE, JIAMIN XUE, DAVID DILLEN, CHRIS CORBET, EMANUEL TUTUC, Univ of Texas, Austin. We investigate the electron transport in graphene-WSe$_2$ heterostructures realized using a layer-by-layer transfer technique. Lateral electron transport shows ambipolar behavior characteristic of graphene, with a marked saturation at high positive (negative) gate bias, associated with the population of the conduction (valence) band in WSe$_2$. The graphene carrier density dependence on gate bias was extracted from magneto-transport measurements. Using WSe$_2$ as a top dielectric in dual-gate graphene field-effect transistors, we determine the WSe$_2$ dielectric constant along the c-axis. By combining the graphene density dependence on gate bias in back-gated graphene-WSe$_2$ heterostructures with the WSe$_2$ dielectric constant, we determine the offset between the graphene charge neutrality point and the WSe$_2$ conduction and valence bands.

12:27PM B2.00007 Strain induced change in electronic and thermoelectric properties in few layers of MoS$_2$. TRIBHUWAN PANDEY, SWASTIBRATA BHATTACHARYYA, ABHISHEK K. SINGH, Materials Research Centre, Indian Institute of Science, Bangalore. The sensitivity of the electronic and thermoelectric properties of MoS$_2$ on application of strain can open up a variety of applications in the emerging area of straintronics. Using first principles calculations, we investigate the effect of normal compressive (NC), bi-axial compressive (BC), and bi-axial tensile (BT) strain on the electronic properties of few layered MoS$_2$. Regardless of the manner of strain, a reversible semiconductor-to-metal transition is observed in this material. We further show that under NC strain, the inter-layer interactions between Mo-$d_{yz}$ and S-$p_y$ causes the S-M transition, whereas under BC and BT strain it is caused by the strong hybridization of the intra-layer Mo-$d_{x^2-}z^2$ and S-$p_z$ orbitals and Mo-$d_{z^2}$ and S-$p_y$ orbitals, respectively. We also study number of layer (nL) and strain dependent transport properties using Boltzmann transport theory. Our study reveals that the 3L and 2L-MoS$_2$ emerge as the most efficient thermoelectric materials under NC and BT strain, respectively. The concept proposed from our study can also be extended to other semiconducting TMDs owing to similar crystal structure and electronic properties.

12:39PM B2.00008 Tuning the Schottky barrier heights at MoS$_2$metal contacts: a first-principles study. MOJTABA FARMANBAR, GEERT BROCKS, MESA+ Institute for Nanotechnology, University of Twente, The Netherlands. The nature of the Schottky barrier at metal contacts with the two-dimensional semiconductor MoS$_2$ is controversial. Using first-principles DFT calculations we show that the Schottky barrier height (SBH) for high work function (> 4.7 eV) metals typically obeys the Schottky-Mott limit, provided that a potential step that arises at the metal-MoS$_2$ interface is taken into account. It suggests that selecting a metal with an appropriate work function may reduce the SBH to zero. However, we find that for low work function metals the Fermi level is pinned below the conduction band edge of MoS$_2$, leading to SBHs of 0.1-0.3 eV. We attribute the pinning to the metal-MoS$_2$ interaction at the interface perturbing the electronic structure of MoS$_2$, and causing a broadening of the MoS$_2$ conduction band edge. Inserting a monolayer of boron nitride (BN) between the metal surface and the MoS$_2$ layer disrupts this interaction. In addition the BN layer effectively decreases the work function, thereby enabling a line-up of the Fermi level with the MoS$_2$ conduction band with a vanishing SBH.

12:51PM B2.00009 Structural and transport properties of finite length grain boundaries in two-dimensional materials. YUHANXI WANG, VINCENT CREPSI, Pennsylvania State University. Grain boundaries in two dimensional materials such as graphene and monolayer transition metal dichalcogenides are a fundamental issue of the material growth from a monocrystalline ground state. We show that when 2D materials are grown on substrates with curved surfaces, grain boundaries produced are self-intersections are in fact the ground state. They screen out the curvature imposed by the substrate and form finite length grain structures, terminating with cone and saddle shapes of partial disclinations. The structural stability and transport properties of finite length grain boundaries are studied at the tight-binding level. Every dislocation in the grain boundary contributes an intrinsic pseudo-flux and induces loop currents during transport. We further show that transport properties depend sensitively on the number of dislocations in the grain boundary.

1:03PM B2.00010 Intrinsic Electron and Hole Transport in Channel Passivated WSe$_2$ Field-Effect Transistors with Graphene Contacts. HSUN JEN CHUANG, Wayne State University, NIRMAL JEEVI GHIMIRE, JIAQIANG YAN, DAVID MANDRU, The University of Tennessee, Knoxville and Oak Ridge National Laboratory, ZHIHUI ZHOU, Wayne State University. We report electrical transport measurement of high-quality WSe$_2$ field-effect transistors. As a nearly intrinsic semiconductor with a relatively large bandgap, WSe$_2$ tends to form substantial Schottky barriers with common contact metals for both electron and hole channels, which obstructs the charge injection especially at low temperatures. In this work, we use highly n- and p-doped graphene as an electrode material to form low resistance electrical contacts to the electron and hole channels, respectively. To minimize surface and interface scattering, hexagonal boron nitride was used to passivate both the top and bottom surfaces of the WSe$_2$ channel. Four-terminal transport measurement was carried out for a wide temperature range to understand the intrinsic transport properties of atomically thin WSe$_2$. Field-effect transport and effective mobility for both electron and hole channels as well as their temperature dependence will be discussed.

This work was supported by NSF (DMR-1308436).

1:29PM B2.00011 Electronic and Optical Properties of MoS$_2$ and its Heterostructures. JUN JUN LIU, TSUYOSHI TAKAMA, Masayuki URASHIMA, Jun-roy KIM, Masaaki NAKAI, Tatsuo MIYASAKA, Hiroyuki NAKAJIMA, and Toyoki KITAO. University of Tokyo, Japan. Using angle-resolved photoemission spectroscopy, we study carrier mobility in few-layer MoS$_2$. We show that carrier mobility can be enhanced by the interface interaction between MoS$_2$ and MoO$_3$. It is found that the carrier mobility is improved when the interface interaction is strengthened under the in-plane tension. The enhancement of the carrier mobility is attributed to the interface interaction between MoS$_2$ and MoO$_3$.
1:15PM B2.00011 The Effect of Substrate on the Electron Transport Properties of MoS₂ Field-Effect Transistors¹ — BHIM CHAMALAGAIN, HSUN-JEN CHUANG, MEEGHAGE MADUSANKA PERERA, ZHIXHRAN ZHOU. Wayne State University — Substrate plays an important role in the performance of field-effect transistors (FETs) with two-dimensional transition metal dichalcogenide (TMD) channels. In this work, we systematically study the transport properties of few-layer MoS₂ FETs consistently fabricated on various substrates including SiO₂, Al₂O₃, SiO₂ modified by octadecyltrimethoxysilane (OTMS) self-assembled monolayers (SAMs), and hexagonal boron nitride (hBN). Standard four-probe electrical transport measurement was carried out at temperatures ranging from 77 K to room temperature to understand the scattering mechanism. Surprisingly, the room temperature mobility extracted from devices on different substrates is nearly the same. In contrast, a substantially higher mobility is observed in MoS₂ devices on clean hBN substrates at low temperatures. The results of various sources of scattering originating from the substrate and the channel/substrate interface such as charged impurities, charge traps, surface roughness, and remote surface optical phonons will be discussed.

¹This work was supported by NSF (No. ECCS-1128297) and Thomas C. Rumble Fellowship Award.

1:27PM B2.00012 Enhanced mobility electrons at the monolayer / multilayer MoS₂ homo-interface¹ — Y. JIA, E.J. LENFERINK, T. STANEV, N.P. STERN. Department of Physics and Astronomy, Northwestern University, Evanston, IL, US 60208 — Energy band alignment at interface of heterostructures can give rise to non-trivial local electronic structure and charge states with low dimensionality. In transition metal dichalcogenides (TMDcS), the optical band gap depends on the number of 2D crystal layers, transitioning from 1.29 eV in bulk to 1.88 eV for 60208 — Energy band alignment at interface of heterostructures can give rise to non-trivial local electronic structure and charge states with low dimensionality. In transition metal dichalcogenides (TMDcS), the optical band gap depends on the number of 2D crystal layers, transitioning from 1.29 eV in bulk to 1.88 eV for a monolayer of MoS₂, for example, and providing the possibility to create unusual charge state at the monolayer/multilayer homo-interface. Here, we examine the boundaries between MoS₂ monolayers and multilayers using scanning photocurrent microscopy and gate-dependent transport. Enhanced photocurrent and conductance were observed at the 1D homo-interface, which can be explained as accumulated carriers in the bent-band region of the junction. Our heterojunction modeling suggests a high local carrier density and enhanced mobility at the homo-interface. Our work presents an opportunity to achieve a 1D electron state in a homojunction and a pathway to break the mobility limit of TMDC monolayer transistors.

1:39PM B2.00013 High Powerfactor in single and few-layer MoS2 — YING WANG, YU YE, KEDAR HIPPAL-GAONKAR, YUAN WANG, XIANG ZHANG, University of California, Berkeley — The thermoelectric effect enables conversion between thermal and electrical energy, and provides one way to extract energy from waste heat. The efficiency of a thermoelectric device can be defined by a dimensionless figure of merit given by $ZT = S^2σT/k$. In order to achieve efficient thermoelectric devices, $S^2σ$ needs to be kept high by optimizing the interplay between the $S$ and $σ$. The thin layered transition-metal dichalcogenide semiconductor MoS₂ has attracted great interest because of its two dimensional density of states and relatively high mobility, which could give a large $S$ and $σ$. Here we study on pristine exfoliated 1L-, 2L- and 3L MoS₂ samples by simultaneous measurement of the Seebeck coefficient$(S)$ and two probe electrical conductivity using nano-fabricated heater and thermometer. It firstly shows that atomic thin MoS₂ which has a large effective band masses $(m^*)$ as well as high mobilities $(μ)$, increases the powerfactor $S^2σ/τ$ as high as 8.5 mWm⁻¹K⁻² at room temperature (twice as high as commercially usedBi₂Te₃). Further, we show for the first time that the confined two-dimensional density of states of the conduction band can be studied in monolayer MoS₂ by measuring the gate-dependent Seebeck voltage.

1:51PM B2.00014 Carrier injection in van der Waals multilayer systems — MARCELO KURODA, CHRISTOPHER COGER, Auburn University — Carrier injection is critical for the use of two-dimensional material systems like transition metal dichalcogenides (TMD) or graphene in electronic devices. Here we use first principles calculations (within the density functional theory) to quantify and classify the contact formed between metals and TMD multilayer systems. In particular we study the cases of multilayer MoS₂ and MoSe₂ with different metal electrodes (e.g. Pd, Au, Ti). We find different behaviors depending on the choice of metal, thickness and electric field. An analytical model is produced accounting for the Fermi level pinning and the layer quantum capacitance. This atomistic description also sheds light on the ambipolar behavior observed in these systems and the gate-dependent contact resistance in field effect transistors.

2:03PM B2.00015 Ambipolar conduction in MoS₂/WSe₂ hetero-bilayers — HEMA CHANDRA PRAKASH MOVVA, SANGWOO KANG, AMRITESH RAI, SANJAY BANERJEE, Microelectronics Research Center, The University of Texas at Austin — Recent interest in layered semiconductors, and the ability to assemble them into artificial heterostructures with atomically sharp interfaces has opened up new avenues for the design of future electronic devices. In this work, we fabricated vertical heterostructures of exfoliated monolayer MoS₂ and monolayer WSe₂ using a facile flake pick-up-and-place technique, and studied their optical and electrical properties. Photoluminescence measurements showed evidence of indirect excitons at ~1.55 eV, indicating a clean interface between the two layers. We observed back-gate tunable, layer-selective ambipolar conduction in field effect transistors (FETs) made using these hetero-bilayers, with e-transport occurring through the MoS₂, and h-transport through WSe₂. The addition of a top-gate using a thin hBN dielectric further enabled selective operation of the hetero-bilayer FET as an n-FET/p-FET depending on the back-gate bias.

Monday, March 2, 2015 11:15AM - 1:39PM — Session B3 FIP: Invited Session: Condensed Matter Physics in Latin America I 002AB - Alex de Lozanne, University of Texas at Austin

11:15AM B3.00001 An overview of Experimental Condensed Matter Physics in Argentina by 2014, and Oxides for Non Volatile Memory Devices: The MeMOSat Project — PABLO LEVY, CNEA +CONICET — In the first part of my talk, I will describe the status of the experimental research in Condensed Matter Physics in Argentina, biased towards developments related to micro and nanotechnology. In the second part, I will describe the MeMOSat Project, a consortium aimed at producing non-volatile memory devices to work in aggressive environments, like those found in the aerospace and nuclear industries. Our devices rely on the Resistive Switching mechanism, which produces a permanent but reversible change in the electrical resistance across a metal-insulator-metal structure by means of a pulsed protocol of electrical stimuli. Our project is devoted to the study of Memory Mechanisms in Oxides (MeMO) in order to establish a technological platform that tests the Resistive RAM (ReRAM) technology for aerospace applications. A review of MeMOSat's activities is presented, covering the initial Proof of Concept in ceramic millimeter sized samples; the study of different oxide-metal couples including (LaPr)₂/3Ca₁/3MnO, La₂/3Ca₁/3MnO₃, YBa₂Cu₃O₇, TiO₂, HfO₂, MgO and CuO; and recent miniaturized arrays of micrometer sized devices controlled by in-house designed electronics, which were launched with the BuzzSat01 satellite in June2014 by the argentinian company Satellogic.
We also discuss the effects of the framing anomaly on linear responses of non-Abelian FQH states. The framing anomaly which fixes the value of thermal Hall conductivity and generates a "finite size correction" to the Hall viscosity of the FQH states on a sphere. This phenomenon is known as the framing anomaly. It is shown that accounting for the framing anomaly of the manifold through the path integral measure.

The Effects of Quantum Dots and Surface Nanotexturization on Solar-Cell Performance

11:15AM B5.00001 Using Composite Fermions to Probe a Wigner Solid in 2D Hole Systems

INSUN JO, YANG LIU, H. DENG, M. SHAYEGAN, L. N. PFIEFFER, K. W. WEST, K. W. BALDWIN, Dept. of Electrical Engineering, Princeton University, Princeton, NJ 08544 — We have studied a GaAs double-quantum-well structure that hosts an interacting, bilayer two-dimensional hole system with a large density difference between the two layers. At very low temperatures and large perpendicular magnetic field, we expect the two layers to exhibit distinct many-body states of holes: The high-density layer develops a Fermi sea of composite fermions when its last Landau Level is half-filled, while the holes in the low-density layer in the same magnetic field range are at very small fillings and should condense into a Wigner crystal. Via measuring the magneto-resistance of the bilayer system, we monitor signatures of the Wigner crystallization and melting.

11:27AM B5.00002 ABSTRACT WITHDRAWN —

11:39AM B5.00003 Framing Anomaly in the Effective Theory of Fractional Quantum Hall Effect

ANDREY GROMOV, ALEXANDER ABANOV, Stony Brook University, GIL YOUNG CHO, YIZHI YOU, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — While the classical Chern-Simons theory is topological, its quantum version is not as it depends on the metric of the base manifold through the path integral measure. This phenomenon is known as the framing anomaly. It is shown that accounting for the framing anomaly of the quantum Chern-Simons theory is essential to obtain the correct gravitational linear response functions of fractional quantum Hall systems (FQH). In the lowest order in gradients the effective action includes Chern-Simons, Wen-Zee and gravitational Chern-Simons terms. The latter term has a contribution from the framing anomaly which fixes the value of thermal Hall conductivity and generates a “finite size correction” to the Hall viscosity of the FQH states on a sphere. We also discuss the effects of the framing anomaly on linear responses of non-Abelian FQH states.
11:51AM B5.00004 Evaluation of Quantum Scattering Time in Ultra-High Quality GaAs Quantum Wells. QI QIAN, SUMIT MONDAL, GEOFFREY C. GARDNER, JOHN D. WATSON, MICHAEL J. MANFRA, Purdue Univ — We present a critical analysis of the extraction of quantum scattering time from Shubnikov-de Haas oscillations in ultra-high quality GaAs quantum wells. In the regime of temperature and magnetic field study here (T~0.3K, B~0.3T) we find the canonical method for determination of quantum scattering time yields unreliable results (cf. Coleridge, Phys. Rev. B 44, 3793). We elaborate a formalism that allows extraction of the quantum scattering time in a regime in which the normalized modulation of the density of states $\Delta g/|g_0|$ is greater than unity. This approach describes well low-field data for samples that display very large excitation gaps for fragile fractional quantum Hall states at large magnetic field.

12:03PM B5.00005 Quantized coefficients for the Chern-Simons terms in bosonic and fermionic symmetry protected topological states in $2n+1$D with $U(1)$ symmetry. CHAO-MING JIAN, Stanford Univ, PENG YE, Perimeter Institute for Theoretical Physics, XIAO-LIANG QI, Stanford Univ — The study of symmetry protected topological (SPT) phases has led to many fruitful results. The classification of SPT states shows a big difference between bosonic systems and fermionic systems even when they share the same symmetry. In this talk, I will focus on SPT states with $U(1)$ symmetry. In $2n+1$ dimensions, when we gauge the $U(1)$ symmetry, the effective actions of the gauge field contain Chern-Simons term (and its generalization in higher dimensions) with quantized coefficients. The quantization of these coefficients is different between bosonic and fermionic systems. I will derive, using different methods, the quantization of coefficients for bosonic systems using general gauge invariance principle. I use Dirac fermions in $2n+1D$ coupled to $U(1)$ gauge field to show the quantization for fermionic systems. I find that the bosonic and fermionic systems have a factor of $(n+1)!$ difference in the quantization unit of the quantized coefficients.

12:15PM B5.00006 An investigation of orienting mechanisms of the quantum Hall stripe phases. J. POLLANEN, S. BRANDSEN, J.P. EISENSTEIN, Institute for Quantum Information and Matter and Department of Physics, California Institute of Technology, Pasadena, California 91125, USA, L.N. PFIEFFER, K.W. WEST, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA — At high magnetic field, two-dimensional electron systems (2DES) exhibit collective states possessing broken rotational symmetry. These states, known as the quantum Hall stripe phases (QHSP), are examples of electronic nematic liquid crystals. Experiments consistently show that the stripes are oriented relative to the GaAs crystal axes, but the exact nature of the native symmetry-breaking field remains unknown. We report here on an extensive study of the QHSPs in a series of high mobility single quantum well samples. These samples all have the same electron density, but differ systematically in the symmetry of the 2DES confinement potential and the distance between the 2DES and the sample surface. Tilted field magneto-transport measurements are used to observe the stripe phases and to assess the strength of the native symmetry-breaking field. We find that the stripes remain oriented in the same way in all our samples. Furthermore, our measurements show that the strength of the orienting potential does not depend on the distance to the sample surface but does exhibit an intriguing dependence on the symmetry of the 2DES confinement potential. We discuss these results in the light of recent suggestions that strain and/or spin-orbit effects may determine the stripe orientation.

12:27PM B5.00007 Numerical characterization of non-Abelian Moore-Read state in the microscopic lattice boson model. WEI ZHU, SHOUSHU GONG, California State University, Northridge, F. D. M. HALDANE, Princeton University, D. N. SHENG, California State University, Northridge — Identifying the interacting systems that host the non-Abelian (NA) topological phases has attracted intense attention in physics. Theoretically, it is possible to realize the NA Moore-Read (MR) state in bosonic system or double-layer system by coupling two Abelian fractional quantum Hall (FQH) states together. Here, based on the density matrix renormalization group and exact diagonalization calculations, we study two such examples in the microscopic lattice models and investigate their NA nature. In the first example, we provide a thorough characterization of the universal properties of MR state on Haldane honeycomb lattice model, including both the edge spectrum and the bulk anyonic quasiparticle statistics. By inspecting the entanglement spectral response to the $U(1)$ flux, it is found that two of Abelian ground states can be adiabatically connected through a charge unit quasiparticle pumping from one edge to the other. In the second example, we study a double-layer bosonic FQH system built from the $\pi$-flux lattice model. Some evidences of NA nature has been identified, including the groundstate degeneracy and finite drag Hall conductance. The numerical methods we developed here provides a useful and practical way for detecting the full information of NA topological order.

12:39PM B5.00008 Fractional quantum Hall and nematic liquid crystal phases in a variable density two-dimensional electron system. S. BRANDSEN, J. POLLANEN, J.P. EISENSTEIN, Institute for Quantum Information and Matter and Department of Physics, California Institute of Technology, Pasadena, California 91125, L.N. PFIEFFER, K.W. WEST, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544 — At high magnetic field, Coulomb interactions in a two-dimensional electron system (2DES) lead to a wide variety of collective phases, including the fractional quantum Hall fluids and the nematic liquid crystals found at high Landau level occupancy. In order to examine the density dependence of these quantum states, we have developed a new sample architecture consisting of a highly doped, yet transparent, conducting cap layer grown atop a conventional modulation-doped heterojunction where the 2DES resides. Separate contacts to the 2DES and the cap layer allow the latter to function as a gate for tuning the 2DES density both before and after low temperature illumination. After illustrating the basic functioning of this structure, we will report results on the density dependence of various quantum Hall and nematic liquid crystal phases of the 2DES.

12:51PM B5.00009 Accessing topological order in fractionalized liquids with gapped edges. THOMAS IADECOLA, Boston University, TITUS NEUPERT, Princeton University, CLAUDIO CHAMON, Boston University, CHRISTOPHER MUDRY, Paul Scherrer Institue — We consider manifestations of topological order in time-reversal-symmetric fractional topological liquids (TRS-FTLs), defined on planar surfaces with holes. We derive a formula for the topological ground state degeneracy of such a TRS-FTL, which applies to cases where the edge modes on each boundary are fully gapped by appropriate backscattering terms. The degeneracy is exact in the limit of infinite system size, and is given by $q^{-N_{fl}}$, where $N_{fl}$ is the number of holes and $q$ is an integer that is determined by the topological field theory. When the degeneracy is lifted by finite-size effects, the holes realize a system of $N_{fl}$ coupled spin-like $q$-state degrees of freedom. In particular, we provide examples where $Z_{q}$ quantum clock models are realized on the low-energy manifold of states. We also investigate the possibility of measuring the topological ground state degeneracy with calorimetry.
1:03PM B5.00010 Topology and interactions in a frustrated slab: tuning from Weyl semimetal to $C > 1$ fractional Chern insulators\(^1\). ZHAO LIU, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA, EMIL BERGHOLTZ, MAXIMILIAN TRESCHER, Dahlem Center for Complex Quantum Systems and Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany, RODERICH MOESSNER, Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Straße 38, D-01187 Dresden, Germany, MASAFUMI UDAWAGA, Department of Applied Physics, University of Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113-8656 — We show that a [111] slab of spin-orbit coupled pyrochlore lattice can become a Weyl semi-metal phase with exotic surface states called as Fermi arcs, i.e., these states are localized to different surfaces depending on their quasi-momentum. Remarkably, in this model, these Fermi arcs persists even when there is no Weyl point in the bulk. Considering interacting electrons in slabs of finite thickness, we find a plethora of known fractional Chern insulating phases, including a new discovered higher Chern number state which is likely a generalization of the Moore-Read fermionic fractional quantum Hall state. By contrast, in the three-dimensional limit, we argue for the absence of gapped states of the flat surface band due to a topologically protected coupling of the surface to gapless states in the bulk. We comment on generalizations as well as experimental perspectives in thin slabs of pyrochlore iridates.

1:15PM B5.00011 Detecting fractional statistics in anyon interferometry employing thermal excitation. CHEOLHEE HAN, HEUNG-SUN SIM, KAIST — In this work, we propose an interferometry setup of anyons, a setup slightly modified from a usual Fabry-Perot interferometry. In this interferometry, there appears anyon braiding between thermally excited anyons and an anyon injected from a source of the setup. This braiding process, which has unnoticed before and does not exist in bosons and fermions, results in a temperature dependent phase shift of the interference pattern of the setup. Experimental observation of the phase shift will provide a direct evidence of fractional statistics.

1:27PM B5.00012 Reordering Fractional Chern Insulators into Stripes of Fractional Charges Using Long-Range Interactions\(^1\). MENGSIU CHEN, VITO SCAROLA, Virginia Tech — Long-range interactions contribute to the rich phenomenology of quasiparticle collective states in the fractional quantum Hall regime. We test for analogues in models of fractional Chern insulators derived from a screened Coulomb interaction. We project the interaction to the lowest band and numerically diagonalize it. We find that the uniform fractional Chern liquid is surprisingly robust to long-range interactions but gives way to a unidirectional charge density wave fractionally charged quasiparticles with increased screening length. Our results show that fractional Chern insulators offer a robust and important platform for studying quasiparticles collective states.

\(^1\)We acknowledge support from ARO (W911NF-12-1-0335), AFOSR (FA9550-11-1-0313), and DARPA-YFA.

1:39PM B5.00013 Composite Fermions with a Warped Fermi Contour\(^1\). M.A. MUEED, DOBROMIR KAMBUROV, YANG LIU, MANSOUR SHAYEGAN, LOREN PFIEFFER, KEN WEST, KIRK BALDWIN, Princeton Univ, ROLAND WINKLER, Northern Illinois Univ — Composite fermions (CFs), quasi-particles formed by attaching an even number of flux quanta to each charged carrier in high perpendicular magnetic fields ($B$), capture many phenomena exhibited by an interacting system of two-dimensional carriers. The flux attachment cancels out the external $B$ at a half-filled Landau level, enabling CFs to occupy a Fermi sea and possess a Fermi contour, similar to their $B = 0$ carrier counterparts. Because the CFs are primarily a manifestation of interaction, one might argue that they should retain no memory of the $B = 0$ particles, including their energy band properties. We present tantalizing evidence through commensurability measurements that the composite fermions can be strongly influenced by the characteristics of the Landau level in which they are formed. In particular, the composite fermions have a warped Fermi contour when their Landau level originates from a hole band with significant warping.

\(^1\)We acknowledge support through the DOE (DEFG02-00-ER45841) for measurements, and the Gordon and Betty Moore Foundation (Grant No. GBMF4420), Kec Foundation, and the NSF (DMR-1305691 and MRSEC DMR-0819860) for sample fabrication.

1:51PM B5.00014 Flat Chern Bands and Edge States in the Hofstadter Model Near to Rational Flux. FENNER HARPER, STEVEN SIMON, University of Oxford, RAHUL ROY, University of California, Los Angeles — We present a perturbative approach to the study of the Hofstadter model for when the amount of flux per plaquette is close to a rational fraction [Phys. Rev. B 90, 075104 (2014)]. Within this approximation, the eigenstates of the system connect smoothly to the Landau levels of the continuum, but in general develop an additional species (or colour) degree of freedom. Using the formalism of Haldane pseudopotentials, we describe the fractional quantum Hall-like wavefunctions that arise when interactions are turned on. We also discuss the form and energy spectrum of the bosonic edge excitations that would occur in the presence of a confining harmonic trap, making connections to the recent experimental realizations of the Hofstadter model using ultracold atoms.

2:03PM B5.00015 Topological textures and metal-insulator transition in Reentrant Integer Quantum Hall Effect: role of disorder\(^1\). YULI LYANDA-GELLER, GEORGE SIMION, Department of Physics and Astronomy, Purdue University, West Lafayette, IN 47907 USA — We investigate a ground state of the two-dimensional (2D) electron liquid in the presence of disorder for Landau level filling factors, for which the re-entrant integer quantum Hall effect is observed. Our particular interest is the range of filling factors, which in a clean 2D system is favorable to formation of the two-electron (2e) bubble crystal. For the smooth random potential due to charged impurities placed far away from the 2D gas, the ground state is a lightly distorted 2e bubble crystal. However, for positively or negatively charged residual impurities located approximately within about three magnetic lengths from the 2D electrons, the ground state contains charged 2e complexes formed either by positively charged impurity and 3e defect bubble, or negatively charged impurity and 2e defect bubble. In the vicinity of 1e and 3e defect bubbles, the 2e bubbles of the crystal change their shape from round to elongated forming hedgehog (for 1e defect) or vortex (for 3e defect) textures. The topological textures due to these complexes interact with vortex and hedgehog excitations, generated as temperature increases that are not bound by residual impurities. The temperature of insulator to metal transition calculated with both bound and unbound defects agrees with experiment.

Monday, March 2, 2015 11:15AM - 2:15PM – Session B6 DMP DCOMP: Focus Session: Proper and Improper Ferroelectrics 006A - Manfred Fiebig, ETH Zurich
11:15AM B6.00001 Ferroelectric Transition in Compressively Strained Epitaxial SrTiO$_3$, AMIT VERMA, Electrical Engineering, Univ. of Notre Dame, SANTOSH RAGHAVAN, SUSANNE STEMMER, Materials Dept., Univ. of California, Santa Barbara, DEBBIE JENA, Electrical Engineering, Univ. of Notre Dame — Strontium titanate (SrTiO$_3$) is a transition metal oxide semiconductor that crystallizes in the cubic perovskite crystal structure and exhibits incipient ferroelectricity. The dielectric constant of bulk unstrained SrTiO$_3$ crystals saturates at temperatures below 4K while above ~ 50K, its dielectric constant decreases following the Curie-Weiss law of ferroelectricity [Muller et al., Phys. Rev. B 19, 3593 (1979)]. Based on the Landau-Ginzburg-Devonshire theory of ferroelectrics, it is theoretically predicted that under biaxial compressive or tensile strain, SrTiO$_3$ thin films should become ferroelectric [Perstew et al., Phys. Rev. B 61, R255 (2000)]. Heteroepitaxial growth on lattice-mismatched substrates was used earlier to demonstrate near room temperature in-plane ferroelectricity in tensile strained SrTiO$_3$ thin films [Haeurn et al., Nature 390, 758 (2004)]. In this work, we have epitaxially grown compressively strained SrTiO$_3$ thin films on (001) LSAT substrates, fabricated Pt/SrTiO$_3$ Schottky diodes, and performed temperature-dependent capacitance-voltage (CV) measurements of these diodes. As predicted by the theory, the out-of-plane dielectric constant of SrTiO$_3$ extracted from these CV measurements shows a divergence, implying a ferroelectric transition in compressively strained SrTiO$_3$.

11:27AM B6.00002 Structural Stability of Nano-scale SrTiO$_3$ Under Pressure, HAN ZHANG, TREvor TYSOn, New Jersey Institute of Technology, XINGUO HONG, MEGAN SCOFIELD, STANISLAUS WONG, State University of New York at Stony Brook — The bulk phase of SrTiO$_3$ (STO) is paraelectric and exhibits a structural phase transition near ~ 6 GPa under hydrostatic pressure. It has recently been found that nano-scale STO is polar under ambient conditions. We have conducted pressure dependent structural measurements on monodispersed nano-scale samples with 10 nm and 83 nm particle size. The structures of both samples were explored and the results are compared with the reported studies of bulk STO. This work is supported by DOE Grant DE-FG02-07ER46402.

11:39AM B6.00003 Hybrid Improper Ferroelectricity, S.-W. CHEONG, YOON SEOK OH, Rutgers University, XUAN LUO, Pohang University of Science and Technology, FEI-TING HUANG, YAZHONG WANG, Rutgers University — Utilizing trilinear coupling of two types of octahedron rotations, hybrid improper ferroelectricity has been theoretically predicted in double layered compounds such as (Ca,Sr,Ba)$_2$MnTi$_2$O$_6$. On the other hand, there exists little theoretical prediction on practical properties of the potentially ferroelectric compounds such as ferroelectric transition temperature, switchability of polarization, and chemical phase stability. We have attempted to fabricate single crystals of some of these compounds, and examined the physical properties of the crystals with the aim of discovering new bulk ferroelectrics with switchable polarization at room temperature. We will report the results of our comprehensive experimental investigation.

11:51AM B6.00004 Experimental Demonstration of Hybrid Improper Ferroelectric in the Layered Ruddlesden-Popper Compounds , YOON SEOK OH, Department of Physics, Ulsan National Institute of Science and Technology (UNIST) — Geometric ferroelectrics are called as improper ferroelectrics where geometric structural constraints, rather than typical cation-anion paring, induce proper ferroelectric polarization. Hybrid improper ferroelectricity, one kind of geometric ferroelectricity, results from the combination of two or more non-ferroelectric structural order parameters. In recent, hybrid improper ferroelectricity has been theoretically predicted in ordered perovskites and the Ruddlesden-Popper compounds. However, the ferroelectricity of these compounds has never been experimentally confirmed and even their polar nature has been under debate. In this talk, we report our experimental results of exploring switchable electric polarization and domain structures in the single crystals of the $n = 2$ layered Ruddlesden-Popper compounds. In collaboration with Xuan Luo, Laboratory for Pohang Emergent Materials, Postech; Fei-Ting Huang, Department of Physics & Astronomy, Rutgers University; Yazhong Wang, Department of Physics & Astronomy, Rutgers University; and Sang-Wook Cheong, Department of Physics & Astronomy, Rutgers University.

12:27PM B6.00005 Single crystal ternary oxide ferroelectric integration with Silicon, SAIDUR BAKAUL, CLAUDY SERRAO, LONG YOUN, ASIF KHAN, SAYEEF SALAHUDDIN, University of California, Berkeley — Integrating single crystal, ternary oxide ferroelectric thin film with Silicon or other arbitrary substrates has been a holy grail for the researchers since the inception of microelectronics industry. The key motivation is that adding ferroelectric materials to existing electronic devices could bring into new functionality, physics and performance improvement such as non-volatile memory, sub-threshold swing of field effect transistor (FET) below 60 mV/decade in FET [Salahuddin, S, Datta, S. Nano Lett. 8, 405(2008)]. However, fabrication of single crystal ferroelectric thin film demands stringent conditions such that lattice matched single crystal substrate and high processing temperature which are incompatible with Silicon. Here we report on successful integration of Pb$_{2/3}$Ti$_{1/3}$O$_3$ in single crystal form with by using a layer transfer method. The lattice structure, surface morphology, piezoelectric coefficient d$_{33}$, dielectric constant, ferroelectric domain switching and spontaneous and remnant polarization of the transferred PZT are as good as these characteristics of the best PZT films grown by pulsed laser deposition on lattice matched oxide substrates. We also demonstrate Si based, FE gate controlled FET devices.

12:39PM B6.00006 Optical second-harmonic characterization of ferroelectricity in double perovskites Ca$_{2-x}$Mn$_x$Ti$_2$O$_6$, YUJIN CHO, FARBOD SHAFIEI, Department of Physics, University of Texas at Austin, ZONGYAO LI, JIANSHI ZHOU, Department of Mechanical Engineering, University of Texas at Austin, MICHAEL DOWNER, Department of Physics, University of Texas at Austin — Perovskite-type ferroelectric oxides such as BaTiO$_3$ are used widely as actuators and memory storage devices. Recently ferroelectricity was demonstrated in the double perovskite CaMnTi$_2$O$_6$, which represents a fundamental new class of ferroelectrics in which dipoles from Mn$^{2+}$ at the A-site and Ti$^{4+}$ at the B site are cooperatively coupled [1]. However, synthesis of CaMnTi$_2$O$_6$ from CaTiO$_3$-MnTiO$_3$ required pressure as high as 7GPa. We are developing spark plasma sintering (SPS) methods to synthesize Ca$_{2-x}$Mn$_x$Ti$_2$O$_6$ at pressures as low as 50 MPa, and using Second Harmonic Generation (SHG) microscopy to characterize the strength of ferroelectricity. Preliminary SHG results show that ferroelectric CaMnTi$_2$O$_6$ can be synthesized at low pressure with stronger ferroelectricity. Higher pressure SPS-synthesized sample present comparative SHG results for SPS-synthesized and high-pressure-synthesized CaMnTi$_2$O$_6$ and relate them to the underlying origins of ferroelectricity. [1] A. Aimi et al., Chem. Mat. 26, 2601 (2014).

12:51PM B6.00007 Local Structure Study of the Diffuse Phase Transitions in 0.75Pb(Mg$_{1/3}$Nb$_{2/3}$)$_2$O$_3$-0.25PbTiO$_3$, HIROYUKI TAKE NAKA, ILYA GRINBERG, ANDREW M. RAPPE, University of Pennsylvania, THE MAKINENI THEORETICAL LABORATORIES TEAM — Relaxor ferroelectrics have been of scientific interest and importance due to their fascinating properties such as a giant piezoelectric response, high permittivity over a broad temperature range, and unique dielectric response with frequency dispersion with the diffuse phase transitions. The experimental results undoubtedly explain the transitions with the widely accepted model of polar nanoregions (PNRs), appear at $T_b$, in a non-polar matrix. Local structure distortions using diffuse scattering (DS) technique had been reported already. Intensities of DS raise below the intermediate temperature $T_a$, a few degrees below $T_b$, and can be seen even at low temperature where system undergoes the frozen phase. Formations of local dipoles which give rise to the DS intensities are still unclear. We study DS by performing molecular dynamics simulations with the first-principle-based potential for 0.75Pb(Mg$_{1/3}$Nb$_{2/3}$)$_2$O$_3$-0.25PbTiO$_3$ without invoking the PNRs. Our results show that DS patterns form the experimentally reported shapes and integrated DS intensities as a function of temperature reveal a similar trend to the experimental results. Our results indicate that the local structure correlations in lead-based relaxors can arise from local random fields without PNRs. Instead, we find that the DS patterns are due to formations of slush-like dipole multidomains.
1:03PM B6.00008 Relative Stability of FE and AFE States in (Na0.5Bi0.5)TiO3-based Solid Solutions , V.L. SOBOLEV, South Dakota School of Mines & Technology, Rapid City, SD 57701, USA, V.M. ISCHCHUK, L.G. GUSAKOVA, N.G. KISEL, D.V. KUZENKO, N.A. SPIRIDONOV, Science & Technology Center “Reactivelectron” of the Nat. Acad. of Sci. of Ukraine, 83049 Donetsk, Ukraine — Changes of the relative stability of antiferroelectric (AFE) and ferroelectric (FE) phases in the [(Na0.5Bi0.5)0.80Ba0.20]Ti1−xByO3 system of solid solutions with the B-site ion substitutions have been studied. Ions of zirconium and tin along some ions complexes such as (InNb), (FeNb) and several others were used for substitutions. The increase in the substituent ion content leads to nearly linear variation of the crystal cell size along with changes of the relative stability of the AFE and FE phases according to the tolerance factor variation. Substituent ions with ionic radii larger than the ionic radius of original ion evoke a decrease of the FE-AFE phase transition temperature. The substituent ions with smaller ionic radii have the opposite effect. Our results demonstrate that the size of the substituent ion causes a predominant influence on the relative stability of the FE and AFE states in (Na0.5Bi0.5)TiO3-based solid solutions. Our studies also indicate the way to raise the FE-AFE phase transition temperature.

1:15PM B6.00009 Negative Capacitance transients in a ferroelectric capacitor , ASIF KHAN, KOROK CHATTERJEE, BRIAN WANG, STEVEN DRAPCHO, LONG YOU, CLAUDY SERRAO, SAIDUR BAKAUL, RAMAMOORTHY RAMESH, SAYEEF SALAHUD-DIN, University of California, Berkeley — The Boltzmann distribution of electrons poses a fundamental barrier to lowering energy dissipation in conventional electronics, often termed as Boltzmann Tyranny [1,2]. Negative capacitance in ferroelectric materials, which stems from the stored energy of phase transition, could provide a solution, but a direct proof of negative capacitance has so far been elusive. Here we demonstrate the negative differential capacitance in a thin, single crystalline ferroelectric film, by constructing a simple R-C network and monitoring the voltage dynamics across the ferroelectric capacitor. When a voltage pulse is applied, the voltage across the ferroelectric capacitor is found to be decreasing with time—in exactly the opposite direction to which voltage for a regular capacitor should change. The results are analyzed on the basis of the Landau-Khalatnikov equation, which shows that as the ferroelectric polarization switches its direction, it passes through the unstable negative capacitance region resulting in the characteristic “negative capacitance transients”. Analysis of this “inductance”-like behavior from a capacitor allows us to calculate the value of the negative capacitance directly and presents an unprecedented insight into the intrinsic energy profile of the ferroelectric material.

1:27PM B6.00010 Double hysteresis in BaTiO3/PbZr0.2Ti0.8O3 ferroelectric bilayer thin film , PAVEL SALEV, ALEXEI GRIGORIEV. The University of Tulsa — We observed two hysteresis loops in BaTiO3/PbZr0.2Ti0.8O3 (BTO/PZT) bilayer thin film. The first loop with polarization of 27 μC/cm2 was measured in the applied voltage of ±5V. The second hysteresis loop with polarization of 76 μC/cm2 was measured in the applied voltage of ±55V. Both hysteresis loops showed characteristic shape with concave region followed by saturation region in the broad range of applied voltage frequencies providing strong evidence for ferroelectric origin of both loops. We performed computational analysis of BTO/PZT bilayer based on Landau-Ginzburg-Devonshire model including contributions of electronic band structure. We found an increased concentration of free charge carriers at the interface between BTO and PZT which provides compensation for the bound charge due to polarization mismatch of the layers. Moreover, as the free charge effectively screens polarization in one layer from another, polarization switching of individual layers can be possible. This leads to the conclusion that two hysteresis loops can be a result of polarization switching of the individual layers.

1:39PM B6.00011 Ferroelectric Field Effect in Ultrathin Epitaxial Sm0.5Nd0.5NiO3 Films , LE ZHANG, H. JEFFREY GARDNER, VIJAY RAJ SINGH, XIA HONG, University of Nebraska - Lincoln — We report the study of ferroelectric field effect modulation of the metal-insulator transition in ultrathin Sm0.5Nd0.5NiO3 (SNO) films. We have fabricated high quality epitaxial SNO thin films and Pb(Zr,Ti)O3 (PZT)/SNO heterostructures on (001) LaAlO3 substrates using off-axis RF magnetron sputtering. X-ray diffraction and atomic force microscopy studies reveal (001) oriented films with high crystallinity and surface roughness of 3-4 Å. Thin SNO films (4-6 nm) typically have the transition temperature TMI around 230 K, showing thermally activated transport below TMI followed by 3D variable range hopping at low temperature. Hall effect measurements reveal p-type conduction with ~4 holes/uc in the metallic phase. Working with films one to two unit cells thicker than the electrical dead layer thickness (~4 nm), we have demonstrated nonvolatile, reversible ferroelectric field effect modulation of TMI in SNO by up to 10 K. The maximum resistance ratio Rhigh/Rlow is 1.7 at 140 K, which is in the thermally activated regime. In the metallic phase, the carrier density has been modulated by 1x1015 cm−2, corresponding to the polarization field of PZT of 80 μC/cm2.

1:51PM B6.00012 Electrical Properties of Tetragonal-PZT Thin Film Capacitors from 5 K to 300 K, D.R. DAUGHTON, Lake Shore Cryotronics, J.T. EVANS, S.P. CHAPMAN, Radiant Technologies, Inc — Rapid assessment of ferroelectric device characteristics is critical to improving ferroelectric materials processing as well as developing accurate ferroelectric device models. Here, we demonstrate automated electrical testing of thin PZT and Nb-doped PZT thin film devices at temperatures ranging from 300 K down to 5 K in a cryogenic probing environment. In this configuration, temperature-dependent dielectric constant, remanent polarization, coercive voltage, switching speed, and leakage are measured in a single pass on a single sample. From these measurements, it appears that tetragonal PZT does not have a phase boundary from room temperature down to 5 K. Retention tests conducted on several capacitors while transitioning from room temperature to 200 K, 100 K, and 6.5 K showed no loss of remnant polarization indicating 20/80 PZT and its niobium-doped cousins remain fully functional as memory devices down to 5 K.

11:15AM B7.00001 Engineering Majorana fermions in atomic chains with collinear magnetic order , PANAGIOTIS KOTETES, ANDREAS HEIMES, DANIEL MENDLER, GERD SCHÖN, Karlsruhe Institute of Technology — We propose new mechanisms for engineering Majorana fermions (MFs) based on atomic chains with collinear magnetic order, on top of a conventional superconductor. For antiferromagnetic ordering, we show [1] that a weak Zeeman field and a supercurrent convert the preexisting topologically-protected Shiba states into MFs, without the requirement of Rashba spin-orbit coupling (SOC). Remarkably, the electronic spin-polarization of the arising edge MF wavefunctions depends solely on the parity of the number of magnetic moments, which can serve as a unique signature of the MFs. Instead, if Rashba SOC is present, both ferro- and anti-ferromagnetic orders can lead to topological phases which are reflected in the spatial profile of the MF wavefunctions. Our findings connect to the recent observations of MFs in atomic chains [3] and can open alternative routes for confirming the emergence of MFs. [1] A. Heimes, P. Kotetes, and G. Schö,PRB 90, 060507(R) (2014). [2] A. Heimes, D. Mendler, and P. Kotetes, arXiv:1410.6367. [3] S. Nadj-Perge et al., Science 346, 602 (2014).
11:27AM B7.00002 Majorana Fermions in Quantum Wires with Helical Magnetic Textures1, GEOFFREY FATIN, ALEX MATOS-ABIAIQUÉ, BENEDIKT SCHARF, IGOR ZUTIC, University at Buffalo - SUNY — Magnetic textures can lead to the formation of Majorana states in a quantum wire located nearby an s-wave superconductor [1-3]. We investigate theoretically the formation of Majorana fermions in quasi-one-dimensional quantum wires in the presence of different kinds of helical-like magnetic textures. Our calculations reveal that finite-size effects as well as non-trivial helical magnetic configurations can lead to the formation of multiple Majorana states. Under some specific conditions it is possible to localize some of the Majorana modes at certain points within the wire. The positions of these points can be controlled by properly tuning the system parameters. The conditions governing the transitions from the trivial to the topological state are found and the different Majorana modes are characterized according to their local spin polarization. The possibility of experimentally realizing the proposed models in actual physical systems is also discussed.

11:39AM B7.00003 Interplay of Majorana and Kondo modes in an interacting quantum dot coupled to a topological quantum wire1, DAVID A. RUIZ-TIJERINA, Instituto de Física, Universidade de São Paulo, EDSON VERNEK, Instituto de Física, Universidade Federal de Uberlândia, LUIS G. V. DIAS DA SILVA, Instituto de Física, Universidade de São Paulo, J. CARLOS EGUES, Instituto de Física de São Carlos, Universidade de São Paulo — We investigate the low-temperature conductance of an interacting quantum dot (QD) coupled to a topological quantum wire. Our realistic model includes the Rashba spin-orbit interaction, proximity s-wave superconductivity, an applied magnetic field, and an Anderson-type interacting QD. Using recursive Green’s function techniques we find a QD conductance of $0.5e^2/h$, associated with the emergent Majorana end mode in the wire “leaking” into the QD. This signature is robust, appearing in the presence of Zeeman fields and even when the QD is deep in the Coulomb blockade. We further study the Kondo regime using the numerical renormalization group. Our results indicate a strong interplay between Majorana & Kondo physics. The Kondo effect can be quenched by Zeeman fields, revealing a persistent $0.5e^2/h$ conductance coming from the Majorana mode leaking into the QD. These properties can be used for the experimental identification of Majorana-Kondo physics in these systems. Our results here corroborate and extend those of Phys. Rev. B 89, 165314 (2013) by showing that the Majorana resonance pinned to the Fermi level arising in the QD is robust and survives even in the presence of Coulomb effects within the QD.

11:51AM B7.00004 Topological superconductivity and Majorana fermions in chains of magnetic atoms on the surface of a superconductor1, ALI YAZDANI, Princeton University — Chain of magnetic atoms on the surface of a BCS superconductor is a versatile platform for the realization of one-dimensional superconductors with Majorana bound states that lends itself to high-resolution scanning tunneling microscopy studies [1,2]. In this talk, I will describe experimental efforts to realize this platform using self-assembled chains of Fe atoms on the surface of Pb (110) and to directly visualize Majorana quasi-particle bound states at their edges [2]. Using spin-polarized STM studies, we show that Fe chains are ferromagnetic while tunneling into Pb’s substrate demonstrates signatures of strong spin-orbit interaction at its surface. Comparison of experimental measurements of structure and normal state electronic structure with DFT calculations suggest that these are triple zigzag chains with an odd number of band-crossings at the Fermi level. The onset of superconductivity in the Pb strongly modifies the low energy density of states of the Fe chains and induces a zero energy state at their ends. I will describe how these observations are consistent with the formation of a topological superconducting phase with Majorana edge states.

12:27PM B7.00005 Topological phase transitions of interacting Majorana fermions in an array of vortices, JIANSHENG WU, South University of Science and Technology of China, Shenzhen, China, HSIANG-HSUAN HUNG, University of Texas at Austin, Austin, Texas 78712-1192, USA, CHING-KAI CHIU, University of British Columbia, Vancouver, British Columbia, Canada V6T 1Z1, KUIE SUN, The University of Texas at Dallas, Richardson, Texas 75080-3021, USA — We study a vortex array in a p-wave superconducting thin film that produces ladder-like lattices with interacting Majorana fermions. We construct a model Hamiltonian with parameters which are tunable via the deformation of the vortex array. We explore topological phase transitions of the system and compute phase diagrams using the density-matrix-renormalization-group method. We further investigate transport properties for experimental detection. Our results have potential application on building devices to engineer strongly correlated Majorana fermions.

12:39PM B7.00006 Majorana Fermions in Chiral Topological Ferromagnetic Nanowires1, EUGEN DUMITRESCU, BRENDBEN ROBERTS2, SUMANTA TEWARI, Clemson University, JAY D. SAU, University of Maryland — Motivated by a recent experiment in which zero-bias peaks have been observed in STM experiments performed on chains of magnetic atoms on a superconductor, we show that a multichannel ferromagnetic wire deposited on a spin-orbit coupled superconducting substrate can realize a non-trivial chiral topological superconducting state with Majorana bound states localized at the wire ends. The non-trivial topological state occurs for generic parameters requiring no fine tuning, at least for very large exchange spin splitting in the wire. We theoretically obtain the signatures which appear in the presence of an arbitrary number of Majorana modes in multi-wire systems incorporating the role of finite temperature, finite potential barrier at the STI tip, and finite wire length. These signatures are presented in terms of spatial profiles of STI differential conductance which clearly reveal zero energy Majorana end modes and the prediction of a multiple Majorana based fractional Josephson effect.

12:51PM B7.00007 ABSTRACT WITHDRAWN —
1:03PM B7.00008 Majorana bound states without topological superconductivity, PABLO SAN-JOSE, JORGE CAYAO, Consejo Superior de Investigaciones Científicas (CSIC) - Spain, ELSA PRADA, Universidad Autónoma de Madrid (UAM) - Spain, RAMÓN AGUADO, Consejo Superior de Investigaciones Científicas (CSIC) - Spain — Recent experimental efforts towards the detection of Majorana bound states have focused on creating the conditions for topological superconductivity. Here we demonstrate an alternative route, which achieves fully localised zero-energy Majorana bound states when a topologically trivial superconductor is opened to a normal region. The emergence of Majorana states is a consequence of non-hermitian degeneracies of the resulting open quantum system, while arbitrarily large Majorana lifetimes follow from high junction transparency and helicity of the normal side. At these degeneracies, also known as “exceptional points,” both the eigenvalues and the eigenstates coalesce, and acquire Majorana properties (zero-energy, self-conjugation, 1r-periodic braiding...) despite the trivial band topology. Exceptional Majoranas are thus the open-system counterparts of conventional Majorana bound states, to which they are continuously connected, and exhibit all their phenomenology while not requiring topological superconductivity.

1:15PM B7.00009 Disorder-induced phase transitions in a quasi 1-D Majorana wire, MARIA-THERESA RIEDER, PIET W. BROUWER, Freie Universität Berlin, JINANC ADADIGELI, Sabanci University, Istanbul — In a strictly 1D spinless p-wave superconductor, disorder is known to induce a phase transition between a topologically nontrivial phase and a trivial insulating phase when the mean free path l becomes of the order of the superconducting coherence length ξ. We show that, in constrast, a multichannel spinless p-wave superconductor goes through a series of phase transitions alternating between topologically trivial and nontrivial phases upon increasing the disorder strength. The number of phase transitions equals the channel number N and each phase transition is accompanied by a Dyson singularity in the density of states v(ε) ∝ ε−1/2. The observed behavior is the result of an effective chiral symmetry allowing us to analytically investigate the phase boundaries and the density of states. The latter displays a power-law singularity v(ε) ∝ εα−1 for small energies ε away from the critical points. Using the concept of “superuniversality,” we relate the exponent α to the wire’s transport properties at zero energy and, hence, to the mean free path and the superconducting coherence length.

1:27PM B7.00010 Parity crossings of Shiba states and Majorana-like zero bias anomalies in hybrid superconductor-normal nanowire systems with quantum dot behavior, RAMON AGUADO, CSIC - Madrid, ROK ZITIKO, Jozef Stefan Institute, Jamova 39, SI-1000 Ljubljana, Slovenia, ROSA LOPEZ, IFISC (UIB-CSIC), Palma de Mallorca, Spain, JONG SOO LIM, School of Physics, Korea Institute for Advanced Study, Seoul, Korea. — Although recent experiments with semiconducting nanowires are partially consistent with the existence of Majorana bound states (MBS) at normal-superconductor junctions, other mechanisms cannot be completely ruled out. In this talk, I will focus on short nanowires with quantum dot behavior and discuss the magnetic field dependence of Shiba states [1] as well as novel Kondo features induced by the weak coupling to a normal lead [2]. Our results are based on the phase diagram of an Anderson impurity in contact with superconducting and normal-state leads. This phase diagram is obtained by means of the numerical renormalization group technique and is valid for arbitrary ratio of the superconducting gap to the Kondo temperature. Overall, we find a very rich behavior of spectral functions with zero-bias anomalies which can emerge irrespective of whether the ground state is a doubllet or a singlet. This phenomenon originates from crossings of the ground state fermionic parity and mimics that of MBS. [1] E. J. H. Lee, X. Jiang, M. Houzet, R. Aguado, C. M. Lieber, and S. De Franceschi, Nature Nanotechnology, 9, 79 (2014). [2] R. Zitko, J. S. Lim, R. Lopez and R. Aguado, arXiv:1405.6084 (2014).

1:39PM B7.00011 Helical Majorana surface states of strongly disordered topological superconductors with time-reversal symmetry, RAQUEL QUEIROZ, ANDREAS SCHNYDER, Max Planck Institute for Solid State Physics — Noncentrosymmetric superconductors with strong spin-orbit coupling and the B phase of 3He are possible realizations of topological superconductors with time-reversal symmetry. The nontrivial topology manifests itself at the material’s surface in terms of linearly dispersive helical Majorana modes protected by symmetry from disorder weaker than the superconducting gap. Using extensive numerical simulations, we investigate the stability and properties of these Majorana states under strong disorder, which influences both bulk and surface states. A critical crossover from weak to strong disorder is observed in both two and three dimensions, through which an extended state exactly at zero energy always persists. The localization properties of the ingap states are studied through the distribution of the local density of states and level repulsion statistics.

1:51PM B7.00012 Floquet Majorana Modes in Graphene Quantum Dots, YANTAO LI, Sun Yat-sen Univ. & Indiana Univ - Bloomington, ARJIT KUNDU, BABA SERADJHEH, Indiana Univ - Bloomington — We propose a possible way to realize Floquet Majorana fermions in graphene quantum dots connected by a superconducting island. The effective crossed Andreev reflection and hopping amplitudes between the dots are calculated as a function of system parameters. It is shown that the spin degeneracy is broken when the dots are driven out of phase. This all-electric, highly tunable device could be a realistic platform for uncovering dynamically generated Majorana fermions in graphene systems.

2:03PM B7.00013 Exploring signatures of Majorana fermions in Fe chains on Pb using a dilution refrigerator scanning tunneling microscope, BENJAMIN E. FELDMAN, ILYA K. DROZDOV, MALLIKA T. RANDERIA, JIAN LI, B. ANDREI BERNEVIG, ALI YAZDANI, Princeton University — Recently, it was shown that Majorana fermions can be realized by depositing chains of magnetic atoms on a superconductor if the spins are non-colinear or if they are ferromagnetic and subject to large spin-orbit coupling. Scanning tunneling microscopy (STM) studies of Fe chains on a Pb(110) surface revealed zero-energy states localized to the ends, and a spin-polarized tip was used to show ferromagnetism in the chains as well as spin-orbit coupling on the Pb surface, providing strong evidence for Majorana fermions. These measurements were performed at 1.4 K, and the width of the zero-energy mode was limited by thermal broadening. In this talk, I will present subsequent measurements in which we extend these results to temperatures below 250 mK using a dilution refrigerator STM. The low temperature allows us to obtain significantly higher energy resolution, and I will discuss our results in the context of Majorana fermions.

Session B8 DCMP: From Single Molecules to Molecular Assemblies on Surfaces

11:15AM B8.00001 Long Range Modification of a Metal Surface Electronic Structure by an Organic Semiconductor, JINGYING WANG, DANIEL DOUGHERTY, North Carolina State Univ — In an organic spintron device the interaction between electrode surface and organic semiconductor layer plays an important role in spin injection at this interface. The antiferromagnetic material Cr(001) is known to have a spin-polarized state near Fermi level that could potentially hybridize with organic molecules. Here we report our STM/STS study of electronic structure at interface between an organic semiconductor, PTCDA, and Cr(001) surface. The study shows that the surface state at Fermi level of Cr(001) can be broadened by PTCDA molecules deposited on the surface due to hybridization of PTCDA molecular orbital and conduction sp band of Cr(001). This indirect modification is not only localized at molecular adsorption sites, but also extends several nm to bare surrounding Cr(001) surface and decays with distance away from PTCDA molecules.
11:27 AM B8.00002 Accurate Energy Level Alignment at Physisorbed Molecule-Metal Interfaces from a Density Functional Theory-Based Approach, DAVID A. EGGER, Weizmann Institute of Science, ZHENFEI LIU, Molecular Foundry, Lawrence Berkeley National Laboratory, JEFFREY B. NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, and Department of Physics, UC-Berkeley, LEEROR KRONIK, Weizmann Institute of Science — A highly relevant physical quantity for nanostructured molecule-metal interfaces is the energy level alignment of the molecular electronic states with respect to the Fermi level of the metal. Here, we introduce an efficient theoretical method that is based on density functional theory, but in contrast to common approximations fulfills physically motivated criteria for exchange-correlation interactions and can therefore yield quantitatively accurate energy level alignment information for physisorbed metal-molecule interfaces. We validate our approach by a detailed comparison with experimental and theoretical reference data for several prototypical interfaces of this kind: benzene on graphite (0001), and 1,4-benzenediamine, Cu-phthalocyanine, and 3,4,9,10-perylene-tetracarboxylic-dianhydride on Au(111). Our results indicate that obtaining quantitatively accurate energy level alignment information from density functional theory is possible.

11:39 AM B8.00003 Rethinking chemisorption: New insights into the factors controlling the binding energy1, MARISOL ALCANTARA ORTIGOZA, SERGEY STOLBOV, University of Central Florida — Chemisorption of atomic and molecular species on a substrate induces electronic redistribution upon which substrate nuclei respond by adjusting their positions. This lattice distortion has been linked to the binding energy $E_B$ of the adsorbed species and attributed to the so-called surface relaxation energy, $E_{rx}$. We have found, however, that for transition metals the energy associated with the mere charge redistribution $E_{elec}$ is much larger than $E_{rx}$ and thus both contributions must be considered [1]. In this work, we quantify the electronic and structural perturbation energy $E_P$ brought by various adsorbates on surfaces to understand anomalous adsorbate binding energies, i.e., those in which $E_B$ strongly influences the magnitude of $E_{rx}$. For example, for O adsorption on Au(111), while $E_{rx}$ is only 0.25 eV, the overall perturbation energy $E_P$ affecting $E(B,O) \sim 1$ eV [1]. This indicates that $E_P$ cannot be ignored but also that local bonds may not be as weak as portrayed by $E_{elec}$, even though $E_B$ is significantly reduced. We expose cases in which $E_P$ is really dominated by the lattice distortion energy, as well as a rationale for its trends as a function of the substrate and adsorbate. We discuss the implications of the fact that $E_B$ is not always predominately controlled by the bond-strength on heterogeneous catalysis, as well as the applications of the same fact. M. Alcántara Ortigoza and S. Stolbov; “The Perturbation Energy: The missing key to understand gold ‘nobleness.’” Submitted in October 2014

12:03 PM B8.00005 Surface-Mediated Self-Assembly Controlled by Interfacial Charge-Transfer1, OLIVER MONTI, NAHID ILYAS, BRET MAUGHAN, Univ of Arizona, PERCY ZAHL, ROCIO CORTES-RODRIGUEZ, PETER SUTTER, Brookhaven National Laboratory — Precise control of molecular self-assembly is desirable and essential to understand electronic structure and dynamics at organic semiconductor interfaces. Self-assembly into ordered supramolecular structures for such pi-conjugated molecules is determined by a subtle balance between surface-molecule and molecule-molecule interactions, and a predictive mechanistic understanding has remained a substantial challenge for most commonly used organic semiconductors. Here we show by a combination of low-temperature scanning tunneling microscopy and two-photon photoemission spectroscopy for the model system of chloro-boron subphthalocyanine on Cu(111) that interfacial charge-transfer results in fundamentally different self-assembly mechanisms for different molecular orientations on the surface. We uncover a novel mechanism that controls thin film growth for an important class of organic semiconductors. We conclude that the adsorption geometry may be exploited in self-assembly to control electronic structure and dynamics at organic semiconductor interfaces.

1 NSF CHE-1213243 and DOE DE-AC02-98CH10886

12:15 PM B8.00006 Photo-Activation of Single Molecules and Assemblies on Au{111}, YUXI ZHAO, MOONHEE KIM, NATCHA WATTANATORN, Department of Chemistry and Biochemistry, University of California, Los Angeles, JEFFREY SCHWARTZ, Department of Physics & Astronomy, University of California, Los Angeles, HONG MA, ALEX JEN, Department of Materials Science and Engineering, University of Washington, PAUL WEISS, Department of Chemistry and Biochemistry, University of California, Los Angeles — Understanding electron transfer at the molecule-surface interface is critical to the rational design and improvement of organic optoelectronics and photovoltaics. The behavior of photoactive molecules depends critically on their local environment and defects present in the surface. Here, we use a custom-built, laser-assisted scanning tunneling microscope to probe the photocurrent of isolated anthracene derivates on Au(111). The photocurrent originates from charge-transfer transitions of anthracene into an excited state when illuminated by an evanescent field. The influence of the image potential states on terraces and at defects in the gold surface on photo-induced charge transfer will be discussed.

12:27 PM B8.00007 Anchoring and Bending of Pentacene on Aluminum (001), GUIDO FRATESI, ETSF, CNISM, Dip. di Fisica, Università di Milano, Via Celoria 16, I-20133 Milano, Italy, and Dip. di Scienza dei Materiali, Milano-Bicocca, ANU BABY, Dipartimento di Scienza dei Materiali, Università di Milano-Bicocca, Via Cozzi 55, I-20125 Milano, Italy, SHITAL R. VAIDYA, LAERTE E. PATERA, CNR-IOM, Lab TASC, Dep. of Physics, and Grad. School of Nanotechnology, Univ. of Trieste, Via Valerio 2, I-34127 Trieste, Italy, CRISTINA AFRICH, LUCA FLOREANO, CNR-IOM, Laboratorio TASC, Basovizza SS-14, Km 163.5, I-34149 Trieste, Italy, CRISTINA AFRICH, LUCA FLOREANO, CNR-IOM, Laboratorio TASC, Basovizza SS-14, Km 163.5, I-34149 Trieste, Italy — We study the structural, electronic, and spectroscopic properties of pentacene adsorbed on Al(001) surface, combining density functional theory (DFT) methods including van der Waals interactions with x-ray photoemission spectroscopy (XPS), near-edge x-ray absorption fine structure (NEXAFS), and scanning tunneling microscopy (STM). We find a major change of the molecular backbone resulting into a peculiar V-shape conformation, as driven by the link of the central carbon atoms of pentacene to a pair of slightly displaced Al atoms. Remarkably, V-shape bending, due to the direct anchoring of the two central carbons atop two Al atoms underneath. In the most stable adsorption configuration, pentacene V-shape conformation, as driven by the link of the central carbon atoms of pentacene to a pair of slightly displaced Al atoms.

12:39 PM B8.00008 Pentacene thin films on flat and vicinal Au(111) surfaces, M. FATIH DANIMAN, Middle East Technical University, ERSEN METE, Balikesir University, EROL ALBAYRAK, Ahi Evran University — Here we present a structural study of pentacene thin films on flat and vicinal Au(111) surfaces by He atom diffraction measurements and dispersion corrected density functional theory (DFT) calculations. Though experimentally investigated parameter space was limited, no significant difference between the films prepared by different deposition energies was observed. Completion of monolayer coverage was confirmed by simultaneous helium scattering and quartz crystal resonance frequency shift measurements during pentacene film growth on the gold electrode of a quartz resonator. Monolayer films were found to adopt a (6x3) unit cell which was also observed for pentacene monolayers on Ag(1 1 1). However no ordered multilayer film structure could be observed which is in contrast with the previous Ag(1 1 1) studies. DFT calculations were performed with and without dispersion correction. Adsorption site of isolated pentacene molecules, crystal and electronic structure of monolayers and multilayers (up to 4 ML) were studied. The most stable monolayer structure was found to be the (6x3) unit cell in agreement with the experimental findings.
Conducted at Oak Ridge National Laboratory is sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. DOE.

Molecular ordering and orientation at the hetero-interface with the silicon substrate to be tuned accordingly. This mechanism provides new control over the development of organic and molecular electronics. Combining scanning tunneling microscopy and density functional theory, we show that by appropriately extending the site preferences of benzenes substituted with various activating and deactivating functional groups has been explored.

Choosing the coordinated transition-metal ion in metal phthalocyanine, the strength of the molecule-substrate interaction can be tailored, allowing for the substrates can lead to desired transport properties such as charge transfer, charge injection, exciton diffusion, etc., at the hetero-interface, which is crucial to understanding of the structure of such interfaces can potentially guide nanoscale modifications for improved electrical transport and energy-conversion efficiency in future devices.

1:03PM B8.00010 Layer resolved evolution of α-sexithiophene films: Correlation between PEEM and optical reflectance, EBRAHIM GHANBARI, THORSTEN WAGNER, PETER ZEPPENFELD, Johannes Kepler university — α-sexithiophene (α-6T) is a well-known organic dye pigment which represents a model system to study the photo-physical properties of π-conjugated molecules. We apply a combination of Differential Reflectance Spectroscopy (DRS) and Photo Electron Emission Microscopy (PEEM) to follow the growth of α-6T on Cu(111) surfaces in real time. The deposition of the molecules changes the density of states at the surface as well as the actual photoelectron emission barrier. Therefore, the lateral variation of the electron yield can be used to follow the growth of layers and 3D crystallites. Upon opening of the shutter, the PEEM intensity rises uniformly across the entire field of view (145 µm) until the first layer is closed. The following drop of the electron yield is terminated when the wetting layer is completed and the nucleation of 3D islands sets in. The DRS and the PEEM are synchronized and both signals are recorded simultaneously. The evolution of different features in the normalized differential optical reflectance can be attributed to the formation of the first layer, the second layer, the nucleation and growth of 3D crystallites. Therefore, we can make a direct correlation between the PEEM and the transients of the spectral reflectance.

1:15PM B8.00011 Spatially-resolved molecular Quantum Dots at the Surface of a Gated Graphene Device, HSIN-ZON TSAI, SEBASTIAN WICKENBURG, UC Berkeley physics/ LBNL, JIONG LU, UC Berkeley physics/ NUS Graphene Research Centre, ARASH A. OMRAI, SINISA COH, HAN SAE JUNG, DILLON WONG, JOHANNES LISCHNER, RAMIN KAHEJ, UC Berkeley physics, ALEXANDER RISS, UC Berkeley physics/ TU Wien applied physics, AARON J. BRADLEY, UC Berkeley physics, ERIK PIATTI, Politecnico di Torino DI SAT, ALEX ZETTL, STEVEN G. LOUIE, MARVIN L. COHEN, MICHAEL F. CROMMIE, UC Berkeley physics/ LBNL MSD — The ability to modify the electronic properties of monolayer graphene via charge-donating or charge-accepting molecules creates new opportunities for fabricating nano-scale hybrid devices. Understanding the charge transfer process at the single molecule level is essential for tuning the electronic and magnetic characteristics of such hybrid devices. We have used scanning tunneling microscopy (STM) to locally probe how different molecular assemblies (including single molecules, molecular chains, and 2D molecular islands) exchange charge with a graphene substrate as the device backgate voltage is varied. Different molecular configurations exhibit substantially different charging behavior - some are permanently charged while others can be controllably ionized using the device backgate. Electrostatic interactions lead to charge heterogeneity at the molecular level. Single-chemical-bond-resolved atomic force microscopy allows us to correlate chemical structure and adsorption geometry of the molecules with their electronic properties.

1:27PM B8.00012 Tailored Organic Molecular Growth on Silicon Studied by STM and DFT*, SEAN WAGNER, Michigan State University, BING HUANG, CHANGWON PARK, Oak Ridge National Laboratory, JIAJUI FENG, Michigan State University, MINA YOON, Oak Ridge National Laboratory, PENGPENG ZHANG, Michigan State University — Control of highly ordered organic molecular thin films with extended π systems is currently of intense interest for integrating molecules into modern electronics due to their tunable nature. Selection of molecules and substrates can lead to desired transport properties such as charge transfer, charge injection, exciton diffusion, etc., at the hetero-interface, which is crucial to the development of organic and molecular electronics. Combining scanning tunneling microscopy and density functional theory, we show that by appropriately choosing the coordinated transition-metal ion in metal phthalocyanine, the strength of the molecule-substrate interaction can be tailored, allowing for the molecular ordering and orientation at the hetero-interface with the silicon substrate to be tuned accordingly. This mechanism provides new control over the deliberately balanced molecule-substrate and intermolecular interactions, opening a route towards well-ordered molecular organic growth. *Experimental work is funded by the U.S. DOE Office of Science Early Career Research Program (DE-SC0006400) through the Office of Basic Energy Sciences. Theory work conducted at Oak Ridge National Laboratory is sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. DOE.

1:39PM B8.00013 Bonding at the Metal-Organic Interface, EVA ZUREK, University at Buffalo, SUNY — We present the results of density functional theory calculations that account for dispersion, which systematically study the perturbations of the electronic structure of various organic molecules physisorbed or weakly chemisorbed to the (111) surfaces of the coinage metal surfaces copper, silver and gold. The molecules considered include: benzene, substituted benzenes, 4-fluorostyrene, tetr phenyl porphyrin, a quinonoid zwitterion, croconic acid and rhodzonic acid. We have employed a frontier orbital perspective to analyze the bonding between the substrate and the adsorbate, studied the charge redistribution at the organic-metal interface, and analyzed how this affects the self-assembly. Our theoretical studies have helped to explain the experimental observations of STM (scanning tunneling microscopy) groups by showing that: tetr phenyl-porphyrin forms attractive networks on the Ag(111) surface and repulsive ones on Cu(111) because of the larger amount of charge transfer on Cu(111); the 10 D dipole of a quinonoid zwitterion changes substantially upon adsorption to the coinage metal surfaces Cu(111), Ag(111) and Au(111) as a result of donation of charge from the molecular HOMO to the surface and back donation to the LUMO; the charge transfer which occurs between the quinonoid zwitterion and Au(111) has been studied as a function of surface coverage; 4-fluorostyrene molecules form clusters of “magic” sizes that depend on the metal surface and can be understood in terms of a balance between attractive H-bonding and van der Waals interactions as well as Coulomb repulsion between the molecules; the topological organic ferroelectric molecule croconic acid forms chiral honeycomb networks on the Ag(111) surface. Moreover, our calculations have illustrated that classic activating groups generally increase and prototypical deactivating groups decrease the amount and direction of charge transferred from a substituted benzene derivative to the Cu(111) and Ag(111) surfaces. The effect of functionalization on the binding site preferences of benzenes substituted with various activating and deactivating functional groups has been explored.

1:39 PM B8.00013 Bonding at the Metal-Organic Interface, EVA ZUREK, University at Buffalo, SUNY — We present the results of density functional theory calculations that account for dispersion, which systematically study the perturbations of the electronic structure of various organic molecules physisorbed or weakly chemisorbed to the (111) surfaces of the coinage metal surfaces copper, silver and gold. The molecules considered include: benzene, substituted benzenes, 4-fluorostyrene, tetr phenyl porphyrin, a quinonoid zwitterion, croconic acid and rhodzonic acid. We have employed a frontier orbital perspective to analyze the bonding between the substrate and the adsorbate, studied the charge redistribution at the organic-metal interface, and analyzed how this affects the self-assembly. Our theoretical studies have helped to explain the experimental observations of STM (scanning tunneling microscopy) groups by showing that: tetr phenyl-porphyrin forms attractive networks on the Ag(111) surface and repulsive ones on Cu(111) because of the larger amount of charge transfer on Cu(111); the 10 D dipole of a quinonoid zwitterion changes substantially upon adsorption to the coinage metal surfaces Cu(111), Ag(111) and Au(111) as a result of donation of charge from the molecular HOMO to the surface and back donation to the LUMO; the charge transfer which occurs between the quinonoid zwitterion and Au(111) has been studied as a function of surface coverage; 4-fluorostyrene molecules form clusters of “magic” sizes that depend on the metal surface and can be understood in terms of a balance between attractive H-bonding and van der Waals interactions as well as Coulomb repulsion between the molecules; the topological organic ferroelectric molecule croconic acid forms chiral honeycomb networks on the Ag(111) surface. Moreover, our calculations have illustrated that classic activating groups generally increase and prototypical deactivating groups decrease the amount and direction of charge transferred from a substituted benzene derivative to the Cu(111) and Ag(111) surfaces. The effect of functionalization on the binding site preferences of benzenes substituted with various activating and deactivating functional groups has been explored.

11:15AM B9.00001 Evidence for phononic pairing in extremely overdoped “pure” d-wave superconductor Bi2212, YU HE, Department of Applied Physics, Stanford University, Stanford, CA, MAKOTO HISHIMOTO, Stanford Synchrotron Radiation Lightsource, SLAC, CA, DONGJOON SONG, HIROSHI EISAKI, AIST, Japan, ZHI-XUN SHEN, Department of Applied Physics, Stanford University, Stanford, CA — Recent advancement in High Tc cuprate superconductor research has elucidated strong interaction between superconductivity and competing orders. Therefore, the mechanism behind the ‘pure’ d-wave superconducting behavior becomes the next stepping stone to further the understanding. We have performed photoemission study on extremely overdoped Bi2212 single crystal synthesized via high pressure method. In this regime, we demonstrate the much reduced superconducting gap and the absence of pseudogap. Clear gap shifted bosonic mode coupling is observed throughout the entire Brillouin zone. Via full Eliashberg treatment, we find the electron-phonon coupling strength capable of producing a transition temperature very close to Tc. This strongly implies bosonic contribution to cuprate’s superconductivity’s pairing glue.

11:27AM B9.00002 Spectral moment sum rules for electron-phonon coupled superconductors in equilibrium and nonequilibrium, KHADIJEH NAJAFI, JAMES FREERICKS, Georgetown University — Recent developments in high-resolution time- and angle-resolved photoemission spectroscopy (trARPES) has opened a new path to study the dynamics of quantum materials in nonequilibrium. Several experimental studies have used trARPES to characterize the dynamics of the energy gap in superconductors. One experiment from the Lanzara group indicates that the fluence dependence of the photoemission signal is consistent with a weakening of the electron-phonon coupling in the superconducting state that increases with increasing fluence. The normal state sum rules shows that the integrated spectral weight in the normal state is constant if the phonon fluctuations are unchanged. Here we discuss the extension of these sum rules to the superconducting state.

11:39AM B9.00003 RIXS Study on the Doping Dependence of Elementary Excitations across AFM-SC Phase Boundary in Electron-doped Cuprates1, WEI-SHENG LEE, SIMON GERBER, SLAC National Accelerator Lab., USA, Y. B. HUANG, Paul Scherrer Institut, Switzerland, GUICHUAN YU, University of Minnesota, USA, BRIAN MORTIZ, SLAC National Accelerator Lab., USA, H. Y. HUANG, R. P. WANG, W. B. WU, NSRRC, Taiwan, V. N. STROCov, Paul Scherrer Institut, Switzerland, E. M. MOTOYAMA, Stanford University, USA, C. T. CHEN, D. J. HUANG, NSRRC, Taiwan, MARTIN GREVEN, THORSTEN SCHMITT, University of Minnesota, USA, Z. X. SHEN, T. P. DEVEREAUX, SLAC National Accelerator Lab., USA — Tracking the doping dependence of elementary excitations in cuprates is an important approach to gain further insight into the high temperature superconductivity. Recently, RIXS measurements have revealed two surprising behaviors in the electron-doped cuprates: (i) the bandwidth of magnetic excitation increases, and (ii) an unexpected branch of collective modes emanating from the zone center was found in superconducting compounds, indicating the existence of a quantum phase distinct from superconductivity. Yet, a detailed doping dependence study of these two behaviors in the phase diagram, especially near the antiferromagnetic-superconductivity phase boundary, is still lacking. Here we report RIXS measurements on electron-doped cuprates, Nd$_{2-x}$Ce$_x$CuO$_4$. Doping dependence of magnetic and these zone-center excitations will be presented.

11:51AM B9.00004 Terahertz nano-spectroscopy and imaging of superfluid surface plasmons in conventional and anisotropic superconductors, H. T. STINSON, J. S. WU, B. Y. JIANG, Z. FEI, University of California San Diego, A. S. RODIN, Boston University, B. CHAPLER, A. S. MCLEOD, University of California San Diego, A. CASTRO NETO, National University of Singapore, Y. S. LEE, Soongsil University, M. M. FOGLER, D. N. BASOV, University of California San Diego, H. T. STINSON, J. S. WU, B. Y. JIANG, Z. FEI, University of California San Diego — We numerically model terahertz plasmonics experiments on conventional and unconventional superconductors in the infrared and terahertz regime. Our modeling shows that near-field spectroscopy can measure the magnitude of the superconducting gap in Bardeen-Cooper-Schrieffer superconductors with nanoscale spatial resolution. We demonstrate how the same technique can measure the c-axis plasma frequency, and thus the c-axis superfluid density, of layered unconventional superconductors such as cuprates and pnictides with identical spatial resolution. We discuss the development of a cryogenic terahertz near-field microscope designed to perform these proposed experiments.

12:03PM B9.00005 The fate of quasiparticles in the superconducting state, S.V. DORDEVIC, The University of Akron, D. VAN DER MAREL, Universite de Geneve, Switzerland, C.C. HOMES, Brookhaven National Laboratory — Quasiparticle properties in the superconducting state are masked by the superfluid and are not directly accessible to infrared spectroscopy. We show how one can use a Kramer-Kronig transformation to separate the quasiparticle from superfluid response and extract intrinsic quasiparticle properties in the superconducting state. We also address the issue of a narrow quasiparticle peak observed in microwave measurements, and demonstrate how it can be combined with infrared measurements to obtain unified picture of electrodynamics properties of cuprate superconductors.

12:15PM B9.00006 Broken time reversal symmetry states in superconductors using the ultrafast pump-probe method, CHANDAN SETTY, JIANGPING HU, Purdue Univ — The excitation of vibrational modes by ultrafast optical pulses can be a useful probe of the electronic ground state in a solid through the electron-phonon interactions. In this work, we show that the phase of the oscillations of reflectivity/transmissivity as a function of the delay time can contain signatures of broken time reversal symmetry (BTRS) in the superconducting ground state. To illustrate this, we consider a simple Hamiltonian consisting of a two band electronic part and a phononic part; additionally, we include terms which couple electrons to phonons and light. In the absence of dissipation, we show that entry into the BTRS superconducting state, the phase of the reflectivity oscillations deviates from the normal state values of $\pm \pi/2$ in a continuous fashion. We will also comment on the effects of dissipation and the dependence of our result on the opacity of the superconductor.

12:27PM B9.00007 Reduction of dissipative nonlinear conductivity of superconductors by static and microwave magnetic fields, ALEXANDER GUREVICH, Old Dominion University — A theory of dissipative nonlinear conductivity, $\sigma_1(\omega, H)$, of s-wave superconductors under strong electromagnetic fields at low temperatures and frequencies $\hbar \omega \ll k_B T$ is proposed. Closed-form expressions for $\sigma_1(H)$ and the surface resistance $R_s(\omega, H)$ are obtained in the nonequilibrium dirty limit for which $\sigma_1(H)$ has a significant minimum as a function of the amplitude of magnetic field $H$. The calculated microwave suppression of $R_s(\omega, H)$ is in good agreement with recent experiments on alloyed Nb resonator cavities. It is shown that superimposed dc and ac fields, $H = H_0 + H_0 \cos \omega t$, can be used to reduce dc dissipation in thin film nanostructures by tuning $\sigma_1(H_0)$ with the dc field, consistent with experiments performed in the sixties.

12:39PM B9.00008 The non-linear response of a superconductor to a few-cycle THz pulse\(^1\). G.L. CARR, XIAOXIANG XI\(^2\). Photon Sciences, Brookhaven National Laboratory — We present a time-domain analysis of the response of a BCS superconductor (in the low temperature limit) to a few cycle THz pulse whose spectral content may span the absorption threshold for pair breaking. The analysis is based on the finite-difference time-domain (FDTD) approach, in combination with a model susceptibility for a superconductor that includes an explicit dependence on the energy gap\(^1\). The FDTD approach allows us to calculate the THz induced current density, from which we determine the modified energy gap at each instant of time during the THz wave’s passage. The resulting non-linear susceptibility causes up-conversion of the incident THz wave into odd harmonics. The model results are compared with experiment for thin NbN films in both linear\(^2\) and non-linear\(^3\) regimes. [1] Xiaoxiang Xi and G.L. Carr, Supercon. Sci. & Technol. 26, 114001 (2013). 12:51PM B9.00009 What does resonant inelastic x-ray scattering at the Cu L-edge measure? CHUNJING JIA, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford Institute for Materials and Energy Sciences, SLAC National Laboratory and Stanford University, Menlo Park, CA 94025, USA, KRZYSZTOF WOHLFELD, 1) SLAC and Stanford University; 2) Institute of Theoretical Physics, University of Warsaw — Recent resonant inelastic x-ray scattering (RIXS) experiments at the transition metal L-edge of copper oxides suggest that this technique can be regarded as one of the best momentum-resolved probes of low energy excitations. However, the theoretical understanding of this technique remains incomplete \([1]\). Here we show, using both numerical studies and analytical approaches, which low energy excitations are probed by RIXS in both undoped and doped cuprates, as modeled by the Hubbard Hamiltonian. We conclude on a qualitative level that (i) RIXS is sensitive to the spin dynamical structure factor in the cross-polarized geometry, whereas (ii) RIXS is sensitive primarily to the \(A_{1g}\) projected charge dynamical structure factor, i.e. to both charge excitations and the two-spin excitations (including e.g. bimagrons) in the parallel scattering geometry.

1:03PM B9.0010 Terahertz transient photoconductivity of insulating cuprates, J. STEVEN DODGE, JESSE PETERSEN, AMIR FARAHANI, DEREK SAHOTA, Simon Fraser University, RUIXING LIANG, University of British Columbia — We establish a detailed phenomenology of photoconductivity and transient THz transport in the copper oxide plane by studying the terahertz transient photoconductivity of \(\text{Sr}_2\text{CuO}_2\text{Cl}_2\) and \(\text{YBa}_2\text{Cu}_3\text{O}_6\). We observe a common dependence on time, fluence, and temperature. We infer an intrinsic photocarrier mobility from the peak photoconductivity, and show that this description fails. The pump-probe signal saturates at a characteristic fluence that depends on pump wavelength. In all three materials, the saturation fluence reaches a minimum at a pump photon energy 0.6 eV above the optical absorption peak associated with the charge transfer gap. We associate both the pump-probe spectrum and its saturation behavior with the thermalization of the initial photoexcitations, indicating a lack of interaction among photoexcitations. We observe a crossover with time, to a thermalized regime characterized by hopping conductivity with a low activation energy.

1:15PM B9.00011 Pump-probe excitation spectroscopy of insulating cuprates, DEREK SAHOTA, Department of Physics, Simon Fraser University, HANNA DABKOWSKA, Brockhouse Institute for Materials Research, McMaster University, GRAEME LUKE, Department of Physics and Astronomy, University of British Columbia, RUIXING LIANG, Department of Physics and Astronomy, University of British Columbia — We examine the transient optical response of optically thick single crystals of the Department of Physics and Astronomy, McMaster University, RUIXING LIANG, Department of Physics and Astronomy, University of British Columbia, J. STEVEN DODGE, Department of Physics, Simon Fraser University — We examine the transient optical response of optically thick single crystals of the insulating cuprates \(\text{La}_2\text{CuO}_4\), \(\text{YBa}_2\text{Cu}_3\text{O}_6\), and \(\text{Sr}_2\text{CuO}_2\text{Cl}_2\), as a function of probe wavelength, pump excitation wavelength, and pump fluence. At pump-probe time delay \(t > 1\) ps, the transient reflectance spectrum mimics a change in temperature, while for \(t < 1\) ps we observe a non-thermal response for which this description fails. The pump-probe signal saturates at a characteristic fluence that depends on pump wavelength. In all three materials, the saturation fluence reaches a minimum at a pump photon energy 0.6 eV above the optical absorption peak associated with the charge transfer gap. We associate both the pump-probe spectrum and its saturation behavior with the thermalization of the initial photoexcitations, and argue that the saturation spectrum indicates a relaxation bottleneck just above the charge transfer gap.

1:27PM B9.00012 Effect of pressure on the Fermi-surface reconstruction in the cuprate superconductor \(\text{YBa}_2\text{Cu}_3\text{O}_7\), SVEN BADOUX, OLIVIER CYR-CHONIERE, SOPHIE DUFOUR-BEAUSEJOUR, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, University of Sherbrooke, Sherbrooke, Canada, DAVID VIGNOLLES, MARC NARODNE, CYRIL PROUST, LNCMI, Toulouse, France, DOUGLAS BONN, WALTER HARDY, RUIXING LIANG, University of British Columbia, Vancouver, Canada — Quantum oscillations and transport measurements have shown that the Fermi surface of cuprate superconductors undergoes a reconstruction near optimal doping \([1-5]\). It has recently become clear that charge-density-wave order and Fermi-surface reconstruction in the copper oxide plane by studying the terahertz transient photoconductivity of \(\text{Sr}_2\text{CuO}_2\text{Cl}_2\) and \(\text{YBa}_2\text{Cu}_3\text{O}_6\). We observe a common dependence on time, fluence, and temperature. We infer an intrinsic photocarrier mobility from the peak photoconductivity, and show that this description fails. The pump-probe signal saturates at a characteristic fluence that depends on pump wavelength. In all three materials, the saturation fluence reaches a minimum at a pump photon energy 0.6 eV above the optical absorption peak associated with the charge transfer gap. We associate both the pump-probe spectrum and its saturation behavior with the thermalization of the initial photoexcitations, and argue that the saturation spectrum indicates a relaxation bottleneck just above the charge transfer gap.

1:39PM B9.00013 Magnetic excitations in the superconducting and pseudogap states of the slightly underdoped high-temperature superconductor \(\text{HgBa}_2\text{CuO}_4+\delta\), MUN CHAN, Los Alamos National Laboratory, C. J. DOROW, Y. TANG, M. J. VEIT, Y. GE, M. GREVEN, University of Minnesota, L. MANGIN-THRO, Y. SIDIS, P. BOURGES, Laboratoire Léon Brillouin, France, X. ZHAO, Jilin University, China, D. L. ABERNATHY, Oak Ridge National Laboratory — We present an inelastic neutron scattering study of the magnetic excitations in slightly underdoped cuprate high-temperature superconductor \(\text{HgBa}_2\text{CuO}_4+\delta\) \((\text{Hg}2101, \rho=0.117, T_c = 88 \text{ K})\). Unlike more underdoped \(\text{Hg}1201\), the magnetic spectrum exhibits an X-shaped hourglass dispersion with an incommensurate low energy response and a clear resonance mode in the superconducting state. At temperatures above \(T_c\), the low energy incommensurate excitations disappear, replaced by a commensurate Y-shaped spectrum characteristic of the pseudogap state. The magnetic excitations become weaker with increasing temperature and are no longer discernable above the pseudogap temperature \(T^*\). The temperature evolution of the magnetic spectrum across \(T_c\) is consistent with models based on excitations of itinerant spins with a d-wave superconducting order parameter. Our work suggests that itinerant carriers should play an integral part for the understanding of the pseudogap state as well.

1:51PM B9.00014 Quasiparticle mass enhancement approaching optimal doping in \(\text{YBa}_2\text{Cu}_3\text{O}_6+\delta\) \(x\). BRAD RAMSHAW, Los Alamos National Laboratory, SUCHITRA SEBASTIAN, Cambridge University, ROSS MCDONALD, Los Alamos National Laboratory, JAMES DAY, University of British Columbia, BENG TAN, Cambridge University, ZENGWEI ZHU, JON BETTS, Los Alamos National Laboratory, RUIXING LIANG, DOUG BONN, WALTER HARDY, University of British Columbia, NEIL HARRISON, Los Alamos National Laboratory — Unconventional superconductivity is almost always found in proximity to other broken-symmetry states. The high-Tc cuprates exhibit a rich phase diagram that includes both spin and charge order. Previous quantum oscillation studies on \(\text{YBa}_2\text{Cu}_3\text{O}_6+\delta\) \(x\) have addressed how broken symmetry reconstructs the Fermi surface, but the evolution of the Fermi surface toward optimal doping was missing due to the high upper-critical fields. We use magnetic fields approaching 100 tesla to measure quantum oscillations in \(\text{YBa}_2\text{Cu}_3\text{O}_6+\delta\) \(x\) at three new doping levels with Tcs of 75, 81, and 91 K. We find that the quasiparticle effective mass is strongly enhanced approaching a hole doping of \(p=0.18\) — the same doping where experimental signatures of broken symmetry terminate and superconducting properties are enhanced. This is suggestive of a quantum critical point underlying the superconducting dome near optimal doping.
2:03PM B9.00015 Photo-induced Ultra-fast Carrier Dynamics in a Mott Insulator with Antiferromagnetic Long-range Order, SUMIO ISHIHARA, Department of Physics, Tohoku University, EIKI IVODA, Department of Basic Science, The University of Tokyo — We study transient dynamics of conduction carriers injected into a Mott insulator with antiferromagnetic long-range order, motivated from the recent optical pump-probe experiments in high-Tc superconductors. This is termed ?dynamical hole doping? in contrast to the chemical hole doping. The theoretical framework for the transient carrier dynamics is presented based on the two-dimensional t-J model [1]. The time dependencies of the optical conductivity spectra, as well as the one-particle excitation spectra, are calculated based on the Keldysh Green’s function formalism, associated with the self-consistent Born approximation. In the early stage, the Drude component only appears, and then incoherent components originating from hole-magnon scattering start to grow. Fast oscillatory behavior owing to coherent magnon and slow relaxation dynamics are confirmed in the spectra. The time profiles are interpreted as doped bare holes being dressed by magnon clouds and relaxed into spin polaron quasiparticle states. Implications for recent pump-probe experiments are discussed. [1] E. Iyoda, and S. Ishihara, Phys. Rev. B 89, 125126 (2014).

Monday, March 2, 2015 11:15AM - 2:15PM — Session B10 DCMP: Topological Insulators - Materials and Structures (Theory) 007A - Arijit Kundu, University of Indiana, Bloomington

11:15AM B10.00001 Numerical studies on the robustness of the topological surface modes of the topological insulator nanostructures, HSU-JUAN HSU, AJIT COIMBATORE BALRAM, JAINENDRA JAIN, CHAOXING LIU, The Pennsylvania State University, DEPARTMENT OF PHYSICS TEAM — It has been found experimentally that the magnetoconductance oscillates as a function of the magnetic flux with a period of $\phi_0$ ($\phi_0 = \hbar/e$, one flux quantum) in strongly disordered topological insulator (TI) nanotubes. In an effort to understand the origin of the oscillation, we calculate the magnetoconductance of TI nanowire and nanotube within the Landauer formalism at different disordered strengths and Fermi levels. We found unambiguous oscillation features of the magnetoconductance which survive even in extreme disordered regime. The oscillation is attributed to the occurrence of gapless helical surface modes when the surface encloses a magnetic flux of integer multiples of $\phi_0/2$. These features demonstrate a robust transport signature of the helical surface mode(s) of the TI nanostructures.

11:27AM B10.00002 Wire deconstructionism of two-dimensional topological phases1, RONNY THOMALE, Wuerzburg University, TITUS NEUFURT, Princeton University, CLAUDIO CHAMON, Boston University, CHRISTOPHER MUDRY, PSI Zurich — A scheme is proposed to construct integer and fractional topological quantum states of fermions in two spatial dimensions. We devise models for such states by coupling wires of non-chiral Luttinger liquids of electrons, that are arranged in a periodic array. Which inter-wire couplings are allowed is dictated by symmetry and the compatibility criterion that they can simultaneously acquire a finite expectation value, opening a spectral gap between the ground state(s) and all excited states in the bulk. First, with these criteria at hand, we reproduce the tenfold classification table of integer topological insulators, where their stability against interactions becomes immediately transparent in the Luttinger liquid description. Second, we construct an example of a strongly interacting fermionic topological phase of matter with short-range entanglement that lies outside of the tenfold classification. Third, we expand the table to long-range entangled topological phases with intrinsic topological order and fractional excitations.

11:51AM B10.00004 Magnetic Susceptibility and Quantum Oscillations in a Buckled Honeycomb Lattice, CALVIN TABERT, University of Guelph, JULES CARBOTTE, McMaster University, ELISABETH NICOL, University of Guelph — We calculate the magnetic response of a low-buckled honeycomb lattice with intrinsic spin-orbit coupling which is described by the Kane-Mele Hamiltonian (a model which would describe the low-energy physics of a material like silicene). Included in the Hamiltonian, is a sublattice potential difference term which may be induced by a perpendicular electric field; this field can tune the system from a topological insulator (TI), through a valley-spin polarized metal, to a trivial band insulator (BI). In an external magnetic field, a distinct signature of the phase transition is seen in the derivative of the magnetization with respect to chemical potential; this gives the quantization of the Hall plateaus through the Streda relation. The results are compared with the zero-frequency conductivity obtained from the Kubo formula. The magnetic susceptibility also displays signatures of the different topological phases. We also explore the de-Haas van-Alphen effect. At the transition point between the TI and BI, magnetic oscillations exist for any value of chemical potential. Away from the critical point, the chemical potential must be larger than the minimum gap. For large chemical potential (or small but finite sublattice potential difference), there is a strong beating pattern.

12:03PM B10.00005 Properties of interacting 2D chiral tensor network states, BARRY BRADLYN, Yale University, JEROME DUBAIL, CNRS Nancy, NICHOLAS READ, Yale University — In a recent paper, Dubail and Read [1] gave a construction for free fermion tensor network states [2] (TNSs) in the chiral $p + ip$ and $\nu = 1$ Chern insulator topological phases in two dimensions, and gave a generalization to Laughlin-like states. However, on general principles these free fermion states must be ground states of gapless local Hamiltonians. In this talk, we address the issue of the energy gap in the interacting states, with a particular focus on the $\nu = 1/2$ bosonic Laughlin-like TNS. Through a combination of analytic and numerical arguments, we will show that these states too have gapless local parent Hamiltonians. Nevertheless, we will explore to what degree they can be used as numerical approximations to gapped phases.

12:15PM B10.00006 Exactly soluble 3D lattice models and the braiding statistics of their loop excitations, CHIEN-HUNG LIN, MICHAEL LEVIN, University of Chicago — We construct two exactly soluble 3D lattice models that belong to distinct topological phases in the sense that they cannot be smoothly connected without an intervening phase transition. What is interesting is that the two models have very similar physical properties: both are gapped and both support particle-like and loop-like excitations with non-trivial mutual statistics similar to that of charges and vortex lines in a $Z_2 \times Z_2$ gauge theory. The only difference between the two models lies in the braiding statistics of their loop excitations. As an application of these results, we construct two other closely related spin models with $Z_2 \times Z_2$ global symmetry. We show that one of these spin models realizes a $Z_2 \times Z_2$ symmetry protected phase with protected surface states while the other realizes a trivial phase without a protected surface.

12:27PM B10.00007 Topological phases in Iridium oxide superlattices: quantized anomalous charge or valley Hall insulators, HAE-YOUNG KEE, YIGE CHEN, University of Toronto — Designing materials is one of the hottest topics in modern condensed matter physics. Recently, how to achieve a topological insulator in transition metal oxides with strong spin-orbit coupling became an interesting subject. We have investigated possible topological phases in orthorhombic perovskite Ir oxide superlattices grown along the $[001]$ crystallographic axis. We found that bilayer Ir oxide superlattices exhibit quantized anomalous Hall effects in magnetic topological insulating phases. We also found, depending on the stacking of two layers, a valley Hall insulator with nontrivial valley dependent surface modes and a topological crystalline insulator with the crystal symmetry protected edge states can be realized. Experimental tools to detect such topological phases are also discussed.

12:39PM B10.00008 Surface States of Perovskite Iridates $\alpha$Al$\text{IrO}_3$: Signatures of Topological Crystalline Metal with Nontrivial $Z_2$ Index, HEUNG-SIK KIM, YIGE CHEN, HAE-YOUNG KEE, Department of Physics, University of Toronto — There have been increasing efforts in realizing topological metallic phases with nontrivial surface states, including a topological crystalline metal phase with flat surface states suggested recently. Here we perform first-principles electronic structure calculations for epitaxially stabilized orthorhombic perovskite iridates with $P\text{mmm}$ symmetry. Remarkably, two types of distinct topological surface states are found depending on the surface direction. On the side surfaces, flat surface states protected by the mirror symmetry emerge manifesting the topological crystalline character. On the top surface where mirror symmetry is broken, a Dirac cone appears indicating a non-trivial topology of the nodal metal. There, we find a well-defined two dimensional topological $Z_2$ index associated with time reversal symmetry. Transitions to weak and strong topological insulators and implications of different surface states in light of angle resolved photoemission spectroscopy are also discussed.

12:51PM B10.00009 Topological phase transitions in TiBiS$_2$ and TiSbS$_2$ under strain, QINGYUN ZHANG, YINGCHUN CHENG, UDO SCHWINGENSCHEIDL, Physical Sciences and Engineering, King Abdullah University of Science and Technology, COM-PUTATIONAL PHYSICS AND MATERIALS SCIENCE TEAM — Using first-principles calculations, we investigate the band structure evolution and topological phase transitions in TiBiS$_2$ and TiSbS$_2$ under hydrostatic pressure as well as uniaxial and biaxial strain. For TiBiS$_2$ topological transitions occur around 0 and 5 GPa, the system remaining a direct gap semiconductor up to 8 GPa. On the other hand, for TiSbS$_2$ the transitions occur around 2 and 5 GPa and the system transform from a direct gap semiconductor to a semimetal around 2 GPa. Biaxial and uniaxial strains are compared to each other. The phase transitions are identified by parity analysis and by calculating the surface states. Zero, one and four Dirac cones are found for the $(111)$ surfaces of both TiBiS$_2$ and TiSbS$_2$ when increasing the pressure, which confirms the trivial-nontrivial-trivial phase transitions. The Dirac cones at the $M$ points are anisotropic with a large out-of-plane component and inversely related in-plane spin and momentum direction. By examining the states on different surfaces we show that TiBiS$_2$ under 8 GPa pressure is a topological crystalline insulator. This finding makes the thallium-based III-V-VI$_2$ ternary chalcogenides candidates for studies on topological crystalline phase.

1:03PM B10.00010 A Novel Quasi-One-Dimensional Topological Insulator in Bismuth Iodide $\beta$-Bi$_4$I$_4$: Theoretical Prediction and Experimental Confirmation, OLEG V. ZAYZEV, GABRIEL AUTÉS, EPFL, ANNA ISAEVA, TU Dresden, LUCA MORESCHINI, LBNL, JENS C. JOHANNSSEN, ANDREA PISONI, EPFL, TATISCHI G. FILATOVA, ALEXEY N. KUZNETSOV, MSU, ŁAŚZLÓ FORRÓ, EPFL, WOUTER VAN DEN BROEK, LUL University, YEONGKwan KIM, JONATHAN D. DENLINGER, ELI TROETENBERG, AARON BOSTWICK, LBNL, MARCO GRIONI, EPFL — A new strong $Z_2$ topological insulator is theoretically predicted and experimentally confirmed in the $\beta$-phase of quasi-one-dimensional bismuth iodide Bi$_4$I$_4$. According to our first-principles calculations the material is characterized by $Z_2$ invariants $\{1;110\}$ making it the first representative of this topological class. Importantly, the electronic structure of $\beta$-Bi$_4$I$_4$ is in proximity with both the weak topological insulator phase $(0;000)$ and the trivial phase $(0;000)$, suggesting that a high degree of control over the topological electronic properties of this material can be achieved. Experimentally produced samples of this material appears to be practically defect-free, which results in a low concentration of intrinsic charge carriers. By using angle-resolved photoemission spectroscopy (ARPES) on the $(001)$ surface we confirm the theoretical predictions of a highly anisotropic band structure with a small band gap hosting topological surface states centered at the $M$ point, at the boundary of the surface Brillouin zone.

1:15PM B10.00011 ABSTRACT WITHDRAWN —

1:27PM B10.00012 Topological phases in SnTe thin films with a periodic array of defects and charge doping, MINSUNG KIM, JISOON IHAM, Dept. of Physics and Astronomy, Seoul Natl Univ — In this study, we investigate the topological phases of two-dimensional SnTe thin films with defect superstructures and charge doping. We find that the Sn-Te bilayer is a two-dimensional normal insulator, but can be transformed into a topological insulator by introducing an appropriate array of defects. Also, the topological phases of the films can be further controlled by charge doping due to the narrow bandwidth of the topologically nontrivial defect-induced bands. The results could be useful for the realization and control of the topological phases in nano-scale thin films.

1:39PM B10.00013 Topological states of non-Dirac electrons on $\text{Si}[111]$ surface, RUI YU, International Center for Materials Nanoarchitectonics (WPI-MANA) National Institute for Materials Science, Tsukuba 305-0044, Japan, QIFENG LIANG, Department of Physics, Shaoxing University, Shaoxing 312000, China, XIAO HU, International Center for Materials Nanoarchitectonics (WPI-MANA) National Institute for Materials Science, Tsukuba 305-0044, Japan — In the present work, we demonstrate the possibility of nontrivial topology of non-Dirac electrons. In particular, we show that, in two dimensional systems with $C_4$ crystal symmetry and time reversal symmetry, multiple $p$-orbitals exhibit a degeneracy and quadratic non-Dirac band dispersions at $\Gamma$ point. When the atomic spin-orbit coupling (SOC) is taken into account, a gap is opened at $\Gamma$ point and a quantum spin Hall effect state is realized. We construct a $k\cdot p$ model to reveal the nontrivial topology which is associated with a meron structure with double vorticity in the pseudo spin texture, a mechanism different from that on honeycomb lattice and the band inversion. We propose that $\text{Si}[111]$ surface with $1/3$ regular coverage of Bi atoms is a realization of our idea. First-principles calculations show that this system takes a quantum spin Hall phase with topological gap as large as $0.15eV$.

2This work is supported by WPI Initiative on Materials Nanoarchitectonics, MEXT, Japan.
topologically nontrivial. This can occur when either spatial inversion (P) or time-reversal (T) symmetry is broken, and spin-orbit is present. Taking ferromagnetic iron as a prototypical T-broken metal, we determine the Chern indices of all the Fermi sheets, starting from a census of the isolated band touchings in the Brillouin zone. Although there are many band touching points carrying a topological charge, the Chern index vanishes for most Fermi sheets. The reason is that they surround different Fermi arcs in the (010) surface bandstructure. We map out the phase diagram as a function of both nearest- and next-nearest-neighbor interaction strengths for an infinite cylinder geometry and find different charge-ordered phases but no sign of the interaction driven Chern insulator phase.

Monday, March 2, 2015 11:15AM - 2:15PM
Session B11 DCMP: Cuprate Superconductivity

11:15AM B11.00001 Intra unit cell electronic structure of the d-symmetry form factor density wave in the underdoped cuprates – Part I

KAZUHIRO FUJITA, MOHAMMAD HAMIDIAN, STEPHEN EDKINS, Cornell University, CHUNG KOO KIM, Brookhaven National Laboratory, ANDY MACKENZIE, University of St. Andrews, HIROSHI EISAKI, Brookhaven National Laboratory, JOHANNES MOTRUK, ADOLFO G. GRUSHIN, FRANK POLLMANN, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Mean field calculations in the literature have suggested the existence of an interaction-induced Chern insulator (CI) phase in a tight-binding model of spinless fermions on a honeycomb lattice with nearest- and next-nearest-neighbor interactions. The CI phase is an example of a state that breaks time-reversal symmetry and possesses a quantized Hall conductance. However, it has been proven elusive in exact diagonalization (ED) studies of this system. Since ED is limited to small system sizes, the fate of this phase in the thermodynamic limit still remains unclear. Using the infinite density matrix renormalization group (iDMRG) algorithm we reach system sizes exceeding those accessible in ED calculations while keeping track of quantum fluctuations neglected in mean field studies. We map out the phase diagram as a function of both nearest- and next-nearest-neighbor interaction strengths for an infinite cylinder geometry and find different charge-ordered phases but no sign of the interaction driven Chern insulator phase.

11:27AM B11.00002 Intra unit cell electronic structure of the d-symmetry form factor density wave in the underdoped cuprates – Part II

STEPHEN EDKINS, University of St Andrews, Cornell University, KAZUHIRO FUJITA, Cornell University, CMPMS Brookhaven National Lab, University of Tokyo, MOHAMMAD HAMIDIAN, Cornell University, CHUNG KOO KIM, CMPMS Brookhaven National Lab, Cornell University, ANDREW MACKENZIE, MIFI PFNS, University of St. Andrews, HIROSHI EISAKI, Institute of Advanced Industrial Science and Technology, SHINICHI SHIGETA, University of Tokyo, MICHAEL LAWLER, Binghamton University, Cornell University, EUN-AH KIM, Cornell University, SUBIR SACHDEV, Harvard University, SEAMUS DAVIS, Cornell University, KAZUHIRO FUJITA, Cornell University

In this talk we report on the electronic structure of Pb-Bi-2201. We develop a technique of sub-lattice phase-resolved electronic structure visualization within each CuO$_2$ unit-cell, we discovered a d-symmetry form factor density wave within the cuprate pseudogap state. In this talk, part I, we demonstrate that d-symmetry is the predominant form factor in the density wave within pseudogap states and show how this situation evolves upon doping.

11:39AM B11.00003 Decoding Spatial Complexity of Local Charge Modulations in Superconducting Pb-Bi-2201

ERICA CARLSON, Purdue University, CAN-LI SONG, ELIZABETH MAIN, Harvard University, SHUO LIU, BENJAMIN PHILLABABUM, Purdue University, KARIN DAHMEN, University of Illinois, Urbana-Champaign, ERIK HUDSON, Pennsylvania State University, JENNIFER HOFFMAN, Harvard University

In unconventional superconductors, real-space orders such as charge density modulations can coexist with superconductivity. In the cuprate superconductors, it has recently been recognized that local charge modulations are a ubiquitous feature and likely important for understanding the superconductivity in these materials. However, there are still open issues surrounding the dimensional profile of these charge modulations, including whether the modulation wavevector is unidirectional or bidirectional, and also whether the charge modulations extend beyond the surface of the material into the bulk. In bismuth-based cuprates, material disorder is a severe enough effect so as to preclude understanding the charge modulations through bulk scattering techniques. In order to resolve these issues, we use a local technique, scanning tunneling microscopy, to image the static charge modulations in Pb-Bi-2201. We find that the charge modulations are more consistent with an underlying tendency to a unidirectional charge density wave than a bidirectional charge density wave. Using recently developed cluster analysis techniques, we show that these locally 1D structures are more than surface deep, extending into the bulk of the material throughout the doping range.

11:51AM B11.00004 Resonant x-ray scattering study of charge order in the electron-doped cuprate Nd$_2$Ce$_{1-x}$CuO$_4$

EDUARDO DA SILVA NETO, RICCARDO COMIN, University of British Columbia, FEI ZHUO HE, RONNY SUTARTO, Canadian Light Source, YEPING JIANG, RICHARD GREENE, UNIVERSITY OF MARYLAND, GEORGE SAWATZKY, ANDREA DAMASCHELL, University of British Columbia

In cuprate high-temperature superconductors, an antiferromagnetic Mott insulating state can be destabilized toward unconventional superconductivity by either hole- or electron-doping. In hole-doped (p-type) cuprates a charge ordering (CO) instability competes with superconductivity inside the pseudogap state. In this talk we report resonant x-ray scattering measurements that demonstrate the presence of charge ordering in the n-type cuprate Nd$_2$Ce$_{1-x}$CuO$_4$ (NCCO) near optimal doping. We find that the CO in NCCO occurs with similar periodicity, and along the same direction as in p-type cuprates. However, in contrast to the latter, the CO onset in NCCO is higher than the pseudogap temperature, and is in the temperature range where antiferromagnetic fluctuations are first detected. Our discovery opens a parallel path to the study of CO and its relationship to antiferromagnetism and superconductivity. E.H. da Silva Neto, R.C. Comin et al. arXiv 1410.2253 (2014).
12:03PM B11.00005 Mapping the Striped Phase Diagram of La$_{2-x}$Ba$_x$CuO$_4$ with Resistance Fluctuation Spectroscopy, ADAM WEIS, AZTON WELLS, JUSTIN LANE, University of Illinois at Urbana-Champaign, SO RA CHUNG, Belmont University, PATHIKUMAR SELAPPAN, WALTRAUD KRIVEN, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign — La$_{2-x}$Ba$_x$CuO$_4$ (LBCO) is an exceptional high-temperature superconductor in which, near $x=1/8$ doping, superconductivity is suppressed and ‘striped’ charge order emerges. The charge stripes cause short-range conductance anisotropy that may be observed as fluctuations in resistance. In thin film LBCO devices grown by pulsed laser deposition, we measure time-resolved resistance as a function of bias current, temperature, and doping. As is consistent with charge stripes, the resistance noise exhibits a critical onset temperature and suppression at high currents. Combining resistance fluctuation spectroscopy with combinatorial laser deposition techniques, we are able to tune the doping of LBCO and map its phase diagram.

12:15PM B11.00006 Magnetic-field-driven superconductor-insulator transition in stripe-ordered La$_{1.48}$Nd$_{0.43}$Sr$_{0.12}$CuO$_4$, PAUL BAITY, ZHENZHONG SHI, DRAGANA POPOVIĆ, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ., T. SASAGAWA, Tokyo Inst. of Tech. — The effects of the magnetic field ($H$) in underdoped cuprates, the nature of the $H$-driven superconductor-insulator transition (SIT), and the interplay with charge ordering are some of the key questions in high-temperature superconductivity. A recent study of the $H$-driven SIT in highly underdoped ($T_c \sim 4$ K) La$_{2-y}$Sr$_y$CuO$_4$ (LSCO) revealed an intermediate phase, with two quantum critical points separating the superconductor and the insulator. While charge distribution in highly underdoped LSCO seems to be inhomogeneous, its sister compound La$_{2-y}$No$_{0.4}$Sr$_{0.6}$CuO$_4$ (LNSCO) with $y = 0.12$ is known to have a charge-stripe order already in $H = 0$ at low enough temperatures ($T$). In order to address the above issues, we carry out detailed measurements of the in-plane and out-of-plane magnetoresistance with different $H$ orientations and over a wide range of $T$ on LNSCO single crystals with $y = 0.12$ and $T_c \sim 4$ K. The results will provide insight into the universality of the $H$-driven SIT in cuprates with different types or, at least, varying degrees of charge order.

12:27PM B11.00007 Pairing interaction near a nematic QCP of a 3-band CuO$_2$ model, THOMAS MAIER, Oak Ridge National Lab, DOUGLAS SCALAPINO, University of California, Santa Barbara — We calculate the pairing interaction and the k-dependence of the gap function associated with the nematic charge fluctuations of a CuO$_2$ model. We find that the nematic pairing interaction is attractive for small momentum transfer and that it gives rise to d-wave pairing. As the doping $\nu$ approaches a quantum critical point, the strength of this pairing increases and higher d-wave harmonics contribute to the k-dependence of the superconducting gap function, reflecting the longer range nature of the nematic fluctuations.

12:39PM B11.00008 Doping dependence of fluctuation diamagnetism in High Tc superconductors, SUBROTO MUKERJEE, KINGSHUK SARKAR, Indian Institute of Science, SUMILAN BANERJEE, Weizmann Institute of Science, T. V. RAMAKRISHNAN, Banaras Hindu University — Using a recently proposed Ginzburg-Landau-like energy functional due to Banerjee et. al. Phys. Rev. B 83, 024510 (2011), we calculate the fluctuation diamagnetism of high-Tc superconductors as a function of doping $x$ in addition to the magnetic field $H$ and temperature $T$ by employing classical Monte-Carlo simulations. We explicitly show that the doping dependence of our diamagnetism results are in good qualitative agreement and reasonable quantitative agreement with experimental data. Our calculations show that a model where the pairing scale increases and superfluid density decreases with underdoping produces features of the observed magnetization in the pseudogap region. In particular we show that the magnetization tracks the superconducting dome instead of the pseudogap temperature as seen in experiment and also comment on the determination of doping dependence of the upper-critical field.

12:51PM B11.00009 Fermi Arc Evolution and Doping Mechanism in High-Temperature Superconductors, DENIS K. SUNKO, DAMJAN PELC, MIROSLAV POŽEK, VITO DESPOJA, Department of Physics, Faculty of Science, University of Zagreb, Bijenčka cesta 32, HR-10000 Zagreb, Croatia, PREDRAG LAZIC, Theoretical Physics Division, Rudjer Boskovic Institute — We calculate realistic Fermi surface (FS) evolution of La$_{2-x}$Sr$_x$CuO$_4$ (LSCO) with Sr doping within an extensive ab-initio framework including advanced band-unfolding techniques. We show that ordinary Kohn-Sham DFT+U can reproduce the observed metal-insulator transition and arc growth, when not restricted to the paramagnetic solution space. We elucidate both arc protection and the inadequacy of the rigid-band picture as consequences of a rapid change in orbital symmetry at the Fermi energy: the material undergoes a dimensional crossover along the Fermi surface, between the nodal (2D) and antinodal (3D) regions. In LSCO, this crossover accounts for FS arcs and the antinodal pseudogap, otherwise ubiquitous phenomena in high-Tc cuprates. The orbital transition is experimentally confirmed by replacing 4% of planar Cu in nearly optimally doped YBa$_2$Cu$_3$O$_{7-\delta}$ powder with $^{67}$Zn isotope, lowering $T_c$ to 57 K. The NQR spectrum of $^{67}$Zn, measured for the first time, shows that each Zn dopand surrounds itself with an insulating cluster. Zn destroys the SC metal by a Coulomb “domino effect” which reverts the orbital transition locally and pushes a significant number of surrounding sites back towards the parent-compound configuration.

1:03PM B11.00010 Andreev-Bragg reflection from an Amperian superconductor, PAUL BAIREUTHER, TIMO HYART, BRIAN TARASINKSI, CARLO BEENACKER, Instituut-Lorentz, Universiteit Leiden — We show how an electrical measurement can detect the pairing of electrons on the same side of the Fermi surface (Amperian pairing), recently proposed by Patrick Lee for the pseudogap phase of high-$T_c$ cuprate superconductors. Bragg scattering from the pair-density wave introduces odd multiples of $2\hbar \omega$ momentum shifts when an electron incident from a normal metal is Andreev-reflected as a hole. These Andreev-Bragg reflections can be detected in a three-terminal device, containing a ballistic Y-junction between normal and superconductor. The cross-conductance $\frac{dI_1}{dV_2}$ has the opposite sign for Amperian pairing than it has either in the normal state or for the usual BCS pairing.

1:15PM B11.00011 Shearconductivity as evidence for broken mirror symmetries, PATRIK HLOBIL, Karlruhe Institute of Technology, Stanford University, SRINIVAS RAGHU, AKASH MAHARAJ, PAVAN HOSUR, Stanford University — We propose the possible detection of broken mirror symmetries in highly correlated two-dimensional materials by elastotransport measurements. Using linear response theory we calculate the shearconductance $\Gamma_{xx,xy} = \sigma_{xx,xy}$, the linear change of the longitudinal conductivity $\sigma_{xx}$ due to a shear strain $\epsilon_{xy}$. This quantity can only be non-vanishing if the in-plane mirror symmetries are broken and we show that a square lattice with checkerboard charge and bond density wave shows a finite shearconductivity. This implies that a measurement of $\Gamma_{xx,xy}$ opens the possibility to verify broken mirror symmetry in the pseudogap regime of high-$T_c$ superconductors. Experimental setups to detect shearconductance are presented.
1:27PM B11.00012 Nanoscale phase separation in deep underdoped Bi$_2$Sr$_2$CuO$_{6+y}$ and Ca$_3$CuO$_2$Cl$_2$\textsuperscript{1} PETER MISTARK, ROBERT MARKIEWICZ, ARUN BANSIL, Northeastern University — We demonstrate that the tunneling spectra from deeply underdoped Bi$_2$Sr$_2$CuO$_{6+y}$ (Bi2201) and Ca$_3$CuO$_2$Cl$_2$ (CCOC) provide clear evidence for a nanoscale phase separation (NPS), which causes the gap to fill rather than close with doping. The phase separation extends from half-filling to a doping of $x \sim 0.09$. Assuming that the NPS is in the form of stripes, the nodal gap, which we model as a Coulomb gap, arises from impurity pinning of the charged stripes, and ultimately drives a metal-insulator transition.

1:39AM B11.00003 Enhancement of thermoelectric performance by phase separation of Ag$_2$Te in quaternary Ag$_x$Bi$_{0.5}$Sb$_{1.5-x}$Te$_3$\textsuperscript{*} YOO JANG SONG, JONG-SOO RHYEE, Kyung Hee Univ - Suwon Campus, BONG SEO KIM, Su DONG PARK, Korea Electrotechnology Research Institute, JAE HOON JUNG, Korea University, BYUNG-GIL RYU, JONG RAE LIM, LG Advanced Research Institute — Quaternary Ag–Bi–Sb–Te alloys with the general formula of Ag$_x$Bi$_{0.5}$Sb$_{1.5-x}$Te$_3$ are synthesized by solid state reaction for the high Ag doping $x=0.1, 0.2,$ and $0.3$. The powder x-ray diffraction analysis of the melted ingot shows the phase separation of AgSbTe$_3$ and Bi$_{0.5}$Sb$_{1.5}$Te$_3$ phases. After the hot press sintering at 350 $^\circ$C, we found Ag$_x$Te/Bi$_{0.5}$Sb$_{1.5}$Te$_3$ composite, instead of AgSbTe$_3$ phase separation, from the energy dispersive x-ray spectroscopy and x-ray diffraction measurements. The electrical conductivities of the Ag$_x$Te/Bi$_{0.5}$Sb$_{1.5}$Te$_3$ composite are significantly increased comparing with that of conventional p-type Bi$_{0.5}$Sb$_{1.5}$Te$_3$ composite, implying that the interface effect by phase separation can attribute to the increase of electrical conductivity. The maximum power factor and ZT values are reached up to 2.1 mW K$^{-2}$ m$^{-1}$ ($\sim 400$ K) and 1.1 (at 570 K), respectively, for $x = 0.1$ composite. Here we propose that the phase separation of Ag$_2$Te in Bi$_{0.5}$Sb$_{1.5}$Te$_3$ matrix can increase thermoelectric performance at mid-temperature temperature range.

1:51PM B11.00014 The insulator and pseudogap states coalescence beneath the superconductor dome . ALEJANDRO CABO MONTES DE OCA, ICMAT, La Habana, Cuba, ALEJANDRO CABO-BIZET, CEADEN, La Habana, Cuba, VICTOR MARTINEZ, YOANDRI VIELZA, Department of Physics, University of Pernambuco, Recife, Brasil, CONDENSED MATTER GROUP TEAM — The pseudogap effects and the expected quantum phase transitions (QPT) in cuprate materials are yet unclear in nature. A single band Tight-Binding (TB) model for the CuO planes of these materials had predicted the existence of definite pseudogap states at half-filling, after considering that a crystal symmetry breaking and non-collinear spin orientations of the single particle states are allowed. Here we show that after including hole doping in the model, a QPT which lies beneath the superconducting dome exists and is a second order one. In it, an insulator ground state (AFI), showing strong spin fluctuations at low doping, coalesce with an excited paramagnetic pseudogap (PPG) state, exhibiting a broken lattice symmetry at the critical hole density $x_c = 0.2$. Above this value the system becomes a paramagnetic metal. The band structures and Fermi surfaces with doping are evaluated and their evolution show a close resemblance with the experimental observations, including the topological change in structure for varying hole density.

2:03PM B11.0015 Charge Order in the Three-Band Model of Cuprate Superconductors\textsuperscript{2} BILL ATKINSON, Trent University, ARNO KAMPF, SINAN BULUT, Augsburg University — Numerous experiments have pointed to the widespread occurrence in underdoped high temperature superconductors of charge order with a strong intra-unit cell component. Motivated by this, we have performed theoretical calculations of charge instabilities in cuprate superconductors. First, we discuss a persistent discrepancy between theoretical predictions and experimental observations of the ordering wavevector $q^*$. We show that the correct direction and magnitude for $q^*$ can be obtained under the assumption that the charge order emerges from a pre-formed pseudogap. Second, we show that this type of long-range charge order reacts sensitively to dilute concentrations of strongly scattering impurities such as zinc, unlike the pseudogap which has been found to be robust against zinc doping. Taken together, these suggest that the pseudogap is a distinct phenomenon from charge order.

11:15AM B12.00001 Investigation of InSb-In$_2$XTe (X=Ge & Sn) pseudo binary alloys as potential thermoelectric materials*, VIJAYABARATHI PONNAMBALAM, DONALD T. MORELLI, Dept. of Chemical Engineering and Materials Science, University of Michigan, Ann Arbor, MI, U.S.A. — We have fabricated high quality pseudo binaries InSb-In$_2$XTe (X=Ge & Sn) hold the promise of offering reduced thermal conductivity while maintaining the other thermoelectric properties intact. A series of InSb-In$_2$XTe type alloys has been synthesized. Thermal and electrical transport properties have been studied, and the results will be discussed with an emphasis on how the thermal conductivity is affected by the concentration of solute atoms. This work was supported as part of the Center for Revolutionary Materials for Solid State Energy Conversion, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0001054.

11:27AM B12.00002 Study on thermoelectric performance by Na doping in nanostructured Mg$_{1-x}$Na$_x$Ag$_{0.97}$Sb$_{0.99}$, JING SHUAI, HEE SEOK KIM, YUCHENG LAN, SHUO CHEN, YUAN LIU, HUAIZHOU ZHAO, JIEHE SUI, ZHIFENG REN, Department of Physics and TsSUH, University of Houston, TX 77024 — MgAg$_{0.97}$Sb$_{0.99}$ was found to be potentially a new class of thermoelectric materials with ZT values above 1 in the temperature from 100 to 300 $^\circ$C. In this report, we systematically studied the effect of Na doping in Mg$_{1-x}$Na$_x$Ag$_{0.97}$Sb$_{0.99}$, on the thermoelectric properties and found Na was effective to increase the carrier concentration and power factor, especially below 180 $^\circ$C, which led to higher ZT values, a better self-compatibility factor, and ultimately a higher output power at the optimal Na concentration of $x = 0.005-0.0075$.

11:39AM B12.00003 Enhancement of thermoelectric performance by phase separation of Ag$_2$Te in quaternary Ag$_x$Bi$_{0.5}$Sb$_{1.5-x}$Te$_3$. YOO JANG SONG, JONG-SOO RHYEE, Kyung Hee Univ - Suwon Campus, BONG SEO KIM, SU DONG PARK, Korea Electrotechnology Research Institute, JAE HOON JUNG, Korea University, BYUNG-GIL RYU, JONG RAE LIM, LG Advanced Research Institute — Quaternary Ag–Bi–Sb–Te alloys with the general formula of Ag$_x$Bi$_{0.5}$Sb$_{1.5-x}$Te$_3$ are synthesized by solid state reaction for the high Ag doping $x=0.1, 0.2,$ and $0.3$. The powder x-ray diffraction analysis of the melted ingot shows the phase separation of AgSbTe$_3$ and Bi$_{0.5}$Sb$_{1.5}$Te$_3$ phases. After the hot press sintering at 350 $^\circ$C, we found Ag$_x$Te/Bi$_{0.5}$Sb$_{1.5}$Te$_3$ composite, instead of AgSbTe$_3$ phase separation, from the energy dispersive x-ray spectroscopy and x-ray diffraction measurements. The electrical conductivities of the Ag$_x$Te/Bi$_{0.5}$Sb$_{1.5}$Te$_3$ composite are significantly increased comparing with that of conventional p-type Bi$_{0.5}$Sb$_{1.5}$Te$_3$ composite, implying that the interface effect by phase separation can attribute to the increase of electrical conductivity. The maximum power factor and ZT values are reached up to 2.1 mW K$^{-2}$ m$^{-1}$ ($\sim 400$ K) and 1.1 (at 570 K), respectively, for $x = 0.1$ composite. Here we propose that the phase separation of Ag$_2$Te in Bi$_{0.5}$Sb$_{1.5}$Te$_3$ matrix can increase thermoelectric performance at mid-temperature temperature range.
2:27PM B12.00005 Nanostructured YbAgCu₄ for potential cryogenic thermoelectric cooling

MACHHINDRA KOIRALA, HUI WANG, Department of Physics and TcSÜH, University of Houston, Houston, TX, 77204, MANI POKHAREL, CYRIL OPEIL, Department of Physics, Boston College, Chestnut Hill, MA, 02467, ZHIFENG REN, Department of Physics and TcSÜH, University of Houston, Houston, TX, 77204 — We have studied thermoelectric properties of nanostructured YbAgCu₄ for cryogenic temperature range. Nanostructured YbAgCu₄ has been prepared using arc melting method followed by ball milling and hot pressing process. Thermal conductivity of the nanostructured samples has been reduced at 42 K by 30-50 % compared to the previously reported value. A high power factor of 131 µW m⁻¹ K⁻² has been obtained at 22 K. A peak dimensionless figure of merit ZT of 0.11 has been achieved at 42 K. With the variation of Cu-Ag composition, the temperature of peak ZT can be tuned, which could be useful for the preparation of segmented legs. The method of nanostructuring can be implemented with different fermen ions for obtaining high power factor with reduced thermal conductivity.

12:39PM B12.00006 Atomic Disorder in Tetrahedrite

JOHN ROBERT SALASIN, Univ of Tennessee, Knoxville, BRYAN CHAKOUMAKOS, Oak Ridge National Lab, CLAUDIA RAWN, Univ of Tennessee, Knoxville, ANDREW MAY, EDGAR LARA-CURZIO, MICHAEL MCGUIRE, HUIBO CAO, Oak Ridge National Lab — Thermoelectrics (TE) are materials which turn heat energy into electrical energy with applications spanning multiple disciplines including space exploration, Peltier cooling, and engine efficiency. Tetrahedrite is a copper sulfosalt with the general formula Cu₃₋ₓMₓ(Sb,As)₅S₁₃. Where M denotes a Cu²⁺ or Sb³⁻ site frequently replaced in natural tetrahedrite with Zn, Fe, Hg, or Mn. It has a cubic structure with an I-43m symmetry, c/a=10.4 Å, and only a handful of adjustable parameters. This structural study corroborates theoretical calculations on atomic disorder. Positional disorder of the trigonally coordinated Cu(2) site is suggested from the temperature dependence of the atomic displacement parameters determined from single-crystal x-ray and neutron diffraction. The displacements are extremely anisotropic for Cu(2) with a maximum rms static displacement of ~ 0.25 Å.

12:51PM B12.00007 Exploring Materials Properties via Simulations and Experiments for Thermoelectricity

ARTEM KHABIBULLIN, LILIA WOODS, GEORGE NOLAS, University of South Florida — Thermoelectricity is an alternative route for energy conversion and suitable materials play an important role for enhanced efficiency of related applications. The optimization of the thermoelectric transport relies on the microscopic understanding of the materials internal properties, such as electronic structure characteristics. Simulations methods and effective medium theories are utilized to investigate advantageous features in materials composed of earth-abundant elements. Some general trends in the electronic structure influencing the transport are formulated for chalcopyrite and clathrate systems suitable for thermoelectricity. We emphasize the importance of theoretical and computational efforts not only to identify existing classes, but also predict new structures with desirable internal characteristics for effective materials design and optimization.

1:39PM B12.00009 Ab Initio Electron Relaxation Times and Computational Screening of Thermoelectric Materials

BORIS KOZINSKY, GEORGE SAMSONIDZE, Bosch Research, Cambridge MA — We report recent progress in development of an efficient approximation scheme for computing electron relaxation times in bulk crystalline materials from first principles. This technique takes into account electron-phonon coupling and opens up the possibility for ab initio calculations of electronic transport coefficients: electrical conductivity, the electronic part of thermal conductivity, and Seebeck coefficient. We find that electron relaxation times and transport coefficients are very sensitive to carrier concentration, and their accurate prediction is necessary for computational optimization of thermoelectric material composition. For a given thermoelectric material, we are able to determine the optimal carrier concentration which maximizes ZT at a target temperature. With this methodology at hand, systematic computational screening is performed in the compositional space of half-Heusler materials selected from materials databases and consisting of cheap earth-abundant elements. Good agreement is found with the available experimental data for previously synthesized half-Heusler compounds, and several new promising candidates for thermoelectric applications are identified, which have been synthesized and validated by experimental collaborators. Based on the results of our calculations, we also discuss the validity and applicability limits of the Wiedemann-Franz law for thermoelectric materials.

1:51PM B12.00010 NMR study of Cu₂Se and Cu₁₉₈Ag₄₂Se superionic conductors

ALI SIRUSI ARVJU, JOSEPH H. ROSS, JR., Department of Physics and Astronomy, Texas A&M University, SEDAT BALLIKAYA², CIRAD UHER, Department of Physics, University of Michigan — Cu₂Se and Cu₁₉₈Ag₄₂Se are well known as superionic conductors and recently as thermoelectric materials due to observation of high ZT. We will report NMR of these compounds. Our results include indications of glassy anharmonic behavior at low temperatures, Cu ion motion which becomes initiated near 90K, and motional narrowing near the phase transition at high temperatures as well as modified dynamics observed in the Ag-doped sample. NMR is particularly well suited to probe low frequency dynamics and at low temperatures the relaxation rate indicates anharmonic rattling behavior similar to what has been observed in other thermoelectric materials. A 90K change in the NMR spectra corresponds to the recently observed transport anomaly and indicates that the slow motion of Cu ions is initiated at this temperature and eventually becomes liquid-like at higher temperatures. We detect fast ion motion in Cu₂Se starting at 140K whereas in the Ag-doped compound this onset shifts to a higher temperature around 300K. At high temperatures the spectra become motional narrowed, and we will discuss the narrowing and shifts in terms of activated carrier density and ionic motion.

2:03PM B12.00011 Mechanical robust BiSbTe alloys with superior thermoelectric performance: A case study of stable hierarchical nanostructured thermoelectric materials. XIANLI SU, YUN ZHENG, XINFENG TANG, Wuhan University of Technology, CTIRAD UHER, University of Michigan, TANG’S GROUP TEAM, UHER’S GROUP TEAM — Poor machinability and susceptibility to brittle fracture of commercial ingots often impose significant limitations on the manufacturing process and durability of thermoelectric devices. In this study, melt spinning combined with plasma activated sintering (MS-PAS) method is employed with commercial p-type zone-melted (ZM) ingots of Bi$_{0.5}$Sb$_{1.5}$Te$_3$. This fast synthesis approach achieves hierarchical structures and in-situ nanoscale precipitates, resulting in the simultaneous improvement of thermoelectric performance and mechanical properties. Benefiting from a strong suppression of the lattice thermal conductivity, a peak ZT of 1.22 is achieved at 340 K in MS-PAS synthesized structures, representing about a 40% enhancement over that of ZM ingots. Moreover, MS-PAS specimens with hierarchical structures exhibit superior machinability and mechanical properties with an almost 30% enhancement in the fracture toughness, eightfold and a factor of six increase in the compressive and flexural strength respectively.

11:15AM B13.00001 Topological properties and correlation effects in oxide heterostructures, SATOSHI OKAMOTO, Oak Ridge National Lab — Transition-metal oxides (TMOs) have long been one of the main subjects of material science because of their novel functionalities such as high-$T_c$ superconductivity in cuprates and the colossal magnetoresistance effect in manganites. In recent years, we have seen tremendous developments in thin film growth techniques with the atomic precision, resulting in the discovery of a variety of electronic states in TMO heterostructures. These developments motivate us to explore the possibility of novel quantum states of matter such as topological insulators (TIs) in TMO heterostructures. In this talk, I will present our systematic theoretical study on unprecedented electronic states in TMO heterostructures. An extremely simple but crucial observation is that, when grown along the [111] crystallographic axis, bilayers of perovskite TMO form buckled honeycomb lattices of transition-metal ions, similar to graphene. Thus, with the relativistic spin-orbit coupling and proper band filling, two-dimensional TI states or spin Hall insulators are anticipated. Based on tight-binding modeling and density-functional theory calculations, possible candidate materials for TIs are identified. By means of the dynamical-mean-field theory and a slave-boson mean field theory, correlation effects, characteristics of TMO heterostructures, are also examined. I will further discuss future prospects in topological phenomena in TMO heterostructures and related systems.

The author thanks D. Xiao, W. Zhu, Y. Ran, R. Arita, Y. Nomura and N. Nagaosa for their fruitful discussions and collaboration.

12:03PM B13.00003 Raman Scattering in La$_{0.2}$Sr$_{0.8}$FeO$_{8-d}$ thin film: annealing-induced reduction and phase transformation, MOHAMMAD ISLAM, State University of New York at Oswego, YUJUN XIE, MARK SCAFETTA, STEVEN MAY, JONATHAN SPANIER, Drexel University — Raman scattering in thin film La$_{0.2}$Sr$_{0.8}$FeO$_{8-d}$ on MgO(001) collected at 300 K following different stages of annealing at selected temperatures (300 K < $T$ < 543 K, to 10 h.) and analysis reveal changes in spectral characteristics due to loss of oxygen, onset of oxygen vacancy-induced disorder, and activation of Raman-inactive modes that are attributed to symmetry transformation. The interpretation is further supported by carrier transport measurements under identical conditions showing orders of magnitude increase in the resistivity induced by oxygen loss. After prolonged annealing in air, evolution of the spectrum is consistent with the appearance of a topotactic transformation of the crystal structure from that of the rhombohedral ABO$_3$ perovskites to that of Brownmillerite-like structure consisting of octahedrally and tetrahedrally coordinated Fe atoms.

12:15PM B13.00004 Strain control of oxygen stoichiometry in epitaxial perovskites, HO NYUNG LEE, TRICIA MEYER, JONATHAN PETRIE, SHINBUHM LEE, JOHN NICHOLS, Oak Ridge National Laboratory, S.S. AMBROSE SEO, University of Kentucky, JOHN FREELEND, Argonne National Laboratory — Many physical properties of transition metal oxides (TMOs) are critically dependent upon the oxidation state of transition metals. Thus, a precise control of oxygen stoichiometry is critical to unambiguously understand many intriguing properties and functionalities. Based on a recent discovery of TMO-based oxygen sponges that can shed or absorb oxygen at highly reduced temperatures as low as 200 °C [Leeen et al., Nature Mater. 12, 1057 (2013) and Choi et al., Phys. Rev. Lett. 111, 097401 (2013)], we have explored various complex oxide materials to control the oxygen stoichiometry and, thereby, the critical physical properties. The latter include superconductivity in doped La$_2$CuO$_4$, metal-insulator transition in VO$_2$, and electronic and ionic conductivity as well as magnetism in SrCoO$_{3-d}$. In particular, by tuning strain systematically via lattice mismatching, we found that the epitaxial strain is a great tool to create functional defects that are critical in discovering new functionalities and/or improving the performance of materials especially for electronic and ionic conduction in complex oxides.

12:27PM B13.00005 Epitaxial Growth of BaSnO₃ using Hybrid Molecular Beam Epitaxy¹
ABHINAV PRAKASH, TIANQI WANG, Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455, CHRISTIAN M. SCHLEPÜTZ, X-Ray Science Division, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439, BHARAT JALAN, Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455 — Using co-deposition of a chemical precursor for Sn, a solid source for Ba and an RF plasma source for oxygen, we have extended the hybrid MBE approach for the growth of stoichiometric BaSnO₃. First, we present a detailed growth study of SnO₂ on r-plane sapphire as a function of Sn flux, oxygen pressure and substrate temperature. High-resolution x-ray diffraction (HRXRD) and AFM showed single-phase, epitaxial SnO₂ films and smooth surfaces, respectively. Three growth regimes were identified: reaction-, flux- and desorption-limited with increasing substrate temperature. Further study at constant substrate temperature revealed growth rate increases first and then becomes constant with increasing tin flux. We will then present a comprehensive study of the growth of phase-pure, smooth epitaxial BaSnO₃ films on SrTiO₃. HRXRD of 5nm BaSnO₃ on SrTiO₃ using synchrotron radiation suggest that films grow mostly coherent with out-of-plane lattice parameters of 4.20-4.25 Å for different cation flux ratios, remarkably similar to the calculated value of 4.26 Å using elastic tensors assuming BaSnO₃ grows coherent on SrTiO₃. Strain relaxation, stoichiometry control and their roles on the electronic transport will be discussed.

12:39PM B13.00006 Structure and Electronic Transport in BaSnO₃ Deposited via High Pressure Oxygen Sputtering
KOUSTAV GANGULY, PALAK AMBWANI, JONG SEOK JEONG, K. ANDRÉ MKHOYAN, PENG XU, CHRISTIAN M. SCHLEPÜTZ, BHARAT JALAN, University of Minnesota — We present structural and electronic transport properties of oxygen vacancy-doped BaSnO₃ films grown on SrTiO₃(001) and MgO(001) using the high pressure oxygen sputtering technique. High-resolution x-ray diffraction (HRXRD), combined with scanning transmission electron microscopy (STEM), confirms phase-pure epitaxial BaSnO₃(001) films on both substrates. The out-of-plane lattice parameter obtained from wide-angle x-ray diffraction is used as a sensitive probe for cation stoichiometry and strain relaxation. Irrespective of growth parameters, the out of plane lattice parameter remains unchanged, close to that of bulk (4.116 Å). A detailed thickness-dependent structural study using HRXRD and STEM suggests the formation of misfit dislocations as the primary mechanism for strain relaxation. We further show that as-grown, insulating BaSnO₃ films can be made conductive with n-type carriers (with typical room temperature concentrations and Hall mobilities being $10^{19}$ cm⁻¹ and 12 cm²/V·s) via high temperature (900 °C) vacuum annealing. Analysis of transport data from films with fixed density indicates a significant influence of film thickness, and thus strain relaxation, on the electron mobility. Temperature-dependent transport and magnetotransport studies will be described in detail as a function of annealing conditions, and will be correlated to strain relaxation. This work is supported by NSF through the UMN MRSEC.

12:51PM B13.00007 A Conductive Polar Interface with high mobility formed between LaInO₃ and BaSnO₃ perovskite oxides
USEONG KIM, CHULKWON PARK, Seoul Natl Univ, TAEWOO HA, YONSEI UNIV, YOUNG MO KIM, NAMWOOK KIM, CHANCHUNG JU, JAEJUN YU, Seoul Natl Univ, JAE HOON KIM, YONSEI UNIV, KOOKRN CHAR, SEOUL NATL UNIV — LaInO₃/BaSnO₃ (LIO/BSO) polar interface is the interface between BaSnO₃ (BSO), a non-polar perovskite oxide with high oxygen stability and electron mobility, and LaInO₃ (LIO), a polar perovskite oxide with the matched lattice parameters. Once the LIO/BSO interface forms, the conductance in the interface is significantly enhanced. The high oxygen stability of BSO enables dopant-controlled transport experiments by ruling out the involvement of oxygen vacancies in the transport phenomena. The conductance enhancement at the LIO/BSO interface was monitored while varying the doping rate of La dopants in the BSO layer. As a result, we found that the La doping rate was a dominant factor determining the extent to which the conductance was enhanced. It implies that the electronic reconstruction at the polar interface depends critically on the initial position of the Fermi level in the BSO side. The high electron mobility of BSO enables the exploitation of the conductive LIO/BSO interface at room temperature. We fabricated a field effect transistor utilizing such interface. At room temperature the device shows outstanding performances in terms of three key parameters: field effect mobility higher than 90 cm²/V·s, on/off ratio as high as 10⁷, and subthreshold swing as low as 0.65 V/dec.

1:03PM B13.00008 Enhanced electrical mobility in the (La,Ba)SnO₃ film grown on BaSnO₃ (001) substrate
KEE HOON KIM, Dept of physics and astronomy, CeNSCMR, Seoul Natl Univ, HYUNG JOON KIM, HYUNG-JHAE LEE, TAI HOON KIM, EGGON SOHN, JU-YOUNG PARK, KI-YOUNG CHOI, Seoul Natl Univ — Doped BaSnO₃ (BSO) systems with a perovskite structure are drawing increasing interests because of their high electrical mobility ($\approx 300$ cm²/V·s⁻¹), wide optical band gap ($\geq 3.1$ eV) and superior oxygen stability. In order to realize a semiconducting device with high speed based on the doped BSO films, an insulating substrate made of the BSO single crystal will be indispensable to the realization of truly epitaxial films without structural defects. Here, we report the successful growth of an insulating BSO single crystal by using the cupric-oxide-based flux growth method with an oxidizer. After preparing the BSO(001) substrate with one side polished, we deposited epitaxial La doped BSO films on the BSO substrate (BLSO/BSO(001)) by using the pulsed laser deposition. The electrical mobility ($\mu$) of BLSO/BSO(001) films are found to be $\approx 70$-$100$ cm²/V·s⁻¹ in the low ($10^{19}$ cm⁻³) to high ($10^{20}$ cm⁻³) doping ranges, which are clearly larger than those grown on SrTiO₃ (STO) substrate ($\approx 15$-$60$ cm²/V·s⁻¹). We’ll also show some of our recent efforts to realize the field effect transistor based on the BSO single crystal substrate. The present results show that the single crystal BSO substrate can offer various opportunities to realize practical electronic devices based on the doped BSO films.

1:15PM B13.00009 Interfacial engineering of optical absorption in epitaxial La(Cr,Ti)O₃SrTiO₃ superlattices
RYAN COMES, TIFFANY KASPAR, Pacific Northwest National Laboratory, STEVE HEALD, Advanced Photon Source, Argonne National Laboratory, MARK BOWDEN, SCOTT CHAMBERS, Pacific Northwest National Laboratory — SrTiO₃ (STO) is a wide-gap semiconductor well suited for photocatalytic H₂ production due to the alignment of its band edges with the half-cell reactions of the H₂O redox reactions. However, the wide optical gap of STO (3.3 eV) makes the material an inefficient light absorber in the visible spectrum, preventing formation of electron-hole pairs needed for photocatalysis. Superlattice films comprised of alternating layers of band insulator SrTiO₃ and Mott insulator LaCrO₃ (LCO) have been theoretically predicted to offer intriguing optical properties due to the broken symmetry between the unoccupied Ti dx²-y² and Ti dxz and dxy orbitals. In this work, we examine the properties of LCO-STO superlattices grown with various periodicities on (La,Sr)(Al,Ta)O₃ (LSAT) (001) substrates using oxide molecular beam epitaxy. Films were characterized via in situ x-ray photoelectron spectroscopy to measure valence band structure and interfacial band bending. Polarized Ti and Cr K-edge x-ray absorption near edge spectroscopy was used to examine the bonding anisotropy. Spectroscopic ellipsometry measurements show the presence of interfacially-induced visible light absorption not found in either STO or LCO.

1:27PM B13.00010 Tuning the physical properties in strontium iridate heterostructures
JOHN NICHOLS, TRICIA MEYER, HO NYUNG LEE, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA — Strontium iridate operates as a high mobility, high Tc superconductor with a smooth surface. Lots of attention recently for its potential to reveal novel physical phenomena due to strong spin-orbital coupling with an interaction energy comparable to that of the on-site Coulomb interaction and crystal field splitting. The coexistence of fundamental interactions has created an exotic $J_{eff}$ = 1/2 antiferromagnetic insulating ground state in Sr$_2$IrO$_4$. In particular, it is known that this system can be driven into a metallic state with the simultaneous increase in dimensionality (n) and strain. We have investigated the effects of electron confinement by interfacing strontium iridium oxides with other perovskite oxides. We have synthesized thin film heterostructures, SrIrO₃/AMO$_3$ (A = Sr, La, B = Ti, Mn, Rh), layer-by-layer with pulsed laser deposition equipped with reflection high-energy electron diffraction. Based on investigations with x-ray diffraction, dc transport, SQUID magnetometry, and various spectroscopic measurements, we will present that the physical properties of the heterostructures are strongly dependent on spatial confinement and epitaxial strain. *This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division.
1:39PM B13.00011 Strain-controlled easy axis orientation of epitaxial CoFe₂O₄ films by He implantation, ANDREAS HERKLOTZ, ANTONY T. WONG, Oak Ridge National Laboratory, STEFANIA F. RUS, National Institute for Research and Development in Electrochemistry and Condensed Matter, THOMAS Z. WARD, Oak Ridge National Laboratory — Heteroepitaxial strain engineering is an essential tool in the strongly correlated systems for investigating fundamental coupling effects and for more practical control of thin film properties. Here, we use strain doping by He implantation as an alternative technique to control thin film functionalities. We demonstrate the tuning of the magnetic anisotropy of CoFe₂O₄ (CFO) films through He implantation. Compressively strained thin films of CFO are grown coherently on MgO substrates and show pronounced out-of-plane magnetic anisotropy. Successive doping of the CFO films with He using a commercial ion gun results in an expansion of the out-of-plane lattice parameter while maintaining in-plane epitaxial lock to the substrate. We observe a continuous rotation of the magnetic easy axis towards the film plane with increasing unit cell tetragonality. The results are in agreement with the strain-induced change of the magnetic anisotropy due to the large negative magnetostriction of CFO and demonstrate that strain doping via He implantation is an elegant path to tune desired characteristics of transition metal oxide thin films. This work was supported by the U. S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division.

1:51PM B13.00012 Atomic structure, electronic properties, and band offsets of SrRuO₃/TiO₂ heterojunctions, NAHEED FERDOUS, ELIF ERTEKIN, Univ of Illinois - Urbana — Photocatalytic water splitting by sunlight can in principle be an environmentally green approach to hydrogen fuel production, but at present photocatalytic conversion efficiencies remain too small. In titanium dioxide (TiO₂), the most commonly used photocatalyst, the biggest limitation arises from poor absorption of visible light. One way to increase the visible light absorption is to create a composite heterojunction by integrating TiO₂ with a strongly light absorbing material. Inspired by experimental results demonstrating good light absorption in the correlated metal oxide Strontium Ruthenate (SrRuO₃), as well as enhanced photocatalytic activity of SrRuO₃/TiO₂ heterojunctions [1], we have carried out electronic structure calculations based on density functional theory to explain and improve on the observed properties of such heterojunctions. Our calculations present that this heterojunction exhibits type-II band alignment which is necessary to transport optically excited electrons from the SrRuO₃ to the TiO₂, with calculated work functions in good agreement with experimental measurements. Also, DFT calculations help to explain the origin of large light absorption in this system, which is due to enhanced optical transitions leading to the observation of a zero-dimensional Fermi-liquid-like$^*$ quasiparticle states are suppressed at the metal-insulator transition observed in transport. We also will describe some recent unpublished work using epitaxial strain to drive a Lifshitz transition in atomically thin films of the spin-triplet ruthenate superconductor Sr₃Ru₂O₇, where we also can dramatically alter the quasiparticle scattering rates and drive the system towards non-Fermi liquid behavior near the critical point ($B$. Burganov, C. Adamo, in preparation).

11:15AM B14.00001 Atomic Scale Control of Competing Electronic Phases in Ultrathin Correlated Oxides$^*$, KYLIE SHEN, Cornell University — Ultrathin epitaxial thin films offer a number of unique advantages for engineering the electronic properties of correlated transition metal oxides. For example, atomically thin films can be synthesized to artificially confine electrons in two dimensions. Furthermore, using a substrate with a mismatched lattice constant can impose large biaxial strains of larger than 3% (Δa/a), much larger than can achieved in bulk single crystals. Since these dimensionally confined or strained systems may necessarily be less than a few unit cells thick, investigating their properties and electronic structure can be particularly challenging. We employ a combination of reactive oxide molecular beam epitaxy (MBE) and angle-resolved photoemission spectroscopy (ARPES) to investigate how dimensional confinement and epitaxial strain can be used to manipulate electronic properties and structure in correlated transition metal oxide thin films. We describe some of our recent work manipulating and studying the electronic structure of ultrathin LaNiO₃ through a thickness-driven metal-insulator transition between three and two unit cells (Nature Nanotechnology 9, 443, 2014), where coherent Fermi liquid-like quasiparticle states are suppressed at the metal-insulator transition observed in transport. We also will describe some recent unpublished work using epitaxial strain to drive a Lifshitz transition in atomically thin films of the spin-triplet ruthenate superconductor Sr₃Ru₂O₇, where we also can dramatically alter the quasiparticle scattering rates and drive the system towards non-Fermi liquid behavior near the critical point (B. Burganov, C. Adamo, in preparation).

11:51AM B14.00002 Extremely large electronic anisotropy caused by electronic phase separation in Ca₃(Ru₀.₉₇Ti₀.₀₃)O₇ single crystal, JING PENG, Tulane University and Nanjing University, XIAOSHAN WU, Nanjing University, ZHIQIANG MAO, Tulane University — Bilayered ruthenate Ca₃Ru₂O₇ exhibits rich electronic and magnetic properties. It orders at 56K, with FM bilayers antiferromagnetically coupled along c-axis (AFM-a). The AFM transition is closely followed by a first-order metal-insulator (MI) transition at 48K where spin directions switch to the b-axis (AFM-b). While this MI transition is accompanied by the opening of an anisotropic charge gap; small Fermi pockets survive from the MI transition, thus resulting in quasi-2D metallic transport behavior for T<30K. We previously showed such a quasi-2D metal with the AFM-b order composed of FM bilayers can be tuned to a Mott-insulating state with a nearest-neighbor AFM order via Ti doping [Ke et al, PRB 84, 201102(11)]. Ca₃(Ru₀.₉₇Ti₀.₀₃)O₇ is close to the critical composition for the AFM-b-to-IG-AFM phase transition. Our recent studies show the sample with this composition is characterized by an electronic phase separation between the insulating G-AFM phase (major) and the localized AFM-b phase (minor). The minor AFM-b phase forms a conducting path through electronic percolation within the ab-plane, but not along the c-axis, thus resulting in extremely large electronic anisotropy with 10⁷, which may be the largest among bulk materials.

12:03PM B14.00003 Separation of transport and Hall scattering rates in SrTiO₃/ReTiO₃ two-dimensional electron gases, EVGENY MIKHEEV, BRANDON ISAAC, TYLER CAIN, CHRISTOPHER FREEZE, SUSANNE STEMMER, Univ of California - Santa Barbara — ReTiO₃/SrTiO₃/ReTiO₃ (Re=Gd, Sm) quantum well structures that contain a high-density, two-dimensional electron gas (2DEG) exhibit phenomena that are reminiscent of the normal state behavior of unconventional superconductors, including a pseudogap, proximity to two-dimensional antiferromagnetism, and non-Fermi liquid behavior. Here we will discuss another transport anomaly, namely that scattering rates measured in the longitudinal and Hall conductivities are distinct and have different temperature dependences. We show that the two-scattering rate framework provides a remarkably simple, consistent, and accurate description for the dependencies of the Hall effect on temperature and quantum well thickness. This analysis reveals signatures of a spin density wave gap opening (Re=Sm) and a divergent Hall effect in the T=0 limit for an intermediate quantum well thickness (near 5 SrO layers), indicating a quantum critical point. Several theoretical proposals exist that may explain the two-lifetime separation. We discuss how the results in this system introduce a number of new, specific constraints and the need for a unifying microscopic theory.
12:15PM B14.00004 Odd frequency Density Waves1, YARON KEDEM, Nordic Institute for Theoretical Physics (NORDITA), Roslagstullsbacken 23, S-106 91 Stockholm, Sweden, ALEXANDER BALATSKY, Institute for Materials Science, Los Alamos National Laboratory, Los Alamos, NM 87545, Nordic Institute for Theoretical Physics (NORDITA), Roslagstull — A new type of hidden order in many body systems is explored. This order appears in states which are analogous to charge density waves, or spin density waves, but involve anomalous particle hole correlations that are odd in time and frequency. These states are shown to be inherently different from the usual states of density waves. We discuss a method to experimentally observe the new type of pairing by measuring the density-density correlation, both in time and space, where a clear distinction between odd and even correlations can be detected. An order parameter for these states is defined and calculated for a simple model, eliminating the physical nature of this phenomenon.

12:27PM B14.00005 Controlling Magnetism in Spin-Orbit-Driven Oxides with Epitaxial Strain, PATRICK CLANCY, University of Toronto — The layered perovskite iridates Sr$_2$IrO$_4$ and Ba$_2$IrO$_4$ are the prototypical spin-orbital Mott insulators, displaying a novel $j_{	ext{eff}} = 1/2$ ground state driven by strong 5d spin-orbit coupling effects. Efforts to understand, and ultimately control, this spin-orbit-induced ground state have led to the emergence of a new type of thin film iridates, which offer unique opportunities for the tuning of electronic and magnetic properties via epitaxial strain. We have performed complementary resonant magnetic x-ray scattering (RMXS) and resonant inelastic x-ray scattering (RIXS) measurements on epitaxial thin film samples of Sr$_2$IrO$_4$ and Ba$_2$IrO$_4$. By measuring 13 to 50 nm films grown on a variety of different substrates (PSO, GSO, STO, LSAT), we are able to investigate the impact of applied tensile and compressive strain on the magnetic structure, correlation lengths, and characteristic excitations of these materials. We find that the dispersion of the low-lying magnetic and orbital excitations is strongly affected by strain-induced structural changes, and show that epitaxial strain provides an effective method for tuning three distinct energy scales: the magnetic ordering temperature ($T_N$), the magnetic exchange interactions ($J$), and the non-cubic crystal field splitting ($\Delta_{\text{CEF}}$). Perhaps most strikingly, we demonstrate that hard x-ray RIXS can be used to perform detailed magnetic dispersion measurements on thin film samples of 13 nm (~5 unit cells) or less.

1:03PM B14.00006 Series of alternating states with unpolarized and spin-polarized bands in dimerized IrTe$_2$, V. KIRYUKHIN, G.L. PASCUT, T. BIROL, S.-W. CHEONG, K. HAULE, Rutgers U., M.J. GUTMANN, ISIS, J.J. YANG, Pohang U. — A series of states with different densities of stripes of Ir dimers is investigated using x-ray diffraction and density functional theory in layered nonmagnetic metal IrTe$_2$. With decreasing temperature, structures with and without inversion symmetry alternate. In non-centrosymmetric states, spin-orbit coupling splits the electronic energy bands into spin-polarized pairs. Factors affecting the stability of the observed dimerized states are established, and it is conjectured that an infinite series of alternating states with and without polarized bands is realized in IrTe$_2$. Switching dimerized states with different symmetries by changing temperature or strain enables control of band polarization, adding a new tool for spintronics and valleytronics research.

1:15PM B14.00007 Quantum Monte Carlo study of the nematic quantum critical point in a metal, YONI SCHATTNER, Weizmann Institute of Science, SAMUEL LEDERER, Stanford University, EREZ BERG, Weizmann Institute of Science, STEVEN A. KIVELSTON, Stanford University — The coupling of fermions to gapless collective modes can lead to interesting critical phenomena, non-Fermi-liquid behavior and/or superconductivity. As an example for such a system, we present a sign-problem free lattice model of quantum-critical Ising-nematic bosons coupled to fermions in two dimensions. Determinantal Quantum Monte-Carlo simulations show a second order nematic transition at low temperatures. As the transition is approached, we find evidence of non-Fermi-liquid behavior. At the temperature scales accessible to us, we find no traces of superconductivity.

1:27PM B14.00008 Itinerant density instability at classical and quantum critical points, YEJUN FENG, Argonne National Laboratory, JASPER VAN WEZEL, FELIX FLICKER, Univ. of Bristol, JIYANG WANG, D.M. SILEVITCH, P. B. LITTLEWOOD, T. F. ROSENBAUM, Univ. of Chicago — Itinerant density waves are model systems for studying quantum critical behavior. In both the model spin- and charge-density-wave systems Cr and NbSe$_2$, it is possible to drive a continuous quantum phase transition with critical pressures below 10 GPa. Using x-ray diffraction techniques, we are able to directly track the evolution of the order parameter vector Q across the pressure-temperature phase diagram. We find a non-monotonic dependence of Q on pressure. Using a Landau-Ginzburg theoretical framework developed by McMillan for CDWs, we evaluate the importance of the physical terms in driving the formation of ordered states at both the thermal and quantum phase transitions. We find that the itinerant instability is the deciding factor for the emergent order, which is further influenced by the quantum fluctuations in both the thermal and quantum limits.

1:39PM B14.00009 Emergence of charge density wave domain walls above the superconducting dome in 1T-TiSe$_2$, PETER ABBAMONTE, YOUNG IL JOE, XIAOQIAN CHEN, POUYAN GHAEMI, KEN FINKELSTEIN, GILBERTO DE LA PENA, YU GAN, University of Illinois, JAMES LEE, Lawrence Berkeley National Laboratory, SHI YUAN, University of Illinois, JOCHEN GECK, Leibniz Institut, GREG MACDOUGALL, TAI CHANG, LANCE COOPER, EDUARDO FRADKIN, University of Illinois — Superconductivity in so-called unconventional superconductors is nearly always found in the vicinity of another ordered state, such as antiferromagnetism, charge density wave (CDW), or stripe order. This suggests a fundamental connection between superconductivity and fluctuations in some other order parameter. To better understand this connection, we used high-pressure X-ray scattering to directly study the CDW order in the layered dichalcogenide TiSe$_2$, which was previously shown to exhibit superconductivity when the CDW is suppressed by pressure or intercalation of Cu atoms. We succeeded in suppressing the CDW fully to zero temperature, establishing for the first time the existence of a quantum critical point (QCP) at $P_c = 5.1 \pm 0.2$ GPa, which is more than 1 GPa beyond the end of the superconducting region. Unexpectedly, at $P \sim 3$ GPa we observed a reentrant, weakly first order, incommensurate phase, indicating the presence of a Lifshitz tricritical point somewhere above the superconducting dome. Our study suggests that superconductivity in TiSe$_2$ may be connected to the formation of CDW domain walls

1:51PM B14.00010 Nanoscale Charge-order Dynamics in Stripe-phase Nickelates Probed via Ultrafast THz Spectroscopy1, GIACOMO COSLOVICH, SASCHA BEHL, BERNHARD HUBER, Lawrence Berkeley National Laboratory, WEI-SHENG LEE, ZHI-XUN SHEN, SIMES, SLAC National Accelerator Laboratory, Stanford University, TAKAO SASAGAWA, Tokyo Institute of Technology, HANS A. BECHTEL, MICHAEL C. MARTIN, ROBERT A. KAINDL, Lawrence Berkeley National Laboratory — Here we report ultrafast optical pump-THz probe spectroscopy of the model stripe-ordered system Li$_x$Sr$_{2}$Ir$_{2}$O$_{5}$NiO$_{2}$. Ultrafast experiments in the multi–THz spectral range show strong THz reflectivity variations around the phonon bending mode frequency ($\approx 11$ THz). At low temperatures this phonon mode exhibits a splitting directly related to the formation of long-range stripe-order, while the background conductivity is reminiscent of the opening of the mid-IR pseudogap due to charge localization. The transient THz probe response therefore captures both the electronic and structural dynamics in a single light pulse. The results reveal the dynamical interplay between charge localization and the bending mode folding, providing insight in the emergence of nanoscale charge-order in complex oxides.

11:15AM B15.00001 Dynamical and anharmonic effects on the electron-phonon coupling and the zero-point renormalization of the band structure, GABRIEL ANTONIUS, University of Montreal, SAMUEL PONCÉ, Université Catholique de Louvain, ÉTIENNE LANTAGNE-HURTUBISE, GABRIEL AUCLAIR, MICHEL CÔTÉ, University of Montreal, XAVIER GONZE, Université Catholique de Louvain — The electron-phonon coupling in solids renormalizes the band structure, reducing the band gap by several tenths of an eV in light-atoms semiconductors. Using the Allen-Heine-Cardona theory (AHC), we compute the zero-point renormalization (ZPR) as well as the quasiparticle lifetimes of the full band structure in diamond, BN, LiP and MgO. We show how dynamical effects can be included in the AHC theory, and still allow for the use of a Sternheimer equation to avoid the summation over unoccupied bands. The convergence properties of the electron-phonon coupling self-energy with respect to the Brillouin zone sampling prove to be strongly affected by dynamical effects. We complement our study with a frozen-phonon approach, which reproduces the static AHC theory, but also allows to probe the phonon wavefunctions at finite displacements and include anharmonic effects in the self-energy. We show that these high-order components tend to reduce the strongest electron-phonon coupling elements, which affects significantly the band gap ZPR.

11:27AM B15.00002 Raman spectra calculations for nanostructures using ab initio real-space methods, N. SCOTT BOBBITT, JAMES R. CHELIKOWSKY, University of Texas at Austin — We use a real-space pseudopotential method within density functional theory to calculate Raman spectra for Si nanocrystals. We examine the effects of quantum confinement and the presence of impurities, including dopant concentration and location of dopant within the nanocrystal. The ability to predict the effects of dopant concentration and location on a Raman spectrum from first principles suggests that this calculation technique could be coupled with spectroscopic experiments to identify the size and nature of doped nanocrystals.

1This work is supported by the DOE under grant number DE-FG02-06ER46286. Computations were performed on machines at TACC and NERSC.

11:39AM B15.00003 The atomistic limit of envelope function theory, CRAIG PRYOR, Dept. of Physics and Astronomy, University of Iowa, Iowa City, IA 52242, MATS-ERIC PISTOL, Lund University, Solid State Physics and the Nanometer structure consortium, Box 118, SE-221 00, Lund, Sweden — Electronic properties of semiconductor nanostructures and impurity states are typically calculated using one of three different methods: tight-binding models, pseudopotentials, or envelope function theory. The first two are well suited to modeling atomistic scale structures, however their parameters must be fit to bulk properties which can be a complicated procedure. In contrast, envelope function theory is best at describing larger scales in which the placement of individual atoms is not important and the parameters are directly related to experimentally determined quantities. As usually implemented, envelope function theory is insensitive to atomic scale structure. We show that this does not need to be the case, and construct an atomistic envelope function theory. This is advantageous for nanostructure modeling because it provides an atomistic model parameterized in terms of physical matrix elements rather than by complicated fitting procedures.

11:51AM B15.00004 Quantum Mechanics of Chemisorption on GaAs Clusters, FRANK NARANJO, AJIT HIRA, RUBEN RIVERA, OLIVER OVIEDO, Northern New Mexico College — This research focuses on the theoretical study of molecular clusters to examine the chemical properties of small Ga₅₅As₅₅ clusters (n = 2 - 10). We study the chemisorption of different atomic and molecular species on small clusters of metallic elements, by examining the interactions of H, H₂, Li and Be adsorbates with the GaAs clusters. Semiconductor clusters are of interest for the study of quantum size effects and for metallization phenomena. Hybrid ab initio methods of quantum chemistry (particularly the DFT-B3LYP model) are used to derive optimal geometries for the clusters of interest. We compare calculated binding energies, bond-lengths, ionization potentials, electron affinities and HOMO-LUMO gaps for these clusters. Mapping of the singlet, triplet, and quintet, potential energy surfaces is performed. Implications for fundamental mechanisms of atomistic assembly on the GaAs surfaces are examined.

12:03PM B15.00005 Stress effects on Raman spectroscopy of aSi:H — theory and experiment, DAVID A. STRUBBE, ERIC C. JOHLIN, Dept. of Materials Science and Engineering, Massachusetts Institute of Technology, TIMOTHY R. KIRKPATRICK, TONIO BUONASSISI, Dept. of Mechanical Engineering, Massachusetts Institute of Technology, JEFFREY C. GROSSMAN, Dept. of Materials Science and Engineering, Massachusetts Institute of Technology — Raman microscopy has proven to be a very useful technique for inferring stress distributions in materials, since the positions of vibrational peaks are sensitive to local stress. This method has been applied extensively for crystalline silicon, and would be useful for amorphous silicon as well, particularly for studying local stress and composition of nanostructured amorphous/crystalline devices. Toward that goal, we have simulated the Raman spectrum of hydrogenated amorphous silicon with density-functional perturbation theory, using atomistic structures from the WWWW algorithm with different stress states. We obtain a spectrum in good agreement with experimental results, and calculate a coefficient for the change in the TO peak position proportional to stress. We then performed Raman experiments on an a-Si:H film deposited on a c-Si wafer, in which stress was applied with a 4-point bending setup, and found a stress coefficient consistent with the simulations, in contrast to inconsistent previous results in the literature. These results can be used to map out local stress distributions, and also relate to thermal expansion and vibrational anharmonicity via the Gruneisen parameter.
12:15PM B15.00006 Angle resolved photoemission studies of the Rashba states in ferroelectric GeTe, BEOMYOUNG KIM, WONSEOK KYUNG, GARAM HAN, Institute of Physics and Applied physics, Yonsei University, 134 Shinchon-Dong, Seodaemun-Gu, Seoul 120-749, Republic of Korea, YEONGKWAN KIM, JONATHAN DENLINGER, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA., IN CHUNG, Graduate School of Nanoscience and Technology, KAIST, 291 Daehak-ro, Yuseong-gu, Daejeon 305-701, Republic of Korea, CHANGYOUNG KIM, Institute of Physics and Applied physics, Yonsei University, 134 Shinchon-Dong, Seodaemun-Gu, Seoul 120-749, Republic of Korea — There has been significant increase in the research of spin orbit coupling (SOC) induced exotic phenomena. The Rashba effect, theoretically predicted to exist, is one of the SOC related phenomena. The phenomenon was later experimentally observed in the surface states of metals and topological insulators as well as interfaces of hetero structures that have inversion symmetry breaking (IBS). Even bulk states with intrinsic IBS such as BiTe is found to have Rashba split bands. It was very recently proposed that ferroelectric GeTe has Rashba effect in the bulk. This is a unique situation where IBS is provided not by the structure IBS but by an electrical polarization. We have performed angle-resolved photoemission spectroscopy (ARPES) on GeTe single crystals to investigate the unique bulk Rashba state. Our results indeed show the existence of a Rashba-type band splitting as theoretically predicted. We discuss various aspect of the Rashba state in GeTe.

12:27PM B15.00007 Electronic structure of parabolically confined quantum wire with Rashba and Dresselhaus spin-orbit interactions under the influence of perpendicular magnetic field 1. SEVIL SARIKURT, Department of Materials Science and Engineering, Texas A&M University, College Station, TX 77843-3003, SERPIL SAKIROGLU, KADIR AKGUNOR, ISMAIL SOKMEN, Department of Physics, Faculty of Science, Dokuz Eylul University, Izmir, 35390, TURKEY — We have investigated the effect of spin-orbit (SO) coupling on the energy level spectrum and spin texturing of parabolically confined quantum wire that is subjected to an externally applied perpendicular magnetic field. Additionally we have also taken into account exchange-correlation contribution. Highly accurate numerical calculations have been carried out by finite element method. Our results have revealed that the interplay of the SO coupling with effective magnetic field significantly modifies the band structure, producing additional subband extrema and energy gaps. Energy subband structure varies depending on which type of SO coupling strength is considered and also the magnitude of SO coupling. We also obtain that spatial modulation of spin density along the wire width can be considerably modified by SO coupling strength, magnetic field and charge carrier concentration. Besides, we have observed that the presence of exchange-correlation contribution leads to a softening behavior in the local maxima at subbands and shifts all energy subbands to lower energy values. Numerical results point out that the combined effect of exchange-correlation and SO coupling produces asymmetry in the dispersion relations.

12:39PM B15.00008 Strongly Anisotropic Ballistic Magnetoresistance in Compact Three-Dimensional Semiconducting Nanodevices 1. CARMINE ORTIX, CHING-HAO CHANG, JEROEN VAN DEN BRINK, Institute for Theoretical Solid State Physics - IFW Dresden — In this talk, I will show that in non-magnetic semiconducting bilayer or multilayer thin film systems rolled-up into compact quasi-one-dimensional nanodevices, the ballistic magnetoresistance is very anisotropic: conductances depend strongly on the direction of an externally applied magnetic field. This phenomenon originates from the curved open geometry of rolled-up nanotubes, which leads to a tunability of the number of one-dimensional magnetic subbands crossing the Fermi energy. The experimental significance of this phenomenon is illustrated by a sizable anisotropy that scales with the inverse of the number of windings, and persists up to a critical temperature that can be strongly enhanced by increasing the strength of the external magnetic field or the characteristic radius of curvature, and can reach room temperature.

12:51PM B15.00009 Electronic Structure Evolution of Fullerene on CH3NH3PbI3 1. CHENGGONG WANG, CONGCONG WANG, university of rochester, XIAOLIANG LIU, Hunan Key Laboratory for Super-microstructure and Ultrafast Process, College of Physics and Electronics, Central South University, Changsha, 410083, P. CHENGBI, YUCHUANSHAO, ZHENGGUOXIAO, JINSONGHUANG, University of Nebraska, Lincoln, YONGLI GAO, university of rochester — The thickness dependence of fullerene on CH3NH3PbI3 perovskite film surface has been investigated by using ultraviolet photoemission spectroscopy (UPS). X-ray photoemission spectroscopy (XPS) and inverse photoemission spectroscopy (IPES). The lowest unoccupied molecular orbital (LUMO) and highest occupied molecular orbital (HOMO) can be observed directly with UPS and IPES. It is observed that the HOMO level in fullerene shifts to lower binding energy. The XPS results show an initial shift of core levels to lower binding energy in the perovskite, which indicates that electrons transfer from the perovskite film to fullerene molecules. We observed that the WF of the perovskite is 5.0 eV and the VBM is 0.6 eV. The band gap of the perovskite is 1.66 eV, which is in accordance with previous reports. We also observed the HOMO level of C60 shifts to lower binding energy, indicating a band bending in the C60 region. The perovskite core levels show a strong initial shift to lower binding energy, indicating electron transfer from the perovskite film to fullerene molecules. The strongest electron transfer happened at 1/4 monolayer of fullerene, and further deposition reduced the transfer as forms fullerene forms C60 solid film.

1:03PM B15.00010 Auger recombination in scintillator materials from first principles 1. ANDREW MCALLISTER, EMMANOULI KIOUPAKIS, University of Michigan, DANIEL ÅBERG, Lawrence Livermore National Laboratory, ANDRÉ SCHLEIFE, University of Illinois at Urbana-Champaign — Scintillators convert high energy radiation into lower energy photons which are easier to detect and analyze. One of the uses of these devices is identifying radioactive materials being transported across national borders. However, scintillating materials have a non-proportional light yield in response to incident radiation, which makes them less useful. One possible cause of the non-proportional light yield is non-radiative Auger recombination. Auger recombination can occur in two ways - direct and phonon-assisted. We have studied both types of Auger recombination from first principles in the common scintillating material sodium iodide. Our results indicate that the phonon-assisted process, assisted primarily by short-range optical phonons, dominates the direct process. The corresponding Auger coefficients are $5.6 \pm 0.3 \times 10^{-32} \text{cm}^6 \text{s}^{-1}$ for the phonon-assisted process versus $1.17 \pm 0.01 \times 10^{-32} \text{cm}^6 \text{s}^{-1}$ for the direct process. At higher electronic temperatures the direct Auger recombination rate increases but remains lower than the phonon-assisted rate.

1:15PM B15.00011 Pressure Dependent Electronic Properties of Organic Semiconductors from First Principles, FRANZ KNUTH, CHRISTIAN CARBONOGHI, Fritz-Haber-Institut der MPG, Berlin, DE; VOLKER BLUM, Fritz-Haber-Institut der MPG, Berlin, DE; DUKE UNIVERSITY, Durham, NC, USA; MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, DE. — The electronic properties of organic semiconductors typically exhibit a significant dependence on the strain, stress, and pressure [1]. In this contribution, we present the theoretical background, assessment of approximations, and results of electronic and transport properties in the framework of density-functional theory. Our implementation considers the analytical strain derivatives (stress tensor) including the contributions that stem from (a) van-der-Waals interactions [2] and (b) the Fock-exchange in hybrid functionals. We validate our approach by investigating the geometric and electronic changes that occur in polyacetylene and anthracene under hydrostatic pressure. We show that the fraction of exact exchange included in the calculations is critical — and non-trivial to choose — for a correct description of these systems. Furthermore, we point out trends for the electrical conductivity under pressure and identify the dominant charge carriers and transport directions.

1:27PM B15.00012 Investigation of Observing the role of orbital angular momentum with in Rashba and Dresselhaus effects system, SOOHYUN CHO, WONSIG JUNG, BEOMYOUNG KIM, GARAM HAN, Yonsei University, MATS LEANDERSSON, BALASUBRAMANIAN THIAGARAJAN, MAX Laboratory, CHANGYOUNG KIM, Yonsei University, MAX LABORATORY COLLABORATION — In our previous studies of Au(111) surface states with circular dichroism angle-resolved photoemission spectroscopy (CD-ARPES), we found strong CD signal, indicating probable existence and role of orbital angular momentum (OAM) in the Rashba effect. We proposed that OAM plays a key role in the electronic structures of such systems in the presence of inversion symmetry breaking and spin-orbit coupling (SOC). Semiconductors with the zinc blende structure with an inversion symmetry breaking have band splitting near the \( \Gamma \) point as predicted by the band calculation. In addition, the overall spin structure can be understood within in the Dresselhaus effect. While the net OAM in the bulk should be normally zero for semiconductors with an inversion symmetry, non-zero OAM can appear in the bulk of zinc-blende structures due to the inversion symmetry breaking. Moreover, as for ARPES experiments, the sample surface provide an additional inversion symmetry breaking. To investigate the OAM structure, we have performed CD-ARPES experiments on InSb, CdTe and GaAs. Our results show CD signal in the \( J_{3/2} \) states (heavy and light hole band). We attribute the CD modulations of the three bands (heavy hole, light hole and split-off bands) to the existence of OAM. The OAM structure deduced from the CD-ARPES results is explained if we assume both the Rashba (from surface) and Dresselhaus (from bulk) effects are present. These results suggest that OAM also plays a role in the Dresselhaus effect through SOC.

1:39PM B15.00113 Towards simple orbital-dependent density functionals for molecular dissociation, IGOR YING ZHANG, Fritz-Haber-Institut der MPG, Berlin, DE; PATRICK RICHTER, Aalto University, Helsinki, FI, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, DE. — Density functional theory (DFT) is one of the leading first-principles electronic-structure theories. However, molecular dissociation remains a challenge, because it requires a well-balanced description of the drastically different electronic structure at different bond lengths. One typical and well-documented case is the dissociation of both \( \text{H}_2^+ \) and \( \text{H}_2 \), for which all popular DFT functionals fail [1,2]. We start from the Bethe-Goldstone equation to propose a simple orbital-dependent correlation functional which generalizes the linear adiabatic connection approach. The resulting scheme is based on second-order perturbation theory (PT2), but includes the self-consistent coupling of electron-hole pairs, which ensures the correct \( \text{H}_2 \) dissociation limit and gives a finite correlation energy for systems with a (near)-degenerate energy gap. This coupling PT2-like (CPT2) approximation delivers a significant improvement over all existing functionals for both \( \text{H}_2 \) and \( \text{H}_2^+ \) dissociation. We will demonstrate the reason for this improvement analytically for \( \text{H}_2 \) in a minimal basis. [1] A. J. Cohen et al., Chem. Rev. 112 289 (2012), [2] F. Caruso et al., Phys. Rev. Lett. 110 146403 (2013).

1:51PM B15.00014 DFT Predictions of Electronic, Transport, and Bulk Properties of Li_2S, YURI MALOZOVSKY, LASHOUNDA FRANKLIN, Southern Univ & A&M Coll, CHINEDU EKUMA, Louisiana State University and A&M College, DIOLA BAGAYOKO, Southern Univ & A&M Coll, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, DE. — Density functional theory (DFT) is one of the leading first-principles electronic-structure theories. However, molecular dissociation remains a challenge, because it requires a well-balanced description of the drastically different electronic structure at different bond lengths. One typical and well-documented case is the dissociation of both \( \text{H}_2^+ \) and \( \text{H}_2 \), for which all popular DFT functionals fail [1,2]. We start from the Bethe-Goldstone equation to propose a simple orbital-dependent correlation functional which generalizes the linear adiabatic connection approach. The resulting scheme is based on second-order perturbation theory (PT2), but includes the self-consistent coupling of electron-hole pairs, which ensures the correct \( \text{H}_2 \) dissociation limit and gives a finite correlation energy for systems with a (near)-degenerate energy gap. 2:03PM B15.00015 Metallic 2D Surface State of Silicon by Ionic Liquid gating and observation of Reentrant Insulating behavior, J.J. NELSON, A.M. GOLDMAN, Univ of Minn - Minneapolis — Metal insulator transitions are usually observed in high mobility and low carrier density 2D electron systems. There are several open questions regarding the metallic state including its existence in the limit of zero temperature. The current experimental focus is on the production of higher mobility samples to push the critical carrier density to even lower values, which will increase the effects of the Coulomb interaction. Here we report an unexpected result, the observation of the onset of a metallic state at high carrier densities in silicon gated with the ionic liquid DEME-TFSI. In addition we have observed a return to the insulating state as the carrier density was further increased. This reentrant insulating behavior is an effect that was recently predicted [Das Sarma, S. and Hwang, E. H., PRB 89 121413, 2014].

11:15AM B16.00001 Computational Discovery of Metal-Organic Frameworks for CO$_2$ Capture and Energy Storage, DONALD SIEGEL, Univ of Michigan - Ann Arbor — Because of their high surface areas, crystallinity, and tunable properties, metal–organic frameworks (MOFs) have attracted intense interest as materials for gas capture and energy storage. An often-cited benefit of MOFs is their large number of possible structures and compositions. Nevertheless, this design flexibility also has drawbacks, as pinpointing optimal compounds from thousands of candidates can be time consuming and costly using experimental approaches. Consequently, computational approaches are garnering increasing importance as a means to accelerate the discovery of high-performing MOFs. Here we combine several computational techniques to identify promising MOFs for CO$_2$ capture and the storage of gaseous fuels (methane and hydrogen). The techniques include: (i) high-throughput screening based on data-mining and empirical correlations [1]; (ii) Monte Carlo simulations based on quantum-mechanically-informed forcefields [2,3]; and (iii) first-principles calculations of thermodynamics and electronic structure [4,5]. For CO$_2$ capture and CH$_4$ storage, these techniques are used to explore metal-substituted variants of M-DODBC and M-HKUST-1. In the case of H$_2$, we identify trends and promising adsorbents amongst 4,000 compounds mined from the Cambridge Structure Database.

11:27AM B16.00002 Computational screening and design of new materials for energy storage and conversion: batteries and thermoelectrics, BORIS KOZINSKY, Bosch Research, Cambridge MA — Understanding the atomic-level origins of thermoelectricity is necessary for the design of higher-performing materials, and we demonstrate that ab-initio computation is a valuable tool. By developing and using advanced methods to compute intrinsic contribution to electron lifetimes from electron-phonon coupling, we are able to predict temperature and doping dependence of electronic transport properties in doped semiconductors. We combine these tools to perform rapid screening of new thermoelectric compositions. In energy storage, a promising path to enabling safe high-energy-density batteries is the introduction of inorganic solid electrolytes that can protect the Li-metal anode. We have achieved a detailed understanding of a promising class of garnet compounds by developing a set of efficient atomistic computational techniques to analyze structure ordering and ionic transport mechanisms. These methods allow us to map the transport phase diagram of a broad range of compositions and to predict new phases and phase transitions. The computational techniques are coupled with a novel software platform AiiDA that combines high-throughput automation with data analysis capabilities.

11:39AM B16.00003 Discovery of optimal zeolites for challenging separations and chemical conversions through predictive materials modeling, J. ILJA SIEPMANN, PENG BAI, MICHAEL TSAPATSIS, University of Minnesota, CHRIS KNIGHT, Argonne National Laboratory, MICHAEL W. DEEM, Rice University — Zeolites play numerous important roles in modern petroleum refineries and have the potential to advance the production of fuels and chemical feedstocks from renewable resources. The performance of a zeolite as separation medium and catalyst depends on its framework structure and the type or location of active sites. To date, 213 framework types have been synthesized and ~330,000 thermodynamically accessible zeolite structures have been predicted. Hence, identification of optimal zeolites for a given application from the large pool of candidate structures is attractive for accelerating the pace of materials discovery. Here we identify, through a large-scale, multi-step computational screening process, promising zeolite structures for two energy-related applications: the purification of ethanol beyond the ethanol/water azeotropic concentration in a single separation step from fermentation broths and the hydroisomerization of alkanes with 18-30 carbon atoms encountered in petroleum refining. These results demonstrate that predictive modeling and data-driven science can now be applied to solve some of the most challenging separation problems involving highly non-ideal mixtures and highly articulated compounds.

11:51AM B16.00004 Novel tools for accelerated materials discovery in the AFLOWLIB.ORG repository: breakthroughs and challenges in the mapping of the materials genome, MARCO BUONGIANNI, NARASIMHULU, Univ of North Texas — High-Throughput Quantum-Mechanics computation of materials properties by ab initio methods has become the foundation of an effective approach to materials design, discovery and characterization. This data driven approach to materials science currently presents the most promising path to the development of advanced technological materials that could solve or mitigate important social and economic challenges of the 21st century. In particular, the rapid proliferation of computational data on materials properties presents the possibility to complement and extend materials property databases where the experimental data is lacking and difficult to obtain. Enhanced repositories such as AFLOWLIB, open novel opportunities for structure discovery and optimization, including uncovering of unsuspected compounds, metastable structures and correlations between various properties. The practical realization of these opportunities depends on the development of algorithms for electronic structure simulations of realistic material systems, the systematic compilation and classification of the generated data, and its presentation in easily accessed form to the materials science community, the primary mission of the AFLOW consortium.

12:27PM B16.00005 Computational search for rare-earth free hard-magnetic materials, JOSÉ A. FLORES LIVAS, SANGEETA SHARMA, JOHN KAY DEWHURST, EBERHARD GROSS, Max Planck Inst Microstructure, MAGMAT TEAM — It is difficult to overstate the importance of hard magnets for human life in modern times; they enter every walk of our life from medical equipments (NMR) to transport (trains, planes, cars, etc) to electronic appliances (for house hold use to computers). All the known hard magnets in use today contain rare-earth elements, to over state the importance of hard magnets for human life in modern times; they enter every walk of our life from medical equipments (NMR) to transport (trains, planes, cars, etc) to electronic appliances (for house hold use to computers). An often-cited benefit of MOFs is their large number of possible structures and compositions. Nevertheless, this design flexibility also has drawbacks, as pinpointing optimal compounds from thousands of candidates can be time consuming and costly using experimental approaches. Consequently, computational approaches are garnering increasing importance as a means to accelerate the discovery of high-performing MOFs. Here we combine several computational techniques to identify promising MOFs for CO$_2$ capture and the storage of gaseous fuels (methane and hydrogen). The techniques include: (i) high-throughput screening based on data-mining and empirical correlations [1]; (ii) Monte Carlo simulations based on quantum-mechanically-informed forcefields [2,3]; and (iii) first-principles calculations of thermodynamics and electronic structure [4,5]. For CO$_2$ capture and CH$_4$ storage, these techniques are used to explore metal-substituted variants of M-DODBC and M-HKUST-1. In the case of H$_2$, we identify trends and promising adsorbents amongst 4,000 compounds mined from the Cambridge Structure Database.

12:39PM B16.00006 Combinatorial Libraries of Transition Metal Oxides Using an Ab Initio High Throughput Approach¹

GUO LI, QIMIN YAN, Lawrence Berkeley Natl Lab, PAUL NEWHOUSE, LAN ZHOU, JOHN GREGOIRE, California Institute of Technology, JEFFREY NEATON, Lawrence Berkeley Natl Lab, UC-Berkeley, KAVLI Energy NanoSciences Institute at Berkeley — Using the results of first-principles calculations and data from the Materials Project (materialsproject.org), we have developed a simple but efficient scheme to theoretically simulate phase coexistence in experimental combinatorial libraries as a function of composition and temperature. In our approach, each experimental sample in a combinatorial library at a fixed composition is considered as a mixture of all the known compounds; and the compound concentrations are determined from calculations of their compositions and relevant thermodynamic potentials. Consequently, multiple compounds can be identified in every sample. To test our approach, we studied the pseudobinary library MnxV(1-x)Oy, and found that, together with those stable compounds predicted in a phase diagram, some of the above-convex-hull compounds, which are viewed unstable, also play a significant role in the combinatorial library. We validated our approach via comparison of calculated X-ray diffraction spectra for multiple phases and recent measurements.

12:51PM B16.00007 Combinatorial Search of Hydrogen Catalysts Based on Transition Metal Embedded Graphitic Carbons

WOON IH CHOI, BRANDON WOOD, ERIC SCHWEGLER, TADASHI OGITSU, Lawrence Livermore National Laboratory, QUANTUM SIMULATION GROUP TEAM — To find right d-orbital configuration for hydrogen catalyst among embedded transition metal (TM) atoms into the lattice of graphene, we performed high-throughput computational search out of 300 combinatorial material pools. Theoretical criteria, so called descriptors regarding material stability and catalytic activity are considered and we were able to narrow down to ten materials for hydrogen evolution, two for hydrogen oxidation reaction. Since catalytically active sites are related to single TM atom, Volmer-Kasuya type of new reaction pathway is expected for hydrogen evolution. Earth-abundant element Mo, bulk form of which doesn’t show good catalytic activity at all, turns into catalytically active site as it is dispersed atomically and its d-orbitals splits by the symmetry of local coordination at the binding sites.

1:03PM B16.00008 A Computational Method for Materials Design of New Interfaces

JAKUB KAMINSKI, CHRISTIAN RATSCH, University of California Los Angeles, JUSTIN WEBER, MICHAEL HAVERTY, Intel Corporation, SADASIVAN SHANKAR, formerly Intel Corporation — We propose a novel computational approach to explore the broad configurational space of possible interfaces formed from known crystal structures to find new heterostructure materials with potentially interesting properties. In a series of steps with increasing complexity and accuracy, the vast number of possible combinations is narrowed down to a limited set of the most promising and chemically compatible candidates. This systematic screening encompasses (i) establishing the geometrical compatibility along multiple crystallographic orientations of two materials, (ii) simple functions eliminating configurations with unfavorable interatomic steric conflicts, (iii) application of empirical and semi-empirical potentials estimating approximate energetics and structures, (iv) use of DFT based quantum-chemical methods to ascertain the final optimal geometry and stability of the interface in question. For efficient high-throughput screening we have developed a new method to calculate surface energies, which allows for fast and systematic treatment of materials terminated with non-polar surfaces. We show that our approach leads to a maximum error around 3% from the exact reference. The representative results from our search protocol will be presented for selected materials including semiconductors and oxides.

1:15PM B16.00009 Property-based cascade genetic algorithms for tailored searches of metal-oxide nano-structures

SASWATA BHATTACHARYA, LUCA M. GHIRINGHELLI, Fritz-Haber-Institut der MPG, Berlin, DE, NOA MAROM, Physics and Engineering Physics, Tulane University, New Orleans, LA, USA — There is considerable interest in the computational determination of structures of atomic clusters that are detected in spectroscopy experiments. It has been suggested that in photo-emission experiments performed on anions, isomers of small (TiO)n clusters with high electron affinity (EA) are selectively observed rather than those with the lowest energy [1]. For the theoretical modelling of these situations, searching for the energy global minimum of the potential energy surface (PES) is inefficient. By using such an approach, in fact, it is unlikely to find meta-stable isomers that have high EA or low ionization potential (IP), but energy significantly above the ground state. We present an extension to our recently developed ab initio cascade genetic algorithm [2], here tailored to conduct property-based (e.g., high EA, low IP) searches over the PES. The term cascade refers to a multi-stepped algorithm where successive steps employ a higher level of theory, and each step of the next level takes information obtained at the immediate lower level. The new algorithms are benchmarked and validated for (TiO)n clusters (n = 3 − 10, 15, 20). — [1] N. Marom et al. PRL 108, 106801 (2012) [2] S. Bhattacharya et al., NJP, in press (2014).

1:27PM B16.00010 First principles characterization of novel single-layer materials predicted with an evolutionary algorithm¹

BENJAMIN REVARD, WILL TIPTON, Department of Materials Science and Engineering, Cornell University, RICHARD HENNIG, Department of Materials Science and Engineering, University of Florida — Single-layer materials represent a new materials class with potentially transformative properties for applications in nanoelectronics and solar-energy harvesting. With the goal to discover novel 2D materials with unexpected compositions and structures, we have developed a grand-canonical evolutionary algorithm for two-dimensional materials. Here we present the results of applying the algorithm, coupled with first principles total energy methods, to several technologically relevant binary 2D systems, including C-Si, Sn-S and Pbo. We currently use computational techniques to characterize the vibrational and electronic properties of the low energy 2D materials predicted by the algorithm and will report the findings.

1:39PM B16.00011 High-throughput thermodynamics of vibrational degrees of freedom with AFLOW

PINKU NATH, JOSE J. PLATA, CORMAC TOHER, STEFANO CURTAROLO, Duke University, MEMS Department — Phonons are responsible for many thermodynamic properties of the materials. Quasiharmonic approximations have been used successfully as a strong theory in order to incorporate phonon contributions to material properties [1]. We have implemented this method to calculate Gruneisen parameter (GP) which captures the properties related to thermal variations and connects two important thermodynamic variables such as isobaric and isochoric specific heat. This method has been implemented in AFLOW framework for high-throughput computational materials science to accelerate the discovery of new materials and properties interesting for industries. GP has been calculated with the derivative of the frequency and the Feynman-Hellman technique, and the results for both techniques are consistent. We have also calculated coefficient of thermal expansion and bulk modulus using a quadratic fit followed by Birch Murnaghan fit of volume-energy data. For a large set of the materials tested, our results are in agreement with the experimental data.

11:51AM B17.00002 Measurement of the resistance induced by a single atomic impurity on a (7,6) semiconducting carbon nanotube: scattering strength of individual potassium atoms as a function of gate voltage. SHU-JEN HAN, IBM T. J. Watson Research Center — In the last four decades, we have witnessed a tremendous information technology revolution originated from the relentless scaling of Si complementary metal-oxide semiconductor (CMOS) devices. CMOS scaling provides ever-improved transistor performance, density, power and cost, and will continue to bring new applications and functions to our daily life. However, the conventional homogeneous scaling of silicon devices has become very difficult, firstly due to the unsatisfactory electrostatic control from the gate dielectric. In addition, as we look forward to the technology nodes with sub-10 nm channel length, non-Si based channel materials will be required to provide continuous carrier velocity enhancement when the conventional strained-Si techniques run out of steam. Single-walled carbon nanotubes are promising to replace silicon as the channel material for high-performance electronics near the end of silicon scaling roadmap, with their superb electrical properties, intrinsic ultrathin body, and nearly transparent contact with certain metals. This talk discusses recent advances in modeling and experimental works that reveal the properties and potential of ultra-scaled nanotube transistors, separation and assembly techniques for forming nanotube arrays with high semiconducting nanotube purity and tight pitch separation, and engineering aspects of their implementation in integrated circuits and functional systems. A concluding discussion highlights most significant challenges from technology points of view, and provides perspectives on the future of carbon nanotube based nanoelectronics.

12:03PM B17.00003 Unusual conductance suppression in metallic carbon nanotubes. AMIN AHMADI, RYUICHI TSUCHIKAWA, DANIEL HELIGMAN, University of Central Florida, ZHENGYI ZHANG, Columbia University, EDUARDO MUCCIOLI, University of Central Florida, JAMES HONE, Columbia University, MASA ISHIGAMI, University of Central Florida — Despite many years of research, no measurements have been performed to determine resistance induced by impurities in carbon nanotubes. Over the last few years, we have developed a capability to measure the resistance induced by a single impurity atom on nanotubes with known chirality. Using this capability, we measured the resistance induced by an individual potassium atom on a (7,6) semiconducting carbon nanotube. The “atomic” resistance of potassium is found to be in the kohm range and has a strong dependence on the applied gate voltage. The scattering strength of the p-type (valence band) channel is approximately 20 times greater than that of the n-type (conduction band) channel. We integrate our atomically-controlled experimental result to a numerical recursive Green’s function technique, which can precisely model the experiment, to understand the measured “atomic” resistance and the asymmetry.

2This work is based upon research supported by the National Science Foundation under Grant No. 0955625 and 1006230.

12:15PM B17.00004 Electrical contact to carbon nanotubes encapsulated in hexagonal boron nitride. JHAO-WUN HUANG, CHENG PAN, SON TRAN, Department of Physics and Astronomy, University of California, Riverside, CA, USA, TAKASHI TANIGUCHI, National Institute for Materials Science, Namiki 1-1, Tsukuba, Ibaraki 305-0044, Japan, MARC BOCKRATH, JEANIE LAU, Department of Physics and Astronomy, University of California, Riverside, CA, USA — Hexagonal boron nitride has been an excellent platform for low dimensional materials. We have fabricated ultra clean single-walled carbon nanotube (SWNT) devices encapsulated in hexagonal boron nitride by a dry transfer technique. Contacts to the SWNTs were made by reactive ion etching to expose the ends of SWNTs, followed by metal deposition. Ohmic contacts to SWNTs were achieved. We will discuss the quality of the contacts using different combinations of metals and present latest transport data.

12:27PM B17.00005 One-dimensional Poole-Frenkel conduction in the single defect limit. ELLIOT J. FULLER, DENG PAN, BRAD L. CORSO, O. TOLGA GUL, PHILIP G. COLLINS, Dept. of Physics and Astronomy, University of California Irvine — Theory predicts a range of phenomena in disordered one-dimensional (1D) conductors, but few physical systems exist for direct comparison with experimental observation. Recently, we demonstrated an electrochemical technique for adding a single, isolated point defect to a single-walled carbon nanotube (SWNT) in a field effect transistor device. A point defect, surrounded on either side by quasi-ballistic, semi-metallic SWNT is an ideal system for investigating disorder in 1D. Here, transport and Kelvin probe force microscopy independently demonstrate high-resistance depletion regions that can extend from 0.3 - 2.0 µm wide surrounding the defect site. The defect assists tunneling through this depletion region via a modified, 1D version of Poole-Frenkel conduction. The width of the depletion region is found to depend sensitively on SWNT diameter and carrier density, as expected for a molecular scale wire. Surprisingly, conduction is well described by the 1D Poole-Frenkel model over a wide range of temperature from 77 - 300 K and over a wide range of source-drain bias from 0.1 - 2.0 V.

This work is based upon research supported by the National Science Foundation under Grant No. 0955625 and 1006230.
12:39PM B17.00006 Electronic Properties of Graphene and Single Wall Carbon Nanotubes in the Presence of Hexagonal BN Islands, MOHAMMED ALABBOODI, JAIME BOHORQUEZ, ERIKA PUTZ, HANSIKA SIRIKUMARA, THUSHARI JAYASEKERA, Southern Illinois University, Carbondale — Silicon Carbide (SiC) is a semiconductor material with wide band gap and high thermal conductivity. One of the most promising uses of single walled carbon nanotubes is in a two-level system near the nanotube or noncovalently attached to the nanotube perturbs the current electrostatically. In a second case, a sidewall defect or other covalent modification sensitizes one site along the conductor. Comparative research has helped reveal differences in the transduction mechanism of the two cases and provides design rules for maximizing reliable signals for sensing applications. The covalent modifications are not mere perturbations and they are far more sensitive than noncovalent attachments, for example. However, the new degrees of freedom that accompany covalent disorder often have similar energy scales, leading to multiple independent fluctuations that degrade the overall signal-to-noise. Noncovalent sensitization generally produces a smaller signal amplitude in a background of other low-energy fluctuators, but a well-designed noncovalent linker can result in a highly predictable signal amplitudes. Furthermore, noncovalent fabrication methods are scalable, so that wafer-scale arrays of molecular sensors are most likely to follow this path.

12:51PM B17.00007 Ambipolar Transistors with Heterostructures of Single-Walled Carbon Nanotubes and Zinc Tin Oxide, BONGJUN KIM, SEONPIL JANG, Microelectronics Research Center, The University of Texas at Austin — The unique operation of ambipolar thin-film transistors (TFTs), in which both electrons and holes can be injected and transported in a single device, have attracted significant attention since it was first demonstrated in mid-1990s. In addition to their unique operation, these devices have great potential in complementary-like circuits and novel light emitting transistors. Single-walled carbon nanotubes (SWCNTs) exhibit ambipolar behavior intrinsically; however, SWCNTs under ambient conditions show strong p-type behavior due to adsorption of oxygen and moisture from air. In this work, we will discuss the performance characteristics of ambipolar TFTs with heterostructures of a network of SWCNTs and amorphous zinc tin oxide. These TFTs exhibit well-balanced electron and hole mobilities under ambient conditions, and both carriers are injected through Ti/Au contacts without large injection barriers. Charge transport in this material system will be described. In addition, complementary-like inverters which are composed of two ambipolar TFTs will be demonstrated.

1:03PM B17.00008 Zero-Dimensional Electrical Contact to a One-Dimensional Material, CHENG PAN, JHAO-WUN HUANG, SON TRAN, BIN CHENG, CHUN NING LAU, MARC BOCKRATH, University of California - Riverside — Recent work has shown that one-dimensional contacts can be made to two-dimensional graphene using boron nitride encapsulated graphene structures along with an etch process[1]. Here we report the encapsulation of carbon nanotubes, a one-dimensional material, between layers of boron nitride. By etching the edges we are able to use only the zero-dimensional ends of the carbon nanotube to yield high-quality electrical contacts. This end-contact geometry along with an encapsulated nanotube provides possibilities for the realization of more complex nanotube heterostructure devices. [1] L. Wang et al., Science 342, 614-617 (2013).

1:15PM B17.00009 Sensitizing Carbon Nanotube Transistors for Single Molecule Sensor Applications, PHILIP G. COLLINS, MAXIM AKHTEROV, PATRICK C. SIMS, ELLIOT J. FULLER, O. TOLGA GUL, DENG PAN, Department of Physics and Astronomy, University of California Irvine, Irvine, California 92697, USA — Recent work has demonstrated single-charge sensitivity in two types of carbon nanotube transistors. In one case, a two-level system near the nanotube or noncovalently attached to the nanotube perturbs the current electrostatically. In a second case, a sidewall defect or other covalent modification sensitizes one site along the conductor. Comparative research has helped reveal differences in the transduction mechanism of the two cases and provides design rules for maximizing reliable signals for sensing applications. The covalent modifications are not mere perturbations and they are far more sensitive than noncovalent attachments, for example. However, the new degrees of freedom that accompany covalent disorder often have similar energy scales, leading to multiple independent fluctuations that degrade the overall signal-to-noise. Noncovalent sensitization generally produces a smaller signal amplitude in a background of other lower-energy fluctuators, but a well-designed noncovalent linker can result in a highly predictable signal amplitudes. Furthermore, noncovalent fabrication methods are scalable, so that wafer-scale arrays of molecular sensors are most likely to follow this path.

1:27PM B17.00010 Defect Screening Effects of Fluoropolymer Capping in Single Walled Carbon Nanotube Transistors, SEONPIL JANG, BONGJUN KIM, The University of Texas at Austin, MICHAEL GEIER, MARK HERSAM, Northwestern University, ANANTH DODABALAPUR, The University of Texas at Austin — One of the most promising uses of single walled carbon nanotubes (SWCNTs) is as active channel semiconductor materials in field-effect transistors (FETs). Recent advances in the availability of highly sorted semiconducting SWCNT source material and in printing such nanotubes to realize high-performance thin-film transistors make them very promising candidates for printed electronics. In this presentation, we report on the substantial improvements in the characteristics of SWCNT FET devices and circuits comprised of these devices by the use of coatings of the fluoropolymer containing copolymer, PVDF-TrFE. The origins of these improvements may be attributed to the polar nature of C-F bonds and the local organization of the fluoropolymer at the interfaces with the SWCNTs so as to partially neutralize charged defects. This hypothesis was tested by the experiments using a number of vapor phase polar molecules which produce similar effects on the FET characteristics. The polar vapor experiments show that dipoles can partially neutralize residual charges arising from defects/impurities. The dipole present in polar molecules adopts an orientation that tends to cancel the effects of the charged defect/impurity from the perspective of mobile charges in the SWCNTs.

1:39PM B17.00011 Low Energy Dissipation Nano Device Research, JENNY YU, Cal Poly - Pomona — The development of research on energy dissipation is rapid in energy efficient area. Nano-material power FET is operated as an RF power amplifiers, the transport is ballistic, noise is limited and power dissipation is minimized. The goal is Green-save energy by developing the Graphene and carbon nanotube microwave and high performance devices. Higher performing RF amplifiers can have multiple impacts on widely for broad field, for example communication equipment, (such as mobile phone and RADAR); higher power density and lower power dissipation will improve spectral efficiency which translates into higher system level bandwidth and capacity for communications devices. Thus, fundamental studies of power handling capabilities of new RF (nano)technologies can have broad, sweeping impact. Because it is critical to maximizing the power handling ability of graphene and carbon nanotube FET, the initial task focuses on measuring and understanding the mechanism of electrical breakdown. We aim specifically to determine how the breakdown voltage in graphene and nanotubes is related to the source-drain spacing, electrode material and thickness, and substrate, and thus develop reliable statistics on the breakdown mechanism and probability.

1:51PM B17.00012 ABSTRACT MOVED TO W22.00012 —

2:03PM B17.00013 ABSTRACT WITHDRAWN —

Monday, March 2, 2015 11:15AM - 2:15PM
Session B18 GQI DAMOP: Invited Session: Optimal Control of Quantum Systems
Mission Room 103A - Adolfo del Campo, University of Massachusetts Boston
11:51AM B18.00002 Optimizing control for implementing error correction in superconducting quantum circuits. RAMI BARENDS, Google, Santa Barbara — Fault-tolerant quantum computing hinges on implementing gates and measurement with fidelities above the threshold for error correction schemes. We have constructed a nine qubit device with integrated control and readout to implement the repetition code error correction scheme, a one-dimensional version of the surface code. We show how rapid scans, randomized benchmarking, and the error correction code itself can be used to optimize gates in this complex quantum device to fidelities which allow for protecting states from environmentally-induced bit errors.

12:27PM B18.00003 Controlling open quantum systems: Tools, achievements, limitations. CHRISTIANE KOCH, Universität Kassel — Quantum control is an important prerequisite for quantum devices. A major obstacle is the fact that a quantum system can never completely be isolated from its environment. The interaction with the environment causes decoherence. Optimal control theory is a tool that can be used to identify control strategies in the presence of decoherence. I will show how to adapt optimal control theory to quantum information tasks for open quantum systems and present examples for cold atoms and superconducting qubits. In particular, I will discuss how non-Markovianity of the open system time evolution can be exploited for control. The perspective on decoherence only as the adversary of quantum control is nevertheless too narrow. There exist a number of control tasks, such as cooling and measurement, that can only be achieved by an interplay of control and dissipation. I will show how to utilize optimal control theory to derive efficient cooling strategies when the timescales of coherent dynamics and dissipation are very different. Our approach can be generalized to quantum reservoir engineering, opening up new avenues for control.

1:03PM B18.00004 Quantum Control Engineering with Trapped Ions. MICHAEL BIERCUK, University of Sydney — Technologies fundamentally enabled by quantum mechanics are poised to transform a broad range of applications from computation to precision metrology over the coming decades. This talk will introduce a new field of research which is seeing concepts from control engineering translated to the domain of quantum mechanics in an effort to realize the full potential of engineered quantum technologies. We focus on understanding the physics underlying controlled quantum dynamics in the presence of rapidly fluctuating time-dependent Hamiltonians, leveraging the unique capabilities provided by trapped ions as a model quantum system. Our results introduce and experimentally validate generalized filter-transfer functions which cast arbitrary quantum control operations on qubits as noise spectral filters. We demonstrate the utility of these constructs for directly predicting the evolution of a quantum state in a realistic noisy environment, for developing novel robust control and sensing protocols, and for improving the stability of atomic clocks. This work demonstrates how quantum control can be leveraged to overcome some of the most challenging problems in quantum engineering, and even provide totally new functionality to quantum systems.

1:39PM B18.00005 A general transfer-function approach to noise filtering in open-loop quantum control1. LORENZA VIOLA, Dartmouth College — Hamiltonian engineering via unitary open-loop quantum control provides a versatile and experimentally validated framework for manipulating a broad class of non-Markovian open quantum systems of interest, with applications ranging from dynamical decoupling and dynamically corrected quantum gates, to noise spectroscopy and quantum simulation. In this context, transfer-function techniques directly motivated by control engineering have proved invaluable for obtaining a transparent picture of the controlled dynamics in the frequency domain and for quantitatively analyzing performance. In this talk, I will show how to identify a computationally tractable set of “fundamental filter functions,” out of which arbitrary filter functions may be assembled up to arbitrary high order in principle. Besides avoiding the infinite recursive hierarchy of filter functions that arises in general control scenarios, this fundamental set suffices to characterize the error suppression capabilities of the control protocol in both the time and frequency domain. I will show, in particular, how the resulting notion of “filtering order” reveals conceptually distinct, albeit complementary, features of the controlled dynamics as compared to the “cancellation order,” traditionally defined in the Magnus sense. Implications for current quantum control experiments will be discussed.

11:15AM B19.00001 The Use of Theater and the Performing Arts in Science Education and the Teaching of History1. BRIAN SCHWARTZ, Brooklyn College and the Graduate Center of the City University of New York — Over the past 15 years there has been a surge in the general field of the interaction of STEM and the arts including theatre, music dance and the visual arts leading to STEAM. There seems to be no limits to the amount of creativity and diversity of subject matter especially in areas of biography; major science events, scientific and technical innovation, the benefits and dangers of modern science, and science as metaphor. For the past 15 years, I and my colleagues have been running a science outreach series under the title Science & the Performing Arts at the Graduate Center of the City University of New York. The objective is to bring science to students and the public in ways that are engaging, instructive, and artistic and always, content-driven: the medium is the arts; the message is the joy of science. This has resulted in over 120 science and performing arts programs which have been documented on the website http://sciart.commons.gc.cuny.edu/staging-science/outline-of-the-course-staging-science/ with Marvin Carlson, Professor of Theatre at CUNY. An excellent book, Science on Stage: From Doctor Faustus to Copenhagen by Kirsten Shepherd-Barr, can be used. The author co-taught a course titled Staging Science, http://sciart.commons.gc.cuny.edu/staging-science/outline-of-the-course-staging-science/ with Marvin Carlson, Professor of Theatre at CUNY. An excellent book, Science on Stage: From Doctor Faustus to Copenhagen by Kirsten Shepherd-Barr, can be used.

1Supported in part by the National Science Foundation

11:51AM B19.00002 Bruno, Galileo, Einstein: The Value of Myths in Physics. ALBERTO MARTINEZ, University of Texas at Austin — Usually, historical myths are portrayed as something to be avoided in a physics classroom. Instead, I will discuss the positive function of myths and how they can be used to improve physics education. First, on the basis of historical research from primary sources and significant new findings about the Catholic Inquisition, I will discuss how to use the inspirational story of Giordano Bruno when discussing cosmology. Next, I will discuss the recurring story about Galileo and the Leaning Tower of Pisa. Finally, I will discuss how neglected stories about the young Albert Einstein can help to inspire students.
This paper will argue that incorporation of nanoscopic fluctuations is a necessary component for post-yield stress softening and its dependence on annealing time, (ii) the inversion of the strain dependence of nonlinear stress relaxation with the loading rate, (e.g. local stress and local entropy) vs. traditional viscoelastic/viscoelastic models where macroscopic mobility depends upon the macroscopic state. The SCM behavior of polymeric glasses, where (i) temporal fluctuations are explicitly included and (ii) the postulate. In order to acknowledge dynamic heterogeneity, a Stochastic Constitutive Model (SCM) has been developed to describe the nonlinear viscoelastic a critical challenge to the traditional nonlinear continuum models, where both temporal and spatial fluctuations are averaged as a result of the continuum.
1:03PM B20.00004 Atomic motion and physical aging in structural glasses revealed by coherent X-rays, BEATRICE RUTA, ESRF- The European Synchrotron, Grenoble. — Glasses are essential materials in present day science and technology. Nevertheless, many of their properties remain the subject of numerous studies, since their intrinsic non-equilibrium nature poses formidable problems both at the technological and fundamental level. Although their physical aging has practical implication for material science, a microscopic understanding is still missing since experiments that study the dynamics at the microscopic level are extremely challenging [1]. Here, we will report on the first experiments that follow the evolution of the structural relaxation process in glasses at the atomic length scale. Measurements on metallic glasses have revealed the existence of microscopic structural rearrangements, contrary to the common expectation of a completely arrested state [2,3]. In these systems, the dynamics evolves from a diffusive atomic motion in the supercooled liquid phase to a stress-dominated dynamics in the glass, characterized by a complex hierarchy of aging regimes. These finding present many similarities with the dynamics of various complex soft materials, like emulsions, gels and glassy colloidal suspensions [4] suggesting the existence of a common physical mechanism. Albeit this apparent universal out-of-equilibrium dynamics, an even more complex scenario emerges when the investigation is enlarged to other glasses. Measurements on sodium-silicate glasses show a surprising fast atomic motion, even hundreds degrees below the glass transition temperature [5]. In addition, aging of glassy materials is observed on experimental time scales of several hours, not even in the glass transition regions, in marked disagreement with macroscopic studies. This surprising stationary dynamics has been observed also in the case of metallic glasses but only for very large annealing times [2,3] and suggests the existence of a very peculiar relaxation dynamics at the atomic level, unaccounted for in previous experimental and theoretical works [1]. [1] L. Berthier and G. Biroli, Rev. Mod. Phys. 83, 587 (2011). [2] B. Ruta et al. Phys. Rev. Lett. 109, 165701 (2012). [3] B. Ruta et al. J. Chem. Phys. 138, 054508 (2013). [4] L. Cipelletti et al. Faraday Discuss. 123, 237, (2003). [5] B. Ruta et al. Nature Commun. 5, 3939 (2014).

1:39PM B20.00005 Inelastic Neutron Scattering Studies of the Dynamics of Glass-Forming Materials in Confineoment, REINER ZORN, JCSN-1, Forschungszentrum Juelich, D-52425 Juelich, Germany — The study of the dynamics of glass-forming liquids in nanoscopic confinement may contribute to the understanding of the glass transition. Especially, the question of a cooperativity length scale may be addressed. In this presentation, results obtained by inelastic neutron scattering are presented. The first experiments were done to study the α relaxation of glass-forming liquids and polymers in nanoroporous silica. Neutron scattering is a suitable method to study such composite materials because the scattering of the liquid component can be emphasized by the choice of isotopes. By combining time-of-flight spectroscopy and backsctattering spectroscopy it is possible to cover the large dynamical range spanned by the dynamics of glass-forming materials. The experiments demonstrated a broadening of the spectrum of relaxation times with faster as well as slower components compared to the bulk. In later experiments 'soft' confinement in a microemulsion was used to reduce surface effects. In this system a definite acceleration of the dynamics was observed. In all cases the glass-specific fast vibrational dynamics (boson peak) was also studied revealing a characteristic confinement dependence which allows conclusions on its nature. Finally, studies were carried out on polymers by neutron spin echo spectroscopy with the aim of observing the confinement effect on polymer specific dynamics (Rouse motion). These studies showed that a comparatively simple model is able to explain the deviation from bulk behavior.

Monday, March 2, 2015 11:15AM - 2:03PM –
Session B21 GIMS: Detectors, Sensors, & Transducers 201 - Charles Mielke, Los Alamos National Laboratory

11:15AM B21.00001 Neutron detection using far ultraviolet radiation from noble-gas excimers, MICHAEL A. COPLAN, JACOB C. MCCOMB, MOHAMAD I. AL-SHEIKHLY, University of Maryland, ERIC MILLER, CHRISTOPHER M. LAVELLE, Johns Hopkins University Applied Physics Laboratory, ALAN K. THOMPSON, ROBERT E. VEST, National Institute of Standards and Technology, CHARLES W. CLARK, Joint Quantum Institute, NEUTRON OBSERVATORY COLLABORATION — When triggered in a noble gas medium at around atmospheric pressure, low-energy neutron-absorption reactions such as \(^{4}\text{He}(n,\alpha)\text{He}^+\) and \(^{10}\text{B}(n,\alpha)\text{Li}^+\) can generate tens of thousands of far ultraviolet photons per neutron absorbed. In some cases, up to 30% of the \(\sim\) MeV nuclear reaction energy is channeled into far ultraviolet emission. The far ultraviolet photons are produced by noble-gas excimer radiation, to which the noble gas medium is transparent, facilitating efficient optical detection. We report progress in the development of the Neutron Observatory, http://j.mp/N3utr0n, an absolute neutron detector stationed at the fundamental physics beamline at the NIST Center for Neutron Research. Our reaction initiators consist of arrays of thin films of \(^{10}\text{B}\) and boron-coated vitreous carbon foams.

11:27AM B21.00002 Shunt-Enhanced, Lead-Driven Bifurcation of Epilayer GaAs based EEC Sensor Responsivity, STUART SOLIN1, FLETCHER WERNER2, Washington Univ — The results reported here explore the geometric optimization of room-temperature EEC sensor [1] responsivity to applied bias by exploring contact geometry and location. The EEC sensor structure resembles that of a MESFET, but the measurement technique and operation distinguish the EEC sensor significantly; the EEC sensor employs a four-point resistance measurement as opposed to a two-point source-drain measurement and is operated under both forward and reverse bias. Under direct forward bias, the sensor distinguishes itself from a traditional FET by allowing current to be admitted from the gate, referred to as a shunt, into the active layer. We show that the observed bifurcation in EEC sensor response to direct reverse bias depends critically on measurement lead location. A dramatic enhancement in responsivity is achieved via a rotation of the four-point measurement leads. [1] A.K.M. Newaz, et al, Phys Rev B. 79, 195308 (2009).

2Current Address: Cutting Edge Optronics

11:39AM B21.00003 The GlueX Start Counter, ERIC POOSER, Florida Intl Univ, GLUEX COLLABORATION — The GlueX experiment will study meson photoproduction with unprecedented precision. This experiment will use the coherent bremsstrahlung technique to produce a 9 GeV linearly polarized photon beam incident on an liquid H\(_2\) target. A Start Counter detector has been fabricated to identify the accelerator electron beam, approximately 2 ns apart, and to provide accurate timing information which is used in the level-1 trigger of the experiment. This detector is designed to operate at photon intensities of up to \(10^{7}\gamma/s\) in the coherent peak and provide a timing resolution < 350 ps so as to provide successful identification of the electron beam buckets to within 99\% accuracy. Furthermore, the Start Counter detector will provide excellent solid angle coverage, \(\sim 90\%\) of \(4\pi\) hemericty, and a high degree of segmentation for background rejection. It consists of a cylindrical array of 30 scintillators with pointed ends that bend towards the beam at the downstream end. Silicon PhotoMultiplier (SIPM) detectors have been selected as the readout system. The physical properties of the Start Counter have been studied extensively. The results of these studies are discussed.

12:03PM B21.00005 Ranged Isotope Detection and Identification Using Gas Ionization, BENJAMIN GRABER, DONG HO WU, US. Naval Research Laboratory — Radioactive isotopes produce gamma rays, and the gamma rays ionize gases. Since an isotope has a characteristic gamma energy spectrum, and also gas molecules have characteristic ionization energies, we speculated that the gas ionization rate would uniquely depend on not only the type of isotope but also the type of gas. Our experiments have confirmed these concepts — the experiments clearly exhibit that different isotopes produce different ion densities in different gases. Utilizing a set of four gas cells with embedded ion counters, it is then possible to construct a standoff nuclear-isotope detection system. This system has demonstrated a standoff detection and identification of isotopes at a substantial distance (more than 5 m) while testing Am, Ba, Co, Cs and Na isotopes of less than 75 uCi activity. Our prototype is cheaper, faster and easier to operate than commercial gamma-ray spectrometers. In this talk our experimental results and theoretical models for gas ionization will be presented.

12:15PM B21.00006 Broadband Coupling of Microwave Signals to Thin Conductors in Cryogenic Systems1, SCOTT DIETRICH, WILLIAM MAYER, JESSE KANTER, Graduate Center, City University of New York, New York 10016, USA, SERGEY VITKALOV, CUNY-CCNY — Three techniques are used to determine the microwave (MW) coupling through semi-rigid coaxial lines to samples installed on stages at the bottom of long probes (≈1m or longer) placed in a liquid helium cryostat. Samples are mounted between the MW delivery line and ground and are placed in parallel with a 50Ω impedance-matching terminal resistor. One method to determine the delivery of MW signal uses bolometric measurements of the MW power dissipated at the terminal resistor. Another method employs reflection measurements to obtain the reflection coefficient Γ of the sample stage, which is sensitive to variations in sample resistance. A third method initially uses the sample itself as a detector of a small, amplitude-modulated MW signal; the resulting variations of sample resistance are then applied as a calibration factor. Each method appears to reliably measure the actual MW signal delivered to the sample. The presented studies focus on two different electronic systems: GaAs quantum wells and La(2–x)Sr,xCuO superconducting films.

12:27PM B21.00007 ABSTRACT WITHDRAWN —

12:39PM B21.00008 ABSTRACT WITHDRAWN —

12:51PM B21.00009 SAW devices based on novel surface wave excitations, JOEL THERRIEN, LIAN DAI, ECE Dept, U Mass Lowell — Surface Acoustic Wave (SAW) devices have applications in radio frequency and microwave filtering as well as highly sensitive sensors. Current SAW design employs the use of an array of electrode pairs, referred to as Inter-Digitated Transducers (IDTs) for creating and receiving surface waves on piezoelectric substrates. The pitch of the electrode pairs along with the properties of the substrate determine the operating frequency. The number of electrode pairs determines the bandwidth of the emitted waves. We will present a novel configuration that eliminates the need for the IDTs and replaces with a single circular electrode located inside a larger ground ring. This configuration induces drumhead modes. We will show that the resonant frequencies follow the zeros of Bessel functions of the first kind. Applications in RF filtering and mass sensing will be presented.

1:03PM B21.00110 Multifunctional sensors operating at 300 K based on quasi-ballistic InSb quantum well nanostructures, ADAM GILBERTSON, DOMINIC MOSELEY, MIKHAIL KUSTOV, STUART SOLIN1, LESLEY COHEN, Imperial College London, SIMON BENDING, University of Bath — The high mobility (μ) of InSb quantum well (QW) heterostructures at 300 K makes them ideally suited for both magnetic and optical sensing. While macroscopic InSb Hall sensors offer the best magnetic sensitivity at 300 K of any material, the operation of sub-micron InSb QW Hall probes have not been reported. Ballistic transport at 300 K in nano-InSb devices was recently described [1]. Here we report the 300 K sensing properties of InSb QW structures fabricated into scanning probe geometries operating in the photoconductive (PC), Hall, and magnetocductive modes. Sub-micron InSb QW probes exhibit excellent magnetic sensitivity <1μT/Hz and are demonstrated in a scanning Hall probe measurement. InSb QWxs exhibit long lived negative photoconductivity in the visible to near-IR for cw excitation, however, significant improvements in dynamic response are found with ac modulated techniques. From spatially resolved PC measurements we determine μT ~ 3.5 x 10^−3 cm²/V. These results provide a benchmark for developing novel InSb QW-metal hybrid nanosensors [2].

1On sabattical from Washington University in St. Louis.

1:15PM B21.00011 A Simple Instrument for Measuring Surface Forces in Liquids, JAMES HANNON, RUDOLF TROMP, RICHARD HAIGHT, ARTHUR ELLIS, IBM Research Division — We have constructed a simple instrument to measure the interaction force between two surfaces in solution, or in vacuum. Specifically, we measure the interaction between a lens and a thin silicon cantilever. Either the lens, or the cantilever (or both) can be coated with the species of interest. When the lens is brought close to the cantilever surface, the force of interaction causes the cantilever to bend. By measuring the deflection as a function of the distance between the lens and cantilever, the long-range interactions between the two surfaces can be determined. Our approach includes three important innovations. First, a commercial lens with a radius of ≈1 cm is used for one surface. The relatively large radius of curvature enhances force sensitivity of the method. Second, we use optical interference (Newton’s Rings) to determine the distance between lens and cantilever with ~ 1 nm accuracy. Third, we make use of thin crystalline cantilevers (100 μm thick) whose elastic properties can be easily measured. We have achieved a force sensitivity F/R better than 0.001 mN/m. I will discuss the theory of operation of the new instrument and describe measurements made on SiO2 and metal oxide surfaces in water.

11:51AM B21.00004 Alpha-particle emissivity screening of materials used for semiconductor manufacturing, MICHAEL GORDON, KENNETH RODBELL, IBM TJ Watson Research Center — Single-Event Upsets (SEU’s) in semiconductor memory and logic devices continue to be a reliability issue in modern CMOS devices. SEU’s result from deposited charge in the Si devices caused by the passage of ionizing radiation. With technology scaling, the device area decreases, but the critical charge required to flip bits decreases as well. The interplay between both determines how the SEU rate scales with shrinking device geometries and dimensions. In order to minimize the alpha-particle component of SEU, the radiation in the device environment has to be at the Ultra-Low Alpha (ULA) activity levels, e.g. less than 2nCi/khr-cm². Most detectors have background levels that are significantly larger than that level which makes making these measurements difficult and time consuming. A new class of alpha particle detector, utilizing pulse shape discrimination, is now available which allows one to make measurements quickly with ultra-low detector background. This talk will discuss what is involved in making alpha particle measurements of materials in the ULA activity levels, in terms of calibration, radon adsorption mitigation, the time required for obtaining reasonable statistics and comparisons to other detectors.
1:27PM B21.00012 Particle Imaging, Characterization and Extinction Measurement with Digital Holography. NAVA SUBEDI, MATTHEW BERG, Mississippi State University — This work extends the concept of application of digital holographic microscopy (DHM) from particle imaging to the measurement of photothermally induced particle expansion and energy flow that gives rises to extinction cross section. In this work, a particle is illuminated by a pulsed laser and the interference pattern produced by superposition of particle’s forward-scattered wave with the incident wave is recorded by a digital camera. This recorded pattern constitutes a digital hologram which can be numerically processed to get image, photo-thermally induced expansion and extinction cross-section of the particle. These information of the particle are the basic requirements for the characterization of respirable-sized (1-10 μm) aerosol particles.

1:39PM B21.00013 Highly sensitive direct conversion ultrasound interferometer. OLEKSY SVITELSKY, Gordon College, MA 01942, JOHN GROSSMANN, Colgate University, NY 13436, ALEXEY SUSLOV, National High Magnetic Field Laboratory, FL 32310 — Being invented more than fifty years ago, the ultrasonic pulse-echo technique has proven itself as a valuable and indispensable non-destructive tool to explore elastic properties of materials in engineering and scientific tasks. We propose a new design for the instrument based on mass-produced integral microchips. In our design the radiofrequency echo-pulse signal is processed by AD8302 RF gain and phase detector (www.analog.com). Its phase output is linearly proportional to the phase difference between the exciting and response signals. The gain output is proportional to the log of the ratio of amplitudes of the received to the exciting signals. To exclude the non-linear fragments and to enable exploring large phase changes, we employ parallel connection of two detectors, fed by in-phase and quadrature signals respectively. The instrument allowed us exploring phase transitions with precision of Δϕ<10^-7 (ϕ is the ultrasound speed). The high sensitivity of the logarithmic amplifiers embedded into AD8302 requires good grounding and screening of the receiving circuitry.

1:51PM B21.00014 Resonance Splitting in RF Cylindrical Cavities with Circular Apertures. LUIS MARTINEZ, University of California, Merced — Coupling of two RF cylindrical cavities is achieved with the use of a single, thin, circular aperture (iris) located between the two cavities in the transverse plane. A tunable splitting, in which the single resonance splits into a closely spaced doublet for the TE011 mode is experimentally observed. It is found that the frequency spacing of the doublet is related to the circular aperture size. A model based on the analogy of a multi-mirror optical Fabry-Perot cavity, in which the frequency spacing of the doublet is related to the reflection coefficient, is found to be in excellent agreement with the experimental results. Calculation of the reflection coefficient for the circular aperture is performed using the closed form solutions derived from scattering amplitude and circular aperture theory.

Monday, March 2, 2015 11:15AM - 2:03PM — Session B22 DCMP: Optical Studies of Strongly Correlated Systems 202A.

11:15AM B22.00001 Spatially ordered transit through a canonical Mott transition revealed by cryogenic nano-imaging. A.S. MCLEOD, University of California San Diego, 9500 Gilman Dr, La Jolla, CA 92093, E. VAN HEUMEN, University of Amsterdam, Sciepark 904, 1098 XH Amsterdam, Netherlands, J.G. RAMIREZ, S. WANG, T. SAERBECK, S. GUENON, M. GOLDFLAM, L. ANDEREGG, P. KELLY, A. MUELLER, M.K. LIU, I.K. SCHULLER, D.N. BASOV, University of California San Diego, 9500 Gilman Dr, La Jolla, CA 92093 — We report on temperature-dependent (24K-300K) near-field infrared (IR) imaging of the canonical Mott insulator VO2 across its temperature-driven metal-insulator transition. This was accomplished using a home-built s-SNOM (scattering-type scanning near-field optical microscope) affording unprecedented spatial resolution (~20 nm) to surface optical properties with simultaneously acquired AFM topography at cryogenic temperatures. Our VO2 thin film is found to exhibit extreme nano-scale electronic heterogeneity near the Mott transition (170K) from paramagnetic metal to antiferromagnetic insulator. A sequence of nano-IR images acquired across the transition provides a direct probe of the metal/insulator fill fraction in accord with an observed percolation-driven resistive transition. We resolve dynamic evolution of electronic phases and a crossover from long- to short-range spatial correlations. Identification of the attendant VO2 structural transition by X-ray diffraction reveals an unexpected decoupling of Mott and structural transitions. Supported by nano-IR imaging of remnant metallic puddles below the Mott transition, these observation point towards a novel low-temperature metallic phase.

11:27AM B22.00002 New Insights into the Diverse Electronic Phases of a Novel Vanadium Dioxide Polymorph: A Terahertz Spectroscopy Study. JAMES LOUREMBAM, Nanyang Technological University, AMAR SRIVASTAVA, National University Singapore, CHAN LA-O-VORAKIAT, Nanyang Technological University, HELENE ROTELLA, THIRUMALAI VENKATESAN, National University Singapore, ELBERT CHIA, Nanyang Technological University — A remarkable feature of vanadium dioxide is that it can be synthesized in two polymorphs. The electronic phase diagram is constructed, revealing that the width and onset of the metal-insulator transition in the B phase develop differently from the two polymorphs. The conductivity mechanism in the metastable layered polymorph VO2(B) thin films has been investigated by terahertz time-domain spectroscopy (THz-TDS). In VO2(B), a critical temperature of 240 K marks the appearance of a non-zero Drude term in the observed complex conductivity, indicating the evolution from a pure insulating state towards a metallic state. In contrast, the THz conductivity of the well-known VO2(M) is well fitted only by a modification of the Drude model to include backscattering. We also identified two different THz conductivity regimes separated by temperature in these two polymorphs. The electronic phase diagram is constructed, revealing that the width and onset of the metal-insulator transition in the B phase develop differently from the M1 phase.

11:39AM B22.00003 On the Repeatability of Domain Formation and Growth During the Metal-Insulator Transition in Vanadium Dioxide Films. T.J. HUFFMAN, PENG XU, M.M. QAZILBASH, Department of Physics, College of William and Mary, BONG-JUN KIM, HYUN-TAK KIM, Electronics and Telecommunications Institute (ETRI) — Nanoscale phase coexistence between insulating and metallic domains has been observed in films of vanadium dioxide (VO2) using scattering-type scanning near-field infrared microscopy (s-SNIM). When insulating VO2 transitions to the metallic phase, small regions of the metallic phase first nucleate, and then grow as the metal-insulator transition (MIT) progresses. It is an open question if the patterns of insulating and metallic VO2 in a given scan area are reproducible upon repeated thermal cycling across the MIT. To investigate this matter, we image the same area of a VO2 film with s-SNIM over multiple thermal cycles through the MIT. In this way, we uncover the relative contributions of deterministic and random events occurring at the nanoscale during the progress of the MIT. Our experiments reveal the nature of phase coexistence in VO2 films and the real-space dynamics of the MIT.

12:03PM B22.00005 Closing of the pseudogap in Fe$_{1.03}$Te$^1$. C.C. HOMES, Y.M. DAI, J. SCHNEELOCH, R.D. ZHONG, Q. LI, G.D. GU, Condensed Matter Physics and Materials Science Dept., Brookhaven National Laboratory, Upton, New York, A. AKRAP, Ecole de Physique, Université de Genève, CH-1211 Genève 4, Switzerland — The optical properties of strongly-correlated Fe$_{1.03}$Te have been measured over a wide frequency range for light polarized in the a-b planes at temperatures above and below the structural and magnetic transition, $T_N \approx 68$ K. For $T > T_N$, in the paramagnetic state, the resistivity is increasing with decreasing temperature, and the optical conductivity is flat over much of the infrared region, except for a weak Drude-like response at low frequency. Below $T_N$, in the antiferromagnetic state, there is dramatic increase in the low-frequency conductivity with a commensurate transfer of spectral weight (area under the conductivity curve) from low to high energy. The roughly constant value of the scattering rate indicates that it is the plasma frequency ($\omega_p$) that is increasing. This increase in $\omega_p \propto n/m^* \propto 1/T$ is associated with the closing of the pseudogap on the electron pocket resulting in an increase in the number of carriers (n). In addition, below $T_N$ the effective mass ($m^*$) is also thought to decrease. Both effects lead to an increase in $\omega_p$ on the electron pocket.$^{[1]}$

12:15PM B22.00006 Optical spectroscopy of the metallic Nd$_{1-x}$TiO$_3$ system. NATHAN ARMSTRONG, McMaster University, ATHENA SEFAT, Materials Science and Technology Division, Oak Ridge National Laboratory, JING YANG, Tianjin University, JOHN GREEDAN, THOMAS TIMUSK, McMaster University — The neodymium titanate system, Nd$_{1-x}$TiO$_3$, exhibits two metal-to-insulator transitions at $x = 0.08$ and $x = 0.24$. The n-type metallic regime between the two transitions exhibits the Fermi liquid $T^2$ DC resistivity over a large range of temperatures. We have measured the reflectivity of the $x = 0.15$ and $x = 0.2$ samples from 4 meV to 5.5 eV at temperature from 15 K to 300 K. Previous optical work by Yang et al. measured an insulating, a semiconducting, and a metallic sample. The metallic sample was found to have the Fermi liquid $\omega^2$ dependence in the scattering rate. We reevaluate the Yang et al. data for the $x = 0.095$ metallic sample, just inside the MIT, and compare it to our samples deeper in the metallic regime that have $T^2$ coefficients an order of magnitude smaller.

12:27PM B22.00007 Resilient quasiparticles in Ruthenates: transport properties within LDA+DMFT method. XIAOYU DENG, KRISTIAN HAULE, GABRIEL KOTLIBAR, Rutgers Univ — Many Rutheniums are strongly correlated metals with Fermi Liquid behavior found only a small temperature scale. Non-Fermi signatures appear in both their resistivity and optical conductivity. We study the transport properties of a set of Ruthenates within first principle methods in combination with dynamical mean field theory and find reasonable agreement with experimental findings. The non-Fermi-liquid features are attributed to the temperature dependence of resilient quasiparticles, which survives above the Fermi liquid temperature scale and exhibits a strong temperature dependence in their effective mass enhancement and scattering rate.

12:39PM B22.00008 Abrupt changes in electronic relaxation and lattice dynamics across the structural phase transition in lightly doped Ca$_3$RuO$_4$ observed via time-resolved optical reflectivity. HAO CHU, DARIUS TORCHINSKY, LIUJIAN ZHAO, PATRICK RALL, Institute for Quantum Information and Matter, California Institute of Technology, JASMINKA TERRACE, GANG CAO, Department of Physics and Astronomy, University of Kentucky, DAVID HSIEH, Institute for Quantum Information and Matter, California Institute of Technology, INSTITUTE FOR QUANTUM INFORMATION AND MATTER, CALIFORNIA INSTITUTE OF TECHNOLOGY COLLABORATION, DEPARTMENT OF PHYSICS AND ASTRONOMY, UNIVERSITY OF KENTUCKY COLLABORATION — Ca$_3$RuO$_4$ is a multiband strongly correlated electron system that undergoes a structural phase transition at $T_s$ 360K that is concomitant with an insulator-to-metal transition and a rearrangement of orbital occupancy. Understanding its structural and electronic response to ultrafast optical excitation can provide insight about the microscopic mechanism of this phase transition. We report temperature and fluence dependent time resolved optical reflectivity measurements from lightly doped Ca$_3$RuO$_4$ single crystals. Abrupt changes in both the electronic relaxation dynamics and multiple lattice vibrational modes are observed, including the softening of two optical phonon modes as $T_s$ is approached. We will discuss the relevance of our results to existing theories of the mechanism underlying the structural phase transition in Ca$_3$RuO$_4$ as well as the possibility of photo-inducing this phase transition on ultrafast time scales.

12:51PM B22.00009 THz investigation of non-Drude transport in the ferromagnetic metal SrRuO$_3$. GRACE BOSE, Y. LUBASHEVSKY, The Institute for Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University, D. E. SHAI, Department of Physics, Laboratory of Atomic and Solid State Physics, Cornell University, C. ADAMO, Department of Materials Science and Engineering, Cornell University, D. G. SCHLOM, K. M. SHEN, Kavli Institute at Cornell for Nanoscale Science, N. P. ARMITAGE, The Institute for Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University — While the highly correlated complex oxide perovskite ferromagnet SrRuO$_3$ has been studied for decades, interest remains in its unusual transport properties. In view of this, we present time-domain terahertz conductivity measurements taken from room temperature to 5K on a low disorder film of SrRuO$_3$. Previous optical measurements have shown a deviation from Fermi liquid transport predictions in this material. We investigate these deviations in the context of both an extended Drude model analysis and the previously used fractional power law form. The high quality of our film, reflected in its large residual resistivity ratio, allows us to better isolate the inelastic scattering channels, which were masked by disorder in earlier studies. We also comment on the possible ferromagnetic resonance present in our optical data.

Observation of a third, previously unknown charge-density-wave order in RTe$_3$ by optical spectroscopy

Antiferromagnetic fluctuations in the metallic state of organic superconductor κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Br observed by Raman scattering

Optical Conductivity in the Cuprates from Unparticle

Why a quantum wire can act as an optical amplifier

Applications of the explicitly correlated Gaussian approach to cold few-atom systems

With infinitely large interspecies s-wave scattering length consisting of up to ten particles. As a second example, we investigate the behavior of weakly-bound as aspects of ultracold gaseous and liquid few-atom systems using explicitly correlated Gaussians. In the ultracold regime, where the de Broglie wave length is setting are capable of yielding power law optical conductivities observed in the cuprates is examined critically. We first show that charge density in the Q-lattice conducor simply expanding a four-point correlation function using Wick's theorem is not sufficient to obtain the power law. We investigate the role played by non-Wick power law behavior. We apply unparticle-gauge couplings and linear response theory at finite temperature to calculate the optical conductivity. We find that scale-invariant matter with an algebraic propagator, is a candidate to explain this phenomenon. We explore the possibility of using unparticle to produce such processes in determining the power law.

We would like to thank NSF Contract No. DMR-1104909 for partially funding of this project. K. L. is supported by the Department of Physics at the University of Illinois and by the Ministry of Science and Technology, Royal Thai Government.

We present results of a recent study of the magnetic field induced second and third charge-density-wave (CDW) orders in the organic superconductor R$_x$Cu[N(CN)$_2$]Cl. The occurrence of the second CDW order with the wave vector $q_2$ has been observed in many R$_x$Cu[N(CN)$_2$]Cl compounds, while the third CDW order has only been observed in a few R$_x$Cu[N(CN)$_2$]Cl compounds. In this talk, we will discuss the observation of the third CDW order in the series by optical spectroscopy probe. This third CDW order also evolves systematically with the size of R element. With increased chemical pressure, the first and third CDW orders are both substantially suppressed and compete with the second one by depleting the low energy spectral weight. A complete phase diagram for the multiple CDW orders in this series is established. We acknowledge B. Cheng and R. H. Yuan for their help in the experiments.

Donald and Shirley Jones Graduate Research Fellowship

We discuss the fundamental issues associated with the magnetoplasmon excitations in a semiconducting quantum wire characterized by a harmonic confining potential and subjected to an applied (perpendicular) magnetic field. Essentially, we focus on the device aspects of the intersubband collective (magnetoroton) excitation, which observes a negative group velocity (NGV) between maxon and roton. Consequently, it leads to tachyon-like (superluminal) behavior without one's having to introduce the negative energies. Existence of the NGV is a clear manifestation of a medium with population inversion brought about due to a metastable state caused by the magnetic field that satisfies the condition $B > B_c$. $B_c$ being the threshold value below which the magnetoroton does not exist. The interest in NGV is based on anomalous dispersion in a medium with inverted population, so that gain instead of absorption occurs at the frequencies of interest. A medium with an inverted population has the remarkable ability of amplifying a small optical signal of definite wavelength, and serves as an optical amplifier. Examining the life-time of magnetorotons leads us to infer that relatively smaller magnetic fields are optimal.

Applications of the explicitly correlated Gaussian approach to cold few-atom systems

Supported by the NSF.
11:51 AM B23.00002 Very accurate variational non-relativistic non-Born-Oppenheimer atomic & molecular spectra predictions employing explicitly correlated Gaussian basis functions\(^1\), KEEPER SHARKEY, University of Arizona — Due to the fast increasing capabilities of modern computers it now becomes feasible to calculate spectra of small atom and molecules with accuracy which matches the accuracy of high-resolution measurements. The algorithms for the calculations are directly derived from the first principles of quantum mechanics. The Hamiltonian operator used in the approach is called the internal Hamiltonian and is obtained by rigorously separating out the center-of-mass motion from the laboratory-frame Hamiltonian. Algorithms for determining the isotopic energy shifts of L=0 and M=0 states of atoms were implemented and tested in the calculations of the ground \(^5S\) state of the nitrogen atom. Bound states of diatomic molecules corresponding to the total angular momentum quantum number equal to one (\(N=1\)) was derived and implemented and was tested in the calculations of the \(N=–1, v=0, \ldots, 22\) states of the HD\(^+\) ion and in the calculations of the ortho-para spin isomerization of the hydrogen molecule in its all bound vibrational states. This has lead to the development of a new studying of muonic molecules (\(dp, tp\) and \(td\)). The algorithms for calculating rovibrational states of small molecules is currently being extended to H\(_2^+\) using \(\sin\) and \(\cos\) ECGs.

\(^1\)National Science Foundation

12:03 PM B23.00003 Challenges and advances in calculations of highly non-adiabatic systems employing the explicitly correlated Gaussian functions, NIKITA KIRNOSOV, The University of Arizona — Accurate calculations of the highly non-adiabatic systems have been drawing attention for several decades. While most accurate modern methods allow outstanding accuracy, they are limited to only three or four particles. In the current work we have developed a highly accurate method which is not limited by the number of particles in the system but is only limited by the computer resource available. Examples of calculations of exotic systems with and without rotational excitation and of conventional electronic molecule are presented and the future development of the method is discussed.

12:15 PM B23.00004 High precision variational calculations of five-electron systems: S-states of boron, SERGIY BUBIN, Nazarbayev University, LUDWIK ADAMOWICZ, University of Arizona — We have performed benchmark variational calculations of the lowest two S-states of the boron atom. The spatial part of the wave function has been expanded in terms of all-particle explicitly correlated Gaussians, whose nonlinear variational parameters were extensively optimized. We have also computed leading relativistic corrections and various expectation values for both states. This work demonstrates that the level of accuracy achievable in calculations of five-electron atoms is now approaching the one previously seen only in three- or four-electron systems.

12:27 PM B23.00005 Calculation of energies of three-electron systems in a strong magnetic field using Explicitly Correlated Gaussian Basis, JORGE SALAS, KALMAN VARGA, Vanderbilt University — Strong magnetic fields can significantly alter the properties of atoms and allow the formation of stable negative ions such as He\(^–\). We have calculated the energies of systems comprised of three electrons in the presence of strong magnetic fields by using the Stochastic Variational Method with deformed Explicitly Correlated Gaussian basis. This approach yields accurate values for three-electron systems and predicts that the He\(^–\) ion in a strong magnetic field has stable states, within the non-relativistic framework, in the infinite nuclear mass approximation. The energy spectrum and the properties of three-electron systems as a function of the strength of the magnetic field show the effect of the rivalry between the Coulomb interaction and the magnetic confinement.

12:39 PM B23.00006 High-order Path Integral Monte Carlo methods for solving strongly correlated fermion problems, SIU A. CHIN, Texas A&M Univ — In solving for the ground state of a strongly correlated many-fermion system, the conventional second-order Path Integral Monte Carlo method is plagued with the sign problem. This is due to the large number of anti-symmetric free fermion propagators that are needed to extract the squared of the ground state wave function at large imaginary time. In this work, I show that optimized fourth-order Path Integral Monte Carlo methods, which uses no more than 5 free-fermion propagators, in conjunction with the use of the Hamiltonian energy estimator, can yield accurate ground state energies for quantum dots with up to 20 polarized electrons. The correlations are directly built-in and no explicit wave functions are needed.

12:51 PM B23.00007 Beyond the Born-Oppenheimer approximation with quantum Monte Carlo, NORM TUBMAN, University of Illinois - Urbana Champaign, ILKKA KYLANPAA, Tampere University of Technology, SHARON HAMMES-SCHIFFER, DAVID CEPERLEY, University of Illinois - Urbana Champaign — We develop tools that enable the study of non-adiabatic effects with variational and diffusion Monte Carlo methods. We introduce a highly accurate wave function ansatz for electron-ion systems that can involve a combination of both clamped ions and quantum nuclei. We explicitly calculate the ground state energies of H\(_2\), LiH, H\(_2\)O and FHF\(^–\) using fixed-node quantum Monte Carlo with wave function nodes that explicitly depend on the ion positions. The obtained energies implicitly include the effects arising from quantum nuclei and electron-nucleus coupling. We compare our results to the best theoretical and experimental results available and find excellent agreement.

1:03 PM B23.00008 Physical Sputtering vs. Gas Assisted Etching of Silicon Dioxide with a Gallium Focused Ion Beam: Elucidating Experiments via Monte Carlo Simulations, RAJENDRA TIMILSINA, University of Tennessee Knoxville, SHIDA TAN, RICHARD LIVENGROOT, Intel Corporation, PHILIP RACK, University of Tennessee Knoxville and CNMS, Oak Ridge National Laboratory — In order to increase ion beam nanomachining precision and improve imaging resolution, fine tuning of the ion beam profile is absolutely necessary. To understand the effects of ion beam tails, experiments and Monte Carlo simulations were conducted with a 40 keV gallium beam with and without gas assisted chemical etching. A gallium ion beam was scanned in an area of 25x25 nm\(^2\) on a silicon dioxide film with and without a localized XeF\(_2\) gas at 1pA current. Four different ion doses (0.23, 0.9, 1.8 and 3.6 nC/\(\mu\)m\(^2\)) were experimentally considered to study the sputtered and etched via profiles. Monte Carlo simulations using EnvisiON program was performed to elucidate the sputtered and gas-assisted etch process. New features including gas-assisted etching by secondary electrons and a binary collision model to dissociate the precursor molecules were introduced. Sputtered via and gas assisted etching (XeF\(_2\) precursor gas) via profiles with various gas-assist pressures were studied to understand the experimental temporal behavior. Various contributions including sputtering from primary, forward scattered, backscattered ions as well as etching by recoiled atoms and secondary electrons will be discussed.
unbiased way. First we consider a multiband model for graphene, where we integrate out the resulting effective interactions to the cRPA. The employed wick-ordered fRG scheme generalizes the cRPA approach by including all interaction channels in an interactions. Here we present applications of a constrained functional renormalization group (cfRG) scheme to two simple multi-band systems and compare the solids targeting the bands near the Fermi level, the constrained random phase approximation (cRPA) has become an appreciated tool to compute the effective, MICHAEL KINZA, CARSTEN HONERKAMP, RWTH Aachen University — In the derivation of low-energy effective models for

1:15PM B23.00009 Fully Exponentially Correlated Wave Functions for Few-Body Systems . FRANK E. HARRIS, University of Utah and University of Florida — Analytical methods now make practical the study of three- and four-body problems using wave functions in which all the interparticle distances (and not just their squares) occur as exponentials. This type of basis yields wave functions that exhibit superior initial convergence toward exact results and that facilitate the accurate treatment of systems in which no one of the particles is far more massive than the others. Progress in the practical use of this formulation is reviewed.

1:27PM B23.00010 Calculating Properties of Finite Mass Atoms . STEVEN ALEXANDER, Southwestern University, R.L. COLDWELL, Retired — Most atomic calculations assume that the mass of the nucleus is finite. If one is interested in evaluating atomic properties to high precision then this approximation cannot be made. We have developed a simple method that includes the kinetic energy of the nucleus into atomic calculations and does not increase the time or the complexity of these calculations. Our results for a variety of properties for several different atoms will illustrate some of the advantages of this method.

1:39PM B23.00011 ABSTRACT WITHDRAWN –

1:51PM B23.00012 Electron shake-off and recoil following 6He beta decay\(^1\) . GORDON W.F. DRAKE, EVA SCHULHOFF, University of Windsor — When the helium isotope \(^6\)He undergoes beta decay in the process \(^6\)He \rightarrow \(^6\)Li \(e^- + \nu\), the atomic electrons suddenly find themselves in a \(^6\)Li\(^+\) environment. The electrons subsequently redistribute themselves over all possible states of the \(^6\)Li\(^+\) ion, including the continuum leading to \(^6\)Li\(^{3+}\) and \(^6\)Li\(^{4+}\). There is currently considerable interest in studying the recoil ions in connection with experiments to look for evidence of new physics as revealed by angular correlations between the electron and the antineutrino \([1]\). We will present calculations employing Stieltjes imaging techniques in Hylleas coordinates to study the probabilities for the shake-up and shake-off mechanisms, and especially the additional recoil accompanying the emission of the shake-off electrons.

2:15PM B23.00014 Low-energy effective interactions beyond cRPA by the functional renormalization group , MICHAEL KINZA, CARSTEN HONERKAMP, RWTH Aachen University — In the derivation of low-energy effective models for solids targeting the bands near the Fermi level, the constrained random phase approximation (cRPA) has become an appreciated tool to compute the effective interactions. Here we present applications of a constrained functional renormalization group (cfRG) scheme to two simple multi-band systems and compare the resulting effective interactions to the cRPA. The employed wick-ordered fRG scheme generalizes the cRPA approach by including all interaction channels in an unbiased way. First we consider a multiband model for graphene, where we integrate out the \(\sigma\)-bands to get an effective theory for \(\sigma\)-bands. It turns out that terms beyond cRPA are strongly suppressed by \(xy\)-plane reflection-symmetry of the bands and that in our model, the cRPA stays qualitatively correct even if one breaks this symmetry slightly. The second example is a model for a Cu-O-chain, where we consider an effective theory for the Cu 3d-orbital. Here the RG data points to relevant corrections compared to the cRPA results.

11:15AM B24.00001 Electron localization in exact time-dependent density-functional potentials , MATTHEW HODGSON, JAMES RAMSDEN, University of York, Department of Physics, THOMAS DURRANT, JACOB CHAPMAN, University College London, Department of Physics and Astronomy, PIERS LILLYSTONE, University of Waterloo, Department of Physics and Astronomy, REX GODBY, University of York, Department of Physics — By propagation of the exact many-electron wavefunction, we determine exact Kohn-Sham (KS) potentials for 1D systems with strong correlation \([1]\). From this we have developed a density functional which incorporates several features, present in the exact KS potential, that are entirely missing from the usual approximations made in time-dependent density-functional theory (TDDFT) \([2]\). We find a strong and time-dependent self-interaction correction, owing to electron localization, as well as large static and dynamic spatial steps in the KS potential. Our new functional, suited to simulating ground-state and time-dependent electronic systems, combines an expression for the exact KS potential in the limit of complete electron localization with a measure of the actual localization. Self-consistent application of the functional provides accurate densities for a range of systems, even where the KS potential requires non-local dependence on the charge density, such as potential steps; the self-interaction correction is accurately described. We explore the relationship between features in the KS potential and the “derivativeness of discontinuity.”

11:27AM B24.00002 Constructing Multi-Slater-Jastrow Wavefunctions via Reduced Density Matrix Covariance . KIEL WILLIAMS, LUCAS WAGNER, Univ of Illinois - Urbana — The multi-determinant Slater-Jastrow ansatz wavefunction is a powerful tool for conducting ab initio electronic structure calculations in strongly correlated systems. We illustrate a new method of systematically constructing multi-determinant expansions by analyzing the covariance of elements of the two-body reduced density matrix (2RDM) with respect to the local energy distribution for a Slater-Jastrow wave function. By ordering the elements of the 2RDM with respect to their computed mean and associating each matrix element with a new determinant, we construct new multi-determinant expansions. We show that the energies of an H\(_2\) and stretched N\(_2\) molecule converge more rapidly with respect to the number of included determinants using this technique than in conventional configuration interaction calculations. This suggests that our analysis of the 2RDM captures qualitative differences between the single Slater determinant and the Slater-Jastrow wave function. This method provides a new way of diagnosing and correcting the deficiencies of certain trial wavefunction types in quantum Monte Carlo calculations. This work was supported by NSF DMR 12-06242.
11:39 AM B24.00003 Unitarily Invariant Self-Interaction Corrections to the Uniform Electron Gas, MARK PEDERSON, Department of Energy - US, JIANWEI SUN, Department of Physics, Temple University — A new formulation of the self-interaction correction (SIC) to density functional theory (DFT) based upon symmetrically orthogonalized “Fermi-Löwdin orbitals” (FLO) is reviewed [1]. This method leads to an energy that is explicitly unitarily invariant and size extensive and allows for implementation of SIC with the same efficient scaling offered by DFT. Initial applications to small molecules [1] provided orbitals that are similar to past results but yielded SIC-LDA cohesive energies that are competitive with GGA results. Investigations on a uniform electron gas (UEG) provide an additional challenging limit to consider. Results from FLO-based SIC calculations on the UEG, enclosed in a finite box, are presented. In accord with Ref. [2], the FLO-based formulation of SIC finds that localized Wannier orbitals lead to lower energies than plane waves in the exchange-only limit. We compare total energies of the uniform electron gas, calculated within DFT, FLO-SIC-DFT, and HF, as a function of functional (including MGGA[3]), electron number, volume, and Fermi-surface shape.

11:51 AM B24.00004 Using Dielectric Properties to Design Nonempirical Hybrid Functionals for Accurate Electronic Structure, JONATHAN SKONE, Institute for Molecular Engineering, The University of Chicago; Materials Science Division, Argonne National Laboratory, MARCO GOVONI, Institute for Molecular Engineering, The University of Chicago, GIULIA GALLI, Institute for Molecular Engineering, The University of Chicago — Building upon a recently proposed self-consistent hybrid (sc-hybrid) functional [1], where the optimal dielectric screening is included self-consistently, we propose an improved form by incorporating range-separation of the exchange part. We discuss the choice of the non-empirical parameters defining range separation, and we present results for condensed media including semiconductors, amorphous insulators, and molecular crystals. We find that the range-separated sc-hybrid functional further improves upon the electronic gaps obtained with full-range sc-hybrids, thus providing an accurate functional for high throughput band gap engineering.

12:03PM B24.00005 Range optimized theory of electron liquids with application to jellium, JAMES DONLEY, Valence Technologies, CRAIG PRYOR, University of Iowa — A simple optimization scheme is used to compute the density-density response function of the 3-D homogeneous electron gas at zero temperature. Higher order terms in the perturbation expansion beyond the random phase approximation are summed approximately by enforcing the constraint that the spin density radial distribution functions be positive. Quantitative comparison is made with previous theory and data from quantum Monte Carlo simulation. Agreement with the available simulation data is good for the entire paramagnetic region. Generalization of the theory to inhomogeneous electron liquids such as in semiconductors will be discussed.

12:15PM B24.00006 Inaccurate prediction of metal properties by hybrid functionals, WEIWEI GAO, TESFYAYE ABTEW, PEIHONG ZHANG, Department of Physics, University at Buffalo, SUNY, Buffalo, New York 14260 — Although computationally demanding, hybrid functionals have been widely used in electronic structure calculations and have demonstrated certain advantages in predicting the band gap of semiconductors and insulators. The applications of hybrid functionals to metals, however, results in several serious issues. In this talk, we will discuss the applicability and limitations of hybrid functionals when it comes to predicting several important properties of metals such as electron-photon coupling, lattice stability, and magnetism.

12:27PM B24.00007 Density matrix perturbation theory for magneto-optical response of periodic insulators, IRINA LEBEDEVA, ILYA TOTKATLY, ANGEL RUBIO, Nano-bio Spectroscopy Group and ETSF Scientific Development Centre, Universidad del Pais Vasco, Spain — Density matrix perturbation theory offers an ideal theoretical framework for the description of response of solids to arbitrary electromagnetic fields. In particular, it allows to consider perturbations introduced by uniform electric and magnetic fields under periodic boundary conditions, though the corresponding potentials break the translational invariance of the Hamiltonian. We have implemented the density matrix perturbation theory in the open-source Octopus code on the basis of the efficient Sternheimer approach. The procedures for responses of different order to electromagnetic fields, including electric polarizability, orbital magnetic susceptibility and magneto-optical response, have been developed and tested by comparison with the results for finite systems and for wavefunction-based perturbation theory, which is already available in the code. Additional analysis of the orbital magneto-optical response is performed on the basis of analytical models. Symmetry limitations to observation of the magneto-optical response are discussed.

12:39PM B24.00008 Theoretical and experimental electronic structure of quinacridone, SIVAN REFAELY-ABRAMSON, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovoth, Israel, DANIEL LUEFTNER, Institute of Physics, University of Graz, Graz, Austria, MICHAEL PACHLER, Institute of Physics, University of Graz, Graz, Austria; Institute of Solid State Physics, Graz University of Technology, Graz, Austria, ROLAND RESEL, Institute of Solid State Physics, Graz University of Technology, Graz, Austria, MICHAEL G. RAMSEY, Institute of Physics, University of Graz, Graz, Austria, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovoth, Israel, PETER PUSCHNIG, Institute of Physics, University of Graz, Graz, Austria — Although density functional theory is often used to study the frontier energy levels of organic electronic materials, standard functionals tend to predict too small fundamental gaps, may lead to wrong orbital energy ordering, and do not capture polarization-induced gap renormalization. We examine a strategy for overcoming these issues by studying the gas phase and bulk electronic structure of the organic molecule quinacridone, a promising material for organic devices. We employ the recently developed optimally tuned screened range-separated hybrid (OT-SRSH) functional [PRB 88, 081204(R) (2013)], where the electronic screening is taken into account, and compare with angle-resolved photoemission spectroscopy on multi-layers of quinacridone. Our method leads to the desired band gap renormalization and results in a valence band spectrum in excellent agreement with experimental data and with full-frequency G0W0 results based on a hybrid functional starting point. [PRB 90, 075204 (2014)]
**12:51PM B24.00009** Helmholtz Fermi surface harmonics: an efficient approach for treating anisotropic problems involving Fermi surface integrals, ASIER EIGUREN, IDOIA G. GURTUBAY, Condensed Matter Physics. University of the Basque Country & Donostia International Physics Center (DIPC). — We present a new efficient numerical approach for representing anisotropic physical quantities and/or matrix elements defined on the Fermi surface (FS) of metallic materials. The method introduces a set of numerically calculated generalized orthonormal functions, which are the solutions of the Helmholtz equation defined on the FS, where the periodicity of the reciprocal space is treated as a boundary condition. In essence, what we introduce is a generalization of the Spherical Harmonics for any periodic Fermi Surface and regardless of its topology. The main motivation of the approach is to handle an-isotropic many-body problems very efficiently. In this context we demonstrate how our theory reduces, by several orders of magnitude, the computational effort when applied to several well known many-body theoretical models such as the electron-phonon. Moreover, the method is demonstrated to be very robust in handling problems with any crystal structure or topology of the FS. We illustrate the method showing applications on several relevant surface and bulk systems.

**1:03PM B24.00010** Efficient mixing scheme for self-consistent all-electron charge density, TATSUYA SHISHIDOU, Hiroshima University, MICHAEL WEINERT, University of Wisconsin, Milwaukee — In standard ab initio density-functional theory calculations, the charge density $\rho$ is gradually updated using the “input” and “output” densities of the current and previous iteration steps. To accelerate the convergence, Pulay mixing has been widely used with great success. It expresses an “optimal” input density $\rho^{\text{opt}}$ and its “residual” $R^{\text{res}}$ by a linear combination of the densities of the iteration sequences. In large-scale metallic systems, however, the long range nature of Coulomb interaction often causes the “charge sloshing” phenomenon and significantly impacts the convergence. Two treatments, represented in reciprocal space, are known to suppress the sloshing: (i) the inverse Kerker metric for Pulay optimization and (ii) Kerker-type preconditioning in mixing $R^{\text{res}}$. In all-electron methods, where the charge density does not have a converging Fourier representation, treatments equivalent or similar to (i) and (ii) have not been described so far. In this work, we show that, by going through the calculation of Hartree potential, one can accomplish the procedures (i) and (ii) without entering the reciprocal space. Test calculations are done with a FLAPW method.

**1:15PM B24.00011** Quest for a workhorse MGGA functional, BERNARD DELLEY, Paul Scherrer Institut — A semi-empirical, numerically robust, parametrization of the exchange functional has been obtained by optimization of bond energies in a database of 500 species. The variables, density, gradient and kinetic energy density, can differentiate efficiently among the wide variety of bonds in the database. The resulting MGGA rivals the thermochmistry accuracy of composite quantum chemistry approaches when applied to a wider data set. But, not only, it also provides noticeable improvements over GGA’s for solid state properties, including properties not obviously related to bonding energies. As an MGGA is not significantly more demanding computationally than a GGA, this MGGA may become the workhorse density functional for a wide range of applications.

**1:27PM B24.00012** First-Principles Investigation of Electronic Excitation Dynamics in Water under Proton Irradiation, KYLE REEVES, YOSUKE KANAI, Univ of NC - Chapel Hill — A predictive and quantitative understanding of electronic excitation dynamics in water under proton irradiation is of great importance in many technological areas ranging from utilizing proton beam therapy to preventing nuclear reactor damages. Despite its importance, an atomistic description of the excitation mechanism has yet to be fully understood. Identifying how a high-energy proton dissipates its kinetic energy into the electronic excitation is crucial for predicting atomistic damages, later resulting in the formation of different chemical species. In this work, we use our new, large-scale first-principles Ehrenfest dynamics method [1,2] based on real-time time-dependent density functional theory to simulate the electronic response of bulk water to a fast-moving proton. In particular, we will discuss the topological nature of the electronic excitation as a function of the proton velocity. We will employ maximally-localized functions to bridge our quantitative findings from first-principles simulations to a conceptual understanding in the field of water radiolysis. [1] “Plane-wave Pseudopotential Implementation of Explicit Integrators for Time-Dependent Kohn-Sham Equations in Large Scale Simulations” A. Schleife, E. W. Draeger, Y. Kanai, A. A. Correa, J. Chem. Phys., 137, 22A546 (2012) [2] “Quantum Dynamics Simulation of Electrons in Materials on High-Performance Computers” A. Schleife, E. W. Draeger, V. Anisimov, A. A. Correa, Y. Kanai, Computing in Science and Engineering, 16 (5), 54 (2014).

**1:39PM B24.00013** Strongly Constrained and Appropriately Normed (SCAN) Meta-Generalized Gradient Approximation for Exchange and Correlation1, JIANWEI SUN, ADRIENN RUZSINSZKY, JOHN PERDEW, Department of Physics, Temple University — Meta-generalized gradient approximations (meta-GGAs) construct the exchange-correlation (xc) energy density from the local electron density, its gradient, and the orbital kinetic energy density. They are the most accurate of the computationally-efficient semilocal density functionals. We construct a SCAN meta-GGA which satisfies all the known exact constraints that a meta-GGA can, including a new tight lower bound on the exchange energy [1]. SCAN is constructed as an interpolation/extrapolation on $\alpha$, the dimensionless variable that can recognize covalent single ($\alpha \approx 0$), metallic ($\alpha \approx 1$), and weak ($\alpha >> 1$) bonds [2]. A few parameters are included for appropriate norming on systems where a meta-GGA should be especially accurate due to xc hole localization.

**1:51PM B24.00014** A Generalized Slave-Particle Method1, ALEXANDRU BOGDAN GEORGESCU, Department of Physics and Center for Research on Interface Structures and Phenomena, Yale University, SOHRAB ISMAIL-BEIJI, Department of Physics, Department of Applied Physics and Center for Research on Interface Structures and Phenomena, Yale University — Two slave-particle methods, namely the slave-rotor and the slave-spin approaches, have been of recent interest in the computational correlated electron community. Both methods solve Hubbard-type models and go beyond the single-particle approximations by describing aspects of correlated electron behavior in a computationally efficient manner. We present a generalized slave-particle formalism that connects the the two while reproducing the results of each method in the appropriate limit. The framework automatically corrects the problematic small U behavior of the slave-rotor approach while reproducing its behavior in situations where it has been found physically relevant (e.g., for nickelate heterostructures).

**2:03PM B24.00015** Selectively localized Wannier functions, RUNZHI WANG, Columbia University, EMANUEL LAZAR, University of Pennsylvania, HYOWON PARK, University of Illinois at Chicago, ANDREW MILLIS, CHRIS MARIANETTI, Columbia University — Since the seminal work of Marzari and Vanderbilt, maximally localized Wannier functions have become widely used as real-space representations of electronic structure in periodic systems. In this talk we discuss selectively localized Wannier functions (SLWF) which allow localization of a particular subset of orbitals of interest, and also enable the fixing of orbital centers and ensuring the preservation of point-group symmetries. Applications of our method to GaAs, SmMnO$_3$, and Co demonstrate that SLWF can offer improvements over standard techniques, especially in beyond DFT methods.
11:15AM B26.00001 Multistate trajectory and statistical theories of spin-forbidden kinetics. AHREN JASPER, Sandia National Laboratory — Rate coefficients for several spin-forbidden reactions relevant to combustion are calculated using multistate trajectory and statistical theories. The two approaches are compared, and the appropriateness of treating singlet/triplet crossing seams as “nonadiabatic transition state” for spin-forbidden reactions is discussed. We show that the spin-forbidden reaction coordinate is coupled to the remaining nuclear degrees of freedom, leading to multidimensional effects not typically included in statistical treatments. We identify: static multidimensional effects due to the geometry-dependence of the shape of the crossing seam and spin-orbit coupling, dynamical multidimensional effects where the electronic transition probability depends on the distribution of the total internal energy of the system, and nonlocal multidimensional effects due to the instantaneous value of the electronic phase at multiple seam crossings. A semiclassical model based on short-time full-dimensional trajectories that includes all three multidimensional effects as well as a model for electronic decoherence is presented. The results of this new multidimensional nonadiabatic statistical theory are compared with the results of one-dimensional Landau-Zener and weak coupling models for several reactions.

11:51AM B26.00002 Evidence for quantum effects in laser driven photodissociation of methyamines. ILANA BAR, MICHAEL EPSHTEIN, ALEXANDER PORTNOV, Ben-Gurion University of the Negev — Non-adiabatic dynamics at conical intersections (CI) extensively affects the photostability of biomolecules by efficiently photoinducing decay routes that dissipate harmful excess ultraviolet energy. Here the photodissociation of the model test molecules, methylamine (CH₃NH₂) and its partially deuterated isotopeologue (CD₃ND₂), excited to different specific vibrational modes in the electronically excited state has been investigated by H(D) photofragments detection with two-color reduced-Doppler ion imaging [1]. The H products, resulting from N-H bond cleavage via two dissociation pathways, showed anomalous distributions for some of the vibronic states, as indicated by dynamic resonances in the product branching ratio and in the anisotropy parameters. This vibronic-specific control is attributed to distinctive dynamical interferences of the initially prepared wavepackets, affecting the passage efficiency through the S₁/S₀ CIs. It is suggested that the H product distributions are extremely sensitive to the positions and energies of the CIs in the two molecules, rather than to the unique initial nuclear motion that promotes the coupling between the two electronic states. These observations reveal uniquely detailed insights into the dynamics of state-specific control of internal conversion.

12:03PM B26.00003 ABSTRACT MOVED TO Q48.00005 —

12:15PM B26.00004 Real-Time Subsystem TD-DFT and its Ehrenfest Dynamics: Applications to solvation and exciton transfer. MICHELE PAVANELLO, Rutgers Univ - Newark — The subsystem formulation of DFT known as Frozen Density Embedding (FDE) provides a divide-and-conquer approach to Kohn-Sham DFT for a collection of weakly bound subsystems. We present theory and computer code development of the time-dependent extension of FDE. The code is now part of the Quantum–ESPRESSO suite of softwares. We also present the associated Ehrenfest dynamics, in which nuclei and electrons of selected subsystems are propagated simultaneously. Application of the code to exciton transfer phenomena as well as to solvatochromic shifts are discussed.

12:27PM B26.00005 Ultrafast dynamics in DNA base pairs following ultraviolet excitation. ANDREW ORR-EWING, University of Bristol — Photo-protective mechanisms in DNA are essential to maintain the integrity of the genetic code by preventing damage from absorption of solar ultraviolet (UV) radiation. We have used time-resolved infra-red (TRIR) spectroscopy to observe the dynamics of Watson-Crick nucleobase pairs following absorption of femtosecond UV laser pulses. The base pairs are prepared as nucleosides in solution, and photo-induced dynamics are probed in the carbonyl and N-H bond stretching regions using broadband IR pulses with picosecond time resolution. Results will be presented for the guanine- and cytosine (G-C) base pair, contrasting the rapid recovery of ground-state products (the photo-protection pathway) with formation of other photoproducts which are probed in the carbonyl and N-H bond stretching regions using broadband IR pulses with picosecond time resolution. Results will be presented for the guanine- and cytosine (G-C) base pair, contrasting the rapid recovery of ground-state products (the photo-protection pathway) with formation of other photoproducts which might represent photo-damage mechanisms. This work is a collaboration with the group of Prof F. Temps (Christian-Albrechts-Universität zu Kiel).

1:03PM B26.00006 Femtosecond Heterodyne Transient Grating Studies of Nonradiative Decay in β-Carotene and Peridinin: Contributions of Dark Intermediates and Double Quantum Coherences. SOUMEN GHOSH, JEROME ROSCIOLI, Michigan State Univ, HARRY FRANK, University of Connecticut, WARREN BECK, Michigan State Univ — Femtosecond transient grating spectroscopy with optical heterodyne detection was employed to characterize the ultrafast events in the nonradiative decay of β-carotene and peridinin in solution from the S₂ state. The contribution of double-quantum coherences to the time evolution of the third order signal was probed by scanning the interpulse delay between the first two pulses in the transient grating or stimulated photon-echo sequence. The results show that the double-quantum coherence pathways contribute significantly to the transient grating signal only at negative population delays, which is consistent with the requirements determined from double-sided Feynman diagrams when the third order signal is detected in the −k₁ + k₂ + k₃ direction. Response function calculations support the conclusion that the ultrafast (<20 fs) decay that contributes to the third order signal at positive population delays arises from an intermediate, which has been previously assigned to the S₄ state. We suggest that this intermediate arises not from a discrete electronic state but rather from a twisted conformation of the conjugated polyene. This proposal has significant implications with respect to the energy transfer function of carotenoids in photosynthesis.

1:15PM B26.00007 Vibrational Conical Intersections: Implications for Ultrafast Vibrational Dynamics. MAHESH DAWADI, BISHNU PRASAD THAPALIYA, Department of Chemistry, The University of Akron, RAM BHATTA, Department of Polymer Science, The University of Akron, DAVID PERRY, Department of Chemistry, The University of Akron — The presence of conical intersections (CIs) between electronic potential energy surfaces is known to play a key role in ultrafast electronic relaxation in diverse circumstances. Recent reports have documented the existence of vibrational CIs connecting vibrationally adiabatic surfaces. Just as electronic CIs are now appreciated to be ubiquitous, controlling the rates of many photochemical processes, the present work on methanol and methyl mercaptan suggests that vibrational CIs may also be widespread, possibly controlling the outcome of some high-energy processes where vibrationally excited species are present. Other examples of vibrational CIs include the vibrationally Jahn-Teller effect in C₂O₂ organic molecules and transition metal complexes. While the present work addresses only the couplings within bound molecules, the concept of vibrational CIs providing pathways for ultrafast relaxation also applies to molecular collisions.

11:15AM B27.00001 Tracking the charge and spin dynamics of electronic excited states in inorganic complexes\(^1\), KELLY GAFFNEY, Stanford Synchrotron Radiation Lightsource and PULSE Institute at SLAC National Accelerator Laboratory and Stanford University — Inorganic complexes have many advantageous properties for solar energy applications, including strong visible absorption and photocatalytic activity. Whether used as a photocatalyst or a photosensitizer, the lifetime of electronic excited states is a key property for solar energy applications. This work demonstrates the usefulness of many coordination compounds. Isoelectronic iron and ruthenium based complexes represent a clear example. Ru-porphyril based molecules have been the workhorse of solar energy related research and dye sensitized solar cells for decades, but the replacement of low abundance Ru with Fe leads to million-fold reductions in metal to ligand charge transfer (MLCT) excited state lifetimes. Understanding the origin of this million-fold reduction in lifetime and how to control excited state relaxation in 3d-metal complexes motivates the work I will discuss. We have used the spin sensitivity of hard x-ray fluorescence spectroscopy and the intense femtosecond duration pulses generated by the LCLS x-ray laser to probe the spin dynamics in a series of electronically excited \([\text{Fe} (\text{CN})_6]^{-2N} [2,2’-\text{bipyridine}]_N^{2N-4}\) complexes, with \(N = 1-3\). These femtosecond resolution measurements demonstrate that modification of the solvent and ligand environment can lengthen the MLCT excited state lifetime by more than two orders of magnitude. They also verify the role of triplet ligand field excited states in the spin crossover dynamics from singlet to quintet spin configurations.\(^1\)

11:51AM B27.00002 Time-resolved X-Ray Absorption Spectroscopy of a Cobalt-Based Hydrogen Evolution System for Artificial Photosynthesis, DOOSHAYE MOonsoHiram, Argonne National Laboratory, CAROLINA GIMBERT, Institut Català d’Investigació Química, CARL LEHMANN, STEPHEN SOUTHWORTH, Argonne National Laboratory, ANTONI LLORET, Institut Català d’Investigació Química, ARGONNE NATIONAL LABORATORY TEAM, INSTITUT CATALÁ D’INVESTIGACIÓ QUÍMICA COLLABORATION — Production of cost-effective hydrogen gas through solar power is an important challenge of the Department of Energy among other global industry initiatives. In natural photosynthesis, the oxygen evolving complex (OEC) can carry out four-electron water splitting with an efficiency of around 60\%. Although much progress has been carried out in determining mechanistic pathways of the OEC, biophysical approaches have not duplicated Nature’s efficiency in function. Over the past years, we have witnessed progress in developments of light harvesting modules, such as chromatophore/catalytic assemblies. In spite of reportedly high catalytic activity of these systems, quantum yields of hydrogen production are below 40\% when using monochromatic light. Proper understanding of kinetics and bond making/breaking steps has to be achieved to improve efficiency of hydrogen evolution systems. This project shows the timing implementation of ultrafast x-ray absorption spectroscopy to visualize in “real time” the photo-induced kinetics accompanying a sequence of redox reactions in a cobalt-based molecular photocatalytic system. Formation of a Co(I) species followed by a Co(III) hydride species all the way towards hydrogen evolution is shown through time-resolved XANES.

12:03PM B27.00003 Spatiotemporal Imaging of Chemical Reactions: Making Molecular Movies with Femtosecond X-Ray Scattering, J.M. BUDARZ, Brown Univ., SLAC National Accelerator Laboratory, M.P. MINITTI, SLAC National Accelerator Laboratory, A. KIRRANDER, Univ. of Edinburgh, J.B. HASTINGS, SLAC National Accelerator Laboratory, P.M. WEBER, Brown Univ. — The study of ultrafast reaction dynamics of molecular systems has benefited from the rapid development of spectroscopic and imaging techniques that follow their temporal evolution on a sub-picosecond time scale. More complete understanding of molecular behavior, however, is expected to arise from a full observation of electronic and nuclear motions during reactions. Our recent experiments at the Linc Coherent Light Source (LCLS) have allowed us to develop and implement a method wherein the ultrafast reaction dynamics of molecules in dilute gases (4 Torr) are captured by time-resolved x-ray scattering. Using a pump-probe scheme with 267 nm excitation laser and 8.3 keV x-ray probe pulses, we performed a series of measurements on the interatomic positions at variable delay relative to a 'molecular movie.' In our experiment, 1,3-cyclohexadiene (CHD) is excited on an excited state surface, causing the molecule to accelerate down several potential energy surfaces coupled by conical intersections, to open into 1,3,5-hexatriene within 80 fs. The resulting 'movie' has been supplemented with molecular trajectory calculations to separate the multiple pathways the excited molecule takes toward the open ring. In this talk, the experimental methods and designs that made these experiments possible will be presented together with the first results describing the photochemical reaction dynamics of CHD.

12:15PM B27.00004 The orbital-based view on reaction dynamics: ligand exchange of \(\text{Fe}(\text{CO})_5\) in solution, ALEXANDER FÖHLSICH, Helmholtz-Zentrum Berlin für Materialien und Energie, Potsdam University — Time resolved soft x-ray spectroscopy has proven recently, that it can be applied to the complex dynamics occurring in materials and chemical processes by its high selectivity towards elemental, chemical, and magnetic properties. Changes in chemical bonding, in particular bond breaking and bond formation seem conceptually simple, but as a result of coherent wave packet motion it is difficult to access the dynamic pathways in a multidimensional potential energy landscape. In this contribution we exploit the unique approach of femtosecond time resolved resonant inelastic x-ray scattering at LCLS to derive information about excited state configurations and electronic excited states. As an outlook, it will be discussed, how non-linear X-ray processes can push time resolved soft X-ray spectroscopy to a new phase. In particular, stimulated Raman scattering and amplified spontaneous emission can overcome the weak scattering cross-sections of spontaneous processes, help to suppress sample damage and increase spectral resolution and excited state selectivity through the exploitation of Anti-Stokes Raman Scattering.

12:51PM B27.00005 Tracking picosecond molecular dynamics in solution using a suite of synchrotron-x-ray spectroscopic tools\(^1\), ANNE MARIE MARCH, GILLES DOUMY, ELLIOT P. KANTER, STEFAN LEHMANN, DOOSHAYE MOonsoHiram, STEPHEN H. SOUTHWORTH, LINDA YOUNG, Argonne National Lab, TADESSE A. ASSEFA, CHRISTIAN BRESSLER, WOJCIECH GWALEDA, European XFEL, ZOLTÁN NEMETH, GYÖRGY VANKÓ, Hungarian Academy of Sciences — Laser-pump, X-ray-probe techniques are powerful tools for exploring molecular structures and electronic states in complex environments such as solutions, during a photo-initiated reaction. We are developing such methods using hard x-rays from the Advanced Photon Source, combining x-ray emission spectroscopy and x-ray absorption spectroscopy as probes of electronic and geometric structure and using high-power, MHz lasers as pumps. The high-duty-cycle pump-probe measurements efficiently utilize the synchrotron-x-ray source and enable high-fidelity measurement of intermediates. We present measurements of two model systems, \([\text{Fe}(\text{II})(\text{CN})_6]^{4-}\) (ferrocyanide) in an aqueous solution after excitation with 355 nm and 266 nm laser light. The system undergoes two wavelength dependent reactions: photooxidation and photoaquation. Iron K-edge absorption spectra were obtained along with iron emission spectra. Our data support the presence of a previously unobserved pentacoordinated intermediate species in the photoaquation reaction. Its lifetime has been measured to be 4.6 ns and details of its structure will be discussed.\(^1\)

1:03PM B27.00006 Ultrafast Coherent Photoelectron Spectroscopy of Electronic States on a Cu (111) Surface, ADRA CARR, CONG CHEN, ZHENSHENG TAO, MARGARET MURNANE, HENRY KAPTEYN, PIOTR MATYBA, JILA/NIST, SEBASTIAN EMMERICH, MARTIN AESCHLIMANN, University of Kaiserslautern, Germany, ULRICH HOFEPER, University of Marburg, Germany — We use laser-assisted high-harmonic time- and angle-resolved photoemission to directly observe coherent photoemission from a Cu(111) metal surface and the interferences between the emitted photoelectron wavepackets. A comb of high harmonics in combination with interferometrically timed infrared pulses enable a powerful combination of attosecond time resolution and high energy resolution, making it possible to extract phase information about the emitted photoelectron wavepackets and the distinct electronic states from which they emerge. By comparing photoemission from the well-known Shockley surface state to the sp and d bulk bands of Cu(111), we can observe non-negligible phase shifts in the emitted wavepackets, which cannot be attributed to time delays resulting from classical electron transport to the surface. Rather, we interpret these phase shifts as due to an intrinsic photoemission phase that is different for the sp and d band wavefunctions, thus providing a physical interpretation of temporal delays observed in photoemission from surfaces.

1:15PM B27.00007 Circularly polarized attosecond pulses for molecular atto-magnetism, ANDRE D. BANDRAUK1, University of Sherbrooke — Circularly polarized molecular high order harmonic generation, MHOHG, is modelled from numerical solutions of the time-dependent Schrödinger equation, TDSE, for the one-electron H2+ in the nonlinear nonperturbative regime of laser-molecule interaction. It is shown that molecules due to their nonspherical symmetry are the preferred medium for producing circularly polarized harmonics by few cycle intense IR (800,400nm) circularly polarized laser pulses. An intense Terahertz (4um) pulse is combined to force recollision of the ionized electron with the parent ion thus enhancing the efficiency of the circularly polarized MHOHG process through single recollision [1]. Superposition of these harmonics allows for the synthesis of single circularly polarized attosecond (10-18s) pulses. Such new ultrashort pulses allow for controlling electrons on their natural time scale [2]. In particular the TDSE simulations illustrate the generation with such new pulses coherent quantum electronic currents inside molecules for the creation of attosecond magnetic field pulses of intensity >10 Teslas [3].

1:27PM B27.00008 Coherent Chemistry with THz Pulses: TDDFT-Ehrenfest Simulations of Field-Induced LiNC Isomerization1, LENSON PELLOUCHOUD, EVAN REED, Stanford Univ — The ability to coherently rearrange molecular structures is among the grand challenges of physical chemistry. Some of the primary obstacles are non-adiabatic increases in energy, such as intramolecular vibrational relaxation (IVR) and electronic excitations. Motivated by recent advances in the generation and control of strong terahertz (THz) pulses, we have investigated their potential to circumvent these obstacles. THz pulses are promising because their spectral content is well separated from electronic excitation frequencies, yet they may be fast enough to add and remove energy from the electronic system without allowing IVR to take place. In this work, we utilize simulations to discover that LiNC can be isomerized to two distinct metastable conformations with very low residual heating and ionization rates, pointing out a new route towards THz coherent control of chemical bonds and materials. We use time-dependent DFT (TDDFT)-based Ehrenfest molecular dynamics simulations to test a variety of strong time-varying THz pulses applied to the molecule. We find the limits of how quickly an activation barrier can be surmounted before the driving pulse becomes strong enough to ionize the molecule, and how well the target must be aligned in order for the final configuration to be stable.

1:39PM B27.00009 Ultrafast high harmonics for probing the fastest spin and charge dynamics in magnetic materials, PATRICK GRYCHTOL, JILA, University of Colorado, Boulder, CO 80309, USA — Ultrafast light based on the high-harmonic up-conversion of femtosecond laser pulses have been successfully employed to access resonantly enhanced magnetic contrast at the μ-absorption edges of the 3d ferromagnets Fe, Co and Ni in a table-top setup. Thus, it has been possible to study element-specific dynamics in magnetic materials at femtosecond time scales in a laboratory environment, providing a wealth of opportunities for a greater fundamental understanding of correlated phenomena in solid-state matter. However, these investigations have so far been limited to linear polarized harmonics, since most techniques by which circular soft x-rays can be generated are highly inefficient reducing the photon flux to a level unfit for scientific applications. Besides presenting key findings of our ultrafast studies on charge and matter, we interpret these phase shifts as due to an intrinsic photoemission phase that is different for the sp and d bands, thus providing a physical interpretation of temporal delays observed in photoemission from surfaces.

11:15AM B28.00001 Investigation on spin-orbit torque induced perpendicular switching through voltage controlled magnetism1, CHONG BI, MENG XU, MARCUS ROSALES, TY NEWHOUSE-ILLIGE, HAMID ALMASI, WEIGANG WANG, Department of Physics, University of Arizona, Tucson, Arizona 85721, USA — Spin-orbit torques are shown to induce perpendicular magnetic switching in ultrathin ferromagnets (FM)s adjacent to heavy metals (HMs). Here, we demonstrated that the critical current density (Jc) for such perpendicular switching in HM/FM/oxide structures can be dramatically modulated by gate voltage induced reversible oxidation at FM/oxide interfaces [1]. Through controlling perpendicular anisotropy and saturation magnetization (M_s) of FM layer, respectively, we show M_s, rather than anisotropy field as suggested in macrospin model [2], dominates Jc. Moreover, the measured external field dependent Jc results indicate that the spin-orbit torques have either a bulk or interface origin under different magnetization states. These results not only provide a promising means toward energy-efficient switching, but also offer further insights in understanding the reversal mechanism of the ferromagnetic layer. This work was supported in part by NSF (ECCS-1310338) and by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA.[1] C. Bi et al, submitted, [2] L. Liu et al. Phys. Rev. Lett. 109, 096602 (2012).

11:27AM B28.00002 Magnon-phonon interactions and spin transport in insulators1. STEPHEN R. BOONA, HYUNGYU JIN, Department of Mechanical and Aerospace Engineering, The Ohio State University, Columbus, OH, JOSEPH P. HEREMANS, Department of Mechanical and Aerospace Engineering, Department of Physics, The Ohio State University, Columbus, OH — The spin Seebeck effect (SSE) is now a well-established phenomenon whereby a spin current can be thermally pumped from a ferromagnetic (FM) material into a normal metal (NM), where the spin current is then converted into a transverse charge current through the inverse spin Hall effect. The most interesting feature of SSE is that it occurs even if the FM is an insulator, e.g., yttrium iron garnet (YIG). Although the existence of the effect is well established, its microscopic origins are still not completely understood; the detailed nature of interactions between the elementary excitations (electrons, phonons, and magnons) that give rise to SSE are complex and strongly dependent on factors like materials selection and temperature. One particularly important issue that remains unclear is the role that magnon-phonon interactions play in generating spin currents, especially within the context of diffusive vs drag currents. This talk will address this question by discussing some of our recent experiments aimed at exploring the temperature and length dependence of thermal and spin transport phenomena in magnetoically ordered insulators.

11:39AM B28.00003 Temperature-dependent spin Hall magnetoresistance in ferromagnetic insulator/normal metal hybrids1, MATTHIAS ALTHAMMER, SIBYLLE MEYER, STEFAN GEPRÄGS, MATTHIAS OPEL, RUDOLF GROSS, SEBASTIAN T.B. GOENNENWEIN, Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, Walther-Meissner-Strasse 8, 85748 Garching, Germany — Pure spin currents, i.e. the net flow of spin angular momentum without an accompanying charge current, represent a new paradigm for spin transport and spintronics. We have experimentally studied a new type of magnetoresistance effect, which arises from the interaction of charge and spin current flows in ferromagnetic insulator/normal metal hybrid structures. The resistance changes observed can be quantitatively traced back to the combined action of spin Hall and inverse spin Hall effect in the normal metal layer, and are thus termed spin Hall magnetoresistance (SMR) [1,2]. In more detail, we studied the temperature dependence of the SMR in yttrium iron garnet / platinum hybrid structures via magnetization orientation dependent magnetoresistance measurements. Our experiments show that the SMR amplitude decreases with decreasing temperature, which can be quantitatively modeled in terms of a spin Hall angle in platinum decreasing from 0.11 at 300K to 0.075 at 10K [3], while the spin diffusion length and the spin mixing conductance of the ferrimagnetic insulator / normal metal interface remain almost constant.

11:51AM B28.00004 Spin Seebeck effect in YIG-based systems, GENE SIEGEL, MEGAN PRESTGARD, SHIANG TENG, ASHUTOSH TIWARI, University of Utah, Department of Materials Science & Engineering — Recently, the use of magnetic insulators (yttrium iron garnet, YIG) in conjunction with platinum has sparked interest in spintronics research. This is due to the existence of the spin Seebeck effect which could potentially be a source of pure spin current for spintronic devices. Furthermore, these coatings could potentially show the versatility of spintronics by acting as a spin-based thermoelectric generator, thereby providing a new method of transforming heat into power. However, there remain questions regarding the origins and legitimacy of the spin Seebeck effect. Moreover, recent publications claim that the observed effects are a manifestation of magnetic proximity effects in platinum and not a true SSE signal. Because of these concerns, we are providing supporting evidence that the voltages observed in the YIG/Pt films are truly SSE voltages. We are reaffirming claims that magnon transport theory provides an accurate basis for explaining SSE behavior. Finally, we illustrate the advantages of pulsed laser deposition, as these YIG films possess a large SSE voltage compared to those films grown using liquid phase deposition techniques.

12:03PM B28.00005 Subthermal-magnon-driven longitudinal spin Seebeck effect in yttrium iron garnets (YIG)1, STEPHEN BOONA, Department of Mechanical and Aerospace Engineering, The Ohio State University, Columbus, OH, ZHIAO YANG, ROBERTO MYERS, Department of Materials Science and Engineering, The Ohio State University, Columbus, OH. — Since its discovery in 2008, the spin Seebeck effect (SSE) has intrigued many interesting research all around the world, which has led to the birth of a new field of research, called “spin caloritronics”. Of the two different experimental configurations used for detecting SSE, the longitudinal geometry (LSSE) seems to be generally accepted [1]. The yttrium iron garnet (YIG) / Pt bilayer structure has been most commonly used for LSSE experiments because absence of electrons in YIG excludes contaminations from other thermomagnetic effects. The dependence of the LSSE on YIG film thickness [2] and on temperature [3] have been reported, but not yet both together. Here we present experimental data on the temperature dependence of LSSE in Pt/YIG below room temperature in systems in which the thickness of YIG varies. Detailed discussion is given on the experimental results, with emphasis on the role of subthermal-magnons in the temperature dependence of LSSE in the YIG/Pt system.

12:15PM B28.00006 Spin Seebeck Effect in a Compensated Ferrimagnet, SEBASTIAN T.B. GOENNENWEIN, S. GEPRÄGS, Walther-Meissner-Institut, Garching, Germany, A. KEHLBERGER, T. SCHULZ, C. MIX, University of Mainz, Mainz, Germany, F. DELLA COLETTA, S. MEYER, Walther-Meissner-Institut, Garching, Germany, A. KAMRA, Kavli Institute of Nanoscience, Delft, The Netherlands, G. JAKOB, University of Mainz, Mainz, Germany, M. ALTHAMMER, H. HUEBL, R. GROSS, Walther-Meissner-Institut, Garching, Germany, M. KLÄUI, University of Mainz, Mainz, Germany — Thermal gradients allow for driving pure spin currents in electrically insulating magnetic materials. In magnetic insulator/normal metal heterostructures, such thermally driven spin currents can be electrically detected via the inverse spin Hall effect in the normal metal, in so-called spin Seebeck effect (SSE) experiments. We have fabricated Gadolinium Iron Garnet/Platinum (GdIG/Pt) thin film heterostructures, and measured the spin Seebeck effect in these samples as a function of temperature. We observe two sign changes as a function of T in the SSE signal. The first sign change occurs around the GdIG magnetic compensation temperature, and can be straightforwardly understood in terms of the reorientation of the iron sublattice magnetizations at this temperature. The second, more gradual SSE sign change takes place around the ordering temperature of the Gd magnetic sublattice, suggesting that the thermally driven spin current is mainly determined by the Gd sublattice at low T. Our results thus show that the SSE spin currents do not simply replicate the effective magnetization of the magnetic insulator, but rather reflect a complex interplay of magnetic sublattice properties.
12:27PM B28.00007 Transverse Spin Seebeck Effect on YIG/Pt

HYUNGYU JIN, JOSEPH HEREMANS, The Ohio State University — The existence of the longitudinal spin-Seebeck effect (LSSE) is well established and supported by theory. Much more controversial is the nature of the signals observed in the transverse spin-Seebeck (TSSE) geometry, where the heat current (x) is orthogonal to the direction of spin current propagation (y). TSSE has been described as simply non-local thermal spin-injection [1], but questions remain about the fact that the effect is observed at macroscopic length scales. To explore possible explanations for the observed TSSE signals, we report data from new TSSE measurements on the YIG/Pt system. The system studied has multiple Pt strips deposited in series upon bulk single crystals of YIG. We investigate the TSSE coefficient as a function of four variables: (1) sample temperature; (2) magnitude of the temperature gradient; (3) position of Pt strips along x; and (4) width of Pt strips along x. We consider nonlinear effects and the role of magnon density in the interpretation of our results. [1] Boona et al., Energy and Environ. Sci. 7 885 (2014)

12:39PM B28.00008 DC Rectification of Microwaves in YIG/Pt/Pt Trilayers 1, JOSEPH SKLENAR, JOHN KETTERSON, Northwestern University, MATTHIAS JUNGFLEISCH, WANJUN JIANG, WEI ZHANG, JOHN PEARSON, AXEL HOFFMANN, Argonne National Laboratory, ONGHUI YANG, QIYE WEN, HUAIWU ZHANG, State Key Laboratory of Electronic Films and Integrated Devices, University of Electronic Science and Technology, Chengdu, Sichuan, China, 610054 — The DC voltage arising from the rectification of microwaves passing through a ferromagnet/spin Hall bilayer structure at ferromagnetic resonance is a powerful tool in understanding spin-orbit torques from spin Hall effects. Rectification mechanisms such as anisotropic magnetoresistance of the ferromagnetic or spin Hall magnetoresistance of the spin Hall metal can contribute depending on whether the ferromagnet is conductive or insulating. For both types of ferromagnets, spin pumping acting in concert with the inverse spin Hall effect can also generate additional DC voltages. We have studied rectification in a trilayer system of YIG/Pt/Pt under conditions where both ferromagnets are simultaneously excited. By tipping the DC magnetic field out of the sample plane we can make the resonances of both ferromagnet materials degenerate. In this simultaneous resonance regime we observe an enhancement in the voltage of the YIG lineshape coming at the expense of the Py signal. Furthermore, at arbitrarily tipped out-of-plane tipping angles we observe asymmetries of the Py signal under field reversal. We compare this observation with the DOE, Office of Science, Materials Science and Engineering Division.

12:51PM B28.00009 Surface sensitivity of the spin Seebeck effect in the Pt/YIG system 1, AISHA AQEEQ, IVAN J. VERA-MARUN, BART J. VAN WEES, THOMAS T.M. PALSTRA, Zernike Institute for Advanced Materials, University of Groningen — It is well-known that the surface plays an important role in the spin Seebeck effect (SSE) [1]. However the effect of mechanical treatment on the SSE has not been systematically studied yet. Here, we have investigated the influence of the interface quality on the SSE in a bilayer system of platinum and yttrium iron garnet (Pt/YIG). The surfaces of the YIG crystals are modified by different types of mechanical polishing before Pt deposition for different samples. We observed that the magnitude and magnetic field dependence of the SSE is strongly influenced by mechanical treatment of the YIG surface. No definite relation has been found between the SSE response and the sample roughness. However, we observe a direct correlation between the saturation magnetic field (Hsat) of the SSE and the roughness of sample, as the former increases by moving from soft toward coarse particle polishing. The change in the magnitude of Hsat can be attributed to the presence of a perpendicular magnetic anisotropy due to the treatment induced surface strain or shape anisotropy in the Pt/YIG system [2].

1:03PM B28.00010 Magnons and Phonons Driven out of Equilibrium in a Magnetic Insulator 1, KYONGMO AN, KEVIN OLSSON, NIKITA KLIMOVICH, Department of Physics, The University of Texas at Austin, SEAN SULLIVAN, ANNIE WEATHERS, LUKE MARSHALL, XI CHEN, JIANSHI ZHOU, LI SHI, Department of Mechanical Engineering, The University of Texas at Austin, XIAOQIN LI, Department of Physics, The University of Texas at Austin — We investigate magnons and phonons in a bulk YFeO3 (YIG) under a large temperature gradient created by laser radiation. YIG is a good playground to study the interaction between phonons and magnons. Because of its absence of itinerant electrons, energy transport is only carried by magnons and phonons. Understanding the coupling between them is a key to the thermally driven spin transport such as Spin Seebeck Effect. We use Brillouin light scattering technique to measure phonon and magnon temperature. We found that they can be driven out of equilibrium under a large temperature gradient. We numerically simulate the phonon and magnon temperatures using two-temperature model. Our results suggest a lower bound of magnon phonon relaxation time in YIG.

1We acknowledge support from DOE, AOR under contract W911NF-14-1-0016 and NSF via grant CBET-1336968.

1:15PM B28.00011 Engineering damping in insulating magnet-metal bilayers using ultrathin spacer layers 1, SRIHARSHA V. ARADHYA, COLIN L. JERMAIN, HANJONG PAIK, JOHN T. HERON, DARRELL G. SCHLOM, DANIEL C. RALPH, ROBERT A. BUHRMAN, Cornell University — Insulating magnetic materials, particularly yttrium iron garnet (YIG), are of significant interest for fundamental research as well as technological applications. Thus far copper spacer layers of ~10 nm - 1 µm thickness sandwiched between YIG and heavy metal films have been shown to modulate the damping of the magnetic layer either higher or lower. We report on the effect of ultrathin nonmagnetic spacer layers on the damping of YIG with different heavy metal overlayers. We start with YIG films grown by oxide molecular beam epitaxy with thicknesses below 20 nm and Gilbert damping as low as 0.0005. We observe that a spacer layer can increase the damping by 50% in YIG/spacer/Ta samples compared to YIG/Ta, and the increase can be as large 500% for YIG/spacer/Pt compared to YIG/Pt. These observations suggest a significant increase in the effective spin mixing conductance at the YIG-heavy metal interface that might be used to improve the efficiency of the spin torque produced by the spin Hall effect.

1:27PM B28.00012 Low-temperature magnetization dynamic properties of yttrium iron garnet films 1, YUE ZHAO, QI SONG, WEI YUAN, TANG SU, International Center for Quantum Materials, Peking University, Beijing, YONG WU, YONG JIANG, School of Materials Science and Engineering, University of Science and Technology Beijing, Beijing, WEI HAN, International Center for Quantum Materials, Peking University, Beijing, JING SHI, Department of Physics and Astronomy, University of California, Riverside, California 92521, USA — The long lifetime of collective spin excitations in yttrium iron garnet (YIG) has spurred intense interest in spintronics. Ferromagnetic resonance (FMR) is a sensitive tool for investigating the magnetization dynamics in YIG films as well as YIG-based heterostructure devices. Previous studies have been mainly focused on the room temperature magnetization dynamics of YIG thin films. In this talk, I will first describe a low-temperature broad-band FMR setup with a wide frequency range from 1 to 18 GHz incorporated in Quantum Design’s Physical Properties Measurement System. Using this setup, we study the magnetization dynamic properties of the YIG thin films. In YIG films we observe an intriguing non-monotonic behavior in the temperature dependence of the FMR linewidth from which the Gilbert damping parameter can be extracted. Furthermore, various thicknesses of YIG films are studied to probe the underlying mechanisms that dominate the low-temperature magnetization dynamic behavior. Our temperature-dependence FMR results are very important for the understanding of the relaxation processes of YIG thin films.
1:39PM B28.00013 Growth of high-quality nanometre-thick yttrium iron garnet by sputtering and their magnetic properties , ARPITA MITRA, OSCAR CESPEDES, MANNAN ALI, B.J. HICKEY, Univ of Leeds, UNIVERSITY OF REGENSBURG COLLABORATION — Observation of Spin Seebeck effect (SSE) in magnetic insulators has led to dramatic advances in spin currents research and its applications for thermo-spintronics devices. Here we report deposition of high quality nm-thick yttrium iron garnet(YIG) film on gadolinium gallium garnet(GGG) by RF magnetron sputtering. The morphology and magnetic properties of the films were studied by using AFM and SQUID VSM respectively. 10-60 nm thick films have surface roughness of 1.3Å and (111) orientation. Our results show that magnetic properties of YIG depend strongly on thickness: magnetic moment has linear dependence at room temperature. The saturation magnetization and coercive field observed in thick films are 136 emu/cc and 0.50 Oe, respectively. Temperature dependence of magnetization of nm-thick YIG films has revealed an interesting result, which can be attributed to an additional magnetic phase at the YIG/GGG interface. The reduction in magnetization at low temperatures up to now has not been reported, but has significant relevance for the spin hall magnetoresistance(SMR) at low temperature. Our results on the temperature dependence of Gilbert damping factor of YIG and YIG/Pt films will lead to new physics, to understand its effect on spin mixing conductance and SMR in magnetic insulators.

1:51PM B28.00014 Modeling the Interface of a Heavy Metal/Ferromagnetic Bilayer Using the Boltzmann and Drift-Diffusion Equations , VIVEK AMIN, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, KYOUNG-WHAN KIM, Basic Science Research Institute, Pohang University of Science and Technology, Pohang 790-784, Korea, KYUNG-JIN LEE, Department of Materials Science and Engineering, Korea University, Seoul 136-701, Korea, HYUN-WOO LEE, PCTP and Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea, M.D. STILES, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA — Accurate models for spin torques due to electrical currents in heavy metal/ferromagnetic bilayers allow for the meaningful extraction of parameters from measurements and optimization of devices. Descriptions of coherent spin transport across magnetic interfaces used to date typically take the form of resistor-like components that neglect the spin-orbit interaction. Using the Boltzmann equation, we develop new boundary conditions for the drift-diffusion equations to include both interfacial spin-orbit coupling and the exchange interaction due to the magnetization. These boundary conditions capture interfacial spin-flip scattering, coupling between longitudinal and transverse spin components, and significant modifications to the interfacial torques on the magnetization. They address the spin-orbit interaction at the interfaces of heavy metal/ferromagnetic bilayers, and allow for the calculation of interfacial spin-orbit torques within the drift-diffusion approach.

11:15AM B29.00001 Thermalization, Charge Ordering, and other Recent Developments in Artificial Spin Ice1,2 , PETER SCHIFFER2, Department of Physics, University of Illinois at Urbana-Champaign — Artificial spin ice consists of arrays of lithographically fabricated single-domain ferromagnetic elements, arranged in different geometries such that the magnetostatic interactions between the moments are frustrated. Magnetic force microscopy imaging of these arrays allows us to study the accommodation of frustration through the local correlations between the moments as a function of both the strength of the interactions and the geometry of the frustration. The interactions can be closely mapped onto those of the “spin ice” materials, and allow a detailed analysis of the local correlations and monopole-like excitations. We have probed a number of different lattice geometries and find both local ordering and disordered states that match classic models for frustrated spin systems. Our recent work has focused on thermalization of these arrays as well as investigation of lattice geometries that are unavailable in natural systems and are specifically designed to exhibit unusual behavior associated with frustration, e.g., the shakti lattice. Thermalization reveals ordering both of the moments and of the effective magnetic charges that characterize correlated many-body dynamics in these systems. Other recent work has involved studies of return point memory as well as measurements of electrical transport in these systems.

11:51AM B29.00002 ABSTRACT WITHDRAWN —

12:03PM B29.00003 Dynamics of artificial square spin ice during a non-equilibrium field ramp and quench1,2 , JUAN CARLOS ANDRESEN, Department of Theoretical Physics, KTH Stockholm, SHRAWAN MISHRA, Advanced Light Source, Lawrence Berkeley National Laboratory, JAMES LEE, XIAOWEN SHI, Advanced Light Source, Lawrence Berkeley National Laboratory & Department of Physics, University of Oregon, BARRY FARMER, LANCE DE LONG, University of Kentucky, PATRIK HENELIUS, Department of Theoretical Physics, KTH Stockholm, STEVE KEVAN, SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Laboratory — Recent advances in nanotechnology make it possible to create arrays of single-domain ferromagnetic nanowires that can be fabricated to mimic a variety of Ising-like model systems. This has opened up new ways of studying frustrated systems, such as artificial square spin ice. One of the main advantages of studying these nanomagnet systems is that the Ising-like moments can be directly visualized; but a persistent drawback has been the inaccessibility of the ground state, due to the highly athermal nature of these systems. We present the magnetic autocorrelation function of artificial square spin ice, as measured by XPCS following a non-equilibrium field quench. Our large-scale Monte Carlo simulations agree qualitatively with the experimental relaxation measurements. Furthermore, our simulation results indicate that a simple field ramp demagnetization protocol can be a viable way of reaching a low-energy state.

12:15PM B29.00004 Exchange Bias and Magnetotransport in Permalloy Connected Kagome Artificial Spin Ice , BRIAN LE, University of Illinois at Urbana-Champaign, DAVID RENCH, RAJIV MISRA, Pennsylvania State University, LIAM O’BRIEN, CHRIS LEIGHTON, University of Minnesota, NITIN SAMARTH, Pennsylvania State University, PETER SCHIFFER, University of Illinois at Urbana-Champaign — Artificial spin ice consists of nanoscale ferromagnets arranged in a periodic lattice, with the resultant magnetostatic interactions emulating the local magnetic behavior of spin ice. Kagome artificial spin ice consists of elongated ferromagnetic islands or nanowires arranged in a honeycomb lattice. We present magnetotransport results in connected kagome artificial spin ice composed of permalloy (Ni81Fe19) nanowires. Magnetoresistance was measured as a function of applied field strength at different temperatures. At temperatures below 20 K, the field reversal symmetry of the magnetoresistance is broken. This asymmetry appears to be associated with exchange bias due to the surface oxidation of permalloy and is suppressed in aluminum-capped samples. These results signify that exchange bias can play a substantial role in the physics of artificial spin ice that has potential as a new mode of controlling its behavior. Supported by the US Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division under grant number DE-SC0010778. Work at the University of Minnesota was supported by the NSF MRSEC under award DMR-0819885 and a Marie Curie International Outgoing Fellowship within the 7th European Community Framework Programme (project no. 299376).
12:27PM B29.00005 Return Point Memory in Artificial Spin Ice1. JAN GILBERT, University of Illinois at Urbana-Champaign, GIA-WEI CHERN, Los Alamos National Laboratory, BRYCE FORE, YUYANG LAO, University of Illinois at Urbana-Champaign, CRISTIANO NISOLI, Los Alamos National Laboratory, PETER SCHIFFER, University of Illinois at Urbana-Champaign — Return point memory, in which the spins of a magnet return to their original configuration after the magnet is driven through a hysteresis loop, has been studied extensively with theory, simulations, and bulk experimental probes. However, due to the difficulties associated with directly imaging single spins, microscopic experimental examination of return point memory has proven to be elusive. Here we describe a study of return point memory in arrays of single-domain nanomagnets known as artificial spin ice. In this system, the individual moments can be experimentally resolved by magnetic force microscopy (MFM), so we can both verify the existence of return point memory and explore the mechanism by which it develops. We find that, in artificial spin ice, magnetic monopole excitations drive the development of return point memory through a ratchet-like interaction with the local field produced by the surrounding nanoislands. The number of hysteresis loops required to produce return point memory can be adjusted by tuning the applied magnetic field and array geometry.

12:39PM B29.00006 Charge-ordering in FePd3 artificial kagome ice . JASPER DRISKO, STEPHEN DAUNHEIMER, JOHN CUMINGS, University of Maryland, College Park — Artificial spin ices (ASIs) are arrays of lithographically-patterned, Ising-like nanomagnets built-by-design to be geometrically frustrated. ASIs have proven to be a novel and powerful tool for studying the effects of frustration due to its success in modeling real frustrated materials like spin ice, its highly tunable nature, and its amenability to a variety of techniques to directly characterize exact spin configurations. A fundamental question for frustrated systems is how they find long-range ordered states or whether this is even possible at all in the presence of frustration. In this work we investigate theoretical predictions of charge-ordering in the kagome ice-II state [1]. We employ ASI fabricated from FePd3, which has a relatively low Curie temperature and thus easily allows for thermally activated reversal of individual spins. We have fabricated samples with magnets of varying lengths and investigate them using Lorentz Transmission Electron Microscopy. Samples are heated above their Curie temperature and cooled slowly back to room temperature, allowing the macro-spins to interact, flip, and relax during the cooling process. We find that shorter lattice constant samples tend to exhibit better ordering of magnetic charges after cooling. We have also performed simulations of our samples using a kinetic Monte Carlo technique. We find very good agreement between the simulations and experiment when we incorporate a disordered spread of magnet widths into the simulations, representative of our real samples due to lithography artifacts.

12:51PM B29.00007 Nanoscale SEMPA imaging of an artificial quasicrystal spin ice at remanence , ANDREW BALK, Center for Nanoscale Science and Technology, National Institute of Standards and Technology. Maryland Nanocenter, University of Maryland, VINAYAK BHAT, BARRY FARMER, LANCE DELONG, University of Kentucky, Department of Physics and Astronomy, JOHN UNGURIS, Center for Nanoscale Science and Technology, National Institute of Standards and Technology., ELECTRON PHYSICS GROUP, CNST TEAM — Artificial spin ice has emerged in the past decade as a model metamaterial for studying frustrated magnetic ordering at length scales large enough to be experimentally probed in real space. Recently, complex designs have been engineered to explore exotic behavior in non-square lattices. However, direct measurements of the actual moment directions have not been very common, and interpretation from techniques such as magnetic force microscopy and magneto-optical Kerr effect magnetometry can be complicated by the more complex geometries. Here we demonstrate using SEMPA (scanning electron microscopy with polarization analysis) as a method to robustly measure the ordering direction of elements in a connected artificial quasicrystal. We discuss the applicability of SEMPA to this system, details of the imaging and potential artifacts, and conclusions that can be drawn from the nanoscale two dimensional maps of the moment direction.

1:03PM B29.00008 First observation of ferromagnetic order in an artificial 2D quasicrystal1. BARRY FARMER, VINAYAK BHAT, University of Kentucky, Department of Physics and Astronomy, ANDREW BALK, JOHN UNGURIS, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, LANCE DE LONG, University of Kentucky, Department of Physics and Astronomy — Magnetic order in bulk quasicrystals is not well understood and known materials exhibit short-range, spin-glass order. We patterned ferromagnetic (FM) thin films into artificial quasicrystals, a new class of metamaterials that exhibits complex magnetic reversal and dynamics that can be controlled via tiling design. We analyzed two-dimensional SEMPA images of magnetization textures of Penrose P2 tilings (P2T) patterned into Permalloy. Samples are heated above their Curie temperature and cooled slowly back to room temperature, allowing the macro-spins to interact, flip, and relax during the cooling process. We find that shorter lattice constant samples tend to exhibit better ordering of magnetic charges after cooling. We have also performed simulations of our samples using a kinetic Monte Carlo technique. We find very good agreement between the simulations and experiment when we incorporate a disordered spread of magnet widths into the simulations, representative of our real samples due to lithography artifacts.

1:27PM B29.00010 Honeycomb artificial spin ice at low temperatures1. KATHARINA ZEISSLER, MEGHA CHADHA, LESLEY COHEN, WILL BRANDFORD, Imperial College London — Artificial spin ice is a macroscopic playground for magnetically frustrated systems. It consists of a geometrically ordered but magnetically frustrated arrangement of ferromagnetic macroscopic spins, e.g. an arrangement of single domain ferromagnetic nanowires on a honeycomb lattice. Permalloy and cobalt which have critical temperature scales far above 290 K, are commonly used in the construction of such systems. Previous measurements have shown unusual features in the magnetotransport signature of cobalt honeycomb artificial spin ice at temperatures below 50 K which are due to changes in the artificial spin ice’s magnetic reversal. In that case, the artificial spin ice bars were 1 micron long, 100 nm wide and 20 nm thick. Here we explore the low temperature magnetic behavior of honeycomb artificial spin ice structures with a variety of bar dimensions, indirectly via electrical transport, as well as, directly using low temperature magnetic imaging techniques. We discuss the extent to which this change in the magnetic reversal at low temperatures is generic to the honeycomb artificial spin ice geometry and whether the bar dimensions have an influence on its onset temperature.

11:51 AM B30.00004 (001) Oriented \( L_10 \) FeCuPt for Heat-Assisted Magnetic Recording, Kai Liu, University of California - Davis — High magnetic anisotropy materials are critical to key technologies such as ultrahigh density magnetic recording and permanent magnets. Among them, ordered FePt alloys in the \( L_10 \) phase are particularly sought after, for the emerging heat-assisted magnetic recording (HAMR) media. However, the highly desirable properties are associated with the tetragonal \( L_10 \) phase. Key challenges exist in the high annealing temperature necessary to transform the as-deposited disordered cubic \( L_1 \) phase into the ordered tetragonal \( L_10 \) phase and the ability to maintain the magnetic easy axis perpendicular to the film. We have achieved (001) oriented \( L_10 \) FeCuPt thin films, with magnetic anisotropy up to \( 3.6 \times 10^7 \) erg/cm\(^2\), using atomic-scale multilayer sputtering and rapid thermal annealing (RTA) at 400 °C for 10 seconds, which is much more benign compared to earlier studies [1]. The artificial ordering in the multilayer structure and a significant tensile stress exerted by the underlying Si/SiO\(_2\) during RTA facilitate the formation of (001) oriented \( L_10 \) phase. The \( L_1 \) to \( L_10 \) phase transformation has been investigated by x-ray diffraction and the first-order reverse curvature (FORC) method [2]. The \( L_10 \) ordering takes place via a nucleation-and-growth mode. Traditional x-ray diffraction is not always reliable in generating a true order parameter, due to non-ideal crystallinity of the \( L_1 \) phase in some of the samples. A magnetization-based \( L_10 \) phase fraction is extracted, providing a quantitative measure of the \( L_10 \) phase homogeneity [3].

12:39PM B30.00006 Tuning magnetic properties of metallic nanostructures on semi-insulating substrates, Oleg Brovko, Valeri Stepanyuk, Max Planck Institute of Microstructure Physics, Halle, Germany — In the past two decades, the properties of metallic nanostructures on metallic surfaces have been studied in minute detail and possibilities to tune them have been explored both experimentally and theoretically. [1] Recently the focus has been shifting towards insulating or semi-insulating substrates, [2] the reason being that while on metallic surfaces the magnetism of nanostructures is determined by the coupling of the localized magnetic moment of the ad-structure to a bath of itinerant electrons of the substrate, on insulating substrates the spin is largely isolated and often exhibits emergent quantum properties. In this work we simulate semi-insulating substrates open an additional possibility of adjusting the coupling of the ad-structure spin to the substrate. In the present contribution we show the possibility to tune magnetic properties of metal nanostructures and their interaction among each other on such semi-insulating substrates as thin decoupling CuN, h-BN and MgO layers. As a means of tuning we focus on adsorption site tailoring and exposure to external electric field. [1] O. Brovko et al., JPCM 26, 093001 (2014). [2] S. Loth et al., Science 335, 196 (2012), T. Schuh et al., Nano Lett. 12, 4805 (2012)

12:51PM B30.00007 Effects of exchange interactions on magnetic anisotropy and spin-dynamics of adatoms on metallic surfaces, Pedro Ruiz Diaz, Max Planck Institute of Microstructure Physics, Oleg Stepanyuk, Physics Department, Moscow State University, Valeri Stepanyuk, Max Planck Institute of Microstructure Physics — A common belief is that magneto-crystalline anisotropy energy (MA) mainly arises from the spin-orbit coupling interaction. Here, throughout an ab initio study we show that direct exchange interactions (Eex) together with substrate-mediated interactions rules the MA nature in Co inter-acting adatoms supported on Cu(001) and Pt(001) surfaces. MA exhibits a non-trivial behavior and is found to be strongly sensitive to Eex, magnetic order and substrate composition. Oscillatory magnetization switching is also revealed. Further, by means of a stochastic method, for the first time to our knowledge, the spin-dynamics of these single-spin systems assessed in the hysteresis loops is presented. Insights about the interplay between Eex and MA which determines the onset of the magnetization curves and their shape are discussed.

1:15PM B30.00009 A New Method Based on RF Impedance Technology and Soft Ferromagnetic Ribbons for Real-Time Corrosion Monitoring, Izabella Berman, Jagannath Devkota, Harinaran Srikanth, Mahn-Huong Phan, None — Development of a quick, cheap, and reliable technique to estimate the concentration of corrosive chemicals has been of technological interest for safety in industries and the environment for many years. Here we present a new approach for real-time monitoring of chemical corrosion based on the radio-frequency (RF) impedance technology and soft ferromagnetic ribbons. The impedance \( Z \), resistance \( R \), and reactance \( X \) of a commercial METGLAS®2714A ribbon was measured in real time for \( 5 \mu l \) of drop-casted HNO\(_3\) of various concentrations. Variations in the concentration of the drop-casted acid were assessed by considering the difference of \( \Delta Z \) in the Z, R, and X with and without the acid treatment. The measurements performed at 0.2 MHz showed a large linear increase in the \( \Delta Z \) and \( \Delta R \) with the acid concentration which is ideal for developing highly sensitive chemical sensors. Since the ribbon used is commercially available at low cost and the measurement system is quick and low power consuming, the proposed sensor can be used as an easy, quick, and low-cost chemical probe in industries and environmental safety purposes.

1:27PM B30.00010 Stochastic magnetization dynamics of biochemically bound magnetic nanoparticles, Daniel Reeves, Department of Physics and Astronomy, Dartmouth College, John Weaver, Department of Physics and Department of Radiology, Dartmouth College — Understanding the dynamics of magnetic nanoparticles in applied magnetic fields is critical for biosensing and therapeutic applications. In biological environments, the nanoparticles may clump together and the resultant dynamics are interesting and important. We show simulation schemes using stochastic Langevin equations that describe the particle rotations in various conditions and suggest ways to improve the applications. Biochemical binding is described in terms of changes of the size distribution from network theory perspective. Also, using log-normally size distributed particles, a master variable is derived that contains all the significant variables. This compacts the parameter space, quickens simulation, and improves intuition. An approximate closed form solution to the magnetization harmonics in an oscillating field is given in terms of this variable using the Langevin function.
1:39PM B30.00011 Iron oxide nanoparticles with controlled morphology for advanced hyperthermia

ZOHREH NEMATI PORSOKHOU, HAFSA KHURSHID, Univ of South Florida-physics, JAVIER ALONSO MESSA, Univ of South Florida-physics and BC Materials (Spain), MANH-HUONG PHAN, HARIRHAN SRIKANTH, Univ of South Florida-physics — Magnetic nanoparticles (NPs) are interesting for a wide range of applications. In biomedicine, they have been exploited for use in drug delivery, magnetic resonance imaging, and magnetic hyperthermia. While magnetic hyperthermia, using NPs to convert electromagnetic energy into heat to destroy the cancer cells, represents a novel cancer treatment technique, a poor heating conversion efficiency of the existing NPs restricts its practical use. Different strategies have been proposed to overcome this limitation, mainly by tuning the size, saturation magnetization and effective anisotropy of the NPs. Here we report a magnetic hyperthermia study on Fe3O4 NPs, where the effective anisotropy was tuned by varying particle morphology from the spherical to octopod shape. The Fe3O4 NPs were synthesized using a thermal decomposition method. Transmission electron microscopy (TEM) and high-resolution TEM images show high crystalline monodisperse nanoparticles. X-ray diffraction patterns confirm the presence of Fe3O4 phase. Hyperthermia experiments indicate that the octopod possesses a higher SAR as compared to their spherical counterpart. Our findings provide an effective approach to improve the SAR of NPs by manipulating the shape anisotropy of the nanoparticles.

1:51PM B30.00012 Magneto-impedance based detection of magnetically labeled cancer cells and bio-proteins

J. DEVKOTA, Department of Physics, University of South Florida, M. HOWELL, S. MOHAPATRA, Department of Molecular Medicines, University of South Florida, T.H. NHUNG, Institute of Physics, Vietnam Academy of Science and Technology, P. MUKHERJEE, H. SRIKANTH, M.H. PHAN, Department of Physics, University of South Florida — A magnetic biosensor with enhanced sensitivity and immobilized magnetic markers is essential for a reliable analysis of the presence of a biological entity in a fluid. Based on conventional approaches, however, it is quite challenging to create such a sensor. We report on a novel magnetic biosensor using the magneto-impedance (MI) effect of a Co-based amorphous ribbon with a microhole-patterned surface that fulfills these requirements. The sensor probe was fabricated by patterning four microholes, each of diameter 2 µm.H. PHAN, Department of Physics, University of South Florida — Magnetic nanoparticles (NPs) are being considered as therapeutic tools for cancer treatments. Most of the existing NPs, where the effective anisotropy was tuned by varying particle morphology from the spherical to octopod shape. The Fe3O4 NPs were synthesized using a thermal decomposition method. Transmission electron microscopy (TEM) and high-resolution TEM images show high crystalline monodisperse nanoparticles. X-ray diffraction patterns confirm the presence of Fe3O4 phase. Hyperthermia experiments indicate that the octopod possesses a higher SAR as compared to their spherical counterpart. Our findings provide an effective approach to improve the SAR of NPs by manipulating the shape anisotropy of the nanoparticles.

2:03PM B30.00013 Comparison of Coil Designs for Transcranial Magnetic Stimulation on Mice

PRIYAM RASTOGI, RAVI HADIMANI, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University — Transcranial magnetic stimulation (TMS) is a non-invasive treatment for neurological disorders using time varying magnetic field. The electric field generated by the time varying magnetic field is used to depolarize the brain neurons which can lead to measurable effects. TMS provides a surgical free method for the treatment of neurological brain disorders like depression, post-traumatic stress disorder, traumatic brain injury and Parkinson’s disease. Before using TMS on human subjects, it is appropriate that its effects are verified on animals such as mice. The magnetic field intensity and stimulated region of the brain can be controlled by the shape, position and current in the coils. There are a few reports on the designs of the coils for mice. In this paper, different types of coils are developed and compared using an anatomically realistic mouse model derived from MRI images. Parameters such as focality, depth of the stimulation, electric field strength on the scalp and in the deep brain regions, are taken into account. These parameters will help researchers to determine the most suitable coil design according to their need. This should result in improvements in treatment of specific disorders.

11:15AM B31.00001 The Relationship Between Torsion and Anisotropic Exchange Coupling in a Tb(III)-Radical Complex

MICHAEL L. BAKER, TAKUYA TANAKA, Tohoku University, SEIKO KAWAMURA, KENJI NAKAJIMA, J-PARC, TAKAYUKI ISHIDA, The University of Electro-Commun., HIROYUKI NOJIRI, Tohoku University — The incorporation of paramagnetic ligands within anisotropic rare earth ion clusters has provided significant advance to the design of single molecule magnets with large blocking temperatures [1]. The exchange interaction in such systems is complex, difficult to probe, and little is known about structural relations. Inelastic neutron scattering and sub-THz electronic paramagnetic resonance are used complimentary to investigate the large exchange interaction between a rare earth - radical pair in the Tb(hfac)3(2pyNO) complex [2]. Two molecular species exhibiting different Tb-O-N-C torsion angles of the paramagnetic 2pyNO ligand are compared. Antiferromagnetic Ising type 2p – 4f exchange is determined for a low torsion angle (3.8 degrees) species. A different species with a larger torsion angle (15.8 degrees) is found to have weaker antiferromagnetic exchange and a non-degenerate ground state doublet. The origin of degeneracy lifting is due to an in-plane ferromagnetic component to the exchange matrix originating from 2p – 5d charge transfer rather than a Dzyaloshinski-Moriya interaction.

11:27AM B31.00002 Magnetic Behavior of a Dy8 Molecular Nanomagnet

QING ZHANG, MYRIAM SARACHIJK, City College of New York, MICHAEL BAKER, City College of New York and New York University, YIZHANG CHEN, ANDREW KENT, New York University, THEOCHRIS STAMATATOS, Brock University, Ontario — As part of a study of quantum tunneling in a newly synthesized family of dysprosium-based molecular magnets that exhibit a chiral spin structure, we report initial investigations of the magnetic response of a Dy8 cluster with the formula (Et2N)2[Dy8O(μ4-O)2(NO3)10(H2O)2]·2MeCN [1]. The molecular complex contains triangular arrangements of exchange coupled Dy(III) ions [2]. The compound forms an approximate snub-square Archimedeans lattice unit. The measured magnetization of this network of four triangles suggests the presence of multiple spin chiral vortices. Single crystal susceptibility and magnetization measurements indicate the presence of a hard-axis direction and an easy plane. These principal orientations have been investigated in magnetic fields up to 5 Tesla for temperatures between 1.8 and 100 K using a SQUID-based Quantum Design MPMS magnetometer. Complex easy plane magnetic hysteresis loops emerge at lower temperatures measured using Hall probe magnetometry at sub 1 K temperatures. The analysis of these measurements will be discussed and compared with results of theoretical calculations. [1] D. I. Alexandropoulos, et al., Inorg. Chem. 53, 5420 (2014). [2] J. Luzon, et al., Phys. Rev. Lett. 100, 247201 (2008).

1 Work supported by ARO W911NF-13-1-1025 (CCNY), NSF-DMR-I309202 (NYU); the synthesis of the Dy8 cluster was supported by NSERC (Discovery grant to Th.C.S.).
11:39AM B31.00003 Magnetic Properties of Electrically Contacted Fe₄ Molecular Magnets
JACOB BURGESS, MPSD and MPI FKF, Germany, LUIGI MALAVOLTI, VALERIA LANZILOTTO, MATTEO MANNINI, FREDERICO TOTTI, SILVIYA NINOVA, Dept of Chem, UniFi and INSTM, Florence, Italy, SHICHAO YAN, DEUNG-JANG CHOI, STEFFEEN ROLF-PISSARCZYK, MPSD and MPI FKF, Germany, ANDREA CORNIA, Dept of Chem and Geo Sciences, UniMoRE and INSTM, Italy, ROBERTA SESSOLI, Dept of Chem, UniFi and INSTM, Florence, Italy, SEBASTIAN LOTH, Max Planck Institute for the Structure and Dynamics of Matter (MPSD), Hamburg and Max Planck Institute for Solid State Research (MPI FKF), Stuttgart — Single molecule magnets (SMMs) are often large and fragile molecules. This poses challenges for the construction of SMM based spintronics. Device geometries with two electronic leads contacting a molecule may be explored via scanning tunneling microscopy (STM). The Fe₄ molecule [1] stands out as a robust, thermally evaporable SMM, making it ideal for such an experiment. Here we present the first STM investigations of individual Fe₄ molecules thermally evaporated onto a monolayer of Cu₂N on a Cu (100) crystal. Using inelastic electron tunneling spectroscopy (IETS), spin excitations in single Fe₄ molecules can be detected at meV energies. Analysis using a Spin Hamiltonian [2] allows extraction of magnetic properties of individual Fe₄ molecules, and investigation of the influence of the electronic leads. The tip and sample induce small changes in the magnetic properties of Fe₄ molecules, making Fe₄ a promising candidate for the development of spintronics devices based on SMMs.

11:51AM B31.00004 Single-Molecule Toroics in Ising-type lanthanide molecular clusters
LVIIU CHIBOTARU, KU Leuven — The toroidal magnetic moment [1] is an antisymmetric combination of second-order magnetic moments, possessing distinct symmetry from first-order electromagnetic moments due to the sign change under both space and time inversion. It has been observed for the first time in LiCoPO₄ as a homogeneous distribution of toroidal polarization [2], which was also the first evidence for the fourth fundamental form of ferroic order, the ferrotoroidicity [3]. Recently an almost net toroidal moment has been detected in Dy₃ triangles, implying the existence of toroidal quantum states in these complexes [4]. Single-molecule toroics (SMTs) are defined, by analogy with single-molecule magnets (SMMs), as bistable molecules with toroidal magnetic state, which seem to be most promising for future applications in quantum computing and information storage and as molecular multiferroic materials with magnetoelectric effect. The key features offering advantages to CMTs as potential units for storage and processing of information are (i) their insensitivity to external homogeneous magnetic fields and a remarkably weak magnetic interaction between themselves and (ii) the possibility to manipulate the toroidal states by electrical means (charge currents and variable electric fields). In this interdisciplinary research area that spans chemistry, physics and material sciences, synthetic chemists have already produced SMT systems suitable for detailed experimental study, while ab initio calculations have proven their reliability in the description of toroidal magnetization [6]. In this presentation, I will review the emerging field of SMTs with particular focus on how recent studies tend to address the issue of toroidal arrangement of local magnetic moment on the metal sites. Nine lanthanide-based SMTs will be presented showing, in particular, that the assembly of wheel-shaped complexes with the high symmetry of the molecule unit and combining strong intermetallic dipolar interactions with strong axial ferrotoroidicity [3]. Recently an almost net toroidal moment has been detected in Dy₃ triangles, implying the existence of toroidal quantum states in these complexes [4]. Single-molecule toroics (SMTs) are defined, by analogy with single-molecule magnets (SMMs), as bistable molecules with toroidal magnetic state, which seem to be most promising for future applications in quantum computing and information storage and as molecular multiferroic materials with magnetoelectric effect. The key features offering advantages to CMTs as potential units for storage and processing of information are (i) their insensitivity to external homogeneous magnetic fields and a remarkably weak magnetic interaction between themselves and (ii) the possibility to manipulate the toroidal states by electrical means (charge currents and variable electric fields). In this interdisciplinary research area that spans chemistry, physics and material sciences, synthetic chemists have already produced SMT systems suitable for detailed experimental study, while ab initio calculations have proven their reliability in the description of toroidal magnetization [6].

12:27PM B31.00005 Spontaneous Magnetic Deflagration of Mn₁₂tBuAc in a Transverse Field
YIZHANG CHEN, A. D. KENT, New York University, QING ZHANG, M. P. SARACHIK, City College of New York, MICHAEL L. BAKER, New York University & City College of New York, D. A. GARANIN, Lehman College of CUNY, NAJAH MHESN, CHRISTOS LAMPROPOULOS, University of North Florida — Magnetic deflagration has been triggered in molecular magnets with a swept longitudinal magnetic field [1], acoustic waves [2], and by applying a heat pulse [3-4]. In this work we report a study of the conditions for the spontaneous ignition of magnetic deflagration in the axially symmetric single molecule magnet Mn₁₂tBuAc. The onset of spontaneous deflagration shows clear resonant features in the Hₓ ⊗ Hₐ plane; here Hₓ is the longitudinal magnetic field, the bias that reduces the height of the magnetic anisotropy barrier, and Hₐ is the field transverse to the easy axis that mixes spin states on opposite sides of the anisotropy barrier. Consistent with expectations, the conditions (Hₓ, Hₐ) for spontaneous ignition vary with temperature. We show that the speed of the deflagration fronts are strongly reduced near quantum tunneling resonances due to magnetic relaxation prior to spontaneous deflagration events.

12:39PM B31.00006 Understanding and controlling the magnetic interaction between Ln(III) bis-(phenthalocyanine)’s “Double Decker” molecular nanomagnets and a magnetic substrate
ANDREA CANDINI, SIMONE MAROCCO, VALDIS CORRADINI, FILIPPO TROIANI, VALERIO BELLINI, Istituto Nanoscienze - CNR, Italy, ROBERTO BIAGI, VALENTINA DE RENZI, UMBERTO DEL PENNINO, MARCO AFFRONTE, Università di Modena e Reggio Emilia, Italy, SVETLANA KLYATSKAYA, MARIO RUBEN, Karlsruhe Institute of Technology (KIT), Germany, DAVID KLAR, HEIKO WENDE, University of Duisburg-Essen, Germany — Understanding and controlling the interaction between molecules and substrate is of crucial importance for the realization and implementation of molecular devices. Here we present the study by means of XAS and XMCD of the magnetic coupling between LnPc2 “Double Decker” (Ln = Tb, Dy, Er) molecular nanomagnets sublimated in situ on top of a Ni(111) single crystal. We find an antiferromagnetic exchange coupling between the molecules and the Ni substrate. The observed dependence of the coupling strength on the specific Ln ion is explained by the analysis of the Ln spin-polarized density of states as calculated by DFT. This allows us to identify the microscopic origin of the magnetic interaction between the Ln ions and the molecule environment which happens by the mediation of the organic part of the molecule. This result will be particularly relevant also for the investigation of molecular spintronics devices employing TbPc₂ molecules. Finally, we show how this interaction can be further tuned by the insertion of a graphene layer.

12:51PM B31.00007 Pushing the Limits of Magnetic Anisotropy in a Mononuclear Ni(II) Single-Molecule Magnet: a High-Field EPR Study, LAKSHMI BHASKARAN, Department of Physics, Florida State University (NHMFL), Tallahassee, Florida, USA, KATIE MARRIOTT, MARK MURRIE, Department of Chemistry, University of Glasgow, Scotland, UK, STEPHEN HILL, Department of Physics, Florida State University (NHMFL), Tallahassee, Florida, USA — Single-Molecule Magnets (SMMs) are potential candidates for nanoscale magnetic information storage, where slow magnetization dynamics (bistability) is realized at low temperatures due to a magnetic anisotropy barrier separating the “spin-up” and “spin-down” states of the SMMs. Here, we report spectroscopic evidence for a huge easy-axis anisotropy in a trigonal bipyramidal (TBP) [NiII(3dabco)2] complex with an orbitally degenerate ground state. Single-crystal EPR studies were carried out in a 35T resistive magnet at the NHMFL. A very strong angle-dependence of the spectrum was observed within a few degrees of the hard plane, suggesting a huge zero-field-splitting (zfs) parameter, |D|>300 cm⁻¹, associated with first order spin-orbit coupling. This value is considerably larger than previously reported for a NiII TBP complex [1], and is thought to be due to the rigidity of the ligand that prevents Jahn-Teller type effects that can reduce D [2]. This is confirmed by the small value of the rhombic parameter, |E|= 0.66 cm⁻¹.

1:03PM B31.00008 Observation of Highly Forbidden Single-Photon Transitions in a Ni₄ Single-Molecule Magnet¹, YIMING CHEN, Amherst College and University of Massachusetts at Amherst, MOHAMMAD D. ASHEKEZARI, Amherst College, RAFAEL CASSARO, University of Massachusetts at Amherst, JONATHAN FRIEDMAN, Amherst College — We report electron-spin resonance experiments on a crystal of the single-molecule magnet (SMM) [Ni(hmp)(dmb)Cl]₂ (hereafter Ni₄), which is an S=4 system with large uniaxial anisotropy. At 115.4 GHz and low magnetic fields (below the anisotropy field for the SMM), we observe two weak resonances that correspond to highly forbidden transitions between magnetic sublevels, one corresponding to Δm = 0 and another corresponding to Δm = −1. The interpretation of the observed transitions is confirmed by following how the peak positions change with the angle between the sample’s easy axis and the applied field. The selection rules forbidding these transitions are lifted by tunneling between m states. The observed forbidden transitions can be viewed as tunneling-assisted direct single-photon transitions between spin states. Equivalently, the forbidden transitions can be interpreted as resonant tunneling between one spin state of the molecule and the dressed state of another spin state. The forbidden transitions have much narrower line widths than the allowed transitions, which suggests that the lines are not inhomogeneously broadened by local fields. Assuming homogeneous broadening, we infer a decoherence time T₂ of ~0.5 ns.

1:15PM B31.00009 Single Molecule Metamagnetism and the Single Energy Scale Model, BELLAVE SHIVARMA, University of Virginia, PRADEEP KUMAR, University of Florida, RICHARD WINPENNY, University of Manchester, MICHAEL OSOFSKY, Naval Research Labs, V. CEILLI, University of Virginia — Measurements of the magnetization isotherms at low temperatures are used to extract the linear, χ₁ and third order, χ₃, magnetic susceptibilities of two distinct single molecule magnets (SMM), (UO₂⁻L₁)₃ and Cr₆F₁₁. In (UO₂⁻L₁)₃ the behavior of χ₃ is consistent with a peak appearing at a temperature T₀ which is ~ 0.5 T₁; the temperature at which a peak in χ₁ is observed. In Cr₆F₁₁ a peak in χ₁ is not present neither is a peak in χ₃ observed. Nevertheless, a simple phenomenological model with only a single energy scale, is able to account for the two distinct behaviors in the linear and nonlinear magnetic response of these two SMMs.

1:27PM B31.00011 Role of spin-orbit fluctuations in spin decoherence, MATHEW MARTENS, Florida State University, National High Magnetic Field Lab, JOHAN VAN TOL, National High Magnetic Field Lab, NARESH DALAL, Florida State University, SYLVAIN BERTAINA, Aix-Marseille University, CNRS, IM2NP UMR7334, 13397 cedex 20, Marseille, France, IRINEL CHIORESCU, Florida State University, National High Magnetic Field Lab — We performed a systematic study of the decoherence mechanism in the molecular compound K₆[As⁶⁺O₁₂D₂O] · 8D₂O, in short V₁₅ utilizing high-field electron spin resonance at 120 GHz, 241 GHz, and 336 GHz. This system has shown important quantum effects such as coherent spin oscillations as well as interesting out-of-equilibrium spin dynamics due to phonon bottlenecking. The spectra of a single V₁₅ crystal were measured and linewidths as a function of orientation, temperature, and field were extracted. By analyzing the shape and orientation anisotropy of the linewidths, we study how fluctuations in each term of the spin Hamiltonian contribute to the spin decoherence with much attention given to the spin-orbit coupling that generates g-factor anisotropy. Our conclusion is that fluctuations in the spin-orbit coupling can play an important role in the linewidth of a spin resonance.

1:39PM B31.00011 Low Temperature Scanning Tunneling Spectroscopy of isolated Mn₁₂-Ph Single Molecule Magnets, K. REAVES, Dept of Materials Science and Engineering and Physics and Astronomy, Texas A&M University; WPI-AIMR, Tohoku University, Sendai, Japan, P. HAN, K. IWAYA, H. HITORUGI, D. PACKWOOD, WPI-AIMR, Tohoku University, Sendai, Japan, H. G. KATZGRABER, Dept of Materials Science and Engineering and Physics and Astronomy, Texas A&M University, Santa Fe Institute, H. ZHAO, K.R. DUNBAR, Dept of Chemistry, Texas A&M University, K. KIM, W. TEIZER, Dept of Materials Science and Engineering and Physics and Astronomy, Texas A&M University; WPI-AIMR, Tohoku University, Sendai, Japan — We study Mn₁₂O₁₂(C₆H₅COO)₁₅(H₂O)₄ (Mn₁₂-Ph) single-molecule magnets on a Cu(111) surface using scanning tunneling microscopy and scanning tunneling spectroscopy at cryogenic temperatures (T<6K). We report the observation of Mn₁₂-Ph in isolation and in thin films, deposited through in situ vacuum spray deposition onto clean Cu(111). The tunneling current of isolated Mn₁₂-Ph, normalized with respect to the Cu background, shows a strong bias voltage dependence within the molecular interior. The qualitative features of these I vs.V curves differ by spatial location in several intriguing ways (e.g. fixed junction impedance with increasing bias voltages). We explore these normalized I vs. V curves and present a phenomenological explanation for the observed behaviors, corresponding to the physical and electronic structure within the molecule.

1:51PM B31.00012 Quantum coherence in Mn-based single molecule magnets . C. ABEYWARDANA, F.H. CHO, University of Southern California, A. MOWSON, G. CHRISTOU, University of Florida, S. TAKAHASHI, University of Southern California — As spin systems in solids, single-molecule magnets (SMMs) form a unique class of materials that have a high-spin, and their spin state and interaction can be easily tuned by changing peripheral organic ligands and solvate molecules. In addition, it has been shown that an individual or a small ensemble of SMMs can be transferred to surface with retention of their magnetic behavior. SMM is therefore a promising system for fundamental quantum science and for applications to dense and efficient quantum memory, computing, and molecular spintronics devices. In spite of diverse interests on quantum properties in SMMs, decoherence properties that ultimately limit such behaviors have not been understood yet. Until now, coherent manipulation of spin states in SMMs has been experimentally demonstrated only in a few SMMs [1-2]. In this presentation, we investigate quantum coherence in Mn-based SMMs using a high-frequency pulsed EPR technique, which has a significant advantage to quench the spin decoherence due to electron spins [3].

2:03PM B31.00013 Interface Effects in Spin-crossover (SCO) Thin Films on Au(111). SUMIT BENIWAL, XIN ZHANG, University of Nebraska - Lincoln, PATRICK ROSA, JEAN-FRANCOIS LETARD, TATIANA PALAMARCIC, Universite de Bordeaux, BERNARD DOUDIN, Universite Louis Pasteur Strasbourg, PETER DOWBEN, AXEL ENDEERS, University of Nebraska - Lincoln — Thin films of the SCO molecules [Fe(H_2B(pz)_2)(bipy)] on Au(111) are investigated. The growth mode is determined by low temperature scanning tunneling microscopy, whereas chemical and electronic properties are determined with X-ray photoemission spectroscopy (XPS) and inverse photoemission spectroscopy (IPES). The role of substrate in determining the electronic structure is determined from thickness and temperature dependent XPS. Thin films exhibit coexistence of Fe(II) and Fe(III) oxidation states, which is different from the Fe(II) oxidation state in bulk. The fraction of molecules in the Fe(II) state increases with film thickness, which suggests that the molecules at the interface are in the Fe(III) state. Cooling the films to 100 K triggers an irreversible transition from Fe(III) to Fe(II). This transition coincides with spin phase transition, where shift of the conduction band edge away from the Fermi level is observed in IPES. These results demonstrate that thin films of this complex have different phase transition behavior as compared to bulk-like samples and underline that substrate interaction is a powerful parameter to control their structural conformation, spin state as well as electronic properties.

Monday, March 2, 2015 11:15AM - 12:15PM — Session B32 GMAG DMP: Focus Session: Transition Metal Oxides I 207B - 11:15AM B32.00001 Probing functional perovskites through scanning transmission electron microscopy and first-principles theory1. STEPHEN PENNYCOOK, National University of Singapore — The aberration-corrected scanning transmission electron microscope (STEM) can provide real space imaging and spectroscopy at atomic resolution with a new level of sensitivity to chemical and electronic properties that ultimately limit such behaviors have not been understood yet. Until now, coherent manipulation of spin states in SMMs has been experimentally demonstrated only in a few SMMs [1-2]. In this presentation, we investigate quantum coherence in Mn-based SMMs using a high-frequency pulsed EPR technique, which has a significant advantage to quench the spin decoherence due to electron spins [3].

11:51AM B32.00002 Spin-state blockade in Te⁶⁺-substituted electron-doped LaCoO₃¹. KEISUKE TOMIYASU, SHUN-ICHI KOYAMA, MASANORI WATAHlKI, MIKA SATO, KAZUKI NISHIHARA, MITSUGI ONODERA, KAZUAKI IWASA, TSUTOMU NOJIMA, Tokohu Univ, YUICHI YAMASAKI, HIROHITO NAKAO, YOICHI MURAKAMI, KEN — Perovskite-type LaCoO₃ (Co²⁺: d⁶) is a rare inorganic material with sensitive and characteristic responses among low, intermediate, and high spin states. For example, in insulating nonmagnetic low-spin states below about 20 K, light hole doping (Ni substitution) induces much magnetization than expected; over net 10µB/hole (5µB/Ni) for 1µB/hole (1µB/Ni), in which the nearly isolated dopants locally change the surrounding Co low-spin states to magnetic ones and form spin molecules with larger total spin [1-4]. Further, the former is isotropic, whereas the latter exhibits characteristics anisotropy probably because of Jahn-Teller distortion [2]. In contrast, for electron doping, relatively insensitive spin-state responses were reported, as in LaCo(Ti⁴⁺)O₃, but are not clarified, and are somewhat controversial. Here, we present macroscopic measurement data of another electron-doped system LaCo(Te⁶⁺)O₃ and discuss the spin-state responses. – Refs. [1] S. Yamaguchi et al., PRB (1996). [2] K. 12:03PM B32.00003 Crystal Fields as a Probe of the Valence Transition in Pr-based Cobaltites . D. PHELAN, S. ROSENKRANZ, Argonne National Laboratory, D.M. PAJEROWSKI, NIST Center for Neutron Research, C. LEIGHTON, University of Minnesota — Upon cooling, a unique first-order metal-insulator transition (MIT) has been observed in cobaltite perovskites at certain compositions with Pr on the A-site; this is strongly suspected as a consequence of electron transfer from Pr³⁺ ions to hybridized Co-O orbitals. Here we discuss the crystal field levels of Pr³⁺ and Pr⁴⁺ ions which we have investigated using inelastic neutron spectroscopy as a function of temperature for three samples: one insulating, one metallic, and one that undergoes the MIT. We show that the insulating compound, PrCoO₃₋δ, contains Pr⁴⁺ ions (J=4) whose ground state multiplet is split into nine singlets, and we extract its crystal field parameters. In the hole-doped metal, Pr₀.₇Ca₀.₃CoO₃₋δ, which also contains Pr⁴⁺ ions, the crystal field levels maintain the same energy-level structure but are noticeably broadened. The scattering from the Pr⁴⁺ crystal fields, though present, is diminished in the sample that undergoes the MIT (Pr₀.₆₉Y₀.₀₇Ca₀.₃CoO₃₋δ), consistent with a decrease in the concentration of Pr⁴⁺; moreover, the levels are severely broadened. The experiments illustrate the inhomogeneous charge distribution that occurs around the Pr sites upon substitution.

12:15PM B32.00004 Spatial Magnetic Phase Separation in the Oxygen Deficient Perovskite SrCoO$_{1-x}$O$_x$. Z.H. ZHU, Physics Department at University of Connecticut, F.J. RUECKERT, Wentworth Institute of Technology, J.I. BUDNICK, W.A. HINES, B.O. WELLS, Physics Department at University of Connecticut, CH. NIEDERMAYER, Laboratory for Neutron Scattering at Paul Scherrer Institut, B. DABROWSKI, Department of Physics at Northern Illinois University — We report here the unique local structure of the magnetically phase separated perovskite SrCoO$_{1-x}$O$_x$ by means of transverse field (TF) and zero field (ZF) muon spin rotation. Previously we reported samples of SrCoO$_3$ and SrCoO$_2$, both have unique magnetic and crystallographic phases, whereas samples of intermediate composition have multiple magnetic transitions but a single structural phase (Appl. Phys. Lett. 99, 052503 (2011)). Muon measurements establish that the intermediate compounds show spatially separated, distinct magnetic phases – true magnetic phase separation. In addition, the two magnetic phases evolve with temperature in a way indicating that the two phases remain coupled.

12:27PM B32.00005 Atomic-resolution scanning transmission electron microscopy study of the valence state transition in (Pr$_{0.85}$Y$_{0.15}$)$_{0.75}$Ca$_{0.3}$CoO$_3$, ROBERT KLIE, AHMET GULEC, University of Illinois at Chicago, DANIEL PHELAN, CHRIS LEIGHTON, University of Minnesota — The observation of a first-order magnetic/electronic transition in certain Pr-based perovskite cobaltites, such as Pr$_{0.5}$Ca$_{0.5}$CoO$_3$, has attracted significant attention. A simultaneous metal to insulator transition, a sharp drop in the magnetic moment and a change in the electronic structure has been reported to occur below $T_{MI}$. It was suggested that the low-temperature phase is stabilized by a shift of the mixed valence Co$^{3+}$/Co$^{4+}$ toward pure Co$^{3+}$, enabled by a valence change of Pr$^{3+}$ to Pr$^{4+}$. We present an atomic-scale study of (Pr$_{1-y}$Y$_y$)$_{0.75}$Ca$_{0.3}$CoO$_3$ using atomic-resolution imaging, electron energy-loss spectroscopy and in-situ cooling experiments in a scanning transmission electron microscope. The valence state transition in (Pr$_{1-y}$Y$_y$)$_{0.75}$Ca$_{0.3}$CoO$_3$ occurs at a transition temperature $T_{MI}$ ~ 135K for $y = 0.15$ and the in-situ cooling experiments are conducted at 90 K. At room temperature, we find oxygen vacancy ordering associated with a Co valence state ordering and we will demonstrate that the electron transfer occurs from Pr to Co below the transition temperature. The oxygen vacancy ordering disappears as a result of the Co valence state transition. The effects of oxygen mobility, sample homogeneity and the impact on the observed transition will be discussed.

12:39PM B32.00006 Brownmillerite CaCoO$_{2.5}$: Synthesis, Re-entrant Structural Transitions and Magnetic properties 1 JUNJIE ZHANG, HONG ZHENG, CHIRSTOS MALLIAKAS, JARED ALLRED, YANG REN, QING'AN LI, TIAN-HENG HAN, JOHN MITCHELL, Argonne Natl Lab. — Cobalt oxides attract both fundamental and technological attention due to their physical properties including thermoelectricity, giant magnetoresistance, superconductivity and multiferroicity [1]. Here we report the first synthesis of CaCoO$_{2.5}$, single crystals using a high pressure optical-image floating zone technique. We find that it is an ordered oxygen-deficient perovskite of the brownmillerite type, and it undergoes an unprecedented re-entrant structural phase transitions (Pcmb→P2/c11→P12/1/m→Pcm) with decreasing temperature. We describe its temperature-dependent structural, thermal, and magnetic properties, including AFM ordering near 240 K, with a weakly spin canted ferromagnet ground state below 140 K. The magnetic response of CaCoO$_{2.5}$ depends markedly on the cooling rate and field history. Magnetization data also imply the potential of a distinct, field-induced phase arising uniquely from the P12/1/m structure, revealed as kinetically trapped by a rapid-cooling protocol.

12:51PM B32.00007 Neutron Scattering Study on the Spin-1/2 Triangular-Lattice Antiferromagnet Ba$_2$CoSb$_2$O$_9$. JIE MA, Oak Ridge National Laboratory, Y. KAMIYA, iTHES Research Group and Condensed Matter Theory Laboratory, RIKEN, Japan, TAO HONG, H.B. CAO, G. EHLERS, Oak Ridge National Laboratory, Z.L. DUN, University of Tennessee, Knoxville, W. TIAN, Oak Ridge National Laboratory, C.D. BATISTA, Los Alamos National Laboratory, H.D. ZHOU, University of Tennessee, Knoxville, M. MATSUDA, Los Alamos National Laboratory, OAK RIDGE NATIONAL LABORATORY TEAM, iTHES RESEARCH GROUP AND CONDENSED MATTER THEORY LABORATORY, RIKEN, JAPAN COLLABORATION, UNIVERSITY OF TENNESSEE, KNOXVILLE COLLABORATION, LOS ALAMOS NATIONAL LABORATORY COLLABORATION — Ba$_2$CoSb$_2$O$_9$ is a spin-1/2 triangular-lattice antiferromagnet with uniform bond length that has attracted a lot of attention in the past decade. This compound is recognized as an ideal material to study the interplay between frustration, low-dimensionality, and strong quantum fluctuations. Both neutron diffraction and inelastic neutron scattering measurements were performed on Ba$_2$CoSb$_2$O$_9$ by obtaining the neutron scattering technique. According to our unpolarized and polarized neutron diffraction measurements, the Co$^{2+}$ magnetic moments form a 120 degree structure in the easy ab-plane. The intra- and inter-plane exchange interactions were determined by fitting the measured spin-wave dispersion with an S=1/2 XXZ model.

1:03PM B32.00008 Anisotropic dispersion of charge stripe fluctuations in La$_{1.75}$Sr$_{0.25}$NiO$_4$. JOHN TRANQUADA, RUIDIAN ZHONG, GENDA GU, Brookhaven Natl Lab, DMITRY REZNIK, U. Colorado, BARRY WINN, ORNL — It has recently been demonstrated that charge stripe fluctuations can be detected in La$_2$Sr$_2$NiO$_6$ by inelastic neutron scattering at temperatures close to the charge-ordering transition [1]. The next step is to characterize the dispersion of these excitations. To do this, we have studied a crystal with $x = 0.25$ using the HYSPEC instrument at the Spallation Neutron Source. The clearest picture has been obtained at a temperature of 160 K, where spin order is absent while the charge order is weak but finite. The effective observation window is limited to $E < 8$ meV, as acoustic phonons dispersing from neighboring Bragg peaks obscure the weak signal of interest at higher energies. Measuring about the charge-order peak at wave vector (4.4,3,0), where $q* = 1.150$ Å$^{-1}$, we observe a dispersion with a velocity of ~ 20 meVÅ along the stripe-modulation direction, but no clear dispersion in the orthogonal direction. The detected velocity has the scale of lattice, rather than purely electronic, excitations.

1:15PM B32.00009 ABSTRACT WITHDRAWN —
11:27PM B32.00010 Low-energy description of rare-earth nickelates. OLEG PEIL, University of Geneva, ALASKA
SUBEDI, Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, ANTOINE GEORGES, College de France, Paris — We propose a simple low-energy theory of rare-earth nickelates that involves only two \( e_g \) orbitals per nickel site. We show that this theory, in particular, captures all important features of the metal-insulator transition of nickelates. In the monoclinic insulating state, bond-length disproportionation splits the manifold of \( e_g \) bands, leading to a modulation of the effective on-site energy. We show that, when subject to a local Coulomb repulsion \( U \) and Hund’s coupling \( J \), the resulting bond-disproportionated state is a paramagnetic insulator for a wide range of interaction parameters. Furthermore, we find that when \( U - 3J \) is small or negative, a spontaneous instability to bond disproportionation takes place for large enough \( J \). In the metallic phase, on the other hand, this negative effective coupling results in the suppression of the orbital polarization of \( e_g \) states, consistent with experiments and earlier calculations. This minimal theory emphasizes that a small or negative charge-transfer energy, a large Hund’s coupling, and a strong coupling to bond-disproportionation are the key factors determining the physics of nickelates. Finally, we discuss particular experimental consequences of this theoretical picture.

11:39PM B32.00011 Exchange and Magnetic Anisotropic Interactions of Magnetic Ions in Antiferromagnetic Materials, \( \text{Nd}_4\text{CuO}_4 \), ALEXANDER BAZHAN, P.L.Kapitza Institute for Physical Problems, RAS, Kosygin str, 2, Moscow, Russia — Investigations of magnetic ions interactions, based on theory of crystallographic and magnetic symmetry, which indicate quadratic forms of thermodynamic potentials, presented in irreducible representations of interacting magnetic moments, described by antiferromagnetic and magnetic vectors, which determine antiferromagnetic orderings, are caring out using vector v.s.magnetometer, in example, of non collinear antiferromagnetic orderings of four \( \text{Cu} \) ions in magnetic unit cells in \( \text{Nd}_4\text{CuO}_4 \) of tetragonal symmetry, applying in HTS. Magnetic field dependencies of three separate components of samples magnetic moments directly indicate magnetic moments orientations, determined by magnetic ions interactions. Transformations of non collinear antiferromagnetic orderings of \( \text{Cu} \) ions in magnetic fields \( H_0 \sim 42kOe \) and \( H_2 \sim 8.4kOe \), at fields orientations along \([100]\) and \([110]\) axis, \( T \sim 1.8K \), which are discussing using representations, determined by two antiferromagnetic vectors in equations of magnetic states, can be used in investigations, when two dimensional correlated electrons systems are introduced in such materials, before HTS.

2:03PM B32.00013 ABSTRACT MOVED TO W32.00006 —

Monday, March 2, 2015 11:15AM - 1:27PM — Session B33 GPC: Focus Session: The Physics of Climate

11:15AM B33.00001 A Test for Periodic and Quasi-Periodic Fluctuations in Past Climate Change Data, JAMES OTTO, JAMES ROBERTS, University of North Texas — In this work the temperature fluctuations for a number of proxy data sets were analyzed to test for periodic and quasi-periodic fluctuations in climate changes in the past. The data sets analyzed identify temperature functions which could be modeled using amplitude and frequency modulated sinusoidal waves. Data for the past 2000 years were tested and they show select periods of 11 years, 100 years, 300 years and 600 years. Longer term data (million years) indicate periods of 21000 and 41000 years as predicted by Milankovitch.

11:27AM B33.00002 Nonlinear/Non-Gaussian Data Assimilation\(^1\), JUAN RESTREPO, Department of Mathematics, Oregon State University — Data and models, with their inherent uncertainties and errors, are blended within a Bayesian framework with the aim of improving estimates of dynamic processes. This process, called data assimilation, is said to be responsible for significantly better weather/climate forecasts. Nonlinear/non-Gaussian processes, however, pose special conceptual and computational challenges. In the context of generic transport problems of importance in climate and weather a strategy which I have been investigated involves adding physically based constraints, leading to smaller but higher quality ensembles with which to produce estimates. I will describe some of the tradeoffs and their implications on filtering and forecasting.

\(^1\)Supported by NSF and BP/GoMRI

11:39AM B33.00003 The Role of Radiation in Organizing Tropical Convection\(^1\), SHARON SESSIONS, STIPO SENTIC, MICHAEL HERMAN, DAVID RAYMOND, New Mexico Institute of Mining and Technology — Convective organization regulates the radiation emitted to space, and therefore is important for the global heat budget. Organized convection—regions of intense convection surrounded by large cloud-free regions—permit more longwave radiation to escape and therefore may constitute a net cooling effect, while more scattered convection promotes greenhouse warming. Models which simulate the spontaneous organization of deep tropical convection—self-aggregation—suggest that radiative cooling in response to water vapor content is essential for convection to spontaneously organize. Multiple equilibria—steady states which maintain persistent precipitating convection or are completely dry—in small domains with weak temperature gradients (WTG) are analogous to dry and moist regions in large scale simulations of convective self aggregation. We explore the role of radiative cooling in multiple equilibria. Interactive radiative cooling suppresses convection in the dry state and it permits multiple equilibria over a larger parameter range. However, multiple equilibria still exist with fixed radiative cooling. This suggests that while interactive radiation is conducive for organizing convection, it is not essential. This study elucidates radiation’s role in convective organization.

11:51AM B33.00004 Thermodynamics of Hurricanes, KERRY EMANUEL, MIT — No abstract available.
12:27PM B33.00005 Stratified shear flow instability: Application to oceanic overflows, ROBERT ECKE, Los Alamos National Laboratory, PHILIPPE ODIER, Ecole Normale Superieure Lyon — The Earth’s thermohaline circulation provides major oceanic transport of heat and salinity and is an important determining factor in the climate of nearby land areas. We address the stability of overflow currents of heavier water moving into a region of less heavy quiescent fluid using experimental measurement of wall bounded stratified boundary currents under controlled laboratory conditions. In these currents, the stratification acts to stabilize the flow whereas the shear associated with the moving current produces turbulent kinetic energy fluctuations. We derive an expression for the potential for dissipation of these fluctuations. Our experimental measurements using particle-image velocimetry and laser-induced fluorescence allow the simultaneous acquisition of velocity and density fields, respectively. Rather than using traditional time-averaged statistics, we consider the stability of unperturbed sections of the interface and use a measure of the overturning or mixing called the Thorpe length. We present evidence for universal behavior in the normalized Thorpe length probability distribution and the general properties of the system under increasingly stable conditions. We relate these properties to realistic circumstances in the ocean.

12:39PM B33.00006 Eliminating Major Tornadoes in Tornado Alley, R. TAO, Temple Univ — In my recent paper, I propose that major tornadoes in Tornado Alley can be eliminated by building east-west ranged walls, 300 meter high and 50 meter wide. The work has received much attention, but some meteorologists are against the idea, claiming that the major tornadoes in Tornado Alley are not related to the collisions between northbound warm air flow and southbound cold air flow because supercells are not at the collision front. In this talk, we will show that wind tunnel experiments and airplane wing tip vortices clearly demonstrate that vortices produced by air mass collisions are usually not at the collision front because of the extremely volatile condition over there; they are either near the ends or at sides of the collision fronts. When the warm and moist wind collides with the cold wind violently in Tornado Alley, similarly, the supercell storms cannot be right at the collision fronts, but are near the ends or at sides of the collision fronts. While only a small portion of vortices in the warm air side may have a chance to develop into tornadoes, the major tornadoes in Tornado Alley indeed start from the air mass clashes. If we can weaken such violent air mass collisions, we will eliminate the major tornadoes in Tornado Alley.

12:51PM B33.00007 Random Focusing of Tsunami Waves, HENRI-PHILIPPE DEGUELDER, JAKOB J. METZGER, RAGNAR FLEISCHMANN, THEO GEISEL, Max Planck Institute for Dynamics and Self-Organization, Goettingen — When waves propagate through a weakly scattering, correlated random medium, the consecutive effects of small focusing events give rise to the phenomenon called branched flow, producing patterns of high-energy fluctuations. These structures can be found in the depth profile of the ocean floor, we investigate how it affects tsunami propagation and derive the typical length scale on which the highest waves are to be expected. We show that as a consequence of this effect the inaccuracies in the current knowledge of the ocean floor topography can prevent reliable tsunami forecasts on medium to large length scales.

1:03PM B33.00008 Energy Dissipation when Internal Wave Beams Reflect from a Slope, BRUCE RODENBORN, Centre College, DANIEL KIEFER, Center for Nonlinear Dynamics, University of Texas at Austin, HEPENG ZHANG, Jiao Tung University, HARRY L. SWINNEY, Center for Nonlinear Dynamics, University of Texas at Austin — Internal wave reflection from a uniform sloping boundary is often analyzed using linear or a weakly nonlinear inviscid theory. Under these assumptions for a linearly stratified fluid, Thorpe and Tabaei et al. derived predictions for the boundary angle where second harmonic generation should be most intense. We previously conducted experiments and simulations that found that the angle that maximizes second harmonic generation is given instead by an empirical geometric relationship between the wave beam and boundary angle. In the previous study, we used integrated kinetic energy as a measure of beam intensity. We compare these results with a method using energy flux. We also study the energy flux into and out of a surface above the reflection region $E_{\text{out}}/E_{\text{in}}$ and find high rates of energy dissipation $O(90\%)$. The rates remain high even for weakly nonlinear wave beams and with the viscosity reduced by an order of magnitude.

1:15PM B33.00009 Lamination in Atmospheric Ozone: A Diagnostic for Tracer Transport Mechanisms, KENNETH MINSCHWANER, Department of Physics, New Mexico Institute of Mining and Technology, GLORIA MANNEY, NorthWest Research Associates, LUIS TORRES, Department of Physics, New Mexico Institute of Mining and Technology — An understanding of ozone variability in the upper troposphere (from ~5 km altitude up to the tropopause level) is critical to assessing the radiative forcing of climate by ozone, and for evaluating the impact of transport on regional air quality. Part of this variability arises in fine-layered (~0.2 to ~2 km) structures seen in vertical profile measurements of ozone. These laminae are also generally limited on horizontal scales (10’s to 100’s of km), leading to spatial ozone variability observed on quasi-horizontal coordinate surfaces. Given the relatively long photochemical time constants for ozone in the upper troposphere, most of the observed variability arises from transport rather than photochemistry. There are a wide range of dynamical processes that can generate ozone laminae in the upper troposphere, such as gravity and Rossby waves, convective lofting and detrainment of either high or low ozone amounts from the boundary layer, and intrusions of air masses with high ozone concentrations from the stratosphere. Here, we examine the range of observed laminae characteristics and describe methods for tracing the origins of tropospheric ozone laminae.

Monday, March 2, 2015 11:15AM - 1:27PM – Session B34 GERA: Electrochemical Reactions 210A -
**11:15AM B34.00001 Modeling the Voltage Dependence of Electrochemical Reactions at Solid-Solid and Solid-Liquid Interfaces in Batteries**, KEVIN LEUNG, Sandia National Laboratories — Electrochemical reactions at electrode/electrolyte interfaces are critically dependent on the total electrochemical potential or voltage. In this presentation, we briefly review ab initio molecular dynamics (AIMD)-based estimate of voltages on graphite basal and edge planes [1], and then apply similar concepts to solid-solid interfaces relevant to lithium ion and Li-air batteries. Thin solid films on electrode surfaces, whether naturally occurring during power cycling (e.g., undesirable lithium carbonate on Li-air cathodes) or are artificially introduced, can undergo electrochemical reactions as the applied voltage varies. Here the onset of oxidation of lithium carbonate and other oxide thin films on model gold electrode surfaces is correlated with the electronic structure in the presence/absence of solvent molecules. Our predictions help determine whether oxidation first occurs at the electrode-thin film or electrolyte-thin film interface. Finally, we will critically compare the voltage estimate methodology used in the fuel cell community [2] with the lithium cohesive energy calibration method broadly applied in the battery community, and discuss why they may yield different predictions.

Our results supported by Nanostructures for Electrical Energy Storage (NEES), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DESC0001160. Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

**11:51AM B34.00002 Carbon composites with metal nanoparticles for Alcohol fuel cells**, LAKSHMAN VENTRAPRAGADA, Clemson University, R.S. SIDDHARDHA, Sri Sathy Sai Institute of Higher Learning, RAMAKRISHNA PODILLA, Clemson University, V.S. MUTHUKUMAR, Sri Sathy Sai Institute of Higher Learning, STEPHEN CREAGER, A.M. RAO, Clemson University, SAI SATHISH RAMA-MURTHY, Sri Sathy Sai Institute of Higher Learning — Graphene due to its high surface area and superior conductivity has attracted wide attention from both industrial and scientific communities. We chose graphene as a substrate for metal nanoparticle deposition for fuel cell applications. There are many chemical routes for fabrication of metal-graphene composites, but they have an inherent disadvantage of low performance due to the usage of surfactants, that adsorb on their surface. Here we present a design for one pot synthesis of gold nanoparticles and simultaneous deposition on graphene with laser ablation of gold strip and functionalized graphene. In this process there are two natural advantages, the nanoparticles are synthesized without any surfactants, therefore they are pristine and subsequent impregnation on graphene is linker free. These materials are well characterized with electron microscopy to find their morphology and spectroscopic techniques like Raman, UV-Vis. for functionality. This gold nanoparticle decorated graphene composite has been tested for its electrocatalytic oxidation of alcohols for alkaline fuel cell applications. An electrode made of this composite showed good stability for more than 200 cycles of operation and reported a low onset potential of 100 mV more negative, an important factor for direct ethanol fuel cells.

This work was supported by Nanostructures for Electrical Energy Storage (NEES), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences. Our results provide insight into metal ion storage mechanisms on two-dimensional materials and also suggest a route to preparing bare MXene nanosheets. Moreover, stable multilayer adsorption is predicted for Mg and Al, which significantly increases their theoretical capacities. High capacities and good rate capabilities, while bare MXenes show better performance. Our experiments clearly demonstrate the feasibility of Na- and K-ion intercalation into terminated MXenes. Moreover, stable multilayer adsorption is predicted for Mg and Al, which significantly increases their theoretical capacities. Our results provide insight into metal ion storage mechanisms on two-dimensional materials and also suggest a route to preparing bare MXene nanosheets.

**12:03PM B34.00003 Prediction and Characterization of MXenes for non-lithium ion battery anodes**, PAUL KENT, YU XIE, HOULONG ZHUANG, Oak Ridge National Lab, YOHAN DALL’AGNESE, Université Paul Sabatier, Toulouse, France, MICHAEL NAGUIB, Oak Ridge National Lab, MICHEL BARSOUIM, YURY GOGOTSI, Drexel University — Rechargeable non-lithium-ion (Na+, K+, Mg2+, Ca2+, and Al3+) batteries have attracted great attention as emerging low-cost and high energy-density technologies for energy storage applications. However, their development is hindered by the limited performance of high choice of MXene electrode materials. Building on our previous work for lithium-ion applications, here we show that MXene nanosheets, a class of two-dimensional transition-metal carbides, may serve as high-performing anodes for non-lithium-ion batteries by combined first-principles simulations and experimental measurements. Both O-terminated and bare MXenes are shown to be promising anode materials with high capacities and good rate capabilities, while bare MXenes show better performance. Our experiments clearly demonstrate the feasibility of Na- and K-ion intercalation into terminated MXenes. Moreover, stable multilayer adsorption is predicted for Mg and Al, which significantly increases their theoretical capacities. Our results provide insight into metal ion storage mechanisms on two-dimensional materials and also suggest a route to preparing bare MXene nanosheets.

**12:15PM B34.00004 Positive lithiation potential on functionalized Graphene sheets**, RAJIV KUMAR CHOUGHAN, PUSHPA RAGHANI, Boise State University, Boise, ID 83725, USA — Designing lithium batteries with high capacities is major challenge in the field of energy storage. As an alternative to the conventional graphitic anode with a capacity of ~372 mAh g⁻¹, we look at the adsorption of lithium on 2D graphene oxide (GO) sheets. We have included van-der-waals’s interaction in our calculation and compared with literature showing its importance in Li binding on Graphene sheets. In comparison to the negative lithiation potential in pristine graphene sheets, we were able to get positive lithiation potential by introducing functional groups such as epoxy(-O-) and hydroxy(-OH) on graphene. Also the non-stoichiometric nature of GO provides better potential to increase the lithiation potential in compare to the defects induced graphene 2D sheet. Dramatic charge redistribution within the sheet due to presence of highly electronegative oxygen plays an important role in increasing the capacity.

This work was supported as part of the Fluid Interface Reactions, Structures and Transport (FIRST) Center, an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Office of Basic Energy Sciences.

**12:27PM B34.00005 Simulating Electric Double Layer Capacitance by Using Lattice Boltzmann Method**, NING SUN, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University, Stony Brook, NY, 11794, USA — By using the Lattice Boltzmann Method (LBM) we studied diffuse-charge dynamics in electrochemical systems. We use the LBM to solve Poisson-Nernst-Planck equations (PNP) and Modified Poisson-Nernst-Planck equations (MPNP). The isotropic permittivity of electrolyte is modeled using the Booth field. The results show that both steric effect (MPNP) and isotropic permittivity (Booth model) can have large influence on diffuse-charge dynamics, especially when electrolyte concentration or applied potential is high. This model can be applied to simulate electric double layer capacitance of super capacitors with complex geometry and also incorporate other effects such as heat convection in a modular manner.

1:03PM B34.00008 Role of site-disorder in energy materials: case of Li$_x$Nb$_2$O$_5$ pseudocapacitor and $\beta$-Li$_3$PS$_4$ solid electrolyte$^\dagger$. P. GANESH, ANDREW A. LUBIMTSEV, GOPI K.P. DATHAR, JONATHAN ANCHELL, PAUL R.C. KENT, ADAM J. RONDIÈRE, BOBBY G. SIMPTER, Center for Nanophase Materials Science. Oak Ridge National Laboratory — In this study, we will present computational studies to elucidate the importance of site-disorder in energy materials. We will specifically focus on two recently discovered materials: a Li-ion intercalation pseudocapacitor Li$_x$Nb$_2$O$_5$ (Nature Materials, 12 518 (2013)) and a Li-ion solid-electrolyte. ($\textit{JACS}$, 135 975 (2013)). A combination of theoretical methods, such as density functional theory (DFT) based cluster-expansion, basin hopping, ab initio molecular dynamics, and nudged-elastic-bands calculations were employed to understand the origin of intercalation pseudocapacitance in the niobate-system. ($\textit{J. Materials Chem.}$ 114951 (2013)). It was found that having multiple sites with similar energies for ion-adsorption, lead to a site-occupancy disorder that eventually lead to a capacitative slope in the voltage profile over the entire range of ion intercalation, as seen in experiments. A similar site-occupancy induced sublattice melting in the $\beta$-Li$_3$PS$_4$ solid-electrolyte, which when “frozen” to RT, lead to high Li-ion conductivity. (G.K.P.Dathar et al, submitted (2014)). Further, we will elucidate how to take advantage of this control over site-disorder to better engineer improved energy materials for batteries and fuel-cells.

1:15PM B34.00009 Al-Air Batteries: Fundamental Thermodynamic Limitations from First Principles Theory$^\dagger$, LEANNE D. CHEN, JENS K. NOERSKOV, ALAN C. LUNTZ, SUNCAT Center for Interface Science and Catalysis, SLAC National Accelerator Laboratory/Stanford University — The Al-air battery possesses high theoretical specific energy (4140 Wh/kg) and is therefore an attractive candidate for vehicle propulsion applications. However, the experimentally observed open-circuit potential is much lower than what thermodynamics predicts, and this potential loss is widely believed to be an effect of corrosion. We present a detailed study of the Al-air battery using density functional theory. The results suggest that the difference between bulk thermodynamic and surface potentials is due to both the effects of asymmetry in multi-electron transfer reactions that define the anodic dissolution of Al and, more importantly, a large chemical step inherent to the formation of bulk Al(OH)$_3$ from surface intermediates. The former results in an energy loss of 3%, while the latter accounts for 14—29% of the total thermodynamic energy depending on the surface site where dissolution occurs. Therefore, the maximum open-circuit potential of the Al anode is only $\approx 1.87$ V vs. SHE in the absence of thermal excitations, contrary to $\approx 2.34$ V predicted by bulk thermodynamics at pH 14.6. This is a fundamental limitation of the system and governs the maximum output potential, which cannot be improved even if corrosion effects were completely suppressed.

Monday, March 2, 2015 11:15AM - 2:15PM – Session B35 DAMOP: Circuit QED, Optomechanics and Hybrid Systems 210B -

11:15AM B35.00001 Experimental Study of Short-time Brownian Motion, JIANYONG MO, AKARSH SIMHA, DAVID RIEGLER, MARK RAIZEN, The University of Texas at Austin — We report our progress on the study of short-time Brownian motion of optically-trapped microwaves. In earlier work, we observed the instantaneous velocity of microwaves in gas and in liquid, verifying a prediction by Albert Einstein from 1907. We now report a more accurate test of the energy equipartition theorem for a particle in liquid. We also observe boundary effects on Brownian motion in liquid by setting a wall near the trapped particle, which changes the dynamics of the motion. We find that the velocity autocorrelation of the particle decreases faster as the particle gets closer to the wall.

11:27AM B35.00002 Loading an Optical Trap with Diamond Nanocrystals Containing Nitrogen-Vacancy Centers from a Surface, JEN-FENG HSU, PENG JI, M. V. GURUDEV DUTT, BRIAN R. D’URSO, Univ of Pittsburgh — We present a simple and effective method of loading particles into an optical trap. Our primary application of this method is loading photoluminescent material, such as diamond nanocrystals containing nitrogen-vacancy (NV) centers, for coupling the mechanical motion of the trapped crystal with the spin of the NV centers. Highly absorptive material at the trapping laser frequency, such as tartrazine dye, is used as media to attach nanodiamonds and burn into a cloud of air-borne particles as the material is swept near the trapping laser focus on a glass slide. Particles are then trapped with the laser used for burning or transferred to a second laser trap at a different wavelength. Evidence of successful loading diamond nanocrystals into the trap presented includes high sensitivity of the photoluminescence (PL) to the excitation laser and the PL spectra of the optically trapped particles.

11:39AM B35.00003 Investigations of a voltage-biased microwave cavity for quantum measurements of nanomechanical resonators$^1$, FRANCISCO ROUXINOL, HUGO HAO, MATT LAHAYE, Syracuse Univ — Quantum electromagnetic systems incorporating superconducting qubits have received extensive interest in recent years due to their promising prospects for studying fundamental topics of quantum mechanics such as quantum measurement, entanglement and decoherence in new macroscopic limits, also for their potential as elements in technological applications in quantum information network and weak force detector, to name a few. In this presentation we will discuss our efforts toward to devise an electromechanical circuit to strongly couple a nanomechanical resonator to a superconductor qubit, where a high voltage dc-bias is required, to study quantum behavior of a mechanical resonator. Preliminary results of our latest generation of devices integrating a superconductor qubit into a high-Q voltage biased microwave cavities are presented. Developments in the circuit design to couple a mechanical resonator to a qubit in the high-Q voltage bias CPW cavity is discussed as well prospects of achieving single-phonon measurement resolution.

$^1$National Science Foundation under Grant No. DMR-1056423 and Grant No. DMR-1312421

11:51AM B35.00004 A broadband reflective filter for applying dc biases to high-Q superconducting microwave cavities$^1$, YU HAO, FRANCISCO ROUXINOL, MATT LAHAYE, Syracuse Univ — The integration of dc-bias circuitry into low-loss microwave cavities is an important technical issue for topics in many fields that include research with qubit- and cavity-coupled mechanical system, circuit QED and quantum dynamics of nonlinear systems. The applied potentials or currents serve a variety of functions such as maintaining the operating state of device or establishing tunable electrostatic interactions between devices (for example, in order to couple a nanomechanical resonator to a superconducting qubit to generate and detect quantum states of a mechanical resonator). Here we report a bias-circuit design that utilizes a broadband reflective filter to connect to a high-Q superconducting coplanar waveguide (CPW) cavity. Our design allows us to apply dc-voltages to the center trace of CPW, with negligible changes in loaded quality factors of the fundamental mode. Simulations and measurements of the filter demonstrate insertion loss greater than 20 dB in the range of 3 to 10 GHz. Transmission measurements of the voltage-biased CPW show that loaded quality factors exceeding $10^5$ can be achieved for dc-voltages as high as $V=\pm 20$V for the cavity operated in the single photon regime.

$^1$National Science Foundation under Grant No. DMR-1056423 and Grant No. DMR-1312421
12:03PM B35.00005 Superconducting Coplanar Waveguide Resonators For A Hybrid Rydberg Atom-Superconductor Interface. MATTHEW BECK, JONATHAN PRITCHARD, JOSHUA ISAACS, MARK SAFFMAN, ROBERT MCDERMOTT, University of Wisconsin, Madison — Superconducting qubits achieve fast gate times (∼1 ns); however, coherence times are relatively short (∼10 μs). In contrast, atomic qubits based on Rydberg atoms achieve long coherence times of order 1 s, but are limited by slow gate times (∼1 μs). Combining these disparate technologies in a hybrid quantum processor would provide both a long-lived memory and the ability to run computations quickly. Here we describe the design, fabrication, and characterization of superconducting coplanar waveguide resonators optimized to achieve strong coupling between the resonator mode and a single trapped Cs Rydberg atom. We discuss the dependence of resonator quality factor and coupling strength on device geometry and describe the integration of superconducting thin-film processing with MEMS-style thick film fabrication in order to increase the spatial extent of the resonator’s electric field.

12:15PM B35.00006 Microwave frequency electromagnetic coupling to a thin membrane at one end of a cylindrical cavity. ALESSANDRO CASTELLI, LUIS MARTINEZ, Univ of California - Merced, JERRY SPEER, None, JAY SHARPING, RAYMOND CHIAO. Univ of California - Merced — We demonstrate coupling of an 11.1 GHz radio frequency (RF) TE011 cylindrical cavity mode to the mechanical motion of a silicon nitride (Si3N4) membrane. The membrane is driven into motion through radiation pressure forces arising from the transverse magnetic field present at the membrane boundary. We use a cylindrical aluminum cavity where one end consists of a 500-nm thick Si3N4 membrane that has been sputtered with 300 nm of niobium (Nb). Cavity frequency tuning is controlled via an aluminum plunger attached to a micrometer at the other end of the cavity. The membrane is driven into motion by modulating the amplitude of the RF signal at the membrane’s resonant frequency in the KHz range. The membrane’s displacement is measured by means of a Michelson interferometer. We compare results from experimental runs utilizing both square and circular membrane geometries. This experiment shows that the TE011 mode gives rise to radiation pressure on the ends of a cylindrical cavity and demonstrates the feasibility of future work using high Q superconducting RF cavities to realize a dynamical Casimir effect (DCE) due to the membrane’s motion at GHz frequencies.

12:27PM B35.00007 Motional sideband asymmetry in a quantum electro-mechanical device. AARON WEINSTEIN, CHAN U LEI, EMMA WOLLMAN, Caltech. JUNHO SUH, KRISS, ANJA METELMANN, AASH CLERK, McGill University, KEITH SCHWAB, Caltech — Quantum electro-mechanical systems offer a unique opportunity to probe quantum noise properties in macroscopic devices, properties which ultimately stem from Heisenberg’s uncertainty relations. A simple example of this is expected to occur in a microwave parametric transducer, where mechanical motion generates motional sidebands corresponding to the up and down frequency-conversion of microwave photons. Due to quantum vacuum noise, the rates of these processes are expected to be unequal. We measure this fundamental imbalance in a microwave transducer coupled to a radio-frequency mechanical mode, cooled near the ground state of motion. We also discuss the subtle origin of this imbalance: with linear detection of the output light field, the imbalance is most naturally attributed to the quantum fluctuations of the electromagnetic field.

12:39PM B35.00008 Tailoring the flow of light and sound in an optomechanical array. MICHAEL SCHMIDT, VITTORIO PEANO, FLORIAN MARQUARDT, University of Erlangen-Nuernberg — Recent progress in the field of optomechanics may soon allow the realization of optomechanical arrays, i.e. periodic arrangements of optical and vibrational modes whose interaction can be tuned in-situ by a laser. The most promising implementation is based on a simple setting, a dielectric slab with a suitable pattern of holes. The flow of light and sound in such a device could be tailored by engineering the laser wavefront, e.g. creating effective potential landscapes, tuning the phonon hopping range, or creating artificial gauge fields. We show that photons and phonons on a honeycomb lattice will produce an optically tunable Dirac-type band structure. Transport in such a system can exhibit transmission through an optically created barrier, similar to Klein tunneling, but with interconversion between light and sound.

12:51PM B35.00009 Testing Time Reversal Symmetry in Artificial Atoms. FREDERICO BRITO, Unio de Sao Paulo, FRANCISCO ROUXINOL, MATTHIEU LAHAYE, Syracuse University, AMIR CALDEIRA, Universidade Estadual de Campinas — Over the past several decades, a rich series of experiments has repeatedly verified the quantum nature of superconducting devices, leading some of these systems to be regarded as artificial atoms. In addition to their application in quantum information processing, these “atoms” provide a test bed for studying quantum mechanics in macroscopic limits. Regarding the last point, we present here a feasible protocol for directly testing time reversal symmetry in a superconducting artificial atom. Time reversal symmetry is a fundamental property of quantum mechanics and is expected to hold if the dynamics of the artificial atom strictly follow the Schrödinger equation. However, this property has yet to be tested in any macroscopic quantum system. The test we propose is based on the verification of the microreversibility principle, providing a viable approach to verify quantum work fluctuation theorems - an outstanding challenge in quantum statistical mechanics. For this, we outline a procedure that utilizes the microreversibility test in conjunction with numerical emulations of Gibbs ensembles to verify these theorems over a large temperature range.

1:03PM B35.00010 Theory of on-chip integrated microwave-to-optical quantum coherent converter. CLEMENT JAVERZAC-GALY, KIRILL PLEKHANOV, LASZLO TOTH, ALEXEY FEOFANOVI, TOBIAS J. KIPPPENBERG, Ecole Polytechnique Federale de Lausanne — We present a proposal for implementing a direct quantum electro-optical converter based on a nonlinear optical microresonator. The hybrid system combines planar superconducting microwave circuits and integrated nonlinear ultrahigh-Q crystalline whispering gallery mode (WGM) optical microresonator. It features low footprint and scalability. The electro-optical dynamics of the device is similar to that of a cavity quantum optomechanical system and Pockels effect is used as the coupling interaction. We simulate the system and show that high-conversion performance can be achieved with current technology. On-chip, such integrated device holds promise for use in large-scale quantum applications as a first direct microwave-to-optical quantum repeater.

1:15PM B35.00011 Ultrahigh Q Bulk Acoustic Wave Cavities at the Quantum Limit. MICHAEL TOBAR, MAXIM GORYACHEV, EUGENE IVANOV, FRANK VAN KANN, The University of Western Australia, SERGE GALLIOU, FEMTO-ST — A Fabry-Perot cavity is an optical resonator, which can store photons for milliseconds and enhance interaction between light and matter. The acoustics analogue (phonon trapping), is the Bulk Acoustic Wave device (in thin film or crystal lattice). Measurements provide the ultimate material loss regimes, minimizing clamping losses and achieving record high Q products [1], allowing observation of various loss mechanisms such as Landau-Rumer, phonon-phonon dissipation and Rayleigh phonon scattering, as well as previously non-observed non-linear effects [2]. This presentation will summarize our recent work towards cooling such modes to the ground state and operating the device at the Quantum Limit [3]. This includes the first measurements of the Nyquist noise near at 4K [4], as well as details on using such devices to test fundamental physics [5]. [1] M Goryachev etal, Observation of rayleigh phonon scattering through excitation of extremely high overtones in low-loss cryogenic acoustic cavities for hybrid quantum systems, PRL, 111 085502 2013 [2] M Goryachev etal, Jump chaotic behaviour of ultra low loss bulk acoustic wave cavities, APL 105 063501 2014 [3] M Goryachev etal, Effects of geometry on quantum fluctuations of phonon-trapping acoustic cavities, NJP 16 063007 2014 [4] M Goryachev etal, Observation of the Fundamental Nyquist Noise Limit in an Ultra-High Q-Factor Cryogenic Bulk Acoustic Wave Cavity, APL 105 153505 2014 [5] M Goryachev etal, Gravitational wave detection with high frequency phonon trapping acoustic cavities, PRD 2014

1 Funded by ARC Grant No. CE110001013.
1:27PM B35.00012 Coherent coupling between ferromagnetic magnon and superconducting qubit. YUTAKA TABUCHI, SEICHIRO ISHINO, ATSUSHI NOGUCHI, TOYOICHI ISHIKAWA, REKISHU YAMAZAKI, KOJI USAMI, RCAST, The University of Tokyo, YASUNOBU NAKAMURA, RCAST, The University of Tokyo, CEMS, RIKEN — Coherent coupling between paramagnetic spin ensembles and superconducting quantum circuits is now widely studied for quantum memories and microwave-to-optical quantum transducers. Since those applications require strong coupling and sufficiently long coherence time simultaneously, collective excitation (magnon) in yttrium iron garnet (YIG), a typical ferromagnetic insulator, is an alternative promising candidate. The material is known to have a high spin density and a narrow ferromagnetic-resonance (FMR) linewidth. Recently, we achieved strong coupling between a 3D microwave cavity and the uniformly precessing spin mode. In this talk, we step forward to the control and measurement of magnons using superconducting circuits. We demonstrate coherent coupling between a magnon excitation in a millimeter-sized ferromagnetic sphere and a superconducting qubit, in which the interaction is mediated by a microwave cavity. We observe the coupling strength exceeding the damping rates, revealing that the system is in the strong coupling regime. Furthermore, we study a tunable coupling scheme using a microwave drive and the time-domain control of magnons. Our approach provides a versatile tool for control and measurement of the magnon excitations in the quantum regime.

1:39PM B35.00013 Novel techniques for strong coupling between spin ensembles and cavity resonators. DANIEL CREEDON, MAXIM GORYACHEV, WARRICK FARR, JEAN-MICHEL LE FLOCH, YAOHUI FAN, NATÁLIA CARVALHO, MICHAEL TOBAR, ARC Centre of Excellence for Engineered Quantum Systems, University of Western Australia, MIKHAIL KOSTYLEV, Magnetisation Dynamics and Spintronics Group, School of Physics, University of Western Australia, STEFANIA CASTELLETTO, ARC Centre of Excellence for Engineered Quantum Systems, RMIT University, Melbourne, PAVEL BUSHEV, Universität des Saarlandes, Saarbrücken, Germany — Spins in solids are a promising physical subsystem for the realization of hybrid quantum systems. We focus on experiments coupling spins to three dimensional cavities, a system where it is critical to achieve operation in the strong coupling regime. This has been achieved using two approaches: coupling to impurity ions in single-crystal Whispering Gallery photonic resonators, and by using a novel field focusing re-entrant cavity. The first approach has allowed us to investigate various impurities in sapphire, quartz, and YAG, as well as iron group ions in YSO. This method is characterised by relatively narrow photon linewidths, higher filling factors and lower impurity concentration. The second approach allowed strong coupling to P1 impurities in diamond and operation in the ultra-strong coupling regime with magnons in YIG. This method is designed to achieve spatial separation of the cavity magnetic and electric fields, relatively high filling factors with sub-mm crystals of any shape and a high concentration of magnetic ions, as well as arbitrary engineering of the cavity spectrum and field distribution.

2:03PM B35.00015 High-frequency and multi-mode operation of substrate-free micromembrane resonator. SUNGWAN CHO, Korea Research Institute of Standards and Science, MYUNG RAE CHO, Seoul National University, SANG GOON KIM, JUNHO SUH, Korea Research Institute of Standards and Science, YUN DANIEL PARK, Seoul National University, SEUNG-BO SHIM, Korea Research Institute of Standards and Science — Micromembrane mechanical resonator is fabricated from stoichiometric silicon nitride and its resonant motions are actuated with electrical field gradient pumping method. Using electrical field gradient force by electrode deposited near the suspended structure, micromembrane resonator can be actuated without electrical components on the movable component. We can drive and investigate multiple modes of micromembrane up to 32th mode with 78 MHz resonant frequency by optical measurement technique. This membrane can be applicable to optical system compatible with cavity without external driving technique.

Monday, March 2, 2015 11:15AM - 2:15PM — Session B36 DAMOP: Focus Session: Artificial Gauge Fields and Spin Orbit Coupling in Cold Atoms 211 - Martin Zwierlein, Massachusetts Institute of Technology

11:15AM B36.00001 Ultracold atoms in strong synthetic magnetic fields. WOLFGANG KETTERLE, MIT, Cambridge — The Harper Hofstadter Hamiltonian describes charged particles in the lowest band of a lattice at high magnetic fields. This Hamiltonian can be realized with ultracold atoms using laser assisted tunneling which imprints the same phase into the wavefunction of neutral atoms as a magnetic field does for electrons. I will describe our observation of a bosonic superfluid in a magnetic field with half a flux quantum per lattice unit cell, and discuss new possibilities for implementing spin-orbit coupling. Work done in collaboration with C.J. Kennedy, G.A. Siviloglou, H. Miyake, W.C. Burton, and Woo Chang Chung.

11:51AM B36.00002 Emergence of Quantum Liquid Crystals of Bosons in Kagome Lattices with Synthetic Gauge Fields. GUANYU ZHU, JENS KOCH, Northwestern University, IVAR MARTIN, Argonne National Laboratory — We consider a family of tight-binding models based on a kagome lattice with local synthetic gauge flux, which have a lowest flat band in the single particle spectrum. The flat band is spanned by eigenstates forming localized loops on the lattice, with the maximally compact loop states typically breaking the discrete rotational symmetry of the lattice. When populated by locally-interacting particles, the close packing of such maximally compact loop states leads to a nematic loop crystal ground state. If the particles are bosons, we show that mean field theory predicts that increasing filling beyond the close packing filling fraction leads to the formation of quantum liquid crystals including a nematic supersolid and a nematic superfluid phase with broken lattice rotation and \( U(1) \) symmetry.

12:03PM B36.00003 Strongly correlated atoms in artificial gauge fields. CIARÁN HICKEY, PRATIK RATH, ARUN PARAMEKANTI, Univ of Toronto — We study ultracold spinor atomic gases in an optical lattice in the presence of artificial gauge fields and a strong Hubbard repulsion. Using a combination of strong coupling approaches and novel numerical techniques, we explore exotic magnetic ground states and their thermal phase transitions induced by the interplay of momentum space topology and real space strong correlation effects.

12:15PM B36.00004 Realization of BEC on Cylindrical Surfaces with a Landau Gauge. BIAO HUANG, TIN-LUN HO, Ohio State Univ - Columbus — Landau’s famous solution of 2D electron gas on a cylindrical surface with the Landau gauge is one of the most important paradigm in condensed matter physics. Here, we point out the ways to create the Bose analog of this paradigm and discuss the property of a BEC in this setting. The synthetic “magnetic field” normal to the cylindrical surface is created through the Berry’s phase effects of bosons with hyperfine spins \( S \). As the strength of synthetic field increases, the vortex pattern on the surface undergo a sequence of transitions. These vortex patterns are very different from the triangular lattice array in rotating gases. They have dramatic signatures in time of flight measurements and can be revealed easily.

This work is supported by the NSF grant DMR-1309615, a MURI grant from ARO, and a grant from the NASA Fundamental Physics program.
12:27PM B36.00005 Synthetic magnetic fields in strained graphene-like optical lattices. BINBIN TIAN, University of Pittsburgh, MANUELE ENDRES, Max-Planck-Institut für Quantenoptik, DAVID PEKKER, University of Pittsburgh — Integer and fractional quantum hall effects are an area in which ultra cold atoms experiments could address long-standing problems of many-body physics. However there is a missing experimental ingredient: a good way to make “synthetic magnetic fields” for the neutral atoms that does not heat the atoms too quickly. Here we present a proposal for a solution by appealing to the physics of graphene. The motion of electrons in graphene is described by the Dirac equation. In the presence of strain the Dirac equation becomes modified as if there is a local magnetic field. We propose to use three laser beams to create a graphene-like optical lattice for ultra cold atoms. By mis-aligning the beams, we can encode a strain into the optical lattice and hence synthesize a uniform “magnetic” field. Using a tight binding model, we show that the synthetic magnetic field results in the formation of distinct Landau levels. These levels will persist in presence of a trap potential. The Landau levels can be detected using spectroscopic methods, like Bragg spectroscopy, or alternatively “kick” methods, like Bloch oscillations.

12:39PM B36.00006 Large Artificial Magnetic Fields Realized in a Synthetic Two-Dimensional Lattice, LAUREN AYCOCK, Joint Quantum Institute/ Cornell University/ National Institute of Standards and Technology/ University of Maryland, BEN STUHL, HSIN-I LU, DINA GENKINA, JQI/NSF/UMD, MARCELL GALL, JQI/NSF/UMD/Universitat Heidelberg, IAN SPIELMAN, JQI/NSF/UMD — We experimentally realize a large artificial magnetic field for a $^{87}$Rb Bose-Einstein condensate in a synthetic two-dimensional lattice [1]. This lattice combines a 1064nm 1D optical lattice along $\chi$ in real space while the 3 internal states of the manifold $F=1$ define a 3-site wide lattice in a second, synthetic dimension. These internal states are either RF- or Raman-coupled with a bichromatic light field allowing for tunneling in this synthetic dimension. The finite number of sites in this dimension naturally creates a hard walled potential ideal for studying edge states. The wavelength ratio between the optical lattice potential and the Raman coupling fields imprints a phase around each plaquette, creating a large, artificial magnetic field. We observe cyclotron orbits of the atoms and measure the edge state currents for opposite flux and varying group velocities. [1] A. Celi, P. Massignan, J. Ruseckas, N. Goldman, I. B. Spielman, G. Juzeliunas, and M. Lewenstein, Phys. Rev. Lett. 112, 043001 (2014)

12:51PM B36.00007 Striped Ferronematic ground states in a spin-orbit coupled spin-1 Bose gas, STEFAN NATU, XIAOPENG LI, WILLIAM COLE, University of Maryland and the Joint Quantum Institute — Motivated by recent experiments on spin-orbit coupled quantum gases, and the recent cooling to degeneracy of large spin atoms, we explore the ground state phase diagram of a spin-orbit coupled spin-1 Bose gas. A key new feature of large spin systems is the appearance of liquid crystalline order such as nematic or more exotic platicon solid order, which has no analog in solid state. Here we explore the interplay between spin order, translational symmetry breaking induced by spin-orbit coupling and these liquid crystalline order parameters in the experimentally relevant spin-1 system, finding a rich phase diagram. For repulsive spin-dependent interaction, we find a transition from a uniaxial ferronematic phase with XY spinor order but unique total density to a biaxial ferronematic phase with stripes in the total density. As a function of the quadratic Zeeman shift $\Omega$, for attractive spin dependent interactions, we find a transition from a ferromagnetic stripe phase which breaks translational symmetry in real space to a uniform ferromagnet for $\Omega>0$ and a uniform nematic phase for $\Omega<0$. We discuss the implications of our predictions to ongoing experiments on spin-orbit coupled large spin quantum gases.

1:03PM B36.00008 Spin-orbit coupled Fermi gas under sudden quench of Zeeman field, LIN DONG, Rice University, YING DONG, Hangzhou Normal University, MING GONG, The Chinese University of Hong Kong, HAN PU, Rice University — Motivated by recent efforts to achieve effective spin-orbit coupling in cold degenerate gases, we study the dynamical response of a spin-orbit coupled Fermi gas after a sudden quench of external Zeeman field. By solving the time-dependent Bogoliubov-de Gennes equation self-consistently, we have found three dynamical phases emerging from the time and the characteristic field strength, changing the above mentioned behavior of the order parameter. We further map out the phase diagram for the various dynamical states in the parameter space spanned by the initial and final values of the Zeeman field strength. In certain parameter regimes, the dynamical states possess nontrivial topological properties, manifested by the presence of the zero-energy edge state localized at a confining boundary. We present a detailed characterization of these phases.

1:15PM B36.00009 Bose-Einstein condensates with spin and orbital angular momentum coupling, KUEI SUN, CHUNLEI QU, CHUANWEI ZHANG, The University of Texas at Dallas — Spin-orbit coupling (SOC) plays a crucial role in many branches of physics. In this context, the recent experimental realization of the coupling between spin and linear momentum of ultra-cold atoms opens a completely new avenue for exploring new spin-related superfluid physics. Here we propose that another important and fundamental SOC, the coupling between spin and orbital angular momentum (SOAM), can be implemented for ultra-cold atoms using higher order Laguerre-Gaussian laser beams to induce Raman coupling between two hyperfine spin states of atoms. We study the ground state phase diagrams of SOAM coupled Bose-Einstein condensates (BECs) on a ring trap and explore their applications in gravitational force detection. We further investigate two-dimensional disk-shaped BECs with focus on the interplay between SOAM coupling, interaction, and external trapping. Our results provide the basis for further investigation of intriguing superfluid physics induced by SOAM coupling.

1:27PM B36.00010 Berezinskii-Kosterlitz-Thouless Phase Transition in 2D Spin-Orbit Coupled Fulde-Ferrell Superfluids, YONG XU, CHUANWEI ZHANG, The University of Texas at Dallas — The experimental observation of traditional Zeeman-field induced Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) superfluids has been hindered by various challenges, in particular, the requirement of low dimension systems. In 2D, it is well known that finite temperature phase fluctuations lead to extremely small Berezinskii-Kosterlitz-Thouless (BKT) transition temperature, raising serious concern regarding the observability of 2D FFLO superfluids. Recently, it was shown that FFLO superfluids can be realized using a Rasha spin-orbit coupled Fermi gas subject to Zeeman fields, which may also support topological excitations such as Majorana fermions in 2D. Here we address the finite temperature BKT transition issue in this system, which may exhibits gapped, gapless, topological, and gapless topological FF phases. We find a large BKT transition temperature due to large effective superfluid densities, making it possible to observe 2D FF superfluids at finite temperature. In addition, we show that gapless FF superfluids can be stable due to their positive superfluid densities. These findings pave the way for the experimental observation of 2D gapped and gapless FF superfluids and their associated topological excitations at finite temperature.

1:39PM B36.00011 Superfluid Breakdown and Multiple Roton Gaps in Spin-Orbit Coupled Bose-Einstein Condensates on an Optical Lattice, DANIELE TONIOLÒ, JACOB LINDER, NTNU — Based on the results of Phys. Rev. A 89, 061605(R) (2014) I discuss the superfluid phases of a Rasha spin-orbit coupled Bose-Einstein condensate residing on a two-dimensional square optical lattice in the presence of an effective Zeeman field $\Omega$. At a critical value $\Omega = \Omega_c$, the single-particle spectrum $E_k$ changes from having a set of four degenerate minima to a single minimum at $k = 0$, corresponding to condensation at finite or zero momentum, respectively. I describe this quantum phase transition and the symmetry breaking of the condensate phases. The superfluid phase is discussed using the Bogoliubov theory, I present the phase diagram, the excitation spectrum and the sound velocity of the phonon excitations. A novel dynamically unstable superfluid regime occurring when $\Omega$ is close to $\Omega_c$ is analyzed using the Bogoliubov-de Gennes equation. In this regime a late time dynamic superfluid depletion is discussed. Moreover, I show that there are two types of roton excitations occurring in the $\Omega < \Omega_c$ regime and obtain explicit values for the corresponding energy gaps.
1:51PM B36.00012 Fermi Superfluids with Engineered Dispersion: A Consistent Treatment of Fluctuation Effects, BRANDON ANDERSON, CHIEN-TE WU, RUFUS BOYACK, KATHYRN LEVIN, James Franck Institute, University of Chicago — Recent experimental advances in cold atoms allows for the possibility of engineered dispersion that give rise to novel physics. For example, in systems with either spin-orbit coupling (SOC) or shaken optical lattices, momentum fluctuations can have energy cost that is quartic instead of quadratic at small momenta. The resulting density of states (DOS) will then more accurately resemble a system with lower dimension, leading to, e.g., enhanced depletion of Bose condensates or enhanced binding energy of Fermions. We consider the effects of the reduced DOS on the stability of fermionic superfluids in the presence of SOC or optical lattice shaking. We establish and characterize fluctuations associated with the standard mean field equations of the superfluid instability. This introduces bosonic degrees of freedom at a level beyond Gaussian fluctuations. Moreover, these bosons must necessarily condense in order for the fermionic superfluid to be stable. This is a non-trivial constraint for fermions, as seen from the observation that, e.g., Rashba SOC destroys a condensate instability. This introduces bosonic degrees of freedom at a level beyond Gaussian fluctuations. Moreover, these bosons must necessarily condense in order for the fermionic superfluid to be stable. This introduces bosonic degrees of freedom at a level beyond Gaussian fluctuations. Moreover, these bosons must necessarily condense in order for the fermionic superfluid to be stable.

2:03PM B36.00013 Quantum phase transition in the interacting two-dimensional boson systems with Rashba spin-orbital coupling, CONGJUN WU, JIANDA WU, Univ of California - San Diego — The two-dimensional free bosons condensate at zero momentum at zero temperature. After turning on the Rashba spin-orbital coupling, the system displays a ring condensation in momentum space with highly degenerate quantum ground states [1]. It is pointed out that, after a mean-field treatment, the ring condensation will disappear when turning on and tuning the Zeeman coupling to a critical value, leading to a novel quantum phase transition in the system [2]. It is of great theoretical and experimental interests for the role the interaction plays in the system. Here we further explore the system via a relatively full treatment of the interaction. We find the presence of the interaction on one hand modifies the mean-field results, and on the other hand also drives the system undergoing quantum phase transition, leading to a new novel phase of “boson metal.”

11:15AM B37.00001 Overcoming erasure errors in quantum memories with multilevel systems, SRERAMAN MURALIDHARAN, Department of Electrical Engineering, Yale University, JIANMING WEN, LINSHU LI, LIANG JIANG, Department of Applied Physics, Yale University — We propose the usage of highly efficient error correcting codes of multilevel systems to encode quantum memories that suffer from erasure errors and introduce efficient hardware to repetitively correct these errors. Our scheme makes use of quantum polynomial codes to encode a quantum memory and generalized one-bit teleportation circuits for multilevel systems to repetitively correct photon erasure errors and operation errors in a fault-tolerant manner. We compare our scheme with earlier known schemes to encode quantum memories that use quantum parity codes and surface codes respectively and discuss the application of our encoded quantum memories for one-way quantum repeaters and show that they achieve a superior performance.

11:27AM B37.00002 Preserving flying qubit in single-mode fiber with Knill Dynamical Decoupling (KDD), MANISH GUPTA, Louisiana State Univ - Baton Rouge, ERIK NAVARRO, California State University, TODD MOULDER, JASON MUELLER, ASHKAN BALOUCHI, KATHERINE BROWN, HWANG LEE, JONATHAN DOWLING, Louisiana State Univ - Baton Rouge — The implementation of information-theoretic-crypto protocol is limited by decoherence caused by the birefringence of a single-mode fiber. We propose the Knill dynamical decoupling scheme, implemented using half-wave plates, to minimize decoherence and show that a fidelity greater than 96% can be achieved even in presence of rotation error.

11:39AM B37.00003 Multipulse dynamical decoupling-like protocol for controlling the light emission line of a two-level system, HERBERT F. FOTSO, Ames Laboratory, ADRIAN FEIGUIN, Northeastern University, VIACHESLAV DOBROVITSKI, Ames Laboratory — Emission lines of quantum systems in solids, such as quantum dots or color centers, are often significantly affected by the coupling to the solid-state environment, so that the frequencies of the emitted light slowly but uncontrollably fluctuates over time [1,2]. These fluctuations impede the photonic-based quantum information processing schemes (e.g. the two-photon interference, where the frequencies of the photons should stay close), and impair the protocols using the stationary-to-flying-qubit conversion. We present a possible solution for this problem, which employs optical pulses applied to the emitting system, which stabilize the position of the emission line at the desired location. Modeling the emitter as a two-level system, we analyze performance of the scheme both analytically and numerically. We show that already a few pulses, with rather large inter-pulse delay, can stabilize the emission line. We discuss application of the proposed scheme for stabilization of the zero-phonon emission line of the NV centers in diamond, and the possible use of this scheme for facilitating the long-distance entanglement between the NV centers [3]. 11:51AM B37.00004 Irreducible normalizer operators and thresholds for degenerate quantum codes with sublinear distances, LEONID P. PRYADKO, ILYA DUMER, University of California, Riverside, ALEXEY A. KOVALEV, University of Nebraska—Lincoln — We construct a lower (existence) bound for the threshold of scalable quantum computation which is applicable to all stabilizer codes, including degenerate quantum codes with sublinear distance scaling. The threshold is based on enumerating irreducible operators in the normalizer of the code, i.e., those that cannot be decomposed into a product of two such operators with non-overlapping support. For quantum LDPC codes with logarithmic or power-law distances, we get threshold values which are parametrically better than the existing analytical bound [1] based on percolation. The new bound also gives a finite threshold when applied to other families of degenerate quantum codes, e.g., the concatenated codes. [1] A. A. Kovalev and L. P. Pryadko, PRA 87, 020304(R) (2013).

quantum annealing with applications to hard optimization problems. We explore a variety of techniques for leakage resilience in topological codes. Our contributions are twofold. First, we develop a leakage model that differs in critical details from earlier models. Secondly, we use Monte-Carlo simulations to survey several syndrome extraction circuits. Third, given the capability to perform 3-outcome measurements, we present a dramatically improved syndrome processing algorithm. Our simulations show that simple circuits with one extra CNOT per qubit reduce the accuracy threshold by less than a factor of 4 when leakage and depolarizing noise rates are comparable. This becomes a factor of 2 when the decoder uses 3-outcome measurements. Finally, when the physical error rate is less than $2 \times 10^{-4}$, placing LRUs after every gate may achieve the lowest logical error rate. We expect that the ideas may generalize to other topological codes.

The D-Wave Two (DW2) device has demonstrated the effectiveness of using error correction and suppression for quantum annealers. As the size of a quantum system increases, the number of logical qubits that can be encoded into the ground subspace of a Hamiltonian comprising a sum of commuting terms increases. Since such Hamiltonians are gapped they are considered natural candidates for protection of quantum information and topological or adiabatic quantum computation. However, we prove that they cannot be used to this end in the 2-local case. By breaking the favorable assumption that the gap is infinite we show that single-site perturbations can generate a degeneracy splitting in the ground subspace of this type of Hamiltonians which is of the same order as the magnitude of the perturbation, and is independent of the number of interacting sites and their Hilbert space dimensions, just as in the absence of the protecting Hamiltonian. This splitting results in decoherence of the ground subspace, and we demonstrate that for natural noise models the coherence time is proportional to the inverse of the degeneracy splitting. With the help of active error correction, this scheme is fault-tolerant, in the sense that the computation time can be arbitrarily long for large enough lattice size. It is shown that the frequency of error correction and the physical resources needed can be greatly reduced by the constant energy gap.

Quantum error suppression with commuting Hamiltonians: Two-local is too local. We consider error suppression schemes in which quantum information is encoded into the ground subspace of a Hamiltonian comprising a sum of commuting terms. Since such Hamiltonians are gapped they are considered natural candidates for protection of quantum information and topological or adiabatic quantum computation. However, we prove that they cannot be used to this end in the 2-local case. By breaking the favorable assumption that the gap is infinite we show that single-site perturbations can generate a degeneracy splitting in the ground subspace of this type of Hamiltonians which is of the same order as the magnitude of the perturbation, and is independent of the number of interacting sites and their Hilbert space dimensions, just as in the absence of the protecting Hamiltonian. This splitting results in decoherence of the ground subspace, and we demonstrate that for natural noise models the coherence time is proportional to the inverse of the degeneracy splitting. With the help of active error correction, this scheme is fault-tolerant, in the sense that the computation time can be arbitrarily long for large enough lattice size. It is shown that the frequency of error correction and the physical resources needed can be greatly reduced by the constant energy gap.

Fault-tolerant Holonomic Quantum Computation in Surface Codes. We show that universal holonomic quantum computation (HQC) can be achieved by adiabatically deforming the gap-stabilizer Hamiltonian of the surface code, where quantum information is encoded in the degenerate ground space of the system Hamiltonian. We explicitly propose procedures to perform each logical operation, including logical state initialization, logical state measurement, logical CNOT, state injection and distillation, etc. In particular, adiabatic braiding of different types of holes on the surface leads to a topologically protected, non-Abelian geometric logical CNOT. Throughout the computation, quantum information is protected from both small perturbations and low weight thermal excitations by a constant energy gap, and is independent of the system size. Also the Hamiltonian terms have weight at most four during the whole process. The effect of thermal error propagation is considered during the adiabatic code deformation. With the help of active error correction, this scheme is fault-tolerant, in the sense that the computation time can be arbitrarily long for large enough lattice size. It is shown that the frequency of error correction and the physical resources needed can be greatly reduced by the constant energy gap.

Quantum Error Correction for Minor Embedded Quantum Annealing. We consider error correction schemes in which quantum information is encoded into the ground subspace of a Hamiltonian comprising a sum of commuting terms. Since such Hamiltonians are gapped they are considered natural candidates for protection of quantum information and topological or adiabatic quantum computation. However, we prove that they cannot be used to this end in the 2-local case. By breaking the favorable assumption that the gap is infinite we show that single-site perturbations can generate a degeneracy splitting in the ground subspace of this type of Hamiltonians which is of the same order as the magnitude of the perturbation, and is independent of the number of interacting sites and their Hilbert space dimensions, just as in the absence of the protecting Hamiltonian. This splitting results in decoherence of the ground subspace, and we demonstrate that for natural noise models the coherence time is proportional to the inverse of the degeneracy splitting. With the help of active error correction, this scheme is fault-tolerant, in the sense that the computation time can be arbitrarily long for large enough lattice size. It is shown that the frequency of error correction and the physical resources needed can be greatly reduced by the constant energy gap.

Comparing codes for error corrected quantum annealing. We consider error correction schemes in which quantum information is encoded into the ground subspace of a Hamiltonian comprising a sum of commuting terms. Since such Hamiltonians are gapped they are considered natural candidates for protection of quantum information and topological or adiabatic quantum computation. However, we prove that they cannot be used to this end in the 2-local case. By breaking the favorable assumption that the gap is infinite we show that single-site perturbations can generate a degeneracy splitting in the ground subspace of this type of Hamiltonians which is of the same order as the magnitude of the perturbation, and is independent of the number of interacting sites and their Hilbert space dimensions, just as in the absence of the protecting Hamiltonian. This splitting results in decoherence of the ground subspace, and we demonstrate that for natural noise models the coherence time is proportional to the inverse of the degeneracy splitting. With the help of active error correction, this scheme is fault-tolerant, in the sense that the computation time can be arbitrarily long for large enough lattice size. It is shown that the frequency of error correction and the physical resources needed can be greatly reduced by the constant energy gap.

Comparing codes for error corrected quantum annealing. Session B38 GQI: Focus Session: Quantum Foundations and Technologies I 212B - Matthew Pusey, Perimeter Institute for Theoretical Physics

11:15AM B38.00001 Understanding Nature from Experimental Observations: A Theory Independent Test for Gravitational Decoherence . STEPHANIE WEHNER, TU Delft — Quantum mechanics and the theory of gravity are presently not compatible. A particular question is whether gravity causes decoherence - an unavoidable source of noise. Several models for gravitational decoherence have been proposed, not all of which can be described quantum mechanically. In parallel, several experiments have been proposed to test some of these models, where the data obtained by such experiments is analyzed assuming quantum mechanics. Since we may need to modify quantum mechanics to account for gravity, however, one may question the validity of using quantum mechanics as a calculational tool to draw conclusions from experiments concerning gravity. Here we use ideas from quantum information to propose an experiment to estimate gravitational decoherence whose conclusions hold even if quantum mechanics would need to be modified. We first establish a general information-theoretic notion of decoherence which reduces to the standard measure within any physical process for any physical theory satisfying only very mild conditions. Finally, we propose a concrete experiment using optomechanics to estimate gravitational decoherence in any such theory, including quantum mechanics as a special case. Our work raises the interesting question whether other properties of nature could similarly be established from experimental observations alone - that is, without already having a rather well formed theory of nature like quantum mechanics to make sense of experimental data. We conclude by discussing this possibility.

Joint work with C. Pfister, J. Kaniewski, M. Tomamichel, A. Mantri, R. Schmucker and G. Milburn

11:51AM B38.00002 A loophole-free Bell test with spin qubits in diamond1, ANAIS DREAU, BAS HENSEN, HANNES BERNIEN, ANDREAS REISERER, JUST RuitenBerg, MACHIEL BLOK, Kavli Institute of Nanoscience Delft, Delft University of Technology, MATTHEW MARKHAM, DANIEL TWITCHEN, Element Six, Ltd., Kings Ride Park, Ascot, Berkshire SL5 8BP, UK, STEPHANIE WEHNER, RONALD HANSON, Kavli Institute of Nanoscience Delft, Delft University of Technology, QUANTUM TRANSPORT GROUP TEAM2, ELEMENT 6 TEAM — One of the most intriguing phenomena in quantum physics is the entanglement of spatially separated objects. The benchmark to prove the fundamental non-locality of remote entanglement is provided by the famous Bell’s theorem. Nevertheless, all its experimental implementations to date open the door to loopholes that restrict the practical validity of this theorem. , we present our latest experimental results towards the realization of a Bell test, aimed to close the detection loophole and address the locality and free-will loopholes in a single experiment. Our qubits consist of the electronic spin associated with single NV center defects in diamond. An efficient remote entanglement protocol allows us to generate entangled qubit pairs between two labs separated by 1.3 km on the TU Delft campus. The moderate time (<3.5 us) required for high fidelity (>99%) qubit rotations and efficient (>97%) readout make our setup a good candidate to allow the experimental violation of Bell’s inequalities between two space-like separated entangled spins without relying on the fair sampling assumption.

what the necessary requirements for speed-up in conventional quantum computing are. Between quantum and classical are much starker. By trying to identify which aspects of quantum theory are essential to this speed-up we can gain insight into applicable, kind of Turing machine. In this restricted setting results about quantum advantage become far easier to prove and the difference in capabilities factory can perform tasks which are impossible in the classical case. In some sense the Bernoulli factory can be considered as an alternate, although less superposition and mixture. We take a classical sampling problem, the Bernoulli coin factory, and explore a quantum version of it. We find that the quantum dependent subtleties of Huygens' principle. We will also discuss several implications of this effect in diverse scenarios ranging from quantum communication to quantum optical techniques.

The inspiration for the hypothesis was found as an undergrad at Princeton and the initial development was done as a grad student at Stanford.

ANDREY AKHMETELI, LTASolid Inc. — Is it possible to offer a “no drama” quantum electrodynamics, as simple (in principle) as classical electrodynamics – a theory described by a system of partial differential equations (PDE) in 3+1 dimensions, but reproducing unitary evolution of a quantum field theory in the Fock space? The following results suggest an affirmative answer: 1. The scalar field can be algebraically eliminated from scalar electrodynamics. 2. After introduction of a complex 4-potential (producing the same electromagnetic field (EMF) as the standard real 4-potential), the spinor field can be algebraically eliminated from spinor electrodynamics. 3. The resulting theories describe independent evolution of EMF and can be embedded into quantum field theories. Another fundamental result: in a general case, the Dirac equation is equivalent to a 4th order PDE for just one component, which can be made real by a gauge transform. Issues related to the Bell theorem and the connection with Barut’s self-field electrodynamics are discussed. A. Akhmeteli, Int’l Journal of Quantum Information, Vol. 9, Suppl., 17-26 (2011) A. Akhmeteli, Journal of Mathematical Physics, Vol. 52, 082303 (2011) A. Akhmeteli, quant-ph/1111.4630 A. Akhmeteli, European Physical Journal C, Vol. 73, 2371 (2013) (open access)

GELO NOEL TABIA, University of Tartu — In cryptography, the notion of a zero-knowledge proof was introduced by Goldwasser, Micali, and Rackoff [1]. An interactive proof system is said to be zero-knowledge if any verifier interacting with an honest prover learns nothing beyond the validity of the statement being proven. With recent advances in quantum information technologies, it has become interesting to ask if classical zero-knowledge proof systems remain secure against adversaries with quantum computers. The standard approach to show the zero-knowledge property involves constructing a simulator for a malicious verifier that can be rewinded to a previous step when the simulation fails. In the quantum setting, the simulator can be described by a quantum circuit that takes an arbitrary quantum state as auxiliary input but rewinding becomes a non trivial problem. Watrous proposed a quantum rewinding technique in the case where the simulation’s success probability is independent of the auxiliary input [2]. Here I present a more general quantum rewinding scheme that employs the quantum phase estimation algorithm. References: [1] S. Goldwasser, S. Micali, and C. Rackoff, SIAM J. Comput. 18(1) 186-208, 1989. [2] J. Watrous, SIAM J. Comput. 39(1) 25-58, 2009.

A Weak Value Based QKD Protocol Robust Against Detector Attacks. JAMES TROUPE, Applied Research Laboratories, University of Texas at Austin — We propose a variation of the BB84 quantum key distribution protocol that utilizes the properties of weak values to insure the validity of the quantum bit error rate estimates used to detect an eavesdropper. The protocol is shown theoretically to be secure against recently demonstrated attacks utilizing detector blinding and control and should also be robust against all detector based hacking. Importantly, the new protocol promises to achieve this additional security without negatively impacting the secure key generation rate as compared to that originally promised by the standard BB84 scheme. Implementation of the weak measurements needed by the protocol should be very feasible using standard quantum optical techniques.

Quantum Collect Calling. EDUARDO MARTIN-MARTINEZ, Institute for Quantum Computing / Perimeter Institute for Theoretical Physics — We show that it is possible to use a massless field in the vacuum to communicate in such a way that the signal travels slower than the speed of light and such that no energy is transmitted from the sender to the receiver. Instead, the receiver has to supply a signal-dependent amount of work to switch his detector on and off. This type of signalling is related to Casimir-like interactions and it is made possible by dimension —and curvature— dependent subtleties of Huygens’ principle. We will also discuss several implications of this effect in diverse scenarios ranging from quantum communication to Cosmology.

The Quantum Bernoulli Factory. HOWARD DALE, DAVID JENNINGS, TERRY RUDOLPH, Imperial College London — Understanding the difference between quantum mechanics and classical probability theory amounts to understanding the difference between superposition and mixture. We take a classical sampling problem, the Bernoulli coin factory, and explore a quantum version of it. We find that the quantum factory can perform tasks which are impossible in the classical case. In some sense the Bernoulli factory can be considered as an alternate, although less applicable, kind of Turing machine. In this restricted setting results about quantum advantage become far easier to prove and the difference in capabilities between quantum and classical are much starker. By trying to identify which aspects of quantum theory are essential to this speed-up we can gain insight into what the necessary requirements for speed-up in conventional quantum computing are.
1:39PM B38.00011 Certifying Unpredictable Randomness from Quantum Nonlocality, PETER BIERHORST, Tulane University — A device-independent quantum randomness protocol takes an initial random seed as input and then expands it to a longer random string. It has been proven that if the initial random seed is trusted to be unpredictable, then the longer output string can also be certified to be unpredictable by an experimental violation of Bell's inequality. It has furthermore been argued that the initial random seed may not need to be truly unpredictable, but only uncorrelated to specific parts of the Bell experiment. In this work, we demonstrate rigorously that this is indeed true, under assumptions related to "no superdeterminism/no conspiracy" concepts along with the no-signaling assumption. So if we assume that superluminal signaling is impossible, then a loophole-free test of Bell's inequality would be able to generate provably unpredictable randomness from an input source of (potentially predictable) classical randomness.

1:51PM B38.00012 Adaptive Quadrature Detection for Multicarrier Continuous-Variable Quantum Key Distribution, LASZLO KYONGYO, Budapest University of Technology, Hungarian Academy of Sciences, SANDOR IMRE, Budapest University of Technology — We propose the adaptive quadrature detection for multicarrier continuous-variable quantum key distribution (CVQKD). A multicarrier CVQKD scheme uses Gaussian subcarrier continuous variables for the information conveying and Gaussian sub-channels for the transmission. The proposed multicarrier detection scheme dynamically adapts to the sub-channel conditions using a corresponding statistics which is provided by our sophisticated sub-channel estimation procedure. The sub-channel estimation phase determines the transmittance coefficients of the sub-channels, which information are used further in the adaptive quadrature decoding process. We define the technique called subcarrier spreading to estimate the transmittance conditions of the sub-channels with a theoretical error-minimum in the presence of a Gaussian noise. We introduce the terms of single and collective adaptive quadrature detection. We also extend the results for a multiuser multicarrier CVQKD scenario. We prove the achievable error probabilities, the signal-to-noise ratios, and quantify the attributes of the framework. The adaptive detection scheme allows to utilize the extra resources of multicarrier CVQKD and to maximize the amount of transmittable information.

This work was partially supported by the DFG and the Hungarian National Project.

2:03PM B38.00013 Highly Efficient Long-Distance Quantum Communication: a Blueprint for Implementation, LINSHU LI, SRERAMAN MURALIDHARAN, Yale University, JUNGSANG KIM, Duke University, NORBERT LUTKENHAUS, University of Waterloo, MIKHAIL LUKIN, Harvard University, LIANG JIANG, Yale University — Quantum repeaters provide a way for long distance quantum communication through optical fiber networks. Transmission losses and operation errors are two major challenges to the implementation of quantum repeaters. At each intermediate repeater station, transmission losses can be overcome using either heralded entanglement generation or quantum error correction, while operation errors can be corrected via entanglement purification or quantum error correction. Depending on the mechanisms used to correct loss and operation errors respectively, three generations of quantum repeaters have been proposed. We present a quantitative comparison of different quantum repeater schemes by evaluating the time- and qubit-resource consumed simultaneously. We can identify the most efficient scheme for given technological capabilities, which characterized by fiber coupling efficiency, local gate fidelity, and local gate speed. Our work provides a roadmap for high-speed quantum networks across continental distances.

Monday, March 2, 2015 11:15AM - 2:15PM

Session B39 GQI: Superconducting Circuits: Decoherence

11:15AM B39.00001 Comparison of 2D transmon coherence for different capacitive shunt fabrication methods, JONILYN YODER, MIT Lincoln Laboratory, ARCHANA KAMAL, FEI YAN, MIT, THEODORE GUDMUNDSEN, MIT Lincoln Laboratory, PAUL WELANDER, SLAC National Accelerator Laboratory, SIMON GUSTAVSSON, MIT, DAVID HOVER, ANDREW KERMAN, ADAM SEARS, WILLIAM OLIVER, MIT Lincoln Laboratory — Improvements in superconducting qubit coherence times and reproducibility have been demonstrated using capacitive shunting. In this study, we present a side-by-side comparison of two distinct methods for preparing the aluminum shunt capacitor material for 2D transmon superconducting qubit devices. The first method involved in situ wafer outgassing prior to molecular beam epitaxy aluminum evaporation. The second method involved outgassing prior to electron gun aluminum evaporation. Materials analysis for each process will be detailed. Experimental results, including qubit coherence times and superconducting coplanar waveguide resonator internal quality factors, will be presented for representative devices prepared using both methods. This work is sponsored by the Assistant Secretary of Defense for Research and Engineering under Air Force Contract FA8721-05-0002. Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the United States Government.

11:27AM B39.00002 Optimizing Hardware Compatibility for Scaling Up Superconducting Qubits, MICHAEL FANG, Univ of California - Santa Barbara, BROOKS CAMPBELL, ZIJUN CHEN, BEN CHIARO, ANDREW DUNSWORTH, JULIAN KELLY, ANTHONY MEGRANT, CHARLES NEILL, PETER O'MALLEY, CHRIS QUINTANA, AMIT VAINSENCHER, JIM WINNER, TED WHITE, University of California, Santa Barbara, RAMI BARENDS, YU CHEN, AUSTIN FOWLER, EVAN JEFFREY, JOSH MUTUS, PEDRAM ROUSHAN, DANIEL SANK, Google, Santa Barbara. JOHN MARTINIS, University of California and Google, Santa Barbara — Since quantum computation relies on the manipulation of fragile quantum states, qubit devices must be isolated from the noisy environment to prevent decoherence. Custom made components make isolation from thermal and infrared radiation possible, but have been unreliable, massive, and show sub-ideal microwave performance. Infrared isolation for large scale experiments (≥ 8 qubits) was achieved with compact impedance matched microwave filters which attenuate stray infrared signals on cryogenic cables with only -25 dB reflection up to 7.5 GHz. In addition, a thermal anchoring system was designed to effectively transfer unwanted heat from more than 100 coaxial cables in the dilution refrigerator and yielded a 33 percent improvement in base temperature and 50% improvement in hold time.
11:39AM B39.00003 Experiments on Interaction of Quasiparticles with Two-Level-Systems in a Superconducting Phase Qubit

ALEXANDER BILMES, JÜRGEN LISENFELD, ANDREAS HEIMES, SEBASTIAN ZANKER, Gerd SCHÖN, Alexey Ustinov, Karlsruhe Inst of Tech (KIT), PI TEAM 1, FTP TEAM 2 — Two-Level-Systems (TLS) are one of the main sources of decoherence in superconducting qubits. Some individual and coherent TLS, present in the tunnel barrier of the qubit’s Josephson junction, can be coherently operated via the qubit. In the past, experiments on superconducting glasses indicated that quasiparticles may give rise to TLS energy loss similar to Korringa relaxation 1. We will present experiments in which we use a phase qubit to explore the interaction of single TLS with non-equilibrium quasiparticles. We have implemented in-situ quasiparticle injection by using an on-chip dc-SQUID that is pulse-biased beyond its critical current. The quasiparticle density is calibrated by measuring associated characteristic changes to the qubit resonance frequency and energy relaxation rate 2. The coherence times of individual TLS is measured in dependence of the non-equilibrium quasiparticle density and compared to thermally generated quasiparticles.

11:51AM B39.00004 Characterization of a Scalable Chip Mount Using a 5 Xmon Qubit Chain

BROOKS CAMPBELL, Z. CHEN, B. CHIARO, A. DUNSWORTH, I.-C. HOI, J. KELLY, A. MEGRANT, C. NEILL, P. J. J. O’MALLEY, C. QUINTANA, A. VAINSENCHER, J. WENNER, T. WHITE, UC Santa Barbara, R. BARENDS, Y. CHEN, A. FOWLER, E. JEFFREY, J. MUTUS, P. ROUSHAN, D. SANK, Google, Santa Barbara, John M. Martinis, UC Santa Barbara and Google, Santa Barbara — Superconducting quantum computing technology has progressed to the point that experiments involving the full control more than ten qubits will be realized in the next few years. As such, a scalable chip mount, able to accommodate dozens of microwave signal lines, will likely become necessary since current Xmon technology requires two control lines per qubit. Additionally, understanding parasitic coupling of Xmon qubits to control lines will aid in the proper design of both chips and chip mounts for even higher density circuits. We will present coherence, gate fidelity, and qubit-cross-talk benchmark measurements from a high performance 5 Xmon chain in various chip mount designs and materials.

12:03PM B39.00005 Influence of Non-equilibrium Noise on Quantum Superconducting Devices

JEN-HAO YEH, Laboratory for Physical Sciences; Department of Physics, University of Maryland, Jay LeFebvre, Department of Physics, University of Maryland, BALADITYA SURI, SERGEY NOVIKOV, Laboratory for Physical Sciences; Department of Physics, University of Maryland, FREDERICK WELLSTOOD, Department of Physics, University of Maryland; Joint Quantum Institute, University of Maryland, Benjamin Palmer, Laboratory for Physical Sciences; Department of Physics, University of Maryland — Non-equilibrium noise from temperatures larger than T ~ 20 mK coupled to quantum superconducting devices can cause energy relaxation [1], dephasing [2], and initialization errors [1]. In particular at low temperatures, any dissipated power can drive the electrons out of equilibrium with the phonons and produce thermal noise. To understand thermal noise driven out of equilibrium, we have created both finite element simulations using COMSOL and some simple analytical models. Based on these thermal simulations and models as well as microwave simulations, we have designed and fabricated some devices to decrease the amount of non-equilibrium noise influencing our devices. The design of these devices as well as preliminary characterization using a transmon device will be discussed.

12:15PM B39.00006 Non-exponential energy decay and quasi-particle fluctuations in a superconducting flux qubit

SIMON GUSTAVSSON, FEI YAN, MIT, GIANLUIGI CATELANI, Forschungszentrum Jülich, Germany, Archana KAMAL, MIT, Jonas Bylander, Chalmers University of Technology, Sweden, Fumiki Yoshihara, NICT, Japan, Yasunobu Nakamura, The University of Tokyo, Tokyo, Terry Orlando, MIT, William Oliver, MIT Lincoln Laboratory — We measure pronounced non-exponential energy relaxation in a superconducting flux qubit, observing a decay function that exhibits a fast initial decay followed by a much slower decay for long times. When applying a sequence of pi pulses to the qubit and measuring the decay after the last pi pulse, we observe strong modifications to the decay function, including a slow-down of the fast initial decay and a three-fold increase of the 1/e-time. If we attribute the non-exponential decay to quasiparticle number fluctuations, we speculate that the improvements in T1 are due to a qubit-mediated shuffling of quasiparticles between the metallic islands of the device, which will eventually pump them away from the Josephson junctions to a larger ground plane where their contribution to qubit energy relaxation become negligible.

12:27PM B39.00007 Laser made from a superconducting lumped-element resonator and random defects

YANIV ROSEN, Laser Laboratory for Physical Sciences, College Park, MD, MOE KHALIL, Laboratory for Physical Sciences, College Park, MD and University of Maryland, College Park, MD, Alex Burin, Department of Chemistry, Tulane University, New Orleans, LA, Kevin Osborn, Laboratory for Physical Sciences, College Park, MD and Joint Quantum Institute, College Park, MD — Random two-level system defects in dielectrics absorb energy and limit the quality factors of superconducting qubits and resonators used in quantum computing applications. We have found a method to invert the population of these random defects and pass them through resonance with a lumped-element superconducting microwave resonator. Stimulated emission of the defects causes the internal quality factor of the resonator, measured by an injection locking tone, to cross through an infinitely large value before becoming negative. In the latter case the defects emit more than they absorb and the internal lasing threshold is reached. With further population inversion, amplification of the injection locking tone is observed.

12:39PM B39.00008 Investigation of Limiting Decoherence Mechanisms in Xmon Qubits

C. M. Quintana, UC Santa Barbara, R. Barends, Google, Santa Barbara, B. Campbell, UC Santa Barbara, Y. Chen, Google, Santa Barbara, Z. Chen, B. Chiaro, A. Dunssworth, UC Santa Barbara, A. G. Fowler, Google, Santa Barbara, I.-C. Hoi, UC Santa Barbara, E. Jeffrey, Google, Santa Barbara, J. Kelly, A. Megrant, UC Santa Barbara, J. Mutus, Google, Santa Barbara, C. Neill, P. J. J. O’Malley, UC Santa Barbara, P. Roushan, D. Sank, Google, Santa Barbara, A. Vainsencher, J. Wenner, T. C. White, A. N. Cleland, UC Santa Barbara, J. M. Martinis, University of California and Google, Santa Barbara — Xmon-style transmon qubits have demonstrated a high level of coherence and controllability, enabling high-fidelity quantum gates and measurement at the levels required for surface code error correction. However, decoherence is still a limiting factor for fidelities, and further improvements to coherence could significantly reduce the overhead required to build a fault-tolerant quantum computer. We report on relaxation and dephasing mechanisms relevant to the Xmon qubit. In particular, we discuss dielectric loss from stray Josephson junctions and the dependence of dephasing on qubit temperature.
1:03PM B39.00010 Collective modes in the fluxonium qubit. GIANLUIGI CATELANI, Forschungszentrum Julich PGI-2, GIOVANNI VIOLA, RWTH Aachen - IQI - In the fluxonium qubit, an array comprising a large number of identical Josephson junctions form a so-called superinductance. The superinductance is connected to a junction - the phase slip element - with a smaller Josephson energy and a different charging energy. We investigate the effects of unavoidable capacitive couplings to ground as well as non-linearities of the superinductance: they both introduce interactions between the low-energy qubit degree of freedom and higher-energy collective modes of the circuit. We also consider the role of the additional capacitances that are used to couple the qubit to a resonator for driving and read-out. We show that the interactions with the collective modes can affect not only the spectrum of the qubit but also its coherence.

1:15PM B39.00011 Spurious modes in 3D multi-qubit circuits. MARTIN SANDBERG, DOUGLAS MCCLURE, HANHEE PAIK, IBM T.J. Watson Research Center, Yorktown Heights, New York, 10598, USA, DANIELA F. BOGORIN, B.L.T. PLOURDE, Syracuse University, Physics Department, Syracuse, NY 13244 USA, OLIVER DIAL, BALEEGH ABDI, IBM T.J. Watson Research Center, Yorktown Heights, New York, 10598, USA - In superconducting 3D circuits coherence times exceeding 100 microseconds are readily achieved for qubits in single cavities. One approach to building more complex circuitry in the 3D architecture is to use "bridge" qubits that span into two adjacent cavities. It has been found that these qubits exhibit reduced coherence compared to single cavity qubits. Significant effort has been put into understanding and improving the coherence of the bridge qubit. So far the mechanisms behind the reduced coherence have remained somewhat unclear. Here we present simulations and measurements indicating that stray modes in the microwave environment are one contributing factor to the reduced coherence. One potential location of such stray modes is at the boundary regions between sections of the cavity enclosure, where both machining imperfections and dielectric layers such as oxides can prevent perfect electrical contact. As these systems are scaled up, the spectrum of the modes becomes increasingly dense, presenting an increasing challenge. We present multiple methods that can be implemented to mitigate these modes.

1:27PM B39.00012 Cavity-induced decoherence in a long-lived superconducting flux qubit. FEI YAN, ARCHANA KAMAL, Research Laboratory for Electronics, Massachusetts Institute of Technology, THEODORE GUDMUNDSEN, JONILYN YODER, MIT Lincoln Laboratory, SIMON GUSTAVSSON, MIT Lincoln Laboratory; Research Laboratory for Electronics, Massachusetts Institute of Technology, WILLIAM OLIVER, Research Laboratory for Electronics, Massachusetts Institute of Technology — We implement a circuit QED system with a capacitively shunted (C-shunt) flux qubit coupled to a transmission line resonator. The improved design substantially enhances qubit coherences, achieving T1 of 55us at degeneracy. Dephasing is also improved, giving a spin-echo decay of 40us. We found that the dephasing is limited by photon shot noise at a residual thermal photon population of 0.006. The driven-evolution T1rho-spectroscopy and free-evolution CPMG results both validate the finding.

1:39PM B39.00013 Quantum optical theory of electronic noise in coherent conductors. FARZAD QASSEMI, BERTRAND REULET, ALEXANDRE BLAIS, Université de Sherbrooke — We investigate the quantum properties of radiated electromagnetic field from a quantum conductor, i.e., a conductor where the electron transport is governed by quantum mechanics. In particular, using tools borrowed from quantum optics such as input-output theory and Lindblad master equations, we demonstrate how the electron shot noise in the conductor tailors the properties of radiated field, leading to nonclassical electromagnetic radiation. Our results allow us to calculate the outcome of any measurement on the electromagnetic field in terms of the statistical properties of the current in the conductor. As an example, we explain the existence of squeezing, recently observed by G. Gasse et al [1].

1:51PM B39.00014 Spectroscopy of Nanoscale Two-Level Systems in Insulating Films. BAHMAN SARABI, ARUNA RAMANAYAKA, Laboratory for Physical Sciences, FREDERICK WELLSSTOOD, University of Maryland,College Park, KEVIN OSBORN, Laboratory for Physical Sciences — Nanoscale tunneling two level systems (TLSs) are viewed as defects in dielectric films because they are parasitic to the performance of superconducting qubits and resonators. Using a calibrated and uniform dc electric field within a special superconducting resonator we modify the energy potential of random TLSs in amorphous insulating films and measure them. As the dc electric field is applied, TLS energies are observed near the tunneling energies from their double-well degeneracy. From these measurements, the dipole moment projected along the field axis is directly extracted for each TLS. The random distribution of projected dipole moments shows that there are multiple dipole sizes in a silicon nitride film. This contrasts other techniques which find a single dipole size in an amorphous film. Spectroscopic splittings are observed which arise from a coherent exchange of a single photon between a TLS and the resonator, and they allow an overconstrained validation of cavity quantum electrodynamics with a TLS. The method used to measure multiple dipole moments is believed to be generally useful for the classification of TLSs, which can be used to test and screen films fabricated for coherent superconducting devices.
Mechanism of charge recombination in organic-inorganic hybrid perovskite solar cells

Au Nanocluster assisted PCE improvement in PEDOT: PSS - Si Hybrid Devices

Co-Assembling P3HT/ZnO as Parallel-Lane Hybrid Nanowires for Photovoltaics Application

Fulleropyrrolidine interlayers lower cathode work function to raise organic solar cell efficiency
and demonstrate that we can utilize these strategies for the synthesis of block copolymers beyond P3HT-b-PFTBT. We investigated the chemical composition, structure and electrical characteristics of the polymers prepared by the different synthetic methods, which served as model systems to study fundamental questions regarding optoelectric properties and charge transfer. However, the synthesis of fully conjugated block copolymers remains a challenging issue in the field. We have optimized the two-step synthesis of P3HT-b-PFTBT, which is comprised of the two blocks. Our morphological studies thus support the proposed alloying model that was put forth originally.

The role of exciton ionization processes in bulk heterojunction organic photovoltaic cells. YUNLONG ZOU, RUSSELL HOLMES, Univ of Minn - Minneapolis — Dissociating photogenerated excitons into their constituent charges is essential for efficient photon conversion in organic semiconductors. Organic photovoltaics cells (OPV) widely adopt a heterojunction architecture where dissociation is facilitated by charge transfer at a donor-acceptor (D-A) interface. Interestingly, recent work on MoO3/C60 Schottky OPVs has demonstrated that excitons in C60 may also undergo bulk-ionization to generate photocurrent, driven by the built-in field at the MoO3/C60 interface. Here, we show that bulk-ionization processes also contribute to the photocurrent in bulk heterojunction (BHJ) OPVs with fullerene-rich compositions. The short-circuit current density (Jsc) in a MoO3/C60 Schottky OPVs shows almost no dependence on temperature down to 80 K. This characteristic of bulk-ionization allows the use of temperature-dependent measurements of Jsc to distinguish bulk-ionization from charge transfer at a D-A interface. For BHJ OPVs constructed using the D-A pairing of boron subphthalocyanine chloride (SubPc)-C60, bulk-ionization is found to contribute >10% of the total photocurrent and >30% of the photocurrent from C60. We further find that fullerene-rich SubPc-C60 BHJ OPVs show a larger open-circuit voltage (Voc) than evenly mixed BHJs due to the presence of bulk-ionization. This talk will examine the dependence of Jsc and Voc on the relative fraction of dissociation by charge transfer and bulk-ionization processes.

Novel solar energy harvesting options based on solution-processable inorganic/organic hybrid materials. NATALIE STINGELIN, Imperial College London — The growing demand for energy and increasing concerns for the effect of the excessive abuse of fossil fuels on the environment force the scientific world to search for alternative, clean and safe energy sources. Finding ways to harvest solar energy is one of the most appealing options. Here, we present a novel approach that exploits the versatile properties of recently developed, photoactive organic/inorganic hybrid fluids based on titanium oxide hydrates and polyalcohols for the production of versatile solar fuels. We will show that such systems can absorb light in the UV-near visible wave-length range. The sunlight’s energy is then converted into chemical energy in the form of reduced titanium species, which can be re-oxidised by oxygen when required. Therefore, the absorbed energy is stored as long as oxygen is excluded by the hybrid system. We, furthermore, demonstrate that once discharged, the fluid can be activated again by exposing it to sunlight and recycled – a property that is important technologically. The same hybrids can also be exploited to produce structures that permit efficient management of light. We will illustrate the potential of this class of materials based on some of our recent approaches to fabricate light-scattering and light-in-coupling structures, and discuss future opportunities they open up.

Dark current of organic heterostructure devices with insulating spacer layers. SUN YIN, Shandong University, China, WANYI NIE, ADITYA D. MOHITE, AVADH SAXENA, DARRYL L. SMITH, Los Alamos National Lab, P. PAUL RUUDEN, University of Minnesota — The dark current density at fixed voltage bias in donor/acceptor organic planar heterostructure devices can either increase or decrease when an insulating spacer layer is added between the donor and acceptor layers. The dominant current flow process in these systems involves the formation and subsequent recombination of an interfacial exciplex state. If the exciplex formation rate limits current flow, the insulating interface layer can increase dark current whereas, if the exciplex recombination rate limits current flow, the insulating interface layer decreases dark current. We present a device model to describe this behavior and illustrate it experimentally for various donor/acceptor systems, e.g. P3HT/LiF/C60.

Unpinning the Open-Circuit Voltage in Organic Solar Cells through Tuning Ternary Blend Active Layer Morphology. PETR KHYABICH, Princeton University, Department of Chemical and Biological Engineering, BARRY THOMPSON, University of Southern California, Department of Chemistry and Loker Hydrocarbon Research Institute, YUEH-LIN LOO, Princeton University, Department of Chemical and Biological Engineering — The use of ternary, as opposed to binary, blends having complementary absorption in active layers of organic bulk heterojunction solar cells is a simple approach to increase overall light absorption. While the open-circuit voltage (Voc) of such solar cells have generally been shown to be pinned by the smallest energy level difference between the donor and acceptor constituents, there have been materials systems, that when incorporated into active layers of solar cells, exhibit composition dependent and tunable Voc. Herein, we demonstrate that this Voc tunability in ternary blend solar cells is correlated with the morphology of the active layer. Chemical compatibility between the constituents in the blend, as probed by grazing-incidence X-ray diffraction (GIXD) measurements, affords Voc tuning. The constituents need not “co-crystallize”; limited miscibility between the constituents in the active layers of solar cells affords Voc tunability. Poor physical interactions between the constituent domains within the active layers, on the other hand, result in devices that exhibit an invariant Voc that is pinned by the smallest energy level difference between the donor(s) and the acceptor(s). Our morphological studies thus support the proposed alloying model that was put forth originally.

Synthesis and Structure of Fully Conjugated Block Copolymers Utilized in Organic Photovoltaics. YOUNGMIN LEE, MELISSA APLAN, QING WANG, ENRIQUE D. GOMEZ, Pennsylvania State Univ — Fully conjugated block copolymers have the potential to overcome many of the limitations of mixtures and blends as photoactive layers in solar cells; furthermore, they may serve as model systems to study fundamental questions regarding optoelectric properties and charge transfer. However, the synthesis of fully conjugated block copolymers remains a challenging issue in the field. We have optimized the two-step synthesis of P3HT-b-PFTBT, which is composed comprised of Grignard metathesis for polymerization of P3HT followed by chain extension through a Suzuki-Miyaura polycondensation. We find that the concentration of the Grignard reagent is critical for end-group control such that P3HT is terminated by H at one end and Br at the other. Furthermore, we can utilize an asymmetric feed ratio of monomers for the Suzuki-Miyaura reaction to minimize the amount of uncoupled homopolymers and to control the molecular weight of the second block. We investigated the chemical composition, structure and electrical characteristics of the polymers prepared by the different synthetic methods, and demonstrate that we can utilize these strategies for the synthesis of block copolymers beyond P3HT-b-PFTBT.
1:39PM B41.00011 Comparison of Reverse Leakage Current Density in Bilayer and Bulk Heterojunction Organic Photodetectors. XIN XU, ANANTH DODABALAPUR, University of Texas Austin — Soft materials such as organic semiconducting polymers and small molecules will allow the development of next generation photodetectors. Their ease of manufacturing and ability to be placed on flexible substrates allow new innovations such flexible camera elements. While organic photodetectors are structurally similar to their solar cell counterparts, their operation under reverse bias is an important difference which leads to differences in optimization. Reverse leakage current within photodetectors is a key metric in their performance. Minimizing these leakage currents is an important research goal for the advancement of organic photodetectors. We have examined different material systems such as ZnO/CuPc, ZnO/P3HT, and P3HT/PCBM. Using all of this data, we will present a broad picture on how to improve organic photodetector performance.

1We acknowledge support from the NASCENT NSF ERC.

1:51PM B41.00012 Analysis of Charge Carrier Transport in Organic Photovoltaic Active Layers. XU HAN, DIMITRIOS MAROUDAS, University of Massachusetts, Amherst — We present a systematic analysis of charge carrier transport in organic photovoltaic (OPV) devices based on phenomenological, deterministic charge carrier transport models. The models describe free electron and hole transport, trapping, and detrapping, as well as gerninate charge-pair dissociation and gerninate and bimolecular recombination, self-consistently with Poisson’s equation for the electric field in the active layer. We predict photocurrent evolution in devices with active layers of P3HT, P3HT/PMMA, and P3HT/PS, as well as P3HT/PCBM blends, and photocurrent-voltage (I-V) relations in these devices at steady state. Charge generation propensity, zero-field charge mobilities, and trapping, detrapping, and recombination rate coefficients are determined by fitting the modeling predictions to experimental measurements. We have analyzed effects of the active layer morphology for layers consisting of both pristine drop-cast films and of nanoparticle (NP) assemblies, as well as effects on device performance of insulating NP doping in conducting polymers and of specially designed interlayers placed between an electrode and the active layer. The model predictions provide valuable input toward synthesis of active layers with prescribed morphology that optimize OPV device performance.

2:03PM B41.00013 Ultrafast Measurement Confirms Charge Generation through Cold Charge Transfer States. BHJ CAUTAM, ROBERT YOUNTS, North Carolina State University, LIANG YAN, University of North Carolina at Chapel Hill, EVGENY DANILOV, HARALD ADE, North Carolina State University, WEI YOU, University of North Carolina at Chapel Hill, KENAN GUNDOGDU, North Carolina State University — The role of excess energy in generation and extraction of charges through charge transfer (CT) states in polymer solar cells is a subject of debate. There are reports suggesting increase of charge generation yield with excess energy based on ultrafast experiments. On the other hand time delayed collection field measurements shows that excess photon energy has no effect in photovoltaic efficiency. Here we resolved this discrepancy by studying the dynamics of CT excitons and polarons in blends of medium gap copolymers. We found that low-lying charge transfer (CT) excitons can generate charges over a long time period (nanosecond) and contribute photocurrent on the bulk heterojunction devices. By performing resonant CT excitation as well as above gap excitation transient absorption measurements we investigated that the charges are generated more efficiently through low-lying CT states in efficient devices independent of excitation energy.

Monday, March 2, 2015 11:15AM - 2:15PM — Session B42 DPOLY: Focus Session: Block Copolymer Thin Films I 214B - Gila Stein, University of Houston

11:15AM B42.00001 Morphology of Conjugated Block Copolymers: Self-Assembly, Crystallization, and Phase Separation. RAFAEL VERDUSCO, William Marshall Rice University — All-Conjugated Block Copolymers comprised of donor and acceptor polymer blocks are currently under development for use in organic photovoltaic devices. An attractive feature of these materials is their potential to self-assemble into well-defined donor and acceptor domains. However, achieving self-assembled film structures requires additional processing and annealing due to the high crystallization temperature of conjugated polymers and low Flory-Huggins chi interaction parameter between polymer blocks. This talk will present experimental studies into the processing-dependent morphology of all-conjugated block copolymer films relevant for organic photovoltaic devices. Conjugated block copolymer films that contain poly(3-hexyl thiophene) (P3HT) as the donor block exhibit crystallization as the predominant feature. Even at relatively low mass contents, the P3HT block crystallizes in solvent cast films. The orientation of P3HT crystallites is face-on for as-cast or low-temperature annealed films, but under annealing at elevated temperature, the crystallite orientation flips to an edge-on orientation. This behavior is observed for a wide-range of acceptor polymer blocks. Analysis of films by grazing-incidence X-ray scattering shows that conjugated block copolymers exhibit poor mesoscale ordering in solvent cast or thermally annealed films. Under solvent annealing, periodic lamellae with characteristic domain size of 4 nm are observed. The domain size is independent of block copolymer molecular weight and composition, and we hypothesize is driven by a combination of crystallization and micro-phase segregation. Finally, we investigate the morphology of PTB7 block copolymers as compatibilizers for PTB7-fullerene blends. Addition of PTB7 block copolymers can increase or decrease domain sizes, and morphology is stable to long-term thermal annealing.

11:51AM B42.00002 Polypeptoids: A model system for exploring sequence and shape effects on block copolymer self-assembly. RACHEL SEGALMAN, University of California, Santa Barbara — While our ability to understand the detailed relationship between block copolymer chemistry and mesoscopic self-assembly has made remarkable progress over the last many years, yet we are still limited to a relatively small number of blocks in terms of structure-property understanding. Thus, there is a need to explore self-assembly phase space with sequence using a model system. Polypeptoids are non-natural, sequence specific polymers that offer the opportunity to probe the effect of sequence on self-assembly with much simpler molecular interactions and more scalable synthesis than traditional polypeptides. In this talk, I will discuss the use of this model system to understand the role of sequence on chain collapse and globule formation in solution, polymer crystallization, and block copolymer self-assembly. I will then discuss potential application as surface active agents for anti-fouling.
12:27PM B42.00003 Morphology Development in Block Copolymer Thin Films via Direct Immersion Annealing , ARVIND MODI, SARANG BHAWAY, BRYAN VOGT, The University of Akron, ASHUTOSH SHARMA, IIT Kanpur, ALAMGIR KARIM, The University of Akron — Conventional methods of annealing thin block copolymer (BCP) films include Thermal Annealing and Solvent Vapor Annealing (SVA) processes. Both of the processes have demonstrated excellent control over morphologies and nanostructures. However, both have constraints including long annealing time duration and/or complicated setup requirement. We introduce Direct Immersion Annealing (DIA) of thin block copolymer (BCP) films involving immersion of polymer films directly into the solvent mixture composed of selective non-solvent and solvent for blocks. Non-solvent prevents the dissolution of films while the good solvent permeates the film and plasticizes the blocks. A fine control of swelling ratio can be achieved through an easy and robust control of solvent volume fractions. We studied cylindrical Poly(styrene-block-methyl methacrylate) system in detail and quantified the growth of correlation length ($\xi$) with time($t$) ($\xi \sim t^{\alpha}$). We observe a reduction in growth exponent ($\alpha$) with several fold increase in pre-exponential factor ($A$) compared to isotropic thermal annealing. We further demonstrate the extension of this strategy to systems with diverse range of $\chi$, molecular weight and other morphologies.

12:39PM B42.00004 Real-Time observation of PS-PDMS block copolymer self-assembly under solvent vapor annealing $^1$, WUBIN BAI, MIT, KEVIN YAGER, Brookhaven National Laboratory, CAROLINE ROSS, MIT — Solvent annealing provides a convenient way to produce microphase separation in films of block copolymers, but the morphology transition of the film during the solvent absorption, equilibrium solvent-BCP concentration and solvent desorption process are not well known. An in situ study of solvent annealing of polystyrene-block-polydimethylsiloxane (PS-PDMS, 16 kg/mol, fPDMS = 30%, period 17 nm) diblock copolymer was carried by synchrotron grazing-incidence small-angle X-ray scattering (GISAXS). The swollen film morphology was found to be strongly dependent on swelling ratio. A transition from the disordered state to a highly ordered state which contained multiple layers of in-plane cylinders was observed at a swelling ratio around 1.45 from samples with 100nm to 1000nm as-cast thickness. The rate of solvent absorption was found to be less important to the dried morphology, while the time of equilibrium solvent-BCP concentration stage was found to influence the orientation of self-assembled microdomains and the drying rate was found to affect the degree of structure deformation. The implications of the results to pattern generation for block copolymer directed self-assembly will be discussed.

12:51PM B42.00005 The kinetics of swelling in block copolymer thin films during “solvo-microwave” and solvo-thermal annealing: The effect of vapour pressure , PARVANRH MOKARIAN-TABARI, University College Cork and Tyndall National Institute; Centre for Research on Adaptive Nanostructures, TIMOTHY COLLINS, CIAN CUMMINS, University College Cork and Tyndall National Institute, CLAUDIA DELGADO SIMÃO, OLIVIA SOTOMAYOR, ICN2, Campus de la UAB, Barcelona 08193, Spain, MICHAEL A. MORRIS, University College Cork and Tyndall National Institute; Centre for Research on Adaptive Nanostructures — Long annealing time associated with high chi block copolymers is a major disadvantage for their integration in industrial applications. Microwave-assisted microphase separation appears to offer considerable benefits in reducing annealing times for BCPs. However, despite the promise of this technique, little is known about the mechanism of how microwave irradiation might sponsor the molecular motion that accompanies microphase separation. In our earlier work we carried out an in situ temperature measurement during “solvo-microwave” annealing of poly(styrene-b-lactic acid) (PS-b-PLA) in presence of THF and also in the conventional oven. Comparing the results indicated that vapour pressure of THF might have a major role to achieve fast self-assembly (60 seconds) in PS-b-PLA film. Here, we study the kinetics of swelling by monitoring the pressure through in situ pressure experiments during “solvo-microwave” and solvo-thermal annealing. The preliminary data suggest that the rate at which the THF pressure increases is the key factor. This suggests that kinetics, i.e., the rate of film swelling and diffusion, affects the order and the coherence length of the pattern. We estimated the defect density in the patterns by our recently developed defect analysis software.

1:03PM B42.00006 Fluorine effects on morphology and surface energy of diblock copolymer thin films $^1$, UMESH SHRESTHA, DVORA PERAHIA, Clemson University, STEPHEN CLARSON, University of Cincinnati — The interfacial composition and structure formed by the segregation between the incompatible blocks in a diblock copolymer thin film influence the stability and response of the film to external stimuli. Introduction of fluorine enhances the interfacial energy as well as chemical and thermal stability of the polymer film. Here we follow the interfacial structure and response of Si containing diblock co-polymer poly trifluoro propyl methyl siloxane-poly(styrene) (PTEPSMS-PS) with the SiF fraction ranging from 0.3 to 0.5 in surface of the films as a function of temperature and solvent, using atomic force microscopy and contact angle measurement. We found that the tendency of the fluorine to migrate towards surface affects the surface energy while Si in backbone enhances the flexibility of the chains. Thin films prepared from selective good solvent for one of the blocks and good solvent for both blocks formed different structures compared to their melts. Correlation between morphology and volume fraction is dominant above the Tg of the polystyrene whereas below Tg limited effect is observed.

1:15PM B42.00007 Perpendicularly oriented nanostructures by using star-shaped poly(methyl methacrylate)-block-poly(dimethylsiloxane) thin film , SANGSHIN JANG, KYUSEONG LEE, HONG CHUL MOON, JICHEOL PARK, JONGHEON KWAK, GUMHYE JEON, JIN KON KIM $^2$, Pohang Univ of Sci & Tech — Thin films of star-shaped 18-arm poly(methyl methacrylate)-block-poly(dimethylsiloxane) copolymers ((PMMA-b-PS)$_s$) with two different volume fraction of PS block (f$_{PS}$) (0.60 and 0.75). Interestingly, perpendicularly oriented lamellar and cylindrical domains were observed by atomic force microscopy (AFM) and grazing-incidence small-angle X-ray scattering (GISAXS), after thermal annealing without additional treatment such as random copolymer treatment or solvent annealing. Perpendicularly oriented nanostructures were also achieved for versatile substrates such as PS(OR PMMA)-brushed substrate, flexible substrate ( PEN) or gold-deposited substrate.

1:27PM B42.00008 Vertical Continuity and Alignment of Block Copolymer Domains by Kinetically Controlled Electrospray Deposition , HANQIONG HU, YOUNGWOO WOO, XUNDA FENG, CHINEDUM OSUJI, Yale University, OSUJI LAB TEAM — We report the fabrication of vertically aligned cylindrical block copolymer (BCP) domains using continuous electrospray deposition (ESD) onto bare wafer surfaces. The out-of-plane orientation of hexagonally packed styrene cylinders was achieved in a “fast-wet” deposition regime where rapid evaporation of solvent in droplets of polymer solution drove the vertical alignment of SBS domains. The deposition conditions were optimized such that thermally activated crosslinking of the polybutadiene matrix provided kinetic control of the morphology, locking in the vertical alignment and preventing relaxation of the system to its preferred parallel orientation on the non-treated substrate. Physically continuous and vertically oriented domains is achieved over several microns of film thickness. We describe the effects of flow rate, collection distance and substrate temperature on thin film morphology and demonstrate selective etching capabilities. The ability of ESD to fabricate well-ordered and aligned BCP films on non-treated substrates, the low utilization of material relative to spin-coating and the continuous nature of the deposition may open up new opportunities for BCP thin films. We are exploring ESD as a new platform for sequential deposition of BCPs with different functionalities.
1:39PM B42.00009 Edge effects and surface patterns in a quenched lamella forming block copolymer, ANDREW B. CROLL, PEGGY WILLENBRING, ALEXANDER WAGNER, North Dakota State Univ — Thin lamellar systems are well known to form structures when cast in a thickness that is not commensurate with a lamellar spacing. The structures have often been considered an ideal two-dimensional system and much has been learned of the patterns dynamics. This early work considered a uniform isotropic film in a region infinitely far from a boundary. Here we specifically consider the influence of a pre-existing boundary on the pattern formation process, and identify the emergence of a unique new lengthscale in the problem. Our work combines an idealized experimental system (polystyrene-poly(2-vinylpyridine) diblock near the order-to-disorder transition point) with precise numerical computation (a Lattice-Boltzmann model) in order to develop an understanding of the relative importance of the key physical phenomena underlying the results. The new lengthscale is found to be inversely proportional to both total film thickness and quench depth and offers unique opportunities to engineer structures extending beyond the 2D layer into the 3rd dimension.

1:51PM B42.00010 A Stable Hexagonally Modulated Lamellar (HML) Structure of Asymmetric Polystyrene-b-Poly(2-vinylpyridine) in Film Geometry, SUNGMIN PARK, Yonsei University, HYUNGJU AHN, Pohang Accelerator Laboratory, BYEONGDU LEE, Argonne National Laboratory, DU YEOL RYU, Yonsei University, YONSEI UNIVERSITY COLLABORATION, POHANG ACCELERATOR LABORATORY COLLABORATION, ARGONNE NATIONAL LABORATORY COLLABORATION — When a block copolymer (BCP) is confined in film geometry, the phase transitions would be different or shifted from those of the corresponding bulk. In this study, the phase transition of an asymmetric polystyrene-b-poly(2-vinylpyridine) (PS-b-P2VP) films in the presence of the strong interfacial interactions were investigated by grazing incidence small-Angle x-ray scattering (GISAXS) and transmission electron microscopy (TEM). The order-to-order transition (OOT) and order-to-disorder transition (ODT) in film geometry were influenced by the strong favorable forces between the P2VP block and substrate, resulting in the thickness-dependent phase diagram. The phase stability of a hexagonally modulated lamellar (HML) structure was identified in film geometry, and in the films below 10Lo it was extended over the entire temperature range even above the ODT temperature of the bulk.

2:03PM B42.00011 Adsorbed block copolymer nanolayers on solids, JENNIFER IMBROGNO, State Univ of NY-Stony Brook, MANI SEN, Department of Materials Science and Engineering, Stony Brook University, Stony Brook, NY 11794-2275, STEVEN KAHN, Department of Chemistry, University at Buffalo, The State University of New York, Buffalo, NY 14260-3000, SHOTARO NISHITSUJI, Department of Polymer Science and Engineering, Graduate School of Science and Engineering, Yamagata University, Yamagata, 992-8510, Japan, E. BHOJE GOWD, CSIR-NIIST, Trivandrum-695 019, Kerala, India, MAYA K. ENDOH, TADANORI KOGA, Department of Materials Science and Engineering, Stony Brook University, Stony Brook, NY 11794-2275 — Directed self-assembly of block copolymers (BCP) has been used as an advanced lithography method. In this study, we aim to shed light onto the structures of BCP at the polymer melt-solid interface. Polystyrene-block-poly(4-vinylpyridine) (PS-b-P4VP) block copolymer was used. Spin-cast 32 nm PS-b-P4VP films on silicon substrates were (i) thermally annealed at high temperature above Tg of the polymers or (ii) solvent vapor annealing with chloroform (non-selective solvent) and subsequent 1,4-dioxane (selective solvent). Using atomic force microscopy (AFM), we found perpendicular hexagonally packed cylinders at the topmost surface of the resultant PS-b-P4VP films regardless of the annealing processing. In addition, to study the adsorbed layer structure, we rinsed the annealed films with toluene and characterized the morphologies and film structures using grazing incidence small-angle X-ray scattering, X-ray reflectivity and AFM. The details will be discussed.

Monday, March 2, 2015 11:15AM - 2:15PM — Session B43 DPOLY: Focus Session: Fluids Under Confinement, Water at Interfaces and in Confinement 214C - Elisa Riedo, Georgia Institute of Technology

11:15AM B43.00001 Molecular Dynamics Simulations of Water Evaporation, CHENGYUAN WEN1, 2. Virginia Tech, GARY GREST3, Sandia National Laboratories, SHENGFENG CHENG4, Virginia Tech — The evaporation of water from the liquid/vapor interface is studied via large-scale molecular dynamics simulations for systems of more than a million atoms at 550K and 600K. The TIP4P-2005 water model whose liquid/vapor surface tension is in excellent agreement with experiments is used. Evaporative cooling at the interface is observed from temperature profiles determined from both translational and rotational kinetic energy. During evaporation, the density of water is slightly enhanced near the liquid-vapor interface. The velocity distribution of water molecules in the vapor phase during evaporation at various distances relative to the interface fit a Maxwell-Boltzmann distribution. While our results indicate an imbalance between evaporating and condensing water molecules, local thermal equilibrium is found to hold in addition to mechanical equilibrium.

11:27AM B43.00002 Structure of the Ice-Clathrate Interface, ANDREW NGUYEN, The University of Utah, MATTHEW KOC, TRICIA SHEPHERD, Westminster College, VALERIA MOLINERO, The University of Utah — In the laboratory, clathrates are customarily synthesized from ice and gas guest. It is not clear how and whether ice assists in the nucleation of clathrate hydrates. The structure of the ice-clathrate interface can help assess the role of ice in clathrate nucleation. However, only few studies have addressed the structure of the ice-clathrate interface. Here, we use molecular dynamic simulations to study the structure of the ice-clathrate interface. There is no lattice matching between any plane of ice and clathrate hydrates, therefore an interfacial transition layer has to form to connect the two crystals. We investigate the structure of the ice-clathrate interface produced by alignment and equilibration of the crystals, competitive growth of the two crystals from a common solution, and nucleation of hydrate in the presence of a growing ice front. We find that the interfacial transition layer between ice and clathrate has a width of two to three water layers and it is disordered in all cases. Water in the interfacial transition layer has tetrahedral order lower than either ice or clathrate and higher than liquid water under the same thermodynamic conditions.

11:39AM B43.00003 Experimental evidence for empty cage methane clathrate hydrates grown using surfactants. JEFFREY BOTIMER, DEREK DUNN-RANKIN, PETER TABOREK, Univ of California - Irvine — Clathrate hydrates are non-stoichiometric ice-like crystalline compounds consisting of host water molecules forming a cage-like structure around guest molecules. The guest molecule is necessary for the stability of the hydrate. Surfactants have been shown to greatly enhance the kinetics of hydrate growth, which is important for many applications. We have built custom cells that allow in situ Raman and optical imaging of the growth of methane clathrate hydrates from liquid water. In our studies, above 0°C, we observe the formation of solid that precedes the absorption of methane gas required to form clathrate hydrates. Our research shows that sodium dodecyl sulfate (SDS) causes a fundamental change in the growth mechanism of methane hydrates, creating a temporary empty cage clathrate structure. This change is confirmed by in situ Raman spectroscopy and in situ NMR. Water uptake can simultaneously monitor the gas uptake, and the NMR signal of the growing hydrate in a high pressure NMR cell. The empty cage solid structure appears to be unique to surfactant assisted hydrate growth, and begins to disappear for low SDS concentrations (<25ppm).

11:51AM B43.00004 Formation of 1D adsorbed water structures on CaO(001), XUNHUA ZHAO, SASWATA BHATTACHARYA, LUCA M. GHIRINGHELLI, SERGEY V. LEVCHENKO, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin — Understanding the interaction of water with oxide surfaces is of fundamental importance for basic and engineering sciences. Recently, a spontaneous formation of one-dimensional (1D) adsorbed water structures have been observed on CaO(001) [1]. Interestingly, at other alkaline earth metal oxides, in particular MgO(001) and SrO(001), such structures have not been found experimentally. We calculate the relative stability of adsorbed water structures on the three oxides using density-functional theory combined with the 

of one-dimensional (1D) adsorbed water structures have been observed on CaO(001) [1]. Interestingly, at other alkaline earth metal oxides, in particular MgO(001) and SrO(001), such structures have not been found experimentally. We calculate the relative stability of adsorbed water structures on the three oxides using density-functional theory combined with the ab initio atomistic thermodynamics. Low-energy structures at different coverages are obtained with a first-principles genetic algorithm. Finite-temperature vibrational spectra are calculated using ab initio molecular dynamics. We find a range of (T, p) conditions where 1D structures are thermodynamically stable on CaO(001). The orientation and vibrational spectra of the 1D structures are in agreement with the experiments [1]. The formation of the 1D structures is found to be actuated by a symmetry breaking in the adsorbed water tetramer, as well as by a balance between water-water and water-substrate interactions, determined by the lattice constant of the oxide.—[1] X. Shao, Y. Fujimori, M. Sterrer, H.-J. Freund, and N. Nilius, to be published.

12:03PM B43.00005 Characterization of the Mobility and Reactivity of Water Molecules on TiO2 Nanoparticles by 1H Solid-State Nuclear Magnetic Resonance1, XIAOLIANG WANG, LILI ZHU, Nanjing University, PINGCHUAN SUN, Nankai University, DONGSHAN ZHOU, GI XUE, Nanjing University — Understanding interfacial water behavior is essential to improving our understanding of the surface chemistry and interfacial properties of nanomaterials. Here we use 1H solid-state nuclear magnetic resonance (1H SSNMR), we successfully monitored ligand exchange reaction between oleylamine (OLA) and adsorbed water on titanium dioxide nanoparticles (TiO2 NPs). Three different types of interfacial waters with different reactivities were distinguished. The mobility of the adsorbed water molecules was characterized by dipolar filtered 1H SSNMR. Our experimental results demonstrate that the adsorbed water can be categorized into three different layers: rigid water species with restricted mobility closest to the surface of TiO2 NPs; less mobile water species weakly confined on TiO2 NPs; and water molecules with high mobility. Water in the third layer could be replaced by OLA, while water in the first and second layers remained intact. The finding that the interfacial water with the highest mobility has the strongest reactivity has guiding significance for tailoring the hydrophilic and hydrophobic properties of TiO2 NPs.

12:15PM B43.00006 Diffusive Dynamics of Water inside Hydrophobic Carbon Micropores Studied by Neutron Spectroscopy and MD Simulation, SOULEYMANE DIALLO, LUKAS VLOEK, EUGENE MAMONTOV, JONG KEUM, JIHUA CHEN, Oak Ridge National Laboratory, JOSEPH HAYES, American Technical Trading, DAVID WESOLOWSKI, ARIEL CHIALVO, Oak Ridge National Laboratory — Using neutron scattering, we have investigated the ambient pressure diffusive dynamics of water in microporous Kynol®TM= ACF-10 (with average micropore size of ~11.6 Å) from temperature T = 280 K in its stable liquid state down to T = 230 K into the metastable supercooled phase. The observed characteristic relaxation times and diffusion coefficients are found to be respectively higher and lower than those in bulk water, indicating a slowing down of the water mobility with decreasing temperature. Comparison between the experimental observations and complementary molecular dynamics simulations of a model system, in which we studied the diffusion of water within the 12 Å gap of two parallel graphene sheets will be presented.

12:27PM B43.00007 Quantum tunneling and vibrational dynamics of ultra-confined water, ALEXANDER I. KOLENSIKOV, LAWRENCE M. ANOVITZ, GEORGE EHLERS, EUGENE MAMONTOV, ANDREY PODLESNYAK, TIMOTHY R. PRISK, Oak Ridge National Laboratory, TN, ANDREW SEEL, ISIS Facility, UK, GEORGE F. REITER, University of Houston, TX — Vibrational dynamics of ultra-confined water in single crystals beryl, the structure of which contains ~ 5 Å diameter channels along the c-axis was studied with inelastic (INS), quasi-elastic (QENS), and deep inelastic (DINS) neutron scattering. The results reveal significantly anisotropic dynamical behavior of confined water, and show that effective potential experienced by water perpendicular to the channels is significantly softer than along them. The observed 7 peaks in the INS spectra (@ energies 0.25 to 15 meV), based on their temperature and momentum transfer dependences, are explained by transitions between the split ground equivalent positions across the channels. DINS study of beryl at T = 4.3 K shows narrow, anisotropic water proton momentum distribution with corresponding kinetic energy, E_p = 95 meV, which is much less than was previously observed in bulk water (~150 meV). We believe that the exceptionally small E_K in beryl is a result of water quantum tunneling \ delocalization in the nanometer size confinement and weak water-cage interaction.

12:39PM B43.00008 Nanomechanical measurements of ionic effect on nanoconfined water, EDWARD KRAMKOWSKI, Wayne State University, SHAH KHAN, University of Peshawar, PETER HOFFMANN, Wayne State University — The behavior of liquid molecules confined to nanometer-scale spaces is a topic of particular interest to a variety of fields. From lab-on-a-chip medical device manufacturers to petroleum engineers involved in oil recovery, a wide range of researchers could benefit from a better understanding of the mechanics of nanconfined liquids. Previous research has shown that above a critical strain rate, a confined liquid exhibits a solid-like response that oscillates with a period roughly equal to the molecular diameter of the liquid being observed. This indicates that when a liquid is compressed at a rate faster than the molecules can diffuse in bulk out from between the confining surfaces, it dynamically solidifies into an anisotropic layered liquid. We have simultaneously monitored their uptake and their mechanical behavior. We believe that the exceptionally small E_K in beryl is a result of water quantum tunneling \ delocalization in the nanometer size confinement and weak water-cage interaction.

The neutron experiment at ORNL was sponsored by the Sci. User Facilities Div., BES, U.S. DOE. This research was sponsored by the Div. Chemical Sci, Geosciences, and Biosciences, BES, U.S. DOE. The STFC RAL is thanked for access to ISIS neutron facilities.
12:51PM B43.00009 Supressed Water Crystallization in Nano-Structured Physical Hydrogel. CLINTON WIENER, BRYAN VOGT, ROBERT WEISS, Univ of Akron — Suppressed water crystallization occurs in some organisms, such as the common wood frog, which allows it to hibernate in a frozen state without damage to its cells. Knowledge of the behavior of supercooled water and alternate ice forms may have many implications to many fields of science. Supercooled water by several degrees below the normal freezing point is often observed in hydrogels that have attractive interactions with water, e.g., hydrogen bonding. Repulsive confinement, such as in hydrophobic porous carbon, can have even more significant effects on the supercooling of the entrapped water. This talk describes the freezing behavior in nano-structured, hydrophobically modified poly(dimethyl acrylamide) hydrogels that possess attractive and repulsive interactions with water and are physically crosslinked by hydrophobic nanodomains. Three distinct water freezing regimes were observed in the hydrogel swollen to about 50% water by weight. Differential scanning calorimetry detected three crystallization exotherms at 254K, 244K, and 227K. Quasi-elastic neutron scattering experiments have shown that although the water mobility was suppressed at room temperature, the water remained significantly mobile below the normal freezing point of water. The talk will discuss how tuning the concentration of the hydrophobic composition of the hydrogel affects the porous length scales in the hydrogel, which may alter the state of water and the crystal form produced by supercooling.

1:03PM B43.00010 ABSTRACT WITHDRAWN

1:15PM B43.00011 Ice-like Behavior of Ultra-Confined Water1. TIMOTHY PRISK, ALEXANDER KOLESNIKOV, EUGENE MAMONTOV, LAWRENCE ANOVITZ. Oak Ridge National Laboratory — Water confined within microporous minerals presents an extreme example of fluid confinement, where the water molecule is trapped within cages or pore channels which are not much larger than the water molecule itself. Hemimorphite Zn$_4$SiO$_4$(OH)$_2$·H$_2$O is a microporous silicate mineral containing confined molecular water which interacts with the crystal structure by means of hydrogen bonding. The water molecule forms a supercooled hydrogen bonds with the hydroxyl groups, forming a system of two-dimensional ice within the pore channel. In this presentation, we report quasi-elastic and inelastic neutron scattering studies of water and hydroxyl proton dynamics within hemimorphite. The scattering data reveal strong anisotropy in the vibrational behavior of the water molecule, with the scissors and stretching normal mode motions occurring only on a single crystallographic plane. The effective density of states of the protons extracted from the scattering data reproduces the water contribution to the mineral’s heat capacity.

1:27PM B43.00012 The consequences of water in adhesion, friction and wetting2, ALI DHINOJWALA, ADRIAN DEFANTE, TARAK BURALI, MATTHEW BECKER, Univ of Akron — The interactions of hydrophobic surfaces are relevant to numerous processes in physical and biological sciences. We have used contact mechanics, contact angle measurements, and a biaxial friction cell to quantify adhesion, wetting and friction behavior in wet environments between two low energy surfaces. To gain an understanding of the role of water in these processes we have coupled these measurements with surface sensitive sum frequency generation to directly measure the contacting interface. These results provide a direct molecular probe to understand macroscopic phenomena.

1:39PM B43.00013 How different is water crystallization from polymer crystallization under confinement? . GEORGE FLOUDAS, University of Ioannina, YASUHITO SUZUKI, Max Planck Institute for Polymer Research, HATICE DURAN, TOBB University of Economics and Technology, MARTIN STEINHART, University of Osnabrueck, HANS-JUERGEN BUTT, Max Planck Institute for Polymer Research — The freezing mechanism of water under confinement can be fundamentally different from the bulk. Despite fundamental importance, the lack of well-defined confining media precluded a systematic investigation. Herein we employ self-ordered nanoporous aluminum oxide (AAO) which contains arrays of discrete, parallel and cylindrical nanochannels with uniform pore length and diameter to study the effect of confinement on water crystallization. By varying different parameters such as pore size, temperature and cooling rate, the respective conditions under which the hexagonal form (I$_h$) and the less common form of cubic ice (I$_c$) could be studied. We found a transition from homogeneous nucleation of I$_h$ to homogeneous nucleation of predominantly I$_c$, with decreasing pore diameter. Furthermore, the monotropic I$_c$ → I$_h$ transition commonly observed upon heating is suppressed inside pores having diameters ≤ 35 nm. These findings lead to the phase diagram of water under confinement. It contains a predominant cubic form, a form known to exist only in the upper atmosphere. There are many similarities between the freezing of water and the crystallization of polymers under confinement.

1:51PM B43.00014 Frictional energy barrier and blocking temperature in water molecules and carbon nanotubes system1. JIANWEI ZHANG, JIAJI LI, WENFENG LI, School of physics, Tongji University — Water transport through hydrophobic channels of single-walled carbon nanotubes has attracted a lot interests, especially, various potential applications of SWCNTs have been proposed for designing novel nanofluidic devices. By adopting Molecular dynamics method, we investigated mechanics and statistics properties of water molecules escaping from a confined single-walled carbon nanotube. From our numerical MD simulations and statistical model, we determined the friction energy barrier of water molecules in (10.10) SWCNT is 9.88 kcal/mol, and which is the minimal energy for flowing a water molecules in CNT. By only using friction energy barrier and relaxation time parameter, our model can fit all different situations MD simulation results. In order to describing the frictional lock behavior of water molecules, we introduced a new blocking temperature, below this temperature (391K for our system), water is locked in CNT due to friction energy barrier. We found that the blocking temperature is closely related to system response time, and it also shows a linear behavior to frictional energy barrier. Furthermore, we found several other interesting statistics results when a water molecules leaving SWCNTs.

2:03PM B43.00015 The Role of Water and Carbon Dioxide Intercalation on Na-Montmorillonite Swelling Behavior at Geological Carbon Sequestration Conditions1 MEYSAM MAKAREMI, KENNETH JORDAN, GEORGE GUTHRIE, EVGENIY MYSHAKIN, National Energy Technology Laboratory, and University of Pittsburgh, Pittsburgh, PA — Swelling of Na-montmorillonite in the environment relevant to geological CO$_2$ sequestration in deep underground formations is investigated by conducting classical Monte Carlo and molecular dynamics simulations. Both the binary (clay-water or clay–CO$_2$) and the ternary (clay-water–CO$_2$) systems containing the clay, water and carbon dioxide phases are simulated, and the free energy for clay swelling is calculated as a function of the interlayer distance. The calculations indicate that while water intercalates into the clay layer and forms stable monolayer and bilayer hydration states, in the absence of interlayer water adsorption of dry carbon dioxide is thermodynamically unfavorable. In the ternary system, two hydration states are observed with interlayer spacings corresponding closely to those of the pure water binary system. In addition, the simulations of the ternary system show that the incomplete first hydration state is more effective at adsorbing CO$_2$ molecules than is the incomplete second hydration state.

22:17AM B44.00002 Origami Mechanics: Bistability and Isometries, MOKHTAR ADDA-BEDIA, FREDERIC LECHENAULT, Laboratoire de Physique Statistique de l’ENS, MORPHOGENESIS AND MULTISCALE PHENOMENA TEAM — Origami structures are usually seen as assemblies of rigid faces articulated around creases with hinge-like behaviour. Their deployment and degrees of freedom are purely kinematic, resulting only from the geometry of the crease network. However, in real folded structures, the base material can deform outside the creases. In such situations, face bending competes with crease actuation in a morphogenetic way. In order to rationalise this interplay, we investigate the mechanical behaviour of an infinite sheet on which one or more straight creases meet at a single vertex. We find that these structures generically exhibit bistability, in the sense that they can snap through from one metastable configuration to another. Furthermore, we uncover a new class of isometry of the plane, which corresponds to metastable states of a creased sheet for which the hoop stress vanishes, an instability mechanism that is also responsible for the wrinkling of thin plates.

11:39AM B44.00003 ABSTRACT WITHDRAWN —

11:51AM B44.00004 Topological mechanics: from metamaterials to active matter, VINCENZO VITELLI, Leiden University — Mechanical metamaterials are artificial structures with unusual properties, such as negative Poisson ratio, bistability or tunable acoustic response, which originate in the geometry of their unit cell. At the heart of such unusual behavior is often a mechanism: a motion that does not significantly stretch or compress the links between constituent elements. When activated by motors or external fields, these soft motions become the building blocks of robots and smart materials. In this talk, we discuss topological mechanisms that possess two key properties: (i) their existence cannot be traced to a local imbalance between degrees of freedom and constraints (ii) they are robust against a wide range of structural deformations or changes in material parameters. The continuum elasticity of these mechanical structures is captured by non-linear field theories with a topological boundary term similar to topological insulators and quantum Hall systems. We present several applications of these concepts to the design and experimental realization of 2D and 3D topological structures based on linkages, origami, buckling meta-materials and lastly active media that break time-reversal symmetry.

12:27PM B44.00005 Critical transition to bistability arising from hidden degrees of freedom in origami structures, ITAI COHEN, JESSE SILVERBERG, Physics, Cornell Univ., JUN-HEE NA, Polymer Science and Engineering, UMass Amherst, ARTHUR EVANS, Physics, UMass Amherst, BIN LIU, Physics, Cornell Univ., THOMAS HULL, Maths, Western New England University, CHRISTIAN SANTANGELO, Physics, UMass Amherst, ROBERT LANG, Lang Origami, RYAN HAYWARD, Polymer Science and Engineering, UMass Amherst — Origami, the traditional art of paper folding, is now being used to design responsive, dynamic, and customizable mechanical metamaterials. The remarkable abilities of these origami-inspired devices emerge from a predefined crease pattern, which couples kinematic folding constraints to the geometric placement of creases. In spite of this progress, a generalized physical understanding of origami remains elusive due to the challenge in determining whether local kinematic constraints are globally compatible, and an incomplete understanding of how bending and crease plasticity found in real materials contribute to the overall mechanical response. Here, we show experimentally and theoretically that the traditional square twist, whose crease pattern has zero degrees of freedom (DOF) and therefore should not be foldable, is nevertheless able to be folded by accessing higher energy scale deformations associated with bending. Due to the separation of bending and crease energy scales, these hidden DOF lead to a geometrically-driven critical bifurcation between mono- and bistability. The scale-free geometric underpinnings of this physical phenomenon suggest a generalized design principle that can be useful for fabricating micro- and nanoscale mechanical switches.

12:39PM B44.00006 A probabilistic approach to randomness in geometric configuration of scalable origami structures, KE LIU, GLAUCIO PAULINO, PAOLO GARDONI, University of Illinois at Urbana-Champaign — Origami, an ancient paper folding art, has inspired many solutions to modern engineering challenges. The demand for actual engineering applications motivates further investigation in this field. Although rooted from the historic art form, many applications of origami are based on newly designed origami patterns to match the specific requirements of an engineering problem. The application of origami to structural design problems ranges from micro-structure of materials to large scale deployable shells. For instance, some origami-inspired designs have unique properties such as negative Poisson ratio and flat foldability. However, origami structures are typically constrained by strict mathematical geometric relationships, which in reality, can be easily violated, due to, for example, random imperfections introduced during manufacturing, or non-uniform deformations under working conditions (e.g. due to non-uniform thermal effects). Therefore, the effects of uncertainties in origami-like structures need to be studied in further detail in order to provide a practical guide for scalable origami-inspired engineering designs. Through reliability and probabilistic analysis, we investigate the effect of randomness in origami structures on their mechanical properties. Dislocations of vertices of an origami structure have different impacts on different mechanical properties, and different origami designs could have different sensitivities to imperfections. Thus we aim to provide a preliminary understanding of the structural behavior of some common scalable origami structures subject to randomness in their geometric configurations in order to help transition the technology toward practical applications of origami engineering.

12:51PM B44.00007 Exponential Number of Shapes in Origami Metasheets, PETER DIELEMAN, Univ of Leiden / AMOLF, SCOTT WAITUKAITIS, Univ of Leiden, MARTIN VAN HECKE, Univ Leiden / AMOLF — The simplest possible fold pattern that allows motion, the 4-vertex, has two distinct branches of motion. By deriving a local combinatorial rule, we show that the number of branches in a tesselated sheet of such 4-vertices grows exponentially with the number of vertices. We introduce energy in the system by approximating the folds as torsional springs and show that we can create an arbitrary number of well separated minima, i.e. shapes. With 3D printing, we bring these shape-shifting structures to life.
1:03PM B44.00008 Topological modes bound to lattice dislocations in mechanical metamaterials. JAYSON PAULOSE, BRYAN CHEN, VINCENZO VITELLI, Lorentz Institute — The mechanical rigidity of frameworks – nodes connected by springs or rigid bars – underlies the structural integrity of bridges, the response of granular materials, and the design of metamaterials with unusual mechanical properties. A fundamental question governing rigidity is the existence of mechanisms: motions that do not significantly stretch or compress the constituent elements of the structure. We demonstrate a novel way to introduce approximate mechanisms at desired locations in a metamaterial, by exploiting the properties of a recently introduced class of topological metamaterials. These special periodic frameworks which exhibit localized edge modes, analogous to the electronic edge states of topological insulators. We show that dislocations in such metamaterials are associated with soft modes of topological origin. The existence of the modes is determined by the interplay between two Berry phases – the Burgers vector of the dislocation and a topological “polarization” characterizing the underlying lattice. Simple prototypes built out of triangular plates joined by hinges provide a visual demonstration of these modes.

1:15PM B44.00009 Wave Propagation in Origami-inspired Foldable Metamaterials. PAI WANG, SIJIE SUN, Harvard University, KATIA BERTOLDI, bertoldi@seas.harvard.edu — We study the propagation of elastic waves in foldable thin-plate structures. Both 1D systems of periodic folds and 2D Miura-Ori patterns are investigated. The dispersion relations are calculated by finite element simulations on the unit cell of spatial periodicity. Experimental efforts and considerations are also discussed. The characteristic propagating bands and bandgaps are found to be very sensitive to the folding angles. The existence of highly tunable bandgap makes the system suitable for potential applications including adaptive filters in vibration-reduction devices, wave guides and acoustic imaging equipment.

1:27PM B44.00010 Quantification of a Helical Origami Fold. ERIC DAI, Washington University in St. Louis, XIAOMIN HAN, ZI CHEN, Dartmouth College — Origami, the Japanese art of paper folding, is traditionally viewed as an amusing pastime and medium of artistic expression. However, in recent years, origami has served as a source of inspiration for innovations in science and engineering. Here, we present the geometric and mechanical properties of a twisting origami fold. The origami structure created by the fold exhibits several interesting properties, including rigid foldability, local bistability and finely tunable helical coiling, with control over pitch, radius and handedness of the helix. In addition, the pattern generated by the fold closely mimics the twist buckling patterns shown by thin materials, for example, a mobius strip. We use six parameters of the twisting origami pattern to generate a fully tunable graphical model of the fold. Finally, we present a mathematical model of the local bistability of the twisting origami fold. Our study elucidates the mechanisms behind the helical coiling and local bistability of the twisting origami fold, with potential applications in robotics and deployable structures.

1:39PM B44.00011 Associative memory through rigid origami. ARVIND MURUGAN, MICHAEL BRENNER, Harvard University — Mechanisms such as Miura Ori have proven useful in diverse contexts since they have only one degree of freedom that is easily controlled. We combine the theory of rigid origami and associative memory in frustrated neural networks to create structures that can “learn” multiple generic folding mechanisms and yet can be robustly controlled. We show that such rigid origami structures can “recall” a specific learned mechanism when induced by a physical impulse that only need resemble the desired mechanism (i.e. robust recall through association). Such associative memory in matter, seen before in self-assembly, arises due to a balance between local promiscuity (i.e., many local degrees of freedom) and global frustration which minimizes interference between different learned behaviors. Origami with associative memory can lead to a new class of deployable structures and kinetic architectures with multiple context-dependent behaviors.

1:51PM B44.00012 Hiding the weakness: structural robustness using origami design. BIN LIU, Physics Department, Cornell University, CHRISTIAN SANTANGELO, Department of Physics, University of Massachusetts, Amherst, ITAI COHEN, Physics Department, Cornell University — A non-deformable structure is typically associated with infinitely stiff materials that resist distortion. In this work, we designed a structure with a region that will not deform even though it is made of arbitrarily compliant materials. More specifically, we show that a foldable sheet with a circular hole in the middle can be deformed externally with the internal geometry of the hole unaffected. Instead of strengthening the local stiffness, we fine-tune the crease patterns so that all the soft modes that can potentially deform the internal geometry are not accessible through strain on the external boundary. The inner structure is thus protected by the topological mechanics, based on the detailed geometry of how the vertices in the foldable sheet are connected. In this way, we isolate the structural robustness from the mechanical properties of the materials, which introduces an extra degree of freedom for structural design.

2:03PM B44.00013 Untangling the mechanics versus topology of overhand knots. PEDRO REIS, MOHAMMAD JAWED, Massachusetts Institute of Technology, PETER DIELEMAN, Leiden University, BASILE AUDOLY, Sorbonne Universités, UPMC Univ Paris & CNRS — We study the interplay between mechanics and topology of overhand knots in slender elastic rods. We perform precision desktop experiments of overhand knots with increasing values for the crossing number (our measure of topology) and characterize their mechanical response through tension-displacement tests. The tensile force required to tighten the knot is governed by an intricate balance between topology, bending, friction, and contact forces. Digital imaging is employed to characterize the configuration of the contact braid as a function of crossing number. A robust scaling law is found for the pulling force in terms of the geometric and topological parameters of the knot. A reduced theory is developed, which predictively rationalizes the process.

Monday, March 2, 2015 11:15AM - 2:15PM — Session B45 DPOLY: Polymer Melts & Solutions I 216AB - Debra Audus, National Institute of Standards and Technology

11:15AM B45.00001 Domain Growth Kinetics in Stratifying Foam Films. YIRAN ZHANG, VIVEK SHARMA, Chemical Engineering, University of Illinois Chicago — Baking bread, brewing cappuccino, pouring beer, washing dishes, shaving, shampooing, whipping eggs and blowing bubbles all involve creation of aqueous foam films. Typical foam films consist of two surfactant-laden surfaces that are 5 nm – 10 micron apart. Sandwiched between these interfacial layers is a fluid that drains primarily under the influence of viscous and interfacial forces, including disjoining pressure. Interestingly, for certain low molecular weight surfactants, a layered ordering of micelles inside the foam films (thickness <100 nm) leads to a stepwise thinning phenomena called stratification. We experimentally elucidate the influence of these different driving forces, and confinement on drainage kinetics of horizontal stratifying foam films. Thinner, darker domains spontaneously grow within foam films. Quantitative characterization of domain growth visualized in a using Scheludko-type thin film cell and a theoretical model based on lubrication analysis, provide critical insights into hydrodynamics of thin foam films, and the strength and nature of surface forces, including supramolecular oscillatory structural forces.
11:27AM B45.00002 Atomic Simulations of Poly(N-isopropylacrylamide) Surfactants in Water, LAUREN J. ABBOTT, MARK J. STEVENS, Sandia National Laboratories — The amphiphilic polymer poly(N-isopropylacrylamide) (PNIPAM) displays a sharp phase transition at its LCST around 32 °C, which results from competing interactions of the hydrophobic and hydrophilic groups with water. This thermoresponsive behavior can be exploited in more complex architectures, such as block copolymers or surfactants, to provide responsive PNIPAM head groups. In these systems, however, changes to the hydrophobic/hydrophilic balance can alter the transition behavior. In this work, we perform atomistic simulations of PNIPAM-alkyl surfactants to study the temperature dependence of their structures. A single chain of the surfactant does not show temperature-responsive behavior. Instead, below and above the LCST of PNIPAM, the surfactant folds to bring the hydrophobic alkyl tail in contact with the PNIPAM backbone, shielding it from water. In addition to single chains, we explore the self-assembly of multiple surfactants into micelles and how the temperature-dependent behavior is changed. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

11:39AM B45.00003 Self-assembly of Giant Molecular Shape Amphiphiles in Solution, RONG WANG, SHIYING MA, Nanjing University — The self-assembly of giant molecular shape amphiphiles consisting of a hydrophilic head and one or more hydrophobic tails is investigated by dissipative particle dynamics. The morphology can transform from vesicles to worm-like cylinders and further to spheres by increasing the interaction parameter between the hydrophilic heads. The results are in agreement with the experimental observations. Through changing the interaction parameter between hydrophilic head and solvents, the length of hydrophobic tail and the size of hydrophilic head, the self-assembled aggregates exhibit a rich variety of morphological structures, such as, spheres, vesicles, worm-like cylinders, disk-like micelles and layered-rod-like micelles. Vesicles form for short hydrophobic tail, while disk-like micelles are taken shape for longer hydrophobic tail. As further increasing the diameter of hydrophilic head, large compound micelles are obtained for short hydrophobic tail, however layered-rod-like micelles form for longer tail. The simulation findings might be valuable for guiding the experimental studies and fascinating new possibility and applications in material science. This work was financially supported by NNSFC (21374041, 21207405), NBRPC (2010CB923303) and PCSIRT.

11:51AM B45.00004 Transition to Area-Dependent Dissipation in Droplet Spreading, KARI DALNOKI-VERESS, MARK ILTON, Department of Physics & Astronomy, McMaster University, Hamilton, Ontario, Canada, OLIVER BÄUMCHEN, Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077, Göttingen, Germany — We have studied the spreading dynamics of a liquid diblock copolymer in the pseudo-partial wetting regime, in which disordered droplets coexist with a wetting layer of the same liquid. Using optical microscopy, the relaxation time of the droplets is measured as they evolve towards an equilibrium contact angle. The relaxation is investigated as a function of the contact angle, droplet volume, and viscosity. In this unique system all three parameters can be systematically varied on the same sample and for both advancing and receding motion. The relaxation time of the droplets does not scale with the length of the contact line as is typically the case. Instead, the relaxation time depends on the contact area. We are able to describe the experiments with a model that assumes area-dependent dissipation with only two adjustable parameters.

12:03PM B45.00005 Patterning Polymer Films with Bidirectional Control of Marangoni Flow by Photochemically Manipulating Surface Tension, CHAE BIN KIM, DUSTIN JANES, SUNSHINE ZHOU, AUSTIN DU-LANEY, CHRISTOPHER ELLISON, University of Texas at Austin - McKetta Department of Chemical Engineering — Small variations in temperature or composition at a fluid interface, often spontaneously generated, can cause local changes in surface tension and promote dramatic movement of fluids through convective motion. This phenomenon, often referred as Marangoni convection, is typically experienced in everyday life as a macroscopic and seemingly stochastic phenomenon. One might imagine attempting to direct this process for reproducibly forming microscale and nanoscale patterns. While this might initially seem impractical, here we will report a photochemical strategy to harness the Marangoni convection as a versatile patterning method. Two photo-exposures with different irradiating wavelengths were applied to a solid, glassy styrene-acrylic copolymer thin film. Each photo-exposure imposes either a higher or lower surface energy in the light exposed regions without inducing topography on the flat film surface. Once this solid film is heated to a liquid state, however, bidirectional Marangoni-flows occur spontaneously from low-to-high surface tension regions.

12:15PM B45.00006 Coffee Stains from Drops with Receding Contact Lines1, JULIAN FREED-BROWN, University of Chicago — We present a framework for calculating the surface density profile of a coffee stain deposited by a drying drop with a receding contact line. For standard coffee stains, the fluid pins to the substrate, forces flow towards the exterior of the drop and deposits a thin, concentrated ring of particles. Unlike a pinned drop, a receding drop pushes fluid towards its interior and continuously deposits mass across its substrate as it evaporates. This gives rise to a new class of mountain-like morphologies that are not seen in the standard coffee ring effect but are reminiscent of recent experimental results. For a thin, circular drop with uniform evaporation, we calculate the surface density profile analytically and find that it diverges towards the center of the drop as $\rho \propto r^{-1/2}$, where $r$ is the distance from the center. We show that this divergence is softened due to solute interactions at the final stage of drying. Our framework can be extended numerically or analytically to investigate novel stain morphologies left by drying drops of different shapes and evaporation profiles.

12:27PM B45.00007 Supramolecular Structural Forces and Hydrodynamics of Stratifying Foam Films, VIVEK SHARMA, YIRAN ZHANG, SUBINUER YILIXIATI, Chemical Engineering, University of Illinois Chicago — Liquid foams are complex fluids, mostly formed by gas bubbles dispersed within a surfactant solution. The lifetime of foams depends critically on stability and drainage of thin film layers. Unlike a pinned drop, a receding drop pushes fluid towards its interior and continuously deposits mass across its substrate as it evaporates. This gives rise to a new class of mountain-like morphologies that are not seen in the standard coffee ring effect but are reminiscent of recent experimental results. For a thin, circular drop with uniform evaporation, we calculate the surface density profile analytically and find that it diverges towards the center of the drop as $\rho \propto r^{-1/2}$, where $r$ is the distance from the center. We show that this divergence is softened due to solute interactions at the final stage of drying. Our framework can be extended numerically or analytically to investigate novel stain morphologies left by drying drops of different shapes and evaporation profiles.

12:39PM B45.00008 Concentration Dependent Structure of Block Copolymer Solutions1, SOOHYUNG CHOI, Hongik University, FRANK S. BATES, TIMOTHY P. LODGE, University of Minnesota — Addition of solvent molecules into block copolymers can induce additional interactions between the solvent and both blocks, and therefore expands the range of accessible self-assembled morphologies. In particular, the distribution of solvent molecules plays a key role in determining the microstructure and its characteristic domain spacing. In this study, concentration dependent structures formed by poly(styrene-b-ethylene-alt-propylene) (PS-PEP) solution in squalane are investigated using small-angle X-ray scattering. This reveals that squalane is essentially completely segregated into the PEP domains. In addition, the conformation of the PS block changes from stretched to nearly fully relaxed (i.e., Gaussian conformation) as amounts of squalane increases.

12:51PM B45.00009 Structure and flow properties of trilobic copolyelectrolyte hydrogels. SAMAN-VAYA SRIVASTAVA, MATTHEW TIRRELL, Univ of Chicago — Polyelectrolyte complexes (PEC) are dense, polymer-rich phases that form when oppositely charged polyelectrolyte chains spontaneously associate and phase separate in aqueous mediums. Bulk phase separation of the PECs can be evaded by combining one or both of the polyelectrolytes with a neutral polymer, thus engineering pathways for self-assembly of PEC based micelles and hydrogels with large-scale ordering of the nanoscale PEC domains. The PEC domains in these assemblies can encapsulate both hydrophobic and hydrophilic therapeutics and thus have tremendous potential in drug delivery, diagnostic and tissue engineering applications. This study will present insights on the equilibrium structure and self-assembly kinetics of PEC hybrid hydrogels through detailed rheology studies of self-assembled materials comprising of functionalized polylallyl glycidyl ethers (PAGE) connected to either single poly(ethylene glycol) (PEG) chain to form diblock copolymers or as functionalized end-groups on a trilobic copolymer with a PEG midblock. The effect of key parameters such as polymer concentration, polymer block lengths, salt, ionic strength, and degree of charge mismatch on the equilibrium material properties will be discussed, with a special emphasis on the temporal evolution of flow properties, and will lead to comparisons with the rheology models for associating polymers. Complementary studies with extensive static and dynamic light, X-ray and neutron scattering investigations will also be presented, thus providing a comprehensive structural description of these materials.

1:03PM B45.00010 Network structures of trilobic copolymer by two-step phase separation. MIKIHITO TAKENAKA, Kyotou University, RIKEN, AYANO INOUE, HIROKAZU HASEGAWA, Kyoto University — We investigated network structures of poly(styrene-b-polyisoprene-polydimethylsiloxiane (PS-PI-PDMS) trilobic copolymer formed solvent cast processes. The obtained morphologies were observed by 3D-TEM and SAXS. Two-step phase transition occurs during the self-assembling processes of PS-PI-PDMS in solvent cast processes, resulting in the morphologies such as OBDD and P-surface, which is not formed in the equilibrium state of trilobic copolymer.

1:15PM B45.00011 The Amphiphilic Character of Cellulose Molecules in True Solution in Solvent Mixtures Containing Ionic Liquid and its Utilization in Emulsification. SOFIA NAPSO, YACHIN COHEN, DMITRY REIN, RAFAIL KHALFAN, Technion, Israel, NOEMI SZEKELY, Forschungszentrum Juelich, Germany — Cellulose is the most abundant renewable material in nature that is utilized as a raw material for manufacturing of synthetic products. Although it is not soluble in common solvents, there is significant interest in the use of solvent mixtures containing ionic liquids (IL) and polar organic solvents for cellulose dissolution. We present evidence for true molecular dissolution of cellulose in binary mixtures of common polar organic solvents with an ionic liquid, using cryogenic transmission electron microscopy, small-angle neutron-, x-ray- and static light scattering. In particular, the measured low values of the molecular, gyration radius and persistence length indicate the absence of significant aggregation of the dissolved chains. We conjecture that the dissolved cellulose chains are amphiphilic. This can be inferred from the facile fabrication of cellulose-encapsulated colloidal oil-in-water or water-in-oil dispersions. This may be done by mixing water, oil and cellulose solution in an ionic liquid. A more practical alternative is to form first a hydrogel from the cellulose/ionic liquid solution by coagulation with water and applying it to sonicated water/oil or oil/water mixtures. Apparently the dissolution/ regeneration process affords higher mobility to the cellulose molecules so an encapsulation coating can be formed at the water-oil interface.

1:27PM B45.00012 The Effect of Illumination on the Gelation Process of Optoelectronic Materials. BRIAN MORGAN, MARK DADMUN, University of Tennessee — A tremendous amount of insight into the functionality of conjugated polymers in optoelectronic devices can be gained by the study of these materials as they progress through the gelation process. The nature of the percolated network structures formed directly affects exciton transport and device efficiency, thus precise knowledge of the evolution of structures provides crucial information towards improving device efficiency via processing techniques. Additionally, select optoelectronic polymers have exhibited reversibly altered physical properties such as viscosity upon exposure to white light, potentially indicative of temporary conformation changes. We have conducted a series of small angle neutron scattering experiments to probe the temperature-driven gelation process of the conjugated photoactive polymer poly(3-hexylthiophene-2,5-diyl) (P3HT) in both the presence and complete absence of white light. Fitting the resultant data indicates the creation and steady growth of cylindrical aggregates formed by the agglomeration of free chain P3HT as the growth process. Furthermore, clear differences between illuminated and non-illuminated gels are observed across multiple length scales, pointing towards an optically-induced variation in the gelation process.

1:39PM B45.00013 Effect of Water Concentration on the Molecular Structure of Polyacrylate Gels. SRIAMVIGNESH MANI, FARIDIN KHABAZ, RAJESH KHARE, Texas Tech Univ — Recent studies have suggested pervaporation to be an efficient alternative method of alcohol recovery compared to distillation based separation processes. The ability to tune the hydrophobic/hydrophilic character makes polyacrylate gels attractive candidate materials for separating water-alcohol mixture by pervaporation. Experimentally, it is observed that the amount of water absorbed in the gel i.e. the degree of swelling of the gel shows a large variation with polymer chemistry. Relatively few studies exist highlighting the effects of water concentration on the membrane separation efficiency which in turn is directly related to the internal molecular structure of the water rich membranes. In this regard, an all-atom molecular dynamics (MD) simulation is employed to study water structure in polyacrylate gels. As a first step, polyacrylate copolymer systems with varying degree of hydrophobicity are prepared using the simulated annealing polymerization technique. Atomistic structures of gels containing different amounts of water are also prepared. Effect of water content on the acrylate-water system microstructure is determined by characterizing the packing of water molecules as well as the hydrogen bonding in these systems. In addition, the change in dynamics of water molecules due to the interactions with polymer is captured by monitoring the auto-correlation function of their dipole vector.

1:51PM B45.00014 Polymer-Carbon Nanotube Composite Films at the Oil/Water Interface: Assembly and Properties. DAVID HOAGLAND, TAO FENG, THOMAS P. RUSSELL, Univ of Massachusetts Amherst — Efficient carbon nanotube assembly at the oil/water interface was achieved by dissolving cationic polymers in the oil phase and oxidized nanotubes in the water phase, the two components spontaneously forming salt bridges to produce a composite interfacial film of nanoscopic thickness. As seen by pendant drop tensiometry, parameters such as carbon nanotube and polymer concentration, pH, polymer molecular weight, and degree of nanotube oxidation all affect assembly strongly, with measured trends to be described and explained. The frequency-dependent elastic and viscous moduli of films in dilution were characterized by interfacial pendant drop rheology. Structural (fast, minutes) and adsorption/desorption (slow, tens of minutes) relaxations were both noted, and at frequencies intermediate to the two, almost insensitive to assembly parameters, the films displayed expected behaviors for 2D critical gels, i.e., at the crossover between fluid and solid. Tan(delta) was frequency-independent over one to two decades of frequency, and the modulus of linear stress relaxation was a power law in time. Films wrinkled by larger (nonlinear) strains recovered over the structural relaxation time.

1:51PM B45.00014 Polymer-Carbon Nanotube Composite Films at the Oil/Water Interface: Assembly and Properties. DAVID HOAGLAND, TAO FENG, THOMAS P. RUSSELL, Univ of Massachusetts Amherst — Efficient carbon nanotube assembly at the oil/water interface was achieved by dissolving cationic polymers in the oil phase and oxidized nanotubes in the water phase, the two components spontaneously forming salt bridges to produce a composite interfacial film of nanoscopic thickness. CHRISTOPHER JARZYNSKI, Univ of Maryland-College Park — Physical systems, including biological organisms, are capable of gathering information about their surroundings and acting in response to that information. When two physical systems interact with one another, each one affects and is affected by the other. It is often convenient to view such interactions in the context of measurement and feedback, with one system observing and exercising control over the other. I will discuss fundamental limits that thermodynamics places on such processes, when the systems are small and thermal fluctuations play an important role.

This research is supported by the U. S. Army Research Office under contract number W911NF-13-1-0399.

HONG QIAN, University of Washington, Department of Applied Mathematics — Adenosine triphosphate (ATP) molecule is used in living cells as a universal “energy currency.” The Gibbs free energy liberated from hydrolysis reaction of ATP to ADP + Pi is used for (a) biosynthesis, (b) ionic and neutral molecular pumping, and (c) mechanical movement. They are known collectively as the three major energy sinks at the cellular level. Using biochemical activities of various enzymes, a cell carries out information processing, known as signal transduction. Essentially all signal transduction reactions also require ATP (or GTP) hydrolysis. In the past, such energy dissipative reactions are considered as “futile.” However, it is clear that the free energy derived from a futile cycle is used to correct errors in biomolecular recognition, improve robustness in cell development, overcome Boltzmann’s equilibrium law of probability, and drive Maxwell’s demons (one notes that Gibbs’ chemical potential is a thermodynamic force without mechanical interpretation). The free energy involved in processing information will be explained in terms of stochastic entropy production — the central concept in irreversible and nonequilibrium steady-state (NESS) thermodynamics.

12:27PM B46.00003 A synthetic playground for non-equilibrium error correction and information processing , ARVIND MURUGAN, Harvard — Biological proofreading mechanisms can lower error rates well below Boltzmann statistics by consuming free energy. By abstracting the principles behind these biochemical mechanisms, we discuss the central ingredients needed for any complex reaction network to perform error correction and the inherent energy-error tradeoffs. We propose that such abstract principles can be implemented and tested in synthetic systems using DNA strand displacement reactions. Such DNA circuits can mimic biochemical models of proofreading because of two central features: 1. exquisite control over reaction kinetics, 2. a DNA analog of ATP hydrolysis. Indeed, such DNA circuits may be used to mimic any non-equilibrium information processing scheme seen in biochemistry, such as adaption and ultrasmall sensitivity in addition to error correction. We discuss the conceptual and practical benefits from having a well-controlled synthetic playground for non-equilibrium ideas.

1:03PM B46.00004 Experimental Demonstration of Information-to-Energy Conversion in Small Fluctuating Systems , MASAKI SANO, University of Tokyo — What is the relation between information and thermodynamics has been a long standing question in science. In 1867, J.C. Maxwell proposed a Gedanken experiment to demonstrate violation of the second law of thermodynamics by assuming a small creature called Maxwell’s demon which separates hot atoms from cold atoms. In 1929, L. Szilard formulated the idea of Maxwell for a more tractable setup in which a single particle is thermally moving in a box immersed in a heat bath. He succeeded to relate information entropy and the second law of thermodynamics in this Gedanken experiment. It has led to long and intense debates on the relation among thermodynamics, information, observation, and even computation until it was clarified recently. Nevertheless, experimental realization of information-energy-conversion has been elusive. Recently, we succeeded to demonstrate the information-energy-conversion by observing Brownian motion of colloidal particles and controlling them. We introduced a feedback control protocol based on the information of Brownian particle by electric fields and found that the particle rotates against the torque exerted by an external electric field and obtains free energy larger than the amount of work performed on it. By measuring detailed process, validity of a new nonequilibrium equality concerning the feedback control has been shown. Efficiency of information-energy conversion was evaluated in this feedback system. Moreover, I will discuss on possible generalization of this concept to information processing in cell chemotaxis.

1:39PM B46.00005 ABSTRACT WITHDRAWN —
A computational investigation of the role of behavioral heterogeneities on cell cluster motion. KATHERINE COPENHAGEN, Unv of California - Merced, NIR GOV, Weizmann Institute, AJAY GOPINATHAN, Univ of California - Merced — Collective motion of cells is a common occurrence in many biological systems, including tissue development, repair, and tumor formation. Recent experiments have shown that malignant B and T lymphocytes form clusters in a chemical gradient of CCL19 which display three different phases: translational, rotational, and random. Could these phases be due to interactions between cells as well as chemotaxis of individuals? If so what types of local interactions can lead to the three phases seen in experiment? We model cell clusters with a continuous two dimensional agent based model. To form a single cell cluster, which displays all three of the phases described above, cells interact with one another through a Lennard-Jones collision avoidance and cohesion interaction, and a long range spring interaction to prevent fracture. By changing the behaviors of individual cells depending on the number of cells they are contacting, we are able to create clusters that occupy these phases with varying likelihood. Our results show that heterogeneous behaviors of individuals based on local environment can lead to novel phases seen in experiments.

Optimal Intermittent Reorientation in Insect Navigation. ORIT PELEG, LAKSHMINARAYANAN MAHADEVAN, SEAS, Harvard University, APPLIED MATH LAB TEAM — The process of navigation is often accompanied by several cognitive demanding activities, such as motor control, locomotion planning, and multi-sensory acquisition and integration. Organisms with limited cognitive resources must therefore multitask and develop optimal schemes to dynamically allocate resources to the different tasks. An extreme example of task alternations during navigation is the hallmark of ball rolling dung beetles. The beetles need to roll their dung-ball along a straight path away from the dung pile where intense competition occurs [1]. Before initiating a roll, dung beetles climb on top of the ball and rotate about their vertical axis. This action serves as an orientation mechanism that allows them to set an initial bearing, and to regain this bearing if they experience an unintentional disturbance along the way [2]. We developed a model inspired by the beetle’s navigational scheme, where an agent performs a random walk intermittent by reorientation events, in which its heading direction is corrected. We show that the resultant paths are a characteristic of correlated diffusion in short time scale, and biased diffusion in the long time scale [3]. We identify optimal alternation schemes and characterize their robustness upon introducing noisy sensory acquisition and rough environmental conditions.

Self-righting behavior of cockroaches. CHEN LI, University of California, Berkeley, TONI WOHLR, University of Jena, HAN LAM, ROBERT FULL, University of California, Berkeley — Small insects must be able to right themselves from an upright-down orientation to survive. Previous studies described diverse self-righting strategies in insects. Here, we compare the self-righting behaviors in three cockroach species on a flat, rigid ground to begin to reveal what governs the choice of dominant behaviors. All species self-righted successfully (75 +/− 11 % probability) and quickly (as low as 140 ms and typically within 2 s). The smallest winged American cockroach, which has the most elongate, least flattened body, and longest legs, primarily pushed legs against the ground to roll its body to the side to self-right (relative frequency = 93%). The largest wingless Madagascar hissing cockroach with the shortest legs primarily (84%) hyperextended body to roll to the side and then rubbed its legs on the ground to self-right. The intermediate winged discoid cockroach, which has the least elongate, most flattened body, more often (57%) abducted wings and flexed body to raise center of mass and reduce ground contact and rotated about the wing edges to self-right. We hypothesize that, given morphological and physiological constraints, the gravitational potential energy landscape resulting from the animals’ body-appendage-ground interaction governs their dominant behaviors. Our study provides inspiration for robotics, as many current terrestrial robots have rigid, cuboidal bodies which hinder self-righting.

Tiger beetle’s pursuit of prey depends on distance. ROBERT NOEST, JANE WANG, Cornell University — Tiger beetles are fast predators capable of chasing prey under closed-loop visual guidance. We investigated their control system using high-speed digital recordings of beetles chasing a moving prey dummy in a laboratory arena. Analysis reveals that the beetle uses a proportional control law in which the angular position of the prey relative to the beetle’s body axis drives the beetle’s angular velocity with a delay of about 26 ms. The system gain is shown to depend on the beetle-prey distance in a pattern indicating three hunting phases over the observed distance domain. We show that to explain this behavior the tiger beetle must be capable of visually determining the distance to its target and using that to adapt the gain in its proportional control law. We will end with a discussion on the possible methods for distance detection by the tiger beetle and focus on two of them. Motion parallax, using the natural head sway induced by the walking gait of the tiger beetle, is shown to have insufficient distance range. However elevation in the field of vision, using the angle with respect to the horizon at which a target is observed, has a much larger distance range and is a prime candidate for the mechanism of visual distance detection in the tiger beetle.

Hierarchy and predictability in spontaneous behavior. GORDON BERMAN, WILLIAM BIALEK, JOSHUA SHAEVITZ, Princeton University — Animals perform a complex array of behaviors, from changes in body posture to vocalizations to other dynamic outputs. Far from being a disordered collection of actions, however, there is thought to be an intrinsic structure to the set of behaviors and their temporal organization. This structure has often been hypothesized to be hierarchical, with certain behaviors grouped together into modules that interact with other modules at time scales that are long with respect to that of an individual behavior. There have been few measurements, however, showing that a particular animal’s behavioral repertoire is organized hierarchically. This has largely resulted from an inability to measure the entirety of an animal’s behavioral repertoire or even to define precisely what a “behavior” is. In this talk, I will apply our novel method for mapping the behavioral space of animals to videos of freely-behaving fruit flies (D. melanogaster), showing that the organisms’ behavioral repertoire consists of a hierarchically-organized set of stereotyped behaviors. This hierarchical patterning results in the emergence of long time scales of memory in the system, providing insight into the mechanisms of behavioral control and patterning.

Environmental statistics and optimal regulation. DAVID SIVAK, Simon Fraser University, MATT THOMSON, University of California, San Francisco — The precision with which an organism can detect its environment, and the timescale for and statistics of environmental change, will affect the suitability of different strategies for regulating protein levels in response to environmental inputs. We propose a general framework—here applied to the enzymatic regulation of metabolism in response to changing nutrient concentrations—to predict the optimal regulatory strategy given the statistics of fluctuations in the environment and measurement apparatus, and the costs associated with enzyme production. We find: (i) relative convexity of enzyme expression cost and benefit influences the fitness of thresholding or graded responses; (ii) intermediate levels of measurement uncertainty call for a sophisticated Bayesian decision rule; and (iii) in dynamic contexts, intermediate levels of uncertainty call for retaining memory of the past. Statistical properties of the environment, such as variability and correlation times, set optimal biochemical parameters, such as thresholds and decay rates in signaling pathways. Our framework provides a theoretical basis for interpreting molecular signal processing algorithms and a classification scheme that organizes known regulatory strategies and may help conceptualize heretofore unknown ones.
12:27PM B47.00007 Quantification of Behavior During Drosophila Courtship. UGNE KLIABITE, GORDON BERMAN, Princeton University, JESSICA CANDE, DAVID STERN, Janelia Research Campus, HHMI, JOSHUA SHAEVITZ, Princeton University — Fruit flies display varying and species-specific behavioral repertoires, especially during highly stereotyped activities such as courtship. Interspecies differences in specific behaviors may arise from physical differences, e.g. a different type or speed of appendage motion, or higher-order changes such as differences in the frequencies of particular actions. One example is the use of wing-rowing by D. santomea males that is rarely, but sometimes, seen during D. yakuba courtship. We wish to study the complex interaction of two individuals during courtship. We extensively worked on mapping the postural dynamics of individual flies to analyze the simultaneous mapping of male and female behavior for hundreds of hours of courtship video data. Using this algorithm, we compare courtship behavior of dozens of targeted introgressions between D. yakuba and D. santomea to probe for differences in courtship and to determine which regions of the genome are responsible for this diversity.

12:39PM B47.00008 Intrinsic fluctuations and driven response of insect swarms, RUI NI, Yale University, JAMES G. PUCKETT, Gettysburg College, ERIC R. DUFRESNE, NICHOLAS T. OUELLETTE, Yale University — Much of our understanding of collective behavior in social animals comes from passive observations of animal groups. To understand the group dynamics fully, however, we must also characterize the response of animal aggregations to disturbances. Using three-dimensional particle tracking, we study both the intrinsic fluctuations of laboratory swarms of the non-biting midge Chironomus riparius and the response of the swarms to controlled external perturbations: the amplitude-modulated sound of male midge wingbeats. Although these perturbations have an insignificant effect on the behavior of individuals, we find that they can have a strong impact on the collective movement. Intriguingly, the response of the swarm is similar reminiscent to that of a passive equilibrium system to an external driving force, with microscopic fluctuations underlying combining to produce a macroscopic linear response over a wide range of driving frequencies.

12:51PM B47.00009 Measuring Whole-Brain Neural Dynamics and Behavior of Freely-Moving C. elegans, FREDERICK SHIPLEY, JEFFREY NGUYEN, GEORGE PLUMMER, JOSHUA SHAEVITZ, ANDREW LEIFER, Princeton University — Bridging the gap between an organism’s neural dynamics and its ultimate behavior is the fundamental goal of neuroscience. Previously, to probe neural dynamics, we have been limited to measuring from a limited number of neurons, whether by electrode or optogenetic measurements. Here we present an instrument to simultaneously monitor neural activity from every neuron in a freely moving Caenorhabditis elegans’ head, while recording behavior at the same time. Previously, whole-brain imaging has been demonstrated in C. elegans, but only in restrained and anesthetized animals (1). For studying neural coding of behavior it is crucial to study neural activity in freely behaving animals. Neural activity is recorded optically from cells expressing a calcium indicator, GCaMP6. Real time computer vision tracks the worm’s position in x-y, while a piezo stage sweeps through the brain in z, yielding five brain-volumes per second. Behavior is recorded under infrared, dark-field imaging. This tool will allow us to directly correlate neural activity with behavior and we will present progress toward this goal.

1Thank you to the Simons Foundation and Princeton University for supporting this research.

1:03PM B47.00010 Modulation of orthogonal body wave enables high maneuverability in sidewinding locomotion, HENRY ASTLEY, Georgia Institute of Technology, CHAOHUI GONG, MATT TRAVERS, Carnegie Mellon University, MIGUEL SERRANO, PATRICIO VELA, Georgia Institute of Technology, HOWIE CHOSEST, Carnegie Mellon University, JOSEPH MENDELSON III, DAVID HU, DANIEL GOLDMAN, Georgia Institute of Technology — To simplify control of high degree of freedom bodies, organisms may target a set of simple shape changes (a “template”). Recent work has revealed that the locomotion of sidewinder rattlesnakes can be described by a combination of horizontal and vertical body waves with a phase difference of ±π/2, representing a possible control template. These animals display high maneuverability which we hypothesize emerges from their ability to independently modulate these waves. Snakes used two distinct turning methods which we term differential turning (24° turn per cycle) and reversal turning (90°). Kinematic data suggested that during differential turning the animals imposed an amplitude modulation in the horizontal wave while in reversal turning they shifted the phase of the vertical wave by π. We tested these mechanisms in the robot, generating differential and reversal turning. Further manipulations of the two-wave system revealed a third turning mode, “frequency turning,” not observed in biological snakes which allowed the robot to execute large (127°) in-place turns. The two-wave system enables unprecedented maneuverability of high degree-of-freedom systems, revealing a practical benefits of the search for control templates.

1:15PM B47.00011 Building spatially-structured biofilms with single-cell control using laser trapping, CHRISTOPHER RODENSEY, JAIME HUTCHISON, KARISHMA KAUSHIK, HENRY LE, DANIEL HURWITZ, Univ of Texas, Austin, YA-SUHIKO IRIE, Univ of Bath, VERNITA GORDON, Univ of Texas, Austin — Biofilms are sessile communities of microbes adhered to each other and to an interface. Biofilm infections are notoriously difficult to eradicate, and this arises in part from phenotypic changes due to the spatial structure of the biofilm. Spatial structure controls the microenvironment and intercellular associations, which in turn controls gene expression, virulence, and antibiotic resistance. There are few tools available for elucidating the role of spatial structure in biofilms. We present a method for controlling the positions of bacteria on a surface using optical trapping without impinging cell viability. Initial positions propagate into the developing biofilm, creating spatial structure. The native growth, motility, and surface adhesion of positioned cells are preserved, as shown for model organisms Pseudomonas aeruginosa and Staphylococcus aureus. We demonstrate statistically-significant effects of spatial structure on the growth of monoculture P. aeruginosa biofilms and for co-culture biofilms of P. aeruginosa and S. aureus. Because the laser trap we use is very basic and the other equipment required is inexpensive and standard, we believe that our technique will be a widely-useful tool for biological and physical collaborators at many types of institutions.

1:27PM B47.00012 Legless locomotion in lattices, PERRIN SCHIEBEL, Georgia Institute of Technology, JIN DAI, CHAOHUI GONG, Carnegie-Mellon University, MIGUEL M. SERRANO, Georgia Institute of Technology, JOSEPH R. MENDELSON III, Zoo Atlanta, HOWIE CHOSEST, Carnegie-Mellon University, DANIEL I. GOLDMAN, Georgia Institute of Technology — By propagating waves from head to tail, limbless organisms like snakes can traverse terrain composed of rocks, foliage, soil and sand. Previous research elucidated how rigid obstacles influence snake locomotion by studying a model terrain—symmetric lattices of pegs placed in hard ground. We want to understand how different substrate-body interaction modes affect performance in desert-adapted snakes during transit of substrates composed of both rigid obstacles and granular media (GM). We tested Chionactis occipitalis, the Mojave shovel-nosed snake, in two laboratory treatments: lattices of 0.64cm diameter obstacles arrayed on both a hard, slick substrate and in a GM of ~0.3mm diameter glass particles. For all lattice spacings, d, speed through the hard ground lattices was less than that in GM lattices. However, maximal undulation efficiencies $u_\eta$ (number of body lengths advanced per undulation cycle) in both treatments were comparable when $d$ was intermediate. For other $d$, $u_\eta$ was lower than this maximum in hard ground lattices, while on GM, $u_\eta$ was insensitive to $d$. To systematically explore such locomotion, we tested a physical robot model of the snake; performance depended sensitively on base substrate, $d$ and body wave parameters.
1:39PM B47.00013 Human pair walking behavior: evaluation of cooperation strategies. ULRICH DOBRAMYS, University of Oxford, KATARINA BODOVÁ, IST Austria, RICHARD KOLLAR, Comenius University Bratislava, RADEK ERBAN, University of Oxford — Human walkers are notoriously poor at keeping a direction without external cues: Experimental work by Souman et al. with blindfolded subjects told to walk in a straight line revealed intriguing circular and spiraling trajectories, which can be approximated by a stochastic process. In this work, motivated by pair walking experiments by Miglierini et al., we introduce an analysis of various strategies employed by a pair of blindfolded walkers, who are communicating via auditory cues, to maximize their efficiency at walking straight. To this end, we characterize pairs of strategies such as free walking, side-by-side walking and unconditional following from data generated by robot pair walking experiments (using computer vision techniques) and numerical simulations. We extract the mean exit distances of walker pairs from a corridor with finite width to construct phase portraits of the walking performance. We find intriguing cooperative effects leading to non-trivial enhancements of the efficiency at walking straight. ¹

¹The research leading to these results has received funding from the European Research Council under the European Community’s Seventh Framework Programme (FP7/2007-2013) / ERC grant agreement No. 239870; and from the Royal Society through a Research Grant.

1:51PM B47.00014 Pili-mediated Interactions between Neisseria Gonorrhoeae Bacteria are the Driving Mechanism of Microcolony Merging. WOLFRAM POENISCH, CHRISTOPH WEBER, Max Planck Institute for the Physics of Complex Systems, KHALED ALZURQA, HADI NASROLLAHI, NICOLAS BIAIS, Brooklyn College, NY, VASILY ZABURDAEV, Max Planck Institute for the Physics of Complex Systems, COLLECTIVE DYNAMICS OF CELLS TEAM, MECHANO-MICRO-BIOLOGY LAB TEAM — During the early infection with Neisseria gonorrhoeae the bacteria form microcolonies consisting of a few hundreds to a few thousands of cells. The formation of colonies is mediated by type IV pili, thin and long filaments that are also involved in the motion of single cells over a substrate. A related process causes attractive cell-cell-interactions. While the motion of single cells has been extensively studied during the past years, the physical principles driving the growth of these colonies are poorly understood. One key mechanism of colony growth is coalescence of smaller colonies. Therefore we experimentally examine the process of merging of two Neisseria gonorrhoeae colonies. We develop a theoretical microscopic model of single cells interacting solely by their pili. The experimental data and the results obtained from our model are in excellent quantitative agreement. We observe a fast initial approach of the two merging colonies within a few minutes, that is followed by a slow relaxation of the colony shape with a characteristic time of several hours. These findings suggest that pili-mediated interactions are the primary driving mechanism of the microcolony merging process.

2:03PM B47.00015 The growth and form of plant shoots. RAGHUNATH CHELAKKOT, SEAS, Harvard University, L. MAHADEVAN, SEAS. Department of organismic and evolutionary biology, Harvard university — Growing plant stems and shoots exhibit a variety of shapes that embody growth in response to various stimuli. We provide a quantitative biophysical theory for these shapes by accounting for the inherent observed passive and active effects: (i) the passive elastic deflection of the shoot due to its own weight, and (ii) the active controllable growth response of the shoot in its orientation relative to gravity, and (iii) proprioception, the shoot’s growth response to its own observable shape, which is itself determined by its elasticity and weight. A morphospace diagram in terms of two dimensionless parameters representing a scaled local active gravitropic sensitivity, and a scaled passive elastic sag shows how a variety of observed transient and steady morphologies with effective positive, negative and oscillatory gravitropic behaviors arise in a sentient growing filament naturally, without the need for ad-hoc complex spatio-temporal control strategies.

11:15AM B48.00001 ABSTRACT WITHDRAWN –

11:27AM B48.00002 Coarsening of protein clusters on subcellular drops exhibits strong and sudden size selectivity. AIDAN BROWN, ANDREW RUTENBERG, Dalhousie University — Autophagy is an important process for the degradation of cellular components, with receptor proteins targeting substrates to downstream autophagy machinery. An important question is how receptor protein interactions lead to their selective accumulation on autophagy substrates. Receptor proteins have recently been observed in clusters, raising the possibility that clustering could affect autophagy selectivity. We investigate the clustering dynamics of the autophagy receptor protein NBR1. In addition to standard receptor protein domains, NBR1 has a “J” domain that anchors it to membranes, and a coiled-coil domain that enhances self-interaction. We model coarsening clusters of NBR1 on the surfaces of a polydisperse collection of drops, representing organelles. Despite the disconnected nature of the drop surfaces, we recover dynamical scaling of cluster sizes. Significantly, we find that at a well-defined time after coarsening begins, clusters evaporate from smaller drops and grow on larger drops. Thus, coarsening-driven size selection will localize protein clusters to larger substrates, leaving smaller substrates without clusters. This provides a possible physical mechanism for autophagy selectivity, and can explain reports of size selection during peroxisome degradation.

11:39AM B48.00003 Mechanism of bacterial membrane poration by Antimicrobial Peptides. ANKITA ARORA, ABHIJIT MISHRA, Materials Science & Engineering, Indian Institute of Technology, Gandhinagar, India — Bacterial resistance to conventional antibiotics is a major health concern. Antimicrobial peptides (AMPs), an important component of mammalian immune system, are thought to utilize non-specific interactions to target common features on the outer membranes of pathogens; hence development of resistance to such AMPs may be less pronounced. Most AMPs are amphiphilic and cationic in nature. Most AMPs form pores in the bacterial membranes causing them to lyse, however, the exact mechanism is unknown. Here, we study the AMP CHRG01 (KSTGRRKSSRRKK), derived from human β defensin 3 (hBD3) with all Cysteine residues substituted with Serine. Circular Dichroism studies indicate that CHRG01 shows helicity and there is change in helicity as it interacts with the lipid membrane. The AMP was effective against different species of bacterial cells observed by SEM and AFM indicates AMP action by pore formation. Confocal microscopy studies on giant vesicles incubated with AMP confirm poration. The effect of this AMP on model bacterial membranes is characterized using Small Angle X-ray scattering and Fluorescence spectroscopy to elucidate the mechanism behind antimicrobial activity.
11:51 AM B48.00004 Dissecting EB1-microtubule interactions from every direction: using single-molecule visualization and static and dynamic binding measurements , BENJAMIN LOPEZ, Univ of California - Santa Barbara — EB1 is an important microtubule associating protein (MAP) that acts as a master coordinator of protein activity at the growing plus-end of the microtubule. We can recapitulate the plus-end binding behavior of EB1 along the entire length of a static microtubule using microtubules polymerized in the presence of the nonhydrolyzable GTP analogs GMPCPP and GTP\(^\gamma\)S instead of GTP. Through the use of single-molecule TIRF imaging we find that EB1 is highly dynamic (with a sub-second characteristic binding lifetime) and continuously diffusive while bound to the microtubule. We measure the diffusion coefficient, \(D\), through linear fitting to mean-squared displacement of individually labeled proteins, and the binding lifetime, \(\tau\), by fitting a single exponential decay to the probability distribution of trajectory lifetimes. In agreement with measurements of other diffusive MAPs, we find that \(D\) increases and \(\tau\) decreases with increasing ionic strength. We also find that \(D\) is sensitive to the choice of GTP analog: EB1 proteins bound to GTP\(^\gamma\)S polymerized microtubules have a \(D\) half of that found with GMPCPP polymerized microtubules. To compare these single-molecule measurements to the bulk binding behavior of EB1, we use TIRF imaging to measure the intensity of microtubules coated with EB1-GFP as a function of EB1 concentration. We find that EB1 binding is cooperative and the cooperative nature of EB1-microtubule binding leads to a decrease in \(D\) with increasing EB1 concentration. Interestingly, we also find an increase in \(\tau\) at high EB1 concentrations, consistent with attractive EB1-microtubule interactions driving the cooperativity. To further understand the cooperativity we estimate the interaction energy by measuring the association and dissociation rates (\(k_{\text{on}}\) and \(k_{\text{off}}\) respectively) at different concentrations of EB1.

12:27PM B48.00005 A Compete-and-Survive Mechanism Explains the Single FtsZ-Ring Formation , GANHUI LIM, LI-PING XIONG, George Washington University — Cytokinesis is a critical step in cell reproduction. In bacterial cells, this process is mediated by the cytoskeletal Z ring which is assembled from FtsZ filaments that are “anchored” to the cell membrane through ZipA/FtsA molecules. Fluorescence Recovery after Photobleaching experiments have shown that the Z ring is highly dynamic, with recovery half time of \(\sim 30\) seconds, yet has a rather persistent overall structure. But it is unclear how a single narrow dynamic Z ring emerges from a big pool of cytoplasmatic FtsZ molecules. Here, we developed a rule-based molecular model with FtsZ and ZipA/FtsA molecules, by explicitly considering the elementary assembling events of molecules and their diffusion. Our model can not only efficiently reproduce the Z ring but also obtained experimentally observed statistical properties, but provide a convenient way to combine biochemical dynamic and physical assembling processes within the same spatiotemporal modeling framework. In agreement with experiments, we showed that the spontaneous self-assembling process relies on the molecular “stoichiometry”: either high or low FtsZ to ZipA/FtsA ratios would result in multiple Z rings or aggregated bundles. Our in silico FRAP experiment further yields a recovery half time comparable to experimental results. These results indicate that the rapid turnover dynamics prevents the FtsZ molecules from being sequestered by small FtsZ bundles dispersed over the membrane, allowing single Z ring to emerge and mature. This dynamic colonolization mechanism provides cells a simple way for spatial regulation.

12:39PM B48.00006 Characterizing the statistical properties of protein surfaces , JI HYUN BAK, ANNE-FLORENCE BITTOL, WILLIAM BIALEK, Princeton University — Proteins and their interactions form the body of the signaling transduction pathway in many living systems. In order to ensure the accuracy as well as the specificity of signaling, it is crucial that proteins recognize their correct interaction partners. How difficult, then, is it for a protein to discriminate its correct interaction partner(s) from the possibly large set of other proteins it may encounter in the cell? An important ingredient of recognition is shape complementarity. The ensemble of protein shapes should be constrained by the need for maintaining functional interactions while avoiding spurious ones. To address this aspect of protein recognition, we consider the ensemble of proteins in terms of their three-dimensional shapes, more precisely in terms of their solvent-excluded surfaces. We take into account all high-resolution structures from E.coli non-DNA-binding cytoplasmic proteins that can be retrieved from the Protein Data Bank. We aim to characterize the statistical properties of the ensemble of protein surfaces, including the dimensionality of the space of surfaces.

12:51PM B48.00007 Microfluidic free-flow electrophoresis for the discovery and characterisation of calmodulin binding partners , THERESE HERLING, University of Cambridge, SARA LINSE, Lund University and University of Cambridge, TUOMAS KNOWLES, University of Cambridge — Non-covalent and transient protein-ligand interactions are integral to cellular function and malfunction. Key steps in signalling and regulatory pathways rely on reversible non-covalent protein–protein binding or ion chelation. Here we present a microfluidic free-flow electrophoretic method for detecting and characterising protein-ligand interactions in solution. We apply this method to probe the binding of calmodulin, a central protein to calcium signalling pathways. In this study we characterise the specific binding of calmodulin to phosphorylase kinase, a known target, and create a kinase, which we identify as a putative binding partner through high-throughput screening and surface plasmon resonance experiments. We verify the interaction between calmodulin and creatine kinase in solution using free-flow electrophoresis and investigate the effect of calcium and sodium chloride on the calmodulin-ligand binding affinity in free solution without the presence of a potentially interfering surface. Our results demonstrate the general applicability of quantitative microfluidic electrophoresis to characterise binding equilibria between biomolecules in solution.

1:03PM B48.00008 Atomic force microscopy based nanoassay: a new method to study \(\alpha\)-Synuclein-dopamine bioaffinity interactions , STEFANIA CORVAGLIA, Elettra-Sincrotrone Trieste S.C.p.A., BARBARA SANAVIO, IFOM, Italy, BARBARA SORCE, ETH-Zurich, ALESSANDRO BOSCO, Elettra-Sincrotrone Trieste S.C.p.A., STEFANIA SABELLA, PIERPAOLO POMP, Istituto Italiano di Tecnologia, Lecce, Italy, GIACINTO SOLE, University of Udine, Italy, LOREDANA CAVALISI, Elettra-Sincrotrone Trieste S.C.p.A. — Intrinsically Disordered Proteins (IDPs) are characterized by the lack of well-defined 3-D structure and show high conformational plasticity. For this reason, they are a strong challenge for the traditional characterization of structure, supramolecular assembly and biorecognition phenomena. We show here how the fine tuning of protein orientation on a surface turns useful in the reliable testing of biorecognition interactions of IDPs, in particular \(\alpha\)-Synuclein. We exploited atomic force microscopy (AFM) for the selective, nanoscale confinement of \(\alpha\)-Synuclein on gold to study the early stages of \(\alpha\)-Synuclein aggregation and the effect of small molecules, like dopamine, on the aggregation process. Capitalizing on the high sensitivity of AFM topographic height measurements we determined, for the first time in the literature, the dissociation constant of dopamine-\(\alpha\)-Synuclein addsucts.

1:15PM B48.00009 Non-covalent interactions between ATP and RecA DNA-repairing proteins: DFT and semiempirical calculations , JORGE RODRIGUEZ, Department of Physics and Astronomy, Purdue University — The role of Bacterial RecA in the structural maintenance of genomes and the genetic information they carry has been established. In particular, the RecA DNA-repairing protein from \(D\). Radiodurans, a radiation-resistant bacteria, is crucial for the repair of double strand breaks (DSBs). We have performed semi-empirical free-energy calculations and QM/MM calculations to study their non-covalent interactions with ATP and ADP. Such studies provide insight into the mechanisms of ATP/ADP \(\rightarrow\) RecA energy transfer and, therefore, about specific functional uses of incoming energy for DNA repairing mechanisms. We present a detailed analysis of the non-covalent interactions which minimize the interaction Gibbs free energies leading to the most stable non-covalent binding sites. Van der Waal, hydrogen bonding and electrostatic interactions has been quantified which provides a detailed insight into the mechanisms of ATP-RecA interaction. Further, possible chemical interactions and functional roles of RecA proteins are explored based on the previously mentioned studies. Acknowledgements: Funded, in part, by DTRA award 106339 (JHR). Dr. Mark C. Palenik and Mrs. Lora Beard are gratefully acknowledged

1:27PM B48.00010 Photo-Activated Localization Microscopy of Single Carbohydrate Binding Modules on Cellulose Nanofibers. AMY HOR, DARYL DAGEL, QUOCANH LUU, MADHUSUDAN SAVAIAKAR, South Dakota School of Mines and Technology, SHI-YOU DING, Michigan State University, STEVE SMITH, South Dakota School of Mines and Technology — Photo-Activated Localization Microscopy (PALM) is used to conduct an in vivo study of the binding affinity of polysaccharide-specific Carbohydrate Binding Modules (CBMs) to insoluble cellulose substrates. Two families of CBMs, namely TrCBM1 and CiCBM3, were modified to incorporate photo-activatable mCherry fluorescent protein (PAmCherry), and exposed to highly crystalline Valonia cellulose nano-fibers. The resulting PALM images show CBMs binding along the nano-fibril long axis in a punctuated linear array, localized with an average, 10 nm precision. Statistical analysis of the binding events results in nearest neighbor distribution peaks but differences in the overall binding density. The form is attributed to steric hindrance among the CBMs on the nano-fibril whereas the latter is attributed to differences in the CBMs’ binding strength. These results are compared to similar distributions derived from TEM measurements of dried samples of CiCBM3-CdS quantum dot bioconjugates and AFM images of CiCBM3-GFP bound to similar Valonia nano-fibers.

1:39PM B48.00011 Force spectroscopy of biomolecular folding and binding: theory meets experiment. OLGA DUDKO, University of California, San Diego — Conformational transitions in biological macromolecules usually serve as the mechanism that brings biomolecules into their working shape and enables their biological function. Single-molecule force spectroscopy probes conformational transitions by applying force to individual macromolecules and recording their response, or “mechanical fingerprints,” in the form of force-extension curves. However, can we decode these fingerprints so that they reveal the kinetic barriers and the associated timescales of a biological process? I will present an analytical theory of the mechanical fingerprints of macromolecules. The theory is suitable for decoding such fingerprints to extract the barriers and timescales. The application of the theory will be illustrated through recent studies on protein-DNA interactions and the receptor-ligand complexes involved in blood clot formation.

11:15AM B50.00001 Spontaneous emergence of autocatalytic information-coding polymers. ALEXEI TKACHENKO, SERGEI MASLOV, Brookhaven National Laboratory — Self-replicating systems based on information-coding polymers are of crucial importance in biology. They also recently emerged as a paradigm in design on nano- and micro-scales. We present a general theoretical and numerical analysis of the problem of spontaneous emergence of autocatalysis for heteropolymers capable of template-assisted ligation driven by cyclic changes in the environment. Our central result is the existence of the first order transition between the regime dominated by free monomers and that with a self-sustaining population of sufficiently long oligomers. We provide a simple mathematically tractable model that predicts the parameters for the onset of autocatalysis and the distribution of chain lengths, in terms of monomer concentration, and two fundamental rate constants. Another key result is the emergence of the kinetically-limited optimal overlap length between a template and its two substrates. Template-assisted ligation allows for heritable transmission of information encoded in oligomer sequences thus opening up the possibility of long-term memory and evolvability of such systems.

Research was carried out in part at the Center for Functional Nanomaterials at Brookhaven National Laboratory, which is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886. Work at Biosciences Department was supported by US Department of Energy Office of Biological Research Grant PM-031.

11:27AM B50.00002 Evidence against a mean field description of short-range spin glasses revealed through thermal boundary conditions. JONATHAN MACHTA, WENLONG WANG, University of Massachusetts Amherst, HELMUT KATZGRABER, Texas A&M University — A theoretical description of the low-temperature phase of short-range spin glasses has remained elusive for decades. It is not known if there is a single pair of pure states as predicted by the droplet model, or infinitely many pure states, as predicted by mean field theory. Here we study the three-dimensional Edwards-Anderson Ising spin glass in thermal boundary conditions using population annealing Monte Carlo. In thermal boundary conditions all eight combinations of periodic vs antiperiodic boundary conditions in the three spatial directions appear in the ensemble with their respective Boltzmann weights, thus minimizing finite-size corrections due to domain walls. From the relative weighting of the eight boundary conditions for each disorder instance a sample stiffness is defined, and its typical value is shown to grow with system size according to a stiffness exponent. An extrapolation to the large-system-size limit is consistent with a single pair of pure states in every volume but incompatible with the mean field, replica symmetry breaking picture.

11:39AM B50.00003 Probing temperature chaos through thermal boundary conditions. WENLONG WANG, JONATHAN MACHTA, University of Massachusetts Amherst, HELMUT KATZGRABER, Texas A&M University — Using population annealing Monte Carlo, we numerically study temperature chaos in the three-dimensional Edwards-Anderson Ising spin glass using thermal boundary conditions. In thermal boundary conditions all eight combinations of periodic vs antiperiodic boundary conditions in the three spatial directions appear in the ensemble with their respective Boltzmann weights, thus minimizing finite-size corrections due to domain walls. By studying salient features in the specific heat we show evidence of temperature chaos. Our results suggest that these bumps are mainly caused by system-size excitations where the free energy of two boundary conditions cross. Furthermore, we study the scaling of both entropy and energy at boundary condition crossings and find that the scaling of the entropy is very different from the scaling obtained by a simple change of boundary conditions. We attribute this difference to the stronger finite-size effects induced via a simple change of boundary conditions all eight combinations of periodic vs antiperiodic boundary conditions in the three spatial directions appear in the ensemble with their respective Boltzmann weights, thus minimizing finite-size corrections due to domain walls. By studying salient features in the specific heat we show evidence of temperature chaos. Our results suggest that these bumps are mainly caused by system-size excitations where the free energy of two boundary conditions cross. Furthermore, we study the scaling of both entropy and energy at boundary condition crossings and find that the scaling of the entropy is very different from the scaling obtained by a simple change of boundary conditions. We attribute this difference to the stronger finite-size effects induced via a simple change of boundary conditions. Finally, we show that temperature chaos occurs more frequently at higher temperatures within the spin-glass phase and for larger system sizes, while the normalized distribution function with respect to temperature is about the same for different system sizes.

1:15PM B50.00004 Effective Hamiltonians of 2D Spin Glass Clusters. COLIN CLEMENT, Cornell University, DANILIO LIARTE, University of Sao Paulo, ALAN MIDDLETON, Syracuse University, JAMES SETHNA, Cornell University — We have a method for directly identifying the clusters which are thought to dominate the dynamics of spin glasses. We also have a method for generating an effective Hamiltonian treating each cluster as an individual spin. We used these methods on a 2D Ising spin glass with Gaussian bonds. We study these systems by generating samples and correlation functions using a combination of Monte Carlo and high-performance numerically exact Pfaffian methods. With effective cluster Hamiltonians we can calculate the free energy asymmetry of the original clusters and perform a scaling analysis. The scaling exponents found are consistent with Domain-Wall Renormalization Group methods, and probe all length scales. We can also study the flow of these effective Hamiltonians by clustering the clustered spins, and we find that our hard spin Hamiltonians at high temperature retain accurate low-temperature fluctuations when compared to their parent models.

The work is supported from NSF (Grant No. DMR-1208046).
12:03PM B50.00005 Overfrustrated and Underfrustrated Spin-Glasses in d=3 and d=2: Evolution of Phase Diagrams and Chaos Including Spin-Glass Order in d=2, EFE ILKER, Sabanci University, A. NIHAT BERKER, Sabanci University and MIT — In spin-glass (SG) systems, frustration can be adjusted continuously and considerably, without changing the antiferromagnetic (AF) bond probability p, by using locally correlated quenched randomness, both on hypercubic and hierarchical lattices [1]. With removal of 51% frustration, a SG phase occurs in d=2. With addition of 33% frustration, the SG phase disappears in d=3. In general, frustration lowers the SG ordering temperature. At low temperatures, increased frustration favors the spin-glass phase (before it disappears) over ferromagnetic (F) and AF phases. When any amount of frustration is introduced, chaotic rescaling of local interactions occurs in the SG phase. Chaos increases with increasing frustration. The distinct Lyapunov exponents of all chaotic phases and phase boundaries are calculated. From entropy and specific-heat curves in d = 3, it is seen that frustration lowers in temperature the onsets of long- and short-range orders in spin-glass phases, more effectively on the former. From entropy versus p, it is seen that ground-state and low-temperature entropy already mostly sets in within the F and AF phases, before the SG phase is reached.

12:15PM B50.00006 The cavity method for phase transitions in sparse reconstruction algorithms, MOHAMMAD RAMEZANALLI, Rutgers University, PARTHA MITRA, Cold Spring Harbor Laboratory, ANIRVAN SENGUPTA, Rutgers University — Compressed sensing methods are capable of reconstructing high-dimensional sparse signals using a limited amount of measurements under certain conditions. The boundaries of good performance of compressed sensing methods are associated with certain phase transitions when the number of variables go to infinity. Many compressed sensing methods are formulated as optimization problems. Usual statistical physics approach to this problem involves inventing a finite temperature version of the problem, analyzing the mean field theory via replica trick, and, then taking the zero temperature limit. Although this method has been very successful in reproducing the observations, the replica trick and the non-trivial zero temperature limit obscure the essential reasons for failure of a compressed sensing algorithm. In this work, we employ the cavity method to give an alternative derivation of the phase transitions, working solely with the zero-temperature limit and providing insight into the origin of different terms in the mean field self-consistency equations. The cavity method naturally invokes a susceptibility which is central to understanding different phases in this system, and could be generalized to a much broader class of compressed sensing problems.

12:27PM B50.00007 Multiply charged monopoles in cubic dimer model , SREEJITH GANESH JAYA, Max Planck Institute for Physics of Complex Systems, STEPHEN POWELL, The University of Nottingham — The classical cubic dimer model is a 3D statistical mechanical system whose degrees of freedom are dimers that occupy the edges between nearest neighbour vertices of a cubic lattice. Dimer occupations are subject to the local constraint that every vertex is associated with exactly one dimer. In the presence of an aligning interaction, it is known that the system exhibits an unconventional continuous thermal phase transition from a symmetry broken columnar phase to a Coulomb-phase. The transition is in the NCCP1 universality class, which also describes the Neel-VBS transition in the JQ model and the $S = \frac{1}{2}$ Heisenberg model with suppression of hedgehog defects. Using Monte-Carlo simulations of a pair of defects in a background of fluctuating dimers, we calculate the scaling exponents for fugacities of monopole defects of charge $Q = 2$ and $3$ at this critical point. Our estimates suggest that $Q = 3$ monopoles are relevant and could therefore drive the JQ model away from the NCCP1 critical point on a hexagonal lattice.

12:39PM B50.00008 A matrix product state method for solving combinatorial optimization problems1, S.S. PELTON, University of Central Florida, C. CHAMON, Boston University, E.R. MUCCIOLLO, University of Central Florida — We present a method based on a matrix product state representation to solve combinatorial optimization problems. All constraints are met by mapping Boolean gates into projection operators and applying operators sequentially. The method provides exact solutions with high success probability, even in the case of frustrated systems. The computational cost of the method is controlled by the maximum relative entropy of the system. Results of numerical simulations for several types of problems will be shown and discussed.

1:03PM B50.00010 Large-Scale Quantization and consequences in statistical mechanics, GEORGE LIVADIOTIS, Southwest Research Institute, USA — Recent developments revealed the existence of a new quantization constant $\hbar_\ast$, similar to the Planck constant $\hbar$, but $10^{12}$ orders of magnitude larger. Planck’s constant constitutes the smallest possible phase-space parcel for collisionless particle systems characterized by collective behavior and local correlations. The majority of space plasmas throughout the heliosphere are such systems, but any other type of systems exhibiting collective behavior and correlations between their particles can be characterized by the large-scale quantization. Here, we discuss the consequences of this alternative phase-space scale to statistical mechanics. The generalization of the old-known Sackur-Tetrode entropic formulation for systems with local correlation is such an example.

1:15PM B50.00011 Modeling the thermal conductivity and shear viscosity of mixtures of methane and n-decane under high pressure and high temperature conditions using molecular simulations, JOHN SHELTON, Carnegie Mellon Univ — Atomistic molecular dynamics simulations were carried out at equilibrium to calculate the shear viscosity and thermal conductivity of various mixtures of methane and n-decane within the range of ambient to extreme temperature and pressure conditions (i.e. up to 500 degree F and 35,000 psi). Both a computationally efficient united-atom force field and an all-atom force field were employed in this investigation. A quantitative comparison of the results was performed against experimental values and values predicted from a high temperature - high pressure perturbed chain - statistically associated fluid theory (HPHT PC-SAFT) model. Analysis of the intermolecular structure of the fluid as well as its dynamical characteristics were performed.
While recent self-propelled particle models generically predict a glass/jamming transition that is driven by packing density, our work suggests that biological tissues can accommodate these disparate requirements because the tissues are close to glass or jamming transition. Initially rearrange and move over relatively large distances, like a liquid. Subsequently, these same tissues must undergo buckling and support shear stresses, like a solid.

1:30PM B50.00013 Unleashing the Power of Microcanonical Inflection-Point Analysis: The Principle of Minimal Sensitivity

Using selected-bond removal networks, we demonstrate that one can drive the overall system to different regimes of behavior. Consequently one can exploit disorder to achieve unique, varied, textured and tunable global response.

1:51PM B50.00014 Optimisation by hierarchical search

We investigate adsorption properties of a simple-cubic lattice polymer model. The pseudophase diagram based on microcanonical inflection-point analysis is constructed. This example confirms the general potential of microcanonical statistical analysis for studies of pseudophase transitions for systems of finite size.

Independence of bond-level response means that one can drive the overall system to different regimes of behavior. Consequently one can exploit disorder to achieve unique, varied, textured and tunable global response.

11:15AM B51.00002 A theoretical framework for jamming in confluent biological tissues

A theoretical framework for jamming in confluent biological tissues, M. LISA MANNING, Syracuse University — For important biological functions such as wound healing, embryonic development, and cancer tumorogenesis, cells must initially rearrange and move over relatively large distances, like a liquid. Subsequently, these same tissues must undergo buckling and support shear stresses, like a solid. Our work suggests that biological tissues can accommodate these disparate requirements because the tissues are close to glass or jamming transition. While recent self-propelled particle models generically predict a glass/jamming transition that is driven by packing density, they happen at some critical \( \varphi = \frac{c}{c} \) and depend only on single cell properties such as cell-cell adhesion, cortical tension and cell elasticity. This model additionally predicts that an experimentally observable parameter, the ratio between a cell's perimeter and the square root of its cross-sectional area, attains a specific critical value at the jamming transition. We show that this prediction is precisely realized in primary epithelial cultures from human patients, with implications for asthma pathology.

12:27PM B51.00003 Arboreal solutions: diodes, pumps, and diggers inspired by trees

Arboreal solutions: diodes, pumps, and diggers inspired by trees, ANETTE HOSONI, Massachusetts Institute of Technology — Many natural systems have evolved to perform certain tasks – climbing, sensing, swimming – as perfectly as possible within the limits set by the laws of physics. This observation can be used both to guide engineering design, and to gain insights into the form and function of biological systems. In this talk we will consider both of these themes in the context of trees. Beginning with the roots, we examine the role of flexibility in moving through granular substrates. Next we discuss fluid transport in tall plants and finally we apply our findings to the design of engineered solid state pumps and diodes.

This work was partially funded by DARPA’s Maximum Mobility and Manipulation (M3) Program.
1:03PM B51.00004 Mechanical Instabilities at Finite Temperature. XIAOMING MAO, University of Michigan — The “softness” of soft materials oftentimes originates from their proximity to mechanical instabilities. Recent advances in soft matter research have revealed multiple classes of mechanical instabilities, featuring different scalings, different patterns of emergent rigid structure, and even different orders of rigidity transitions. These interesting behaviors have been observed in a wide range of systems, from granular packings to biological tissues and self-assembled structures. In this talk, we review this rich spectrum of behavior and discuss dramatic effects of thermal fluctuations near mechanical instabilities. We discuss a few ordered and disordered lattice models that represent different classes of mechanical instabilities, and show using analytic theories how thermal fluctuations lead to interesting finite-temperature phase diagrams in each case. In particular, (i) using a square lattice model that exhibits a mechanical instability towards exponentially many degenerate ground states, we show that fluctuations can drive the mechanical instability to a first-order transition, owing to divergent fluctuations near the isostatic point; and (ii) using two classes of disordered lattices, we show how under-coordinated random networks can be stabilized by fluctuations and discuss various regimes of unusual entropic rigidity, sharing similarities with jammed packings at finite temperature.

1:39PM B51.00005 Soft interfaces: complex, dynamic, reacting and evolving. TODD SQUIRES, UCSB Chemical Engineering — Various surface-active species ranging from small, amphiphilic molecules to proteins to colloidal particles—adsorb to fluid interfaces, enabling multiphase materials like foams and emulsions. Biophysical structures like cell membranes and lung surfactant monolayers, and a host of novel two-dimensional materials more generally. Moreover, many such interfaces exhibit rich structural and dynamical properties, including the two-dimensional (surface) analogs of three-dimensional rheology, including viscoelasticity, shear thickening and thinning, and yield stresses. We have developed active interfacial micro rheology techniques that simultaneously track the evolution of the microstructure of these complex interfaces, enabling morphology to be directly related to rheology. We will highlight particularly interesting two-dimensional materials, and will also discuss interfaces that evolve as surfactants adsorb (as occurs, e.g., in micro emulsions, or protein solutions) or as reagents react (e.g., during interfacial polymerization reactions). In addition to probing the heterogeneous and mechanical properties of such evolving interfaces, we have developed techniques to visualize the evolution of bulk concentration fields as such reactions proceed, yielding new capabilities to probe reacting and evolving interfaces.

11:15AM B52.00001 Yb$_2$Pt$_2$Pb: Emergent Criticality on the Frustrated Shastry-Sutherland Lattice'. MEIGAN ARONSON, Stony Brook University/Brookhaven National Lab — Metallic Yb$_2$Pt$_2$Pb forms in the U$_3$Pt$_5$S$_3$ structure, with layers of Yb ions forming the orthogonal dimers of the Shastry-Sutherland lattice (SSL). The Yb$^{3+}$ moments are strongly Ising-like, with an energetically isolated doublet ground state. Fits to the temperature dependent susceptibility confirm that dimerization occurs, and that the B=0 energy separation of the singlet ground state and the triplet excited state $\Delta \sim 4.5$ K. Yb$_2$Pt$_2$Pb orders antiferromagnetically at 2.06 K, with a striped modulation of the Yb moments in the SSL plane, with two wave vectors $q_{AF} = (0.2, 0.2, 0)$ rlu. The Yb moments are oriented perpendicular to the (1,1,0) dimer bond directions, and the dimers form the rungs of two orthogonal spin ladders along the c-axis. A non-dispersing and inelastic excitation with energy $\sim 0.4$ meV is found for wave vectors in the SSL plane, in good agreement with the singlet-triplet gap $\Delta$ inferred from susceptibility measurements. The dispersion of the excitations along $\{00l\}$ closely resembles that of a spinon continuum, such as those found in spin chain compounds, with an effective c-axis exchange of $\sim 0.12$ meV. Yb$_2$Pt$_2$Pb is a unique system, where strong quantum fluctuations related to the spin-ladder or SSL characters of this compound may lead to unusual correlations in this excellent metallic host.

11:51AM B52.00002 Magnetic Frustration in the Shastry-Sutherland Kondo lattice and the Global Phase Diagram of Heavy Fermion Metals. JEDEDIAH PIXLEY, Condensed Matter Theory Center, Department of Physics, University of Maryland — Over the past decade there has been significant theoretical and experimental progress in our understanding of antiferromagnetic quantum critical heavy fermion metals [1]. Recent years have seen a surge of studies on heavy fermion compounds with local moments that reside on geometrically frustrated lattices, which may host entirely new types of quantum critical points [2]. With a particular emphasis on Yb$_2$Pt$_2$Pb [3] and related 221 systems [4,5], we consider the Shastry-Sutherland Kondo lattice [6]. We determine the zero temperature phase diagram as a function of magnetic frustration and Kondo coupling. We study the transition between the valence bond solid phase of the Shastry-Sutherland lattice and a heavy fermi liquid, and find a phase diagram remarkably similar to the theoretically proposed global phase diagram of heavy fermion metals. We discuss the implications of our results for other geometrically frustrated heavy fermion metals.

12:27PM B52.00003 Fragile antiferromagnetism in the heavy-fermion compound YbBiPt. ALAN I. GOLDMAN, Ames Laboratory and Iowa State University — The discovery of YbBiPt [1] generated strong interest due to its extraordinary Sommerfeld coefficient ($\sim 8 J/molK^2$) and the fact that all of its relevant energy include the Kondo temperature, Weiss temperature, crystal field splitting, and a proposed antiferromagnetic (AFM) ordering below $T_N \approx 0.4$ K are small and comparable, suggesting a complex interplay of competing interactions at low temperature. Much of the recent attention on YbBiPt has focused on the possibility of a magnetic-field-tuned AFM quantum critical point occurring at a low critical magnetic field of $\mu_0 H_c \approx 0.4$ T [2]. Although thermodynamic and transport measurements in ambient fields suggested that YbBiPt manifests AFM order below $T_N$, scattering measurements over the past 22 years failed to identify magnetic ordering in powder or single-crystal samples. In this talk, I will present recent elastic and inelastic neutron scattering experiments on single crystals of YbBiPt that demonstrated clear scattering signatures of unusual AFM order at low temperature [3]. The ambient field elastic scattering consists of two components: a narrower component that appears below $T_N \approx 0.4$ K, which can be identified with features observed in the bulk transport measurements; and a broad scattering component that persists up to $T^* \approx 0.7$ K corresponding to AFM correlations extending over $\sim 200$ rlu. The Yb moments are strongly Ising-like, with an energetically isolated doublet ground state. Fits to the temperature dependent susceptibility confirm that dimerization occurs, and that the B=0 energy separation of the singlet ground state and the triplet excited state $\Delta \sim 4.5$ K. Yb$_2$Pt$_2$Pb orders antiferromagnetically at 2.06 K, with a striped modulation of the Yb moments in the SSL plane, with two wave vectors $q_{AF} = (0.2, 0.2, 0)$ rlu. The Yb moments are oriented perpendicular to the (1,1,0) dimer bond directions, and the dimers form the rungs of two orthogonal spin ladders along the c-axis. A non-dispersing and inelastic excitation with energy $\sim 0.4$ meV is found for wave vectors in the SSL plane, in good agreement with the singlet-triplet gap $\Delta$ inferred from susceptibility measurements. The dispersion of the excitations along $\{00l\}$ closely resembles that of a spinon continuum, such as those found in spin chain compounds, with an effective c-axis exchange of $\sim 0.12$ meV. Yb$_2$Pt$_2$Pb is a unique system, where strong quantum fluctuations related to the spin-ladder or SSL characters of this compound may lead to unusual correlations in this excellent metallic host.

1:03PM B52.00004 Strange metal without magnetic instability in $\beta$–YbAlB$_4$, SATORU NAKATSUJI, ISSP, University of Tokyo — Many prototypical quantum critical materials found within the class of 4$f$ heavy fermion compounds are known to have an almost integral valence and appear at the border of magnetism. An exception to this rule was recently discovered in $\beta$–YbAlB$_4$, which exhibits quantum criticality despite strong mixed valency.$^{[4]}$ Ultrasonic single crystals of this material exhibit intrinsically singular thermodynamic and transport behaviors, which are extremely sensitive to a magnetic field.$^{[5]}$ In particular, $T/B$ scaling of the magnetization has been observed over four decades of $T/B$, projected to extend down to fields as small as 0.1 mT. In this talk, we will discuss our results on the zero field criticality by the $T/B$ scaling in a broad regime of $T$ and $B$, and through an extensive series of pressure measurements.$^{[6]}$ We will show that the intrinsic quantum criticality of YbAlB$_4$ occupies an extended region of pressure, indicating a formation of a phase. Furthermore, we will present that the strange metal region is clearly surrounded and separated from a high-pressure magnetic instability by a finite pressure range of Fermi liquid behavior.

1:39PM B52.00005 Kondo effect and quantum criticality in Ce-based pnictides, YONKANG LUO, Los Alamos National Laboratory — The pnictides have not only triggered enthusiasm in searches for high-$T_c$ superconductors, but also paved a new way for investigating the Kondo effect and quantum criticality. In this talk, I will start with the phase diagram of CeFeAs$_1-x$P$_x$O which hosts two possible quantum critical points (QCPs) [1]. Due to the entanglement of 3d and 4f magnetism, CeFeAsO is not a good candidate for investigating quantum criticality, therefore we turn to CeAs. The Ce-sublattice shows two successive AFM transitions at $T_{\text{N1}} = 9.3$ K and $T_{\text{N2}} = 7.3$ K, while the Ni-sublattice is nonmagnetic [2]. Under pressure, both AFM transitions are suppressed, and a QCP is obtained at $p_c = 6.5$ kbar. Similar phenomenon was also observed by P/As-substitution, which leads to a critical doping at $x_c = 0.4$. The quantum fluctuations near these QCPs are discussed, and the possibility of a Kondo-destruction type QCP is addressed [3]. Finally, I will briefly talk about the pressure effect on the 122 cousin, CeNi$_2$As$_2$ [4], which seems to provide a rare paradigm of quantum criticality in the low carrier density limit.

**2:42PM D0.00002 Strong electron-phonon interaction in an FeSe monolayer**

**SINISA COH, MARVIN L. COHEN, STEVEN G. LOUIE, UC Berkeley, Lawrence Berkeley National Laboratory — We show that the electron-phonon coupling in an FeSe monolayer on a \(\text{SrTiO}_3\) substrate is significantly larger than in earlier theoretical estimates. The role of the \(\text{SrTiO}_3\) substrate is two-fold. First, the interaction of the FeSe and \(\text{TiO}_2\) terminated face of \(\text{SrTiO}_3\) prevents the FeSe monolayer from undergoing a shearing-type (orthorhombic) structural phase transition. Second, the substrate allows an anti-ferromagnetic ground state of FeSe which opens certain electron-phonon coupling channels within the monolayer that are prevented by symmetry in the non-magnetic phase. The spectral function for the electron-phonon coupling (\(\alpha^2 F\)) in our calculations agrees well with inelastic tunneling data.**

3:06PM D0.00004 Fermi surface topology and gap anisotropy in monolayer FeSe thin film

YAN ZHANG, SIMES, LBNL; JAMES LEE, ROBERT MOORE, WEI LI, MING YI, SIMES, Stanford Unv.; MAKOTO HASHIMOTO, DONGHUI LU, SSRL, SLAC, ZAHID HUSSAIN, LBNL; TOM DEVEREAUX, SIMES, Stanford Unv.; DUNG-HAI LEE, UC Berkeley, ZHI-XUN SHEN, SIMES, Stanford Unv.

The discovery of superconductivity in monolayer FeSe thin film has generated great interests. The superconducting transition temperature (Tc) was reported to be over 65 K, which holds the record in iron-based superconductors. More intriguingly, the superconductivity was found only in one monolayer (1ML) film, while the films thicker than 1ML are non-superconducting. Utilizing the angle-resolved photoemission spectroscopy (ARPES), we studied the Fermi surface topology and superconducting gap anisotropy in 1ML FeSe. We resolved two ellipse-like electron pockets at the zone corner overlapping with each other. No hybridization between these two electron pockets was observed, which indicates that the glide mirror symmetry breaking due to the substrate is extremely weak in 1ML FeSe. Multi-gap behavior and gap anisotropy were further observed on the electron pockets. The superconducting gap minimums locate along the M-X direction for both inner and outer electron pockets. The observed Fermi surface topology and gap distribution provide a good starting point for constructing theoretical models and put strong constrains on determining the pairing symmetry in 1ML FeSe.

3:18PM D0.00005 STM investigation of FeSe/SrTiO3 band structure1

TATIANA A. WEBB, University of British Columbia, DENNIS HUANG, CAN-LI SONG, Harvard University, CUI-ZU CHANG, JAGADEESH MOODERA, Massachusetts Institute of Technology, JENNIFER E. HACKMAN, Harvard University — Growing a single unit cell of FeSe on a SrTiO3 substrate (1 u.c. FeSe/STO) enhances the superconducting transition temperature (Tc) by an order of magnitude. While the dramatic effect of the interface is evident, a mechanism is not. ARPES studies have revealed that the band structure differs significantly from bulk FeSe and the majority of other Fe-based superconductors, most notably in lacking a hole pocket at the Fermi level. ARPES, however, is limited to probing the filled electron states. STM/STS has access to the band structure, both above and below the Fermi level, with spatial resolution, and the data encodes electronic properties including orbital character and interactions. We present an STM/STS study of 1 u.c. FeSe/STO grown by molecular beam epitaxy (MBE), focusing on the empty-state band structure of this new high Tc superconductor.

3:30PM D0.00006 Investigation of superconductivity in single layer FeSe on SrTiO3 (001) by quasi-particle interference and impurity states 

TONG ZHANG, QIN FAN, WENHAO ZHANG, XI LIU, MIAO XIA, HONGYAN CHEN, RUI PENG, HAICHAO XU, BINPING XIE, DONGLAI FENG, Fudan University — Recently, single layer FeSe films on SrTiO3 (001) were discovered to have much enhanced superconductivity [1]. Here by using scanning tunneling microscopy/spectroscopy, we investigated the superconductivity of single layer FeSe through quasi-particle interference (QPI), magnetic vortex mapping and impurity induced bound states. The films were grown by MBE and transfer to STM in-situ. The magnetic vortex lattice was observed in dI/dV mappings in the field. QPI mappings show that intra-band and inter-band scattering of superconducting quasi-particles have significant anisotropy. Single atom impurities were introduced on the surface by in-situ deposition. We found that nonmagnetic impurities (Zn, Ag, K) do not induce bound states in the superconducting gap, but the magnetic ones (Cr, Mn) do. Upon these observations, the pairing symmetry of single layer FeSe will be discussed.

3:42PM D0.00007 Interface enhanced superconductivity in one unit-cell FeSe films grown on SrTiO3 

XUCUN MA, Department of Physics, Tsinghua University — Heterostructure based interface engineering has been proved an effective method for finding new superconducting systems and raising superconducting transition temperature (Tc). Recently discovered high temperature superconductivity in one unit-cell (UC) FeSe films on SrTiO3 (STO) substrate grown by molecular beam epitaxy has attracted intensive attention. In sharp contrast to FeSe films on graphite where a 2.2 meV superconducting gap is observed on thick films and no superconducting gap on 1-UC FeSe films grown by MBE, we discovered a large superconducting gap in 1-UC FeSe films grown on STO substrate. Another interesting point of this system is its simple band structure consists of only electron Fermi pockets at M points, which is different from that of bulk FeSe. In this talk, a comprehensive study of 1-UC FeSe films by in situ scanning tunneling microscopy/spectroscopy (STM/STS) and angle-resolved photoemission spectroscopy (ARPES) and ex situ transport measurements are presented to discuss the possible superconducting mechanism in this well-defined heterostructure.

4:18PM D0.00008 Phase separation or not in KxFe2−xSe2 (KFs) 

DESPINA LOUCA, JUNJIE YANG, University of Virginia — The coexistence of insulating and superconducting phases in the KxFe2−xSe2 family of Fe-based superconductors is investigated using neutron scattering on samples grown under different conditions. In this family, three scenarios have so far been proposed regarding the superconducting phase. In the first, a superconducting minority phase with the 122 composition is separated from the insulating and majority 245 phase. Under this scenario several phase diagrams have been developed in which the superconducting phase is sandwiched between semiconducting and insulating, antiferromagnetic phases. In the second, the superconducting phases exists in an inhomogeneous structure, hence no phase separation. And in the third, a purely superconducting phase of the alkali intercalated FeSe can be made with the 122 structure that has no other phases. By probing the local structure, we previously observed that superconductivity emerges in a locally distorted Fe sublattice that accommodates two kinds of bonding environments, forming a double-band distribution that changes with the concentration of K. In addition, the Fe bond distribution changes with the annealing treatment. Implications to the coexistence of the two phases will be discussed.

4:30PM D0.00009 Suppression of Phase Separation and Enhanced Superconducting Transition Temperature of FeSe1−xTe x Thin Films1

FUYUKI NABESIMA, YUICHI SAWADA, YOSHINORI IMAI, ATSUTAKA MAEDA, The University of Tokyo — To clarify the mechanism of superconductivity of Fe-based superconductors, it is crucial to investigate superconductivity of FeSe1−xTeX, which has the simplest crystal structure. There is, however, a serious obstacle to the understanding of its superconductivity; phase separation by spinodal decomposition occurs in the region of 0.1 < x < 0.4 and thus a whole phase diagram has not been available. A useful method to fabricate metastable materials is thin-film deposition because of its thermodynamically non-equilibrium growth. In the presentation we will report the first demonstration of the suppression of the phase separation of FeSe1−xTeX thin films on CaF2 substrates[1]. Surprisingly the optimal composition to achieve the highest superconducting transition temperature, Tc, was found in this phase separation region; Tc reaches ~23 K. A whole phase diagram we will present provides a new perspective for the superconductivity of this material. [1] F. Nabeshima et al., Appl. Phys. Lett. 103 (2013) 172602.

4:42PM D0.00010 Fermi surface deformation in a simple iron-based superconductor, FeSe$^1$

AMALIA COLDEA, MATTHEW WATSON, University of Oxford, UK, TIMUR KIM, Diamond Light Source, UK, AMIR HAGHIGHIRAD, University of Oxford, UK, ALIX MCCOLLAM, High Field Magnet Laboratory, Nijmegen, The Netherlands, MORITZ HOERSCH, Diamond Light Source, UK, ANDREW SCHOFIELD, University of Birmingham — One of the outstanding problems in the field superconductivity is the identification of the normal state out of which superconductivity emerges. FeSe is one of the simplest and most intriguing iron-based superconductors, since in its bulk form it undergoes a structural transition before it becomes superconducting, whereas its single-layer form is believed to be a high-temperature superconductor. The nature of the structural transition, occurring in the absence of static magnetism, is rather unusual and how the electronic structure is stabilized by breaking of the rotational symmetry is the key to understand the superconductivity in bulk FeSe. Here we report angle-resolved photoemission spectroscopy measurements on FeSe that gives direct access to the band structure and orbital-dependent effects. We complement our studies on bulk FeSe with low-temperature angular-dependent quantum oscillation measurements using applied magnetic fields that are sufficiently strong to suppress superconductivity and reach the normal state. These studies reveal a strong deformation of Fermi surface through the structural transition driven by electronic correlations and orbital-dependent effects.

4:54PM D0.00011 Electronically-driven orthorhombic distortion in FeSe$^1$

MATTHEW WATSON, NATHANIEL DAVIES, AMIR HAGHIGHIRAD, ARJUN NARAYANAN, Clarendon Laboratory, Department of Physics, University of Oxford, Parks Road, Oxford OX1 3PU, TIMUR KIM, MORITZ HOERSCH, Diamond Light Source, Harwell Campus, Didcot, OX11 0DE, SAMUEL BLAKE, AMALIA COLDEA, Clarendon Laboratory, Department of Physics, University of Oxford, Parks Road, Oxford Oxford OX1 3PU — FeSe is structurally the simplest of Fe-based superconductors, and exhibits a tetragonal-to-orthorhombic structural transition at $\sim$ 90 K, but no long-range magnetism at any temperature. We report measurements of the resistivity anisotropy in FeSe above $T_s$ finding a large and divergent response to an applied strain, with a comparable magnitude and temperature-dependence to measurements in Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$, but opposite sign. We compare this data with literature reports on NMR and our own ARPES data, which taken together indicate that the structural transition is electronically-driven with orbital degrees of freedom playing a central role.

$^1$This work was supported by EPSRC, UK (EP/I004475/1) and Diamond Light Source.

5:06PM D0.00012 The superconductivity in single-layer FeTe$_{1-x}$Se$_x$ films on SrTiO$_3$.

LILI WANG, XUCUN MA, QIKUN XUE, Tsinghua University, XUE TEAM — For bulk FeSe, the highest transition temperature $T_c = 9$ K has been observed for the composition with stoichiometry Fe$_{1.1}$Se$_{1.1}$. The tetragonal-orthorhombic structural transition observed in FeSe is suppressed with Te substitution and the superconducting transition temperature reaches a maximum of $T_c = 15.2$ K at about 50% Te substitution. For single-layer FeSe films on SrTiO$_3$, in situ scanning tunneling microscopy and angle resolved photoemission spectroscopy have revealed a superconducting gap as large as 20 meV, and $\textit{ex situ}$ transport measurements have confirmed the interface enhanced superconductivity with $T_c$ above 55 K. Here we report a detailed $\textit{in situ}$ scanning tunneling microscopy and transport study of the single-layer FeTe$_{1-x}$Se$_x$ films on SrTiO$_3$. We found that Te substitution in the single-layer FeSe films doesn’t induce further increase of the transition temperature $T_c$, which is in contrast to the results for the corresponding bulk materials. This implies that the SrTiO$_3$ substrates play important role in the interfacial superconductivity.

5:18PM D0.00013 Theoretical studies of the effects of orbital ordering on spin fluctuations and superconductivity in FeSe.

SHANTANU MUKHERJEE, ANDREAS KREISEL, Niels Bohr Institute, University of Copenhagen, PETER J. HIRSCHFELD, Department Of Physics, University of Florida, BRIAN M. ANDERSEN, Niels Bohr Institute, University of Copenhagen — FeSe is currently one of the most hotly debated iron-based systems due in part to its very high $T_c$, when monolayers are placed on STO substrates, and in part due to the fact that the material exhibits a structural distortion near $T_S$ $\sim$ 90K without any concomitant magnetic order. In addition, undoped bulk FeSe samples, which become superconducting below $T_c$ $\sim$ 8K, display evidence of orbital ordering setting in near $T_S$. We discuss the normal and superconducting properties of FeSe using a ten orbital tight-binding model, and include the effect of ferro-orbital ordering. The model reproduces the essential features of FeSe band structure seen in ARPES [1] and quantum oscillation experiments [3]. Using this model, the spin lattice relaxation rate is calculated and the results are compared with recent NMR experiments [2]. We next discuss the consequences of a spin fluctuation mediated superconducting pairing in FeSe and the resulting gap structure. Finally, the local density of states derived from our calculations is compared to STM experiments [4].

2:30PM D1.00001 Strain-Engineering of Giant Pseudo-Magnetic Fields in Graphene/Boron Nitride (BN) Periodic Nanostructures$^1$

CHEN-CHIH HSU, JIAQING WANG, MARCUS TEAGUE, CHIEN-CHANG CHEN, NAI-CHANG YEH, Caltech — Ideal graphene is strain-free whereas non-trivial strain can induce pseudo-magnetic fields as predicted theoretically and manifested experimentally. Here we employ nearly strain-free single-domain graphene, grown by plasma-enhanced chemical vapor deposition (PECVD) at low temperatures, to induce controlled strain by placing the PECVD-graphene on substrates containing engineered nanostructures. We fabricate periodic pyramid nanostructures (typically 100 $\sim$ 200 nm laterally and 10 $\sim$ 60 nm in height) on Si substrates by focused ion beam, and determine the topography of these nanostructures using atomic force microscopy and scanning electron microscopy after we transferred monolayer h-BN followed by PECVD-graphene onto these substrates. We find both layers conform well to the nanostructures so that we can control the size, arrangement, separation, and shape of the nanostructures to generate desirable pseudo-magnetic fields. We also employ molecular dynamics simulation to determine the displacement of carbon atoms under a given nanostructure. The pseudo-magnetic field thus obtained is $\sim$150T in the center, relatively homogeneous over 50% of the area, and drops off precipitously near the edge. These findings are extended to arrays of nanostructures and compared with topographic and spectroscopic studies by STM.

ZHIGONG SONG, ZHIPING XU, Tsinghua Univ — Defects in solids commonly limit mechanical performance of materials by reducing their rigidity and strength. In this talk, we report measurements of adhesion properties of large-area graphene transferred onto silicon oxide. Measurement of interfacial properties is crucial for practical and reliable applications of graphene. In this talk, we report measurements of adhesion properties of large-area graphene transferred onto silicon oxide. Using a high sensitive nanoindentation tool, we observed nonlinear adhesive interactions of graphene with an indenter. The nanoindentation measurements also provided interesting local behaviors of graphene related to wettability. The experimental results were analyzed with numerical simulation for further understanding.

4:18PM D1.00010 Basal-plane dislocations in bilayer graphene - Peculiarities in a quasi-2D material¹. BENJAMIN BUTZ, Center for Nanoanalysis and Electron Microscopy (CENEM), University Erlangen-Nuremberg — Dislocations represent one of the most fascinating and fundamental concepts in materials science. First and foremost, they are the main carriers of plastic deformation in crystalline materials. Furthermore, they can strongly alter the local electronic or optical properties of semiconductors and ionic crystals. In layered crystals like graphene, dislocation movement is restricted to the basal plane. Thus, those basal-plane dislocations cannot escape their confinement in between only two atomic layers of the material. So-called bilayer graphene is the thinnest imaginable quasi-2D crystal to explore the nature and behavior of dislocations under such extreme boundary conditions. Robust graphene membranes derived from epitaxial graphene on SiC provide an ideal platform for their investigation. The presentation will give an insight in the direct observation of basal-plane partial dislocations by transmission electron microscopy and their detailed investigation by diffraction contrast analysis and atomistic simulations. The investigation reveals striking size effects. First, the absence of stacking fault energy, a unique property of bilayer graphene, leads to a characteristic dislocation pattern, which corresponds to an alternating AB ↔ BA change of the stacking order. Most importantly, our experiments in combination with atomistic simulations reveal a pronounced buckling of the bilayer graphene membrane, which directly results from accommodation of strain. In fact, the buckling completely changes the strain state of the bilayer graphene and is of key importance for its electronic/spin transport properties. Due to the high degree of disorder in our quasi-2D material it is one of the very few examples for a perfect linear magnetoresistance, i.e. the linear dependency of the in-plane electrical resistance on a magnetic field applied perpendicular to the graphene sheet up to field strengths of more than 6 T.

4:54PM D1.00011 Strain and defect induced enhancement of Young’s modulus of graphene. GUILLERMO LOPEZ-POLIN, CRISTINA GOMEZ-NAVARRO, MIRIAM JAAFAF, JULIO GOMEZ-HERRERO, Universidad Autonoma de Madrid, VINCENZO PARENTE, RAFAEL ROLDAN, Instituto de Ciencia de Materiales de Madrid, MIKHAIL KATSNELSON, Radboud University, FRANCESC PEREZ MURANO, Instituto de Microelectronica de Barcelona, FRANCISCO GUINEA, Instituto de Ciencia de Materiales de Madrid — Graphene, due to its extremely high in plane stiffness and low bending rigidity, presents important out of plane thermal fluctuations crucial for the understanding of its mechanical properties. In this work we measure Young’s modulus of graphene with induced vacancy density using AFM nanoindentations. Unlike predicted, we find that the stiffness of graphene increases with defect content until a vacancy density of 0.2 percent, where it doubles its initial value. For higher defect density the elastic modulus exhibits a decreasing tendency. We attribute the initial increase in stiffness to the quenching of the out of plane oscillations of graphene due to defects [1]. In order to validate this interpretation we also study the dependence of the elastic modulus with strain. We observe an increase of the Young’s modulus at pre-strains higher than 0.5 percent where it again doubles its initial value.

5:06PM D1.00012 Irradiation-Induced Superplasticity of Graphene and Carbon Nanotubes. ZHUHUA ZHANG, YU LIN, Department of Materials Science and Nanoeengineering, and the Smalley Institute for Nanoscale Science and Technology, Rice University, Houston, TX 77005, FENG DING, Institute of Textiles and Clothing, Hong Kong Polytechnic University, Kowloon, Hong Kong, Peoples Republic of China, BORIS I. YAKOBSON, Department of Materials Science and Nanoeengineering, and the Smalley Institute for Nanoscale Science — The superplasticity of carbon nanotubes has been related to the dynamics of pentagon-heptagon (57) dislocations, but the mechanism remains elusive in light of prohibitively high barrier (~ 7 eV) of dislocation migration [1,2]. Here, we reveal the key role of electron irradiation in facilitating the dislocation migration and promoting nanotube plasticity. Atomistic simulations show that irradiation-induced adatoms and monovacancies diffuse towards the sessile 57 dislocations and switch them into a mobile radical state with a migration barrier as low as 1.6 eV, thereby significantly enhancing the plastic flow. The radical dislocations also act as defect scavengers to prevent lattice disorder in the tube wall, in agreement with experimental phenomena. Further, a formula is derived to quantify the plasticity in terms of irradiation intensity, aimed to guide the irradiation engineering of plasticity of carbon nanomaterials.

5:18PM D1.00013 ABSTRACT WITHDRAWN –

Monday, March 2, 2015 2:30PM - 5:30PM – Session D2 DMP: Focus Session: Beyond Graphene - Optics in 2D Semiconductors I 001B - Farhan Rana, Cornell University

2:30PM D2.00001 Dependence of Monolayer WS2-Substrate Interaction on Substrate Type and Bonding Investigated by High-temperature Raman and Photoluminescence , LIQIN SU, Univ of NC - Charlotte, YIFEI YU, LINYOU CAO, North Carolina State University, YONG ZHANG, Univ of NC - Charlotte — We report the temperature and excitation wavelength dependence of the electronic and vibration properties of epitaxially grown WS2 monolayers on different substrates, SiO2 and sapphire, using photoluminescence (PL) and Raman spectroscopy with temperatures up to 500 °C. Similar to our previous study on MoS2 (Su et al., Nanoscale 6, 4920, 2014), the WS2 monolayers are shown to also exhibit strong interaction with substrates, manifesting as that their electronic and optical properties depend sensitively on the substrate type and film-substrate bonding. Raman frequency shifts for E1g(Γ) and A1g(Γ) modes and PL energy shifts are measured from room temperature up to 500 °C. Raman spectra shows strong substrate dependence, and the thermal quenching of the PL intensity in the high temperature region reveal nonradiative channels with large activation energies in the order of 0.5 eV. This study suggests the critical need to assess the potential impact of the substrate on the intrinsic properties of such 2-D materials and the opportunities for tailoring their properties by selecting different substrates.

2:42PM D2.00002 Single Quantum Emitters in Monolayer Tungsten Diselenide. GENEVIEVE CLARK, JOHN SCHABILEY, University of Washington, YU-MING HE, YU HE, M. C. CHEN, Y. J. WEI, X. DING, QIANG ZHANG, JIAN-WEI PAN, University of Washington - Single quantum emitters (SQEs) are central emerging photonemission technologies. While they have been realized in variety of solid state systems, all solid-state quantum emitters to date are embedded in a three dimensional bulk matrix. We present a new type of single quantum emitter in a two-dimensional system, in the form of neutral excitons localized to defects within atomically thin tungsten diselenide monolayers. These localized excitons show strong photoluminescence with 130 μeV emission lines from two non-degenerate, cross-polarized transitions. Their narrow line width is characteristic of localized exciton emission, and is several orders of magnitude narrower than seen from excitons delocalized in a monolayer. Second-order correlation measurements show strong photon anti-bunching, establishing that these localized excitons are single photon emitters. Magneto-optical measurements reveal an exciton g-factor of 8.7, significantly larger than that of delocalized excitons. SQE’s in monolayer WS2 may offer practical advantages such as efficient photon extraction and scalability, and in-situ control of local environment.

— Charlotte, YIFEI YU, LINYOU CAO, North Carolina State University, YONG ZHANG, Univ of NC - Charlotte — We report the temperature and excitation, LIQIN SU, Univ of NC - Charlotte, YIFEI YU, LINYOU CAO, North Carolina State University, YONG ZHANG, Univ of NC - Charlotte — We report the temperature and excitation,
2:54PM D2.00003 Quantum dots in graphene-like materials, THAKSHILA HERATH, VADYM APALIKOV, Georgia State University — We study numerically the electron states in silicenene and germainene quantum dots within the effective low energy model of silicene and germanene. The quantum dots are realized through spatial variation of perpendicular electric field, i.e., bias voltage. The energy spectra of such quantum dots are obtained for different parameters of the dots, which are the size of the dot and the strength of external electric field. For cylindrically symmetric spatial profile of electric field, the electron states of the dot are characterized by z-component of the angular momentum. Due to strong spin-orbit interactions in such buckled graphene-like materials, the states in the quantum dots have unique spin texture, which is more pronounced for germanene quantum dots. The dependence of spin polarization of electron states in the quantum dots on the strength of electric field is also obtained.

3:06PM D2.00004 Ultrafast laser spectroscopy of two-dimensional materials and their heterostructures, HUI ZHAO, University of Kansas — Monolayer transition metal dichalcogenides are new two-dimensional materials beyond graphene. Recently, extensive studies have revealed several unique properties of these materials and their potential applications in electronic and renewable-energy technologies. Furthermore, it is possible to use these atomic layers as building blocks to fabricate new van der Waals heterostructures with emergent properties. In this talk, I will report our recent ultrafast laser studies of several types of two-dimensional transition metal dichalcogenides and their heterostructures. First, we studied several nonlinear optical processes, such as second harmonic generation, which allows detection of the crystal orientation and symmetry of MoS$_2$ monolayers, and two-photon absorption, which was used to measure the bandgap and exciton binding energy of WSe$_2$ monolayers. Second, we used a transient absorption microscopy technique with high spatial resolution to study exciton dynamics in these materials, and measured their exciton lifetime, diffusion coefficient, and ballistic transport. Third, by performing transient absorption measurements with polarization resolution, we studied spin and valley dynamics of excitons in monolayer MoSe$_2$ and deduced a spin relaxation time of about 9 ps at room temperature. Finally, we used the transient absorption technique with layer selectivity to study heterostructures of graphene-WS$_2$, MoS$_2$-MoSe$_2$, and WSe$_2$-MoSe$_2$. We observed ultrafast and efficient charge and exciton transfer across the van der Waals interface in all these structures. The formation of spatially indirect excitons in the transition-metal-dichalcogenide heterostructures was also studied. Furthermore, we found that the optical properties of WS$_2$ can be effectively tuned by carriers in graphene in the graphene-WS$_2$ heterostructure.

3:42PM D2.0005 Pressure-Dependent Optical and Vibrational Properties of Monolayer Molybdenum Disulfide, AVINASH NAYAK, UT Austin, TRIBHUWAN PANDEY, Materials Research Center, Indian Institute of Science, Bengaluru, 560-012, India, DAMIEN VOIRY, Department of Materials Science and Engineering, Rutgers University, JIN LIU, Department of Geological Sciences, The University Of Texas at Austin, SAMUEL MORAN, ANKIT SHARMA, CHENG TAN, UT Austin, CHANG-HSIAO CHEN, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, 10617, Taiwan, LAIN-JONG LI, Physical Science and Engineering Division, King Abdullah University of Science & Technology (KAUST), Thuwal 23955, Saudi Arabia, MANISH CHHOWALLA, Department of Materials Science and Engineering, Rutgers University, JUNG-FU LIN, Department of Geological Sciences, The University Of Texas at Austin, ABHISHEK SINGH, Materials Research Center, Indian Institute of Science, Bengaluru, 560-012, India, DEJI AKINWANDE, UT Austin, DEJI AKINWANDE TEAM, ABHISHEK SINGH TEAM, LANCE LI COLLABORATION, MANISH CHHOWALLA COLLABORATION, HPSTAR COLLABORATION, — We study numerically the electron states in silicene and germanene quantum dots within the effective low energy model of silicene and germanene. When subjected to biaxial elastic strain, monolayer MoS$_2$ can embed wide band gap variations overlapping the visible spectrum, with calculations showing the modified electronic potential emanating from point-induced tensile strain perturbations mimicking the Coulomb potential in a mesoscopic atom. We have realized and confirmed this “artificial atom” concept via capillary-pressure-induced nanoindentation of monolayer MoS$_2$ from a tailored nanostructure. We demonstrate that a synthetic lattice of these building blocks forms an optoelectronic crystal capable of broadband light absorption and efficient funneling of photogenerated excitons to points of maximum strain at the atom centers. Such 2D semiconductors with spatially textured band gaps represent a new class of materials which may find applications in next-generation optoelectronics or photovoltaics.

3:54PM D2.00006 Optoelectronic Crystal of Artificial Atoms in Strain-Textured MoS$_2$, ALEX W. CONTRYMAN, HONG LI, ALEX H. FRAGAPANE, Stanford University, XIAOFENG QIAN, SINA MOEINI ARDAKANI, Massachusetts Institute of Technology, YONGJI GONG, XINGLI WANG, Rice University, JEFFREY M. WEISSE, CHI HWAN LEE, JIHENG ZHAO, Stanford University, PULICUEL M. AJAYAN, Rice University, JU LI, Massachusetts Institute of Technology, XIAOLIN ZHENG, HARI C. MANOHARAN, Stanford University — The atomically thin semiconductor MoS$_2$ possesses exceptional strength and a strain-tunable band gap. When subjected to biaxial elastic strain, monolayer MoS$_2$ can embed wide band gap variations overlapping the visible spectrum, with calculations showing the modified electronic potential emanating from point-induced tensile strain perturbations mimicking the Coulomb potential in a mesoscopic atom. We have realized and confirmed this “artificial atom” concept via capillary-pressure-induced nanoindentation of monolayer MoS$_2$ from a tailored nanostructure. We demonstrate that a synthetic lattice of these building blocks forms an optoelectronic crystal capable of broadband light absorption and efficient funneling of photogenerated excitons to points of maximum strain at the atom centers. Such 2D semiconductors with spatially textured band gaps represent a new class of materials which may find applications in next-generation optoelectronics or photovoltaics.

4:06PM D2.00007 Electronic and optical properties of single-layer, double-layer, and bulk SnSe and GeSe, EMMANOUIL KIOUPAKIS, GUANGSHA SHI, Materials Science and Engineering, University of Michigan — We used density functional and many-body perturbation theory to calculate the quasiparticle band structures and optical properties of single-layer, double-layer, and bulk SnSe and GeSe. The calculated direct and indirect band gaps of the bulk materials are in good agreement with experiment. While the electronic band gaps increase by up to 600 meV in the single-layer, double-layer, and bulk SnSe, the transition energy of the n = 1 exciton does not change as a function of thickness. The same trend was also discovered in GeSe. The fundamental band gaps were found to be direct in SnSe and GeSe monolayers. We calculated the absorption spectra for both the bulk and 2-dimensional systems, and determined the light absorbance for light polarization along the in-plane armchair and zigzag directions. This research was supported by the National Science Foundation CAREER award through Grant No. DMR-1254314. Computational resources were provided by the DOE NERSC facility.

4:18PM D2.00008 Light-matter interactions of monolayer semiconductors integrated with photonic microcavities, Y.-J. CHEN, T. STANEV, G. WEI, N. P. STERN, Department of Physics and Astronomy, Northwestern University, J. D. CAIN, V. DRAVID, Materials Science and Engineering, Northwestern University — Enhanced light-matter interactions in optical microcavities can enable hybrid photon-exciton quasiparticle excitations when in a regime of strong light-matter coupling. Because of their direct bandgap, atomic-scale thickness, and strong spin-orbit coupling, monolayers of transition metal dichalcogenides (TMDs) allow for exciton-polaritons in a two-dimensional regime with rich correlations between spin, momentum, and light polarization. We demonstrate integrated TMD photonic devices with MoS$_2$ grown by vapor transport and sandwiched between dielectric Bragg mirrors. We discuss evidence for exciton-polaritons in monolayer TMDs at room temperature using angle-resolved cavity reflectivity spectroscopy. This interpretation is supported by the dependence on MoS$_2$ layer number. Calculations of light-matter coupling parameters in TMDs yield values consistent with recent observations. We discuss our approach to integrated 2D monolayer photonics in the context of the valley-sensitive bandstructure of excitons in TMDs.

1 This work was supported by the National Science Foundation CAREER award through Grant No. DMR-1254314. Computational resources were provided by the DOE NERSC facility.

4:30PM D2.00009 Optical Two Dimensional Fourier Transform Spectroscopy of Layered Metal Dichalcogenides¹, P. DEY, J. PAUL, C.E. STEVENS, Dept of Physics, University of South Florida, Z.D. KOVALYUK, Z.R. KUDRYNSKYI, The National Academy of Sciences of Ukraine, A.H. ROMERO, Dept of Physics, West Virginia University, A. CANTARERO, Material Science, University of Valencia, D.J. HILTON, Dept of Physics, University of Alabama at Birmingham, J. SHAN, Dept of Physics, Pennsylvania State University, D. KARAIKAJ, Dept of Physics, University of South Florida, Z.D.KOVALYUK AND Z.R.KUDRYNSKYI COLLABORATION, A.H.ROMERO COLLABORATION, A. CANTARERO COLLABORATION, D.J.HILTON COLLABORATION, J. SHAN COLLABORATION — Nonlinear two-dimensional Fourier transform (2DFT) measurements were used to study the mechanism of excitonic dephasing and probe the electronic structure of the excitonic ground state in layered metal dichalcogenides. Temperature-dependent 2DFT measurements were performed to probe exciton-phonon interactions. Excitation density dependent 2DFT measurements reveal exciton-exciton and exciton-carrier scattering, and the lower limit for the homogeneous linewidth of excitons on positively and negatively doped samples.

¹U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-SC0012635

4:42PM D2.00010 Layer-structured hexagonal boron nitride carbon semiconductor alloys for deep UV photonics¹, MD RAKIB UDDIN, Research Assistant, Nanophotonics Center, Texas Tech University, JING LI, Research Professor, Nanophotonics Center, Texas Tech University, JINGYU LIN, HONGXING JIANG, Professor, Electrical and Computer Engineering Department, Texas Tech University — Hexagonal boron nitride carbon alloys, \( h-(\text{BN})_{1-x} (\text{C}_2)_x \), are layer-structured semiconductor materials with a tunable bandgap energy from 0 eV (graphite) to 6.5 eV (h-BN). We report on synthesizing (BN)-rich \( h-(\text{BN})_{1-x} (\text{C}_2)_x \) semiconductor alloys using standard MOCVD growth technique on sapphire substrate. Bandgap energy variation with carbon concentration in the deep UV spectral range has been demonstrated through optical absorption measurements. Experimental results suggest that the critical carbon concentration \((x_c)\) to form the homogenous \( h-(\text{BN})_{1-x} (\text{C}_2)_x \) alloys is about 3.2% at a growth temperature of 1300 °C. It is expected that homogenous \( h-(\text{BN})_{1-x} (\text{C}_2)_x \) alloys with higher \( x \) can be achieved by increasing the growth temperature. This is a huge advantage over the InGaN alloy system in which higher growth temperatures cannot be utilized to close the miscibility gap. Together with our ability for producing high quality h-BN epilayers, \( h-(\text{BN})_x \) alloys and quantum wells open up new possibilities for realizing novel 2D optoelectronic devices with tunable physical properties.

¹National Science Foundation

4:54PM D2.00011 Electrically controlled fluorescence quenching of quantum dots on monolayer Molybdenum Disulfide – Part II, ANDREY KLOTS, DHIRAJ PRASAI, Department of Physics and Astronomy, Vanderbilt University, A.K.M. NEWAZ, Department of Physics and Astronomy, San Francisco State University, SCOTT NIEZGODA, NOAH ORFIELD, SANDRA ROSENTHAL, Department of Chemistry, Vanderbilt University, KANE JENNINGS, Chemical and Biomolecular engineering, Vanderbilt University, KIRILL BOLOTIN, Department of Physics and Astronomy, Vanderbilt University — In the second part of this talk, we investigate the mechanisms that enable energy exchange between semiconductor quantum dots (QDs) and two-dimensional (2D) materials. First, we study possible contributions due to multiple mechanisms such as charge transfer, metallic screening, mechanical strain, and Forster resonant energy transfer (FRET). By implementing different 2D materials (graphene, MoS\(_2\), hexagonal boron nitride), varying their thickness and QD emission wavelengths we demonstrate that QD fluorescence quenching is dominated by FRET. Next, we study the dependence of the FRET rate on electrostatic doping of 2D materials, focusing on the case of monolayer MoS\(_2\). We develop a simple model, which shows that that moderate (<10%) changes in MoS\(_2\) absorption induced by gating lead to much larger (∼50%) modulation of QD photoluminescence intensity. Finally, we demonstrate that FRET can be used as an efficient spectroscopic tool that proves states in 2D materials that are not accessible via conventional absorption spectroscopy.

5:06PM D2.00012 Electrically controlled fluorescence quenching of quantum dots on monolayer Molybdenum Disulfide – Part I, DHIRAJ PRASAI, ANDREY KLOTS, Department of Physics and Astronomy, Vanderbilt University, A.K.M. NEWAZ, Department of Physics and Astronomy, San Francisco State University, SCOTT NIEZGODA, NOAH ORFIELD, SANDRA ROSENTHAL, Department of Chemistry, Vanderbilt University, KANE JENNINGS, Chemical and Biomolecular engineering, Vanderbilt University, KIRILL BOLOTIN, Department of Physics and Astronomy, Vanderbilt University — We study hybrid electronic structures in which zero-dimensional semiconductor quantum dots (QDs) are coupled with two-dimensional monolayer molybdenum disulfide (MoS\(_2\)). To fabricate such devices, we mechanically transfer MoS\(_2\) onto a sub-monolayer of QDs assembled on a functionalized glass surface. We investigate quenching of the fluorescence of QDs which are selectively synthesized to have emission spectra which overlap with the excitonic absorption peak (2.1eV) in MoS\(_2\). Both photoluminescence intensity and lifetime for QDs on MoS\(_2\) decrease ∼ 5 times due to near-field energy transfer from QDs to MoS\(_2\). Furthermore, by electrostatically gating MoS\(_2\), we control the rate of energy transfer and modulate the photoluminescence intensity of QDs by ∼ 50%.

5:18PM D2.00013 Energy transfer between quantum dots and 2D materials: graphene versus MoS\(_2\), ARCHANA RAJA, JOHANNA ZULTAK, XIAOXIAO ZHANG, ANDRES MONTOYA-CASTILLO, ZILIANG YE, CYRIELLE ROQUELET, AREND VAN DER ZANDE, DANIEL CHENET, LOUIS BRUS, TONY HEINZ, Columbia University — Understanding charge and energy transfer processes at the interface of nanostructures is an important area of research, both from the fundamental and application points of view. Interactions between 0D semiconductor quantum dots and 2D van der Waals materials have been a subject of recent investigations [1,2]. Here, we report highly efficient near-field energy transfer from core-shell quantum dots to monolayer and few layer graphene, a semi-metal and MoS\(_2\), a semiconductor. We observe both quenching of single quantum dot photoluminescence (PL) and decreasing lifetime in time resolved PL. Our measurements show that increasing the number of layers in the acceptor van der Waals material results in contrasting trends in the rate of non-radiative energy transfer. The energy-transfer rate increases significantly with increasing layer thickness for graphene, but decreases with increasing thickness for MoS\(_2\) layers. Energy transfer rates on the order of 1-10ns\(^{-1}\) are determined. We interpret the results in terms of differences in the interplay between dielectric loss and screening.

Monday, March 2, 2015 2:30PM - 5:30PM
Session D4 APS: Undergraduate Research/Society of Physics Students II — Mayor Cockrell Room 004 - Cortney Bougher, American Physics Society
2:30PM D4.00001 Photoresponsive memory device based on Graphene/Boron Nitride heterostructure . SALMAN KAHN, JAIRO VELASCO JR, LONG JU, DILLON WONG, JUWON LEE, HSIN ZON TSAI, Department of Physics, University of California, Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, ALEX ZETTL, FENG WANG, MICHAEL CROMMIE, Department of Physics, University of California, Berkeley — Recent technological advancements have allowed the stacking of two dimensional layered material in order to create van der Waals heterostructures (VDH), enabling the design of novel properties by exploiting the proximal interaction between layers with different electronic properties. We report the creation of an optoelectronic memory device using a Graphene/Boron Nitride (hBN) heterostructure. Using the photo-induced doping phenomenon, we are able to spatially ‘write’ a doping profile on graphene and ‘read’ the profile through electrical transport and local probe techniques. We then utilize defect engineering to enhance the optoelectronic response of graphene and explore the effect of defects in hBN. Our work introduces a simple device architecture to create an optoelectronic memory device and contributes towards understanding the proximal effects of hBN on Graphene.

2:42PM D4.00002 High quality factor titanium nitride and aluminum resonators for increased superconducting qubit coherence 1. N. E. FRATTINI, A. DOVE, D. M. TOYLI, S. HACOHEN-GOURGY, A. EDDINS, I. SIDIQI, QNL, University of California, Berkeley — Superconducting qubits have successfully realized effective two–level quantum systems whose state can be read out by dispersive coupling to a linear resonator. Superconducting films which exhibit low loss in the microwave frequency regime at millikelvin temperatures and single photon excitation provide an essential ingredient in realizing high-coherence qubits and high-fidelity readout. To explore the magnitude of these losses and their correlation with fabrication recipes, we prepare and characterize both lumped element and distributed element resonators derived from titanium nitride on silicon and aluminum on sapphire. We study the role of substrate annealing, film growth conditions, and lithographic technique on resonator quality factor.

2:54PM D4.00003 The Characteristic Phase Transitions of Co-doped BaFe2As2 Synthesized via Flux Growth 1. C. H. SHEA, Ithaca College, Department of Physics and Astronomy, C. RONCAIOLI, C. ECKBERG, T. DRYE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, M. C. SULLIAVAN, Ithaca College, Department of Physics and Astronomy, J. PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland — Since the discovery of a new family of type II superconductors in 2008, the iron pnictides, researches have had suspicions that they might bear similar electronic properties to the well-known (but not easily realized) oxide superconductors. For this reason studies of this family of compounds has been of great interest to the materials science community. Our efforts have been aimed at single crystal growth and measurement of a particular member of this family, BaFe2As2. While this material is not superconducting at standard pressure, the partial substitution of cobalt on the iron site has been shown to suppress an anti-ferromagnetic phase transition occurring at lower temperatures allowing for the appearance of a superconducting phase. Transport and low field magnetization measurements taken on our samples show clean transitions, indicating Tc's of up to 24 K in optimally doped samples. We will discuss the growth methods and temperature dependent phase transitions of this material at different cobalt concentrations.

3:06PM D4.00004 ABSTRACT WITHDRAWN

3:18PM D4.00005 Measurements of Viscosity and Dynamics of Thin Films of Organic Glass TPD via Hole Growth Dewetting Studies 1. KAREEM WAHID, University of Texas Pan American, YUE ZHANG, MU LI, ZAHRAR AGHRAI, Department of Chemistry, University of Pennsylvania — In this study, we aim to measure the viscosity of thin glassy films of the small organic molecule N,N-Bis(3-methylphenyl)-N,N-diphenylbenzidine (TPD). Organic glasses such as TPD have various applications in organic light emitting diodes (OLED), and organic photovoltaics. An understanding of the origin for nano-scale properties (e.g. viscosity) would allow for better design of such devices in future applications. Viscosity is simple to measure in bulk systems but challenging at the nanometer scale. Dewetting experiments provide a simple and non-invasive method to measure viscosity in thin film systems. By following dewetting kinetics over time, we are able to identify material related viscous dissipation and substrate related frictional dissipation involved during dewetting. Both homogeneously and heterogeneously nucleated holes have been observed on TPD films of various thicknesses or various substrates. There is reasonable agreement between these observations and with full-slip dewetting models among heterogeneously nucleated holes. However, this is not observed in homogeneously nucleated holes. Careful substrate treatment and control of substrate properties influence the slip length and the dewetting dynamics.

3:30PM D4.00006 Monitoring Residual Solvent Additives and Their Effects in Solution Processed Solar Cells 1, DEREK M. FOGEL, Wake Forest University, JAMES I. BASHAM, NIST and Penn State University, SEBASTIAN ENGMANN, SUJITRA J. POOKPANRATANA, EMILY G. BITTLE, NIST, OANA D. JÜRCHESCU, Wake Forest University, DAVID J. GUNDLÄCH, NIST — High boiling point solvent additives are a widely adopted approach for increasing bulk heterojunction (BHJ) solar cell efficiency. However, experiments show residual solvent can persist for hours after film deposition, and certain common additives are unstable or reactive. We report here on the effects of residual 1,8-diiodooctane on the electrical performance of poly(3-hexylthiophene-2,5-diyl) (P3HT) phenyl-C71-butyric acid methyl ester (PC(71)BM) BHJ photovoltaic cells. We optimized our fabrication process for efficiency at an active layer thickness of 220 nm, and all devices were processed in parallel to minimize unintentional variations between test structures. The one variable in this study is the active layer post spin drying time. Immediately following the cathode deposition, we measured the current-voltage characteristics at one sun equivalent illumination intensity, and performed impedance spectroscopy to quantify charge density, lifetime, and recombination process. Spectroscopic ellipsometry, FTIR, and XPS are also used to monitor residual solvent and correlated with electrical performance. We find that residual additive degrades performance by increasing the series resistance and lowering efficiency, fill factor, and free carrier lifetime.

3:42PM D4.00007 Solution Processed Polymeric Semiconductors for Carbon Nanotube-Enabled, Vertical, Organic Field Effect Transistors 1. ALEXANDER SCHACHTNER2. Dept. of Physics, University of Oregon, NICHOLAS S. CUNNINGHAM, CHRISTOPHER C. SAMOUCHE, MAXIME C. LEMAITRE, ANDREW G. RINZLER, Dept. of Physics, University of Florida — Carbon nanotube-enabled, vertical, organic field effect transistors (CN-FETs) based on the small molecule diphenyl[2,3-b:2′,3′-f]thieno[3,2-b]thiophene (DTNT) have demonstrated high current, low-power operation suitable for driving active matrix organic light emitting diode (AMOLED) displays [1]. This performance is achieved without the need for costly high-resolution patterning, despite the low mobility of the organic semiconductor, by employing sub-micron channel widths, defined in the vertical devices by the thickness of the semiconducting layer. Replacing the thermally evaporated small molecule semiconductor with a solution-processed polymer would possibly further simplify the fabrication process and reduce manufacturing cost. Here we investigate several polymer systems as wide bandgap semiconducting channel layers for potentially air stable and transparent CN-FETs. The field effect mobility and optical transparency of the polymer layers are determined, and the performance and air stability of CN-FVET devices are measured. 1. M. A. McCarthy et al. extend lanthanum dititanate’s (LTO), La$_2$Ti$_2$O$_7$, and dimensions in order to optimize the enhancement. Ultimately, we will fabricate devices and characterize the plasmonic properties with optical techniques, which could be useful in a wide range of applications. Finite element methods are used to approximate the electromagnetic responses, giving the ability to alter the designs and more localized plasmonically enhanced electric fields. These unique metal devices encompass tunable, enhanced plasmonic and optical properties that can overcome the resolution limits of traditional electron beam lithography and can also be used to increase resolution in photolithography fabrication as well.

determined enhancement factors and the plasmonic and optical properties of these structures. The nanomasking technique is a new process that is employed in the devices fabricated with a recently developed nanomasking technique that is based on the self-aligned process. Computational electromagnetic modeling has approximated using poor man’s scaling analysis. Here, we focus on using the more accurate numerical renormalization group method to calculate the location of quantum phase transitions around the Fermi energy, then quantum phase transitions will occur. The phase boundaries of the pseudogap Anderson impurity model have been previously approximated using poor man’s scaling analysis. Here, we focus on using the more accurate numerical renormalization group method to calculate the location of these boundaries. We then compare these numerical results with the predictions derived from the scaling approximations. The development of nanotechnology like quantum dots and STM have rekindled interest in the Kondo effect since it can now be studied within controlled settings.

5:06PM D4.00014 Measurement of Specific Heat of Pr$_{1-x}$Nd$_x$Os$_2$Sb$_{12}$ from 11K-300K$^1$ —  TAYLOR MCCULLOUGH-HUNTER, SHOJI HISHIDA, PEI-CHUN HO, Physics Department, California State University, Fresno, BRIAN MAPLE, Physics Department, University of California, San Diego, TATSUYA YANAGISAWA, Physics Department, Hokkaido University, Japan — The filled skutterudite compound Pr$_{1-x}$Nd$_x$Os$_2$Sb$_{12}$ exhibits heavy fermion behavior and unconventional superconductivity at low temperatures (T$_c$ = 1.85K). The exact causes of these behaviors are unknown. The compound Nd$_2$Os$_2$Sb$_{12}$ exhibits ferromagnetism at a Curie temperature near 1 K. Originally, Nd doped compounds of the form Pr$_{1-x}$Nd$_x$Os$_2$Sb$_{12}$ were developed to investigate the effect of ferromagnetism on the unconventional superconductivity and heavy fermion behavior of Pr$_2$Os$_2$Sb$_{12}$. The specific heat of Pr$_{1-x}$Nd$_x$Os$_2$Sb$_{12}$ (where x = 0.25, 0.5, 0.75, 0.8, and 1) is measured at 11K-300K to investigate the compounds' normal state properties. The specific heat is measured using relaxation calorimetry of finite heat pulse in a cryocooler system. Values of the electronic specific heat coefficient, $\gamma$, for these compounds are estimated to be 10-60 mJ/K$^2$.mol. This contrasts with previous low temperature measurements (<10K) of Nd$_2$Os$_2$Sb$_{12}$ with $\gamma$ approximately 520 mJ/K$^2$.mol.

$^1$Research at USF-Fresno is supported by NSF DMR-1104544; at UCSD by NSF DMR-1206533 and US DOE DE FGO2-04ER46105; and at Hokkaido Univ. by MEXT, Japan.

5:18PM D4.00015 Colossal Piezoresistance in strained La$_{0.67}$Sr$_{0.33}$MnO$_3$ thin films$^1$ — MARIA VI-ITANIEMI, IN HAE KWAK, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — Piezoresistance is the change in electrical resistance as a function of strain. A known mechanism leading to piezoresistance is thermodynamic phase separation. It has been shown that the compound (La$_{1-x}$Pr$_x$)$_{1-x}$Ca$_x$MnO$_3$ (LPCMO) exhibits colossal piezoresistance (CPR) for a wide range of electronic phase separation. For use in many applications, such as sensors, materials must exhibit CPR near room temperature. A possible candidate compound is La$_{0.67}$Sr$_{0.33}$MnO$_3$ (LSMO) which has a Curie temperature of approximately 350 K. However, bulk LSMO single crystals do not show CPR since such samples are uniformly ferromagnetic and metallic with no phase separation. In this study, we examine the piezoresistance of ultrathin LSMO films grown on SrTiO$_3$ (STO) substrates using a three-point beam bending method to control the compressive and tensile strain. It has been suggested that the lattice mismatch strain due to the substrate induces phase separation in these thin films. We have observed CPR in such strained LSMO thin films even at room temperature.

Monday, March 2, 2015 2:30PM - 5:30PM — Session D5 FIAP: Fractional Quantum Hall Effect III

2:30PM D5.00001 Position-Momentum Duality, Geometrical Description and Ideal Host Lattices for Fractional Chern Insulators — MARTIN CLAASSEN, Department of Applied Physics, Stanford University, CHING-HUA LEE, Department of Physics, Stanford University, RONNY THOMALE, Institute for Theoretical Physics, University of Wuerzburg, XIAO-LIANG QI, Department of Physics, Stanford University, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory, Stanford Institute for Materials and Energy Sciences — The recent discovery of fractional quantum Hall (FQH) physics in flat-band Chern insulators without external magnetic field presents a profound theoretical challenge to understand the interplay of universal long-wavelength physics of the FQH effect and short-wavelength physics determined by the host lattice. Here, we present a first quantization description of fractional Chern insulators that is dual of the anisotropic FQH problem, with the roles of position and momentum interchanged. The fundamental guiding-center geometry of the problem emerges from the interplay of lattice and interaction metrics that act as momentum-space duals of Haldane’s geometrical description of the anisotropic FQH effect. We introduce a novel broad class of ideal C$_2$1 Chern insulator lattice models that are duals of the isotropic limit of the conventional FQH effect. These models afford a particularly elegant analytical framework and act as parent Hamiltonians for lattice FQH states with emergent guiding-center and SU(C) symmetry. Resulting microscopic insight into stabilization of FQH states on the lattice provides a foundation for future analyses of non-Abelian phases and fractional topological insulators.

2:42PM D5.00002 Projective construction of the $Z_k$ Read-Rezayi fractional quantum Hall states and their excitations on the torus geometry — CECILE REPPELLIN, Ecole Normale Superieure, France, TITUS NEUPERT, Princeton center for theoretical science, B. ANDREI BERNEVIG, Princeton University, NICOLAS REGNAULT, Ecole Normale Superieure, France, Princeton university — The torus is an ideal mathematical object for developing projective construction methods for fractional quantum Hall states and their excitations. We use the independence of these states on the choice of projective construction method as a tool to construct new models of fractional quantum Hall states.
3:06PM D5.00004 Magneto-transport characteristics of a 2D electron system driven to negative magneto-conductivity by microwave photoexcitation1. RAMESH MANI, Georgia State University, A. KRIISA, Emory University — Negative diagonal magneto-conductivity/resistivity is a spectacular and thought provoking property of driven, far-from-equilibrium, low dimensional electronic systems. The physical response of this exotic electronic state is not yet fully understood since it is rarely encountered in experiment. The microwave-radiation-induced zero-resistance state in the high mobility GaAs/AlGaAs 2D electron system is believed to be an example where negative magneto-conductivity/resistivity is responsible for the observed phenomena. Here, we examine the magneto-transport characteristics of this negative conductivity/resistivity state in the microwave photo-excited two-dimensional electron system (2DES) through a numerical solution of the associated boundary value problem. The results suggest, surprisingly, that a bare negative diagonal conductivity/resistivity state in the 2DES under photo-excitation should yield a positive diagonal resistance with a concomitant sign reversal in the Hall voltage.

1Transport measurements are supported by the DOE, Office of Basic Energy Sciences, Material Sciences and Engineering Division under DE-SC0001762. Additional support by the ARO under W911NF-07-01-015

3:18PM D5.00005 Non-Abelian two dimensional topological phases constructed from coupled wires and connections to exceptional lie algebras. MAYUKH KHAN, Department of Physics, University of Illinois at Urbana-Champaign, IL 61801, USA, JEFFREY TEO, Department of Physics, University of Virginia, Charlottesville, VA 22904 USA, TAYLOR HUGHES, Department of Physics, University of Illinois at Urbana-Champaign, IL 61801, USA — Non-abelian anyons exhibit exotic braiding statistics which can be utilized to realize a universal topological quantum computer. In this work we focus on Fibonacci anyons which occur in Z2 Read Rezayi fractional quantum hall states. Traditionally they have been constructed using su(2)/u(1) coset theories. We introduce conformal field theories (CFTs) of exceptional and non-simply laced Lie Algebras at level 1, for example G2, F4 which host Fibonacci anyons. We realize these CFT’s concretely on the 1d gapless edge of an anisotropic 2d system built out of coupled, interacting Luttinger wires. Interactions are introduced within a bundle of wires to fractionalize the original chiral bosons into different sectors. Next, we couple these sectors to get the desired topological phase in the bulk. The 2d bulk of the stack is gapped by backscattering terms between counterpropagating modes on different bundles. The emergence of this topological phase can be interpreted using techniques of anyon condensation. We also explicitly construct the Kac Moody algebra on the edge CFT using original bosonic degrees of freedom. We acknowledge support from NSF CAREER DMR-1351895 (TH) and Simons Foundation (JT).

3:30PM D5.00006 Variational study of bosonic phases in two dimensions: fractional Chern insulator, Mott insulator and superfluid. BRYAN CLARK, HASSAN SHAPOURIAN, University of Illinois at Urbana Champaign — We numerically study the model wave functions for a system of hard core bosons at half filling on a square lattice. The candidate wave functions are based on the projective construction approach [1] where a boson is decomposed into two (slave) fermions, each described by a Chern insulator model. Our results confirm that the wave functions demonstrate the following phases: the superfluid, the Mott insulator and the fractional Chern insulator. In addition, we find that the wave functions can be continuously tuned from one phase to another by varying the parameters of slave particles. We further propose a microscopic Hamiltonian with a rich phase diagram which supports all the aforementioned phases in different regimes of parameters. The critical behavior across the phase boundaries is investigated and the critical exponents are computed. [1] M. Barkseshi and J. McGreevy, Phys. Rev. B 89, 235116 (2014).

3:42PM D5.00007 Pairing in half-filled Landau level1. ZHIQIANG WANG, UCLA, IPSITA MANDAL, Perimeter Institute for Theoretical Physics, Canada, SUDIP CHAKRAVARTY, UCLA — Pairing of composite fermions in half-filled Landau level state is reexamined by solving the BCS gap equation with full frequency dependent current-current interactions. Our results show that there can be a continuous transition from the Halperin-Lee-Read state to a chiral odd angular momentum Cooper pair state for short-range contact interaction. This is at odds with the previously established conclusion of first order pairing transition, in which the low frequency effective interaction was assumed for the entire frequency range. We find that even if the low frequency effective interaction is repulsive, it is compensated by the high frequency regime, which is attractive. We construct the phase diagrams and show that l = 1 angular momentum channel is quite different from higher angular momentum channel l ≥ 3. Remarkably, the full frequency dependent analysis applied to the bilayer Hall system with a total filling fraction ν = 1/2 + 1/2 is quantitatively changed from the previously established results but not qualitatively.

1This work was supported by US NSF under the Grant DMR-1004520, the funds from the David S. Saxon Presidential Chair at UCLA (37952), and by the Institute for Basic Science in Korea through the Young Scientist grant (5199-2014003).

3:54PM D5.00008 What Determines the Fermi Wave Vector of Composite Fermions1. DOBROMIR KAMBUROV, Princeton Univ, YANG LIU, M.A. MUEED, MANSOUR SHAYEGAN, LOREN PFIEFFER, KENNETH WEST, KIRK BALDWIN, Princeton University — We report the observation of a pronounced asymmetry in the magnetic field positions of the commensurability resistance minima of fully spin-polarized composite fermions (CFs) with respect to the field at ν = 1/2 in two-dimensional (2D) electron and hole systems. The asymmetry is observed across a wide range of 2D densities and modulation periods. We present evidence the asymmetry quantitatively if we assume that the CFs are fully spin-polarized and their density is equal to the density of the minority carriers in the lowest, spin-resolved Landau level (LL), namely the density of electrons when ν < 1/2 and of holes when ν > 1/2. Our results provide direct evidence that CFs are formed by pairing up of the minority carriers in the lowest spin-resolved LL with flux quanta. They further indicate that the CF commensurability minima are not observed at ν and (1 − ν), as expected from a simple particle-hole symmetry principle, pointing to a subtle breaking of this symmetry.

1We acknowledge support through the DOE BES (DEFG02-00-ER45841), the Gordon and Betty Moore Foundation (Grant GBMF4420), Keck Foundation, NSF (ECCS-1001719, DMR-1305691, and MRSEC DMR-0819860). A portion of this work was performed at the NHMFL.

4:06PM D5.00009 Continuous preparation of a fractional Chern insulator. CHRISTOPHER LAUMANN, University of Washington, MAISSAM BARKESHLI, Microsoft Station Q, NORMAN YAO, University of California, Berkeley — We present evidence of a direct, continuous quantum phase transition between a Bose superfluid and the ν = 1/2 fractional Chern insulator in a microscopic lattice model. In the process, we develop a detailed field theoretic description of this transition in terms of the low energy vortex dynamics. The theory explicitly accounts for the structure of lattice symmetries and predicts a Landau forbidden transition that is protected by inversion. That the transition is continuous enables the quasi-adiabatic preparation of the fractional Chern insulator in non-equilibrium, quantum optical systems.
4:18PM D5.00010 Optical Signatures of Competing Quantum Phases in the Second Landau Level1. ANTONIO LEVY, Columbia University Department of Physics, URSULA WURSTBAUER, Technische Universität München Department of Physics, ARON PINCZUK, Columbia University Department of Physics, JOHN WATSON, GEOFF GARDNER, MICHAEL MANFRA, Purdue University Department of Physics, KEN WEST, KIRK BALDWIN, LOREN PFEIFFER, Princeton University Department of Electrical Engineering — The fractional quantum Hall states and anisotropic phases of electrons in the N=1 Landau Level (LL) have drawn considerable experimental focus in recent years[1-3]. We report evidence that the competition and coexistence of these phases is probed directly by optical recombination from the partially populated N=1 LL at dilution refrigerator temperatures. Spectral bands that display striking dependence on perpendicular magnetic field in the full range 3−8 T are interpreted as linked to anisotropic phases. Optical recombination thus enables the monitoring of the evolution competing phases as the N=1 LL filling is changed. Remarkable changes in the optical recombination reveal that coexistence of distinct quantum phases has a marked dependence on filling of the N=1 LL. The signatures of anisotropic phases remain strong at filling factors of the FQHE. This is consistent with recent reports on anisotropic IQHE states in the second Landau level[1-3]. 4:30PM D5.00011 DMRG Study of a $\nu = 1/3 + 1/3$ Bilayer Fractional Hall System, SCOTT GERAEDTS, California Institute of Technology, MICHAEL ZALETEL, Microsoft Station Q, ZLATKO PAPIĆ, Perimeter Institute, ROGER MONG, University of Pittsburgh — DMRG Study of a $\nu = 1/3 + 1/3$ Bilayer Fractional Hall System Bilayer quantum Hall systems provide new experimental parameters that generate a rich phase diagram proposed to contain a new non-Abelian phase. We use the density matrix renormalization group (DMRG) and exact diagonalization to study a bilayer quantum Hall system with filling fraction 1/3 per layer. Using this method, we can study the phase diagram in terms of parameters such as interlayer separation, interlayer tunnelling, layer width, and density imbalance between the layers. We identify the possible phases based on their entanglement properties and determine the order of phase transitions. Prospects for stabilizing new non-Abelian phases with small perturbations to the Coulomb interaction will be discussed.

4:42PM D5.00012 Microwave spectroscopic observation of multiple phase transitions in the bilayer electron solid in wide quantum wells, ANTHONY HATKE, LLOYD ENGEL, NHMFL, YANG LIU, MANSOUR SHAYEGAN, LOREN PFEIFFER, KEN WEST, KIRK BALDWIN, Princeton University — The termination of the low Landau filling factor ($\nu$) fractional quantum Hall series for a single layer two dimensional system results in the formation of a pinned Wigner solid for $\nu < 1/5$ [1]. In a wide quantum wells the system can support a bilayer state in which interlayer and intralayer interactions become comparable, which is measured in traditional transport as an insulating state for $\nu < 1/2$ [2]. We perform microwave spectroscopic studies of this bilayer state and observe that this insulator exhibits a resonance, a signature of a solid phase. Additionally, we find that as we increase the density of the well at fixed $\nu$ this bilayer solid exhibits multiple sharp reductions in the resonance amplitude vs $\nu$. This behavior is characteristic of multiple phase transitions, which remain hidden from dc transport measurements.

5:00PM D5.00014 Collapse of the $\nu = 1$ quantum Hall effect near a Landau level crossing1. SUKRET HASDEMIR, YANG LIU, M.A. MUEED, LOREN PFEIFFER, KEN WEST, KIRK BALDWIN, MANSOUR SHAYEGAN, Princeton University — We report magneto-resistance measurements of 2D hole systems (density $2.1 \times 10^{11}$ cm$^{-2}$) confined to a 40-nm-wide GaAs quantum well as a function of tilted magnetic fields. We observe a strong $\nu = 1$ quantum Hall effect (QHE) at zero parallel field ($B_{||}$). The $\nu = 1$ QHE disappears at $B_{||} \approx 4.8$ T, where we expect a crossing between the lowest two Landau levels. Near this crossing, the energy gap for the $\nu = 1$ QHE collapses from 6 K to zero in a very small $B_{||}$ range of 0.3 T. The $\nu = 1$ QHE comes back at $B_{||} \approx 8.1$ T and eventually disappears at $B_{||} > 17$ T where the system becomes bilayer-like. The sudden collapse of the $\nu = 1$ QHE and the fact that it comes back after a large $B_{||}$ range of 3.3 T is intriguing and suggests a pinning of the Landau levels near the crossing.

1We acknowledge support through the NSF (DMR-1305691, DMR-1310199 and MRSEC DMR-0819860), the DOE BES (DE-FG02-00-ER45841), the Gordon and Betty Moore Foundation (Grant GBMF4420), and the Kwon Foundation.

5:18PM D5.00015 Exact diagonalization study of $\nu = 1/3 + 1/3$ bilayer quantum Hall in search of Fibonacci anyons1. EUN-AH KIM, ABOLHASSAN VAEZI, KYUNGMIN LEE, Cornell University — Non-abelian states with Fibonacci anyons that can support universal topological quantum computation have been elusive. Recently it has been proposed that a remarkably simple setting of Abelian quantum Hall bilayer could support an exotic state with Fibonacci anyons (Vaezi and Barkeshli, arXiv:1403.3383). Here we explore $\nu = 1/3 + 1/3$ bilayer quantum Hall system considering different possibilities for interaction between bilayers using exact diagonalization. We find a sizable region in phase space potentially exhibiting topological degeneracy expected of Fibonacci anyon states.

1This work has been supported by NSF CAREER with grant number DMR-0955822

Monday, March 2, 2015 2:30PM - 5:30PM – Session D6 DMP DCOMP: Focus Session: Domain Walls, Surfaces, Interfaces 006A - Xiaqing Pan, University of Michigan
2:30PM D6.00001 Universal intrinsic origin for ferroelectric domain wall motion¹, SHI LIU, ILYA GRINBERG, ANDREW RAPPE, The Makeni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania — The existence of domain walls in ferroelectric materials can have a profound influence on the properties of ferroelectrics [1]. We explored the dynamics of the 90° domain walls in PbTiO$_3$ with molecular dynamics simulations [2] under a wide range of temperatures and electric fields. We found an intrinsic “creep-depinning” transition for the temperature- and field-dependence of the wall velocity, resulted from the nucleation-and-growth mechanism. By mapping non-180° domain walls to a 180° domain wall, we proposed an analytical model that is able to quantify the dynamics of all types of domain walls in various ferroelectrics, enabling rapid estimation of the domain wall velocity with first-principles inputs. This work offers a unified picture for domain wall motion and an efficient framework for computational optimization of ferroelectrics.

¹NSF ONR DOE HPCMO NERSC

2:42PM D6.00002 Anomalous Dielectric Loss at Ferroelectric Domain Walls Revealed by Microwave Impedance Microscopy, XIAOYU WU, YUAN REN, Department of Physics, University of Texas at Austin, RONGWEI HU, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University, KEJI LAI, Department of Physics, University of Texas at Austin — Domain walls (DWs) in multiferroic materials, within which the ferroic order parameter changes its orientation, may possess emergent properties that are absent in the bulk domains. Combining the standard piezo-force microscopy (PFM), conductive atomic-force microscopy (C-AFM), and a novel microwave impedance microscopy (MIT), we observed strong dielectric loss at the domain walls and vortex cores on the (001) charge neutral surface of hexagonal manganite in the bulk domains. We explored the dynamics of the 90° microdomains (MIM) technique, we observed strong dielectric loss at the domain walls and vortex cores on the (001) charge neutral surface of hexagonal manganite YMnO$_3$. The DW contrast was detected for a broad frequency range between 100MHz and 3GHz. The equivalent DW conductivity inferred from the MIM images is estimated to be five orders of magnitude higher than that of the bulk YMnO$_3$, which cannot be explained within the existing theoretical framework. By applying a DC bias on the MIM probe, we have also observed the transition from DW contrast to domain contrast in the impedance images. The MIM technique provides a unique opportunity to probe the nanoscale electronic anomalies in various topological defects, which will be crucial for future device applications of multiferroics.

2:54PM D6.00003 All-Epitaxial Ferroelectric Tunnel Junctions with Ultrathin BaTiO$_3$, DANIEL SANDO, SEUNGRAN LEE, YEONG JAE SHIN, Center for Correlated Electron Systems, IBS, Seoul National University, MYEONG RAE CHO, YUN PARK, Department of Physics and Astronomy, Seoul National University, TAE WON NOH, Center for Correlated Electron Systems, IBS, Seoul National University — Ferroelectric tunnel junctions (FTJs) are a promising route toward the development of high density, nonvolatile memories with non-destructive readout [1]. The principle of operation is polarization-dependent tunneling electroresistance (TER). The direction of polarization in the ferroelectric layer defines high and low resistance states. So far, the most impressive results regarding TER ON/OFF ratios have been either without a top electrode, or using a top electrode of a non-oxide metal. However, defects in the ferroelectric [2] or interfacial layer can reduce performance. To overcome these limitations, we have fabricated fully-strained epitaxial FTJs using perovskite oxides for all layers. L$_{3a}$Sr$_{0.7}$Fe$_{1.3}$MnO$_3$/BaTiO$_3$/SrRuO$_3$/SrTiO$_3$. The heterostructures are grown by pulsed laser deposition at high substrate temperatures of 900°C. The electrodes are patterned using e-beam lithography. Piezoresistance and microwave impedance microscopy shows that ferroelectricity is maintained for a barrier thickness as low as 3 unit cells. We present our results on TER performance and the dependence of switching properties on the BaTiO$_3$ thickness. [1] V. Garcia, et al. Nature 460, 81-84 (2009). [2] M. Dawber, K. M. Rabe, J. F. Scott, Rev. Mod. Phys. 77, 1083 (2005).

3:06PM D6.00004 Direct visualization of magnetoelectric domains in hexagonal manganites¹, WEIDA WU, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854, USA — Multiferroics are materials with coexisting magnetic and ferroelectric orders, where the cross-coupling between two ferroic orders can result in strong magnetoelectric effects [1-4]. Therefore, it is of both fundamental and technological interest to visualize cross-coupled magnetoelectric domains and domain walls in multiferroics. Recently, introducing top electrodes of six interlocked structural antiphase and ferroelectric domains merging into a vortex core were revealed in multiferroic hexagonal R$^e$Mn$_3$O$_7$ (RE=rare earths) [5, 6]. Many emergent phenomena, such as enhanced conduction and unusual piezoelectric response, were observed in charged ferroelectric domain walls protected by these topological defects [7-9]. More interestingly, alternating uncompensated magnetic moments were discovered at coupled structural antiphase and ferroelectric domain walls in hexagonal manganites using cryogenic magnetic force microscopy (MFM) [10], which demonstrates the cross-coupling between ferroelectric and magnetic orders. Using a newly-developed Magnetoelectric Force Microscopy (MeFM), which combines MFM with in-situ modulating high electric fields, we directly visualize the magnetoelectric response of the multiferroic domains in hexagonal manganites. The development of MeFM opens up explorations of emergent phenomena in multifunctional materials with multiple coupled orders [11, 12].

³The work is supported by DOE BES under Award # DE-SC0008147.

3:42PM D6.00005 Dynamical magnetoelectric effects associated with ferroelectric domain walls¹, SERGEY PROSANDEEV, Univ of Arkansas-Fayetteville, ANDREI MALASHEVICH, Yale University, New Haven, IGOR RAEVSKI, Southern Federal University, Rostov-na-Donu, LAURENT BELLAICHE, Univ of Arkansas-Fayetteville — Molecular dynamics simulations using a first-principles-derived effective Hamiltonian are conducted on lead zirconium titanate ultrathin films possessing nanoscale ferroelectric domains and being under GHz electric field. Pulses of magnetization are predicted to occur in this system, when sudden changes of magnetization result from switching of ferroelectric domains. A simple equation relating the magnetization and product between the electrical polarization and its time derivative is further derived from a simple model (via the relation between the magnetization and time derivative of the so-called electrical toroidal moment). This equation naturally explains our numerical findings, as well as previously observed magnetoelectric effects in moving ferroelectric domain walls/phase boundaries in ferroelectrics and magnetoelectrics.

3:54PM D6.00006 First-principles study of the effect of oxygen vacancies around the 180° ferroelectric domain walls of tetragonal PbTiO$_3$. HOE-CHEOL SONG, HYE JUNG KIM, YOUNG-HAN SHIN*, University of Ulsan. People have extensively studied the dynamics of ferroelectric materials to apply them to nonvolatile memory devices. One of the issues in ferroelectric random access memory is the fatigue effect, which results from the presence of oxygen vacancy. Many cycles of polarization switching increase the density of oxygen vacancy around ferroelectric domain walls, and it makes the ferroelectric energy barrier higher to slow down the switching rate. In this presentation, we examine the domain dynamics around the 180° ferroelectric domain walls of tetragonal PbTiO$_3$ with and without the oxygen vacancy by using the first-principles calculations. We estimate the energy barriers of several possible reaction paths with the nudged elastic band method. Compared to the oxygen vacancy far away from domain walls, the oxygen vacancy around ferroelectric domain walls tends to be thermodynamically stable with lower energy barriers. Finally, we expect that by controlling of oxygen vacancy density around the ferroelectric domain wall could be the solution for solving fatigue problem in ferroelectric materials.

4:06PM D6.00007 Pinning of Ferroelectric Domain Walls in Nanostructured CoFe$_2$O$_3$-BiFe$_3$O$_4$ Composite, KEREN FREEDY, RYAN COMES, University of Virginia. Department of Materials Science and Engineering, Charlottesville, VA, KERRY SIEBEN, National Institute of Standards and Technology, Center for Nanoscale Science and Technology, Gaithersburg, MD, JIWEI LU, University of Virginia, Department of Materials Science and Engineering, Charlottesville, VA, STUART WOLF, University of Virginia, Department of Materials Science and Engineering, Department of Physics, Charlottesville, VA — Ferroelectric domain walls in BiFe$_3$O$_4$ thin films have attracted interest due to the observation of enhanced electronic transport at the domain walls in an otherwise insulating material. To understand the properties of domain walls in nanostructured thin films having matrix-pillar morphology, thin films of CoFe$_2$O$_3$ (CFO)-BiFe$_3$O$_4$ were grown epitaxially by pulsed electron deposition on SrTiO$_3$ (STO) substrates. Piezoresistance, force microscopy (PFM) measurements indicate that the vertically-oriented CFO nanopillars act as pinning sites for the in-plane domain walls. The pinning effect is most likely due to misfit dislocations at the matrix/pillar interface which have been identified in transmission electron microscopy images. The ability to produce ordered nanocomposites by directed self-assembly offers potential for more extensive investigation of domain wall behavior.

4:18PM D6.00008 Ferroelectric Striped Nanodomains in PbTiO$_3$/SrTiO$_3$ Superlattice Islands, QINGTENG ZHANG, JOONKYU PARK, Univ of Wisconsin, Madison, ROSS HARDER, JORG M. MASER, Argonne National Laboratory, MOHAMMED YUSUF, MATTHEW DAWBER, Stony Brook University, PAUL G. EVANS, Univ of Wisconsin, Madison — The ferroelectric remnant polarization of isolated, unscreened ferroelectric layers in ultrathin films or ferroelectric/dielectric superlattices spontaneously forms striped domains to minimize the total electrostatic energy. The X-ray scattering patterns of domains in a PbTiO$_3$/SrTiO$_3$ ferroelectric/dielectric superlattice indicate that the striped domains have a highly disordered arrangement with an average period of approximately 8 nm. Isolated superlattice islands have been fabricated with lengths of 2 μm and widths ranging from 150 nm to 800 nm using focused ion beam (FIB) patterning. Coherent x-ray scattering patterns show that the striped domain pattern is preserved in the nanopatterned islands. Neither the width nor the in-plane coherence length of the domains have shown any meaningful dependence on the width of the island. In addition, the correlation of the coherent scattering patterns indicates that the temporal fluctuation of the domain patterns is different from what has been previously observed in the unpatterned areas. We expect that such difference be due to the mechanical boundary introduced by the FIB etching.

4:30PM D6.00009 Electrical and Magnetic Properties of PbTiO$_3$/SrRuO$_3$ superlattices, HSJING-HUNG HSING, SARA CALLORI, JUDITH GABEL, SIMON DIVILOV, PIRANAVAN KUMARAVADIVEL, XU DU, MARIVI FERNÁNDEZ-SERRA, MATTHEW DAWBER., Stony Brook University — Theoretical calculations on PbTiO$_3$/SrRuO$_3$ (PTO/SRO) superlattices suggest that the SRO layer should retain metallic character, even when their thickness is only a single unit cell. They further suggest that when the SRO layer is 2 unit cells or thicker there is coupling between spin and the electric polarization. Here we report on the electrical transport properties of PTO/SRO superlattices, which were fabricated using off-axis RF magnetron sputtering. In the out of plane direction, the samples demonstrate ferroelectricity and tunneling current characteristics that confirm the metallicity of the SrRuO$_3$ layers. We also studied the impact of the compositionally broken inversion symmetry and magnetic field on the capacitance-voltage characteristic of our superlattices. Changes in the dielectric constant were induced by the application of magnetic field at low temperatures.

5:45PM D6.00011 Fluctuating defects in the incipient relaxor K$_{x}$Li$_{1-x}$TaO$_3$ (x = 0.02), PETER GEHRING, NIST · Natl Inst of Stds & Tech, CHRIS STOCK, University of Edinburgh, GUANGYONG BU, Brookhaven National Lab, DANIEL LAMAGO, Karlsruher Inst fur Technologie, DMITRY REZNICH, University of Colorado, MARGARITA RUSSINA, Helmholtz Zentrum Berlin, JINSHENG WEN, Nanjing University, LYNN BOATNER, Oak Ridge National Lab — We have measured the structural correlations associated with the apparent relaxor transition near 70 K in K$_{0.98}$Li$_{0.02}$TaO$_3$ (KLT(0.02)) with neutrons. No elastic diffuse scattering or soft mode anomaly is observed, a situation that diverges from that in other relaxors like PMN. The structural correlations in KLT(0.02) are dynamic at all temperatures with timescales of ~THz. The fluctuations are overdamped, non-propagating, spatially uncorrelated, and absent in the parent material KTaO$_3$. The temperature dependence correlates with the dielectric response, implying that the fluctuations are associated with local, ferroelectric regions induced by the Li-doping. The ferroelectric transition induced by the introduction of sufficient Li cations is thus characterized by quasistatic fluctuations, which is a stark contrast to the soft-harmonic-mode-driven transition observed in perovskite ferroelectrics like PbTiO$_3$. The glass-like structural correlations in KLT(0.02) are much faster than those in random-field, lead-based relaxors, which occur on the ~GHz timescale, and they are better correlated spatially. Our results support the view that random fields give rise to the relaxor phenomena, and that the glassy dynamics observed here represent a nascent response.

5:06PM D6.00012 Polar State in Freestanding Strontium Titanate Nanoparticles, TREVOR TYSION, TIAN YU, New Jersey Institute of Technology, MARK CROFT, Rutgers University, MEGAN SCOFIELD, DARIE BOBB-SEMPLE, State University of New York at Stony Brook, JING TAO, Brookhaven National Laboratory, CHERNO JAYS, DANIEL FISCHER, National Institute of Standards and Technology, STANISLAUS WONG, State University of New York at Stony Brook — Monodispersed strontium titanate nanoparticles were prepared and studied in detail. It is found that ~10 nm as-prepared stoichiometric nanoparticles are in a polar structural state (with possibly ferroelectric properties) over a broad temperature range. A tetragonal structure, with possible reduction of the electronic hybridization is found as the particle size is reduced. In the 10 nm particles, no change in the local Ti off-centering is seen between 20 and 300 K. This work is supported by DOE Grant DE-FG02-07ER46402.

Session D7 DMP DCMP: Focus Session: Synthesis & Characterization of Topological Insulators

006B - Anthony Richardella, Pennsylvania State University

2:30PM D7.00001 Single crystal growth and characterization of Na$_3$Bi and Bi$_2$Te$_2$Se topological materials$^1$. SATYA K. KUSHWAHA, JASON W. KRIZAN, R.J. CAVA, Princeton University — In recent years, the discoveries of topological insulators (TI) and three-dimensional (3D) Dirac semimetals (TDS) have been of significant interest in condensed matter science. To study these materials experimentally, it is of great importance to grow them in the form of high quality single crystals. Na$_3$Bi is recently discovered TDS and Bi$_2$Te$_2$Se$_2$ (BTS) is one of the interesting TI materials. Na$_3$Bi is extremely air sensitive and shows nontrivial crystallization behavior. BTS crystals usually grow with various point defects and typically exhibit metallic behavior. Here we will report the crystal growth of high quality Na$_3$Bi and insulating BTS single crystals. The characterization of their electronic properties by our collaborators in physics at Princeton and Brookhaven National Laboratory will be briefly described.

$^1$The growth of single crystals of TIs and TDS is supported at Princeton by grants from the ARO MURI and DARPA.

2:42PM D7.00002 Intrinsic conduction through topological surface states of insulating Bi$_2$Te$_3$ epitaxial thin films$^1$. KATHARINA HOEFER, CHRISTOPH BECKER, DIANA RATA, Max Planck Institute for Chemical Physics of Solids, Dresden, JESSE SWANSON$^2$, University of British Columbia, Vancouver, PETER THALMEIER, LIU HAO T.JEUNG, Max Planck Institute for Chemical Physics of Solids, Dresden — Topological insulators represent a novel state of matter with surface charge carriers having a massless Dirac dispersion and locked helical spin polarization. Many exciting experiments have been proposed by theory, yet, their execution have been hampered by the extrinsic conductivity associated with the unavoidable presence of defects in Bi$_2$Te$_3$ and Bi$_2$Se$_3$ (BTS) is one of the interesting TI materials. Na$_3$Bi is extremely air sensitive and shows nontrivial crystallization behavior. BTS crystals usually grow with various point defects and typically exhibit metallic behavior. Here we will report the crystal growth of high quality Na$_3$Bi and insulating BTS single crystals. The characterization of their electronic properties by our collaborators in physics at Princeton and Brookhaven National Laboratory will be briefly described.

2:54PM D7.00003 Stability investigation on the non-basal surfaces of topological insulator Bi$_2$Te$_3$: a first-principles study$^1$. NA WANG, Tsinghua Univ, YIYANG SUN, Rensselaer Polytechnic Institute, YUANG ZHANG, Vanderbilt University, DAMIEN WEST, Rensselaer Polytechnic Institute, WENHUI DUA, Tsinghua Univ, SHENGBAI ZHANG, Rensselaer Polytechnic Institute — The basal (0001) surface of Bi$_2$Te$_3$ is the most stable surface and has been predominantly observed in experiment and studied in great details. The stability of other surfaces has been rarely discussed so far despite the fact that vicinal surfaces are always present at the crystal edges. In this work, we systematically study the thermodynamic stability of the vicinal surfaces of Bi$_2$Te$_3$ based on first-principles calculations. In particular, it is found that the (0015) surface has a surface energy of only about two times larger than that of the (0001) surface. Due to the particularly low surface energy, the sidewalks of free-standing Bi$_2$Te$_3$ crystals are predicted to be the (0015) surface, which is not perpendicular to the basal (0001) surface. The Wulff construction based on our calculated surface energies is consistent with experiment. However, in the presence of substrates, e.g., in molecular beam epitaxial growth, the shape of a crystal flake is further affected by the interface energy. In this case, the sidewalks could be (0110), (011 10) or (0114) depending on the binding strength between the flake and the substrate.

3:06PM D7.00004 Measuring Surface and Bulk Conductance of a Topological Insulator Using Top and Bottom Contacts$^1$. YUN SUK EO, STEVEN WOLGAST, CAGLIYAN KURDAK, Randall Laboratory of Physics, University of Michigan - Ann Arbor — In most 3D topological insulators, the existence of bulk conduction makes electrical transport measurements of the surface conduction very challenging. Standard transport measurements that are performed only on one side of a bulk crystal are not capable of distinguishing surface conduction from bulk conduction. Recently, configurations that measure top and bottom surfaces together have enabled researchers to distinguish surface conduction from bulk conduction in the mixed-valence compound SnB$_6$F$_6$. Inspired by these measurements, we analyze different types of top/bottom transport geometries such as a Corbino disc patterned on the top surface/a metal disc patterned on the bottom surface, a four-probe measurement on the top/entirely metalized on the bottom, etc. by numerical simulations. Although each configuration has certain limitations, the surface and bulk conductance can be found respectively from our results.

various orientations of the magnetic field \((B)\). Interestingly, it was found that the \(B\) showed a clear oscillation signal under the in-plane \(B\). In addition, the observed oscillation was quite periodic in \(1/B\) implying that the Landau quantization plays a role. As the orientation of \(B\) was rotated toward the direction perpendicular to the plane, the oscillation signal disappeared and the resistance showed a very sharp decrease at low magnetic fields, which was consistent with the weak antilocalization (WAL) behavior. Those new findings are believed to be related to the nature of \(Bi\textsubscript{2}Te\textsubscript{3}\) films as a topological insulator (TI) and to unveil the unexplored aspects of TIs waiting for an explanation.

3:30PM D7.0006  Study of long-time aging effect on low carrier MBE-grown Bi2Se3 with various capping layers . MARYAM SALEHI, MATTHEW BRAHLEK, NIKESH KOIRALA, SEONGSHIK OH, Rutgers university — Although there have been a lot of advances in the growth engineering and characterization of the topological insulators (TI) since their discovery, one of the remaining challenges is to stabilize them against degrading due to aging over time. Stabilizing the properties of TIs under the ambient conditions is of great interest, and indeed is a crucial step towards building stable TI-integrated electronic devices. One of the immediate and effective solutions to the aging problem is to find an efficient, and compatible capping layer. In this work we focus on how properties of \(Bi\textsubscript{2}Se\textsubscript{3}\) as a prototypical TI can be stabilized in air. We were able to achieve high quality \(Bi\textsubscript{2}Se\textsubscript{3}\) thin films with low carriers concentration and high mobility using Molecular Beam Epitaxy (MBE). Aging study of samples with such low carriers will be more reliable compared to other MBE grown samples with higher carriers concentration. In this work, long-term study (over 200 days) of aging effect on the transport properties of thin films with no capping layer, and ones with various in-situ (in the MBE chamber) and ex-situ deposited capping layers will be presented. Finally, by comparing the results between different capping layers, the most effective capping layer will be reported.

3:42PM D7.0007  Investigation of the transport properties of \(Bi\textsubscript{2}Se\textsubscript{3}\) films grown on various substrates . YANG, Dept. of Physics, National Taiwan Univ., Taipei 10617, Taiwan, Y.H. LIN, K.H. CHEN, B.Y. YANG, Dept. of Physics, National Taiwan University, Taipei 10617, Taiwan, M. HONG, Graduate Institute of Applied Physics, National Taiwan University, Taipei 10617, Taiwan, J. KWO, Dept. of Physics, National Tsing Hua Univ., Hsinchu 30013, Taiwan — Topological insulators, a new state of quantum matter, displayed a variety of physical phenomena. We have obtained high quality TI films of \(Bi\textsubscript{2}Se\textsubscript{3}\), \(Bi\textsubscript{2}Te\textsubscript{3}\), and \(Sb\textsubscript{2}Te\textsubscript{3}\) grown on various substrates with streaky RHEED patterns and large domains 1-2um in size. However, the Fermi level of \(Bi\textsubscript{2}Se\textsubscript{3}\) tends to locate in the bulk conduction band due to the high density of intrinsic defects in TIs. To fine tune the Fermi level to be within the band gap, \(Bi\textsubscript{2}Se\textsubscript{3}\) films were grown on amorphous oxide layers such as \(SiO\textsubscript{2}\), \(Y\textsubscript{2}O\textsubscript{3}\), and \(Al\textsubscript{2}O\textsubscript{3}\) thick deposited on GaAs and Si substrates in back gate structure for the electrical field effect. Compare to \(Bi\textsubscript{2}Se\textsubscript{3}\) thin films on crystalline substrates such as sapphire, samples grown on amorphous oxides such as \(Al\textsubscript{2}O\textsubscript{3}\) showed lower carrier concentration for the film thickness less than 10 QL, and the resistivity showed an insulating behavior at T below 50K. Other transport properties such as mobility, WAL effects are underway.

3:54PM D7.0008  Demonstration of large field effect in topological insulator films via a high-\(\kappa\) back gate . YANG, H.Y. LIN, Dept. of Physics, Natl Tsing Hua Univ., Hsinchu 30013, Taiwan, Y.H. LIN, K.H. CHEN, B.Y. YANG, Graduate Institute of Applied Physics and Dept. of Physics, Natl Tsing Hua Univ., Taipei 10617, Taiwan, K.H.M. CHEN, J.Z. PENG, Dept. of Physics, Natl Tsing Hua Univ., Hsinchu 30013, Taiwan, S.F. LEE, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan, M. HONG, Graduate Institute of Applied Physics and Dept. of Physics, Natl Tsing Hua Univ., Hsinchu 30013, Taiwan — In topological insulators (TI) the spins are locked to opposite momentum direction when the Fermi level passes through Dirac point of its helical surface states, and the electrical field effect is a very promising way to manipulate TI spins for spintronic devices. We have fabricated the back gate structure by growing TI films on high-\(\kappa\) oxide layers including amorphous oxides of \(SiO\textsubscript{2}\), \(Y\textsubscript{2}O\textsubscript{3}\), and \(Al\textsubscript{2}O\textsubscript{3}\) deposited on conducting substrates for applying the field effect with smaller operating voltage compared to SiC back gate. We have performed the surface conduction measurements of thin films with different thicknesses of FIM/TI, SC/TI structures intended for various studies. For \(Bi\textsubscript{2}Se\textsubscript{3}\) grown on these amorphous oxide thin films, streaky RHEED patterns indicated the film is highly crystalline. Weak antilocalization effect was observed to verify the time-reversal symmetry protected transport property. Very large field effect was demonstrated; for example, in the 6QL samples we are able to modulate as much as \(2E\textsubscript{13}\) cm\(^{-2}\) holes in applying negative gate bias. Field effect of Sb doped \(Bi\textsubscript{2}Te\textsubscript{3}\) to realize sign reversal of carrier concentration will also be presented.

4:06PM D7.0009  Shubnikov-de Haas Oscillations from topological surface states of metallic \(Bi\textsubscript{2}Se\textsubscript{3}\) on \(Te\textsubscript{0.9}\). KESHAV SHRESTHA, TcSUH and Department of Physics, University of Houston, 3201 Cullen Blvd., Houston, Texas 77204, USA, VERA MARIANOVA, Institute of Optical Materials and Technology, Bulgarian Academy of Sciences, Acad. G. Bonchev Str. 109, Sofia 1113, Bulgaria, BERND LORENZ, PAUL C.W. CHU\textsuperscript{2}, TcSUH and Department of Physics, University of Houston, 3201 Cullen Blvd., Houston, Texas 77204, USA — We have studied the quantum oscillations in the conductivity of metallic, \(p\)-type \(Bi\textsubscript{2}Se\textsubscript{3}\) at 10\textsuperscript{-18} cm\(^{-2}\) holes in applying negative gate bias. Field effect of Sb doped \(Bi\textsubscript{2}Te\textsubscript{3}\) to realize sign reversal of carrier concentration will also be presented.

4:18PM D7.00010  Synthesis and low-temperature transport measurement of pure and In-doped SnTe nanoplate . JIE SHEN, YUJUN XIE, JUDY J. CHA, Yale Univ — SnTe is a topological crystalline insulator that possesses different surface states on the \{100\}, \{110\}, and \{111\}surfaces. Thus, to access surface states selectively, it is critical to control the morphology of SnTe. Moreover, indium doping in SnTe induces superconductivity, making it a candidate for a topological superconductor. Here, we grow pure and In-doped SnTe nanoplates, whose top and bottom surfaces are either \{100\} or \{111\}, via vapor-liquid-solid and vapor-solid growth mechanisms. For pure SnTe nanoplate, we observe a structural phase transition from rock salt to rhombohedral structure in samples with low carrier density and electron-electron interactions in samples with high carrier density. In addition, by studying nanoplates with indium-doping concentrations ranging from 0% to 10%, we show that nanoplates become more diffuse in bulk and such that the surface states appear at higher concentrations of indium. This is supported by a three-dimensional weak antilocalization in low magnetic fields and a two-dimensional(2D) linear magnetoresistance(LMR) in high magnetic fields. This 2D LMR comes from the Dirac-dispersive surface state, in agreement with Abrikosov’s quantum limit model.
4:30PM D7.00011 Defect induced negative magnetoresistance and surface state immunity in topological insulator BiSbTeSe
2. KARAN BANERJEE, JAESUNG SON, PRAVEEN DEORANI, Nati Univ of Singapore, PENG REN, Nanyang Technological University, LAN WANG, RMIT University, HYUNSOO YANG, Nati Univ of Singapore — The absence of backscattering due to time reversal symmetry is one of the hallmark features of a topological insulator. However, the introduction of defects can result in diminishing the transport properties of topological insulators. In this work, we introduce defects into the topological insulator BiSbTeSe
2 by subjecting it to ion milling and study the effect of disorder on the transport properties. We find that a negative contribution arises in the magnetoresistance of BiSbTeSe
2 at low temperatures. However, the surface state remains remarkably robust to the introduction of disorder. We demonstrate that the negative magnetoresistance originates from an increase in the density of defect states created by the introduction of disorder. We also find the bulk contribution to remain negligible even after subjecting to ion milling.

4:42PM D7.00012 ABSTRACT WITHDRAWN —

4:54PM D7.00013 Surface conduction in encapsulated topological gated structures
1. YURY DESHEKO, INNA KORZHOVSKA, LUKAS ZHAO, The City College of New York, GHIDEWON AREFE, Columbia University, MARCIN KONCZYKOWSKI, Ecole Polytechnique, France, LIA KRUSIN-ELBAUM, The City College of New York — In three-dimensional (3D) topological insulators (TIs), the surface Dirac fermions intermix with the conducting bulk, thereby complicating access to the low-energy surface charge transport or magnetic response. The subsurface 2D states of bulk origin are vulnerable to bandbending due to surface adatoms, a band modification thought to be responsible for the ‘aging’ effect. To minimize this effect, we have developed an inert environment mechanical exfoliation technique to fabricate transistor-like gated structures in which prototypical binary TIs as well as ultra-low bulk carrier density ternaries (such as Bi
2
2
and Te
2
2
and Sb
2
2
and Se
2
2
) were encapsulated by thin h-BN layers, with electrical contacts made using exfoliated graphene. The effects of electrostatic tuning by the gate bias voltage on surface conductivity as a function of thickness of the TI layers and the variation with disorder will be presented.

5:06PM D7.00014 Van der Waals epitaxy of Bismuth Telluro-Sulfide nanosheats and magneto-transport in devices. TANUJ TRIVEDI, SUSHANT SONDE, SANJAY K. BANERJEE, Microelectronics Research Center, The University of Texas at Austin — Growing interest in probing topological surface states from transport experiments has led to the recent development of ternary and quaternary compounds of Bismuth chalcogenides. The search for complex 3D topological insulator compounds is motivated by the need for reduced bulk conduction and easier access to the Dirac point of the surface states, as compared to in the binary phases Bi
x
2
x
3
(X=Te,Se). To this end, we have grown nanosheats of Bismuth Telluro-Sulfide directly on different substrates with van der Waals epitaxy. The growth method utilizes novel solid-state, non-elemental precursors of Bismuth, Tellurium and Sulfur. Nanosheet growth is observed on different substrates, such as amorphous SiO
x
(2.5<10nm) and mica, and grow layer-by-layer in varying thicknesses (3 nm to >100 nm) and sizes (up to few microns). Stoichiometric analysis of the nanosheats is close to previously reported crystal growth of tetradymites, and the crystalline nature is confirmed with Raman and XRD measurements. We have fabricated devices on as-grown nanosheets of varying thicknesses, with nonmagnetic metal contacts. Preliminary magneto-transport experiments are promising, motivating further in-depth transport analysis for probing topological surface states.

5:18PM D7.00015 Molecular Beam Epitaxy of Ultra-Thin Sb Films for Surface Transport Studies
3. KAUSHINI WICKRAMASINGHE, CHOMANI GASPE, SHAYNE CAIRNS, NOLAN TEASDALE, TETSUYA MISHIMA, JOEL KEAY, MATTHEW JOHNSON, SHEENA MURPHY, MICHAEL SANTOS, University of Oklahoma, Homer L. Dodge Department of Physics and Astronomy — Our growth study of ultra-thin Sb films is motivated by theoretical studies that predict a topoelectronic phase transition as a function of Sb film thickness due to quantum confinement and surface coupling effects. In thick films, transport measurements will be dominated by bulk conduction because the band structure of bulk elemental Sb is semi-metallic. Our goal is to enable transport measurements of topological surface states by suppressing the bulk conductivity through quantum confinement in thin Sb layers. Good control over the growth conditions allowed us to vary the thickness of the Sb films ranges from 0.7 nm to 6 nm with good repeatability. Electrical transport measurements indicate that surface states are responsible for about 25% of the conductivity at 20K in a 3.7 nm thick Sb layer where the bulk conductivity is suppressed by about a factor of 2. We will discuss the structural properties of the Sb films using different electron microscopy techniques.

Monday, March 2, 2015 2:30PM - 5:18PM — Session D8 DCMP: Complex Films & Surfaces: Oxides, Alloys, and Semiconductors 006C -

2:30PM D8.00001 Investigation of Thin Layered Cobalt Oxide Nano-Islands on Gold. MICHAL BAJDICH, SLAC - STANFORD, ALEX S. WALTON, JAKOB FESTER, iNANO, Aarhus University, MOHAMMAD A. ARMAN, JACEK OSIECKI, JAN KNUDSEN, Lund University, ALEKSANDRA VOJVODIC, SLAC - STANFORD, JEPPE V. LAURITSEN, iNANO, Aarhus University — Layered cobalt oxides have been shown to be highly active catalysts for the oxygen evolution reaction (OER), but the synergistic effect of contact with gold is yet to be fully understood. The synthesis of three distinct types of thin-layered cobalt oxide nano-islands supported on a single crystal gold (111) substrate is confirmed by combination of STM and XAS methods. In this work, we present DFT+U theoretical investigation of above nano-islands using several previously known structural models. Our calculations confirm stability of two low-oxygen pressure phases: (a) rock-salt Co-O bilayer and (b) wurzite Co-O quadrayer and single high-oxygen pressure phase: (c) O-Co-O trilayer. The optimized geometries agree with STM structures and calculated oxidation states confirm the conversion from Co2+ to Co3+ found experimentally in XAS. The O-Co-O trilayer islands have the structure of a single layer of CoOOH proposed to be the true active phase for OER catalyst. For that reason, the effect of water on the Pourbaix stabilities of basal planes and edge sites is fully investigated. Lastly, we also present the corresponding OER theoretical overpotentials.
2:2PM D8.00002 Effects of hydroxylated $\gamma$-Al₂O₃ support and H adsorbate on the Geometry and Electronic Structure of Pt Nanoparticles¹, GHAZAL SHAFAI, University of Central Florida, Orlando, FL, 32816, SAMPYO HONG, University of Central Florida, Orlando, FL, 32816 — We have studied the effects of hydroxylated $\gamma$-Al₂O₃(110) support and H adsorbate on the geometry and electronic structures of Pt$_n$ (n=22,44) nanoparticles (NP) using DFT. We find that Pt$_{22}$ interacts more strongly with a less hydrated support, while Pt$_{44}$ more with a hydroxylated one. We also find a structural transition of the Pt$_{22}$ (and not Pt$_{44}$) from a bliparal to a 3D-like shape as a function of hydroxilation. H induces a much larger shift in the unoccupied d-band center than does the support. Also, these shifts are well correlated with metal-support interaction. The increased hydroxylation on $\gamma$-Al₂O₃(110) causes weaker metal-support interaction. As a result, the d-band width of a Pt NP decreases causing the center of the unoccupied d band to shift to lower energy (red shift). In the light of these results, we will discuss the features of XANES spectra obtained for $\gamma$-Al₂O₃(110) supported Pt nanoparticles [1].

2:54PM D8.00003 A new model for $\sqrt{3} \times \sqrt{3} \times R9^\circ$ reconstruction of $\alpha$-Al₂O₃ (001), HAWOONG HONG, Argonne National Laboratory, AARON GRAY, TAI-C. CHIANG, University of Illinois, Urbana-Champaign — Research in oxides surface suffers reproducibility problems on its structure. However, $\sqrt{3} \times \sqrt{3} \times R9^\circ$ reconstructed $\alpha$-Al₂O₃ (001) surface has been generated repeatedly by many different groups. This sapphire surface structure was known to be quite inert even to air exposure. The detailed structures have been studied with LEED, x-ray diffraction and AFM. The recent experimental studies conclude that the few topmost layers are composed of aluminum atoms and have metallic properties [1, 2]. Then a question arises why this surface seems to be inert to air exposure. Metallic aluminum is prone to oxidation according to theoretical investigation. Here we propose a new model for the $\sqrt{3} \times \sqrt{3} \times R9^\circ$ reconstruction involving oxidized top layers. For the direct structural information in the surface-normal direction, specular and non-specular crystal truncation rods were measured with x-ray diffraction. Only successful, if not perfect, fitting occurs with a dense top layer, which is reminiscent of oxidized aluminum (111) surface [3].

2:06PM D8.00004 Preparation of atomically flat TiO$_2$ (001) surfaces¹, YANG WANG, Oak Ridge National Lab, HANNO H. WEITERING, University of Tennessee, Knoxville, PAUL C. SNIJJDERS, Oak Ridge National Lab — Transition metal oxides with the rutile structure (MO$_2$, M = e.g. Ti, V, or Nb) have highly directional partially occupied t$_{2g}$ orbitals. Some of these orbitals form quasi-1D electronic bands along the rutile c-axis, and Peierls-like ordering phenomena have been observed in VO$_2$ and NbO$_2$. Tailoring the electronic properties of these materials via quantum confinement requires epitaxial growth on suitable substrates such as low index TiO$_2$ surfaces. Because of the high surface energy of rutile TiO$_2$(001), the standard approach of sputtering and annealing usually introduces faceting. Here we demonstrate a facile method to create atomically flat, non-faceted TiO$_2$(001) surfaces. Using scanning tunneling microscopy we observe terraces with a width of approximately 150 nm. Step heights of approximately 0.3 nm are observed, consistent with the c lattice parameter of rutile TiO$_2$. Low energy electron diffraction patterns reveal sharp diffraction spots with an in-plane lattice constant of 0.358 nm which is consistent with a (1x1) ordering of the (001) plane. These TiO$_2$(001) single crystal surfaces can serve as an ideal substrate for further growth of rutile heterostructures.

3:18PM D8.00005 Physical Character and Morphology of Platinum Nanocrystals on Strontium Titanate, JOSHUA GILD, MICHAEL PIERCE, Rochester Institute of Technology, VLADIMIR KOMANICKY, University of Pavol Jozef Safarik, ANDI BARBOUR, HOYDOO YOU, Argonne National Lab — The physical characteristics of platinum nanocrystals on single crystal strontium titanate, SrTiO$_3$, can effect the chemical properties of this important model catalyst. The morphology, epitaxy, distribution, and size of the Pt nano-crystals can all be controlled through different growth and processing mechanisms. Nanometer scale platinum thin films are deposited on strontium titanate at ambient temperatures then annealed at range of temperatures and in various oxidizing environments. The process of how these conditions influence the formation of uniformly epitaxial platinum crystals on the sample surface has been investigated using basic materials characterization techniques. Single crystal x-ray diffraction is the primary tool for these experiments, coupled with atomic force microscopy for morphology and x-ray and electron spectroscopy to determine chemical bonding between the particles and gases introduced into the system. These substrate supported nanoparticle samples will then be utilized in experiments to test their catalytic activity compared to an amorphous platinum film.

3:30PM D8.00006 Imaging of Pt Nanocrystals on SrTiO$_3$ Substrate: Coherent X-ray Diffraction and Scanning Microscopy Studies, TRAVIS DOUGLAS, JOSHUA GILD, MICHAEL PIERCE, Rochester Institute of Technology, VLADIMIR KOMANICKY, Faculty of Science, Safarik University, ANDI BARBOUR, HOYDOO YOU, Argonne National Laboratory — Imaging of nano-scale structures, particularly those in real-world environments, presents a significant challenge. X-ray Coherent Diffractive Imaging (CDI) provides one avenue of accessing the structural information of a nano-scaled sample in a harsh environment. However, while this problem has been solved for Au and Pb nano-crystals in clean, vacuum environments, much work remains before it can be rapidly employed in other systems. Our efforts center on determining the real-space structure of Pt nanocrystals grown on SrTiO$_3$ substrates using a combination of CDI and atomic force scanning microscopy (AFM). X-ray speckle patterns have been obtained using coherent diffraction of these crystals which can be transformed back to real space coordinates to calculate the crystal structure using CDI algorithms. Microscopy provides complementary information allowing us to simulate the speckled diffraction patterns from real-space images of the actual particles. This dual approach of using both real and reciprocal space information to solve the structures should lead to a practical set of algorithms and procedures whereupon the samples can be imaged quickly in the environments and conditions of interest.
3:42PM D8.00007 Probing the role of Ga in amorphous conducting oxides through local structure studies, STEPHANIE MOFFIT, QIMIN ZHU, QING MA, DONALD BUCHHOLZ, ROBERT CHANG, THOMAS MASON, TOBIN MARKS, MICHAEL BEDZYK, Northwestern University — The study of amorphous (a-) conducting oxides is an emerging field. The lack of grain boundaries, smooth surfaces, and low temperature deposition position these materials as ideal candidates for large area applications and flexible electronics. Most impressively, these materials maintain high electron mobility in the amorphous state. These benefits have led the recent commercialization of a-IGZO (Ga and Zn doped indium oxide) as a replacement for a-Si as the channel layer of thin film transistors in display technology. Despite this success, fundamental understanding of structure-property relationships is still lacking and must be improved to guide further development of amorphous conducting oxides. X-ray absorption spectroscopy (XAS) is one of the few tools that can be used to probe the structure of amorphous materials. Amorphous indium oxide doped with Ga (a-IGO) is a model system to help develop the role of dopants in amorphous oxides. An in depth XAS study was carried out to determine inter-atomic distances, coordination numbers, and structural disorder parameters as a function of Ga doping level. The correlation between XAS-derived structural properties and the dopant-dependent evolution of both electrical properties and thermal stability of a-IGO will be discussed.

3:54PM D8.00008 Optical constants and transient absorption of solution-deposited RuO2 thin films, JEFFREY OWURTSKY, RYAN COMPTON, JAMES LONG, CHRISTOPHER CREVIN, KONRAD BUSSMANN, ADAM DUNKELBERGER, BRYAN SPANN, IRINA PALIN, DEBRA ROLISON, PAUL CUNNINGHAM, JOSEPH MELINGER, PAUL DESARIO, Naval Research Lab, DAN WEIDINGER, Schaffer Corp., EDWIN HEILWEIL, National Institute of Standards & Technology — Optical and electrical conductivity properties are determined for the promising, broadband transparent conductor material, solution-deposited RuO_2 nanostructured films. The 10-30 nm thick films or nanoskins are less conductive but more optically transmissive than polycrystalline, sputtered RuO_2 films which are inherently metallic. The optical constants (0.6 to 4.5 eV) determined by ellipsometry show that c_1 is positive for the nanoskins in the spectral region investigated so they are not plasmonic. Transient picosecond absorption with visible (400 nm) pump and various probe wavelengths (visible and THz) are performed for nanoskins calcined to different temperatures. When heated to 200°C the absorption increases in the visible and THz. After heating to 300°C, the films become more polycrystalline and there is evidence for the appearance of a new absorption. Decreased absorptions or bleaches are observed in the THz and for longer visible wavelengths (> 750 nm). The absorption is ascribed to a damped plasmon band of the crystalline nanoparticles formed in the film upon heating.

4:06PM D8.00009 Effect of Ions and pH on the H-bond Network at the Quartz(101)-Water Interface, MARK DELLOSTRITTO, JAMES KUBICKI, JORGE SOFO, The Pennsylvania State University — Reactions in aqueous systems are common, and yet can be difficult to study, as the structure and dynamics of the H-bond network can dominate the rates of reactions by determining the access reactants have to each other. This is thought to be the case at the quartz-water interface, where the addition of ions to solution or an increase in pH can increase the dissolution rate by an order of magnitude without any change in the activation energy. This suggests that the dissolution reaction is unchanged and the ions modify the structure of water at the interface such that the reaction occurs at a greater frequency. To investigate this effect, we performed ab-initio molecular dynamics (AIMD) simulations of the quartz(101)-water interface in several different ionic solutions under different pH and temperature conditions. We found that both anions and cations in a near-surface configuration tend to increase the order of interfacial water, although at neutral pH this competes with a decrease in the H-bond lifetime induced by the presence of an anion-pair cation. We also found that neither the H or O atoms of H_2O or OH^- have greater access to the surface with the introduction of ions, but there is a greater incidence of intrasurface H-bonding in all systems studied. This suggests that intrasurface proton transfer could be an important component of the dissolution reaction, while nucleophilic attack of Si by H_2O is unlikely to occur at the interface studied.

4:18PM D8.00010 N vacancy, self-interstitial diffusion, and Frenkel-pair formation/dissociation in TiN studied by ab-initio and classical molecular dynamics, DAVIDE G. SANGIOVANNI, BJØRN ALLING, LARS HULTMAN, IGOR A. ABRIKOSOV, Department of Physics (IFM), Linköping University, Sweden — We use ab-initio and classical molecular dynamics (AIMD, CMD) to simulate diffusion of N vacancy and N self-interstitial point-defects in B1 TiN. The physical properties of TiN, important material system for thin film and coatings applications, are largely dictated by concentration and mobility of point defects. We determine N dilute-point-defect diffusion pathways, activation energies, attempt frequencies, and diffusion coefficients as a function of temperature. In addition, MD simulations reveal an unanticipated atomistic process, which controls the spontaneous formation of N-self-interstitial/N-vacancy pairs (Frenkel pairs) in defect-free TiN. This entails that a N lattice atom leaves its bulk position and bonds to a neighboring N lattice atom. In most cases, Frenkel-pair N and N^V reconstruct within a fraction of ns; 50% of these processes result in the exchange of two nitrogen lattice atoms. Occasionally, however, Frenkel-pair N-interstitial atoms permanently escape from the anion vacancy site, thus producing unpaired N^3 and N^1 point defects.

4:42PM D8.00012 Surface nanocrystalline and hardening effects of Ti–Al–V alloy by electrospinning ultrasonic shock1, XIAOXIN YE, GUOYI TANG, Tsinghua University — The effect of electrospinning ultrasonic shock (EUS) on the surface hardening and microstructure of Ti6Al4V alloy was studied. It was found that electrospinning improved the microhardness dramatically both in the influential depth and maximum value, compared with the only ultrasonic- shocked sample. It’s indicated that refined surface layer with nanocrystalline and improved microhardness were obtained on account of surface severe plastic deformation, dynamic recrystallization (DRX) and phase change, which was implemented at relative low temperature and high strain rate/capacity due to the coupling of the thermal and athermal effects of EUS. It’s different from conventional experiments and theory. It’s discussed that the positive contributions of EPT in the thermodynamics and kinetics of microstructure and properties change were attributed to the reduction of nucleation energy barrier and acceleration of atomic diffusion. Therefore, it’s supposed that EUS is an energy-saving and high-efficiency method of surface treatment technique with the help of high-energy electropoles, which is promising in cost reduction of the surface engineering and energy management.

4:54PM D8.00013 Shedding Light on the Emission Mechanisms of In_{0.54}Ga_{0.46}N Disks in GaN Nanowires Using C.W. Non-Linear Spectroscopy1, CAMERON NELSON, ALBERT LIU, SANIYA DESHPANDE, SHAHAF JAHANGIR, PALLAB BHATTACHARYA, DUNCAN STEEL, University of Michigan, Ann Arbor: EECS Department — Linear and non-linear spectroscopy has been performed on an ensemble of 3 nm thick In_{0.54}Ga_{0.46}N disks grown in self-assembled GaN nanowires (∼30 nm diameter). PLE measurements near resonant with the PL show a mostly broad, featureless spectrum with a linear increase in absorption as a function of energy, similar to InGaN/GaN quantum wells. Unlike InGaN quantum wells, the centroid of the PL spectrum shows a negligible intensity-dependent shift in PL emission wavelength. Further, the non-linear optical spectrum is dominated by excitonic resonances with line widths ~20-30 meV in the same region as the PLE data. Distinguishable peaks in the PL spectrum overlap with the non-linear resonances. Continuous-wave nearly degenerate pump-probe absorption measurements show no evidence of spectral hole burning within the resonances; however there is evidence of population pulsations in the 3rd order signal. This data shows evidence consistent with regular excitonic saturation and two beam coupling similar to that expected in discrete (e.g. 2 or 3 level systems). The excitonic behavior is also consistent with anti-bunching seen in g2 measurements from single dots.

5:06PM D8.00014 Chemical Reactions and Atomic Removal Dynamics during Gallium Nitride Chemical Mechanical Polishing Process: Quantum Chemical Molecular Dynamics Simulations1, KENTARO KAWAGUCHI, YUJI HIGUCHI, NOBUKI OZAWA, MOMOJI KUBO, Fracture and Reliability Research Institute Graduate School of Engineering, Tohoku University — The chemical mechanical polishing (CMP) is promising for efficient polishing of the GaN substrate, and it is essential for manufacturing of GaN devices. However, the detailed CMP mechanisms are unclear, and then the design of efficient and precise CMP process is difficult. We performed polishing simulations of a GaN substrate by a SiO₂ abrasive grain in a solution including OH radicals in order to reveal effects of OH radicals on the polishing process. The OH radicals in the solution are adsorbed on the GaN surface and occupy the hollow sites on the surface. Then, a surface-adsorbed O atom is generated by the chemical reaction between the surface-adsorbed OH species and a OH radical in the solution. In the friction interface between the GaN substrate and the abrasive grain, the surface-adsorbed O atom is mechanically pushed into the GaN substrate by the abrasive grain. This O atom intrusion induces the dissociation of Ga-N bonds of the GaN substrate. Moreover, volatile N₂ molecules and soluble Ga(OH)₂ molecules are generated due to the dissociation of Ga-N bonds. Then, we suggested that the GaN CMP process efficiently proceeds by the mechanically induced chemical reactions: a surface-adsorbed O atom is generated and pushed into the GaN bulk by the abrasive grain.

Session D9 DCMP: Superconduction in Cuprates: Photoemission 006D - Donghui Lu, Stanford University

2:30PM D9.00001 An Angle Resolved Thermodynamics Study of Cuprate Superconductors, XIAOAING ZHOU, HAOXIANG LI, STEPHEN PARHAM, JUSTIN VAUGH, University of Colorado at Boulder, JOHN SCHNEELOCH, RUIDAN ZHONG, Brookhaven National Lab, ENDA GU, University of Colorado at Boulder, HELMUTH BERGER, Département de Physique, Ecole Polytechnique Fédérale de Lausanne, KUNIHICO OKA, University of Colorado at Boulder, HIROSHI EISAKI, Nanoelectronics Research Institute, National Institute of Advanced Industrial Science and Technology (AIST), GERALD ARNOLD, DANIEL DESSAU, University of Colorado at Boulder — The thermodynamics properties of a system contain vital information on its electronic states, the contribution of which in typical bulk measurements is averaged and integrated over momentum and energy space. Therefore, it’s supposed that EUS is an energy-saving and high-efficiency method of surface treatment technique with the help of high-energy electropoles, which is promising in cost reduction of the surface engineering and energy management. It’s discussed that the positive contributions of EPT in the thermodynamics and kinetics of microstructure and properties change were attributed to the reduction of nucleation energy barrier and acceleration of atomic diffusion. Therefore, it’s supposed that EUS is an energy-saving and high-efficiency method of surface treatment technique with the help of high-energy electropoles, which is promising in cost reduction of the surface engineering and energy management.

2:42PM D9.00002 Extraction of normal and pairing self-energies and Eliashberg functions of high temperature superconductor Bi2212 from Laser-based ARPES experiment1, JIN MO BOK, National Laboratory for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Science, SEUNG HWAN HONG, JONG JU BAE, HAN-YONG CHOI, Department of Physics and Institute for Basic Science Research, SungKyunKwan University, CHANDRA M. VARMA, Department of Physics and Astronomy, University of California, Riverside, WENTAO ZHANG, JUNFENG HE, YUXIAO ZHANG, LI YU, X.J. ZHOU, National Laboratory for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Science — The angle-resolved photoemission (ARPES) measurements provide momentum and frequency dependence of the electronic structure that enables quantitative analysis using single particle Green’s function. This is particularly important for studying the cuprate superconductors that are known to have anisotropic electronic structure and anisotropic d-wave superconducting gap. Here we report the extraction of the normal and pairing self-energies from high resolution Laser-based ARPES data of the underdoped and overdoped Bi2212. We also obtain the Eliashberg functions, η₂ and η₆, by inverting Eliashberg equations using maximum entropy method. Implications of these results for understanding the superconductivity mechanism will be discussed.

1NSFC (Grant No. 11190022) and the MOST of China (Program No: 2011CB921703 and 2011CB605903)
extend these studies for the first time to a Bi2212 sample in the superconducting state, and disentangle the shift in chemical potential from surface voltage.

Intriguing results on several materials showing how laser pulses can manipulate their chemical potential on ultrafast timescales, and it’s been suggested that high-temperature superconductors, including the quasiparticle relaxation, cooper pair recombination, and many-body interactions. There have also been several conceptual differences between the two lifetimes.

In order to reduce the correlation length we substituted Cu$^{2+}$ ($S=1/2$) by Zn$^{2+}$ ($S=0$). The modification of the AF correlation length as a function of Zn concentration and temperature was derived using NMR and a direct correspondence between the amplitude of the spectral weight beyond the AF zone boundary and the correlation length was established. Remarkably, even at correlation lengths as short as 3 lattice constants we still observe a significant spectral weight in the back-bended band. These findings prove that the ARPES technique is very sensitive to short-range correlations and provide a hint for the understanding of ARPES results in the underdoped regime of high temperature superconductors.

We employ femtosecond time- and angle-resolved photoelectron spectroscopy to study optimally doped Bi-2212 ($T_c = 96$ K). In the low excitation limit, the energy-resolved population lifetime displays abrupt changes near 60-80 meV both below and above $T_c$. Moreover, the lifetime near this characteristic energy is independent of excitation density. These behaviors are consistent with theories based on electron-phonon interactions, which connect the population lifetimes to the single-particle lifetimes measured by equilibrium photoemission. However, the absolute values of these two quantities are different by one to two orders of magnitude. We further demonstrate that this discrepancy is independent of experimental techniques and materials, and point out the fundamental conceptual differences between the two lifetimes.

The relationship between the pseudogap and superconducting gap in high temperature cuprate superconductors remains an outstanding issue. In this talk, we will present our high resolution laser-ARPES measurement on Bi2212CaCu2O8 superconductor. We will use the latest generation of ARPES system equipped with the VUV laser and the time-of-flight (TOF) electron energy analyzer. This enables us to have super-high energy resolution, high momentum resolution, simultaneous coverage of two-dimensional momentum space, high data acquisition efficiency and much reduced nonlinearity effect. From detailed temperature dependence near the nodal and antinodal regions, we will discuss on the relationship between the pseudogap and superconducting gap in the cuprate superconductors.

The extremely correlated Fermi liquid (ECFL) theory recently introduced by Shraer has renewed interest in quantitatively understanding ARPES line shapes. In this talk, we combine certain phenomenological considerations with the ECFL framework in order to describe the ARPES data. Our phenomenological models have the property of preserving the universal property of the original ECFL theory, while introducing phenomenological changes in a non-universal property. Our models describe, with unprecedented fidelity, the key aspects of the dichotomy between momentum distribution curves (MDCs) and energy distribution curves (EDCs) of high-$T_c$ ARPES data. Therefore, our study goes well beyond the prevailing studies that discuss only MDCs and EDCs.

This work was supported by Berkeley Lab’s program on Quantum Materials, funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract No. DE-AC02-05CH11231.
threshold for superconductivity has not yet been undertaken. Here we report the results of studying this regime.

quasiparticle dynamics in the very high and very low pump fluence regimes, but a systematic study of the changes in dynamics across the fluence vaporization to underlying mechanisms governing superconductivity, antiferromagnetism, charge ordering, and other types of competing orders. Time- and angle-resolved Technology, DUNG-HAI LEE, ALESSANDRA LANZARA, Materials Sciences Division, Lawrence Berkeley National Laboratory / Department of Physics, UC Berkeley, CHRIS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Laboratory, TAKASHI NOJI, YOJI KOIKE, Department of Applied Physics, Tohoku University, HIROSHI EISAKI, Electronics and Photonics Research Institute, National Institute of Advanced Industrial Science and Technology, RUIDAN ZHONG, GENDA GU, Brookhaven National Laboratory, DANIEL DESSAU, University of Colorado at Boulder — The field of time-resolved ARPES (trARPES) has matured greatly in the last several years and has proven a useful tool in the study of cuprate superconductivity. However, previous experiments have been limited in the pump wavelength to energies of 1.5 eV (or more), far above the relevant energy scales for superconductivity. Here we use an OPA/DFG setup to create a mid-infrared pump, with tunable photon energies from 60-300 meV, allowing us to weakly perturb the superconductivity of optimally doped Bi$_2$Sr$_2$CaCu$_2$O$_{8+}$ under this excitation scheme.

We acknowledge funding from the Deutsche Forschungsgemeinschaft and the Center for Emergent Superconductivity, a BES EFRC.

Can La$_2$CuO$_4$ be made into an undoped metal / superconductor: insights from angle-resolved photoemission spectroscopy, HAOFEI WEI, Cornell University, CAROLINA ADAMO, Stanford University, DARRELL SCHLOR, KYLE SHEN, Cornell University — La$_2$CuO$_4$ is a well-known parent compound for the hole-doped cuprate superconductors. However, by shifting the apical oxygen away from the Cu-O plane, it can also be made into the parent for an electron-doped superconductor. La$_2$CuO$_4$ in this so-called T$'$ structure is metastable in bulk, but recent reports have succeeded in stabilizing thin films via molecular-beam epitaxy. These samples were reported to be metallic and even superconducting, in contrast to the Mott insulating state found in all other underdoped cuprate parent compounds. To determine whether it is truly a metal in its undoped state, we have for the first time directly measured the electronic structure of epitaxially grown thin films of nominally undoped T$'$-La$_2$CuO$_4$ using in-situ angle-resolved photoemission spectroscopy (ARPES). We observe dispersive bands which form a well-defined Fermi surface with intensity modulations consistent with scattering from an underlying SDW order, similar to those observed in doped n-type cuprates. We have also characterized the carrier density using Luttinger's rule, and will discuss what information our measurements provide on the role of oxygen non-stoichiometry in determining the properties of this system and on the potential for a metallic undoped cuprate.

Photodoping of Effects in Heavily Underdoped Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ Revealed by Time and Angle Resolved Photoemission Spectroscopy

4:42PM D9.00012 Photodoping of Effects in Heavily Underdoped Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ Revealed by Time and Angle Resolved Photoemission Spectroscopy

4:54PM D9.00013 Analyzing of Superconductivity from Fitting Result of the Diverging Effective Mass in YaBa$_2$Cu$_3$O$_{x+y}$, HYUN-TAK KIM, MIT Center in ETRI, South Korea — For cuprate superconductors, the mechanism of high-$T_c$ superconductivity is still an unclear and unsolved problem, because they are inhomogeneous. Here, we show analysis of superconductivity from the fitting result of the diverging-effective mass (DEM) extracted from the quantum-oscillation data in YaBa$_2$Cu$_3$O$_{6+y}$ [1]. The fitting was performed by extended Brinkman-Rice picture [2]. The fitting result presents the Fermi arc observed by angle-resolved-photoemission-spectroscopy data is presented. In particular, the growing Fermi arc from the nodal Fermi point to the isotropic Fermi surface with increasing $x$ and the nodal constant Fermi energy are revealed. Further, pairing symmetry of cuprate superconductors is analyzed as $\sigma$-wave. The quantum critical point is regarded as the nodal Fermi point: The intrinsic superconducting gap is formed at node. The mass diverges is an average effect and the true effective mass is constant.

Ultrafast Quasiparticle Relaxation Dynamics across the Superconducting Vaporization Threshold in Bi$_2$2212>

5:06PM D9.00014 Ultrafast Quasiparticle Relaxation Dynamics across the Superconducting Vaporization Threshold in Bi$_2$2212>

CHRISTOPHER SMALLWOOD, Materials Sciences Division, Lawrence Berkeley National Laboratory, WENTAO ZHANG, TRISTAN MILLER, GREG AFFELDT, KOSHI KURASHIMA, Materials Sciences Division, Lawrence Berkeley National Laboratory / Department of Physics, UC Berkeley, CHRIS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Laboratory, TAKASHI NOJI, YOJI KOIKE, Department of Applied Physics, Tohoku University, HIROSHI EISAKI, Electronic and Photonics Research Institute, National Institute of Advanced Industrial Science and Technology, DUNG-HAI LEE, ALESSANDRA LANZARA, Materials Sciences Division, Lawrence Berkeley National Laboratory / Department of Physics, UC Berkeley — In cuprate superconductors, an important open question is the degree to which the timescales and pathways for quasiparticle relaxation relate to underlying mechanisms governing superconductivity, antiferromagnetism, charge ordering, and other types of competing orders. Time- and angle-resolved photoemission spectroscopy (time-resolved ARPES) is uniquely poised to address this question because of the technique’s exceptional ability to simultaneously probe the time-, energy-, and momentum-dependent properties of quasiparticles and band structure. Previous time-resolved ARPES studies have examined quasiparticle dynamics in the very high and very low pump fluence regimes, but a systematic study of the changes in dynamics across the fluence vaporization threshold for superconductivity has not yet been undertaken. Here we report the results of studying this regime.
RAM SHARMA, University of Illinois at Chicago, Chicago, IL — It has been revealed that the two high energy kinks in high $T_c$ superconductors (HTSC) in electron energy at $\sim 100$ meV and $\sim 160$ meV which were stated as found new [1], were discovered earlier [2] via dipolon theory [3,4] in explaining the photoemission line shape (sharp peak, dip and broad peak) and the low energy kink at $\sim 70$ meV. It was also mentioned [2] that the details for the high energy kinks would be reported elsewhere [5]. Thus Ref. 1 should be corrected by replacing “new” by “discovered earlier” in the text including the title. The dipolon theory is strong coupling field-theory including Mott renormalization, nonrigid electron bands, electron-hole attraction and all important and necessary electron correlations and not only explains but also predicts correctly the properties of HTSC [2-5].

Monday, March 2, 2015 2:30PM - 5:30PM — Session D10 DCMP: Optical and THz Properties of Topological Insulators 007A - Dennis Drew, University of Maryland

2:30PM D10.00001 Transient reflectance of photoexcited electrons and holes in cadmium arsenide$^1$, CHRIS WEBER, BRYAN BERGGREN, Department of Physics, Santa Clara University, ERNEST ARUSHANOV, Institute of Applied Physics, Academy of Sciences of Moldova, TAHEREH HOSSEINI, NIKOLAI KOULKIN, Departments of Electrical Engineering and Computer Science, University of Wisconsin-Milwaukee — We report ultrafast transient-grating measurements of crystals of the three-dimensional Dirac semimetal cadmium arsenide, Cd$_3$As$_2$, at both room temperature and 80 K. After photoexcitation with 1.5-eV photons, charge-carriers relax by two processes, one of sub-picosecond duration and the other of duration 3 ps. By measuring the complex phase of the change in reflectance, we determine that the faster signal corresponds to an increase in phase velocity, and the slower signal to a decrease in absorption, at the probe energy. We assign the fast signal to free-carrier absorption from photoexcited electron and hole populations, which relax by recombination, and the slower signal to phase-space filling by thermally excited electrons. The proposed processes closely mirror the response of graphene to photoexcitation. We also present evidence that both the electrons and the lattice are strongly heated.

2:42PM D10.00002 Gated Terahertz Magneto-optical Measurements of 3D Dirac Semimetals$^1$, DON C. SCHMADEL, GREGORY S. JENKINS, ANDREI B. SUSHKOV, REMINGTON L. CAREY, H. DENNIS DREW, Dept of Physics & CNAM, Univ of Maryland-College Park, JASON W. KRIZAN, SATYA KUSHWAHA, QUINN GIBSON, ROBERT J. CAVA, Dept of Chemistry, Princeton Univ — We report gated terahertz magneto-optical measurements of the bulk and surface states of Na$_3$Bi and Cd$_3$As$_2$. The onset of interband transitions within the bulk 3D Dirac cone is observed. A gate is used to modulate surface carriers and bulk carriers near the surface resulting in differential optical signals. Gate-modulated cyclotron resonance and Fourier transform infrared spectroscopy characterize the bulk Dirac carriers along all three crystal axes as well as the Fermi-arc carriers, with Fermi Energy. The transport scattering and Fermi velocity anisotropy as well as potential fluctuations characterized near the Dirac point will be discussed.

2:54PM D10.00003 Theory of Kerr and Faraday rotation in Topological Weyl Semimetals$^1$, MEHDI KARGARIAN, MOHIT RANDERA, NANDINI TRIVEDI, Department of Physics, The Ohio State University, Columbus, OH 43210, USA — Topological Weyl semimetals are characterized by bulk Dirac nodes separated in momentum space by a distance $2b$ and lead to Fermi arcs in the surfaces electronic structure. We calculate the Faraday $\theta_F$ and Kerr $\theta_K$ angles for electromagnetic waves scattered from such a Weyl semimetal using the Kubo formalism. (1) For thin films with electromagnetic radiation incident on a surface without arcs, we show that $\theta_K = bd/\alpha \pi$ and $\theta_F = \alpha \pi/ bd$ where $\alpha$ is the fine structure constant, and the film thickness $d \ll \lambda$, the wavelength. We further show multiple reflections give rise to giant Kerr rotation, under certain conditions, for a film on a substrate. (2) In the case when the electromagnetic radiation is incident on the surface with arcs, the wave propagating inside the material acquires a longitudinal component $F$, $\theta \propto F$ and $\theta_L \propto F$. We discuss the implications of our results for thin films of pyrochlore iridates, and also for the recently discovered Dirac semimetals in a magnetic field.

3:06PM D10.00004 Temperature-driven band inversion in Pb$_{0.77}$Sn$_{0.23}$Se: Optical and Hall-effect studies, NAWEEN ANAND, Univ of Florida - Gainesville, FL, ZHIGUO CHEN, NHMFL Florida State University, Tallahassee, FL, SANAL BUADEV, Univ of Florida - Gainesville, FL, CARTIN, Ramapo college, Mahwah, NJ, KAMAL CHOUTHARY, Univ of Florida - Gainesville, FL, GENDU GU, Brookhaven National Lab, Upton, NY, S. SINNOTT, Univ of Florida - Gainesville, FL, ZHIQIANG LI, NHMFL Florida State University, Tallahassee, FL, A. HEBARD, D. TANNER, Univ of Florida - Gainesville, FL — Optical and Hall-effect measurements have been performed on single crystals of Pb$_{0.77}$Sn$_{0.23}$Se, a IV-VI mixed chalcogenide. The temperature dependent (10-300 K) reflectance was measured over 40-7000 cm$^{-1}$ (5-870 meV) with an extension to 15.50 cm$^{-1}$ (1.92 eV) at room temperature. The reflectance was fit to the Drude-Lorentz model using a single Drude component and several Lorentz oscillators. The optical properties at the measured temperatures were estimated via Kramers-Kronig analysis as well as by the Drude-Lorentz fit. The carriers were p-type with the carrier density determined by Hall measurements. A signature of valence intraband transition is found in the low-energy optical spectra. It is found that the valence-conduction band transition energy as well as the free carrier effective mass reach minimum values at 100 K, suggesting temperature-driven band inversion in the material. Some of the results from optical studies were compared with density function theory calculations.

3:18PM D10.00005 Single Photon Transport through an Atomic Chain Coupled to a One-dimensional Photonic Waveguide, ZEYANG LIAO, XIAODONG ZENG, M. SUHAIL ZUBAIRY, Texas A&M University — We study the dynamics of a single photon pulse travels through a single atomic chain coupled to a one-dimensional (1D) single mode photonic waveguide. We derive a time-dependent dynamical theory for this collective many-body system which allows us to study the real time evolution of the photon transport and the atomic excitations. Our result is consistent with previous calculations when there is only one atom. For an atomic chain, the collective interaction between the atoms mediated by the waveguide mode can significantly change the dynamics of the system. The reflectivity can be tuned by changing the ratio of coupling strength and the photon linewidth or by changing the number of atoms in the chain. The reflectivity of a single photon pulse with finite bandwidth can even approach 100%. The spectrum of the reflected and transmitted photon can also be significantly different from the single atom case. Many interesting physics can occur in this system such as the photonic bandgap effects, quantum entanglement generation, Fano-type interference, superradiant effects and nonlinear frequency conversion. For engineering, this system may be used as a single photon frequency filter, single photon modulation and photon storage.
3:30PM D10.00006 Electrostatic tuning of the surface states of irradiated topological insulators\textsuperscript{1} INNA KORZHNOVSKA, LUKAS ZHAO, YURY DESHKO, The City College of New York-CUNY, GIDEON AREFE, Columbia University, MARCIN KONCZYKOWSKY, Emanuele Polini, France- LIA KRUSIN-ELBAUM, The City College of New York-CUNY, COLUMBIA UNIVERSITY COLLABORATION — One of the main obstacles to accessing charge transport through Dirac surface states of topological insulators (TIs) is a significant conduction in the bulk. We have developed a new approach of reaching a stable charge neutrality point (CNP) using irradiation with 2.5 MeV energy electrons. By controlling the beam fluence and annealing protocol we can convert bulk conductivity from $p$- (hole-like) to $n$-type (electron-like) and back, crossing the Dirac point while preserving the robust topological signatures of surface channels. Electron beams act to compensate charged bulk defects and pull the Fermi level into the bulk gap – a process that decreases bulk conductivity by orders of magnitude to a minimum, $\sigma_{\text{Ti}},$ at CNP. We study the origins of minimum conductivity in electron-irradiated TIs in a transistor-like gated structures fabricated in inert environment by mechanical exfoliation with $\text{Bi}_2\text{Te}_3$ as a prototypical TI and h-BN as a gate dielectric. The effects of electrostatic tuning by the gate bias voltage on surface conductivity near CNP will be presented.

3:42PM D10.00007 Effects of the topological phase transition and band inversion on ultrafast dynamics in topological crystalline insulators\textsuperscript{1} Y.M. DAI, J. BOWLAN, A.J. TAYLOR, D.A. YAROTSKI, R.P. PRASANKUMAR, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, Los Alamos, NM 87545, R.D. ZHONG, G.D. GU, T. VALLA, C.C. HOMES, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, NY 11973, T. YILMAZ, B. SINKOVIC, Department of Physics, University of Connecticut, Storrs, Connecticut 06269 — Topological crystalline insulators, characterized by a gapless metallic state on their high-symmetry surfaces that is protected by crystalline symmetry, are realized both theoretically and experimentally in the $\text{Pb}_1-x\text{Sn}_x\text{Te}$ and $\text{Pb}_1-x\text{Sn}_x\text{Se}$ compounds. In these materials, a topological phase transition and band inversion can be induced by doping, pressure or temperature. We use femtosecond optical pump-probe spectroscopy to study the evolution of the ultrafast dynamics as a function of both temperature and doping in the $\text{Pb}_1-x\text{Sn}_x$ Te system. The influence of these parameters on the topological phase transition and band inversion, as well as on quasiparticle dynamics, will be discussed.

3:54PM D10.00008 Cyclotron resonance of surface states in the bulk-insulating topological insulator $\text{Bi}_2\text{Se}_3$ by THz spectroscopy LIANG WU, The Johns Hopkins University, WANG-KONG TSE, Los Alamos National Laboratory, CHRISTOPHER MORRIS, The Johns Hopkins University, MATTHEW BRAHLEK, NIKESH KOIRALA, SEONGSHIK OH, Rutgers the State University of New Jersey, PETER ARMITAGE, The Johns Hopkins University, THE JOHNS HOPKINS UNIVERSITY TEAM, LOS ALAMOS NATIONAL LABORATORY TEAM, RUTGERS THE STATE UNIVERSITY OF NEW JERSEY TEAM — We have utilized magneto-optical time-domain terahertz spectroscopy to investigate the low frequency optical response of topological insulator films of $\text{Cu}_x\text{Bi}_2\text{Se}_3$ and $\text{Bi}_2\text{Se}_3$. Such experiments give sufficient information to measure the mobility and density of multiple conduction channels simultaneously. Sharp cyclotron resonances (CRs) were observed in both samples by Faraday rotation experiments. We find that the $\text{Cu}_x\text{Bi}_2\text{Se}_3$ films with certain Cu concentration are bulk insulators with only surface conduction channels. This is consistent with pure topological surface states conduction and an $E_F$ that is $\sim 150$ meV above Dirac point (around 70meV below conduction band minimum). Hence, a true topological insulator with insulating bulk is realized. In contrast, we find that $\text{Bi}_2\text{Se}_3$ with $E_F < -350$ meV above Dirac point has two channels; a dominant one that exhibits a CR in the Faraday rotation comes from surface states and a second channel which does not show a CR comes from bulk and/or 2DEG. Orbital effect on the electrodynamics of surface states and electron-phonon interaction are also discussed.

4:06PM D10.00009 Probing topological transitions in HgTe/CdTe quantum wells by magneto-optical measurements\textsuperscript{1} BENEDIKT SCHRÄF, ALEX MATOS-ABIAGIU, Department of Physics, SUNY at Buffalo, JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg, IGOR ZUTIC, Department of Physics, SUNY at Buffalo — In two-dimensional topological insulators, helical Quantum Spin Hall (QSH) states persist even at finite magnetic fields below a critical magnetic field $B_c$, above which only Quantum Hall (QH) states can be found [1]. Using linear response theory we theoretically investigate the magneto-optical properties of inverted HgTe/CdTe quantum wells, both for infinite two-dimensional and finite-strip geometries, and possible signatures of the transition between the QSH and QH regimes. In the absorption spectrum, several peaks arise due to non-equidistant quasiparticles levels in both regimes. However, in the QSH regime, we find an additional absorption peak at low energies in the finite-strip geometry. This peak arises due to the presence of edge states in this geometry and persists for any Fermi level in the QSH regime, while in the QH regime the peak vanishes if the Fermi level is situated in the bulk gap. Thus, by sweeping the gate voltage, it is potentially possible to distinguish between the QSH and QH regimes. Moreover, we investigate the effect of spin-orbit coupling and finite temperature on this measurement scheme.

4:18PM D10.00010 Coupling two lasers on a dielectric surface CRISTIAN BAHRIM, MD KHAIRUZZAMAN, MD MOZAMMAL RAJU, WEI-TAI HSU, Physics Department, Lamar University — We can modify the radiation perceived by a dielectric surface using a capacitor voltage set up across. The associated uniform electric field allows us to shift toward shorter wavelengths the optical response of the dielectric surface for a given monochromatic laser radiation incident on it. We use this capacitor configuration for coupling two laser beams incident simultaneously on the surface. The stronger coupling laser couples with the electric dipoles and impedes a probe laser to oscillate the same dipoles. The interaction between the two laser beams creates a destructive interference pattern in the Brewster angle region of the probe. Clear evidence of several minima of diffraction shows along the direction of reflection of the probe laser. This diffraction pattern indicates the ‘lock in’ of the probe laser on the surface. This new physics is related to an electromagnetic induced transparency (EIT)-type phenomenon with the major difference that in our case the coupling between two lasers is produced at the dielectric’s surface.

4:30PM D10.00011 Measurement of a topological edge invariant in a microwave network JASON C. PILLAY, WENCHAO HU, Nanyang Technological University, KAN WU, Shanghai Jiao Tong University, MICHAEL PASEK, PERRY PING SHUM, YIDONG CHONG, Nanyang Technological University — We report on the experimental measurement of topological edge invariants in an electromagnetic analog of a topological insulator, realized by a classical microwave network. This experiment serves as a classical electromagnetic realization of Laughlin’s “topological pumping” thought experiment for the quantum Hall effect. The experiment consists of determining the electromagnetic scattering matrix, based on the input and output wave amplitudes measured at the edges of the network via a network analyzer. The winding on the scattering matrix eigenvalues, resulting from a tunable phase shift built into the network, forms a topological invariant. We demonstrate the existence of a topologically trivial phase, where the winding is zero (no edge states), as well as a topologically nontrivial phase, where the winding is non-zero (topological edge states present). Unlike most other systems used to study topological insulator physics, the full complex scattering parameters can be measured in this setup. As in most microwave experiments, however, our system is susceptible to losses. We show that topological behavior can be meaningfully defined in the experiment despite the effects of loss.
4:42PM D10.00012 Experimental realization of microwave photonic topological insulators
JIANWEN DONG, Sun Yat-sen University — Topological properties play a fundamental role in many physical phenomena. While topology focus on electronic systems, there has been a recent emergence of interest in exploring topological orders with photons. Recent experiments have demonstrated substantial progress towards the implementation of Hamiltonians with topological robustness, from microwave to visible frequency domains. Here, we will show the demonstration on nontrivial photonic bandgaps, as well as the topologically protected edge states. We designed and fabricated a metacrystal comprising non-resonant meta-atoms sandwiched between two metallic plates. Spin Chern number of photonic crystals is calculated based on group theory and accurately predicts topological characters of edge states in different gaps. Topologically nontrivial gaps are achieved by mode exchange at high symmetric k-points. Nontrivial bandgap was confirmed by experimentally measured transmission spectra and calculated nonzero spin Chern number. Gapless spin-filtered edge states were demonstrated experimentally by measuring Ez fields and Hz fields, as well as their phase differences. Robustness of the edge states were also observed when an obstacle is introduced near the edge.

4:54PM D10.00013 Persistent Optical Gating of a Topological Insulator Heterostructure
ANDREW L. YEATS, Institute for Molecular Engineering, University of Chicago, Chicago, IL 60637 & Dept. of Physics, University of California, Santa Barbara, CA 93106, YU PAN, ANTHONY RICHARDELLA, Dept. of Physics, Penn State University, University Park, PA 16802, PETER J. MINTUN, Institute for Molecular Engineering, University of Chicago, Chicago, IL 60637, NITIN SAMARTH, Dept. of Physics, Penn State University, University Park, PA 16802, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago, Chicago, IL 60637 & Dept. of Physics, University of California, Santa Barbara, CA 93106 — We demonstrate persistent, bidirectional control of the chemical potential in a (Bi,Sb)2Te3/SrTiO3 heterostructure through a two-color all-optical technique. By manipulating the space-charge distribution in a SrTiO3 substrate, we locally tune the field effect in a (Bi,Sb)2Te3 channel comparatively to electrostatic gating techniques but without additional materials or processing. The effect persists for thousands of seconds and functions from cryogenic to ambient temperatures. This enables us to write and re-write arbitrarily shaped p- and n-type regions, which we characterize electrically and image with scanning photocurrent microscopy. The ability to rapidly prototype mesoscopic electronic structures in a topological insulator may aid in the investigation of the spin-polarized surface and edge states unique to the topological insulating phase. The optical patterning technique may be adaptable to other material systems, which could form a basis for reconfigurable electronics.

5:06PM D10.00014 Circular Dichroism Observed by Photoemission from Ultrathin Bi2Te3 Films
CAI-ZHI XU, YANG LIU, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801, USA, HYUK JONG KIM, Institute of Solid State Physics, The University of Tokyo, Kashiwa, Chiba 277-8581, Japan, LONG-XIANG ZHANG, TOM MILLER, TAI-CHANG CHIANG, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801, USA — Circular dichroism (CD) observed by photoemission from the surface states of topological insulators has drawn much interest. It was initially attributed to the spin polarization or chiral orbital momentum of the initial states, but later proven to also involve the final states. The detailed mechanism remains controversial. To address this question, we have performed measurements of ultrathin films of the prototypical topological insulator Bi2Te3 over a wide range of film thickness and photon energy. The results show that the CD depends not only on the photon energy, but also on the film thickness in a nontrivial manner. A theoretical model has been developed that involves dipole transition, surface photoemission, and spin-orbit coupling. The computed results are in good agreement with the general trends of the data including sign reversals as a function of photon energy and film thickness. The complex behavior of the measured CD function is partially caused by modifications of both the initial and final states in the thin film geometry.

5:18PM D10.00015 Rashba effect and beating patterns in the THz magneto-photoresponse of a HgTe-based two-dimensional electron gas
MEHDI PAKMEHR, University at Buffalo, CHRISTOPH BRUENE, HARTMUT BUHMANN, LAURENS MOLENKAMP, University of Utrecht, BRUCE MCCOMBE, University at Buffalo — HgTe quantum wells with a gapped single Dirac cone electronic dispersion relation have been investigated by THz magneto-photoresponse (PR) and magneto-transport measurements. The HgTe has the conventional band alignment at well thickness of 6.1 nm, slightly smaller than the critical thickness for the topological phase transition. The effective gap is roughly 10 meV, and the large sheet density of electrons (n~≈1.5×1012 cm−2) results in a very large Fermi energy (EF~≈160 meV). We have found several interesting effects at these high densities. We focus here on an observed beating of quantum oscillations in the PR signal (at 1.83 THz) and compare it with direct measurements of oscillations in the longitudinal magneto-resistance (Rxx). The mechanism for the PR is cyclotron resonance absorption heating of the electrons (an electron bolometric effect). We attribute the beating to Rashba splitting of the spin states, which is barely observable in direct Rxx measurements even under strong gate-induced electric fields. We will discuss the origin of the enhanced visibility of the Rashba effect in the PR and the magnitude of the Rashba coefficient (αR) from these data.

5:29PM D10.00016 Experimental realization of microwave photonic topological insulators
JIANWEN DONG, Sun Yat-sen University — Topological properties play a fundamental role in many physical phenomena. While topology focus on electronic systems, there has been a recent emergence of interest in exploring topological orders with photons. Recent experiments have demonstrated substantial progress towards the implementation of Hamiltonians with topological robustness, from microwave to visible frequency domains. Here, we will show the demonstration on nontrivial photonic bandgaps, as well as the topologically protected edge states. We designed and fabricated a metacrystal comprising non-resonant meta-atoms sandwiched between two metallic plates. Spin Chern number of photonic crystals is calculated based on group theory and accurately predicts topological characters of edge states in different gaps. Topologically nontrivial gaps are achieved by mode exchange at high symmetric k-points. Nontrivial bandgap was confirmed by experimentally measured transmission spectra and calculated nonzero spin Chern number. Gapless spin-filtered edge states were demonstrated experimentally by measuring Ez fields and Hz fields, as well as their phase differences. Robustness of the edge states were also observed when an obstacle is introduced near the edge.

Monday, March 2, 2015 2:30PM - 5:30PM – Session D11 DMP: Coexisting Orders In Underdoped Cuprates
007B - Vivek Mishra, Argonne National Laboratory

2:30PM D11.00001 Combinatorial Deposition of La2−xBaxCuO4 Thin Films Across the x=1/8 Anomaly
JUSTIN LANE, ADAM WEIS, AZTON WELLS, University of Illinois at Urbana-Champaign, SO RA CHUNG, Belmont University, PATHIKUMAR SELLAPPAN, WALTRAUD KRIVEN, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign — La2−xBaxCuO4 (LBCO) has an unusual phase diagram that includes a charge stripe phase in proximity to suppressed superconductivity near x=1/8 doping. We will present recent improvements to LBCO thin films grown by pulsed laser deposition from high-quality metalorganic-synthesized ceramics. Using a combination of Ba-poor and Ba-rich deposition sources and a combinatorial pulsed laser deposition technique, we are able to tune doping of LBCO and measure the superconducting transition temperature as a function of doping. We correlate the spatial offset between deposition plume and substrate with the resultant sample’s dopant distribution. Characterization of these films by a high-throughput resistence technique and use of the samples in ongoing experiments will be discussed.

2:42PM D11.00002 ABSTRACT WITHDRAWN
2:54PM D11.00003 In-plane resistivity anisotropy in underdoped cuprates due to scattering by charge and spin fluctuations. MICHAEL SCHÜTT, RAFAEL M. FERNANDES, University of Minnesota — The existence of strong in-plane electronic anisotropies in underdoped cuprates has been reported by a variety of experimental probes, such as transport measurements, scanning tunneling microscopy, and x-ray and neutron scattering. Understanding the origin of these anisotropies and their interplay is fundamental to elucidate the role played by electronic nematicity in the phase diagram of the cuprates. Here we employ a Boltzmann equation approach to investigate the resistivity anisotropy due to scattering by anisotropic spin and charge fluctuations. We show that while spin fluctuations give rise to larger resistivity along the b direction, charge fluctuations promote larger resistivity along the a direction. Therefore, charge and spin fluctuations compete, these behaviors give rise to a particular dependence of the resistivity anisotropy with doping, which is consistent with transport experiments performed in YBa$_2$Cu$_3$O$_{6.5}$H$_x$. We discuss the important role played by the CuO chains in YBCO to select the observed type of nematic domains, and propose transport measurements in strained HgBa$_2$CuO$_4$ and Bi$_2$Sr$_2$CaCu$_2$O$_{y+δ}$ to shed light on the interplay between anisotropic fluctuations and anisotropic resistivity.

3:06PM D11.00004 Superconducting and charge order in 1/8 doped LBCO probed by proton-induced disorder. MAXIME LEROUX, VIVEK MISHRA, HELMUT CLAUS, ULRICH WELP, Materials Science Division, Argonne National Laboratory, ASGHAR KAYANI, Department of Physics, Western Michigan University, ZAHIRUL ISLAM, Advanced Photon Source, Argonne National Laboratory, GENDA GU, Department of Physics, Brookhaven National Laboratory, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory — The question of how charge order coexists with superconductivity in underdoped cuprates is an important open question that has yet to be fully understood. Recently, the role played by the CuO chains in La$_2$CuO$_4$ has been probed and measured by neutron scattering and NMR, but the role played by the CuO chains in YBCO to select the observed type of nematic domains, and propose transport measurements in strained HgBa$_2$CuO$_4$ and Bi$_2$Sr$_2$CaCu$_2$O$_{y+δ}$ to shed light on the interplay between anisotropic fluctuations and anisotropic resistivity.

3:18PM D11.00005 $^{17}$O NMR Study of Under-doped Single Crystals of the High Temperature Superconducting Compound Hg1201. W.P. HALPERIN, JEONGSEOP A. LEE, YIZHOU XIN, Northwestern University, A.M. MOUNCE, Los Alamos National Laboratory, A.F. REYES, P.L. KUHNS, National High Magnetic Field Laboratory — We present measurements of $^{17}$O high field NMR on oxygen isotope exchanged under-doped single crystals of the single layer superconductor, HgBa$_2$CuO$_{4+y}$, a compound having a known tetragonal lattice. Our $^{17}$O data for two under-doped samples (T$_c$ of 87 K and 79 K) indicates that there are two inequivalent oxygen planar sites based on measurements of upper and lower quadrupolar satellites. Spectra were taken with 4 K $<$ T $<$ 400 K and 6 T $<$ H $<$ 30 T with a goniometer to precisely orient crystals relative to the magnetic field. We found an asymmetry in the line shape between the upper and lower satellites that cannot be accounted for by a model with a single planar oxygen site. Comparison will be made to earlier work on under-doped YBa$_2$Cu$_3$O$_{y+δ}$. [1] A.M. Mounce, et al., Phys. Rev. Lett. 111, 187003 (2013).

3:30PM D11.00006 Enhanced Fluctuation/Inhomogeneity Effects Near The Superconductor-Insulator Transition in Severely Underdoped 2D Films of Ca$_{0.3}$Y$_{0.7}$Ba$_2$Cu$_3$O$_{6.4}$+δ. THOMAS LEMBERGER, The Ohio State University — It has been shown that the superconductor-insulator transition in two-dimensional, severely underdoped films of Ca$_{0.3}$Y$_{0.7}$Ba$_2$Cu$_3$O$_{6.4}$+δ is accompanied by a linear scaling between the zero temperature superfluid density n$_s$(T = 0) and the temperature for the unbinding of thermally excited vortex pairs, T$_{BD}$. We present results from resistivity and magnetic screening studies on 2D Ca$_{0.3}$Y$_{0.7}$Ba$_2$Cu$_3$O$_{6.4}$+δ showing a linear relationship between the width of tails in the resistive transition and T$_{BD}$. These tails show a significant suppression of resistivity and can extend down for tens of Kelvin's before the films exhibit magnetic screening. We examine this relationship in light of a possible enhancement of inhomogeneous effects in the vicinity of the superconductor-insulator transition with underdoping.

3:42PM D11.00007 Simultaneous AFM-STM on BSCCO. DREW EDELBerg, MIHiR BHASKAR, PINSHANE HUANG, ABHAY PASUPATHY, Columbia University — Scanning tunneling microscopy is limited by its inability to resolve the difference between local electronic structure and surface topology since the tunneling current is a convolution of electronic density and tip height. Such a limitation is especially problematic in studying or order coexists with superconductivity in underdoped cuprates. Here we report that the T$_c$ of La$_{1.87}$Ba$_{0.125}$Cu$_2$O$_{6.5}$ (LBCO) increases by up to 50% after proton irradiation. At high enough energy, proton irradiation creates a uniform density of small nm-sized amorphous clusters and point defects, which results in a uniform and isotropic 3D distribution of defects [1]. However, it is well known that non-magnetic defects are pair-breaking for d-wave superconductivity, and should therefore reduce Tc. We speculate that proton-induced disorder directly affects the balance between competing density wave and superconducting ground states. [1] Jia, Y. et al. Appl. Phys. Lett. 103, 122601 (2013); M. A. Kirk, Cryogenics 33, 235 (1993); M. A. Kirk, Y. Yan, Micron 30, 507 (1999). This work is supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. D.O.E., Office of Science, Office of Basic Energy Sciences and by the D.O.E, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

3:54PM D11.00008 Nonlinear Hall effect and Shubnikov-de Haas quantum oscillations in thin films of the electron doped superconductor Pr$_2$CuO$_4$. NICHOLAS BREZNAy, Lawrence Berkeley National Lab, NITYAN NAIR, JAMES ANALYTIS, University of California Berkeley, ZENGWEI ZHU, KIMBERLY MODIC, ROSS MCDONALD, Los Alamos National Lab, YOSHIHARU KROCKENBERGER, NTT Basic Research Labs — Recent quantum oscillation studies in cuprate superconductors have allowed for considerable progress in understanding their Fermi surface topology. However, important questions remain about the influence of quantum criticality and competing orders, as well as the universality of these results; in particular quantum oscillation studies to date have largely been confined to a limited range of hole-doped bulk crystal systems. We have observed a field nonlinear Hall effect in superconducting thin films of the cuprate Pr$_2$CuO$_4$, and studied the temperature and magnetic field dependence of this behavior. The Hall effect data are consistent with a simple two-band transport model in this material, and we will interpret them in light of recently observed Shubnikov-de Haas quantum oscillations in these films.

4:06PM D11.00009 Near-Room Temperature Studies of the Pseudogap Phase of Underdoped Bi-2212. LING FU, AARON KRAFT, Clark University, GENDA GU, Brookhaven National Laboratory, MICHAEL BOYER, National High Magnetic Field Laboratory — We present measurements of the pseudogap state of underdoped Bi-2212 in the vicinity of T$_c$.
4:18PM D11.00010 Signatures of the Berezinskii–Kosterlitz–Thouless transition in highly underdoped La$_{2-x}$Sr$_x$CuO$_4$ 1, ZHENZHONG SHI, PAUL BAITY, XIAOYAN SHI, DRAGANA POPOVIĆ, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ. — We investigated the nature of the thermally driven transition to a superconducting state on MBE-grown 100 nm thick La$_{2-x}$Sr$_x$CuO$_4$ films ($x = 0.07$ and 0.08) by studying a) superconducting fluctuations (SCFs), as determined from the magnetoresistance, b) voltage ($I-V$) characteristics, and c) fluctuations of conductance with time (noise). Noise was studied on confined width (20 μm) samples specifically designed for measurements in the eight-probe double-bridge configuration. We observe: a) the contribution of the SCFs to the conductivity increases monotonically with decreasing $T$ and diverges exponentially at $T_{BKT}$, where resistance also goes to zero; b) power-law behavior $V \propto T^\alpha(T)$ with $\alpha(T) \geq 3$ for $T < T_{BKT}$; and c) an orders-of-magnitude enhancement of the noise near $T_{BKT}$. Possible long-range correlations in the phase fluctuations near $T_{BKT}$ are also studied with higher-order spectrum analysis. Our observations suggest that the transition from superconductor to the normal state exhibits signatures of the Berezinskii–Kosterlitz–Thouless (BKT) transition.

4:30PM D11.00011 Double criticality in the magnetic field driven transition of a high-TC superconductor 1, BRIGITTE LERIDON, LPEM/CNRS-ESPCIParisTech - UPMC, 10 rue Vauquelin - 75005 Paris - France, JOHAN VANACKEN, V.V. MOSCHHALKOV, INPAC-KULeuven, Celestijnenlaan 200 D, B-3001 Heverlee, Belgium, BAPTISTE VIGNOLLE, CNRS/LNCMI, 143 Avenue de Rangueil, 31040 Toulouse, France, RAJNI PORWAL, R.C. BUDHANI, NPL, CSIR, New Delhi 110012, and IIT Kanpur, Kanpur 208016, India — The magnetic-field driven transition of a set of high critical temperature $La_{2-x}Sr_xCuO_4$ superconducting thin films has been investigated using high pulsed magnetic fields. For the underdoped samples, the existence of two distinct critical regions in the superconductor/insulator transition has been evidenced for the first time. The first quantum critical region is observed at intermediate magnetic fields ($\approx 19T$) and temperatures and gives way at lower temperature to a quantum critical point at about twice critical magnetic field and resistance per square. The critical exponents inferred from scaling behaviour are markedly different for the two regions. We attribute this behaviour to the existence of a clean/dirty crossover due to the presence of electronic inhomogeneities.

This work has been supported by a SESAME grant from Region Ile-de-France. Part of the experiments at KULeuven have been founded by EuroMagNET II under the EU contract number 228043.

4:42PM D11.00012 Examining non-Fermi liquid behavior through magnetoresistance in nearly continuously doped La$_{(2-x)}$Sr$_x$CuO$_4$, ZAC STEGEN, ARKADY SHEKHTER, GREG BOEBINGER, Florida State University, FEDOR BALAKIREV, ROSS MCDONALD, Los Alamos National Laboratory, JIE WU, ANTHONY BOLLINGER, XI HE, IVAN BOZOVIC, Brookhaven National Laboratory — We report magnetoresistance in thin films of the cuprate superconductor $La_{2-x}Sr_xCuO_4$ in pulsed magnetic fields up to 65 tesla. The films are synthesized using combinatorial molecular beam epitaxy, which allows for continuous tuning of doping. They are patterned into an array of pixels with steps of $\Delta x \approx 0.0002$, which is 25 times smaller than experiments using conventional sample growth methods. These films allow a detailed analysis of the doping evolution of non-Fermi liquid magnetoresistance in the vicinity of optimal doping.

4:54PM D11.00013 Magnetic field induced ordering and phase diagram in underdoped LSCO, JESSE HALL, McMaster University, TOOMAS RÖÖM, URMAS NAGEL, DAN HUVONEN, National Institute for Chemical Physics and Biophysics, D. HAWTHORNE, S. WAKIMOTO, H. ZHANG, University of Toronto, JUNGSEEK HWANG, Sungkyunkwan University, SEIKI KOMIYA, Central Research Institute of Electric Power Industry, THOMAS TIMUSK, McMaster University — The existence of ordered phases in superconducting cuprates has come under intense scrutiny with the revelation of charge-ordering near the superconducting transition in YBCO. Previous results demonstrating the existence of exotic ordered phases, including the existence of stripe order, and the richness of the magnetic-field/doping/temperature phase diagram, suggest that the underdoped region of the phase diagram may contain a wealth of information that has yet to be revealed. We turn our attention to $La_{2-x}Sr_xCuO_4$ on the boundary of superconductivity by studying the far-infrared optical properties of three single crystals with $x=0.05$, 0.06, and 0.07: the first is non-supercconducting, the others have transition temperatures of 6 K and 12 K respectively. By applying a magnetic field up to 17 T we are able to suppress superconductivity where it exists and compare the field-induced normal state to that induced by temperature or by doping. By studying the optical conductivity of these materials and the changes in the spectral weight with temperature and field, we can gain insight into the field induced ordered states of underdoped cuprate superconductors.

5:06PM D11.00014 Doping-dependent critical Cooper-pair momentum $p_c$ in thin underdoped cuprate films 1, THOMAS LEMBERGER, JOHN DRASKOVIC, STANLEY STEERS, THOMAS MCIJUNKIN, ADAM ANMED, Ohio State Univ - Columbus — We apply a low-field ($< 100$ G) technique to measure the critical Cooper pair momentum $p_c$ in thin, underdoped films of $Y_{0.9}Cu_{0.9}Ba_2Cu_3O_{7-δ}$ and $Bi_2Sr_2CaCu_2O_{8+δ}$, where doping is effected by adjusting the oxygen stoichiometry through post-deposition annealing. The technique is based on applying a perpendicular magnetic field to the center of a superconducting film and measuring the field at which the screening of the field catastrophically fails. Theory together with measurements on thin films of conventional superconductors Nb and MoGe argue for the validity of the technique. In underdoped cuprates, spectroscopy identifies multiple characteristic energy scales, e.g., the pseudogap and the “nodal” gap, neither of which is proportional to $T_c$. On general grounds, we expect to find that $p_c \propto T_c$ is proportional to the characteristic superconducting energy scale. We observe that $p_c \propto T_c^\alpha$, where $\alpha \approx 0.75$ decreases with underdoping, identifying $k_BT_c$ as the characteristic energy. While this result is trivial in conventional superconductors whose spectroscopic gaps are proportional to $T_c$, it is significant in cuprates.

5:18PM D11.00015 A mean-field phase diagram with a pair density wave state in relation to cuprate phenomenology 1, AKASH MAHARAJ, LAIMEI NIE, Stanford University, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign, STEVENC KIVELSON, Stanford University — The possible role of the pair density wave (PDW) phase in the cuprate phase diagram is discussed. We examine the mean field Landau theory which intertwines PDW order with uniform superconduct- tivity as well as incommensurate spin- and charge-density wave order, and show how many unique experimental features of different cuprate families are qualitatively reproduced naturally from this perspective. In particular, we focus on the existence of the twodimensional charge order – both in the presence and absence of a magnetic field – and show that various observed trends can be understood from this perspective. This, in turn, is consistent with the supposition that the charge ordering phenomena observed in different cuprates have a common underlying origin.

Molecular Dynamics Study of Heat Transport in Silicon–Germanium Nanoscale Metamaterials, Weinan Chen, Materials Science Department, Pennsylvania State University, Gerald Mahan, Vincent Crespi, Department of Physics, Pennsylvania State University, Ismaila Dabo, Materials Science Department, Pennsylvania State University — We have studied the thermal properties of Si–Ge metamaterials with lattice constants of up to tens of nanometers using molecular dynamics simulations and the Green–Kubo method. Validation of this approach is provided by comparing computed thermal conductivities to experimental data for bulk Si–Ge alloy systems. Close agreement with experiment in a large temperature range is found when isotopic effects are taken into account and interatomic potentials are directly parameterized against higher-level semilocal density-functional theory calculations. These simulations highlight the importance of surface morphology, isotopic substitution, alloy fraction, and superlattice periodicity in determining the thermal properties of these metamaterials, suggesting design strategies to control heat transport in nanostructures.

2:42PM D12.00002 First principles study of thermoelectric properties of IV-VI semiconductor superlattices, P.D. Borges, Universidade Federal de Víciosa, Brazil, J.E. Petersen, L. Scolfaro, Texas State University, USA, H.W. Leite Alves, Universidade Federal de São João del Rei, Brazil, T.H. Myers, Texas State University, USA — Thermoelectric materials (TE) have attracted great attention due to their ability to convert heat directly into electricity. However, to be commercially competitive with existing technology, TE devices must have a higher value of figure of merit ZT. It has been proposed to improve ZT by using multilayered systems or superlattices (SLs) resulting in 1D or 2D carrier confinement, reduction of the phonon thermal conductivity, and introduction of anisotropy effects. Here we study the TE properties of IV-VI derived semiconductor SLs. By using the Boltzmann transport theory, within the constant scattering time approximation, in conjunction with first principles calculations, we study the Seebeck coefficient (S) and ZT of PbTe/SnTe SLs. The calculated S shows good agreement with recent experimental data. An anisotropic behavior is observed for low carrier concentrations less than 10^18 cm^-3. For T = 900 K, a large value of ZT parallel to the SL axis equal to 2.6 is predicted for n = 1.2 x 10^18 cm^-3, whereas ZT perpendicular to the SL axis peaks at the value 1.4 for n = 5.5 x 10^17 cm^-3. Both electrical conductivity enhancement and reduction of thermal conductivity are analyzed, and a comparison with other multilayered systems such as planar-doped PbTe is done.

2:54PM D12.00003 How bilayer excitons can greatly enhance thermoelectric efficiency, Kai Wu, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, LOUK Rademaker, Kavli Institute for Theoretical Physics, University of California Santa Barbara, Jan Zaanen, Institute-Lorentz for Theoretical Physics, Leiden University — Presently, a major nanotechnological challenge is to design thermoelectric devices that have a high figure of merit. To that end, we propose to use bilayer excitons in two-dimensional nanostructures. Bilayer exciton systems are shown to have an improved thermopower and an enhanced electric counterflow and thermal conductivity, with respect to regular semiconductor-based thermoelectrics. We suggest an experimental realization of a bilayer exciton thermocouple. Based on current experimental parameters, a bilayer exciton heterostructures of p- and n-doped Bi$_2$Te$_3$ can enhance the figure of merit an order of magnitude compared to bulk Bi$_2$Te$_3$. Another material suggestion is to make a bilayer out of electron-doped SrTiO$_3$ and hole-doped Ca$_3$Co$_4$O$_9$.

3:06PM D12.00004 Effect of phonon-blocking at sintered interfaces, Junichiro Shiomi, The University of Tokyo — With an aim to develop high-figure-of-merit silicon nanocrystalline thermoelectrics, controllability of thermal conductivity is demonstrated by combining computation, measurement, and material synthesis. Direct measurements of interfacial thermal conductance at sintered interfaces using a 2D model interface reveal that the interfacial thermal conductance can be greatly reduced by precipitating silicon oxide crystalline nano-dots at the interface. Furthermore the impact of the reduction in interfacial thermal conductance on the overall thermal conductivity of the bulk nanocrystalline material is identified by multiscale phonon transport calculation using intrinsic phonon properties obtained from first principles. These analyses help us identify the required interfacial structure and grain size (mean value and distribution) for targets thermal conductivity. Attempts to implement this in the actual material development will be also introduced.

3:42PM D12.00005 Thermal boundary resistance in Si/Ge interfaces determined by approach-to-equilibrium simulations, Marcello Puligheddu, Konstanz Hahn, Claudio Melis, Luciano Colombo, Department of Physics, University of Cagliari, Italy — Nanostructured materials hold great promises as efficient thermoelectrics. In such materials, the propagation of phonons is hindered by the internal interfaces (grain boundaries), leading to a reduced overall thermal conductivity and, therefore, to a larger figure of merit. Any further improvement in this field does, however, require a better fundamental understanding of the specific interface effects on thermal transport. In the present work we use approach-to-equilibrium molecular dynamics simulations (AEMD) [1] to investigate the interfacial thermal resistance (ITR) of Si/Ge interfaces, occurring in very promising nanostructured SiGe alloys [2]. We discuss how ITR depends on the thickness of the interface layer, as well as on its composition. Furthermore, the effect of the heat flux direction has been investigated at ambient temperature showing lower ITR for thermal transport from Si to Ge than vice versa. This feature is discussed in connection to possible rectification effects.

5:06PM D12.00012 Thermal Conductivity of Nanocrystalline Silicon Prepared by Chemical-Vapor Deposition

Lifetime decreasing with increasing QD size. Data from TA experiments using a white light probe is also used to study the picosecond carrier dynamics. These PL decays for CdSe QDs with MPA, DDT and Cys ligands compared to OA and TOPO. The PL decay shows multi-exponential behavior with the average intensity accompanied by a larger surface trap state to excitonic PL intensity ratio. This is consistent with the TRPL measurements, which show faster exciton excitonic PL and a broad surface trap state PL. The ligand exchange of OA CdSe QDs with MPA, DDT and Cys leads to quenching of excitonic PL.

Combined with ab-initio calculations, we demonstrate that the rock-salt structure of this system has an intrinsic lattice instability similar to the resonant bond oxide (TOPO), oleic acid (OA), dodecanethiol (DDT), mercaptopropionic acid (MPA), and L-cysteine (Cys). These ligands have different chemical structures and which effects the optical properties of the QDs. Measurements were conducted on QD sizes ranging from Ø 2.5nm to 4.6nm with smaller QDs showing a higher quantum yield of the CdSe/CdS NCs.

Reasons for the higher quantum yield of the CdSe/CdS NCs.

The core of the NCs, and the e-h Coulomb interaction energies. We argue that although both types of core-shell NCs have similar confinement of the WFs, models, compared to the properties of CdSe/CdS NCs. We further looked into the spatial confinement of the HOMO and LUMO wavefunctions (WFs) within different diameters, 2.4 nm and 3.0 nm. We show that the electronic and optical properties of the CdS/ZnS NCs are influenced more by the different structural models, compared to the properties of CdSe/CdS NCs. We further looked into the spatial confinement of the HOMO and LUMO wavefunctions (WFs) within the core of the NCs, and the e-h Coulomb interaction energies. We argue that although both types of core-shell NCs have similar confinement of the WFs, the lowering of the e-h Coulomb interaction energies, hence increasing the AR lifetimes, in the CdSe/CdS NCs, compared to the CdSe/ZnS NCs, is one of the main reasons for the higher quantum yield of the CdSe/CdS NCs.

Monday, March 2, 2015 2:30PM - 5:30PM – Session D13 DCMP DMP: Focus Session: Optical Properties of Semiconductor Nanostructures

2:30PM D13.00001 Comparative study of the electronic and optical properties of core-shell nanocrystals. VANCHO KOCEVSKI, JAN RUSZ, OLLE ERIKSSON, Department of Physics and Astronomy, Uppsala University, Uppsala, D.D. SARMA, Department of Physics and Astronomy, Uppsala University, Uppsala; Solid State and Structural Chemistry Unit, Indian Institute of Science, Bangalore — The photoluminescence (PL) properties of semiconducting nanocrystals (NCs) can be notably improved by capping the NCs with a shell of another semiconductor, making core-shell structures. Furthermore, their PL properties can be manipulated by changing the core type or the interface between the core and the shell. Here we present a comparative first-principles study of the electronic and optical properties of two different types of core-shell NCs, CdSe/CdS and CdS/ZnS, with four different structural models: pure core, graded core, alloyed interface and graded interface. For the purpose of the study we made NCs with two different diameters, 2.4 nm and 3.0 nm. We show that the electronic and optical properties of the CdS/ZnS NCs are influenced more by the different structural models, compared to the properties of CdSe/CdS NCs. We further looked into the spatial confinement of the HOMO and LUMO wavefunctions (WFs) within the core of the NCs, and the e-h Coulomb interaction energies. We argue that although both types of core-shell NCs have similar confinement of the WFs, the lowering of the e-h Coulomb interaction energies, hence increasing the AR lifetimes, in the CdSe/CdS NCs, compared to the CdSe/ZnS NCs, is one of the main reasons for the higher quantum yield of the CdSe/CdS NCs.

2:42PM D13.00002 Effect of Different Ligands on Carrier Dynamics of CdSe Quantum Dots for Solar Cells Applications

BAICHHABI R. YAKAMI, URICE TOGHA, University of Wyoming, MEG MAHAT, University of North Texas, SHASHANK N. NANDYALA, MILAN BALAZ, JON M. PIKAL, University of Wyoming, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING TEAM, DEPARTMENT OF CHEMISTRY TEAM, DEPARTMENT OF PHYSICS TEAM — We have carried out steady state absorption and photoluminescence (PL), as well as time resolved PL and ultrafast transient absorption (TA) studies of CdSe quantum dots (QD) with five different capping ligands: trioclyphosphine oxide (TOPO), oleic acid (OA), dodecanethiol (DDT), mercaptopropionic acid (MPA), and L-cysteine (Cys). These ligands have different chemical structures and which effects the optical properties of the QDs. Measurements were conducted on QD sizes ranging from Ø = 2.5nm to 4.6nm with smaller QDs showing an excitonic PL and a broad surface trap state PL. The ligand and exchange of OA CdSe QDs with MPA, DDT and Cys leads to quenching of excitonic PL intensity accompanied by a larger surface trap state to excitonic PL intensity ratio. This is consistent with the TRPL measurements, which show faster exciton PL decays for CdSe QDs with MPA, DDT and Cys ligands compared to OA and TOPO. The PL decay shows multi-exponential behavior with the average lifetime decreasing with increasing QD size. Data from TA experiments using a white light probe is also used to study the picosecond carrier dynamics. These measurements shed light on the role of capping ligands on the carrier dynamics of the QD used as sensitizers in solar cells.
2:54PM D13.00003 Ultrafast Electron Trapping in Ligand-Exchanged Quantum Dot Assemblies

J. M. KIKKAWA, M. E. TURK, P. M. VORA, A. T. FAFARMAN, B. T. DIROLL, C. B. MURRAY, C. R. KAGAN, University of Pennsylvania — We use time-integrated and time-resolved photoluminescence and absorption to characterize the low-temperature (10 K) optical properties of CdSe quantum dot (QD) solids with different ligand and annealing preparation. Close-packed CdSe quantum dot solids are prepared with native aliphatic ligands and with thiocyanate with and without thermal annealing. Using sub-picosecond, broadband time-resolved photoluminescence and absorption, we find that ligand exchange increases the rate of carrier surface trapping. We further determine that holes within the QD core, rather than electrons, can bleach the band-edge transition in these samples at low temperature, a finding that comes as a surprise given what is known about the surface treatment in these QDs. We find that our ligand treatments lead to faster electron trapping to the quantum dot surface, a greater proportion of surface photoluminescence, and an increased rate of nonradiative decay due to enhanced interparticle coupling upon exchange and annealing.

3:06PM D13.00004 Van der Waals materials for the passivation of monolayer closed-packed films of CdSe quantum dots.

DENNIS ZI-REN WANG, DATONG ZHANG, RICHARD CRESWELL, Columbia University, CHENGUANG LU, National Center for Nanoscience and Technology, JIAYANG HU, IRVING P. HERMAN, Columbia University — Van der Waals (vdW) materials are shown to protect CdSe quantum dots (QDs) from oxidation. Few-layer vdW materials, e.g. graphene and MoS2, were transferred onto a monolayer closed-packed CdSe quantum dots and were examined by photoluminescence (PL) after different time periods. By comparing the PL of CdSe QDs in uncovered areas and those covered by different numbers of layers of graphene and MoS2, we saw that vdW encapsulation slows down the aging of CdSe QDs dramatically. PL mapping results clearly showed better protection of the CdSe QDs under the central part of the vdW material compared to that at the edge; this can be explained by the diffusion of oxygen and water vapor from the edge of the vdW materials.

YOUNG-SHIN PARK, CHTM, University of New Mexico, Albuquerque, NM, and Chemistry Division, Los Alamos National Laboratory, Los Alamos, NM, WAN-KI BAE, Photoelectronic Hybrid Research Center, Korea Institute of Science and Technology, Seoul, Korea, ANDREW FIDLER, TOMAS BAKER, JAEOHUN LIM, JEFFREY PIETRYGA, VICTOR KLIMOV, Chemistry Division, Los Alamos National Laboratory, Los Alamos, NM — We report amplified spontaneous emission (ASE) and lasing with very low thresholds obtained using thin films made of engineered thick-shell CdSe/CdS QDs that have a CdSeS alloyed layer between the CdSe core and the CdS shell. These “alloyed” QDs exhibit considerable reduction of Auger decay rates, which results in high bieicton emission quantum yields (Q_{bix}) of ~12%) and extended bieicton lifetimes (τ_{bix} of ~4ns). By using a fs laser (400 nm at 1 kHz repetition rate) as a pump source, we measured the threshold intensity of bieicton ASE as low as 5 µJ/cm^2, which is about 5 times lower than the lowest ASE thresholds reported for thick-shell QDs without interfacial alloying. Interestingly, we also observed bieicton random lasing from the same QD film. Lasing spectrum comprises several sharp peaks (linewidth ~0.2 nm), and the heights and the spectral positions of these peaks show strong dependence on the exact position of the excitation spot on the QD film. Our study suggests that further suppression of nonradiative Auger decay rates via even finer grading of the core/shell characteristics of the transparency. The study tests the molecular polaron formation as a function of the longitudinal acoustic phonon density of states in the optical phonons and we investigate an analogous transparency induced by acoustic phonons. Photoluminescence excitation spectroscopy is used to probe the quantum interference between discrete interdot excitons and continuum single dot-like polaron states [1] revealed the molecular polaron. It has been shown that the phonon-induced transparency is highly controllable by electric field, excitation energy and power. Here we review the molecular polaron formation via optical phonons and we investigate an analogous transparency induced by acoustic phonons. Photoluminescence excitation spectroscopy is used to probe the characteristics of the transparency. The study tests the molecular polaron formation as a function of the longitudinal acoustic phonon density of states in the range from 10 meV to 20 meV above the bare single dot-like neutral exciton ground state transition. [1] M. L. Kerfoot et al., Nat. Commun. 5, 3299 (2014).
4:06PM D13.00009 Quantum-confined Stark shifts of quantum-dot like states in GaAs/AlGaAs core multi-shell nanowires, TENG SHI, BEKELE BADADA, HOWARD JACKSON, LEIGH SMITH, Dept. of Physics, Univ of Cincinnati, CHANGXIN ZHENG, JOANNE ETHERIDGE, Monash Centre for Electron Microscopy, Monash University, NIAN JIANG, QIANG GAO, HOE TAN, CHENNUPATI JAGADISH, Dept. of Electronic and Materials Engineering, Australian National University — A 4nm GaAs quantum well tube sandwiched by AlGaAs barriers is formed surrounding a central 50nm GaAs core. The GaAs/AlGaAs core multi-shell nanowires were grown by MOCVD. Single nanowire devices were fabricated through photolithography followed by deposition of Ti/AI metal contacts. We observed photoluminescence (PL) emission with multiple sharp peaks on a single nanowire device at 10K. We attribute this quantum-dot (QD) like states to well width and alloy fluctuations. We apply a bias across the device to investigate the quenching of PL due to external field ionization of excitons and the Stark shifts in these QD like states. Integrated PL emission show quenching on the high energy side at a lower bias voltage compared to the low energy side. Quantum confined Stark shifts on individual QDs are observed in the range of couple hundreds of micro-eV, suggesting QD sizes varying from 7 to 15nm. We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, and the Australian Research Council.

4:18PM D13.00010 Probing the band-structures and carrier dynamics of single GaAsSb nanowire heterostructures, YUDA WANG, BEKELE BADADA, HOWARD JACKSON, LEIGH SMITH, Dept. of Physics, Univ of Cincinnati, XIAOMING YUAN, PHILIPPE CAROFF, LAN FU, HOE TAN, CHENNUPATI JAGADISH, Dept. Electronic and Materials Engineering, Australian National University — We present the band structure and carrier relaxation of MOVCD grown single GaAs1-xSbx using photocurrent (PC) spectroscopy and transient Rayleigh Scattering (TRS) spectroscopy techniques. The PC spectroscopy was performed on nanowire devices fabricated using e-beam lithography and deposition of Ti/Au as contacts. The devices show nearly Ohmic behavior and are photosensitive. PC spectra shows an onset of absorption at room temperature in agreement with reported values of bulk GaAs0.6Sb0.4. We also used low temperature (10K) transient Rayleigh scattering (TRS) spectroscopy to measure the band structure as well as carrier relaxation dynamics of individual GaAsSb (x=30% and 40%) nanowires with and without InP passivation layers. The band gaps extracted from the TRS experiments are consistent with both photoluminescence (PL) measurements and theoretical predictions. The InP passivated GaAsSb shows smaller Eg due to the tensile strain from InP on GaAsSb as well as longer lifetimes due to the surface passivation. The carrier density and temperature are extracted by a phenomenological fitting model based on band to band transition theory. We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, and the Australian Research Council.

4:30PM D13.00011 Superfluorescence from semiconductor quantum wells: magnetic field, temperature, and density dependence, KANKAN CONG, Rice University, JI-HEE KIM, Sungkyunkwan University, G. TIMOTHY NOE II, Rice University, STEPHEN A. MCGILL, National High Magnetic Field Laboratory, Florida State University, YONGRUI WANG, ALEXEY A. BELYANIN, Texas A&M University, JUNICHIRO KONO, Rice University, STEPHEN A. MCGILL COLLABORATION, ALEXEY A. BELYANIN COLLABORATION — In the phenomenon of superfluorescence (SF), a macroscopic polarization spontaneously builds up from an initially incoherent ensemble of excited dipoles and then cooperatively decays, producing giant pulses of coherent radiation. SF arising from electron-hole recombination has recently been observed in semiconductor quantum wells, but its observability conditions have not been fully understood. Here, by fully mapping out the magnetic field (B), temperature (T), and pump power (P) dependence of SF intensity and linewidth, we have constructed a “phase” diagram, showing the B-T-P region in which SF is observable. In general, SF can be observed only at low enough temperatures, high enough magnetic fields, and high enough laser powers with characteristic threshold behaviors. For example, for the (11) inter-Landau-level transition, when B = 17.5T and P = 4mW, SF can be observed only when T < 105K; at B = 17.5T and T = 4K, SF can only be induced by excitation power P > 0.05mW. These results lay the foundation of our understanding of electron-hole SF and provide guidelines for our search for a Bardeen-Cooper-Schrieffer state of excitons.

4:42PM D13.00012 Artificial graphene in nanopatterned GaAs Quantum Wells1, SHENG WANG, DIEGO SCARABELLI, Department of Applied Physics, Columbia University, ANTONIO LEVY, Department of Physics, Columbia University, LOREN PFEIFFER, KEN WEST, Department of Electrical Engineering, Princeton University, VITTORIO PELLEGRINI, Italian Institute of Technology, Genoa, Italy, MICHAEL J. MANFRA, Department of Physics and Astronomy, and School of Materials Engineering, and School of Electrical and Computer Engineering, Purdue University, SHALOM WIND, Department of Applied Physics, Columbia University, ARON PINCZUK, Department of Physics and Department of Applied Physics, Columbia University — Electrons in graphene have linear energy-momentum dispersion, making them massless Dirac fermions. An alternative way to achieve massless Dirac-fermions in a controllable and tunable manner is to construct a honeycomb lattice potential for a 2D electron gas in a semiconductor quantum well. We report realization of very short period (as small as 40 nm) honeycomb lattice pattern using e-beam lithography and drying etching on a GaAs quantum well and scanning electron microscopy (SEM) images of the honeycomb pattern. We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, and the Australian Research Council.

4:54PM D13.00013 Nanoscale light emission: direct bandgap versus indirect bandgap1, JUN-WEI LUO, SHU-SHEN LI, Institute of Semiconductors, Chinese Academy of Sci (CAS) — The electron-hole Coulomb interaction bounds an electron and a hole together forming an exciton and the e-h exchange interaction lifts the spin-allowed bright exciton state up with respect to the spin-forbidden dark state by an energy of ~1 meV to tens meV depending on the NCs size. The recombination dynamics of the NC exciton remains open to debate, especially at high temperatures (T > 20 K). One perception is a weak exchange interaction of dark excitons with the ensemble of dangling bonds on the NC surface, resulting in spin flip assisted recombination directly from the dark state. Another perception is thermal redistribution of excitons between the dark and bright states. By performing atomistic pseudopotential calculations of indirect bandgap Si NCs and direct bandgap InAs NCs in a large range of NC sizes, we found that the predicted recombination rates of NC excitons are in excellent agreement with experimental data provided by various groups. This agreement confirms the explanation of thermal activation of bright state of excition recombination dynamics in NCs. We also found that the exciton recombination rates, as function of confinement energy, of indirect bandgap NCs is distinct from direct bandgap NCs. More detail theoretical analyses will be presented.

5:06PM D13.00014 White and Red Light Photoluminescence of ZnS:Eu$^{3+}$ - CMC Nanophosphors, AHEMEN IKORKYA, Department of Physics, University of Agriculture Makurdi, Nigeria, DILIP DE, Department of Physics, Covenant University, Ota, Ogun State, Nigeria, OSITA MELEDU, Department of Physics, Modibo Adamawa University of Technology, Yola, Adamawa, Nigeria, V. BRUNO, Laboratoire de Chimie de la Matière Condensée de Paris — White and red photoluminescence based on europium-doped zinc sulfide nanocrystals capped with sodium carboxymethyl cellulose (ZnS: Eu$^{3+}$ - CMC) was synthesized using precipitation technique with Eu$^{3+}$ ions doping concentrations of 1 mol% and 5 mol%. Some portions of the doped samples were annealed at 300 °C in a sulfur-rich atmosphere. All samples show cubic (zinc blende) structure with crystal sizes; 2.56 nm and 2.91 nm, for the as-synthesized samples, 4.35 nm and 3.65 nm for thermally treated samples, respectively. The as-synthesized samples have equal energy band gap of 4.2 eV, but decreased to 3.76 eV and 3.81 eV after heat treatment. Photoluminescence studies indicate defect emission bands and Eu$^{3+}$ ion lines for the as-synthesized samples. The as-synthesized samples gave pure orange-red emission when excited at wavelength of 394 nm and 465 nm. After thermal annealing of the samples, a broad emission band in the blue-green region assigned to defect related states emerged or were enhanced. Also enhanced were the emission lines of Eu$^{3+}$ ions in the orange-red region. A combination of these two transitions gave white light of different shades depending on Eu concentration or excitation wavelength. Different shades of white light from cool white through Day-light to warm white light were recorded on the CIE 1931 chromaticity diagram. The source excitation wavelengths range from UV-330 nm through near UV ~ 396 nm to blue - 465 nm wavelengths which are in the range of InGaN - based LEDs emissions.

5:18PM D13.00015 The Influence of Impurity Doping On the Phase Transition and Morphology Tuning of Sr/CaFCl: Yb$^{3+}$, Er$^{3+}$ Nanoparticles, YUE CUI, Wake Forest Univ, SULING ZHAO, Beijing Jiaotong University, WENXIAO HUANG, Wake Forest Univ, ZHENGYU XU, Beijing Jiaotong University, YUAN LI, DAVID CARROLL, Wake Forest Univ, SULING ZHAO TEAM — Upconversion nanoparticles (UCNPs) are well-known for their unique luminescent properties that enable the conversion of low-energy photons into high-energy photons by multiphoton processes. In this work, Sr/CaFCl: Yb$^{3+}$,Er$^{3+}$ NCs with a wide range of ions dopant concentrations were synthesized, and strong green and red upconversion fluorescence were observed under laser excitation at a wavelength of 980 nm. The influence and mechanism of ions dopant are demonstrated and discussed. The ions doped concentration has a significant influence on the phase-transfer of the host material and on the corresponding upconversion emissions, and the mechanism of which was studied. In addition, the optimized concentration represents a good balance between the occurrence of the phase transition and concentration quenching. These high-efficiency nanoparticles have potential applications in the fields of optical nanodevices and biomedicine.

Session D14 DCMP: Invited Session: Bulk and Surface Spectroscopy of Mixed Valence Topological Insulator Samarium Hexaboride 008A - James W. Allen, University of Michigan

2:30PM D14.00001 Quantum Oscillations in Kondo Insulator SmB$_6$, LU LI, University of Michigan — In Kondo insulator samarium hexaboride SmB$_6$, strong correlation and band hybridization lead to a diverging resistance at low temperature. The resistance divergence ends at about 3 Kelvin, a behavior recently demonstrated to arise from the surface conductance. However, questions remain whether and where a topological surface state exists. Quantum oscillations have not been observed to map the Fermi surface. We solve the problem by resolving the Landau Level quantization and Fermi surface topology using torque magnetometry. The observed angular dependence of the Fermi surface cross section suggests two-dimensional surface states on the (101) and (100) plane. Furthermore, similar to the quantum Hall states for graphene, the tracking of the Landau Levels in the infinite magnetic field limit points to -1/2, the Berry phase contribution from the 2D Dirac electronic state.

3:06PM D14.00002 Spin- and angle-resolved photoemission on the first topological Kondo Insulator: SmB$_6$, MING SHI, Paul Scherrer Institute — The concept of a topological Kondo insulator (TKI) has been brought forward as a new class of topological insulators in which non-trivial surface states appear in the bulk Kondo band gap at low temperatures due to the strong spin-orbit coupling. Theoretical considerations have shown that SmB$_6$ is a promising candidate for the first realization of TKIs. In this contribution we will present comprehensive studies of the bulk and surface electronic structures of SmB$_6$. Using high-resolution angle-resolved photoemission spectroscopy (ARPES) we revealed that the two-dimensional surface states reside within a bulk Kondo gap and form three Fermi surfaces in the surface Brillouin zone [1]. The odd number of surface bands crossing the Fermi level fulfills the necessary condition of topologically nontrivial surface states and is in good agreement with the theoretical prediction. Applying spin-resolved ARPES to SmB$_6$, we show that the energy bands of the surface states around the X bar points are spin-polarized. The spins of the surface states are locked to crystal momentum and the spin-helical structure fulfills the requirement of time-reversal symmetry [2]. Our results prove that SmB$_6$ is the first realization of strongly correlated topological Kondo insulator. We will also show the evolution of the bulk electronic structure from a metallic state at high temperatures to a Kondo insulating phase, and how the non-trivial states appear in the system [3].

This work was supported by the Sino-Swiss Science and Technology Cooperation and the Swiss National Science Foundation.

3:42PM D14.00003 Interaction-driven sub-gap resonance in the topological Kondo insulator SmB$_6$, WESLEY FUHRMAN, Johns Hopkins University — Samarium hexaboride (SmB$_6$) is a strongly correlated Kondo Insulator with a non-trivial band-structure topology. I will discuss recent neutron scattering experiments and analysis that expose a 14 meV resonant mode in SmB$_6$ and relate it to the low energy insulating band structure. Repeating outside the first Brillouin zone, the mode is coherent with a 5d-like magnetic form factor. I will discuss how band inversion can be inferred from neutron scattering and show that a perturbative slave boson treatment of a hybridized 2 species (d/f) band structure within an Anderson model can produce a spin exciton with the observed characteristics. This analysis provides a detailed physical picture of how the SmB$_6$ band topology arises from strong electron interactions, and accounts for the 14 meV resonant mode as a magnetically active exciton.

This work was supported by the US Department of Energy, office of Basic Energy Sciences, Division of Material Sciences and Engineering under grant DE-FG02-08ER46544.
4:18PM D14.00004 Surface structure of SmB$_6$ investigated by STM and HAXPES. STEFFEN WIRTH, MPI for Chemical Physics of Solids Dresden, Germany — The intermediate-valence compound SmB$_6$ is typically considered a “Kondo insulator” albeit the concept of the Kondo effect does, in principle, not hold for an intermediate-valence material. Nonetheless, the hybridization between conduction electrons and the strongly interacting Sm $f$-electrons results in a gap at the Fermi energy and hence, an insulating ground state arises at temperatures below about 40 K. Recently, SmB$_6$ has become of enormous topical interest because it is a candidate material for hosting topologically protected surface states. The intermediate valence of Sm in SmB$_6$ was confirmed by HAXPES measurements down to 5 K. Such measurements conducted at high photon energies for improved probing depth are of importance in view of valency limits given for strong topological insulators [1]. Scanning tunneling microscopy (STM) has the unique capability of providing combined topographic and spectroscopic information. We conducted STM on numerous samples cleaved in situ at around 20 K [2]. Cleavage along the (001) plane of the cubic structure through breaking inter-octahedral B-B bonds gives rise to polar surfaces. In result, we found disordered chain-like as well as ordered (2 x 1) surface reconstructions. Occasionally, we also observed patches of non-reconstructed surface areas of both, Sm and B termination. On such areas, we found indications for the Kondo effect being at play. Also, for non-reconstructed surface areas of some ten nanometers in size the $dI/dV$-curves can be well described by a Fano resonance. Thus, the hybridization picture typically considered for this material could be fully confirmed. All types of surfaces, reconstructed and non-reconstructed, displayed a finite zero-bias conductance of considerable magnitude. This finding, in spite of different surface topologies, confirms the robustness of the metallic states and is in line with the proposal of SmB$_6$ being a topological insulator.

4:54PM D14.00005 Temperature dependence, termination dependence, and the spin chirality of the electronic structure of a mixed-valent topological insulator: SmB$_6$. BYUNG IL MIN, POSTECH — A great deal of recent effort has been paid to demonstrate the topological origin of a strongly correlated mixed-valent insulator SmB$_6$. Despite extensive research, however, there is no consensus yet on the topological nature of the Kondo insulator SmB$_6$. In this respect, the works reported so far need be reexamined carefully to see whether the reported results are relevant to the intrinsic property or not. For example, the termination-dependent physical properties of the surface in-gap states in SmB$_6$ have hardly been examined seriously. Also it is important to investigate the spin chirality of the surface states in SmB$_6$. Furthermore, if bulk SmB$_6$ is really a Kondo insulator, its energy gap should have a many-body origin. Then the temperature-dependent evolution of electronic structure is expected in both the bulk and surface bands, which can be measured by ARPES. We have investigated the topological properties of SmB$_6$, based on the dynamical mean-field theory (DMFT) calculations [1] and the density-functional theory (DFT) slab calculations [2], and compared them with those of a similar mixed-valent system of golden phase SmS and other hexaboride systems.

Session D15 DCMP: Invited Session: Quantum Criticality at the Superconductor-Insulator Transition and the Higgs Mode 008B — Subir Sachdev, Harvard University

1Support of US-Israel Binational Science Foundation is gratefully acknowledged

3:06PM D15.00002 Quantum critical dynamics without quasiparticles. WILLIAM WITCZAK-KREMPA, Perimeter Institute for Theoretical Physics — Understanding the real-time behavior of quantum systems without long-lived excitations (quasiparticles) constitutes a challenging problem. I’ll discuss recent progress concerning the dynamics of quantum critical systems, in which quantum fluctuations destroy quasiparticles. I’ll show concrete results stemming from an interdisciplinary approach combining field theory, quantum Monte Carlo simulations, and the holographic gauge/gravity duality (AdS/CFT). In particular, experimental predictions will be made regarding the charge response near the superfluid-insulator quantum critical transition of bosons on a 2d lattice. Extensions to other observables and universality classes will be discussed.

3:42PM D15.00003 Evolution of the electronic spectral function and dynamical conductivity across the disorder-tuned superconductor-insulator transition¹. NANDINI TRIVEDI, The Ohio State University, Columbus, OH 43220 — I will discuss the behavior of the single particle electronic spectral function, the bosonic (pair) spectral function \( P(\omega) \), and the dynamical conductivity \( \sigma(\omega) \) across the superconductor-insulator transition (SIT) calculated using quantum Monte Carlo simulations [1]. The transition is driven by tuning the charging energy relative to the Josephson coupling or by varying the degree of disorder. We identify a prominent Higgs mode in the superconductor, and characteristic energy scales in the insulator, that vanish at the transition due to enhanced quantum phase fluctuations, despite the persistence of a robust fermionic gap across the SIT [2]. Disorder leads to increased absorption at low frequencies compared to the SIT in a clean system. Disorder also expands the quantum critical region, due to a change in the universality class, with an underlying \( T=0 \) critical point. Obtaining the conductivity at the transition has been problematical because of analytic continuation of numerical data. We propose a well-defined integrated low-frequency conductivity that can be reliably estimated and discuss its universality.

4:18PM D15.00004 Emergence of nanoscale inhomogeneity and finite frequency superfluid response in disordered superconductors, PRATAP RAYCHAUDHURI, Tata Institute of Fundamental Research, Mumbai — The notion of spontaneous formation of an inhomogeneous superconducting state is at the heart of most theories attempting to understand the superconducting state in the presence of strong disorder. Using a combination of low-temperature scanning tunneling spectroscopy and high resolution scanning transmission electron microscopy, we experimentally demonstrate that under the competing effects of strong homogeneous disorder and superconducting correlations, the superconducting state of a conventional superconductor, NbN, spontaneously segregates into domains. Tracking the superconducting state as a function of temperature we show that these superconducting domains persist across the bulk superconducting transition, \( T_c \), and disappear close to the pseudogap temperature, \( T^* \), where signatures of superconducting correlations disappear from the tunneling spectrum and the superfluid response of the system. These results along with complementary measurements of the superfluid stiffness at microwave frequencies underpins the importance of phase fluctuations in strongly disordered s-wave superconductors.

4:54PM D15.00005 The Higgs Mode in Disordered Superconductors Close to a Quantum Phase Transition¹. AVIAD FRYDMAN, Bar Ilan University — The Higgs theory, which generates mass for elementary particles, was inspired by screening of magnetic fields in superconductors. The same theory also predicts an amplitude mode whose high-energy-physics analogue is the famous Higgs particle. It is somewhat disappointing that in superconductors, the Higgs-amplitude mode has not yet been observed, partially because it can rapidly decay into unpaired electrons. Nevertheless, recent theories show that if the Higgs mass could be softened below the pairing gap it should be visible in two dimensions. Such conditions can be met by tuning a superconducting film towards a quantum critical point (QCP). I will report on spectroscopic studies in the terahertz frequency regime of thin superconducting films for which the superconductor to insulator transition (SIT) is tuned by disorder. Tunneling spectroscopy determines the pairing gap \( 2\Delta \) which remains finite on both sides of the SIT. In contrast, the threshold frequency for dynamical conductivity, which in BCS theory is associated with the gap, vanishes critically toward the SIT. The excess optical spectral weight below \( 2\Delta \) is identified as an unambiguous observation of the Higgs mode in a superconductor.

Monday, March 2, 2015 2:30PM - 5:18PM — Session D16 DMP: Focus Session: Machine Learning For Materials Discovery 101AB - Marco Nardelli, University of North Texas

2:30PM D16.00001 Machine Learning methods in fitting first-principles total energies for substitutionally disordered solid¹. QIN GAO, SANXI YAO, MICHAEL WIDOM, Carnegie Mellon University — Density functional theory (DFT) provides an accurate and first-principles description of solid structures and total energies. However, it is highly time-consuming to calculate structures with hundreds of atoms in the unit cell and almost not possible to calculate thousands of atoms. We apply and adapt machine learning algorithms, including compressive sensing, support vector regression and artificial neural networks to fit the DFT total energies of substitutionally disordered boron carbide. The nonparametric kernel method is also included in our models. Our fitted total energy model reproduces the DFT energies with prediction error of around 1 meV/atom. The assumptions of these machine learning models and applications of the fitted total energies will also be discussed.

¹Financial support from McWilliams Fellowship and the ONR-MURI under the grant NO. N00014-11-1-0678 is gratefully acknowledged.

2:42PM D16.00002 Phase Transitions of Boron Carbide: Pair Interaction Model of High Carbon Limit. SANXI YAO, MICHAEL WIDOM, Carnegie Mellon University, WILLIAM HUHN, Duke University, QIN GAO, Carnegie Mellon University — Boron carbide is a structure that exhibits a broad composition range, implying a degree of intrinsic substitutional disorder. While the observed symmetry is rhombohedral, the enthalpy minimizing structure has lower, monoclinic, symmetry. With high melting temperature, it is difficult to experimentally study its phase transition at low temperature and there is discrepancy among different research groups. Moreover, the widely-accepted phase diagram suggests substitutional disorder at low temperature, implying a non vanishing entropy. Here we use computational method to study its phase transition. We implement a pair interaction model and fit to a database of structural energies. Utilizing histogram methods to analyze Monte Carlo simulations of this model, we investigate the symmetry-restoring phase transition that explains the observed rhombohedral symmetry at high temperatures.
2:54PM D16.00003 Unsupervised machine learning on atomistic configurations: examples on amorphous defects and energy landscapes, EKIN CUBUK, Harvard University, SAMUEL SCHOENHOLZ, ANDREA LIU, University of Pennsylvania, EFTIMIOS KAXIRAS, Harvard University — Due to the recent availability of very large datasets, machine learning (ML) methods are gaining popularity as approximation and optimization tools in solid state physics. We have recently shown that supervised ML can also be used to identify and analyze soft particles, particles susceptible to rearrangement, in amorphous solids [1]. Our method can be used to understand what makes certain configurations of particles more prone to rearrangement, and design stronger materials. We use unsupervised ML and nonlinear dimensionality reduction methods, where we do not need a “training set” to train the algorithm, to explore better representations of atomic configurations. These representations are shown to provide important physical insights into the structure of soft spots and stable regions in several computational and experimental glassy systems, as well as the energy landscapes of quantum mechanical systems based on Density Functional Theory calculations. By discovering an improved representation and visualization of relevant energy landscapes, discovery and optimization efforts can be simplified.

3:06PM D16.00004 Machine Learning Methods for the Sampling of Chemical Space From First Principles, RAGHU RAMAKRISHNAN, University of Basel — Computational brute force high-throughput screening of compounds is beyond any capacity for all but the most restricted systems due to the combinatorial nature of chemical space, i.e. all the compositional, constitutional, and conformational isomers. Efficient computational materials design algorithms must therefore make good trade-offs between the accuracy of the applied model and computational speed. Overall, rapid convergence in terms of number of compounds visited is highly desirable. In this talk, I will describe recent contributions in this field based on statistical approaches that can serve as inexpensive surrogate models to reduce the computational load of quantum mechanical calculations. Such surrogate machine learning (ML) models infer quantum mechanical observables of novel materials, rather than solving approximate variants of Schrodinger’s equation. We developed accurate ML models for the rapid prediction of atomization energies and enthalpies, cohesive energies, and electronic properties that conventionally can only be predicted using quantum mechanics. All our ML models have been trained using large data bases containing properties of thousands of chemical compounds and materials. I will exemplify our approach for the prediction of properties from scratch for out-of-sample compounds. These predictions reach quantum chemical accuracy and are basically instantaneous, i.e. at a computational cost reduced by several orders of magnitude.

3:42PM D16.00005 Informatics guided Search for Magnetic Apatites, PRASANNA V. BALACHANDRAN, TURAB LOOKMAN, Los Alamos National Laboratory — Materials with apatite crystal structure have applications ranging from biomaterials to electrolytes for solid oxide fuel cells. Their chemical flexibility and structural diversity provide a fertile ground to tune functionalities as potential candidates for many applications. However, magnetic apatites are rare. In this work, we use machine learning methods to rapidly screen a vast chemical space and identify novel apatite compositions with magnetic ions. We first construct a database of known materials from searching the experimental literature. We then augment the database with features that capture the trends in geometry and bonding characteristics of apatites. Supervised classification learning forms the basis of our machine learning approach through which we uncover design rules that enable prediction of potentially stable magnetic apatite compositions, prior to experimental synthesis. Finally, we validate our predictions using density functional theory calculations.

3:54PM D16.00006 Using Data Mining Algorithms in Solid State Physics, TROY LYONS, Central Michigan University, NICHOLAS MECHOLSKY, The Catholic University of America, STEFANO CURTAROLO, Duke University, MARCO BUONGIORNO NARDELLI, University of North Texas, MARCO FORNARI, Central Michigan University — We processed large materials databases with data mining methods such as clustering and classification in order to assign specific questions in the field of thermoelectric materials and transparent conductors. Our goal is to extract meaningful information from band structures repositories such as AFLLOWLIB. Our implementation is validated using a toy database that mimics the complexity of AFLLOWLIB, which has also been solved analytically. We found that even when the analytical solution is known, proper data analysis can help to understand physical phenomena.

4:06PM D16.00007 Interplay of Atomic and Electronic Structure in Second Harmonic Generating Nonlinear Optical Materials, ANTONIO CAMMARATA, Czech Technical University in Prague, JAMES RONDINELLI, Northwestern University — Group theoretical methods and ab initio electronic structure calculations are combined to formulate a general Symmetry-Assisted Functional Optical Response (SAFOR) protocol to understand and predict the second harmonic generation (SHG) response in nonlinear optical crystals. We show that the SHG coefficients may be decomposed into atomic contributions from various inversion symmetry lifting distortions, which we parametrize as symmetry-adapted displacement patterns that transform as irreducible representations of a relevant centrosymmetric parent structure. The SAFOR protocol is then combined with an electronic descriptor for bond covalency to explain the origin of SHG in noncentrosymmetric-nonpolar JTeMoO$_6$ telluromolybdate compounds. We show that the SHG response has a complex dependence on the asymmetric geometry of the polyhedral units and the orbital character at the valence band edge. The atomic scale and electronic structure understanding of the macroscopic SHG behavior obtained with these descriptions is then used to identify hypothetical HgTeMoO$_6$ as a candidate telluromolybdate, which we predict should exhibit the largest SHG response in the JTeMoO$_6$ family.

4:18PM D16.00008 Materials Cartography: Representing and Mining Material Space Using Structural and Electronic Fingerprints, COREY OSES, Duke Univ, OLEXANDR ISAYEV, DENIS FOURCHES, EUGENE MURATOVI, UNC Chapel Hill, KEVIN RASCH, Duke Univ, ALEXANDER TROPISHA, UNC Chapel Hill, STEFANO CURTAROLO, Duke Univ, CENTER FOR MATERIALS GENOMICS, DUKE UNIVERSITY COLLABORATION, LABORATORY FOR MOLECULAR MODELING, UNC CHAPEL HILL COLLABORATION — As the proliferation of high-throughput approaches in materials science is increasing the wealth of data in the field, the gap between accumulated-information and derived-knowledge widens. We address the issue of scientific discovery in materials databases by introducing novel analytical approaches based on structural and electronic materials fingerprints. The framework is employed to (i) query large databases of materials using similarity concepts, (ii) map the connectivity of the materials space (i.e., as a materials cartogram) for rapidly identifying regions with unique organizations/properties, and (iii) develop predictive Quantitative Materials Structure-Property Relationships (QMSPR) models for guiding materials design. In this study, we test these fingerprints by seeking target material properties. As a quantitative example, we model the critical temperatures of known superconductors. Our novel materials fingerprinting and materials cartography approaches contribute to the emerging field of materials informatics by enabling effective computational tools to analyze, visualize, model, and design new materials.
several decades ago, enabled an average success in classification of (non-rocksalt structures and thus performed a binary classification task. We found that using the standard indices various forms of cross-validation, for the task of classifying the crystal structures of the octet AB solids. We partitioned a set of 75 solids into rocksalt and PILANIA, T. LOOKMAN, Los Alamos National Laboratory — We explored the use of machine learning methods, specifically support vector machines and in GNEMR and may help further study of the intrinsic electrical properties of the materials under strain. model-based fittings determine the intrinsic stain and mass of graphene samples accurately. Our devices allow thorough exploration of the nonlinear dynamics the model and matches with experimental data. Results from numerical simulation demonstrate also the transition in the nonlinear behavior. Additionally, the nanoelectromechanical resonators (GNEMR) on flexible substrates. The intrinsic stain in graphene is tuned by bending the substrate, during which a transition from hardening to softening resonance behavior and a minimum resonance frequency are observed. To explain these observations, a resonator model taking from hardening to softening resonance behavior and a minimum resonance frequency are observed. To explain these observations, a resonator model taking 1Supported by the Department of Energy.

4:42PM D16.00010 Structure classification of AB solids via machine learning1, J.E. GUBERNITIS, G. PILANIA, T. LOOKMAN, Los Alamos National Laboratory — We explored the use of machine learning methods, specifically support vector machines and various forms of cross-validation, for the task of classifying the crystal structures of the octet AB solids. We partitioned a set of 75 solids into rocksalt and non-rocksalt structures and thus performed a binary classification task. We found that using the standard indices (rσ, rπ), suggested by St. John and Bloch several decades ago, enabled an average success in classification of 92%. Our main new result is our finding that using just rσ and the excess Born effective charge ∆Z_A of the A atom, computed by DFT, enabled an average success of 98%, prompting us to propose (rσ, ∆Z_A) as a replacement for the St. John-Bloch pair. In general, we found that adding one or two other features to the St. John-Bloch pair, unless they include the excess Born effective charge, generally decreases the average success rate.

5:06PM D16.00012 Force field development from first principles for materials design, MARIA CHAN, ALPER KINACI, BADRI NARAYANAN, FAITH SEN, STEPHEN GRAY, MICHAEL DAVIS, SUBRAMANIAN SANKARANARYANAN, Argonne National Laboratory — The ability to perform accurate calculations efficiently is crucial for computational materials design. In this talk, we will discuss a stream-lined approach to force field development using first principles density functional theory training data and machine learning algorithms. We will also discuss the validation of this approach on precious metal nanoparticles.

2:30PM D17.00001 Graphene Electrostatic Microphone, QIN ZHOU1, SEITA ONISHI2, A. ZETTL3, Department of Physics, University of California - Berkeley — We demonstrate a wideband electrostatic graphene microphone displaying flat frequency response over the entire human audible region as well as into the ultrasonic regime. Using the microphone, low-level ultrasonic bat calls are successfully recorded. The microphone can be paired with a similarly constructed electrostatic graphene loudspeaker to create a wideband ultrasonic radio.

4:24PM D17.00002 Nonlinear dynamics in tunable graphene nanoelectromechanical systems, FEN GUAN, PIRANAVAN KUMARAVADIVEL, DIMITRI AVERIN, XU DU, Stony Brook University — We report the fabrication and characterization of graphene nanoelectromechanical resonators (GNEMR) on flexible substrates. The intrinsic stain in graphene is tuned by bending the substrate, during which a transition from hardening to softening resonance behavior and a minimum resonance frequency are observed. To explain these observations, a resonator model taking into account the intrinsic strain and electrostatic force is developed. Including higher-order nonlinear terms, a minimum frequency is obtained analytically from the model and matches with experimental data. Results from numerical simulation demonstrate also the transition in the nonlinear behavior. Additionally, the model-based fittings determine the intrinsic strain and mass of graphene samples accurately. Our devices allow thorough exploration of the nonlinear dynamics in GNEMR and may help further study of the intrinsic electrical properties of the materials under strain.
2:54PM D17.00003 High frequency nanomechanical resonators in ultraclean suspended graphene pn junctions, MINKYUNG JUNG, PETER RICKHAUS, SIMON ZIHMANN, PETER MAKK, Department of Physics, University of Basel. ALEXANDER EICHLER, Department of Physics, ETH Zurich, MARKUS WEISS, CHRISTIAN SCHÖNENBERGER, Department of Physics, University of Basel. DEPARTMENT OF PHYSICS, UNIVERSITY OF BASEL TEAM, DEPARTMENT OF PHYSICS, ETH ZURICH TEAM — Here, we demonstrate high frequency nanomechanical resonators in ultraclean suspended graphene pn junctions. The suspended graphene resonators are fabricated on two bottom gates (left and right) covered with lift-off resist (LOR) by using a mechanical transfer technique. After current annealing, the device exhibits a clear charge neutrality point around zero gate voltage. Depending on the left and right bottom gate voltages, the device shows four different conductance regimes: pp, np, pn and pp regimes. The clear Fabry-Perot interference pattern is observed, indicating ballistic transport behavior over 1 μm-long channel. Then, the mechanical resonance is measured in the same device with a frequency modulation (FM) mixing technique at 4.2 K in the vacuum chamber. The resonance frequency is about 405 MHz. By fitting resonance frequency, we deduce both the mass density and the built-in tension in the graphene sheet. In a similar device structure with different strain environment, we observe a resonance frequency as high as 1.17 GHz for the fundamental mode.

3:06PM D17.00004 Angle dependent phonon spectra and thermal properties of misoriented bilayer graphene, MAHESH NEUPANE, Department of Electrical and Computer Engineering, Univ of California - Riverside, PANKAJ RAMNANI, Department of Chemical and Environmental Engineering, Univ of California, Riverside, SUPENG GE, Department of Physics and Astronomy, University of California, Riverside, ASHOK MULCHANDANI, Department of Chemical and Environmental Engineering, Univ of California, Riverside, ROGER LAKE, Department of Electrical and Computer Engineering, Univ of California - Riverside — The Raman spectra of misoriented bilayer graphene (MBG) show angle dependent signatures of the misorientation angle (θ) in the low frequency breathing modes. We investigate these low frequency modes using molecular dynamics including temperature dependent phonon anharmonicity. The calculated vibrational and thermal properties are compared against our experimental data. Our theoretical investigations reveal that the layer breathing mode (LBM) frequencies at 100 ± 10 cm⁻¹ for angles 6° ≤ θ ≤ 30° are consistent with the observed frequencies of ZO modes in the Raman spectrum. For the smaller θ (or larger L), the reduced BZ leads to the zone-folding of the phonon dispersion and doping depends on the orientation of the lattice specific heat capacity.

3:18PM D17.00005 Strain in Transferred Graphene at Low Temperatures, JUAN AGUILERA-SERVIN, ADRIAN NOSEK, CHENG PAN, MARC BOCKRATH, Univ of California - Riverside — Strain in graphene layers produces synthetic gauge fields that may be used to modify the properties of its electron system [1,2]. We study single layers of graphene transferred over Ti/Au electrical contacts on oxidized Si wafers with etched triangular holes in the oxide. The layers are strainied by applying pressure electrostatically using a gate voltage and hydrostatically using an external inert gas. We investigate electronic transport in this suspended variable-strain graphen system at low temperatures. We will discuss our latest results.

3:30PM D17.00006 Control Over the Adhesion and Strain on Graphene Using Arrays of Mesoscale Pyramids, STEPHEN GILL, University of Illinois at Urbana-Champaign, SHUZE ZHU, University of Maryland, J. HENRY HINNEFELD, WILLIAM SWANSON, University of Illinois at Urbana-Champaign, TENG LI, University of Maryland, NADYA MASON, University of Illinois at Urbana-Champaign — Applying non-uniform shear stress to graphene can lead to new electronic states. For example, strain having triangular symmetry has been shown theoretically and experimentally to generate a nearly uniform pseudo-magnetic field [1,2]. However, the lack of methods to control non-uniform strain in graphene devices has limited the ability to explore transport phenomena tuned by strain. In this talk, we demonstrate that the adhesion and strain of graphene can be controlled by using arrays of mesoscale pyramids. By manipulating the arrangement of pyramids and the aspect ratio of the array, graphene’s adhesion to the array range from conformal to suspended between pyramids. Strain in graphene adhered to pyramids is revealed by Raman spectroscopy, and the amount of strain experienced is shown to depend on the adhesion to the pyramids. Support calculations demonstrate the pseudo-magnetic field profile for graphene adhered to pyramids for different strains. These results indicate a potential route for exploring strain-controlled transport phenomena in graphene.

3:42PM D17.00007 Electron-phonon interactions in bilayer graphene, HELI VORA, NIST-Boulder, XU DU, Department of Physics and Astronomy, Stony Brook University — We report measurements on electron thermal conductance in bilayer graphene due to cooling via phonons. The measurements were carried out using bilayer graphene-superconductor tunnel junctions, where the superconducting contacts effectively confine the hot electron inside the graphene channel, allowing access to the electron cooling at low temperatures. We show results on the temperature and doping dependence of the cooling power in bilayer graphene. Contrary to what was observed in monolayer graphene, the phonon cooling power decreases with increasing carrier density in bilayer graphene. The temperature dependence of the phonon cooling power can be described by a power law with a power factor ~ 5, again, qualitatively different from the T^3 temperature dependence observed in the disordered monolayer graphene. These new results may shed light on the dominating mechanisms for hot electron cooling bilayer graphene.

3:54PM D17.00008 Dissipation and feedback cooling of graphene and MoS2 nanomechanical resonators, RONALD VAN LEEUWEN, GARY STEELE, WARNER VENSTRA, HERRE VAN DER ZANT, Delft Univ of Tech, KAVLI INSTITUTE OF NANOSCIENCE TEAM — The interesting mechanical and electronic properties of 2-dimensional materials make them candidates for nano-electromechanical systems. Remarkably, the mechanical resonance linewidth of such suspended structures is found to be invariably low at room temperature. Time-domain measurements were used as a tool to differentiate between dissipation and non-dissipative frequency fluctuations, thus providing more insight in the origin of the low linewidth. We perform time-domain measurements on MoS2 resonators with thickness down to a single layer, and compare the relaxation times obtained from ringdown measurements to the resonance linewidth obtained from Brownian motion and driven frequency responses. We conclude that dephasing plays a negligible role in the thermal relaxation process as the finite damping linewidth is limited by the signal to noise ratio. To improve the damping we introduce an optical feedback technique. We demonstrate continuous tuning of the oscillator linewidth, by modifying the linewidth over 2 orders of magnitude. Feedback also enables cooling of the fundamental mode of graphene and MoS2 drum resonators down to an effective temperature of 100 K.

4:06PM D17.00009 Electron transport in graphene with uniaxial local strain, HIKARI TOMORI, Japan Science and Technology Agency and Univ. Tsukuba, RINEKE HIRAIIDE, HIROKAZU TANAKA, YU ITOU, KENTA KATAKURA, YOUSHI OOTUKA, AKINOBU KANDA, Univ of Tsukuba — Transport engineering is a promising method for controlling electron transport in graphene; Spatial variation of pseudo-vector potential and pseudo-scalar potential induced by lattice strain modulate transport property of graphene. We have succeed in fabricating a graphene FET with uniaxial local strain, and observed clear deformation in gate voltage dependence of conductivity (σ – Vg curve). From a comparison with numerical calculation, we conclude that strain-induced scalar potential is responsible for the deformation of the σ – Vg curve.
4:30PM D17.00011 Thermal Conductance of Epitaxial and Transferred CVD-Grown Graphene, JOYCE COPPOCK, PAVEL NAGORNYKH, IAN MCADAMS, BRUCE KANE, University of Maryland, College Park — Two-dimensional materials such as graphene tend to ripple in the out of plane direction. These ripples arise both due to thermal fluctuations and uneven stress forces at the boundary. In this work, we study the effect of the rippling on the effective mechanical properties of graphene: Young’s modulus and bending rigidity. To accomplish this, we developed a non-contact technique that allows probing mechanical properties of graphene at temperatures between 4K and 400K. We use a high voltage electrostatic force to pull on graphene and high-resolution optical interferometric profilometry to measure its mechanical response. We find that the effective Young’s modulus of graphene is significantly softened and the bending rigidity is increased due to rippling.

4:42PM D17.00012 Graphene Mechanical Resonators under Large Strain, SEITA ONISHI1, QIN ZHOU2, ALEX ZETTL3, Department of Physics, University of California, Berkeley, CA 94720, USA — Graphene has shown promise as a high frequency mechanical resonator due to its high Young’s modulus and light mass [1]. With large strains, theoretical predictions anticipate even changes to graphene’s band structure [2]. We developed an integrated platform to apply large strains on suspended graphene with a MEMS based actuator. We will show preliminary results on the optical detection of the change in resonance frequency as the graphene mechanical resonator is strained.

4:54PM D17.00013 Thermal and Thermoelectric Transport across Graphene/BN and Graphene/BN/Graphene Heterostructures, NIRAkar Poudel, University of Southern California — We report thermal and thermoelectric transport measurements across graphene/hexagonal boron nitride (h-BN)1 and graphene/hexagonal boron nitride (h-BN)/graphene2 heterostructure devices. Using an AC lock-in technique, we are able to separate the thermoelectric contribution to the I - V characteristics of these important device structures. The temperature gradient is measured using optical Raman spectroscopy, which enables us to explore thermoelectric transport produced at material interfaces, across length scales of just 1-2 nm. A temperature drop of 60 K can be achieved across this junction at high electrical powers (14 mW). Based on the temperature difference and the applied power data, we determine the thermal interface conductance of this junction to be 7.4 x108 W/m2·K, which is below the 10^-10 W/m2·K values previously reported for graphene/SiO2 interface. Based on the observed thermoelectric voltage (∆V) and temperature gradient (∆T), a Seebeck coefficient of 99.3 µV/K is ascertained for the heterostructure device.

5:06PM D17.00014 Development of a quadrupole trap apparatus for UHV measurements of levitated graphene, JOYCE COPPOCK, PAVEL NAGORNYKH, IAN MCADAMS, BRUCE KANE, University of Maryland, College Park — Completely decoupling graphene from any substrate opens up new possibilities for measurement of its electrical and mechanical properties as well as the exploration of novel methods of crystal growth and fabrication of 2D materials. We levitate a charged micron-scale few-layer graphene-like flake on copper foil and after it is transferred to a deposited copper substrate. It is found out that the thermal conductance of un-annealed transferred SLG on copper foil is around 20 MW/m·K, much lower than that of SLG grown on copper foil which is approximately 30 MW/m·K. Annealing in forming gas/vacuum causes the thermal conductance of transferred SLG to increase to 31 MW/m·K. X-ray spectroscopy (XPS) and Atomic force microscopy (AFM) are employed to investigate the various factors, (i.e., copper oxide, polycarbonate (PC) residue, roughness and conformity) that may cause a decrease in thermal conductance after the transfer. XPS measurement results show an absence of PC residue, even before annealing. The results also reveal that annealing in forming gas reduces the copper oxide thickness by about 2.5nm, and such a small reduction in oxide thickness is not sufficient to cause a drastic increase of approximately 10MW/m·K in thermal conductance. AFM results show that before annealing, the SLG has elongated ridges-like morphology. This morphology is different from that of copper which has circular-like features. After annealing, the SLG morphology becomes very similar to that of copper — both exhibiting circular-like features. This shows that the SLG can conform better to the copper surface after annealing.

5:18PM D17.00015 Effect of stray electric fields on cooling of center of mass motion of levitated graphite flakes, PAVEL NAGORNYKH, JOYCE COPPOCK, BRUCE KANE, University of Maryland, College Park — Levitation of charged multilayer graphite flakes in a quadrupole ion trap provides a unique way to study graphene in isolated conditions. Cooling of a flake in such a setup is necessary for high vacuum measurements of the flake and is achieved by using a parametric feedback scheme [1]. We present data showing the strong dependence of the cooling of the flake’s center of mass motion on the stray electric fields. We achieve this by using auxiliary electrodes to shift the position of the trap center in space. Once the point of minimum interaction between the trap fields and the particle is found (leading to cooling of the flake motion to temperatures below 20K at pressure of 10^-7 Torr), we can estimate charge and mass of the flake by observing quantized discharge of the particle and measure transient dynamics of the center of mass motion by tuning the cooling off and on. As an additional benefit, the behavior of the flake away from the optimum trap position can be used to quantify stray fields’ effect on the particle motion by measuring its spinning orientation and frequency dependence on offset from the optimum position.

2:30PM D18.00001 Constructing and Deconstructing Non-Abelian Anyons, BELÉN PAREDES, Instituto de Física Teórica UAM/CSIC — Non-Abelian anyons are profoundly unintuitive quasiparticles. When braiding them, the order of the braids matters, dramatically changing the properties of the underlying piece of quantum matter. They are predicted to occur as excitations of certain quantum Hall liquids and as Majorana fermions attached to vortices in special superconductors. But their experimental realization remains a major challenge, possibly because our theoretical understanding of non-Abelian matter is also far from complete. In this talk I will deconstruct non-Abelian anyons, revealing that they are made of clusters of Abelian quasiparticles, Abelian anyons, which become indistinguishable. I will show that deconstruction into identical indistinguishable components is a useful framework for the theoretical understanding of non-Abelian anyons, providing an intuitive picture for the physical mechanism leading to their emergence. Moreover, deconstruction opens a route for the construction and characterization of non-Abelian physical models and for their experimental realization in nature. To illustrate the approach, I will construct and characterize a non-Abelian spin-1 lattice model, discussing directions to detect the emergent non-Abelian anyons in experiments with ultracold atoms.

3:06PM D18.00002 Novel ways of creating and detecting topological order with cold atoms and ions1, MACIEJ LEWENSTEIN, ICF0 - Institut de Ciències Fotòniques and ICREA - Institució Catalana de Recerca i Estudis Avançats — In my talk I will focus on novel physics and novel quantum phases that are expected of lattice systems of ultra-cold atoms or ions in synthetic gauge fields, generated via lattice modulations and shaking. I will discuss fractal energy spectra and topological phases in long-range spin chains realized with trapped ions or atoms in nanofibers, and synthetic gauge fields in synthetic dimensions. I will spend large part of the talk discussing the ways to detect topological effects and order, via tomography of band insulators from quench dynamics, or via direct imaging of topological edge states.

3:42PM D18.00003 Effects of Berry Curvature in Ultracold Atomic Gases1, NIGEL COOPER, T.C.M. Group, Cavendish Laboratory, University of Cambridge — Topological energy bands exhibit many fascinating physical phenomena. For instance, topological invariants underlie both the quantum Hall effect and more general topological insulators. There is currently great interest in exploring such physics in ultracold gases. Recent experiments have explored optical lattices with novel geometrical and topological features, and there is much ongoing activity to extend to other situations. Less widely appreciated is the fact that the energy bands of these new forms of optical lattice also have important geometrical properties. In particular, the Berry curvature is a geometrical property of the energy eigenstates, defined locally in the Brillouin zone. When integrated over the Brillouin zone of a two-dimensional band, it gives the Chern number, the topological invariant of the quantum Hall effect. The Berry curvature has many physical consequences in 2D and 3D systems, such as in the anomalous quantum Hall effect. I shall summarize how the Berry curvature can manifest itself in experimental measurements of transport and of collective modes in ultracold atomic gases.

4:18PM D18.00004 Realization of the topological Haldane model, RÉMI DESBUQUOIS, ETH - Zurich — A topologically non-trivial band structure appears in a hexagonal lattice if time-reversal symmetry is broken, as suggested by F. D. M. Haldane. He further pointed out that, in combination with broken inversion symmetry, this gives rise to a phase diagram containing topologically distinct phases, yet without the necessity of a magnetic field. Studying the band structure of a hexagonal lattice with broken time reversal symmetry induced by complex valued next-nearest neighbor couplings, he showed that the boundaries of the topologically different phases are gap opening-and-closing transitions at the Dirac points. Whilst a realization of this model in a material was hardly conceivable, it provided the conceptual basis for other topological insulators and the quantum spin Hall effect. Prospects to realize the model with cold atoms emerged by advances in generating effective magnetic fields for neutral atoms and the idea to employ time-dependent fields to break time-reversal symmetry in a hexagonal lattice. Here we report on the implementation of the Haldane model in a periodically driven honeycomb optical lattice and the characterization of the topological Bloch bands using non-interacting fermionic atoms. Modulating the position of the lattice sites along a circular trajectory generates complex next-nearest-neighbor tunneling and a gap opens at the Dirac points, which we measure using momentum-resolved inter-band transitions. In analogy to a Hall conductance we observe a characteristic displacements of the atomic cloud under a constant force. By additionally breaking the inversion-symmetry, we identify the closing of the gap at an individual Dirac point, associated with the transition between the topologically distinct phases, obtaining good agreement with the calculated phase diagram. Whilst the physics of the non-interacting system is determined by the single-particle band structure, as studied in this work, the cold atom systems is also suited to explore the interplay between topology and interactions.

4:54PM D18.00005 An Aharonov-Bohm interferometer for determining Bloch band topology, ULRICH SCHNEIDER, LMU & MPQ Munich — The geometric structure of an energy band in a solid is fundamental for a wide range of many-body phenomena in condensed matter and is uniquely characterized by the distribution of Berry curvature over the Brillouin zone. In analogy to an Aharonov-Bohm interferometer that measures the magnetic flux penetrating a given area in real space, we realize an atomic interferometer to measure Berry flux in momentum space. We demonstrate the interferometer for a graphene-type hexagonal lattice, where it has allowed us to directly detect the singular x-Berry flux localized at each Dirac point. This interferometer enabled us to determine the distribution of Berry curvature with high momentum resolution. In addition, I will present results on extending these ideas to two-band models, where Berry phases generalize to Wilson loops and give rise to even richer geometric structures. This work can form the basis for a general framework to fully characterize topological band structures and can also facilitate holonomic quantum computing through controlled exploitation of the geometry of Hilbert space.

Monday, March 2, 2015 2:30PM - 5:30PM – Session D19 DCOMP DPOLY GSOFT/DBIO: Invited Session: Fifty Years of Molecular Dynamics Simulations II: Past, Present and Future Mission Room 103B - Rajiv Kalia, University of Southern California

2:30PM D19.00001 A Variational Approach to Enhanced Sampling and Free Energy Calculations, MICHELE PARRINELLO, ETH Zurich and Università della Svizzera italiana, Lugano, Switzerland — The presence of kinetic bottlenecks severely hampers the ability of widely used sampling methods like molecular dynamics or Monte Carlo to explore complex free energy landscapes. One of the most popular methods for addressing this problem is umbrella sampling which is based on the addition of an external bias which helps overcoming the kinetic barriers. The bias potential is usually taken to be a function of a restricted number of collective variables. However constructing the bias is not simple, especially when the number of collective variables increases. Here we introduce a functional of the bias which, when minimized, allows us to recover the free energy. We demonstrate the usefulness and the flexibility of this approach on a number of examples which include the determination of a six dimensional free energy surface. Besides the practical advantages, the existence of such a variational principle allows us to look at the enhanced sampling problem from a rather convenient vantage point.
1:30PM D19.00002 Bridging scales: from atoms to coarse-grained models for soft matter systems, CHRISTINE PETER, University of Konstanz, Konstanz, Germany — Molecular simulation has extended to increasingly complex soft matter systems, and time-scale and system-size requirements have instigated the use of simulation models on multiple levels of resolution. On the classical particle-based level, a large variety of methods to develop coarse grained (CG) simulation models has emerged, an important subgroup being those scale-bridging methods where the CG model is derived from and systematically linked to an underlying atomistic description. In my talk, I will introduce a few of these methods, address the underlying concepts as well as some of the ongoing challenges that are inherent to coarse graining. A natural consequence of reducing the level of resolution in a simulation model is a loss of transferability, i.e. a decreasing ability to correctly describe a system at several thermodynamic state points. Intimately linked to this is a loss of the ability to correctly represent all structural, thermodynamic and dynamic properties of the system. Examples for these limitations are easily found in all CG simulations of multicomponent or multiphase soft matter systems – ranging from liquid crystals, biomolecular aggregates, biomaterials to hard/soft nanocomposites. A correct representation of phase transitions, phase coexistence, environment-induced conformational transitions, or effects due to surfaces and interfaces is a severe challenge for bottom-up CG models. Addressing this challenge requires both a method of generating CG potentials as well as finding and rationalizing an appropriate reference state point to start out from. I will illustrate several of these aspects using examples from the biomolecular and (biomimetic-) materials world.

3:42PM D19.00003 Polymers at Surfaces and Interfaces1. MESFIN TSIGE, The University of Akron — Interfaces between solids, liquids, and gases play an important role in a wide range of practical applications and have been a subject of scientific interest since Poisson showed in 1831 that the order parameter of liquids near interfaces must deviate considerably from its bulk value. In particular, polymers at surfaces and interfaces have been the subject of extensive theoretical, experimental and computational studies for a long time due to their use in many diverse applications ranging from antifouling coatings to flexible electronic devices. Understanding the structure and thermodynamic properties of polymers at surfaces and interfaces is thus an area of fundamental and current technological interest. Although encouraging experimental progress has been made over the years in understanding the molecular structure of polymers in contact with various environments, selectively probing their structure and dynamics at surfaces and interfaces has been extremely difficult. Computer simulations, especially molecular dynamics (MD) simulations, have proven over the years to be an invaluable tool in providing molecular details at interfaces that are usually lacking in the experimental data. In this talk, I’ll give an overview of some previous simulation efforts to understand the structure and dynamics of polymers at surfaces and buried interfaces. I will conclude by presenting our current and ongoing work on combining ab initio calculations and MD simulations with Sum Frequency Generation (SFG) Spectroscopy to study polymer surfaces. This approach demonstrates the future role of MD in surface science.

4:18PM D19.00004 Systematic Coarse-graining of Molecular Dynamics Simulations, GREGORY VOTH, University of Chicago — Coarse-grained (CG) models can provide a computationally efficient means to study biomolecular and other soft matter processes involving large numbers of atoms that are correlated over distance scales of many covalent bond lengths and at long time scales. Systematic variational coarse-graining methods based on information from molecular dynamics simulations of finer-grained (e.g., all-atom) models provide attractive tools for the systematic development of CG models. Examples include the multiscale coarse-graining (MS-CG) and relative entropy minimization methods, and results from the former theory will be presented in this talk. In addition, a new approach will be presented that is appropriate for the “ultra coarse-grained” (UCG) regime, e.g., at a coarse-grained resolution that is much coarser than one amino acid residue per CG particle in a protein. At this level of coarse-graining, one is faced with the possible existence of multiple metastable states “within” the CG sites for a given UCG model configuration. I will therefore describe newer systematic variational UCG methods specifically designed to CG entire protein domains and subdomains into single effective CG particles. This is accomplished by augmenting existing effective particle CG schemes to allow for discrete state transitions and configuration-dependent resolution. Additionally, certain aspects of this work connect back to single-state force matching and open up new avenues for method development. This general body of theory and algorithm provides a formal statistical mechanical basis for the coarse-graining of fine-grained molecular dynamics simulation data at various levels of CG resolution. Representative applications will be described as time allows.

Monday, March 2, 2015 2:30PM - 5:30PM
Session D20 DPOLY: Invited Session: Physics of Glass-Forming Liquids: Challenges and Surprises II Ballroom B - Sindee Simon, Texas Tech University

2:30PM D20.00001 The structure of glass as revealed by dynamical large deviation methods, JUAN P. GARRAHAN, School of Physics & Astronomy, University of Nottingham — The dynamics of many-body systems is often richer than what one can directly infer from their static properties. This dynamical richness is revealed by considering strictly dynamical observables. The full statistical characteristics of such quantities encode the dynamical properties of the system at hand. By considering their large deviations it is possible to derive a statistical mechanics of trajectories, which is to trajectories of the dynamics what equilibrium statistical mechanics is to configurations of the statics. In this talk I will describe this approach and how it can be applied to the glass transition problem. I will show how the underlying kinetic phenomenon of glass formation is a novel class of order disorder transitions in trajectory, rather than configuration, space. I will consider the connection between the inactive dynamical phases this approach reveals and glasses prepared by more standard means. A significant prediction from this approach is the emergence of non-trivial correlations that distinguish glass from its reversible melt. Time permitting I will discuss how these ideas extend to the area of quantum glasses.

3:06PM D20.00002 Approaching the Glass Transition from Various Directions3, JANE LIPSON, Dartmouth College — In recent years a significant amount of experimental work has appeared on glassy systems, both polymeric and small molecule. However, this rich explosion in data has not been met with a concomitant leap in fundamental understanding. We have developed a number of approaches to elucidate some of the underlying mechanisms of behaviour in bulk and confined glassy systems. Using our Limited Mobility (LM) coarse-grained simulation model we have characterized the dynamic heterogeneity associated with approaching the glass transition, explored interfacial behaviour when layering materials of differing mobility, and analyzed the effect of a free surface on a supported thin film. Approaching related problems from a different direction we have modified a simulation technique designed primarily for bulk-bulk and for molecules deposited on a film surface, and substrate interactions in the case of supported films. Characterizing the systems via bulk data alone, we find our film-averaged predictions for the effects of confinement agree well with experimental data on several freestanding and supported polymer films. That work deals with confined systems; a fundamental understanding of bulk glass transitions also remains incomplete. Most recently we have been applying our Locally Correlated Lattice (LCL) equation of state model, which has met with success in modeling polymer melt and mixture behaviour, to reveal hints of the underlying glassy nature of a bulk polymer sample, even while above its transition temperature (Tg). Correlations between Tg and a variety of equilibrium bulk quantities have lead us to make connections not only with a substantive amount of experimental data on a wide range of polymers, but also with other models of glassy polymeric systems. This talk will comprise an efficient summary of past progress from these different directions, and will then focus on our most recent results and current understanding.

3 This work has been supported by NSF-DMR and GAANN.
the mechanisms leading to these striking observations in depth in this presentation. The band gap can be modulated by nearly 3 eV. We will consider distortions are understood in terms of a balance between the electrostatic and mechanical boundary conditions governing the two systems. Below 5 unit cells terminated with negatively charged NiO2-planes are insulating with strongly distorted Ni-O bonds. The differences in the observed structural found. We find that films terminated with positively charged LaO planes preserve bulk-like Ni-O bonding and are metallic. In contrast, films with thicknesses have arisen due to their inherently high carrier densities, as well as the strong coupling of their electronic and magnetic order parameters to structural degrees of freedom. Understanding the structural-property relations in these systems is crucial for designing heterostructure devices for a wide range of applications including KUMAH, ANDREI MALASHEVICH, ANKIT DISA, Yale University, DARIO ARENA, Brookhaven National Laboratory, FRED WALKER, SOHRAB ISMAIL-

Monday, March 2, 2015 2:30PM - 5:30PM –
Session D21 DCMP: Nickelates and Other Transition Metal Oxides 201 - Jack Chakhalian, University of Arkansas

2:30PM D21.00001 Pseudo-gaps at the Mott quantum critical point in the perovskite rare earth nickelates1, S. JAMES ALLEN, Univ of California - Santa Barbara, ADAM HAUSER, EVGENY MIKHEEV, UC Santa Barbara, ANKIT DISA, FRED WALKER, Yale University, NELSON MORENO, UC Santa Barbara, CHARLES AHN, Yale University, LEON BALENTS, SUSANNE STEMMER, SUSANNE STEMMER, UC Santa Barbara — We explore the behavior of the pseudo-gap in the vicinity of the quantum critical point of charge transfer Mott insulators. We focus on NdNiO3 and LaNiO3, which as bulk material bracket the quantum critical point, but tune the nature of the transition in epitaxial ultra-thin films by substrate strain, film thickness and Nd/LaNiO3 composition. We expand our earlier work [1] that documented the energy gaps and pseudo gaps in thick films using tunneling spectroscopy between Al and nickelate films with 1nm Al2O3 barriers. We focus on the relative importance of disorder scattering and electron correlation in the pseudogaps.

2:42PM D21.00002 Carrier localization in correlated nickelates by electron doping1, YOU ZHOU, JIAN SHI2, SHRIRAM RAMANATHAN, Harvard University — The electronic properties of transition metal oxides are often sensitive to the orbital occupancy of the 3d electrons due to non-degenerate energy levels and strong electron correlations. A prototypical rare earth nickelate, SmNiO3 exhibits thermally driven insulator-metal transition at 400 K with one to two orders of magnitude change in its resistivity, characterized by charge ordering of the Ni sites. In this work, by modifying the φ0 orbital filling of Ni through electron doping with reversible hydrogenation and lithium/magnesium intercalation, we realize a deep insulating phase with greater than eight orders of magnitude change in resistivity at room temperature. The band gap can be modulated by nearly 3 eV. We will consider the mechanisms leading to these striking observations in depth in this presentation.

2:54PM D21.00005 Fluids with short-range attractions and longer-range repulsions1, THOMAS TRUSKETT, The University of Texas at Austin — Many complex fluids comprise particles with effective interactions that include short-range attractions and longer-range repulsions. In this talk, I explore—using a simple theoretical model—what behaviors one should expect to find in such systems, including the possibility of equilibrium “cluster” formation and its associated implications for dynamics near structural arrest. I also discuss how one might predict the onset of cluster formation from the static structure factor. Finally, some implications for concentrated liquid formulations of therapeutic proteins are addressed.

3:06PM D21.00004 Electrically induced metal-insulator transition in epitaxial SmNiO$_3$ thin films$^1$, TOYANATH JOSHI, West Virginia University, NIKHIL SHUKLA, SANDEEPAH DASGUPTA, Pennsylvania State University, PAVEL BORISOV, West Virginia University, SUMAN DATTA, Pennsylvania State University, DAVID LEDERMAN, West Virginia University — Materials with metal-insulator transitions (MITs) above room temperature are potentially interesting for electronic applications, inter alia, to design a new class of the so-called Mott field transistors. We studied a member of the rare-earth nickelates family, SmNiO$_3$, with the bulk MIT transition temperature close to 400K. Thin films of SmNiO$_3$ were grown using pulsed laser deposition. Epitaxial structural quality was verified by reflection high-energy electron diffraction, x-ray diffraction, x-ray reflectometry, x-ray photoelectron spectroscopy and atomic force microscopy. Temperature-dependent resistivity measurements showed MIT temperatures close to the bulk values. Electrically driven MIT in two terminal SmNiO$_3$ thin film devices was demonstrated using DC and pulsed mode I-V measurements in the temperature range 273-348 K. The differential conductance $dI/dV$ peaked in the DC mode at switching field of 80 kV/cm at 273 K. The switching behavior became less pronounced with increasing measurement temperature and decreasing time period of the voltage pulses. By analysis of the experimental data we conclude the electrically-driven MIT in SmNiO$_3$ is due to the current-induced Joule self-heating. These findings should contribute to utilization of novel electronic applications.

3:18PM D21.00005 Anti-ferromagnetically driven Mott transition in ultrathin NdNiO$_3$ epitaxial films , MIKHAIL KAREEV, D. MEYERS, Univ of Arkansas-Fayetteville, JIAN LIU, University of California-Berkeley, S. MIDDEY, Univ of Arkansas-Fayetteville, J.W. FREELAND, P. RYAN, Advanced Photon Source, J. CHAKHALIAN, Univ of Arkansas-Fayetteville — The independent roles of anti-ferromagnetism and charge ordering in the realization of the temperature induced Mott metal-to-insulator transition within heteroepitaxial nickelate films remain to be disentangled hindering true understanding of the nature of the hotly debated ground state. To this end, we have investigated ultra thin, fully epitaxial films of the strongly correlated electron system NdNiO$_3$ with hard and soft resonant x-ray scattering. We find a robust E0-type antiferromagnetic transition, identical to the bulk ordering, occurs despite the ultra thin nature of the films. However, many discrepancies with the bulk like charge ordering are found.

3:30PM D21.00006 ABSTRACT WITHDRAWN —

3:42PM D21.00007 Evolution of antiferromagnetic order in rare-earth nickelates probed by muon spin relaxation , BENJAMIN FRANDESEN, LIAN LIU, SKY CHEUNG, YASUTOMO J. UEMURA, Columbia University, TIMOTHY MUNSIE, MURRAY WILSON, ALANNAH HALLAS, GREAME M. LUKE, McMaster University, BJULIAN CHEN, CHANGQING JIN, Institute of Physics, Beijing, CUI DING, FANLONG NING, Zhejiang University, JOSE ALONSO, Instituto de Ciencia de Materiales de Madrid (ICMM) — The rare-earth nickelates with structural formula RNiO$_3$ comprise a well-known family of Mott insulators that exhibits a gradual suppression of the metal-insulator transition and antiferromagnetic (AF) order with increasing rare-earth ionic size, resulting in a zero-temperature quantum phase transition at a rare-earth ionic radius of $\sim$1.17 Å. We present detailed muon spin relaxation ($\mu$SR) measurements of RNiO$_3$ ($R=$Sm,Nd,Pr,La) to investigate the evolution of the antiferromagnetic order across the phase diagram. In the compounds with lower ordering temperatures near the quantum phase transition, we observe a “stretched” Mott transition with phase separation between magnetic and paramagnetic regions over a wide temperature interval. We also find that the suppression of the magnetic order at the quantum phase transition occurs in a first-order manner, with the ordered volume fraction decreasing to zero while the moment size remains large and constant. We compare these observations to other Mott insulator systems and discuss generic behavior.

3:54PM D21.00008 Non-Gaussian resistance noise across the metal-insulator transition in epitaxial NdNiO$_3$ films , ALI ALSAQQA, SUJAY SINGH, State Univ of NY - Buffalo, SRIMANTA MIDDEY, MICHAEL KAREEV, JAN CHAKHALIAN, University of Arkansas - Fayetteville, G. SAMBANDAMURTHY, State Univ of NY - Buffalo — The rich phase diagrams exhibited by strongly correlated rare earth nickelates provide a great playground to investigate the electronic, magnetic and structural properties using a variety of experimental tools. NdNiO$_3$ thin films exhibit a temperature-driven metal-insulator transition (MIT) and the transition temperature is controlled by the interface strain. We present results from transport measurements and noise spectroscopy studies in strained, ultrathin (15 unit cells) NdNiO$_3$ across the MIT. Resistance noise spectroscopy (in the frequency range below 10 Hz) is a powerful tool to statistically investigate the fluctuations of the microscopic scatterers that can dramatically affect macroscopic properties. In our samples, we find that the noise spectrum follows a $1/f$ behavior, however the noise magnitude dramatically peaked in the DC mode at switching field of 80 kV/cm at 273 K. The switching behavior became less pronounced with increasing measurement temperature and decreasing time period of the voltage pulses. By analysis of the experimental data we conclude the electrically-induced MIT in SmNiO$_3$ is due to the current-induced Joule self-heating. These findings should contribute to utilization of novel electronic applications.

4:06PM D21.00009 Nanostructure Investigations of Nonlinear Differential Conductance in NdNiO$_3$ Thin Films , WILL HARDY, HENG JI, Department of Physics and Astronomy, Rice University, EVGENY MIKHEEV, SUSANNE STEMMER, Materials Department, University of California, Santa Barbara, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University — Transport measurements on thin films of NdNiO$_3$ reveal a crossover to a regime of pronounced nonlinear conduction below the well-known metal-insulator transition temperature. The evolution of the transport properties at temperatures well below this transition appears consistent with a gradual formation of a gap in the hole-like Fermi surface of this strongly correlated system. As $T$ is decreased below the nominal transition temperature, transport becomes increasingly non-Ohmic, with a model of Landau-Zener breakdown becoming most suited for describing $I(V)$ characteristics as the temperature approaches 2 K.

4:18PM D21.00010 ABSTRACT MOVED TO J15.00013 —

4:21PM D21.00011 ABSTRACT MOVED TO J15.00012 —

4:21PM D21.00012 Comparative study of Raman excitations in YVO$_3$ and HoVO$_3$, BENOIT ROBERGE, SERGE JANDL, Université de Sherbrooke, AGUSTINUS AGUNG NUGROHO, Institut Teknologi Bandung, THOMAS PALSTRA, University of Groningen — First-order Raman scattering and multiphonons are studied in RVO$_3$(R=Ho and Y) as a function of temperature in the orthorhombic and monoclinic phases. Below $T_{O-O} = 200$ K in YVO$_3$ and $T_{O-O} = 188$ K in HoVO$_3$, a G-type orbital ordering (G-OO) with a concomitant monoclinic transition occurs. The orbital ordering enhances the phonon polarizabilities, it also allows the resolution of room-temperature phonons, and activates new excitations around 700 cm$^{-1}$. Below $T_{N} = 114$ K (in both compounds), a C-type magnetic ordering (C-SO) occurs and some phonon frequency softening or frequency hardening are observed. Following the structural and magnetic transitions, below 40 K in YVO$_3$ and $T_{N}$ = 40 K in HoVO$_3$, important changes are observed in Raman excitations of both compounds. Even if R ionic radii of HoVO$_3$ and YVO$_3$ are nearly equal ($\bar{R}_{Ho} = 192$ pm and $\bar{R}_{V} = 190$ pm), we observe some differences that we report.
5:06PM D21.00014 Self-interaction corrected electronic structure of Ti4O7, TiO2 and Ti2O3
, XIAOLIANG ZHONG, Argonne National Laboratory, IVAN RUNGGER, Trinity College, PETER ZAPOL, OLLE HEINONEN, Argonne National Laboratory — Titanium oxides have a range of applications in, e.g., catalysis and resistive switching. There are many oxide structures with different ground states and electronic properties that have to be understood for potential applications to be possible. We have studied rutile TiO2, Ti2O3, and Magnéli phase Ti3O6 using density functional theory with self-interaction corrections to account for electronic correlations, which are important in these structures. The ground state of the low temperature (LT) phase of Ti3O6 is found to be a new semiconducting state with antiferromagnetic coupling between two sublattices. Depending on the charge screening strength, different Ti-O phases are best described by applying different values of an empirical parameter \( \alpha \), which represents the magnitude of the applied self-interaction correction. We will show that Pauli paramagnetism of the metallic high-temperature Ti3O6 phase is predicted using \( \alpha \approx 0 \), that the band gaps of small-gap LT-Ti3O6 and Ti2O3 are captured by \( \alpha \approx 0 \), while the large band gap of TiO2 is reproduced using \( \alpha \approx 0 \). Nevertheless, restricting \( \alpha \) to a standard value of 0.5 for transition metal oxides is found to be a good compromise describing reasonably well the electronic structures of all these oxides. We gratefully acknowledge the computing resources provided on Blues, a high-performance computing cluster operated by the Laboratory Computing Resource Center at Argonne National Laboratory. Argonne National Laboratory’s work was supported under U.S. Department of Energy contract DE-AC02-06CH11357.

Session D22 DCMP: Theory of Exotic States of Matter 202A - Eun-Ah Kim, Cornell University

Monday, March 2, 2015 2:30PM - 5:18PM —

2:30PM D22.00001 Algebraic spin liquids with emergent generalized gauge boson excitations, ALEX RASMUSSEN, CENKE XU, ZHEN BI, YI-ZHUANG YOU, Univ of California - Santa Barbara — According to an early proposal by Hermele, et.al., (cond-mat/0404751), an algebraic spin liquid state with gapless emergent photon excitations can exist in quantum spin ice systems. This algebraic spin liquid is stable against any weak perturbation. Further work by Xu and Ho?ava (arxiv:1003.0009) concluded that certain lattice models give rise to more exotic stable spin liquid states with graviton-like excitations. In this talk we will show how these algebraic spin liquid states can be generalized to even more exotic types of gapless excitations and then demonstrate that these new phases are stable against weak perturbations.

2:42PM D22.00002 (Almost) naked quantum criticality with non-Fermi liquid behavior at the onset of inhomogeneous Larkin-Ovchinikov superfluidity in two dimensions, PHILIPP STRACK, Harvard University, FRANCESCO PIÀZZA, TU Muenchen — We present a renormalization group analysis for the non-Fermi liquid behavior and quantum criticality arising in coupled quantum wires of attractively interacting fermions with spin imbalance in two spatial dimensions.

2:54PM D22.00003 Topological Phases of Interacting Bosons on the Kagome Lattice, KRISHANU ROYCHOWDHURY, SUBHRO BHATTACHARJEE, FRANK POLLMANN, MPIPKS, Dresden — We consider an extended Hubbard model of hard core bosons including nearest-neighbour hopping and long range repulsive interactions on a kagome lattice. The system is an insulator at commensurate fillings of 1/6, 1/3 and 1/2 and can be mapped to different dimer triangular lattice (depending on the filling). We focus on the filling of 1/3, which transforms to a fully packed loop (FPL) model, and derive the full phase diagram in the low-energy subspace. Similar to the quantum dimer model and easy-axis kagome antiferromagnetic model studied before, we find an extended region of a gapped \( Z_3 \) liquid with vison excitations. The gauge fluctuations, responsible for the vison modes, are dictated by the action of an even Ising gauge theory. In the ordered phase, where the vison gap closes, we observe a 3-fold rotationally symmetric loop order and present the critical theory for the amplitude fluctuations of the condensed modes. We also speculate the phase diagram for the fermionic counterpart of the model at all the above mentioned fractional fillings.

3:06PM D22.00004 Spontaneous Anomalous Hall states in metals, WATHID ASSAWASUNTHONNET, VICTOR CHUA, EDUARDO FRADKIN, Univ of Illinois - Urbana — We explore two phases in 2-D electron fluids with two Fermi surfaces in which the time-reversal symmetry is broken spontaneously by using the method of higher dimensional bosonization. Earlier mean-field calculations [1] showed that the order parameter for both phases can be expressed as two two-component real vectors. There are two phases: the beta phase in which the two order parameters are perpendicular to each other and the alpha phase in which they are parallel. The beta phase exhibits nonvanishing un-quantized spontaneous anomalous Hall effect at zero external magnetic fields, which is determined by a Berry curvature associated with Fermi surfaces. The alpha phase does not have that property. To go beyond mean-field, we use higher-dimensional bosonization. We have identified the two phases as topological phases. In the ordered phase, where the vison gap closes, we observe a 3-fold rotationally symmetric loop order and then present the critical theory for the amplitude fluctuations of the condensed modes. We also speculate the phase diagram for the fermionic counterpart of the model at all the above mentioned fractional fillings.

3:18PM D22.00005 Transition of a \( Z_3 \) topologically ordered phase to a trivial phase\(^1\), CHING-YU HUANG, Tzu-Chieh Wei, C. N. Yang Institute for Theoretical Physics and Department of Physics and Astronomy, State University of New York at Stony Brook — Topologically ordered quantum systems have robust physical properties, such as quasiparticle statistics and ground-state degeneracy, which do not depend on the microscopic details of the Hamiltonian. We consider a topological phase transition under a string tension \( g \) on a \( Z_3 \) topological state. This is first studied numerically in terms of the gauge-symmetry preserved quantum state renormalization group proposed by He, Moradi and Wen (arXiv:1401.5557). Modular matrices \( S \) and \( T \) can be obtained and used as parameters to determine the critical string tension \( g_c \). Then from a mapping to a classical 2D three-state Potts model on square lattice we obtain analytically the transition \( g_c \) via the transition temperature of the three-state Potts model. We find the numerically determined \( g_c \) agrees well with the analytic result via the mapping.

3:30PM D22.00006 Pairing instabilities of a Non-Fermi liquid in the presence of nematic and gauge fluctuations\(^2\), ANDREJ MESAROS, MICHAEL J. LAWLER, EUN-AH KIM, Cornell University — In the absence of Fermi-liquid starting point, instabilities of non-Fermi liquids are theoretically challenging problems. Here we note that a non-Fermi liquid state occurring at \( v = 1/2 \) may be a promising concrete case for theoretical investigation of the issue for two reasons. Firstly, exotic ordered states observed in half-filled Landau levels, namely the FQH state at \( v = 5/2 \) which is most likely best described as a paired state, and the quantum Hall nematic state at \( v = 9/2 \), present a compelling possibility that the non-Fermi liquid state with gauge fluctuations at \( v = 1/2 \) is close to instabilities towards these ordered states. Secondly, a recent theoretical progress [Metlitski et al., arXiv:1403.3694] offers a scheme for a controlled renormalization group study of the problem. We will discuss competition between the two fluctuations in promoting or suppressing a superconducting instability, based on the phase diagram we obtain from a renormalization group calculation.

\(^2\)This research was supported by NSF through CAREER grant DMR-0955822.
The dimerized spin-1/2 Heisenberg ladder is topologically characterized from the viewpoints of symmetry protection and bulk-edge correspondence. Our focus is on the plateau phase at the half of the saturation induced by dimerization and magnetic field. The Berry phase associated with the twisted boundary condition is employed as a topological order parameter. The magnetic field reduces the symmetry of the system, but there is a topological phase protected by a spatial inversion symmetry that is characterized by a Berry phase quantized to $0/\pi$. For a Berry phase quantization, usage of a symmetry-preserving boundary, which leaves at least one inversion center after the system is cut at the boundary, is essential. As a comparison, a symmetry-breaking boundary is also analyzed. Naively, such a boundary is inadequate to make the Berry phase quantized and topological. However, for a specific type of boundary, we found a unique quantization of the Berry phase into $\pm \pi/2$, instead of $0/\pi$ [T. Kariyado and Y. Hatsugai, Phys. Rev. B 90, 085132 (2014)]. Further, for the case of $\pm \pi/2$-quantization, there appears an edge state distinct from the one for the $0/\pi$-quantization, which reveals new aspects of the bulk-edge correspondence for symmetry-breaking boundary.

3:54PM D22.00008 Josephson-coupled Moore-Read states , LAYLA HORMOZI, Massachusetts Institute of Technology, GUNNAR MOLLER, University of Cambridge, JOOST SLINGERLAND, National University of Ireland, STEVEN SIMON, University of Oxford — We study a quantum Hall bilayer system of bosons at total filling fraction $\nu = 1$, and analyze the the coupled Moore-Read state [PRL 108, 256809 (2012)] that results from the interplay between short-ranged interactions and interlayer pair-tunneling terms. Supported by the exact solution of the full zero-energy quasihole spectrum and a conformal field theory analysis, we develop an intuitive picture of this system as two coupled composite fermion superconductors. In this language, pair tunneling plays the role of Josephson coupling between the superconducting phases of the two layers, which gaps out the Goldstone mode associated with interlayer particle distribution. This coupling further implies that non-Abelian quasiparticles are confined between the layers. In the bulk, the resulting phase has the topological order of the Halperin 220 state i.e. $U(1)_2 \times U(1)_2$, but the edge spectrum at a fixed particle number reveals an unexpected $U(1)_3 \times U(1)$ structure. We attribute this behavior to the fact that this state is realized in a rotated basis of layer index, where the charged and neutral sectors are separated. With the charge quantum number being conserved but without any such restriction on the neutral sector we show that the edge spectrum must take the observed form.

4:06PM D22.00009 ABSTRACT WITHDRAWN —

4:18PM D22.00010 Ground State Degeneracy of Topological Phases on Open Surfaces , YIDUN WAN, Perimeter Institute for Theoretical Physics, JANET HUNG, Department of Physics and Center for Field Theory and Particle Physics, Fudan University — we relate the ground state degeneracy (GSD) of a non-Abelian topological phase on a surface with boundaries to the anyon condensates that break the topological phase to a trivial phase. Specifically, we propose that gapped boundary conditions of the surface are in one-to-one correspondence to the sets of condensates, each being able to completely break the phase, and we substantiate this by examples. The GSD resulting from a particular boundary condition coincides with the number of confined topological sectors due to the corresponding condensation. These lead to a generalization of the Laughlin-Wu-Tao charge-pumping argument for Abelian fractional quantum Hall states to encompass non-Abelian topological phases, in the sense that an anyon loop of a confined anyon winding a non-trivial cycle can pump a condensate from one boundary to another. Such generalized pumping may find applications in quantum control of anyons, eventually realizing topological quantum computation.

4:30PM D22.00011 Parent Hamiltonians for Bosonic Symmetry-Protected States , LUZ SANTOS, Perimeter Institute — A platform for constructing parent Hamiltonians describing bosonic symmetry-protected (SPT) states will be presented. The Hamiltonians we consider are examples of frustration-free Kitaev-Kivelson models, which are known to be in one-to-one correspondence with classical stochastic systems in the same spatial dimensionality. By exploring this classical-quantum mapping we are able to propose Hamiltonians which, in a closed manifold, yield a unique gapped symmetric ground state describing the universal properties of SPT states. Specific examples which illustrate our approach shall be discussed.

4:42PM D22.00012 Quasi-one-dimensional superfluid criticality , PIERRE-FRANCOIS DUC, MICHEL SAVARD, MATEI PETRESCU, McGill University, ADRIAN DEL MAESTRO, University of Vermont, GUILLAUME GERVAIS, McGill University — In one of the most celebrated examples of the theory of universal critical phenomena, superfluid $^4$He state belongs to the same three dimensional O(2) universality class as the onset of ferromagnetism in a lattice of XY spins. Its ability to flow without viscosity below the $\lambda$-transition temperature is a paradigmatic manifestation of emergent phenomena and macroscopic quantum coherence, driven by both strong interactions and bosonic quantum statistics. As the number of spatial dimensions decreases, it is expected that enhanced thermal and quantum fluctuations should push $T_{\lambda} \rightarrow 0$. However, in the one dimensional limit, the universal quantum hydrodynamics of Luttinger liquid theory should apply, providing a host of theoretical predictions including the simultaneous algebraic spatial decay of both density-density and superfluid correlation functions. At McGill University, we have designed an experiment and measured the DC mass flow of superfluid helium in single nanopores with radii down to 3 nm. For the smaller aperture, in which helium is expected to be in a ‘quasi-one-dimensional’ regime, the universal critical exponent for the superfluid velocity is found to deviate significantly from its bulk value, $\nu = \frac{3}{2}$.

4:54PM D22.00013 Electronic properties in a superlattice of strongly correlated electron systems , SUGURU UEDA, NORIO KAWAKAMI, Department of Physics, Kyoto University, Kyoto 606-8502, Japan — We theoretically investigate the superlattice consisting of a Mott insulator and a metal by using the dynamical mean-field theory. At low temperature, the quasi-particle state appears in the density of states of the Mott insulator layers. We address how the structure of the superlattice affects the stability of this Fermi liquid state. It is elucidated that the quasi-particle weight shows the characteristic even-odd oscillation depending on the thickness of the metal domain. We confirm this even-odd dependence in the electrical resistivity, and find that the Fermi liquid state is further stabilized by the superlattice with a certain periodicity. We also discuss the importance of our findings comparing with the recent experiments.

5:06PM D22.00014 The theory of cluster Mott insulator: charge fluctuation and spin liquids , GANG CHEN, HAE-YOUNG KEE, YONG BAEK KIM, University of Toronto — I will present recent theoretical work on cluster Mott insulators (CMI) in which interesting physics such as emergent charge lattices, charge fractionalization and quantum spin liquids are proposed. For the anisotropic Kagome system like LiZn2Mo3O8, we find two distinct CMIs, type-I and type-II, can arise from the repulsive interactions. In type-I CMI, the electrons are localized in one half of the triangle clusters of the Kagome system while the electrons in the type-II CMI are localized in every triangle cluster. Both CMIs are $U(1)$ quantum spin liquids (QSL) with a unique $\pi$-band regime with a spin Fermi surface and gapped charge excitations. In type-II CMI, however, the charge fluctuations lead to a long-range plaquette charge order that breaks the lattice symmetry, gives rise to an emergent charge lattice and reconstructs the mean-field spinon band structure of the underlying $U(1)$ QSL. Such a reconstruction gives a consistent prediction of the “fractional spin susceptibility” that is observed in LiZn2Mo3O8. For the pyrochlore system, the CMI can further support a charge fractionalization with an emergent gauge photon in the charge sector in addition to the spin fractionalization in the spin sector. Experimental connection with the several cluster magnets such as LiZn2Mo3O8.
2:30PM D23.00001 Modeling of Singlet Fission Kinetics for a Wide Range of Molecules. SHANE YOST, Lawrence Berkeley National Laboratory — Singlet exciton fission is a process that occurs in organic molecules where one high energy singlet exciton decays into two low energy triplet excitons. Over the years since its first discovery in the 1960s a number of different singlet fission materials have been discovered with a wide range of rates and yields. The mechanism for singlet fission in these materials is still not fully understood, and no method is able to accurately reproduce fission rates over a wide range of timescales. In order to gain a better understanding of the singlet fission mechanism a group of fission materials with vastly different crystal structures and fission rates were modeled. Using a first principles expression the rates were computed with constrained density functional theory with configuration interactions. The computed rates successfully predict the fission rates in the different materials studied. For the slow, weak intermolecular coupling materials singlet fission obeys Marcus theory, but for faster, larger intermolecular coupling materials the rate becomes diabatic in nature. This work alters the guidelines for tailoring molecular properties from a focus on crystal packing and intermolecular coupling to properties like solubility and energy level alignment while maintaining the high fission yield required for photovoltaic applications.

3:06PM D23.00002 GW-BSE, self-consistency, and vertex corrections applied to group IB/IIB atoms and oxide molecules1. LINDA HUNG, SERDAR OGUT, University of Illinois at Chicago — Time-dependent density functional theory (TDDFT), the GW approximation, and the Bethe-Salpeter equation (BSE) are often used for the first-principles calculation of excited-state properties of materials that contain transition metals. Accuracy is improved compared to mean-field theories such as Kohn-Sham DFT or Hartree-Fock; however, predicted quasiparticle levels and optical spectra can still differ from experiment. We model Cu, Zn, Ag, and Cd atoms and their oxide molecules to assess various approximations in many-body perturbation theory methods that contribute to these differences. In particular, we examine how self-consistent iterations and/or a two-point vertex function affect the predicted excitation energies, compared to “one-shot” GCW0 calculations. Experimental measurements of optical spectra and ionization energies for charged and neutral atoms are widely available, and allow us to evaluate excitations from both s and d states. Differences between TDDFT and BSE spectra are also discussed. Calculations are performed with RGWBS, a software suite which uses a basis of transition space and quasiparticle wavefunctions.

3:18PM D23.00003 Quasiparticle Band Gap Renormalization in Doped Two-Dimensional Materials1. YUFENG LIANG, Lawrence Berkeley National Lab, LI YANG, Department of Physics, Washington University in St. Louis — Recently, atomically thin two-dimensional (2D) materials have emerged as new prototypes for a variety of electronic and optoelectronic devices, for which charge carrier doping is an effective approach for modifying their intrinsic properties. In the process of producing monolayer metal dichalcogenides, doping can occur naturally and may lead to exotic many-body phenomena as evidenced in recent optical experiments. Despite the common occurrence of doping in 2D structures, little knowledge has been obtained for the evolution of the band gap with the carrier concentration, which is key to harnessing the electronic properties and understanding more complicated many-body effects. Here, we investigate how the band gap changes with doping density in various 2D structures. Based on the conventional GW method for semiconductors, we devised and implemented an efficient calculation scheme to capture the unique dielectric screening arising from intraband transitions in low-dimensional structures, specifically MoS2 and MoSe2. We reveal that an enhanced band gap renormalization of a few hundred meV can be achieved and the band gap evolution displays an unusual nonlinear behavior with doping density. Our calculated band gap is in excellent agreement with the recent ARPES experiments on MoSe2.

3:30PM D23.00004 Band Structures of Plasmonic Polarons. FABIO CARUSO, HENRY LAMBERT, FELICIANO GIUSTINO, University of Oxford — In angle-resolved photoemission spectroscopy (ARPES), the acceleration of a photo-electron upon photon absorption may trigger shake-up excitations in the sample, leading to the emission of phonons, electron-hole pairs, and plasmons, the latter being collective charge-density fluctuations. Using state-of-the-art many-body calculations based on the ‘GW plus cumulant’ approach, we show that electron-plasmon interactions induce plasmonic polaron bands in group IV transition metal dichalcogenide monolayers (MoS2, MoSe2, WS2, WSe2). We find that the energy vs. momentum dispersion relations of these plasmonic structures closely follow the standard valence bands, although they appear broadened and blueshifted by the plasmon energy. Based on our results we identify general criteria for observing plasmonic polaron bands in the angle-resolved photoelectron spectra of solids.

3:42PM D23.00005 Recent Progress in GW-based Methods for Excited-State Calculations of Reduced Dimensional Systems. FELIPE H. DA JORNADA, University of California at Berkeley and Lawrence Berkeley National Laboratory — Ab initio calculations of excited-state phenomena within the GW and GW-Bethe-Salpeter equation (GW-BSE) approaches allow one to accurately study the electronic and optical properties of various materials, including systems with reduced dimensionality. However, several challenges arise when dealing with complicated nanostructures where the electronic screening is strongly spatially and directionally dependent. In this talk, we discuss some recent developments to address these issues. First, we turn to the slow convergence of quasiparticle energies and exciton binding energies with respect to k-point sampling. This is very effectively dealt with using a new hybrid sampling scheme, which results in savings of several orders of magnitude in computation time. A new ab initio method is also developed to incorporate substrate screening into GW and GW-BSE calculations. These two methods have been applied to mono- and few-layer MoS2, and yielded strong environmental dependent behaviors in good agreement with experiment. Other issues that arise in confined systems and materials with reduced dimensionality, such as the effect of the Tamm-Dancoff approximation to GW-BSE, and the calculation of non-radiative exciton lifetime, are also addressed. These developments have been efficiently implemented and successfully applied to real systems in an ab initio framework using the BerkeleyGW package. I would like to acknowledge collaborations with Diana Y. Qiu, Steven G. Louie, Meiyue Shao, Chao Yang, and the experimental groups of M. Crommie and F. Wang.

4:18PM D23.00006 Ultrafast Hot Carrier Scattering and Generation from Surface Plasmons in Noble Metals, MARCO BERNARDI, JAMAL MUSTAFA, Department of Physics, University of California, Berkeley, and Materials Science Division, Lawrence Berkeley National Lab, Berkeley, CA 94720, USA, JEFFREY B. NEATON, Molecular Foundry, Lawrence Berkeley National Lab, Berkeley, CA 94720, USA, STEVEN G. LOUIE, Department of Physics, University of California, Berkeley, and Materials Science Division, Lawrence Berkeley National Lab, Berkeley, CA 94720, USA — Non-equilibrium “hot” carriers in materials are challenging to study experimentally as they thermalize at subpicosecond time and nanometer length scale. Recent experiments employed hot carriers generated by light absorption or surface plasmon annihilation in noble metals (e.g., Au and Ag) for catalysis and solar cells. The energy distribution and transport of the generated hot carriers play a key role in these experiments. We present ab initio calculations of the energy distribution of hot carriers generated by surface plasmons in noble metals, and the relaxation time and mean free path of the hot carriers along different crystal directions within 5 eV of the Fermi energy. Our calculations show the interplay of the noble metal s and d bands in determining the damping rate of the plasmon and the mean free path of the hot carriers. The trends we find as a function of surface plasmon momentum and frequency allow us to define optimal experimental conditions for hot carrier generation and extraction. Our approach combines density functional theory, GW, and electron-phonon calculations. Our work provides microscopic insight into hot carriers in noble metals, and their ultrafast dynamics in the presence of surface plasmons.

4:30PM D23.00007 First-Principles Simulation of Hot Electron Dynamics at Silicon-Molecule Interfaces, LESHENG LI, YOSUKE KANAI, Univ of NC - Chapel Hill, KANAI GROUP TEAM — Hot carrier relaxation process at an interface between semiconductor and molecular ligands is of great importance for a number of technological applications ranging from photo-electrochemical cells to quantum-dot light emitting diodes. Although a number of spectroscopic experiments suggest important role of molecular ligands at surface in the hot carrier relaxation, a quantitative understanding has not been developed. We investigate the hot electron relaxation process through synergistic use of first-principles molecular dynamics (FPMD), fastest switch surface hopping (FSSH) algorithm, and GW calculations. Using FSSH stochastic dynamics simulation based on non-adiabatic couplings from FPMD and quasi-particle energy level alignment at the interface, we investigate the role of molecular passivation at silicon (111) surface as a representative example. We will discuss how different types of molecules influence the relaxation process and elucidate important factors controlling the relaxation time scale.

4:42PM D23.00008 Improved Description of Electron-Plasmon Coupling In Green’s Function Calculations, JIANQIANG ZHOU, LUCIA REINING, Laboratoire des Solides Irradies, Ecole Polytechnique, CNRS-CEA/DSM, F-91128 Palaiseau, France. European Theoretical Spectroscopy Facility (ETSF) — Green’s function (GF) methods have been very successful for describing one- or two-particle excitations in solids. The GW approximation [1] is a well established approach for describing quasi-particle peaks in the spectral function. Beyond GW, the cumulant expansion, which is based on a hole-boson coupling model, gives a better description of plasmon satellites [2,3]. However, this traditional time-ordered cumulant (TOC) is only valid far from the Fermi level. Recent development [4] of a generalized cumulant (GC) improves the spectral function close to the Fermi level, but a framework for systematically improving is still missing. Here we show how GW, TOC and GC can be derived as a successive series of approximations in a unified way, and how one can go beyond today’s state-of-the-art methods. Results for spectral functions and total energies of an exactly solvable model show that systematic improvement is obtained.

1Work supported by FP7/ERC Grant Agreement n. 320971

4:54PM D23.00009 Plasmon Pole Approximation within the GW Lanczos approach, VINCENT GOSSELIN, BRUNO ROUSSEAU, MICHEL COTE, Univ of Montreal — The well-known DFT gap problem is adressed by computational methods that are more resource intensive both in terms of memory and time requirements. Amongst other methods, the GW approach has known great success in the field of electronic structure calculations. Addressing the main bottlenecks impeding one shot GW calculations, a sum over all conduction states and an integral over all frequencies must be carried. Within an implementation of the GW method based on the Lanczos algorithm, the sum over conduction states is treated with a Sternheimer method whereas the frequency integral is carried out numerically. In this talk, I will present an implementation of a plasmon-pole model combined with the Lanczos method that allows a treatment of this integral that is computationally favorable.

5:06PM D23.00010 Applications of the Retarded Cumulant Expansion to Realistic Systems, J.J. KAS, J.J. REHR, U. Washington — The cumulant expansion of the one-electron Green’s function has proved extremely useful in describing electron correlation in materials beyond the one-electron approximation. For example, the approach improves on the GW approximation, accounting for multiple satellites in the spectral function and x-ray photoemission spectra. Previous implementations based on the time ordered representation ignore diagrams which lead to partial occupations and satellite features in the spectral function above and below the Fermi surface. Recently we have shown that these difficulties can be overcome with a cumulant expansion of the retarded Green’s function. This model was tested on the homogeneous electron gas, giving good results for the spectral function, correlation energies, and occupation numbers. In this follow-up, we discuss the extension of the approach to realistic condensed matter systems, using GW calculations of the self-energy to approximate the cumulant. Results are presented for the spectral function and occupation numbers, and compared to experimental XPS data.

5:18PM D23.00011 Photoelectron spectra of copper oxide (Cu_{x}O_{y} , x = 1 – 2 , y = 1 – 4) clusters from first principles, BIN SHI, University of Illinois at Chicago, SHIRA WEISSMAN, Weizmann Institute of Science, LINDA HUNG, University of Illinois at Chicago, LEEÖR KRONIK, Weizmann Institute of Science, SERDAR OGUT, University of Illinois at Chicago — Copper oxide clusters are systems of current technological and fundamental interest. They have unique electronic and optical properties due to the exchange and correlation effects of their f electrons, which also make their modeling from first principles computationally demanding. We optimize the ground-state structures of copper oxide Cu_{x}O_{y} (x = 1 – 2 and y = 1 – 4) cluster anions using density functional theory (DFT). We compare photoelectron spectra determined at two levels of theory: DFT and the GW approximation. DFT calculations use Perdew-Burke-Ernzerhof (PBE), hybrid, and range-separated exchange-correlation functionals. The calculated photoelectron spectra are compared with available experimental measurements to identify the nature of the observed electronic excitations.

2:30PM D24.00001 Quantum-classical Adaptive Coupling in Grand-Canonical like Adaptive Resolution Simulations, ANIMESH AGARWAL, LUIGI DELLE SITE, Institute for Mathematics, Warmlmalle 6, D-14195, Freie Universität, Berlin, Germany — We have extended the recently developed Grand Canonical AdResS (GC-AdResS) [1,2] to quantum-classical adaptive coupling where the quantum delocalisation of an atom is described by the path integral formalism. Compared to standard adaptive coupling approaches [3], the advantage of GC-AdResS is that there is no need to obtain a coarse-grained model that correctly reproduces the structural and thermodynamic properties of a full PI (path integral) system, thereby eliminating the need to run a full PI simulation before starting the adaptive simulation. In this context, we have shown that spherical molecules described by a simple generic WCA potential in the coarse-grained region, act as a particle reservoir for the PI region. The resulting Grand Canonical set up is such that the structural and dynamical properties of quantum flexible water models in the PI subregion in AdResS are consistent with the properties obtained in the same subregion in full PI simulations.

2:42PM D24.00002 Efficient cluster Monte Carlo algorithm for Ising spin glasses in more than two space dimensions, ANDREW J. OCHOA, ZHENG ZHU, HELMUT G. KATZGRABER, Texas A&M University — A cluster algorithm that speeds up slow dynamics in simulations of nonplanar Ising spin glasses away from criticality is urgently needed. In theory, the cluster algorithm proposed by Houdayer poses no advantage over local moves in systems with a percolation threshold below 50%, such as cubic lattices. However, we show that the frustration present in Ising spin glasses prevents the growth of system-spanning clusters at temperatures roughly below the characteristic energy scale $J$ of the problem. Adding Houdayer cluster moves to simulations of Ising spin glasses for $T \sim J$ produces a speedup that grows with the system size over conventional local moves. We show results for the nonplanar quasi-two-dimensional Chimera graph of the D-Wave Two quantum annealer, as well as conventional three-dimensional Ising spin glasses, where in both cases the addition of cluster moves speeds up thermalization visibly in the physically-interesting low temperature regime.

2:54PM D24.00003 A new class of scalable parallel pseudorandom number generators based on Pohlig-Hellman exponentiation ciphers, PAUL BEALE, University of Colorado Boulder — We propose a new class of pseudorandom number generators based on Pohlig-Hellman exponentiation ciphers. The method generates uniform pseudorandom streams by encrypting simple sequences of short integer messages into ciphertexts by exponentiation modulo prime numbers. The advantages of the method are: the method is trivially parallelizable by parameterization with each pseudorandom number generator derived from an independent prime modulus, the method is fully scalable on massively parallel computing clusters due to the large number of primes available for each implementation, the seeding and initialization of the independent streams is simple, the method requires only a few integer multiplications per pseudorandom number drawn. The state of each instance is defined by only a few integer values, the period of each instance is different, and the method passes a battery of intrastream and interstream correlation tests using up to $10^{15}$ pseudorandom numbers per test. We propose an implementation using 32-bit prime moduli with small exponents that require only a few 64-bit multiply-mod operations that can be executed directly in hardware. The 32-bit implementation we propose has millions of possible instances, all with periods greater than $10^{18}$.

3:06PM D24.00004 Crossover behavior of the thermal conductance and Kramers’ transition rate theory, SUBIN SAHU, Department of Physics, Oregon State University, Corvallis OR, KIRILL VELIZHANIN, Theoretical Division, Las Alamos National Lab, Los Alamos NM, CHIH-CHUN CHIEN, School of Natural sciences, University of California, Merced CA, YONATAN DUBI, Department of Chemistry, Ben-Gurion University of Negev, Israel, MICHAEL ZWOLAK, National Institute of Standards and Technology, Gaithersburg MD — Heat transport plays opposing roles in nanotechnology, hindering the miniaturization of electronics on one hand and forming the core of novel heattronics devices on the other. Moreover, heat transport in one-dimensional nanostructures has become a central tool in studying the onset of Fourier’s law of heat conduction, a yet unresolved puzzle in theoretical physics. We study the paradigmatic setting of heat transport in one-dimensional systems, a lattice coupled to two heat baths held at different temperatures. Using both numerical and analytical tools, we demonstrate that the heat conductance displays a crossover behavior as the coupling to the thermal reservoirs is tuned. We provide evidence that this behavior is universal by examining harmonic, anharmonic, and disordered systems, and discuss the origin of this effect using an analogy with Kramers’ transition state theory for chemical reaction rates. This crossover behavior has important implications in the analysis of numerical results, and suggests a novel way to tune the conductance in nanoscale devices.

3:18PM D24.00005 Accelerated rare event sampling, DAVID YEVICK, University of Waterloo — We suggest a strategy for biased transition matrix Monte-Carlo calculations that both ensures the most rapid coverage of the entire computational window in the macroscopic variables of interest $E$ and yields estimates of transition probabilities between states that are equally accurate in low and high probability regions. Further, paths between different low probability regions are sampled at regular intervals. For the case of a single $E$ variable, a random system realization for which the value of $E$ falls in e.g. the $i$th histogram bin is generated. This state is perturbed and the resulting realization is rejected until a transition is observed to a neighboring bin, taken here as $i + 1$. All accepted and rejected transitions are simultaneously employed to generate the elements of a transition matrix. Subsequently, only a transition to bin $i + 2$ is accepted and this procedure is continued until the last of the $N$ bins comprising the computational window is sampled. The procedure is then repeated but in the direction of decreasing bin number. The probability distribution of $E$ can then be obtained by e.g. repeatedly multiplying a random vector by the transition matrix.

3:30PM D24.00006 The Transition Matrix in Flat-histogram Sampling, GREGORY BROWN, Florida State University, M. EISENBACh, Y. W. LI, G. M. STOCKS, Oak Ridge National Laboratory, D. M. NICHOLSON, University of North Carolina Asheville, KH. ODBADRRAK, University of Tennessee, P. A. RIKVOLD, Florida State University — Calculating the thermodynamic density of states (DOS) via flat-histogram sampling is a powerful numerical method for characterizing the temperature-dependent properties of materials. Since the calculated DOS is refined directly from the statistics of the sampling, methods of accelerating the sampling, e.g. through windowing and slow forcing, skew the resulting DOS. Calculating the infinite-temperature transition matrix during the flat-histogram sampling decouples the sampling from estimating the DOS, and allows the techniques of Transition Matrix Monte Carlo to be applied. This enables the calculation of the properties for very large system sizes and thus finite-size scaling analysis of the specific heat, magnetic susceptibility, and cumulant crossings at critical points. We discuss these benefits in the context of models for magnetocaloric and spin-crossover materials. This work was performed at the Oak Ridge National Laboratory, which is managed by UT-Battelle for the U.S. Department of Energy. It was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Office of Advanced Scientific Computing Research, and the Oak Ridge Leadership Computing Facility. PAR is supported by the National Science Foundation.

5:18PM D24.00015 Molecular dynamics simulations of nanoscale Al structures for energetic formulations, N. SCOTT WEINGARTEN, U. S. Army Research Laboratory, MICHAEL ZACHARIAH, University of Maryland — The addition of metal microparticles, such as aluminum, to molecular explosives results in an increase in the heat of explosion, as well as higher temperatures. It is expected that the use of Al nanoparticles would further enhance these effects, but this has never been realized due to sintering of the nano-Al just prior to the energy release step. Recently, a capability emerged to produce macroscopic quantities of aluminum-based nanoclusters comprising near metallic state Al cores, passivated with an energetic gas generator. We are pursuing the possibility that these nanoclusters can be embedded in a mesoscopic spherical architecture which, upon heating, will lead to the decomposition of the gas generator. This would drive a volumetric expansion that liberates the aluminum nanoclusters which can subsequently undergo exothermic reaction. Atomistic simulations are used to explore the feasibility of this process, and determine the dynamics driving the ejection of the nano-Al particles.

Session D26 DCP: Focus Session: Water and Liquid Dynamics 204A - David Chandler, Sandia National Laboratories

2:30PM D26.00001 ABSTRACT WITHDRAWN

2:42PM D26.00002 New insights into the femtosecond-to-picosecond dynamics of liquid water from temperature dependence using terahertz spectroscopy studies and molecular dynamics simulations, CHOLA REGMI, DEEPU GEORGE, SHENGFENG CHENG, NGUYEN VINH, Virginia Polytechnic Institute and State University — Water plays an active and complex role in sustaining life. The hydrogen bonds between the water molecules exhibit the unique physical properties that distinguish water from other molecular liquids. Nevertheless, there is little agreement regarding the femtosecond to picosecond relaxation dynamics of water. In response, we have used the state-of-the-art terahertz spectroscopy (frequency-domain and time-domain) and molecular dynamics simulation techniques to study the molecular relaxation of water at different temperatures in the femtosecond to picosecond time scale. We show that the two-Debye model is insufficient to explain the observed relaxation dynamics of water and our results on the terahertz dielectric relaxation of water are best described as the sum of three-Debye processes. We compute the time autocorrelation function of the dipole moment of water molecules at different temperatures with molecular dynamics simulations and compare the calculations with the experimental data.

2:54PM D26.00003 Exploring the nonlocal dielectric susceptibility of liquid water in the terahertz regime - propagating modes, Debye relaxation and overscreening, DANIEL ELTON, MARIVI FERNANDEZ-SERRA, Stony Brook University — There is great interest in the dielectric and infrared spectra of water between 1-1000 cm⁻¹ (.03-30 THz). To gain insight into this region we study the nonlocal (wavelength dependent) dielectric susceptibility. A curious feature of water is the presence of a propagating mode in the librational band in the terahertz regime. For the first time we study the temperature dependence of this mode and its range of propagation. We show that the librational band has two components - non-dispersive and dispersive. Previously this mode was suggested to be analogous to an optical phonon propagating along the H-bond network. We suggest a possible alternative - that it is the dipolaron mode predicted for dipolar systems. Next we study the region of 1-10 THz which is relevant to understanding the coupling between proteins and water. We show that in addition to H-bond vibrations, intramolecular inertial relaxations also contribute. We find that the Debye peak is dispersive, confirming its long range cooperativity. We report the first temperature dependent study of the static nonlocal susceptibility, which exhibits a negative region, a phenomena called overscreening. We compare a rigid model (TIP4P/ε), a flexible model (TIP4P/2005f) and a polarizable model (TTM3-F).

3:06PM D26.00004 A Dataset of First-Principles Molecular Dynamics Simulations of Water, FRANCOIS GYGI, WILLIAM DAWSON, Univ of California - Davis — We present a dataset of first-principles molecular dynamics simulations [1] of water performed using Density Functional Theory. A set of 32 independent 64-molecule samples was used in separate, parallel simulations for a duration of 50 ps. An analysis of atomic trajectories is given focusing on correlations of the Kohn-Sham energy, ionic kinetic energy, pair correlation functions, diffusion coefficient, and vibrational spectrum. The availability of 32 independent simulations allows for an estimation of the variance of averaged quantities, both within MD runs and between samples. The variability of oxygen pair correlation functions across samples provides a measure of the uncertainty associated with that quantity. We observe several instances of large fluctuations in the oxygen pair correlation functions that can be associated with increases in the local structure index (LSI) proposed by Shiratani and Sasai [2] supporting the hypothesis that water undergoes frequent changes to locally highly structured configurations. Complete atomic trajectories and simulation output files are available online [3].

3:18PM D26.00005 Mutual Exclusion of Urea and Trimethylamine N-oxide from Amino Acids in Mixed Solvent Environment, PRITAM GANGULY, Univ of California - Santa Barbara, TIMIR HAJIARI, TU Darmstadt, Germany, JOAN-EMMA SHEA, Univ of California - Santa Barbara, NICO F. A. VAN DER VEGT, TU Darmstadt, Germany — We study the solvation thermodynamics of individual amino acids in mixed urea and trimethylamine N-oxide (TMAO) solutions using molecular dynamics simulations and the Kirkwood-Buff theory. Our results on the preferential interactions between the amino acids and the cosolvents (urea and TMAO) show a mutual exclusion of both the cosolvents from the amino acid surface in the mixed cosolvent condition which is followed by an increase in the cosolvent-cosolvent aggregation away from the amino acid surface. The effects of the mixed cosolvents on the association of the amino acids and the preferential solvation of the amino acids by water are found to be highly non-linear in terms of the effects of the individual cosolvents. A similar result has been found for the association of the protein backbone, mimicked by triglycerine. Our results have been confirmed by different TMAO force-fields and the mutual exclusions of the cosolvents from the amino acids are found to be independent of the choice of the strength of the TMAO-water interactions. Based on our data, a general mechanism can potentially be proposed for the effects of the mixed cosolvents on the preferential solvations of the solutes including the case of cosolvency.

and a neutral Ar cluster is dominant in the formation of the cluster complex, \( \text{Co}^{+} \) low-energy collision between clusters. Here we present recent experimental results for the coupling of solution-phase compounds with an optical cavity. Solutions of \( \text{V}(\text{CO})_{6}, \text{Mo}(\text{CO})_{6} \), and NCS \(^{-}\) contained in cavities show strong coupling between the solute chromophores in the mid-infrared and cavity modes. We show that the methodology established with polymer-filled cavities is generally applicable to liquids but that the fluidity of the sample complicates the cavity construction. Varied cavity thicknesses can give rise to spatial gradients in coupling strength and difficulty in targeting a specific cavity-mode order. We also compare the transmission of the mixed vibrational-cavity modes in cavities constructed from either metallic or dielectric reflectors which impacts the cavity resonance line width.

3:30PM D27.00004 Investigations of ice nanoparticles and aerosols in molecular beams\(^1\), MICHAL FARNIK, J. Heyrovsky Institute of Physical Chemistry, ASCR, Dalejovka 3, 18223 Prague 8, Czech Republic — We have recently set up a versatile experiment which allows for different experiments with molecular clusters and nanoparticles in molecular beams. Here we concentrate on the experiments with ice nanoparticles (large water clusters (H\(_2\)O)\(_x\), N \(\sim\)10\(^{-2}-10^3\)) doped with atmospherically relevant molecules, e.g., hydrogen halides, CFCs, nitric acid, N\(_2\)O\(_y\), etc. Such species are relevant to ozone depletion and other atmospheric processes. We investigate (1) the UV-photochemistry using velocity map imaging techniques, and (2) the uptake cross section for the molecules on the ice nanoparticles from velocity measurements. In addition, we record (3) mass spectra of the particles implementing different ionization methods: electron ionization (EI) at variable electron energies, photoionization, and special method of electron photodetachment after Na-doping (NaPI). The unique combination of all these different methods performed with the same nanoparticles provides detailed molecular level information about the studied species and their (photo)physics and chemistry. In particular, an investigation of mixed water-nitric acid particles by means of EI and NaPI revealed the prominent role of the HNO\(_3\) molecule as the condensation nuclei. The uptake of atmospheric molecules by ice nanoparticles has been studied, and the pickup cross sections for some molecules exceed significantly the geometrical sizes of the ice nanoparticles. It has been argued that the large particles composed of several hundred water molecules which grow in the supersonic expansions tend to have highly irregular shapes — nanosnowflakes. Photodissociation of hydrogen halides on ice nanoparticles has been investigated, and shown to proceed via excitation of aciddially dissociated ion pair and subsequent biradical generation and H\(_2\)O dissociation. The photodissociation of CF\(_4\)Cl\(_2\) molecules in clusters leads to efficient CI-fragment caging caused by formation of halogen bond\(^2\).

4:06PM D27.00005 What is the structure of aqueous-alkane nanodroplets?\(^1\), BARBARA WYSLOUZIL, HARSHAD PATHAK, Ohio State Univ - Columbus, ABDALLA OBEIDAT, Jordan University of Science and Technology, GERALD WILEMSKI, Missouri University of Science and Technology — In situ small angle X-ray scattering (SAXS) experiments were conducted on D\(_2\)O-nonane nanodroplets produced in a supersonic nozzle. Fits to the scattering spectra, using standard models for multicomponent droplets such as well-mixed spheres and core-shell structures, were often poor and furthermore the amount of one of the condensed species often violated mass balance. Better fits were obtained using ‘lens-on-sphere’ models suggested by molecular dynamics simulations. Here the amount of nonane condensed, based on the SAXS fitting parameters, was quite close to that measured by infrared absorption spectroscopy although the amount D\(_2\)O condensed was only half of that measured spectroscopically.

4:18PM D27.00006 Nanodroplets of immiscible fluid pairs adopt nonspherical shapes\(^1\), GERALD WILEMSKI, Missouri University of Science and Technology, FAWAZ HRAHSHEH, King Fahd University of Petroleum and Minerals and Missouri University of Science and Technology — To help understand recent experimental results for nonane/water condensation [Pathak, et al. J. Chem. Phys. 140, 224318 (2014)], the structure of water/nonane nanodroplets was investigated using classical molecular dynamics (MD) simulations of SPC/E water and a unified atom model of nonane. Because nonane and water are essentially immiscible fluids that only partially wet each other, one might expect unusual nanodroplet structures to arise. Indeed, nonspherical, phase-separated Russian Doll (RD) structures were found to occur for these nanodroplets over the entire temperature range studied in the MD simulations, 220K – 300K. An idealized, but realistic lens-on-sphere model for the observed RD structures consists of a spherical nonane lens that partially wets a spherical water droplet. This model was used to analyze the experimental small angle X-ray scattering measurements. The simulated contact angle close to the experimental value of 33.6\(^o\) was confirmed.

4:30PM D27.00007 Vapor and Condensed Phase Clusters\(^1\), SHAWN KATHMANN, Pacific Northwest National Laboratory — Given the difficulty of directly observing clustering mechanisms underlying nucleation, classical and ab initio statistical mechanics provide crucial insight into the thermodynamics and kinetics of these processes. Recent experiments have shown nucleation can emit (e.g., crystalloluminescence) and be induced (e.g., IR lasers) by electromagnetic radiation. This opens up the possibility of using luminescence as an exquisite probe of the nucleation mechanism in addition to doing the reverse process by imposing external electromagnetic fields to activate specific modes of nucleation. The inclusion of electronic degrees of freedom as well as excited electronic states lies beyond classical theory. In addition, the osmotic coefficients of sub- and supersaturated aqueous electrolytes may provide quantitative insights into salt cluster distribution functions and free energies of crystal formation. Here we outline the chemical physics relevant to these findings and their consequences on how we understand and model nucleation to control and exploit the synthesis of matter.

consists of quasi-static (swept current) and pulsed-current regimes. Our aim is to investigate the dynamics and efficiency of spin-transfer switching. The layer stacks — We study current-induced switching of thin magnetic layers with perpendicular magnetic anisotropy using in-plane currents and the spin-Hall effect in the YU-MING HUNG, LAURA REHM, GEORG WOLF, ANDREW D. KENT, Department of Physics, New York University. Magnetic Anisotropy is a thousand times too small to account for the changes in switching fields that we observe. through magneto-Seebeck voltage measurements that the charge-currents that would be generated due to the temperature gradient would give rise to STT that significant TSTs in MTJs by generating large temperature gradients across ultrathin MgO tunnel barriers that considerably affect the switching fields of the thermal-spin-torques (TSTs) have been proposed, but so far these TSTs have not been large enough to influence MTJ switching. Here we demonstrate the spin-dependent thermoelectric properties of magnetic materials, novel means of generating spin-currents from temperature gradients, and their associated AAHAKSH PUSHP, TIMOTHY PHUNG, CHARLES RETTNER, BRIAN HUGHES, SEE-HUN YANG, STUART PARKIN, IBM Almaden Research Center —... devices using PMA magnets. using the Spin-Circuit Approach regarding the total energy, the switching speed and energy-delay products for different assisted writing approaches in STT-MTJ such as spin orbit torque, spin Hall effect, voltage controlled magnetic anisotropy and thermal excitation. In this work, we report on our comparative study of their switching properties as well as topography and current mapping by using nanoscale Conductive Atomic Force Microscopy. Our patterning method is based on using hydrogen silsesquioxane resist mask combined with ion beam etching. It allows to fabricate p-MTJ devices down to 40 nm in diameter while maintaining the magnetic quality of the multilayers. Repeatable, consistent switching behaviour has been observed in the obtained p-MTJ devices of 500 nm down to 40 nm with 10 – 800 mV voltage applied. Switching field increased as device diameter decreased, from 580 Oe at 500 nm (MR = 10%) to 410 Oe at 80 nm (MR = 9%). We discuss the effect of device sizes on the switching properties. 1 This work was supported by C-SPIN, one of the six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA. 1 This work was supported in part by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA and in part by the National Science Foundation through the NCN-NEEDS program, contract 1227020-EEC. 

3:30PM D28.00001 Minimization of the energy costs for operating magnetic tunnel junctions1, ILYAS A. H. FARHAT, E. GALE, Khalifa University - KUSTAR, A. F. ISAROVIC, Khalifa University - KUSTAR, KSRC — Increasing prospects of utilizing the STT-MRAM calls for the re-assessment of the overall energy (power) cost of operating magnetic tunnel junctions and related elements. This motivates our design, nanofabrication and characterization of simple tri-layer magnetic tunnel junctions which show measurable decrease in the operating energy cost. The MTJs we report about rely on nanoengineering interfaces between the insulating and magnetic layers in such a way that the area of the hysteresis loops can be controlled in one or both magnetic layers. Our TMR coefficient ranges from 45% to 130%, depending on the MTJ layer materials, and can be anticipated to be further increased. We also report the study of the TMR dependence on the RA product, as an important interface parameter. Lastly, we present an analysis of MTJ parameters affected by our approach and a perspective on further improvements, focusing on the device design parameters relevant for the integration of this type of MTJs. 1This work is supported by the SRC-ATIC grant 2012-VJ-2335. A part of this work is being performed at Cornell University CNF, a member of NNIN. 3:42PM D28.00002 Switching Properties of sub-100 nm Perpendicular Magnetic Tunnel Junctions1, LARYSA TRYPUTEN, Massachusetts Institute of Technology, STEPHEN PIOTROWSKI, MUKUND BAPNA, Carnegie Mellon University, CHIA-LING CHIEN, Johns Hopkins University, WEIGANG WANG, University of Arizona, SARA MAJETICH, Carnegie Mellon University, CAROLINE ROSS, Massachusetts Institute of Technology — Perpendicular magnetic tunnel junctions (p-MTJs) have great potential for realizing high-density non-volatile memory and logic devices. It is critical to solve scalability problem to implement such devices, to achieve low resistance area and to reduce switching current density while maintaining thermal stability. We present our recent results on fabrication of high resolution Ta/CoFeB/MgO/CoFeB/Ta p-MTJ devices and characterization of their switching properties as well as topography and current mapping by using nanoscale Conductive Atomic Force Microscopy. Our patterning method is based on using hydrogen silsesquioxane resin mask combined with ion beam etching. It allows to fabricate p-MTJ devices down to 40 nm in diameter while maintaining the magnetic quality of the multilayers. Repeatable, consistent switching behaviour has been observed in the obtained p-MTJ devices of 500 nm down to 40 nm with 10 – 800 mV voltage applied. Switching field increased as device diameter decreased, from 580 Oe at 500 nm (MR = 10%) to 410 Oe at 80 nm (MR = 9%). We discuss the effect of device sizes on the switching properties. 1 This work was supported by C-SPIN, one of the six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA.
3:42PM D28.00007 Low frequency noise peak near magnon emission energy in magnetic tunnel junctions, LIANG LIU, LI XUANG, HUIQIANG GUO, JIAN WEI, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China, DALAI LI, Z.H. YUAN, JIAFENG FENG, XIUFENG HAN, Beijing National Laboratory of Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, J.M.D. COEY, CRANN and School of Physics, Trinity College, Dublin 2, Ireland — We report on the low frequency noise in magnetic tunnel junctions (MTJs) below 4 K and at low bias, where thermal activation from the bath is suppressed and magnon emission from hot tunneling electrons dominates the transport. For one CoFeB/MgO/CoFeB MTJ, within a narrow range of bias voltage around magnon emission energy, a Lorentzian shape noise spectra is observed. For one CoFeB/AIOx/CoFeB MTJ, at similar bias voltage but within much wider bias range, a much larger Lorentzian shape noise spectra is observed and random telegraph noise is visible in the time traces. In both cases the Lorentzian spectra eventually disappears after repeated measurements, which in combination of the fitted parameters suggests magnon-assisted activation of defects as its origin.

3:54PM D28.00008 ABSTRACT WITHDRAWN —

4:06PM D28.00009 Iterative and self-consistent quantification of nonlocal spin valves with low-resistance oxide barriers, YUNJIAO CAI, Department of Physics and Astronomy, University of Delaware, YONGMING LUO, CHAO ZHOU, Department of Physics, Fudan University, CHUAN QIN, SHUHAN CHEN, Department of Physics and Astronomy, University of Delaware, YIZHENG WU, Department of Physics, Fudan University, YI JI, Department of Physics and Astronomy, University of Delaware — The standard method of quantifying nonlocal spin valves is to assume an exponential decay of the spin signal as a function of the channel length. Then the spin diffusion length and the spin polarization can be extracted via fitting. However, this method does not distinguish between the injection polarization and the detection polarization. In addition, the assumption that the channel length is the only varying parameter may not be always valid. In this work, a large number (>50) of Py-AIOx-Cu NLSV structures on a single substrate are investigated. The standard fitting of exponential decay is initially performed but appears unsatisfactory. We then assume an additional dependence of the spin polarization on the size of the Py/AIOx/Cu junctions, and normalize the spin signals by using the actual junction sizes in individual structures. By feeding the parameters iteratively, we are able to collapse all normalized spin signals on an exponential decay curve with good correlation. The injection/detection polarization strongly depends on the size of the Py/AIOx/Cu junctions. The coexistence of large Cu resistivity and long spin diffusion length points to interesting mechanism of spin relaxation.

4:18PM D28.00010 Inelastic electron tunnelling and noise spectroscopies in organic magnetic tunnel junctions with PTCDI barrier, FARKHAD ALIEV, ISIDORO MARTINEZ, Universidad Autonoma de Madrid, Spain, JHENDY- YONG HONG, National Taiwan University, Taiwan, JUAN PEDRO CASCALES, PABLO ANDRES, Universidad Autonoma de Madrid, Spain, MINN-TSONG LIN, National Taiwan University, Taiwan — The influence of internal barrier dynamics on spin, charge transport and their fluctuations in organic spintronics remains poorly understood. Here we present inelastic electron tunnelling spectroscopy (IETS) and low frequency noise (LFN) studies in magnetic tunnel junctions with thin (1.2-5nm) organic PTCDI barriers in the tunnelling regime at temperatures down to 0.3K. Shot noise is superpoisonian with a Fano factor exceeding 1.5-2 times the maximum values reported for magnetic tunnel barriers with inorganic barriers, indicating spin dependent bunching in tunneling [1]. IETS results show energy relaxation of tunneling electrons through the excitation of collective (librons) and internal (phonons) vibrational modes of the molecules. The bias dependence of the normalised 1/f noise studied up to 350mV reveals that the excitation of some phonon modes has a strong impact on LFN with over a 10-fold reproducible increase near some specific biases. The dependence of the IETS and LFN anomalies with the relative magnetic alignment of the electrodes will also be discussed. [1] J.P.Cascas et al., submitted to Applied Physics Letters

4:30PM D28.00011 Direct Observation of Magnetoresistance Variation in Molecular Junctions Induced by Electrode Geometry, XIANGMIN FEI, GUANGFEN WU, VANESSA LOPEZ, GANG LU, California State University, Northridge, HONG-JUN GAO, Institute of Physics, Chinese Academy of Sciences, LI GAO, California State University, Northridge — Spin-polarized electron transport in the Co/C60/Cu/Ni molecular junctions, in which the fullerene (C60) molecule is in electrical contact with electrodes, has been investigated using an ultra-high vacuum cryogenic scanning tunneling microscope (STM). By combining spin-polarized STM and current-displacement measurements, the spin-polarized contact conductance of molecular junctions has been measured at 5 K. Large tunnel magnetoresistance (TMR) values higher than ~60% have been observed. Depending on electrode geometry, the measured TMR values vary by a factor of ~1.5. The atomic-scale geometry of the electrode apex strongly impacts the spin-polarization of the electrodes and that of the interfacial hybrid molecular states. Our findings suggest that atomic-scale engineering of electrodes represents an additional dependence of the spin polarization on the size of the Py/AIOx/Cu junctions, and normalize the spin signals by using the actual junction sizes in individual structures. By feeding the parameters iteratively, we are able to collapse all normalized spin signals on an exponential decay curve with good correlation. The injection/detection polarization strongly depends on the size of the Py/AIOx/Cu junctions. The coexistence of large Cu resistivity and long spin diffusion length points to interesting mechanism of spin relaxation.

4:42PM D28.00012 Memristive behavior in tunnel junctions with graphene oxide barrier, MIRKO ROCCI, ANA PEREZ-MUÑOZ, JAVIER DEL VALLE, JOSE LUIS VICENT, CARLOS LEON, ZOHAIR SEFRIOU, JACOBO SANTAMARIA, Universidad Complutense de Madrid, FRANCESCO PERROZZI, LUCA OTTAVIANO, MICHELE NARDOINE, SANDRO SANTUCCI, Università degli Studi dell’Aquila, ITALY, EMANUELE TROESSI, CNR-ISOF and Laboratory MIST.E-R, Bologna, Italy, VINCENZO PALERMO, CNR-ISOF, Bologna, Italy — Resistive switching in Graphene Oxide (GO) structures has shown its potential for future nonvolatile memory applications. Here we report on GO (2-20 layers thick) as tunnel barriers in combination with half-metallic La0.75Sr0.25MnO3 (LSMO) manganites, Ag, and Ni as electrodes. Hybrid LSMO/GO/Ag junctions show a memristive-like behavior with more than 5 orders of magnitude resistance change (between high and low states) at low temperature. We explain the resistance switching in terms of (redox) generation of oxygen vacancies at the GO metal interfaces and their diffusion through the GO layer under the large applied electric fields (10^4 V/m). Magnetic tunnel junctions fabricated with Ni (instead of Ag) show a significant tunnelling magnetoresistance (TMR) combined with the nonvolatile memristor response. The sign of the TMR changes from positive to negative upon resistive switching of the GO. We interpret the sign inversion as due to changes in the Ni surface bonding state occurring as the result of the oxygen accumulation (depletion) at its surface.

5:06PM D28.00014 Fluorine Functionalized BNNT as a Spin Filter1, KAMAL DHUNGANA, RANJIT PATI, Michigan Technological University — Spin filtering is a phenomenon that allows one to generate spin-polarized carriers in a circuit comprised of a magnetic channel sandwiched between two non-magnetic electrodes. In recent years, the quest for a novel low-dimensional metal-free magnetic channel that would exhibit both magnetism at a higher temperature and excellent spin filtering property has been intensively pursued. Herein, using a first-principles approach, we study the magnetic property of fluorine functionalized boron nitride nanotube (F-BNNT). A long range ferromagnetic spin ordering is found to occur in the F-BNNT at temperature much above the room temperature. Our spin polarized transport study shows that the fluorine functionalization in BNNT not only enhances its conductance by more than two orders, which is in excellent agreement with the experimental report, but also makes it a perfect spin filter.

5:18PM D28.00015 Antiferromagnet controlled tunneling anisotropic magnetoresistance1. CHENG SONG, YUYAN WANG, FENG PAN, Tsinghua University, School of Materials Science and Engineering, Beijing, SPINTRONICS TEAM — We investigate tunneling anisotropic magnetoresistance (TAMR) in antiferromagnets (AFM)-based junctions, where Co/Pt magnetization drives partial rotation of AFM moments with the formation of exchange-spring [1]. The existence of exchange-spring is further confirmed by element specified x-ray magnetic dichroism [2]. Because of superior thermal tolerance of perpendicular exchange coupling and the stability of moments of ~ 6 nm-thick IrMn in [Pt/Co/IrMn/AOx/Pt] junctions, TAMR gets significantly enhanced up to room-temperature [1]. The TAMR behavior in [Pt/Co/IrMn/AOx/metal] junctions is insensitive to the top metal electrodes [3]. The situation turns out to be different when the top electrode is replaced by AFM. TAMR is observed in IrMn/AOx/IrMn junctions, where the resistance states are governed by the relative arrangement of the AFM moments adjacent to AOx [4]. Our findings would advance the process towards practical AFM spintronics.

2:42PM D29.00002 High-frequency modes of a magnetic antivortex1. MARTIN ASMAT-UCEDA, GRANT RILEY, ARABINDA HALDAR, KRISTEN BUCHANAN, Colorado State University — Magnetic vortices have attracted considerable attention in recent years not only because of their interesting physical properties but also due to their potential for applications. The magnetic antivortex (AV), the topological counterpart of the magnetic vortex, possesses similarly rich dynamics and its spin configuration may prove advantageous for spin-wave-based devices, however, it has not been studied as intensely. Recent experiments show that AV’s will form naturally at the intersections of patterned pound-key-like nanostructures that are magnetically soft. Here we present micromagnetic simulations of the dynamics of AV’s in these structures. The simulations show that pound-key-like structures made of 30-nm thick Permalloy exhibit a complex dynamic profile that includes a number of discrete high-frequency modes (>1 GHz). Spatial maps of the dynamic modes that were constructed using Fourier analysis of the simulation results show modes that are in similar in character to the radial and azimuthal modes observed for magnetic vortices but the spin dynamics also differ from those of a vortex due to the presence of the elongated nanowires in the pound-key-like structure. The frequencies of the observed modes tend to decrease with increasing sample size, however, the general features of the modes remains relatively unaffected by the structure size. The simulations will be compared to Brillouin Light Scattering (BLS) experimental results.

2:54PM D29.00003 Control of magnetic damping and magnetic fluctuations by spin current . YONG PU, CHI ZHANG, SERGEI MANUILOV, EZEKIEL JOHNSTON-HALPERIN, FENGYUAN YANG, CHRIS HAMMEL, The Ohio State University — We use spin hall effect in a non-magnetic film (NM) to generate spin current, which can excite magnetic precesses and manipulate magnetic properties of an adjacent ferromagnetic thin film (FM). We show that both magnetic damping and magnetic fluctuations can be sufficiently suppressed or enhanced by the spin current. We find that the magnetic damping is linear with spin current that is consistent with previous reports; on the other hand, the quasi-uniform precession and magnetic fluctuations show strongly nonlinear behaviors at driving current approaching critical value. The observations suggest that spin current interacts with all allowed spin-wave modes and induces strong nonlinear influence. Our results give an insight of the complex spin-torque driven dynamics in FM/NM systems and suggest a route to control the magnetic damping and magnetic fluctuations in nanodevices.

3:06PM D29.00004 Co1.5Fe1.5Ge and Co2MnSi Half-Metal Magnetic behavior tested by spin-resolved photoemission and ferromagnetic resonance , STEPHANE ANDRIEU, Institut Jean Lamour - Universite de Lorraine — In a magnetic spin-valve or tunnel junction, a crucial parameter to get both large magnetoresistance (MR) and a good Spin Transfer Torque (STT) efficiency is the spin-polarization of the magnetic electrodes. So-called “Half-Metallic” Magnetic (HMM) materials are of interest for such devices due to the existence of a spin-gap at the Fermi level for minority spins [1]. Recently, MR enhancements have been observed by different groups on Co2-xFe1+xGe [1] and Co2MnSi [2] Heusler materials, suggesting HMM behavior. A second consequence of that minority spin gap is that very low magnetic damping is expected. Combining both properties in a device is a challenge for decreasing the critical current necessary to switch the magnetization using STT. Up to now, many Heusler alloys are claimed to get this HMM property [3], but direct demonstration using spin-resolved photoemission is often missing. Here we focus on 2 systems, (i) Co1.5Fe1.5Ge for which a significant increase of the GMR was observed in spin valves [1], and (ii) Co2MnSi for which very large TMR values were observed in MgO-based MTJs [2]. The Co1.5Fe1.5Ge and Co2MnSi(001) films (noted CFG and CMS) were prepared by Molecular Beam Epitaxy and PLD coupled to the Spin-Resolved PhotoEmission (SR-PES) set-up on CASSIOPEE beamline at SOLEIL synchrotron. The L21 chemical ordering was confirmed in CFG films by using anomalous diffraction on (001) Bragg peaks. The spin-polarization of the magnetic electrodes, measured by SR-PES experiments, do not show any HMM behavior on our CFG films [4]. Similar PES experiments performed on CMS showed that the minority spin density of states (DOS) drops down to zero at -0.4eV below EF, leading to a 100% spin polarization. However, we also observed an increase of the minority spin DOS at EF, not predicted by ab initio calculations on the bulk structure. The spin-gap is thus decreased due to the surface symmetry breaking. We will show however that this spin-gap can be enlarged when finishing the surface by 1 Mn atomic plane, or when covering with the MgO barrier. Extremely low damping (<10-3) are observed, making CMS a very good candidate for spintronics devices.

Temperature dependent ferromagnetic relaxation and gyromagnetic ratio in Ni80Fe20/Gd thin films

We report on the temperature dependence of the magnetization dynamics of NiFe thin films (5nm & 10nm) capped with a 3nm Gd layer using broadband ferromagnetic resonance. We observe that the effective Gilbert damping parameter determined from the broadband measurements increases as the temperature approaches the Curie-temperature of the Gd layer. Part of the enhancement can be explained by an increase of the spin-pumping contribution to the relaxation [1,2] as the temperature approaches the Curie temperature of Gd. We also measure a strong increase of the gyromagnetic ratio with decreasing temperature which resembles the increase of the gyromagnetic ratio in rare earth containing transition metals near the compensation point [3,4]. This increase in the gyromagnetic ratio is expected to lead to an increased Gilbert type damping due to spin-orbit interaction [5,6], that likely also contributes to the increase in damping.

This work is supported primarily by C-SPIN (one of the six SRC STAR-net Centers) and partly by the MRSEC Program under Contract No. DMR-0819885.
4:54PM D29.00011 Symmetry-dependent electron-electron interaction in coherent tunnel junctions resolved by measurements of zero-bias anomaly  

JIAN WEI, LIANG LIU, JASEN NIU, LI XIANG, ICQM, Peking Univ, China, D.-L. LI, J.-F. FENG, X.-F. HAN, IOP, CAS, China, X.-G. ZHANG, Oak Ridge National Laboratory and Univ. of Florida, USA, J.M.D. COEY, Trinity College, Ireland — We provide conclusive experimental evidence that zero-bias anomaly in the differential resistance of magnetic tunnel junctions (MTJs) is due to electron-electron interaction (EEI), clarifying a long standing issue. The magnon effect that caused confusion is now excluded by measuring at low temperatures down to 0.2 K and with reduced ac measurement voltages down to 0.06 mV. The normalized change of conductance is proportional to $\ln(e^v/k_{B}T)$, consistent with the Alshuler-Aronov theory of tunneling that describes the reduction of density of states due to EEI, but inconsistent with magnetic impurity scattering. The slope of the $\ln(e^v/k_{B}T)$ dependence is symmetry dependent: the slopes for parallel and antiparallel states are different for coherent tunnel junctions with symmetry filtering, while nearly the same for those without symmetry filtering (amorphous barriers). This observation may be helpful for verifying symmetry preserved filtering in search of new coherent tunneling junctions, and for probing and separating electron Bloch states of different symmetries in other correlated systems.

5:06PM D29.00012 Large resistivity modulation in mixed-phase metallic systems  

YEONBAE LEE, University of California, Berkeley, ZHIQI LIU, Oak Ridge National Laboratory, Center for Nanophase Materials Sciences, JOHN HERON, Cornell University, JAMES CLARKSON, JEONGMIN HONG, CHANGHYUN KO, University of California, Berkeley, MICHAEL BIEGALSKI, Oak Ridge National Laboratory, Center for Nanophase Materials Sciences, ULRICH ASCHAUER, ETH Zurich, SHANG-LIN HSU, MARK NOWAKOWSKI, JUNQIAO WU, University of California, Berkeley, HANS CHRISTEN, Oak Ridge National Laboratory, Center for Nanophase Materials Sciences, SAYEEF SALAHUDDIN, JEFFREY BOKOR, University of California, Berkeley, NICOLA SPALDIN, ETH Zurich, DARRELL SCHLOM, Cornell University, RAMAMOOARTHY RAMESH, University of California, Berkeley — We have investigated the effect of an electric field to FeRh/PMN-Pt heterostructures and report 8% change in the electrical resistivity of FeRh films. Such a “giant” electroresistance (GER) response is striking in metallic systems, in which external electric fields are screened and thus only weakly influence the carrier concentrations and mobilities. We show that our FeRh films comprise coexisting ferromagnetic and antiferromagnetic phases with different resistivities, and the origin of the GER effect is the strain-mediated change in their relative proportions. The observed behavior is reminiscent of colossal magnetoresistance in perovskite manganites, and illustrates the role of mixed-phase coexistence in achieving large changes in physical properties with low-energy external perturbation.

5:18PM D29.00013 Effect of annealing on the surface magnetic and magnetoimpedance properties of Co-based amorphous microwires  

V. KALAPPATTI, J. DEVKOTA, E. CLEMENTS, S. CHANDRA, Department of Physics, University of South Florida, J.S. LIU, H.X. SHEN, J.F. SUN, Institute of Materials Science and Engineering, Harbin Institute of Technology, H. SRIKANTH, M.H. PHAN, Department of Physics, University of South Florida — Magnetic domains of negative magnetostrictive amorphous microwires (AWs) form a core-shell type structure with the core and shell domains preferred along axis and circumference, respectively. In this work, we have studied the effect of a combined current modulation annealing on the bulk and surface magnetic properties of melt-extracted $\text{Co}_{0.55}\text{Fe}_{0.45}\text{B}_{1.5}\text{Si}_{1.5}$ and Co$_{3.3}$Fe$_{1.7}$B$_{1.0}$Si$_{1.5}$Nb$_{0.5}$ AWs and their correlations with the magnetoimpedance (MI) effect. The AWs were annealed by a combination of ac (90 mA, 50 Hz) and dc (60, 63, and 65 mA) currents for 480 seconds each, and magnetic hysteresis loops were measured by VSM and a magneto-optic Kerr effect (MOKE) magnetometer. Compared to VSM loops, MOKE loops for the annealed AWs showed higher coercive and anisotropy fields, indicating that the near-surface region was magnetically harder. The anisotropy fields of the AWs defined as the peaks of the MI spectra at 1 MHz and 500 MHz were found to have a correlation with those probed by VSM and MOKE, respectively. These findings are of practical importance in designing MI-based sensors.

Session D30 GMAG DMP: Focus Session: Magnetic Domains and Domain Walls  
206B - Timothy Phung, IBM Almaden Research Center

2:30PM D30.00001 Highly efficient in-line magnetic domain wall injector  
TIMOTHY PHUNG, AAKASH PUSHP, LUC THOMAS, CHARLES RETTNER, SEE-HUN YANG, KWANG-SU RYU, JOHN BAGLIN, BRIAN HUGHES, STUART PARKIN, IBM Almaden Research Center — The creation and manipulation of domain walls (DWs) in magnetic nano-wires is of considerable interest, and forms the basis of several logic and memory devices. Traditionally, the DWs are created in the nano-wires using local magnetic fields from current injection lines fabricated orthogonal to the nano-wires, whereas the synchronous motion of a series of DWs along a nano-wire is achieved using spin transfer torque (STT) from charge currents that transport spin angular momentum. Here we demonstrate a highly efficient and simple DW injection scheme that uses a combination of STT from nanosecond long, uni-polar, current pulses that cross a $90^\circ$ magnetization boundary along with the fringing fields inherently prevalent at the boundary. The $90^\circ$ magnetization boundary is created by local ion-irradiation at the end of a nano-wire exhibiting perpendicular magnetic anisotropy. Remarkably, we find that the currents needed for this “in-line” DW injection scheme are at least one hundred times smaller than conventional methods. Additional advantages are its significantly smaller footprint than that of conventional methods, its compatibility to the smallest lithographic dimensions, and its ability to continuously inject DWs using uni-polar current. This simplified scheme bodes well for the fruition of spintronics based memory and logic devices.

2:42PM D30.00002 Domain wall motion in sub-100 nm magnetic wire  
SAIMA SIDDIQUI, SUMIT DUTTA, JEAN ANNE CURRIVAN, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, CAROLINE ROSS, Department of Materials Science and Engineering, Massachusetts Institute of Technology, MARC BALDÒ, Electrical Engineering and Computer Science, Massachusetts Institute of Technology — Nonvolatile memory devices such as racetrack memory rely on the manipulation of domain wall (DW) in magnetic nanowires, and scaling of these devices requires an understanding of domain wall behavior as a function of the wire width. Due to the increased importance of edge roughness and magnetostatic interaction, DW pinning increases dramatically as the wire dimensions decrease and stochastic behavior is expected depending on the distribution of pinning sites. We report on the field driven DW statistics in sub-100 nm wide nanowires made from Co films with very small edge roughness. The nanowires were patterned in the form of a set of concentric rings of 10 $\mu$m diameter. Two different width nanowires with two different spacings have been studied. The rings were first saturated in plane to produce onion states and then the DWs were translated in the wires using an orthogonal in-plane field. The position of the DWs in the nanowires was determined with magnetic force microscopy. From the positions of the DWs in the nanowires, the strength of the extrinsic pinning sites was identified and they follow two different distributions in two different types of nanowire rings. For the closely spaced wires, magnetostatic interactions led to correlated movement of DWs in neighboring wires. The implications of DW pinning and interaction in nanoscale DW devices will be discussed.
2:54PM D30.00003 Reversible electrically-driven magnetic domain wall rotation in multiferroic heterostructures to manipulate suspended on-chip magnetic particles1. MARK NOWAKOWSKI, University of California, Berkeley, HYUNMIN SOHN, CHENG-YEN LIANG, JOSHUA HOCKEL, KYLE WETZLAR, SCOTT KELLER, University of California, Los Angeles, BRENDA MCELLENN, NYU Polytechnic School of Engineering, MATTHEW MARCUS, ANDREW DORAN, ANTHONY YOUNG, Advanced Light Source, Lawrence Berkeley National Lab, MATHIAS KLÄUI, University of Mainz, GREGORY CARMAN, JEFFREY BOKOR, University of California, Berkeley, ROBERT CANDLER, University of California, Los Angeles — We experimentally demonstrate reversible electrically-driven, strain-mediated domain wall (DW) rotation in Ni rings fabricated on piezolectric [Pb(Mg1/3Nb2/3)O3]0.66-PbTiO3]0.34 (PMN-PT) substrates. An electric field applied across the PMN-PT substrate induces a strain in the Ni rings producing DW rotation around the ring toward the dominant PMN-PT strain axis by inverse magnetostriiction. We observe DWs reversibly cycled between their initial and rotated state as a function of the applied electric field with x-ray magnetic circular dichroism photo-emission electron microscopy. The DW rotation is analytically predicted using a fully coupled micromagnetic/elastodynamic multi-physics simulation to verify that the experimental behavior is caused by the electrically-generated strain in this multiferroic system. Finally, this DW rotation is used to capture and manipulate magnetic particles in a fluidic environment to demonstrate a proof-of-concept energy-efficient pathway for multiferroic-based lab-on-a-chip applications.

3:06PM D30.00004 Nucleation of 360 deg DWs in a wire using a local circular field1, FIKRIYE IDIL KAYA, ANANDAKUMAR SARELLA, KATHERINE E. AIDALA, Mount Holyoke College — Understanding domain wall (DW) motion in ferromagnetic nanostructures is important to realize proposed magnetic data storage and logic devices. Interest in 360° DWs has increased recently with the recognition that their minimal stray field creates only short range interactions, leading to a potentially higher packing density compared to 180° DWs. Our simulations demonstrate the feasibility of nucleating a 360° DW at a specific location along a wire by applying a local circular field that is centered in close proximity to the wire. We simulate the field strength as if from a current carrying wire, which can be experimentally realized by passing current through the tip of an AFM [1, 2]. The successful nucleation of a 360° DW depends on the dimensions of the Py wire, on the strength of the circular field, and on the distance of the center of the field from the wire. Once a 360° DW is nucleated, its position shifts with time. We use a notch to stabilize the location of the 360° DW. We investigate the optimal size and spacing of the notches to allow the greatest packing density with control over the nucleation and annihilation of individual domain walls. [1] T Yang et al., Appl. Phys. Lett., 98, 242505 (2011). [2] http://math.nist.gov/omnef

3:18PM D30.00005 Reversal-mechanism of in-plane current-induced perpendicular switching: the role of controllable domain behaviors, J. BI, Institute of Microelectronics, Chinese Academy of Sciences, Beijing 100029, China, J.Q. XIAO, Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716, USA, M. LIU, Institute of Microelectronics, Chinese Academy of Sciences, Beijing 100029, China — We propose a magnetization reversal model to explain the perpendicular switching of a single ferromagnetic layer induced by an in-plane current [1]. Our model includes three ingredients: (1) a steady equilibrium magnetization state with equal up and down domains favored by an applied current; (2) domain Wall (DW) motion under the applied current; (3) the up-down (↑↓) DW and down-up (↓↑) DW motions are separately modulated by an applied field. We experimentally demonstrate ingredient (1) can be satisfied in symmetric Pt/Co/Ni/Co/Pt and asymmetric Pt/Co/AlOx structures arising from the magnon instability induced by conventional spin torques [2] and probable spin-Hall torques (SHT) in asymmetric structures. We show ingredient (2) and (3) can also be satisfied in these structures. This model indicates that SHTs mainly play the role of driving DW motion, and a required external field plays the role of modulating the relative velocity of ↑↓ and ↓↑ DWs and thus determines the switching directions. This model also predicts similar switching behaviors in skyrmin structures. [1]L. Liu et al. Science 336, 555 (2012); [2] J. Shibata et al. Phys. Rev. Lett. 94, 076601 (2005).

3:30PM D30.00006 Domain Wall structures in wide palmello strips, VIRGINIA ESTEVEZ, LASSE LAURSON, COMP Centre of Excellence and Helsinki Institute of Physics, Department of Applied Physics, Aalto University — We numerically analyze the equilibrium micromagnetic domain wall structures encountered in Palmello strips of a wide range of thicknesses and widths, with strip widths up to several micrometers. By performing a systematic set of micromagnetic simulations, we show that the equilibrium domain wall structure exhibits additional DWs with respect to the previously found structures (symmetric and asymmetric transverse wall and vortex wall) also a double-vortex domain wall for large enough strip widths and thicknesses. In general, shape anisotropy is less important for wider strips, and thus energy minima with more complex spin structures closing the flux more efficiently than those found for narrow strips may appear. Also several metastable domain wall structures are found, such as structures with three or four vortices or two vortices and an antivortex. We discuss the details of the relaxation process, including the effect of varying the magnitude of the Gilbert damping constant, and the role of using different initial conditions. Finally, we also consider the field-driven dynamics of the double-vortex domain wall.

3:42PM D30.00007 Lateral Domain Transfer In a Magnetic Nanowire With Perpendicular-to-Plane-Anisotropy For Three-Dimensional Memory Applications, AISHA GOKCE, OZHAN OZATAY, BUGRA BULUT, Bogazici University, COLEMAN RAINY, Colombia University, JORDAN A. KATINE, HGST, A Western Digital Company, THOMAS HAUET, Institut Jean Lamour, Nancy Université, ANNA GIORDANO, GIOVANNI FRINGCCHIO, University of Messina — Spin torque driven magnetic domain transport has been of great interest with potential applications in three dimensional magnetic race track memory and also for domain wall logic. Here we report on experimental and micromagnetic modelling results of spin torque driven magnetic domain transport in CoNi/Pd multilayers with perpendicular-to-plane anisotropy patterned to form magnetic nanowires with double constrictions where domains can be moved with spin polarized current pulses in between constricted sites. The domain nucleation was triggered by Joule heating in the presence of a magnetic tip a few nm above the surface which was otherwise in the remanent state. We show that with low or high amplitude nanosecond current pulses two different types of domain transfer behavior is possible: a replicated or partially displaced domain in the neighboring constriction, or an expansion of the domain into the spacer region and the neighboring pinning site. Micromagnetic modelling of the domain transport in such devices suggests that in addition to the experimentally observed behavior a third regime where the full transfer of a single domain is also attainable. Our study shows that CoNi/Pd nanowires can be of potential practical use in a three dimensional memory structure.

3:54PM D30.00008 ABSTRACT WITHDRAWN —

4:06PM D30.00009 Dzyaloshinskii-Moriya Domain Walls in Nanotubes, OLEG TRETIAKOV, IMR, Tohoku University, ARSENII GOUSSEV, Northumbria University, J.M. ROBBINS, VALERIY SLASTIKOV, University of Bristol — We study domain walls in thin ferromagnetic nanotubes with Dzyaloshinskii-Moriya interaction (DMI). Dramatic effects arise from the interplay of space curvature and spin-orbit induced DMI on the domain wall structure in these systems. The domain walls become narrower in systems with DMI and curvature. Moreover, the domain walls created in such nanotubes can propagate without Walker breakdown for arbitrary applied currents, thus allowing for a robust and controlled domain-wall motion. The domain-wall velocity is directly proportional to the non-adiabatic spin transfer torque current term and is insensitive to the adiabatic current term. Application of an external magnetic field along the nanotube axis triggers rich dynamical response of the curved domain wall. In particular, we show that the propagation velocity is a non-linear function of both the applied field and DMI, and strongly depends on the orientation and chirality of the wall.

4:18PM D30.00010 Thermodynamic theory for thermally driven domain wall motion in magnetic nanostructures\textsuperscript{1}, XIANG RONG WANG, Hong Kong Univ of Sci & Tech — It is well-established now that a thermal gradient can be used to manipulate spins in a magnetic texture like skyrmions and domain walls (DWs). A thermal gradient can interact with spins through different channels. For example, a thermal gradient can affect spins through the thermoelectric effects by which spin polarized electric current is generated in a ferromagnetic metal. In turn, the thermally generated electric current can interact with magnetic texture via spin-transfer torque (STT). A thermal gradient can also generate magnons or spin waves that interact with magnetic textures. This effect should be important in a ferromagnetic insulator. Spin waves (or magnons) interact with magnetic domain walls (DWs) in a complicated way that a DW can propagate either along or against magnon flow, similar to its electron counterpart. Probably different from its electron counterpart where one may attribute the “wrong” DW propagation direction to the Dzyaloshinskii-Moriya interaction and various types of torques due to spin-orbit interactions, it will be very difficult to understand why a DW can move along the magnon flow if the angular momentum transfer is the only mechanism behind the magnon driven DW motion. It will also be difficult to explain why “wrong” DW propagation direction has not been observed in thermally driven DW motion in both simulations and experiments. Thus, there must be other interaction(s) between spin waves and magnetic textures. In terms of thermal gradient driven DW propagation along a nanowire, a DW always propagates to the hot region of a magnetic insulator wire. We theoretically illustrate why it is surely so from thermodynamic viewpoint. It is shown that DW entropy is always larger than that of a domain. Equivalently, the free energy difference of a DW and a domain decreases as the temperature increases. The larger DW entropy is related to the increase of magnon density of states at low energy originated from the gapless bound spin waves in DWs. This theory should be applicable to other spin textures like skyrmions as well since bound spin waves generally exist in spin textures. The theory also naturally explains why the magnetic domain widths decrease with the increase of the temperature, a well-known experimental phenomenon. In collaboration with X.S. Wang, Hong Kong University of Science & Technology.

4:54PM D30.00011 Asymmetric domain expansion and dendrite formation in thin films with strong Dzyaloshinskii-Moriya interaction, LUCAS CARETTA, MAXWELL MANN, AIK-JUN TAN, GEOFFREY BEACH, Massachusetts Inst of Tech-MIT — The Dzyaloshinskii-Moriya interaction (DMI) at heavy-metal/ferromagnet interfaces can stabilize chiral spin textures \textsuperscript{1}. It has been recently shown that field-driven bubble domain expansion in perpendicularly-magnetized thin films is asymmetric under the application of an in-plane field, which can be used to quantify the DMI effective field in the (DW). We have imaged domain expansion in Pt(3nm)/Co(0.9nm)/Pt(x)/GdOx(3nm) films using wide-field Kerr microscopy to characterize this behavior systematically as a function of DMI strength. In the case of null or weak DMI, realized when top and bottom Pt layers are of similar thickness, the in-plane field dependence of the DW velocity is well-described by the simple expansion model derived in Ref. \textsuperscript{2}. However, in the case of strong DMI, we find a strongly nonmonotonic behavior due to flattening of the DW, minimizing Zeeman energy and DMI energy. Moreover, we show that when the ratio of the DMI effective field to the perpendicular anisotropy field is large, expanding bubble domains leave behind fine-scale dendritic structures, consisting of coupled 360 degree DWs. We present modeling that qualitatively describes these behaviors. \textsuperscript{1} A. Fert et al., Nat. Nano., 8, 593 (2013). \textsuperscript{2} J. C. Slonczewski, J. Magn. Magn. Mater., 195, 222 (1999).

5:06PM D30.00012 Static and Dynamic Properties of Magnetic Antivortices in Asteroid-Shaped Permalloy Nanomagnets, ALI TAHA HABIBOGLU, VEDAT KARAKAS, MUSTAFA METE, AHMET COSKUNER, YEMLIHA BILAL KALYONCU, AISHA GOKCE, OZHAN OZATAY, Bogazici University, ANNA GIORDANO, MARIO CARPENTIERI, University of Calabria, GIOVANNI FINOCCHIO, University of Messina, FEDERICA CELEGATO, CNR Institute of Materials for Electronics and Magnetism, PAOLA TIBERTO, INRIM National Institute of Research Metrologia — Patterned nanomagnets display unconventional spin configurations like vortex, anti-vortex, bubble, which have unique static and dynamic properties. Such micro-magnetic structures are potentially applicable to ultrafast memory, rf oscillators and detectors. Studies on magnetic thin films containing vortex structures exhibit interesting behavior under external field and/or current bias like polarity switching, core displacement and core gyration with high fields [1]. In this study, we report on our investigation of stable anti-vortex formation conditions and the subsequent magnetic field/dc current driven excitations in 2x2um\textsuperscript{2} Permalloy based asteroid geometry devices which exhibit an anti-vortex pair nucleation at the center. The Magnetic Force Microscopy images show that the antivortex pair can be rotated around the center by an external magnetic field. We obtain a high frequency (GHz) signal measured via anisotropic magneto-resistance effect (AMR) under constant dc current-bias which triggers antivortex pair gyration around the center of the device through spin torque transfer. We study the dynamic response of the structure as a function of current and field to assess utilization of the device as a practical on-chip microwave oscillator.

5:18PM D30.00013 Micro-hysteresis in the Faraday Rotation of Bismuth Doped Iron Garnets\textsuperscript{1}, MANNIX SHINN, DONG HO WU, ANTHONY GARZARELLA, U. S. Naval Research Laboratory, RONGJIA TAO, Temple University — There is strong interest in using the Faraday effect (Magneto-optic effect) for non-invasive detection of weak magnetic fields, since in principle one can construct an ultra-sensitive MO-sensor that could be comparable to a SQUID. Bismuth doped rare earth iron garnets (Bi-RIGs) are a candidate material, however their polarization rotation is often measured at saturating fields. We have found that in some Bi-RIGs there is a coercive field that is less than the noise level of our probe beam, which can lead to mischaracterization of sensitivity. This coercivity appears related to magnetic domain wall motion. In this talk I will discuss our experiments and how domain walls can affect the sensitivity of our MO-sensor.

Monday, March 2, 2015 2:30PM - 5:30PM – Session D31 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors: Magnetic Interactions in Semiconductors 207A - Olaf van ‘t Erve, Naval Research Laboratory
2:30PM D31.00001 GMAG Dissertation Award Talk: Zero-moment Half-Metallic Ferrimagnetic Semiconductors, MICHELLE E. JAMER, Physics, Northeastern University — Low- and zero-moment half-metallic ferrimagnetic semiconductors [1,2] have been proposed for advanced applications, such as nonvolatile RAM memory and quantum computing. These inverse-Heusler materials could be used to generate spin-polarized electron or hole currents without the associated harmful fringing magnetic fields. Such materials are expected to exhibit low to zero magnetic moment at room temperature, which makes them well-positioned for future spin-based devices. However, these compounds have been shown to suffer from disorder [3]. This work focuses on the synthesis of these compounds and the investigation of their structural, magnetic, and transport properties. CrMnCoGa and Mn2Al thin films were synthesized by molecular beam epitaxy, and VFeAl and Cr2CoAl were synthesized via arc-melting. Rietveld analysis was used to determine the degree of ordering in the sublattices as a function of annealing. The atomic moments were measured by X-ray magnetic circular and linear dichroism confirmed antiferromagnetic alignment of sublattices and the desired near-zero moment in several compounds.

In collaboration with George E. Sterbinsky, Photon Sciences Directorate, Brookhaven National Laboratory; Dario Arena Photon Sciences Directorate, Brookhaven National Laboratory; Laura H. Lewis, Chemical Engineering, Northeastern University; and Don Heiman, Physics, Northeastern University.

3:06PM D31.00002 A Designed Room Temperature Multilayered Magnetic Semiconductor, DINAH SIMONE BOUMA, MICHALIS CHARILAOÛ, CATHERINE BORDEL, UC Berkeley Physics Department, RYAN DUCHIN, UC Berkeley Materials Science and Engineering Department, ALEXANDER BARRIGA, ADAM FARMER, FRANCES HELLMAN, UC Berkeley Physics Department, MATERIALS SCIENCE DIVISION, LAWRENCE BERKELEY NATIONAL LAB TEAM — A room temperature magnetic semiconductor has been designed and fabricated by using a combination of antiferromagnet (NiO) grown in the (111) orientation, which gives surface uncompensated magnetism for an odd number of planes, layered with the lightly doped semiconductor Al-doped ZnO (AZO). Magnetization and Hall effect measurements of multilayers of NiO and AZO are presented for varying thickness of each. The magnetic properties vary as a function of the number of Ni planes in each NiO layer; an odd number of Ni planes yields on each NiO layer an uncompensated moment which is RKKY-coupled to the moments on adjacent NiO layers via the carriers in the AZO. This RKKY coupling oscillates with the AZO layer thickness, and it disappears entirely in samples where the AZO is replaced with undoped ZnO. The anomalous Hall effect data indicate that the carriers in the AZO are spin-polarized according to the direction of the applied field at both low temperature and room temperature. NiO/AZO multilayers are therefore a promising candidate for spintronic applications demanding a room-temperature semiconductor.

3:18PM D31.00003 Magnetic Exchange Interactions in Long Range Ordered Diluted Organometallic Semiconductors, NAVIEN RAWAT, LANE MANNING, MADALINA FURIS, University of Vermont — Exchange interactions in diluted organometallic crystalline thin films of Phthalocyanines made of a mixture of organo-soluble derivatives of metal-free (H₂Pc) molecule and MnPc is investigated. The tuning of optical and magnetic properties in organometallics is driven by their emergence in optoelectronic applications involving flexible electronics. Thin films with metal to metal-free Pc ratios ranging from 1: 1 to 1:10 were fabricated using solution processing that produces macroscopic grains. In the case of Mn-Pc, our previous measurements showed enhanced hybridization of ligand π-electronic states with the Mn 3d-orbitals as well as indirect exchange interaction similar to that of RKKY type exchange. The evolution of Zeeman splitting of specific MCD-active states resulted in enhanced effective π-electrons g-factors, analogous to diluted magnetic semiconductors (DMS) systems. Recent Variable temperature Magnetic Circular Dichroism (VTMH-MCD) measurements has now revealed that the exchange interaction is Antiferromagnetic. Recent MCD data for mixed derivatives will be presented along with their temperature dependence that further probes this exchange interaction.

3:30PM D31.00004 ABSTRACT WITHDRAWN —

3:42PM D31.00005 Strong Spin-Exchange Interactions in Magnetically Doped Colloidal Nanocrystals, WILLIAM RICE, WENYONG LIU, THOMAS BAKER, GEN CHEN, JEFFREY PIETRYGA, VICTOR KLIMOV, SCOTT CROOKER, Los Alamos National Lab — Using magnetic circular dichroism, magneto-photoluminescence, and time-resolved Faraday rotation measurements, we study the spin-exchange interactions between excitons and embedded magnetic ions in Mn-doped colloidal nanocrystals. In contrast to undoped nanocrystals, the Mn-doped nanocrystals show giant Zeeman splittings of the nanocrystal conduction and valence bands and a very rapid dephasing of the optically created excitons (two orders of magnitude faster than undoped CdSe). Although the exciton spin coherence is short (less than 10 ps), the spin−d exchange interaction between the exciton and Mn moments induces a long-lived precession of the Mn²⁺ paramagnetic moments that persists out to nanosecond timescales. We study this induced Mn precession as a function of nanocrystal size, Mn doping density, temperature, and magnetic field.

3:54PM D31.00006 Driven magnetic patterns in quantum dots, ALEX MATOS-ABIAIGUE, JAMES PIENTKA, JONG E. HAN, IGOR ZUTIC, University at Buffalo-SUNY — We theoretically investigate the response of magnetic impurities in a quantum dot driven by a dc current. A bias voltage applied between the leads attached to the quantum dot drives the current. In addition, an external gate is used to tune the energy levels of the dot. The steady state magnetic configuration and current are self-consistently determined by using the non-equilibrium Green function formalism. The results reveal the emergence of different magnetization patterns in dependence on the bias and gate voltages for various sets of system parameters (number of magnetic impurities, tunneling coupling between dot and leads, and size of the dot). Under certain conditions and as the result of correlations between current and local magnetization, signatures of magnetic patterns formation can be observed in the I-V characteristics of the quantum dot. This allows for the design and characterization of magnetic patterns in quantum dots by electrical means.

4:06PM D31.00007 Ground State Properties of Magnetic Quantum Dots with Multiple Occupancies, JAMES PIENTKA, Saint Bonaventure University, IGOR ZUTIC, JONG HAN, University at Buffalo — Semiconductor quantum dots doped with magnetic impurities provide an intriguing opportunity to explore the interplay of confinement, Coulomb and exchange interactions [1,2]. Using exact diagonalization we study the ground state properties of a magnetic quantum dot with multiple occupancies. We show that the ground state not only depends on the orientation of the carrier and impurity spins, but is also very sensitive to the position of the magnetic impurities in the quantum dot. Our results reveal magnetic frustration and strongly correlated states, qualitatively different from the Fermi liquid behavior. [1] J. M. Pietkia R. Oszwaldowski, A. G. Petukhov, J. E. Han, and I. Zutic, Phys. Rev. B 86, 161403(R) (2012).[2] R. Oszwaldowski, P. Stano, A. G. Petukhov, and I. Zutic, Phys. Rev. B 86, 201408(R)(2012).

4:18PM D31.00008 Hole States and Magnetic Anisotropy of a Quantum Dot^{1} DAN REDERTH, HARI CHAPAGAIN, RAFAL OSZWALDOWSKI, SDSMT Physics, A.G. PETUKHOV, NASA Ames Research Center — In the era of spin-based advanced semiconductor materials^{1}, spin can be used for the control of quantum devices based on quantum dots (QDs)^{2}. To facilitate the control of the electronic and magnetic properties, magnetic ions can be incorporated in the QDs. We study the properties of such a magnetic II-VI QD charged with one hole. To account for the complex structure of valence band, we propose a method based on the Luttinger-Kohn Hamiltonian. With a robust numerical algorithm suitable for any QD geometry, magnetic properties can be incorporated in the QDs. We study the interplay of quantum confinement and magnetic anisotropy of a flat QD. We go beyond the virtual crystal approximation^{3}, our model also allows for position-dependent direction of magnetization. We discuss the differences between our and previous results, as well as the effects of temperature (mean-field approximation), and of the spin-orbit split-off band. We also discuss possible fluctuations of magnetization in QDs. Supported by DOE DE-SC00004890.

4:30PM D31.00009 Nanostructured lithium oxide-hematite magnetic semiconductor^{1} MONICA SORESCU, BASILII BUSHUNOW, Duquesne University, LUCIAN DIAMANDESCU, FELICIA TOLEA, MIHAELA VALEANU, National Institute of Materials Physics Bucharest, TIANHONG XU, Duquesne University — The study aims at exploring the formation of magnetic oxide semiconductors at the nanoscale, which is of crucial importance for catalysis, sensing and electrochemical applications. xLi2O-(1-x)alpha-Fe2O3 nanoparticles systems were successfully synthesized by mechanochemical activation of Li2O and alpha-Fe2O3 mixtures for 0.12 hours of ball milling time. X-ray powder diffraction (XRD), Mossbauer spectroscopy and magnetic measurements were used to study the phase evolution. Rietveld refinement of the XRD patterns yielded the values of the particle size as function of composition and milling times. The Mossbauer studies showed that the spectrum of the mechanochemically activated composites evolved from a sextet for hematite to sextets and a doublet upon duration of the milling process with lithium oxide. Magnetic measurements recorded at 5 K to room temperature (RT) in an applied magnetic field of 50,000 Oe showed that the magnetization of the milled samples is larger at low temperatures than at RT and increases with decreasing particle size. Zero field cooling measurements made possible the determination of the blocking temperatures of the specimens as function of ball milling time and evidenced the occurrence of superparamagnetism in the studied samples.

4:42PM D31.00010 ABSTRACT WITHDRAWN —

4:54PM D31.00011 Onset of spin polarization degeneracy in quantum wires ALFREDO SANCHEZ, JEAN-PIERRE LEBURTON, Univ of Illinois - Urbana — We report on the emergence of complex spin-polarized regimes arising from electron-electron interactions in quantum wires by using a three-dimensional unrestricted Hartree-Fock approach. We predict three distinct spin-polarized configurations in the presence of a magnetic field, two of which appear only above a concentration threshold. In the limit of vanishing magnetic fields, the electron system evolves into a pair of symmetric and degenerate regimes, indicating spontaneous spin polarization. The value of the concentration threshold and the energy of the polarized states all depend on the transverse dimensions of the wire. In particular, spontaneous spin polarization is suppressed if the wire cross section is highly asymmetric. Our investigations on spin-related effects are of significant relevance for spintronics applications and for the study of the 0.7 conductance anomaly in semiconductor quantum point contacts.

5:06PM D31.00012 π–d Electron Coupling in Excited State in Organic-Magnetic Nanocomposites, MINGXING LI, Univ of Tennessee, Knoxville, MIN WANG, University of Massachusetts, LEI HE, YU-CHE HSIAO, QING LIU, HENGXING XU, Univ of Tennessee, Knoxville, LONG Y. CHIANG, University of Massachusetts, LOON-SENG TAN, AUGUSTINE URBAS, Wright-Patterson Air Force Base, BIN HU, Univ of Tennessee, Knoxville — The coupling between π electron in organic semiconducting materials and d electron in ferromagnetic materials presents an important mechanism, namely π-d electron coupling, to develop magneto-optical and magneto-electronic properties. The π-d electron coupling has been heavily studied in ground state. This presentation reports the π-d electron coupling in excited state by combining intramolecular charge-transfer dipoles in semiconducting π electron system with spin dipoles from surface-modified magnetic nanoparticles based on organic-magnetic nanocomposites. Our magneto-dielectric studies show that the excited state has a much stronger π-d electron coupling, as compared to ground state, under photoexcitation. We further study the coupling mechanism by analyzing the line-shape of magneto-dielectric response. We find that increasing the Coulomb interactions between electrical dipoles and spin dipoles causes a line-shape narrowing. On contrast, increasing the spin interactions between them leads to a line-shape broadening. As a result, we conclude that the long-range Coulomb interactions and short-range spin interactions are responsible for realizing strong π-d electron coupling in excited state in organic-magnetic nanocomposites.

5:18PM D31.00013 First-Principles study of tris(8-hydroxyquinoline)iron(III) molecules: A promising spin filter material^{1}, WEI JIANG, MIAO ZOU, ZHENHUI LIU, DALI SUN, Z. VALY VARDENY, FENG LIU, University of Utah, FENG LIU’S GROUP TEAM, Z. VALY. VARDENY’S GROUP TEAM — Using first-principles calculations, we have systematically investigated the structural, electronic, and magnetic properties of face-meridional tris (8-hydroxyquinoline)iron(III) (Feq_{3}) molecules, solvent-free Feq_{3} crystals and thin films. Our calculation results show that both Feq_{3} isomers have a high spin state of 5 \mu_B as the ground state when an on-site Hubbard-U term is included to treat the highly localized Fe 3d electrons, in agreement with experiment, while the standard DFT calculations produce a low spin Fe state of 1 \mu_B. Furthermore, the freestanding Feq_{3} films are found to be paramagnetic, but become Ferromagnetic (FM) within each layer when deposited on a NiFe substrate. This is induced by a strong anti-ferromagnetic (AFM) coupling between the first molecular layer and FM substrate. Also, an AFM coupling is found between the molecular layers. These findings suggest that Feq_{3} molecular films may serve as a promising spin filter material in spintronic devices.

207B - Antonio Cammarata, Czech Technical University, Prague
2:30PM D32.00001 First-principles study of transport in SrTiO3
BURAK HIMMETOGLU, ANDERSON JANOTTI, HARTWIG PEELAERS, AUDRIUS ALKAUSKAS, CHRIS G. VAN DE WALL. University of California Santa Barbara — As a wide-band-gap semiconductor, SrTiO3 has attracted great interest for electronic device applications. While high electron mobilities of around 30,000 cm2 V−1 s−1 have been observed at low temperatures [1], room temperature mobilities are only on the order of a few cm2 V−1 s−1. These low mobilities pose a significant limitation for electronic device applications. In our work, we investigate the transport properties of n-doped SrTiO3 using first-principles calculations. We compute scattering of electrons with longitudinal optical modes in order to determine the scattering rates for the three conduction bands of SrTiO3. These scattering rates are invoked in Boltzmann transport integrals to calculate room-temperature transport coefficients. Our results indicate the strong impact of longitudinal optical phonon scattering as the main mechanism that leads to small electron mobilities at room temperature. In addition, our analysis provides valuable insights into designing high-mobility and high-thermopower materials, based on band-structure and strain engineering. Work supported by ONR and NSF. [1] J. Son, P. Moetakef, B. Jalan, O. Bierwagen, N. J. Wright, R. Engel-Herbert, and S. Stemmer, Nat. Mater. 9, 482 (2010)

2:42PM D32.00002 Many body effects on the formal charge state of 3d - Transition Metal Doped BaTiO3
SUBHASISH MANDAL, Department of Applied Physics, Yale University, New Haven, Connecticut & Geophysical Laboratory, Carnegie Institution of Washington, Washington D. C, R.E. COHEN, Geophysical Laboratory, Carnegie Institution of Washington, Washington D.C. USA & Dept of Earth Sciences, University College London, London, U.K, K. HAULE, Department of Physics, Rutgers University, Picataway, New Jersey, USA — Using density functional theory in combination with dynamical mean field theory in Mn doped BaTiO3, we find a different charge state and 3d - orbital occupations than obtained from either DFT or DFT+U. We find that the explicit treatment of many-body effects induced by the Hund’s rule coupling in Mn shows a donor charge state of Mn2+, instead of usual acceptor charge state of Mn4+ as is found in both DFT and DFT+U. The differences in electron density reveal that charge transfer due to strong Hubbard interactions is not sufficient to describe the electron correlations in transition metal doped ferroelectrics.

2:54PM D32.00003 Pressure induced iron spin state changes in MgGeO3 Perovskite and Post-perovskite
KANCHAN SARKAR, GAURAV SHUKLA, MEHMET TOPSAKAL, RENATA WENTZCOVITCH, University of Minnesota Twin cities — MgGeO3-perovskite is a low pressure analog of MgSiO3-perovskite, the main Earth forming phase, and is used to shed light on several phenomena that occur in MgSiO3, particularly the post-perovskite transition. As such, experimental investigations of spin state changes in Fe-bearing MgGeO3 might help to clarify some aspects of this phenomenon in MgSiO3. Using DFT+U calculations, we have investigated pressure induced spin state changes in Fe2+ and Fe3+ in MgGeO3 perovskite and post-perovskite and their effect on the post-perovskite transition. We uncover a direct relationship between average Fe-O bond-lengths and spin transition pressures in all cases. The effect of iron on the post-perovskite transitions in these phases can also be related to the average Fe-O bond lengths.

3:06PM D32.00004 ABSTRACT WITHDRAWN

3:42PM D32.00005 Oxygen vacancy induced localized state in rutile TiO2
DONGHAN SHIN, CHUNGWEI LIN, ALEXANDER A. DEMKOV, Univ of Texas, Austin — Titanium dioxide (TiO2) is as a promising material for several applications including photocatalysis, solar cells, spintronics and memory devices. Oxygen vacancies (OV) act as active sites for water dissociation and induce ferromagnetism in the bulk. Using density functional theory (DFT) and model Hamiltonian analysis, we investigate the localized states induced by an OV in rutile TiO2. We identify two classes of localized states: a hybrid and polaron states. The hybrid state is caused by the orbital overlap between three Ti atoms next to a vacancy and is mainly driven from the Ti eg orbitals. The polaron state is caused by the local lattice distortion and is mainly composed of one particular t2g orbital from a single Ti atom. The first principles calculation shows that the polaron state is energetically favored, and the tight-binding analysis reveals the underlying connection between the bulk band structure and the orbital character of the polaron. Their respective spin moments are deduced from the on-site electron correlation.

3:54PM D32.00006 The Correlation between Structure, Electronic Structure, and Shift Current in Visible-Light Ferroelectrics from First Principles
FENGONG WANG, STEVE YOUNG, FAN ZHENG, ILYA GRINBERG, ANDREW RAPPE, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104-6323, USA, SOLAR TEAM — Shift current, as a dominant mechanism of the bulk photovoltaic effect (BPVE), remains not well understood, especially in terms of its connection to material’s structure and electronic structure. This holds especially for the recently designed and demonstrated visible-light ferroelectric photovoltaics, Pb(Ni,Ti)O3−δ and (K,Ba)(Ni,Nb)O3−δ, that have great structural and electronic tunabilities. Here, we study the BPVE of the visible-light-absorbing ferroelectrics by calculating shift current from first principles. The effects of phase, lattice distortion, oxygen vacancy, cation arrangement, composition, and strain on BPVE are systematically studied. The wavefunction nature of the contributing electronic states dictates the eventual shift current yield, which can be significantly affected by the change of the O vacancy location, cation arrangement, and strain. Consequently, under broad spectrum illumination, the total current can be greatly enhanced by reducing the cancellation of counter propagating currents and by increasing the shift vector magnitude. This not only is helpful for understanding other photovoltaic mechanisms that relate to the motion of the photocurrent carriers, but also provides guidelines for the design of the photovoltaic converters.

4:06PM D32.00007 ABSTRACT WITHDRAWN

4:18PM D32.00008 First-Principles Physics of Nanocheckerboard Formation in ZnMnGaO Spinels
MORDECHAI KORNBLUTH, CHRIS MARIANETTI, Columbia University — Using first-principles calculations, we present the physics behind spinel nanocheckerboards in ZnMn4Ga2−xO4. Previously, experiments discovered a group of Mn-based spinels that spontaneously phase-separate into nanocheckerboards. We analyze their origin in the Jahn-Teller (JT) effect, which couples local atomic distortions to an electronic degeneracy (here, the eg manifold of the Mn d-orbital). Using density functional theory, we show that the interaction between cubic Mn-poor and tetragonal Mn-rich regions causes phase separation, but diffusion prevents the thermodynamic ground state of bulk separation. We demonstrate that the energetics and geometry mandate a nanocheckerboard configuration.
4:30PM D32.00009 A DFT+DMFT study of Orbital Physics in a Spin Orbital Lattice Coupled 2\(p\) Electron Mott System: KO\(_2\)  
MINJAE KIM, B.I. MIN, Department of Physics, Pohang University of Science and Technology, DEPARTMENT OF PHYSICS, POHANG UNIVERSITY OF SCIENCE AND TECHNOLOGY TEAM — We have investigated the temperature \(T\) - dependent orbital physics in a typical spin-orbital-lattice coupled 2\(p\) electron Mott system KO\(_2\), based on the electronic structures obtained by the dynamical mean-field theory as well as the density functional theory. KO\(_2\) consists of K\(^+\) cations and O\(_2^-\) molecule anions, and there are three electrons in the fourfold degenerate pi anti-bonding orbital of O\(_2^-\) anions. Hence, the orbital degeneracy occurs in a O\(_2^-\) anion with a magnetic moment. We have shown that KO\(_2\) exhibits the orbital fluctuation phenomenon at high \(T\) due to the degenerate pi anti-bonding orbital. Upon cooling, this orbital fluctuation is suppressed by the Jahn-Teller (JT) type crystal field with lowering of the crystal structure symmetry, and then the ferro-orbital (FO) ordering emerges at low \(T\). This FO ordering is compatible with the experimental antiferromagnetic spin order at low \(T\) in KO\(_2\). We suggest that the suppression of the orbital fluctuation in KO\(_2\) upon cooling is similar that in 3d transition-metal oxides such as LaVO\(_3\).

4:42PM D32.00010 Quantum Monte Carlo simulations of Ti4O7 Magnéli phase, ANOUAR BENALI, Argonne Natl Lab, LUKE SHULENBURGER, Sandia National Laboratories, JARON KROGEL, Oak Ridge National Laboratory, XIAOLIANG ZHONG, Argonne National Laboratory, PAUL KENT, Oak Ridge National Laboratory, OLLE HEINONEN, Argonne National Laboratory — Ti4O7 is ubiquitous in Ti-oxides. It has been extensively studied, both experimentally and theoretically in the past decades using multiple levels of theories, resulting in multiple diverse results. The latest DFT+SCF methods and state of the art HSE06 hybrid functionals even propose a new anti-ferromagnetic state at low temperature. Using Quantum Monte Carlo (QMC), as implemented in the QMCPACK simulation package, we investigated the electronic and magnetic properties of Ti4O7 at low (120K) and high (298K) temperatures and at different magnetic states. This research used resources of the Argonne Leadership Computing Facility at Argonne National Laboratory, which is supported by the Office of Science of the U.S. Department of Energy under contract DE-AC02-06CH11357. L.S, J.K and P.K were supported through Predictive Theory and Modeling for Materials and Chemical Science program by the Office of Basic Energy Sciences (BES), Department of Energy (DOE) Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

4:54PM D32.00011 Systematics of spin crossovers across the RECoO3 family\(^1\), MEHMET TOPSAKAL, CHRIS LEIGHTON, RENATA WENTZCOVITCH, Univ of Minn - Minneapolis — We have investigated structural and electronic properties of rare-earth cobaltites (RECoO3) using ab initio DFT + U calculations. A structurally consistent and self-consistent Hubbard U treatment is shown to be essential for the proper description of strongly correlated cobalt-d electrons. We successfully capture the experimentally observed structural variations and explain the trend in the spin transition temperature in cobalt across the RE series. We believe that Hubbard U values presented in this study will allow further predictive studies of RE cobaltites.

5:06PM D32.00012 Spin-orbit effects in iridates via electronic structure calculations: effects of tension and dimensionality\(^1\), VICTOR PARDO, Universidade Santiago de Compostela, JOSE L. LADO, International Iberian Nanotechnology Laboratory — Ab initio calculations have been performed in 5d\(^5\)-electron-based oxides in the large spin-orbit coupling limit. Our work tries to analyze the effects of strain and dimensionality in the electronic structure properties of iridates with 1\(r^{4+}: 5d^5\) electronic configuration in order to understand the different set of properties these materials present: they can be either metals or insulators, e.g. We focus on studying how close to the fully ionic 1\(r_{eff}=1/2\) limit the system is by analyzing the 1\(L_z/S_z\) ratio. We observe that it varies continuously as a function of strain or pressure, changing drastically with relatively small variations. We also analyze what effects on the band structure accompany this variation. In order to do this, we needed to include a full non-collinearity in the calculation of spin-orbit interaction. We have explored SrIrO\(_3\), S\(_2\)IrO\(_4\), S\(_3\)IrO\(_2\)\(_2\), thin films of SrIrO\(_3\) so as to analyze the dimensionality effects and the structural implications.

\(^1\) We acknowledge support of the MINECO through the Ramon y Cajal Program, Xunta de Galicia through project no. EM2013/037 and the EU through the Marie Curie ITN “Spinograph”.

Monday, March 2, 2015 2:30PM - 3:54PM – Session D33 GPC DFD: Focus Session: The Physics of Climate II 208 - Juan Restrepo, Oregon State University

2:30PM D33.00001 Scattering and Absorption of E&M radiation by small particles-applications to study impact of biomass aerosols on climate\(^1\), SOLOMON BILILIGN, North Carolina A&T State University, Department of Physics, SUJEEET SINGH, MARC FIDDLER, DAMON SMITH, North Carolina A&T State University — The phenomena of scattering, absorption, and emission of light and other electromagnetic radiation by small particles are central to many science and engineering disciplines. Absorption of solar radiation by black carbon aerosols has a significant impact on the atmospheric energy distribution and hydrologic processes. By intercepting incoming solar radiation before it reaches the surface, aerosols heat the atmosphere and, in turn, cool the surface. The magnitude of the atmospheric forcing induced by anthropogenic absorbing aerosols, mainly black carbon (BC) emitted from biomass burning and combustion processes has been suggested to be comparable to the atmospheric forcing by all greenhouse gases (GHGs). Despite the global abundance of biomass burning for cooking, forests clearing for agriculture and wild fires, the optical properties of these aerosols have not been characterized at wide range of wavelengths. Our laboratory uses a combination of Cavity ring down spectroscopy and integrating nephelometry to measure optical properties of (extinction, absorption and scattering coefficients) of biomass aerosols. Preliminary results will be presented.

\(^1\) Supported by the Department of Defense under grant #W911NF-11-1-0188.
2:42PM D33.00002 Observations Determination of Surface Radiative Forcing by CO2 and CH41, WILLIAM COLLINS, Lawrence Berkeley Natl Lab and UC Berkeley, DANIEL FELDMAN, Lawrence Berkeley Natl Lab, JONATHAN GERO, University of Wisconsin-Madison, Space Science and Engineering Center, MARGARET TORN, Lawrence Berkeley Natl Lab and UC Berkeley, ELI MLAWER, Atmospheric and Environmental Research, Inc., TIMOTHY SHIPPERT, Pacific Northwest National Laboratory, Fundamental and Computational Sciences — Earth’s background atmospheric CO2 and CH4 concentrations have been steadily rising due to anthropogenic emissions, and these increases since 1750 have implications for the radiative balance of the Earth’s atmosphere. The physics governing how atmospheric CO2 and CH4, both well-mixed greenhouse gases (WMGHGs), influence atmospheric infrared energy balance, and thus climate, are well established, but the impact of recent atmospheric WMGHG trends on the surface energy balance has not been experimentally confirmed in the field. Using infrared WMGHG absorption bands and controlling for atmospheric temperature and water vapor, spectra from the DOE ARM Program’s Atmospheric Emitted Radiance Interferometers (AERI) yield the first direct observational evidence of the time-series of WMGHG surface radiative forcing directly attributable to recent increases in WMGHGs, in this case between 2000-2010. The time-series shows a secular trend of the radiative forcing from both CO2 and CH4. This data record provides the first comprehensive observational evidence of surface radiative forcing by WMGHGs, confirming theoretical predictions of the atmospheric greenhouse effect.

2:54PM D33.00003 Interaction between carbon dioxide and coal: atomic-scale characteristics and electronic structures1, YINCDI LIU, SANWU WANG, Department of Physics and Engineering Physics, The University of Tulsa — Geologic sequestration of CO2 in unmineable coal seams has been suggested to mitigate the effect of the increasing of the atmospheric CO2 concentration on global warming. Extensive experimental studies have been performed for the injection of CO2 into coalbeds. However, the atomic-level mechanism for the interaction between CO2 and coal has not been fully explored. We report first-principles density-functional calculations and ab initio molecular dynamics simulations for the interaction between CO2 and the coal network. In particular, we report results about atomic-scale and electronic properties of the interaction. We also report a comparison with the interaction between CH4 and coal.

1 This research used the supercomputer resources at NERSC, of XSEDE, at TACC, and at the Tandy Supercomputing Center.

3:06PM D33.00004 Polar Oceanography, Arctic Sea Ice and Climate, MARY-LOUISE TIMMERMANS, Yale University — Intensive sampling from oceanographic moorings, shipboard measurements, and drifting autonomous buoy systems has brought new understanding to Arctic freshwater dynamics, ocean heat and mixing processes, circulation and eddies, and atmosphere-ice-ocean interactions. Observations indicate apparently rapid changes in the basin-scale freshwater distribution that have marked effects on Arctic stratification. Recent measurements support the idea that a strengthened stratification limits the vertical flux of deep-ocean heat. All ocean layers exhibit a rich mesoscale eddy field; eddies, with scales comparable to the Rossby Deformation Radius [O(10km)], transport water and heat over long distances and enhance ocean mixing. Measurements further reveal an active submesoscale flow field in the ocean surface layer. These upper-ocean features, having length scales of a few kilometers or less, are dynamically important in that they can impede surface-layer deepening and modify salt, and for they contribute to the surface ocean and adjacent sea-ice cover. This talk will review highlights of recent Arctic Ocean observational studies across a range of temporal and spatial scales, and illustrate advances in our understanding of ocean drivers of sea ice and climate change.

3:42PM D33.00005 Study of Aerosol Chemical Composition Based on Aerosol Optical Properties1, AUSTIN BERRY, RUDRA ARYAL, Eckerd College — We investigated the variation of aerosol absorption optical properties obtained from the CIMEL Sun-Photometer measurements over three years (2012-2014) at three AERONET sites GSFC; MD Science_Center and Tudor Hill, Bermuda. These sites were chosen based on the availability of data and locations that can receive different types of aerosols from land and ocean. These absorption properties, mainly the aerosol absorption angstrom exponent, were analyzed to examine the corresponding aerosol chemical composition. We observed that the retrieved aerosol absorption angstrom exponents on the two sites, GSFC and MD Science_Center, are near 1 (the theoretical value for black carbon) and with low single scattering albedo values during summer seasons indicating presence of black carbon. Strong variability of aerosol absorption properties were observed over Tudor Hill and will be analyzed based on the air mass embedded from ocean side and land side. We will also present the seasonal variability of these properties based on long-range air mass sources at these three sites.

Monday, March 2, 2015 2:30PM - 5:18PM –
Session D34 GSOFT: Gels and Complex Fluids 210A - George Thurston, Rochester Institute of Technology

2:30PM D34.00001 Diffusion of polyelectrolytes in polyelectrolyte gels, ANAND RAHALKAR, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — Using dynamic light scattering, we have investigated the diffusion coefficient of sodium poly(styrene sulfonate) in a matrix of poly(acrylamide-co-acrylate) gels. The diffusion coefficient of the probe polyelectrolyte exhibits a crossover behavior from a particle-diffusion to entropic-barrier dominated diffusion, as the molecular weight is increased. The effect of electrostatics, by varying the charge density of the matrix, on probe diffusion constant will be presented.

2:42PM D34.00002 The origin of and conditions for clustering in fluids with competing interactions, RYAN JADRICH, JONATHAN BOLLINGER, THOMAS TRUSKETT, University of Texas at Austin — Fluids with competing short-range attractions and long-range repulsions exhibit a rich phase behavior characterized by intermediate range order (IRO), as quantified via the static structure factor. This phase behavior includes cluster formation depending upon density-controlled packing effects and the magnitude and range of the attractive and repulsive interactions. Such model systems mimic (to zeroth order) screened, charge-stabilized, aqueous colloidal dispersions of, e.g., proteins. We employ molecular dynamics simulations and integral equation theory to elucidate a more fundamental microscopic explanation for IRO-driven clustering. A simple criterion is identified that indicates when dynamic, amorphous clustering emerges in a polydisperse system, namely when the Ornstein-Zernike thermal correlation length in the system exceeds the repulsive potential tail range. Remarkably, this criterion also appears tightly correlated to crystalline cluster formation in a monodisperse system. Our new gauge is compared to another phenomenological condition for clustering which is when the IRO peak magnitude exceeds ∼ 2.7. Ramifications of crystalline versus amorphous clustering are discussed and potential ways of using our new measure in experiment are put forward.
2:54PM D34.00003 A single parameter description of aggregate morphologies in two-dimensions\footnote{This work was supported by the OIST Graduate University with subsidy funding from the Cabinet Office, Government of Japan} . TAMOGHNA DAS, MAHESH BANDI, OIST Graduate University — A morphological hierarchy of two-dimensional aggregates has been studied using molecular dynamics. Particulate aggregates resulting from the competition between short-range attraction and long-range repulsion show a transition from non-compact to compact to percolated ‘gel’ structures as the competition varies at a constant temperature and density. A three-dimensional (3D) parameter space controlling the competition is mapped to a single dimensionless parameter \( \Lambda \). A unique relation between the reduced second virial coefficient \( B_2^* \), computed for a large set of points in the 3D parameter space, and \( \Lambda \) provides strong support for the proposed description. The observed morphologies were further quantified using an entropic measure \( S_2 \) of positional information. A simple scaling relation between \( S_2 \) and \( \Lambda \) shows the promise of describing the static structures of aggregates in terms of geometry alone.

3:06PM D34.00004 Dynamics across the morphological transition in two-dimensional aggregates\footnote{This work was supported by the OIST Graduate University with subsidy funding from the Cabinet Office, Government of Japan} . MAHESH BANDI, TAMOGHNA DAS, OIST Graduate University — Microscopic dynamics of two-dimensional aggregates have been studied by analysing simulated particle trajectories generated by molecular dynamics. Tuning the competition between the short-range attraction and long-range repulsion in a particulate system at fixed temperature and density results in a continuous non-compact to compact morphological transition. The finite-size aggregates, obtained by very slow cooling, show long-time sub-diffusive behaviour irrespective of their morphologies. By analysing the relative displacement fluctuations of particles with respect to their nearest neighbours, non-compact aggregates can be attributed to bonding between particles while caging is found to be responsible for compact clusters. These dynamical mechanisms are further illustrated by the self-displacement fluctuation of particles which show a continuous change from power-law to exponential behaviour across the non-compact to compact transition.

3:18PM D34.00005 1- and 2-particle Micro rheology of Hyaluronic Acid \footnote{NSF IGERT Fellowship Award No. 0801471} . AUSTIN SAGAN, SARAH KEARNS, DAVID ROSS, MOUNITA DAS, GEORGE THURSTON, SCOTT FRANKLIN, Rochester Inst of Tech — Hyaluronic acid (also called HA or Hyaluronan) is a high molecular weight polysaccharide ubiquitous in the extracellular matrix of soft tissue such as cartilage, skin, the eye’s vitreous gel and synovial fluid. It has been shown to play an important role in mechanotransduction, cell migration and proliferation, and in tissue morphodynamics. We present a confocal micro rheology study of hyaluronic acid of varying concentrations. The mean square displacement (MSD) of sub-micron colloidal tracer particles is tracked in two dimensions and shows a transition from diffusive motion at low concentrations to small-time trapping by the protein network as the concentration increases. Correlations between particle motion can be used to determine an effective mean-squared displacement which deviates from the single-particle MSD as the fluid becomes less homogenous. The real and effective mean-squared displacements are used to probe the local and space-averaged frequency dependent rheological properties of the fluid as the concentration changes.

3:30PM D34.00006 A Rate-Dependent Shear Transformation Zone Model of Shear Band Formation During Flow\footnote{This work was supported by the OIST Graduate University with subsidy funding from the Cabinet Office, Government of Japan} . ADAM R. HINKLE, MICHAEL L. FALK, Johns Hopkins University — Recent shear-experiments of carbopol gels have revealed the formation of a transient shear band before reaching the steady-state characterized by homogeneous flow. Analysis of this phenomenon using a rate-dependent effective temperature in the shear transformation zone (STZ) theory reveals that the observed fluidization proceeds via two distinct processes: A shear band initiates and broadens via disordering at the interface of the band. This is accompanied by spatially homogeneous fluidization outside of the shear band where the disorder of the gel grows uniformly. Experimental data are used to parameterize the STZ theory, and direct, quantitative comparison is made to measurements of the structural evolution of the gel.

3:42PM D34.00007 Effect of short range hydrodynamic on bimodal colloidal gel systems , ARMAR BOROMAND, SAFA JAMALI, JOAO MAIA, Case Western Reserve University — Colloidal Gels and disordered arrested systems has been studied extensively during the past decades. Although they have found their place in multiple industries such as cosmetic, food and so on, their physical principals are still far beyond being understood. The interplay between different types of interactions from quantum scale, Van der Waals interaction, to short range interactions, depletion interaction, and long range interactions such as electrostatic double layer makes this systems challenging from simulation point of view. Many authors have implemented different simulation techniques such as molecular dynamics (MD) and Browninan dynamics (BD) to capture better picture during phase separation of colloidal system with short range attractive force. However, BD is not capable to include multi-body hydrodynamic interaction and MD is limited by the computational resources and is limited to short time and length scales. In this presentation we used Core-modified dissipative particle dynamics (CM-DPD) with modified depletion potential, as a coarse-grain model, to address the gel formation process in short ranged-attractive colloidal suspensions. Due to the possibility to include and separate short and long ranged-hydrodynamic forces in this method we studied the effect of each of those forces on the final morphology and report one of the controversial question in this field on the effect of hydrodynamics on the cluster formation process on bimodal, soft-hard colloidal mixtures.

3:54PM D34.00008 Transient yield in reversible colloidal gels: a micro-mechanical perspective. LILIAN JOHNSON, Cornell University, BENJAMIN LANDRUM, WILLIAM RUSSEL, Princeton University, ROSEANNA ZIA, Cornell University — We study the nonlinear response rheology of colloidal gels via large-scale dynamic simulation, with a view toward understanding the micro-mechanical origins of the transition from solid-like to liquid-like behavior during flow startup, and post-cessation relaxation. Such materials often exhibit an overshoot in the stress response during startup, but the underlying microstructural origin of this behavior remains unclear. The gels studied here comprise Browninan particles interacting via hard-sphere repulsion and short-range attraction of strength of \( O(\xi T) \) that leads to formation of a bi-continuous network. The relatively weak bonds allow the network to restructure over time; our recent work defines the structural evolution and dynamics of such coarsening, and its impact on linear-response rheology. Here we investigate the role of particle attractions and evolving structure on the nonlinear response of the gel. Upon startup of an imposed strain rate, the transition from rest to steady flow is characterized by one or more “overshoots” in the shear stress. Experimental studies, in which the overshoots depend on gel age, strain rate, volume fraction, and attraction strength, suggest that the underlying microstructural origin is a two-step process of cage breaking and bond breaking. However, our detailed studies of the microstructural evolution during startup challenge this view. We present a new model of stress development, relaxation, and memory in reversible colloidal gels in which the ongoing age-coarsening process plays a qualitatively new role.
4:06PM D34.00009 Delayed yield in reversible colloidal gels: a micro-mechanical perspective. ROSEANNA N. ZIA, Cornell University, BENJAMIN J. LANDRUM, Cornell University and Princeton University, WILLIAM B. RUSSEL, Princeton University — We study via dynamic simulation the nonlinear response of a reversible colloidal gel undergoing deformation under applied stress, with a view toward elucidating mechanisms of macroscopic yield at the level of particle dynamics. Under shear, such gels may flow then regain solidlike behavior upon removal of the stress. The transition from solidlike to liquidlike behavior is a yielding process that is not instantaneous but rather occurs after a finite delay. The delay length decreases as stress increases, but the underlying microstructural origin is not clear. Recent experiments reveal two regimes, suggesting multiple yield mechanisms. Theories advanced to link gel structure to rheology aim to predict the ultimate state of a gel under an applied load. While these hypothesize a competition between bond breakage and reconnection rates, no such particle-scale dynamics have been directly observed, and it is not clear these theories reconcile with ongoing structural evolution. To study these behaviors, we conduct large-scale dynamic simulation to model structural evolution and particle transport in colloidal gels subjected to a step stress. A range of volume fraction, attraction strength, and stress is studied, with detailed connection between macroscopic response, microstructure, and particle dynamics.

4:18PM D34.00010 Using dissipative particle dynamics to model micromechanics of responsive hydrogels1. ALEXANDER ALEXEEV, SVETOSLAV NIKOLOV, ALBERTO FERNANDEZ DE LAS NIEVES, Georgia Institute of Technology — The ability of responsive hydrogels to undergo complex and reversible shape transformations in response to external stimuli such as temperature, magnetic/electric fields, pH levels, and light intensity has made them the material of choice for tissue scaffolding, drug delivery, bio-adhesive, bio-sensing, and micro-sorting applications. The complex micromechanics and kinetics of these responsive networks however, currently hinders developments in the aforementioned areas. In order to better understand the mechanical properties of these systems and how they change during the volume transition we have developed a dissipative particle dynamics (DPD) model for responsive polymer networks. We use this model to examine the impact of the Flory-Huggins parameter on the bulk and shear modul. In this fashion we evaluate how environmental factors can affect the micromechanical properties of these networks.

4:30PM D34.00011 Separation and concentration of protein and microgel dispersions, RAFAEL ROA, GERHARD NAE GELE, Forschungszentrum Juelich — Membrane ultrafiltration is a pressure driven process where Brownian particles, such as small colloids or nanoparticles, are concentrated. This process is highly important for the separation and enrichement of protein and microgel dispersions, where convective-diffusive particle transport determines the permeate flux. The efficiency of the separation process is thus strongly dependent on particle hydrodynamic structure and boundary conditions, membrane properties, and particle interactions. We calculate the concentration polarization layer and the permeate flux at different operating conditions for cross-flow ultrafiltration of BSA proteins and for non-ionic and microgel dispersions. We show that the proper specification of the concentration dependent dispersion transport properties and the inclusion of microgel permeability have a significant effect on the filtration behavior on concentrated systems.

4:42PM D34.00012 Relaxation Mode Analysis and Scale-Dependent Energy Landscape Statistics in Liquids, ZHIKUN CAI, YANG ZHANG, Univ of Illinois - Urbana — In contrast to the prevailing focus on short-lived classical phonon modes in liquids, we propose a classical treatment of the relaxation modes in liquids under a framework analogous to the normal mode analysis in solids. Our relaxation mode analysis is built upon the experimentally measurable two-point density-density correlation function (e.g. using quasi-elastic and inelastic scattering experiments). We show in the Laplace-inverted relaxation frequency z-domain, the eigen relaxation modes are readily decoupled. From here, important statistics of the scale-dependent activation energy in the energy landscape as well as the scale-dependent relaxation time distribution function can be obtained. We first demonstrate this approach in the case of supercooled liquids when dynamic heterogeneity emerges in the landscape-influenced regime. And then we show, using this framework, we are able to extract the scale-dependent energy landscape statistics from neutron scattering measurements.

5:44PM D34.00013 Gelation and glass transition of particles with short-range attraction induced by adsorbing microgel1. GUANGCUI YUAN, JUNJUAN LUO, CHARLES C. HAN, Institute of Chemistry, Chinese Academy of Sciences — Mixed suspensions of large hard polystyrene microsphere and small poly(N-isopropylacrylamide) microgel is used as model systems to investigate the static and viscoelastic properties of suspensions which go through liquid to gel and to glass transitions. The microgels cause short-range attraction between microspheres through bridging and depletion mechanism whose strength can be tuned by the microgel concentration. Baxter’s sticky hard-sphere model is used to extract the effective inter-microsphere interaction introduced by bridging or depletion of microgels despite the fact that the physical mechanisms of bridging attraction and depletion attraction are different at a molecular level. A new state diagram of gelation and even of glass transition was constructed by taking the bridges as a short-ranged attractive interaction. With the help of the well-defined bridging bonds, some controversies regarding to the interference between two origins for ergodic to non-ergodic transition in condensed system, i.e. cage effect and bond effect, were clarified.

5:06PM D34.00014 Osmotic Pressure in Ionic Microgel Dispersions, ALAN R. DENTON, QIYUN TANG, Dept. of Physics, North Dakota State University — Microgels are microscopic gel particles, typically 10-1000 nm in size, that are swollen by a solvent. Hollow microgels (microcapsules) can encapsulate cargo, such as dye molecules or drugs, in their solvent-filled cavities. Their sensitive response to environmental conditions (e.g., temperature, pH) and influence on flow properties suit microgels to widespread applications in the chemical, pharmaceutical, food, and consumer care industries. When dispersed in water, polyelectrolyte gels become charged through dissociation of counterions. The electrostatic contribution to the osmotic pressure inside an ionic microgel and the electrostatic contribution to the osmotic pressure. Within a coarse-grained one-component model, we further chart the limits of the cell model for salty dispersions.

Monday, March 2, 2015 2:30PM - 5:30PM – Session D36 DCOMP: Invited Session: Materials for Energy: Predicting the Properties of Solid/Electrolyte Interfaces from First Principles 211 - Giulia Galli, University of Chicago
2:30PM D36.00001 Electronic properties of semiconductor-water interfaces: Predictions from \textit{ab-initio} molecular dynamics and many-body perturbation theory\textsuperscript{1}. TUAN ANH PHAM, Lawrence Livermore National Laboratory — Photoelectrochemical cells offer a promising avenue for hydrogen production from water and sunlight. The efficiency of these devices depends on the electronic structure of the interface between the photoelectrode and liquid water, including the alignment between the semiconductor band edges and the water redox potential. In this talk, we will present the results of first principles calculations of semiconductor-water interfaces that are obtained with a combination of density functional theory (DFT)-based molecular dynamics simulations and many-body perturbation theory (MBPT). First, we will discuss the development of an MBPT approach that is aimed at improving the efficiency and accuracy of existing methodologies while still being applicable to complex heterogeneous interfaces consisting of hundreds of atoms \cite{5,6}. We will then present studies of the electronic structure of liquid water and aqueous solutions using MBPT, which represent an essential step in establishing a quantitative framework for computing the energy alignment at semiconductor-water interfaces \cite{4,5-5}. Finally, using a combination of DFT-based molecular dynamics simulations and MBPT, we will describe the relationship between interfacial structure, electronic properties of semiconductors and their reactivity in aqueous solutions through a number of examples, including functionalized Si surfaces \cite{6} and GaP/InP surfaces in contact with liquid water.

3:06PM D36.00002 First-principles simulations of charge storage at electrochemical interfaces in supercapacitors. BRANDON WOOD, Lawrence Livermore National Laboratory — Supercapacitors store charge via polarization at the electrode-electrolyte interface. Many models of interfacial charge storage focus on the formation of the electric double layer (EDL) in the electrolyte, but it is often assumed that in the electrode, a shift in the Fermi level is the only notable response to interface polarization. In reality, the presence of the interface impacts the fundamental properties of both the electrode and the electrolyte, often in complex and nontrivial ways that are difficult to capture using simple models. I will discuss how including an applied bias potential in \textit{ab initio} first-principles simulations allows one to directly simulate the process of charge storage at the electrode-electrolyte interface, and thereby to unravel the interplay between the electrode and the electrolyte. I will show how these more complex treatments lead to improved descriptions of intrinsic quantum and EDL capacitance contributions in graphene-based supercapacitors, which can be used to suggest engineering strategies for improved electrode materials. I will also discuss how combining theory with in operando X-ray spectroscopy can give insights into nanoscale chemical changes and mesoscale morphological changes in electrodes during charging. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract DE-AC52-07NA27344.

3:42PM D36.00003 Ab initio joint density-functional theory of solvated electrodes, with model and explicit solvation\textsuperscript{1}. TOMAS ARIAS, Cornell University — First-principles guided design of improved electrochemical systems has the potential for great societal impact by making non-fossil-fuel systems economically viable. Potential applications include improvements in fuel-cells, solar-fuel systems ("artificial photosynthesis"), supercapacitors and batteries. Economical fuel-cell systems would enable zero-carbon footprint transportation, solar-fuel systems would directly convert sunlight and water into hydrogen fuel for such fuel-cell vehicles, supercapacitors would enable nearly full recovery of energy lost during vehicle braking thus extending electric vehicle range and acceptance, and economical high-capacity batteries would be central to mitigating the indeterminacy in GaN and SrTiO\textsubscript{3}. MARIVI FERNANDEZ-SERRA, Physics & Astronomy department, Stony Brook University. Stony Brook, NY — No abstract available.

\textsuperscript{1}Supported as a part of the Energy Materials Center at Cornell, an Energy Frontier Research Center funded by DOE/BES (award de-sc0001086) and by the New York State Division of Science, Technology and Innovation (NYSTAR, award 60923).

4:18PM D36.00004 Link between photocatalytic water splitting efficiency and surface acidity in GaN and SrTiO\textsubscript{3}. MARIVI FERNANDEZ-SERRA, Physics & Astronomy department, Stony Brook University. Stony Brook, NY — No abstract available.

oscillations are found to proceed with different phases for the two components of the scattered light. Satisfactory agreement is found between the experimental frequency comb scattering. The spectrum exhibits predicted features such as multiple sidebands when the pulse duration is long enough. In addition, Rabi and second-order correlation function of the scattered light. In particular, the coherently and incoherently scattered light can be distinguished by virtue of the investigated theoretically. By using a high resolution Fabry-Perot interferometer and a stabilized mode-locked laser source we were able to measure the spectrum scattered near-resonantly by a quantum dot under excitation by a periodically-pulsed laser, i.e., a frequency comb. Even though the scattered light spectrum shifts, combined with tunneling of charges from the QD to nearby defects, provide an explanation of the bunching observed in the correlations. Photoluminescence excitation spectra indicate that the QD experiences discrete spectral shifts due to changes in the local charge environment. These spectral charge carriers introduced by a HeNe laser. Second-order correlation measurements show bunching behavior that changes with HeNe laser power. Resonant photoluminescence excitation spectra indicate that the QD experiences discrete spectral shifts due to changes in the local charge environment. These spectral shifts, combined with tunneling of charges from the QD to nearby defects, provide an explanation of the bunching observed in the correlations.

In quantum dots (QDs), optical fields are an attractive medium for qubit manipulation and readout. The entanglement between a QD spin qubit and an emitted photonic qubit allows for the transport of quantum information between distant quantum memories via decoherence resistant photon channels. I will present recent experimental work showing the entanglement between a single electron spin confined to an InAs QD and its spontaneously emitted photon. This entanglement is significant for the further development of quantum information technologies using QDs and forms the foundation of on-chip technologies using photonic crystal pathways. In addition, I will discuss on-going work on teleportation of information from a single photon generated in a spontaneous parametric down conversion (SPDC) process to a QD spin through intermediate interference between the SPDC photon and the dot’s emitted photon. The ability to integrate two quantum information platforms is not only exciting in its own right, but this technique could allow for an entanglement swapping bridge between other matter-qubit (ions, NV centers, etc.) based quantum memories.

This work is funded by NSF, ARO, AFOSR, ONR and DARPA.

**3:06PM D37.00002 ABSTRACT WITHDRAWN**

**3:18PM D37.00003 Photon Statistics of Quantum Dot Resonance Fluorescence under the Influence of a Non-Resonant Laser**. DISHENG CHEN, GARY LANDER, CABOT ZABRISKIE, EDWARD FLAGG, West Virginia University — We study the statistical behavior of resonance fluorescence from self-assembled InAs quantum dots (QDs) as a function of the density of free charge carriers introduced by a HeNe laser. Second-order correlation measurements show bunching behavior that changes with HeNe laser power. Resonant photoluminescence excitation spectra indicate that the QD experiences discrete spectral shifts due to changes in the local charge environment. These spectral shifts, combined with tunneling of charges from the QD to nearby defects, provide an explanation of the bunching observed in the correlations.

**3:30PM D37.00004 Resonance Fluorescence Spectrum from a Quantum Dot Driven by a Periodically-Pulsed Laser**. KUMARSIRI KONTHASINGHE, MANOJ PEIRIS, BENJAMIN PETRAK, University of South Florida, YING YU, ZHICUAN NIU, Chinese Academy of Sciences, ANDREAS MULLER, University of South Florida — We report the measurement of the spectrum of the light scattered near-resonantly by a quantum dot under excitation by a periodically-pulsed laser, i.e., a frequency comb. Even though the scattered light spectrum under monochromatic excitation, the “Mollow triplet”, is well known, the resonance fluorescence spectrum under pulsed excitation has so far only been investigated theoretically. By using a high resolution Fabry-Perot interferometer and a stabilized mode-locked laser source we were able to measure the spectrum and second-order correlation function of the scattered light. In particular, the coherently and incoherently scattered light can be distinguished by virtue of the frequency comb scattering. The spectrum exhibits predicted features such as multiple sidebands when the pulse duration is long enough. In addition, Rabi oscillations are found to proceed with different phases for the two components of the scattered light. Satisfactory agreement is found between the experimental data and simulations when the effect of spectral diffusion is included.

**3:42PM D37.00005 Magneto-photoluminescence study of InAs quantum dots emitting at 1150nm**. LAURA KINNISCHTZKE, YIMING LAI, ANTONIO BADOLATO, NICK VAMIVAKAS, Univ of Rochester — Self-assembled InAs/GaAs quantum dots are frequently designed to emit light in the range of 920-980nm, and the spectroscopic characterization of neutral and charged excitons in this range is well understood. We study the magnetic field dependence of low-temperature photoluminescence from InAs self-assembled quantum dots emitting close to 1 eV (1150 nm). The dots are incorporated into a field-effect device to map the fine structure of charged and neutral excitons using magneto-photoluminescence spectroscopy in the Faraday geometry up to 7 Tesla. Previously developed models of Coulomb blockade and fine structure in InAs/GaAs QDs can be extended to measure the effective g-factor of the exciton complexes in these lower-energy quantum dots.

We acknowledge support from NSF grant no. DMR-1309734.

**3:54PM D37.00006 Dynamic nuclear polarization in self-assembled quantum dot by quadrupole effect**. BAO LIU, PING WANG, WEN YANG, Beijing Computational Science Research Center — We apply the recently developed theory of dynamic nuclear polarization to analyze a new nuclear polarization mechanism assisted by quadrupole interaction. This mechanism was proposed to explain a series of experimental observations in a self-assembled quantum dot. We find that although the steady state nuclear polarization agrees with previous works, the rate at which the nuclear spins are polarized is smaller by two orders of magnitude.
4:06PM D37.00007 Long-range two-qubit gate between nuclear spins in diamond mediated via an optical cavity . ADRIAN AUPER, GUIDO BURKARD, Department of Physics, University of Konstanz, Germany — Nitrogen-vacancy (NV) centers in diamond represent a promising possibility for a solid-state based realization of a qubit due to their excellent electron- and nuclear-spin coherence properties. Single-qubit gates for the nitrogen nuclear spin have been implemented [1]. Here, we extend an earlier proposal [2] for cavity-mediated coupling between NV electron spins and develop a scheme to implement a universal two-qubit gate between $^{14}$N or $^{15}$N nuclear spins. By virtually exciting a single NV center with an external laser field, a photon can be scattered into a surrounding cavity; we show that this process depends on the spin state of the nitrogen nucleus. For the two-qubit gate, we consider two NV centers coupled to a common cavity mode and each being excited individually. Virtual cavity excitation can then mediate an effective interaction between the NV nuclear spin qubits, generating a controlled-Z gate. Operation times for the gate implementation are found to be below 100 nanoseconds, which is orders of magnitude faster than the decoherence time of nuclear spin qubits in diamond.

4:18PM D37.00008 Quantum error correction with nuclear spins in diamond . TIM HUGO TAMINIAU, QuTech, Delft University of Technology, JULIA CRAMER, M. A. ROL, NORBERT KALB, Kavli Institute of Nanoscience, Delft University of Technology, V. V. DOBROVITSKI, Ames Laboratory and Iowa State University, RONALD HANSON, Kavli Institute of Nanoscience, Delft University of Technology — Quantum error correction is essential for large-scale quantum information processing. By encoding a quantum state in an entangled state of multiple qubits errors can be detected and corrected without obtaining information about the encoded state [1,2]. In this talk I will present quantum error correction based on spins in diamond. We used the electron spin of a nitrogen-vacancy centre to selectively initialize, control and read out multiple carbon-13 nuclear spins in the surrounding spin bath [3]. With these spin we implemented a three-qubit quantum-error-correction protocol and demonstrated the robustness of the encoded state against applied errors [1]. Furthermore, I will discuss how working at cryogenic temperatures will make it possible to realize error correction based on projective multi-qubit parity measurements [4], as envisioned in most modern error correction codes.

4:30PM D37.00009 The spin state depolarization induced by charge state conversion of Nitrogen Vacancy center in diamond . XIANGDONG CHEN, Univ of Sci & Tech of China, CHANGLING ZOU TEAM, LEIMING ZHOU TEAM, FANGWEN SUN TEAM — The negatively charged nitrogen vacancy center (NV$^-$) in diamond possesses the optically polarized electron spin state, which enables it to be used for quantum computation and metrology. In this work, we showed the depolarization of NV$^-$ electron spin state induced by charge state conversion. Both the polarization and depolarization of spin state exist during the two-photon charge state conversion process. The fidelity of NV$^-$ spin state initialization is decreased with the laser power. Due to the charge state conversion induced spin state depolarization, the fluorescence intensity of NV center shows a decrease with high laser power. Our work provide the information to further understand the photon induced charge state conversion, and can help to optimize the application based on NV center.

4:42PM D37.00010 ABSTRACT MOVED TO L14.00013 –

5:06PM D37.00012 Control of multi-qubit nodes for diamond quantum networks . JULIA CRAMER, M. ADRIAAN ROL, NORBERT KALB, Kavli Institute of Nanoscience Delft, VIATCHESSLAV V. DOBROVITSKI, Ames Laboratory and Iowa State University, RONALD HANSON, TIM H. TAMINIAU, Kavli Institute of Nanoscience Delft — Quantum networks consisting of multiple connected nodes enable distributed quantum computation and secure quantum communication. Such networks require multi-qubit quantum registers that can be remotely linked. In this work we demonstrate initialization and control of multiple qubits in a nitrogen-vacancy (NV) node in diamond. We use the NV electron spin as an ancillary qubit to detect individual weakly coupled nuclear carbon-13 spins and construct high-fidelity quantum gates [1]. With these gates we show initialization, control and entanglement of multiple nuclear spins. Combined with projective measurements of the NV electron spin [2] and long-range entanglement through optical channels [3] at cryogenic temperatures, this work paves the way for communication between distant quantum nodes via ancillary qubits while preserving complex entangled states in quantum memories within the nodes.

5:18PM D37.00013 Quantum theory of nuclear spin dynamics in optically pumped diamond nitrogen-vacancy center . PING WANG, WEN YANG, Beijing Computational Science Research Center, Beijing 100084, China — We develop a microscopic theory for a variety of nuclear spin dynamics such as dephasing, relaxation, squeezing, and narrowing due to the hyperfine interaction with an optically pumped nitrogen vacancy center. The first-order result justifies the nonlinear Hamiltonian for nuclear spin squeezing [M. S. Rudner et al., Phys. Rev. Lett. 107, 206806 (2011)]. The second-order result provides a reasonable explanation to the experimentally observed 13C nuclear spin bath narrowing [E. Togan et al., Nature 478, 497 (2011)].
2:30PM D38.00001 Optimal spectrum estimation of density operators with alkaline-earth atoms , ALEXEY GORSHKOV, Joint Quantum Institute — The eigenspectrum $\vec{p} = (p_1, p_2, \ldots, p_n)$ of the density operator $\rho$ describing the state of a quantum system can be used to characterize the entanglement of this system with its environment. In the seminal paper [Phys. Rev. A 64, 052311 (2001)], Keyl and Werner present the optimal measurement scheme for inferring $\vec{p}$ given $n$ copies of an unknown state $\rho$. Since this measurement uses a highly entangled basis over the full joint state $\rho^n$ of all copies, it should naively be extremely difficult to implement in practice. In this talk, we give a simple experimental protocol to carry out the Keyl-Werner measurement for $\rho$ on the nuclear spin degrees of freedom of $n$ alkaline-earth atoms using standard Ramsey spectroscopy techniques.

3:06PM D38.00002 Testing Clauser-Horne-Shimony-Holt inequalities with observables with arbitrary spectrum , ANDREAS KETTERER, Laboratoire Matériaux et Phénomènes Quantiques, Sorbonne Paris Cité, Université Paris Diderot, CNRS UMR 7162, 75013 Paris, France — We report the measurement of the two-photon spectrum of the light scattered near-resonantly by a single InAs semiconductor quantum dot exposed to a monochromatic laser. In contrast to the ordinary (one-dimensional) one-photon spectrum, the two-photon spectrum represents the probability of emitting two photons with two different colors. It is obtained experimentally using a pair of frequency-tunable filters in a modified Hanbury-Brown and Twiss setup. We analyze the resulting two-dimensional maps for different parameters including the Rabi frequency, the laser detuning, and the filter bandwidth. We find excellent agreement with the theory of Del Valle et al. In particular, our measurements reveal the interferences of different decay paths to yield overall antibunched photon statistics while the individual filtered pathways may exhibit photon bunching, photon anti-bunching or near-Poisson statistics. We further evidence how the radiative cascade can proceed via virtual intermediate states giving rise to transitions previously termed “leapfrog transitions”. Highly nonclassical physics are seen, which can violate well-known classical inequalities such as the Cauchy-Schwarz inequality or Bells inequalities.

3:18PM D38.00003 Violation of Classical Inequalities in the Light Scattered by a Quantum Dot 1, MANOJ PEIRIS, BEN PETRAK, KUMARASIRI KONTHASINGHE, University of South Florida, YING YU, ZHICHAU NIIU, Chinese Academy of Sciences, ANDREAS MULLER, University of South Florida — We report the measurement of the two-photon spectrum of the light scattered near-resonantly by a single InAs semiconductor quantum dot exposed to a monochromatic laser. In contrast to the ordinary (one-dimensional) one-photon spectrum, the two-photon spectrum represents the probability of emitting two photons with two different colors. It is obtained experimentally using a pair of frequency-tunable filters in a modified Hanbury-Brown and Twiss setup. We analyze the resulting two-dimensional maps for different parameters including the Rabi frequency, the laser detuning, and the filter bandwidth. We find excellent agreement with the theory of Del Valle et al. In particular, our measurements reveal the interferences of different decay paths to yield overall antibunched photon statistics while the individual filtered pathways may exhibit photon bunching, photon anti-bunching or near-Poisson statistics. We further evidence how the radiative cascade can proceed via virtual intermediate states giving rise to transitions previously termed “leapfrog transitions”. Highly nonclassical physics are seen, which can violate well-known classical inequalities such as the Cauchy-Schwarz inequality or Bells inequalities.

3:30PM D38.00004 Classical Model for Measurements of an Entanglement Witness 1, BRIAN LA COUR, E.C. GEORGE SUDARSHAN, The University of Texas at Austin — We describe a classical model that may serve as an analog for joint and local measurements of an entanglement witness. The analogous experimental procedure and data analysis protocol of the model follow those of a previous experiment to measure an entanglement witness with polarized photons prepared in a mixed state [M. Barbieri et al., Phys. Rev. Lett. 91, 227901 (2003)]. Numerical simulations show excellent agreement with both experimental results and quantum mechanical predictions.

3:42PM D38.00005 Real-time adaptive quantum measurements on a single spin in diamond for sensing and quantum information protocols, MACHIEL BLOK, CRISTIAN BONATO, RONALD HANSON, Delft Univ of Tech — Real-time feedback based on quantum measurements is a crucial ingredient for many proposed quantum information and sensing technologies. Implementation requires high-fidelity measurements as well as fast electronics that perform the control operation. A single electron spin, associated with the Nitrogen-Vacancy defect in diamond, forms an excellent test bed for real-time feedback protocols, since it can be read out with high fidelity in a single shot using optical transitions and maintain coherences for long times. Here we demonstrate an adaptive phase estimation protocol that senses DC magnetic fields with very high precision. The magnetic field is measured with a Ramsey interferometry sequence which is repeated many times. When adjusting the parameters of the Ramsey sequence in real time based on the outcome of previous measurements, the sensitivity of our magnetometer shows scaling close to the fundamental Heisenberg limit ($\sim 1/N$) as the number of measurements $N$ is increased.

3:54PM D38.00006 Joint estimation of phase and phase diffusion for quantum metrology, MIHAI VIDRIGHIN, Imperial College London, GAIA DONATI, MARCO GENONI, XIAN-MIN JIN, STEVEN KOLTHAMMER, MYUNSHIK KIM, ANIMESH DATTA, MARCO BARBIERI, IAN WALMSLEY, Oxford University — Phase estimation, at the heart of many quantum metrology and communication schemes, is affected by noise. We have investigated joint estimation of a phase and the amplitude of phase diffusion. The motivation is that the two parameters are not independent in first order. Using a single chiral molecule in a condensed phase environment, with low photon fluxes, we show that our protocol can outperform standard phase estimation, can work at the Heisenberg limit, and does not need adaptive phase control. We also prove by numerical simulations that our method holds for general states at small diffusion amplitudes.

4:06PM D38.00007 Noise-resilient quantum metrology for single-molecule spectroscopy with low light levels, FELIPE HERRERA, ALAN ASPURU-GUZIK, Department of Chemistry and Chemical Biology, Harvard University — Continuous observation of biological processes over long timescales exceeding seconds is challenging using standard fluorescence techniques due to technical issues such as photodamage. Current photonic technology can be exploited to overcome these challenges while preserving sensitivity at the single molecule level. We show that using a simple quantum metrology scheme involving periodic driving for optical state preparation, it is possible to perform spectroscopy of a single chiral molecule in a condensed phase environment, with low photon fluxes. We show that for certain non-classical optical probes and measurement settings, it is possible to exceed the standard quantum limit of precision for a range of driving parameters, even in the presence of high transmission losses due to background absorption. We propose the expected scheme with fluorescence spectroscopy for single molecule detection, and discuss possible applications of quantum metrology in systems biology.

4:18PM D38.00008 Quantum Computation and Quantum Metrology based on Single Electron Spin in Diamond, JIANGFENG DU, University of Science and Technology of China — It is of great challenge to perform the accurate controlling the electron spin qubits in realistic system, due to the noises aroused from the noisy spin bath and the driving field. Firstly, we adopted dynamically corrected gates to realize robust and high-fidelity quantum gates. In this work, the quantum gate’s performance was pushed to T1 limit [PRL 2014, 112, 050503]. Then, a new Rabi Oscillations (ROs) resulting from Landau-Zener (LZ) transitions is observed useful to suppress the fluctuations of the driving field [PRL 2014, 112, 010503]. Besides, quantum error correction is experimentally employed to overcome the noise effect in diamonds [Nature 2014, 506, 204-207]. Precise quantum control and effectively supressing noise of the environment are of great importance for quantum metrology. We succeeded in sensing and atomic-scale analysis of single nuclear spin clusters in diamond at room temperature [Nature Physics 2014, 10, 21-25], and also have succeed to detect a few nuclear spins with single spin sensitivity [Nature Comm., 2014, 4:4703].

4:30PM D38.00009 High-Sensitivity Temperature Sensing Using an Implanted Single Nitrogen-Vacancy Center Array in Diamond\(^1\), GUANZHONG WANG, JUNFENG WANG, Department of Physics, University of Science and Technology of China, ADVANCED THINFILM LABORATORY, UNIVERSITY OF SCIENCE AND TECHNOLOGY OF CHINA TEAM — We present a high-sensitivity temperature detection using an implanted single Nitrogen-Vacancy center array in diamond. The high-order Thermal Carr–Purcell–Meiboom–Gill (TCPMG) method was performed on the implanted single nitrogen vacancy (NV) center in diamond in a static magnetic field. We demonstrated that under small detunings for the two driving microwave frequencies, the oscillation frequency of the induced fluorescence of the NV center equals approximately to the average of the detunings of the two driving fields. On basis of the conclusion, the zero-field splitting D for the NV center and the corresponding temperature could be determined. The experiment showed that the coherence time for the high-order TCMG was effectively extended, particularly up to 108 µs for TCMG-8, about 14 times of the value 7.7 µs for thermal Ramsey method. This coherence time corresponded to a thermal sensitivity of 10.1 mK/Hz\(^{1/2}\). We also detected the temperature distribution on the surface of a diamond chip by using the implanted NV center array with the TCMG-3. Our approach implies the feasibility for using implanted NV centers in high-quality diamonds to detect temperatures with high-sensitivity and nanoscale resolution.

\(^1\)This work was supported by the National Basic Research Program of China (2013CB921800, 2011CB921400) and the Natural Science Foundation of China (Grant Nos. 11374280, 50772110).

4:42PM D38.00010 Nitrogen Vacancy centers in diamond as \(\theta^2\) sensors\(^1\), SHONALI DHINGRA, BRIAN D’URSO, University of Pittsburgh — Nitrogen-vacancy (NV) centers are naturally occurring defects in diamond, which feature an electronic spin with well-defined quantum behavior, including long quantum coherence times and optical addressability. In this work, we show how to align an external magnetic field to the direction of the internally-defined spin axis of the NV center. We further show that this capability can be explored to use an NV center as a \(\theta^2\) sensor in presence of this external magnetic field. The sensitivity of this sensor is shown to increase very rapidly with the external magnetic field, diverging as the external field approaches a value pre-defined by the NV center parameters. We show that the measured sensitivity has excellent agreement with the theoretical predictions. These results show that NV centers may be useful for coupling to torsional nanomechanical oscillators (NMO), to make quantum non-demolition measurements of the number states of the NMO.

3DARPA Young Faculty Award

4:54PM D38.00011 Optimal sensing at the nanoscale with diamond nitrogen vacancy center\(^1\), WEN YANG, PING WANG, Beijing Computational Science Research Center — Diamond nitrogen-vacancy center is a leading platform for ultra-precise sensing at the nanoscale. The sensing is essentially a parameter estimation problem: (1) Encoding the unknown parameters into the NV state; (2) Readout the NV state from the fluorescence; (3) Process the data to infer the unknown parameters; (4) Adaptation of (1)-(3) based on the updated knowledge about the unknown parameters. Recently, dynamical decoupling and adaptive measurement have significantly improved the sensitivity and dynamic range by improving steps (1) and (4), respectively. However, a full optimization of all the steps remains lacking, e.g., the widely used approach to step (3) based on averaging the data from repeated fluorescence measurements or from single-shot fluorescence binarized into 0 and 1 is suboptimal. Here we apply quantum metrology techniques, developed in optical phase estimation, to construct a general framework for optimal sensing using the NV center, incorporating the finite detection efficiency and decoherence. It can be readily applied to various sensing tasks, such as dc/ac magnetometry, noise spectroscopy, and single-molecular NMR. For illustration, we demonstrate significant sensitivity improvement in tracking a time-varying magnetic field with the NV center.

5:06PM D38.00012 ABSTRACT WITHDRAWN

5:18PM D38.00013 Tensor network approach to quantum feedback dynamics, ARNE GRIMSMO, Département de Physique, Université de Sherbrooke — In this talk I consider the problem of a quantum system coupled to a bosonic reservoir creating a coherent feedback loop. Since the system can be strongly correlated with the in-loop field, this is in general a highly non-Markovian quantum problem where no perturbative approach can be expected to work well. I will present the first practical approach to model this type of dynamics for general quantum systems and large delay times. Borrowing ideas from the intersection of condensed matter and quantum information theory, I will show that a formal dynamical solution can be found as the continuum limit of a tensor network, much like the recently introduced continuous matrix product states for one-dimensional field theories. This gives rise to a practical and efficient integration scheme in discrete time, which is numerically exact as the time-step goes to zero. Besides opening the possibility to study a new regime of quantum feedback control, this is also a novel application of tensor network techniques that could pave the way for a new approach to non-Markovian quantum dynamics in a broader context as well.

Monday, March 2, 2015 2:30PM - 5:30PM  —  Session D39 GQI: Superconducting Circuits: Decoherence II 213AB - Robert McDermott, University of Wisconsin-Madison

2:30PM D39.00001 Al/AlOx/Al Josephson junctions fabricated without double-angle evaporation, KYLE SUNDQVIST, PRANAV SHARMA, MICHAEL BABB, JAE WOO SUH, H. RUSTY HARRIS, Texas A&M University — Superconducting circuits are a common means to produce quantum-mechanically coherent structures. It is possible to produce superconducting circuits which may sustain and even amplify coherent states of microwaves close to the quantum limit. To this end, work is underway at Texas A&M University to locally implement Josephson junctions in our research. We have developed our own process flow for Josephson junction fabrication. This technique does not rely on the commonly used Dolan-bridge double-angle evaporation technique, and is easily incorporated into the process flow of other solid-state devices at the AggieFab fabrication facility.
2:42PM D39.00002 Dependence of transmon qubit relaxation rate on cavity photon population\(^1\). S.O. MUNDHADA, S. SHANKAR, Y. LIU, M. HATRIDGE, A. NARLA, K.M. SLIWA, S.M. GIRVIN, M.H. DEVORET, Department of Applied Physics, Yale University — In circuit QED experiments, a qubit is dispersively coupled to a cavity such that the cavity frequency depends on the qubit state. This dispersive shift enables quantum non-demolition readout of the qubit by exciting the cavity with a microwave pulse and detecting the phase shift of the reflected signal. However, this cavity excitation has been observed in experiments to increase the qubit relaxation rate, hence demolishing the qubit state and limiting the maximum measurement strength. Here we experimentally study this effect in a transmon qubit coupled to a three-dimensional superconducting cavity. We also explore alternate qubit circuits designed to mitigate this demodulation effect.

2:54PM D39.00003 Quasiparticles and vortices in superconducting microwave resonators\(^1\). IBRAHIM NSANZINEZA, B.L.T. PLOURDE, Syracuse University — Nowhere in quantum systems has the role of quasiparticles and vortex interactions been as critical as in superconducting microwave resonators. Here we present results of Monte Carlo simulations on a 1D XY spin model that shows how vortices can trap quasiparticles and lead to a reduction in the quasiparticle loss. We will discuss experiments involving the controlled trapping of vortices for reducing quasiparticle densities as well as the use of normal metal quasiparticle traps in superconducting resonators. In our measurements, quasiparticles are generated either by stray pair-breaking radiation or by direct tunnel-junction injection.

3:06PM D39.00004 Quantifying Surface Loss Induced by Anti-Vortex Hole Arrays in Planar Superconducting Circuits for Quantum Computation. B. CHIARO, A. MEGRANT, A. DUNSWORTH, Z. CHEN, B. CAMPBELL, I.-C. HOI, J. KELLY, C. NEILL, P. J. J. O’MALLEY, C. QUINTANA, A. VAINSENCHER, J. WENNER, T. WHITE, UC Santa Barbara, R. BAREND, Y. CHEN, A. FOWLER, E. JEFFREY, J. MUTUS, P. ROUSHAN, D. SANK, Google, Santa Barbara, A. N. CLELAND, UC Santa Barbara, J. M. CAMPBELL, I.-C. HOI, J. KELLY, C. NEILL, P. J. J. O’MALLEY, C. QUINTANA, A. VAINSENCHER, J. WENNER, T. WHITE, UC Santa Barbara, R. BAREND, Y. CHEN, A. FOWLER, E. JEFFREY, J. MUTUS, P. ROUSHAN, D. SANK, Google, Santa Barbara — Two important dissipation sources in superconducting circuits operated at low power are surface loss from two level systems (TLS) and magnetic vortex loss. By patterning the superconducting electrodes with an array of holes, it is possible to reduce or eliminate loss due to magnetic vortices. However, since the highest levels of coherence in planar superconducting circuits have been achieved by improving the electrode-substrate interface, it is natural to expect that adding hole arrays to the electrodes may cause excess surface loss. We present simulations predicting the excess loss magnitude to be < 10% for typical ground plane hole arrays, but for extreme cases of hole size or placement the loss may be much greater. We confirm the simulation result with measurements of high quality factor resonators ($Q_i > 10^6$) with and without the hole patterns.

3:18PM D39.00005 $1/f^{α}$ noise in interacting spin systems: a real space RG approach. KARTIEK AGARWAL, Harvard University, IVAR MARTIN, Los Alamos National Laboratory, EUGENE DEMLER, Harvard University — Localized paramagnetic electrons are believed to be the cause of magnetic flux noise that plagues superconducting qubits, but how such interacting spins generate frequency dependent noise of the form $1/f^{α}$ is not well understood. We describe a novel real space RG procedure that is equipped to calculate directly various dynamical quantities in a strongly disordered Heisenberg spin system (in arbitrary dimensions), including the ‘noise’ from such systems. In 1-D, we find that the RG procedure describes a fairly temperature-independent noise with a power law $α < 1$ that varies smoothly depending on the disorder strength, relative concentration of Ferro-Anti-Ferro bonds and temperature. The dynamic structure factor (of spin-spin correlations) inherits this power law while displaying a crossover to a related power at higher frequencies. In 2-D, the RG results in dynamics that are diffusive at high temperatures but remain anomalous at lower temperatures. A possible connection of the phenomena of $1/f$ noise and Many-Body Localization is also discussed.

3:30PM D39.00006 Flux noise in SQUIDs: Electron versus nuclear spins\(^1\). ROGERIO DE SOUSA, STEPHANIE LAFOREST, University of Victoria, BC — Superconducting Quantum Interference Devices (SQUIDs) are limited by intrinsic flux noise whose origin is unknown. We develop a method to accurately calculate the flux produced by spin impurities in realistic superconducting thin film wires, and show that the flux produced by each spin is much larger than anticipated by former calculations. Remarkably, the total flux noise power due to electron spins at the thin side surface of the wires is found to be of similar magnitude as the one due to electrons at the wide top surface of the wires. In addition, flux noise due to lattice nuclear spins in the bulk of the wires is found to be a sizable fraction of the total noise for some SQUID geometries. We discuss the relative importance of electron and nuclear spin species in determining the total noise power, and propose strategies to design SQUIDs with lower flux noise.

\(^1\)We acknowledge support from the Canadian agency NSERC through its Discovery and Engage programs.

3:42PM D39.00007 Adsorbed Oxygen Molecules as a Possible Source of Flux Noise in SQUIDs\(^1\). CHUNTAI SHI, Univ of California - Irvine, HUI WANG\(^2\), Fudan University, China, JUN HU, CLARE YU, RUQIAN WU\(^3\), Univ of California - Irvine — One of the dominant source of flux noise in SQUIDs is flux noise which has been attributed to mysterious fluctuating magnetic pins on the surface. We propose that the spins producing flux noise could be adsorbed O\(_2\) molecules that have a magnetic moment of about 2 $\mu_B$. Using density functional calculations, we studied O\(_2\) molecules adsorbed on a sapphire surface. We find that the barrier for spin rotation is small enough to allow almost free spin reorientation due to thermal excitations at low temperatures. Monte Carlo simulations of a 2D XY spin model yields $1/f$ noise where $f$ is frequency.

\(^1\)This work was supported by 1000 Talent Program of China through Fudan University. Work at UCI was supported by DOE-BES (Grant No. DE-FG02-05ER46237) and the Army Research Office (Grant No. W911NF-10-1-0494).

\(^3\)Fudan University, China

3:54PM D39.00008 Adsorbed Oxygen Molecules as a Source of Flux Noise in SQUIDs\(^1\). HUI WANG, ZHE WANG, Department of Physics, Fudan University, Shanghai 200433, China, JUN HU, CHUNTAI SHI, CLARE C. YU, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA 92697-4575, USA, DEPARTMENT OF PHYSICS, FUDAN UNIVERSITY, SHANGHAI 200433, CHINA COLLABORATION, DEPARTMENT OF PHYSICS AND ASTRONOMY, UNIVERSITY OF CALIFORNIA, IRVINE, CA 92697-4575, USA COLLABORATION — A major obstacle for using superconducting quantum interference devices (SQUIDs) as qubits is the flux noise generated by fluctuating magnetic pins on the surface of SQUIDs. Using density functional theory (DFT) calculations, we investigated O\(_2\) adsorbates and various vacancies on an $\alpha$-alumina surface as spin candidates. Their spectroscopic features are directly compared to experimental data using the x-ray magnetic circular dichroism. The calculated magnetic anisotropy energy for the spin of O\(_2\) to rotate within a plane perpendicular to the axis of the O-O bond is only about 12 mK ($\sim 1 \mu$eV) so we believe that O\(_2\) molecules are the main source of flux noise in Al SQUIDs.

\(^1\)Work at Fudan was supported by the 1000-Talent funds. Work at UCI was supported by DOE-BES (Grant No. DE-FG02-05ER46237) and by NERSC for computing time.
We have measured the power loss and 1/f permittivity noise of deposited dielectrics at microwave frequencies over a range of millikelvin temperatures. The results will be compared to recent strong-interaction theories. We explain the high frequency (f = 1-10 GHz) Ohmic flux noise observed in SQUIDs and superconducting qubits.

1/f noise, and weakly coupled high frequency ohmic or subohmic noise. Noise components with frequencies higher than the qubit tunneling element result in excitation-relaxation dynamics of the qubit. At the same time the low frequency noise (with frequency lower than the qubit tunneling splitting) causes strong modulation of the level splitting between the ground and excited states. We show that the combined effect of the low and high frequency components of the noise results in the qubit freezing in the excited state with a sizable probability. This mechanism may set an upper bound on the quantum annealing computation time.

Magnetic adsorbates on the surfaces of superconducting thin films. We present the results of SQUID-based susceptibility and noise measurements that are part of an ongoing effort to reduce surface spin density and flux noise by improving the vacuum environment of the superconducting device.

Noise results in the qubit freezing in the excited state with a sizable probability. This mechanism may set an upper bound on the quantum annealing computation time.

In conclusion, we propose routes to improving SQ performance by enhancing or minimizing magnetic ordering of induced spins on Al₂O₃ surface.

We acknowledge support from IARPA under contract W911NF-10-1-0324.
Vertical Phase Separation in Bulk-Heterojunction Polymer Solar Cells

YUEH-LIN LOO, HE WANG, JONGBOK KIM, Princeton University — With soft-contact lamination and delamination, we have elucidated whether and how vertical phase separation of active layers affects solar cell performance. We constructed conventional bulk-heterojunction solar cells comprising P3HT, PCPDTBT, PCBM, and a wetting layer, devices with P3HT exhibit only a marginal drop in its current compared to devices without a P3HT wetting layer. We ascribe this difference in active layer prior to cathode deposition. While devices with PCPDTBT and T1 exhibit drastically reduced current compared to devices without the additional fullerene derivatives. To exaggerate the influence of vertical phase separation, we laminated in each case a thin layer of electron donor on the bulk-heterojunction electron acceptor interface within the molecular structure facilitates studies of charge transfer processes, where we can systematically modulate the chemical structure and energetics to perturb exciton dissociation and charge recombination.

Impacts

Monday, March 2, 2015 2:30PM - 5:30PM –
Session D41 DPOLY: Focus Session: Polymers for Solar Energy Conversion - Morphological Impacts 214A - Bryan Boudouris, Purdue University

Laboratory — Weak intermolecular interactions and disorder at junctions of different organic materials limit the performance and stability of organic interfaces and hence the applicability of organic semiconductors to electronic devices. Our approach has focused on utilizing block copolymer architectures — where critical interfaces are controlled and stabilized by covalent bonds — to provide the hierarchical structure needed for high-performance organic electronics from self-assembled soft materials. For example, we have demonstrated control of donor-acceptor heterojunctions through microphase-separated conjugated block copolymers to achieve 3% power conversion efficiencies in non-fullerene photovoltaics. Characterization through X-ray scattering and electron microscopy reveals that the efficient performance of block copolymer solar cells is due to self-assembly into mesoscale lamellar morphologies with primarily face-on crystallite orientations. Furthermore, incorporating the donor-acceptor interface within the molecular structure facilitates studies of charge transfer processes, where we can systematically modulate the chemical structure and energetics to perturb exciton dissociation and charge recombination.

Computational Description of Donor-Acceptor pi-Conjugated Materials for Organic Photovoltaics Applications

JEAN-LUC BREDAS, King Abdullah University — This presentation will focus on the following topics, related to organic solar cell applications: 1) We will describe our recent work on the electronic structure and local morphology of donor-acceptor interfaces in bulk-heterojunction solar cells. 2) We will discuss how we can evaluate the polarization effects, which play a critical role in the charge-separation process at donor-acceptor interfaces in organic solar cells. 3) Finally, we will describe the peculiarities of the electronic structure of a new pi-conjugated polymer with very high hole mobilities over 20 cm²/Vs.

New Insight into Morphology of High Performance BHJ Photovoltaics Using High Resolution AFM

FENG LIU, Lawrence Berkeley National Lab, DONG WANG, KEN NAKAJIMA, Tohoku University, THOMAS RUSSELL, Lawrence Berkeley National Lab, THOMAS RUSSELL COLLABORATION — Direct imaging of the bulk BHJ thin film morphology in OPV is essential to understand device function and optimize efficiency. While transmission electron tomography provides a 3D, real-space image of the morphology, quantifying the structure is not possible. Here we used high-resolution atomic force microscopy in the tapping and nano-mechanical modes to investigate the BHJ active layer morphology which, when combined with Ar ion etching, provided unique insights with unparalleled spatial resolution. PCBM was seen to form a network that interpenetrated into the fibrillar network of the hole-conducting polymer, both being imbedded in a mixture of the two components. The free surface was found to be enriched with polymer crystals having a face-on orientation, and the morphology at the anode interface was markedly different.

Creating Efficient Quasi-3D Transport Pathways With Crossed-Chain Polymer Interfaces

CHRISTOPHER TAKACS, MICHAEL BRADY, NEIL TREAT, MICHAEL CHABINCY, Univ of California - Santa Barbara — While our understanding of the local molecular packing in many well-performing polymer semiconductors has improved, many open questions regarding the molecular level details of long-range connectivity and the best strategies for optimizing electronic functionality remain. Here we focus on the possible benefits of epitaxy in polymer semiconductors for improving nano-scale connectivity, a concept particularly useful for systems where charge-transport is expected to be highly anisotropic. The periodic crossing of the non-parallel chains at the crystal-crystal interfaces may enable efficient coupling across grain-boundaries and increase the effective dimensionality of the charge transport processes. Using a combination of high-resolution transmission electron microscopy, statistical analysis of the electron micrographs, and a variety of molecular simulation methods, we will demonstrate that such epitaxy relationships can be predicted and observed in a variety of well-performing polymer semiconductors. The results suggest that further engineering of epitaxy may lead to substantial advances in both control of self-assembly and electronic performance.

Small Molecule Bulk Heterojunction: Impact of two thermodynamically stable morphologies on the efficiency of organic photovoltaics devices

NURADHIKA HERATH, VALERIA LAUTER, JIM BROWNING, ILIA IVANOV, JONG KEUM, KAI XIAO, JIAHUA ZHU, Oak Ridge National Laboratory, SANJIB DAS, GONG GU, University of Tennessee Knoxville — Structural characteristics of device active layers play a critical role in charge generation, separation and transport in organic photovoltaics (OPVs). Here we report on morphology and structure control of p-DTS(FBTTh₂)₂:PC₇₀BM films by means of thermal annealing and solvent additive processing. Depth-sensitive neutron reflectometry and X-ray diffraction are employed to characterize the thin film structures, and are correlated to the device performance. The neutron reflectometry results reveal that p-DTS(FBTTh₂)₂:PC₇₀BM films fabricated with 1,8-diiodooctane (DIO) reproducibly exhibit a 3-sublayer morphology similar to thermally annealed films without DIO. Moreover, DIO promotes the formation of a large population of p-DTS(FBTTh₂)₂ nanocrystals leading to a device efficiency (PCE) of 5.9 %. The thermally annealing generate p-DTS(FBTTh₂)₂ crystallites one order of magnitude larger than those formed with the DIO. Our results provide direct evidence that delicate size control of crystal domains closer to the optimum exciton diffusion length is as important as a high crystallinity of charge transport layers.

This research was conducted at Spallation Neutron Source and at the Center for Nanophase Materials Sciences, which is sponsored at ORNL by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.
4:06PM D41.00007 Morphology and performance of organic photovoltaics containing a small-molecule acceptor. KATHRYN O'HARA, University of California, Santa Barbara, DAVID OSTROWSKI, University of Colorado Boulder, CHRISTOPHER TAKACS, University of California, Santa Barbara, LUNS. KOLDEMER, Colorado School of Mines, SEAN SHAHEEN, University of Colorado Boulder, ALAN SELLINGER, Colorado School of Mines, MICHAEL CHABINYC, University of California, Santa Barbara — Fullerenes are derivatives that are widely used as acceptor materials in organic photovoltaics (OPVs). However, they have a high cost, low absorption in the visible range and limited synthetic variability compared to small molecule alternatives, which generally underperform PCBM, but it is unclear if the reason is morphological or due to the electronic structure of the acceptor. A promising fullerene alternative, HPI-BT, is blended with P3HT to achieve a power conversion efficiency (PCE) of 2.1%, which is lower than for fullerene OPVs (10%), but an understanding of the morphology could improve the efficiency of future small-molecule based devices. The active layer microstructure is probed complimentary techniques of atomic force microscopy (AFM), grazing incidence wide angle x-ray scattering (GIWAXS), and scanning transmission electron microscopy (STEM). STEM indicates that HPI-BT crystals are buried in the film upon casting and AFM shows they grow to the film surface upon annealing. GIWAXS reveals the acceptor is crystalline, which should improve charge transport, but film texturing suggests that crystals nucleate off the substrate, cover the anode and ultimately limit cell performance.

4:18PM D41.00008 Direct internuclear distance measurements of P3HT/PCBM interfaces in bulk heterojunction thin films using $^{13}$C $^2$H REDOR NMR. RYAN NIEUWENDAAL, DEAN DELONGHAMP, NIST, ALEX SIEVAL, Solene BV, J.C. HUMMELEN, University of Groningen, MARTIN HEENEY, ZHUHONG FEI, Imperial College — Robust structure/function relationships are generally lacking in organic photovoltaic (OPV) thin film active layers. Structural complexity has contributed to a lack of performance predictability, so there exists a need for measurement tools that can unveil fine details of the bulk heterojunction (BHJ) thin film structure. Optical methods, microscopy (AFM, TEM), and scattering techniques are useful for coarse morphological assessment, but their lack of sub-nm spatial resolution has obscured perhaps the most pertinent morphological quality of the BHJ: the donor/acceptor interface. In this contribution, I will discuss the results of solid state NMR measurements performed in our laboratory to characterize the donor/acceptor interface. $^{13}$C $^2$H REDOR experiments on isotopically-enriched thin film blends of P3HT and PCBM are used to determine distances between nuclei in the donor molecules ($^2$H on P3HT main chain) and acceptor molecules ($^{13}$C-enriched C$_{60}$ cage). Experiments are performed on ~ 100 nm thin film samples utilizing casting recipes that are typical for fabricating real OPV devices.

4:30PM D41.00009 ABSTRACT WITHDRAWN

4:42PM D41.00010 Two-Dimensional Effects on Lateral Organic Bulk Heterojunction Devices. KELLY LIANG, ERIC DANIELSON, Univ of Texas, Austin, ZIEN OOI, Agency for Science, Technology and Research, ANANTH DODABALAPUR, Univ of Texas, Austin — For moderately thick (50 nm) lateral organic bulk heterojunction (OBHJ) photovoltaic devices, a one-dimensional space charge limited current model with electric field independent mobility accurately simulates key device metrics, like photocurrents, mobilities, and bimolecular recombination coefficients. However, as the thickness of these lateral organic devices approaches thinner and thicker limits, two-dimensional effects greatly influence device characteristics, and a one-dimensional approximation is no longer sufficient. Both the two-dimensional electric field spreading in the OBHJ semiconductor and the electric field dependent mobility of the material system need to be considered in these devices. Introducing a geometric prefactor—dependent on the thickness of the organic semiconductor, to the one-dimensional space charge limited model accounts and adjusts for the two-dimensional effects. Using this modified and more accurate model, we further examined the photoconduction and photovoltaic gain in lateral OBHJ devices and reaffirmed that high gains originate from contact injection rather than bulk photoconduction.

4:54PM D41.00011 High-Performance All-Polymer Solar Cells Based on Face-on Stacked Polymer Blends with Low Interfacial Tension.BUMJOON KIM, HYUNBUM KANG, CHANGYEON LEE, TAESU KIM, KAIST — We report highly-efficient all-polymer solar cells with power conversion efficiencies of over 4.5% by highly-intermixed blends of poly[4,8-bis(5-(2-ethylhexyl)thiophen-2-yl)benzo[1,2-b:4,5-b]-dithiophene-3-fluorothieno[3,4-b]thiophene-2-carboxylate] (PTB7-Th) donor and poly[(N,N′-bis(2-octyldodecyl)-naphthalene-1,4,5,8-bis(dicarboximide)-2,6-diyl]-alt-5,5-(2,2′-bithiophene)] (P[NDI2OD-T2]) acceptor polymers. The low interfacial tension and the face-on π–π stackings of the all-polymer blends afforded desired nanophase morphology, which facilitates efficient charge transport from active layer to each electrode. In addition, the incorporation of 1,8-diiodooctane additives was able to tune the degree of crystallinity and orientation of P[NDI2OD-T2] acceptors, resulting in remarkable enhancement of electron mobility, external quantum efficiency and $J_{SC}$ values.

5:06PM D41.00012 All-polymer photovoltaics: Correlating Efficiency and Morphology. YAN JIN, University of Cincinnati, JONG K, KEUM, KUNLUN HONG, JAMES F. BROWNING, GREGORY S. SMITH, Oak Ridge National Laboratory, VIKRAM K. KUPPA, University of Cincinnati, OAK RIDGE NATIONAL LABORATORY COLLABORATION — We have recently demonstrated how the efficiency of devices fabricated from a blend of the polymers P3HT and F8BT increases three-fold by incorporating pristine graphene into the active layer. The fundamental mechanisms underlying this enhancement are investigated, and are shown to arise from improvements in both charge transport and morphology. We investigate the structure via small angle neutron scattering (SANS) studies of the deuterated-P3HT/F8BT system with and without graphene. SANS reveals the existence of disk-like P3HT crystallites distributed in an amorphous miscible blend of P3HT and F8BT. P3HT crystallinity was enhanced upon graphene addition, resulting in larger crystallites and a higher degree of ordering. These structural changes are accompanied by better charge transport, resulting in a peak improvement of over 200% in the short-circuit current of the devices. Results on cell characterization and recombination mechanisms are also reported, and indicate means of addressing fundamental problems in OPV systems.

5:18PM D41.00013 Role of Molecular Linker on Charge Separation and Photovoltaic Performance in All-Conjugated Block Copolymers. JORGE WU MOK, YEN-HAO LIN, KENDALL SMITH, RAFAEL VERDUGO, Rice Univ — Recent studies have demonstrated the potential of all-conjugated donor–acceptor block copolymer for organic photovoltaics, but it remains unclear how molecular structure, morphology, and electronic properties of conjugated block copolymers influence performance. Here, we study the role of chemical linker between donor and acceptor polymers on photovoltaic performance and optoelectronic properties. Two poly[(3-heptylthiophene)-poly(2,7-diyl-alt-[4,7-bis(thiophen-5-yl)]-2,1,3-benzothiadiazole)-2,2′-diyl-(9,9-diocetyfluorene)] (P3HT-PTBTF) donor–acceptor block copolymers which differ only in the chemistry of linking group are studied through device measurements, GIIXS, and steady-state and time-resolved absorbance and photoluminescence. Device studies show that power conversion efficiencies decrease by one order of magnitude by changing the linking group. X-ray analysis shows that the morphology is virtually identical in both samples, as expected. Transient absorption measurements reveal charge separation in block copolymers which contain a wide bandgap monomer at the donor–acceptor interface, but charge separation is suppressed when donor and acceptor blocks are directly linked without this spacer present. This work demonstrates that the linking group chemistry influences charge separation in all-conjugated block copolymer systems, and also suggests that all-conjugated block copolymers can be used as model systems for the donor-acceptor interface in bulk heterojunction blends.

Self-Assembly Thin Films using Inverse Genetic Algorithms

A key obstacle, however, is inducing the resulting structures to align perpendicularly, rather than parallel, to the substrate. In this talk, we present our simulation results relating to some strategies which have been pursued by experimentalists to overcome the above goal. One part of this talk will focus on the self-assembly of block copolymers on a homogeneously patterned surface. The second part of this talk will focus on the case of inhomogeneously patterned surfaces and identify the interplay between pattern width and the surface free energies in dependencies on grafting density, relative chain length between the free and grafted polymers, and blockiness of the random copolymer chains. The second part of this talk will focus on the case of inhomogeneously patterned surfaces and identify the interplay between pattern width and the surface free energies in dependencies on grafting density, relative chain length between the free and grafted polymers, and blockiness of the random copolymer chains.

3:06PM D42.00004 Self-Assembly of Diblock Copolymers on Modified and Patterned Surfaces

VENKAT GANESAN, University of Texas at Austin — The self assembly of diblock copolymer thin films into lamellar and cylindrical structures has been proposed as a method of creating small patterns in polymer thin films for electronic materials applications. A key obstacle, however, is inducing the resulting structures to align perpendicularly, rather than parallel, to the substrate. In this talk, we present our simulation results relating to some strategies which have been pursued by experimentalists to overcome the above goal. One part of this talk will focus on the self-assembly of block copolymers on a homogeneously patterned surface. The second part of this talk will focus on the case of inhomogeneously patterned surfaces and identify the interplay between pattern width and the surface free energies in dependencies on grafting density, relative chain length between the free and grafted polymers, and blockiness of the random copolymer chains. The second part of this talk will focus on the case of inhomogeneously patterned surfaces and identify the interplay between pattern width and the surface free energies in dependencies on grafting density, relative chain length between the free and grafted polymers, and blockiness of the random copolymer chains. The second part of this talk will focus on the case of inhomogeneously patterned surfaces and identify the interplay between pattern width and the surface free energies in dependencies on grafting density, relative chain length between the free and grafted polymers, and blockiness of the random copolymer chains. The second part of this talk will focus on the case of inhomogeneously patterned surfaces and identify the interplay between pattern width and the surface free energies in dependencies on grafting density, relative chain length between the free and grafted polymers, and blockiness of the random copolymer chains.

3:42PM D42.00005 Optimizing the Morphology Characterization of Block Copolymer Directed Self-Assembly Thin Films using Inverse Genetic Algorithms

ADAM HANNON, DANIEL SUNDAY, DONALD WINDOVER, CHRISTOPHER LIMAN, NIST - Natl Inst of Stds & Tech, JUAN DE PABLO, University of Chicago, JOSEPH KLINE, NIST - Natl Inst of Stds & Tech — Block copolymer (BCP) directed self-assembly (DSA) is one of the leading candidate methods for nanopatterning transfer needed in the next generation of integrated circuit and memory storage devices. Much research has gone into precisely controlling the morphology of BCP thin films, making the development and application of metrology methods to BCPs a critical area. In particular, methods for determining the real space structure of the BCP DSA films are needed. Recently, resonant soft X-ray scattering experiments have shown promise as such a method by inversely calculating the real space structure from the scattered intensity profile [Sunday et. al. ACS Nano 2014, 8 (8), 8426-8437]. These inverse methods are limited in application by their computation speed. Here we present recent work in using genetic algorithms to determine the real space structure of PS-PMAA thin films. The calculated results are compared with the structure found in self-consistent field theory simulations using boundary conditions analogous to the experimental DSA templates.

3:54PM D42.00006 Instantaneous Formation of Block Copolymer Patterns via Solvo-Thermal Casting Process

HYUN JUNG WOO, JONGSANG WOO, JUNE HUH, JOONA BANG, Department of Chemical and Biological Engineering, Korea Univ. — A self-assembly of block copolymer (BCPs) exhibits one of the most promising alternative methods for the next-generation lithography. Many semiconductor companies have explored the possibility of implementing this process in actual chip process, whereas the critical challenges such as feature size control, defect density, and long processing time need to be overcome. Regarding the BCP process, the formation of BCP patterns usually requires long processing time via thermal or solvent annealing. Herein we developed a simple processing method to promote a microphase separation of BCPs using solvo-thermal spin casting process. Spin casting has a very similar mechanism to solvent vapor annealing but its short processing time prevents BCP chains from reaching equilibrium morphology. To maximize the chain mobility, we employed a high boiling point solvent and also applied the heat during spin casting. As a result, a well ordered BCP patterns were obtained within less than 5 min via solvo-thermal casting process without further additional annealing step.
4:06PM D42.00007 Cyclic Solvent Vapor Annealing for Rapid, Robust Vertical Orientation of Features in BCP Thin Films. SEAN PARADISO, KRIS DELANEY, GLENN FREDRICKSON. Univ of California - Santa Barbara — Methods for reliably controlling block copolymer self assembly have seen much attention over the past decade as new applications for nanostructured thin films emerge in the fields of nanopatterning and lithography. While solvent assisted annealing techniques are established as flexible and simple methods for achieving long range order, solvent annealing alone exhibits a very weak thermodynamic driving force for vertically orienting domains with respect to the free surface. To address the desire for oriented features, we have investigated a cyclic solvent vapor annealing (CSVVA) approach that combines the mobility benefits of solvent annealing with selective stress-confined domains. It has been shown that structures oriented parallel to the free surface as the film is repeatedly swollen with solvent and dried. Using dynamical self-consistent field theory (DSCFT) calculations, we establish the conditions under which the method significantly outperforms both static and cyclic thermal annealing and implicate the orientation selection as a consequence of the swelling/deswelling process. Our results suggest that CSVVA may prove to be a potent method for the rapid formation of highly ordered, vertically oriented features in block copolymer thin films.

4:18PM D42.00008 Decoupling Substrate Surface Interactions in Block Polymer Thin Film Self-Assembly. CAMERON SHELTON, THOMAS EPPS, University of Delaware — Understanding the impact of the major factors that affect block polymer (BP) thin film self-assembly is necessary to control nanostructure ordering, orientation, and defect density. In this work, we systematically studied the influence of the substrate surface energy, one of the most significant parameters directing self-assembly, on wetting behavior, through-film interactions, and substrate surface field propagation. Notably, we determined the applicability of decoupled surface energy components (dispersive and polar interactions) as opposed to total surface energy, using a suite of chlorosilane monolayers and UV-ozone degradation to create a library of total, dispersive, and polar surface energy effects. Our results could complement literature that indicated repulsive total surface energy interactions are the dominant forces at the substrate-polymer interface, whereas attractive decoupled surface energy interactions become significant past the contacting layer. This work represents a thorough analysis of a vital force affecting BP self-assembly as well as a blueprint for the generalized design of substrate surfaces that achieve target BP nanostructure orientations for nanolithography, templating, and nanoporous membrane applications.

4:30PM D42.00009 A Block Copolymer Self-Assembly Approach for 3D Nanoconfined Dopants in Semiconductors. BHOOSHAN POPERE, BORIS RUSS, WILLIAM CHANG, University of California, Berkeley, ANDREW HEITSCH, The Dow Chemical Company, Midland, MI, PETER TREFONAS, Dow Electronic Materials, Marlboro, MA, RACHEL SEGALMAN, University of California, Santa Barbara — Continuous shrinking of electronic circuits presents a new challenge to demonstrate reliable, uniform nanoscale doping. Directed self-assembly (DSA) of block copolymers (BCP) has proved critical in meeting the technology nodes by enabling excellent pitch control for lithography. Yet, controlling the 3D dopant distribution remains a fundamental design challenge. To this end, we have utilized BCP self-assembly in a novel approach to confine dopants to nanoscopic domains within a semiconductor. The periodic nature of these domains affords precise control over the dosage and spatial positions of dopant atoms. Dopant incorporation within the block copolymer domains via hydrogen bonding eliminates the need for tailored synthesis, making the approach highly modular. Rapid thermal annealing (RTA) effectively drives the dopants into the underlying substrate, thus confining them to within 10-20 nm in all dimensions. Additionally, the size, pitch, dopant dosage and the junction depth can be independently varied for a wide range of dopants. Compositional and electronic measurements indicate that the domains are indeed discrete and nanoconfined. Our approach, thereby, enables a facile method for controlled nanoscopic doping in semiconductors.

4:42PM D42.00010 Defect motion and annihilation in block copolymer thin films1. MARCUS MUELLER, WEIHUA LI, Georg-August University, Institute for Theoretical Physics, Goettingen, Germany — Using self-consistent field theory and computer simulation of a soft, coarse-grained particle model we study defect motion and annihilation in thin films of lamella-forming block copolymers on neutral and chemically patterned substrates. By virtue of the strain-field mediated interactions, dislocation defects with opposite orientation move towards each other. This motion depends both on the thermodynamic, strain-field mediated driving force and the single-chain dynamics that is required to alter the morphology and reduce the distance between the defect cores. This interplay results in a qualitative dependence of the time evolution on the topology of the defect morphology. Upon collision of the defects, they either spontaneously annihilate or form a metastable, tight defect pair. In the latter case, a free-energy barrier has to be overcome to finally produce a defect-free structure. Computing the minimum free-energy path within self-consistent field theory we investigate the dependence of the free-energy barriers of defect motion and annihilation on incompatibility, strength of the chemical surface pattern, and defect morphology.

4:54PM D42.00011 Accelerating the search for globally stable block polymer microphases using genetic algorithms1. CAROL TSAI, KRIS DELANEY, GLENN FREDRICKSON. UC Santa Barbara — The diverse array of block copolymer (BCP) applications is possible because in the melt state, various morphologies that are periodic structures on the nanoscale emerge depending on the particular composition and architecture of the BCPs used. However, knowing which compositional parameters to use to obtain materials with desired properties is a Herculean task: there is an enormous parameter space to search. Furthermore, the problem is exacerbated by the fact that even at a fixed set of compositional parameters, it is difficult to determine the globally stable morphology and low-lying metastable states that will emerge, as complications arise from a rough free-energy landscape. A significant result could be a more efficient and economic screening for the desired microphasology. In this way, the search for optimal microphasology would be reduced to a series of computer simulations, something that can be done on a large scale. This work builds off of previous methods used in conjunction with local optimizations performed by SCFT.

5:06PM D42.00012 Kinetic Aspects of Defect Annihilation in Block Copolymer Thin Films on Patterned Substrates. SU-MI HUR, University of Chicago, PAULINA RINCON-DELGADILLO, IMEC, VIKRAM THAPAR, Cornell University, ABELARDO RAMÍREZ-HERNÁNDEZ, Argonne National Lab., GURDAMAN KHAIRA, PAUL NEALEY, University of Chicago, MARCUS MÜLLER, Institut fur Theoretische Physik, JUAN DE PABLO, University of Chicago — Although there has been significant progress on understanding various aspects of directed self-assembly of block copolymers at equilibrium, important challenges remain regarding the development of materials and processes leading to a perfect, defect-free assembly. We present minimum free-energy pathway calculations for annihilation of dislocation defects in block copolymer thin films using the string method combined with a Theoretically Informed Coarse-Grained (TICG) simulation approach. Our results demonstrate the importance of kinetics in the elimination of defects, where an extraordinarily large thermodynamic driving force is not necessarily sufficient for defect removal. The kinetic path follows a complex three-dimensional morphological changes; the corresponding transition states often consist of a very slight connection between edge dislocation and the neighboring nanodomains. A systematic analysis of the transition states provides useful insights into the possible rate-determining mechanisms for defect motion. We also explore the dependency of the kinetic-energy barriers on the defect type and position, and on processing conditions such as the type of chemical pattern or the strength of the segregation force between the blocks.

Monday, 23, 2015 2:30PM - 5:30PM – Session D43 DPOLY: Focus Session: Self Assembled Block Copolymers and Soft Nanoparticles in Solution 1 214C - Sangwoo Lee, Rensselaer Polytechnic Institute
2:30PM D43.00001 Exotic nanoparticles with block copolymer design and solution construction with kinetic control, DARRIN POCHAN, University of Delaware — Kinetic pathways and temporal stabilities of different micelles and nanoscale aggregates have been used to construct exotic nanoparticles in solution. Due to low chain exchange dynamics between block copolymeric micelles and solvent, global thermodynamic equilibrium is extremely difficult, if not impossible, to achieve in block copolymer assembly. However, by taking advantage of this slow kinetic behavior of polymeric micelles in solution, one can purposely produce multicompartiment nanoparticles and multilength nanoparticles by forcing different block copolymers to reside in the same nanoscale structure through kinetic processing. While kinetically trapped in common nanostructures, local phase separation can occur producing compartments. This compartmentalization can be used within common micelle geometries to make complex spheres and cylinders or can be used to make new nanostructures such as multigometry aggregates (e.g. hybrid cylinder-sphere aggregates, disk-cylinder nanoparticles). Furthermore, new interparticle nanomaterials can be created with hierarchical solution construction methods.

2:42PM D43.00002 Corona contraction and polyelectrolyte complexation of polybasic micelles in buffered aqueous solution, JENNIFER LAASER, YAMING JIANG, THERESA REINEKE, TIMOTHY LODGE, University of Minnesota — We investigate the pH- and ion strength-induced contraction of polycationic micelles with a polystyrene core and poly(dimethylaminoethyl methacrylate) corona in buffered aqueous solutions, and report on complexation of these micelles with poly(styrene sulfonate) under varying ion strength conditions. We find that in monoprotic buffers, the micelle corona behaves as a salted osmotic brush, as has been observed for other block polyelectrolyte micelle systems in unbuffered solutions. In polyprotic buffers, however, we find that concentration of the charged buffer species in the micelle corona shifts the buffer dissociation equilibrium farther toward multivalent species than in the bulk, resulting in an anomalously high degree of corona contraction. In our complexation experiments, we observe two distinct size distributions that evolve on timescales of days to weeks at physiologically relevant ion concentrations, which may have implications for the design of gene- and drug-delivery vehicles using these types of interpolyelectrolyte complexes.

2:54PM D43.00003 Predicting the Solution Morphology of a Sulfonated Block Copolymer in Binary Solvent Mixtures, PHILIP GRIFFIN, GRACE SALMON, JAMIE FORD, KAREN WINEY, University of Pennsylvania — The physicochemical properties of solvent-casted block copolymer films are highly dependent on the microscopic morphology of the solutions from which they are cast. In order to achieve macroscopically homogeneous polymer solutions, binary or higher-degree solvent mixtures are often required, which introduces additional complexity in understanding the molecular level interactions that control block copolymer self-assembly in solution. Using small angle x-ray scattering, we have explored the solution morphology in ternary blends of a sulfonated pentablock copolymer in select binary solvent mixtures over a range of solvent compositions and polymer concentrations. We have found that the solution morphologies in these ternary blends depend strongly on the composition of the solvent mixture. Furthermore, we demonstrate that the solvent-composition-dependent morphologies can be accurately predicted by quantifying the polymer/solvent interactions using Hansen solubility parameters. These studies are an important step toward developing a complete and predictive understanding of the solution morphology of complex polymer/solvent mixtures.

3:06PM D43.00004 Structure of block copolymer micelles in the presence of co-solvents, MEGAN ROBERTSON, SHU WANG, KIM MAI LE, University of Houston, RACHELE PIEMONTE, LOUIS MADSEN, Virginia Tech — Amphiphilic block copolymer micelles in water are under broad exploration for drug delivery applications due to their high loading capacity and targeted drug delivery. We aim to understand the kinetic and thermodynamic processes that underlie the self-assembly of diblock copolymer micelle systems. The present work focuses on diblock copolymers containing poly(ethylene oxide) (a hydrophilic polymer) and polycaprolactone (a hydrophobic polymer), which spontaneously self-assemble into spherical micelles in water. Addition of a common good solvent (a co-solvent) for both of the constituting blocks, such as tetrahydrofuran (THF), reduces the interfacial tension at the core-corona interface. We are currently investigating the effect of this phenomenon on the micelle structural properties, using scattering experiments and nuclear magnetic resonance. We have characterized the hydrodynamic radius, core radius, corona thickness, aggregation number, degree of swelling of the micelle core with the co-solvent, and unimer (free chain) concentration, as a function of the co-solvent concentration. Fundamental knowledge from these studies will inform design of drug delivery systems by allowing us to tailor micelle properties for optimal cargo loading.

3:18PM D43.00005 Solvents effect on the structure of pentablock ionic polymers: A SANS study, MANJULA SENENAYAKE, THUSITHA ETAMPAWALA, SIDATH WIJESINGHE, NARESHT OSTI, Clemson University, LILIN HE, Oak Ridge National Laboratory, DVORA PERAHIA, Clemson University — Solution structure of ionic co-polymers is critical to their processing. The difference of the interactions between blocks with the solvent results in a rich phase diagram. Here, solutions of ABCBA symmetric ionic pentablock copolymer consisting of t-butyl polystyrene end blocks, hydrogenated isoprene inner blocks and randomly and selectively sulfoanted polystyrene as middle block, was studied by small angle neutron scattering (SANS). Specifically the impact of adding 1-propanol, a polar solvent to a cyclohexane-heptane solution was investigated. This polar solvent is associating ionizable block and it’s expected to modify the packing of the polymer. Our results shows upon addition of 1-propanol, the spherical micelles transfer into worm like object. This transformation requires the break up of the ionic clusters formed by this polymer. These changes are in line with rheology measurements of Dr. Robert Weiss who has shown that propanol unlocks ionic clusters in polystyrene sulfonate.

3:30PM D43.00006 Reversible, All-Aqueous Assembly of Hydrogen-Bonded Polymersomes, YUHAO WANG, SVETLANA SUKHISHVILI, Department of Chemistry, Chemical Biology and Biomedical Engineering, Stevens Institute of Technology, Hoboken, New Jersey 07030 — We report on supra-micron-sized polymersomes formed through single-step, all-aqueous assembly of hydrogen-bonded amphiphilic polymers. The hollow morphology of these assemblies was revealed by transmission electron microscopy (TEM), cryogenic scanning electron microscopy (cryo-SEM) and confocal laser scanning microscopy (CLSM). Stable in acidic media, these polymersomes could be dissolved by exposure to basic pH values. Importantly, the diameter of assembled hollow structures could be controlled in a wide range from 30 nm to 1 µm by the molecular weight of hydrogen-bonding polymers. We will discuss key quantitative aspects of these assemblies, including kinetics of hollow structure formation, time evolution of polymersome size, and the role of polymer molecular weight on membrane thickness and bending rigidity. We believe that our approach demonstrates an efficient and versatile way to rationally design nanocounters for drug delivery, catalysis and personal care applications.

Aqueous Self-Assembly of Non-Ionic Bottlebrush Block Copolymer Surfactants with Tunable Molecular Shapes\(^1\). JAVID RZAYEV. University at Buffalo, SUNY — Polymer amphiphiles provide a robust and versatile platform for the fabrication of nanostructured soft matter. In this research, we explore a new class of polymer surfactants based on comb-like bottlebrush architecture as highly tunable molecular building blocks for aqueous self-assembly. Excluded volume interactions between densely grafted polymer side chains in the bottlebrush architecture are alleviated by backbone stretching, which leads to the formation of shape-persistent cylindrical macromolecules whose molecular dimensions can be precisely tailored during chemical synthesis. Amphiphilic bottlebrush block copolymers containing hydrophobic poly(lactide) (PLA) and hydrophilic poly(oligoethylene oxide methacrylate) (PEO) side chains of various lengths were synthesized by a combination of controlled radical and ring-opening polymerizations. In dilute aqueous solutions, bottlebrush surfactants rapidly assembled into spherical, cylindrical and bilayer aggregates, as visualized by cryogenic transmission electron microscopy (cryo-TEM). Depending on the compositional side chain asymmetry, the formation of spherical micelles with different sizes and dispersities was observed.

The molecular shape-dependent assembly was analyzed with help of a packing parameter \(p\) computed from the molecular composition data akin to small molecule surfactants, with most uniform spherical aggregates observed for bottlebrush amphiphiles with \(p\) close to 0.3. The formation of highly uniform micelles and the presence of a rich morphological diagram with relatively narrow compositional windows was attributed to the lack of conformational freedom in bottlebrush surfactants. Similarly, the unusual formation of cylindrical micelles with long aspect ratios was attributed to their inability to stabilize morphological defects, such as Y-junctions, with large deviations from mean curvature.

Financial support for this work was provided by the National Science Foundation (DMR-1409467).

4:18PM D43.00008 Phase Transfer of Polystyrene-b-poly(ethylene oxide) Polymersomes from a Hydrophobic Ionic Liquid to Water. SOONYONG SO, TIMOTHY LODGE. Univ of Minn - Minneapolis — The phase transfer of molecules and supramolecular assemblies from one phase to the other in a biphasic system is desirable for various applications such as catalysis, separation, and delivery. Herein, we describe the phase transfer of polystyrene-b-poly(ethylene oxide) (PS-PEO) polymersomes from a hydrophobic ionic liquid, 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ([EMIM][TFSI]), into water. The phase transfer behavior of PS-PEO polymersomes was studied systematically by varying the molecular weight of PS and the PEO volume fraction of the PS-PEO. We demonstrate a general boundary for the phase transfer in terms of a reduced tethering density for PEO, which is independent of the molecular weight of the hydrophobic PS. The tethering density can be increased by increasing the block length of PEO and the size of the polymersomes, and the increased tethering density induces the phase transfer. This phase transfer were also analyzed thermodynamically with the free energy difference of the polymersomes in [EMIM][TFSI] and water. Higher grafting density can reduce the interfacial tension between PS and water, and leads the polymersomes to transfer from [EMIM][TFSI] to water at room temperature.

4:30PM D43.00009 Micellization and Gelation of Water Soluble Thermo-and Light-sensitive Block Copolymer Investigated by SANS. LILIN HE, Oak Ridge National Laboratory, BIN HU, BIN ZHAO, The University of Tennessee, Knoxville — Here we present an extensive small-angle neutron scattering (SANS) characterization of micellization and gelation of PEO-b-P(TEGA-co-NBA) in deuterated water in a wide range of temperatures and concentrations before and after the removal of o-nitrobenzyl group by UV irradiation. Scattering data analysis indicated that unimers predominated in the solutions at low temperatures and concentrations. The polymer self-assembled into micelles with the P(TEGA-co-NBA) block packed into the core and PEO forming the corona layer. A core-shell model was used to fit SANS data and obtain sizes and scattering length densities. Structural parameters such as the aggregation numbers, the radius of gyration of the chains in the shell region, the number of water molecules to the lack of conformational freedom in bottlebrush surfactants. Similarly, the unusual formation of cylindrical micelles with long aspect ratios was attributed to their inability to stabilize morphological defects, such as Y-junctions, with large deviations from mean curvature.

Monday, March 2, 2015 2:30PM - 5:30PM — Session D44 GSNP GSOFT: Invited Session: Mechanical Metamaterials 214D - Pedro Reis, Massachusetts Institute of Technology
both discrete and continuous Rouse chains. Direct and forward-flux simulations of Rouse chains of different lengths. A good agreement between the analytical calculations and simulations was achieved for the transition processes. Helfand proposed that the arm in the tube can be represented as a harmonic spring with an applied thermal tension such that the arm-end feels an entropic tension due to arm-retraction in which the star arms explore new configurations by withdrawing along their tubes and stretching out towards a new direction. Pearson and co-workers have shown that for a single star polymer in a melt of extremely long linear chains, the stress of star polymer relaxes within a time scale of the Rouse mode relaxation time [et al., 2004].

4:18 PM D44.00004 Performance through Deformation and Instability, KATIA BERTOLDI, SEAS, Harvard University — Materials capable of undergo large deformations like elastomers and gels are ubiquitous in daily life and nature. An exciting field of engineering is emerging that uses these compliant materials to design active devices, such as actuators, adaptive optical systems and self-regulating fluidics. Compliant structures may significantly change their architecture in response to diverse stimuli. When excessive deformation is applied, they may eventually become unstable. Traditionally, mechanical instabilities have been viewed as an inconvenience, with research focusing on how to avoid them. Here, I will demonstrate that these instabilities can be exploited to design materials with novel, switchable functionalities. The abrupt changes introduced into the architecture of soft materials by instabilities will be used to change their shape in a sudden, but controlled manner. Possible and exciting applications include materials with unusual properties such negative Poisson’s ratio, phononic crystals with tunable low-frequency acoustic band gaps and reversible encapsulation systems.

4:54 PM D44.00005 Programmable and Frustrated Mechanical Metamaterials, MARTIN VAN HECKE, Huigens-Kamerlingh Onnes Lab, Leiden University, the Netherlands, and FOM-Institute Amolf, Amsterdam, the Netherlands — Most metamaterials to data consist of periodic lattices of unit cells that work together in harmony. Here we demonstrate how frustration leads to new functionality. First we discuss 2D mechanical metamaterials whose response to uniaxial compression can be programmed by lateral confinement, allowing monotonic, nonmonotonic, and hysteretic behavior. These functionalities arise from a broken rotational symmetry which causes a highly nonlinear competition between two mutually incompatible modes of deformation. Second we show how to create non-periodic 3D metamaterials, leading to a wealth of novel functionalities, including mechanical pattern recognition. By perturbing the stacking order in these materials we incorporate frustration which leads to multistable behavior.

Monday, March 2, 2015 2:30PM - 5:18PM –

Session D45 DPOLY: Polymer Melts & Solutions II 216AB - Muzhou Wang, National Institute of Standards and Technology

2:30PM D45.00001 From form to feel: using origami design principles to shape mechanics, CHRISTIAN SANTANGELO, University of Massachusetts — No abstract available.

3:06PM D44.00002 Mechanical metamaterials for cloaking, MARTIN WEGENER, Karlsruhe Institute of Technology — We review our experiments on mechanical metamaterials for cloaking. This includes two-dimensional graded laminate elastic metamaterials for broadband cloaking of flexural waves in thin plates, three-dimensional pentamode metamaterials and modifications thereof, e.g., for three-dimensional core-shell cloaks, and direct coordinate transformations of discrete hexagonal lattices. We suspect that the latter mimic inhomogeneous and anisotropic Cossatot metamaterial distributions. Polymer structures with sub-micrometer feature sizes are fabricated by galvo-scanner dip-in three-dimensional direct-laser-writing optical lithography, macroscopic structures by a commercially available three-dimensional printer.

3:42PM D44.00003 Mechanical Metamaterials with Negative Compressibility Transitions, ADILSON MOTTER, Northwestern University — When tensioned, ordinary materials expand along the direction of the applied force. In this presentation, I will explore network concepts to design metamaterials exhibiting negative compressibility transitions, during which the material undergoes contraction when tensioned (or expansion when pressured). Such transitions, which are forbidden in thermodynamic equilibrium, are possible during the decay of metastable, super-strained states. I will introduce a statistical physics theory for negative compressibility transitions, derive a first-principles model to predict these transitions, and present a validation of the model using molecular dynamics simulations. Aside from its immediate mechanical implications, our theory points to a wealth of analogous inverted responses, such as inverted susceptibility or heat-capacity transitions, allowed when considering realistic scales. References: Z.G. Nicolaou and A.E. Motter, J. Stat. Phys. 151(6), 1102 (2013); Z.G. Nicolaou and A.E. Motter, Nature Materials 11, 608 (2012).

3:54PM D44.00004 Visco-elasticity of bottlebrush polymer melts: Pushing the lower limit of the entanglement modulus, WILLIAM DANIEL, Univ of NC - Chapel Hill, JOANNA BURDYNASKA, Carnegie Mellon University, ANDREY DOBRYNIN, Univ of Conn, KRZYSZTOF MATYJASZEWSKI, Carnegie Mellon University, MICHAEL RUBINSTEIN, SERGEI SHEIKO, Univ of NC - Chapel Hill, MATERIALS INTERDISCIPLINARY RESEARCH TEAM @ UNC CHAPEL HILL TEAM — Without swelling in a solvent, it is challenging to obtain materials with a modulus below 1 GPa, which is dictated by chain entanglements. Here we analyze the densely grafted molecular brush architecture to create solvent-free neat polymer melts and elastomers with plateau moduli down to hundred Pa. Such materials are theorized to behave as linear chains with rescaled dimensions of the entanglement strand due to the increase in both width and persistence length of polymer bottlebrushes. This simple rescaling leads to a prediction that entanglement modulus decreases with the degree of polymerization (DP) of the sidechains to the -1.5 power. Experimental evidence gives a remarkably close power of -1.38 ± 0.05 with moduli in the hundreds of Pascals for long sidechains with DP≈100. The experimental data have been fit using a combination of the Rouse relaxation and double reputation models lending further evidence that bottlebrush polymer behave as linear polymers with large entanglement weights and longer persistence lengths. With the addition of crystallizable block it will be possible to control the crosslinking density and design ultrasoft shape-memory materials for use in mechanically sensitive applications.

4:24PM D45.00002 First-Passage Time in Entangled Star Polymers Melts, JING CAO, JIAN ZHU, ZUOWEI WANG, ALEXEI LIKHTMAN, Univ of Reading — For a single star polymer in a melt of extremely long linear chains, the stress of star polymer relaxes by arm-retraction in which the star arms explore new configurations by withdrawing along their tubes and stretching out towards a new direction. Pearson and Helfand proposed that the arm in the tube can be represented as a harmonic spring with an applied thermal tension such that the arm-end feels an entropic force if it fluctuates away from its equilibrium position. We have investigated the first-passage(FP) time of the destruction of tube segments by representing the arm as a one-dimensional Rouse chain. In contrast, we found that the disengagement of a tube segment is getting faster with more Rouse modes added in, which means the FP problem can be modelled by a multi-dimensional multi-Schrödinger’s problem. We found a new way of solving the multi-dimensional FP problem by projecting the problem along the most probable trajectory termed “minimal action trajectory” and correcting it by entropy term. In addition, we performed direct and forward-flux simulations of Rouse chains of different lengths. A good agreement between the analytical calculations and simulations was achieved for both discrete and continuous Rouse chains.
2:54PM D45.00003 Simplified tube models for entangled supramolecular polymers \(^1\) — VICTOR BOUDARA, DANIEL READ, University of Leeds — This presentation describes current efforts investigating non-linear rheology of entangled, supramolecular polymeric materials. We describe two recently developed models: 1) We have developed a simplified model for the rheology of entangled telechelic star polymers. This is based on a pre-averaged orientation tensor, a stretch equation, and stretch-dependent probability of detachment of the sticker. In both linear and non-linear regimes, we produce maps of the whole parameter space, indicating the parameter values for which qualitative changes in response to flow are predicted. Results in the linear rheology regime are consistent with previous more detailed models (van Ruijweke et al. Macromolecules, 43, 4401-4411, 2010) and are in qualitative agreement with experimental data. 2) Using the same modelling framework, we investigate entangled linear polymers with stickers along the backbone. We use a set of coupled equations to describe the stretch between each stickers, and use equations similar to our star model for attachment/detachment of the sticky groups. This model is applicable to industrial polymers such as entangled thermoplastic elastomers, or functionalised model linear polymers.

\(^1\)The work leading to these results has received funding from the People Programme (Marie Curie Actions) of the European Union’s Seventh Framework Programme (FP7/2007-2013) under REA grant agreement no. 607937 (SUPOLEN)

3:06PM D45.00004 Fingerprinting the Non-linear Response of Three Arm Star Polystyrene by Mechanical Spectral Hole Burning, Lissajous-Bowditch Loops, and Fourier Transform Rheology \(^2\) — ZHIYUAN QIAN, GREGORY B. MCKENNA, Texas Tech Univ — It is well known that large amplitude oscillatory shear (LAOS) has become a powerful tool to fingerprint the nonlinear response of polymers and other complex fluids. In a recent work, Nabila and McKenna [J. Rheol. 58(1), 43-62, 2014] used the mechanical spectral hole burning (MSHB) which was developed in their labs, along with Lissajous-Bowditch (LB) curves and Fourier transform rheology (FTR) methods to characterize the nonlinearity of linear polystyrene solutions. They observed a linear relationship between the horizontal hole intensity and the square of pump strain amplitude. The similar quadratic dependence was found for the third harmonics from FTR. However, the origins are not same for these two signatures. In the current work, the nonlinearity of polymers with more complicated molecular structure, such as three arm star polystyrene, will be studied by these three methods. The concentration dependence of the fingerprinting will also be discussed.

\(^2\)The authors are thankful to the American Chemical Society, Petroleum Research Fund 53205-ND7, for the support of this project.

3:18PM D45.00005 Breakup dynamics of Non-Newtonian droplets in microfluidic devices: From necking to Rupture — POUYAN BOUKANY, SHAURYA SACHDEV, Delft University of Technology — It has been shown that addition of small amounts of polymers to a Newtonian fluid can exhibit non-Newtonian behavior in extensional flows. For instance, polymeric fluids produce strong filament thinning called necking when subjected to extensional flows. Coiled polymeric chains are expected to be stretched in this exponential necking regime. These stretched long chains induce elastic stress that resist the capillary forces trying to break the filament apart. Still, the molecular picture behind filament thinning and rupture of polymeric threads in extensional flow conditions is unknown. In this work, we study breakup and filament thinning of micro-droplets containing polymeric suspensions by using micro-fluidic devices. To reveal the underlying mechanism of thinning and rupture of polymeric filament, conformation of DNA suspensions were visualized in different flow conditions. Experiments have been done on both dilute and concentrated polymeric solutions. These new results allow us to explain the molecular mechanism behind filament thinning and flow instabilities in strong extensional flows of polymeric fluids.

3:30PM D45.00006 Polymer relaxation and stretching dynamics in semi-dilute DNA solutions: a single molecule study \(^1\) — KAI-WEN HSIAO, Graduate student at University of Illinois at Urbana Champaign, CHRISTOPHER BROCKMAN, Intel, CHARLES SCHROEDER, Associate professor at University of Illinois at Urbana Champaign — In this work, we study polymer relaxation and stretching dynamics in semi-dilute DNA solutions using single molecule techniques. Using this approach, we uncover a unique scaling relation for longest polymer relaxation time that falls in the crossover regime described by semi-flexible polymer solutions, which is distinct from truly flexible polymer chains. In addition, we performed a series of step-strain experiments on single polymers in semi-dilute solutions in planar extensional flow using an automated microfluidic trap. In this way, we are able to precisely control the flow strength and the amount of strain applied to single polymer chains, thereby enabling direct observation of the full stretching and relaxation process in semi-dilute solutions during transient start-up and flow cessation. Interestingly, we observe polymer individualism in the conformation of single chains in semi-dilute solutions, which to our knowledge has not yet been observed. In addition, we observe the relaxation data can be explained by a multi-exponential decay process after flow cessation in semi-dilute solutions. Overall, our work reports key advances in non-dilute polymer systems from a molecular perspective via direct observation of dynamics in strong flows.

3:42PM D45.00007 Optical Nanodozers — AHMED KHORSHID, WALTER REISNER, McGill University, TAKAHIRO SAKAUE, Kyushu University — Experiment, simulation and scaling analytics are converging on a comprehensive picture regarding the equilibrium behaviour of nanochannel confined semiflexible, self-avoiding chains. Yet, strongly non-equilibrium behaviour of confined polymers is largely unexplored from either an experimental or theoretical point of view. Combining optical trapping and nanofluidics, we have developed a “nandozer” assay for quantifying confined polymer dynamics. An optical trap is used to slide a nanosphere at a fixed velocity along a nanochannel. The trapped bead acts as a permeable gasket, letting fluid escape but preventing the polymer from passing. As the sliding bead comes in contact with a nanochannel extended DNA, the molecule is dynamically compressed, undergoing transient dynamics characterized by a traveling concentration “shockwave” before reaching a final steady state with a ramp-like concentration profile. Remarkably, these strongly nonequilibrium measurements can be quantified via a simple nonlinear convective-diffusion formalism and yield insights into the local blob statistics, allowing us to conclude that the compressed nanochannel confined chain exhibits mean-field behaviour.

3:54PM D45.00008 Shear and normal forces in charged polymer brushes — QI LIAO, Chinese Academy of Sci (CAS), MICHAEL RUBINSTEIN, Department of Chemistry, University of North Carolina, Chapel Hill, 27599 NC, USA — We present the results of molecular dynamics simulations of steady shear between a pair of opposing charged polymer brushes in the osmotic-brush regime and compare the results with predictions of scaling models. Using the monomer and counterion density profiles, we have verified different regimes in the diagram of states of compressed polyelectrolyte brushes predicted by the scaling model of Zhuлина et al [Macromolecules, 2014]. Our simulation results for the normal forces of compressed polyelectrolyte brushes are in excellent agreement with predictions of the scaling model. However, our results for the dependence of the shear forces on the separation between brushes are only in qualitative agreement with the predictions of the scaling model. The dependence of the interpenetration length on the separation of polyelectrolyte brushes exhibits a maximum instead of the plateau predicted by the scaling model for the partially interpenetrated brushes. Our simulation results confirm that our implicit solvent simulations of polyelectrolyte brushes that ignore hydrodynamic interaction are in agreement with the scaling predictions that include hydrodynamic interaction because of screening of hydrodynamic interaction and long range electrostatic interactions on the correlation length scale.
A Molecular Mechanism of viscoelasticity in aligned polyethylene

A. Hamad, H. Hasan, T.D. Swinburne, M. Kawaija, Department of Physics, Imperial College London, London SW7 2AZ, S. Del-Rossa, L. Ianniucci, Department of Aeronautics, Imperial College London, London SW7 2AZ — The key observed property of aligned polyethylene is its viscoelastic behaviour, which is traditionally fitted with Maxwell models [1]. Although these empirical models are successful at reproducing the mechanical response of the material, they fail to capture the underlying molecular mechanisms that lead to the observed viscoelastic behaviour. We explain the observed viscoelastic behaviour in terms of the formation, interaction and movement of solitons, and relate these molecular mechanisms to the semi-crystalline microstructure of the material. Using Molecular Dynamics we demonstrate the following results: (a) The formation of solitons from interfaces between crystalline and amorphous regions (b) The transfer of tensile load between molecular chains (c) the pile-up of solitons in a molecular chain that allows the concentration of stress at particular points (d) The disassociation of solitons into π-twistons at 300K.

Electrostatics effects on normal load capacity of two like-charge hydrogels

Aykut Erbas, Jos Zwanikken, Monica Olivera de la Cruz, Northwestern University, OLVERA DE LA CRUZ TEAM — In mammalian joints, an effective lubrication mechanism is maintained under extremely high pressures due to charged polymeric structures coating the surfaces of the relatively moving tissues. Equally low frictional forces are also observed experimentally in the shear motion of polyelectrolyte gel and brush bilayers. The lubrication capabilities of these systems are attributed to either a polymer-free zone, separating the bilayers or hydration layers that can dissolve polymeric segments. Previous hypothesis have stated that the separation zone should decrease the polymer-polymer physical contact, and hence, result in only viscous friction of the liquid filling this layer. In this study, we use extensive Molecular Dynamics simulations and analytical tools, we investigate the separation zone under compression at high electrostatic strengths. We show that Coulomb interactions significantly change the thickness of the separation zone, as well as the normal pressure that a hydrogel bilayer can support upon control-strains deformation. We observe that under high pressures the separation zone completely disappears. As a result, the number of polymer-polymer contacts increases. We speculate that the frictional forces between polymer segments can reduce the efficiency of the lubrication.

Hierarchical assembly of block copolymer micelles into reversible networks: MC simulations

Zilu Wang, Physics Department and Institute of Materials Science, University of Connecticut, Elena Dormidonova, Institute of Materials Science, University of Connecticut — The rapid development of nanoscience has considerably expanded the range of building blocks for complex self-assembled nanostructure formation, which show great potential for numerous advanced applications. We apply Monte Carlo simulations to gain understanding of molecular mechanism of self-assembly of nanostructures formed by diblock copolymer micelles interconnected by means of metal-ligand complexation. These systems exhibit interesting chemical and mechanical stimuli-responsive behavior and possess two levels of self-assembly: 1) self-assembly of diblock copolymers into micelles and 2) reversible inter-micelle bridging by coordination bonding between metal ions and ligands attached to the coronas of nanoparticles, which is responsible for the network viscoelastic properties. Using MC simulations we investigate the effect of metal-ligand complexation on diblock-copolymer micelle formation and vice versa. We analyze the extent of intra- and inter-micelle loops and bridges formed by metal-ligand complexion in relation to the degree of crosslinking and elastic properties of the network. The effect of polymer concentration, hydrophilic block length, metal to oligomer ratio and type of complexation (2:1 or 3:1) on equilibrium properties of reversible networks will be discussed.

217A - Andre Schleife, University of Illinois-Urbana
2:30PM D46.00001 Achieving High Performance Perovskite Solar Cells. YANG YANG, University of California, Los Angeles — Recently, metal halide perovskite based solar cell with the characteristics of rather low raw materials cost, great potential for simple process and scalable production, and extreme high power conversion efficiency (PCE), have been highlighted as one of the most competitive technologies for next generation thin film photovoltaic (PV). In UCLA, we have realized an efficient pathway to achieve high performance perovskite solar cells, where the findings are beneficial to this unique materials/devices system. Our recent progress lies in perovskite film formation, defect passivation, transport materials design, interface engineering with respect to high performance solar cell, as well as the exploration of its applications beyond photovoltaics. These achievements include: 1) development of vapor assisted solution process (VASP) and moisture assisted solution process, which produces perovskite film with improved conformity, high crystallinity, reduced recombination rate, and the resulting high performance; 2) examination of the defects property of perovskite materials, and demonstration of a self-induced passivation approach to reduce carrier recombination; 3) interface engineering based on design of the carrier transport materials and the electrodes, in combination with high quality perovskite film, which delivers 15 ~ 20% PCEs; 4) a novel integration of bulk heterojunction to perovskite solar cell to achieve better light harvest; 5) fabrication of inverted solar cell device with high efficiency and flexibility and 6) exploration the application of perovskite materials to photodetector. Further development in film, device architecture, and interfaces will lead to continuous improved perovskite solar cells and other organic-inorganic hybrid optoelectronics.

3:06PM D46.00002 Modeling organohalide perovskites for photovoltaic applications: From materials to interfaces†. FILIPPO DE ANGELIS, Computational Laboratory for Hybrid/Organic Photovoltaics, CNR-ISTM, Perugia — The field of hybrid/organic photovoltaics has been revolutionized in 2012 by the first reports of solid-state solar cells based on organohalide perovskites, now topping at 20% efficiency. First-principles modeling has been widely applied to the dye-sensitized solar cells field, and more recently to perovskite-based solar cells. The computational design and screening of new materials has played a major role in advancing the DSCs field. Suitable modeling strategies may also offer a view of the crucial heterointerfaces ruling the device operational mechanism. I will illustrate how simulation tools can be employed in the emerging field of perovskite solar cells. The performance of the proposed simulation toolbox along with the fundamental modeling strategies are presented using selected examples of relevant materials and interfaces. The main issue with hybrid perovskite modeling is to be able to accurately describe their structural, electronic and optical features. These materials show a degree of short range disorder, due to the presence of mobile organic cations embedded within the inorganic matrix, requiring to average their properties over a molecular dynamics trajectory. Due to the presence of heavy atoms (e.g. Sn and Pb) their electronic structure must take into account spin-orbit coupling (SOC) in an effective way, possibly including GW corrections. The proposed SOC-GW method constitutes the basis for tuning the materials electronic and optical properties, rationalizing experimental trends. Modeling charge generation in perovskite-sensitized TiO₂ interfaces is then approached based on a SOC-DFT scheme, describing alignment of energy levels in a qualitatively correct fashion. The role of interfacial chemistry on the device performance is finally discussed.

3:42PM D46.00003 Interface Energetics in Organo-Metallic Halide Perovskite-based Photo-voltaic Cells. PHILIP SCHULZ, National Renewable Energy Laboratory — In my presentation I will talk about the most recent findings on the electronic structure of methylammonium lead tri-halide (MAPbX₃, X=I, Br) perovskite films and their interfaces to adjacent transport layers. Intricate knowledge of the electronic alignment at the contact interfaces in perovskite solar cells is essential for the understanding of the working principle as well as improving design and thus performance of respective devices. In our studies we employ ultra-violet, X-ray and inverse photoemission spectroscopy (UPS, XPS, IPES) to directly determine valence and conduction band offsets. In this way we are able to report a direct measurement of the electronic band gap as well as ionization energy and electron affinity found for perovskite surfaces. Furthermore, our findings indicate that the electronic energy level alignment of adjacent organic hole transport layers, such as spiro-MeOTAD, can limit the maximum attainable open circuit voltage (V_{oc}) in solar cells if the highest occupied molecular orbital of the hole transport material is not well aligned to the valence band maximum of the perovskite layer. Using better suited hole transporters, like CBP, values for V_{oc} larger than 1.5 V could be achieved in the case of MAPbBr₃ based devices. More recently, inverted perovskite solar cells based on nickel oxide bottom anodes have been reported to yield viable power conversion efficiencies and stability. We find that the interface between the p-doped NIO surface and the MAPbI₃ layer on top lead to p-type perovskite film while the same material deposited on TiO₂ in the conventional cell geometry turns out to be n-type. A further investigation of a C₆₀ layer deposited on top of p-type perovskite films reveals an ideal alignment between the lowest unoccupied molecular orbital of the organic electron transport materials and the conduction band minimum of the perovskite film underneath. These results explain why the inverted solar cell structure could achieve similar successes as the conventional structure and highlight the versatility of perovskite sub-cells in potential tandem cell architectures.

4:18PM D46.00004 Impact of Atomic Structure on Absolute Energy Levels of Methylammonium Lead Iodide Perovskite. JOSHUA CHOI, University of Virginia — There has been a staggeringly rapid increase in the photovoltaic performance of methylammonium lead iodide (MAPbI₃) perovskite - greater than 19 percent solar cell power conversion efficiency has been reported in less than five years since the first report in 2009. Despite the progress in device performance, structure-property relationships in MAPbI₃ are still poorly understood. I will present our recent findings on the impact of changing the Pb-I bond length and Pb-I-Pb bond angle on the electronic structure of MAPbI₃. By using the combination of temperature dependent X-ray scattering, ultraviolet photoelectron spectroscopy, absorbance and PL spectroscopy, we show that the energy levels of highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) shift in the same direction as MAPbI₃ goes through tetragonal-to-cubic structural phase transition wherein the rotational angle of PbI₆ octahedra is the order parameter of the transition. Our experimental results are corroborated by density functional theory calculations which show that the lattice expansion and bond angle distortion cause different degree of orbital overlap between the Pb and I atoms and the anti-bonding orbital nature of both HOMO and LUMO results in the same direction of their shift. Moreover, through pair distribution function analysis of X-ray scattering, we discovered that the majority of MAPbI₃ in thin film solar cell layer has highly disordered structure with a coherence range of only 1.4 nm. The nanostructuring correlates with a blueshift of the absorption onset and increases the photoluminescence. Our results underscore the importance of understanding the structure-property relationships in order to improve the device performance of metal-organic perovskites.
4:54PM D46.00005 Electronic structure of hybrid halide perovskite photovoltaic absorbers. MARK VAN SCHILFGAARDE, King’s College London — The performance of organometallic perovskite solar cells has rapidly surpassed those of both traditional dye-sensitized and organic photovoltaics, e.g., solar cells based on CH$_3$NH$_3$PbI$_3$ have recently reached 18% conversion efficiency. We analyze its electronic structure and optical properties within the quasiparticle self-consistent GW approximation (QSGW). Quasiparticle self-consistency is essential for an accurate description of the band structure: bandgaps are much larger than what is predicted by the local density approximation (LDA) or GW based on the LDA. Several characteristics combine to make the electronic structure of this material unusual. First, there is a strong driving force for ferroelectricity, as a consequence the polar organic moiety CH$_3$NH$_3$. The moiety is only weakly coupled to the PbI$_3$ cage; thus it can rotate give rise to ferroelectric domains. This in turn will result in internal junctions that may aid separation of photoexcited electron and hole pairs, and may contribute to the current-voltage hysteresis found in perovskite solar cells. Second, spin orbit modifies both valence band and conduction band dispersions in a very unusual manner: both get split at the R point into two extrema nearby. This can be interpreted in terms of a large Dresselhaus term, which vanishes at R but for small excitations about R varies linearly in k. Conduction bands (Pb 6p character) and valence bands (I 5p) are affected differently; moreover the splittings vary with the orientation of the moiety. We will show how the splittings, and their dependence on the orientation of the moiety through the ferroelectric effect, have important consequences for both electronic transport and the optical properties of this material.

3:30PM D47.00001 The neurobiology of individuality. BENJAMIN DE BIVORT, Harvard University — Individuals often display conspicuously different patterns of behavior, even when they are very closely related genetically. These differences give rise to our sense of individuality, but what is their molecular and neurobiological basis? Individuals that are nominally genetically identical differ at various molecular and neurobiological levels: cell-to-cell variation in somatic genomes, cell-to-cell variation in expression patterns, individual-to-individual variation in neuronal morphology and physiology, and individual-to-individual variation in patterns of brain activity. It is unknown which of these levels is fundamentally causal of behavioral differences. To investigate this problem, we use the fruit fly Drosophila melanogaster, whose genetic toolkit allows the manipulation of each of these mechanistic levels, and whose rapid lifecycle and small size allows for high-throughput automation of behavioral assays. This latter point is crucial; identifying inter-individual behavioral differences requires high sample sizes both within and across individual animals. Automated behavioral characterization is at the heart of our research strategy. In every behavior examined, individual flies have individual behavioral preferences, and we have begun to identify both neural genes and circuits that control the degree of behavioral variability between individuals.

2:30PM D47.00002 Higher throughput high resolution multi-worm tracker. AVELINO JAVER, KEZHI LI, BERTALAN GYENES, ANDRE BROWN, MRC CSC, Imperial College London, BEHAVIOURAL GENOMICS TEAM — We have developed a high throughput imaging system for tracking multiple nematode worms at high resolution. The tracker consists of 6 cameras mounted on a motorized gantry so that up to 48 plates (each with approximately 30 worms) can be imaged without user intervention. To deal with the high data rate of the cameras we use real time processing to find worms and only save the immediately surrounding pixels. The system is also equipped with automatic oxygen and carbon dioxide control for observing stimulus response behaviour. We will describe the design and performance of the new system, some of the challenges of truly high throughput behaviour recording, and report preliminary results on inter-individual variation in behaviour as well as a quantitative analysis of C. elegans response to hypoxia, oxygen reperfusion, and carbon dioxide.

3:18PM D47.00003 Locomotion and drag in wet and dry granular media. DANIEL GOLDMAN, ROBYN KUCKUK, SARAH SHARPE, Georgia Institute of Technology — Many animals move within substrates such as soil and dry sand; the resistive properties of such granular materials (GM) can depend on water content and compaction, but little is known about how such parameters affect locomotion or the relevant physics of drag and penetration. We developed a system to create homogeneous wet GM of varying moisture content and compaction in quantities sufficient to study the burial and subsurface locomotion of the Ocellated skink (C. ocellatus) a desert-generalist lizard. X-ray imaging revealed that in wet and dry GM the lizard slowly buried (~30 seconds) propagating a wave from head to tail, while moving in a start-stop motion. During forward movement, the head oscillated, and the forelimb on the convex side of the body propelled the animal. Although body kinematics (and “slip”) were similar in both substrates, the burial depth was smaller in wet GM. Penetration and drag force experiments on smooth cylinders revealed that wet GM was ~3× more resistive than dry GM, suggesting that during burial the lizard operated near its maximum force producing capability and was thus constrained by environmental properties.
