P1.00104 Modeling the Kinetics of a Memory-Associated Immediate Early Gene's Compartmental Expression After Sensory Experience1, ADAM WILLATS, Georgia Institute of Technology and Emory University; Dept. of Biomedical Engineering, TAMARA IVANOVA, ASTRID PRINZ, ROBERT LUU, Emory University; Dept. of Biology — Immediate Early Genes (IEGs) are rapidly and transiently transcribed in neurons after a sensory experience. Some of these genes act as effector IEGs, which mediate specific effects on cellular function. Arc is one such effector IEG that is essential for synaptic plasticity and memory consolidation in hippocampus and cortex. The expression of Arc in neurons has previously been examined using an imaging method known as Compartamental Analysis of Temporal Fluorescent In-Situ Hybridization. Previous work found that the time course of Arc expression within the nuclear and perinuclear cytoplasmic compartments of a neuron is altered by prior sensory experience. We explore a simple model of the kinetics of IEG transcription and nuclear export, with the aim of eventually uncovering possible mechanisms for how experience alters expression kinetics. Thus far, we characterize our compartmental model using phase-plane analysis and validate it against several IEG expression data sets, including one where prior experience with vocalizing mice alters the time course of call-induced Arc expression in the auditory cortex of a listening mouse. Our model provides a framework to explore why Arc expression may change depending on a receiver’s past sound experience and internal state.

P1.00105 The brain as a complex system: plasticity at multiple scales and criticality, TONY NG, PAUL MILLER, Brandeis University — As a complex system, a successful organism is one that can react effectively to environmental fluctuations. Not only should its response repertoire be commensurate with the number of independent conditions that it encounters, behavioral and environmental variations need to be matched at the appropriate scales. In the cortex, neuronal clusters, not individual cells, operate at the proper scale that is necessary to generate appropriate responses to external states of the world. Single neurons, however, serve on a finer scale to mediate interactions between neuronal assemblies. The distinction of scales is significant, as plasticity mechanisms can operate on various spatial and temporal scales. The brain has apparently evolved complex-system strategies to calibrate its own dynamics at multiple scales. This makes the joint study of local balance and global homeostasis fundamentally important, where criticality emerges as a signature of a computationally powerful system. We show via simulations how plasticity mechanisms at multiple scales are inextricably tied to spike-based neuronal avalanches, which are microscopic in origin and poorly predictive of animal behavior, and cluster-based avalanches, which are manifest macroscopically and are relevant to cognition and behavior.

P1.00106 Marginalization in Random Nonlinear Neural Networks, RAJKUMAR VASUDEVA RAJU, Rice University, XAQ PITKOW, Rice University, Baylor College of Medicine — Computations involved in tasks like causal reasoning in the brain require a type of probabilistic inference known as marginalization. Marginalization corresponds to averaging over irrelevant variables to obtain the probability of the variables of interest. This is a fundamental operation that arises whenever input stimuli depend on several variables, but only some are task-relevant. Animals often exhibit behavior consistent with marginalizing over some variables, but the neural substrate of this computation is unknown. It has been previously shown (Beck et al. 2011) that marginalization can be performed optimally by a deterministic nonlinear network that implements a quadratic interaction of neural activity with divisive normalization. We show that a simpler network can perform essentially the same computation. These Random Nonlinear Networks (RNN) are feedforward networks with one hidden layer, sigmoidal activation functions, and normally-distributed weights connecting the input and hidden layers. We train the output weights connecting the hidden units to the output population, such that the output model accurately represents a desired marginal probability distribution without significant information loss compared to optimal marginalization. Simulations for the case of linear coordinate transformations show that the RNN model has good marginalization performance, except for highly uncertain inputs that have low amplitude population responses. Behavioral experiments, based on these results, could then be used to identify if this model does indeed explain how the brain performs marginalization.

P1.00107 Investigating structural details of lipid-cholesterol-A\(\beta\) interactions, DURGESH RAI, DIVINA ANUNCIADO, WILLIAM HELLER, HUGH O’NEILL, VOLKER URBAN, SHUO QIAN, Biology and Soft Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Alzheimer’s disease (AD) is the most common form of dementia and is predicted to affect 1 in 85 people around the world by 2050. Amyloid beta (A\(\beta\))-peptide, a peptide composed of 40-42 amino acids that is the product of cleavage from the amyloid precursor protein (APP), is regarded to play a major role in the development of AD. In addition, accumulating evidence points to a positive association between cholesterol and AD. Here, we present results from our studies about A\(\beta\)-peptide and cholesterol in bilayer by small-angle neutron scattering (SANS) using a combination of dimyristol, phosphocholine (DMPC) and partially deuterated cholesterol (cholesterol-d7) with and without A\(\beta\). We compare the results using gracing incidence and transmission SANS on lipid bilayer films and unilamellar vesicles respectively. The structural details on vesicles and bilayers work in conjunction with the circular dichroism on peptide in solution and oriented circular dichroism in bilayer films. The studies confirm a positive association of A\(\beta\) with the membrane layers. The results from different studies will be compared and contrasted in presentation.

P1.00108 Using Small Angle Neutron Scattering on Glucose Oxidase immobilized on Single Layer Graphene, DURGESH RAI, Oak Ridge National Lab, M. GURUSARAN, IISc Bangalore, S. QIAN, K. WEISS, V. URBAN, Oak Ridge National Lab, P. LI, Harvard Medical School, L. MA, P. AJAYAN, Rice University, T. NARAYANAN, TIFR Hyderabad, K. SEKAR, IISc Bangalore, S. VISWANATHAN, Newton Wellesley Hospital, V. RENUGOPALAKRISHANAN, Harvard Medical School — Reliable blood glucose monitoring using biosensors is valuable for health evaluations and medication in wake of chronic diabetic issues accompanying deviations from evolutionary human lifestyle. Glucose oxidase (GOx) is an ideal enyme because of its specificity and the ability to electrochemically transduce from the enzymatic reaction. We use graphene-based electrode with GOx sensor matrix so that the emitted electrons from sensor matrix can flow across graphene nearly without scattering; crucial for constructing ultrasensitive-sensors. Thereafter, establishing a structure-property based relationships to tune the sensor topology with electrochemically output forms the main focus of the device development process. We have developed a methodology to obtain low-resolution hierarchical models of the aggregate matrix using Small Angle Neutron Scattering (SANS) technique. A Unified Fit model is used in tandem with GNOM, DAMMIN and DAMAVER to construct low-resolution models for the device development process. We have developed a methodology to obtain low-resolution hierarchical models of the aggregate matrix using Small Angle Neutron Scattering (SANS) technique. P1.00109 Interatomic Coulombic Decay Effects in Theoretical DNA Recombination Systems Involving Protein Interaction Sites1, E.L. VARGAS, D.A. RIVAS, A.C. DUOT, R.T. HOVEY, V.M. ANDRIANARIAJONA, Department of Physics, Pacific Union College, Angwin, CA 94508 — DNA replication is the basis for all biological reproduction. A strand of DNA will “unzip” and bind with another complementary strand to produce two identical molecules. In this study, we are considering how this process is affected by interactions for Homocysteine (Hcy) Decoyny (ICD), specifically how ICD affects the individual coding proteins’ ability to hold together. ICD mainly deals with how the electron returns to its original state after excitation and how this affects its immediate atomic environment, sometimes affecting the connectivity between interaction sites on proteins involved in the DNA coding process. Biological heredity is fundamentally controlled by DNA and its replication therefore it affects every living thing. The small nature of the proteins (within the range of nanometers) makes it a good candidate for research of this scale. Understanding how ICD affects DNA molecules can give us invaluable insight into the human genetic code and the processes behind cell mutations that can lead to cancer.

1Authors wish to give special thanks to Pacific Union College Student Senate in Angwin, California, for their financial support.
P1.00110 Gramicidin Induce Local Non-Uniform Distribution of Lipids in Multi-Component Membrane Domains, YU MAO, FAZLE HUSSAIN, JUYANG HUANG, Texas Tech University — In lipid membranes, gramicidin form transmembrane channels that are specific for monovalent cations. We performed Molecular Dynamics simulations of gramicidin in coexisting liquid-ordered (Lo) and liquid disordered (Ld) domains using GROMACS. The lipid compositions of Lo and Ld domains are DOPC/DSPC/Cholesterol = 6.5/52.6/40.9 and 74.4/10.6/15, respectively. In the Ld domain, the membrane thickness matches the hydrophobic length of gramicidin quite well, and water molecules can diffuse through the gramicidin channels. However, in the Lo lipid domain, the bilayer thickness is far greater than the hydrophobic length of gramicidin and majority of gramicidin do not form conducting channel. The simulation result explained our experimental finding that gramicidin partition favorably into the Ld domains. The calculated radial distribution functions of lipids indicate that gramicidin recruit a layer of short DOPC surrounding each protein and keep cholesterol and taller DSPC away from the protein-bilayer interface. Our result indicates that membrane proteins are capable of inducing non-uniform distributions of lipids and creating a local bilayer environment, which favors protein function.

P1.00111 Directly mapping the surface charge density of lipid bilayers under physiological conditions, THOMAS FUHS, LASSE HYLDGAARD KLAUSEN, FLEMMING BESENBAKER, MINGDONG DONG, Interdisciplinary Nanoscience Center, Aarhus University, Denmark — The surface charge density of lipid bilayers governs the cellular uptake of charged particles and guides cell-cell and cell-surface interactions. Direct probing of the potential requires sub nanometer distances as the electrostatic potential is screened by high physiological salt concentrations. This prevented direct measurement of the SCD under physiological conditions. In this study we investigate supported bilayers of lipid mixtures that form domains of distinct surface charges, submerged in 150mM NaCl. We use a scanning ion-conductance microscope (SCM) setup to measure the ionic current through a nanopipette as the pipette is scanned several nanometers above the sample. The charged headgroups of the lipids attract counter ions leading to a charge dependent enhancement of the ion concentration near the surface. This creates a measurable change of conductivity in the vicinity of the surface. As the dependency of the current on the SCD and pipette potential is non-trivial we characterized it using numerical solutions to Poisson and Nernst-Planck equations. Based on the simulation results we propose an imaging method. We confirm feasibility of the proposed method by experimentally mapping the local surface charge density of phase separated lipid bilayers.

P1.00112 Lipid mobility in supported lipid bilayers by single molecule tracking, MARYM KOHRAM, University of Akron, Department of Physics, XIAOJUN SHI, ADAM SMITH, University of Akron, Department of Chemistry — Phospholipid bilayers are the main component of cell membranes and their interaction with biomolecules in their immediate environment is critical for cellular functions. These interactions include the binding of polycationic polymers to lipid bilayers which affects many cell membrane events. As an alternative method of studying live cell membranes, we assembled a supported lipid bilayer and investigate its binding with polycationic polymers in vitro by fluorescently labeling the molecules of the supported lipid bilayer. We use single molecule tracking total internal reflection fluorescence microscopy (TIRF) to study phosphatidylinositol phosphate (PIP) lipids with and without an adsorbed polycationic polymer, quaternized polyvinylpyridine (QPVP). Individual molecular trajectories are obtained from the experiment, and a Brownian diffusion model is used to determine diffusion coefficients through mean square displacements. Our results indicate a smaller diffusion coefficient for the supported lipid bilayers in the presence of QPVP in comparison to its absence, revealing that their binding causes a decrease in lateral mobility.

P1.00113 Nanoparticle size and shape characterization with Solid State Nanopores, SANTOSHI NANDIVADA, MOURAD BENAMARA, JIALI LI, University of Arkansas — Solid State Nanopores are widely used in a variety of single molecule studies including DNA and biomolecule detection based on the principle of Resistive Pulse technique. This technique is based on electrophoretically driving charged particles through 35-60 nm solid state nanochannels. The translocation of these particles produces current blockage events that provide an insight to the properties of the translocation of nanoparticles and the nanopore. In this work we study the current blockage events produced by ~ 30nm negatively charged PS nanoparticles through Silicon Nitride solid state nanochannels. We show how the current blockage amplitudes and durations are related to the ratio of the volume of the particle to the volume of the pore, the shape of the particle, charge of the particle and the nanopore surface, salt concentration, solution pH, and applied voltage. The solid-state nanopores are fabricated by a combination of Focus Ion Beam and low energy Ion beams in silicon nitride membranes. High resolution TEM is used to measure the 3D geometry of the nanopores and a finite element analysis program (COMSOL) is used to simulate the experimental results.

P1.00114 ABSTRACT WITHDRAWN

P1.00115 Characterizing detergent mediated reconstitution of viral protein M2 in large unilamellar vesicles, MARIEL FREYRE, CARL GROSSMAN, CATHERINE CROUCH, KATHLEEN HOWARD, Swarthmore College — Influenza M2 is a model membrane protein whose function is to induce curvature and vesicle formation in the process of viral infection. To study embedded M2 in synthetic phospholipid vesicles (large unilamellar vesicles or LUVs), a concentration of detergent and buffer is optimized to balance protein solubility, proteolipid concentration, and LUV stability. Adding detergent also causes the LUVs to partially disassemble and form micelles, which warrants detergent removal to restore LUV integrity. We explore methods of measuring the coexistence of detergent micelles and LUVs to track the different phases of the system as detergent is removed. A combination of Fluorescence Correlation Spectroscopy, Dynamic Light Scattering, and chemical analysis are used to measure the properties of this system. With detergent/LUV number densities as high as 5 we find coexistence of micelles and LUVs at 50% to 60%. As the detergent is removed, the micelle concentration drops to lower than 30% while detergent levels drop to nearly zero. These results may indicate a polydispersed LUV size distribution after detergent mediated reconstitution.

P1.00116 Preventing drug resistance in severe influenza, HANA DOBOROVNY, Texas Christian Univ, LUCAS DEECKE, University of Cologne — Severe, long-lasting influenza infections are often caused by new strains of influenza. The long duration of these infections leads to an increased opportunity for the emergence of drug resistant mutants. This is particularly problematic for new strains of influenza since there is often no vaccine, so drug treatment is the first line of defense. One strategy for trying to minimize drug resistance is to apply periodic treatment. During treatment the wild-type virus decreases, but resistant virus might increase; when there is no treatment, wild-type virus will hopefully out-compete the resistant virus, driving down the number of resistant virus. We combine a mathematical model of severe influenza with a model of drug resistance to study emergence of drug resistance during a long-lasting infection. We apply periodic treatment with two types of antivirals: neuraminidase inhibitors, which block release of virions; and adamantanes, which block replication of virions. We compare the efficacy of the two drugs in reducing emergence of drug resistant mutants and examine the effect of treatment frequency on the emergence of drug resistant mutants.

P1.00117 Simultaneous influenza and respiratory syncytial virus infection in human respiratory tract, LUBNA JAHAN RASHID PINKY, HANA DOBOROVNY, Texas Christian University — Studies have shown that simultaneous infection of the respiratory tract with at least two viruses is not uncommon in hospitalized patients, although it is not clear whether these infections are more or less severe than single infections. We use mathematical models to study the dynamics of simultaneous influenza (flu) and respiratory syncytial virus (RSV) infection, two of the more common respiratory viruses, in an effort to understand simultaneous infections. We examine the roles of initial viral inoculum, relative starting time, and cell regeneration on the severity of the infection. We also study the effect of antiviral treatment on the course of the infection. This study shows that, unless treated with antivirals, flu always takes over the infection no matter how small the initial dose and how delayed it starts with respect to RSV.
P1.00118 Determining Mechanism of Action of Antivirals for Respiratory Illness. Irma Rodriguez, Hana Dobrovolny, Texas Christian University — Viral infections in the respiratory tract are common in humans and can cause serious illness and death. Drug treatment is the principal line of protection against many of these illnesses and many compounds are tested as antivirals. Often the efficacy of these antivirals is determined before a mechanism of action is understood. We use mathematical models to represent the evolution of these diseases and establish which experiments can help determine the mechanism of action of antivirals.

P1.00119 Object-adapted trapping and shape-tracking to probe a bacterial protein chain motor. Julian Roth, Matthias Koch, Alexander Rohrbach, University of Freiburg — The helical bacterium Spiroplasma is a motile plant and anthropod pathogen which swims by propagating pairs of kinks along its cell body. As a well suited model system for bacterial locomotion, understanding the cell's molecular motor is of vital interest also regarding the combat of bacterial diseases. The extensive deformations related to these kinks are caused by a contractile cytoskeletal protein ribbon representing a linear motor in contrast to common rotary motors as, e.g., flagella. We present new insights into the working of this motor through experiments with object-adapted optical traps and shape-tracking techniques. We use the given laser irradiation from the optical trap to hinder bacterial energy (ATP) production through the production of O₂ radicals. The results are compared with experiments performed under the influence of an O₂ Scavenger and ATP inhibitors, respectively. Our results show clear dependences of the kinking properties on the ATP concentration inside the bacteria. The experiments are supported by a theoretical model which we developed to describe the switching of the ribbon's protein subunits.

P1.00120 Modeling the Lymphocytic Choriomeningitis Virus: Insights into understanding its epidemiology in the wild. Christy Contreras, College of Liberal Arts and Sciences – Physics Department, Arizona State University, John Mckay, Applied Mathematics for the Life and Social Sciences, Arizona State University, Joseph Blattman, Susan Holecheck, The Biodesign Institute, Arizona State University — The lymphocytic choriomeningitis virus (LCMV) is a rodent-spread virus commonly recognized as causing neurological disease that exhibits asymptomatic pathology. The virus is a pathogen normally among rodents that can be transmitted to humans by direct or indirect contact with the virus in excretions and secretions from rodents and can cause aseptic meningitis and other conditions in humans. We consider an epidemiological system within rodent populations modeled by a system of ordinary differential equations that captures the dynamics of the diseases transmission and present our findings. The asymptotic nature of the pathogen plays a large role in its spread within a given population, which has motivated us to expand upon an existing SIRC model (Holechek et al in preparation) that accounts for susceptible-, infected-, recovered-, and carrier-mice on the basis of their gender. We are interested in observing and determining the conditions under which the carrier population will reach a disease-free equilibrium, and we focus our investigation on the sensitivity of our model to gender, pregnancy related infection, and reproduction rate conditions.

P1.00121 ABSTRACT WITHDRAWN —

P1.00122 Feeding strategies as revealed by the section moduli of the humerus bones in bipedal theropod dinosaurs. Scott Lee, Zachary Richards, University of Toledo — The section modulus of a bone is a measure of its ability to resist bending torques. Carnivorous dinosaurs presumably had strong arm bones to hold struggling prey during hunting. Some theropods are believed to have become herbivorous and such animals would not have needed such strong arms. In this work, the section moduli of the humerus bones of bipedal theropod dinosaurs (from Microvenator celer to Tyrannosaurus rex) are studied to determine the maximum bending loads their arms could withstand. The results show that bending strength is not of uniform importance to these magnificent animals. The predatory theropods had strong arms for use in hunting. In contrast, the herbivorous dinosaurs had weaker arms.

P1.00123 Microrheology of single microtubule filaments and synthesized cytoskeletal networks. Matthias Koch, Alexander Rohrbach, Lab for Bio- and Nano-Photonics, University of Freiburg — The ability to sense and respond to external mechanical forces is crucial for cells in many processes such as cell growth and division. Common models on mechanotransduction rely on the conversion of mechanical stimuli to chemical signals in the cell periphery and their translocation by diffusion (passive) or molecular motors (active). These processes are rather slow (~ seconds) and it has been argued that the cytoskeleton itself might be able to transport a mechanical signal within microseconds via stress waves. Microtubules are the stiffest component of the cytoskeleton and thus ideal candidates for this purpose. We study the frequency dependent response of single microtubule filaments and small networks thereof in a bottom-up approach using several (N=2-10) time-multiplexed optical tweezers together with back focal plane interferometry. Small synthesized networks with a defined geometry are constructed using trapped Neutravidin beads as anchor points for biotinylated filaments. The network is then probed by a defined oscillation of one anchor (actor). The frequency dependent response of the remaining beads (sensors) is analyzed experimentally and modeled theoretically over a wide frequency range.

P1.00124 Biviscous blood flow and a new method for velocity profile adjustment. Carlos Velazquez, Adrian Reyes, Universidad Nacional Autonoma de Mexico — In this paper we describe our proposal of a new numerical procedure for the adjusting of the velocity profile of body fluids with two viscosities. We have focused on the relevant case of the human blood and we have selected a particular model, the biviscous blood model, with the purpose of proving the convenience of our method. We start by describing the convenience of the biviscous stress equation as a model for the blood constitutive equation, then we solve it in the particular case of a stationary flow and use this solutions as the basis of our numerical procedure, which is described afterwards. Then, we present its implementation for analyzing in vivo measurements and exhibit its pertinence. Finally, we explain the design of a programmatic code of an automatic routine which is capable of applying our method and therefore could be used as the basis of an automated implementation in new diagnosis software within a measurement device.

P1.00125 Femoral bone strength in large theropod dinosaurs: A study by genus. Scott Lee, University of Toledo — The locomotion of bipedal theropod dinosaurs is controlled by the strength of the femur to resist bending torques (caused by the foot striking the ground and the action of muscles on the femur). The section modulus at the narrowest part measures the ability of the femur to resist such torques. We present the results of our study of the femoral section moduli for six genus of large theropods: Tyrannosaurus, Nanotyrannus, Gorgosaurus, and Albertosaurus of the Late Cretaceous, Acrocanthosaurus of the Early Cretaceous, and Allosaurus of the Late Jurassic. These animals had femora of lengths between 65 and 134 cm. The corresponding section moduli varied between 23 and 570 cm². Some species of Tyrannosaurus, Gorgosaurus, Allosaurus, and Albertosaurus had femora with lengths in the same 75 to 90 cm range. The section moduli of these animals are all in the same range, showing that the animals had the same abilities of locomotion. That is, Allosaurus of the Late Jurassic could locomote just as well as the Late Cretaceous Tyrannosaurus, Gorgosaurus, and Albertosaurus. There is no evidence that these later theropods had evolved to be any faster than similarly-sized theropods living about 80 million years earlier.
P1.00126 Alloometry in dinosaurs and mammals . SCOTT LEE, University of Toledo — The proportions of the leg bones change as the size of an animal becomes larger since the mass of the animal increases at a faster rate than the cross-sectional area of its leg bones. For the case of elastic similarity (in which the longitudinal stress in the legs remains constant in animals of all sizes), the diameter d and length L of the femur should be related as d = A L^{3/2}. For geometric similarity (in which all dimensions are scaled by the same factor), d = A L. For animals with femora longer than 20 cm, we find the power law relationship to be d = A L^3 with b = 1.13 ± 0.06 for extant mammals (the largest mammal being Loxodonta africana with a 1.00-m-long femur) and b = 1.18 ± 0.02 for dinosaurs (the largest dinosaur being Brachiosaurus brancai with a 2.03-m-long femur). These data show that extinct dinosaurs and extant animals scale in the same basic manner. The large sauropods (with femora twice as long as found in elephants) scale in a manner consistent with extrapolation of the scaling shown by extant mammals. These results argue that extinct dinosaurs moved in a manner very similar to extant mammals.

P1.00127 Direct Osmolyte-Macromolecule Interactions Confer Entropic Stability to Folded States1 . FRANCISCO RODRIGUEZ-ROPERO, NICO F. A. VAN DER VEGT, Tech Univ Darmstadt — Protective osmolytes are chemical compounds that shift the (bio)macromolecule folding/unfolding equilibrium toward the folded state under osmotic stresses. Traditionally it has been considered that osmolytes are depleted from the macromolecule first solution shell, leading to entropic stabilization of the folded state. Recent theoretical and experimental studies suggest that protective osmolytes may directly interact with the macromolecule. As an exemplary and experimentally well-characterized system, we herein discuss poly(N-isopropylacrylamide) (PNIPAM) in water whose folding/unfolding equilibrium shifts toward the folded state in the presence of urea. Based on Molecular Dynamics simulations we show that urea preferentially accumulates in the first solvation shell of PNIPAM driven by attractive van der Waals dispersion forces leading to the formation of urea clouds around the polymer. Solvation thermodynamics analysis of the folded and unfolded states discards direct urea/macromolecule interactions as driving force of the folding mechanism. Our data shows that entropic penalization of unfolded polymer chains upon increasing urea concentration drives the collapse of the polymer chain.

P1.00128 Quantifying macromolecular conformational transition pathways , SEAN SEYLER, AVISHEK KUMAR, MICHAEL THORPE, OLIVER BECKSTEIN, Arizona State University — Diverse classes of proteins function through large-scale conformational changes that are challenging for computer simulations. We introduce a comprehensive method (pathway similarity analysis, PSA) for quantitatively characterizing and comparing macromolecular pathways. The Hausdorff and Fréchet metrics (known from computational geometry) are used to identify the degree of similarity between polygonal curves in configuration space. A strength of PSA is its use of the full information available from the 3N-dimensional configuration space trajectory without requiring additional specific knowledge about the system. We compare a sample of eleven different methods for the closed-to-open transitions of the apo enzyme adenylate kinase (AdK) and also apply PSA to an ensemble of 400 AdK trajectories produced by dynamic importance sampling MD and the Geometrical Pathways algorithm. We discuss the method’s potential to enhance our understanding of transition path sampling methods, validate them, and help guide future research toward deeper physical insights into conformational transitions.

P1.00129 Interaction of Human Serum Albumin with Metal Protoporphyrins , JIEHU, URTSA, LORENZO BRANCACLEON, Physics Dept. UTSA — Fluorescence spectroscopy is widely used in biotechnology, nanotechnology, and molecular biophysics, since it can provide information on protein conformations, interactions etc. In this study, we present the photophysical properties of the interaction of human serum albumin (HSA) with a series of metal compound of Protoporphyrin IX (PPIX), including ZnPPIX, FePPIX, MgPPIX, MnPPIX and SnPPIX respectively, as well as the free base PPIX. Binding constants were retrieved independently using the Benesi-Hildebrand analysis of the porphyrin emission or absorption spectra and the fluorescence quenching (i.e. Stern-Volmer analysis) and reveal that the two methods yield a difference of approximately one order or magnitude between the two. Fluorescence lifetimes was used to probe whether binding of the porphyrin changes the conformation of the protein or if the interaction places the porphyrin at a location that can prompt resonance energy transfer with the lone Tryptophan residue. In recent years it has been discovered that HSA provides a specific binding site for metal-chelated protoporphyrins in subdomain IA. This has opened a novel field of study over the importance of this site for biomedical applications but it has also created the necessity to search for novel universality-breaking experimental perturbations.

P1.00130 Replica-exchange Wang-Landau simulations of the H0P model of protein folding, GUANGJIE SHI, DAVID P. LANDAU, Center for Simulational Physics, The University of Georgia, THOMAS WÜST, Scientific IT Services, ETH Zurich — The hydrophobic-polar (HP) model has served as a coarse-grained lattice protein folding model attracting scientists from various disciplines. However, simplification into H and P monomers may yield high ground state degeneracies which stands in contrast to the generally unique native states of natural proteins. We propose a simple modification, by introducing a new type of “neutral” monomer, 0, i.e. neither hydrophobic nor polar, rendering the model more realistic without increasing the difficulties of sampling significantly. With the newly developed parallel Wang-Landau (replica exchange Wang-Landau) scheme and an innovative method of estimating the ground state degeneracies1,2 we investigated some widely studied HP proteins and their H0P counterparts. Dramatic differences in ground state and thermodynamic properties have been observed, e.g. the estimation of ground state degeneracy for the 46mer is 460,000 for the HP version and only 20 for the H0P mapping. Similarly, the specific heat and structural properties: radius of gyration and etc. show more pronounced signals associated with folding.

P1.00131 Ergodic protein dynamics underlie the universal shape of protein distribution in populations , NAAMA BRENNER, EREZ BRAUN, Technion-Israel Institute of Technology, JAMES ROTELLA, HANNA SALMAN, University of Pittsburgh, NAAMA BRENNER COLLABORATION, EREZ COLLABORATION, JAMES ROTELLA AND HANNA SALMAN COLLABORATION — We have previously shown that protein fluctuations in cell populations exhibit a universal distribution shape under a broad range of biological realizations. Here we report new results based on continuous measurement in individual bacteria for over ~ 70 generations, which show that single-cell protein trajectories sample the available states with the same distribution shape as the population, i.e. protein fluctuations are ergodic. Analysis of temporal trajectories reveals that one effective random variable, sampled once each cell cycle, suffices to reconstruct the distribution from the trajectory. This in turn implies that cellular microscopic processes are strongly buffered and population-level protein distributions are insensitive to details of the intracellular dynamics. Probing them thus requires searching for novel universality-breaking experimental perturbations.
P1.00132 Two-Dimensional Graphene Optoelectronic Probes for DNA Detection. TU HONG, Department of Electrical Engineering and Computer Science, Vanderbilt University, RUI WANG, XUANYANG GE, Department of Physics and Astronomy, Vanderbilt University, YAQIONG XU, Department of Electrical Engineering and Computer Science, Vanderbilt University — With high charge-carrier mobility and large surface-area-to-volume ratio, graphene has become one of the most promising materials for biological and biomedical applications. Here, we demonstrate that graphene field-effect transistors combined with scanning photocurrent microscopy are ideal platforms for detecting DNA molecules. When negatively-charged DNA molecules are attached to graphene surface, significant photocurrent signals can be detected due to the local conductivity change in graphene. Our experimental results show that DNA-induced photocurrent response of graphene can be modulated by adjusting the electrochemical potential through an electrolyte gate. This study indicates that two-dimensional graphene optoelectronic probes can be used to explore the local electrostatic environment change with high electrical sensitivity.

P1.00133 FLUIDS —

P1.00134 Effect of Confinement on the Bubble Points of Hydrocarbons in Controlled-Pore Glasses. SHENG LUO, Harold Vance Department of Petroleum Engineering, Texas A&M University, JODIE LUTKENHAUS, Artie McFerrin Department of Chemical Engineering, Texas A&M University, HADI NASRABADI, Harold Vance Department of Petroleum Engineering, Texas A&M University, HADI NASRABADI TEAM — Phase behavior in shale remains a challenging problem in the petroleum industry due to many complexities. One complexity is the strong surface-fluid interactions in shale nano-scale pores. These interactions can lead to a heterogeneous distribution of molecules, which conventional bulk-phase thermodynamics fails to describe. Herein, we report a study on the bubble points of various hydrocarbons confined in nanoporous controlled-pore glasses of 4.3 to 38.1 nm pore diameter. Differential scanning calorimetry is used to measure the temperature at which the gas phase begins to form (i.e. bubble point). Besides pore diameter, the relative hydrocarbon loading in the controlled-pore glass is evaluated. The findings suggest that the bubble point is dramatically affected by pore diameter.

P1.00135 Liquid Crystals under Photo-patterned Spatially Varying Boundary Conditions1. MIAO JIANG, YU-BING GUO, QI-HOU WEI, Liquid Crystal Institute, Kent State Univ, Kent, OH — Liquid crystals under geometric confines are of not only fundamental interest but also practical importance to applications such as chemical sensing and smart windows. Orientations of liquid crystal molecules in most geometric confines are uniform at the boundaries and not highly controllable. In this paper, we will present a novel photoalignment technique to pattern spatially varying complex orientation fields, and discuss experimental studies on nematic liquid crystals under confines of two parallel plates with various well designed molecular orientation fields.

P1.00136 Two-dimensional Yukawa fluids. MINERVA GONZALEZ-MELCHOR, Instituto de Fisica “Luis Rivera Terrazas,” Benemerita Universidad Autonoma de Puebla, Apdo. Postal J-48, Puebla, 72570, Puebla, Mexico, ARLETTE MENDEZ, JOSE ALEJANDRE, Departamento de Quimica, Universidad Autonoma Metropolitana-Iztapalapa, Av. San Rafael Atlicoc 186, Col. Vicentina, 09340 Mexico Distrito Federal, Mex — When the movement of particles is performed predominantly in two dimensions, the systems can be considered at a good extent as two-dimensional. For instance the lipids in a bilayer, micrometric particles in a quasi-two-dimensional colloidal suspension, colloids in a monolayer deposited on the air-water interface, and DNA complexes trapped at the water surface can be described at a first approach as bidimensional fluids. These systems are important for many applications in surface and colloidal science. In simulations where the explicit interface between liquid and vapor is present, the line tension can be directly computed. In this work we present molecular dynamics results obtained for the liquid/vapor coexistence curve of 2D Yukawa fluids and for the line tension. A comparison with the three-dimensional case is also presented.

P1.00137 Heat Transfer Enhancement in Forced Convective Boiling in Microchannels by Periodic Electrospray Nanofiber Coatings. ALEXANDER YARIN, University of Illinois at Chicago, MARTIN FREYSTEIN, FELIX KOLBERG, Technische Universität Darmstadt, SUMIT SINHA-RAY, RAKESH SAHU, University of Illinois at Chicago, LUCAS SPIEGEL, TATIANA GAMBARYAN-ROISMAN, PETER STEPHAN, Technische Universität Darmstadt — To enhance heat transfer in forced convective boiling the microchannel bottom was amended by a nano-texture - periodic rectangular mats of electrospray polymer nanofibers. The fibers were ~300-500 nm in diameter and the mat thicknesses were about 6-15 µm. The test fluid was FC-72 and the flow in microchannels contained trains of Taylor bubbles. The role of the nanofibers was to retain the warm microchannel bottom wet, to prevent dry-out and thus to enhance the heat removal rate. In the present experiments the time-average heat flux and heat transfer coefficient at the nanofiber-covered domains were found to be 1.5-2 times higher than those at the uncoated ones. Accordingly, a significant decrease (by 5-8%) in the superheat was observed at the same Re of 387 and power supply of 36.1 kW/m². At a higher Re of 432 and lower power supply of 28.1 kW/m² similar trends in the heat removal rate and surface superheat were found. The significant enhancement of the heat transfer results from the fact that nanofiber mats facilitate wetting of surface under passing Taylor bubbles, thus delaying formation of vapor flow at the channel bottom. The interstices of the nanofiber mat act as the nucleation sites facilitating formation of tiny bubbles, which eventually results in a higher heat removal rate from the surface at a reduced superheat.

P1.00138 A simulation study of flow dynamics of erythrocytes through diverging and converging bifurcations1. TONG WANG, Nanjing University of Aeronautics and Astronautics, ZHONGWEN XING, Nanjing University — A numerical model has been developed to predict the cells deformation and motion in a symmetric diverging and converging bifurcation of a microchannel. Fluid dynamics and membrane mechanics are incorporated. The model was utilized to evaluate the effect of different biophysical parameters, such as: initial cell position, membrane stiffness and shape of the cells on deformation and motion of the erythrocytes in the bifurcating curved microchannel. The numerical results demonstrate that erythrocytes in microvessels blunt velocity profiles in both straight section and daughter branches, and the transit velocity of erythrocytes is strongly influenced by cell deformability, shape of the cells, and the vessel geometry. These results may provide fundamental knowledge for a better understanding of hemodynamic behavior of microscale blood flow.

P1.00139 Fluid flow calculations of Graphene Composites. AMRHESSAM TAHMASSEBI, ALPER BULDUM, University of Akron, Department of Physics — The flow of fluids through carbon nanotubes was investigated in order to get a better understanding of the unique properties and phenomena of nano-fluidics. The previous modeling and simulation efforts were based on diffusion of atoms or molecules that were thrown to the nanotubes with initial velocities. This talk has shed some light on the flow of fluids using molecular dynamic simulations of different types of carbon nanotubes that were embedded in liquid argon using a moving wall piston of graphene. We focused on analyzing pressure difference, velocities, and momentum conservation in different regions.

P1.00140 The effects of surface roughness on the contact line friction coefficients of water droplets on micro/nano-patterned surfaces, JIANGTAO CHENG, University of North Texas — We report the effects of surface roughness on contact line friction coefficient (CLFC) of water droplets on micro- and nano-patterned surfaces. Both advancing and receding CLFCs have been measured on smooth, one-tier (with micropillars), and two-tier (with CNTs grown on micropillars) surfaces. In comparison with smooth surface, superhydrophobic surfaces can decrease both the advancing and receding CLFCs by more than 10 times. However, droplets on one-tier surfaces exhibit different dynamic behaviors in advancing and receding movements. We investigated the Wenzel-Cassie state transition on micropillar structures and found that the receding motion of a droplet on micropillars is dominated by the Wenzel model with significant receding contact line pinning, which leads to higher receding CLFC. However, rolling mechanism of liquid particles near the advancing contact line controls the advancing motion of a droplet on micropillars. There is a high tendency for an advancing droplet to exhibit Cassie-type behavior on one-tier surfaces and hence advancing CLFC is considerably mitigated. On two-tier superhydrophobic surfaces, it is the Cassie-Baxter behavior that dominates both the advancing and receding contact line motions giving rise to less friction coefficients.

P1.00141 Patterns, Instabilities, Colors, and Flows in Vertical Foam Films, SUBINUER YILXIATI, EWELINA WOJCICK, YIRAN ZHANG, COLLIN PEARSSALL, VIVEK SHARMA, Chemical Engineering, University of Illinois Chicago — Foams find use in many applications in daily life, industry and biology. Examples include beverages, firefighting foam, cosmetics, foams for oil recovery and foams formed by pollutants. Foams are collection of bubbles separated by thin liquid films that are stabilized against drainage by the presence of surfactant molecules. Drainage kinetics and stability of the foam are strongly influenced by surfactant type, addition of particles, proteins and polymers. In this study, we utilize the thin film interference colors as markers for identifying patterns, instabilities and flows within vertical foam films. We experimentally study the emergence of thickness fluctuations near the borders and within thinning films, and study how buoyancy, capillarity and gravity driven instabilities and flows, are affected by variation in bulk and interfacial physicochemical properties dependent on the choice of constituents.

P1.00142 Diving dynamics of seabirds, SUNGHWAN JUNG, BRIAN CHANG, MATT CROSON, Virginia Tech, LORIAN STRAKER, CARLA DOVE, Smithsonian Museum — Diving is the activity of falling from air into water, which is somewhat dangerous due to the impact. Humans dive for entertainments less than 20 meters high, however seabirds dive as a hunting mechanism from more than 20 meters high. Moreover, most birds including seabirds have a slender and long neck compared to many other animals, which can potentially be the weakest part of the body upon axial impact compression. Motivated by the diving dynamics, we investigate the effect of surface and geometric configurations on structures consisting of a beak-like cone and a neck-like elastic beam. A transition from non-buckling to buckling is characterized and understood through physical experiments and an analytical model.

P1.00143 POLYMER PHYSICS —

P1.00144 Orthogonal gradient networks via post polymerization reaction, PANDYARAJAN CHINNAYAN KANNAN, JAN GENZER, North Carolina State University — We report a novel synthetic route to generate orthogonal gradient networks through post polymerization reaction using pentafluorophenylmethacrylate (PFPMac) active ester chemistry. These chemoselective monomers were successfully copolymerized with 5 mole% of the photo (methacryloyloxybenzophenone) and thermal (styrerensulfonylazide) crosslinkers. Subsequently, the copolymers were modified by a seris of amines having various alkyl chain lengths. The conversion of post polymerization reaction was monitored using Fourier Transform Infrared Spectroscopy (FT-IR) and noticed that almost all pentafluorophenyl moieties are substituted by amines within an hour without affecting the crosslinkers. In addition, the incorporation of photo and thermal crosslinkers in the polymer enabled us to achieve stable and covalently surface-bound polymer gradient networks (PGN) in an orthogonal manner, i.e complete control over the crosslink density of the network in two opposite directions (i.e. heat vs photo). The network properties such as wettability, swelling and tensile modulus of the gradient coatings are studied and revealed in the paper.

P1.00145 Enthalpy Relaxation of a DGEBA Epoxy as a function of Time, Temperature, and Cooling Rate, CAITLYN M. CLARKSON, JOHN D. MCCOY, New Mexico Tech, JAMIE M. KROPKA, Sandia National Laboratories — Enthalpy relaxation resulting from physical aging of a DGEBA epoxy, Epon 828, cross-linked with an amine curative, Jeffamine T-403, was studied for two isothermal aging temperatures at sequential aging times up to two weeks. Results were analyzed using the peak shift method to obtain the relaxation parameters \(\beta\), \(\delta\) (\(\delta^H\)), and \(\chi\). The individual effects of cooling rate from the equilibrated state, aging time, and aging temperature were isolated to understand the initial state of the glassy epoxy and its evolution during physical aging. [Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000]

P1.00146 Frank-Kasper and other superlattice formations in a set of giant molecules having ABn type of Janus particles, XUEYAN FENG, YIWEN LI, MINGJUN HUANG, CHI-HAO HSU, STEPHEN Z.D. CHENG, University of Akron — A novel series of precisely defined giant molecules having ABn type of Janus particles has been designed and synthesized. They are consisted of one functionalized hydrophilic polyhedral oligomeric silsesquioxane (POSS) (A) connected with different number of hydrophobic POSS cages (B, \(n=2-6\)). With variation of the interaction functional groups on A and the number of the coordinated hydrophobic POSS B, different superlattice structures could be formed at a sub-10-\(nm\) scale. For example, the superlattice structure of DPOSS-BPOSS2 (DPOSS represents seven hydroxyl group functionalized POSS and BPOSS represents isobutyl POSS) could change from a double-dyroids phase to a hexagonally packed cylinder phase with increasing temperature, due to an order-order transition in the weak segregation region. For DPOSS-BPOSS3 and DPOSS-BPOSS4, both of these giant molecules could form A15 phase, which is a Frank-Kasper phase. With deep understanding of this set of ABn type giant molecules based on the POSS nano atoms, it may be promising to construct new generations of giant molecules for further development of functional materials with desired structures and macroscopic properties.

P1.00147 Strain Rate Dependence of Compressive Yield and Relatization in DGEBA Epoxies, GABRIEL K. ARECHEDDERRA, RILEY C. RÉPROGLE, CAITLYN M. CLARKSON, JOHN D. MCCOY, New Mexico Tech, JAMIE M. KROPKA, KEVIN N. LONG, ROBERT S. CHAMBERS, Sandia National Laboratories — The mechanical response in uniaxial compression of two diglycidyl ether of bisphenol-A epoxies were studied. These were 828DEA (Epon 828 cured with diethanolamine (DEA)) and 828T403 (Epon 828 cured with Jeffamine T-403). Two types of uniaxial compression tests were performed: A) constant strain rate compression and B) constant strain rate compression followed by a constant strain relaxation. The peak (yield) stress was analyzed as a function of strain rate from Eyring theory for activation volume. Runs at different temperatures permitted the construction of a mastercurve, and the resulting shift factors resulted in an activation energy. Strain and hold tests were performed for a low strain rate where a peak stress was lacking and for a higher strain rate where the peak stress was apparent. Relaxation from strains at different places along the stress-strain curve was tracked and compared. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.
P1.00148 Template-directed synthesis of structurally-defined branched polymer architectures, AMANDA MARCIEL, UIUC — In this work, we describe a hybrid synthetic strategy to produce structurally-defined branched polymer architectures based on chemically-modified DNA. Overall, this approach enables precise control over branch placement, grafting density, and chemical identity of side branches. We utilize a two-step scheme based on polymerase chain reaction (PCR) for site-specific incorporation of non-natural nucleotides, followed by copper-free click chemistry for grafting side branches at specific locations along the main polymer backbone. Linear DNA backbones are first synthesized via PCR utilizing the promiscuity of a high yield thermostable DNA polymerase to incorporate nucleotides containing bioorthogonal dibenzocyclooctyne functional groups at precise locations along one strand of a double stranded DNA backbone. Following PCR, copper-free click chemistry is used to attach synthetic polymer branches or oligonucleotide branches to the DNA backbone, thereby allowing for the design and synthesis of a variety of precise polymer architectures, including three-armed stars, H-polymers, and graft block copolymers.

P1.00149 Light scattering measurement of sodium polyacrylate products, NISHA LAMA, DAVID NORWOOD, Southeastern Louisiana Univ, STEVEN BOONE, VALERIE MASSIE-BOYER, Bercen Inc. — In the presentation, we will describe the use of a multi-detector HPLC incorporating the DAWN EOS multi-angle laser light scattering (MALLS) detector to measure the properties such as molecular weight, RMS radius, contour and persistence length and polydispersity of sodium polyacrylate products. The samples of sodium polyacrylate are used in various industries as thickening agents, coating dispersants, artificial snow, laundry detergent and disposable diapers. Data and results obtained from the experiment will be presented.

P1.00150 Kinetics of the coil-to-globule transition in aqueous solution of poly (N-isopropoylacrylamide). REZA FARASAT, University of Alabama at Birmingham — In an aqueous solution, poly (N-isopropoylacrylamide) (PNIPAM) undergoes a reversible coil-to-globule phase transition that occurs above the lower critical solution temperature (LCST). The transition is driven by temperature-dependent molecular interactions that include hydrogen bonding and hydrophobic association. By increasing the temperature above LCST, the PNIPAM-water bonds break, and the polymer coils collapse to globules. The process is accompanied by an endothermic thermal effect which is detectable by Differential Scanning Calorimetry (DSC). A 10 wt. % solution of PNIPAM in water was prepared and subjected to DSC experiments under different heating rates (from 0.5 to 16°C min⁻¹). With increasing the heating rate, the transition temperature as well as the DSC peak shift to higher temperature. The DSC data have been analyzed by an isocorrectional method to evaluate the temperature dependence of the effective activation energy of the process. The resulting dependencies have been interpreted in terms of a nucleation kinetics model. The process has also been studied under nanoconfinement by introducing the PNIPAM solution into the silica nanorods. The results obtained under nanoconfinement are compared to those obtained for the bulk solution.¹

P1.00151 SEMI CRYSTALLINE POLYMERS

P1.00152 Effect of Crystallinity on Melt Memory of Random Ethylene Copolymers, XUEJIAN CHEN, AL MAMUN, ALAMO G. RUFINA, FAMU-FSU College of Engineering, Department of Chemical and Biomedical Engineering, Tallahassee, Fl 32310 — A strong melt memory effect of crystallization has been observed in random ethylene copolymers even above the equilibrium melting temperature. Melt memory is associated with seeds that increase the crystallization rate of copolymers in a range of comonomer content between 0.5 and 4.5 mol%. The seeds are taken as molten ethylene sequences that remain in close proximity and are unable to diffuse fast to the randomized melt state. Fast diffusion is restricted by topological chain constraints (loops, knots, and other entanglements) that build in the intercrystalline region during crystallization. The molten nature of the self-seeds is supported by a linear variation of Tᵢ with Tₘₐₓ n NMR experiments in a range from 180 °C to 100 °C, covering both the homogeneous and heterogeneous melt regions. The effect of topological constraints on melt memory, or on number of seeds that remain in the melt, was analyzed studying copolymers with different levels of crystallinity. There is a threshold level of crystallinity, which depends on type and concentration of comonomer, below which copolymers do not display strong melt memory. Increasing 1-hexene content from 0.5 to 3.5 mol%, the crystallinity threshold decreases from 39 to 4%, while decreasing branch length from hexyl to ethyl, the threshold crystallinity decreases from 18% to 5% in agreement with stronger melt memory in copolymers with increasing comonomer content and with shorter branches.

P1.00153 Structural Analysis of Semiconducting Polymers Exposed to High Energy Radiation, SAEED AHMADI VASELABADI, University of Pittsburgh, NIHKLIA MAHADEVAPURAM, Intel Corporation, DAVID SHAKARISAZ, University of Houston, JOSEPH STRZALKA, Argonne National Laboratory, PAUL RUCHHOEFT, GILA STEIN, University of Houston — Semicrystalline polymers are used in low-cost electronics such as solar cells, thin film transistors, and light-emitting diodes. Their optoelectronic performance in these devices is partly dictated by molecular ordering and nanoscale structure, which the latter is particularly difficult to control. We used atom-beam radiation to crosslink the polymer poly(3-hexylthiophene) into nanoscale and microscale patterns. Ionizing radiation sources generate intermolecular cross-links that render the polymer insoluble in organic solvents. Grazing-incidence Wide-angle X-ray Scattering (GIWAXS) was used to investigate the effects of irradiation on molecular ordering of poly(3-hexylthiophene). We found that crosslinking will disrupt intermolecular ordering (reduce crystallinity and crystalline grain sizes). We also found that X-ray exposure during the WAXS measurements can induce the crosslinking through a similar mechanism, and we propose a simple method to test for the damage caused by these measurements. As an example, we find that poly (3-hexylthiophene) has measurable cross-links after 20 sec exposure to 7.35 keV radiation with flux of 1 × 10¹¹ photons/sec at an incident angle of 0.5°.

P1.00154 Mechanical properties of syndiotactic polypropylene (sPP) gels: the effects of temperature and solute concentration, RYUSUKE OKOSHI, ATSUISHI HOTTIGA, Department of Mechanical Engineering, Keio University — The effects of the solute concentration on the microstructures and the mechanical properties of quenched syndiotactic polypropylene (sPP) gels were investigated. Our group has previously reported a highly resilient sPP gel quenched using liquid nitrogen (Gel LN). In this research, sPP/decahydronaphtalene gels were prepared varying the sPP concentrations from 5 to 20 wt%. Compression test was carried out to evaluate the mechanical properties. Scanning electron microscopy (SEM) was conducted to analyze the microstructures. Gel LN with the sPP concentration of 20 wt% presented a high fracture stress of 2400 kPa. A high fracture strain of 70% was also observed for all Gel LN samples. By contrast, sPP gels with the sPP concentration of 25 wt% cooled at 25 degrees C showed lower fracture stress of 480 kPa. The fracture strain of Gel 25 ranged from 21 to 37% depending on the sPP concentrations. The SEM results revealed that the Gel LN samples had homogeneous networks regardless of the sPP concentrations. The Gel 25, however, possessed inhomogeneous networks with spherulites. It was therefore concluded that the strengthening of the sPP gels could be effectively achieved by Gel LN regardless of the sPP concentrations.
P1.00155 Structural Characterization of Layered Morphologies in Precise Copolymers . EDWARD B. TRIGG, L. ROBERT MIDDLETON, Univ of Pennsylvania, TAYLOR W. GAINES, KENNETH B. WAGENER, Univ of Florida, KAREN J. WINEY, Univ of Pennsylvania — Layered morphologies have been observed in precise polyethylene-based copolymers that contain acid, charged, or polar functional groups precisely spaced along a linear alkane chain. Sufficiently long alkane segments form structures resembling orthorhombic polyethylene crystals, while the functional groups form 2-D layers that disrupt the alkane crystal structure to varying degrees. Here, layered morphologies in precise copolymers containing acrylic acid, phosphonic acid, imidazolium bromide, and sulfone groups are studied via X-ray scattering. Specifically, the composition profiles of the layered structures are obtained by Fourier synthesis, and the coherence length is investigated using peak width analysis. This analysis indicates that the layers of functional groups are frequently bordered by two crystallites, which suggests different dynamics relative to layers bordered by one crystalline and one amorphous microdomain. Detailed understanding of the structure of the layered morphologies will allow for a systematic investigation of proton and ion conductivity mechanisms, which are expected to occur through the high-dielectric layers.

P1.00156 Polymer Crystals Formed at Liquid-Liquid Interface Show Broken Symmetry . WENDA WANG, HAO QI, ZIYIN HUANG, CHRISTOPHER Y. LI, Drexel University, SOFT MATTER RESEARCH GROUP TEAM — Curved space is incommensurate with typical ordered structures with three-dimensional translational symmetry. However, upon assembly, soft matter, including colloids, amphiphiles, and block copolymers, often form structures depicting curved surface/interface. On the other hand, twisted and curved crystals are often observed in crystalline polymers. Various mechanisms have been proposed for these non-flat crystalline morphologies. In this presentation, we will discuss the recent development of crystallization at flat and curved liquid/liquid (L/L) interface. We show that structure, morphology and chain folding behaviors are strongly affected by L/L interfacial energy and polymer chain ends. Both polyethylene and poly-L-lactic acid single crystal shells have been obtained using curved L/L interface. Polymer crystallization behavior at L/L interface will be compared with solution and bulk crystallization.

P1.00157 POLYMERIC ELASTOMERS AND GELS —

P1.00158 Correlating solubility parameters and solvatochromic parameters with the self-assembly of poly(3-hexylthiophene) in mixtures of organic solvents , MADELEINE GORDON, DAVID BOUCHER, College of Charleston — We have studied the assembly and crystallinity of poly(3-hexylthiophene) (P3HT) (M_w ≈ 28.2 kDa, regioregularity > 96%, PDI ≈ 1.3) in >100 binary solvent mixtures using UV-Vis absorption spectroscopy, and it is clear that the identity of the poor solvent used to drive aggregation has a significant impact on the structural order and crystallinity of the P3HT aggregates in solution. Here we report our findings using Hansen solubility parameters (HSPs), specifically the solubility distance vector, R_1, and the Kamlet-Taft solvatochromic parameters of the solvent mixtures to better understand the dominant solvent forces driving the self assembly of P3HT. We find that the directionality of the R_1 vector provides a better measure of the crystallinity of the P3HT assemblies formed in the solvent mixtures than does the magnitude of the R_1 vector. Our analysis of the Kamlet-Taft (α, β, π*) and E(30) solvatochromatic parameters reveals that the β parameter correlates best with the crystallinity of P3HT and that, in general, assemblies having higher structural order are formed in solvent mixtures with lower values of β.

P1.00159 Demixing transition and molecular interactions in Poly(N-isopropyl acrylamide) solutions compared to its monomer , MORITZ FUTSCHER, MARTINE PHILIPP, PETER MUELLER-BUSCHBAUM, Technical University Munich, ALFONS SCHULTE, University of Central Florida — Temperature-sensitive hydrogels such as poly(N-isopropyl acrylamide) (PNIPAM) exhibit a coil to globule transition of the polymer chains with a lower critical solution temperature (LCST) near 305 K. The cooperative dehydration of bound water molecules upon heating plays a significant role. The hydrogen bonding with the amide groups in the side chains has to be contrasted with the hydration interaction of the hydrophobic main chain hydro-carbons. Employing FTIR spectroscopy we probe molecular changes in the various chemical groups. PNIPAM and its monomer NIPAM are investigated at a concentration of 20% in aqueous solution. We observe a nearly discontinuous shift of the peak frequencies and the intensities of vibrational bands (amides, CH) in PNIPAM, whereas in NIPAM there is a continuous linear shift with temperature. The results are discussed with respect to hydration changes in the amide group and cooperative interactions with bound water along the backbone chain.

P1.00160 Pressure and temperature response of Poly(N-isopropyl acrylamide) in aqueous solution probed with Raman microscopy , COLEMAN CARIKER, ALFONS SCHULTE, University of Central Florida — Poly(N-isopropylacrylamide) (PNIPAM) is a thermo-responsive hydrogel that exists in a hydrated state beneath its lower critical solution temperature (LCST) near 305 K. Above this temperature water is expelled by the polymer as it undergoes a coil to globule collapse. High pressure is an important variable as it influences the strength of hydrogen bonding and can destabilize hydrophobic contacts. We present results from optical imaging on a micron scale and Raman spectroscopic measurements as a function of temperature (295 - 315 K) and hydrostatic pressure (0.1 - 400 MPa). Samples consisted of 25% PNIPAM in aqueous solution in micro-capillaries with 100 micron cross section. Our experiments reveal differences in the spatial evolution of the phase change across the temperature and pressure transitions. These are corroborated by bond specific and hydration changes observed in the Raman spectra.

P1.00161 POLYMER MELTS AND SOLUTIONS —

P1.00162 ABSTRACT WITHDRAWN

P1.00163 Systematic Investigation of the Mechanical and Surface Properties of Poly(dimethylsiloxane) Networks , MATTHEW MELILLO, ZOE KLEIN, EDWIN WALKER, JAN GENZER, North Carolina State Univ — Poly(dimethylsiloxane) (PDMS) is one of the most common elastomers. Its applications range broadly from medical devices to absorbents for water treatment, and recently it has seen rapid growth in the use of microfluidic devices. Despite extensive research and characterization of PDMS networks, the static water contact angles of these elastomers reported in the literature range broadly from a low near 90 degrees upwards to greater than 120 degrees. To investigate this large gap in reported surface properties, we have systematically studied the effects of polymer molecular weight, degree of tetra-functional crosslinker loading, end-group chemical functionality, and the extent of dilution of the curing mixture on the mechanical and surface properties of end-linked PDMS networks. The gel and sol fractions, mechanical properties, and water contact angles have been shown to vary greatly based on the aforementioned variables. This study provides insight to the factors that contribute to such a wide range of surface properties reported in the literature. Furthermore, these results demonstrate the need to fully and carefully consider the manner and environment in which PDMS networks are formed when preparing them for specific applications.
P1.00164 Effect of system compliance and indenter geometry on puncture mechanics of soft materials, SHRUTI RATTAN, SAMI FAKHOURI, ALFRED CROSBY, Univ of Mass - Amherst — Puncture mechanics in soft materials is critical for the development of new surgical instruments as well as new materials used in personal protective equipment. However, fundamental knowledge of how geometry and material properties control the nucleation of a crack, i.e., puncture, at large deformations in a soft material is currently limited. We describe a simple experimental method to study the resistive forces and failure of a soft gel being indented and punctured with a small needle. We show that puncture stresses can reach two orders of magnitude greater than the material modulus and that the force-deformation response is insensitive to the geometry of indenter at large indentation depths. We determine a transition between stress-limited and energy-limited failure modes, which is governed by the indenter size and the balance between fracture energy and cohesive stress. In addition, we examine the influence of system compliance on puncture of soft gels. It is well-known that system compliance influences the peak force in adhesion and traditional fracture experiments; however, its effect on crack nucleation is unresolved. We find that as the system becomes more compliant lower peak puncture forces were measured, which is associated with increased energy available for fracture.

P1.00165 Rheology of Poly(V-isopropylacrylamide)-Clay Nanocomposite Hydrogels, JACK LOM-BARDI, DI XU, DIVYA BHATNAGAR, DILIP GERSAPPE, JONATHAN SOKOLOV, MIRIAM RAFAILOVICH, Materials Science and Engineering Department, Stony Brook University, Stony Brook, NY 11790, USA — The stiffness of PNIPA Gels has been reported could be significant improved by gelation with clay fillers. Here we conducted systematic rheology study of synthesized PNIPA-Clay Composites at different clay concentration, in a range from fluid to strong gel, where G”’ dominant changed to G’ dominant. Molecular dynamics simulation was employed to analyze the structure of composites and corresponding mechanical changes with increased clays. Where we found viscoelastic behavior become significant only 1.5 times above percolation threshold. The yield stress extrapolated from our rheology results shows good fitting to modified Mooney’s theory of suspension viscosity.

P1.00166 Self-Assembly and Relaxation Behavior of Graphene Containing Acrylic Triblock Copolymer Gels, MAHLA ZABEL, SEYEDMEYSAM HASEMNEJAD, SANTANU KUNDU, Dave C. Swalm School of Chemical Engineering, Mississippi State University, MS State, MS — Investigation of gel mechanical properties as a function of their structure is a significant research interest. This study presents the effect of graphene (or few-layer graphene) on the self-assembly and the relaxation behavior of a thermoreversible gel consists of a physically cross-linked poly (methyl methacrylate)-poly (n-buty lacrylate)-poly (methyl methacrylate) [PMMA-PnBA-PMMA] triblock copolymer in 2-ethyl-1-hexanol, a midblock selective solvent. Graphene was obtained by sonicating exfoliated graphite in 2-ethyl-1-hexanol at various concentrations. Filtration technique and spectrophotometry were utilized to measure the graphene concentration in the dispersions. The dispersed graphene was then incorporated in a series of gels and the effect of graphene on mechanical properties, including the relaxation behavior were studied. Small angle X-ray scattering (SAXS) was used to investigate the microstructure of these gels at room temperature. SAXS data were analyzed to estimate the number of end blocks per junction zone, the average spacing between the junctions, and the change of these properties as a function of graphene concentration. The results indicate that the presence of graphene affects the self-assembly process.

P1.00167 POLYMER BLENDS —

P1.00168 Bottlebrush additives drive formation of vesicle chains in polymer blends, HUI ZHEN MAH, PANTEA AZFALI, Univ of Houston, RAFAEL VERDÚZCO, Rice University, GILA STEIN, Univ of Houston — The effects of bottlebrush polymer additives with polystyrene (PS) and poly (methyl methacrylate) (PMMA) blends were studied. Results were compared to PS/PMMA blends with diblock copolymer PS-b-PMMA compatibilizer and without any additive. Thin films were spin casted from toluene onto a “neutral” silicon surface and then annealed at a fixed temperature of 150°C for a range of times (up to 85 mins). The morphology of the films was characterized using optical microscopy and atomic force microscopy. In the absence of any additive, the PS/PMMA blend rapidly de-mixes to form macroscale domains, while high loadings of the PS-b-PMMA additive can compatibilize the blend and suppress phase separation. However, the bottlebrush polymer additive drives the formation of well-organized vesicle chains in the PS/PMMA blend films. This morphology is favored by entropic considerations as the bottlebrush polymers are more stable than linear chains at the PS/PMMA interface and the brush like surface attracts.

P1.00169 Phase Equilibria in Ternary Blends of Two Linear Homopolymers and A Ring Gradient Copolymer, DACHUAN SUN, JUNHAN CHO, Dankook Univ — Phase equilibria in a ternary blend of linear A/B homopolymers of equal sizes and a symmetric A-co-B ring gradient copolymer as an amphiphile with α as the ratio of their chain sizes are investigated in the mean-field picture. The monomer sequence on the copolymer chain is taken as either a step gradient or a fully linear gradient, to which a gradient number λ = 0 or 1 is assigned, respectively. Along the isopleth of equal homopolymer amounts, the resultant phase diagrams for the blends are to be built from multicritical points such as Lifshitz or bulk tricritical point depending on α and λ. The stabilization of lamellar mesophase or its equilibrium with A and B-rich bulk phases is accordingly controllable by the pair of α and λ.

The authors also acknowledge the support from the Center for Photofunctional Energy Materials, which is funded by Gyeonggi Regional Research Center Program (GRRCDankook2011-B01).

P1.00170 ABSTRACT WITHDRAWN —

P1.00171 COPOLYMERS —

P1.00172 Characteristic Phase Behaviors for Symmetric PS-b-PAMAs (n= 176) and Their Pressure Dependence, YONGHOON LEE, HOYEON LEE, Yonsei University, DONG HYUN LEE, Dankook University, DU YEOL RYU, Yonsei University, YONSEI UNIVERSITY COLLABORATION, DANKOOK UNIVERSITY COLLABORATION — A series of polystyrene-b-poly(alkyl methacrylates) (PS-b-PAMAs) that pertain to the weakly interacting BCP homologues exhibited a variety of phase behaviors by varying alkyl chain length (n) in methacrylate unit. The enthalpic and volumetric changes at phase transitions were measured by the differential scanning calorimetry (DSC) and in-situ spectroscopic ellipsometry with increasing pressure. Together with the overview on the characteristic phase behaviors for symmetric PS-b-PAMAs (n = 1 ? 6), the pressure coefficient (dT/dP) of transition temperatures was calculated on the basis of the Clauseius-Clapeyron equation and compared with the reference values. The strong baroplastic character of the closed-loop transitions could be attributed to the significant negative volume changes on mixing at both phase transitions.
P1.00173 Orienting Nanostructured Block Copolymer Thin Films via Entropy, TING-YA LO, Department of Chemical Engineering, National Tsing Hua University, ASHKAN DEHGHAH, Department of Physics and Astronomy, McMaster University, PROKOPIOS GEORGOPANOS, APOSTOLOS AVGEROPoulos, Department of Materials Science & Engineering, University of Ioannina, AN-CHANG SHI, Department of Physics and Astronomy, McMaster University, RONG-MING HO, Department of Chemical Engineering, National Tsing Hua University — Controlling the orientation of nanostructured thin films of block copolymers (BCPs) is essential for next generation lithography using BCPs. According to conventional wisdom, the orientation of BCPs is mainly determined by molecular interactions (enthalpy-driven orientation). Here, we demonstrate that entropic effect can also control the orientation of BCP thin films. Specifically, the architecture of star-block copolymers consisting polystyrene (PS) and poly(dimethylsiloxane) (PDMS) blocks is used to regulate the entropic contribution to the self-assembled nanostructures. Our experimental and theoretical results unequivocally demonstrate that entropy-driven perpendicular orientation of BCP nanostructures can be induced by increasing the arm number of the star-block copolymers with the same volume fractions of PS and PDMS.

P1.00174 A Facile Method to Fabricate Double Gyroid as A Polymer Template for Nanohybrids, HISIAO-FANG WANG, RONG-MING HO, Department of Chemical Engineering, National Tsing Hua University — Here, we suggest a facile method to acquire double gyroid (DG) phase from the self-assembly of chiral block copolymers (BCPs*), polystyrene-b-poly(L-lactide) (PS-PDLLA). A wide region for the formation of DG can be found in the phase diagram of the BCPs*, suggesting that helical phase (H*) from the self-assembly of BCPs* can serve as a stepping stone for the formation of the DG due to an easy path for order-order transition from two-dimensional to three-dimensional (network) structure. Moreover, the order-order transition from metastable H* to stable DG can be expedited by blending the PS-PDLLA with compatible entity. Moreover, PS-PDLLA blends are prepared by using styrene oligomer (S) to fine-tune the morphologies of the blends at which the molecular weight ratio of the S and compatible PS block (r) is less than 0.1. Owing to the use of the low-molecular-weight oligomer, the increase of BCP chain mobility in the blends significantly reduces the transformation time for the order-order transition from H* to DG. Consequently, nanoporous gyroid SiO2 can be fabricated using hydrolyzed PS-PDLLA blends as a template for sol-gel reaction followed by removal of the PS matrix.

P1.00175 Selective Permeating Properties of Butanol and Water through Polystyrene-b-polydimethylsiloxilane-b-polystyrene Pervaporation Membranes, CHAEYOUNG SHIN, ZACHARY BAER, X. CHELSEA CHEN, A. EVREN OZCAM, DOUGLAS CLARK, NITASH BALSARA, University of California, Berkeley — Polystyrene-b-polydimethylsiloxane-b-polystyrene (SDS) membranes have been studied in butanol-water binary pervaporation experiments and pervaporation experiments integrated with viable fermentation broth. Polydimethylsiloxane has been widely known to be a particular material for separating organic chemicals from aqueous solutions, and it thus provides a continuous matrix phase in SDS membranes for permeation of small molecules. The polystyrene block provides mechanical stability to maintain the membrane structure in the pervaporation membranes. We take advantage of these features to fabricate a thin and butanol-selective SDS membrane for in situ product removal in fermentation.

P1.00176 Effect of Asymmetric Confinement on the Microdomain Morphology of Block Copolymers, YOUNGKEOL KIM, Seoul Natl Univ, GUIDUK YU, Samsung Electro-Mechanics, KOOKHEON CHAR, Seoul Natl Univ — Nanometer scale confinement could impose constraints to change the bulk equilibrium behavior of block copolymers (BCPs). The self-assembly of BCPs confined by two parallel surfaces (one-dimensional confinement) has been both theoretically and experimentally studied. More recently, cylindrical pores where the diameter of the pores are only several repeat periods of the copolymers have been employed to investigate the influence of two-dimensional confinement on the behavior of BCPs. However, the analysis on confinement by asymmetric geometry has not been thoroughly studied yet. Given the size of confining channels, singularity arising from the asymmetric geometry such as triangles and squares, could have a significant effect on the structure and symmetry of BCP morphologies self-assembled within such confinement. We prepared AAOs with triangular pores based on aluminum substrates with inverse-hexagonal packing pattern. Based on the detailed observation of BCP self-assembly within porous triangular columns, we analyzed the structural transition of BCPs induced by asymmetric confinement. Furthermore, we found that the packing frustration imposed by such confinement could be released by adding homopolymers into the BCP system.

P1.00177 Synthesis of zwitterionic polymer-based amphiphilic triblock copolymers by atom transfer radical polymerization for production of extremely stable nanoemulsions, JIN YONG LEE, JI EUN KIM, JIN WOONG KIM, Hanyang Univ — In fields of soft matter, there have been growing interests in utilizing amphiphilic block copolymers due to their intriguing properties, such as surface activity as well as self-assembly. In this work, we synthesize a series of poly (2-(methacryloyloxy)ethyl phosphorylcholine)-b-poly (ε-caprolactone)-b-poly (2-(methacyryloyloxy)ethyl phosphorylcholine) (PMPC-b-PCL-b-PMPC) triblock copolymers by using atom transfer radical polymerization (ATRP). A particular interest is in using poly (2-(methacryloyloxy)ethyl phosphorylcholine) (PMPC) as a hydrophilic block, since it can have both electrostatic repulsion and steric repulsion in complex fluid systems. Assembling them at the oil-water interface by using the phase inversion method enables production of highly stable nanoemulsions. From the analyses of the crystallography and self-assembly behavior, we have found that the triblock copolymers assemble to form a flexible but tough molecular thin film at the interface, which is essential for the remarkable improvement in the emulsion stability.

P1.00178 Ab initio molecular dynamics simulations of the thermal degradation of model compounds of industrially-relevant copolyesters, EROL YILDIRIM, Fiber and Polymer Science Program, North Carolina State University, ANDREW T. DETWILER, CURT CLEVEN, Eastman Chemical Company, AHMED EL-SHAFEI, MELISSA A. PASQUINELLI, Fiber and Polymer Science Program, North Carolina State University — The thermal degradation of copolyesters can be impacted by a variety of factors beyond the chemical composition of the polymer, including the solvent and processing conditions, as well as the presence of oxygen, moisture, additives, and dyes. Thus, we investigated the role that these factors play for a series of model compounds of industrially relevant copolyesters using ab initio molecular dynamics simulations. Some recent development of in-situ soft x-ray scattering with in-vacuum sample environment will be discussed. In order to study sciences in naturally occurring conditions, we need to overcome the sample limitations by using low penetration depth of soft x-rays and requirement of high vacuum. Adapting to the evolving environmental cell designs utilized increasingly in the Electron Microscopy community, customized designed liquid/gas environmental cells will enable soft x-ray scattering experiments on biological, electro-chemical, self-assembly, and hierarchical functional systems in both static and dynamic fashion. Recent RSoXS results on organic electronics, block copolymer thin films, and membrane structure will be presented.

P1.00180 CHARGED AND ION-CONTAINING POLYMERS —
we found distinctly dissimilar domain sizes at the same molecular weight and composition. A range of ionic liquids (ILs) were incorporated into the PSP-
and hexagonally packed cylindrical phases, were observed with PL. Remarkably, upon comparing the morphology of PSP-
owing to their self-dissociation ability. In this study, we have synthesized a set of phosphonated block copolymers, poly(styrenephosphonate-methylbutylene)
temperature operation has discouraged their practical uses in fuel cells. In this respect, phosphonated polymers have drawn intensive attention in recent years
device efficiency. While the sulfonic acid group guarantees high proton conductivity of membranes under humidified conditions, the growing need for high
transition when assembled in the presence of sodium chloride. The question remains as to how multivalent cations affect the nature of the transition. Here,
hydrates LbL assemblies made of model polyelectrolytes, poly(diallyldimethylammonium chloride) (PDAC) and poly(styrene sulfonate) (PSS), exhibit a thermal transition with features of a glass transition and a lower critical solution temperature transition when assembled in the presence of sodium chloride. The question remains as to how multivalent cations affect the nature of the transition. Here,
we present results on the thermal transition of PDAC/PSS LbL assemblies exposed to various multivalent salts. Quartz crystal microbalance (QCM-D) and
modulated differential scanning calorimetry (MDSC) is used to assess the transition.

The effect of multivalent ions on the thermal transition of hydrated polyelectrolyte multilayers, DARIYA REID, JODIE LUTKENHAUS, Texas A&M University, Department of Chemical Engineering — Layer-by-layer (LbL) assembly is a commonly studied technique in the production of uniform thin films. Hydrate LbL assemblies made of model polyelectrolytes, poly(diallyldimethylammonium chloride) (PDAC) and poly(styrenephosphonate-methylbutylene) (PSP−-PMB), by varying phosphorylation level (PL). A wide variety of self-assembled morphologies, i.e., disordered, lamellar, hexagonally perforated lamellae and hexagonally packed cylindrical phases, were observed with PL. Remarkably, upon comparing the morphology of PSP−-PMB and that of sulfonated analog, we found distinctly disimilar domain sizes at the same molecular weight and composition. A range of ionic liquids (ILs) were incorporated into the PSP−-PMB block copolymers and their ion transport properties were examined. It has been revealed that the degree of confinement of ionic phases (domain size) impacts the ion mobility and proton dissociation efficiency of IL-containing polymers.

Molecular Dynamics of Coarse-grained Ionomers Containing Ionic Liquids , HA YOUNG JUNG, SUNG YEON KIM, MOON JEONG PARK, Pohang Univ of Sci & Tech — As the focus on proton exchange fuel cells continues to escalate in the era of alternative energy systems, the rational design of sulfonated polymers has emerged as a key technique for enhancing device efficiency. While the sulfonic acid group guarantees high proton conductivity of membranes under humidified conditions, the growing need for high

Effect of multivalent ions on the thermal transition of hydrated polyelectrolyte multilayers, DARIYA REID, JODIE LUTKENHAUS, Texas A&M University, Department of Chemical Engineering — Layer-by-layer (LbL) assembly is a commonly studied technique in the production of uniform thin films. Hydrate LbL assemblies made of model polyelectrolytes, poly(diallyldimethylammonium chloride) (PDAC) and poly(styrenephosphonate-methylbutylene) (PSP−-PMB), by varying phosphorylation level (PL). A wide variety of self-assembled morphologies, i.e., disordered, lamellar, hexagonally perforated lamellae and hexagonally packed cylindrical phases, were observed with PL. Remarkably, upon comparing the morphology of PSP−-PMB and that of sulfonated analog, we found distinctly disimilar domain sizes at the same molecular weight and composition. A range of ionic liquids (ILs) were incorporated into the PSP−-PMB block copolymers and their ion transport properties were examined. It has been revealed that the degree of confinement of ionic phases (domain size) impacts the ion mobility and proton dissociation efficiency of IL-containing polymers.

Effects of Acid and Ionic Aggregation on the Polymer Dynamics in Precise Ionomers1, LURI ROBERT MIDDLETON, University of Pennsylvania, JACOB TARVER, National Institute of Standards and Technology, JASON AZOULAY, DUSTIN MURTAGH, Sandia National Laboratory, KEN WAGENER, University of Florida, CHRISTOPHER SOLES, National Institute of Standards and Technology, KAREN WINERY, University of Pennsylvania — Interest in acid- and ion-containing polymers arises from applications as single-ion conductors for selectively transporting a counter ion of the opposite charge for energy applications. The relatively low dielectric constant of the organic polymer and strong ionic interactions leads to ionic aggregation. Ion aggregation anchors the polymer chain, decreasing the mobility of the ion and the polymer. In precise poly(ethylene-acrylic acid) copolymers and ionomers (pAAC-%IL) we report on the effect of carbon spacer length (x=9, 15, 21) between the acid groups and the effect of the percent of acid groups neutralized with Li on backbone dynamics. The polymer backbone motion is investigated through quasi-elastic neutron scattering measurements. At nano-second timescales a single relaxation fits the data. Systematic changes in dynamics were observed with increasing neutralization percent where polymer dynamics are confined due to anchoring effects. Intriguingly, systematic changes in the spacer lengths did not result in similar behavior. At pico-second timescales multiple overlapping relaxations are observed but even at these short timescales systematic changes in atomic motion are observed with ion content.

Structure and Proton Conductivity in Mixtures of Poly(acrylic acid) and Imidazole, HAN-CHANG YANG, PHILIP J. GRIFFIN, KAREN I. WINERY, University of Pennsylvania, UNIVERSITY OF PENNSYLVANIA TEAM — Proton conductivity in polymer electrolyte membranes (PEMs) typically involves water, which requires that during operation the humidity of the PEM be carefully controlled. In contrast, anhydrous protic polymer membranes promote proton transport by incorporating heterocyclic molecules, such as imidazole and its derivatives, into acid-containing polymers. In this work, we explore the interplay between nanoscale-structure and proton conduction of poly(acrylic acid) (PAA) blended at varying compositions with 2-ethyl-4-methylimidazole (EMI). We present the glass transition temperature from differential scanning calorimetry, morphology characterization from X-ray scattering, and proton conduction from electrical impedance spectroscopy.

pH-Responsive Behavior of Poly(acrylic acid) Brushes of Varying Thickness, VIVEK YADAV, MEGAN ROBERTSON, JACINTA CONRAD, Univ of Houston — We have investigated the pH-dependent response of polyelectrolyte brushes of varying thickness. Our model system consists of poly(acrylic acid) brushes, which change from hydrophobic and neutral at low pH to hydrophilic and negatively charged at high pH, by varying phosphorylation level (PL). A wide variety of self-assembled morphologies, i.e., disordered, lamellar, hexagonally perforated lamellae and hexagonally packed cylindrical phases, were observed with PL. Remarkably, upon comparing the morphology of PSP−-PMB and that of sulfonated analog, we found distinctly disimilar domain sizes at the same molecular weight and composition. A range of ionic liquids (ILs) were incorporated into the PSP−-PMB block copolymers and their ion transport properties were examined. It has been revealed that the degree of confinement of ionic phases (domain size) impacts the ion mobility and proton dissociation efficiency of IL-containing polymers.
P1.00188 Influence of Hydration Level on Polymer and Water Dynamics in Alkaline Anion Exchange Fuel Cell Membranes. JACOB TARVER, JENNY KIM, MADHU TYAGI, CHRISTOPHER SOLES, National Institute of Standards and Technology, TSUNG-HAN TSAI, BRYAN COUGHLIN, University of Massachusetts - Amherst — Triblock copolymers based on poly(chloromethylstyrene)-b-poly(ethylene)-b-poly(chloromethylstyrene) can be quaternized to different extents to yield anion exchange membranes for alkaline fuel cells. In the absence of moisture, these membranes demonstrate bilayer lamellar morphology. Upon high levels of hydration, however, in-situ small angle neutron scattering reveals the emergence of higher-order diffraction peaks. This phenomena has previously been observed in analogous diblock copolymer-based membranes and has been attributed to the induction of a multilamellar lamellar morphology in which selective striping of water occurs in the center of the ion-rich domain. By conducting humidity-resolved quasielastic neutron scattering (QENS) measurements using deuterated water, we are able to isolate differences in the pico- to nanosecond timescale dynamics of the hydrogenated membrane upon hydration. QENS measurements in the presence of a hydrogenated water source subsequently permit deconvolution and isolation of the translational and rotational dynamics of water as a function of relative humidity, revealing spatial and temporal changes in polymer and water motion at high levels of hydration.

P1.00189 Understanding the impact of nanoscale aggregation on charge transport and structural dynamics in room temperature ionic liquids. PHILIP GRIFFIN, University of Pennsylvania, ADAM HOLT, University of Tennessee, YANGYANG WANG, Oak Ridge National Lab, ALEXEI SOKOLOV, University of Tennessee — Amphiphilic room temperature ionic liquids (ILs) segregate on the nanoscale, forming intricate networks of charge-rich ionic domains intercalated with charge-poor aliphatic domains. While this structural phenomenon has been well established through x-ray diffraction studies and atomistic MD simulations, the precise effects of nanophase segregation on ion transport and structural dynamics in ILs remains poorly understood. Using a combination of broadband dielectric spectroscopy, light scattering spectroscopy, and rheology, we have characterized the ionic conductivity, structural dynamics, and shear viscosity of a homologous series of quaternary ammonium ionic liquids over a wide temperature range. Upon increasing the length and volume fraction of the alkyl side chains of these quaternary ammonium ILs, ionic conductivity decreases precipitously, although no corresponding slowing of the structural dynamics is observed. Instead, we identify the dynamical signature of supramolecular aggregates. Our results directly demonstrate the role that chemical structure and ionic aggregation plays in determining the charge transport properties of amphiphilic ILs.

P1.00190 Spray-assisted layer-by-Layer (Lbl) assembly of anisotropic materials. SOUVIK DE, PILAR SUAREZ MARTINEZ, AVANTI KAVARTHAPU, JODIE LUTKENHAUS, Department of Chemical Engineering at Texas A&M University — Layer-by-Layer (Lbl) assembly has gained tremendous interest as it allows one to incorporate a large variety of molecules with nano-scale precision and very good reproducibility. In addition to charged polymers, the technique has become extremely popular to fabricate tailor-made thin films containing anisotropic nanomaterials (e.g., graphene oxide sheets). The challenge is that a standard protocol to fabricate “all-polyelectrolyte” Lbl films may not necessarily give rise to satisfactory film growth when applied to Lbl assembly where one of the adsorbing components is an anisotropic nanomaterial. Therefore, in this contribution, we combine polymers and anisotropic nanomaterials via dip- and spray-assisted Lbl assembly and investigate the effect of charge density, exfoliation, concentration etc. of the components on the growth behavior and the film quality. The end result is a conformal, pin-hole free coating on model substrates (glass, silicon, metal) over a large area.

P1.00191 Morphology and charge transport in ammonium based polymerized ionic liquids. MAXIMILIAN HERES, JOSÉPH MINUTOLO, JACOB SHAMBLIN, MAIK LONG, Univ of Tennessee, Knoxville, STEFAN BERDZINSKI, VERONIKA STREML, Department of Chemistry and Institute for Coatings and Surface Chemistry, Hochschule Niederrhein University of Applied Sciences, Krefeld, Germany, JOSHUA SANGORO, Univ of Tennessee, Knoxville — Ionic conduction, structural dynamics and morphology in a series of ammonium based polymers and anisotropics are investigated using broadband dielectric spectroscopy, temperature-modulated differential scanning calorimetry, and neutron as well as x-ray scattering techniques. The dielectric spectra are dominated on the low frequency regime by electrode polarization while hopping conduction is the underlying mechanism at higher frequencies. At their respective calorimetric glass transition temperatures, a strong correlation between the morphology and ionic conductivity is found. These results are discussed within the recent approaches proposed to explain the decoupling of charge transport from structural dynamics.

P1.00192 Effect of Supercharging on Coacervation Between Proteins and Polyelectrolytes. BRADLEY OLSEN, ALLIE OBERMEYER, CAROLYN MILLS, XUEHUI DONG, MIT — Complex coacervates have attracted a great deal of attention as a method to encapsulate biological molecules including DNA and proteins. However, a large fraction of proteins will not form coacervates with oppositely charged polymers unless their surface charge density is increased through a process known as supercharging. Using mass spectrometry, we are able to quantify the formal charge distribution of proteins after supercharging, and with this knowledge of the chemical state of the protein measure coacervate formation for a panel of proteins as a function of charge. While many of the proteins studied do not form coacervates or coacervate over only a narrow range of composition in their native form, all proteins form coacervates above a critical charge level with increasing range of composition as charge density increases. The resulting data is consistent with a strong induced charging effect in the coacervate state, as the largest coacervates form near a charge ratio corresponding to proteins at their maximum charge. These observations in bulk coacervation are translated to the design of coacervate core micelles, providing an increased quantitative description.
Spray Deposition of Multilayer Gas Barrier Thin Films, TARA GIVENS, FANGMING XIANG, JAIME GRUNILAN, Texas A&M Univ — Dip-assisted assembly is the norm for making multilayer thin films (also known as layer-by-layer [LbL] assembly). Spray-based deposition possesses several advantages over dipping, but has not been studied in great detail, especially for gas barrier layers. In this study, polyethyleneimine [PEI]/poly(acrylic acid) [PAA] bilayers were deposited with varying spray parameters. Spraying time was found to be the most influential parameter to control the roughness, thickness, and gas barrier of the PEI/PAA assembly. A spray-coated sample was prepared using optimized parameters and compared to a dip-coated sample using the same deposition time (5s). The sprayed sample was better in terms of thickness, roughness, and gas barrier. This study is the first report showing that a sprayed multilayer assembly has better properties than its dipped counterpart. These findings could revolutionize the multilayer deposition process, making it more commercially-friendly.

Inexpensive Fabrication of Metallic Interconnects on Flexible Substrates, ADITI NAIK, ROHIT KOTHARI, JAMES WATKINS, University of Massachusetts - Amherst — Sub-micron metallic interconnects on flexible substrates are important to produce inexpensive bendable devices and electronics. The key component hindering high-performance flexible electronics is the lack of high transistor integration density. Previous researchers have created solution-processable semiconductor and dielectric layers; however, sub-micron solution-processable copper electrodes have yet to be developed. Using cost-effective processing techniques, including soft nanolithography and photonic sintering, with a commercial copper oxide ink, we have demonstrated the fabrication of sub-micron copper interconnects on glass and plastic substrates. This inexpensive, solution-processable method is amenable to high-speed printing over large areas by roll-to-roll processing and will lead to the development of low-cost flexible electronics.

A Molecular Perspective of Inter-filament Bonding in Fused Deposition Modeling 3-D Printing, EDWARD DURANTY, BRANDON SPRADLIN, MARK DADMUN, University of Tennessee — Fused deposition 3D printing is an important tool for low-cost and rapid prototyping of objects with complex geometries. 3D printed materials are composed of many filaments deposited on a heated substrate, requiring the bonding of neighboring filaments during the deposition process. Filament deposition often creates voids between filaments, which requires necking between them to create a robust sample. Therefore the amount of interfacial contact and interdiffusion between filaments become important parameters that control the macroscopic physical properties of the printed prototype. Our research focuses on quantifying the interfacial adhesion between ABS filaments and its impact on structural properties. The time evolution of the temperature profile near the heated substrate demonstrates that the deposited filaments are repeatedly heated above the Tg of ABS allowing interpenetration of the polymer chains between adjacent filaments. Results of DMA experiments on samples of different geometries have been correlated to microphotography that monitors the degree of necking between filaments and the thermal history. Results indicate that interfacial contact area between filaments and increased thermal energy are crucial to their mechanical properties.

THEORY AND SIMULATION OF MACROMOLECULES

Contrasting Polymer Behavior Under Nanoconfinement using Thermomechanically Consistent Coarse-Grained Models, SINAN KETEN, WENJIE XIA, DAVID HSU, Northwestern University — We present a systematic, two-bead per monomer coarse graining strategy that simulates the thermomechanical behavior of polymers several hundred times faster than all-atom MD (Hsu et al. JCTC, 2014). The predictive capability of the technique is illustrated here for 5 different methacrylate monomers and polystyrene stereoisomers. The approach involves optimization of analytical bonded potentials from atomistic bonded distributions to emulate local structure, as validated by chain end-to-end length and the radius of gyration comparisons with experiments and random coil theory. Nonbonded Lennard-Jones potentials are tuned to reproduce the elastic modulus (E) and glass transition temperature (Tg) at a single thermodynamic state. Density-corrected parameters capture temperature-modulus dependence in the 150-600 K range. Flory-Fox constants of the CG models are commensurate with all atomistic and experimental results, even though all calibrations are done at a single molecular weight. Finally, we further demonstrate the predictive capabilities of the models by examining thin film nanoconfinement effects for different polymers, film thicknesses, interfacial energies, and molecular weights. Our technique, called thermomechanically consistent coarse graining (TCCG), is demonstrated, using polystyrene and poly(methylmethacrylate) as universal benchmarks, to be a robust and effective technique to understand the thermomechanical behavior of polymers thin films and nanocomposites.

ABSTRACT WITHDRAWN

Coarse-Graining in Simulations of Multicomponent Polymer Systems, SETHURAMAN VAIYANATHAN, VENKAT GANESAN, Department of Chemical Engineering, University of Texas at Austin, Austin, Texas 78712, USA — We investigate the mapping required between the interaction parameters of two different coarse-grained simulation models to ensure a match of the long-range structural characteristics of multicomponent polymeric system. We investigate the extensibility of mapping functions deduced in the context of symmetric block copolymers by Morse and coworkers to other polymeric systems by studying a variety of systems, including, asymmetric diblock copolymers, symmetric triblock copolymers and diblock copolymer-solvent mixtures. We observe excellent agreement for peak in the inverse structure between two popular coarse grained models for all polymer concentrations investigated, thus showing that the mapping function proposed for diblock copolymer melts is transferable to other polymer melts irrespective of the blockiness or overall composition. We use our findings to propose a methodology to create ordered morphologies in simulations involving hard repulsive potentials in a computationally efficient manner.

Structural analysis of liquid crystalline order in polymer melts and blends, KIRAN KHANAL, JUTTA LUETTMEER-STRATHMANN, The University of Akron — Blends of liquid crystalline and flexible polymers have interesting physical behaviors and important applications in organic electronics. We investigate the liquid crystalline transition in melts and blends of semiflexible polymers with Monte Carlo simulations of a bond fluctuation lattice model. For polymer melts we study the influence of attractive interactions on the isotropic to nematic phase transition for different polymer concentrations. We observe that the structure of the ordered phase is different for melts with and without attractive interactions. We construct the phase diagram and find the transition temperature increases with increasing strength of the attractive interaction. To analyze the structure of ordered and disordered regions in polymer melts and blends, we calculate a set of pair distribution functions. We also investigate the effect of an ordering field on the liquid crystalline order in polymer melts and blends.

Size and Shape Descriptors of Two Dimensional Polymer Sheets in Solution near the Crossover Concentration, SALOMON TURGMAN COHEN, JACOBI TANNER, Kettering Univ — We investigate the size and shape of two dimensional polymer sheets near the crossover concentration as a function of sheet size and concentration. Specifically, fully flexible sheets with local square connectivity in implicit, atheletic solvent are investigated by molecular dynamics simulations in the NVT ensemble with a Langevin thermostat. Sheet sizes of $N = 100, 400$, and $1600$ are explored. We monitor the average radius of gyration ($R_g$) tensor and the relative shape anisotropy around the cross-over concentration. Opposite to linear, one dimensional polymers, preliminary results show that the size of the sheets as measured by the average radius of gyration increases as the cross-over concentration is approached. The trends in the relative shape anisotropy suggest that the increasing overlap between the sheets at high concentrations leads to the sheets favoring flatter conformations, explaining the larger values of $R_g$ observed.
P1.00205 The effect of copolymers on the interfaces in incompatible homopolymers blend: Molecular dynamics study

JIHO RYU, WON BO LEE, Sogang Univ — Using molecular dynamics simulations the effect of copolymers as compatibilizer for reducing interfacial tension and enhancement of interfacial adhesion at the interface of thermodynamic unfavorable homopolymers blend is studied with block- and graft-copolymers. We have calculated local pressure tensor of system along the axis perpendicular to interface, varying bending potential energy of one part, which consist of just one kind of beads, of copolymer chain to examine the effect of stiffness of surfactin molecules. Here we consider symmetric diblock copolymer (f=1/2) having 1/2 N make of beads of type A and the other part made of beads of type B, and graft copolymer having backbone linear chain consist of 1/2 N beads of type A and branched with two side-chain consist of 1/4 N beads of type B. All simulations were performed under the constant NPT ensemble at T*. Also we studied changes of effect of copolymers with increasing pairwise repulsive interaction potential between two beads of types A and B while homopolymers chain length are fixed, N=30.

\[ P = \frac{\Delta F}{\Delta V} \]

\[ \Delta G = \Delta H - T \Delta S \]

\[ \Delta H = \sum \Delta H_i \]

\[ \Delta S = \sum \Delta S_i \]

\[ V = \sum V_i \]

\[ P = \frac{\Delta F}{\Delta V} = \frac{\Delta G}{\Delta V} = \frac{\Delta H}{\Delta V} - T \frac{\Delta S}{\Delta V} \]

P1.00206 Monte Carlo Simulations on Phase Transitions and Conformational Properties of Catenated Double-ring Copolymers

DACHUAN SUN, JUNHAN CHO, Dankook Univ — The thermodynamic and conformational properties of catenated double-ring A/B copolymer melts are investigated through lattice Monte Carlo simulations. The topological constraint on the catenated copolymers is shown to suppress demixing of A and B monomers. This action results in their order-to-disorder transition (ODT) at an increased segregation level and the lamellae below ODT with reduced order, when compared to diblock copolymers of linear or single-ring topology. The A and B rings are pulled closer by catenation in the copolymer, which leads to its smaller gyration radius, lamellar domain spacing, and distance between mass centers of the two rings than for the diblock copolymers. With increasing segregation tendencies, the gyration radii of the A rings of the catenated copolymers stretch along the direction normal to lamellae, while the A-block conformations of the single-ring copolymers change their shapes from ellipsoid to sphere.

This work was supported by the Basic Science Research Program (No. 2014023297) from National Research Foundation of Korea. The authors also acknowledge the support from the Center for Photofunctional Energy Materials, which is funded by Gyeonggi Regional Research Center Program (GRRCdankook2011-B01).

P1.00207 Using graphs to interrogate the atomic structure of polymer blends

OLGA WODO, State Univ of NY - Buffalo, BASKAR GANAPATHYSUBRAMANIAN, Iowa State University — The nanomorphology of polymer blend thin films critically affects performance especially in electronic devices. However, many aspects of the underlying physics linking morphology to performance are still poorly understood. Furthermore, there is increasing evidence that atomic organization can hold the key to efficient charge transport within organic electronic devices. In this work, we take advantage of recent advances in molecular dynamics simulations and quantify atomic-scale morphological aspects of the thin films. Specifically, we present a graph-based technique that allows quantifying the point-cloud data. In our approach, we first convert the point cloud data from atomic simulation into a labelled, weighted, undirected graph and then use standard graph-based algorithms to calculate and quantify morphology features. The conversion of the CGMD-data into a graph preserves all the topological and geometric information about the internal structure, and local connectivity between individual atoms/atoms/bonds (along and across the polymer chains). Our method provides hierarchical information about the charge paths that a hole/elecbeads needs to take to reach the electrode (path length, fraction of intra-molecular hops, path balance). We showcase capabilities of our approach by analyzing coarse grained molecular simulations, and quantifying effect of various thermal treatment as well as electrode materials on the P3HT:PCBM blend.

P1.00208 An atomistic model for cross-linked HNBR elastomers used in seals

NICOLA MOLINARI, ADRIAN SUTTON, Imperial College London, Department of Physics, London SW7 2AZ, UK, JOHN STEVENS, Baker Hughes, Materials Centre of Excellence, Houston, Texas 77019-2118, USA, ARASH MOSTOFI, Imperial College London, Departments of Materials and Physics, London SW7 2AZ and the Thomas Young Centre for Theory and Simulation of Materials, UK — Hydrogenated nitrile butadiene rubber (HNBR) is one of the most common elastomeric materials used for seals in the oil and gas industry. These seals sometimes suffer “explosive decompression,” a costly problem in which gases permeate a seal at the elevated temperatures and pressures pertaining in oil and gas wells, leading to rupture when the seal is brought back to the surface. The experimental evidence that HNBR and its unsaturated parent, NBR, have markedly different swelling properties suggests that cross-linking may occur during hydrogenation of NBR to produce HNBR. We have developed a code compatible with the LAMMPS molecular dynamics package to generate fully atomistic HNBR configurations by hydrogenating initial NBR structures. This can be done with any desired degree of cross-linking. The code uses a model of atomic interactions based on the OPLS-AA force-field. We present calculations of the dependence of a number of bulk properties on the degree of cross-linking. Using our atomistic representations of HNBR and NBR, we hope to develop a better molecular understanding of the mechanisms that result in explosive decomposition.

P1.00209 Pattern Recognition of Adsorbing HP Lattice Proteins

MARTIN P. LANDAU, Center for Simulational Physics, University of Georgia, THOMAS WUST, Scientific IT Services, ETH Zurich, DAVID P. LANDAU, Center for Simulational Physics, University of Georgia, FRIEDERIKE SCHMID, Institute of Physics, Johannes Gutenberg University — Protein adsorption is relevant in fields ranging from medicine to industry, and the qualitative behavior exhibited by course-grained models could shed insight for further research in such fields. Our study on the selective adsorption of lattice proteins utilizes the Wang-Landau algorithm to simulate the Hydrophobic-Polar (H-P) model with an efficient set of Monte Carlo moves. Each substrate is modeled as a square pattern of 9 lattice sites which attract either H or P monomers, and are located on an otherwise neutral surface. The fully enumerated set of 102 unique surfaces is simulated with each protein sequence. A collection of 27-monomer sequences is used—each of which is non-degenerate and protein-like. Thermodynamic quantities such as the specific heat and free energy are calculated from the density of states, and are used to investigate the adsorption of lattice proteins on patterned substrates.

P1.00210 Calculating Pressure and Surface Tension of Lattice Polymers

QIANG WANG, PENGFEI ZHANG, Department of Chemical and Biological Engineering, Colorado State University — Calculating pressure and related surface tension of polymeric systems in lattice Monte Carlo simulations is an important but nontrivial subject. Here we propose several novel, efficient, and accurate methods. In the first method, we combine chain insertion/deletion with the Wang-Landau — Optimized Ensemble (WL-OE) simulation, which is very efficient at low to intermediate polymer volume fractions . In the second method, we introduce a repulsive wall with bridging bonds, which is similar to the repulsive wall method but eliminates its confinement effects. This method works especially well at high , where all the methods using chain insertion/deletion fail. Finally, we combine the above two methods, which gives complete thermodynamics over the entire range of continuous and exact -values with negligible finite-size effects. To demonstrate our methods, we apply them to calculate the bulk pressure and surface tension of nano-confined homopolymers.
P1.00211 Protein-like folding and other phase transitions of a single polymer chain, MARK TAYLOR, Dept. of Physics, Hiram College, WOLFGANG PAUL, Martin-Luther-Universitat, Halle, Germany, KURT BINDER, Johannes-Gutenberg-Universitat, Mainz, Germany — A single polymer chain can undergo a series of conformational transitions analogous to the phase transitions exhibited by bulk materials. We have recently studied the conformational transitions of a flexible square-well polymer chain using a Wang-Landau simulation approach in which we directly compute the single-chain partition function. For the case of a tangent-sphere chain, the temperature-interaction range phase diagram includes both a coil-globule and globule-crystal transition as well as an “all-or-none” coil-crystal transition. Despite the non-unique homopolymer ground state, the thermodynamics of this direct freezing transition are identical to the thermodynamics of two-state protein folding. Two-dimensional configurational and free energy landscapes reveal both a dominant “folding” pathway and a “dead-end” pathway resulting in a bimodal distribution of structures at the top of the free energy barrier. A simple AB-heteropolymer variant of this model leads to both rod-like and disk-like ground state structures while a fused sphere version of the model produces helical folded structures.

P1.00212 Simulation of dynamics of disordered diblock copolymers near the order-disorder transition, PAVANI MEDAPURAM, DAVID MORSE, Univ of Minnesota - Twin Cities — We present a simulation study of the dynamics of composition fluctuations, chain conformations and stress for diblock copolymers near the order-disorder transition. Specifically, we study the behavior of the van Hove function S(r,t), which is a measure of structural relaxation, the linear response of the bond orientation tensor, which is closely related to optical birefringence, and the linear viscoelastic stress relaxation modulus G(t). We show how a slowly decaying mode associated with slow relaxation of composition fluctuations emerges as the degree of segregation is increased.

P1.00213 Conformation of Single Polymer Chains, HOWARD WANG, Binghamton Univ, XIAORONG WANG, Tongji University — Large biological molecules such as proteins and DNAs can be packed into condensed forms through hydrogen bonding and specific interactions; the conformation of an ultra-long single chain with no specific intra-chain interactions is considered here. We discuss three possible states, (1) uniformly compressed Gaussian, (2) totally irregular aggregates, and (3) long Gaussian sections separated by segments of frustrated local conformation, or “kinks.” Those states could be related to the methods of preparing the condensed form of the single chain globule. We argue that the Gaussian-Kink conformation is preferred and the segregation of kinks to the surface of globules would significantly alter the chain dynamics.

P1.00214 BIOPOLYMERS AND BIOHYBRID POLYMERS —

P1.00215 Binding Affinity Effects on Physical Characteristics of a Model Phase-Separated Protein Droplet, SARA CHUANG, Princeton University, SALMAN BANANI, UT Southwestern Medical Center, MICHAEL ROSEN, UT Southwestern Medical Center, HHHI, CLIFFORD BRANGWYNE, Princeton University — Non-membrane bound organelles are associated with a range of biological functions. Several of these structures exhibit liquid-like properties, and may represent droplets of phase-separated RNA and/or proteins. These structures are often enriched in multi-valent molecules, however little is known about the interactions driving the assembly, properties, and function. Here, we address this question using a model multi-valent protein system consisting of repeats of Small Ubiquitin-like Modifier (SUMO) protein and a SUMO-interacting motif (SIM). These proteins undergo phase separation into liquid-like droplets. We combine micro rheology and quantitative microscopy to determine affect of binding affinity on the viscosity, density and surface tension of these droplets. We also use fluorescence recovery after photobleaching (FRAP), fluorescence correlation spectroscopy (FCS) and partitioning experiments to probe the structure and dynamics within these droplets. Our results shed light on how inter-molecular interactions manifests in droplet properties, and lay the groundwork for a comprehensive biophysical picture of intracellular RNA/protein organelles.

P1.00216 Fluorescence microscopy techniques for characterizing the microscale mechanical response of entangled actin networks, SAVANNA BLAIR, TOBIAS FALZONE, RAE ROBERTSON-ANDERSON, University of San Diego — Actin filaments are semiflexible polymers that display complex viscoelastic properties when entangled in networks. In order to characterize the molecular-level physical and mechanical properties of entangled actin networks it is important to know the in-network length distribution and the response of entangled filaments to local forcing. Here we describe two single-molecule microscopy protocols developed to investigate these properties. Using confocal fluorescence microscopy and ImageJ image analysis we have developed a protocol to accurately measure the in-network actin length distribution. To characterize the deformation of actin filaments in response to perturbation, we trap micron size beads embedded in the network with optical tweezers and propagate the beads through the entangled filaments while simultaneously recording images of fluorescent-labeled filaments in the network. A sparse number of labeled filaments dispersed throughout the network allow us to visualize the movement of individual filaments during perturbation. Analysis of images taken during forcing is carried out using a combination of vector mapping and skeletonization techniques to directly reveal the deformation and subsequent relaxation modes induced in entangled actin filaments by microscale strains. We also determine the dependence of deformation modes on the relative filament position relative to the strain.

P1.00217 Assembly, Properties and Function of Synthetic Phase-Separated RNA/Protein Organelles, NICOLE TAYLOR, SHANA ELBAUM, HOWARD STONE, CLIFFORD BRANGWYNE, Princeton Univ — Non-membrane bound RNA/protein (RNP) bodies play a key role in cellular RNA processing steps. Many RNA helicases, required for RNA processing, are key components of RNPs. Consistent with this, a purified RNA helicase, Laf-1, exhibits a salt and protein concentration dependent phase separation in vitro, resulting in liquid-like droplets. We use such synthetic RNPs to study the biophysics of RNP assembly, and to elucidate the link between their physical properties and function. To accomplish this, we are developing custom microfluidic devices to measure biophysical properties, nucleation and growth kinetics, and RNA processing function of droplets. We measure droplet viscosity by applying a shear stress to protein droplets that adhere to the channel wall; measurements are consistent with those taken using a particle micro rheology approach. We also monitor and control protein droplet nucleation using oil/water emulsions. Our results provide a new platform for addressing how the cell regulates organelle assembly and properties through protein, RNA, and ATP concentration. We anticipate that these findings will offer insight into the contribution of RNPs in key RNA processing functions in the cell.

P1.00218 POLYMERS FOR SOLAR ENERGY —
P1.00219 Design of block and graft copolymers for use as compatibilizers in organic solar cell active layers. DYLAN KIPP, VENKAT GANESAN, University of Texas at Austin — Recent experiments have suggested that the use of block and graft copolymer compatibility in polymer-based donor-acceptor materials can improve the morphology and improve polymer of solar cells. Inspired by these successes, we use this framework of self-consistent field theory to study the influence of copolymer compatibilizers on the interfacial properties of donor-acceptor blends. First, we calculate the reduction in the interfacial tension (and hence the driving force towards macrophase segregation) brought by the copolymer compatibilizer as a function of the copolymer architecture. Second, we calculate the effective interaction between two copolymer monolayers at the interfaces between the donor and acceptor domains. The results of this second study allow us to comment on the expected ability of the copolymer compatibilizer to reduce the coalescence of domains. Overall, our results suggest important rules for designing copolymer compatibilizers to influence both kinetically-trapped and equilibrium morphologies of donor-acceptor blends.

P1.00220 Self-Assembly of Carotenoids During Solution Casting of Solar Devices. DUSANATHA ALWIS, DILRU RATNAWEERA, University of Sri Jayewardenepura, Sri Lanka, THUSITHA ETAMPAWALA, MARK DADMUN, University of Tennessee, Knoxville, UDUMALAGALA CHANDRIKA, PRADEEP JAYAWEERA, University of Sri Jayewardenepura, Sri Lanka — Self-assembly of carotenoids is a common phenomenon in nature and seems to be closely related to the functions of these natural dyes in solar devices. The large absorption coefficients in the visible region of carotenoids make them a well-suited natural resource for dye-sensitized solar cells (DSSC). The performance of carotenoid-based solar devices mainly depends on the photo-electrochemical properties of the active material (carotenoids) and their self-assembled morphology within solar devices. These associations of molecules will affect the light absorption, emission and energy harvesting abilities of these solar devices. Two types of highly conjugated natural carotenoids having mono and dicarboxy terminal groups, namely bixin and norbixin, were extracted from annatto seeds. In the current study, small angle neutron scattering experiments were carried out to examine the modes of assemblies of bixin and norbixin during solution processing of DSSCs. Spherical shape aggregates with rough interfaces were observed in acetonitrile medium, which is a good solvent for hydrocarbon chain. The shape of the aggregates slightly deviates from spherical to slightly elongated shape at high volume fractions of carotenoids. Bixin and norbixin show different association behaviors as a function of their concentration.

P1.00221 Hydrogen Bonding-mediated Conjugated Polymers for Bulk-Heterojunction Organic Photovoltaics. YEN-HAO LIN, Rice University, WAN-YI NIE, ADITYA MOHITE, GAUTAM GUPTA, Los Alamos National Laboratory, RAFAEL VERDUGO, Rice University — We use hydrogen bonding interactions to prevent large scale phase separation and improve polymer of organic solar cells. Poly(3-alkylthiophene) (P3HT) donor polymer and poly(2,7-(9′,9′-dioctyl-fluorene)-alt-5,5-(4′,7′-di-2-thienyl-2′-1′,3′-benzothiadiazole) (PFTBT) acceptor polymer with self-associating, quadruple hydrogen bonding end groups (2-ureido-4[H]-pyrimidinone, UPy) are used to explore the role of hydrogen bonding associations on blend morphology and photovoltaic performance. We study three systems: P3HT:PCBM, PFTBT:PCBM and P3HT:PFTBT and analyze by AFM, impedance, and device performance. In P3HT:PCBM, the performance is improved from 1.21% to 2.16% using UPy-terminated P3HT due to the enhanced long range order of semi-crystalline P3HT. In PFTBT:PCBM, the performance is decreased from 1.84% to 1.08% using UPy-terminated PFTBT due to entanglement of non-crystalline PFTBT chains. In P3HT/PFTBT system, the performance is improved from 0.43% to 0.77% with the use UPy-terminated P3HT and PFTBT because of suppressed macro-phase separation with maintained long range order of P3HT under annealing temperature. The impedance analysis under short circuit and illumination conditions indicates the faster charge transport and reduced charge recombination within the better performed devices. This study shows that the hydrogen bonding interactions can reduce phase separation but not produce better BHJ devices in all cases perhaps because some phase separation in blends is still required.

P1.00222 Side Chain Engineering of Naphthalenediimide-Based N-type Polymer for High-Performance All-Polymer Solar Cell near 6% Efficiency. CHANGYEON LEE, HYUNBUM KANG, WONHO LEE, TAEUS KIM, KI-HYUN KIM, KAIST, HAN YOUNG WOO, PNU, CHENG WANG, Lawrence Berkeley National Laboratory, BUMJOON KIM, KAIST, PUSAN NATIONAL UNIVERSITY (PNU) COLLABORATION, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION — Despite the attractive features of all-polymer solar cells (all-PSCs), i.e., enhanced absorption coefficients, the tunability of their energetic and chemical properties and their thermal and mechanical stabilities, they still face the great challenge of having significantly low power conversion efficiency (PCE) values of only 3-5%. The prominent origins of the poor efficiency of all-PSCs are the undesirable features of the bulk-heterojunction (BHJ) blend morphology including the phase-separated large-scale domain size, reduced ordering of the polymer chains. Tuning side alkyl chains of conjugated polymers is an effective route for manipulating the blend morphology in BHJ type solar cells. However, the role of side chains in all-PSCs is poorly understood. Herein, we report high-performing all-PSCs with 5.96% efficiency by developing a series of naphthalenediimide (NDI)-based polymer donors with different alkyl side chains. We demonstrated that the use of the PNDIT with hexadecyl side chains produced highly-ordered polymer stackings with strong face-on geometry and at the same time, forming the optimal BHJ morphology with finely separated phase domains, all of which contributed together to induce well-balanced μe/μh ratio and generate efficient all-PSCs with PCEs near 6%.

P1.00223 Fabrication of Organic Bulk Heterojunction Solar Cells on Flexible Substrates. GABRIEL CALDERON, MILZAIDA MERCED-SANABRIA, CAROLYN CARRADERO-SANTIAGO, JOSEE VEDRINE-PAULEUS, University of Puerto Rico-Humacao — The active layer for the organic solar cells fabricated is composed of P3HT:PCBM, poly(3-hexylthiophene) (P3HT) as electron donor and phenyl-C61-butyric acid methyl ester(PCBM) as electron acceptor. These polymers were used due to their promising characteristics for devices such as bulk heterojunction solar devices. We used polyethylene terephthalate (PET) substrates, a highly flexible plastic, with indium tin oxide (ITO) as the transparent conducting anode for the device, and UV lithography technique to pattern the ITO; this is to facilitate multiple devices on a single substrate. The fabrication process for pattern transfer incorporates developing and etching processes. We diluted the HCI and DI water to etch out the ITO. PEDOT:PSS and active layer of P3HT:PCBM were deposited on (3.0 sq-cm) patterned of ITO/PET by spin coating method. The cathode was thermally evaporated with Al. We characterized the device using a source meter. We also simulated portions of the device using PET on graphene as the substrate.

P1.00224 ORGANIC ELECTRONICS AND PHOTONICS —

P1.00225 Electroluminescent Molecule for DC-Driven, Sub-2V Solid-State Emissive Devices by Incorporating Redox Co-reactants. HONG CHUL MOON, TIMOTHY P. LODGE, C. DANIEL FRISBIE, University of Minnesota — We have demonstrated a solid-state DC-driven electroluminescent (ECL) device using a solution processable, emissive ECL gel based on polystyrene-based redox polymer molecules containing a one-electron acceptor (Ru(bpy)32+ and PFO2,2) and a two-electron donor (butylammonium oxalate (TBAOX)) was incorporated into the ECL gel for a co-reactant strategy. Oxalate can be viewed as a consumable fuel for the device providing reducing power and cutting the overall operating voltage. The device was fabricated by a simple two-step solution process. Application of 1.6 V DC bias across the device resulted in the onset of light emission. The maximum luminance was achieved at 1.5 mole ratio of ECL luminophore (Ru(bpy)32+) and TBAOX, and the turn-on voltage was independent of the composition. The simplicity of the ECL device and its low voltage operation characteristics make it potentially attractive as a display element for printed electronics.3

P1.00226 Ferroelectric switching behavior in morphology controlled ferroelectric-semiconductor polymer blends for organic memory. EUNHEE LIM, GREGORY SU, EDWARD KRAMER, MICHAEL CHABINYC, University of California, Santa Barbara — Memory is a fundamental component of all modern electronic systems. Organic ferroelectric memories are advantageous because they are thin and lightweight devices that can be made printable, foldable, and stretchable. Organic ferroelectric memories comprise a physical blend of an organic semiconducting polymer and an insulating ferroelectric polymer as the active layer in a thin film diode. Controlling the thin film morphology in these blends is important for electrical properties of the resulting device. We have found that when a semiconducting thiophene polymer with polar alkanoate side chains (P3EPT) is blended with well-studied ferroelectric polymer poly[(vinylenefluoride-co-trifluoroethylene] P (VDF-TrFE), the resulting film has low surface roughness and more controllable domain sizes compared to the widely used poly (3-hexylthiophene). This difference allows more reliable study of the ferroelectric switching behavior in devices with domain size of about 100nm. The influence of the 3D composition measured by a combination of methods, including soft x-ray microscopy, on the electrical characteristics will be presented.

P1.00227 Microscopic simulations of electronic excitations in donor-acceptor heterojunctions of small-molecule based solar cells. BJÖRN BAUMEIER, Max Planck Institute for Polymer Research — Fundamental processes involving electronic excitations govern the functionality of molecular materials, in which the dynamics of excitons and charges is determined by an interplay of molecular electronic structure and morphological order. To understand, e.g., charge separation and recombination at donor-acceptor heterojunctions in organic solar cells, knowledge about the microscopic details influencing these dynamics in the bulk and across the interface is required. For a set of prototypical heterojunctions of small-molecule donor materials with C80, we employ a hybrid QM/MM approach linking density-functional and many-body Green’s functions theory (DFT/GW-BSE) to polarizable force-fields and analyze the charged and neutral electronic excitations therein. We pay special attention the spatially-resolved electron/hole transport levels, as well as the relative energies of Frenkel and charge-transfer excitations at the interface. Finally, we link the molecular architecture of the donor material, its orientation on the fullerene substrate as well as mesoscale order to the solar cell performance.

P1.00228 Enhancing the Thermoelectric Characteristics of PEDOT:PSS Through the Incorporation of a Redox-Active Small Molecule. EDWARD TOMLINSON, MATTHEW WILLMORE, XIAOQIN ZHU, BRYAN BOUDOURIS, Purdue University — The polymer composed of poly(3,4-ethylene dioxythiophene) and poly(styrene sulfonate) (PEDOT:PSS) is a leading organic thermoelectric material due to its high-performance properties. Here, we establish the effect of incorporating the redox-active small molecule 4-hydroxy-2,2,6,6-tetramethylepiperidin-1-oxyl (TEMPO-OH) on the structural and thermoelectric properties of PEDOT:PSS. Specifically, the thermoelectric power factor (PF) was monitored as a function of TEMPO-OH loading, elucidating a clear trend in the PF. Importantly, at loadings as low as 5% TEMPO-OH, by mass, the thermopower of the sample was increased by a factor of two. Furthermore, the role of the TEMPO-OH on the thin film morphology of the composite material is examined through the use of grazing incidence-wide angle x-ray scattering (GI-WAXS) and atomic force microscopy (AFM). Despite the acidic conditions associated with the presence of PSS, the existence of radical functionality is confirmed through electron paramagnetic resonance (EPR) spectroscopy. Through careful tuning, the optimized conditions outlined within this work results in PF gains in excess of 40%.

P1.00229 Morphology optimization for enhanced performance in organic photovoltaics. OLGA WODO, JAROSŁAW ZOLA, State Univ of NY - Buffalo, BASKAR GANAPATYSUBRAMANIAN, Iowa State University — Organic solar cells have the potential for widespread usage due to their low cost-per-watt and mechanical flexibility. Their widespread use, however, is bottlenecked primarily by their low solar efficiencies. Experimental evidence suggests that a key property determining the solar efficiency of such devices is the morphological distribution of the electron-donor and electron-acceptor constituents. By carefully designing the morphology of the device, one could potentially significantly enhance their performance. This is an area of intense experimental effort that is mostly trial-and-error based, and serves as a fertile area for introducing mechanics and computational thinking. In this work, we use optimization techniques coupled with computational modeling to identify the optimal structures for high efficiency solar cells. In particular, we use adaptive population-based incremental learning method linked to graph-based surrogate model to evaluate properties for given structure. We study several different criterions and find optimal structure that that improve the performance of currently hypothesized optimal structures by 29%.

P1.00230 Facile Control of a Wide Range of Regioregularity: Significant Influence on Mechanical and Electrical Properties of Conjugated Polymers. JIN-SEONG KIM, JAE-HAN KIM, WONHO LEE, KAIJean, HOJEOUNG YU, POSTECH, HYEONG JUN KIM, KAIST, INHO SONG, JOON HAK OH, POSTECH, TAEK-SOO KIM, BUMJOON KIM, KAIST, POSTECH COLLABORATION — While regioregularity (RR) has been known to have a strong influence on inherent properties of conjugated polymer, systematic study of RR has been limited due to the lack of synthetic methodology. Herein, we prepared a series of poly(3-hexithiophenes) (P3HTs) having a wide range of RR from 64 to 96% by the modified Grignard metathesis method that utilizes the dimer moiety. We observed that the RR determines crystalline behavior, mechanical and electrical properties of P3HT. Although higher RR P3HT had higher hole mobility, its increased degree of crystallinity induced fragile nature of polymers (elongation break <1%). In contrast, lower RR had lower elastic modulus and thereby leading to significant reduction of fragility. Therefore, our finding suggested that the control of RR is critical to regulate the properties of conjugated polymers between electrical performance and mechanical resilience as depending on the purpose of the applications. (i.e flexible portable devices vs high performance panel)

P1.00231 Using COMSOL Multiphysics Software to Analyze the Thin Film Resistance Model of a Conductor on PET. CAROLYN CARRADERO-SANTIAGO, MILZAIDA MERCED-SANABRIA, JOSE VEDRINE-PAULÉUS, University of Puerto Rico-Humacao — In this research work, we will develop a virtual model to analyze the electrical conductivity of a thin film with three layers, one of graphene or conducting metal film, polyethylene terephthalate (PET) and Poly(3,4-ethylenedioxythiophene) Polystyrene sulfonate (PEDOT:PSS). COMSOL Multiphysics will be the software use to develop the virtual model to analyze the thin-film layers. COMSOL software allows simulation and modelling of physical phenomena represented by differential equations such as that of heat transfer, fluid movement, electromagnetism and structural mechanics. In the work, we will define the geometry of the model; in this case we want three layers-PET, the conducting layer and PEDOT:PSS. We will then add the materials and assign PET as the lower layer, the above conductor as the middle layer and the PEDOT:PSS as the upper layer. We will analyze the model with varying thickness of the top conducting layer. This simulation will allow us to analyze the electrical conductivity, and visualize the model with varying voltage potential, or bias across the plates.
P1.00232 Study of biodegradable polymers for “green” devices, CARLOS PEREZ, XIAOMEI JIANG, University of South Florida, JIANG GROUP TEAM — PI—conjugated polymers such as polythiophenes are conventional picks for cost-effective organic solar cells. However, these organic semiconductors are not environment-friendly since the polymer backbones require temperature higher than 300°C to be decomposed, thus will cause potential environmental problems upon disposal. In this work, the optical and electronic properties of biodegradable polymers, conjugated poly(disulfidediamine), were examined via continuous wave laser spectroscopy, FTIR spectroscopy and conductivity measurement. We found that the attachment of a side chain to aromatic ring increases both photo and thermal stability, as well as higher conductivity. Thermal annealing improved the film morphological, photophysical and electronic properties. Photo-induced Absorption (PIA) reveals different features comparing with conventional pi-conjugated polymers. No observation of long-lived photoexcitations such as polarons or triplets which are common with pi-conjugated polymers. Instead, we found the formation of low energy species upon thermal annealing in these biodegradable polymers.

P1.00233 Electron transport and light absorption/emission in molecular complexes, MIGUEL MARTINEZ. Bronx High School of Science, LEV MOUROKH, Physics Department, Queens College of CUNY — In this work, we address photo-assisted electron transport in molecular triads and tetrads connected to the leads. Donor-bridge-acceptor triads are promising candidates for efficient organic solar cells, as the photon absorption makes it possible to transfer electrons against the applied voltage. Deriving and solving numerically the equations of motion for electron creation/annihilation operators, we obtain the parameters of molecular complexes which are optimal for a maximal efficiency of the light harvesting. For donor-bridge-bridge-acceptor tetrads, we determine the conditions for another phenomenon, optical up-conversion. Electron transport along the applied voltage and the photon absorption at one of the bridges facilitates the photon emission at another bridge with higher frequency. Using the same equations of motion approach, we obtain the emitted electromagnetic energy and its dependence on the system parameters.

P1.00234 Nanostructural Patterning Improves the Performance of Non-volatile Polymer Memory Devices, SEUNG HYUN SUNG, BRYAN W. BOUDOURIS, Purdue University — Organic nonvolatile memory devices based on polymer ferroelectric materials are a promising approach toward the development of low-cost memory due to the ease of processing and flexibility associated with the device. Here, we focus on a memory device with a two-component active layer and a diode structure. This ferroelectric diode (FeD) has a nanostructured active layer, composed of ferroelectric and semiconducting polymers, and it can provide easy access to high-performance polymer-based memory devices. In order to create these nanostructured active layers, we have utilized electron beam (e-beam) lithography for the simple fabrication of a desired pattern on the ferroelectric polymer layer. Then, a semiconducting polymer was deposited into the nanoporous ferroelectric layer to complete the ordered heterojunction. By optimizing the nanostructure, the memory retention and ON/OFF current density ratio performance of FeD is greatly enhanced (e.g., the ON/OFF ratio is a factor of 3 greater) over a traditional blended diode. This ability to control the ferroelectric polymer morphology will open new fields of evaluating the relationships between structure and performance in organic memory devices.

P1.00235 Cross-linking high-K fluoropolymer gate dielectrics enhances the charge mobility in rubrene field effect transistors, JIHALA ADHIKARI, MATTHEW GADINSKI, QING WANG, ENRIQUE GOMEZ, Penn State University — Polymer dielectrics are promising materials where the chemical flexibility enables gate insulators with desired properties. For example, polar groups can be introduced to enhance the dielectric constant, although fluctuations in chain conformations at the semiconductor-dielectric interface can introduce energetic disorder and limit charge mobilities in thin-film transistors. Here, we demonstrate a photopatternable high-K fluoropolymer, poly(vinylidene fluoride-bromotrifluoroethylene) (P(VDF-BTFE)), with a dielectric constant between 8 and 11. The bromotrifluoroethylene moiety enables photolinking and stabilization of gate insulator films while also significantly enhancing the population of trans torsional conformations of the chains. Using rubrene single crystals as the active layer, charge mobilities exceeding 10 cm²/Vs are achieved in thin film transistors with cross-linked P(VDF-BTFE) gate dielectrics. We hypothesize that crosslinking reduces energetic disorder at the dielectric-semiconductor interface by suppressing segmental motion and controlling chain conformations of P(VDF-BTFE), thereby leading to approximately a three-fold enhancement in the charge mobility of rubrene thin-film transistors over devices incorporating uncross-linked dielectrics or silicon oxide.

P1.00236 Monte Carlo simulations of charge transport in heterogeneous organic semiconductors, PYIE PHYO AUNG, KIRAN KHANAL, JUTTA LUETTMER-STRATHMANN, Departments of Physics and Chemistry, The University of Akron, Akron, OH 44325-4001 — The efficiency of organic solar cells depends on the morphology and electronic properties of the active layer. Research teams have been experimenting with different conducting materials to achieve more efficient solar panels. In this work, we perform Monte Carlo simulations to study charge transport in heterogeneous materials. We have developed a coarse-grained lattice model of polymeric photovolaticcs and use it to generate active layers with ordered and disordered regions. We determine carrier mobilities for a range of conditions to investigate the effect of the morphology on charge transport.

P1.00237 ABSTRACT WITHDRAWN

P1.00238 ABSTRACT WITHDRAWN

P1.00239 ABSTRACT WITHDRAWN

P1.00240 The impact of P3HT molecular weight and solvent composition on P3HT films processed from binary solvent mixtures, LAWSON LLOYD, MADELEINE GORDON, DAVID BOUCHER, College of Charleston — Recent experimental endeavors have shown that well-ordered P3HT assemblies formed in solution can improve the crystallinity and morphological uniformity of thin films and composites, thereby providing a promising new route to more efficient polymeric optoelectronic materials. We have studied the assembly and crystallinity of two regioregular poly(3-hexylthiophene) (P3HT) samples, M_n ≈ 28 kDa and M_n ≈ 65 kDa, in several different binary mixtures of organic solvents. We use an excitonic coupling analysis of the UV/Vis absorbance spectra to assess the impact that the solvent and the molecular weight of P3HT have on the relative structural order of the polymer assemblies. In addition, we investigate the influence that the solvent composition and the structural order of P3HT aggregates have on the assembly and organization of P3HT films. We use optical and atomic force microscopy techniques to study thin films of P3HT processed from different solvent mixtures. Our results show that relatively small variations to the P3HT solutions can produce significant changes in the morphology and macromolecular structures of the P3HT films.

P1.00241 POLYMERS IN BATTERIES AND ELECTROCHEMICAL CAPACITORS —
P1.00242 In situ Mechanistic Investigation of an Organic Radical Polymer Cathode on Interfacial Charge Transport and Cycling Stability. FEI LI, JODIE LUTKENHAUS, Artie McFerrin Department of Chemical Engineering, Texas A&M University. Organic radical polymers have gained increased attention as cathodes for organic radical batteries due to their fast charge transport and high cycling stability. These features make them a promising alternative to conventional lithium-ion batteries. One polymer of interest is a nitroxide radical polymer, poly(2,2,6,6-tetramethylpiperidinyl-oxymethylacrylate) (PTMA), which is capable of a two-electron transfer process. The specific capacity of PTMA as cathode has a reported value between 77 to 220 mAh/g, depending on the charge/discharge conditions. Most work with PTMA has largely emphasized electrode optimization to improve its capacity by adding highly conducive materials or by designing new forms of radical polymers. There is little molecular level detail on the charge storage process and electrode/electrolyte interfacial activities in such systems. Here, we present the application of in situ characterization techniques towards the charge storage process in PTMA. Electrochemical quartz crystal microbalance with dissipation monitoring (EQCM-D) monitors various electrode physical properties (e.g. mass, shear viscosity) during controlled electrochemical interrogation (cyclic voltmmetry, charge discharge). Electrochemical impedance spectroscopy probes various charge storage and transport events at a range of frequencies and potentials. With this information attained, a clearer picture of charge storage in organic radical cathode batteries can be formed.

P1.00243 Flexible Hybrid Electrodes Containing Vanadium Pentoxide ($V_5O_8$) and an Electron- and Ion-Conducting Diblock Copolymer for Energy Storage. HYOSUNG AN, JARED MIKE, Texas A&M University, Chemical Engineering, KENDALL SMITH, LISA SWANK, YEN-HAO LIN, STACY PESEK, RAFAEL VERDUCZO, Rice University, Chemical and Biomolecular Engineering, JODIE LUTKENHAUS, Texas A&M University, Chemical Engineering. Vanadium pentoxide ($V_5O_8$) is a promising cathode material for lithium-ion batteries due to its high capacity, high energy density, and cost-effectiveness. However, its low lithium-ion diffusion coefficient ($10^{-12}$ - $10^{-13}$ cm$^2$/s), low electronic conductivity ($10^{-2}$ - $10^{-3}$ S/cm), and severe volumetric changes during cycling have hindered its application in practical devices. One way to address these challenges is to incorporate a second active material. For this purpose, poly(3-hexylthiophene)-block-poly(ethylene oxide) (P3HT-b-PEO) block copolymer containing electron- and ion-conducting polymer blocks was introduced to a $V_5O_8$ electrode system. Cathodes are prepared by mixing aqueous dispersions of block copolymer, $V_5O_8$-, and lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) and drop casting. The $V_5O_8$ and P3HT-b-PEO hybrid electrode showed synergistic results, having improved electrochemical storage performance and mechanical property. We also demonstrated a flexible battery prototype using the P3HT-b-PEO/$V_5O_8$ cathode.

P1.00244 Phase Behavior and Electrical Characterization of Solid-State Magnesium Ion Electrolytes from Diblock Copolymers. JACOB THELEN, University of California Berkeley; Lawrence Berkeley National Laboratory, SEBNEM INCEOGLU, Lawrence Berkeley National Laboratory, NITASH BALSARA, University of California Berkeley; Lawrence Berkeley National Laboratory — Batteries utilizing magnesium metal anodes are considered a promising candidate for the next generation of energy storage with performance beyond lithium ion technology. The development of a safe, stable magnesium ion-conducting electrolyte represents one of the major barriers to the advancement of magnesium battery technology. One approach to increasing the safety and stability of electrolytes is to replace flammable organic solvents with more stable polymeric electrolytes. Here we report the synthesis and characterization of solid-state magnesium ion electrolytes derived from diblock copolymers.

P1.00245 Polyhedral Oligomeric Silsesquioxanes – Based Hybrid Electrolytes with Controlled Network Structure. QIWEI PAN, South China University of Technology; Drexel University, CHRISTOPHER LI, Drexel University, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, SOUTH CHINA UNIVERSITY OF TECHNOLOGY TEAM, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, DREXEL UNIVERSITY TEAM — High ion conductivity and mechanical integrity are the most important properties in the application of solid polymer electrolytes (SPEs). We herein report synthesis and characterization of hybrid electrolytes with inorganic polyhedral oligomeric silsesquioxanes (POSS) as the crosslinker. The SPEs were prepared by a facile one-pot reactions between octakis[3-(glycidyloxy)propyl(dimethyl/silyloxy)]silsesquioxane and bis(3-aminopropyl) terminated poly(ethylene glycol) (PEG) in the present of bis(trifluoromethanesulfonylimide) lithium salt (LiTFSI). Uniform distribution of POSS and LiTFSI in the SPEs were confirmed by SEM-BSD and SEM-EDX. We show that both ionic conductivity and mechanical properties of the SPE can be easily tuned by varying POSS contents. Correlation between the SPE network structure and the ionic conductivity and mechanical properties will be discussed.

P1.00246 HIERARCHICAL ASSEMBLY OF BLOCK COPOLYMERS AND SOFT NANOPARTICLES IN SOLUTIONS.

P1.00247 Structure and Ionic Conductivity Evolution of a Block Copolymer Electrolyte during Thermal Annealing. MAHADI CHINTAPALLI, NITASH BALSARA, Univ of California - Berkeley — Mixtures of block copolymers (BCPs) and lithium salts are promising materials for battery electrolytes because they exhibit high ionic conductivity and high modulus. However, since most polymer electrolytes show high conductivities only at temperatures above ambient, it is important to understand how the structure and ionic conductivity of BCP electrolytes evolve during thermal annealing. In situ small angle X-ray scattering and ac impedance spectroscopy were used to characterize a BCP electrolyte, lamellar polysiloxane-block-poly(ethylene oxide) mixed with lithium bis(trifluoromethanesulfonylimide) (LiTFSI), during thermal annealing. As annealing progressed, long range lamellar order and domain spacing increased, and scattering contrast between the two BCP phases decreased. A concomitant decrease in ionic conductivity was observed.

P1.00248 $\beta$-NMR Measurements of Lithium Ion Transport in Thin Films of Pure and Lithium-Salt-Doped Poly(ethylene oxide). IAIN MCKENZIE, TRIUMF, MASASHI HARADA, University of British Columbia, C.D. PHILIP LEVY, TRIUMF, W. ANDREW MACFARLANE, RYAN M.L. MCFADDEN, University of British Columbia, GERALD D. MORRIS, TRIUMF, SHIN-ICHI OGATA, Toyota Central Research and Development Laboratories, Inc., MATTHEW R. PEARSON, TRIUMF, JUN SUGIYAMA, Toyota Central Research and Development Laboratories, Inc. — $\beta$-Detected nuclear spin relaxation of $^{6}$Li$^+$ has been used to study the microscopic diffusion of lithium ions in thin films of poly(ethylene oxide) (PEO), PEO with lithium bis(trifluoromethanesulfonylimide) (LiTFSI), PEO with lithium trifluoracetate (LiTFA) and PEO with lithium trifluoroacetate (LiTFA) with monomer-to-salt ratios of 8:3:1. Hopping of Li$^+$ above ~ 250 K follows an Arrhenius law in all of the films. Diffusion of Li$^+$ is fastest in pure PEO and decreases in order LiTFSI $>$ LiTFA $>$ LiTFA. We observed the activation energy for hopping $(E_A)$ and the intrinsic hop rate (r$_0$) both increasing in order LiTFA $<$ LiTFSI $<$ PEO but the larger r$_0$ outweighs the larger $E_A$ and results in Li$^+$ motion being fastest in the pure polymer. The results will be discussed in terms of the ionicity of the salt.
P1.00249 Increase of the Effective Dispersity in ARB-Type Triblock Copolymer. SANGHOON WOO, HYUNJUNG JUNG, JUNE HUH. Department of Chemical and Biological Eng., Korea University, Seoul 136-713, Korea, DU YEOL RU, Department of Chemical and Biological Eng., Yonsei University, Seoul 120-749, Korea, JOONA BANG. Department of Chemical and Biological Eng., Korea University, Seoul 136-713, Korea — The domain spacing of block copolymer (BCP) has been mainly controlled by molecular weight and block immiscibility. Instead of these traditional variables, we designed a new type of BCP, namely ARB type triBCP, where the R represents the short middle block composed of A and B random copolymers. It was expected that the R block provide the effect of increased “effective” dispersity via compositional distribution leading to an increased domain size compared to the AB dibCP with same MW and dispersity. We prepared various ARB type triBCPs and AB dibCPs having the similar dispersity via living-radical polymerization, and their morphologies were characterized by TEM, SAXS, and GISAXS. As a result, it was shown that the ARB-type triBCP exhibited a significant increase in the domain spacing compared to the AB dibCPs with same MW and dispersity. These results were also compared with theoretical viewpoint.

P1.00250 Control Large Nanoparticle Assemblies in Suparmolecular Nanoparticle Thin Films. JINGYU HUANG, TING XU. University of California, Berkeley — Nanocomposites can generate new properties beyond those offered by organic and inorganic building blocks. Here we meet the demands in functional nanomaterials design. We study the self-assembly of nanoengineered building block and their spatial arrangements. With the recent development, colloidal synthesis and surface modification methods provide inorganic nanoparticles (NPs) with various sizes, shapes, compositions and properties in a facile manner. Block copolymer-based supramolecules further provide more versatile routes to control spatial arrangement of the nanoparticles over multiple length scales. Nanoparticle size is a critical parameter determining the optical and electronic properties. However, most of studies to date focused on nanoparticle smaller than 10 nm in size. Here, our recent studies showed that the assembly of nanoparticles with size larger than 10 nm can be achieved in the supramolecular nanocomposite thin films by finely tuning the ligand-polymer interactions and the sample treatment conditions. Both the overall morphology of the nanoparticle assemblies and inter-particle distances can be readily tailored. These new results opened a viable approach to construct functional materials using nanoparticles with different quantum confinement effects.

P1.00251 Crystallization Driven Responsive Janus Assembly. HAO QI, SHAN MEI, CHRISTOPHER LI, Drexel university, SOFT MATERIALS LAB TEAM — Responsive and dynamic nanostructures are ubiquitous in Nature, and they are also utter importance for applications such as sensing and drug delivery. Herein we report a series of hierarchical block copolymer nanostructure that is able to undergo 2D (sheet-like) to 3D (bowl-like) shape changing upon specific external stimuli. Freestanding Janus nanosheets were prepared via crystallization-driven self-assembly of poly(ε-caprolactone)-b-poly(acrylic acid) (PCL-b-PAA) and subsequent crosslinking and disassembly process. Due to the mechanical contrast between the two layers, and the chemical responsiveness of the PAA layer, such Janus nanosheets transform a mechanically stable nanobowl upon pH change. Atomic force microscopy and transmission electron microscopy results confirmed the Janus structure and bending property. Detailed structural characterization and shape changing mechanisms will be discussed.

P1.00252 Meso-scale Modeling of Self-assembly of Polymer-Grafted Nanoparticles. DERRICK MANCINI, Illinois Inst of Tech, SANKET DESHMUKH, SUBRAMANIAN SANKARANARAYANAN, Argonne National Laboratory — We develop meso-scale models to explore the self-assembly behavior of polymer-grafted nanoparticles. Specifically, we study nanoparticles with grafts of the thermo-sensitive polymer N-isopropylacrylamide (PNIPAM), which undergoes a coil-to-globule transition across the LCST at around 305 K. The atomic-scale mechanism of the coil-to-globule transition of polymers grafted nanoparticles and their interactions (agglomeration, assembly behavior) with other particles that are in its vicinity is poorly understood, yet knowledge about these interactions would enable designing novel self-assembled materials with well-defined structural and dynamical properties. Additionally, the effects of chemical nature, geometry, and morphology of the nanoparticle surface on the conformational transition of thermo-sensitive polymers is also unknown. We report on 1) development of all-atom models of polymer-grafted nanoparticles to conduct MD simulations at atomic-levels and 2) perform mesoscopic scaling of the conformational dynamics resulting from the atomicistic simulations with the aid of coarse-grained or meso-scale models of PNIPAM and its composites. Coarse-grained simulations allow modeling of larger assemblies of polymer-grafted nanoparticles over longer time scales.

P1.00253 Mesoscopic Polymer Assemblies. SATYAN CHoudhARY, JONATHAN PHAM, ALFRED CROSBY, University of Massachusetts Amherst — Materials encompassing structural hierarchy and multi-functionality allow for remarkable physical properties across different length scales. Mesoscopic Polymer (MSP) assemblies provide a critical link, from nanometer to centimeter scales, in the definition of such hierarchical structures. Recent focus has been on exploiting these MSP assemblies for optical, electronic, photonics and biological applications. We demonstrate a novel fabrication method for MSP assemblies. The current fabrication methods restrict the length scale and volume of such assemblies. A new method, which we developed uses a simple piezo-actuated motion for de-pinning of a polymer solution trapped by capillary forces between a flexible blade and a rigid substrate. The advantages of new method include ability to make MSP of monodisperse length and to fabricate sufficient volumes of MSP to study their physical properties and functionality in liquid dispersions. We demonstrate the application of MSP as filler for soft materials, providing rheological studies of the MSP with surrounding matrices.

P1.00254 SURFACES INTERFACES AND POLYMERIC THIN FILMS –

P1.00255 Structure of polymer brushes on flat substrates and its dependence on the conditions of the surface-initiated polymerization. ROHAN PATIL, JIRI SROGL, North Carolina State Univ, DOUGLAS KISEROW. US Army Research Office, JAN GENZER, North Carolina State Univ — We demonstrate an efficient method of degrafting surface anchored poly(methyl methacrylate) brushes using tetra butyl ammonium fluoride (TBAF). The grafted polymers are grown using standard atom transfer radical polymerization method which provides good control by varying the catalyst ratio (Cu(H):Cu(II)). The sample surface has been characterized before and after degrafting by means of X-ray photoelectron spectroscopy, ellipsometry, and time-of-flight secondary ion mass spectrometry. The degrafted polymer has been characterized using highly sensitive size exclusion chromatography, which provided information about the complete molecular weight distribution. The grafting density of PMMA chains is calculated as 0.517 chains/nm². The study of the dependence of the grafting density on the ATRP inhibitor/catalyst ratio evidences to an effect of early termination of the growing chains when a lower control on the polymerization step is exercised. Control of the degrafting process is provided by tuning time, temperature, concentration of the TBAF, which - in conjunction with spatial control - allows for the creation of polymer brush patterns and surface gradients.

P1.00256 Tribological properties of adsorbed PEO nanolayers on planar solids. WENDUO ZENG, NAISHENG JIANG, JAKE LINDBERG, MAYA K. ENDOH, TADANORI KOGA, State University of New York at Stony Brook — We report tribological properties of irreversibly adsorbed poly(ethylene-oxide) (PEO) nanolayers onto planar Si substrates. The adsorbed nanolayers (~ 3 nm in thickness) were derived from spin-coat polymer thin films (~ 50 nm in thickness) via thermal annealing and subsequent solvent leaching with water. We characterized the formation process of the adsorbed nanolayers and the detailed surface/film structures by using x-ray reflectivity, grazing incidence x-ray diffraction, and atomic force microscopy. In addition, the contact angle and adhesive property of the adsorbed layers were characterized. We will discuss the structure-property relationship of the adsorbed nanolayers.

1 T. K. acknowledges the partial financial support from NSF Grant No. CMMI-1332499.
P1.00257 Effects of the Adsorbed Polymer Nanolayers on the Dewetting of Polystyrene Thin Films. JUSTIN CHEUNG, JIAXUN WANG, NAISHENG JIANG, MAYA ENDOH, TADANORI KOGA, Stony Brook University — It was previously reported that irreversibly adsorbed polymer nanolayers can be produced on solid substrates by thermal annealing. This study sought to determine the impact of the adsorbed nanolayers on film stability of ultrathin polystyrene (PS) films. A series of bilayers composed of the bottom PS adsorbed nanolayers and PS overlayers with different molecular weights were prepared as model systems. The surface structures of the bilayer films annealed above the bulk glass transition temperature were analyzed by using optical and atomic force microscopes. We will discuss the unique roles of the adsorbed polymer chains in the stability of the liquid thin films. 1 T. K. acknowledges the partial financial support from NSF Grant No. CMMI-1332499.

P1.00258 Coatings with Thermally Switchable Surface Energy Produced From Block Copolymer Membranes. RALEIGH DAVIS, RICHARD REGISTER, Princeton University — Polymer-based coatings are employed across a wide array of sectors. One application of such coatings is to impart a prescribed surface energy, i.e., hydrophilic or hydrophobic character. The present work explores an approach to create surfaces with thermally switchable wetting behavior by employing coatings based on block copolymers which possess both hydrophilic and hydrophobic segments. The amphiphilic block copolymers were synthesized by coupling allyl-ended poly(ethylene oxide) (PEO) and hydride-ended poly(dimethylsiloxane) (PDMS) oligomers via a Pt catalyst. One PEO-PDMS diblock possessed an order-disorder-transition-temperature (T_{ODT}) of 64°C as characterized by small angle x-ray scattering. Above the T_{ODT} the polymer is a disordered melt, but below this temperature it self-assembles into alternating lamellae with a repeat spacing of 7.7 nm. When cooled through the T_{ODT} in vacuum or dry air, the PDMS-enriched domains wet the film's surface, producing a hydrophobic surface with a contact angle (CA) ≈ 90° as measured from CA goniometry. However, when cooled under water or in humid air, a PEO-rich hydrophilic surface is produced, yielding CAs ranging from 20-40°. The coatings can then be reversibly switched between the two states by reheating above the T_{ODT}, exposing to the appropriate environment, and re-cooling, ideally “locking in” the structure until the next processing cycle. The T_{ODT}, and thus the switching temperature, can be continuously tuned by blending with PEO-PDMS diblocks of different molecular weights.

P1.00259 Potential Energy Calculations for Water Adsorption on Poly (methyl methacrylate)$.^1$ MATEUSZ J. ZUBA, PATRICK HOWARD, BRIAN FAMILIO, THORIN KANE, ROSS L. NETUSIL, CAROLINA C. ILIE, State University of New York at Oswego — The generosity of the NOYCE Research Grant enabled me to focus on the study of various polymers. The main goal was to study the molecular orbitals of poly (methyl methacrylate) (PMMA) and calculate the energy band gap. We also performed the potential energy calculations for our system: two polymer chains and water molecules. We obtained the activation energy from thermal desorption spectra of water on poly (methyl methacrylate) by employing Arrhenius analysis. 1 NSF - Noyce Scholarship Program

P1.00260 Macroion Interaction at Polyelectrolyte Brush Interfaces. CHEN QU, Univ of Notre Dame — The effect of macromolecules, including synthetic polyelectrolytes, DNA and proteins, on the structure and surface properties of charged polymer thin films remains inadequately understood partially due to the complexity involving the hydrophobic effect and the conformational change of polymeric macromolecules. In this work, we explore a group of inorganic nanocluster based macromolecules, hydrophilic polyoxometalates (POMs) of robust nanocluster structure and carrying high surface charges (~ 2-42 negative charges) to investigate their interaction with surface tethered poly-2-vinylpyridine (P2VP) brush-like thin films immersed in aqueous solution. We observe the collapse of swollen P2VP chains by adding POM macroions of increased concentration by AFM, QCM and contact goniometer measurements, in sharp contrast to the increased chain stretching by adding monovalent salts. A careful comparison is made between distinct POMs based on their charge, size and chemical nature. These findings serve as a good reference for theoretical model modification and design of new mesoporous composite membranes.

P1.00261 Elastocapillarity: Adhesion and Wetting in Soft Polymeric Systems$.^1$ ZHEN CAO, Univ of Connecticut - Storrs, MARK STEVENS, Sandia National Laboratories, ANDREY DÖBRYNIN, Univ of Connecticut - Storrs — We study interactions of nanoparticles with adhesive elastic substrates by using molecular dynamics simulations and theoretical calculations. The deformation of nanoparticles and substrates are obtained as a function of the nanoparticle and substrate shear modulus, nanoparticle size, and strength of interactions. There are two different interaction regimes between nanoparticles and substrates. The classical JKR model can be applied to describe adhesion of strongly cross-linked large nanoparticles on rigid substrates when small nanoparticle deformations and substrate indentation take place. In this adhesion regime the deformation of nanoparticles and substrates is determined by balancing the elastic energy of deformation and the work of adhesion between a nanoparticle and a substrate. However, for the weekly cross-linked (soft) systems, the change of the surface energy of nanoparticle and substrate could play an important role in controlling nanoparticle-substrate interactions. In this so-called wetting regime the interaction between nanoparticle and substrate is determined by the surface tension of substrate or nanoparticle and the work of adhesion. We developed an analytical model describing crossover between adhesion and wetting regimes. In the framework of this model a crossover between different interaction regimes is controlled by a universal dimensionless parameter. 1 NSF # DMR-1004576 DMR-1409710

P1.00262 ABSTRACT MOVED TO V1.00023 —

P1.00263 Understanding “grafting through” polymerization reactions involving surface-bound monomers. PREETI DATTA, JAN GENZER, North Carolina State Univ — “Grafting through” polymerization is based on a bulk radical polymerization reaction utilizing a self-assembled monolayer that contain polymerizable units. Free polymer chains formed in solution can incorporate the surface-bound monomers, and thereby, get covalently bonded to the surface. As more growing chains attach to the surface-bound monomers, an immobilized polymer layer is formed on the surface. We use a combination of computer simulation and experiments to comprehend this process. Specifically, we report on the effect of spatial density of the surface-monomers on the formation of the surface-bound polymers. We use a lattice-based bond fluctuation model with periodic boundary conditions to simulate such systems. For experimental validation, we create gradients of density of methacrylate units on flat Si wafers using silane chemistry. The proximity of the surface-bound polymerizable units promotes the “grafting through” process but prevents more free growing chains to “graft to” the polymerizable units. Our studies indicate that these two counter-active effects balance each other and do not affect the overall density of the surface-bound polymer layer, except in case of the highest theoretical packing density of surface-bound monomers.

P1.00264
The work of adhesion and separation between soft elastomers is commonly used soft elastomers PDMS (Sylgard 184) and Ecoflex 0300 are obtained with the measured pull-in and pull-off forces using a dynamical mechanical analyzer (DMA). The effect of crosslinking density and solvent extraction are examined. It is found that the pull-in adhesion stays more or less constant for all contact pairs we measured. While the effect of crosslinking density is not significant for pristine PDMS, it is very obvious that the higher self-adhesion can be found in less crosslinked PDMS after solvent extraction. Such an effect is even more drastic for PDMS-to-Ecoflex adhesion. A unified adhesion mechanism is proposed to explain these complex adhesion behaviors. It is concluded that the chain-matrix interaction is the most effective adhesion mechanism compared to chain-chain or matrix-matrix interactions and the three interactions are exclusive to each other.

*This work is supported by the NSF CMMI award under Grant No. 1301335.

**P1.00265 Programming Surface Energy Driven Marangoni Convection in Polymer Thin Films to Generate Topographic Patterns**

CHAEBIN KIM, DUSTIN JANES, TALHA ARSHAD, JOSHUA KATZENSTEIN, NATHAN PRISCO, DANA MCGUFFIN, ROGER BONNCEACZE, CHRISTOPHER ELLISON, University of Texas at Austin - McKetta Department of Chemical Engineering — The Marangoni effect describes how fluid flows in response to gradients in surface energy. We recently developed a method for photochemically preprogramming spatial surface energy patterns in glassy polystyrene (PS) thin films. UV irradiation through a mask selectively dehydrogenates the PS, thus increasing surface energy in the UV exposed regions compared to the unexposed regions. After heating the film to the liquid state, transport of polymer occurs from regions of low surface energy to regions of high surface energy. This method can be harnessed to rapidly manufacture polymer films possessing prescribed three-dimensional topographies reflective of the original light exposure pattern. To quantify and verify this phenomenon, a theoretical model that gives a more thorough understanding of the physics of this process, its limits and ways to apply it efficiently for various target metrics will also be presented along with comparisons between theoretical predictions and experimental observations. Finally, while PS dehydrogenation can be used to produce a variety of topographical patterns, judicious selection of the photosensitizing compounds in an otherwise transparent polymer expands the use of this method to more readily available light sources.

**P1.00266 BLOCK COPOLYMER THIN FILMS —**

**P1.00267 Effect of Hydrogen Bonding on the interfacial width of PS-b-PMMA Block Copolymer Microdomains**

KYUSEONG LEE, SUNGHYUN HAN, SANGSHIN JANG, JICHEOL PARK, JONGHEON KWAK, JIN KON KIM, Pohang Univ of Sci & Tech — Sharp interface between two blocks in block copolymer nano pattern is one of the important issues because of strong demand in industrial applications to nano-patterning. We utilized hydrogen bonding between N-(4-aminomethyl-benzyl)-1-hydroxymethyl-bezamid (BA) and urea (U) at the interface of polystyrene-block-poly(methyl methacrylate) copolymer (PS-PMMA). For this purpose, we first synthesized PS by ATRP method, then the end group was converted to amino group. Next, it was reacted with BA, followed by reaction with 4-pentynoic acid, resulting in alkyne-terminated polymer/substrate interactions on silica substrates, and the other set possessing repulsive polymer/substrate interactions using poly(cyclohexylethylene) substrate. D was measured in the melt state (Tg = 48 K) and the D of thick films were identical to the bulk value regardless of the substrate type. The D of a ~19 nm thick film on a repulsive substrate was four times larger than its bulk value while Tg was increased by about 10-15 K. In contrast, attractive substrates typically do not affect D or Tg of PIbMA.

**P1.00268 Long-Range Ordering of Block Copolymers on Well-Controlled Patterned Substrates**

DONG-EUN LEE, NAM-KYUN KIM, JINA PARK, DONGHYUN LEE, Dankook University — In this study, we achieved long-range ordering of block copolymers (BCPs) by combining solvent-annealing process and well-controlled patterned substrates. Nano-lines of poly(tetrafluoro ethylene) (PTFE) were firstly fabricated in large area as a PTFE bar was rubbed on Si substrates at 340 °C. The amplitude and pitch distance of PTFE nanolines were around 17 nm and 150 nm, respectively. Then, asymmetric polystyrene-block-poly(2-vinylpyridine) copolymers (PS-b-P2VP) were subsequently spin-coated on the patterned substrates after a thin layer of poly(vinyl alcohol) (PVA) was prepared on the PTFE patterned substrates to enhance the wettability of BCP thin films. As BCP thin films were solvent-annealed in vapor of organic solvents, highly ordered BCP nanostructures oriented either parallel or perpendicular to the surface were generated in large area. In addition, the nanopatterns were successfully transferred to the underlying PVA layer or Si substrate by dry etching. Thus, the resulting nanopatterns were utilized as templates to synthesize inorganic nanostructures. The ordering behavior of BCP thin films on the patterned substrates was characterized by using AFM, SEM and GI-SAXS.

**P1.00270 Macroscopic Alignment of Cylindrical Block Polymer Thin Film via Raster Solvent Vapor Annealing with Soft Shear**

MING LUO, DOUGLAS SCOTT, THOMAS EPPS, University of Delaware — One challenge associated with the utilization of block polymer thin films in nanotechnology is the difficulty of orienting and aligning the self-assembled nanostructure on macroscopic length scales, as block polymers typically self-assemble in an isotropic manner in the absence of surface forces and external fields. In this work, macroscopic alignment of block polymer cylinders was achieved through raster solvent vapor annealing with soft shear. Spatial control over nanoscale structures was accomplished through the application of a solvent vapor delivery nozzle, poly(dimethylsiloxane) shearing pad, and motorized stage. Complex patterns such as dashes, cross-shapes, and curved structures were demonstrated along with the possibility of scale-up for industry production. The simplicity of instrumentation and the versatility of patterns possess advantages over other directed self-assembly methods that are currently available.
P1.00271 Tracking Solvent Uptake in Block Polymer Thin Films during Solvent Vapor Annealing. CAMERON SHELTON, University of Delaware, RONALD JONES, JOSEPH DURA, National Institute of Standards and Technology, THOMAS EPPS, University of Delaware — A key goal in the block polymer (BP) thin films community is the design of a template-free, universal annealing method to control nanoscale self-assembly over large length scales. Solvent vapor annealing (SVA) offers a unique solution to this challenge with its ability to tune substrate surface, free surface, and polymer-polymer interactions by exposing films to appropriate solvents. However, there is little understanding of how the solvent behaves during the SVA process. In this work, we utilized the combination of deuterated solvents with small-angle neutron scattering (SANS) and neutron reflectometry to track solvent uptake in poly(styrene-b-isoprene-b-styrene) thin films. Two solvents were chosen for this analysis: d-hexane (isoprene selective) and d-benzene (styrne selective). Our work has shown that solvent choice and partial pressure have a significant impact on how solvent segregates within individual polymer domains and the film as a whole, directly impacting the restructuring of polymer domains. This work provides further understanding of the mechanism behind SVA, thereby making it easier to select appropriate conditions for desired self-assembly control.

P1.00272 ABSTRACT WITHDRAWN

P1.00273 Optimization and Characterization of Self-assembled Triblock Polymer Membranes with Chemically-Tunable Pore Walls for Nanofiltration Applications. JESSICA SARGENT, RYAN MULVENNA, RAFAEL PRATO, Purdue University, JACOB WEIDMAN, WILLIAM PHILLIP, University of Notre Dame, BRYAN BOUDOURIS, Purdue University — The field of block polymer-based membranes for separation applications has grown considerably in the past several years. However, decreasing the domain sizes of these membranes to below 5 nm has proven to be a challenge in many instances. Here, we demonstrate that a triblock polymer, polyisoprene-polystyrene-block-poly(tert-butyl methacrylate) (PI-PS-PIBMA), can be utilized to form nanoporous membranes capable of high flux and high selectivity based on both size and chemical composition. By controlling the synthesis, solution self-assembly, and non-solvent induced phase separation of these polymers, a scalable fabrication process can produce the thin-film membranes that feature monodisperse pores approaching 1 nm in diameter, tunable pore-wall chemistry, good mechanical stability, and chlorine degradation resistance. The PI-PS-PIBMA functionality can further be converted to a number of side chain functionalities through simple coupling chemistry to produce membranes with specific chemical and structural characteristics tailored to meet the needs of various applications. In particular, these membranes provide a promising, inexpensive platform for chlorine degradation and fouling-resistant membranes for water purification that can be produced on an industrial scale.

P1.00274 Thin Films of Bottlebrush Block Copolymers with Homopolymer. GAJIN JEONG, Univ of Mass - Amherst, BENJAMIN R. SVEINBJORNSSON, ROBERT HOWARD GRUBBS, California Institute of Technology, THOMAS P. RUSSELL, Univ of Mass - Amherst, POLYMER SCIENCE AND ENGINEERING DEPARTMENT, UNIVERSITY OF MASSACHUSETTS AMHERST TEAM, CHEMISTRY DEPARTMENT, CALIFORNIA INSTITUTE OF TECHNOLOGY TEAM — We have investigated the self assembled structures of bottlebrush block copolymers (BrBCPs) in thin films by blending deuterated homopolymer. By use of neutron reflectivity (NR), the assemblies with microdomain oriented parallel to the substrate, the distribution of the homopolymer in the bottlebrush block copolymer was obtained. Polynorbornene-backbone-based bottlebrush BCPS with polylactide (PLA) and polystyrene (PS) side chains of different molecular weights were investigated. Small angle x-ray scattering was used to complement the NR studies.

P1.00275 Investigation of solvent annealing time dependence on morphology formation in polystyrene–block–polylactide thin films. RYAN GNABASIK, GUNNAR NELSON, ANDREW BARUTH, Creighton Univ — Solvent vapor annealing exposes a block polymer film to the vapors of one or more solvents, swelling the film. This process increases polymer mobility and can direct a self-assembly process by tuning the surface energy. Despite its efficacy to produce well-ordered, periodic nanostructures, no standardized production scheme exists. This is primarily due to a lack of understanding the intricate role multiple, incommensurate parameters play. By analogy to thermal annealing of elemental solids, the time a thin film spends in an equilibrium solvent concentration is one factor that will dictate the degree of ordering. To elucidate, optimized annealing conditions for perpendicular cylinder forming polystyrene-block-polylactide exist at solvent concentrations just below the order-disorder transition, where the kinetic and thermal processes required for recrystallization and crystal growth are optimally fast (similar to thermal annealing). By use of a purpose-built, climate-controlled solvent annealing chamber, we map out the annealing time dependence for non-optimized solvent concentrations. Namely, at lower solvent concentrations, where mobility is limited, longer times are required for large lateral correlation lengths. In situ spectral reflectance monitors solvent concentration, regulated via a mass-flow controlled solvent inlet, offering precision control over annealing. Atomic force microscopy, in conjunction with O2 plasma etching, provides 3-dimensional imaging of the nanoscale morphology. This work was funded by NASA Nebraska Space Grant.

P1.00276 Controlling Structure in Sulfonated Block Copolymer Membranes. PHUC TRUONG, GILA STEIN, Univ of Houston, JOE STRZALKA, Argonne National Lab — In many ionically block copolymer systems, the strong incompatibility between ionic and non-ionic segments will trap non-equilibrium structures in the film, making it difficult to engineer the optimal domain sizes and transport pathways. The goal of this work is to establish a framework for controlling the solid-state structure of sulfonated pentablock copolymer membranes. They have ABCBA block sequence, where A is polystyrene, B is poly(hydrogenated isoprene), and C is poly(styrene sulfonate). To process into films, the polymer is dissolved in toluene/n-propanol solvent mixtures, where the solvent proportions and the polymer loading were both varied. Solution-state structure was measured with small angle X-ray scattering (SAXS). We detected micelles with radii that depend on the solvent composition and polymer loading. Film structure was measured with grazing-incidence SAXS, which shows (i) domain periodicity is constant throughout film thickness; (ii) domain periodicity depends on solvent composition and polymer loading, and approximately matches the micelle radii in solutions. The solid-state packing is consistent with a hard sphere structure factor. Results suggest that solid-state structure can be tuned by manipulating the solution-state self-assembly.

P1.00277 Capillary forces induced wrinkling onto ultrathin single and bilayer polymer films. JOOYOUNG CHANG, JOSEPH PAULSEN, KAMIL TOGA,1 NARAYANAN MENON, THOMAS RUSSELL, Univ of Mass - Amherst — We have studied wrinkling phenomena on ultrathin polymer sheets floated onto the aqueous media. As previously studied (Science, 2007, 317(5838), 650–653, and Soft Matter, 2013, 9, 8289–8296), the capillary forces of a water droplet placed on a floating sheet generate compressive hoop stresses, causing the sheet to wrinkle. In our current work, we investigate this phenomenon over a broader range of film thicknesses (7 nm to 950 nm) of Polystyrene (PS), Poly(methyl methacrylate) (PMMA), as well as with PS/PMMA bilayers. We report that the Young’s modulus of PS (Mw: 97K) inferred from the wrinkle pattern is not significantly affected even if the thickness of PS is less than 10 nm. Furthermore, we also show that the type of the polymer (i.e. PS or PMMA) of the bottom layer of the bilayer system affects the length of the wrinkles.

P1.00278 POLYMER COMPOSITES —
P1.00279 Electrical Properties of PVDF Based Nanocomposites, JERRY CONTRERAS, HEINRICH D. FOLTZ, YUNPING DUAN, Dalian University of Technology, China, HASINA F. HHUQ, STEVEN C. TIDROW, MIRCEA CHIPARA, The University of Texas Pan American — Nanocomposites based on polyvinylidene fluoride (PVDF) have been obtained by melt mixing, loading the polymeric matrix with various weight fraction (between 0 % and 40 %) of different fillers (multiwalled carbon nanotubes, carbon nanofibers, and barium titanate). Pellets of nanocomposites have been obtained by hot pressing at about 175 °C. Copper contacts have been deposited on the as obtained pellets and the electrical features have been measured by using the two point technique. PVDF is a semicrystalline ferroelectric and piezoelectric polymer with a glass transition temperature of -35 °C and a melting temperature of about 175 °C. Electrical measurements have been performed in a wide range of frequencies starting from dc to ac (up to about 250 MHz). The dependence of the resistivity and dielectric constant on frequency and temperature (between -50 °C to 150 °C) was investigated in detail. Supplementary DSC, WAXS, and Raman data provided detailed information regarding the effect of fillers on phase transitions (glass, crystallization, and melting) and crystalline composition/structure of these nanocomposites.

P1.00280 Additive-Driven Assembly of Block Copolymer and Nanoparticles: Influence of Nanoparticle Size and Loading1, YUE GAI, Univ of Mass - Amherst, YING LIN2, 3M, JAMES WATKINS3, Univ of Mass - Amherst — Additive-driven assembly of block copolymer (BCP)/nanoparticle (NP) composites in which functionalized NPs exhibiting strong hydrogen bond interactions with one domain of the BCP has been shown to strengthen phase segregation and yield well-ordered materials at high NP loadings. Here we report a systemic study of how phase behavior and NP distribution in BCP/ NP composites are influenced by the NP size, NP loading and block copolymer domain size. 2nm, 5nm, 9nm and 15nm diameter Au nanoparticles at loadings ranging from 10% to 50% weight percent, in polystyrene-block-poly (2-vinyl pyridine) block copolymers with domain spacing ranging from 14 nm to 75 nm were used in the investigation. We find that strong interactions enable the incorporation of larger diameter NPs with respect to domain size as compared to systems in which interactions between the NP and BCP are weak or enthalpically neutral. 1This work was supported by NSF Center for Hierarchical Manufacturing at the University of Massachusetts, Amherst 2previous post-doc in Univ of Massachusetts, Amherst 3PI

P1.00281 Mechanically Robust Polymer-Graphene Aerogels, HEONJOO HA, University of Texas at Austin - McKetta Department of Chemical Engineering, KADHIRAVAN SHANMUGANATHAN, National Chemical Laboratory, Pune, Maharashtra, India, CHRISTOPHER ELLISON, University of Texas at Austin - McKetta Department of Chemical Engineering — Graphene oxide (GO) aerogels are particularly interesting due to their light weight and excellent performance in various applications, such as environmental remediation, super-hydrophobic and super-oleophobic materials, energy storage, etc. However, GO aerogels are generally weak and delicate which complicates their handling and potentially limits their application outside the research lab. The focus of this work is to synthesize mechanically stable aerogels that are robust and easy to handle without substantially sacrificing their low density. To overcome this challenge, we found that by intermixing a small amount of readily available and thermally crosslinkable manufacturing polymer can enhance the mechanical properties without disrupting other characteristic intrinsic properties of the aerogel itself. This method is a simple straightforward procedure that does not include any tedious chemical reactions or harsh chemicals. Furthermore, we will demonstrate the performance of these materials as a super-absorbent and pressure sensor.

P1.00282 Life-time of the bound layer in nanocomposites, DAN ZHAO, JACQUES JESTIN, SANAT K. KUMAR, Columbia University — It is now well accepted that an effectively irreversibly adsorbed monolayer of polymer forms when a polymer melt is intimately mixed with nanoparticles, in the limit where their enthalpic interactions are favorable. This bound layer has been postulated as being a central player in many of the highly favorable properties that result from polymer based nanocomposite materials. We investigated well-defined nanocomposites formed with different combinations of deuterated and hydrogenated polymers (P2VP and PMMA) and silica nanoparticles. SANS, in conjunction with contrast variation, then provides a direct means of probing the structure of the bound layer as a core-shell and its exchange kinetics with bulk (unbound) chains with annealing time and temperature. SAXS directly provides information on the particle-particle partial structure factor and particle dispersion. Thermodynamic equilibrium of the bound layer is reached one day at 150 °C while its exchange life time is ~ one hour at 180 °C.

P1.00283 POLYMER NANOCOMPOSITES: ACTIVE PARTICLES AND DYNAMICS —

P1.00284 Unusual dielectric loss properties of carbon nanotube - polyvinylidene fluoride composites in low frequency region (100 Hz < \( f < 1 \) MHz)1, GUANG-LIN ZHAO, YI ZHEN, JUAN ARREDONDO, Physics Department, Southern University and A&M College — Systematic investigations on the dielectric properties of multi-walled carbon nanotubes (MWCNTs)-polyvinylidene fluoride (PVDF) composites with a wide MWCNT concentration range (2-9wt%) have been carried out. It was revealed that the dielectric constant are increased by the addition of an appropriate amount of MWCNTs at room temperature. However, when the concentration of MWCNTs in the composites reaches above 5wt%, negative dielectric constants and large dielectric loss in the composites are observed in the low frequency range. The ferroelectric CNT-PVDF polymer composites containing more than 5 wt% MWCNTs have a strong dielectric absorption, which has the potential for acoustic applications. 1The work was funded in part by AFOSR (Award No. FA9550-09-1-0367) and by NSF LASIGMA Project (Award No. EPS-1003897, NSF92010-15-RII-SUBR).

P1.00285 Dispersion of bimodal polymer brushes functionalized anisotropic gold nanoparticles in polymer nanocomposites1, LILI ZHU, Peking University Shenzhen Graduate School, GI XUE, Nanjing University, LINDA REVEN, McGill University — Polymer nanocomposites (PNCs), which are composed of the nanofiller component and polymer matrix, have attracted growing interests due to their fascinating properties. Great efforts have been made to achieve high compatibility between the nanofillers and the polymer matrix. The dispersion of spherical gold nanoparticles (GNPs) in the matrix have been extensively studied, while there are few studies using anisotropic GNPs. The goal of this work is to produce homogeneous PNCs of anisotropic NPs in stimuli responsive polymer matrix. We compared the dispersion of gold nanoprisms (GNPRs) with single and bimodal poly(2-vinylpyridine) P2VP brushes. Bimodal brushes consisted of mixture of low and high molecular weight (Mw) polymers. GNPRs with P2VP were dispersed into polymer matrix and the Mw of the matrix was systematically varied to investigate the Mw effect. UV-Visible-Near Infrared spectroscopy was utilized to monitor the special plasmonic properties and architectures of GNPRs. The dispersion and morphology of PNCs were characterized by electron microscopy. This work will help to establish the correlations between the properties of anisotropic NPs (shape and protecting ligands) and the miscibility of corresponding PNCs. 1We gratefully acknowledge the National Science Foundation of China (nos.21404002)
P1.00286 Time-resolved WAXD studies on the crystallization of isotactic polypropylene/graphene nanocomposites. SHOTARO NISHITSUJI, MAYA ENDOH, YICHEN GUO, MIRIAM RAFAILOVICH, TADANORI KOGA, Department of Materials Science and Engineering, Stony Brook University — Graphene is one layer of carbon atoms, which has good electronic, thermal conductivity and mechanical properties. By adding graphene to isotactic polypropylene (iPP), the mechanical and electrical properties of the polymer are significantly improved. To further achieve high performance of iPP/graphene nanocomposites (“NCs”), it is important to investigate the relationship between the crystalline structure of iPP and the mechanical property of the iPP/graphene NCs. In this study, the effect of the graphene on the crystallization behavior of the polymer was investigated by using time-resolved wide angle X-ray diffraction (WAXD). The iPP/graphene NCs with different weight ratios of graphene were prepared by using a twin screw extruder. After temperature jump from 210 °C (>Tm) to 170 °C, the melt-crystallization process was observed by in situ WAXD. The results showed that the crystalline structure of all the samples was still α-form that is the same as the neat PP, while the ratios of the diffraction peaks are quite different from those of the neat PP. We will discuss the detailed structure in this presentation.

P1.00287 Rheology and Phase Transitions in Highly Filled Additive/Block Copolymer Composites. BENJAMIN M. YAVITT1, ROHIT KOTHARI2, H. HENNING WINTER3, JAMES J. WATKINS4, University of Massachusetts Amherst — We have recently demonstrated that strong, segment-specific interactions between multi-functional additives (organics, nanoparticles and nanotubes) and one segment of a block copolymer can yield highly filled, well-ordered composites. In this study we used rheology to determine phase transitions and materials properties in systems containing high volume fractions of nanoparticles that are not accessible in other ways. We utilized well-defined surface functionalized nanoparticle systems by which we can assess the role of the number, strength, and surface density of functional groups on the phase behavior and mechanical properties of the composites. From this study, we developed an understanding of the interactions and structure between nanoparticles and block copolymer, and the mechanisms by which these characteristics are affected by temperature.

P1.00288 PEO-MWCNTs Nanocomposites: The Effect of the Nature of Solvent on the Morphology and Physical Properties of Nanocomposites. ALFONSO SALINAS, CHARLES CARTWRIGHT, KEVIN L. NEWCOMBE, MIRCEA CHIPARA, IBRAHIM ELAMIN, JAMES HINTHORNE, DORINA M. CHIPARA, KAREN LOZANO, The University of Texas Pan American — Polyaniline (PANI) nanocomposites have been obtained by dissolving the polymer within selected solvents (water, ethanol, toluene, and chloroform), addition of the nanofiller (Multiwalled Carbon Nanotubes: MWCNTs), dispersion of the as obtained mixture by stirring at 500 rotation per minute for 1 h followed by a sonication for 30 minutes using a high power sonicator (500 W), and solvent evaporation in an oven at 110 °C, for 10 h. Nanocomposites containing 0 to 40 wt. MWCNTs have been obtained and investigated. Scanning Electron Microscopy was used to assess the dispersion of MWCNTs within the polymeric matrix. Wide Angle X-Ray Scattering, Raman, FTIR, and UV-VIS were used to characterize the crystalline structure and molecular/atomic motions in the as obtained samples. Differential Scanning Calorimetry was used to estimate the glass, crystallization, and melting temperatures. Thermal stability will be questioned by thermogravimetric analysis. The effect of the nature of the solvent on the dispersion of nanotubes and on the physical properties of the as obtained nanocomposites will be analyzed in detail.

P1.00289 Photo-actuating waveguiding fibers based on light responsive hydrogels. YING ZHOU, ADAM HAUSER, Uni of Mass - Amherst, NATHAN RASMUSSEN, MARK KUZYK, Washington State University, RYAN HAYWARD, Uni of Mass - Amherst — The combination of light-absorbing nanoparticles with thermally sensitive hydrogels has been widely explored as a strategy for photo-thermal actuation. Here, we employ a system of photo-crosslinkable copolymers containing pendant benzophenone units to prepare planar waveguiding polymethylmethacrylate(PMMA) fibers patterned with poly(N-isopropyl acrylamide) (PNIPAM) copolymer hydrogels containing Au nanoparticles. These structures show both thermally- and photo-actuated bending behavior due to swelling stresses developed in the PNIPAM gel layer. Further, we establish that light can be successfully guided through micro-patterned fibers, yielding a route to remotely controlled micro-actuators.

P1.00290 Polymer Crafted Nanoparticle-based Oil Dispersants. DAEHAK KIM, RAMANAN KRISHNAMOORTI, Univ of Houston — Particle-based oil dispersants mainly composed of inorganic nanoparticles such as silica nanoparticles are considered as environmentally friendly oil dispersants due to their biocompatibility and relatively low toxicity. The oil-water interfacial tension is reduced when nanoparticles segregate to the oil-water interface and this segregation is improved by grafting interfacially active polymer brushes. In this study, surfactant-like amphiphilic block copolymers were grafted from silica nanoparticles using an atom transfer radical polymerization (ATRP) method in order to increase their interfacial activity. We have studied the interfacial activity of such hybrid nanoparticles using pendant drop interfacial tension measurements, and their structure using small angle X-ray scattering. Amphiphilic copolymer grafted nanoparticles significantly reduced oil-water interfacial tension compared to the interfacial tension reduction induced by homopolymer grafted nanoparticles or the corresponding free ungrafted copolymer. Moreover, hard and stable oil-water emulsions were formed by applying the block copolymer grafted nanoparticles due to the formation of interfacial nanoparticle structures, which were observed by cryo-scanning electron microscopy (SEM) and small angle neutron scattering (SANS).

P1.00291 PNIPAM grafted on the surface of zirconium phosphate. HAI LI, XUEZHEN WANG, ZHENGDONG CHENG, Texas A&M Univ, DR.CHENG’S GROUP TEAM — We are reporting for the first time the grafting of the thermoresponsive polymer PNIPAM (poly N-isopropylacrylamide) on the surface of inorganic nanophases zirconium phosphate. Particularly, the grafting on inorganic nanophases using gamma rays has never scarcely been reported and yet proved to be successful in our synthesis. We proved that by gamma ray irradiation, the peroxide groups has been produced on the ZrP particles since that peroxide groups, on the surface of the hexagonal nanophases, which upon heating initiated the free radical polymerization and subsequent attachment of PNIPAM. The presence of covalent bond between ZrP and PNIPAM were observed and characterized by TGA, FTIR and solid state NMR respectively. The attachment of a thermoresponsive polymer to ZrP nanocrystals brings thus remarkable possibilities for their employment in the fields of medicine, oil industry, as well as physics.

P1.00292 Toward Designer Nanoparticle Assemblies: Supramolecular Nanocomposites on Patterned Surfaces. KATHERINE EVANS, JOSEPH KAO, TING XU, Univ of California - Berkeley — Nanoparticles have unique properties due to the quantum confinement effect. Controlled assemblies of nanoparticles of different sizes and chemical composition are predicted to have new optoelectronic properties. Supramolecules are ideal structural framework to guide nanoparticle assemblies in thin films without modifying the particle ligand chemistry. We recently showed that optically patterned trench patterns can effectively guide the assembly of supramolecular nanocomposites over micrometer to form aligned nanoparticle lines. I will report our recent investigation on more complex patterns to evaluate how the curvature of the pattern affects the nanoparticle assembly. Preliminary studies show potential for controlling and tailoring nanoparticle assemblies, and in turn, the optical properties of such assemblies.
P1.00293 Fluorescence in nanocomposites based on polyethylene oxides and block copolymers of polyethylene oxide-polypropylene oxide loaded with rare earth doped fluorides. BRIAN YUST, Univ of Texas, Pan American. FRANCISCO PEDRAZA, DHIRAJ SARDAR, University of Texas at San Antonio, AARON SAENZ, MIRCEA CHIPARA, Univ of Texas, Pan American — Rare earth doped fluoride nanoparticles with a size of about 25 nm have been synthesized by a solvothermal process. Polymer-based nanocomposites, containing various weight fraction of nanofillers, have been obtained by dissolving the polymeric matrix (polyethylene oxide) within a solvent (deionized water), adding the nanoparticles, sonicating the mixture, and finally removing the solvent. The complete removal of the solvent has been confirmed by Thermogravimetric Analysis. Additional information about the thermal features have been obtained by Differential Scanning Calorimetry, Wide Angle X-Ray Scattering, FTIR, UV-Visible, and Raman. The effect of the loading with nanoparticles on the glass, crystallization, and melting transition temperatures of the polymeric matrix are reported. Fluorescence of rare earth doped nanoparticles dispersed within the polymeric matrix has been tested by laser spectroscopy. The dependence of fluorescence intensity on the concentration of nanoparticles and on temperature in the range 300 to 400 K is analyzed.

P1.00294 Anisotropic Polymer Conformations in Aligned SWCNT/PS Nanocomposites, WEI-SHAO TUNG, RUSSELL COMPOSTO, University of Pennsylvania, NIGEL CLARKE, University of Sheffield, KAREN WINEY, University of Pennsylvania — In our previous study of isotropic SWCNT/polystyrene (PS) nanocomposites, we found that the polymer radius of gyration (Rg) increases and the SWCNT mesh size decreases with increasing SWCNT concentration. Here, we investigate the effect of aligning SWCNTs on Rg and the SWCNT mesh. SWCNT alignment was accomplished by melt fiber spinning or extrusion, and small angle neutron scattering was used to probe the structure. As expected, SWCNT alignment produces anisotropic meshes. Below 2 wt% SWCNT, no significant change in Rg is observed and Rg parallel and perpendicular to the direction of SWCNT alignment are comparable. More interestingly, at higher wt% SWCNT the polymer conformations are anisotropic with a larger Rg perpendicular to the SWCNT than along the SWCNT. For example, with 6 wt% SWCNT, the Rg perpendicular to the SWCNT is ~15% larger than parallel to the SWCNT. This anisotropy in the polymer conformation becomes more prominent at higher SWCNT concentrations, perhaps because at higher SWCNT concentrations the distribution of mesh shifts to smaller meshes (<2Rg) so that a single polymer chain interacts with multiple SWCNTs. Implications of this finding will be discussed.

P1.00295 THE PHYSICS OF CONFINED FLUIDS –

P1.00296 Capillary instability of periodic polymer structures: Influence of viscosity, substrate confinement and local curvature, ZHENG ZHANG, YIFU DING, Univ of Colorado - Boulder — We investigate the simultaneous capillary instability among periodic polymer lithographic structures supported on an immiscible viscous medium. The first system we studied was straight polystyrene (PS) stripes arranged in parallel in PMMA medium. When annealed at a temperature above the glass transition temperature of both polymers, the stripes undulated and then ruptured via capillary instability. We found that the PS-to-PMMA viscosity ratio strongly affected the rupture kinetics, while it had little influence on the rupture wavelength. The rupture behavior of those stripes could be drastically altered due to initial spacing and substrate confinement. For closely-neighboring stripes that were confined on a rigid substrate, the capillary waves became correlated in-phase among neighbors. Under strong confinement, the capillary rupture was always correlated, irrespective of the viscosity ratio. In addition, we examined the influence of in-plane curvature on capillary instability in concentrically arranged PS rings. When the rings were relatively far apart, their rupture behaviors were independent from each other; when they were close to each other, the primary mode in the capillary breakup became strongly correlated from the center towards the peripheral.

P1.00297 Static and Dynamic Capillary Forces in Pollen Adhesion and Detachment, CARSON MEREDITH, DONGGLEE SHIN, HAISHENG LIN, Georgia Tech — Nature provides remarkable examples of adhesive bioparticles including diatoms, pollens, and fungal spores, which are robust examples of nature’s solutions to particle adhesion. These particle’s interactions are often mediated by liquid films at micro- and nanometer length scales, and their study can lead to new physical insights into confined fluids. This talk will detail recent discoveries of the wet adhesive mechanisms of pollen, which provide useful insights into the role of capillary forces and confined fluids in nature. In particular, we describe how pollenkitt, a viscous fluid coating many pollen particles, forms nanoscale capillary bridges that mediate the adhesion and detachment of pollens from surfaces of insects and plants. We will present experimentally observed static and dynamic regimes of pollenkitt capillary forces. Models are utilized to understand the role of rheological properties of pollenkitt in creating these forces. Importantly, the forces generated by pollenkitt give pollen attachment and release from surfaces a sensitive dependence on humidity, rate, and surface morphology. This talk will explore how the physics of these forces contributes to pollination in nature and how they might be harnessed to engineer new materials.

P1.00298 EXTREME MECHANICS: CONTORTION OF RILAMENTS, RIBBONS AND BUNDLES –

P1.00299 EXTREME MECHANICS OF ORIGAMI: FOLDING, MECHANISMS AND MECHANICS –

P1.00300 Hysteretic self-folding of micro-scale polymer origami films, JUN-HEE NA, University of Massachusetts Amherst, JESSE SILVERBERG, Cornell University, ARTHUR EVANS, CHRISTIAN SANTANGELÒ, University of Massachusetts Amherst, THOMAS HULL, Western New England University, ITAI COHEN, Cornell University, RYAN HAYWARD, University of Massachusetts Amherst — Origami-inspired self-folding materials have attracted interest for the design of actuators and remotely deployable devices. While well-established geometric rules have been used to create rigidly self-foldable origami structures, the behavior of non-rigidly foldable crease patterns remains incompletely understood. In particular, understanding the relationship between crease geometry and the resulting elastic energy barrier remains a central challenge. Here, we describe a simple model system based on the well-known square twist folding pattern to explore how self-folding structures overcome such energy barriers, and the resulting hysteresis in the folding/unfolding behavior. We show that the magnitude of the hysteresis can be tuned by variations in the plane angle characterizing the crease pattern, as well as by selectively weakening the panel diagonals to reduce the energy cost of bending. These results provide insights into geometrically-controlled energy barriers in non-rigidly foldable origami and design rules for the construction of bistable self-folding systems.

P1.00301 CONFORMATIONS AND DYNAMICS OF BIOPOLYMERS –
**P1.00302 Conformations and dynamics of a translocating semi-flexible chain through a Nanopore facilitated by chaperones**, RAMESH ADHIKARI, ANIKET BHATTACHARYA, University of Central Florida — We have studied the translocation dynamics of a semi-flexible polymer through a nanopore from via to trans compartment containing binding particles (chaperones) which introduce a bias for the translocating chain. We have used a model semi-flexible polymer using excluded volume (Lennard-Jones), anharmonic spring (elasticity), and three-body bond bending (chain stiffness) potentials, and applied Langevin dynamics simulation to study various aspects of conformations and dynamics of the translocating chain. In particular, we have investigated the conditions for the most efficient translocation as a function of the chain stiffness, strength of the attractive interaction, and the density of the binding particles, reflected in the mean first passage time (MFPT) of translocating chain through the pore. We have observed that for certain binding strengths and concentrations of the chaperons, the translocation is faster than the ideal Brownian ratchet (BR) process [Simon et al., Proc. Natl. Acad. Sci. U.S.A. 89, 3770 (1992)].

**P1.00303 Uncovering the effect of DNA topology on the mobility and conformational dynamics of crowded DNA molecules**, STEPHANIE GORZCYZA, University of San Diego, COLE E. CHAPMAN, University of California, San Diego, RAE M. ROBERTSON-ANDERSON, University of San Diego — Using single molecule fluorescence microscopy and particle-tracking, we examine the effects of crowding on the diffusion and conformation of large, double-stranded circular DNA molecules. To determine diffusion, we track the mean-squared-displacement of single fluorescent-labeled DNA molecules embedded in solutions of different crowding agents. Using image analysis techniques, we also characterize the conformational change (from random coil configuration) induced in DNA by crowding. Our previous studies with linear DNA crowded by dextran reveal crowding-induced mobility reduction of DNA, dependent on crowder size, and elongation of DNA random coils, dependent on DNA size. Here, we compare our previous results to those for circular DNA crowded by varying crowding agents including dextran, Ficoll and Polyethylene Glycol. We determine the dependence of circular DNA mobility and conformation on the level of crowding, molecular weight of the crowding agent, structure of the crowder, and DNA length (11-115 kilobases). Thus, this research uncovers the underlying mechanisms responsible for observed DNA dynamics in crowded environments and biological cells.

**P1.00304 Dynamics of GLASSY POLYMERS UNDER CONFINEMENT** —

**P1.00305 Glass transition cooperativity from broad band heat capacity spectroscopy**, YEONG ZEN CHUA, GUNNAR SCHULZ, EVGENI SHOFIET, HEIKO HUTH, University of Rostock, REINER ZORN, Juelich Centre for Neutron Science, JUERN W.P. SCHMELZER, CHRISTOPH SCHICK, University of Rostock — Molecular dynamics is often studied by broad band dielectric spectroscopy (BDS) because of the wide dynamic range available and the large number of processes resulting in electrical dipole fluctuation and with that in a dielectrically detectable relaxation process. Calorimetry on the other hand is an effective analytical tool to characterize phase and glass transitions by its signatures in heat capacity. In the linear response scheme, heat capacity is considered as entropy compliance. Consequently, only processes significantly contributing to entropy fluctuations appear in calorimetric curves. The glass relaxation is prominent example for such a process. Here we present complex heat capacity at the dynamic glass transition (segmental relaxation) of polystyrene (PS) and poly(methyl methacrylate) (PMMA) in a dynamic range of 11 orders of magnitude, which is comparable to BDS [1]. As one of the results, we determine the temperature dependence of the characteristic length of the corresponding fluctuations. The characteristic length decreases from about 4 nm to about 0.7 nm in the temperature range from 370 K to 500 K. This proves an estimate for possible confinement effects on the segmental relaxation, which is different from vitrification as discussed by Cangialosi et al. [2]. [1] Y. Z. Chua et al., Col & Poly Sci 292, 2014. [2] D. Cangialosi, J of Phys: Cond Matt 26 (15), 2014.

**P1.00306 STABLE GLASSES, PROPERTIES AND ORIGINS** —

**P1.00307 Thermal Stability of Vapor-Deposited Stable Glasses of an Organic Semiconductor**, DIANE WALTERS, University of Wisconsin-Madison, RANKO RICHERT, Arizona State University, MARK EDIGER, University of Wisconsin-Madison — Organic glasses prepared by physical vapor deposition can be highly stable and resistant to transformation upon heating. Unlike ordinary glasses, transformation to the supercooled liquid is possible through the material at a constant velocity front. In this work, we show that an organic semiconductor commonly used as an active layer in organic electronics, TPD, transforms via propagating fronts when heated above the glass transition temperature. We measure transformation front velocities using spectroscopic ellipsometry. Using high-throughput preparation and annealing techniques, we find that front velocity can vary by over an order of magnitude depending upon the substrate temperature during the deposition of the glass. Transformation front velocity is also influenced by the mobility of the supercooled liquid at the annealing temperatures and, consistent with this view, transformation fronts have the same activation energy for stable glasses prepared with a wide range of the substrate temperatures. These results may aid in designing organic electronic devices with improved lifetimes.

**P1.00308 Effect of absorbed water on the thermodynamic and kinetic properties of vapor-deposited organic glasses**, MARTA GONZALEZ-SILVEIRA, CRISTIAN RODRIGUEZ-TINOCO, JOAN RAFOLS-RIBE, AJTOR F. LOPEANDIA, JAVIER RODRIGUEZ-VIEJO, Physics Dept. - Universitat Autonoma de Barcelona — Most organic glasses absorb water when exposed to ambient conditions. As a consequence, the glass can experiment changes in its physicochemical properties, being the triggering of crystallization one of the most inconvenient drawbacks. The amount of absorbed water depends on the partial pressure but also on the stability of the glass. Previous studies have shown that ultrastable indomethacin glasses absorb less water than the conventional counterpart. We show here how water absorption modifies the kinetic properties of the glass while, unexpectedly, the thermodynamic stability remains unaltered. By means of ex-situ and in-situ calorimetry, we analyze the relationship between water absorption and kinetic properties for glasses that are vapor-deposited at different temperatures around 0.85 Tg. Moreover, glasses exposed to water vapor exhibit a double glass transition, a clear indication of the presence in the glass of regions with different kinetic stability.

**P1.00309 Surface Self-diffusion of Organic Glasses and Low Molecular Weight Polystyrene**, WEI ZHANG, CALEB BRIAN, LIAN YU, Univ of Wisconsin, Madison — The study of surface self-diffusion of organic glasses and low molecular weight polystyrene help understand the formation of stable glasses by vapor deposition, the nature of surface mobility on polymer glasses and the fast surface crystal growth. Surface self-diffusion was measured via surface grating decay. Corrugated patterns were embossed on sample surfaces with master gratings at elevated temperatures. The smoothing of surface gratings was monitored with Atomic Force Microscopy or light diffraction. It was identified by Mullins' model that viscous flow dominates grating decay at high temperatures, but surface diffusion is the leading mechanism upon cooling. Surface diffusion coefficients were measured for organic glasses and polystyrenes with different glass transition temperatures and intermolecular forces. Surface diffusion is at least 10^5 times faster than bulk diffusion at T_g, and unlike bulk diffusion, surface diffusion exhibits strong material dependence. The fast surface diffusion implies fast rearrangement of molecules on surface during vapor deposition and helps the formation of stable glasses.

1 Now at 3 M Inc.
P1.00310 Infrared spectroscopic investigation of stable glasses of indomethacin. JING JIANG, MARK EDIGER, University of Wisconsin-Madison — Glasses with high density and kinetic stability can be prepared by physical vapor deposition. By varying the substrate temperature, stable glasses can be produced with an anisotropic distribution of molecular orientations. We use infrared transmission spectroscopy to investigate the effect of substrate temperature on the structure of indomethacin stable glasses. At normal incidence, height of peaks which are assigned to asymmetric hydrogen-bonded acid C=O stretching vary systematically with the substrate temperature. This indicates either more hydrogen-bonded acid carbonyl groups in the most stable glass or a dependence of molecular orientation upon substrate temperature can be shown by IR.

P1.00311 MANIPULATING GLASSES —

P1.00312 Non-affine reorganizations in glassy polymers under applied strain in the plastic regime. DIDIER LONG, LUCA CONCA, CNRS/Solvay, ALAIN DEQUIDT, Université de Clermont-Ferrand, JEAN-YVES DELANNOY, PAUL SOTTA, CNRS/Solvay, FRANÇOIS LEQUEUX, CNRS/ESPCI — A model for the dynamics of non-polar polymers, based on percolation of slow subunits, has been proposed and developed over the past ten years. This model has been extended for describing plastic deformation of glassy polymers. It has been proposed that the applied stress results in an acceleration of the dynamics of the subunits. At deformation amplitudes of a few percent, we can observe plastic yield. The onset of plasticity is accompanied by an increase of the non-affine nature of the deformation at microscopic scales. Localization phenomena are observed in the plastic regime. We present here a detailed study of the complex reorganization which takes place on a scale of a few nanometers. We show that the correlation length of non-affine deformation increases at yield, but remains finite, with typical value 10-20 nm, corresponding to typical distance between shear bands. We compare in detail the microscopic mechanisms at play during shear deformation, uni-axial extension and compression.

P1.00313 POLYMERIC GLASSES —

P1.00314 Volume Recovery of Polymeric Glasses, N. SAKIB, S.L. SIMON, Texas Tech University — Following the seminal work of Kovacs, capillary dilatometry has been used for the last fifty years to study volume recovery of polymeric glass formers. Our capillary dilatometer, which previously used a Linear Variable Differential Transducer (LVDT) to measure the height of the Hg column in the capillary, has been modified following the work of Richert. The current study demonstrates the use of a capacitance bridge as the transducer. A metallic layer of silver sputtered on the exterior of the dilatometer serves as the outer electrode, mercury (the confining fluid) serves as the inner electrode, and the glass in between serves as the dielectric of the capacitor. The Andeen-Hagerling 2550A 1kHz ultraprecision capacitance bridge is used for the measurements. Volume recovery of various glass formers will be used to test the new design; new measurements are planned to test models of structural recovery.

P1.00315 Cure Kinetics of the Hydroxyl-Epoxide Reaction in DGEBA Epoxy Hardened with Diethanolamine, LEBELO HAILESLASSIE, NARJES FREDJ, CAITLYN M. CLARKSON, JOHN D. MCCOY, New Mexico Tech, MATHEW C. CELINA, JAMIE M. KROPKA, Sandia National Laboratories — The curing of a diglycidyl ether of bisphenol-A Epoxy (Epon 828) with diethanolamine (DEA) involves a fast amine-epoxide reaction followed by a slower hydroxyl-epoxide reaction. At curing temperatures below 70°C, the time scales of these two reactions are well separated. This permits the study of the hydroxyl addition as an “isolated” reaction. The reaction is strongly auto-catalyzed and is well fit to a modified form of the Kamal equation. Here we study the temperature dependence of the Kamal parameters with modulated differential scanning calorimetry and infrared spectroscopy.

P1.00316 Liquid Substrate Effects on the Glass Transition Temperature of Nanoscopically Confined Polystyrene Spheres. DANE CHRISTIE, Princeton University, CHUAN ZHANG, Sphera Materials, RODNEY PRIESTLEY, Princeton University — The effect of the liquid-polymer interface on the glass transition temperature (T_g) of polystyrene (PS) was investigated using differential scanning calorimetry. Polystyrene nanoparticles of different radii were suspended in either water, glycerol or an ionic liquid. Particles suspended in water (or cast in film in air) exhibited a T_g-confinement effect consistent with that of freestanding films of PS. Particles suspended in an ionic liquid exhibited an invariant T_g with confinement while those suspended in glycerol exhibited a modest, depression in T_g with confinement. Upon re-suspension in water, particles formerly suspended in glycerol showed a partial recovery of their T_g in water. However, particles re-suspended in water from an ionic liquid showed no recovery of their T_g. These results are explained in the context of chain mobility and interfacial energy, and provide insight and a probable resolution to contradictory observations in the literature.

P1.00317 POSTDEADLINE ABSTRACTS —

P1.00318 Chirality Induced Spin Selectivity for Memory Applications. RAHAMIM GULIAMOV, SHINTO MATHEW, KIRAN VANKAYALA, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel, HAGAY MOSHE, YITZHAK MASTAI, Department of Chemistry, Bar-Ilan University, Ramat-Gan Israel, RON NAAMAN, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel, PROF. RON NAAMAN GROUP COLLABORATION1, PROF. YITZHAK MASTAI GROUP COLLABORATION2 — Creation and manipulation of spin current is one of major aspects of memory devices. In conventional devices spin-polarized current is created by permanent magnetic layer. Further miniaturization of the memory is limited by super-paramagnetic behavior of layer. Hence, high density memory requires out-of-plane geometry with perpendicular magnetic anisotropy. Achieving this goal with inorganic magnetic layers is a challenge. We present a new approach in which the permanent magnetic layer has been replaced with inorganic chiral film producing spin polarized current due to Chirality Induced Spin Selectivity (CISS) effect. Chiral Al2O3 film grown by ALD on self-assembled monolayer of chiral molecules acts as a spin filter. Spin polarization is parallel/antiparallel to the electron velocity depending on chirality. Devices show asymmetric magneto-resistance and slopes with opposite sign for left/right handed chirality. Hence, CISS-effect based device shows, for first time, an asymmetric magneto-resistance, which has potential application in magnetic memory and magnetic field sensors. Reference: Shint0 P. Mathew et al., Appl. Phys. Lett. 105, 242408 (2014)

P1.00319 Proving grain boundaries and transport study of graphene grown on liquid Cu.
SEONG-YONG CHO, MIN-SIK KIM, KI-JU KIM, MIN-SU KIM, HYUN-MI KIM, SANG-HOON LEE, KI-BUM KIM, Seoul Natl Univ, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING TEAM — We revealed grain boundaries of graphene grown on liquid Cu via hydrogen etching and Cu oxidation, and found out that small gap and voids exist between graphene islands on liquid Cu due to small supersaturation ratio which was required for self-assembly to occur. Modified two-step growth was applied in order to fill the gap between graphene islands and continuous graphene was synthesized on liquid Cu. The continuity of the film was verified through hydrogen etching and NaCl assisted oxidation. Electrical resistance of graphene grown on liquid Cu was lower than graphene grown on solid Cu if there is no crack damage which might be resulted from thermal stress related solidification of Cu and wet-transfer. Also, Hall mobility of graphene grown on liquid Cu shows two times higher value compared to that of graphene grown on solid Cu. In order to verify the aligned grain boundary of graphene on liquid Cu, direct patterning enabled electrode deposition on two neighboring graphene single crystal which aligns in the same orientation. Grain boundary resistance was negligible based on our electrical measurement results which has a great potential impact on graphene growth on liquid Cu.

P1.00320 Enhancement of Electromagnetically Induced Transparency Cooling by an Optical Cavity1, WEI WU, JIE ZHANG, SHUO ZHANG, BAO-QUAN OU, PING-XING CHEN, National University of Defense Technology — One of the most popular methods for cooling trapped ions is to ground state cooling. However, carrier and blue sideband still exist, which are the obstacles for reaching lower phonon number. EIT cooling cancels the carrier transition and suppressed blue sideband transition to some extent, blue sideband transition still exists. To further suppress the blue sideband transition and improve EIT cooling, Introducing an optical cavity provides us a promising way to enhance the EIT cooling and reach lower phonon number for a trapped ion. A Λ-configuration ion with mass M is trapped in a Paul trap, we consider the situation that the radial confinement is much stronger than that of the axial direction, only one dimensional movement along the axis should be concerned. If we set the detuning properly, EIT effect occurs, canceling the carrier transition, while the heating effect from blue sideband transition can be suppressed by quantum interference between the laser and cavity. Analytical calculation shows that cooling limit of this new scheme is

$$\langle n_{st} \rangle = \frac{1}{C},$$

Numerical simulation shows that the standard EIT cooling is enhanced with the help of the high finesse cavity.

P1.00321 Properties of Transparent Conducting Oxides from First Principles: In-O, In-Zn-O, In-Sn-O, and Zn-In-Sn-O, RABI KHANAL, JULIA MEDVEDEVA, Missouri University of Science and Technology — Systematic investigations of amorphous In-based oxides, In-X-O with X=Zn and/or Sn, obtained via ab-initio molecular dynamics liquid-quench simulations, are performed to understand the role of composition in the structural, optical, transport, and mechanical properties of these oxides. First, the structural characteristics of the first, second, and third shells are compared between amorphous In-O, In-Zn-O, In-Sn-O, and Zn-In-Sn-O. The results reveal that the local Metal-Oxygen structure for both In and X cations — and hence, optical band gap and electronic effective mass governed by the metal-oxygen interactions — remains nearly intact upon the transition to amorphous state. In all amorphous oxides considered, Indium is undercoordinated with little dependence on X, whereas the X cations reach their natural coordination. This finding suggests that the carrier generation is primarily governed by In atoms, in agreement with transport measurements in the amorphous oxides. In contrast to the first shell, the composition affects the Metal-Metal distances, coordination, and oxygen sharing. The interconnectivity and spatial distribution of InO6 and XOx polyhedra limits the charge transport via scattering and ultimately determines the formation of the amorphous oxides and their properties.

P1.00322 Perovskite Structured Oxide Thin Film as Photocapacitor, JOYPROKASH CHAKRABARTTY, RIAD NACHACHE, FEDERICO ROSEI, INRS - Energie et Materiaux — Photocapacitor is a device that converts solar energy through photovoltaic effect, and stores the converted energy by maintaining the charge concentration difference across a membrane upon light irradiation. It eliminates additional storage devices, for example, extra battery towards device miniaturization by enabling generated charge storage facilities in the same system. Till to date published reports show those devices that used artificial layer within single structure to make storage facility. Here we show some preliminary results on Bi-Mn-O thin film systems that differ from others in such a way that it will employ self-assembled system to convert and to store solar energy.

P1.00323 Development of Magnetization Detecting Electron Spin Resonance Method, SATOSHI MATSUZAWA, HIROYUKI NOJIRI, Institute for Materials Research, Tohoku University, NOJIRI LAB TEAM — Electron spin resonance: ESR is a spectroscopy by using electromagnetic wave absorption in Zeeman spitted multiplet of spins. The split energy is determined by the resonance field and the line width is governed by relaxation and anisotropies. The absorption intensity is proportional to the population difference between the initial and the final states. These populations also determine the total z-component of magnetization of the system. It means that ESR absorption can be measured by magnetization under electromagnetic wave irradiation. This type of ESR is called magnetization detecting ESR: MDES. We have developed two types MDES, namely, SQUID-ESR and XMCD-ESR. XMCD is the abbreviation of X-ray Magnetic circular dichroism and is the method to measure magnetization in element and orbital selective manner. SQUID-ESR is easy to conduct by attaching radiation source to a conventional MPMS-SQUID machine. The advantage of SQUID-ESR is the evaluation of absolute value of ESR intensity. While, XMCD-ESR is very sensitive and can detect the magnetization of a few atomic layers. Details of the experimental systems and the test results will be presented.

P1.00324 Application of Scanning Probe Nanolithography to fabrication and study of large area graphene and Transition Metal Dichalcogenides heterostructures1, RUI DONG, LOGAN MOORE, IRMA KULJANSHVILI, Saint Louis University — Two-dimensional atomic crystals, such as graphene and layered transition metal dichalcogenides (TMDs), have drawn significant attention because of the unique physical and chemical properties. Recently developed graphene/TMDs stacking structures provide an attracting solution to design and fabricate unique electronic devices and nanostructures. In this study, we employ the “direct write” patterning technique, to fabricate Graphene/TMDs heterostructures. TMDs precursor is utilized as an “ink” to create the arrays of patterns employing multi-pen AFM cantilevers. The patterned structures of TMDs precursor on graphene /silicon oxide/silicon in processed in CVD to produce Graphene/TMDs heterostructures. Raman spectroscopy and AFM characterization demonstrates high quality of as-prepared Graphene/TMDs nanostructures. Mask free approach significantly reduces contamination of the graphene surface during patterning and demonstrates a promising unconventional technology for fabricating high quality Graphene/TMDs or other layered nanostructures in a convenient and economical manner with the nanoscale precision.

P1.00325 Geometric and Electromagnetic Field Effects on the Excitonic Properties of Core-multishell Semiconductor Quantum Wires1, JUŚCİANE ŚLІWA2, Sociedade Brasileira de Física, ANDREY CHAVES COLLABORATION1, GIL DE AQUINO FARIAS COLLABORATION1, SUBENIA MEDEIROS COLLABORATION2 — The effect of eccentricity distortions in the otherwise circular geometry of core-multishell quantum wires on their excitonic transitions is theoretically investigated. Within the effective mass approximation, the Schrödinger equation is numerically solved for electrons and holes in systems with single and double radial heterostructures, whereas the resulting exciton binding energy is calculated by means of a variational approach. Our results demonstrate that for a single shell heterostructure, in-plane electric fields applied in different directions produce qualitatively different energy spectra, which can be used to identify the eccentricity of the system. For a double heterostructure, the eccentricities of the inner and outer shells play an important role on the excitonic binding energy and on the oscillator strength. Our results also show that for a single shell heterostructure with a type-II confinement, i.e. with spatially separated electrons and holes, one of the carriers exhibits either a ring-like or a dot-like energy spectrum, depending on the radius of the system. In this case, a shell-to-core confinement transition for the electron can be induced also by an external magnetic field.

P1.00326 Final state lifetime effects in spectroscopic studies of iridium oxide , J. MATTHIAS KAHK, DAVID J. PAYNE, Imperial College London — Understanding the complex and varied electronic and magnetic properties of late 3rd row transition metal oxides is a topic of significant current interest. The technique of Resonant Inelastic X-ray Scattering (RIXS) is particularly valuable in this field as it provides element- and orbital-specific information about the occupied and unoccupied electronic states. A major advantage of RIXS over techniques such as nonresonant XAS and XES is the sharpening of spectral features due to the absence of a core hole in both the initial and the final states. In typical simulations of RIXS spectra, final state lifetime effects are thus neglected, but this also precludes the possibility to account for the finite lifetime of the excited electron-hole pair created in the RIXS process. Starting from the well-known Kramers-Heisenberg equation, we have developed a new formalism for RIXS simulations which does allow for the inclusion of final state lifetime effects. Results are shown for the O K-edge RIXS of IrO₂, and the new formalism leads to a vast improvement in the agreement between theory and experiment. A similar approach also yields excellent agreement between theory and experiment for the nonresonant XAS and XES of IrO₂, as well as the valence band region of the IrO₂ HAXPES spectrum.

P1.00327 Giant Spin Hall Effect in Perpendicularly Magnetized Ta/CoFeB/MgO Structure and Temperature Dependence1, QIANG HAO, GANG XIAO, Brown University — The Giant Spin Hall Effect (GSHE) in non-magnetic metals with strong spin-orbit coupling (SOC) has been found in various solids like Pt, beta-Ta, and beta-W. The spin current from GSHE solids yields a spin-transfer torque (STT) inside an adjacent ferromagnetic layer with perpendicular magnetic anisotropy (PMA) to effect a magnetization switching. The combination of PMA with STT-induced switching has the advantage of low power consumption, high reliability and durability and data non-volatility over earlier generations of MRAM. Here we first studied the post-annealing effect on achieving PMA in Ta/CoFeB/MgO multilayers. We achieved so far the lowest critical current density of 2.3 MA/cm² for the STT-induced switching in the presence of 5mT magnetic field created in the RIXS process. Starting from the well-known Kramers-Heisenberg equation, we have developed a new formalism for RIXS simulations which does allow for the inclusion of final state lifetime effects. Results are shown for the O K-edge RIXS of IrO₂, and the new formalism leads to a vast improvement in the agreement between theory and experiment. A similar approach also yields excellent agreement between theory and experiment for the nonresonant XAS and XES of IrO₂, as well as the valence band region of the IrO₂ HAXPES spectrum.

P1.00328 Transition to Metallic Phase of Fluid Hydrogen at High Pressure and High Temperature1, MARI EINAGA, SHO KAWAGUCHI, KATSUYA SHIMIZU, KYOKUGEN, Osaka University, KENJI OHTA, Department of Earth and Planetary Sciences, Tokyo Institute of Technology, NAOHISA HIRAO, YASUO OHISHI, Japan Synchrotron Radiation Research Institute — We investigated the phase transition to the metallic fluid phase of hydrogen under high pressure and high temperature by the laser heated diamond-anvil cell (LHDAC) up to 100 GPa and 2500 K. Compressed hydrogen was heated by IR laser with a thin gold foil, acts as the laser absorber. The temperature of hydrogen was determined by National Science Foundation through Grant No. DMR-1307056.

P1.00329 Spin Correlations in Quantum Wires , CHEN SUN, Texas A&M Univ, VALERY POKROVSKY, Texas A&M Univ, Landau Institute for Theoretical Physics — We consider theoretically spin correlations in an 1D quantum wire with Rashba-Dresselhaus spin-orbit interaction (RDI). The correlations of non-interacting electrons display electron-spin resonance at a frequency proportional to the RDI coupling. Interacting electrons on varying the direction of external magnetic field transit from the state of Luttinger liquid (LL) to the spin density wave (SDW) state. We show that the two-time total spin correlations of these states are significantly different. In the LL the projection of total spin to the direction of the RDI induced field is conserved and the corresponding correlator is equal to zero. The correlators of two components perpendicular to the RDI field display a sharp ESR driven by RDI induced intrinsic field. In contrast, in the SDW state the longitudinal projection of spin dominates, whereas the transverse components are suppressed. This prediction indicates a simple way for experimental diagnostic of the SDW in a quantum wire.
P1.00330 Few-layer-thin Two-dimensional Metallic Niobium Disulfide Nanosheets: Preparation, Optical Characterization and Transport Properties1. SIHAN ZHAO, TAKATO HOTT A, TAKUMI SAWAZAKI, MITSUHIRO OKADA, HISANORI SHINOHARA, RYO KITAURA, Nagoya Univ, SHINOHARA'S GROUP TEAM — The semiconducting two-dimensional (2D) transition-metal dichalcogenides (TMDs), such as MoS2, WS2 etc., have recently attracted tremendous research attention in the field of materials science. On the other hand, research work on 2D metallic TMDs, such as NbS2, NbSe2 etc., which show superconductivity and charge-density-wave (CDW) states in bulk, has been limited primarily due to the inaccessible transport behavior in ultrathin high quality samples. In this contribution, we report a direct chemical vapor deposition (CVD) growth of ultrathin 3R-NbS2 nanosheets down to 3 layers on the exfoliated hexagonal boron nitride (hBN) flakes. AFM data show that most of NbS2 samples grown are very thin with an average lateral size of ca. 2 × 3 μm. Detailed Raman spectroscopy studies on layer number-identified NbS2 samples reveal a systematic shift of out-of-plane vibration mode (A1g), which offers a reliable and rapid optical method for layer number identification. Two-terminal devices on thin-layered NbS2 were also fabricated and show a metallic transport behavior as predicted by DFT calculations. The metallic nature of thin-layered NbS2 has also been supported by absence of PL peaks regardless of number of layers. Exploration of 2D superconductivity and CDW states in this system is an on-going work.

P1.00331 A New Carbon Phase Constructed by Long-Range Ordered Carbon Clusters form Compressing C70 Solvates, WEN CUI, MINGGUANG YAO, SHI JIE LIU, FENGXIAN MA, QUANJUN LI, RAN LIU, BO LIU, BO ZOU, TIAN CUI, BINGBING LIU1. Jilin University, STATE KEY LAB OF SUPERHARD MATERIAL COLLABORATION — A novel carbon material has been recently reported from compressing C60 solvates (C60/m-xylene) and the obtained high pressure phase—the ordered amorphous carbon cluster (OACC) structure, breaks our inherent understanding of the categorization of various phases and adds a new member to the list of structures [L. Wang et al, Science 337, 825 (2012)]. Our study reveals that m-xylene plays an important role in both the structure and the property of the formed novel phase [M. Fujihara et al, App Phys Lett 103, 071913 (2013)]. Here, another example of OACC is also presented from compressing C70/m-xylene in which amorphized and highly compressed C70 units act as building blocks. The high pressure phase is exceptional incompressible, which can indent the (100) face of diamond. A new phase transition occurs in the compression process, which is very different from compressing C60/m-xylene, indicating OACC structure can be tuned by changing the initial fullerene molecules. The deformation of fullerene molecules under pressure and the formation mechanism of the high pressure hard phase have also been revealed in this study. Our study extends the OACC structure to larger fullerenes and suggests a universal rule for the high pressure behaviors of lower symmetry systems of solvated fullerenes [W. Cui et al, Adv Mater 26, 7257 (2014)].

P1.00332 Optical properties of highly-extended, ultrathin graphene nanoribbons in carbon nanotubes. HONG EUN LIM, Department of Chemistry, Nagoya University, YASUMITSU MIYATA, Department of Physics, Tokyo Metropolitan University, MIHO FUJIHARA, Department of Chemistry, Nagoya University, SUSUMU OKADA, Graduate School of Pure and Applied Sciences, University of Tsukuba, HARUKA OMACHI, RYO KITAURA, HISANORI SHINOHARA, Department of Chemistry, Nagoya University — Growing graphene nanoribbons (GNRs) inside the carbon nanotubes (CNTs) [1, 2] is tempting, as it provides opportunities to tune the width and edge structure of the ribbons synthesized. To have a better insight into their intrinsic properties, it is therefore necessary to study the GNRs in such a confined state. Herein, we report the optical properties of the coronene-derived GNRs, confined in single-wall CNTs of 1.4-1.6 nm. The electronic structures of the outer CNTs were modified using diazonium chemistry [3], allowing clear absorption signals of the inner GNRs to be detected. The absorption bands around 1.5 and 3.4 eV can be related to the first and second transitions between the energy gaps of the valence and conduction bands, in qualitative agreement with the first principle calculations. Our study deepens the understanding on the ribbons fabricated, providing access towards the interesting physics of confined one-dimensional materials. References: [1] H. E. Lim et al. Nat. Commun. 2013, 4, 2548. [2] M. Fujihara et al. J. Phys. Chem. C 2012, 116, 15141-15145. [3] M. S. Strano et al. Science 2003, 301, 1519-1522.

P1.00333 Growth and Optical Properties of High-Quality WS2 Monolayers on Graphite. YASUMITSU MIYATA, YU KOBAYASHI, SHOGO SASAKI, SHOHEI MORI, YUTAKA MANIWA, Department of Physics, Tokyo Metropolitan University, KENJI WATANABE, TAKASHI TANIGUCHI, Department for Materials Science, HIROKI HIBINO, NTT Basic Research Laboratories, NTT Corporation — Atomic-layer transition metal dichalcogenides (TMDs) have attracted appreciable interest due to their tunable bandgap, spin-valley physics, and potential device applications. However, the quality of TMD samples available still poses serious problems, such as inhomogeneous lattice strain, charge doping, and structural defects. Here, we report on the growth of high-quality, monolayer WS2 onto exfoliated graphite by high-temperature chemical vapor deposition (CVD). Monolayer WS2 single crystals grown presents a uniform, single excitonic photoluminescence peak with a Lorentzian profile and a very small full-width at half maximum of 21 meV at room temperature and 8 meV at 7 K. Furthermore, in these samples, no additional peaks are observed for charged and/or bound excitons, even at low temperature. These optical responses are completely different from the results of previously reported TMDs obtained by mechanical exfoliation and CVD. Our findings indicate that the combination of high-temperature CVD with cleaved graphite surface is an ideal condition for the growth of high-quality TMDs, and such samples will be essential for revealing intrinsic physical properties and for future applications.

P1.00334 Energy landscape scheme for an intuitive understanding of complex domain dynamics in ferroelectric thin films1. JONG-GUL YOON, University of Suwon, T.H. KIM, W.K. PARK, S.M. YANG, S.Y. JANG, T. MIN, J.-S. CHUNG, Center for Correlated Electron Systems, Institute for Basic Science, S.H. BAEK, C.B. EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, T.W. NOH, Center for Correlated Electron Systems, Institute for Basic Science — Fundamental understanding of domain dynamics in ferroelectric thin films has been a longstanding issue because of its relevance to many systems and to the design of nanoscale domain-wall devices. Despite many theoretical and experimental studies, a full understanding of domain dynamics yet remains elusive due to complex interactions between domain-walls and disorder. In this work, by observing domain-wall breathing motion in ferroelectric BiFeO3 thin film using stroboscopic piezoresponse force microscopy, we demonstrate domain-shape-preserving deterministic domain-wall motion, confirming microscopic return point memory. We also map a spatial energy landscape that provides new insights into domain dynamics. The evolution of complex domain structure can be understood by the process of occupying the lowest available energy states of polarization in the energy landscape which is determined by defect-induced internal fields.

P1.00335 Selective formation of zigzag-edges in graphene cracks, MIHO FUJIHARA, Nagoya University, RYOSUKE INOUE, YUTAKA MANIWA, Tokyo Metropolitan University, HISANORI SHINOHARA, Nagoya University, YASUMITSU MIYATA, Tokyo Metropolitan University — Graphene edges have attracted much attention due to their unique electronic and magnetic properties. To understand these properties, it is highly desired to prepare clean, smooth, and structure-controlled edges. However, structure selective preparation of zigzag or armchair edges has not been achieved yet. Here, we report the selective formation of graphene edges aligned in the zigzag orientation by cleavage with thermally-assisted tensile stress. Graphene grains were grown from methane on copper foil by using chemical vapor deposition. After cooling to room temperature, we occasionally observed zigzag-shaped cracks in graphene. Considering the grain edges which have the zigzag face, these cracks are found to propagate parallel to the zigzag edges. The origin of tension is probably due to the non-uniform lattice strain of graphene induced by thermal shrinking of Cu substrates as supported by Raman strain mapping. Furthermore, we demonstrate the carrier tuning around graphene edges by applying the electric field to the cracks. Our findings pave the way for the fabrication and applications of smooth, long zigzag edges of graphene and other two dimensional materials.

P1.00336 Thrust generation of thickness-varying flexible fins, YUANDI LI, PETER YEH, ALEXANDER ALEXEEV, Georgia Institute of Technology — We use three dimensional computer simulations to probe the hydrodynamics and thrust generation of an oscillating flexible fin with varying thickness. The fin is modeled as an elastic rectangular plate that plunges at its leading edge and is submerged in a viscous fluid. Since we assume that the thickest part of the fin is very small compared to its length and width, the plate is modeled as infinitely thin. We introduce an appropriate mass gradient and stiffness gradient in the plate to simulate the effects of the thickness gradient. As the fin flaps, fluid is displaced backwards and a net thrust is generated. We characterize this thrust generation as a function of driving frequency and find optimal conditions for largest propulsion. These findings are useful for designing biomimetic underwater propulsion devices.

P1.00337 Precise Analysis of Perfect Zero-Birefringence Polymer, YUKIYOSHI KADA, OSAMU URAKAWA, TADASHI INOUE, Osaka Univ — Control of strain-induced birefringence of amorphous polymers is an important issue for their optical applications. It is widely accepted that strain-induced birefringence of amorphous polymers has two origins, segment orientation and glassy deformation. The intrinsic birefringence, $\Delta n_{B}$ and the photoelastic coefficient, $C_{ij}$, are indexes of the two origins, respectively. $\Delta n_{B} - C_{ij}$ map help us to predict strain-induced birefringence of copolymers. Perfect zero-birefringence polymers, PZP, means $\Delta n_{B} = 0$ and $C_{ij} = 0$. One of the method to obtain the PZP is random copolymerization of three kinds of monomers. In a three components system, the birefringence of copolymers can be characterized by a point inside of the triangle region formed by three points for homopolymers of the three monomers in $\Delta n_{B} - C_{ij}$ map. In this study, PZP of MMA (Methyl methacrylate), TFEMA (Trifluoroethyl methacrylate) and BzMA (Benzy methacrylate) was synthesized and its birefringence behavior was analyzed. Following the reported composition, we synthesized PZP and conducted dynamic birefringence measurement. $\Delta n_{B}$ value of the synthesized PZP was unexpectedly large at high temperatures because $\Delta n_{B}$ of PMMA and PBzMA showed temperature dependence. More importantly, we found that zero birefringence of PZP is achieved only at a certain temperature. We will also discuss effect of sub relaxations in the talk.

P1.00338 Chaos and Big-Bang singularity in Bianchi type-IX universe for the Einstein equation, YUYA TAKEUCHI, Osaka Prefecture University, TOMIO PETROSKY, LINDA REICHL, The University of Texas at Austin, SATOSHI TANAKA, Osaka Prefecture University — Chaotic dynamics of a spatially homogeneous and anisotropic case in the Bianchi type-IX universe model for the Einstein equation has been studied for the vacuum case. There is a hyperbolic fixed point and a separatrix only for the type-IX model with positive cosmological constant. A difficulty in numerical analysis due to the Big-Bang singularity is avoided by constructing an analytical solution near the singular point. Thanks to the local analytic solution and by combining it with global numerical solution, we are able to construct Poincaré surfaces of a section near the separatrix. A new type of chaotic motion characteristics to the Einstein equation will be discussed.

P1.00339 NMR Spin-Lattice Relaxation Time T1 of Thin Films Obtained by Magnetic Resonance Force Microscopy, SUNGMIN KWON, SEUNGB-BO SAUN, SOONCHIL LEE, KAIST, SOONHO WON, Advanced Metallic Materials Division, Korea Institute of Materials Science — NMR spectrum and spin-lattice relaxation time(T1) of CaF2 thin films deposited on a silicon cantilever tip were obtained by magnetic resonance force microscopy(MRFM). Thickness of the thin films were 50nm and 150nm. In order to measure T1, a cyclic adiabatic inversion method was used with periodic phase inversion. A comparison of the bulk and two thin films showed that T1 becomes shorter as the film thickness decreases. To make the comparison as accurate as possible, all three samples were loaded onto different beams of a multi-cantilever array and measured in the same experimental conditions such as temperature and magnetic field.

P1.00340 Computational and Physical Analysis of Catalytic Compounds, RICHARD WU, JUNG JAE SOHN, RICHARD KYUNG, Choice Research Group — Nanoparticles exhibit unique physical and chemical properties depending on their geometrical properties. For this reason, synthesis of nanoparticles with controlled shape and size is important to use their unique properties. Catalyst supports are usually made of high-surface-area porous oxides or carbon nanomaterials. These support materials stabilize metal catalysts against sintering at high reaction temperatures. Many studies have demonstrated large enhancements of catalytic behavior due to the role of the oxide-metal interface. In this paper, the catalyzing ability of supported nano metal oxides, such as silicon oxide and titanium oxide compounds as catalysts have been analyzed using computational chemistry method. Computational programs such as Gamess and Chemcraft has been used in an effort to compute the efficiencies of catalytic compounds, and bonding energy changes during the optimization convergence. The result illustrates how the metal oxides stabilize and the steps that it takes. The graph of the energy computation step(N) versus energy(kcal/mol) curve shows that the energy of the titania converges faster at the 7th iteration calculation, whereas the silica converges at the 9th iteration calculation.

P1.00341 Superconductivity in Opal-based superconducting nanocomposites, M.K. LEE, MOST Instrument Center At NCKU, Tainan 70101, Taiwan, ÉV CHARNAIY, Institute of Physics, St. Petersburg State University, St. Petersburg, Petrovodets 198504 Russia, L.J. CHANG, Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan, YU. A. KUMZEROV, A. F. Ioffe Physico-Technical Institute RAS, St. Petersburg 194021, Russia, M. F. LÍN, Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan — In this study, we investigate superconducting nanocomposites (SCNs) to elucidate superconductivity in nanostructured type I superconductor. In, Sn and Hg are loaded into opal matrices by high pressure up to 10kbar, in which introducing superconducting metals into templates preserves their own 3D nanostructures. The opal matrices is adopted because it is a well-developed nanoflafennement and widely used in the studies of photonics crystal due to its periodically-superlatticed nanoporous structure. The SCNs are then measured by Quantum Design MPMS 3 under different external magnetic fields reveal the field dependences of Tc and irreversibility field (Hirv). AC susceptibility measurements of SCNs determine strain coupling, vortex dynamics and field dependence of activation barrier (Ua) as well as Tc. Additionally, the phase diagrams of these SCNs are analyzed to study superconductivity for a system with similar nanogeometry. Exotic phase diagrams in the opal SCNs studies reveal an enhanced upper critical field (Hc2 (0)) and curvature crossover of upper critical field line. Additionally, according to the field dependence of Ua(H), curvature crossover of the upper critical field line can occur, owing to vortex phase transition.

P1.00342 The physics of a cell doublet: a minimal system to study early embryo morphogenesis, HERVE TURLIER, JEAN-ÉLON MAITRE, TAKASHI HIIRAGI, FRANCOIS NEDELEC, European Molecular Biology Laboratory — In early embryos, the shape of cells is determined in part by the actomyosin cortex and in part by interactions with the surrounding environment. Cell-cell adhesion, in particular, is determinant for the overall embryo organization. This complex interplay between cell autonomous mechanical properties and cell-cell interactions can advantageously be analyzed in paired isolated cells. We study theoretically and experimentally shape changes in doublets of mouse embryo blastomeres. Simple scaling analysis and numerical simulations can predict the various configurations adopted by blastomere doublets over different stages of embryo development. Our study provides a simple and robust physical framework to understand and characterize quantitatively diverse morphogenetic events such as compaction, entosis and cell internalization.
P1.00343 Calculation of modal contributions to thermal transport across Si/Ge and In\(_{0.53}\)Ga\(_{0.47}\)As/InP interfaces , KIARASH GORDIZ, ASEGUN HENRY, Georgia Institute of Technology — Reliable and quantitative calculation of the conductance of different phonons across an interface can have a significant impact on the applications where thermal interface resistance is limiting and can aid in the rational design of thermal interface materials. A new formalism for extracting the modal contributions to thermal interface conductance with full inclusion of temperature dependent anharmonicity and all of the atom level topography is presented. Application of the formalism to Si/Ge and In\(_{0.53}\)Ga\(_{0.47}\)As/InP interfaces reveals fundamental information on the nature of the vibrational modes involved in heat transfer and the interactions/correlations among them. Four distinct classes of vibrational modes are detected for the two interfaces. For Si/Ge interface, the density of states for these vibrational classes are completely mixed, while surprisingly for In\(_{0.53}\)Ga\(_{0.47}\)As/InP interface they are completely segregated. For Si/Ge interface, interfacial modes, located around 12THz, contribute near 20% to the total conductance, while for In\(_{0.53}\)Ga\(_{0.47}\)As/InP interface, low frequency extended modes contribute more than 50% to the total conductance. The temperature dependent anharmonicity analysis shows that increasing temperature decreases the contribution by extended modes and increases the contribution by partially extended modes. In both of the interfaces, interfacial modes exhibit the maximum per mode contribution.

P1.00344 Coherence lengths in attractively interacting Fermi gases with spin-orbit coupling , YU YIXIANG, JINWU YE, Mississippi State Univ, WUMING LIU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences — Extensive research has been lavished on the effects of spin-orbit couplings (SOCs) in attractively interacting Fermi systems in both neutral cold-atom systems and condensed-matter systems. Recently, it was suggested that a SOC drives a class of BCS to Bose-Einstein condensate (BEC) crossover that is different from the conventional one without a SOC. Here, we explore what are the most relevant physical quantities to describe such a BCS to BEC crossover and their experimental detections. We extend the concepts of the coherence length and \(\xi_{\text{Cooper-pair size}}\) in the absence of SOC to Fermi systems with SOC. We investigate the dependence of chemical potential, coherence length, and \(\xi_{\text{Cooper-pair size}}\) on the SOC strength and the scattering length at three dimensions (3D) (the bound-state energy at 2D) for three attractively interacting Fermi gases with 3D Rashba, 2D Weyl, and 2D Rashba SOC, respectively. We show that only the coherence length can be used to characterize this BCS to BEC crossover. Furthermore, it is the only length which can be directly measured by radio-frequency dissociation spectra type of experiments. We stress crucial differences among the coherence length, \(\xi_{\text{Cooper-pair size}}\) and boundariesize. Our results provide the fundamental and global picture of the BCS to BEC crossover and its experimental detections in various cold-atom and condensed-matter systems.

P1.00345 Theory of Luminescent Emission in a Nanocrystal Doped by Co\(^{2+}\) , GEORGE CHAPPELL, QUE Huong NGUYEN, Marshall University — We theoretically study the effect on the electronic structures and optical properties of a Co-doped semiconductor nanocrystal (NC) of the interaction between the impurity atom and an electron existing inside the NC. The optical properties of impurity centers in NCs are very different from the bulk cases. Beside the strong hybridization of \(s\)-electrons of the semiconductor host and\(d\)electrons of the impurity due to confinement and the modification of the crystal field near the surface of the NCs, the Coulomb and exchange interaction of the \(d\)-electrons of the impurity centers with the confined electrons (or holes) existing inside the NCs could change the photoluminescence properties. In the strong confinement approximation, the boundary conditions enhance the coupling, and the effect on photoluminescence could be large. The transition \(4\text{f}^1\text{d}^1\text{S} \rightarrow 4\text{f}^0\text{d}^0\text{S}\) has been considered. The exchange interaction between the extra electron and the states of the impurity ion together with the confinement effect mix the wave functions, split the impurity energy levels, break the previous selection rules, and change the transition probabilities. Energy, wave functions, luminescence efficiency, and transition lifetime have been calculated. The results imply that the PL intensity increases and the lifetime is shortened inside the NC.

P1.00346 Role of precursor crystal structure on electrochemical performance of carbide-derived carbon electrodes , BENJAMIN PALAZZO, ZACH NORRIS, GREG TAYLOR, Department of Physics and Astronomy, Rowan University, LEI YU, Department of Chemistry and Biochemistry, Rowan University, SAMUEL LOFLAND, JEFFREY HETTINGER, Department of Physics and Astronomy, Rowan University — Binary carbides with hexagonal and cubic crystal structures have been synthesized by reactive magnetron sputtering of vanadium and other transition metals in acetylene or methane gas mixed with argon. The binary carbides are converted to carbide-derived carbon (CDC) films using chlorine gas in a post-deposition process in an external vacuum reaction furnace. Residual chlorine has been removed using an annealing step in a hydrogen atmosphere. The CDC materials have been characterized by x-ray diffraction, x-ray fluorescence, and scanning electron microscopy. The performance of the CDC materials in electrochemical device applications has been measured with the hexagonal phase precursor demonstrating a significantly higher specific capacitance in comparison to that of the cubic phase. We report these results and pore-size distributions of these and similar materials.

P1.00347 Stabilizing the false vacuum: Mott skyrmions\(^1\) , MÁRTÓN KANÁSZ-NAGY, Harvard University and Budapest University of Technology and Economics, BALÁZS DÓRA, Budapest University of Technology and Economics, EUGENE DEMLER, Harvard University, GERGELY ZARAND, Budapest University of Technology and Economics — Topological excitations keep fascinating physicists since many decades. While individual vortices and solitons have been observed in many areas of physics, their intriguing higher dimensional topological relatives, skyrmions remained mostly elusive. In particular, earlier attempts to create stable individual skyrmions in ultracold atomic experiments suffered from important instabilities: skyrmions have a tendency to shrink or expand, and to slip away from the atomic trap. In this work, we propose that loading a three-component nematic superfluid, such as \(^{23}\text{Na}\), into a deep optical lattice and thereby creating an insulating core, one can create topologically stable individual skyrmions, and investigate their properties in detail. Furthermore, the spectrum of the excitations of the superfluid and their quantum numbers change dramatically in the presence of the skyrmion, and they reflect the presence of a trapped monopole, as imposed by the skyrmion’s topology.

P1.00348 In Silico Discovery of High Deliverable Capacity Metal-Organic Frameworks\(^3\) , YI BAO, Rice Univ, RICHARD MARTIN, Lawrence Berkeley National Lab, CORY SIMON, UC Berkeley, MACIEJ HARANCZYK, Lawrence Berkeley National Lab, BEREND SMIT, UC Berkeley, MICHAEL DEEM, Rice Univ, MICHAEL W. DEEM TEAM, MACIEJ HARANCZYK TEAM, BEREND SMIT TEAM — Metal organic frameworks (MOFs) are actively being explored as potential adsorbed natural gas storage materials for small vehicles. Experimental exploration of potential materials is limited by the throughput of synthetic chemistry. We here describe a computational methodology to complement and guide these experimental efforts. The method uses known chemical transformations in silico to identify MOFs with high methane deliverable capacity. The procedure explicitly considers synthesizability with geometric requirements on organic linkers. We efficiently search the composition and conformation space of organic linkers for nine MOF networks, finding 48 materials with higher predicted deliverable capacity (at 65 bar storage, 5.8 bar depletion, and 298 K) than MOF-5 in four of the nine networks. The best material has a predicted deliverable capacity 8% higher than that of MOF-5.

P1.00349 Many-body calculation for charge transport through triangular quantum dot molecules

Many-body calculation for charge transport through triangular quantum dot molecules

CHIH-CHIEH CHEN, YIA-CHUNG CHANG, Department of Physics, University of Illinois Urbana-Champaign, DAVID M.T. KUO, Department of Electrical Engineering and Department of Physics, National Central University — We study the many-body effect of electron tunneling through the coupled quantum dot systems in the Coulomb blockade regime. Using the equation of motion method for the non-equilibrium Green’s function, we calculate the charge current and conductance of junctions consisting of metallic electrodes and a few quantum dots. Many-particle correlation functions are explicitly solved numerically. Quantum phenomena like quantum interference, Coulomb blockade and spin blockade for the triangular quantum dot molecules are discussed. Our work suggests a new method for the modeling of the mesoscopic transport.

P1.00350 Confinement of metal nanoparticles with various sizes in silica matrices

JEUN LEE, SHIN-HYUN KANG, SUNG-MIN CHOI, KAIST — Many studies have been focused on metal nanoparticles since they have interesting properties due to their high surface area to volume ratio. While bulk metals have constant properties regardless of their sizes, the noble properties of metal nanoparticles such as catalytic activity, magnetic, and electronic properties dramatically change depending on their sizes. Here, metal nanoparticles with various sizes are synthesized, functionalized, then confined in stable silica matrices and their physical and chemical properties are investigated. The structure of each system is characterized by transmission electron microscopy (TEM) and scanning electron microscopy (SEM).

P1.00351 Fitness, environmental changes and the growth of modularity- a quasispecies theory for the evolutionary dynamics of modularity

LIANG NISTEMSKI, Western New England University, JEONG-MAN PARK, The Catholic University of Korea, MICHAEL DEEM, Rice University — Although the modularity of a biological system is demonstrated and recognized, the evolution of the modularity is not well understood. We here present a quasispecies theory for the evolutionary dynamics of modularity. Complemented with numerical models, this analytical theory shows the calculation of the steady-state fitness in a randomly changing environment, the relationship between rate of environmental changes and rate of growth of modularity, as well as a principle of least action for the evolved modularity at steady state.

P1.00352 Pressure dependence of the nematic spin correlations in detwinned BaFe$_{1.97}$Ni$_{0.03}$As$_2$

WENLIANG ZHANG, XINGYE LU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, JITAEPARK, Heinz Maier-Leibnitz Zentrum, Technische Universität München, Garching, Germany, PENGCHENG DAI, Department of Physics and Astronomy, Rice University, Houston — In the paramagnetic tetragonal phase of BaFe$_{2-x}$Ni$_x$As$_2$, inelastic neutron scattering shows a spin excitation anisotropy emerges at a temperature well above the structure transition temperature ($T_s$) [1], consistent with the onset of in-plane resistivity anisotropy [2]. However, how the applied uniaxial strain, which artificially breaks the four-fold symmetry, influences the observed anisotropy is still unclear. Here we studied the pressure dependence of the nematic spin correlations in detwinned BaFe$_{1.97}$Ni$_{0.03}$As$_2$. We find that the spin excitation anisotropy temperature ($T^*$) is largely enhanced when changing the pressure from a medium level (~8MPa) to a high level (~15MPa) [3]. Our results suggest the $T^*$ may be not a characteristic temperature where the system transit to a nematic phase, but a temperature the nematic fluctuations can reach under a uniaxial stress.

P1.00353 Evolution of sparsity and modularity in a model of living matter

MATHIEU HEMERY, Laboratoire Interdisciplinaire de Physique (Grenoble), OLIVIER RIVOIRE, CNRS & Université Grenoble Alpes — How much of the sequence of a protein is related to its evolutionary history? We present a theoretical model of a network of interacting proteins whose interactions are influenced by the environment. We show that the network becomes sparse and modular as the environment changes, and that the correlation between the environment and the network structure is related to the amount of information that is stored in the network.

P1.00354 Supramolecular Polymer Nanocomposites – Improvement of Mechanical Properties

JESSE HINRICHER, South Dakota Sch Mines & Tech, COLIN NEIKIRK, RODNEY PRIESTLEY, Princeton University — Supramolecular polymers differ from traditional polymers in that their repeat units are connected by hydrogen bonds that can reversibly break and form under various stimuli. They can be more easily recycled than conventional materials, and their highly temperature dependent viscosities result in reduced energy consumption and processing costs. Furthermore, judicious selection of supramolecular polymer architecture and functionality allows the design of advanced materials including shape memory and self-healing materials. Supramolecular polymers have yet to see widespread use because they can’t support much weight due to their inherent mechanical weakness. In order to address this issue, the mechanical strength of supramolecular polymer nanocomposites based on 1,4-diaminobenzene (DB) terephthalic poly(caprolactone) doped with surface activated silica nanoparticles was investigated by tensile testing and dynamic mechanical analysis. The effects of varying amounts and types of nanofiller surface functionality were investigated to glean insight into the contributions of filler-filler and filler-matrix interactions to mechanical reinforcement in supramolecular polymer nanocomposites.

P1.00355 Slip and flow dynamics of polydisperse thin polystyrene films

SEYED MOSTAFA SABZEVARI, Concordia university, JOSHUA D. MCGRaw, KARIN JACOBS, Saarland University, PAULA M. WOOD-ADAMS, Concordia university — We investigate the slip of binary and ternary mixtures of nearly monodisperse polystyrene samples on Teflon-coated (AF2400) silicon wafers using dewetting experiments. Binary mixtures of long and short chains along with ternary mixtures with a fixed weight-average molecular weight $M_w$ but different number-average molecular weight $M_n$ were prepared. Thin films of ca. 200 nm were spin coated on mica from polymer solutions and transferred to Teflon substrates. Above the glass transition temperature $T_g$ the films break up via nucleation and growth of holes. The hole growth rate and rim morphology are monitored as a function of $M_n$ and annealing protocol of the films before transfer to Teflon substrates. Slip properties, accessed using hydrodynamic models, and flow dynamics are then examined and compared. We found that the rim morphology and slip of polystyrene blends on Teflon depends on the molecular weight distribution. Similarly, flow dynamics is affected by the presence of short chains in mixture. Moreover, we can provoke differences in slip by choosing appropriate annealing and film transfer protocols for PS films that have first been spin cast on mica surfaces.
P1.00356 Particle-Laden Leidenfrost Droplets: Final-Stage Observations, ZECONG FANG, Washington State Univ, JIE XIU, University of Illinois at Chicago — Little interest has been paid to the final stage of a Leidenfrost droplet until a recent study by Celestini et al [Phys. Rev. Lett. 109, 034501 (2012)] reporting an unexpected take-off phenomenon of micrometer sized pure liquid droplets ($R_l < R < R_l$, where $R_l$ is the take-off radius, and $R_i$ is the critical radius above which droplets start to lose sphericity). In our study, we first report an unexpected observation on millimeter sized water Leidenfrost droplets ($R > R_l$), which behave quite differently from the previous study. While an originally micrometer sized Leidenfrost droplet takes off due to breakdown of lubrication regime, and hovers above its vapor layer until disappearing in the final stage of evaporation, an originally millimeter Leidenfrost droplet is observed to hover and oscillate, taking off and falling back consequentially. We further report another interesting observation, that just like pure droplets, these particle-laden drops create an unexpected explosive shoot-up at the end of evaporation.

P1.00357 Carbon Nanotubes Synthesis Through Gamma Radiation, PABLO TIRADO, RAFAEL GARCIA, Center of Research in Physics, University of Sonora, JORGE MONTES, Department of Nanotechnology, University of Sonora, RODRIGO MELENDEZ, MARCELINO BARBOZA, Center of Research in Physics, University of Sonora, OSCAR CONTRERAS, Center of Nano science and Nanotechnology, UNAM — Carbon nanotubes show a great potential of applications since there discovery by Iijima in 1991\(^1\) due to their numerous physical-chemical properties such as their high weight to strength relationship, which make them ideal to use in high resistance compound materials, and in many other applications\(^2\) In this work, a novel method for the synthesis of carbon nanotubes is presented, starting from an ultra-thin sheet of graphite synthesized by the chemical vapor decomposition technique (CVD), using ultra high purity methane and hydrogen at 1200°C in a horizontal quartz reactor. For the synthesis of carbon nanotubes, the graphite sheets were exposed to different doses of radiation, with the objective of breaking the graphite bonds and form carbon nanotubes; A Gammacell equipment model 220 Excel was used for the purpose, which counts with a radiation source of cobalt 60, and a current radiation rate of 0.9 Gy/seconds. The time of exposure to radiation was varied in each sample, according to the desired dose of radiation in each case, afterwards the samples were characterized using the Raman spectroscopy and TEM microscopy techniques with the objective of observing the kind of nanotubes formed, their morphology and their number of defects. Results will be shown during the poster session.

P1.00358 Hydration Layer of Enzymes Partially Controls Conformational Dynamics\(^1\), ZAHRA ALAVI, Student at UCLA, ZOCCHI TEAM — For a typical (20 kD, 4 nm size) monomeric enzyme, more than 50% of the residues are at the surface. The mechanics of these soft, heterogeneous nanoparticles was recently shown to be viscoelastic. Here we explore the contribution of the enzyme’s surface to the mechanics of the molecule. Nano-rheology provides sub-angstrom resolution measurements of the reversible deformation of the enzyme subject to an oscillatory mechanical stress. We perturb the surface of the enzyme by adding small amounts of DMSO, believed to affect ordering of the enzyme - water interface. We observe a dramatic though reversible change in the mechanics of the enzyme, which becomes more viscous. On the other hand, the catalytic speed is unaffected, while at higher DMSO concentrations (>1%) it even increases. Our measurements show that small (<1%) bulk concentrations of DMSO, which have negligible effect on the physico-chemical properties of bulk water, including the viscosity and dielectric constant, have nonetheless dramatic effect on the dynamics of the hydration layer of the enzyme, and ultimately on the enzyme’s mechanics. DMSO accumulates in the hydration layer (“binds to the surface of the enzyme”). Apparently the order - inducing (“kosmotropic”) quality of DMSO leads to a hardening of the enzyme - water interface.

P1.00359 Effect of monomer sequence distribution in poly(vinyl alcohol-co-vinyl acetate) on the hydrogen bonding structure and physical properties, SHUN TASAKA, OSAMU URAKAWA, TADASHI INOUE, Department of Macromolecular Science, Graduate School of Science, Osaka University — It has been well known that hydrogen (H-) bonding interaction in polymer materials strongly affects their properties. For example, glass transition temperature ($T_g$) and terminal relaxation time increase by introducing H-bonding sites. This is because the molecular motion is restricted due to the formation of inter- and intra-chain H-bonds. For H-bonding copolymers in which H-bonding monomer and non-bonding one are incorporated, the fraction dependence of their properties has been examined so far. However, the influence of sequence distribution on their properties has not been studied in detail. In this work, we investigated the H-bonding structure and physical properties of molten poly(vinyl alcohol-co-vinyl acetate) with different monomer sequences to clarify the effect of the sequence distribution. We found that, with increasing the randomness in monomer sequences, the number of H-bonds between carbonyl group and hydroxyl (OH) group increased. Moreover, OH groups form linearly connected structure (OH-OH-OH) and its number also increases with the increase of randomness. $T_g$ for the samples with higher sequence randomness are higher than those with lower randomness for high VOH copolymers. These results indicate that formation of larger number of H-bonds makes $T_g$ higher.

P1.00360 Quantum Behavior of an Autonomous Maxwell Demon, ADRIAN CHAPMAN, AKIMASA MIYAKE, Univ of New Mexico — A Maxwell Demon is an agent that can exploit knowledge of a system's microstate to perform useful work. The second law of thermodynamics is only recovered upon taking into account the work required to irreversibly update the demon’s memory, bringing information-theoretic concepts into a thermodynamic framework. Recently, there has been interest in modeling a classical Maxwell demon as an autonomous physical system to study this information-work tradeoff explicitly. Motivated by the idea that states with non-local entanglement structure can be used as a computational resource, we ask whether these states have thermodynamic resource quality as well by generalizing a particular classical autonomous Maxwell demon to the quantum regime. We treat the quantum description using a matrix product operator formalism, which allows us to handle quantum and classical correlations in a unified framework. Applying this, together with techniques from statistical mechanics, we are able to approximate nonlocal quantities such as the erasure performed on the demon's memory register when correlations are present. Finally, we examine how the demon may use these correlations as a resource to outperform its classical counterpart.

Session Q0 APS: Kavli Foundation Special Symposium: Frontiers of Light Ballroom A –
2:30PM Q0.00001 The Optical Microscopy Revolution, STEFAN HELL, Max Planck Institute —
3:42PM Q0.00003 Developing Photo Activated Localization Microscopy, HARRALD HESS, Janelia Research Campus — Photo Activated Localization Microscopy, PALM, acquires super-resolution images by activating a subset of activatable fluorescent labels and estimating the center of the each molecular label to sub-diffractive accuracy. When this process is repeated thousands of times for different subsets of molecules, then an image can be rendered from all the center coordinates of the molecules. I will describe the circuitous story of its development that began with another super-resolution technique, NSOM, developed by my colleague Eric Betzig, who imaged single molecules at room temperature, and later we spectrally resolved individual luminescent centers of quantum wells. These two observations inspired a generalized path to localization microscopy, but that path was abandoned because no really useful fluorescent labels were available. After a decade of nonacademic industrial pursuits and the subsequent freedom of unemployment, we came across a class of genetically expressible fluorescent proteins that were switchable or convertible that enabled the concept to be implemented and be biologically promising. The past ten years have been very active with many groups exploring applications and enhancements of this concept. Demonstrating significant biological relevance will be the metric if its success.

2:30PM Q1.00001 Bilayer graphene moire pattern amplitude vs. twist angle identified using scanning tunneling microscopy1, JOSHUA THOMPSON, PIJUSH GHOSH, PAUL THIBADO, University of Arkansas, MEHDI NEEK-AMAL, FRANCOIS PEETERS, Universiteit Antwerpen, V.D. WHEELER, R.L. MYERS-WARD, C.R. EDDY, JR., D.K. GASKILL, U.S. Naval Research Laboratory — Twisted stacked layers of graphene have unique electronic properties. The layers produce a moire pattern with a wavelength determined by the twist angle. In addition, however, the surface of the moire pattern also has an increased corrugation amplitude when compared to untwisted AB-stacked graphene. The deformation strains the top-layer graphene lattice and realizes, in a natural way, triaxial stress creation as proposed by Guinea et al. Consequently, very large pseudo-magnetic fields can be created depending on the amplitude of the corrugations. Until now, no relation has been found between the moire twist angle and its corrugation amplitude. We found, using scanning tunneling microscopy, as the wavelength of the moire pattern increases so does its amplitude. Our experiments are supported by first-principles directed elasticity theory. The membrane corrugation amplitude at arbitrary twist angle is found to be a consequence of a competition between the van der Waals bonding energy and the energy required to bend the graphene.

2:42PM Q1.00002 Electronic properties and van Hove singularities of observed moiré patterns of dislocated graphene on HOPG, OGUZ GULSEREN1, H. SENER SEN, Bilkent University, DILEK YILDIZ, OGUZHAN GURLU, Istanbul Technical University — Highly Oriented Pyrolitic Graphite (HOPG) can be described as stacked graphene layers. Due the weak van der Waals interaction between the layers, topmost layer of HOPG can be rotated or shifted by chemical or mechanical means. With rotation of the topmost layer, super periodic structures called as moiré patterns are formed. In this work, moiré patterns on HOPG surfaces due to dislocated graphene layers were studied. A simple geometric investigation of the atomic structure of the moiré patterns revealed that different atomic moiré periodicities result in similar geometric moiré periods. Our calculations showed that the band structure of moiré patterns even though exhibits the fingerprints of those of twisted bilayer graphene system, like the preserved Dirac cone at the K point of moiré Brillouin zone, it has several new emerging features like van Hove singularities and linear or flat bands depending on the moiré periodicity. Our results show that most of the moiré patterns observed on graphene/HOPG system do not have a purely electronic or structural origin, but both. Moreover, our results show that van Hove singularities in these systems with different twist angles have different origins in their respective band structure.

1e-mail: gulneren@fen.bilkent.edu.tr

2:54PM Q1.00003 Transport measurements of van Hove singularity in twisted bilayer graphene, JUNXI DUAN, JINHAI MAO, YUHANG JIANG, GUOHONG LI, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, MONA ZEBARJADI, Department of Mechanical Engineering, Rutgers University, Piscataway, NJ, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ — Crossing between the Fermi energy and a van Hove singularity causes electronic instabilities which may result in new correlated phases such as superconductivity, magnetism and charge density waves. These crossings are usually rare and difficult to control as they are determined by the chemical composition and structure of the material. However, as was recently demonstrated in STM measurements, twisted graphene layers display van Hove singularities whose energy can be controlled by tuning the twist angle between them. Combining this flexibility with the ability to tune the Fermi energy by gating, makes it possible to bring these two energies together. But in order to induce an observable electronic instability the crossing energy must be uniform across the sample, which is difficult to achieve due to the potential fluctuation induced by insulating substrates. To investigate the possibility of a gate induced phase transition we fabricated devices with gated and precisely twisted graphene layers on minimally invasive substrates including hBN and suspended samples. We will report our findings on transport and STM measurements that revealed the global and local effects of gate induced band structure reconstruction.

3:06PM Q1.00004 Electronic signatures of stacking domain boundaries in twisted bilayer graphene¹. FERNANDO GARGIULO, BASTIEN GROSSO, GABRIEL AUTÉS, OLEG YAZYEV, EPFL — Experiments on bilayer graphene (BLG) show the coexistence of regions of inequivalent stacking order (AB and BA) separated by domain boundaries, topological defects akin to solitons [1]. The Frenkel-Kontorova model predicts that in-plane atomic displacements result in stacking domain boundaries of few nanometers width. We show how a hexagonal network of stacking domain boundaries naturally arises in twisted BLG in the limit of small twist angle (below ca. 1°). Equilibrium configurations of twisted BLG have been produced by means of classical force-field simulations. Atomic displacements diminish the area of AA stacking regions and extend the AB and BA stacking regions to triangular domains separated by boundaries of 7–8 nm width. Large-scale tight-binding simulations unveil the electronic properties of such twisted BLG models. A charge density depletion is the low-energy signature of stacking domain boundaries with electronic states mostly confined in AB and BA domains. Zero-energy states at the network nodes reach an asymptotic localization for vanishing twist angles. We propose STM experiments for confirming our predictions.

¹This work is supported by the Swiss NSF Grant no. PP00P2_133552.

3:18PM Q1.00005 Study of the optical phonons on gated twisted bilayer graphene , TING FUNG CHUNG, Purdue Univ, RUI HE, Univ of Northern Iowa, TAI-LUNG WU, YONG P. CHEN, Purdue Univ — In twisted bilayer graphene (tBLG), the low-energy van-Hove singularities (vHs) in the density of states (DOS) can be continuously tuned by twisting the two layers, leading to distinct electronic and optical properties compared to Bernal-stacked BLG (AB-BLG). This effect has been explored using resonance Raman scattering, showing enhanced Raman G and ZO' (low frequency, layer breathing vibration) bands when the vHs energy resonates with excitation laser energy. We have studied the influence on vHs and Raman bands in gated tBLG devices (at resonant twist angle ∼13° under a 532 nm laser light). We observed that the G band splits with increasing doping, attributed to asymmetric doping of charge carriers in the two layers. The strongly quenched G band intensity at high doping level is ascribed to the suppression of resonant interband transitions between the two saddle points (in conduction and valence bands) which are displaced in the momentum space by gate-tuning. We have also measured the doping dependence of ZO' band and R band in tBLG. Our results demonstrate that electric-field can be used to tune the optoelectronic and vibrational properties in tBLG devices.

3:30PM Q1.00006 Electronic Band Structure Modification upon Doping in Twisted Bilayer Graphene , SHENQIANG HUANG, MATTHEW YANKOWITZ, KANOKPORN CHATTRAKUN, ARVINDER SANDHU, BRIAN LEROY, Univ of Arizona — In twisted bilayer graphene, the electronic band structure and phonon dispersion depend on the rotation angle between the layers. From 9 to 15 degrees, the Raman G peak measured with a 532 nm laser is enhanced due to an increased density of states. The enhancement is a maximum at a critical angle of about 12 degrees where the laser energy matches the energy separation between the van Hove singularities in conduction and valence bands. We conduct a systematic study of the G peak enhancement upon doping up to charge densities of 2*10¹³ cm⁻². The G peak enhancement drops monotonously upon doping for angles smaller than the critical angle. In contrast, for angles larger than the critical angle, the G peak enhancement increases with doping at first before decreasing at higher doping levels. The charge density where the maximum enhancement occurs, scales with the rotation angle above the critical angle. This indicates that the band structure of twisted bilayer graphene is modified and the Fermi velocity is reduced upon doping.

3:42PM Q1.00007 The strong coupling limit of twisted bilayer graphene at large twist angles , HRIDIS PAL, STEPHEN SPITZ, MARCUS KINDERMANN, Georgia Institute of Technology — Using a recently proposed long-wavelength theory for twisted bilayer graphene near commensuration [1], we show that a strong distortion of energy bands can occur in such systems at large angles of twist. This is in contrast with the previously accepted belief that such non-trivial physics can arise only at extremely small angles of twist. At large angles, sufficiently close to commensuration, the system is driven to a non-perturbative regime (in the effective interlayer coupling), and it becomes locally gapped. We discuss the implications of this for the energy spectrum of the bilayer. [1] Theory of Twisted Bilayer Graphene Near Commensuration, Hridis K. Pal, Steven Carter, and M. Kindermann, arXiv:1409.1971.

3:54PM Q1.00008 Twisted Graphene Nanostructures , SATRIO GANI, YUDISTIRA VIRGUS, ENRICO ROSSI, College of William and Mary — Recent advances in fabrication techniques have made possible the realization of graphene nanostructures with atomic precision. Some of the nanostructures realized are completely novel. We study the electronic properties of such novel graphene nanostructures when deposited on two dimensional crystals. In particular we study the case when the two dimensional crystal is graphene, or bilayer graphene. We obtain results for the nanostructure electronic spectrum and find how the spectrum is affected by the coupling between the nanostructure and the two-dimensional substrate. In particular we study how the “twist” angle between the graphene nanostructure and the two-dimensional crystal affects the spectrum of the nanostructure.

4:06PM Q1.00009 The Interdependent Atomic and Electronic Structures of Graphene on Hexagonal Boron Nitride¹ , JEIL JUNG, Department of Physics, National University of Singapore, ASHLEY DASILVA, ALLAN MACDONALD, Department of Physics, The University of Texas at Austin, SHAFFIQUE ADAM, Yale-NUS college, Graphene Research Centre and Department of Physics, National University of Singapore — Recent progress in preparing well controlled 2D van der Waals heterojunctions has opened up a new frontier in materials physics. I will address the intriguing energy gaps that are sometimes observed when a graphene (G) sheet is placed on a hexagonal boron nitride (hBN) substrate, demonstrating that they are produced by an interesting interplay between structural and electronic properties, including electronic many-body exchange interactions. Our theory is able to explain the observed gap behavior by accounting first for the structural relaxation of graphene’s carbon atoms when placed on a hBN substrate and then for the influence of the substrate on low-energy π-electrons located at relaxed carbon atom sites. All three contributions of the moire pattern pseudospin Hamiltonian play a role in defining the features of the moire bands including the degeneracy of the mini-Dirac cones and the particle-hole asymmetry. We find that the effective anisotropic strains arising from virtual hopping are associated with effective magnetic fields on the order of ~10 T and they dominate over the pseudomagnetic vector potentials generated by the moire strains due to partial commensuration.

and identify the layer thickness of MX₂ properties distinctly different from those of bulk crystals, such as a direct rather than an indirect band gap, strong photoluminescence, and large exciton binding energy. For the twisted angle 30° or 60°, the photoluminescence spectra of twisted bilayer MoS₂ are investigated, revealing a tunability of the interlayer coupling of bilayer MoS₂. For the twisted angle 0° or 90°, the photoluminescence spectra of the trion and exciton of bilayer MoS₂ shows the highest intensity ratio, and the trion binding energy reaches its maximum value. For the twisted angle 30° or 90°, the situation is the opposite. These experimental observations are mainly attributed to the change of the interlayer coupling with the twisted angle. The first-principles density functional theory analyses further confirm that the band modification by the Moire superlattice is a promising material for optoelectronic devices due to its strong and stable photoluminescence emissions. In this work, the photoluminescence spectra of twisted bilayer MoS₂ materials, such as MoS₂, WS₂, MoSe₂, and WSe₂. Monolayers of these materials exhibit many physical properties distinctly different from those of bulk crystals, such as a direct rather than an indirect band gap, strong photoluminescence, and large exciton binding energies. Raman spectroscopy provides a powerful tool to characterize atomically thin 2D materials, having been utilized to probe the electron-phonon coupling and identify the layer thickness of MX₂ materials. To better understand Raman spectra, we perform systematic studies of Raman scattering in different MX₂ materials as a function of the photon excitation energy, light polarization, and spatial position. I will discuss their implications for quantitative characterization of MX₂ materials using Raman spectroscopy.
2:54PM Q2.00003 Characterizing and tuning excitons in monolayer and few-layer \( \text{MoS}_2 \). DIANA Y. QIU, FELIPE H. DA JORNADA, STEVEN G. LOUIE, Univ of California - Berkeley and Lawrence Berkeley National Lab — We use the GW-BSE method to study excitons arising from transitions in different regions of momentum space in mono- and few-layer \( \text{MoS}_2 \) and consider mechanisms to fundamentally change the features and character of the optical spectra. Our calculations show that sharp spatial variations in dielectric screening make 2D systems, such as \( \text{MoS}_2 \), computationally challenging, requiring very fine \( k \)-space sampling to resolve the structure of excitonic wave functions and converge binding energies. In highly converged calculations, we identify a series of excitons arising from transitions at the \( K/K' \) valleys in the Brillouin zone, a higher energy series arising from transitions in the valley of a Mexican hat potential centered at the \( \Gamma \) point, and transitions at the indirect gap from \( \Gamma \) to \( \Lambda \) in a few-layer \( \text{MoS}_2 \). As layer number changes, these states, which have varying character, momentum-space structure and real-space locations, are affected differently by changes in confinement and hybridization. By tuning layer number and strain, we find that we not only can tune the excitation energies but can also change the relative energies of the various excitonic series, allowing for movement of the lowest energy exciton between different regions of the Brillouin zone.

3:06PM Q2.00004 Exciton band structure of monolayer \( \text{MoS}_2 \). FENGCHENG WU, Department of Physics, University of Texas at Austin, FANYAO QU, Department of Physics, University of Texas at Austin; Instituto de Física, Universidade de Brasília, ALLAN MACDONALD, Department of Physics, University of Texas at Austin — We describe a theory of the momentum-dependent exciton spectrum of monolayer molybdenum disulfide. Low-energy excitons occur both at the Brillouin zone center and at the Brillouin-zone corners. We find that binding energies at the Brillouin-zone center deviate qualitatively from the \( (n-1/2)^{-2} \) pattern of the two-dimensional hydrogenic model. Moreover, the four \( 2p \) states of \( A \) series are lower in energy than the corresponding \( 2s \) states and not degenerate. The two-fold ground-state valley degeneracy is lifted linearly at small momenta by electron-hole exchange processes that establish inter valley coherence. We conclude that although monolayer \( \text{MoS}_2 \) is a direct-gap semiconductor when classified by its quasiparticle band structure it may well be an indirect gap material when classified by its excitation spectra, and speculate on the role of this property in luminescence processes that establish inter valley coherence.

3:18PM Q2.00005 Helicity Resolved Raman Scattering of Atomic Layers of Transition Metal Dichalcogenides, SHAO-YU CHEN, JUN YAN, Univ of Mass - Amherst — Semiconducting transition metal dichalcogenides (TMDs) such as \( \text{MoS}_2 \), \( \text{MoSe}_2 \), \( \text{WS}_2 \) and \( \text{WSe}_2 \) are promising two dimensional (2D) materials for electronic and optoelectronic applications. Moreover, the unique capability to manipulate the valley degree of freedom with circularly polarized light has attracted widespread attention for potential applications in valley- and spintronics. In this talk we present helicity resolved Raman scattering of TMD atomic layers. The dominant first order Raman bands, including the low energy breathing and shear modes as well as the high energy zone center optical phonons, are found to either maintain or completely switch the helicity of incident photons. This helicity selectivity due to phonon scattering is interpreted by symmetry of lattice vibrations without involving intervalley scattering. Our results provide a useful tool for characterization of TMD atomic layers and offer new insights into the connection between photon helicity and valley polarization.

3:30PM Q2.00006 Energy splitting of excitons in gapped Dirac materials. DI XIAO, JIANHUI ZHOU, WENYU SHAN, Carnegie Mellon Univ, WANG YAO, Univ. of Hong Kong, SATOSHI OKAMOTO, Oak Ridge National Laboratory — We show that there is an energy splitting between excitons with opposite angular momentum in gapped Dirac materials, such as monolayers of transition metal dichalcogenides and gapped surface states of topological insulators. This splitting can be traced back to the chiral nature of Dirac electrons. We also discuss the optical selection rule of excitons in gap Dirac materials and clarify the relationship to its single-particle counterpart. A simple estimation of the splitting (~ 10 meV) in monolayer transition metal dichalcogenides is given. Our result reveals the limitation of the venerable hydrogenic model of excitons, and highlights the importance of the Berry phase in...
4:42PM Q2.00010 Temperature and polarization dependence of photoluminescence in monolayer tungsten diselenide. JIANI HUANG, THANG HOANG, MAIKEN MIKKELSEN, Department of Physics, Duke University — Two-dimensional transition metal dichalcogenides (TMDCs) have recently attracted considerable research interest, due to their plasmonic properties and applications in electronics, optics, and spintronics. Here, we experimentally study the evolution of photoluminescence (PL) from mechanically exfoliated monolayer tungsten diselenide (WSe$_2$) from $T = 10$ K to room temperature. At $T = 10$ K, we observe a clear free exciton ($X^0$) emission at 1.75 eV together with a charged trion emission at 1.72 eV, yielding a trion binding energy of 30 meV. Temperature dependent PL measurements show that both the free exciton and trion exist up to room temperature, as a result of the large exciton ($\sim 370$ meV) and trion binding energies of WSe$_2$, while other localized and defect-related emission peaks vanish above $T = 65$ K. Temperature dependent polarization of the exciton and trion emissions reveal a combined effect of large exciton binding energy, anisotropic thermal expansion and exciton-phonon interaction. These findings may provide a new platform to explore the valley polarization and valley-spin coupling in monolayer TMDCs.

5:06PM Q2.00012 Plasmonic enhanced Photoluminescence and absorption in MoS$_2$ single layers. ADNEN MLAYAH, CEMES-CNRS-Paul Sabatier University, Toulouse, SINA NAJMAEI, Department of Mechanical Engineering & Materials Science, Rice University, Houston, INES ABID, CEMES-CNRS-Paul Sabatier University, Toulouse, ARNAUD ARBOUET, CHRISTIAN GIRARD, CEMES-CNRS, Toulouse, JEAN LÉOTIN, LNCMI-CNRS, Toulouse, JUN LOU, Department of Mechanical Engineering & Materials Science, Rice University, Houston — We report the successful transfer of CVD grown MoS$_2$ to Au antenna fabricated using e-beam lithography, and we investigate the photoluminescence properties of this hybrid plasmonic-exciton system. The work is focused on the plasmonic mediated pumping of the MoS$_2$ photoluminescence emission. Off- and in-resonance excitation of the surface plasmons showed drastically different behaviors of the photoluminescence emission from the MoS$_2$. For plasmonically mediated pumping, we found a significant enhancement of the photoluminescence intensity, emission peak broadening and red-shift. Based on numerical simulations of the plasmonic properties of the Au antenna, combined with heat dissipation calculations, we found that the results can be interpreted in terms of efficient light absorption by the plasmonic antenna and conversion into electron-hole pair excitations of the 2D MoS$_2$ layer thus producing a photo-induced heating.

5:18PM Q2.00013 Correlative confocal Raman Imaging for 2D materials. JIANYONG YANG, WEI LIU, WITec Instruments Corp., THOMAS DIEING, HARALD FISCHER, MARIUS HENRICH, OLAF HOLLRICHER, WITec GmbH — Graphene was one of the first two-dimensional materials which soon after its mono-layer production received much attention by many researchers worldwide. Its properties vastly differ from bulk graphite and its potential for applications ranges from transistors to transparent conducting electrodes and solar cell applications. While graphene is arguably the most prominent two-dimensional material there are to date many more that are subject to current research such as MoS$_2$, WS$_2$ or MoSe$_2$. Graphene has been already and still is extensively studied using a variety of characterization techniques. Raman spectroscopy and more importantly still, Raman imaging proved to be of great value due to the clearly different spectra obtained from single, double, triple and multi-layered Graphene. This and more information that can be extracted from Raman spectroscopy and imaging can be well be complemented with various forms of atomic force microscopy (AFM), Scanning Nearfield Optical Microscopy (SNOM), and scanning electron microscopy (SEM). In this contribution we illustrate the benefit of correlating said techniques with confocal Raman imaging in order to deepen the understanding of the samples in question.

Wednesday, March 4, 2015 2:30PM - 4:54PM — Session Q3 FIP: Invited Session: Condensed Matter Physics in Latin America II 002AB - Edmond L Berger, Arqonne National Laboratory

2:30PM Q3.00001 Spin dynamics with Solid State NMR and GPU calculations: Loschmidt Echoes, Intrinsic Decoherence and Quantum Dynamical Phase Transitions. HORACIO M. PASTAWSKI, Instituto de Física Enrique Gaviola, Universidad Nacional de Cordoba — After overviewing argentine Condensed Matter Physics outside the Metropolitain area I will focus on the Loschmidt Echo (LE), a concept developed and pursed at Córdoba. It is the recovered fraction of a localized excitation after a spreading protocol followed by an imperfect time reversal procedure [1]. In Solid State NMR, the LE has allowed us to quantify the decoherence and irreversibility induced by an uncontrolled environment. Notably complex many-body dynamics makes the system particularly sensitive to environmental disturbances presenting a decoherence rate much slower than decoherence expected beyond some small threshold. These experiments and the theoretical analysis based on the Feynman’s path integral, summarized at a tutorial level, fueled the field of dynamical quantum chaos [4]. The quest for a perturbation independent decoherence as an emergent phenomenon in thermodynamic limit, lead us to discuss other dynamical observables that depend non-analytically on the environment strength, i.e. that undergo a quantum dynamical phase transition QDPT [2]. GPU based high performance computing boosts the evaluation of the LE [3], allowing us to asses thermalization and how the Metal-Insulator transition (also a QDPT) emerges in interacting many-body systems.

3:06PM Q3.00002 An Upgrade for the Brazilian Synchrotron Light Source: Are you Sirius? ANTONIO JOSÉ ROQUE DA SILVA, Laboratório Nacional de Luz Síncrotron – LNLS — The application of synchrotron radiation in a great variety of fields in general, and condensed matter in particular, has increased steadily worldwide. This, to a large extent, is a result of the availability of the much brighter third-generation light sources, which opened up new experimental techniques. Recently, new developments in accelerator technology are paving the way for even brighter sources, which are being named fourth-generation light sources. Sirius, the future new Brazilian synchrotron, is one of the first two such machines being currently constructed in the world. Its first light is expected by 2018. It is being planned to be a state of the art machine, providing tools for cutting edge research that are non-existent today in Brazil. It is a project designed and executed by the Laboratório Nacional de Luz Síncrotron – LNLS, which was also responsible for the construction of the current second generation Brazilian light source, the first synchrotron in the southern hemisphere, still the only one in Latin America. In this talk an overview of the status of Sirius will be provided.

3:42PM Q3.00003 Large area radiation detectors based on II VI thin films, MANUEL QUEVEDO-LOPEZ, University of Texas at Dallas — The development of low temperature device technologies that have enabled flexible displays also present opportunities for flexible electronics and flexible integrated systems. Of particular interest are possible applications in flexible, low metal content, sensor systems for unattended ground sensors, smart medical bandages, electronic ID tags for geo-location, conformal antennas, neutron/gamma-ray/x-ray detectors, etc. In this talk, our efforts to develop novel CMOS integration schemes, circuits, memory, sensors as well as novel contacts, dielectrics and semiconductors for flexible electronics are presented. In particular, in this presentation we discuss fundamental materials properties including crystalline structure, interfacial reactions, doping, etc. defining performance and reliability of II-VI-based radiation sensors. We investigate the optimal thickness of a semiconductor diode for thin-film solid state thermal neutron detectors. Besides II-VI materials, we also evaluated several diode materials, Si, CdTe,GaAs, C (diamond), and ZnO, and two neutron converter materials, 10B and 6LiF. We determine the minimum semiconductor thickness needed to achieve maximum neutron detection efficiency. By keeping the semiconductor thickness to a minimum, gamma rejection is kept as high as possible. In this way, we optimize detector performance for different thin-film semiconductor materials.

4:18PM Q3.00004 Condensed Matter Physics in Colombia is in its forties, ANGELA CAMACHO, Universidad de Los Andes — Physics in Colombia started to develop in the 70’s as a research part of basic sciences with the acquisition, at that time, of large research equipments such as x-rays and EPR. Experimental work was soon supplemented by theoretical investigations, which led to the formation of research groups in condensed matter in the early 80’s. The early 80’s existed such groups in five universities. In this report we present, after a short history of the main steps that guided the initial research subjects, the major areas already developed and the minor research groups that are in the stage of consolidation. Currently this type of work is done at least in 20 universities. We also show the actual numbers of researchers, publications, PhD students and laboratories discriminated in gender to complete an overview of Condensed Matter Physics in Colombia. Finally, we present a short review of the main theoretical issues that have been worked in the last decade focusing on low dimensional systems, their structural and optical properties.

Wednesday, March 4, 2015 2:30PM - 5:30PM – Session Q4 DCMP: Invited Session: Fractional Quantum Hall Effect: New Directions Mayor Cockrell Room 004 - Jainedra Jain, Pennsylvania State University

2:30PM Q4.00001 Interacting Flatland Electrons Never Stop Surprising, MANSOUR SHAYEGAN, Princeton University — I will present the highlights of several new magneto-transport experiments that probe the physics of interacting two-dimensional (2D) electrons (or holes) at high magnetic fields and low temperatures. These include: (1) observation of rare fractional quantum Hall states at even-denominator (1/2) filling factor in 2D hole systems at an unusual crossing of the two lowest Landau levels [1,2]; (2) tuning and measuring the shape and anisotropy of the composite fermion (CF) Fermi contours [3-5], and (3) data suggesting that CFs themselves can be interacting and form their own fractional quantum Hall and Wigner solid states [6]. I will also discuss a bilayer experiment where the CFs in one layer are used to probe an electron Wigner solid in the other layer [7]. (Work done in collaboration with Yang Liu, D. Kamburov, M.A. Mueed, S. Hadsenir, I. Jo, H. Deng, L.N. Pfeiffer, K.W. West, and K.W. Baldwin. Supported by the NSF, DOE, Keck, and Moore Foundations.)

3:06PM Q4.00002 Composite Fermions and Broken Symmetries in Graphene, DAVID GOLDHABER-GORDON, Stanford Univ — No abstract available.

3:42PM Q4.00003 Even-denominator fractional quantum Hall physics in ZnO, JURGEN SMET, Max Planck Institute for Solid State Research — The study of even denominator fractional quantum Hall physics has for a long time been the exclusive privilege of the III-V semiconductor community. Its discovery at filling 5/2 and 7/2 in GaAs unleashed a flood of theoretical as well as experimental work, because these states are in essence thought to be p-wave superconducting ground states possessing non-abelian excitations. Recently however even-denominator fractional quantum Hall physics has been observed outside of the realm of III-V heterostructures in the emergent ZnO 2D electron system. ZnO not only exhibits a robust quantum Hall state at filling 7/2, but also at unconventional fillings. There is an incipient 9/2 state in perpendicular field and a fully resolved 3/2-state emerges when tilting. The latter is believed to be, just like the 7/2 state, a genuine single component state analogous to the 5/2 and 7/2 states in GaAs. Alternatively, it could be a two component spin state, a variant two-component state that has not previously been reported. The use of ZnO for investigating this even denominator FQH-physics offers a powerful additional degree of freedom. Because the Zeeman splitting and the cyclotron energy are comparable, it is possible to alter the orbital character of the partially filled level at fixed filling by tilting the sample. Our studies show unequivocally that the orbital nature of the partially filled level is crucial for the appearance of even-denominator fractional quantum Hall physics. While a basic understanding has been developed, key features remain to be understood with the spin degree of freedom likely playing a prominent role. This work has been performed together with J. Faison (University of Tokyo), D. Maryenko (RIKEN), B. Friess (MPI-FKF), D. Zhang (MPI-FKF), Y. Kozuka (University of Tokyo), A. Tsukazaki (Tohoku University and JST), M. Kawasaki (University of Tokyo and RIKEN).
4:18PM Q4.00004 Proliferation of Neutral Modes in Fractional Quantum Hall Regimes, HIROYUKI INOUE, Braun Center for Submicron Research, Department of Condensed Matter Physics, Weizmann Institute of Science — The fractional quantum Hall effect (FQHE) is a canonical example of 2D topological phases. Being incompressible in the bulk, available low-energy charged excitations are only at the edge: gapless chiral 1D edge channels. Various collective phenomena can emerge when interactions take place between coexisting multiple edge channels. Recently, there is a surge of energy transport in FQHEs besides the charge transport. A notable example is upstream neutral edge modes in so-called hole-like fractional FQHEs, arising from the interacting channels, which remained elusive despite of an early theoretical prediction. In this talk, I will describe the observation of such neutral modes stabilized via our sensitive shot noise measurements. Surprisingly, they were found not only in the hole-like FQHEs, as theoretically expected, but also in particle-like FQHEs and, furthermore, in the bulk. Our result presents a new picture of energy transport in FQHEs. The presence of various neutral modes may imply their unfavorable roles as potential decoherers for fractional quasiparticles. Hence, understanding the properties of the neutral modes may allow us to control decoherence and thus to conclusively observe quantum oscillations of the fractional quasiparticles.

In collaboration with Anna Grivnin, Yuval Ronen, Moty Heiblum, Vladimir Umansky, Diana Mahalu, Braun Center for Submicron Research, Department of Condensed Matter Physics, Weizmann Institute of Science.

4:54PM Q4.00005 NMR probing of quantum electron solids in high magnetic fields, TREvor DAVID ROHNE, NTT and ERATO-JST — In the presence of a high magnetic field, a two dimensional electron system (2DES) is expected to manifest Wigner crystal phases. Over thirty years ago, the search for the Wigner solid led to the discovery of the fractional quantum Hall effect (FQHE). Since then, with the advent of GaAs quantum wells with increasingly high mobility, 2DESs in the quantum Hall regime have proved to be a hunting ground for exceedingly rich many-body physics. Incompressible liquid FQHE states were found to occur in the first Landau level at several fractional filling factors \( v \) with odd-denominator. The sequence of FQHE states is truncated by the formation of a Wigner crystal of electrons at very low filling factors, the transition being affected by disorder. In the second Landau level, composite fermions, the quasiparticles of the FQHE, can pair to yield a remarkable even-denominator FQHE state, whose properties are at the forefront of investigation. More recently, electronic solid phases have been shown to emerge among integer quantum Hall states. In this talk, I will discuss a new tool, resistively detected NMR, which serves as a direct local probe of in-plane charge density modulations in the 2DES. In our recent work we probe the local charge density landscape of Wigner solids in the vicinity of \( v = 2 \) and \( v < 1/3 \) revealing quantum correlations. This unprecedented access to the microscopic behavior of these exotic solid phases opens up new venues in FQHE studies. Furthermore, our NMR technique can probe in-plane charge density fluctuations due to disorder, allowing increased access to understanding roles of disorder in quantum Hall systems. In addition, our latest NMR measurements reveal evidence for charge inhomogeneity in the third Landau level which leads to the possibility of studying bubble and stripe phases in this regime. Future directions may find our NMR technique applied to other exotic phases such as quasiparticle solid phases, which have been proposed to emerge near the \( v = 1/3 \) and 5/2 FQHE states.

Wednesday, March 4, 2015 2:30PM - 5:18PM – Session Q5 DMP DCOMP: Focus Session: Search for New Fe-based Superconductors II

2:30PM Q5.00001 Itinerant magnetism in metallic CuFe2Ge2\(^2\), K. V. SHANAVAS, D. J. SINGH, Oak Ridge National Laboratory — Discovery of superconductivity in iron pnictides and chalcogenides has generated interest in the coexistence and interplay of superconductivity and magnetism. Antiferromagnetic spin fluctuations are believed to be mediating superconductivity in these systems. The large spin-fluctuations may arise as a consequence of nearness to a quantum critical point (QCP), which can also lead to non-Fermi liquid behavior, unusual transport and novel ground states. Thus, it is of interest to look for other materials that share similar characteristics. Using density functional theory based calculations we have studied the electronic structure and magnetic properties of CuFe2Ge2 based on it’s structural similarities with recently discovered YFe2Ge2. We find large density of states at the Fermi level \([N(E_F)]\), consistent with itinerant character. Fermi surfaces in this system have a sheet like structure amenable to nesting and consequently to magnetic instabilities. Our results suggest that CuFe2Ge2 is an antiferromagnetic metal, with similarities to the Fe-based superconductors; such as magnetism with substantial itinerant character and coupling between magnetic order and electrons at the Fermi energy.

2:42PM Q5.00002 Universal V-shaped phase diagram in the iron-based superconductors XFe2As2 (X = K, Rb, Cs) , ALEXANDRE OUELLET, FAZEL FALLAH TAFTI, ALEXANDRE JUNEAU-FECTEAU, SAMUEL FAUCHER, MAXIME LAPOINTE-MAJOR, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, University of Sherbrooke, AIFENG WANG, XIGANG LUO, XIANHUI CHEN, University of Science and Technology of China — Following the discovery of a sharp reversal in the dependence of \( T_c \) on pressure in KFe2As2 [1] and CsFe2As2 [2], we report a similar behavior in RbFe2As2. The application of hydrostatic pressure initially decreases \( T_c \), until a critical pressure \( P_c = 11 \) kbar where \( T_c \) suddenly starts to increase. For the three materials, we find a universal V-shaped temperature-pressure phase diagram, with identical slopes above and below \( P_c \). Upon crossing \( P_c \), the upper critical field \( H_{c2} \) is observed to jump, by a similar factor for KFe2As2 and RbFe2As2. We interpret these universal features in terms of a pressure-induced change in the pairing state of these superconductors. [1] F. F. Tafti et al., Nature Physics 9, 349 (2013). [2] F. F. Tafti et al., Physical Review B 89, 134502 (2014).

2:54PM Q5.00003 Field dependence of thermal conductivity in XFe2As2 (X = K, Rb, Cs), PATRICK BOURGEOIS-HOPE, F. F. TAFTI, B. VINCENT, N. DOIRON-LEYRAUD, L. TAILLEFER, University of Sherbrooke, Sherbrooke, Canada, A.F. WANG, X.-G. LUO, X.H. CHEN, University of Science and Technology of China, Hefei, China — There is ongoing debate over the pairing symmetry in the hole-overdoped iron-based superconductor KFe2As2. While thermal conductivity [1] and penetration depth [2] data have been taken as evidence of a d-wave pairing state, heat capacity [3] and ARPES [4] have been interpreted within an s-wave state with accidental nodes on some parts of the Fermi surface. Here we report a complete study of the magnetic field dependence of thermal conductivity in the \( T = 0 \) limit for the isostructural materials XFe2As2 with X = K, Rb and Cs. Extending our previous results of KFe2As2 to RbFe2As2 and CsFe2As2 reveals a universal behaviour, implying that all three materials must have a very similar nodal structure. All data are found to be in excellent agreement with calculations for a d-wave superconductor. A similar nodal quasiparticle behaviour across different materials is natural within a d-wave state, a common nodal structure being automatically imposed by symmetry. By contrast, such similarity would be highly coincidental if nodes are accidental, as in an s-wave state.

3:06PM Q5.00004 Novel Materials & Multi-scale Analysis of the Superconducting State in Iron Based Superconductors1, ATHENA S. SEFAT, Oak Ridge National Laboratory — The understanding of the fundamental nature of a material's superconducting state is of crucial importance, if superconductors are to fulfill their promise for widespread use in energy-related needs. Our research applies multi-scale characterization techniques to study and probe the nuclear, electronic, and magnetic details of single crystals. The importance of such broad investigative work is demonstrated in our recent publication on praseodymium-doped BaFe2As2 for which non-uniform local distortions through isolated Pr atoms do not provide percolation path superconductivity [1]. For CaFe2As2, it is found that large Fermi-surface reconstruction in the non-magnetic phase causes a non-superconducting ground state [2], while different crystalline domains with varying lattice parameters are identified [3]. For Co-doped BaFe2As2 it is found that orthorhombic distortion below Tc leads to magnetically ordered state of FeAs planes, hence no superconductivity [4]. Studies of this nature can yield groundbreaking results by demonstrating that many parameters can compete in a bulk material and even be spatially and electronically non-homogeneous on nanometers.

1This work was primarily supported by the U. S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division.

3:42PM Q5.00005 Enhancement of transition temperature in iron based superconductor KFe2As2 under pressure, YASUYUKI NAKAJIMA, RENXIONG WANG, TRISTIN METZ, XIANGFENG WANG, Univ of Maryland-College Park, JASON JEFFRIES, Lawrence Livermore National Laboratory, JOHNPIERRE PAGLIONE, Univ of Maryland-College Park — Superconducting pairing symmetry in the iron pnictides is one of the key issues to clarify the origin of high Tc superconductivity. The versatile pairing symmetry, including sign-reversed full gap, symmetry-imposed, or accidental nodal states, has been proposed theoretically and experimentally [1,2], and it can undergo a transition from one to another by chemical substitution or pressure. For instance, recent pressure study on heavily hole-doped KFe2As2 may imply a possible symmetry change accompanied by sudden reversal in pressure dependence of Tc [3]. To explore the phase diagram of KFe2As2 in a wider pressure range, we here report low-temperature transport study under high pressure up to 33 GPa by utilizing a designer diamond anvil cell. We will discuss the evolution of the superconducting and structural properties of this material, highlighting novel changes in the system at high pressure. [1] J.P. Reid et al., PRL 109, 087001 (2012). [2] T. Shibauchi et al., Annu. Rev. Condens. Matter Phys. 5, 113 (2014). [3] F. Tafti et al., Nat. Phys. 6, 349 (2013).

3:54PM Q5.00006 Fermi-Surface Reconstruction in the collapsed-tetragonal phase of KFe2As2, LIMIN WANG, YASUYUKI NAKAJIMA, XIANGFENG WANG, Univ of Maryland-College Park, JASON JEFFRIES, Lawrence Livermore National Laboratory, JOHNPIERRE PAGLIONE, Univ of Maryland-College Park — Recent experiments reveal that applying pressure to KFe2As2 produces a rich phase diagram that includes the reversal in pressure dependence of Tc and without electronic structure change [1] and evolution of structural properties. Inspired by these, we investigate the electronic structure of KFe2As2 as a function of pressure using first-principles theory. Comparing with the ambient pressure tetragonal phase, we find that the Fermi surface topology undergoes significant changes at high pressures, with possible Lifshitz transition in the Fermi surface at high pressure. Together, our results suggest an interesting scenario of superconductivity in this material. [1] F. Tafti et al., Nat. Phys. 6, 349 (2013).

4:06PM Q5.00007 Microscopic, Transport and Thermodynamic properties of Ca10(2Pt5As5)((Fe1-xTMx)2As2)5 (TM=Co, Ni) single crystals, SHAN JIANG, NI NI, Univ of California - Los Angeles — Here we report detailed microscopic, transport and thermodynamic measurements on two series of high quality single crystals Ca10(2Pt5As5)((Fe1-xTMx)2As2)5 (TM=Co, Ni). With electron doping on Fe sites, the structural/magnetic phase transitions in the parent compound were suppressed at a rate of roughly -7K per 0.01Co doping and -9K per 0.01Ni doping. Superconductivity emerges in the region of 0.048 < x < 0.20 for Co doping with optimal Tc of 13.5K (x = 0.11) while it occurs in the region of 0.035 < x < 0.11 for Ni doping with optimal Tc of 9.6K (x = 0.064). No coexistence of AFM and SC is observed, which is different from the well-studied 122 Fe-pnictides but reminiscent the one of La1111. The comparison of the effect between Co- and Ni- doping on 10-3-8 shows that rigid band approximation is likely working for these two dopants in this superconducting family.

4:18PM Q5.00008 Vortex Lattice Anisotropy and Pauli Limiting in KFe2As2, S.J. KUHN, M.R. ESKILDSEN, University of Notre Dame, H. KAWANO-FURUKAWA, M. ONO, Ochanomizu University, Japan, E.M. FORGAN, E. JELLYMAN, R. RIYAT, University of Birmingham, United Kingdom, C.H. LEE, K. KIHOU, AIST, Japan, J. GAVILANO, Paul Scherrer Institute, Switzerland — In superconducting KFe2As2 (KFA), Hc2 (in Tesla) parallel to the basal plane is much larger than Hc1 (in Kelvin) suggesting Pauli limiting. We have used small-angle neutron scattering (SANS) with H applied close to the basal plane to study the vortex lattice (VL) anisotropy and scattered intensity in KFA. The VL anisotropy reflects the intrinsic anisotropy of the superconducting state (Γac), and may differ significantly from the Hc2 anisotropy (ΓHc2) as recently seen in Sr2RuO4 [C. Rastovsky et al., Phys. Rev. Lett. 111, 087003 (2013)]. Our data indicates a field dependent VL anisotropy in KFA, increasing with H, possibly caused by multi-band effects. At high fields Γac > ΓHc2, supporting Pauli limiting. Due to the moderately high anisotropy, both the longitudinal and transverse VL field modulation may contribute to the SANS signal, occurring as non-spin-flip and spin-flip scattering respectively. This allows us to determine the possible Pauli paramagnetic effects (spin polarization of un-paired quasiparticles in the vortex cores) along the two different directions.

4:30PM Q5.00009 Influence of doping on the physical properties of Ca10-xRExPt5As5(Fe2-yPyAs2)5, JIAYUN PAN, AMAR KARKI, RONGYING JIN, Louisiana State Univ - Baton Rouge — Ca10-xRExPt5As5(Fe2-yPyAs2)5 is a new FeAs-based superconductor. We report the change of its superconducting transition temperature Tc and physical properties upon chemical doping in either Ca (using La or Gd) or Fe (using Pt) site. While partial replacement of Fe by Pt results in Tc up to 21K, we find that the substitution of Ca by La is most effective pushing Tc to 30 K. The doping dependence of electrical transport properties will be presented and discussed.
4:42PM Q5.00010 Field dependence of thermal conductivity in the iron-based superconductor KFe$_2$As$_2$: Evidence of a $d$-wave state. FAZEL FALLAH TAFTI, ALEXANDRE JUNEAU-FECTEAU, PATRICK BOURGOIS-HOPE, SAMUEL RENE DE COTRET, JEAN-PHILIPPE REID, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, Univ of Sherbrooke, AIFENG WANG, XINGANG LUO, XIANHUI CHEN, University of Science and Technology of China — Pairing symmetry in the iron-arsenide superconductor KFe$_2$As$_2$ is the subject of active debate. Thermal conductivity at milliKelvin temperatures is a sensitive and directional probe of the superconducting gap structure. Thermal conductivity measured along both [100] and [001] directions reveal that Fermi surfaces in KFe$_2$As$_2$ must have vertical line nodes. This stringent constraint is automatically satisfied by $d$-wave symmetry, but not likely to be satisfied by an $s$-wave state, where nodes are accidental. Here, we report a detailed study of the magnetic field dependence of thermal conductivity in KFe$_2$As$_2$, measured in the $T = 0$ limit. The data are found to be in excellent agreement with $d$-wave calculations. Our data are also compatible with low-temperature specific heat data as a function of field, within a multi-band $d$-wave scenario. Using Fermi surface parameters from quantum oscillations, we estimate the thermal conductivity expected of the gap structure extracted from ARPES measurements on KFe$_2$As$_2$ for the different Fermi surface sheets. We find a result that is incompatible with our thermal conductivity data, and conclude that the superconducting state at the surface, accessed by ARPES, must be different from the state in the bulk, accessed by transport and thermodynamic measurements.

4:54PM Q5.00011 Huge enhancement of superconductivity in the collapsed tetragonal KFe$_2$As$_2$. JIANJUN YING, LING-YUN TANG, Center for High Pressure Science and Technology Advanced Research, HO-KWANG MAO, VIKTOR STRUZHZKIN, Geophysical Laboratory, Carnegie Institution of Washington, AI-FENG WANG, XIAN-HUI CHEN, University of Science and Technology of China, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research — Recent work (F. F. Tafit, et al. Nature Phys. 9, 349 (2013)) on hole-doped iron pnictide KFe$_2$As$_2$ indicated a paring symmetry change at pressure of around 1.7 GPa. The investigation for the low-pressure region (below 7 GPa) revealed oscillation of $T_c$ with pressure. Here we report results of high-pressure transport and XRD measurements on KFe$_2$As$_2$ single crystals at high pressures up to 30 GPa. We map out the phase diagram of KFe$_2$As$_2$ and find a huge enhancement of $T_c$ in the collapsed tetragonal phase. The correlation between $T_c$ electronic and crystal structures is discussed. The strong electronic correlations are proposed to account for such an unexpected $T_c$ enhancement in KFe$_2$As$_2$.

5:06PM Q5.00012 Superconducting Properties of KFe$_2$Se$_2$. YOSHIHIKO TAKANO. National Institute for Materials Science (NIMS) — Layer structured iron selenide, FeSe has the simplest crystal structures among iron-based superconductors. It shows superconductivity with transition temperature ($T_c$) of 13 K under ambient pressure. The $T_c$ increases up to 37 K by applying high pressure [1-3]. These facts indicate that the FeSe-layers are favorable structures to show superconductivity. When potassium is doped to the interlayer of FeSe, the resulting compound KFe$_2$Se$_2$ shows superconductivity at around 31 K under ambient pressure. However, the superconducting properties have no consensus even in the ambient pressure condition, because of its reproducing, inhomogeneity, and instability, and so on. It is necessary to obtain the high-quality single crystals to clarify the intrinsic properties. In this study, we cultivate the preparation method for the single crystalline KFe$_2$Se$_2$ [4], and investigate its superconducting properties by electrical properties using ARPES, magnetic susceptibility and transport properties, and single crystal structural analysis. Ozaki et al., Euro. Phys. Lett., 98, 27002 (2012).

Wednesday, March 4, 2015 2:30PM - 5:30PM — Session Q6 DMP DCOMP: Focus Session: Coupling Polarization and Magnetism II 060A - Haidan Wen, Argonne National Laboratory

2:30PM Q6.00001 Magnetically induced ferroelectricity in single crystalline Lu$_2$CoMnO$_6$. SHA-LINEE CHIKARA, JOHN SINGLETON, National High Magnetic Field Lab, Los Alamos Natl Lab, HWAN YOUNG CHOI, NARA LEE, YOUNG J CHOI, Yonsei University, South Korea, VIVIEN ZAPF, National High Magnetic Field Lab, Los Alamos Natl Lab — We present pulsed-magnetic-field measurements on Lu$_2$CoMnO$_6$ single crystals. We are able to resolve electric polarization in single crystals for the first time. The bulk hysteric magnetization couples to the electric polarization resulting in a hysteretic, ferroelectric behavior. The alternating $S = 3/2$ Co$^{2+}$ and Mn$^{4+}$ ions sit in a corner-sharing octahedral oxygen environment. The Co-Mn-Co-Mn spins order in an up-up-down-down (uudd) arrangement along the $c$-axis. The ferroelectricity was believed to originate from the exchange striction due to the uudd spin arrangement. However, recent dielectric measurements suggest polarization along the $b$- not the $c$-axis. Our results confirm that ferroelectricity is indeed observed along the $b$-axis and not along the uudd spin-ordering direction. This indicates a different origin for the multiferroic behavior. The frustrated spin system displays an incommensurate long-wavelength modulation that may play a role in inducing ferroelectricity.

2:42PM Q6.00002 Multiferroicity in HoFeO$_3$. PRATIK DHUVD, XIFAN WU, Physics Department, Temple University, Philadelphia, PA 19122 — Rare-earth ferrites are becoming popular among multiferroic materials due to its spontaneous magnetic and electric orderings. After discovery of new family of multiferroic RFeO$_3$(R=Lu,LuF) which shows simultaneous ferroelectricity and weak ferromagnetic moment, HoFeO$_3$(HFO) is explored as a potential candidate in multiferric materials. Combined theoretical and experimental study has been done to understand ferroelectric and ferromagnetic properties of HFO. Our calculations suggest that iron in HFO exhibits very large canting, about one order of magnitude, compared to canting of iron in LFO, which is consistent with experimental findings. Analysis of structural phase transitions and calculation of phonon modes governing this ferroelectric transition revealed that HFO is improper ferroelectric with ferroelectric polarization about 8.3 $\mu$C/cm$^2$. These ferroic properties advocate HFO to be a useful multiferroic among other rare-earth ferrites.

2:54PM Q6.00003 ABSTRACT WITHDRAWN

3:06PM Q6.00004 A study of the origin of large magnetic field coupled electric polarization in HoAl(BO$_3$)$_4$. TIAN YU, HAN ZHANG, TREVOR TYSON, New Jersey Institute of Technology, ZHIQIANG CHEN, State University of New York at Stony Brook, MILINDA ABEYKOON, CHRISTIE NELSON, Brookhaven National Laboratory, LEONARD BEZMATERNYKH, L. V. Kirensky Institute of Physics — The multiferroic system RAl(BO$_3$)$_4$ is known to exhibit a strong coupling of magnetic field to the electrical polarization. Recently a giant magnetoelectric effect was found in HoAl(BO$_3$)$_4$. This phenomenon is considered quite interesting because the value discovered is significantly higher than reported values of linear magnetoelectric or even multiferroic compounds. We are conducting detailed structural measurements to understand the coupling. We are exploring the local and long range structure in these systems using x-ray PDF, XAFS and single crystal diffraction measurement between 10 K and 400 K. Structural parameters including lattice parameters and ADPs are being determined over the full temperature range. This work is supported by DOE Grant DE-FG02-07ER46402.

3:18PM Q6.00005 High Pressure Study on the Multiferroic State in Mn1-xCoxWO4: x = 0.135 and x = 0.15, MELISSA GOOCH, NARAYAN POUDEL, BERND LORENZ, K.C. LIANG, Y.Q. WANG, Y.Y. SUN, Texas Center for Superconductivity at the University of Houston, JINCHEN WANG, FENG YE, Oak Ridge National Laboratory, JAIME FERNANDEZ-BACA, Oak Ridge National Laboratory and Department of Physics and Astronomy at The University of Tennessee, CHING-WU CHU, Texas Center for Superconductivity at the University of Houston and Lawrence Berkeley National Laboratory — Mn1-xCoxWO4 has an interesting and complex phase diagram where 2 multiferroic phases coexist at x = 0.15. For x < 0.15 a spiral spin structure forms, while in contrast a conical spin is observed for x > 0.15. High pressure polarization measurements on x = 0.135 observed a polarization flop and an increase in the polarization, indicating the a-c spiral is converted to the conical spin. An enhancement of the polarization by ∼ 400% is seen for x = 0.15, at the highest pressure measured. High pressure neutron measurements found supporting results.

3:30PM Q6.00006 Temperature and high-pressure dependent X-ray absorption of SmNiO3 at K-Ni and Sm-L3 edges , N.E. MASSA, LANAIS EFO-CQUEINOR, UNLP, La Plata, Argentina, A.Y. RAMOS, H.C.N. TOLENTINO, Inst. Neu-CNRS, F-38042 Grenoble, France, N. SOUSA NETO, J. FONSECA JR., NLNS, 13084-971, Campinas, Sao Paulo, Brazil, M.J. MARTINEZ-LOPE, J.A. ALONSO, ICMC-CSIC, Madrid, Spain — We report XANES and EXAFS measurements of SmNiO3 from 20 K to 600 K and up to 38 GPa done at NLNS, Campinas, Brazil, in the DXAS energy dispersive beamline. SmNiO3 undergoes an atmospheric pressure insulator to metal transition at TMI ∼ 400 K, orders magnetically at T N ∼ 205 K, and shares with all RNiO3 (R = Rare Earth) a negative ∆TMI/∆P slope. Ni white line peak energies show an abrupt 2.4 GPa and 8.11 GPa valence discontinuity at 300 K and at 20 K respectively, due to non-equivalent Ni sites with Ni++ and Ni−− charge disproportion in a monoclinic distortion turning at TMI into Ni+3+ in the orthorhombic Pbnm metal oxide phase. Increasing pressure induces Ni-O-Ni angle increments toward more symmetric NiO6 octahedra of rhombohedral R−3c space group (metallic LaNiO3). At 38 GPa, there is a clear split of the main EXAFS band according to the cell volume decrease due to contraction. Pre-edge tail accounts for e−-t2g splitting and a stronger band growing in intensity in the higher symmetry metallic phases associated to e− electron delocalization hopping conductivity. The Ni+3+ post-edge becomes smoother and intensity increased by the reduction of electron-phonon interaction as the pressure-induced phases set in. We also found that Sm L1-edge does not show distinctive behaviors either at 300 K or 20 K up about 35 GPa.

3:42PM Q6.00007 Driving the magnetic response of BiFeO3 by hydrostatic pressure . C. TOULOUSE, J. BUHOT, Y. GALLAIS, A. SACUTO, Laboratoire Matériaux et Phénomènes Quantiques - Université Paris Diderot-Paris7, A. FORGET, D. COLSON, DSM/DRECAM/SPEC - Service Physique de l’Etat Condensé - CEA Saclay, R. DE SOUSA, Department of Physics and Astronomy - University of Victoria, D. WANG, Electronic Research and Development Center - Xi’an Jiaotong University, L. BELLACHE, Physics Department and Institute for Nanoscience and Engineering - University of Arkansas, M. BIBES, A. BARTHELÉMY, Unité Mixte de Recherche CNRS/Thales, M. CAZAYOUS, M. MEASSON, Laboratoire Matériaux et Phénomènes Quantiques - Université Paris Diderot-Paris7, — BiFeO3 exhibits ferroelectric and magnetic orders at room temperature, which makes it an ideal candidate for spintronics, electro-optics and data storage applications. Most of its properties are related to its ferroelectric character, especially studied under electric or magnetic fields, however the antiferromagnetism has not been extensively investigated, in particular under pressure. Here, we bring insight into the rich spin physics of BiFeO3 in a detailed study of the dynamic magnetic response of bulk BiFeO3 under pressure up to 12GPa measured by Raman spectroscopy. As pressure increases, multiple spin excitations associated to non-collinear cycloidal magnetism collapse into two excitations, which show jump discontinuities at some of the ensuing crystal phase transitions. Using effective hamiltonian simulations of both the structure and the magnetism and Ginzburg-Landau theoretical calculations we show that the pressure controls both the structural phase and the magnetic anisotropy that drives the spin excitations.

3:54PM Q6.00008 Multiferroicity in Ni doped MnWO4 , N. POUDEL, B. LORENZ, B. LV, TcSUH and Department of Physics, University of Houston, F. YE, Neutron Scattering Science Division, Oak Ridge National Laboratory, Y.Q. WANG, Y.Y. SUN, TcSUH and Department of Physics, University of Houston, J.A. FERNANDEZ-BACA, Neutron Scattering Science Division, Oak Ridge National Laboratory and Dept. of Physics and Astronomy, Univ. of Tennessee, C.W. CHU, TcSUH and Department of Physics, University of Houston and Lawrence Berkeley National Laboratory — In this work, we studied the multiferroic properties of MnWO4:Ni for Ni content up to 0.30 with ferroelectric, magnetic and heat capacity measurements. For x = 0.05 and 0.10, the maximum polarization is 38 μC/m2 and ferroelectric transition temperature (Tc) is 13.2 K which is 0.5 K higher than in parent compound. For other increasing values of x, the polarization decreases. For x = 0.15, due to onset of AF4 collinear phase, the polarization becomes maximum and then decreases at lower temperature. A small polarization of 2.3 μC/m2 is observed for x = 0.20 with Tc lowered at ~9.5 K and the polarization is completely suppressed for x = 0.30. Unlike in Co doped MnWO4, neutron scattering reveals only two AF2 and AF4) AF magnetic phases and the onset of the AF4 phase shift to higher temperatures with increasing value of x.

4:06PM Q6.00009 A second ferroelectric transition induced by pressure in multiferroic GdMn2O5 , BERND LORENZ, NARAYAN POUDEL, MELISSA GOOCH, CHING-WU CHU, Texas Center for Superconductivity and Department of Physics, University of Houston, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University — In multiferroic materials different magnetic and ferroelectric states compete for the ground state and are usually close in energy. This results in a high sensitivity of the multiferroic state to external perturbations, such as magnetic fields or pressure, which has been demonstrated, e.g. in Fe3V2O8, MnWO4, and RMn2O5 (R = Tb, Ho, Dy, Y). Here we report the results of a high-pressure study of the multiferroic and ferroelectric properties of GdMn2O5, the RMn2O5 compound with the highest value of the polarization. The ferroelectric polarization below 29 K is enhanced upon application of pressure. Above a critical pressure, a second ferroelectric transition at even higher temperature is detected through a sizable increase of the polarization and a second peak of the dielectric constant. The ferroelectric polarization at high pressures exhibits two step-like increases upon decreasing temperature. This work was supported by the US AFOSR, the T.L.L. Temple Foundation, the John J. and Rebecca Moores Endowment, and the State of Texas through TcSUH.

4:18PM Q6.00010 Evolution of weak ferromagnetism in BiFeO3 under applied epitaxial strain , HEMANT DIXIT, JUN HEE LEE, VALENTINO R. COOPER, Oak Ridge National Lab — The magnetoelectric effect has been a focus of research in multiferroic materials due to potential applications in magnetic data storage, spintronics and memory devices. We perform first principles calculations based on density functional theory to explore the evolution of weak ferromagnetism under compressive and tensile strains in BiFeO3. An isosymmetric phase transition between the rhombohedral ground state and strained phases (Cc space group) is considered which confines the polarization vector to rotate in the (110) plane. For the ground state, we find that the easy spin axis is degenerate in a plane perpendicular to the polarization direction. This weak ferromagnetic moment also persists for the tested strain values (up to ±5%). Under compressive strains, the easy spin axis is also degenerate in a plane perpendicular to the polarization vector. On the other hand for tensile strain the weak ferromagnetic ordering is stabilized along the [1-10] direction. Further, calculated Dzyaloshinskii-Moriya interactions help us to understand the stabilization of weak ferromagnetic moments in the tensile region. Our study thus offers useful insights for manipulating the magnetic response and utilizing the magnetoelectric effect.

4:30PM Q6.00011 Control of oxygen octahedral rotation in BiFeO$_3$ films using modulation of SrRuO$_3$ bottom electrode layer, Sungsu Lee, Ji Young Jo, School of Materials Science and Engineering, Gwangju Institute of Science and Technology (GIST), Gwangju 500-712, Korea — Oxygen octahedral rotation of multiferroic BiFeO$_3$ (BFO) has attracted great attention due to changes of electrical and magnetic properties. Coupling of octahedral rotation in BFO-bottom electrode layer interface remains unexplored. Recently, there have been reported the control of octahedral rotation in SrRuO$_3$ (SRO) film on SrTiO$_3$ (001) substrate by coherently controlling the oxygen pressure during growth and interfacial coupling [1]. Here we demonstrate that the octahedral rotation of BFO film is changed using tetragonal a$_x$I$a$-c$_x$ tilted-SRO bottom electrodes. In this work, BFO/SRO heterostructure is fabricated to SrTiO$_3$ (001) single crystal substrates by pulsed laser deposition at different oxygen partial pressures. The rotation pattern of FeO$_6$ and the structural symmetry are identified from half-integer reflections using high-resolution X-ray diffraction. The effects depending on octahedral tilting of BFO films on the magnetic and ferroelectric properties will be presented.

4:42PM Q6.00012 Predicting a Ferrimagnetic-Ferroelectric Phase of Zn$_2$FeOsO$_6$ with Strong Magnetoelectric Coupling, Hongjun Xiang, P.S. Wang, Fudan University, Wei Ren, Shanghai University, L. Bellaiche, University of Arkansas — Multiferroic materials, in which ferroelectric and magnetic order coexist, are of fundamental interest for the development of novel memory devices that allow for electrical writing and non-destructive magnetic readout operation. The great challenge is to create room temperature multiferroic materials with strongly coupled ferroelectric and ferromagnetic (or ferrimagnetic) orderings. BiFeO$_3$ has been the most heavily investigated single-phase multiferroic to date due to the coexistence of its magnetic order and ferroelectric order at room temperature. However, there is no net magnetic moment in the cycloidal (antiferromagnetic-like) magnetic state of bulk BiFeO$_3$, which severely limits its realistic applications in electric field controlled spintronic devices. Here, we predict that double perovskite Zn$_2$FeOsO$_6$ is a new multiferroic with properties superior to BiFeO$_3$. First, there are strong ferroelectricity and strong ferrimagnetism at room temperature in Zn$_2$FeOsO$_6$. Second, the easy-plane of the spontaneous magnetization can be switched by an external electric field, evidencing the strong magnetoelectric coupling existing in this system. Our results suggest that ferrimagnetic 3d-5d double perovskite may therefore be used to achieve voltage control of magnetism in future spintronic devices.

4:54PM Q6.00013 Prediction of electromagnons in BiFeO$_3$ from atomistic simulations, Brajesh Mani, Chun-Min Chang, Sergey Lisenkov, Inna Ponomareva, Department of Physics, University of South Florida, Tampa, Florida 33620, USA — We developed a first-principles-based computational approach to study the finite-temperature complex dynamics in multiferroics. Application of this technique to one of the most well-known multiferroic, BiFeO$_3$, revealed that the most general form of the magnetoelectric coupling that is allowed in any multiferroic, may produce an electromagnon in antiferromagnetic ferroelectric. Such an electromagnon shares most of the features with the magnon, but is activated by an electric, rather than magnetic, field. We also found that the A$_1$ phonon mode is repelled by the magnon mode, while the E phonon modes is rather insensitive to the presence of electromagnons. We believe that our findings will aid to a deeper understanding of electromagnon modes and their origin in multiferroics as well as provide a computational methodology for further research.

5:18PM Q6.00015 Magnetic structures in potential multiferroic GdCrO$_3$, Pascal Manuel, ISIS Pulsed Neutron and Muon Facility, Laurent Chapon, Institut Laue Langevin, Dmitry Khalyavin, ISIS Pulsed Neutron and Muon Facility, Wang Xueyun, Sang-Wook Cheong, Rutgers University — For the past decade, multiferroics materials have attracted a lot of attention in the condensed matter community because of potential applications for devices. A somewhat ambiguous addition to the multiferroics family was recently reported in the perovskite based GdCrO$_3$, in both bulk and thin film samples. Indeed, ferroelectricity was evidenced by a strong enhancement of the capacitance in a field but significant leakage and no well developed P-E hysteresis blurred the picture. Our own measurements clearly indicate the existence of a polar phase below 2K. To complete the understanding of this material, the determination of the magnetic structure is required but is hampered by the fact Gd is a strong neutron absorber. We will present some neutron diffraction data collected on an isotopic $^{160}$GdCrO$_3$ sample at the WISH diffractometer at ISIS which confirm the presence of three successive magnetic phases, previously only seen by magnetization, as a function of temperature. We will compare our determined structures against predictions based on group theoretical considerations and experimental work on other rare-earth ortho-chromates and discuss the mechanism for multiferroicity.

Wednesday, March 4, 2015 2:30PM - 5:30PM
Session Q7 DCMP: Topological Insulators: Theory and Experiment 006B - Ken Burch, Boston College

2:30PM Q7.00001 Magnetic ordering on edges of topological insulator, Yea-Lee Lee, Seoul Natl Univ, Hee Chul Park, Korea Institute for Advanced Study, Jisoon Ihm, Seoul Natl Univ, Young-Woo Son, Korea Institute for Advanced Study — Based on first-principles calculations, we show that the B$_2$I$_3$Se$_3$ crystal, which is a prototypical topological insulator, with different crystal-face orientation surfaces generates a built-in electric field around the facet edges due to the work function differences. For a given broken time reversal symmetry in the crystal, the electric field, in turn, induces a net magnetic ordering along the edges by the topological magnetoelectric coupling. The predicted magnetic ordering depending on the work function differences between facets would be a unique manifestation of the axion electrodynamics in real solids and suggests a route to reveal novel properties of macroscopic topological edge states.
2:42PM Q7.00002 Exotic quantum phase transitions of 2+1d Dirac fermions, and connections to 2d and 3d topological insulators, KEVIN SLAGLE, YI-ZHUANG YOU, CENKE XU, Univ of California - Santa Barbara — Using determinant quantum Monte Carlo simulations, we demonstrate that an extended Hubbard model on a bilayer honeycomb lattice has two novel quantum phase transitions, each with connections to symmetry protected topological states. 1) The first is a continuous phase transition between the weakly interacting gapless Dirac fermion phase and a strongly interacting fully gapped and symmetric trivial phase. Because there is no spontaneous symmetry breaking, this transition cannot be described by the standard Gross-Neveu model. We argue that this phase transition is related to the Z_{16} classification of the topological superconductor 2He-B phase with interactions. 2) The second is a quantum critical point between a quantum spin Hall insulator with spin S^z conservation and the previously mentioned strongly interacting gapped phase. At the critical point the single particle excitations remain gapped, while spin and charge gaps close. We argue that this transition is described by a bosonic O(4) nonlinear sigma model field theory with a topological O(2)-term.

2:54PM Q7.00003 Phase diagrams of disordered 3D topological insulators and superconductors, TOMI OHTSUKI, Sophia University, KOJI KOBAYASHI, Sophia University, KEN-ICHIRO IMURA, Hiroshima University, KEN NOMURA, Tohoku University — A global phase diagram of disordered weak and strong topological insulators belonging to the class AII is obtained by numerically calculating the conductance, the Lyapunov exponents and the density of states. The location of the phase boundaries, i.e., the mass parameter, is renormalized by disorder, a feature recognized in the study of topological Anderson insulator. We report quantized conductance on the phase boundaries between topologically distinct phases, which is interpreted as the robustness of conductance against disorder. This robustness is also confirmed by the large-scale numerical calculation of the density of states, which remains parabolic up to certain strength of disorder with renormalized Dirac electron velocity. From the size dependence of the conductance, we also point out that the surface states of weak topological insulator are either robust or “defeated”. The nature of the two distinct types of behavior is further revealed by studying the Lyapunov exponents. (K. Kobayashi et al., Phys. Rev. Lett. vol. 110, 236803 (2013)). We also obtain the phase diagram of disordered topological superconductors belonging to the class DIII. Similar renormalization of mass and velocity due to disorder is found.

3:06PM Q7.00004 Surface-to-bulk scattering in topological insulator films, KUSH SAHA, ION GARATE, University of Sherbrooke, Sherbrooke, Quebec, Canada — We present a quantitative microscopic theory of the disorder- and phonon-induced coupling between surface and bulk states in topological insulator (TI) films. We find a simple mathematical structure for the surface-to-bulk scattering matrix elements and confirm the importance of bulk-surface coupling in transport and photoemission experiments, assessing its dependence on temperature, carrier density, film thickness and film-hole asymmetry.

3:18PM Q7.00005 Sum rule constraints on the surface state conductance of topological insulators, K.W. POST, B.C. CHAPLER, M.K. LIU, H.T. STINSON, M.D. GOLDFLAM, Univ of California - San Diego, A.R. RICHARDELLA, J.S. LEE, Pennsylvania State University, A.A. REJINDERS, University of Toronto, K.S. BURCH, Boston College, N. SAMARTH, Pennsylvania State University, D.N. BASOV, Univ of California - San Diego — We report the Drude oscillator strength (D) and the magnitude of the bulk band gap of the epitaxial topological insulator alloy (Bi,Sb)_{1-x}Te_{x}. The bulk band gap is used in conjunction with f-sum rules to establish an upper bound for the D expected in a typical Dirac like system composed of linear bands. We expand our result from the linear band model to include both hexagonal warping and electron-hole asymmetry, as is typical in topological insulator systems. The corresponding maximum value of D arising from Dirac bands in this more complex system is also determined. The observed D is found to be close to this upper bound, demonstrating the effectiveness of alloying in eliminating bulk charge carriers. Moreover, Hall effect parameters and the weak anti-localization observed in transport on the same sample support assignment of the low-energy conduction to topological surface states.

3:30PM Q7.00006 Many-Body Effects in 2D Topological Kondo Insulators, JASON IACONIS, Univ of California - Santa Barbara, LEON BALENTS, Kavli Institute for Theoretical Physics - Univ of California - Santa Barbara — Recently there has been an immense amount of interest in studying the effect of interactions on systems with a nontrivial topology. Perhaps the simplest manifestation of this phenomena, and that which is most closely related to experimental materials, can be found in the so called topological Kondo insulators. In our work we study a model of graphene which is doped with localized partially filled d-shell electron moments. We model this system using a simple Hamiltonian in which the Kondo interaction can lead to the formation of a topological insulating phase with many-body correlations. I will discuss a mean field treatment of this model where we map out the different possible interacting phases of the system. It is of particular interest to study the effect of interactions on the symmetry protected gapless edge states, as such edge states are perhaps the most dramatic consequence of having a band structure with a nontrivial topology. We discuss the possibility that the Kondo interaction leads to edge states which spontaneously break time-reversal symmetry, while preserving the symmetry within the bulk.

3:42PM Q7.00007 Quantum criticality in Kondo quantum dot coupled to helical edge states of interacting 2D topological insulators, CHUNG-HOU CHUNG, SALMAN SILOTRI, Department of Electrophysics, National Chiao-Tung University, HsinChu, Taiwan, R.O.C. — We investigate theoretically the quantum phase transition (QPT) between the one-channel Kondo (1CK) and two-channel Kondo (2CK) fixed points in a quantum dot coupled to helical edge states of interacting 2D topological insulators (2DTI) by tuning Kondo couplings at a fixed Luttinger parameter K < 1. The system can be mapped onto an anisotropic two-channel Kondo Hamiltonian, and the 2CK fixed point was argued to be stable for infinitesimally weak tunnelings between dot and the 2DTI. We re-examine this model beyond the bare scaling dimension analysis via a controlled perturbative renormalization group (RG) approach combined with bosonization and re-fermionization techniques near weak-coupling and strong-coupling (2CK) fixed points. For $K$ close to but less than 1, we find the 2CK fixed point can be unstable towards the 1CK fixed point and the system is expected to undergo a quantum phase transition between 1CK and 2CK fixed points. Our system serves as the first example of the 1CK-2CK QPT that is accessible by the controlled RG approach though this transition has been known to exist in Kondo dot coupled to two conventional Luttinger liquid leads with a critical value $K_c = 1/2$. We extract quantum critical and crossover behaviors from various observables near criticality.

3:54PM Q7.00008 Electrical Detection of Spin-Polarized Surface States Conduction in (Bi$_{0.53}$Sb$_{0.47}$)$_2$Te$_3$ Topological Insulator$^1$, JIANSHI TANG, LI-TE CHANG, XUFENG KOU, KOICHI MURATA, MURONG LANG, YABIN FAN, MOHAMMAD MONTAZERI, WANJIUN JIANG, LIANG HE, KANG L. WANG, Univ of California - Los Angeles, EUN SANG CHOI, National High Magnetic Field Laboratory, YING JIANG, YONG WANG, Zhejiang University — Strong spin-orbit interaction and time-reversal symmetry in topological insulators enable the spin-momentum locking for the helical surface states. Here we report the electrical detection of spin-polarized surface states conduction using a Co/Al$_2$O$_3$ ferromagnetic tunneling contact, in which the compound topological insulator (Bi$_{0.53}$Sb$_{0.47}$)$_2$Te$_3$ was used to achieve low bulk carrier density [1]. Resistance (voltage) hysteresis was observed when sweeping the magnetic field to change the relative orientation between the Co electrode magnetization and the spin polarization of surface states. The two resistance states were reversible by changing the electric current direction, affirming the spin-momentum locking in the topological surface states. Angle-dependent measurement was also performed to further confirm that the abrupt change in the voltage (resistance) was associated with the magnetization switching of the Co electrode. Our results show a direct evidence of spin polarization in the topological surface states conduction. It might open up great opportunities to explore energy-efficient spintronic devices based on topological insulators. This work is supported by DOE-BES (Grant No. DE-FG02-04ER46148) and NSF-MRSEC (Grant No.DMR-1121252).

4:06PM Q7.00009 Tuning Topological Edge States of Bi(111) Bilayer Film by Edge Adsorption, ZHENGFEI WANG, University of Utah, LI CHEN, Linyi University, FENG LIU, University of Utah — Based on first-principles and tight-binding calculations, we report that the topological edge states of zigzag Bi(111) nanoribbon can be significantly tuned by H/S element adsorption. The Fermi velocity is increased by 1 order of magnitude, as the Dirac point is moved from the Brillouin zone boundary to the Brillouin zone center, and the real-space distribution of Dirac states are made twice more delocalized. These intriguing changes are explained by an orbital filtering effect of edge H atoms, which pushes certain components of the p orbital of edge Bi atoms out of the band gap regime that reshapes the topological edge states. In addition, the spin texture of the Dirac states is also modified, which is described by introducing an effective Hamiltonian. Our findings not only are of fundamental interest but also have practical implications in potential applications of topological insulators. This work is supported by DOE-BES (Grant No. DE-FG02-04ER46148)

4:18PM Q7.00010 Crossover between Weak Antilocalization and Weak Localization of Bulk States in Ultrathin Bi$_2$Se$_3$ Films, HUICHAO WANG, HAIWEN LIU, YANFEI ZHAO, YI SUN, X.C. 4:30PM Q7.00011 Crossover from 3D to 2D Quantum Transport in Bi$_2$Se$_3$/In$_2$Se$_3$ Superlattices, ZHAO YANFEI, LIU HAIWEN, ICQM, Peking University, GOU XIN, Physics Department, The University of Hong Kong, JIANG YING, Department of Materials Science and Engineering, Zhejiang University, SUN YI, WANG HUICHAO, ICQM, Peking University, WANG YONG, Department of Materials Science and Engineering, Zhejiang University, LI HAN DONG, University of Electronic Science and Technology of China, XIE MAO HAI, Physics Department, The University of Hong Kong, XIE XINCHE NG, WANG JIAN, ICQM, Peking University — The topological insulator/normal insulator (TI/Ni) superlattices (SLs) with multiple Dirac channels are predicted to offer great opportunity to design novel materials and investigate new quantum phenomena. Here, we report first transport studies on the SLs composed of TI/Bi$_2$Se$_3$ layers sandwiched by Ni In$_2$Se$_3$ layers artificially grown by molecular beam epitaxy (MBE). The transport properties of two kinds of SL samples show convincing evidence that the transport dimensionality changes from three-dimensional (3D) to two-dimensional (2D) when decreasing the thickness of building block Bi$_2$Se$_3$ layers, corresponding to the crossover from coherent TI transport to separated TI channels. Our findings provide the possibility to realizing 3D surface states in TI/Ni SLs.

4:42PM Q7.00012 Surface state of Bi$_{1.5}$Sb$_{0.5}$Te$_{1.7}$Se$_{1.3}$ investigated by terahertz emission and visible second-harmonic generation techniques, SOON-HEE PARK, S.Y. HAMH, J.S. LEE, Gwangju Inst of Sci & Tech, JOONBUM PARK, JUN SUNG KIM, Pohang Univ. of Sci & Tech — One of the key issues in three-dimensional topological insulators is to separate a response of the surface from the bulk to exploit novel spin-momentum-locked Dirac fermionic surface state, and Bi$_{1.5}$Sb$_{0.5}$Te$_{1.7}$Se$_{1.3}$ is one of such materials having a negligible contribution of the bulk conduction. We investigate the surface state of Bi$_{1.5}$Sb$_{0.5}$Te$_{1.7}$Se$_{1.3}$ single crystals by using terahertz emission spectroscopy and second harmonic generation techniques. We observed a clear distinction in the phases of emitted terahertz electric field and azimuth-dependent second harmonic intensity in different pieces of the sample, and found their clear correlation with carrier types which can be attributed to upward or downward band bending. We examined variations of such optical responses after the cleavage of the samples under different atmospheric environments, and discussed the time-evolution of the surface state particularly in comparison with previous results on n-type Bi$_2$Se$_3$.

4:54PM Q7.00013 Parity blocking in quenching dynamics of Majorana wires, SUraj HEGDE, Univ of Illinois, Urbana-Champaign, VASUDHA SHIVAMOGGI, Northrop Grumman Electronic Systems, SMITHA VISHVESHWARA, Univ of Illinois, Urbana-Champaign, DEPTMANN GE, ICQM, Peking University for High Energy Physics, Indian Institute of Science, Bangalore, India. — We study the point where the ground state changes parity. We develop a real-space formalism for calculating the dynamics of excited state, even when the quenching is very slow. Termed as “parity-blocking,” this happens when the fermion parity of the ground state is changing with time. This change in parity is related to the oscillation of near zero energy mid-gap states of the end Majorana modes. Using exact Majorana wave functions and transfer matrix techniques, we track the points where the ground state changes parity. We develop a real-space formalism for calculating the dynamics of quantities such as the many-body wavefunction overlap and residual energy. Using these techniques for numerical calculations, we demonstrate parity blocking and other scaling effects with the quench rate and length of the chain.

5:06PM Q7.00014 Chiral electromagnetic waves in Weyl semimetals, ALEXANDER ZYUZIN, University of Basel, VLADIMIR ZYUZIN, University of Florida — We show that Weyl semimetals with broken time-reversal symmetry is an optically gyrotropic medium and can host chiral electromagnetic waves. The magnetization in the system that results in a momentum space separation of a pair of opposite chirality Weyl nodes is also responsible for the non-zero gyration vector in the system. We show that in the region where the magnetization flips its directions (magnetic domain wall) there exist a chiral electromagnetic field localized at the domain wall and propagating along it. The direction of propagation is determined by the sign of the gyrotyro factor. Such magnetic domain walls might appear naturally in the Weyl semimetal materials, or, for example, they can be created with a help of a ferromagnetic material placed in proximity. The chiral electromagnetic wave propagating at the domain walls is an analog of quantum Hall state for photons.

Here we apply a highly efficient eigenvalue solver of arbitrary two-dimensional (2D) systems [2] to study scarring phenomena in generic situations. In particular, we report unexpectedly strong scarring in 2D quantum wells perturbed by random potential bumps of variable characteristics [3]. The scars resemble classical periodic orbits of the unperturbed system (no bumps), but there appears to be no clear connection to the periodic orbits of the perturbed system, as would be the case for conventional scarring. The scars are also robust to increasing distortion amplitude, and show a tendency to pin to the potential bumps. We have used a variety of tools to analyze the origin of the scarring, in particular its relation with Anderson localization. [1] E. J. Heller, Phys. Rev. Lett. 53, 1515 (1984); [2] P. J. J. 4:06PM Q8.00007 Semiclassical propagation of correlation functions in closed electromagnetic environments\textsuperscript{1}, GABRIELE GRADONI, STEPHEN CREAGH, GREGOR TANNER, University of Nottingham, United Kingdom — Field-field correlation functions can be propagated efficiently within confined systems through the Wigner-Weyl formalism. A semiclassical Frobenius-Perron operator is derived for the propagation of Wigner functions as a solution of the associated boundary integral equation. This idea is used to study the effect of non-integrable (chaotic) dynamics on the propagation of classical noisy fields. Model systems for quantum mechanics are used to mimic the radiation into closed spaces. A realistic model of statistical sources into a semi-open polygonal billiard is also presented. We find that the simplest description in terms of the classical Frobenius-Perron operator provides a description of the frequency-averaged correlation function but that wave-resonant and interference effects can also be accounted for. Application of the theory focus on the prediction of energy distribution through electromagnetic environments in electromagnetic compatibility, wireless communication systems, and imaging optics.

4:18PM Q8.00008 ABSTRACT WITHDRAWN

4:30PM Q8.00009 Massive simulation of complex electromagnetic cavities\textsuperscript{1}, FRANCO MOGLIE, LUCA BASTIANELLI, VALTER MARIANI PRIMIANI, Universita Politecnica delle Marche - DII, Ancona — The analysis of the chaotic behavior of complex electromagnetic cavities benefits from the availability of a large amount of data on field samples. The application of a code running on a supercomputer is able to reproduce accurately electromagnetic simulations of electrically large structures. The simulations of mode-stirred reverberation chamber (RC) were performed using an in-house parallel finite-difference time-domain (FDTD) code. The code is divided into three modules that are managed by a unique, single-step job: the electromagnetic solver based on the FDTD method; a fast Fourier transform (FFT) to obtain the frequency domain behavior; a statistical tool to obtain the RC properties. A tool allows for the saving of intermediate data. The code implements a hybrid parallelization as function of the number of processors and the cavity volume. Specifically, such a computation is known to be “embarrassingly parallel” with respect to the cavity angle. The excitation is a Gaussian pulse modulated sinusoid at 1.1 GHz: the 95% bandwidth is 0.2 and 2 GHz. After the FDTD simulation is completed, the FFT module gives the frequency behavior of the fields in each point with a resolution of about 50 kHz.

4:42PM Q8.00010 Nonlinear elastic waves in solids: Deriving simplicity from complexity, MAHMOUD I. HUSSEIN, ROMIK KHAJEHTOURIAN, University of Colorado Boulder — The introduction of nonlinearities to the dynamics of a homogeneous elastic medium alters the underlying wave dispersion characteristics. In this work, we present an exact formulation for the treatment of geometric nonlinearity in one-dimensional elastic wave propagation in a rod, considering both a thin rod where the thickness is small compared to the wavelength and a thick rod where lateral inertia is accounted for. Our derivation starts with the implementation of Hamilton’s principle and terminates with an expression for the finite-strain dispersion relation in closed form. We explore the effect of wave amplitude on the derived dispersion relation and compare with results obtained by direct time-domain simulations followed by Fourier transformations. While often dispersion is attributed to only linear mechanisms, here we show that an otherwise linearly non-dispersive elastic solid may exhibit dispersion solely due to the presence of a nonlinearity. This work provides insights into the fundamentals of nonlinear wave propagation in solids, which represents one of the agents of wave chaos in complex systems.

5:06PM Q8.00012 Non-Harmonic Pressure Fluctuations by the Self-Excited Oscillations in a Reactor-Column, HASSON M. TAVOSSI, Valdosta State University, Department of Physics, Astronomy, and Geosciences — Self-excited non-harmonic pressure oscillations that result from non-linearity in the system are generated in an air-flow in a reactor column. The uniform steady flow is converted spontaneously into an oscillatory flow, under the especial experimental conditions in a reactor column that includes a thin layer of dissipative porous medium. The uniform steady flow is converted spontaneously into an oscillatory flow, under the especial experimental conditions in a reactor column that includes a thin layer of dissipative porous medium. The resulting large-amplitude non-harmonic pressure fluctuations in the air-flow are similar to the bifurcation in chaotic systems; where two or more energy states can occur simultaneously, with the system oscillating between them. Experimental results will be presented to demonstrate this abrupt change in flow-regime, from steady-flow to chaotic turbulent vibrations. Our results show that a low-pressure shock-wave-front is established in the column and precedes the self-excitation oscillations in the system. Results show that there exists a threshold for flow-rate, beyond which the transition from steady-flow to pulsating-flow occurs. A numerical model is developed to express this behavior terms of system variables, such as; dominant frequencies, obtained from fast-Fourier-transforms of time-domain pressure signals, flow-rate, dimensionless aerodynamic characteristic numbers, relaxation-time, and energy dissipation in the system.

5:18PM Q8.00013 A spectral force based version of the Wigner-Liouville equation, MAARTEN VAN DE PUT, WIM MAGNUS, BART SOREE, Univ of Antwerp, imec — Traditionally, a direct numerical solution of the Wigner-Liouville (WL) equation has been plagued with high computational burden and instability inherent to the integration of the highly oscillatory Wigner potential kernel. We have developed a method based on the spectral decomposition of the force which recasts the WL equation into a manageable form. By removing one integral, this new form is computationally less demanding. Furthermore a damping term naturally appears which reduces the instability caused by the oscillatory terms. Finally, the new form is local in position as opposed to the original WL equation which is non-local in both position and momentum. The spectral force WL equation is interpreted as a representation of a classical evolution with a constant force, and a local quantum generation term with positive and negative contributions mediated by the spectral components of the force. This interpretation allows for a straightforward implementation using a finite difference scheme for the classical evolution coupled with direct evaluation of the discretized generation terms. We observe a good match between results obtained using our method and theoretical results.

2:30PM Q9.00001 Anomalous pressure dependence of thermal conductivities of large mass ratio compounds

L. LINDSAY, Oak Ridge National Laboratory, D.A. BROIDO, Boston College, J. CARRETE, N. MINGO, CEA-Grenoble, T.L. REINECKE, U.S. Naval Research Laboratory — The lattice thermal conductivities \( k \) of binary compound materials are examined as a function of hydrostatic pressure, \( P \), using a first-principles approach. Compound materials with relatively small mass ratios, such as MgO, show an increase in \( k \) with \( P \), consistent with measurements. Conversely, compounds with large mass ratios (e.g., BiSb, BAs, BeTe, BeSe) exhibit decreasing \( k \) with increasing \( P \), a behavior that cannot be understood using simple theories of \( k \). This anomalous \( P \) dependence of \( k \) arises from the fundamentally different nature of the intrinsic scattering processes for heat-carrying acoustic phonons in large mass ratio compounds compared to those with small mass ratios. This work demonstrates the power of first principles methods for thermal properties and advances the understanding of thermal transport in non-metals. * * *J. 2:42PM Q9.00002 Numerical solution of the drift-diffusion equation for a p-i-p diode

ANGEL MANCEBO, SELMAN HERSHFIELD, Univ of Florida — In low carrier density semiconductors such as organic semiconductors the leads supply carriers to the sample. The extra charge flowing into the sample causes the phenomena of space charge build up. In its simplest form this is characterized by the Mott-Gurney law, where the current is proportional to the voltage squared. The Mott-Gurney law as usually derived includes the drift term for the current but omits the diffusion term. The diffusion term cannot be neglected as the diffusion coefficient is proportional to the mobility by the Einstein relationship. We numerically solve the drift-diffusion equation and Poisson’s equation for a p-i-p diode, where \( p \) refers to a p-type semiconductor and \( i \) to an intrinsic semiconductor with very few charge carriers. The model includes no charge traps. By including both the drift and the diffusion terms we find that the current is no longer proportional to the voltage squared but primarily linear with a slight upturn at higher voltages. Furthermore, by examining the carrier density vs. electric field in the sample, we are able to show that for fixed length, there is a maximum current for which there is a physical steady state solution. We will discuss the implications of our results for using the Mott-Gurney law to fit for carrier mobility.

2:54PM Q9.00003 Theory of multiphonon inelastic scattering and carrier capture by defects in semiconductors - Application to capture cross sections

GEORGIOS D. BARMPARIS, YEVGENY S. PUZYREV, Vanderbilt University, X.-G. ZHANG, University of Florida, SOKRATES T. PANTELIDES, Vanderbilt University — Inelastic scattering and carrier capture by defects in semiconductors are the primary causes of hot-electron-mediated degradation of power devices. At the same time, carrier capture is a major issue in the performance of solar cells and light-emitting diodes. First-principles, parameter-free calculations of inelastic-scattering and capture cross sections as functions of carrier energy can provide guidance for modeling device degradation based on atomic-scale physical mechanisms. Here we report the construction of a comprehensive theory of multiphonon inelastic scattering by defects, with carrier capture being a special case. We resolve the old debate about what constitutes a correct theory of capture cross sections and report first-principles density-functional-theory calculations of capture cross section for three prototype defects. A Monte Carlo algorithm has been developed to obtain converged sum over all possible phonon configurations. The results reveal that the capture cross section depends strongly on the energy of the incoming electron.

2:54PM Q9.00003 Theory of multiphonon inelastic scattering and carrier capture by defects in semiconductors - Application to capture cross sections

3:06PM Q9.00004 Giant thermal resistivity of interlaced nanoparticles

YEVGENY S. PUZYREV, XIAO SHEN, SOKRATES PANTELIDES, Vanderbilt University — We present a theoretical study of thermal resistivity of “interlaced crystals,” recently discovered in hexagonal-CuInS\(_2\) nanoparticles [1]. Interlaced crystals exhibit a perfect global Bravais lattice with two cations and multiple ordering patterns within the cation sublattice. The interlaced crystal consists of interlaced domains and phases where the corresponding phase/domain boundaries are not uniquely defined. Since there are no structural defects or strain, the interlacing has a minimal effect on electronic properties, but causes a large increase in phonon scattering at the boundaries. The size of domains reaches down to one nanometer, resulting in a high density of the boundaries, making interlaced crystals an attractive candidate for thermoelectric applications. Large-scale molecular dynamics calculations show orders of magnitude increase in the thermal resistivity caused by a high density of boundaries. This is a general effect, arising due to a mass disparity of the cations present in interlaced crystals.

[1]“Interlaced crystals having a perfect Bravais lattices and complex chemical order revealed by real-space crystallography.” X. Shen, et. al, Nature Comm. 10.1038/ncomms6431.

3:18PM Q9.00005 First-principles calculation of phonon-limited mobility in silicon

YUNING WU, XIAOQIANG ZHANG, Department of Physics and Quantum Theory Project, University of Florida, SOKRATES PANTELIDES, Department of Physics and Astronomy, Vanderbilt University — We introduce a new first-principles method to calculate phonon-scattering-limited electron mobilities. The lifetime of a Bloch state due to scattering is represented by an imaginary electron self-energy which is extracted from the complex band structure of a supercell that contains the phonon vibrations within the frozen-phonon approximation. The phonon vibrations are modeled by a set of configurations generated from a Monte Carlo simulation. Mobility contributions are dominated by electrons on the transverse ellipsoids with low effective mass and long lifetime. The results indicate that high-mobility channels form a conduction network above the percolation threshold. As a result the Matthiessen’s rule does not hold for phonon scattering. The overall mobility is evaluated through the configurational average of the percolation-dominant resistor network. The calculated electron mobility agrees with available experimental data.

3:30PM Q9.00006 Three-dimensional Fully-coupled Electrical and Thermal Transport Model of Oxide Memristors 1

These results show the utility of such measurements in better understanding the material properties of QW’s. Accompanying the spectatorial progress in experimental demonstration of oxide-based memristors, there has been significant modeling effort to aid in understanding of switching physics in memristive devices. However, existing models often simplify the treatment of electronic transport and the interplay of electrically and thermally driven processes. In this work, we present a fully-coupled electrical and thermal numerical model that treats the transport of electrons, holes, and vacancies, together with the Joule heating on an equal footing. Namely, we solve simultaneously the five coupled partial differential equations: the time-dependent drift-diffusion equations for electrons and holes, the time-dependent lattice heat equation, and the Poisson equation for all the charged species in three spatial dimensions. This fully coupled model allows us to investigate the microscopic interplay of field drift, Fickian diffusion, Soret effect, and Joule heating, and to facilitate the understanding of physical mechanisms responsible for the SET and RESET switching processes in tantalum oxide memristors.

3:42PM Q9.00007 Fast response time of electron plasma in high electron mobility transistor channels

These results are important for developing a new generation of terahertz electronic devices and comparing different materials systems for their potential of reaching ultimate switching speed and/or the highest frequency of operation.

3:54PM Q9.00008 Phonon Anharmonicity in Silicon from 100 to 1500 K

Large phonon anharmonicities manifested by phonon energy shifts and broadenings at high temperatures were observed in measured phonon dispersions, and in the phonon density of states. At 1500 K the anharmonicity contributes approximately 80% of the deviation from the harmonic vibrational entropy. These large effects are beyond the predictions of the quasiharmonic model and demonstrate that phonon anharmonicity is a major contributor to both vibrational entropy and phonon lifetimes.

4:00PM Q9.00009 Measurement of the hot electron mean free path in GaN

We present a method for measuring the mean free path (MFP) and relaxation time of hot electrons in GaN using the hot electron transistor (HET). In this device electrons are injected over a high energy emitter barrier into the base, where the carrier density produces a quasiballistic transport well above the conduction band edge. After traversing the base, high energy electrons either surmount the base-collector barrier and become collector current or reflect off the barrier and become base current. We fabricate HETs with various base thicknesses and measure the common emitter transfer ratio (α) for each device. The MFP is extracted by fitting a decaying exponential to a function of base width and the relaxation time is computed using a suitable injection velocity. For current devices with an injection energy of ~1eV, we measure a hot electron MFP of 14nm and calculate a relaxation time of 16fs. These values are in agreement with theoretical calculations where longitudinal optical (LO) phonon scattering is the dominant relaxation mechanism.

4:18PM Q9.00010 Anisotropic lattice thermal conductivity for chain tellurium

Using the ab initio calculations combined with the phonon Boltzmann transport equation we calculate the temperature and pressure dependent lattice thermal conductivity of chain tellurium. The heat transport along and perpendicular to the chain has large anisotropic character, and also for the gruneisen parameter and phonon velocity. The three-phonon scattering rate of the acoustic branches and the phonon mean free path of tellurium are also investigated, which are important for the nanostructure thermoelectric material developing.

4:30PM Q9.00011 Transport Properties of InAs/GaSb Bilayers with a Tunneling Barrier

We have investigated the transport properties of InAs/GaSb bilayers in similarly inverted bands, but with an AlGaSb tunneling barrier placed between InAs and GaSb quantum wells. While the interlayer tunneling are essentially suppressed by increasing the barrier width, we found that the 2D bulk can still be turned into an insulating state that is characterized by a temperature-dependent resistance peak as a function of gate biases. On the other hand, we found no such peak for the 2D bulk in the InAs/GaSb system proposed in Naveh and Lahkim, Phys Rev. Lett. 77, 900 (1996). Work in Rice was supported by DOE DE-FG02-06ER46274.

3:42PM Q9.00012 Estimation of in-plane g-factor and disorder of InSb quantum wells via magnetococonductance mapping

We show the magnetococonductance mapping of an InSb quantum well (QW) and use the mapping to estimate material properties. Measurement and fitting of the suppression of weak antilocalization by an in-plane field oriented along in-plane crystal axes provides estimates of the QW’s g-factor and disorder. By comparing the measurements along different crystal axes, a variation in the estimated parameters is observed. The observed variation is consistent across different hall bars and is dependent on the direction of the applied field with respect to the crystal axes. These results show the utility of such measurements in better understanding the material properties of QW’s.
5:06PM Q9.00014 Ab initio study of complex defects and optical transitions in MgAl₂O₄¹. J.C. GARCIA, P.D. BORGES, Texas State University, USA, F.G. PINTO, J. TRONTO, Universidade Federal de Víncios, Brazil, L. SCOLFRARO, Texas State University, USA — The excellent optical properties of the Magnesium aluminate (MAO) spinel makes it an important material for novel technological applications. Considering that a presence of native defects can promote important changes in these properties, we present in this work a study of the structural, electronic and thermodynamic properties of the MAO. The calculated formation energy for isolated defects, such as the vacancies of manganese, aluminum and oxygen, oxygen interstitial, manganese and aluminum antisites, as well as the complexes in the most stable charge states are shown. In good agreement with experimental data, we obtained that complex centers, such as oxygen vacancies in conjunction with oxygen interstitialal, manganese or aluminum antisites at different charge states are good candidates for the observed optical transitions at 4.75, 5.3, and 6.4 eV. Our findings were obtained from ab initio electronic structure calculations performed within the Density Functional Theory. For the exchange-correlation potential, the generalized gradient approximation was used. Furthermore, a modified Becke-Johnson correction to the exchange potential was applied to obtain a suitable value for the band gap energy, 7.40 eV, in good agreement with the experimental one of 7.8 eV.

5:18PM Q9.00015 Native point defects and conductivity of ZnRh₂O₄: a GGA + U study¹. PIOTR BOGUSLAWSKI, OKSANA VOLNIAŃSKA, Institute of Physics PAS, Warsaw — ZnRh₂O₄ spinel belongs to the family of transparent conducting oxides, which are promising for applications in optoelectronic technology. To assess essential material properties, we analysed energy levels and formation energies of native point defects, i.e., vacancies (V), interstitials, and cation antisites in ZnRh₂O₄. Calculations were based on generalized gradient approximation (GGA) to the Density Functional Theory supplemented by the +U corrections. The value of U was treated as a free parameter, which allowed for the systematic study of the U-induced changes of the electronic structure. The experimental band gap of ZnRh₂O₄ is reproduced only when the +U term is imposed on both d(Rh) and p(O) orbitals, and the pronounced distortions of the oxygen sublattice are included. Zn:Rh is the dominant acceptor that can be responsible for the observed p-type conductivity in ZnRh₂O₄. The low formation energy of Zn:Rh can make the intentional n-doping difficult. In the O-rich conditions, the second important acceptor is V:Zn. The two dominant donors in Zn-rich and O-rich conditions are V:O and Rh:Zn, respectively. Growth conditions leading to the lowest concentrations of native defects were identified.

Session Q10 DCMP: Emergent Dirac and Weyl Semimetals in Three Dimensions

2:30PM Q10.00001 Building topologic device through emerging robust helical surface states, ZIBO WANG, International Center for Quantum Materials, Peking University, Beijing, China, HUA JIANG, College of Physics, Optoelectronics and Energy, Soochow University, Suzhou, China, XINCHENG XIE, International Center for Quantum Materials, Peking University, Beijing, China — In a 3D Cd₃As₂ ribbon with proper sizes, the system can exhibit a unique finite-size effect. Namely, if magnetic impurities are doped on one side, the surface states on the other side can be altered according to the strengths of these magnetic impurities. As a result, the conductance of the system will also be changed. This finding can be explained by the backscattering between the hybridized surface states due to finite size confinement and the normal surface states. Moreover, this phenomenon can be used to build new topologic devices.

2:42PM Q10.00002 Photoemission studies on the 3D Dirac semiential state in Na₃Bi¹. SUYANG XU, LIU CHANG, SATYA K. KUSHWAHA, Princeton University, RAMAN SANKAR, National Taiwan University, JASON W. KRIZAN², ILYA BELOPOLSKI, MADHAB NEUPANE, GUANG BIAN, NASSER ALIDOUST, Princeton University, TAY-RONG CHANG, HORNG-TAY JENG, National Tsing Hua University, CHENG-YI HUANG, WEI-FENG TSAI, National Sun Yat-Sen University, HSIN LIN, National University of Singapore, PAVEL P. SHIBAYEV, Princeton University, FANGCHENG CHOU, National Taiwan University, ROBERT J. CAVA, M. ZAHID HASAN, Princeton University — A three-dimensional Dirac semimetal is a novel state of matter that has recently attracted interest in condensed matter physics and materials science. We present electronic structure measurements on the (100) surface of a recently discovered Dirac semimetal material Na₃Bi. Our experimental data, for the first time, reveal a Lifshitz transition between the two bulk Dirac cones in the bulk band structure of Na₃Bi. These results identify the first example of a band structure singularity in 3D Dirac materials. This is in contrast to its 2D analogs such as in twisted bilayer graphene or the surface states of topological crystalline insulators, which have been studied extensively. The observation of multiple bulk Dirac nodes along the rotational crystal axis away from the Kramers point also serve as a signature for the symmetry-protected nature of the Dirac semimetal state in Na₃Bi as elaborated in recent theories.

2:54PM Q10.00003 Linear magnetoresistance caused by mobility fluctuations in a bulk three-dimensional Dirac semi-metal, Cd$_3$As$_2$\textsuperscript{1}, ARJUN NARAYANAN, MATTHEW WATSON, SAMUEL BLAKE, YULIN CHEN, DHARMALINGAM PRABHAKARAN, Oxford University, BINGHAI YAN, Max-Planck-Institut fur Chemische Physik, NICOLAS BRUYANT, Laboratoire National des Champs Magnétiques Intenses, LOIS DRIGO, Laboratoire National des Champs Magn “A”etiques Intenses, IGOR MAZIN, Naval Research Laboratory, CLAUDIA FELSER, Max-Planck-Institut fur Chemische Physik, TAI KONG, PAUL CANFIELD, Ames Laboratory, Iowa State University, AMALIA COLDEÀ, Oxford University — Dirac semimetals and Weyl semimetals are 3D analogues of graphene in which crystalline symmetry protects the nodes against gap formation. Cd$_3$As$_2$ was predicted to be Dirac semimetal \cite{1}, and recently confirmed to be so by photoemission \cite{2,3}. Here we report an interesting property in Cd$_3$As$_2$ that was unpredicted, namely a remarkable protection mechanism that strongly suppresses backscattering in zero H. In single crystals, the protection results in ultrahigh mobility $\mu \sim 9 \times 10^{5} \text{cm}^2\text{V}^{-1}\text{s}^{-1}$ \cite{4} at 5 K. Suppression of backscattering results in a transport lifetime $\tau \sim 10^{9}$ times longer than the quantum lifetime. The lifting of this protection by H leads to a very large magnetoresistance. Quantum oscillations in resistivity, Seebeck and Nernst, show beating effect. We discuss how this may relate to changes to the Fermi surface induced by H. \cite{5} Wang, Z. J. et al., Phys. Rev. 3:30PM Q10.00006 Interacting Dirac liquid in three-dimensional semimetals\textsuperscript{1}, JOHANNES HOFMANN, EDWIN BARNES, Univ of Maryland-College Park, CONDENSED MATTER THEORY CENTER TEAM — We study theoretically the properties of the interacting Dirac liquid, a novel three-dimensional many-body system which was recently experimentally realized and in which the electrons have a chiral linear relativistic dispersion and an axial Coulomb interaction. We find that the “extrinsic” Dirac liquid, where the Fermi energy lies exactly at the nodes of the band dispersion, displays unusual Fermi liquid properties, whereas the “intrinsic” system with finite detuning or doping behaves as a standard Landau Fermi liquid. We present analytical and numerical results for the self-energy and spectral function based on both Hartree-Fock and the random phase approximation (RPA) theories and compute the quasiparticle lifetime, residue, and renormalized Fermi velocity of the extrinsic Dirac liquid. A full numerical calculation of the extrinsic RPA spectral function indicates that the Fermi liquid description breaks down for large-energy excitations. Furthermore, we find an additional plasmon quasiparticle sideband in the spectral function which is discontinuous around the Fermi energy. Our predictions should be observable in ARPES and STM measurements.

3:42PM Q10.00007 Axial anomaly and negative longitudinal magnetoresistance: theory vs. experiment, PALLAB GOSWAMI, PED PIXLEY, University of Maryland — Traditionally axial anomaly is associated with quantum mechanical violation of U(1) axial symmetry of relativistic Dirac/Weyl fermions in odd spatial dimensions, in the presence of electromagnetic gauge fields. Recently there has been considerable interest in both condensed matter and high energy physics communities in Nielsen and Ninomiya’s original proposal that the axial anomaly can lead to a negative longitudinal magnetoresistance for condensed matter realization of Weyl fermions. In this talk I will show that the axial anomaly can arise in any generic three dimensional material placed under parallel electric and quantizing magnetic fields. However, the emergence of negative magnetoresistance depends crucially on the forward scattering nature of the underlying relaxation mechanism. Therefore, sufficiently clean and dilute three dimensional materials without magnetism or magnetic impurities can be promising candidates for observing this phenomenon. I will briefly discuss concrete experimental evidence of this enigmatic effect in quasi-2D layered materials.

3:54PM Q10.00008 Molecular beam epitaxial growth of a three-dimensional topological Dirac semimetal Na$_3$Bi, SUNG-KWAN MO, YI ZHANG, YEONGKWAN KIM, ZAHIH HUSSAIN, Advanced Light Source, Lawrence Berkeley National Lab, ZHONGKAI LIU, ZHI-XUN SHEN, SIMES, Stanford University, BO ZHOU, YULIN CHEN, University of Oxford — Three-dimensional topological Dirac semimetals (3D TDS) represent an unusual state of quantum matter that can be viewed as a bulk analogue of graphene. The realization of 3D TDS is recently verified experimentally in Na$_3$Bi and Cd$_3$As$_2$. We report a molecular beam epitaxial growth of Na$_3$Bi on bilayer graphene and Si(111). Our in-situ angle-resolved photoemission data reveal the 3-dimensional Dirac-cone band structure in such thin films even down to 12 unit cell thickness. Our approach of growing Na$_3$Bi thin film provides a potential route for fabrication into practical devices while preserving unique properties of 3D TDS. *Yi Zhang et al. Appl. Phys. Lett. 105, 031901 (2014).
4:06PM Q10.00009 Magnetic Catalysis and Axionic Charge-Density-Wave order in Weyl semimetals, BITAN ROY, JAY DEEP SAU, Condensed Matter Theory Center, University of Maryland — Three-dimensional Weyl and Dirac semimetals are extremely robust against impurity and magnetic correlations. However, when placed in strong magnetic fields, they can support a chiral-symmetry-breaking charge-density-wave order even for sufficiently weak electron-electron repulsion. Such novel phenomena stems from the existence of one-dimensional chiral zero Landau levels which can hybridize for arbitrarily weak interactions. In the former systems, due to the momentum space separation of Weyl nodes the ordered phase lacks translational symmetry and represents a dynamic axionic phase of matter. I will demonstrate the scaling behavior of the spectral gap for a wide range of subcritical (weak) interactions as well as that of diamagnetic susceptibility with magnetic field. I will argue that similar mechanism for charge-density-wave ordering remains operative in double-Weyl semimetals, where dispersion is linear (quadratic) for the $z$ (planar) component(s) of momentum. Role of topological defects, e.g., axion strings, existence of 1-dimensional gapless dispersive modes along the core of such defects, anomaly cancellation through Callan-Hervey mechanism will also be discussed. Pertinence of our study in recently observed Dirac semimetals, such as $Cd_3As_2$, Na$_3$Bi, will be addressed.  

4:18PM Q10.00010 Dirac and Weyl Superconductors in Three Dimensions 1, SHENGYUAN YANG, Singapore, HUI PAN, Beihang University, FAN ZHANG, The University of Texas at Dallas — Inspired by the recent discovery of Dirac and Weyl semimetals, we introduce the concept of 3D Dirac (Weyl) superconductors (SC), which have protected bulk four(two)-fold nodal points and surface Andreev arcs at zero energy. We provide a sufficient criterion for realizing them in centrosymmetric SCs with odd-parity pairing and mirror symmetry. Pairs of Dirac nodes appear in a mirror-invariant plane when the mirror winding number is nontrivial. Breaking mirror symmetry may gap Dirac nodes producing a topological SC. Each Dirac node evolves to a nodal ring when inversion-gauge symmetry is broken, whereas it splits into a pair of Weyl nodes only when time-reversal symmetry is broken. Our physics might be realized in the nodal phase of Cu-doped Bi$_2$Se$_3$ or UPt3.

4:30PM Q10.00011 Magnetization-dynamics-induced current in Weyl semimetals, DAICHI KURE-BAYASHI, KENTARO NOMURA, Institute for Materials Research, Tohoku University — Weyl semimetals recently gather attention because of its novel transport properties, the anomalous Hall effect (AHE) and the chiral magnetic effect (CME), originated from the chiral anomaly. In contrast to the AHE which has been understood after intensive theoretical and experimental studies in condensed matters, the existence of the CME in static cases is still in debate. We propose a magnetically induced current with temporal varying chiral vector potential, which is a new transport phenomenon and essentially different from the CME. We consider the magnetically doped Weyl semimetals, and theoretically study the dynamical effect of the magnetization. As a model, we use the Dirac Hamiltonian coupled to the magnetizations with the exchange interaction. We apply field theoretical methods to derive the expression of the current, and find the magnet-field-driven current induced by the dynamics of magnetic collective excitations. Furthermore, we also conduct the numerical calculation for the lattice model, and obtain the results which agree with the analytical result. Our result, therefore, is not an artifact of taking continuous model, but experimentally observable in solids.

4:42PM Q10.00012 Quantum transport in three-dimensional Weyl electron system — in the presence of charged impurity scattering, YUYA OMINATO, MIKITO KOSHINO, Tohoku Univ — Quantum transport in 3D Weyl electron system with the charged impurity is studied theoretically using a self-consistent Born approximation (SCBA). The scattering strength is characterized by the effective fine structure constant which depends on the dielectric constant and the Fermi velocity of the linear band. The Boltzmann transport theory works well in a condition that the level broadening is much smaller that the Fermi energy, but it fails near the Weyl point. At the Weyl point, the conductivity takes a nearly constant value which is almost independent of the effective fine structure constant, even though the density of states linearly increases with the effective fine structure constant. The qualitative behavior is significantly different from the case of the Gaussian impurities, where the conductivity exhibits exponentially vanishing behavior and vanishes at the Weyl point below a certain critical disorder strength.

4:54PM Q10.00013 Anomalous Conductivity Tensor and Quantum Oscillations in the Dirac Semimetal Na$_3$Bi 1, JUN XIONG, SATYA KUSHWAHA, JASON KRIZAN, TIAN LIANG, ROBERT J. CAVA, NAI PHUAN ONG, Princeton University — Na$_3$Bi is a 3D Dirac semimetal with protected nodes. Angle-resolved photoemission experiments have observed these massless Dirac fermions in the bulk band, but transport experiments have been hampered by the extreme air sensitivity of Na$_3$Bi crystals. Transport experiments can potentially address interesting issues such as charge pumping between the separated Weyl nodes when the time-reversal symmetry is broken by a strong magnetic field. Here we report a transport measurement that reveals robust anomalies in both the conductivity and resistivity tensor. The resistivity $\rho_{xx}$ exhibits a B-lineup up to 317, while the Hall exhibit an unusual profile approaching a step-function. In addition, we have also observed a prominent beating pattern in the Shubnikov de Haas (SdH) oscillations indicating the existence of two nearly equal SdH frequencies when the Fermi energy falls inside the non-trivial gap-inverted regime.

5:06PM Q10.00014 Unconventional localisation transition in high-dimensional semiconductors and Weyl semimetals, SERGEY SYZRANOV, VICTOR GURARIE, LEO RADZIHOVSKY, Univ of Colorado - Boulder — We study a class of non-interacting electron systems with a power-law quasiparticle dispersion $\varepsilon_k \propto k^{\alpha}$ and a random short-correlated potential. We show that, unlike the case of lower dimensions, for $d > 2\alpha$ there exists a critical disorder strength (set by the band width), at which the system exhibits a disorder-driven quantum phase transition at the bottom of the band, that lies in a universality class distinct from the Anderson transition. In contrast to the conventional wisdom, it manifests itself, in e.g., the disorder-averaged density of states. In systems for symmetry classes that permit localisation, the striking signature is a non-analytic behaviour of the mobility edge that is pinned to the bottom of the band for subcritical disorder and grows for disorder exceeding a critical strength. Focusing on the density of states, we calculate the critical behaviour (exponents and scaling functions) at this novel transition, using a renormalisation group, controlled by an $\varepsilon = d - 2\alpha$ expansion. We also apply our analysis to Dirac materials, e.g., Weyl semimetal, where this transition takes place in physically interesting three dimensions.

5:18PM Q10.00015 Density of states scaling at the semimetal to metal transition in three dimensional topological insulators, IGOR HERBUT, Simon Fraser University, KEN IMURA, Hiroshima University, TOMI OHTSU, KOJI KOBAYASHI, Sophia University — The quantum phase transition between the three dimensional Dirac semimetal and the diffusive metal can be induced by increasing disorder. Taking the system of disordered Z2 topological insulator as an important example, we compute the single particle density of states by the kernel polynomial method. We focus on three regions: the Dirac semimetal at the phase boundary between two topologically distinct phases, the tricritical point of the two topological insulator phases and the diffusive metal, and the diffusive metal lying at strong disorder. The density of states obeys a novel single parameter scaling, collapsing onto two branches of a universal scaling function, which correspond to the Dirac semimetal and the diffusive metal. The diverging length scale critical exponent and the dynamical critical exponent are estimated, and found to differ significantly from those for the conventional Anderson transition. Critical behavior of experimentally observable quantities near and at the tricritical point is also discussed. (K. Kobayashi et al, Phys. Rev. Lett. vol. 112, 016402 (2014))
3:20PM Q11.00001 Phonon-driven surface superconductivity in the vicinity of ferroelectric and charge density wave ordering in La(O,F)BiX2 (X=S, Se, O) — TANER YILDIRIM, National Institute of Standards and Technology — Examples of layered superconductors include cuprates, MgB2, CaC2, and recent iron-pnictides. Recently a new family of layered materials containing BiS2 planes was discovered to be superconducting at temperatures up to 10 K. In order to reveal the mechanism of superconductivity, here we present results from first-principles calculations with many surprising findings for La(O,F)BiX2 for X=S, Se, and O. The parent compound LaOBiS2 possesses anharmonic ferroelectric soft phonons at the zone center with a rather large polarization of P ≈ 10 μC/cm². Upon electron doping, new unstable phonon branches appear along the entire line Q=(q,q,0), causing Bi/S atoms to order in a one-dimensional charge density wave (CDW). We find that BiS2 is a strong electron-phonon coupled superconductor in the vicinity of competing ferroelectric and CDW phases. We discuss similar results for X=Se and hypothetical compound X=O. These results will be compared with another interesting system, namely Ba1−xF3BiO3, which exhibits several phases, including CDW, an incommensurate pseudo ferroelectric, and superconductivity at 31 K. Our results suggest new directions to tune the balance between these phases and increase Tc in this new class of materials.

2:42PM Q11.00002 Coexistence of ferromagnetism and superconductivity in CeO3.3F0.7BiS2 — JOOSEP LEE, Oak Ridge National Laboratory, SATOSHI DEMURA, National Institute for Material Science, MATTHEW STONE, Oak Ridge National Laboratory, KAZUKI IIDA, University of Virginia, GEORCH EHLERS, CLARINA DELA CRUZ, MASAAMI MATSUEDA, Oak Ridge National Laboratory, KEITA DEGUCHI, YOSHIHIKO TAKANO, YOSHIKAZU Mizuguchi, National Institute for Material Science, O SUKE MIURA, Tokyo Metropolitan University, DESPINA LOUCA, SEUNG HUN LEE, University of Virginia — Bulk magnetic transport and neutron scattering measurements were performed to investigate the electronic and magnetic properties of a polycrystalline sample of the newly discovered ferromagnetic superconductor, CeO3.3F0.7BiS2. Ferromagnetism develops below Tc( FM ) = 6.54(8) K and superconductivity coexists with the ferromagnetic state below Tc(SC) = 4.5 K. Inelastic neutron scattering measurements reveal a very weakly dispersive magnetic excitation at 1.8 meV that can be explained by an Ising-like spin Hamiltonian. Under application of an external magnetic field, the direction of the magnetic moment changes from the c-axis to the ab-plane and the 1.8 meV excitation splits into two modes. A possible mechanism for the unusual magnetism and its relation to superconductivity is discussed.

2:54PM Q11.00003 Observation of anomalous temperature dependence of spectrum on small Fermi surfaces in a BiS2-based superconductor — L.K. ZENG, X.B. WANG, J. MA, P. RICHARD, S.M. NIE, H.M. WENG, N.L. WANG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, Z. WANG, Department of Physics, Boston College, Chestnut Hill, Massachusetts 02467, USA, T. QIAN, H. DING, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We have performed an angle-resolved photoemission spectroscopy study of the BiS2-based superconductor Nd(O,F)BiS2. Two small electron-like Fermi surfaces around (π,π,0) are observed, which enclose 2.4% and 1.1% of the Brillouin zone area, respectively, corresponding to an electron doping of 7% per Bi site. The low-energy spectrum consists of a weakly-dispersing broad hump and a dispersive branch, which follows well the calculated band dispersion. This hump is drastically suppressed with increasing temperature, while the dispersive branch is essentially unaffected. The anomalous thermal effect indicates a highly interacting electronic state, in which the superconducting pairing develops along the entire line Q=(q,q,0), causing Bi/S atoms to order in a one-dimensional charge density wave (CDW). We find that BiS2 is a strong electron-phonon coupled superconductor in the vicinity of competing ferroelectric and CDW phases. We discuss similar results for X=Se and hypothetical compound X=O. These results will be compared with another interesting system, namely Ba1−xF3BiO3, which exhibits several phases, including CDW, an incommensurate pseudo ferroelectric, and superconductivity at 31 K. Our results suggest new directions to tune the balance between these phases and increase Tc in this new class of materials.

3:06PM Q11.00004 Single crystal growth and superconducting properties of the Bi(S,Se)2-based superconductor — TAKUMA YAMAKI, YOSHIHIKO TAKANO, National Institute for Materials Science (NIMS) — Introduction After the discovery of superconductivity in Bi4O4S3 [1], much attention has been paid to synthesizing new superconductors. The BiS2-based compounds have a layered structure similar to those of cuprates or Fe-based superconductors. In these compounds, superconducting layers and blocking layers are stacked alternatively. Many BiS2-based superconductors have been discovered by arranging the blocking layer so far. The modification in superconducting layer is important to clarify the superconducting mechanism of BiS2-based superconductor and the single crystal preparation is necessary to discuss such a intrinsic properties. In this study, we perform the single crystal growth of La(O,F)Bi(S,Se)2 and investigate the substitution effect for the superconducting properties by replacing Se with S. Results and discussion Single crystals of LaO1−xF3BiS2−ySey (0≤y≤2) were synthesized by CsCl flux method. The single crystals were plate-like shape with approximately 1 mm in size, which is sufficient to perform various characteristic measurements, such as single crystal X-ray analysis and electrical resistivity measurement, and so on. We will discuss the crystal structure, electrical resistivity and magnetic properties in detail. [1] Y. Mizuguchi et.al.,Phys. Rev. B 86,220510(2012)

3:18PM Q11.00005 Superconductivity in PdxBi2Se3 by anneal doping — GRACE MCCLINTOCK, J. T. MLACK, NINA MARKOVIC, Johns Hopkins University — We show that superconductivity can be induced in Bi2Se3 by palladium doping via annealing. Thin films of palladium are deposited on prefabricated Bi2Se3 nanodevices and annealed at temperatures in excess of 100 Celsius. We find that Bi2Se3 absorbs Pd under these conditions and that the absorption of Pd results in superconductivity, as evidenced by resistance and magnetoresistance measurements below 1K.

3:30PM Q11.00006 Charge fluctuations in a disordered superconductor, LaO1−xF3BiS2 — ANUSHKA ATHAUDA, SEUNG HUN LEE, DESPINA LOUCA, Univ of Virginia, YOSHIKAZU Mizuguchi, Tokyo Metropolitan University — LaO1−xF3BiS2 is a disordered, non-magnetic superconductor with a transition temperature of 10.8 K at x = 0.5. The parent compound, LaOBiS2, is a band insulator with a layered tetragonal structure. The evolution of the crystal structure and nano-scale atomic fluctuations are investigated as a function of temperature and composition using neutron scattering. Even though the symmetry remains unchanged with doping, lattice strain develops along the c-axis and buckling of the Bi2Se plane changes orientation. In addition, strong local distortions are observed around the Bi ion that are in response to charge fluctuations. Two distinct Bi-S plaquettes are present due to atomic displacement of in-plane sulfur because the Bi ion undergoes a charge disproportionation. The charge fluctuations along with spin-orbit coupling most likely play important roles in the mechanism of superconductivity in this system.

3:42PM Q11.00007 Anisotropic spin-singlet pairings in CuxBi2Se3 and Bi2Te3 — WEI-FENG TSAI, National Sun Yat-sen University, Kaohsiung, Taiwan, LEI HAO, GUI-LING WANG, Southeast University, Nanjing, China, TING-KUO LEE, Institute of Physics, Academia Sinica, Taipei, Taiwan, JUN WANG, YONG-HONG YANG, Southeast University, Nanjing, China — We report possible anisotropic spin-singlet pairings in Bi2X3 (X = Se or Te). Among six pairings compatible with the crystal symmetry, two novel pairings show nontrivial surface Andreev bound states, which form flat bands and could produce zero-bias conductance peak in measurements such as point-contact spectroscopy. By considering purely repulsive short-range Coulomb interaction as the pairing mechanism, the dominant super-exchange terms are all antiferromagnetic, which would usually favor spin-singlet pairing in Bi2X3. Mean-field analyses show that the inter-orbital pairing interaction favors a mixed spatial-parity anisotropic pairing state, and one pairing channel with zero-energy surface states has a sizable component. The results provide important information for future experiments.
3:54PM Q11.00008 Structural role of the pressure-dependent charge-density-wave to superconductor transition in ZrTe$_2$: an inelastic light scattering study$^1$. YEOWN GIM, SAM GLEASON, TAYLOR BYRUM, ASTHA SETHI, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois, Urbana, Illinois 61801, USA. C. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973, USA. S.L. COOPER, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois, Urbana, Illinois 61801, USA — One of the most exciting areas of condensed matter research involves the study of how superconductivity evolves from magnetic- or charge-ordered phases in strongly correlated systems. We present a Raman scattering study of the temperature- and pressure-induced structural changes leading to the transition between charge-density wave (CDW) and superconducting phase regimes in ZrTe$_2$. We show that the internal deformation modes associated with the Te-Te chains—which support the CDW in this material—exhibit anomalous linewidth changes as a function of temperature, indicating strong electron-phonon coupling associated with these modes. Additionally, the pressure-dependence of these modes suggests that dissociation of the Te-Te chain bonds may be responsible for the suppression of the CDW phase as a function of pressure. These studies provide insight into the structural changes responsible for CDW collapse in this material.

4:06PM Q11.00009 A DFT study of electron-phonon coupling in proxy rocksalt CuX (X = S, Se, Te) structures and its relationship to possible manifestation of superconductivity. PAUL GRANT, W2AGZ Technologies, ROBERT HAMMOND, Stanford University — We have previously reported our computational studies on idealized copper monochalcogenide rocksalt structures, both cubic and tetragonal, focusing on their possible antiferromagnetic properties as determined within a Van Vleck-Mott-Anderson-Hubbard framework [1]. For all values of Hubbard U in the range 0-7 eV, only copper monoxide exhibits a Mott-Hubbard electronic structure [2-3], the remainder (S, Se, Te) yielding metallic states characterized by nesting Fermi surfaces arising from Jahn-Teller degenerate s-p overlap. These results suggest exploring possible manifestation of superconductivity via electron-phonon mediated Cooper pairing. We will disclose our results to date applying the Eliashberg-McMillan-Allen-Dynes strong coupling framework to the DFT–derived electronic and vibrational states of CuS, CuSe and CuTe.

4:18PM Q11.00010 Competition between Weak Localization and Superconductivity in Ta$_{1-x}$Pt$_x$Se$_2$ Single Crystal. JINYU LIU, Tulane University, ALI RADMANESH, University of New Orleans, JIN HU, Tulane University, LEONARD SPINU, University of New Orleans, ZHIQIANG MAO, Tulane University — Exotic properties such as superconductivity and charge density wave (CDW) in transition metal dichalcogenides (TMDCs) have attracted a great deal of interest in past decades. Research in this area is focused on understanding the interplay between CDW, structure instability and superconductivity in doped/intercalated TMDCs. We have recently studied the Pt doping effect on electronic properties of 2H – Ta$_2$Se$_2$. With only 2% Pt doping, we observed dramatic changes in its electronic properties. Firstly, Pt doping leads to an evolution from an anisotropic, three-dimensional (3D) metal to a quasi-2D metal. Secondly, while Pt doping suppresses the CDW of Ta$_2$Se$_2$ only to some extent, its superconducting transition temperature is remarkably increased, from 0.2K to 2.1 K. Moreover, Pt doping induces quantum transport behavior prior to the superconducting transition, i.e. weak localization (WL) and strong competition between WL and superconducting pairing was probed in angle-resolved magnetoresistance measurements. We will discuss the origin of the evolution of such exotic phenomena.

4:30PM Q11.00011 STM study on single crystal of noncentrosymmetric superconductor PbTaSe$_2$. RUI WU, ZHIYANG YE, Institute of Physics, Chinese Academy of Sci (CAS) & Department of Physics and Texas Center for Superconductivity, University of Houston., JIHLI WANG, Department of Physics and Texas Center for Superconductivity, University of Houston, XUEJIN LIANG, HANQING MAO, LINGXIAO ZHAO, GENFU CHEN, Institute of Physics, Chinese Academy of Sci (CAS). SHUHENG PAN, Institute of Physics, Chinese Academy of Sci (CAS) & Department of Physics and Texas Center for Superconductivity, University of Houston, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM, TEXAS CENTER FOR SUPERCONDUCTIVITY TEAM — We use low temperature scanning tunneling microscopy (STM) to study the single crystal of noncentrosymmetric superconductor PbTaSe$_2$. Two types of atomically resolved topographic image have been observed on the surfaces exposed by low temperature in situ cleaving. One of the topographic images clearly displays the noncentrosymmetric crystal structure, which we identify as the Se terminated surface. With the help of lattice symmetry and the step between two terraces, we also identify that the other topographic image belongs to the Pb terminated surface. With the help of lattice symmetry and the step between two terraces, we also identify that the other topographic image belongs to the Pb terminated surface, which is the complementary exposure of the Se terminated. In addition to the lattice symmetry and the surface reconstruction, there is a super modulation with a period of about 10.5 unit cells. This super modulation persists through the superconducting transition (Tc = 3.7K), but is energy dependent, indicating its electronic nature. We will show how this super modulation relates to the normal state tunneling spectrum.

4:42PM Q11.00012 STS study on single crystal of noncentrosymmetric superconductor Pb-TaSe2. ZHIYANG YE, RUI WU, Institute of Physics, Chinese Academy of Sciences, Beijing. Department of Physics and Texas Center for Superconductivity, University of Houston., JIHLI WANG, Department of Physics and Texas Center for Superconductivity, XUEJIN LIANG, HANQING MAO, LINGXIAO ZHAO, GENFU CHEN, Institute of Physics, Chinese Academy of Sciences, SHUHENG PAN, Department of Physics and Texas Center for Superconductivity, University of Houston. Institute of Physics, Chinese Academy of Sciences, Beijing — We report our low temperature scanning tunneling spectroscopic study on single crystals of noncentrosymmetric superconductor PbTaSe$_2$. On the background of the normal state tunneling spectrum, a superconducting energy gap opens at a temperature below the bulk Tc = 3.7K. At $t = 1.4K$, the gap magnitude is estimated to be about 1meV. This energy gap is particle-hole symmetry and is homogeneous in space. Extrapolating the low energy part of the spectrum, we find that the low energy part of the gap spectrum is linear like “V” shape. We will present the results of the numerical fit with various gap functions of proposed possible pairing symmetry. We will also present our preliminary results of the magnetic field dependence measurement and discuss the implications of these observations.

Wednesday, March 4, 2015 2:30PM - 5:30PM – Session Q12 DMP GERA FIAP DCOMP: Focus Session: Theory of Bulk Thermoelectric Materials 007C - David Singh, Oak Ridge National Laboratory
2:30PM Q12.00001 Thermal transport properties of complex oxides from first principles. AQYAN BHATTI, Univ of Texas, Austin, ANKIT JAIN, ALAN MCGAUGHLEY, Carnegie Mellon University, NICOLE BENEDEK, Univ of Texas, Austin — Thermal transport properties of materials are key parameters in the design of many engineering devices. For this reason, it is highly desirable to be able to control or tailor the thermal properties of materials for specific applications. Complex oxides are attractive in this regard, due to their low and potentially highly tunable thermal conductivity. However, the theoretical description of the thermal transport properties of oxides presents a number of challenges compared to conventional semiconductors. For example, oxides tend to have complex crystal structures and the atoms interact through long-range electrostatic forces. In this talk, we use the example of PbTiO$_3$ to discuss some of the challenges and opportunities associated with thermal transport predictions in complex oxides. For example, many oxides contain very low-lying optical branches, which may provide important acoustic-optical scattering channels. In addition, it is often possible to tune the frequencies of such optical modes with epitaxial strain. We also link the observed negative thermal expansion behavior of PbTiO$_3$ to two zone-boundary modes with large, negative Grüneisen parameters and comment on the consequences of this finding for the thermal transport properties of this material.

3:06PM Q12.00004 Part-crystalline part-liquid state and electrical/thermal transport in materials with chemical-bond hierarchy, WENQING ZHANG, Materials Genome Institute, Shanghai University, Shanghai, 200444, China — A concept of part-crystalline part-liquid state (or liquid-like), and even part-crystalline part-glass state (or glass-like), was demonstrated in some materials such as CuSb$_3$S$_3$ with chemical-bond-hierarchy, in which certain constituent species weakly bond to other part of the crystal. Such a material could intrinsically manifest the coexistence of rigid crystalline sublattices and other fluctuating noncrystalline sublattices with thermally induced large amplitude vibrations and even flow of the group of species atoms. The large-amplitude vibrations and movement of atoms can generate unusual severe phonon scattering and thermal damping due to the collective low-frequency vibrations similar to the Boson peak in amorphous or liquid materials. While different phase or state may have large energetic discrepancy, whether the thermally-induced part-crystalline state is undergoing phase transition becomes an interesting issue. In addition, our earlier work reported that second-order phase transition could induce extreme electron and phonon scattering in thermoelectrics. The above work clearly demonstrated that the unusual effect from structural fluctuations on thermal and electrical transport in thermoelectrics should be paid attention to. While materials with these structural changes can retain extremely low lattice thermal conductivity and unusual electron transport and become promising candidates for high-performance thermoelectrics, underlying mechanism is yet to be explored.

3:42PM Q12.00005 Compressed sensing approach for calculating lattice thermal conductivity of complex thermoelectric compounds, VIDVUDS OZOLINS, YI XIA, WESTON NIELSON, Dept of Materials Science and Engineering, University of California, Los Angeles, FEI ZHOU, Lawrence Livermore National Laboratory — Earth-abundant minerals such as tetrahedrite Cu$_{12}$Sb$_3$S$_{13}$ have recently received attention as promising thermoelectrics due to a combination of a relatively high figure of merit (ZT > 1 at T ≈ 700 K in tetrahedrite), good mechanical properties and inexpensive bulk processing methods. Like many large unit-cell thermoelectrics, these compounds often have complex chemical formulas with very large unit cells that pose challenges to our ability to study their lattice dynamical properties theoretically. Here we show that a recently introduced approach, compressive sensing lattice dynamics (CSDL) (F. Zhou et al., Phys. Rev. Lett. 113, 185501 (2014)) provides an accurate and computationally efficient platform for investigating anharmonic lattice dynamics in complex materials. We will discuss the basic ideas and illustrate the performance of CSDL for the lattice thermal conductivity κL of tetrahedrite, collusite, pyrite, and other earth-abundant mineral compounds.

3:54PM Q12.00006 A Robust Approach to Lattice Thermal Conductivity, WESTON NIELSON, Univ of California - Los Angeles, FEI ZHOU TEAM, YI XIA TEAM, VIDVUDS OZOLINS TEAM — Thermal conductivity is a key parameter in designing high performance thermoelectric materials. A multitude of computational methods have been developed to calculate lattice thermal conductivity. Molecular dynamics (MD) based techniques, including equilibrium and non-equilibrium methods, in addition to non MD-based solutions, such as the Boltzmann Transport Equation (BTE), are all capable of calculating thermal conductivity, but each comes with different sets of limitations and difficulties. After extensive use of these different methods, we have developed a robust set of tools for obtaining high-quality lattice thermal conductivity values of crystalline solids. The crux of our method involves a novel compressive sensing (CS) based approach for efficiently calculating high quality force constants for crystalline materials. The result is a technique for building lattice dynamical models that can treat compounds with large, complex unit cells and strong anharmonicity, including those with harmonically unstable phonon modes.

4:06PM Q12.00007 Temperature dependent phonon properties of thermoelectric materials1, OLLE HELLMAN, Department of Applied Physics and Materials Science, California Institute of Technology, Pasadena, California 91125, USA, DAVID BROIDO, Department of Physics, Boston College, Chestnut Hill, Massachusetts 02467, USA, BREN'T FULTZ, Department of Applied Physics and Materials Science, California Institute of Technology, Pasadena, California 91125, USA — We present recent developments using the temperature dependent effective potential technique (TDNP) to model thermoelectric materials. We use an ab initio molecular dynamics method to generate an effective Hamiltonian that reproduce neutron scattering spectra and phonon self energies and heat capacities. Results are presented for (among others) SnSe, Bi$_2$Te$_3$, and Cu$_2$Se proving the necessity of careful modelling of finite temperature properties for strongly anharmonic materials.

1Supported by the Swedish Research Council (VR) project number 637-2013-7296.
4:18PM Q12.00008 Density functional study of silver defects in telluride thermoelectric materials1, BYUNGKI RYU, MIN-WOOK OH, SU-DONG PARK, Korea Electrotech Res Inst — Silver impurity in telluride thermoelectric materials forms various defect and impurity structures, such as AgSb rich nanoregion in Ag-Sb-Pb-Te, Ag2Te and metallic silver in PbTe. To understand the atomic, electronic, energetic, and diffusion properties of silver impurities in telluride systems, we have performed the density functional theory and density functional perturbation theory calculations of silver doped PbTe. Under Te and Ag rich condition, silver telluride impurity phase or Ag-dimer defects are expected to be easily formed. Under Te poor condition, silver point defects are calculated to be easily formed and they are more stable than native point defects of PbTe, implying that silver point defect might be the major dopant responsible for the carrier generation in PbTe. We also calculated the diffusion coefficient and diffusion length of silver point defect in PbTe. Based on the results, we discussed the electrical and thermoelectric properties of silver doped PbTe.

4:30PM Q12.00009 Quasiparticle structure and thermoelectric transport properties of p-type SnSe, GUANGSHA SHI, EMMANOUIL KIOUPAKIS, Materials Science and Engineering, University of Michigan — We used density functional and many-body perturbation theory to calculate the band structure and electronic transport parameters of p-type SnSe both for the low-temperature Phmnm and high-temperature Cmcm phases. The Phmnm phase has an indirect band gap of 0.829 eV while the Cmcm has a direct band gap of 0.464 eV. Both phases exhibit multiple local band extrema within an energy range comparable to the thermal energy of carriers from the global extrema. We calculated the electronic transport coefficients within the constant relaxation time approximation as a function of doping concentration and temperature for single-crystal and polycrystalline materials to understand experimental measurements. The electronic transport coefficients are highly anisotropic and are strongly affected by bipolar transport effects at low doping and high temperature. Our results indicate that SnSe exhibits optimal thermoelectric performance at high temperature when doped in the 10^13–10^20 cm^{-3} range. This work was supported in part by the National Science Foundation (DMR-1254314) and in part by CSTEM, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science. Computational resources were provided by the DOE NERSC facility.

4:42PM Q12.00010 Thermostrophic properties of higher manganese silicides (HMS) 1, YU-CHIH TSENG, Natural Resources Canada, VIJAY SHANKAR VENKATARAMAN, HAE-YOUNG KEE, University of Toronto — Higher manganese silicides (HMS) are promising thermoelectric materials that may be broadly deployable because of the abundance of the constituent elements and their non-toxic nature. We study the thermostrophic properties of HMS using density functional theory calculations and tight-binding models to fit these calculations. We estimate charge carrier density and mobility, and compare with experimental data. Theoretically obtained thermal and electrical conductivities, and the Seebeck coefficients are presented. Possible scattering mechanisms and relations to figure of merit are also discussed.

1NSERC CREATE - HEATER Program

4:54PM Q12.00011 First-principles Study of Lattice Thermal Conductivity of Cu_{2}SnSe_{2} and Cu_{2}SbSe_{2}, YI XIA, Department of Materials Science and Engineering, University of California, Los Angeles, CA 90095, USA, FEI ZHOU, Physical and Life Sciences Directorate, Lawrence Livermore National Laboratory, Livermore, California 94550, USA, WESTON NIELSON, VIDVUDS OZOLINS, Department of Materials Science and Engineering, University of California, Los Angeles, CA 90095, USA — Linearized self-consistent Boltzmann transport equation (BTE), utilizing interatomic force constants (IFCs) obtained via compressive sensing lattice dynamics (CSLD), is used to study the lattice thermal conductivity (κ_{L}) of Cu_{2}SnSe_{2}, Cu_{2}SbSe_{2} and their solid solutions. With these IFCs we obtain bulk lattice thermal conductivity in good agreement with experimental measurements. We also compare Cu_{2}SnSe_{2} and Cu_{2}SbSe_{2} with respect to Grüneisen parameter, group velocity, phonon lifetime, mean free path and cumulative κ_{L}. All the analysis indicates that (1) slightly larger group velocity and lifetime of acoustic modes found in Cu_{2}SnSe_{2} lead to larger κ_{L} compared with Cu_{2}SbSe_{2} over the whole temperature range. Contributions from optical modes to κ_{L} for both compounds are about 25% at temperature higher than 300K. This large portion of κ_{L} can not be neglected if one aims to predict accurate κ_{L}; (2) Nanostructures with length less than 10nm can effectively reduce κ_{L} by about 80% for both of the compounds; (3) solid solution of two compounds can effectively reduce κ_{L} as much as 40% at room temperature.

5:06PM Q12.00012 New insights into thermal conductivity by non-equilibrium molecular dynamics1, PHILIP ALLEN, Stony Brook University, YERONG LI, Nanjing University — Non-equilibrium molecular dynamics (NEMD) is often used to simulate thermal conductivity (κ). A steady state heat current and corresponding temperature gradient are created computationally over a simulation cell of thousands of atoms. We advocate a variation that gives directly the Fourier transform of the non-local (κ(x − x′)) that relates J(z) to 1/V z(x′). The algorithm is tested on the Lennard-Jones liquid and crystal, and is efficient for extraction of the macroscopic κ = −lim_{q→0} q/4πκ_{q} as well as a detailed comparison with simulation. For an isotropic cell (N_x = N_y = N_z), the behavior is κ(q) = κ−A∗q^{1/2}. For the more typical anisotropic cell with one length (N_x) large compared to the others, there is an additional term ∝ q^{−1/2}/N_x N_y. This divergent contribution disappears in the bulk limit. Strategies for extrapolation of simulations are suggested.

5:18PM Q12.00013 Strain-induced semi-metal to semiconductor transition and strong enhancement in thermopower of TiS_{2}, ATANU SAMANTA, TRIBHUWAN PANDEY, ABHISHEK K. SINGH, Materials Research Centre, Aeronautical Development Agency (ADA) under NPMASS and Department of Science and Technology(DST) nanomission

Indian Institute of Science, Bangalore-560012 — Electronic properties of transition-metal dichalcogenides (TMDs) (MX_{2}, where M = Mo, W and X = S, Se, Te) are very sensitive to the applied pressure/strain, causing a semiconductor to metal transition. Using first principles density functional theory calculations, we demonstrate that bulk TiS_{2} changes from semi-metal to semi-conducting electronic phase upon application of uniform biaxial strain. This phase transition is responsible for the charge transfer from Ti to S and reduces the overlap between Ti-(d)- and S-(p)-orbitals. The transport calculations show a three-fold enhancement in thermopower for both p- and n-type TiS_{2} due to opening of band gap along with changes in dispersion of bands. The electrical conductivity and thermopower shows a large anisotropy due to the difference in the effective masses along the in-plane and out-of-plane directions. We further demonstrate that the enhancement of thermoelectric performance, can also be achieved by doping TiS_{2} with larger iso-electronic elements such as Zr or Hf at the Ti sites.

1Aeronautical Development Agency (ADA) under NPMASS and Department of Science and Technology(DST) nanomission

Wednesday, March 4, 2015 2:30PM - 5:30PM –
Session Q13 DMP: Focus Session: Complex Oxide Interfaces - LaAlO3/SrTiO3 II
007D - Sohrab Ismail-Beigi, Yale University
2:30PM Q13.00001 Combining Mott insulators and ferroelectrics, AGNÈS BARTHELEMY, Unité Mixte de Physique CNRS/Thales — We investigated the properties of high quality heterostructures consisting of a Mott insulator, (Ca,Ce)MnO$_3$ (CCMO) and a ferroelectric, BiFeO$_3$ in the supertetragonal phase (T-BFO) materials. In particular, we studied the electrical response induced by ferroelectric switching in both planar and vertical devices. In the planar geometry, we used thick T-BFO films to explore the possibility to electrically tune the properties of the CCMO compound in a ferroelectric field-effect device with a CCMO channel and a T-BFO gate. Upon polarization reversal of the T-BFO ferroelectric gate, the CMO channel exhibits a nonvolatile resistance switching by a factor of 4 around room temperature, and up to a factor of 10 at 200 K [1]. We also studied Ferroelectric tunnel junctions (FTJs) composed of an ultrathin ferroelectric tunnel barrier of T-BFO sandwiched between a CCMO electrode and a Co/Pt counter-electrode. In these junctions, the tunneling current significantly depends on the orientation of the ferroelectric polarization, resulting in large electroresistance enabling a simple nondestructive readout of the ferroelectric state [2]. FTJs based on ultrathin T-BFO films show fast, stable multistate switching with very high resistance ratios of up to four orders of magnitude [3]. Combined piezoresistance force microscopy (PFM) and electrical measurements give a clear correlation between ferroelectric domain configurations and multiple resistance states. They also provide insights into the switching dynamics in response to trains of nanosecond pulses. Additionally, we demonstrated the very good endurance and retention characteristics of these FTJs [4].

3:06PM Q13.00002 First-principles many-body investigation of δ-doped titanates, FRANK LECHEMANN, MICHAEL OBERMEYER, I. Institute for Theoretical Physics, University of Hamburg — Studying oxide heterostructures provides the possibility for exploring novel composite materials beyond nature’s original conception. In this respect, the doping of Mott-insulating distorted-perovskite titanates such as LaTiO$_3$ and GdTiO$_3$ with a single SrO layer gives rise to a very rich correlated electronic structure [1]. A realistic superlattice by means of the charge self-consistent combination of density functional theory (DFT) with dynamical mean-field theory (DMFT) reveals layer- and temperature-dependent multiorbital metal-insulator transitions. In [001] stacking, an orbital-selective metallic layer at the interface dissolves via an orbital-polarized doped-Mott state into an orbital-selective metallic layer at the interface. We find large differences in the scattering behavior within the latter. Breaking the spin symmetry in δ-doped GdTiO$_3$ results in blocks of ferromagnetic itinerant and ferromagnetic Mott-insulating layers which are coupled antiferromagnetically.

3:18PM Q13.00003 Towards enhancing two-dimensional electron gas quantum confinement effects in perovskite oxide heterostructures, KESONG YANG, SAFDAR NAZIR, MAZIAR BEHTASH, University of California, San Diego — The two-dimensional electron gas (2DEG) in LaAlO$_3$/SrTiO$_3$ perovskite-oxide heterostructure has attracted much attention because of its potential applications in nanoelectronic devices. A 2DEG has two landmark characters: strong charge confinement in the third dimension and high electron conductivity in two dimensions. In an ideal 2DEG system, electrons can move freely along the interface but are tightly confined in the c-axis that is perpendicular to the interface. Nevertheless, the actual electron gas in the SrTiO$_3$-based perovskite heterostructures is extended a few nanometers along the c-axis into the SrTiO$_3$ substrate, and thus they are also called quasi-2DEG. Actually, it is a problem of both fundamental and practical interest to achieve an ideal 2DEG via enhancing the lateral quantum confinement effects. By using first-principles electronic structure calculations, we propose two possible approaches to enhance the quantum charge confinement effects by confining the electron gas within one single atomic layer in the perovskite oxide heterostructure.

3:30PM Q13.00004 Two-dimensional electron gas at the epitaxial alumina/SrTiO$_3$ interface: control of oxygen vacancies, KRISY KORMONDY, AGHAM POSADAS, University of Texas at Austin, THONG NGO, Univ of Texas, Austin, SIRONG LU, Arizona State University, NICHOLAS GOBLE, Case Western Reserve University, JEAN JORDAN-SWEET, IBM T.J. Watson Research Center, XUAN GAO, Case Western Reserve University, MARTHA MCCARTNEY, DAVID SMITH, Arizona State University, JOHN EKERDT, ALEXANDER DEMKOV, University of Texas at Austin — A highly interesting application for SrTiO$_3$ is the formation of a high mobility two-dimensional electron gas (2DEG) at the oxide/oxide interface. We report on the conducting layer formed at the crystalline γ-α alumina/SrTiO$_3$ (STO) interface which is attributed to oxygen vacancies. We describe the structure of thin γ-α alumina layers deposited by molecular beam epitaxy on STO (001), as determined by reflection-high-energy electron diffraction (RHEED), grazing incidence X-ray diffraction, and high-resolution electron microscopy. In-situ x-ray photoelectron spectroscopy was used to confirm the presence of oxygen vacancies at the interface. Electrical characterization indicates a higher sheet resistance for lower deposition temperature. A maximum electron Hall mobility of 3100 cm$^2$/V·s at 3.2 K and room temperature mobility of 22 cm$^2$/V·s are measured.

3:42PM Q13.00005 Optical properties of transition metal oxide quantum wells, ALEXANDER DEMKOV, MIRI CHOI, MATTHEW BUTCHER, The University of Texas, CESAR RODRIGUEZ, New Mexico State University, QIAN HE, Oak Ridge National Laboratory, AGHAM POSADAS, The University of Texas, ALBINA BORISEVICH, Oak Ridge National Laboratory, STEFAN ZOLLNER, New Mexico State University, CHUNGWEE LIN, ELLIOTT ORTMANN, The University of Texas at Austin — We report on the investigation of SrTiO$_3$/LaAlO$_3$ quantum wells (QWs) grown by molecular beam epitaxy (MBE) on LaAlO$_3$ substrate. Structures with different QW thicknesses ranging from two to ten unit cells were grown and characterized using x-ray photoemission spectroscopy, reflection high-energy electron diffraction (RHEED), grazing incidence x-ray diffraction, transmission electron microscopy (TEM), and high-resolution electron microscopy (HREM). Optical properties (complex dielectric function) were measured by spectrophotometric ellipsometry (SE) in the range of 1.0 eV to 6.0 eV at room temperature. We observed that the absorption edge was blue-shifted by approximately 0.39 eV as the STO quantum well thickness was reduced to two unit cells (uc). Density functional theory and tight-binding are used to model the optical response of these heterostructures. Our results demonstrate that the energy level of the first sub-band can be controlled by the QW thickness in a complex oxide material. We acknowledge support from Air Force Office of Scientific Research (FA9550-12-10494).

3:54PM Q13.00006 Polar-nonpolar Oxide heterostructures for photocatalysis, HONGLI GUO, Department of Physics, University of Science and Technology of China, JIN ZHAO, Department of Physics, University of Science and Technology of China, The International Center for Quantum Design of Functional Materials, WISSAM SAID, Department of Chemical and Petroleum Engineering, University of Pittsburgh, Pittsburgh, Pennsylvania, 15261, United States — The discovery of two-dimensional electron gas (2DEG) at the interface of polar LaAlO$_3$ (LAO) and non-polar SrTiO$_3$ (STO) opens the research field of layered oxide heterostructures. In this study, we propose new application of oxide heterostructures for photocatalysis. We take a sandwich-like heterostructure STO/LAO/STO as an example and prove it to be a promising photocatalyst which is active for near-infrared light. Because the sandwiched LAO is polarized and generates a build-in electrostatic field, the valance band and conduction band locates on two opposite STO surfaces. First principles calculations prove that the band gap is reduced and the absorption of near-infrared to visible light is improved distinctly. Simultaneously, the build-in electric field in LAO accelerates the electrons and holes into opposite directions, preventing the recombination, and generates an electron doped surface and a hole doped STO surface, which could be used for H$_2$O reduction and oxidation separately. Our study gives a new perspective into the applications of oxide heterostructures in solar energy conversion.

4:06PM Q13.00007

SHIRIN MOZAFFARI, MARK C. MONTI, Department of Physics, The University of Texas at Austin, SAMARESH GUCHHAIT, Microelectronics Research Center, The University of Texas at Austin, JEREMY W. PASTER, DANIEL M. TENNANT, JOHN T. MARKERT, Department of Physics, The University of Texas at Austin — We explored the electronic and magnetic behavior of epitaxial PrAlO$_3$ films on TiO$_2$-terminated SrTiO$_3$ (PAO/STO) substrates grown by pulsed laser deposition at various oxygen pressures. We report structural (x-ray and AFM), electronic (van der Pauw resistivity, magnetoresistance (MR), and Hall effect), and magnetic data for PAO films grown in $10^{-3}$–$10^{-6}$ torr O$_2$. Resistivity data exhibit metallic behavior from 300 K down to 100–150 K (75 K; 40 K) for the interface grown in $10^{-3}$ ($10^{-4}$; $10^{-5}$) torr O$_2$, and semiconducting behavior below that. One $10^{-3}$ torr O$_2$ interface shows typical behavior for current parallel to atomic terraces, and a resistance anomaly in the range 50–100 K for current perpendicular to step edges. MR data for all $10^{-1}$–$10^{-2}$ torr O$_2$ samples show a small ($<0.5\%$) positive MR at low fields, and a larger negative MR (2–30\%) at high fields; for $10^{-2}$ torr O$_2$, the MR is positive up to 9 tesla. Sheet resistivity for the $10^{-3}$ torr O$_2$ interface is anomalously low, suggesting a thick conducting layer. Hall effect data exhibit several variations in the carrier density. We discuss these data considering intrinsic charge transfer, oxygen vacancies and interstitials, and cation interdiffusion.

Orbital order and effective mass enhancement in $t_{2g}$ two-dimensional electron gases

4:18PM Q13.00008

JOHNS TOLMA, University of Texas at Austin, ALESSANDRO PRINCIPI, University of Missouri, MARCO POLINI, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, ALLAN MACDONALD, University of Texas at Austin — It is now possible to prepare d-electron two-dimensional electron gas systems that are formed near oxide heterojunctions and contain $t_{2g}$ electrons with a density much smaller than one electron per metal atom. We will discuss a generic model that captures all qualitative features of electron-electron interaction physics in $t_{2g}$ two-dimensional electron gas systems, and the use of a GW approximation to explore $t_{2g}$ quasiparticle properties in this new context. $t_{2g}$ electron gases contain a high density isotropic light mass $xz$ and low-density $yz$ and $yz$ anisotropic components with light and heavy masses in orthogonal directions. The high density light mass band screens interactions within the heavy bands. As a result the wave vector dependence of the self-energy is reduced and the effective mass is increased. When the density in the heavy bands is low, the difference in anisotropy between the two heavy bands favors orbital order. When orbital order does not occur, interactions still reshape the heavy-band Fermi surfaces. I will discuss these results in the context of recently reported magnetotransport experiments.

4:30PM Q13.00009

ABSTRACT WITHDRAWN

4:42PM Q13.00010 Non-local Signal in Quasi-2DEG of LAO/STO

MI-JIN JIN, Ulsan Natl Inst of Sci & Tech, SEON YOUNG MOON, Korea Institute of Science Technology (KIST), VIJAYAKUMAR MODEPALL, JUNHYEON JO, JUNMINS PARK, Ulsan Natl Inst of Sci & Tech, SEUNG-HYUB BAEK, Korea Institute of Science Technology (KIST), JUNG-WOO YOO, Ulsan Natl Inst of Sci & Tech — Electron gas arizen at the insulating oxide interfaces exhibits high electron mobility, tunable carrier densities and related unique behaviors such as coexistence of superconductivity and ferromagnetism, Kondo resistance, etc. Itinerant electrons at the oxide hetero-interface are predicted to have long spin diffusion length, while they are under the relatively strong Rashba-type spin orbit coupling due to inversion symmetry breaking. We studied non-local spin signal induced by spin orbit coupling with additional gate-controlled Rashba field in quasi-2DEG of LaAlO$_3$/SrTiO$_3$ (LAO/STO) interface. We fabricated simple hall-bar like geometry to measure non-local signal with the variation of channel length ($2 \sim 10 \mu$m). Cleaned sample was patterned using e-beam lithography and reactive ion etching followed by oxygen treatment to anneal out oxygen vacancies. When an electric current flows one line of the hall bar structure, spin orbit coupling will induce the current flow away from the source current channel via spin hall and inverse spin hall effects. The non-local signals were studied under different angles of magnetic field and the variation of applied gate voltage.

4:54PM Q13.00011 Contact resistance tuning at metal / Nb:SrTiO$_3$ interfaces using LaAlO$_3$ interlayers

HISASHI INOUE, ADRIAN SWARTZ, GLAM, Stanford University, TAKASHI TACHIKAWA, Dept. of Adv. Mat. Sci., The Univ. of Tokyo, SIMEIS, SLAC Nat. Accel. Lab., YASUYUKI HIKITA, SIMEIS, SLAC Nat. Accel. Lab., HARALD HWANG, Stanford Univ., SLAC Nat. Accel. Lab. — SrTiO$_3$ (STO) exhibits coexistence of high mobility electrons and possible unconventional superconductivity (SC) [1]. Transition metal (TM) contacts to epitaxial insulator/Nb doped STO (NSTO) structures are prototypically used to probe the electronic structure (ES) of n-type STO in tunneling experiments. However, the field dependent permissivity in STO at low temperatures makes it difficult to probe ES when the barrier height (BH) is large [2]. We show that the contact resistance $R_c$ across TM/NSTO interfaces (IF) can be effectively tuned by inserting a thin LaAlO$_3$ (LAO) interlayer (IL) between the TM and NSTO. Change of IL thickness from 0 to 2 u.c. in Co/LAO/NSTO (100) structures results in systematic reduction of $R_c$ by orders of magnitude, as evidenced by a transition from Schottky-type rectifying to nearly ohmic current-voltage curves. This is because the polar nature of the LAO surface, generating an IF dipole, lowers the Schottky BH. This is a useful method to optimize $R_c$ for tunneling experiments in doped STO with possible applications for SC and spintronics. It is also important that this effect fails for ex-situ deposited TM and we discuss the distinction. [1] Richter et al., Nature 502, 528 (2013) [2] Tsukada et al., Phys. Rev. B 76, 155110 (2007)

5:06PM Q13.00012 Spin injection and spin-charge conversion in LaAlO$_3$/SrTiO$_3$ 1, MANUEL BIBES, EDOUARD LESUE, JUAN CARLOS ROJAS SANCHEZ, CNRS/Thales, SIMON OYARZUN, YU FU, Institut Nanosciences et Cryogénie, CEA & Université Grenoble Alpes, NICOLAS REYREN, CNRS/Thales, MATHIEU JAMET, Institut Nanosciences et Cryogénie, CEA & Université Grenoble Alpes, ERIC JACQUET, AGNES BARTHELEMY, JEAN-MARIE GEORGE, ALBERT FERT, HENRI JAFFRES, CNRS/Thales, LAURENT VILA, Institut Nanosciences et Cryogénie, CEA & Université Grenoble Alpes — The perovskite oxides family provides materials to efficiently generate and control spin polarized currents using respectively half-metallic ferromagnets such as mixed-valence manganites or ferroelectrics and multiferroics. More recently channel materials to transport spin information have also emerged. These include the LaAlO$_3$/SrTiO$_3$ two-dimensional electron system (2DES) which, in addition, possesses a gate-tunable spin-orbit coupling. A limitation of this system is however the minimum LaAlO$_3$ thickness of 4 uc required for 2DES formation. In this presentation we will show that this thickness can be reduced if the LaAlO$_3$ is capped by appropriate metals. We will also present different approaches to inject spins in these engineered LaAlO$_3$/SrTiO$_3$ 2DES and introduce detection schemes taking advantage of efficient spin-charge conversion via interfacial spin-orbit effects.

1 Support by ERC Consolidator grant MINT (no. 615759) is acknowledged.
Therefore, we propose that a moderately Sn-rich condition is optimal when CsSnI$_3$ as hole-transport material in solar cells. In contrast, when Sn becomes richer, the concentration of acceptor defects decreases, so the p-type conductivity may degrade quickly when exposed to heat and moisture. This degradation limits the large scale production of the device. In this work we use molecular dynamics simulations to study CH$_3$NH$_2$PbI$_3$ when exposed to high temperatures (30 – 80°C) and water. The force fields used in the simulations were determined from ab initio calculations on the system. The structural changes that occur in methylammonium lead halide perovskites under conditions of high temperature and humidity will be inferred from the simulations.

In this talk, I will review the developmental milestones in this field and distil the recent findings on the photophysical mechanisms of this remarkable material. I will also highlight some of our latest charge dynamics studies and other investigations on the novel properties of this amazing material system.

The Photophysics of Perovskite Solar Cells . TZE-CHIEN SUM, Nanyang Technological University — Solution processed organic-inorganic lead halide perovskite solar cells, with power conversion efficiencies approaching 20%, are presently the forerunner amongst the next generation photovoltaic technologies. These remarkable performances can be attributed to their large absorption coefficients, long charge carrier diffusion lengths and low non-radiative recombination rates. In addition, these materials also possess excellent light emission and optical gain properties. In this talk, I will review the developmental milestones in this field and distil the recent findings on the photophysical mechanisms of this remarkable material.

The Photovoltaic Properties of Perovskite Solar Cells with Organic-Inorganic Halide Perovskites . PENG XU, Fudan University, SHIYOU CHEN, East China Normal University, HONGJUN XIANG, XIN-GAO GONG, Fudan University, SU-HUAI WEI, National Renewable Energy Laboratory — CsSnI$_3$ is a prototype inorganic halide perovskite that has recently been proposed as a photovoltaic material. Through first-principles calculations, we show that the concentration control of intrinsic defects is critical for optimizing the photovoltaic properties of CsSnI$_3$. Under a Sn-poor condition, high concentration of acceptor defects such as Sn or Cs vacancies can form easily and produce a high p-type conductivity, and deep level defects that can become electron-hole recombination centers, all have high energy. This condition is optimal for growing CsSnI$_3$ as hole-transport material in solar cells. In contrast, when Sn becomes richer, the concentration of acceptor defects decreases, so the p-type conductivity may drop to a moderate level, which can increase the shunt resistance and thus the efficiency of the solar cells with CsSnI$_3$ as the light absorber material (LAM). However, under the Sn-rich condition, the concentration of a deep-level donor defect Sn$_1$ will increase, causing electron trapping and non-radiative electron-hole recombination. Therefore, we propose that a moderately Sn-rich condition is optimal when CsSnI$_3$ is used as LAM.

New GeSi doping strategies based on P(SiH$_3$)$_3$ for next-generation CMOS technologies . ANDREW CHIZMESHYA, CHI XU, Dept of Chem-Biochem, Arizona State University, JAMES GALLAGHER, Dept of Physics, Arizona State University, PATRICK SIMS, Dept of Chem-Biochem, Arizona State University, DAVID SMITH, JOSE MENENDEZ, Dept of Physics, Arizona State University, JOHN KOVETAKIS, Dept of Chem-Biochem, Arizona State University — GeSi n-type films are synthesized using the specially designed hydrides P(SiH$_3$)$_3$, GeH$_4$ and Ge$_2$H$_6$ for applications in next-generation CMOS technologies. The films are grown on Ge-buffered Si(100) at 340 °C using two methods. The first employs a gas-source molecular epitaxy approach and Ge$_2$H$_6$ to yield films with P doping densities up to 3.5 x 10$^{19}$/cm$^3$. The amount of Si incorporated equals or exceeds the 3:1 ratio in the P(SiH$_3$)$_3$ compound. The second approach applies an ultra-high vacuum chemical vapor deposition technique and Ge$_2$H$_6$ in place of Ge$_2$H$_6$ to achieve higher carrier concentrations up to 6 x 10$^{19}$/cm$^3$. The Si:P ratio in this case is well below the 3:1 value expected from the precursor. The electron mobilities for both types of samples are significantly higher than state-of-the-art prototypes, probably due to superior microstructure and dearth of intrinsic donors. The relative stability of P and Ge-P bonds in a Ge matrix is studied with ab initio methods. P − I − N diodes fabricated using P(SiH$_3$)$_3$ show excellent I-V characteristics that are virtually undistinguishable from similar diodes doped with the P(GeH$_3$)$_3$ precursor. These results confirm P(SiH$_3$)$_3$ as a viable doping source that is practical from a process standpoint and therefore attractive for industrial scale-up.

Theoretical study of defect properties in thermoelectric \((\text{GeTe})_2(\text{AgSbTe}_2)_{1-x}\)  
Hikari Shinya, Akira Masago, Tetsuya Fukushima, Hiroki Funashima, Hiroshi Katayama-Yoshida, Osaka Univ. - We investigate the structural stability of a pseudo-binary alloy \((\text{GeTe})_2(\text{AgSbTe}_2)_{1-x}\) called TAGS by the density functional theory. TAGS shows intermittent reductions of the thermal conductivity without change of the electric conductivity. However, the mechanism of the drastic change of the thermal conductivity has yet to be understood, and even the crystal structures are still under discussion. In this presentation, we will discuss these problems from a viewpoint of the structural stability. To clarify the stable structure, we estimate the formation energies of the point and the complex defects. As a result, a chain structure of Ag-Te-Sb in GeTe host crystal has a lower formation energy compared to the homogeneous distribution. Moreover, the calculated mixing energy shows that the system is favorable to the phase separation. In the phase separation, the grain boundary must play an important role in the large phonon scattering, therefore, it can lead to the thermal conductivity reduction. These calculations were done with Vienna ab initio Simulation Package and MACHIKANEYAMA2002 program package.

A first-principles study of co-doping in lanthanum bromide, Daniel Aberg, Babak Sadigh, Lawrence Livermore Natl Lab, Andre Schleife, University of Illinois at Urbana-Champaign, Paul Erhart, Chalmers University of Technology. - It was recently shown that the energy resolution of Ce-doped LaBr₃ scintillator radiation detectors can be crucially improved by co-doping with Sr, Ca, or Ba. Here we outline a mechanism for this enhancement on the basis of deep electronic structure calculations. We show that Sr dopants create and bind to Br vacancies, resulting in stable neutral complexes. The association with Sr causes the deep vacancy level to move toward the conduction band edge. This is essential for reducing the effective carrier density available for Auger quenching during thermalization of hot carriers. Subsequent de-trapping of electrons from the complexes can activate Ce dopants which have previously captured a hole leading to luminescence. This mechanism implies an overall reduction of Auger quenching of free carriers, which is expected to improve the linearity of the photon light yield with respect to the energy of incident electron or photon. Optical properties of the Ce-Sr-vacancy triple complex are discussed and compared to experiment. Prepared by LLNL under Contract DE-AC52-07NA27344.

Formation and function of vacancies in Si/Ge Clathrates: The importance of broken symmetries, Amrita Bhattacharya, Christian Carbogno, Matthias Scheffler, Fritz Haber Institute of the MPG, Berlin, DE. - One promising material class for improved thermoelectrics are the clathrates, i.e., semiconducting host lattices encapsulating guest atom. Even in simple clathrates such as Si₄₄ and Ge₄₄, the introduction of guests can result in important but not yet understood effects. In Si hosts, the addition of K (or Ba) results in defect-free K₂Si₄₄ (Ba₂Si₄₄) phases. In spite of their structural and electronic similarity, Ge hosts behave fundamentally different upon filling, where the spontaneously formed framework vacancies completely (or partially) balance the electron donated by K (or Ba) guests leading to K₆Ge₄₄ (or Ba₆Ge₄₄) clathrates. In this work, we use density-functional theory, carefully validating the exchange correlation functional, to compute the formation energies of vacancies and vacancy complexes in Si- and Ge-hosts as function of the filling of guests. By taking into account of the structural disorder, geometric relaxations, and vibrational entropies, we verify the experimentally found vacancy concentration and the thermodynamic stabilities of these compounds. We can trace back the contrasting behaviour of Si/Ge clathrates upon filling to a curious, charged vacancy induced break in symmetry that occurs in Si but not in Ge hosts.

Cation-vacancy and electron-hole relaxation in single-walled aluminosilicate nanotubes: a linear-scaling Density Functional Theory study, Emiliano Poli, Gilberto Teobaldi, Univ of Liverpool. - We report a linear-scaling Density Functional Theory (DFT) study of cation-vacancy related defects in single-walled aluminosilicate nanotubes (AlₓSiᵧNTs), based on the structures derived from solid-state Nuclear Magnetic Resonance (NMR). Defect geometry optimization leads to water condensation and modifications to the AlSi NT hydrogen network around the defect sites, leaving no dangling bond. Electronic structure analysis indicates that defect-states are highly localized in real-space and energy, with appearance of shallow and deep occupied defect states above the valence band (VB) edge of the pristine-NT. Electrostatic alignment of the defect states suggests energetically favourable separation of photo-generated electrons and holes on different defects, which may promote defect-centred photochemistry. The peculiar energy alignment of the defect-states is found to be qualitative unaffected by protonation of the defect-sites. These results should be a useful complement to ongoing experimental research in the potential of (alumino)silicate-based nano-porous materials for photocatalysis.

Electronic structure of vitamin B₁₂ within the framework of the Haldane-Anderson impurity model, Zafar Kendemir, Selma Mayda, Nejat Bulut, Izmir Inst of Tech. - We study the electronic structure of vitamin B₁₂ (cyanocobalamin C₈₈H₇₆CoN₁₄O₁₄F₈P) by using the framework of the multi-orbital single-impurity Haldane-Anderson model of a transition-metal impurity in a semiconductor host. Here, our purpose is to understand the many-body effects originating from the transition-metal impurity. In this approach, the cobalt 3d orbitals are treated as the impurity states placed in a semiconductor host which consists of the rest of the molecule. The parameters of the resulting effective Haldane-Anderson model are obtained within the Hartree-Fock approximation for the electronic structure of the molecule. The quantum Monte Carlo technique is then used to calculate the one-electron and magnetic correlation functions of this effective Haldane-Anderson model for vitamin B₁₂. We find that new states form inside the semiconductor gap due to the on-site Coulomb interaction at the impurity 3d orbitals and that these states become the highest occupied molecular orbitals. In addition, we present results on the charge distribution and spin correlations around the Co atom. We compare the results of this approach with those obtained by the density-functional theory calculations.
5:06PM Q14.00012 Characterization of structural defects in GST based nano-PCM devices through resistance drift measurements1, Ibrahim Cinar, Egecan Cogulu, Aisha Gokce, Bogazici University, Barry Stipe, Jordan Katine, HGST, A Western Digital Company, Guleh Akta, Ozhan Ozatay, Bogazici University — Phase change memory (PCM) is a promising nonvolatile data storage technology with its high signal with noise ratio and superior scalability. Resistance drift in amorphous phase of the phase change material poses a crucial reliability problem, especially in multiple-bit-per cell PCM devices. The resistance of the amorphous phase uncontrollably increases with time after a reset operation which alters the read/write conditions of the device. Structural relaxation (SR) through a defect annihilation process is considered to be the underlying physical mechanism for resistance drift. Here, we report on our measurements of the resistance drift in a phase change memory device with a single layer Ge2Sb2Te5 (GST) material not only in the amorphous state but also in the intermediate resistance state in devices with square top contact geometry which enables us to assess the reliability of multiple-bit per cell PCM memory devices. Through an analysis of electrical measurements as a function of time and temperature for increasing annealing times, we estimate a rate of change in trap density for both amorphous and mixed phases of the GST material after a switching operation. Our study allows engineering the phase change materials and optimizing programing conditions for future PCM applications.

5:18PM Q14.00013 Bulk photovoltaic effect in CH₃NH₃PbI₃ and CH₃NH₃PbI₃₋ₓClₓ — Nathan Z. Koocher, Fan Zheng, Hiroyuki Takenaka, Fengfeng Wang, Andrew M. Rappe, Univ. of Pennsylvania — The power conversion efficiency of organometal halide perovskites has increased to nearly 20%, fueling interest in understanding the mechanism of its photovoltaic effect. High open-circuit photocurrents and J/V hysteresis curves have been experimentally measured for these materials, which suggest that the bulk photovoltaic effect (BPVE) could be in operation. Shift current is a main mechanism of the BPVE in ferroelectric perovskite oxides, and thus in our work, we calculate the shift current response of MAPbI₃ and MAPbI₃₋ₓClₓ. We find that MAPbI₃ and MAPbI₃₋ₓClₓ have shift current responses about three times larger than that of BiFeO₃. Specifically, the shift current response is enhanced when the molecular dipoles from the methylammonium molecules are aligned in the same direction and when Cl is substituted into the lattice. Because of the large shift current response, the BPVE may play a role in enhancing the performance of the solar cells.

Wednesday, March 4, 2015 2:30PM - 5:30PM — Session Q15 DMP: Focus Session: Energy and Electron Flow at Interfaces in Nanostructures

2:30PM Q15.00001 Schottky barrier formation and reduction at Au/TiO₂ interfaces by dopants from quantum simulations, Yang Jiao, Anders Hellman, Yurui Fang, Applied Physics, Chalmers University of Technology, Shiwu Gao, Beijing Computational Science Research Center, Michael Kall, Applied Physics, Chalmers University of Technology — Excitation of localized surface plasmon resonances (LSPRs) in metallic nanoparticles, especially particles made of noble metals, results in efficient light absorption and strong field enhancement, thereby enabling a multitude of nanooptical applications of high current interest. Recently, the possibility of utilizing LSPRs to generate hot electrons has attracted considerable attention. One method to extract and make use of the hot electrons is by attaching the nanoparticles on a semiconductor surface such that excited electrons with proper energy and momentum can be transferred through the Schottky barrier at the interface. Using ab initio calculations for Au/TiO₂ interfaces, we investigate dopant induced Schottky barrier height reduction effects. We show that dopant induced polarization at the interface is the dominant reason behind the semiconductor band bending and Schottky barrier formation. Calculations for Nb-dopants at different depths (d) below the interface show that the Schottky barrier height reduction depends on the depth and varies from 0.1 eV at d = 4 nm to up to 1.3 eV when the dopant is situated at the interfacial layer. The calculations also indicate that the Schottky barrier can be tuned by up to 1.5 eV by using different transition metal dopants.

2:42PM Q15.00002 Manipulating the charge state and conductance of a single molecule on a semiconductor surface by electrostatic gating1, Jesus Martinez-Blanco, Christophe Nacci, Paul-Drude-Institut fuer Festkörperelektronik, Germany, Steven C. Erwin, Naval Research Laboratory, USA, Kiyoshi Kanisawa, NTT Basic Research Laboratories, Japan, Elina Locane, Martin Thöny, Felix Erwenn, Feit-Brockower, Technische Universität Berlin, Germany, Stefan Foelsch, Paul-Drude-Institut fuer Festkörperelektronik, Germany — We studied the charge state and tunneling conductance of single phthalocyanine molecules adsorbed on InAs(111)A using scanning tunneling microscopy (STM) at 5 K. On the InAs(111)A surface, native +1 charged indium adatoms can be repositioned by the STM tip using atomic manipulation. This allows us to electrostatically gate an individual adsorbed molecule by placing charged adatoms nearby or, alternatively, by repositioning the molecule within the electrostatic potential landscape created by an STM-engineered adatom corral. By stepwise increasing the gating potential, the molecular charge state can be tuned from neutral to -1, as well as to intermediate states. We find that the molecule changes its orientational conformation when the charge state is switched. Scanning tunneling spectroscopy measurements reveal that the conductance gap of the single-molecule tunneling junction can be precisely controlled by the electrostatic gating. We discuss the observed gating-dependent single-molecule tunneling conductance in terms of charge transport through a gated quantum dot.

1Granted by the German Research Foundation (FO 362/4-1; SFB 658).

2:54PM Q15.00003 Self-energy-corrected electronic energy level alignment in molecular junctions and at interfaces with hybrid functionals1, Michele Kotiuga, Physics Department, UC Berkeley & Molecular Foundry, LBNL, David Egger, Leeor Kronik, Department of Materials and Interfaces, Weizmann Institute of Science, Jeffrey B. Neaton, Physics Department, UC Berkeley & Molecular Foundry, LBNL — Accurate calculations of energy level alignment at complex interfaces are imperative for understanding a variety of transport and spectroscopy measurements, as well as for elucidating new interfacial electronic structure phenomena. However, standard approaches to such calculations, based on density functional theory (DFT), are well known to be deficient. In prior work on molecular junctions and physisorbed molecules on surfaces, an approximate GW approach, DFT+Σ, has been successful in describing the conductance and level alignment of amine and pyridine terminated molecules on gold surfaces and in junctions. Here, via the use of hybrid functionals, we perform quantitative studies of the level alignment of thiol- and carbon-terminated phenyls on gold, where the formation of a strong chemical bond and presence of gateway states limit the validity of the DFT+Σ approximation as currently formulated. We contrast these systems to prior work on weakly-coupled molecules, including bipyrindine or phenyl-diamines. Additionally, we compute transmission functions using both DFT-PBE and DFT-HSE starting points and predict conductance and thermopower with these methods, comparing to experiments where possible.

1We acknowledge DOE, DOD, NERSC, ERC, ISF, and FWF.
the contributions arising from inelastic effects. The provided new perspective on interface thermal transport can open new gates towards deeper understanding interfaces and present thermal interface conductance accumulation functions, two-dimensional cross-correlation matrices, and a quantitative determination of and exhibit a high conductance contribution on a per mode basis by strongly coupling to other types of vibrational modes. We apply our formalism to different these new modes, certain classifications emerge, as most modes extend at least partially into the other material. Localized interfacial modes are also present transport across the interface. The new set of vibrational modes is inconsistent with the physical picture described by phonon gas model (PGM), because some of the most important modes are localized and non-propagating and therefore do not have a well-defined velocity nor do they impinge on the interface. Among these new modes, certain classifications emerge, as most modes extend at least partially into the other material. Localized interfacial modes are also present forward the challenge that soft X-rays cannot easily peek into the high-pressure catalytic cells or liquid electrochemical cells. In this presentation a number of examples are given, including the nanocatalysts and the recent experiment performed for studying the hole generation in a specifically designed photothermal chemical cell under operando conditions.

In Situ Soft X-ray Spectroscopy Characterization of Interfacial Phenomena in Energy Materials and Devices. JINGHUA GUO, YI-SHENG LIU, MIKES KAPILASHRAMI, PER-ANDERS GLANS, ALS/LBNL, DEBAJEE BORA, ARTUR BRAUN, EMPA, JUAN JESÚS VELASCO VELÉZ, MIQUEL SALMERON, MSD/LBNL, ALS/LBNL TEAM, EMPA, MSD/LBNL COLLABORATION — Advanced energy technology arises from the understanding in basic science, thus rest in large on in-situ/operando characterization tools for observing the physical and chemical interfacial processes, which has been largely limited in a framework of thermodynamic and kinetic concepts or atomic and nanoscale. In many important energy systems such as energy conversion, energy storage and catalysis, advanced materials and functionality in devices are based on the complexity of material architecture, chemistry and interactions among constituents within. To understand and thus ultimately control the energy conversion and energy storage applications calls for in-situ/operando characterization tools. Soft X-ray spectroscopy offers a number of very unique features. We will present our development of the in-situ/operando soft X-ray spectroscopic tools of catalytic and electrochemical reactions in recent years, and reveal how to overcome the challenge that soft X-rays cannot easily peek into the high-pressure catalytic cells or liquid electrochemical cells. In this presentation a number of examples are given, including the nanocatalysts and the recent experiment performed for studying the hole generation in a specifically designed photothermal chemical cell under operando conditions.

Determining level alignment and coupling strength in single-molecule junctions with chemically-enhanced Raman spectroscopy. PIERRE DARANCET, Center for Nanoscale Materials, Argonne National Laboratory, ALEXEY ZAYAK, Department of Physics, Bowling Green State University — Raman spectroscopy can be used at the nanoscale to probe binding geometries [1], molecule concentrations [2], carrier densities [3], and charging effects [4]. In this talk, we use finite-difference total-energy and energy corrected density functional theory calculations in conjunction with Landauer framework, to study the Raman spectra and transport properties of model nanoscale interfaces, single-molecule junctions – individual molecules contacted with macroscopic metallic electrodes. In the cases of 4,4′-bipyrindine/Gold and polyphenylene vinylene/Gold junctions, we will show how conductance and chemically-enhanced Raman measurement can be used in conjunction to determine the energy scales controlling electron transport i.e. frontier orbital energies and coupling strength.

Nanoscale optical spectroscopy of CdTe photovoltaic devices. NIKOLAI ZHITENEV, CNST/NIST, YOHAN YOON, JUNSEOK CHAE, CNST/NIST and U. Maryland NanoCenter, AARON KATZMENZER, CNST/NIST, HEA YOUNG YOON, CNST/NIST and U. Maryland NanoCenter, ANDREA CENTRONE, CNST/NIST — Thin film solar cells are based on polycrystalline materials such as CdTe and CIGs that are structurally and electronically non-uniform. To further advance the power conversion efficiency it is important to understand the properties of interfaces (p-n junction, contacts) and microstructure (composition, grains) of these inhomogeneous devices. We apply two local optical techniques for spectroscopic characterization of CdTe photovoltaic devices. The samples are cross-sectional lamellas extracted from CdTe cell with sub-micron thickness prepared by focused ion beam. The first tool is variable wavelength infrared interferometry (VWIR) and the second is optical images of the transmitted / absorbed power. The optical wavelength was varied in the range from 400 nm to 900 nm. The contrast of the spatial maps of optical absorption is the strongest at excitation energies close to the band gap of CdTe and it can be associated with the composition variation throughout the device. The second technique uses the photo-thermal effect as a local measurement of absorption and can be used for broader range of wavelengths. Pulsed laser with variable wavelength is used for the excitation, and the local thermal expansion is detected by an atomic force microscope. We compare the resolution and the sensitivity of these two approaches in the range of photon energies close to the band gap where both techniques can be used.

Variable temperature shot noise measurements in mechanically controlled gold break junctions. RUOYU CHEN, LELAND RICHARDSON, DOUGLAS NATELSON, Rice University — Shot noise originates from the discreteness of charge carriers when a finite bias is applied. The noise spectral density reflects the effective charge and the Fano factor. The former may be modified by electron-electron interactions, while the latter can be affected by both interactions and the microscopic nature of transport. The temperature dependence of shot noise is interesting due to the fact that both interactions and the microscopic dynamics and geometries can vary with temperature, as well as length scales associated with scattering. Previous excess noise measurements demonstrate the existence of shot noise in ballistic atomic-scale contacts at room temperature, indicating that the quantum coherence length is at least larger than atomic scale even at 300 K. A detailed temperature dependent study from cryogenic conditions to room temperature is still absent. Here we will present progress on using lithographically patterned gold bowtie junctions on mechanically-bended substrates to study the broadband rf excess noise over different conductance values, electric biases and temperatures.

Dissipation and heating in C$_{60}$ molecular junctions. PAVLO ZOLOTVIN, CHARLOTTE EVANS, DOUGLAS NATELSON, Department of Physics & Astronomy, Rice University — We present a novel experimental approach to study energy dissipation during electron transport through the molecular scale junction containing a C$_{60}$ molecule. One of the pathways for a tunneling electron to dissipate energy in the junction is to excite vibrations of the molecule. Previously, such vibrational heating had been observed by measuring the intensity of anti-Stokes modes in the surface enhanced Raman spectra (SERS). A complimentary electron-focused approach is to use inelastic electron tunneling spectroscopy (IETS) to study the electron-vibronic interactions by tracking the effects of vibrations upon the electronic current. A combination of these two techniques should allow for a quantitative study of the energy dissipation in molecular junctions. The preliminary results of simultaneous IETS and SERS measurements in C$_{60}$ molecular junctions will be presented. We discuss the vibrational heating of C$_{60}$ molecule and future expansion of this work to junctions containing semiconductor nanocrystals. (ARO award W911 NF-13-1-0476)
necessarily on the film thickness. Further, when the conductive filaments in tantalum oxide devices. The effects of Joule heating, chemical species migration and pulsed ionizing radiation from an external source are included in the model. Interface tunneling current is determined via a WKB model, in conjunction with a lattice defect generation scheme. 4:18PM Q15.00010 Low temperature high bias enhanced noise in atomic-scale Au junctions

1D.N., P.Z., R.C. and L.S. acknowledge support from NSF award DMR-1305879.

4:30PM Q15.00011 Edge-Localised Spin-Polarized State in Nanofacet Formed on SiC(0001)

Surfaces, KEISUKE SAWADA, JUN-ICHI IWATA, ATSUSHI OSHIYAMA, Department of Applied Physics, The University of Tokyo — The nanometer-scale facet (nanofacet) are self-organized on the SiC(0001) surfaces being slightly misoriented toward the (1120) direction[1, 2]. It is known that the nanostructure induces the novel electronic property such as localized states at zigzag graphene edges[3]. In this study, we perform density-functional calculations on the nanofacet formed on the SiC(0001) surface. We find peculiar electron transport in different films without dispersion along the step edges (SEs) near the Fermi level. To explore possibilities of the observation of these peculiar states, we examine the situation that the nanofacet is covered by H atoms and calculate the H absorption energy at the several positions on the nanofacet. We then find that absorbed H atoms energetically prefer terraces to SEs. This leads to a situation in which H atoms at SE C atoms are desorbed. In this case, we find an electronic state distributed along the SE and is spin-polarized. Implication of magnetic transport in such nanofacet will be discussed. [1] H. Nakagawa et al., PRL 91, 226107 (2003). [2] M. Fuji and S. Tanaka, PRL 99, 016102 (2007). [3] M. Fujita et al., JPSJ 65, 1920 (1996).

4:42PM Q15.00012 Thermal conductivity and interfacial thermal conductance of HfN/ScN superlattices

B O SUN, N atl Univ of Singapore, JEREMY SCHROEDER, Linkoping University, YEEKAN KOH, Natl Univ of Singapore — Metal/semiconductor superlattices are known for their potential application as thermionic devices. Understanding thermal properties of such superlattices is essential for the design of new material structures and devices. Here, we measured the cross-plane thermal conductivity of HfN/ScN metal/semiconductor superlattices using time-domain thermoreflectance (TDTR). HfN/ScN superlattices with different period thickness (2nm to 24 nm) were grown on MgO substrate using reactive magnetron sputtering. We found that the minimum thermal conductivity is 4.3 W/m K when the period thickness is 6 nm. By changing the ratio of layer thickness of HfN and ScN (1:4 to 4:1), we studied the contributions electrons and phonons to the thermal conductivity of superlattices. Use a simple thermal resistance calculation, we extract the interfacial thermal conductance between HfN and ScN. The interfacial thermal conductance is 1.8 GW/m2 K, which is 3 times higher than that of AlN/GaN.

4:54PM Q15.00013 Resistivity of thiol-modified Au thin films

, PATRICIO HÄBERLE, JONATHAN CORREA-PUERTA, VALERIA DEL CAMPO, RICARDO HENRIQUEZ, Universidad Técnica Federico Santa María, Chile — Electrical transport in conductors with sizes in the nanoscale range is indeed a surface dependent feature. We report on the modification of electrical transport in thin gold films by the functionalization of alkanethiols, which form a self-assembled monolayer. Theoretical models such as the Fuchs-Sondheimer-Lucas and Namba[1], have been used to describe the electrical conduction, including size effects. Within these models, the resistivity can be attributed to an electron-surface scattering mechanism. Measurements performed in different films display an increased resistivity in the functionalized films. This increment depends mainly of the gold surface topography and not necessarily on the film thickness.

5:06PM Q15.00014 Direct measurement of the intrinsic linewidth of a resonant state

, ZACHARY KOBOS, Department of Electrical Engineering, Yale University, MARK REED, Departments of Electrical Engineering and Applied Physics, Yale University — We have applied inelastic electron tunneling spectroscopy (IETS) techniques to a resonantly-coupled system to determine quantitative differences in resonant versus non-resonant IETS. We use as a model system a set of GaAs-AlGaAs resonant tunneling diodes (RTDs)(footnote: with different barrier widths to tune resonant state linewidths and transmission coefficients. Modulation-broadening studies confirm theoretical predictions; however, the thermal dependence is markedly different than expected from classical IETS theory[1]. An analysis of resonances shut-off reveals that the thermal dependence reflects the thermal broadening of the injector and resonant state density of states. Using this analysis, we show that one can extract both the transmission coefficient and the intrinsic linewidth of the resonant state. This is compared for RTDs of different tunneling barrier widths, and we observe the expected increase in resonance width for thinner barriers.

5:18PM Q15.00015 The Role of Joule Heating and Defect Chemistry in Memristor Modeling

, BRIAN TIERNEY, HAROLD HJALMARSON, MICHAEL MCCLAIN, DENIS MAMALUY, Sandia National Laboratories — Resitive switching in electroformed metal/metal-oxide/metal memristive devices involves the growth and dissolution of conductive filaments within the metal-oxide. These filaments are typically formed/dissolved by applying a voltage pulse of the appropriate polarity across the metal contacts. The induced electric field across the oxide causes Joule heating. This heating is a significant contributor to the migration of lattice defects such as charged oxygen vacancies, which modulate the time-evolution of the conductive filaments, and hence the device resistance. In this talk, continuum calculations are presented that model the temporal evolution of conductive filaments in tantalum oxide devices. The effects of Joule heating, chemical species migration and pulsed ionizing radiation from an external source are included in the model. Interface tunneling current is determined via a WKB model, in conjunction with a lattice defect generation scheme. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

Session Q16 DMP: Focus Session: van der Waals Bonding in Advanced Materials: Nano-Materials 101AB - Alexandre Tkatchenko, Fritz Haber Institute of the Max Planck Society
2:30PM Q16.00001 Beller Lectureship: Van der Waals interactions in adhesion, adsorption and friction experiments1, KARIN JACOBS, Experimental Physics, Saarland University, Saarbrücken, Germany — Van der Waals (vdW) forces are commonly regarded as being weak and of short range and are thus often neglected. However, our experiments give clear evidence that vdW forces significantly contribute to a range of phenomena at interfaces, like thin film stability, protein adsorption, bacterial and gecko adhesion as well as single asperity friction [1-5] and that vdW forces can be of long range. The key for an apt description of vdW and further relevant forces present in these diverse system is a precise knowledge about the interacting objects, for instance their chemical composition from the surface up to roughly 100 nm into the bulk. The effective interface potentials used to describe and understand the different experimental situations can additionally serve as useful descriptions for future simulations of similar systems, which will gain in precision and predictive power when taking vdW interactions into account.

1Financial support of by the German Research Foundation DFG via grants SPP 1164 and SFB 1027 are gratefully acknowledged.

3:06PM Q16.00002 Van der Waals-coupled electronic states in incommensurate double-walled carbon nanotubes, CHENHAO JIN, Department of Physics, UC Berkeley, KAIHUI LIU, Department of Physics, Peking University, XIAOPING HONG, JIHOON KIM, ALEX ZETTLE, Department of Physics, UC Berkeley, ENGE WANG, International Center for Quantum Materials and Collaborative Innovation Center of Quantum Matter, Peking University, FENG WANG, Department of Physics, UC Berkeley — In two-dimensional materials consisting of elements without finite unit cell, such as twisted graphene bilayer or graphene on boron nitride, the incommensurate van der Waals coupling can give rise to emerging physics like Van Hove singularities, pseudospin-mixing potential and Hofstadter butterflies. However, their 1D counterpart, incommensurate double-walled carbon nanotube (DWNT), is conventionally believed to have negligible electron hybridization due to destructive interference. Here we for the first time demonstrate strong and chirality-dependent intertube electronic coupling in DWNTs, which can be well described by a zone folding model of twisted and “stretched” graphene bilayers. Our results demonstrate that incommensurate van der Waals interactions can be important for engineering the electronic structure and optical properties of one-dimensional materials.

3:18PM Q16.00003 Double-walled carbon nanotubes as one-dimensional moiré crystals1, PILKYUNG MOON, NYU Shanghai, MIKITO KOSHINO, Tohoku University, YOUNG-WOO SON, Korea Institute for Advanced Study — Being multi-shell structure, the well-defined atomic periodicity is hardly realizable in double-walled nanotubes because the periodic units of individual tubes therein cannot match well except very few cases, posing a challenge to understand its physical properties. Here we show that moiré patterns generated by superimposing atomic lattices of individual tubes are decisive in determining its electronic structures [1]. By using double-walled carbon nanotubes as an example, we demonstrate that even the combination of semiconducting nanotubes with almost the same physical properties such as diameter and energy gap can end up with very different double-walled nanotubes, of which electronic properties vary from metallic to semiconducting and further to insulating states, depending on the interlayer moiré interference. Our study puts forth a new classification of nanotubes as the first example of one-dimensional moiré crystals and paves a firm ground to utilize superb technological merits of double-walled carbon nanotubes. [1] Mikito Koshino, Pilkyung Moon, and Young-Woo Son, arXiv:1410.7544 (2014).

3:30PM Q16.00004 Dynamical Screening of van der Waals interactions in nanostructures: Sublimation of fullerenes1, ANDREW M. RAPPE, JIANMIN TAO, JING YANG, University of Pennsylvania — Sublimation energy is one of the most important properties of molecular crystals, but it is difficult to study, because the attractive long-range van der Waals (vdW) interaction plays an important role. In this talk, I will discuss our recent work on the calculation of the sublimation of fullerenes, using efficient semilocal density functional theory (DFT), corrected with the dynamically screened vdW interaction (DFT+vdW), the Langreth-Lundqvist nonlocal vdW-DF, and the pairwise-based dispersion-corrected DFT-D2, to study the sublimation of fullerenes. We find that the short-range part, which accounts for the interaction due to the orbital overlap between fullerenes, is negligibly small. Our calculation shows that there exists a strong screening effect on the vdW interaction. On the other hand, higher-order contributions can be as important as the leading-order term. However, these two effects make opposite contributions, leading to significant error cancellation. We demonstrate that, by considering higher-order contributions and the dynamical screening, the DFT+vdW method can yield sublimation energies of fullerenes in good agreement with reference values, followed by vdW-DF and DFT-D2. The insights from this study are important for better understanding of the long-range nature.

3:42PM Q16.00005 van der Waals density functional comparison for water monomers, dimers and clusters and the implications on the dynamics of liquid water1, ADRIAN SOTO, MARIVI FERNANDEZ-SERRA, Department of Physics and Astronomy, Stony Brook University, DEyü LU, Center for Functional Nanomaterials, Brookhaven National Laboratory — The appearance of van der Waals (vdW) density functionals has allowed the efficient ab initio molecular dynamics (AIMD) study of systems for which dispersion forces are critical. Despite the great improvement over GGA functionals, the errors in the simulations are still too large for some applications of interest. Furthermore, different vdW functionals can produce qualitatively different results. In particular, for liquid water at ambient conditions there is a discrepancy of approximately 20% in the yielded P(\rho) “equations of state”; the radial distribution functions (RDF) disagree substantially with experiment, giving an overstructured liquid mainly due to an overbinding of the hydrogen bond; the self-diffusion coefficients can vary over 75% [J. Chem Phys. 139, 194502(2013)]. In this study we focus on the role of the electronic polarizabilities, responsible for the vdW dispersion forces using two very different vdW functionals. In particular we study how 1-body, 2-body and 3-body terms modify the molecular polarizabilities and how these effects are linked to the many-body decomposition of the total energy of the systems.

1This work was partially supported by DOE Award No. DE-FG02-09ER16052 and by DOE Early Career Award No. DE-SC0003871.
3:54PM Q16.00006 Van der Waals Coefficients between Clusters or Fullerenes: A Simple but Accurate Model beyond the Atom-Pair Interaction Picture1, JOHN P. PERDEW, ADRIENN RUZSINSZKY, Department of Physics, Temple U., JIANMIN TAO, Department of Chemistry, U. of Pennsylvania — The van der Waals coefficients of all orders between two spherical objects may be computed from the dynamical multipole polarizabilities of the two objects via the Casimir-Polder formula. We present an analytic model [1] for the dynamical polarizabilities that is exact for a classical conducting sphere or spherical shell, exact in the zero- and nearly-exact in the high-frequency limits, and generally accurate. From this model, we compute the low-order van der Waals coefficients for a variety of atom pairs and pairs of clusters or carbon-based fullerenes. We find that the lowest-order coefficient C6 per atom pair may increase or decrease strongly with cluster size, signaling a failure of the simplest version of the atom-pair interaction picture. [1] J. Tao and J.P. Perdew, J. Chem. Phys. 141, 141101 (Commun.) (2014).

4:06PM Q16.00007 Van der Waals’ corrected linear-scaling Density Functional Theory investigation of inner-surface functionalized inorganic nanotubes, JOSHUA ELLIOTT, GILBERTO TEOBALDI, Univ of Liverpool — We report a linear-scaling Density Functional Theory investigation of single-walled open-ended aluminosilicate nanotubes with inner metal functionalization (AlSiMe NTs). In line with the experimental pore-size distribution, optimization of the AlSiMe NT structure with six different semi-local and non-local van der Waals DFT functionals suggests the presence of a shallow energy minimum for NTs with 28 to 32 Al-atoms in the NT circumference, resulting in larger diameter than for aluminosilicate (AlSi) NTs. Analysis of the AlSiMe NTs electronic structure reveals the wall-polarization and real-space separation between Valence Band and Conduction Band, characteristic of AlSi NTs1. Regardless of the functional, the wall of the AlSiMe NTs are however found to be less polarized than AlSi NTs, with NTs of larger diameter being more polarized. We quantify the effect of the AlSiMe NTs wall-polarization and polarizability on the absolute alignment of the states for adsorbed H2O molecules inside and outside the tube-cavity. The simulations indicate shifts as large as 2 eV between the H2O-states for molecules adsorbed inside and outside the NT-cavity.

4:18PM Q16.00008 ABSTRACT WITHDRAWN —

4:30PM Q16.00009 Water Dissociation Mechanism in MOF-741, SEBASTIAN ZULUAGA, Wake Forest University, KUI TAN, University of Texas at Dallas, PIEMANUELE CANEPA, Wake Forest University, YVES CHABAL, University of Texas at Dallas, TIMO THON-HAUSEN, Wake Forest University — Water dissociation represents one of the most important reactions in catalysis, essential to surface and nano sciences. Combining in-situ IR spectroscopy and first-principles calculations, we demonstrate, for the first time, that water starts to dissociate at the metal centers of MOF-74 at temperatures as low as 150 °C. The fingerprint of this reaction is a sharp band in the IR spectrum at 970 cm−1 when D2O is introduced into the MOF. Surprisingly, this fingerprint is not detected with experiments with H2O. To explain this peculiar finding, we perform DFT simulations of the reaction, utilizing vdW-DF to capture the important van der Waals interactions. Our calculations show that, once the D2O molecule is adsorbed at the metal center, the D atom is transferred to the oxygen of the linker (phenolate group), producing the notable O-D absorption band at 970 cm−1, while the OD remains at the open metal sites. Even though we find that H2O undergoes an analogous dissociation reaction, the corresponding O-H mode is strongly coupled to MOF vibrations and cannot easily be detected by experiments. Overall, this work elucidates water interactions with cation-exposed surfaces and aids in the development of more efficient catalysts for water dissociation.

4:42PM Q16.00010 Distortion of a liquid crystal bulk by the Casimir torque, DAVID SOMERS, JEREMY MUNDAY, University of Maryland, College Park — We present an experimental method for measuring the Casimir torque acting on liquid crystals from a birefringent crystal. A liquid crystal bulk that is uniformly aligned at one surface is twisted at the other surface by a crystal such as barium titanate. The liquid crystal is separated from the solid crystal by an isotropic, transparent material such as SiO2. By varying the thickness of the deposited layer, we can observe the effect of retardation on the torque (which differentiates it from the close-range van der Waals torque) and compare experimental results to dispersion data of the materials. We find that a barium titanate slab could cause 5CB liquid crystal to rotate by 10 degrees through its bulk, even when separated by 35 nm of SiO2. The optical technique for measuring this distortion is also outlined.

4:54PM Q16.00011 Casimir-like Forces via Charge Fluctuations1, DAVID DROSDOFF2, University of South Florida, IGOR BONDAREV, North Carolina Central University, LILIA WOODS, University of South Florida — Fluctuations of observables give rise to different forces. Dipolar fluctuations have been studied extensively for a variety of systems as they give rise to Casimir-like forces with particular importance in biological systems. We show that such phenomena are also of relevance to capacitor systems especially when nanostructured materials are involved. We present a theory with a novel view of charge fluctuations induced interactions via the quantum capacitance concept. It is demonstrated that such Casimir-like forces can be important, especially in nanostructures. The theory is applied to nanoscale capacitors involving graphene and other characteristic materials.

5:06PM Q16.00012 Measurement of Casimir forces with nonmonotonic distance dependence between silicon structures with non-conventional shapes, LU TANG, JIE ZOU, HO BUN CHAN, The Hong Kong University of Science and Technology, MILOS NIKOLIC, ALEJANDRO RODRIGUEZ, Princeton University — We measure the Casimir force between silicon components of non-conventional shapes on a silicon-on-insulator wafer. The device consists of a force-sensing micromechanical beam and a comb-drive actuator for controlling the distance. The magneto-motive technique is used to measure the shift in the resonance frequency of the force sensing beam. Each of the interacting surfaces contains an array of T-shaped protusions. Since the protusions on both sides are created by lithography and reactive ion etching, both their shapes and relative positions can be accurately defined. Here, the protusions on the two surfaces are offset by half the period. As the movable electrode is pushed towards the silicon beam by the comb drives, the two sets of protusions inter-penetrates. The lateral Casimir force between the top parts of the T-shaped structures produces in an overall interaction that is either apparently attractive or repulsive depending on the displacement of the comb actuators. The measured non-monotonic dependence of the Casimir force on distance is in qualitative agreement with preliminary calculations using the boundary elements method.
2:30PM Q17.00001 Conductivity noise as a transport-based probe to study the charge-carrier transmission across grain boundaries in polycrystalline graphene

VIDYA KOCHAT, Dept. of Physics, IISc, India, CHANDRA SEKHAR TIWARY, Dept. of Materials Engineering, IISc, India, TATHAGATA BISWAS, Dept. of Physics, IISc, India, GOPALAKRISHNAN RAMALINGAM, Materials Research Centre, IISc, India, SRINIVASAN RAGHAVAN, Materials Research Centre, Centre for Nano Science and Engineering, IISc, India, KAMANIO CHATTOPADHYAY, Dept. of Materials Engineering, IISc, India, MANISH JAIN, ARINDAM GHOSH, Dept. of Physics, IISc, India — Grain boundaries (GBs) form a class of topological defects, intrinsically present in polycrystalline graphene films and inevitably affect the electronic properties of the otherwise perfect honeycomb lattice. In this work, we have studied the charge carrier transmission across individual GBs in graphene having varying levels of disorder. We find that the defect density in the interface region of two adjoining graphene grains is directly related to their misorientation angle. Conductivity noise (low frequency 1/f noise) is a more sensitive probe to identify the microscopic mechanism of carrier scattering and can quantify the disorder levels of various types of GBs. The 1/f noise across wider interfaces were found to be higher by an order of magnitude when compared to the single-crystalline graphene regions, indicating huge amount of disorder at the interface region. We also obtain evidence for enhanced spin-flip scattering at the GBs from the measured conductivity noise at low temperatures suggestive of the fact that the GBs in graphene could sustain local magnetic moments.

2:42PM Q17.00002 Intrinsic carrier mobility of Dirac cones: limitations of the deformation potential theory

ZHENZHU LI, JINYING WANG, ZHIRONG LIU, Peking Univ — An analytic formula for the intrinsic carrier mobility of Dirac cones under acoustic phonon scattering mechanism was obtained for 2D systems such as graphene and graphyne. The influence of both transverse acoustic (TA) and longitudinal acoustic (LA) phonon modes as well as the anisotropy were considered. Some extraordinary characteristics different from the prediction of the deformation potential theory were revealed: the mobility at the neutrality point is proportional to $1/T^3$ where $T$ is the temperature; carrier scattering by TA phonons dominates the mobility of graphene, which explains the overestimated measured deformation potential of graphene in experiments. The theory was combined with first-principles calculation to determine the mobility of graphene and five graphynes with Dirac cones. It was predicted that most graphynes possess much higher mobility than graphene due to the suppression of the scattering by TA phonons.

2:54PM Q17.00003 Dephasing time in graphene due to interaction with flexural phonons

WELIZHAO, KONSTANTIN TIKHONOV, ALEXANDER FINKEL’STEIN, Texas A&M Univ — We investigate decoherence of an electron in graphene caused by electron-flexural phonon interaction. We find out that the flexural phonons can produce dephasing rate comparable to the electron-electron one. The problem appears to be quite special because there is a large interval of temperatures where dephasing rate cannot be obtained using the golden rule. We evaluate this rate for a wide range of density ($n$) and temperature ($T$) and determine several asymptotic regions with temperature dependence crossing over from $\tau_\phi^{-1} \sim T^2$ to $\tau_\phi^{-1} \sim T$ when temperature increases. We also find $\tau_\phi^{-1}$ to be a non-monotonic function of $n$. These distinctive features of the new contribution can provide an effective way to identify flexural phonons in graphene through the electronic transport by measuring the weak localization corrections in magnetoresistance.

3:06PM Q17.00004 ABSTRACT WITHDRAWN

3:18PM Q17.00005 Multi-Band Electron Tunneling Effects in Bilayer and Gapped Graphene

DIPENDRA DAHAL, Hunter College, CUNY, GODFREY GUMBS, Hunter College, CUNY and Donostia International Physics Center (DIPC), ANDRII IUROV, University of New Mexico and Hunter College, CUNY — A detailed study has been made of electron tunneling through a square potential barrier in bilayer, gapped graphene and the relatively new material silicone. The investigation has covered dressed electron states by circularly polarized light of electrons in bilayer graphene for various angles of incidence and through a periodic sequence of potential barriers as well as a quasiperiodic arrangement. The spin degenerate states of silicone may be lifted by a perpendicular electric field. We report spin-dependent tunneling in silicone.

3:30PM Q17.00006 Violation of the Wiedemann-Franz law in clean graphene layers

ALESSANDRO PRINCIPI, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211, USA — The Wiedemann-Franz law, connecting the electronic thermal conductivity to the electronic conductivity of a disordered metal, is generally found to be well satisfied even when electron-electron ($e-e$) interactions are strong. In ultra-clean conductors, however, large deviations from the standard form of the law are expected, due to the fact that $e-e$ interactions affect the two conductivities in radically different ways. Thus, the standard Wiedemann-Franz ratio between the thermal and the electric conductivity is reduced by a factor $1 + \tau/\tau_{1h}^e$, where $1/\tau$ is the momentum relaxation rate, and $1/\tau_{1h}^e$ is the relaxation time of the thermal current due to $e-e$ collisions. Here we study the density and temperature dependence of $1/\tau_{1h}^e$ in the important case of doped, clean single layers of graphene, which exhibit record-high thermal conductivities. We show that at low temperature $1/\tau_{1h}^e$ is $8/5$ of the quasiparticle decay rate. We also show that the many-body renormalization of the thermal Drude weight coincides with that of the Fermi velocity.

This work was supported in part by DOE grant DE-FG02-05ER46203 and by a Research Board Grant at the University of Missouri.

3:42PM Q17.00007 Dilute fluorinated graphene and bilayer graphene: resonant impurity scattering, anomalous magneto-transport and local spin-orbit coupling

J. ZHU, X. HONG, A. STABILE, C. HERDING, S.-H. CHENG, K. ZOU, B. WANG, J. LI, Penn State University — Graphene is a high-mobility semi-metal with weak spin-orbit coupling (SOC). I will discuss the striking effects of a dilute coverage of chemisorbed fluorine adatoms ($F < 0.1\%$) on charge transport and magneto-transport of graphene and bilayer graphene. We show that electron scattering with the F-adatoms can be quantitatively described by resonant impurity scattering. The $T$-dependence of conductivity reveals strong quantum corrections not yet understood, which differs qualitatively between F-monolayer and F-bilayer. Both F-monolayer and F-bilayer exhibit weak localization in a magnetic field. The dephasing rate $\tau_\phi^{-1}$ is dramatically enhanced in fluorined samples, compared to pristine and defluorinated control samples. It is further tunable by a perpendicular electric field in dual-gated F-bilayer devices. Strikingly, the ratio of $\tau_\phi^{-1}$ over the transport relaxation rate $\tau_\tau^{-1}$ is independent of $n_F$ and scales with the carrier density $n$ as $n^{-1/2}$ in both F-monolayer and F-bilayer. Strong local SOC induced by the F-adatoms, combined with the unusual effect of SOC on the magneto-resistance of WL, is likely to play a key role. Fluorine induced SOC has important implications on spin relaxation and spin Hall current in these engineered materials.
Scattering of two-dimensional massless Dirac electrons in a circular potential barrier. JHJH-JHENG WU, MICHAEL FOGLER, University of California, San Diego — We calculate the differential, total, and transport cross-sections for scattering of two-dimensional massless Dirac electrons in a circular barrier. For scatterer of a small radius, the cross-sections are dominated by quantum effects such as resonant scattering that can be computed using the partial-wave series. Scattering by larger size barriers is better described within the classical picture of reflection and refraction of rays, which leads to phenomena of caustics, rainbow, and critical scattering. Refraction can be negative if the potential of the scatterer is repulsive, so that a p-n junction forms at its boundary. Qualitative differences of this case from the n-N doping case are examined. Quantum interference effects beyond the classical ray picture are also considered, such as normal and anomalous diffraction, and also whispering-gallery resonances. Implications of these results for transport and scanned-probe experiments in graphene and topological insulators are discussed.

Phonon coupling and disorder induce infrared optical transparency in graphene. BRUNO ROUSSEAU, Université de Montréal, FRANÇOIS LAROYONTE, Fritz-Haber-Institut der Max-Planck-Gesellschaft, MICHEL CÔTÉ, RICHARD MARTEL, Université de Montréal — Recent infrared spectroscopy measurements of doped graphene grafted with iodophenyl moieties have revealed fairly narrow transmission windows which vary as a function of the chemical potential, in contrast to the featureless, Drude-like spectrum of pristine graphene in this frequency range. These asymmetric features appear at energies corresponding to phonon modes near the Γ and K points. We propose a model which involves coherent inelastic scattering with defects and phonons, thus relaxing the optical selection rule forbidden access to q ≫ Γ phonons. Numerical simulations based on the model reproduce the features of the experimental observations (number of bands, energies, variation in energy and intensity with respect to chemical potential).

Electron transmission through the stacking domain boundary on multilayer graphene. NAM NGUYEN, MIKITO KOSHINO, Tohoku Univ — We present a theoretical study on the electron transmission through the AB-BA stacking boundary in bilayer trilayer and tetrallyer graphene. Using the Green function method, we calculate the electron transmission probability through the stacking faults as the Fermi energy. In AB-BA bilayer boundary, the system is almost insulating at the low energy, while the transmission sharply rises as the Fermi energy increases to higher energy. This suggests that the stacking fault crucially suppresses the electron transmission in the intrinsic graphene bilayer at the charge neutral. We also study the effect of the perpendicular electric field which opens an energy gap, and find that the gap-opening and the Mexican-hat band deformation significantly enhance the electron transmission at the low-electron density. For the ABA-ABC domain boundary in trilayer graphene, we notice a similar behavior of electron transmission to the bilayer case, but in the tetralayer case (ABAB-ABAC boundary), the low-energy transmission is not much suppressed unlike in bilayer and trilayer cases.

Inelastic carrier lifetime in a coupled graphene electron-phonon system: Role of plasmon-phonon coupling. HONGKI MIN, SEONGJIN AHN, Department of Physics and Astronomy and Center for Theoretical Physics, Seoul National University, E.H. HWANG, SKKU Advanced Institute of Nanotechnology and Department of Physics, Sungkyunkwan University — We calculate the inelastic scattering rates and the hot electron inelastic mean free paths for both monolayer and bilayer graphene on a polar substrate. We study the quasiparticle self-energy by taking into account both electron-electron and electron-surface optical (SO) phonon interactions. In this calculation the leading order dynamic screening approximation (G0W approximation) is used to obtain the quasiparticle self-energy by treating electrons and phonons on an equal footing. We find that the strong coupling between the SO phonon and plasmon leads to a new decay channel for the quasiparticle through the emission of the coupled mode, and gives rise to an abrupt increase in the scattering rate, which is absent in the uncoupled system. In monolayer graphene a single jump in the scattering rate occurs, arising from the emission of the low energy branch of the coupled plasmon-phonon modes. In bilayer graphene the emission of both low and high energy branches of the coupled modes contributes to the scattering rate and gives rise to two abrupt changes in the scattering rate. The jumps in the scattering rate can be potentially used in the hot electron device such as switching devices and oscillators. Ref) Seongjin Ahn, E. H. Hwang, and Hongki Min, arXiv:1409.8394.

Conductivity and thermoelectric power in graphene: Interplay of disorder, Coulomb interaction, and optical phonons. MATTHEW FOSTER, HONG-YI XIE, Rice University — We study the electric and thermoelectric transport of Dirac fermions in graphene using the Boltzmann-equation approach. We consider the effects of quenched disorder, Coulomb interactions, and optical-phonon scattering and analyze the electric conductivity and the thermoelectric power (TEP) as functions of temperature T and chemical potential μ by unbiased numerical solutions to the Boltzmann equation. In the absence of optical phonons, for very clean graphene we observe the crossover from the interaction-limited hydrodynamic regime μ ≪ T to the disorder-limited Fermi liquid regime μ ≫ T. In the hydrodynamic regime, the TEP significantly deviates from Mott’s law and follows the result anticipated by the relativistic hydrodynamic theory. Moreover, we analyze the doping and screening effects upon the quantum minimal conductance, which indicates the dissipation induced by inelastic electron-hole scattering. On the other hand, we find that optical phonons start to contribute at relatively low temperatures, about one order of magnitude less than the phonon excitation energy. Especially, the TEP shows a non-monotonic temperature dependence and a peak appears at about T ≈ 200-300 K for a large variety of doping.

Temperature and bias dependence of barrier heights in graphene / semiconductor Schottky diodes under reverse bias. DUSHYANT TOMER, SHIVANI RAJPUT, LAWRENCE HUDY, LIAN LI, Univ of Wisconsin, Milwaukee — Sensors based on graphene / semiconductor Schottky diodes have shown significant enhancement in sensitivity over field effect devices when operated under reverse bias, where the conductivity has an exponential dependence on the Schottky barrier height. In this work, chemical vapor deposited monolayer graphene is transferred onto Si- and C-face of hexagonal SiC, Si(111), and GaAs001 substrates, as confirmed by scanning tunneling microscopy. Temperature and bias dependence of the barrier height are obtained by current-voltage measurements between 250 and 340 K. For all four junctions, the barrier increases linearly with temperature. However, as a function of reverse bias, it decreases linearly for graphene / SiC, but exhibits a non-linear dependence for graphene / (Si, GaAs) Schottky junctions. These findings and their implication on the performance of sensors based on graphene / semiconductor Schottky diodes will be discussed at the meeting. Supported by U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02-07ER46228.
5:18PM Q17.00015 Screening of substrate charged impurities as mechanism of conductance change in graphene gas sensing

Sang-Zi Liang, Pennsylvania State University, Gugang Chen, Avetik Harutyunyan, Honda Research Institute USA Inc., Jorge Sofo, Pennsylvania State University — In graphene sensing of gaseous NO, NO₂, and NH₃, the measured conductance change after the sensor is exposed to the molecules has been traditionally attributed to carrier density change due to charge transfer between the sample and the adsorbed molecule. However, this explanation ignores the effect of the adsorbates on the electron mobility, and analysis of the electron affinity/ionization potential does not favor charge transfer. In this talk, we propose and explore an alternative mechanism. When adsorbed, charged and dipolar functional on the surface of graphene may counteract and screen charged impurities on the substrate. Because scattering of electrons with these charged impurities has been shown to be a limiting factor in graphene conductivity, the screening leads to significant changes in the transport behavior. A model for the conductivity is established using the random phase approximation dielectric function of graphene and the first-order Born approximation for scattering. The model predicts maximal screening magnitudes for the charge and dipole moment. The dipole screening is generally weaker than the charge screening although the former becomes more effective with higher gate voltage.

Session Q18 DFD GSOFT: Invited Session: Recent Advances in Field-Responsive Fluids and Suspensions

Mission Room 103A - Rongjia Tao, Temple University

2:30PM Q18.00001 Complex magnetic fields breathe life into fluids. James Martin, Sandia National Laboratories — There are many areas of science and technology where being able to generate vigorous, noncontact flow would be desirable. We have discovered that three dimensional, time-dependent electric or magnetic fields having key symmetries can be used to generate controlled fluid motion by the continuous injection of energy [1-8]. Unlike natural convection, this approach does not require a thermal gradient as an energy source, nor does it require gravity, so space applications are feasible. The result is a highly active material we call a vortex fluid. The homogeneous torque density of this fluid enables it to climb walls, induce ballistic droplet motion, mix vigorously, even in such complex geometries as porous media, and effect highly efficient heat transfer. This vortex fluid can also exhibit a negative viscosity, which can immeasurably extend the control range of the “smart fluids” used in electro- and magnetorheological devices and can thus significantly increase their performance. Because the applied fields are uniform and moderate in strength, vortex fluids of any scale can be created, making applications of any size, from direct microdroplet motion to controlling damping in magneto-rheological dampers that protect bridges and buildings from earthquakes, feasible. Finally, we will demonstrate that such fields can animate fluids in remarkable ways that resemble living systems.

3:06PM Q18.00002 Suppressing turbulence and enhancing the liquid suspension flows in pipelines with electrorheology

Rongjia Tao, Temple University — Flows through pipes, such as crude oil through pipeline, are the most common and important transportation of fluids. To enhance the flow output along the pipeline requires reducing viscosity and suppressing turbulence simultaneously and effectively. Unfortunately, no method is currently available to accomplish both goals simultaneously. The talk will show that electrorheology (ER) provides an efficient solution. When a strong electric field is applied along the flow direction in a small section of pipeline, the field polarizes and aggregates the particles suspended inside the base liquid into short chains along the flow direction. Such aggregation breaks the rotational symmetry and makes the fluid viscosity anisotropic. Along the flow direction, the viscosity is significantly reduced; thus the flow along the pipeline is enhanced. In the directions perpendicular to the flow, the viscosity is substantially increased, effectively suppressing the turbulence. Recent field tests with crude oil pipeline have confirmed that this new technology works very well. For untreated crude oil, the flow inside the pipeline is turbulent as the Reynolds number exceeds 2300. However, for ER treated oil, the flow remains laminar even when the Reynolds number reaches 6000. The combination of the viscosity reduction along the flow direction and the turbulence suppression greatly saves the energy required to transport crude oil. In addition, both effects have found lasting more than 11 hours inside the pipeline after one ER treatment. No additive is needed. The process is repeatable. As turbulence is classified as one of the most important unsolved classical physics, this development is not only important for technology applications, but significant for basic physics as well.

3:42PM Q18.00003 ER fluid in microfluidic Systems

Weijia Wen, The Hong Kong University of Science and Technology — Electrorheological (ER) fluid is considered as a kind of smart material which is able to be used for microfluidic systems to achieve active and precise control of fluid by electrical signal. While, microfluidics, especially droplet microfluidic, attracts much attention recently from diverse research fields due to its highly integration, digitalization and computercontrolled characteristics. Here, we will introduce our recent experimental results of ER fluid-based microfluidic droplet generation and manipulation. Two methodologies by employing ER fluid into microfluidic system: digital generation, manipulation of “smart droplets” and droplet manipulation by ER fluid will be presented. Once it is combined with real-time detection, electrorheologically integrated chip with many functions can be realized. Some other applications of using GER fluid in microfluidic chips, such as the microfluidic logic gates, are also introduced. Some potential application of ER fluid for hydraulic system will be also introduced.

4:18PM Q18.00004 Magnetorheological fluids in occupant protection systems

Norman Wereley, University of Maryland — No abstract available.
4:54PM Q18.00005 MR effect enhancement of bidisperse MR fluids containing micron- and nano-sized iron particles, MASAMI NAKANO, Institute of Fluid Science, Tohoku University — Magnetorheological (MR) fluids are suspensions of micron-sized magnetic particles dispersed into carrier oils and behave like a Bingham fluid having magnetic-field responsive yield stress. In this research, bidisperse MR suspensions containing micron- (6.6 mm) and nano- (110nm) sized spherical iron particles into silicone oil were fabricated to enhance the MR effects. The steady and dynamic MR properties have been investigated in close relation to the magnetic-induced particle cluster structure and the visualized shear flow behaviors. The static and dynamic behaviors of the particle cluster structures formed in the MR fluids under applied magnetic fields were directly visualized using an optical microscope. And the steady and dynamic MR properties of the bidisperse MR fluids were measured using a magnetic field applicable parallel-disk rheometer. The MR effects of the bidisperse MR fluids changed significantly as a function of the solid fraction of nano-particles. Interestingly, field-induced shear stress was remarkably enhanced at higher shear rate when the solid fraction of nano-particles was around 25%. The enhancement of the shear stress can be attributed to the formation of distinct and wide particle cluster chains.

Session Q19 FLAP: Invited Session: Industry Day: Rheology and Processing for Additive Manufacturing Mission Room 103B - Tirtha Chatterjee, The Dow Chemical Company

2:30PM Q19.00001 Polymer Physics as a Key to Advanced Manufacturing at Dow, FLORIAN SCHATTENMANN, The Dow Chemical Company — Dow combines the power of science and technology to passionately innovate what is essential to human progress. The Company is driving innovations that extract value from the intersection of chemistry, physical and biological sciences to help address many of the world’s most challenging problems such as the need for clean water, clean energy generation and conservation, and increasing agricultural productivity. Dow’s integrated, market-driven, industry-leading portfolio of specialty chemical, advanced materials, agrosciences and plastics businesses delivers a broad range of technologies, services and solutions across high-growth sectors such as packaging, electronics, water, coatings and agriculture. In 2013, Dow had annual sales of more than $57 billion with more than 6,000 products manufactured at 201 sites in 36 countries across the globe. Given the large scale of Dow’s manufacturing footprint and broad range of industries, markets and applications Dow serves, a wide range of advanced manufacturing technologies are being developed. The presentation will give an overview of select manufacturing technologies and how polymer physics, modelling, analytical techniques and experimental validation are being employed to drive world leading innovation. We will discuss examples from several product technologies including composites, adhesives and polymers synthesis.

3:06PM Q19.00002 New insights on cellulosic ether hydrogels, ROBERT SAMMILER, The Dow Chemical Company — Aqueous hydroxypropylmethylcellulose materials (HPMC) often have much lower hot gel moduli (<10 Pa) relative to those (3,000 Pa) of aqueous methylcellulose materials (MC) at end-use conditions (<2 wt.%, 90 °C), and these lower moduli limit their use in applications. The origin of their lower moduli is suspected to arise from the order of two thermal transitions when warming. One transition, thought to involve a chain conformation transition, is referred to here as chain collapse. Another, thought to involve the self-assembly of chains into a three-dimensional physical network, is referred to as gelation. Often, chain collapse is thought to proceed gelation when slowly warming aqueous commercial HPMC materials from 5 to 90 °C at 1 °C/min, while the opposite order is thought to occur for many aqueous commercial MC materials. Chain collapse is identified as a sharp drop in the solution viscosity at pre-gel temperatures as T increases. The insensitivity of the chain collapse temperature to HPMC concentration is used to argue that this thermal event is distinct from gelation. These concepts are supported with the preparation of two developmental HPMC materials with similar MW and substitution levels (DS and MS). One HPMC material, prepared by a unique process, is designed to reverse order of the thermal transitions. This HPMC material is found to exhibit high hot gel moduli similar to those of aqueous MC materials; moreover, its gel is able to form syneresis fluid as it contracts in size when warmed. The gel contraction is thought to be a manifestation of chain collapse.

3:42PM Q19.00003 Particle laden interfaces and dispersions: Enabling high performance and multifunctional materials, RAVI SHARMA, Cabot Corporation — Particles at interfaces are finding increasing use in Pickering emulsions due to their superior stability compared to surfactant-stabilized emulsions. In this presentation we present an overview of particle laden interfaces and particle concepts for development of high performance materials, some of which could be used to address current materials problems in additive manufacturing.

4:18PM Q19.00004 Modifying polymer rheology by using nanofillers: applications in additive manufacturing, DILIP GERSAPPE, Stony Brook University — The ability to control the flow properties of polymers is critical to developing materials that can be used for additive manufacturing. The use of nanofillers in polymer matrices can significantly affect the rheological properties of the flow and rheological properties. We use Molecular Dynamics simulations to examine the role nanofillers have on polymer melts and polymer blends. In homopolymer systems, our results indicate that above a critical concentration of filler particles, the network structure formed between the fillers and the polymers strongly affects the dynamics of the nanocomposite under shear. However, we also find that low concentrations of filler particles leads to a large increase in chain orientation (relative to the pure polymer case) when shear is applied. Our results indicate that the ability of fillers to maintain the network during shear in the enhancement of the shear thinning effect at high concentrations of filler particles, while the ability to maintain high degrees of orientation in polymer chains results in shear thinning being present even at lower concentrations of fillers. In particle blends, we show that the nanofillers can reduce the slip at the interface between the two components. We also examine the role of the aspect ratio of the nanofiller on the rheological properties of polymer nanocomposites.

4:54PM Q19.00005 Rheology and Flow-Induced Crystallization of Polyolefins, ANTONIOS DOUFAS, Exxonmobil Chemical Research and Development — This talk will give an overview of melt rheology in shear and extensional flow kinematics as well as flow-induced crystallization (FIC) behavior of polyolefin systems relevant to polymer processing. Examples for both polypropylene (PP) and polyethylene (PE) systems will be discussed. The effect of shear on FIC of several PP resins of various microstructures is studied using parallel-plate and capillary rheometry. Generally, an increase in strain and strain rate to increase of temperature is found to decrease the thermodynamic barrier for crystal formation enhancing the crystallization kinetics at temperatures between the melting and crystallization points. FIC kinetics were enhanced with increased PP molecular weight indicating the importance of the high-end tail of the MWD on FIC. Various dies of different contraction angle and different length-to-diameter (L/D) ratios were used to investigate the effect of flow (mainly extensional kinematics in die entrance) on FIC. Extensional strain is found to be a key parameter influencing FIC. The effect of different molecular structures (from linear to long chain branched) on melt rheology and FIC response of several PE systems will be discussed. The melt rheology and FIC characteristics of thermoplastic materials are important for their processability performance in conventional and advanced fabrication processes such as Additive Manufacturing.

Wednesday, March 4, 2015 2:30PM - 5:30PM –
Session Q20 DMP: Focus Session: Superconductivity in the 2D Limit II Ballroom B - Hanno Wieringa, University of Tennessee, Knoxville
2:30PM Q20.00010 Remarkable effects of disorder on superconductivity of single atomic layers of lead on silicon\(^1\), CHRISTOPHE BRUN, Sorbonne Universit\'es, UPMC Univ Paris 06 et CNRS, UMR 7588, Institut des Nanosciences de Paris, F-75005, Paris, France — It is well known that conventional superconductivity is very robust against non-magnetic disorder \([1]\). Nevertheless for thin and ultrathin films the structural properties play a major role in determining the superconducting properties, through a subtle interplay between disorder and Coulomb interactions \([2]\). Unexpectedly, in 2010 superconductivity was discovered in single atomic layers of lead and indium grown on silicon substrate using scanning tunneling microscopy \([3]\) and confirmed later on by macroscopic transport measurements \([4]\). Such well-controlled and tunable crystalline monolayers are ideal systems for studying the influence of various kinds of structural defects on the superconducting properties at the atomic and mesoscopic scale. In particular, Pb monolayers offer the opportunity of probing new effects of disorder because not only superconductivity is 2D but also the electronic wave functions are 2D. Our study of two Pb monolayers of different crystal structures by very-low temperature STM (300 mK) under magnetic field reveals unexpected results involving new spatial spectroscopic variations \([5]\). Our results show that although the sheet resistance of the Pb monolayers is much below the resistance quantum, strong non-BCS corrections appear leading to peak heights fluctuations in the dI/dV tunneling spectra at a spatial scale much smaller than the superconducting coherence length. Furthermore, strong local evidence of the signature of Rashba effect on the superconductivity of the Pb/Si(111) monolayer is revealed following filling of in gap states and local spatial variations of this filling. Finally the nature of vortices in a monolayer is found to be very sensitive to the properties of step edges areas.

3:06PM Q20.00002 Josephson Vortex in Indium Monatomic Superconductor on Silicon Terraces\(^1\), TAKUTO KAWAKAMI, International Center for Materials Nanoarchitectonics, National Institute for Materials Science, YUKI NAGAI, CCSE, Japan Atomic Energy Agency, SHUNSUKE YOHIZAWA, International Center for Materials Nanoarchitectonics, National Institute for Materials Science, HOWON KIM, The Institute for Solid State Physics, University of Tokyo, TOMONOBU NAKAYAMA, International Center for Materials Nanoarchitectonics, National Institute for Materials Science, YUKIO HASEGAWA, The Institute for Solid State Physics, University of Tokyo, TAKASHI UCHIHASHI, XIANG HU, International Center for Materials Nanoarchitectonics, National Institute for Materials Science — Superconductivity in Indium monatomic layer on a surface of Silicon substrate is intriguing where the terraces and steps exist. Recently, elliptic vortices trapped at steps have been observed by STM/STS measurement under magnetic field \([1]\). Motivated by this experiment, we clarify the quasiparticle excitation by using Bogoliubov-de Gennes approach \([2]\). The current distribution and zero energy density of states at vortex core show elliptic shape with longer axis parallel to the step. Moreover, the order parameter is restored at the vortex core. By comparing theoretical results with experiments, we conclude that the recent STS measurement has directly detected Josephson vortex. \([1]\) S. Yoshizawa, et al., Phys. Rev. Lett. (in press, arXiv:1405.5953). \([2]\) T. Kawakami, et al., J. Phys.: Conf. Ser. (in press).

3:18PM Q20.00003 High temperature superconductivity in one unit cell FeSe and superconductivity in two-monolayer Ga\(^1\), JIAN WANG, Peking University — By direct transport and magnetic measurements, we provide definitive evidence for high temperature superconductivity in the 1-UC FeSe films on insulating STO substrates with the onset Tc and critical current density much higher than those for bulk FeSe. In addition, by both in situ scanning tunneling microscopy/spectroscopy and ex situ transport and magnetization measurements, we find that the two-atomic-layer Ga film with hexagonal structure on wide band-gap semiconductor GaN is superconducting with Tc up to 5.4 K.

3:30PM Q20.00004 Ballistic superconductivity in high mobility two dimensional electron gas in GaAs heterostructures, ZHONG WANG, ALEKSANDR KAZAKOV, MICHAEL MANFRA, Purdue univ, LOREN PFEIFFER, KEN WEST, Princeton Univ, LEONID ROKHINSON, Purdue.edu — Introduction of a Josephson field effect transistor (JFET) concept sparked active research on proximity effects in semiconductors. Induced superconductivity and electrostatic control of critical current has been demonstrated in two-dimensional gases in InAs, graphene, and top of thical monolayer, but Coulomb repulsion acts as superconductivity friend rather than a foe. Such repulsion-to-attraction transmutation allows to access strong-coupling superconductivity regime even when intrinsic pairing interaction is weak. We analyze pairing interaction in 2DC crystals placed atop a highly polarizable dielectric with dispersive permittivity \(\varepsilon(\omega)\) and predict that by optimizing system parameters a substantial enhancement can be achieved. We also argue that the SCC mechanism can be responsible, at least in part, for 100 K superconductivity recently observed in FeSe monolayers grown on SrTiO\(_3\) substrate, with \(T_c\) more than 10 times larger than in bulk 3D FeSe crystals, arxiv:1406.3435.

4:18PM Q20.00006 Synthetic Superconductivity in Single-Layer Crystals, LEONID LEVITOV, DAN BORG-NIA, PATRICK LEE, Massachusetts Inst of Tech-MIT — Electronic states in atomically thin 2D crystals are fully exposed and can couple to extrinsic degrees of freedom via long-range Coulomb interactions. Novel many-body effects in such systems can be engineered by embedding them in a polar environment. Superconducting pairing interaction induced in this way can enhance the intrinsic electron-phonon pairing mechanism. We take on this notion, which was around since the 60’s ("excitonic superconductivity"), and consider synthetic superconductivity (SSC) induced in 2D crystals by a polar environment. One intriguing aspect of this scenario is that Coulomb repulsion acts as superconductivity friend rather than a foe. Such repulsion-to-attraction transmutation allows to access strong-coupling superconductivity regime even when intrinsic pairing interaction is weak. We analyze pairing interaction in 2DC crystals placed atop a highly polarizable dielectric with dispersive permittivity \(\varepsilon(\omega)\) and predict that by optimizing system parameters a substantial enhancement can be achieved. We also argue that the SCC mechanism can be responsible, at least in part, for 100 K superconductivity recently observed in FeSe monolayers grown on SrTiO\(_3\) substrate, with \(T_c\) more than 10 times larger than in bulk 3D FeSe crystals, arxiv:1406.3435.
4:30PM Q20.00007 The Meissner and Mesoscopic Superconducting States in the Ultrathin FeSe-Films, L. Z. DENG, B. LV, Z. WU, Y. Y. XUE, Texas Center for Superconductivity at the University of Houston, W. H. ZHANG, F. H. LI, Department of Physics, Tsinghua University, Beijing, L. L. WANG, X. C. MA, Institute of Physics, Chinese Academy of Sciences, Beijing, Q. K. XUE, Department of Physics, Tsinghua University, Beijing, C. W. CHU, Texas Center for Superconductivity at the University of Houston; Lawrence Berkeley National Laboratory, Berkeley, California — We carried out a detailed investigation on the superconductivity in eight 1-4 unit-cell FeSe-films on SrTiO3(STO) substrates by measuring their magnetization and resistivity in a field between 5E2 and 7E4 Oe over the last one and half years as a function of temperature and frequency, from 2 to 300 K and 0 to 1.5 kHz, respectively. Systematic aging effect for these samples was also well studied. The results show that samples display a complex superconducting structure, i.e. a Meissner state but populated with weak-links below 20 K, and an unusual superconducting mesostructure up to 45 K. A model is proposed to account for such a superconducting mesoscopic structure, similar to the Andreev reflection between the normal and superconducting carriers. Above 45 K, collective glass-like excitations are evident although their nature is yet to be determined.

4:42PM Q20.00008 ABSTRACT WITHDRAWN

4:54PM Q20.00009 ABSTRACT WITHDRAWN

5:06PM Q20.00010 Superconductivity in a two-dimensional repulsive Rashba gas at low density, LUYANG WANG, HONG YAO, Institute for Advanced Study, Tsinghua University — We study the superconducting instability and the resulting superconducting states in a two-dimensional repulsive Fermi gas with Rashba spin-orbit coupling at low electron density. We find that the superconductivity is enhanced as the Fermi energy $E_F$ decreases, due to two reasons: first, the density of states at $E_F$ increases as $1/\sqrt{E_F}$; second, the particle-hole bubble gains a more significant structure, resulting in an increasing effective attraction. The superconducting state is always in the total angular momentum $j_z = \pm 2$-channel, and breaks time-reversal symmetry. Once a sufficiently large Zeeman coupling is applied to the superconducting state, the spectrum Chern number becomes $\pm 1$, depending on the direction of the Zeeman field, and Majorana zero modes appear in the vortex cores. Collective modes in this superconducting state are also studied.

5:18PM Q20.00011 Metallic ground state in an ion-gated two-dimensional superconductor, YOSHIHOJI IWASA, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, The University of Tokyo, Japan, YU SAIITO, QPEC and Department of Applied Physics, The University of Tokyo, Japan, YUICHI KASAHARA, Department of Physics, Kyoto University, Japan, JIANTING YE, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands, TSUTOMU NOJIMA, Institute for Materials Research, Tohoku University, Japan — Ever since a discovery of insulator-superconductor transition in metallic thin films, the ground state of clean two-dimensional (2D) superconductors has been a long standing fundamental question. Recently emerging electric double layer transistors enabled researchers to realize electric-field-induced superconductivity in various substances, which provides us with new opportunities to investigate the ground state of 2D superconductivity. In this presentation, we report that the majority of the field-temperature phase diagram of electric-field-induced superconductivity in ZrNCl including $T = 0$ K is occupied by a metallic state with finite resistance due to the quantum tunneling of isolated vortices and flux flow caused by extreme two-dimensionality and weak pinning potential. These results imply that electric-field-induced superconductivity can be an ideal platform for accessing quantum vortex states in clean 2D superconductors.

Wednesday, March 4, 2015 2:30PM - 5:18PM — Session Q21 DCMP: Metal Insulator Transitions 201 - Dragana Popovic, National High Magnetic Field Laboratory

2:30PM Q21.00001 ABSTRACT WITHDRAWN

2:42PM Q21.00002 An apparent metal insulator transition in high mobility 2D InAs heterostructures, JAYAD SHABANI, CHRIS PALMSTROM, University of California, Santa Barbara — We report on the first experimental observation of an apparent metal insulator transition in a 2D electron gas confined in an InAs quantum well. At high densities we find that the carrier mobility is limited by background charged impurities and the temperature dependence of the resistivity shows a metallic behavior with resistivity increasing with increasing temperature. At low densities we find an insulating behavior below a critical density of $n_c = 5 \times 10^{15}$ cm$^{-2}$ with the resistivity decreasing with increasing temperature. We analyze this transition using a percolation model arising from the failure of screening in random background charged impurities [1]. We also examine the percolation transition experimentally by introducing remote ionized impurities at the surface. Using a bias during cool-down, we modify the screening charge at the surface which strongly affects the critical density. Our study shows that transition from a metallic to an insulating phase in our system is due to percolation transition.

2:54PM Q21.00003 Electrically induced Metal-Insulator Transition in Nb/NbO$_2$/TiN Devices, YUHAN WANG, STUART A WOLF, JIWEI LU, Univ of Virginia — Niobium dioxide (NbO$_2$) exhibits a metal insulator transition (MIT) as well as a structural transition at 1081 K. It has also been observed that an MIT could be induced by applied electrical field, which makes it attractive as potential electric and optical switch applications. A reactive bias target ion beam deposition (RBTIBD) technique was employed to synthesize Nb/NbO$_2$ thin films on TiN/Si substrates, in which the Nb top layer was used as the top electrodes. Electrically induced MIT was observed in the Nb/NbO$_2$/TiN devices, showing threshold characteristics. The electrically induced MIT was uni-polar with very minimal hysteresis behavior and good reproducibility. Such transitions were observed up to 200 $^\circ$C without obvious phase changes of NbO$_2$, indicating good thermal stability. We will discuss the evolution of electrical fields, current densities and input power at switching with the number of switches, as well as their dependence on the size of contacts. To study the possible effects from the interfaces between NbO$_2$ films and contacts, annealing processing in forming gas was conducted and transition behaviors were compared before and after annealing. The possible mechanisms for this induced MIT will be discussed.
3:06PM Q21.00004 Electrical transport properties of CaB₆₁

JOLANTA STANKIEWICZ, Instituto de Ciencia de Materiales de Aragón and Departamento de Física de la Materia Condensada, CSIC–Universidad de Zaragoza, 50009-Zaragoza, JAVIER SESE, Instituto de Nanociencia de Aragon and Departamento de Física de la Materia Condensada, Universidad de Zaragoza, 50018-Zaragoza, Spain, GEETHA BALAKRISHNAN, Department of Physics, University of Warwick, Gibbet Hill Road, Coventry CV4 7AL, UK, ZACHARY FISK, Department of Physics and Astronomy, University of California, Irvine, CA 92697, USA — We report results from a systematic electron-transport study in a broad temperature range on twelve CaB₆ single crystals. None of the crystals were intentionally doped. The different carrier densities observed presumably arise from slight variations in the Ca:B stoichiometry. In these crystals, the variation of the electrical resistivity and of the Hall effect with temperature can be consistently explained by a variable charge state of intrinsic defects, most likely B-antisites (B atom replacing Ca atom). Our model is also consistent with the presence of a narrow, defect related, impurity band close to the Fermi level. Thus it may indicate the validity of defect-driven intrinsic ferromagnetism in alkaline-earth hexaborides. The magnetotransport measurements reveal that most of the samples we have studied are close to a metal-insulator transition at low temperatures. The magnetoresistance changes smoothly from negative—for weakly metallic samples—to positive values—for samples in a localized regime.

3:18PM Q21.00005 Metallic Hydrogen

ISAAC SILVERA, MOHAMED ZAGHO, ASHRAN SALAMAT, Lyman Laboratory of Physics, Harvard University — Hydrogen is the simplest and most abundant element in the Universe. At high pressure it is predicted to transform to a metal with remarkable properties: room temperature superconductivity, a metastable metal at ambient conditions, and a revolutionary rocket propellant. Both theory and experiment have been challenged for almost 80 years to determine its condensed matter phase diagram, in particular the insulator-metal transition. Hydrogen is predicted to dissociate to a liquid atomic metal at multi-megabar pressures and T = 1.1-1.7 Mbar and up to 2200 K. We observe a first-order phase transition in the liquid phase, as well as sharp changes in optical transmission and reflectivity when this phase is entered. The optical signature is that of a metal. The mapping of the phase line of this transition is in excellent agreement with recent theoretical predictions for the long-sought plasma phase transition to metallic hydrogen.

3:30PM Q21.00006 Nanoscale Electrical Imaging of Metal-Insulator Transition in Ion-Gel Gated ZnO Field Effect Transistors

YUAN REN, Department of Physics, University of Texas at Austin, HONGTAO YUAN, Geballe Laboratory for Advanced Materials, Stanford University, XIAOYU WU, Department of Physics, University of Texas at Austin, YOSHIHIRO IWASA, Quantum Phase Electronics Center and Department of Applied Physics, University of Tokyo, YI CUI, HAROLD HWANG, Geballe Laboratory for Advanced Materials, Stanford University, KEJI LAI, Department of Physics, University of Texas at Austin — Electric double-layer transistors (EDLTs) using ionic liquid as the gate dielectric have demonstrated a remarkably wide range of density modulation, a condition crucial for the study of novel electronic phases in complex quantum materials. Yet little is known microscopically when carriers are modulated in the EDLT structure because of the technical challenge to image the buried electrolyte-semiconductor interface. With a novel nanoscale resistive microscope, we demonstrate the real-space conductance imaging and mapping in ZnO EDLTs with a spatial resolution of 100nm. A thin layer of ion gel, which solidifies below the glass transition temperature of 200K, was spin-coated on the ZnO surface to induce the metal-insulator transition. The microscope images acquired at different channel conductance clearly showed the spatial evolution of local conductivity through the transition. In addition, by applying a large source-drain bias, electrical inhomogeneity was also observed across the source and drain electrodes.

3:42PM Q21.00007 Metal-insulator transition in 2D quantum walks

JONATHAN EDGE, Nordita, JANOS ASBOTH, MTA Wigner FK SZFKI — We investigate the localisation properties due to disorder of several different two-dimensional quantum walks. We find that, contrary to claims in the literature, the Hadamard quantum walk does not localise. In a different quantum walk system we find a way to induce localisation. By tuning the parameters of the system we further manage to drive the quantum walk through a metal-insulator transition and show that the transition is related to the plateau transition of the integer quantum Hall effect.

3:54PM Q21.00008 Compression-Driven Enhancement of Electronic Correlations in Simple Alkali Metals

GILBERTO FABBRI, Argonne National Lab./Washington University in St. Louis, JINHYUK LIM, Washington University in St. Louis, LARISSA VEIGA, Argonne National Lab./Brazilian Synchrotron Light Lab., DANIEL HASKEL, Argonne National Lab., JAMES SCHILLING, Washington University in St. Louis — Alkali metals are the best realization of the nearly free electron model. This scenario appears to change dramatically as the alkalis are subjected to extreme pressure, leading to unexpected properties such as the departure from metallic behavior in Li and Na, and the occurrence of remarkable low-symmetry crystal structures in all alkalis. Although the mechanism behind these phase transitions is currently under debate, these are believed to be driven by electronic quantum melting. In this study the high-pressure electronic and structural ground state of Rb and Cs was investigated through low temperature XANES and XRD measurements combined with ab initio calculations. The results indicate that the pressure-induced localization of the conduction band triggers a Peierls-like mechanism, inducing the low symmetry phases. This localization process is evident by the pressure-driven increase in the number of d electrons, which takes place through strong spd hybridization. These experimental results indicate that compression turns the heavy alkali metals into strongly correlated electron systems.

4:06PM Q21.00009 From Coulomb Fluid to Self-Generated Charge Glass due to Long-Range Interactions and Geometric Frustration

SAMIYEH MAHMOUDIAN, National High Magnetic Field Laboratory and Florida State University, LOUK RADEMAKER, Kavli Institute for Theoretical Physics, University of California Santa Barbara, ARNAUD RALKO, SIMONE FRATINI, Institut Néel-CNRS and Université Joseph Fourier, VLADIMIR DOBROSAVLJEVIĆ, National High Magnetic Field Laboratory and Florida State University — We show that introducing long-range Coulomb interactions immediately lifts the massive ground state degeneracy induced by geometric frustration for electrons on quarter-filled triangular lattices in the semi-classical regime. This products not only a stripe-ordered (global) crystalline ground state, but also very many low-lying metastable states with amorphous “stripe-glass” spatial structure. At intermediate temperatures, such a frustrated Coulomb liquid shows remarkably slow (viscous) dynamics, with very long relaxation times growing in Arhenius fashion upon cooling, as typical of “strong glass formers.” On shorter time scales, the system falls out of equilibrium and displays the “aging” phenomena characteristic of supercooled liquids around the glass transition. Our results, which are obtained using mean field theory, classical Monte Carlo simulations and exact diagonalization, show remarkable similarity with the recent observations of charge-glass behavior in ultra-clean triangular organic materials Ω-RbZn and Ω-CsZn.

4:18PM Q21.00010 Strong-disorder renormalization group study of the Anderson localization transition in three and higher dimensions, HOSSEIN JAVAN MARD, VLADIMIR DOBROSAVLJEVIĆ, National High Magnetic Field Laboratory, Florida State University, JOSE A. HOYOS, Instituto de Física de São Carlos, Universidade de São Paulo, EDUARDO MIRANDA, Universidade Estadual de Campinas(Unicamp), SP, Brazil — We implement an efficient strong-disorder renormalization group (SDRG) procedure for disordered tight-binding models in dimension $D > 3$, including the localization properties on Erdős-Rényi random graphs, which represent an appropriate infinite dimensional limit. Our dramatically improved SDRG algorithm is based on a judicious elimination of most (irrelevant) new bonds generated under RG. It yields excellent agreement with exact numerical results for universal properties at the critical point, without significant increase of the required computer time, even as the spatial dimension is increased beyond $D = 3$. This opens an efficient avenue to explore the critical properties of Anderson transition in the strong-coupling limit of high spatial dimensions.  

4:30PM Q21.00011 Unstable Domain-Wall Solution in the Metal-Mott Insulator Coexisting Regime, TSUNG-HAN LEE, VLADIMIR DOBROSAVLJEVIC, Florida State University and National High Magnetic Field Laboratory, JAKSA VUCICEVIC, DARKO TANASKOVIC, Institute of Physics Belgrade, Serbia, EDUARDO MIRANDA, Campinas State University, Brazil — We employ Dynamical Mean Field Theory (DMFT) with multiphysical optimization (Conjugate Gradient and Broyd method) to investigate the transport properties of the unstable solution in the Mott metal-insulator coexisting regime. Physically, this solution is expected to describe the properties of the domain wall separating the metallic and the Mott-insulating regions in a spatially inhomogeneous case. We show that the multidimensional optimization can efficiently converge not only to the local minima of the free energy, describing the two coexisting phases, but also to the saddle-point describing the unstable solution. This unstable solution represents a new phase of matter: its low temperature transport properties differ qualitatively from both the metal and the insulator, displaying incoherent metallic behavior down to lowest temperatures.

4:42PM Q21.00012 ABSTRACT WITHDRAWN —

5:04PM Q21.00013 Large Disorder Renormalization Group Study of the Anderson Model of Localization1, SONIKA JOHRI, R. N. BHATT, Princeton University — We describe a large disorder renormalization group (LDRG) scheme for the Anderson model of localization in one dimension which eliminates eigenstates based on the size of their wavefunctions rather than their energy[1] (as done in RG models to date). We show that our LDRG scheme flows to infinite disorder, and thus becomes asymptotically exact. We use it to obtain the disorder-averaged inverse participation ratio and density of states and compare these with results obtained by exact numerical diagonalization for the entire spectrum. A modified method is formulated for higher dimensions, which is found to be less efficient, but capable of improvement. The possibility of extending this scheme to many-body localized states will be discussed.

5:06PM Q21.00014 Quantum phase transitions of a boson Hubbard model in one and two dimensions: a modified Time-Evolving Block Decimation study1, J-WOO LEE, SONG MOON KIM, HWAN BIN CHOI, Myongji University — We study quantum phase transitions of a boson Hubbard model in one and two dimensions at zero temperature. The model has a repulsive energy term ($U$) between the bosons located at the same site and a hopping energy term ($t$) to nearest neighboring sites. We construct matrix product states for one dimension and projected entangled pair states for two dimensions to represent ground states by a modified Time-Evolving Block Decimation. By exploring the energies and correlation functions, we obtain a phase diagram for this model as a function of chemical potential ($\mu$) and hopping energy ($t$) as we fix $U = 1$. Our results are compared with other methods, such as strong-coupling perturbation results and Monte Carlo results. Our method can be useful in calculating ground-state properties since we can control the accuracy of the ground state and the number of parameters for quantum entanglement.

Wednesday, March 4, 2015 2:30PM - 5:06PM —
Session Q22 DCMP: Heavy Fermions: Ce-based Compounds: Experiment 202A - Sergey Bud’ko, Ames Laboratory/Iowa State University

2:30PM Q22.00001 Surface bulk differences in a Kondo lattice system, KALOBARAN MAITI, Tata Inst of Fundamental Res, Thomas PRUSCHKE, University of Goettingen, KHADIZA ALI, DEEPNARAYAN BISWAS, SANGEETA THAKUR, SWAPNIL PATIL, NISHAINA SAHADEV, GANESH ADHIKARY, Tata Inst of Fundamental Res, G. BALAKRISHNAN, University of Warwick — Antiparallel coupling between the magnetic moment and conduction electrons leads to a non-magnetic Fermi liquid phase in a magnetic material - this is known as Kondo effect. Such coupled electronic states appear as a sharp feature at the chemical potential at low temperatures, called Kondo resonance feature. Photoemission spectra of Kondo systems often exhibit growth of multiple Kondo resonance features with large intensity at temperatures much higher than the Kondo temperature. We studied the evolution of the Kondo resonance feature in CeB6 employing high resolution photoemission spectroscopy and state of the art calculations based on dynamical mean field theory. We observe multiple Kondo resonance features with anomalies in their temperature evolution. It appears that the surface of these systems possess high Kondo temperature compared the bulk that causes unusual temperature evolution in these materials.

4:24PM Q22.00002 Spin fluctuations in the Kondo Semimetal CeRu4Sn6,1 WESLEY FUHRMAN, IQM, Johns Hopkins University, J. HAENEL, A. PROKOFIEV, S. PASCHEN, Vienna University of Technology, D.T. ADROJA, ISIS, J.A. RODRIGUEZ, NIST, C.L. BROHOLM, IQM, NIST, Johns Hopkins University — We present neutron scattering results for CeRu4Sn6. Tentatively classified as one of the few non-cubic Kondo insulators, CeRu4Sn6 has highly anisotropic physical properties. Using cold neutron inelastic neutron scattering, we have identified a magnetic signal for $h\nu < 1$ meV with a $4\pi$ like form factor and Q-dependence that is indicative of anisotropic antiferromagnetic spin correlations. The implications for the classification and understanding of CeRu4Sn6 are discussed.

1The work at IQM was supported by the US Department of Energy, office of Basic Energy Sciences, Division of Material Sciences and Engineering under grant DE-FG02-08ER46544.
2:54PM Q22.00003 Quantum Criticality in Kondo Compound CeAgBi2, SEAN THOMAS, PRISCILA ROSA, ZACHARY FISK, JING XIA. Univ of California - Irvine — We report a systematic study of the dense Kondo compound CeAgBi2 by means of electrical resistivity, heat capacity, and magnetic measurements, including torque magnetometry and Sagnac interferometry. By comparing our results with previous reports, we observe at zero field a slightly larger antiferromagnetic ordering temperature than $T_N = 0.4$ K. Moreover, five field-induced metamagnetic transitions are observed in magnetic fields up to 12 T applied parallel to the $c$-axis, including a remarkable signature for a first order transition at $H_c$. The low temperature specific heat coefficient $\gamma$ and the $T^2$ resistivity coefficient also show a divergence at the same $H_c$, indicating a putative quantum critical point. This work is supported by NSF grant DMR-1350122. The development of Sagnac interferometer is supported by NSF grant ECCS-1346603.

3:06PM Q22.00004 Doping Dependence of the Structural and Magnetic Properties of CeCu$_{6-x}$T$_x$ ($T$ = Ag, Pd). L. POUDDEL, Univ of Tennessee, Knoxville and Oak Ridge National Laboratory, M.A. MCGUIRE, C. DE LA CRUZ, S. CALDER, A.F. MAY, W. TIAN, M. MATSUDA, H.B. CAO, T. HONG, A.E. PAYZANT, Oak Ridge National Laboratory, H. JEEN, Oak Ridge National Laboratory and Pusan National University, S. Korea, H.N. LEE, Oak Ridge National Laboratory, M. KOEHLER, H. ZHOU, V. KEPPENS, Univ. of Tennessee, Knoxville, D. MANDRUS, A.D. CHRISTIANSON, Univ. of Tennessee, Knoxville and Oak Ridge National Laboratory — CeCu$_{6-x}$Au$_x$ is a well-known heavy fermion system that exhibits an antiferromagnetic quantum critical point (QCP) at $x \sim 0.1$. The end-member, CeCu$_6$ undergoes a structural transition, which is suppressed as Cu is partially substituted by Au in CeCu$_{6-x}$Au$_x$: the critical concentration being at $x \sim 0.1$. This critical point occurs in close proximity to the antiferromagnetic QCP. Here, we study related systems, CeCu$_{6-x}$Ag$_x$ and CeCu$_{6-x}$Pd$_x$, to determine more globally the role of structural degrees of freedom in the observed critical behavior. For magnetically ordered compositions of CeCu$_{6-x}$Ag$_x$ and CeCu$_{6-x}$Pd$_x$, we find a long-range order with the wave-vector similar to that observed in CeCu$_{6-x}$Au$_x$. The structural transition temperature of CeCu$_{6-x}$Ag$_x$ decreases linearly with Ag concentration until the transition is completely suppressed at $x \sim 0.1$. In contrast, moderate Pd-doping does not affect the structural transition, which is observed in CeCu$_{6-x}$Pd$_x$ with $x \lesssim 0.4$.

3:18PM Q22.00005 High Magnetic Field Properties of Ce$_3$Rh$_3$Ge$_5$, MARK WARTENBE, NHML, FSU, LANL, FERMILOGY OF Ce2Rh3Ge5 TEAM$^1$ — The competition between localized and delocalized f electrons in heavy fermion materials produces a wide variety of interesting physical phenomena. Among these compounds is Ce$_2$Rh$_3$Ge$_5$. This heavy-fermion system undergoes an antiferromagnetic transition below 4K and exhibits an angle dependent magnetic phase transition around 25 K. In addition, we conduct inelastic neutron measurements in pulsed field (65T) that reveal quantum oscillations. Temperature dependence at fixed angle indicates relatively high effective masses of values ranging from around 3m to 10m. This indicates that the narrow f-electron density of states is partially hybridized close to the Fermi energy, but also places strict cryogenic constraints upon the measurement ($^3$He temperatures are required). Fermi surface calculations have produced complex figures which lend validation to such rich behavior.

3:30PM Q22.00006 $^{119}$Sn NMR studies on the heavy fermion compound CeSn$_3$, JOHN CROCKER, ANDREW KIM, PETER KLAVINS, NICHOLAS CURRO, UC Davis — CeSn$_3$ does not exhibit long-range order at low temperatures, thus it provides an interesting baseline for NMR studies of the Knight shift. We report the synthesis and characterization of single crystals of CeSn$_3$, as well as $^{119}$Sn nuclear magnetic resonance (NMR) measurements from 4.5K to room temperature. Our data reveal a broad peak in the knight shift ($K$) at $T_{\text{max}} \approx 135$ K, and a knight shift anomaly at $T^* \approx 85$K.

3:42PM Q22.00007 Magnetic structure and CEF levels in CeNiAsO$^1$, S. WU, C. BROHOLM, W.A. PHELAN, T.M. MCQUEEN, Johns Hopkins University, J.C. NEUFELD, M.B. STONE, Oak Ridge National Laboratory — Some HF materials like CeCu$_x$-xAux and YbRh$_2$Si$_2$ have been interpreted as exhibiting unconventional local criticality, rather than a conventional magnetic instability. However, the situation is far from settled so there is great interest in exploring new HF systems in the proximity of magnetic instabilities. Recent reports on CeNiAsO indicate this is a good candidate for such studies. CeNiAsO is isomorphous with the 1111 Fe-based superconductors but exhibits a different type of itinerant magnetism associated with the rare earth site. CeNiAsO has two successive phase transitions at 9.3K and 7.3K that were tentatively associated with antiferromagnetism. To understand these transitions, we carried out magnetic neutron diffraction experiments at the Spallation Neutron Source. We have identified the long range magnetic order and associated the lower transition with a reorientation of the magnetic moment. We also report inelastic neutron powder experiments that determine the crystal field level scheme, which differs from that reported for CeFeAsO and corroborate our analysis of the magnetic structure.

$^1$This research was supported by the U.S. Department of Energy, office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02-08ER46544.

3:54PM Q22.00008 Momentum space of quasielectronic spin fluctuations in Ce$_3$Pd$_{20}$Si$_5$, ALISTAIR CAMERON, PAULO PORTNICHENKO, MAKSYM SURMACH, Institut für Festkörperphysik, TU Dresden, PASCALE DEEN, European Spallation Source, SILKE PANZEN, ANDREY PROKOFIEV, Institute of Solid State Physics, Vienna University of Technology, JEAN-MICHEL MIGNOT, Laboratoire Léon Brillouin, ANDRE STRYDOM, Physics Department, University of Johannesburg, MARK TELLING, ISIS Facility, Rutherford Appleton Laboratory, ANDREY PODLESNYAK, Quantum Condensed Matter Division, Oak Ridge National Laboratory, DIMYTO INOSOV, Institut für Festkörperphysik, TU Dresden — Ce$_3$Pd$_{20}$Si$_5$ is one of the heaviest electron systems amongst the heavy-Fermion metals. We have used high-resolution neutron spectroscopy to observe the low-energy region of magnetic scattering from the paramagnetic state, finding that at low temperatures the quasielastic magnetic response is present throughout the Brillouin zone. It forms a broad hump, centred at the (111) scattering vector, surrounded by minima of intensity at (002), (220) and the equivalent wavevectors. This momentum space structure distinguishes it from a simple crystal-field excitation, as proposed previously, and suggests it results from short-range dynamical correlations between the Ce ions, mediated by itinerant $f$-electrons via the RKKY interaction. The momentum-space symmetry of the quasielastic response suggests that it stems from the cubic Ce sub-lattice occupying the 8c Wyckoff site, which is responsible for hosting static AFM order below $T_N$, in contrast to the crystallographically inequivalent 4a site which does not appear to contribute magnetically.

4:06PM Q22.00009 Complex T-H phase diagram in Ce$_3$TiSb$_5$, D.E. JACKSON, T. STEVENSON$^2$, D. VANGENNEP, B. JONES, J.J. HAMLIN, University of Florida - Gainesville, Florida 32611 — We have carried out a detailed characterization of single crystals of the hexagonal compound Ce$_3$TiSb$_5$, via electrical resistivity, magnetization, and specific heat. These results are consistent with Kondo lattice behavior and an antiferromagnetic ordering temperature of 5.5 K. For magnetic fields applied along specific crystallographic orientations, metamagnetic transitions appear and are accompanied by a large negative magnetoresistance. As the temperature is progressively lowered, the metamagnetic transitions bifurcate.

Shubnikov-de Haas Oscillations of filled skutterudite compounds CeOs$_4$Sb$_{12}$ and NdOs$_4$Sb$_{12}$: P.-C. HO, Physics/CSU-Fresno, J. SINGLETON, F. F., BALAKIREV, NHMFL/LANL, M. B. MAPLE, Physics/UC San Diego, T. YANGASGAWA, Hokkaido U, Japan — The filled skutterudite compounds CeOs$_4$Sb$_{12}$, PrOs$_4$Sb$_{12}$, and NdOs$_4$Sb$_{12}$ are respectively a 1 K antiferromagnetic (AFM) Kondo insulator, a 1.85 K unconventional superconductor (SC), and a 1 K mean-field type ferromagnet (FM). Since SC in PrOs$_4$Sb$_{12}$ exhibits non-BCS properties, it may originate from proximity to AFM and FM quantum-critical points. Therefore, Fermi-surface measurements of NdOs$_4$Sb$_{12}$ and CeOs$_4$Sb$_{12}$ become crucial in understanding the SC pairing mechanism in PrOs$_4$Sb$_{12}$. MHz skin-depth measurements of single crystals of CeOs$_4$Sb$_{12}$ and NdOs$_4$Sb$_{12}$ were performed for temperatures down to 1.3 K and magnetic fields of up to 60 tesla in the Pulsed Field Facility at NHMFL/LANL. Proximity detection oscillator (PDO) data are taken in the 60 tesla generator-driven magnet (∼1 s) using a rotational probe. Shubnikov-de Haas oscillations were detected for various direction of the magnetic field with respect to the crystalline orientations. The results indicate that NdOs$_4$Sb$_{12}$ has similar Fermi surfaces to those of PrOs$_4$Sb$_{12}$ and LaOs$_4$Sb$_{12}$ but that the Fermi surface of CeOs$_4$Sb$_{12}$ is much different from those of the other three compounds.

3Research at CSU-Fresno is supported by NSF DMR-1104544; at UCSD by NSF DMR-1206553 and US DOE DE-FG02-04ER46105; at NHMFL by DOE, NSF, and FL; at Hokkaido U by MEXT, Jpn.

Magnetic Structure of the Heavy-fermion Compound CeAuSb$_2$ in Zero-field: GUY G. MARCUS, Institute for Quantum Matter and Johns Hopkins University, DAE-JEONG KIM, HANNOH LEE, ZACHARY FISK, University of California at Irvine, JOSE A. RODRIGUEZ-RIVERA, NIST Center for Neutron Research, COLLIN L. BROHOLM, Institute for Quantum Matter, Johns Hopkins University, and NIST Center for Neutron Research — We have used neutron diffraction to determine the zero-field magnetic structure of the heavy-fermion compound CeAuSb$_2$. Below $T_N \approx 0.2 K$, we observe the development of antiferromagnetic Bragg diffraction consistent with previous transport and magnetization measurements. The intensities observed at 7 magnetic satellite locations indicate the staggered magnetization is predominantly along the $c$-axis. The maximum moment size is $1.15 \pm 0.08 \mu_B$ which is large compared with the $0.4 \mu_B$ moment in the isostructural heavy fermion ferromagnet CeAgSb$_2$. This suggests that the antiferromagnetic CeAuSb$_2$ is deeper into a magnetic phase. The spin structure, due mainly to the Ce-4f sites, is described as a transverse polarized spin density wave with an incommensurate component of the wave vector in the basal plane. We will discuss these results and bulk measurements in terms of an ANNNI model and effective near neighbor exchange interactions.

Structural and physical properties of new Ce-based silicides CeMAL4Si2 (M= Rh, Ir, Pt) and germanides: NIRMAL GHIMIRE, FILIP RONNING, DARRICK WILLIAMS, BRIAN SCOTT, YONGKANG LUO, Los Alamos Natl Lab, SAMANTHA CARY, THOMAS ALBRECHT-SCHMITT, Florida State University, JOE THOMPSON, ERIC BAUER, Los Alamos Natl Lab — There is a great deal of interest in the Ce-based intermetallic compounds because of the wide variety of strongly correlated electron behavior they exhibit including heavy Fermanion behavior, quantum criticality, unconventional superconductivity and complex magnetic order. Recently we have synthesized new Ce-based tetragonal layered silicides - CeMAL$_4$Si$_2$ (M= Rh, Ir, Pt) that show anisotropic behavior in magnetic susceptibility and electrical resistivity. Furthermore, electronic structure calculations reveal a quasi 2D-character of the Fermi surface. We will discuss the importance of these observations and relevance of these and the related compounds in search of new heavy fermion superconductors. We will also present the structural and physical properties of the related Ce-based tetragonal/hexagonal germanides.

4:42PM Q22.00002 Converged Nuclear Quantum Statistics from Semi-Classical Path Integrals, IGOR POLTAVSKY, ALEXANDRE TKATCHENKO, Dr. — The quantum nature of nuclear motions plays a vital role in the structure, stability, and thermodynamics of molecular systems. The standard approach to take nuclear quantum effects (NQE) into account is the Feynman-Kac imaginary-time-path integral molecular dynamics (PIMD). Conventional PIMD simulations require exceedingly large number of classical subsystems (beads) to accurately capture NQE, resulting in considerable computational cost even at room temperature due to the rather high internal vibrational frequencies of many molecules of interest. We propose a novel parameter-free form for the PI partition function and estimators to calculate converged thermodynamic averages. Our approach requires the same ingredients as the conventional PIMD simulations, but decreases the number of required beads by roughly an order of magnitude. This greatly extends the applicability of ab initio PIMD for realistic molecular systems. The developed method has been applied to study the thermodynamics of N$_2$, H$_2$O, CO$_2$, and C$_2$H$_4$ molecules. For all of the considered systems at room temperature, 4 to 8 beads are enough to recover the NQE contribution to the total energy within 2% of the fully converged quantum result.

2:30PM Q22.00010 Converged Nuclear Quantum Statistics from Semi-Classical Path Integrals, IGOR POLTAVSKY, ALEXANDRE TKATCHENKO, Dr. — The quantum nature of nuclear motions plays a vital role in the structure, stability, and thermodynamics of molecular systems. 4:42PM Q24.00012 Overcoming the fermion sign problem in homogeneous systems, ETH Zürich, JONATHAN DUBOIS, BERNI ALDER, Lawrence Livermore National Laboratory — Explicit treatment of many-body Fermi statistics in path integral Monte Carlo results in exponentially scaling computational cost due to the near cancellation of contributions to observables from even and odd permutations. Through direct analysis of exchange statistics we find that individual exchange probabilities in homogeneous systems are, barring known combinatorial factors, independent of the configuration of other permutations present. For two representative systems, 3-He and the homogeneous electron gas, we find that this allows the entire antisymmetrized density matrix to be generated from a simple model depending only on a few parameters obtainable directly from a standard PIMC simulation. Finally, we show this model may be extended to arbitrary order, resulting in a polynomial scaling algorithm for measuring fermionic observables.

4:54PM Q24.00013 Infinite Variance in Fermion Quantum Monte Carlo Calculations Without the Sign Problem1, SHIWEI ZHANG, HAO SHI, William & Mary Coll — For several important classes of fermion problems, for example the half-filled repulsive Hubbard model and the spin-balanced attractive Hubbard model, quantum Monte Carlo methods using auxiliary-fields allow exact calculations without the sign problem. We show, however, that in most commonly employed algorithms the variance diverges, leading to unreliable estimates of the Monte Carlo statistical error. An approach is proposed to solve the problem. Illustrative results in Hubbard model will be presented.

5:06PM Q24.00014 Spin-Liquid Behavior of a Simple Spin Model on the Triangular Lattice1, RIBHU KAUL, University of Kentucky — I will report on numerical studies of phase transition between competing magnetic (M) and valence bond solid states (VBS) using unbiased quantum Monte Carlo methods in sign-problem free models on non-bipartite lattices in two dimensions. On bipartite lattices the transition between these two phases is a direct second order critical point - consistent with various aspects of the “deconfined” criticality scenario. In contrast, on non-bipartite lattices an intermediate phase appears between M and VBS. We present evidence that this new phase is a quantum spin liquid.

1Supported by NSF and DOE.

Wednesday, March 4, 2015 2:30PM - 5:30PM — Session Q25 DMP: Focus Session: Cooperative Phenomena in Plasticity II — Georgios Tsekenis, Harvard University

2:30PM Q25.00001 Satisfying Detailed Balance in Mesoscale Lattice Models of Amorphous Plastic Deformation, MICHAEL FALK, Johns Hopkins Univ — A number of lattice and finite element models have been proposed to model the correlations and localization transitions that occur during driven plastic flow in glasses and granular media. Green’s function formulations are used to redistribute stress from local shear transformation events. However the ad hoc kinetic assumptions used in such models often lead to violations of detailed balance. These violations preclude the association of a given configuration of the model with a well-defined energy. In this way these models are very different from atomistic models of deformation, where energy is explicitly defined and forces are derived from the underlying energy description. Here we discuss the origin of these violations of detailed balance, and discuss how mesoscale lattice models of shear transformation activity that satisfy detailed balance can, in principle, be constructed.

2:42PM Q25.00002 Modeling the toughness of metallic glasses, CHRIS RYCORFT, Harvard University, ERAN BOUCHBINDER, Weizmann Institute of Science — Metallic glasses are a new type of alloy whose atoms form an amorphous structure in contrast to most metals. They have many favorable properties such as excellent wear resistance and high tensile strength, but are prone to breakage in some circumstances, depending on their method of preparation. This talk will describe the development of a quasi-static projection method in an Eulerian finite-difference framework, for simulating a physical model of a metallic glass based on the shear transformation zone theory. The simulations are capable of resolving the multiple timescales that are involved, and provide an explanation of the experimentally observed differences in breakage strength.

2:54PM Q25.00003 Statistical modeling of athermal micromechanical yielding in amorphous solids and mean-field approaches, STEFANOS PAPANIKOLAOU, Johns Hopkins University — We investigate the micromechanical properties of non-equilibrium yielding under stress of an amorphous solid, modeled in terms of shear-transformation zones. First, we investigate in detail the possible mean-field limits of such models and their capacity to capture the character of the original micromechanical model. For this purpose, we utilize exact as well as numerical solutions. Second, we study the dynamical features of such models when short-time relaxation effects (induced by beta-relaxation modes) are incorporated in simple ways: we demonstrate that shear-banding and stick-slip serrated plastic flow are generic outcomes of such features. Finally, we discuss the relation of this mechanism with the self-induced stochastic resonance effects in non-linear dynamical systems.

3:06PM Q25.00004 Reversible Avalanches and Criticality in Amorphous Solids, CHARLES REICH-HARDT, Los Alamos National Laboratory — Despite its importance for basic science and industry, the physical process that causes a solid to change its shape permanently under external deformation is still not well understood. In this paper we use molecular dynamics simulations of amorphous solids under oscillatory shear to study this phenomenon, and show that at a critical strain amplitude, the size of the cooperative atomic motion that allows for a permanent deformation diverges. We compare this non-equilibrium critical behavior to that of a “front depinning” transition. This viewpoint, based on fluctuations and statistics, is complementary to the dynamical “transition to chaos” which was previously identified at the same strain amplitude. Below this irreversible-depinning transition, we observe large avalanches which are completely repetitive with each shear strain cycle. This suggests that while avalanches on their own do not cause irreversible deformation, it is likely that the irreversibility transition and the “depinning-like” transition are two aspects of the same phenomena. One implication is that the transition could be detected before the onset of irreversible flow by an analysis of the power spectra of avalanches.

Experimental evidence for both progressive and simultaneous shear during quasistatic compression of a bulk metallic glass, YI CUI, HAROLD HWANG, WENDY MAO, Stanford University; QIAOSHI ZENG, ZHENXIAN LIU, Geophysical Laboratory, Carnegie Institution of Washington; KIRIT PATEL, GUNVANT SOLANKI, Sardar Patel University.

Layered transition-metal dichalcogenides 2H-MX2, Jonathann Uhl, Private, Karin Dahmen, Department of Physics, University of Illinois at Urbana Champaign.

Atomic signatures of beta relaxations in metallic glasses will be addressed based on recent computer simulations. Understanding of chemical influence to get desirable properties [1]. Atomic signatures of beta relaxations in metallic glasses will be addressed based on recent computer simulations. Understanding of chemical influence to get desirable properties [1].

A model for flash heating in sheared fault gouge, Jean Carlson, University of Illinois Urbana Champaign; Ahmed Elbanna, University of California Santa Barbara.

We develop a model for sheared gouge layers that accounts for the local increase in temperature at the grain contacts during sliding. We use the shear transformation zone (STZ) theory, a statistical thermodynamic theory, to describe irreversible macroscopic plastic deformations due to local rearrangements of the gouge particles. We track the temperature evolution at the grain contacts using a one dimensional heat diffusion equation. Our model predicts a logarithmic rate dependence of the steady state shear stress in the quasi-static regime.

A simple model for flash heating in sheared fault gouge was performed under the auspices of the U.S. Dept. of Energy under contract DE-AC52-06NA25396. The support of the LANL ASC-PEM program is gratefully acknowledged.

We use the shear transformation zone (STZ) theory, a statistical thermodynamic theory, to describe irreversible macroscopic plastic deformations due to local rearrangements of the gouge particles. We track the temperature evolution at the grain contacts using a one dimensional heat diffusion equation. Our model predicts a logarithmic rate dependence of the steady state shear stress in the quasi-static regime.

In contrast to MoS2, the crystal structure of MoS2 does not exhibit a two-dimensional layered structure. Instead, the transition to MoS2 results from a reorganization of the constituent atoms into a more stable configuration. The initial grain structure evolves to a complex dynamic steady state grain morphology that is very different from the initial grain structure and is characterized by large plastic strains and strain rates in a deformation region of thickness 150 nm at the interface in the normal direction. The steady state shows a sequence of grain growth and refinement and a highly strained graded microstructure. This behavior is similar to that seen in simulations for 13 and 20 nm grains and a mesoscale model that takes into account the large plastic strains and strain rates, and the size of the deformation region is able to reproduce the values of the frictional force per unit area.

Metaheuristic optimization algorithms for the simulation of slip and flow in sheared gouge, John Houghton, Los Alamos National Laboratory; R.J. Ravelo, University of Texas, El Paso; T.C. Germain, Los Alamos National Laboratory.

Amorphous metallic glasses are fascinating materials with unique properties that are not found in crystalline counterparts. These materials possess highly tunable optical and electrical transport properties as a function of pressure, which is essentially determined by the narrowing of its band gap followed by closure at around 40 GPa. Our ab-initio calculations further support the semiconductor to metal transition.

5:06PM Q25.00010 Frictional sliding at a compressed polycrystalline 50 nm grain size Al-Al interface, J.E. Hammerberg, Los Alamos National Laboratory; R.J. Ravelo, University of Texas, El Paso.
of the 1.4-MHz peak. The T dependences of this 3-Lor set and their B-field dependences at 17°C are reported and discussed, and their relation to precursor earthquake-like O-valency effects. Research supported by RSAC-SJSU, SETI, WISE-SJSU and AFC San Jose.

Wednesday, March 4, 2015 2:30PM - 4:42PM —
Session Q26 DCP: Focus Session: Non-Adiabatic Dynamics: New Insights from Experiment and Theory IV

2:30PM Q26.00001 Multi-reference vs. single-reference quantum chemical methods in surface hopping dynamics, HANS LISCHKA, Texas Tech University — The reliability of quantum chemical methods plays a critical role in performing reliable nonadiabatic dynamics simulations. Unfortunately, the methods for computing excited states including larger regions of the energy surfaces are still computationally expensive or need support from higher level methods. In this talk the capabilities of multireference (MR) versus single reference (SR) methods will be discussed. In terms of SR approaches we focus our attention on the second-order algebraic diagrammatic construction method (ADC(2)). In addition to the direct calculation of nonadiabatic coupling vectors also the method of computing wavefunction overlaps between consecutive time steps is used. Several interesting examples are discussed such as the charge transfer between systems and the photodecatavation of adenine. The in latter example an extensive comparison of the results concerning deactivation pathways and decay times is given for different methods including multireference configuration interaction, ADC(2) and time-dependent density functional theory (TDDFT) using various functionals. The surface hopping dynamics simulations are performed on the basis of the public domain program system NEWTON-X [M. Barbatti, M. Ruckenbauer, F. Plasser, G. Granucci, M. Persico, and H. Lischka, WIREs:CMS 2014, 4, 26-33].

3:06PM Q26.00002 Unravelling Two State Reactivity: New Insights Combining Experimental, Ab Initio, and Statistical Modelling Techniques, SHAUN ARD, AFRL, JOSHUA MELKO, University of North Florida, OSCAR MARTINEZ, AFRL, VLADIMIR USHAKOV, Max Plank Institute, ANYANG LI, RYAN JOHNSON, University of New Mexico, NICHOLAS SHUMAN, AFRL, HUA GUO, University of New Mexico, JURGEN TROE, Max Plank Institute, ALBERT VIGGIANO, AFRL — Non-Adiabatic dynamics have long played a role in understanding numerous ion molecule reactions. As calculation techniques have improved, even spin-allowed reactions have been found to be significantly impacted by low lying excited spin states, so-called Two-State reactivity. This talk will focus on recent studies of several canonical examples, FeO+ + H2FeO+ + CH4, and Fe2+ + N2O. Experimentally, the kinetics of these reactions are studied from 100 to 700K. Combined with computations of the reaction surface, statistical modelling employing the Statistical Adiabatic Channel Model (SACM) of this near thermal energy range gives unique insight into kinetic details of these systems. Implications of this combined approach, specifically towards better quantifying Two-State reactivity in ion-molecule reactions, will be discussed.

3:18PM Q26.00003 New insights into the nonadiabatic dynamics of proton-coupled electron transfer reactions from the mixed quantum-classical Liouville approach, GABRIEL HANNA, FARNAZ SHAKIB, University of Alberta — The nonadiabatic dynamics of model proton-coupled electron transfer (PCET) reactions is studied for the first time using a surface-hopping solution of the mixed quantum-classical Liouville (MQCL) equation. In contrast to Fewest Switches Surface-Hopping (FSSH), which is commonly used in the simulation of PCET, the MQCL approach provides a rigorous treatment of decoherence in dynamics simulations of MQC systems. The studied model consists of a proton and an electron in a donor-acceptor complex (i.e. quantum subsystem) and a collective solvent coordinate (i.e. classical environment). Using this model, both concerted and sequential PCETs are studied under different proton/electron-solvent coupling conditions, and insights into the dynamical principles underlying these reactions are gained. Notably, an analysis of the trajectories reveals that the solvent coordinate spends a large fraction of its time on the mean of two coherently coupled potential energy surfaces (PESs), as opposed to on single PESs as in the FSSH approach. The results of this study not only demonstrate the applicability of the MQCL approach for PCET simulations, but also emphasize the importance of incorporating decoherence effects through mean surface evolution into calculations of PCET rate constants.

3:30PM Q26.00004 Variational state specific solvent models for excited states from time dependent self-consistent field methods, JOSIAH BJORGAARD, KIRILL VEZIZHANIN, SERGEI TRETIAK, Los Alamos National Laboratory — The effect of a dielectric environment on a molecule can be profound, causing changes in nuclear configuration and electronic structure. Quantum chemical simulation of a solute-solvent system can be prohibitively expensive due to the large number of degrees of freedom attributed to the solvent. To remedy this, the solvent can be treated as a dielectric cavity. Mutual polarization of the solute and solvent must be considered for accurate treatment of an optically excited state (ES) with a state-specific solvent model (SSM). In vacuum, time dependent self-consistent field (TD-SCF) methods (e.g. TD-HF, TD-DFT) give variational excitation energies. With the well known Z-vector equation, a variational ES energy is used to explore the ES potential energy surface (PES) with analytical gradients. Modification of the standard TD-SCF eigensystem to accommodate a SSM creates a nonlinear TD-SCF equation with non-variational excitation energies. This prevents analytical gradients from being formulated so that the ES PES cannot be explored. Here, we show how a variational formulation of existing SSMs can be derived from a Lagrangian formalism and give numerical results for the variability of calculated quantities. Model dynamics using SSMs are showcased.
3:42PM Q26.00005 Electronic Structure and Potential Fitting Methods Suitable For Multi-state Reactive Surfaces. RICHARD DAWES, Missouri University of Science and Technology — Part of this talk describes the development of a ab initio data software that can be used to geometric problems on High-Performance Computing (HPC) clusters to construct PESs automatically. The electronic structure of molecules is described to be difficult to describe continuously across global reactive PESs since it changes qualitatively as bonds are formed and broken along reaction coordinates. I will discuss a high-level ab initio method (GDW-SA-CASSCF/MRCI) designed to allow the electronic wavefunction to smoothly evolve across the PES and provide an accurate and balanced description of the entire region. These methods are combined to study a number of small gas-phased molecules from the areas of atmospheric, combustion and interstellar chemistry including a large variational calculation of all of the vibration states of ozone and the photodissociation dynamics of the simplest Criegee intermediate (CH$_2$OO).

4:18PM Q26.00006 Phase-space formulation of Nonadiabatic Quantum Processes. ANDRES ESTRADA-GUERRA, LEONARDO PACHON, Univ de Antioquia — Based on Schwinger’s exact mapping of the discrete quantum variables onto continuous degrees of freedom and the phase-space path-integral representation of quantum dynamics by Marínov, a phase-space approach is developed here to analyze the quantum features of non-adiabatic processes. Being a phase-space formulation, the associated semiclassical description is by construction an initial value representation and allows for clearly analyzing classical and quantum contributions to the dynamics. The formulated theory is applied to the context of light-harvesting systems in photosynthetic complexes to understand the extent to which quantum effects are determinant in this nonadiabatic process.

4:30PM Q26.00007 Coherent Dynamics Following Strong Field Ionization of Polyatomic Molecules. ARKAPRABHA KONAR, YINAN SHU, VADIM LOZOVoy, JAMES JACKSON, BENJAMIN LEVINE, MARCOS DANTUS, Michigan State University — Molecules, as opposed to atoms, present confounding possibilities of nuclear and electronic motion upon strong field ionization. The dynamics and fragmentation patterns in responses to the laser field are structure sensitive: therefore, a molecule cannot be treated as a “bag of atoms” during field induced ionization. We consider here to what extent molecules retain their molecular identity and properties under strong laser fields. Using time-of-flight mass spectrometry in conjunction with pump-probe techniques we study the dynamical behavior of these molecules, monitoring ion yield modulation caused by intramolecular motions post ionization. The delay scans show that among positional isomers the variations in relative energies, amounting to only a few hundred meVs, influence the dynamical behavior of the molecules despite their having experienced such high fields (V/A). Ab initio calculations were performed to predict dynamics along with single and multiphoton resonances in the neutral and ionic states. We propose that single electron ionization occurs within an optical cycle with the electron carrying away essentially all of the energy, leaving behind little internal energy in the cation. Evidence for this observation comes from coherent vibrational motion governed by the potential energy surface of the ground state of the cation. Subsequent fragmentation of the cation takes place as a result of further photon absorption modulated by one- and two-photon resonances, which provide sufficient energy to overcome the dissociation energy.

Wednesday, March 4, 2015 2:30PM - 4:54PM — Session Q27 DCP: Focus Session: Chemical Physics of Clusters: Bridging from Angstrom-scale Clusters to Micron-scale Aerosol Particles IV

2:30PM Q27.00001 Stability of Phosphine-Ligated Gold Cluster Ions toward Dissociation: Effect of Ligand and Cluster Size. JULIA LASKIN, Pacific Northwest National Laboratory — Precise control of the composition of phosphine-ligated gold clusters is of interest to their applications in catalysis, sensing, and drug delivery. Reduction synthesis in solution typically generates a distribution of ligated clusters containing different number of gold atoms and capping ligands. Ligand binding energy is an important factor determining the kinetics of cluster nucleation and growth in solution and hence the resulting cluster distribution. Phosphines are popular capping ligands with tunable electronic and steric properties that affect their binding to the gold core. We examined the effect of the number of gold atoms in the cluster and the properties of the phosphine ligand on the ligand binding energy to the gold core using surface-induced dissociation (SID) of mass selected cluster cations produced through electrospray ionization. SID of vibrationally excited ions is ideally suited for studying gas-phase fragmentation of complex ions such as ligated gold clusters. The energetics, dynamics, and mechanisms of cluster ion fragmentation in the absence of solvent are determined through RRKM modeling of time and kinetic energy dependent SID spectra. This novel method provides quantitative information on the ligand binding energies in phosphine-ligated gold clusters important for understanding their formation in solution. Furthermore, ligand binding energies derived from SID data provide the first benchmark values for comparison with electronic structure calculations.

3:06PM Q27.00002 Novel Electro catalysts Prepared by Soft Landing of Mass-Selected Cluster Ions. GRANT JOHNSON, TREVOR MOSEr, NIGEL BROWNING, MARK ENGELHARD, JULIA LASKIN, Pacific Northwest National Laboratory — Metal clusters, which possess size and composition dependent properties, are promising materials for use as catalysts to promote electrochemical reactions in fuel cells. A physical synthesis technique, magnetron sputtering combined with gas-aggregation, has been employed to produce anionic metal clusters in the gas-phase across a range of sizes, shapes, and compositions for mass-selection and deposition onto glassy carbon electrodes. Sputtering of multiple targets in the same region of gas aggregation is demonstrated to produce uncapped binary and ternary alloy clusters with defined composition and morphology that are not accessible through synthesis in solution. Introduction of reactive gases including acids, alkanes, and amines into the sputtering region is shown to result in the formation of complex cluster morphologies containing carbon, nitrogen, and oxygen. A suite of cutting-edge characterization techniques is utilized to demonstrate how the size, shape, elemental composition, and surface density of clusters may be tuned through variations in source parameters such as the sputtering power, gas flow rates, and aggregation distance. The catalytic activity of the soft landed clusters towards the oxygen reduction reaction, a critical process occurring in hydrogen fuel cells, is measured using cyclic voltammetry. Alloy clusters containing reduced quantities of precious metals are shown to exhibit promising catalytic activity.

3:18PM Q27.00003 Quantum Monte Carlo study of charged transition-metal organometallic cluster systems. KAMIL TOKAR, RENE DERIaN, IVAN STICH, Inst. of Physics, Slovak Academy of Sciences — Using accurate fixed-node quantum Monte Carlo (QMC) methods we study 1D clusters formed by transition metal atoms separated by benzene molecules (TMBz), both positively and negatively charged. TMBz are among the most important π-bonded organometallics, which, however, often require charged states for experimental studies. We have performed a systematic study of ground-state spin multiplet, ionization potentials, electron affinities, and dissociation energies of vanadium-benzene cationic and anionic half- and full-sandwiches. By comparison of QMC and DFT results, we find a very strong impact of electronic correlation on properties of these systems, such as dissociation energies, where ≈1 eV energy corrections are found. In particular, the anions are unstable at the DFT level and are stabilized only at the QMC level after sophisticated optimization of the trial wavefunction.

3:30PM Q27.00004 Isolation and structural characterization of a silver-platinum nanocluster, Ag₄Pt₂(DMSA)₄. ANTHONY PEDICINI, ARTHUR REBER, Virginia Commonwealth University, SCOTT BILTEK, AYUSMAN SEN, Pennsylvania State University, SHIV KHANNA, Virginia Commonwealth University — Cluster assembled materials offer an attractive prospect of making nanoscale materials with tunable characteristics. Here, we report the synthesis, isolation, and characterization of the ligand-protected bimetallic cluster, Ag₄Pt₂(DMSA)₄ (DMSA=meso-2,3-dimercaptosuccinic acid) and its analogue, Ag₄Pd₂(DMSA)₄. The procedure is similar to the one employed previously for the synthesis of Ag₄Ni₂(DMSA)₄. Theoretical studies show that the Pt and Ni atoms are square planar in configuration. Furthermore, the dependence on the optical spectrum due to congener replacement of the transition metal is highlighted. Since the crystal field splitting of 5d orbitals is typically larger than that for 3d orbitals, we show the Pt-based cluster has an optical spectrum that is significantly blue shifted as compared to the Ni-based cluster.

This work was supported by an Air Force Office of Scientific Research (AFOSR) Basic Research Initiative Grant FA9550-12-1-0481.

3:42PM Q27.00005 Cluster size matters: Size-driven performance of subnanometer clusters in catalysis, electrocatalysis and Li-air batteries, STEFAN VAJDA, Argonne National Laboratory — This paper discusses the strongly size-dependent performance of subnanometer cluster based catalysts in 1) heterogeneous catalysis, 2) electrocatalysis and 3) Li-air batteries. The experimental studies are based on I. fabrication of ultrasmall clusters with atomic precision control of particle size and their deposition on oxide and carbon based supports; II. test of performance, III. in situ and ex situ X-ray characterization of cluster size, shape and oxidation state; and IV. electron microscopies. Heterogeneous catalysis. The pronounced effect of cluster size and support on the performance of the catalyst (catalyst activity and the yield of C₁ products) will be illustrated on the example of nickel and cobalt clusters in Fischer-Tropsch reaction. Electrocatalysis. The study of the oxygen evolution reaction (OER) on size-selected palladium clusters supported on ultrananocrystalline diamond show pronounced size effects. While Pd₃ clusters show no reaction, Pd₄ and Pd₁₇ clusters are among the most active catalysts known (in terms of turnover rate per Pd atom). The system (soft-landed Pd₄, Pd₁₇, or Pd₁₇ clusters on an UNCD Si coated electrode) shows stable electrochemical potentials over several cycles, and the characterization of the electrodes show no evidence for evolution or dissolution of either the support. Theoretical calculations suggest that this striking difference may be a demonstration that bridging Pd-Pd sites, which are only present in three-dimensional clusters, are active for the oxygen evolution reaction in Pd₃Oₓ Li-air batteries. The studies show that sub-nm silver clusters have dramatic size-dependent effect on the lowering of the overpotential, charge capacity, morphology of the discharge products, as well as on the morphology of the nm size building blocks of the discharge products. The results suggest that by precise control of the active surface sites on the cathode, the performance of Li-air cells can be significantly improved.

4:18PM Q27.00006 Theoretical Study of Chemisorption on Small Palladium Clusters, AJIT HIRA, FRANK NARANJO, FELIPE MUNOZ, DANIELLE JARAMILLO, Northern New Mexico College — We continue our interest in the chemisorption of different atomic and molecular species on small clusters of metallic elements, by examining the interactions of H, H₂, Li and O adsorbates with Pdₙ clusters (n = 2 thru 20). Transition-metal clusters are specially suited for the study of quantum size effects and for formation of metallic states, and are ideal candidates for catalytic processes. Hybrid ab initio methods of quantum chemistry (particularly the DFT-B3LYP model) are used to derive optimal geometries for the clusters of interest. We compare calculated binding energies, bond-lengths, ionization potentials, electron affinities and HOMO-LUMO gaps for the clusters. Of particular interest are the comparisons of binding strengths at the three important types of sites: edge (E), hollow (H), on-top (T), threefold sites and fourfold sites. Effects of crystal symmetries corresponding to the bulk structures are investigated. The capacity of Pd clusters to adsorb H atoms will be compared to Ni clusters.

Research Supported by National Science Foundation

4:30PM Q27.00007 Role of electronic structure and surface structuring effects in the synergistic catalytic activity of Ni-Pd nanoparticles, LINN LEPPERT, Theoretical Physics IV, University of Bayreuth, 95440 Bayreuth, RHETT KEMPE, Inorganic Chemistry II, University of Bayreuth, 95440 Bayreuth, STEPHAN KUEMMEL, Theoretical Physics IV, University of Bayreuth, 95440 Bayreuth — Nickel-palladium nanoalloys show a drastically enhanced catalytic activity in a variety of hydrogenation reactions as compared to pure nickel or palladium nanoparticles. We explore the mixing behavior, electronic structure and magnetic properties of nickel-palladium clusters using density functional theory to gain insight into this synergistic effect. We show that the binding energy of hydrogen to the metal nanoparticle’s surface, which can be tuned via the nickel-palladium composition, is the decisive factor determining how efficiently the reaction can take place. The optimal magnitude of the binding energy for intermediate nickel-palladium ratios can be traced back to a purely electronic effect: a balanced hybridization of the hydrogen s with the metal particle d and s states. This explanation not only holds for small clusters, but also for nickel-palladium surfaces. Finally, we demonstrate that catalytic activity on nickel-palladium surfaces might not only benefit from alloying, but also from the formation of nanostructures on surfaces.

4:42PM Q27.00008 Ultrasmall Carbidic Nanospheres - Formation and Electronic Properties, PETRA REINKE, EHSAN MONAZAMI, University of Virginia, JOHN McCLIMON, University of Pennsylvania — Metallic nanoparticles are highly coveted but are subject to rapid Ostwald ripening even at moderate temperatures limiting study of their properties. Ultrasmall transition metal carbide “nanospheres” are synthesized by a solid-state reaction between fullerene as carbon scaffold, and a W surface. This produces nanospheres with a narrow size distribution below 2.5 nm diameter. The nanosphere shape is defined by the scaffold and densely packed arrays can be achieved. The metal-fullerene reaction is temperature driven and progresses through an intermediate semiconductor phase until the fully metallic nanospheres are created at about 350 C. The reaction sequence is observed with STM, and STS maps yield the local density of states. The reaction presumably progresses by stepwise introduction of W-atoms in the carbon scaffold. The results of high resolution STM/STS in combination with DFT calculations are used to unravel the reaction mechanism. We will discuss the transfer of this specific reaction mechanism to other transition metal carbides. The nanospheres are an excellent testbed for the physics and chemistry of highly curved surfaces.

Wednesday, March 4, 2015 2:30PM - 5:30PM — Session Q28 GMAG DMP: Focus Session: Honeycomb Antiferromagnets — 205 - James Analytis, University of California, Berkeley
but it changes to the antiferromagnetic Neel state with increase of the Hund's rule coupling. Interestingly enough, the valence bond solid (AKLT) state found for the noninteracting electrons survives the increase of the on-site (Hubbard) repulsion, making these states difficult to realize. Indeed, except for the one dimensional spin-

Institute of Science, Israel, DANIEL KHOMSKII, University of Cologne, ERAN SELA, Tel Aviv University — The models constructed by Affleck, Kennedy, Lieb, Modic, Ross McDonald, Arkady Shekter, Los Alamos Natl Lab, James Analytis, UC Berkeley, Brad Ramshaw, Los Alamos Natl Lab — We examine magnetic Hamiltonians for this family and show how a trio of nearest-neighbor exchanges, which arise from strong spin-orbit coupling, are sufficient for reproducing this spiral order on both lattices. We analyze the origin of this phenomenon by presenting a simple 1D model, transparently demonstrating how the counter-rotating spiral is stabilized by strong Kitaev exchange. We also discuss proximate quantum spin liquid phases which arise from spin-orbit coupling.

3:18PM Q28.00003 Unified theory of Kitaev-based spiral magnetism in the harmonic-honeycomb iridates $\alpha$, $\beta$, $\gamma$-Li$_2$IrO$_3$, ITAMAR KIMCHI, University of California, Berkeley, RADU COLDEA, University of Oxford, JAMES ANALYTIS, ASHVIN VISHWANATH, University of California, Berkeley — We review the recent theoretical developments triggered by the experimental discovery of remarkable 3D polymorphs of Li$_2$IrO$_3$, where $J=1/2$ moments form two new 3D lattices which generalize the 2D honeycomb lattice. Measurements on both compounds found that they magnetically order into remarkably similar spiral phases, exhibiting a pattern of non-coplanarity and counter-rotation. We examine magnetic Hamiltonians for this family and show how a trio of nearest-neighbor exchanges, which arise from strong spin-orbit coupling, are sufficient for reproducing this spiral order on both lattices. We analyze the origin of this phenomenon by presenting a simple 1D model, transparently demonstrating how the counter-rotating spiral is stabilized by strong Kitaev exchange. We also discuss proximate quantum spin liquid phases which arise from spin-orbit coupling.

3:30PM Q28.00004 Synthesis and doping of nonmagnetic honeycomb iridate single crystals, GILBERT LOPEZ, NICHOLAS BREZNAY, XUE FAN, JAMES ANALYTIS, Univ of California - Berkeley — The honeycomb iridare Na$_2$IrO$_3$ has been proposed to exhibit many unique properties, including possible spin liquid and topological insulator phases. Although the widely studied layered phase of Na$_2$IrO$_3$ is an antiferromagnetic Mott insulator, I will discuss single-crystal synthesis and electrical and thermodynamic properties of a weakly magnetic Na$_2$Ir$_{1-x}$O$_3$ relative. I will also discuss the effects of chemical doping on the electrical transport and magnetic properties of honeycomb iridate materials.

3:42PM Q28.00005 Thermodynamic Study of 3D “Harmonic” Honeycomb Li$_x$IrO$_3$, ALEJANDRO RUIZ, TONI HELM, NICHOLAS BREZNAY, GILBERT LOPEZ, JAMES ANALYTIS, Univ of California - Berkeley — Honeycomb iridates have been the focus of substantial interest due to the strong magnetic frustration that arises from their edge-shared bonding environment, which favors a strongly anisotropic Ising-like exchange between bonds. In materials with edge-shared IrO$_6$ octahedra, spin-anisotropy of the exchange between neighboring effective spin-1/2 states is enhanced by the interference of the two exchange paths across the planar Ir-O$_{5}$-Ir bond. In the honeycomb lattice, such an interaction couples different orthogonal spin components for the three nearest neighbors; no single exchange direction can be simultaneously satisfied, leading to strong frustration which can be described by the Kitaev-model. We have recently synthesized a new structure that retains the same bonding environment as the honeycomb lattice, and extends this physics to three-dimensions. Previous RMXD experiments on our orthorhombic $H^1$(-1)-Li$_2$IrO$_3$ samples revealed an incommensurate, non-coplanar magnetic structure with counter-rotating moments, suggesting that Kitaev exchange is the dominant spin interaction in this system. In this work, we study the thermal properties of our single crystals as a function of temperature and applied magnetic field.

1Berkeley Chancellor’s Fellowship & NSF-GRFP

3:54PM Q28.00006 Magnetic Anisotropy of a Three-Dimensional Honeycomb Iridate, KIMBERLY MODIC, ROSS MCDONALD, ARKADY SHEKTER, Los Alamos Nati Lab, JAMES ANALYTIS, UC Berkeley, BRAD RAMSHAW, Los Alamos Nati Lab — We present the magnetic anisotropy of a 3-dimensional honeycomb iridate, where the large spin-orbit coupling of iridium provides the possibility for exotic magnetic ground states. A complete angular dependence of magnetic torque provides evidence for highly spin-anisotropic exchange interactions at low temperature. An extension of these measurements to high magnetic fields shows that the magnetic anisotropy switches sign at 50 T and becomes five times larger than the anisotropy at low fields. The anisotropy continues to increase up to the largest applied fields suggesting the presence of new magnetically ordered states.

4:06PM Q28.00007 Valence bond solid (AKLT) state from $t_{2g}$ electrons, MACIEJ KOCH-JANUSZ, Weizmann Institute of Science, Israel, DANIEL KHOMSKII, University of Cologne, ERAN SELA, Tel Aviv University — The models constructed by Affleck, Kennedy, Lieb, and Tasaki (AKLT) describe gapped quantum spin liquids with fractionalized boundary spin excitations. The AKLT spin-spin interactions consist of projection operators onto the maximal possible spin formed between nearest neighbors, which involves a linear combination of powers of the Heisenberg coupling $(\vec{S}_i \cdot \vec{S}_j)^n$, making these states difficult to realize. Indeed, except for the one dimensional spin-1 case, simple antiferromagnetic Heisenberg interactions which are typically found in magnetic insulators, do not stabilize these spin liquid states, but rather generate conventional antiferromagnetically ordered states. We show that this type of interactions can be generated by orbital physics in multiorbital Mott insulators. Motivated by microscopic modeling of spin-orbit entangled Mott insulators such as the layered hexagonal lattices, we focus on $t_{2g}$ electrons on the honeycomb lattice and propose a physical realization of the spin-3/2 AKLT state. Interestingly enough, the valence bond solid (AKLT) state found for the noninteracting electrons survives the increase of the on-site (Hubbard) repulsion, but it changes to the antiferromagnetic Neel state with increase of the Hund’s rule coupling.

4:18PM Q28.00008 Competing quantum phases in the $K_1$-$K_2$ Kitaev model on the honeycomb lattice, JOHANNES REUTHER, Free University Berlin, RONNY THOMALE, University of Würzburg, STEPHAN RACHEL, Technical University Dresden — The Kitaev-spin model on the honeycomb lattice has attracted enormous interest in recent years as an exactly solvable 2D spin system. Research in this field has been fueled by the possibility to realize the Kitaev model in strongly spin-orbit coupled iridate compounds of the form $A_2$IrO$_3$. In these materials, the bond-dependent spin anisotropies of the Kitaev model are provided by spin-orbit entangled Kramers doublets. Experimental as well as theoretical investigations indicate that second neighbor honeycomb interactions are not necessarily small, which particularly applies to the second neighbor Kitaev exchange. We study the $K_1$-$K_2$ Kitaev model on the honeycomb lattice with nearest neighbor and second neighbor Kitaev couplings $K_1$ and $K_2$, respectively. Using a pseudo-fermion functional renormalization group approach for spin systems we map out the entire phase diagram of this model, allowing both couplings to be positive and negative. Aside from Kitaev-spin liquid phases at $K_2 = 0$ we find spin chain-like phases at $K_1 = 0$ where correlations only take place along effective 1D chains. Away from these special points we identify four different types of magnetic phases with collinear orders which retain a clear 1D character in large parts of the phase diagram.

4:30PM Q28.00009 Density matrix renormalization group study of triangular Kitaev-Heisenberg model, SHIGETOSHI SOTA, RIKEN, KAZUYA SJINJO, Yukawa Institute for Theoretical Physics, Kyoto University, TOMONORI SHIRAKAWA, RIKEN, TAKAMI TOHYAMA, Department of Applied Physics, Tokyo University of Science, SEIJI YUNOKI, RIKEN — Topological insulator has been one of the most active subjects in the current condensed matter physics. For most of topological insulators electron correlations are considered to be not essential. However, in the case where electron correlations are strong, novel phases such as a spin liquid phase can emerge in competition with a spin-orbit coupling. Here, using the density matrix renormalization group method, we investigate magnetic phase of a triangular Kitaev-Heisenberg (quantum compass) model that contains a spin-orbital interaction and spin frustration in the antiferromagnetic region. The triangular Kitaev-Heisenberg model is regarded as a dual model of the honeycomb Kitaev-Heisenberg model that is usually employed to discuss $A_2$CuO$_3$ ($A$=Na, K). Systematically calculating ground state energy, entanglement entropy, entanglement spectrum, and spin-spin correlation functions, we discuss the duality between the triangular and the honeycomb Kitaev-Heisenberg model as well as the ground state magnetic phases.

4:42PM Q28.00010 Dynamical properties of honeycomb-lattice magnets Na$_2$IrO$_3$, TAKAFUMI SUZUKI, University of Hyogo — We studied dynamical properties of magnetic effective models for Na$_2$IrO$_3$. The effective magnetic models have been much discussed to explain the zigzag magnetic ordering of this compound [1-6]. The most characteristic point of the proposed models is that the presence of the Kitaev type anisotropy is expected in addition to the Heisenberg coupling. Although there are several proposals for the coupling magnitude of the effective models, the qualitative and quantitative magnetic ordering have been still lacking from the viewpoint of dynamics. From the above background, we carried out numerical exact diagonalization and calculated the dynamical structure factors for the proposals in pioneering works [2,3,5,6]. The obtained results were compared with inelastic-neutron-scattering measurements [2]. We found that the parameter set proposed in ref. [6] well explains a characteristic boundary structure of the lowest excitation around Y point and an intensity distribution in the low energy region [2].

4:54PM Q28.00011 Theory of Magnetic Phases in Hyperhoneycomb and Harmonic-honeycomb Iridates, ERIC KIN HO LEE, YONG BAEK KIM, Univ of Toronto — Motivated by recent experiments, we consider a generic spin model in the $J_{ab} = 1/2$ basis for the hyperhoneycomb and harmonic-honeycomb (H-H) lattices via a combination of the Luttinger-Tisza approximation, single-Q variational ansatz, and classical Monte Carlo simulated annealing. The resulting phase diagrams on both systems show the existence of incommensurate, non-coplanar spiral magnetic orders as well as other commensurate magnetic orders. The spiral orders show counter-propagating spiral patterns, which may be favorably compared to recent experimental results on both iridates. The parameter regime of various magnetic orders and ordering wavevectors are quite similar in both systems. We discuss the implications of our work to recent experiments and also compare our results to those of the two dimensional honeycomb iridate systems.

5:06PM Q28.00012 CaMn$_2$Sb$_2$: Spin Waves Near a Tricritical Point of the Antiferromagnetic Honeycomb Lattice, DANIEL MCNALLY, Stony Brook University, JACK SIMONSON, SUNY Farmingdale, JED KISTNER-MORRIS, GREG SMITH, JULIAN HASSINGER, Stony Brook University, LISA DEBEER-SCHMIDT, ALEXANDER KOLESNIKOV, Spallation Neutron Source, Oak Ridge National Lab, MEIGAN ARONSON, Stony Brook University — The classical Heisenberg model for a honeycomb lattice of spins predicts at least three tricritical points, where three different long range ordered magnetic phases co-exist, depending on the relative strength of the nearest and next-nearest exchange interactions. J$_1-J_2$, where we performed inelastic neutron scattering at T = 5 K, $T_N = 85$ K on oriented single crystals of the antiferromagnetic insulator CaMn$_2$Sb$_2$, where the Mn spins $\mu = 2.8 \mu_B$/Mn form a corrugated honeycomb lattice. Spin wave excitations were observed up to E = 24 meV and these data were fit to the spin wave dispersion expected from the classical Heisenberg model to determine the individual exchange interactions $S_{J_1} = 8.22 \pm 0.23$ meV, $S_{J_2} = 1.29 \pm 0.09$ meV, $S_{J_3} = 0.56 \pm 0.04$ meV, where $J_i$ is the exchange interaction between honeycomb planes. The quantum fluctuations resulting from proximity to the tricritical point at $J_2/J_1 = 1/6$ are responsible for the relatively low ordering temperature of CaMn$_2$Sb$_2$, $T_N = 85$ K, much reduced from the mean field ordering temperature $T_{NFM} = 2\alpha J_1(S(S+1))^{1/3}$ $g = 560$ K.

1 Computations were performed on the GPC supercomputer at the SciNet HPC Consortium. This research was supported by the NSERC, CIFAR, and Centre for Quantum Materials at the University of Toronto.

5:06PM Q28.00012 CaMn$_2$Sb$_2$: Spin Waves Near a Tricritical Point of the Antiferromagnetic Honeycomb Lattice, DANIEL MCNALLY, Stony Brook University, JACK SIMONSON, SUNY Farmingdale, JED KISTNER-MORRIS, GREG SMITH, JULIAN HASSINGER, Stony Brook University, LISA DEBEER-SCHMIDT, ALEXANDER KOLESNIKOV, Spallation Neutron Source, Oak Ridge National Lab, MEIGAN ARONSON, Stony Brook University — The classical Heisenberg model for a honeycomb lattice of spins predicts at least three tricritical points, where three different long range ordered magnetic phases co-exist, depending on the relative strength of the nearest and next-nearest exchange interactions J$_1-J_2$, where we performed inelastic neutron scattering at T = 5 K, $T_N = 85$ K on oriented single crystals of the antiferromagnetic insulator CaMn$_2$Sb$_2$, where the Mn spins $\mu = 2.8 \mu_B$/Mn form a corrugated honeycomb lattice. Spin wave excitations were observed up to E = 24 meV and these data were fit to the spin wave dispersion expected from the classical Heisenberg model to determine the individual exchange interactions $S_{J_1} = 8.22 \pm 0.23$ meV, $S_{J_2} = 1.29 \pm 0.09$ meV, $S_{J_3} = 0.56 \pm 0.04$ meV, where $J_i$ is the exchange interaction between honeycomb planes. The quantum fluctuations resulting from proximity to the tricritical point at $J_2/J_1 = 1/6$ are responsible for the relatively low ordering temperature of CaMn$_2$Sb$_2$, $T_N = 85$ K, much reduced from the mean field ordering temperature $T_{NFM} = 2\alpha J_1(S(S+1))^{1/3} g = 560$ K.

offering a way to control the properties of domain wall propagation via electric gating. We show that the Walker breakdown threshold scales with the magnitude of a perpendicular electric field, the direction of the wall motion also is sensitive to an applied dc E field. Moreover, we determine the interaction between spin-transfer torque from an electric field. Waves exert magnetic torques in multiferroic materials can cause not only domain wall motion, but also magnetization dynamics for homogeneous magnetization.

3:18PM Q28.00013 Exotic magnetism on the FCC lattice of 5$d^n$ double perovskites. D.D. MAHARAJ, E. KERMARREC, C.A. MARJERISSLON, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, L8S 4M1, Canada; C.M. THOMPSON, Department of Chemistry, McMaster University, Hamilton, Ontario, L8S 4M1, Canada; K. LEVIN, S. KROEKER, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, L8S 4M1, Canada — In the search for exotic quantum states, the impact of strong spin-orbit interaction has been recently underlined with the discovery of the $J_{eff}=\frac{1}{2}$ spin-orbital Mott state in the 5$d^n$ layered perovskites iridates. The double perovskite structure can accommodate numerous 5$d$ ions and therefore offers a playground for systematic studies of the exotic ground states stabilized by strong spin-orbit coupling (SOC). Here, we report time-of-flight neutron scattering measurements on the antiferromagnetic (AF), frustrated system, Ba$_2$YOsO$_6$. This 5$d^3$ system undergoes a magnetic transition to a long range ordered AF state below $T_N=70K$. Our results reveal a large spin gap $\Delta=18(2)$meV, unexpected for an orbitally quenched $d^3$ system. We compare this result to the recent observation of a $\Delta=5$meV spin gap in the related 4$d^5$ system, Ba$_2$YRuO$_6$, and conclude to an effect of enhanced SOC.

Session Q29 GMAG DMP FIAP: Focus Session: Spin-waves and Magnetization Dynamics

2:30PM Q29.00001 Excitation and detection of propagating spin waves at the single magnon level. ALEXY KARENOWSKA, ANDREW PATTERSON, MICHAEL PETERER, EINAR MAGNUSSON, PETER LEEK, University of Oxford — The fields of spin-wave dynamics and magnonics have made substantial contributions to our understanding of fundamental magnetism, and are increasingly widely acknowledged to be areas of solid-state physics with significant technological potential. To date however, experimental activity has focused on the study of possible applications of room-temperature systems operating within classical limits. Here, we report a series of experiments in which we demonstrate, for the first time, the excitation and detection of propagating spin waves at the single magnon level. Our results, which have been obtained at cryogenic temperatures using an yttrium iron garnet spin-wave waveguide, serve as evidence that the experimental tools now exist to permit us to create microwave (i.e. GHz frequency) quantum circuits incorporating dispersive magnon systems. This allows us to anticipate the possibility both of exploring quantum aspects of magnon physics with new experimental clarity, and of examining how this physics — in particular, the magnon’s highly tunable dispersion, its readily accessible nonlinearity, and its capacity to couple to optical excitations and electron-based spintronic systems — might have a role to play in new microwave quantum technologies.

2:42PM Q29.00002 Surface Acoustic Waves for Traveling Spin-Wave Resonance Spectroscopy. PRAVEEN GOWTHAM, Cornell University, TAKAHIRO MORIYAMA, Institute for Chemical Research, Kyoto University, DANIEL RALPH, ROBERT BUHRMAN, Cornell University, BUHRMAN/RALPH RESEARCH GROUP TEAM — Gigahertz frequency surface acoustic waves (SAWs) can, via the magnetoelastic interaction, generate effective RF pump fields that can resonantly excite spin waves in a thin-film ferromagnet. SAWs provide a powerful means to study spin waves because the pump field excites traveling spin waves with a definite nonzero wave-vector $\mathbf{q}$. This enables studies, at fixed $\mathbf{q}$, of the spin-wave self-interaction energies and damping. Here we report measurements of the angular dependence of SAW-induced magnetic resonance in Al(10)/AlO$_x$(2)/Ni(10)/Pt(15) structures (thicknesses in nm). We characterize the resonances by measurement of both the acoustical transmission loss in a SAW delay line and the inverse spin Hall voltage generated in the Pt layer by spin pumping. The measurements allow quantitative determinations of the effective RF field generated by the SAW, the magnetoelastic coupling, and damping. The angular dependence reveals that, within the range of $q$ studied, the spin-wave self-interactions are dominated by dipolar fields rather than exchange.

2:54PM Q29.00003 Control of Spin Wave Band Structure and Propagation in Two-Dimensional Magnonic Crystals. GLADE SIETSEMA, MICHAEL E. FLATTÉ, Department of Physics and Astronomy, University of Iowa — We have studied the properties of spin waves in two-dimensional magnonic crystals consisting of a magnetic material arranged in a lattice of cylinders and embedded in a second magnetic material. Dispersion curves, linewidths, and spin wave propagation patterns were obtained from the Landau-Lifshitz-Gilbert equation using the plane wave expansion method[1]. We have examined these results are affected by various parameters including the shape of the cylinders, the lattice structure, the material properties, and the spin-orbit interaction. Adjusting these values can open or close band gaps and drastically shift the frequency range of the band structure. The spin wave propagation patterns were found to exhibit high directionality dependent on the excitation frequency and can also be modified with the aforementioned parameters.[1]arXiv:1111.2506

3:06PM Q29.00004 Spin Wave Directional Coupler. KASUNI NAYAYAKKARA, ALEXANDER KOZHANOV, Center for Nano Optics, Department of Physics and Astronomy, Georgia State University, Atlanta, GA — Spin wave based logic devices are evolved as promising candidates for information processing due to potential in scaling and low power consumption. An element performing directional energy transfer between spin waveguides is required in order to implement existing proposed spin wave logic devices. Optical waveguide couplers are well studied and widely used in integrated and fiber optics applications. In this work we apply the concept of optical directional coupler to design and investigate the spin wave directional coupler comprised of the two ferromagnetic stripes separated by a nanometer scale air gap. Micromagnetic simulations and experimental spin wave energy transfer investigations using propagating spin wave spectroscopy were carried out. Spin waves are generated at one of the ends of the input waveguide while detected at remaining three ends of both spin waveguides. Spin wave coupling is investigated as the coupler geometry, bias magnetic field amplitude and orientation and the spin wave length are varied. Results are modeled as coupled backward volume magnetostatic spin wave modes.

3:18PM Q29.00005 Electric-Field Control over Spin-Wave and Current Induced Domain Wall Motion and Magnonic Torques in Multiferroics. IRYNA KULAGINA, JACOB LINDER, NTNU — We discover that the way spin waves and current exert magnetodynamic effects in multiferroic materials can cause not only domain wall motion, but also magnetization dynamics for homogeneous magnetization textures. Interestingly, the domain wall motion can be controlled via purely electrical means with the spin-waves being generated by an ac electric field E while the direction of the wall motion also is sensitive to an applied dc E field. Moreover, we determine the interaction between spin-transfer torque from an electric current and a magnetic domain wall in multiferroics and show that the Walker breakdown threshold scales with the magnitude of a perpendicular electric field, offering a way to control the properties of domain wall propagation via electric gating.
3:30PM Q29.00006 Generalized stochastic Landau-Lifshitz-Gilbert equation for yttrium-iron garnet films. ANDREAS RÜCKRIEGEL, PETER KÖPIETZ, Institut für Theoretische Physik, Universität Frankfurt, Max-von-Laue Strasse 1, 60438 Frankfurt, Germany — We derive a generalization of the well-known stochastic Landau-Lifshitz-Gilbert equation starting from a microscopic Heisenberg model coupled to the lattice degrees of freedom. By integrating out the phonons we obtain a non-Markovian, stochastic equation of motion for the spin degrees of freedom satisfying a Fluctuation-Dissipation theorem. We apply our theory to study the parametric pumping and thermalization of spin excitations in thin yttrium-iron garnet films.

3:42PM Q29.00007 Angle-dependent 2D domain wall motion with Dzyaloshinskii-Moriya interaction1, JIN LAN, JIANG XIAO2, Department of Physics, Fudan University, Shanghai 200443, China, RUQIAN WU3, Department of Physics and Astronomy, University of California, Irvine, CA 92697-4575 — We explore the dependence of the 2D domain wall motion on the incident angle of magnons (spin waves), in the presence of the Dzyaloshinskii-Moriya interaction (DMI). It is found that the domain wall may either be dragged toward or be pushed away from the magnon source, depending on the incident angle of the magnons. This is mainly contributed by the linear momentum absorbed or released by the DMI when magnons pass through the domain wall. In addition, the total internal reflection of magnons beyond a critical incident angle from one side also contributes to the pushing effect. This adds a new mechanism for the magnetic domain wall motion.

3:54PM Q29.00008 ABSTRACT WITHDRAWN —

4:06PM Q29.00009 Field- and current- induced domain wall creep motions in Tb-based ferromagnetic alloys with varying compositions. MICHAEL QUINSAT, SHIHO NAKAMURA, TAKUYA SHIMADA, YASUAKI OOTERA, HIROFUMI MORISE, TSUYOSHI KONDO, Corporate R&D Center, Toshiba Corporation — Due to their tunable magnetization (Ms), Tb-based ferromagnetic alloys are expected as promising materials for spintronic devices utilizing current-induced domain wall motion (CIDWM) with low current-density. On this material system, we have investigated domain wall motions (DWM) induced by magnetic field $H$ or electric current $J$ in creep regime. We fabricated 2-µm-wide and 9-nm-thick wires made of Tb-based alloys of various composition ratios Tb/CoFe, resulting in Ms of 35-150 emu/cc. From the DW velocities $v$ - $H$ characteristics for the wires, we obtained creep exponents between 1 and 1/4 suggesting strong potential-disorder for DW in the samples[1]. In CIDWM experiments, we also identified creep with $J$ ranging from 5 to 20 MA/cm$^2$. It is found that the creep driven by $J$ is impeded more seriously by increasing the DW pinning strength observed in the creep by $H$, while the $J$-induced DW motion is in the electrons' flow. We infer that the observed DW motion by $J$ for the present samples is interfered with the potential disorders, unlike to the case of Co/Ni wires in a literature[e]. [1] A.B. Kolton et al., Phys. Rev. Lett. 94, 047002 (2005). [2] T. Koyama et al., Nature Materials 10, 194 (2011).

4:18PM Q29.00010 Comparison of Field and Drive Field Domain Wall Motion in Beaded Permalloy Nanowires1. ENNO LAGE, SUMIT DUTTA, CAROLINE A. ROSS, Massachusetts Institute of Technology — Domain wall based devices are promising candidates for non-volatile memory devices with no static power consumption. A common approach is the use of (field assisted) current driven domain wall motion in magnetic nanowires. In such systems local variations in linewidth act as obstacles for propagating domain walls. In this study we compare simulated field driven wall motion and current driven domain wall motion in permalloy nanowires with anti-notches. The simulations were obtained using the Object Oriented Micromagnetics Framework (OOMMF). The wires with a constant thickness of 8 nm exhibit linewidths ranging from 40 nm to 300 nm. Circular shaped anti-notches extend the linewidth locally by 10% to 30% and raise information about the domain wall propagation in such beaded nanowires. The results are interpreted in terms of the observed propagation behavior and summarized in maps indicating ranges of different ability to overcome the pinning caused by anti-notches of different sizes. Furthermore, regimes of favored domain wall type (transverse walls or vortex walls) and complex propagation effects like wall breakdown behavior or dynamic change between domain wall structures are identified

The authors thank the German Academic Exchange Service (DAAD) for funding.

3:42PM Q29.00012 Spin transport and dynamics in the F/N junction. HUA LI, KEVIN BEDELL, Boston College — We study the spin transport in the low temperature regime (often referred to as the precession-dominated regime) between a ferromagnetic Fermi liquid (FFL) and a normal metal metallic Fermi liquid (NFL), the F/N junction, which is considered one of the basic spintronic devices. In particular, we explore the propagation of spin waves and transport of magnetization through the interface of the F/N junction where non-equilibrium spin polarization is created on the normal metal side of the junction by spin injection. We calculate the probable spin wave modes in the precession-dominated regime on both sides of the junction especially on the NFL side where the system is out of equilibrium. Proper boundary conditions at the interface are introduced to establish the transport of the spin properties through the F/N junction. In the end, a possible transmission and dephasing electron spin resonance experiment is suggested on the F/N junction to see if the predicted spin wave modes could propagate through the junction.
In addition, the FePt has excellent structural properties with a high degree of L1\textsubscript{0} ordering. Granular FePt on TiN most often produces inter-connected, worm-like grains with low coercivity. We will show that by optimizing the deposition conditions, crystal structure and lattice constant as MgO, the higher surface energy of TiN causes more wetting of the FePt grains on the TiN surface. As a result, mechanically robust, TiN can be DC-sputtered, which produces fewer particles and has a faster deposition rate. Even though TiN has the same rocksalt sublayers beneath the MgO, there are possible concerns associated with using MgO in the media structure. MgO is highly sensitive to moisture, and perpendicular to the film plane and high perpendicular magnetic anisotropy. MgO is also an effective diffusion barrier between the FePt grains and the metallic underlayer material of choice for granular FePt thin film media for heat assisted magnetic recording, because MgO (001) seeds L1\textsubscript{0} ordering of element doping, optimization of preparation parameters, and temperature dependence of properties also will be discussed.

Wednesday, March 4, 2015 2:30PM - 5:30PM – Session Q30 MAG DMP: Focus Session: Magnetic Films and Magnetic Anisotropy 206B - David Sellmyer, University of Nebraska

2:30PM Q30.00001 Magnetic properties and structures of fibrous R\textsubscript{11}Ni\textsubscript{100} intermetallics (R = heavy rare earths), ALESSIA PROVINO, Dept of Chemistry, University of Genova, CLEMENS RITTER, ILL, Grenoble, KARL A. GSCHNEIDER, Ames Laboratory & DMSE, Iowa State University, PIETRO MANFRINETTI, Dept of Chemistry, University of Genova, SUDESH K. DHAR, CMP & MS Deptm, TIFR, Mumbai, India, VITALIJ K. PECHARSKY, Ames Laboratory & DMSE, Iowa State University — The existence and the unusual self-assembled nano/microfibrous morphology of the R\textsubscript{11}Ti\textsubscript{100} (R = rare earth, T = Ni, Pd, Pt) phases has been recently studied [1,2,3]. All the rare earths (but Sc, Eu, Yb) form this ternary compound (orthorhombic Ni\textsubscript{11}Pd\textsubscript{100} type, cC\textsubscript{4h}1, Cmmm). The bundles of fibers grow parallel to the temperature gradient and along the short c-axis. In this presentation we describe the results of a detailed investigation of the physical properties (electrical resistivity, heat capacity, magnetization measurements) of Tb\textsubscript{11}Ni\textsubscript{100}, Dy\textsubscript{11}Ni\textsubscript{100} and Ho\textsubscript{11}Ni\textsubscript{100} by orienting the fibers parallel and orthogonal, respectively, to the electric current and magnetic field. The unusual fibrous microstructure of these compounds leads to a strong anisotropy in their physical properties, with the c-axis of the orthorhombic cell being the easy magnetization and high electrical-conductivity direction. The magnetic structures of Tb\textsubscript{11}Ni\textsubscript{100} and Ho\textsubscript{11}Ni\textsubscript{100}, which have multiple magnetic orderings, have been investigated by neutron diffraction. The complex magnetic behavior found in these phases is a result of the competing ferrimagnetic (along the c-axis) and antiferromagnetic (on the a – b plane) orderings of the five R sublattices.

2:42PM Q30.00002 Structural, Magnetic and Electronic Transport Properties of Rapidly Quenched CoFeCrAl Nanostructures1, P. KHAREL, R. FUGLSBY, S. GILBERT, Y. HUH, Department of Physics, South Dakota State University, W. ZHANG, Nebraska Center for Materials and Nanoscience and Department of Physics and Astronomy, University of Nebraska, S. VALLOP-PILLY, Nebraska Center for Materials and Nanoscience, University of Nebraska, R. SKOMSKI, D.J. SELLMYER, Nebraska Center for Materials and Nanoscience and Department of Physics and Astronomy, University of Nebraska — Materials with moderate magnetization, high spin polarization at the Fermi level and high Curie temperature well above room temperature have huge potential for spin-based electronic devices. Several Heusler compounds including a quaternary compound CoFeCrAl are predicted to have these interesting materials properties. We have used a rapid quenching technique to prepare single-phase CoFeCrAl nanostructured ribbons in a cubic L2\textsubscript{1} crystal structure and have investigated the magnetic and electrical properties. As-quenched ribbons are ferrimagnetic at room temperature with a Curie temperature of about 500 K. The saturation magnetization is 1.9 \textmu\textsubscript{B}/f.u, which is very close to the value predicted by the Slater-Pauling Rule. The ribbons are conducting with a room temperature resistivity of about 80 m\Omega cm, but the resistivity is almost independent of temperature. The thermal coefficient of resistivity is very small and is negative. These ribbons show a small positive magnetoresistance (1.5% at 5 K) between 5 K and 300 K. We will also discuss the effect of vacuum annealing on the structural and magnetic properties of this material.

2:54PM Q30.00003 Control of anisotropy and magnetism of MnBi nanomaterials1, WENYONG ZHANG, DAVID SELLMYER, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE 68588 — High-anisotropy MnBi nanostructures have been fabricated by in-situ annealing of Bi/Mn/Bi multilayers and magnetic-field annealing of melt-spin Mn\textsubscript{100-x}Bi\textsubscript{x} ribbons. The ratio of Mn to Bi affects the concentration of NiAs-type MnBi, the degree of c-axis orientation, and phase distribution. For x = 50, the Mn\textsubscript{100-x}Bi\textsubscript{x} film exhibits the optimum nanostructure in which MnBi grains are uniformly separated by a thin layer of Bi. This has produced a record value of (BH)\textsubscript{max} = 16.3 MGOe for this compound. A good c-axis texture has been developed for Mn\textsubscript{90}Bi\textsubscript{10} ribbon with a remanence ratio of 0.94 after magnetic-field annealing and this result subsequently leads to (BH)\textsubscript{max} = 9.2 MGOe, the highest value for bulk MnBi materials. The reason for the much higher energy product for the Mn\textsubscript{90}Bi\textsubscript{10} film compared to the Mn\textsubscript{90}Bi\textsubscript{10} ribbon is that the ribbon has a comparatively lower coercivity induced by inhomogeneous distribution of intergranular Bi. The effect of element doping, optimization of preparation parameters, and temperature dependence of properties also will be discussed.

3:06PM Q30.00004 Well-isolated FePt grains with high coercivity on TiN underlayers for heat-assisted magnetic recording media, TIFFANY SANTOS, SHIKHA JAIN, AKEMI HIROTUNE, OLAV HELLWIG, HGST — MgO is the underlayer material of choice for granular FePt thin film media for heat assisted magnetic recording, because MgO (001) seeds L1\textsubscript{0} ordered FePt with c-axis perpendicular to the film plane and high perpendicular magnetic anisotropy. MgO is also an effective diffusion barrier between the FePt grains and the metallic underlayers beneath the MgO. However, there are possible concerns associated with using MgO in the media structure. MgO is highly sensitive to moisture, and hydration of MgO could potentially degrade film properties. In addition, many particulates are incorporated into the film during the RF-sputtering process, which can be sources of domain wall pinning points and magnetic loss. The low-flying recording heads, TiN is an attractive alternative to MgO because it is chemically and mechanically robust, and TiN can be DC-sputtered, which produces fewer particles and has a faster deposition rate. Even though TiN has the same rocksalt crystal structure and lattice constant as MgO, the higher surface energy of TiN causes more wetting of the FePt grains on the TiN surface. As a result, deposition of granular FePt on TiN most often produces inter-connected, worm-like grains with low coercivity. We will show that by optimizing the deposition of FePt and segregant material on the TiN underlayer, we are able to fabricate FePt media with well-isolated grains and high coercivity reaching nearly 4 Tesla. In addition, the FePt has excellent structural properties with a high degree of L1\textsubscript{0} atomic ordering and minimal c-axis in-plane oriented grains.
**3:18PM Q30.00005 Thickness Dependent Magnetoelastic Effects and Perpendicular Magnetic Anisotropy in the Ta/CoFeB/MgO system.** GREGORY STEIHL, PRAVEEN GOWTHAM, DANIEL RALPH, ROBERT BUHRMAN, Cornell University, Ithaca, New York, 14853 — We report the observation of strong thickness-dependent in-plane magnetoelastic coupling in Ta/CoFeB\(x=0.7-2\) nm/MgO multilayers. Measurements are made using a four-point bend test strain fixture, revealing the emergence of large effective surface and volume magnetoelastic couplings after post-deposition annealing. When such surface and volume magnetoelastic interactions are included in the standard Neel model of surface anisotropy, they provide a natural explanation for the nonmonotonic \(K_{\text{eff}}(x)\) vs. \(x\) curves measured for CoFeB films in the thickness range that yields perpendicular magnetic anisotropy (PMA). The magnitude of the magnetoelastic coupling terms suggest that enhanced control of thin film strains could be used to beneficially manipulate the PMA in CoFeB/MgO magnetic tunnel junctions and other thin film multilayer nanostructures.

**3:30PM Q30.00006 Tunable magnetic anisotropy in perpendicular exchange-coupled CoFeB/(Co/Pt) films.** LONG YOU, OUKJAE LEE, Department of Electrical Engineering and Computer Sciences, University of California at Berkeley, TERRÉLL GLENN, Department of Physics, Morehouse College, HARAM ABDEL-RAZIQ, SAYEEF SALAHUDDIN, Department of Electrical Engineering and Computer Sciences, University of California at Berkeley — Spintronic materials with strong perpendicular magnetic anisotropy (PMA), such as Co/Pd, Co/Pt and Co/Ni multilayers, have been introduced to improve the functional performance of STT devices (e.g. enhanced thermal stability, scalability and switching speeds of spin memory/logic). Furthermore, by coupling magnetic layers with PMA and longitudinal magnetic anisotropy (LMA), added benefits such as a variable magnetization tilt angle and tunable damping have been shown. In our study, we discuss how to precisely control the anisotropy tilt angle by coupling the PMA hard layer (Co/Pt) with an in-plane soft layer (IMA, CoFeB). Due to the competition between the PMA and IMA, the tilted angle can be tuned by varying thickness of IMA. The stack of Pt(5nm)/Co (1nm)/CoFeB(xnm)/MgO (2nm) \((x\) varied from 0 to 1nm) was deposited by magneto-sputtering system. The magnetic properties were measured by vibrating sample magnetometer and anomalous Hall effect. The electric transport of microscale devices comprised of that stack were also studied by our probe station with electromagnet. The experiments show the magnetic anisotropy can be tuned well by changing thickness of in plane layer and open a promising new avenue to next generation spintronic devices.

**3:42PM Q30.00007 ABSTRACT WITHDRAWN**

**3:54PM Q30.00008 Isothermal tuning of magnetic coercivity in NiFe/NiO/[Co/Pt] heterostructures with orthogonal easy axes.** ANDREW BARUTH, Department of Physics, Creighton University — Heterostructures of NiFe/NiO/[Co/Pt] with mutually orthogonal easy axes allow for isothermal tuning of the magnetic coercivity at room temperature with no associated shift in the hysteresis loop along the applied field axis. This is in contrast to what is typically seen in exchange biased heterostructures. The application of moderate dc magnetic fields of \(< 3 \text{kOe}\) enhances the NiFe coercivity from 14.5 to 105 Oe. The application of a similarly sized dc magnetic field perpendicular to the film completely resets this enhancement back to 14.5 Oe. We propose that the in-plane magnetization of both the NiFe and [Co/Pt] adjacent layers greatly influences the pinning of the antiferromagnetic NiO interlayer (with a blocking temperature expected to be well below 50 K at this thickness). In addition, these heterostructures show unique high and low-field training effects due to alignment of [Co/Pt] stripe domains during field cycling. The dynamic, yet predictable, behavior of isothermally tuning the magnetic coercivity without any permanent structural/chemical modifications has potential uses in advanced magnetic logic/storage, as well as tuning the interfacial coupling in spintronic applications.

**4:06PM Q30.00009 Controllable magnetic phase front in a vertically graded Ni,Cu\(_{1-x}\) alloy film.** BRIAN KIRBY, NIST - Natl Inst of Stds & Tech, H.F. BELLIVEAU, D.D. BELYEA, T. EGERS, University of South Florida, P.A. KIENZLE, A.J. GRUTTER, NIST - Natl Inst of Stds & Tech, P. RIEGO, A. BERGER, CIC nanoGUNE Consolidor, C.W. MILLER, Rochester Institute of Technology — We have used polarized neutron reflectometry to study the temperature and magnetic field dependent magnetization depth profile of a ferromagnetic 100 nm Ni,Cu\(_{1-x}\) alloy film with \(x\) that varies linearly from 0.61 - 0.70 along the growth axis. Modeling the data in terms of a mean-field exchange strength gradient theory, we find that with increasing temperature, the magnetized thickness of the film continuously decreases, indicating a continuous vertical distribution of effective ferromagnetic transition temperatures. For temperatures corresponding to a partially magnetized film, increasing the applied field from 5 mT to 500 mT is observed to significantly alter the shape of the profile, consistent with magnetization of an effectively paramagnetic region. Thus, we demonstrate that this system exhibits a vertical magnetic phase boundary that can be moved continuously along the growth axis with temperature. Such temperature and field control of the magnetized phase boundary could have important implications for our understanding of metamagnetic transitions, as well as for magnetoelastic and thermomagnetic device applications.

**4:18PM Q30.00010 Strain effect on magnetocrystalline anisotropy of 5d TM/Fe and TM/Fe/MgO(001) (TM=Ta, Ir, Pt, Au): A first principles study\(^1\).** PUREV TAIVANSAIKHAN, Department of Physics and Energy Harvest Storage Research Center, University of Ulsan, Ulsan 680-749, Republic of Korea, DORJ ODKHUU, Department of Physics, Incheon National University, Incheon 406-722, Republic of Korea, SUNG-HYON RHIM, SOON CHEOL HONG, Department of Physics and Energy Harvest Storage Research Center, University of Ulsan, Ulsan 680-749, Republic of Korea — Strain effect on magnetization and magnetocrystalline anisotropy (MCA) of TM/Fe(001) [TM=Ta, Ir, Pt and Au] with and without MgO(001) substrate has been investigated using first-principles calculations. It is found that perpendicular MCA of Pt/Fe(001) changes in-plane MCA in the presence of MgO substrate, where lattice is extended by 3.8% with respect to that without MgO. For Ta/Fe(001) and Au/Fe(001), PMCA is significantly enhanced by the MgO substrate, whereas MCA of Ir/Fe(001) remains in-plane. Furthermore, thickness dependence of MCA on both the TM and Fe layers will be also discussed.

\(^1\)Supported by Basic Research Program (2010-0008842) and Research Centers Program (2009-0093818) through National Research Foundation of Korea.

**4:30PM Q30.00011 Multilayer FeRh/MgO for an antiferromagnetic system.** GUOHUI ZHENG, ODKHUU DORJ, California State University Northridge, SANHUANG KE, Tongji University, Shanghai, China, RAMMOÖRTHY RAMESH, University of California Berkeley, MAOSHENG MIAO, NICKOLAS KIOUSSIS, California State University Northridge — Controlling the magnetocrystalline anisotropy (MCA) of ferromagnetic (FM) thin films by tunable strain and electric field has been pursued as an effective method of achieving low-power and highly scalable memory. Comparing with FM materials, AFM are much less sensitive to external magnetic field, a substantial advantage for memory devices. Inspired by recent work on AFM memory resistors based on FeRh, we carried out a systematic first-principles study of the MCA of multi-layer FeRh, either stand alone, or combined with MgO layers. FeRh is a unique material that undergoes a transition from AFM (type-II) to FM at elevated temperature of 370 K. Our calculations for thin films of FeRh from 5-15 atomic layers reveal that AFM is always the most stable configuration for Fe terminated films; while for Rh terminated films, there is a transition from FM to a configuration featured AFM at the center layers and FM at the surface layers (reconstructed). While applying the spin-orbit interactions (SOI) for the valence electrons, we found Fe-terminated films exhibit a relatively small MCA that varies and may change sign with film thickness, substrate and strain, providing a possibility of spin reorientation via the control of strain and electric field. The k-resolved MCA values reveals that the region around Gamma point adds the major contribution to the MCA.
Heat assisted magnetic recording (HAMR) is a promising approach for increasing the storage density of hard disk drives. To increase data density, information is recorded by using a laser to heat the magnetic medium to a temperature close to its Curie point, thereby reducing its coercivity, making it difficult to write the data with existing recording heads. This issue can be overcome by the technique of HAMR, where a laser is used to heat the recording medium to reduce its coercivity while retaining good thermal stability at room temperature due to the large anisotropy energy. One of the keys to the success of HAMR is the precise control of writing process. In this talk, I will propose a Monte Carlo simulation, based on an atomistic model, that would allow us to study the magnetic properties of L1₀ FePt and dynamics of spin reversal for the writing process in HAMR.

4:06PM Q30.00014 Atomistic modeling of L1₀ FePt: path to HAMR 5Tb/in² . TIANRAN CHEN, Department of Physics, West Chester University, West Chester, PA 19383, MOURAD BENAKLI, CHRIS REA, Seagate Technology, Bloomington, MN 55435 — Heat assisted magnetic recording (HAMR) is a promising approach for increasing the storage density of hard disk drives. To increase data density, information must be written in small grains, which requires materials with high anisotropy energy such as L1₀ FePt. On the other hand, high anisotropy implies high coercivity, making it difficult to write the data with existing recording heads. This issue can be overcome by the technique of HAMR, where a laser is used to heat the recording medium to reduce its coercivity while retaining good thermal stability at room temperature due to the large anisotropy energy. One of the keys to the success of HAMR is the precise control of writing process. In this talk, I will propose a Monte Carlo simulation, based on an atomistic model, that would allow us to study the magnetic properties of L1₀ FePt and dynamics of spin reversal for the writing process in HAMR.

5:18PM Q30.00015 Ferromagnetic thickness dependence of exchange bias: breaking of the inverse proportionality law1 . RAFAEL MORALES, Dept. Chemical-Physics & BCMaterials, UPV/EHU and IKERBASQUE Basque Foundation for Science, Bilbao, Spain, ALI C. BASARAN, Dept. of Physics and Center for Advanced Nanoscience, University of California San Diego, La Jolla, USA, J.E. VILLEegas, Uni 10 Mixte de Physique CNRS/Thales, Université Paris Sud, Orsay, France, D. NAVAS, IFIMUP-IN and Dept. Física e Astronomía, Universidade do Porto, Portugal, N. SORIANO, B. MORA, C. REDONDO, Dept. of Chemical-Physics, UPV/EHU, Leioa, Spain, X. BATLLE, Dept. de Física Fonamental and Instituto de Nanociencia i Nanotecnologia IN2UB, Universitat de Barcelona, Barcelona, Spain, IVAN K. SCHULLER, Dept. of Physics and Center for Advanced Nanoscience, University of California San Diego, La Jolla, USA — The exchange coupling between antiferromagnetic/ferromagnetic (AF/FM) materials shifts the hysteresis loop along the field axis by an amount known as exchange bias field. It is believed that the ferromagnetic thickness dependence of the exchange bias field follows an inverse proportionality law. This has experimentally and theoretically been confirmed for FM thicknesses below the FM domain wall width. In this work we demonstrate that this exchange bias dependence is broken for certain FM spin structures, even though in FM layers thinner than the FM domain wall width. We present experimental data of FeF₂/FeNi bilayers that deviate from the inverse proportionality law, as well as a theoretical calculation that accounts for the results.

5:38PM Q31.00002 5:38PM - 5:45PM — Session Q31 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors: Spin Injection 207A - Connie Li, Naval Research Laboratory

2:30PM Q31.00001 Spin-dependent transport across SrTiO₃-based heterostructures . ADRIAN SWARTZT, Stanford University — Identification of candidate spin-preserved materials is of crucial importance for the realization of functional spin logic devices. An oxide spin channel is particularly attractive because of the ease of epitaxial integration with other functional complex oxides, which could manipulate spins in transit. Electron-doped SrTiO₃ is one emerging material that has high mobility conductions has been realized at the interface between LaAlO₃ and SrTiO₃, as well as in more traditional semiconducting Nb-doped SrTiO₃ thin films. We have investigated spin injection in both systems using a three-terminal (3T) geometry with ferromagnetic electrodes and have observed magnetoresistance commonly attributed to dephasing of an ensemble spin population (Hanle effect), with associated spin lifetimes in the range of 40-130 ps, large enough for the realization of lateral spin transport devices. However, such a picture fails to explain all the experimentally observed behavior. Further experiments indicate contributions from magnetic-field modulation of spin-dependent transport through defect states in the barrier region, suggesting that the 3T approach does not uniquely probe spin accumulation in the SrTiO₃ channel.
3:06PM Q31.00002 Spin Transport Properties in Nondegenerate Si at Room Temperature
TAKAYUKI TAHARA, Kyoto University, HAYATO KOIKE, TDK Corporation and Osaka University, TOMOYUKI SASAKI, TDK Corporation, YUICHIRO ANDO, Kyoto University, MAKOTO KAMENO, YOSHISHIGE SUZUKI, Osaka University, MASASHI SHIRAISHI, Kyoto University, KYOTO UNIVERSITY TEAM, TDK CORPORATION COLLABORATION, OSAKA UNIVERSITY COLLABORATION — So-called beyond-CMOS technologies have been intensively investigated. Among them, Si spintronics is now a promising candidate, since Si has good spin coherence, enabling novel spin-based logic systems. We have been investigating spin transport properties in degenerate Si up to room temperature (RT) and recently, spin transport in a non-degenerate n-Si at RT was successfully achieved where the doping concentration of Si was $2 \times 10^{19} \text{ cm}^{-3}$. Spin drift in non-degenerate Si allows apparent modulation of Hanle spin signals under applications of bias- and gate-electric fields. The magnitude of the spin signals exceeds 1 mV under an bias electric current of 1 mA, which is ten times greater than previously reported values in degenerate-Si-based spin devices. The detail of the observation of large spin signals and other spin transport properties will be discussed in the presentation.

3:18PM Q31.00003 Investigation of spin drift velocity and the modulation of spin signals under spin drift in highly-doped n-type Si
MAKOTO KAMENO, Osaka University, YUICHIRO ANDO, TERUYA SHINJO, MASASHI SHIRAISHI, Kyoto University, HAYATO KOIKE, TOMOYUKI SASAKI, TOHRI OIKAWA, TDK Corporation, TOSHIO SUZUKI, AIT, OSAKA UNIVERSITY TEAM, KYOTO UNIVERSITY COLLABORATION, TDK CORPORATION COLLABORATION, AIT COLLABORATION — Spin drift enables to modulate a spin transport length scale in semiconductor. We have experimentally investigated a role of spin drift in spin transport in highly-doped n-Si, i.e., the modulation of a spin transport length scale by using an electrical spin transport method. The results directly show that spin drift becomes prominent in spin transport in semiconductor. In addition, spin drift velocity in the highly-doped Si channel was quantitatively estimated by introducing a new experimental technique. It was revealed that Hanle-type spin precession signals from the Si were modulated by spin drift and were theoretically reproduced.

3:30PM Q31.00004 Spin lifetime dependence on spin injection orientation in strained silicon films
JOYDEEP GHOSH, DMITRI OSIUTSEV, VIKTOR SVERDLOV, SIEGFRIED SELBERHERR, Institute for Microelectronics, TU Wien — Growing technological challenges and costs are guiding MOSFET scaling to an end. This accelerates the search of alternative devices principles, including concepts based on electron spin. As of the ongoing shift to thin silicon films and fins-based devices for the 14nm node and beyond, spin lifetime in such structures becomes a dominant issue. Large spin lifetime enhancement in (001) thin silicon films subjected to [110] uniaxial tensile stress was predicted for spin injected perpendicular to the film [1]. Here we find that the spin relaxation rate is further reduced and the spin lifetime is thus increased for spin injected in-plane. To explain the observed behavior we look at the spin relaxation hot spots. For an in-plane injection along OX the spin expectation value projections at the hot spots are: $\sigma_x = \sin^2(\arctan(p_x/p_y))$, $\sigma_y = -(p_y/p_x)\sigma_x$, $\sigma_z = 0$, while for spin injected perpendicular to the film the spin expectation value at the hot spots is zero, resulting in maximal spin randomization at any in-plane momentum $(p_x, p_y)$. Therefore the spin relaxation rate is the strongest for spin injected perpendicularly explaining the spin relaxation time increase for an in-plane spin injection. I.D. Osintsev et al., Solid-State Electron.90, 34 (2013).

3:42PM Q31.00005 Challenging the spin accumulation interpretation of local “3T” measurements
HOLLY TINKEY, IAN APPELBAUM, PENGKE LI, University of Maryland- College Park — The recent observation of magnetoresistance in local “three-terminal” (3T) measurements on ferromagnet/insulator/semiconductor junctions have spawned many claims of direct bulk spin injection or “accumulation”. We present a self-consistent model to rigorously calculate expected voltage changes due to electrochemical potential splitting from spin accumulation driven by pure elastic tunnel injection in such junctions, and find that the experimentally observed magnetoresistance vastly exceeds theoretical predictions in all doping, temperature, and bias voltage regimes. Our own experimental measurements using inelastic electron tunneling spectroscopy reveal that extrinsic impurities and defects within the junctions are responsible for the observed magnetoresistance signals, which cannot possibly be attributed to spin dephasing of polarized bulk electrons from elastic injection as claimed by proponents of the method.

3:54PM Q31.00006 Exchange Driven Spin Relaxation in Ferromagnet/Oxide/Semiconductor Heterostructures
YU-SHENG OU, YI-HSIN CHIU, The Ohio State University, DEPT OF PHYSICS, NICHOLAS HARMS, University of Iowa, DEPT OF PHYSICS, PATRICK O'DENTHAL, UNIV OF CALIFORNIA, RIVERSIDE, DEPT OF PHYSICS, ROLAND KAWAMAKI, THE OHIO STATE UNIVERSITY, DEPT OF PHYSICS, MICHAEL FLATTE, UNIVERSITY OF IOWA, DEPT OF PHYSICS, EZEKIEL JOHNSTON-HALPERIN, THE OHIO STATE UNIVERSITY, DEPT OF PHYSICS — Time-resolved Kerr rotation (TRKR) is employed to study the exchange coupling between spin ensembles in GaAs and a neighboring ferromagnet (FM) in an Fe/MgO/GaAs heterostructure. The time-resolved spin dynamics in GaAs provide local magnetometry, revealing the strength and sign of the exchange field as well as its impact on electron and nuclear spins. Consistent with previous studies, we see a hyperpolarization of the nuclei induced by the dynamic exchange at the Fe/MgO/GaAs interface that results in a large effective nuclear field on the electrons (Bn = 0.2 T). Unexpectedly, we observe that the spin relaxation time in GaAs, T2*, depends on the strength of the exchange-driven nuclear field rather than the applied field. In addition, the temperature dependence of T2* shows a crossovers of relaxation mechanism from hyperfine dominated to D'yakonov-Perel' (DP) dominated at temperatures above 40 K. These results not only resolve a long-lasting puzzle of the GaAs spin relaxation mechanism, but further demonstrate the ability to detect exchange-driven dissipation in FM/NM heterostructures. We discuss the potential for this work to define a novel detection scheme for exchange-driven spin injection in FM/semiconductor heterostructures, such as ferromagnetic resonance driven spin pumping.

4:06PM Q31.00007 Non-local spin transport with two coupled channels: Manifestation of the inter-channel tunneling in the shapes of the Hanle curves1, MIKHAIL RAIKH, ROBERT ROUNY, MAGAN PRESTGARD, ASHUTOSH TIWARI, EUGENE MISHCHENKO, University of Utah — Dynamics of charge-density fluctuations in a system of two tunnel-coupled channels contains two diffusion modes with dispersion $\omega = Dq^2$ and $\omega = Dq^2 + \frac{\omega_L}{t}$, where $D$ is the diffusion coefficient and $\tau_s$ is the tunneling time between the channels. The dispersion of corresponding spin-density modes depends on magnetic field as a result of spin precession with Larmor frequency, $\omega_L$. The presence of two modes affects the shape of the Hanle curve, describing the non-local resistance between the injector and the detector. We calculate the shapes, $R_{11}(\omega_L)$ and $R_{12}(\omega_L)$, of the Hanle curves, for geometries in which detector is located, respectively, in the same and in the different channel than the detector. We demonstrate that the relative shapes of $R_{11}(\omega_L)$ and $R_{12}(\omega_L)$ depend on the ratio $\tau_s/\tau_L$, where $\tau_s$ is the spin-diffusion time. If the coupling between the channels is local, i.e. only at the point $x = 0$, then the shapes of the $R_{11}(\omega_L)$ and $R_{12}(\omega_L)$ curves reflects the difference in statistics of diffusive trajectories which “switch” or do not switch near $x = 0$.

4:18PM Q31.00008 Detecting spin accumulation in FM/n-GaAs heterostructures using ferromagnetic resonance1, CHANGJIAN LIU, CHAD GEPPERT, KEVIN CHRISTIE, GORDON STECKLEIN, University of Minnesota, SAHIL PATEL, CHRIS PALMSTRØM, University of California, Santa Barbara, PAUL CROWELL, University of Minnesota — A distinguishing feature of spin accumulation in ferromagnet (FM)/semiconductor heterostructures is precession. This is the basis for detection techniques such as the Hanle effect, but these approaches become less effective as the spin lifetime in the semiconductor decreases. We report here on a technique in which the source magnetization is forced to precess at the ferromagnetic resonance frequency, allowing for the detection of spin accumulation even when the spin lifetime is short (less than 100 psec). The samples used in the experiments are MBE-grown FM/(001) n-GaAs heterostructures, in which the FM are the Heusler alloys Co2MnSi and Co2FeSi. These samples show non-local spin valve and Hanle signals in conventional electrical spin injection/detection measurements at low temperatures. Using the FMR technique, we detect the spin accumulation from 30 K to room temperature as a sharp resonance peak. The frequency dependence of the magnitude of the resonance peak allows for a measurement of the spin lifetime. Spin lifetimes as short as 40 psec are measured at room temperature in channels doped at 3x1016 cm$^{-3}$.

4:30PM Q31.00009 Spin transport at high temperatures in epitaxial Heusler alloy/n-GaAs lateral spin valves1, TIMOTHY A. PETERSON, KEVIN D. CHRISTIE, University of Minnesota, SAHIL J. PATEL, University of California Santa Barbara, PAUL A. CROWELL, University of Minnesota, CHRIS J. PALMSTRØM, University of California Santa Barbara — We report on electrical injection and detection of spin accumulation in ferromagnet/n-GaAs lateral spin-valve devices, observed up to and above room temperature. The ferromagnet in these measurements is the Heusler alloy Co2FeSi, and the semiconductor channel is GaAs doped at 3x1016 cm$^{-3}$. The spin signal is enhanced by operating the detection contact under forward bias. The enhancement originates from drift effects at low-temperatures and an increase of the detection efficiency at all temperatures. The detector bias dependence of the observed spin-valve signal is interpreted by taking into account the quantum well (QW) which forms in the degenerately doped region immediately behind the Schottky tunnel barrier. In particular, we believe the QW is responsible for the minority spin accumulation (majority spin current) under large forward bias. The spin diffusion length and lifetime are determined by measuring the separation dependence of the non-local spin valve signal in a family of devices patterned by electron beam lithography. A spin diffusion length of 700 nm and lifetime of 46 picoseconds are found at a temperature of 295 K.

4:42PM Q31.00010 g-factor modification by an in-plane electric field in a bulk In$_{0.03}$Ga$_{0.97}$As epilayer1, MARTA LUENGO-KOVAC, SIMON HUANG, RACHEL GOLDMAN, VANESSA SIH, Univ of Michigan - Ann Arbor — The response of an electron spin to a magnetic field, determined by the g-factor, is important for any spin-based device. The modification of the g-factor by a perpendicular electric field has been demonstrated in quantum wells and dots. This can be explained by the electric field shifting the electron wavefunction into the barrier. We found that the g-factor also changes when an in-plane electric field is applied across an In$_{0.03}$Ga$_{0.97}$As epilayer. We performed external magnetic field scans of the Kerr rotation of the InGaAs film in order to measure the g-factor independently of the spin-orbit fields. Measurements performed along the [110] and [1-10] crystal axes show the same electric-field dependence of the g-factor, indicating that this change in the g-factor is not related to the spin-orbit fields. Temperature and voltage dependent photoluminescence measurements were also performed, showing that change in the g-factor was not caused by channel heating by the electric field. As there is no quantum confinement along the direction of the electric field, this change in the g-factor is fundamentally different from that seen in quantum wells and dots.

4:54PM Q31.00011 Spin Lifetimes in annealed GaInNAs epilayers1, YUTSUNG TSAI, BIPLOB BARMAN, THOMAS SCRACE, ATHOS PETROU, SUNY at Buffalo, MIWA FUKUDA, IAN SELLERS, University of Oklahoma, MATTHIEU LEROUX, MOHAMED KHALFIOUI, CRHEA-CNRS, France, SUNY AT BUFFALO COLLABORATION, UNIVERSITY OF OKLAHOMA COLLABORATION, CRHEA-CNRS COLLABORATION — We have carried out Hanle measurements of the electron spin lifetime $T_{2\text{in}}$ optically pumped annealed GaInNAs epilayers (undoped and p-type doped). The samples were prepared in a 7T optical magnet cryostat with the magnetic field applied in the epilayer plane. The emitted light was collected along the normal to the epilayer. The PL was excited using the 1064 nm line from a Nd:YAG laser which gives a polarization P = 5% at B = 0. The transverse magnetic field results in a reduction of $P^*$, from which we determine $T_{2\text{s}}$. At $T = 50$ K, the electron spin lifetime $T_{2\text{in}}$ was measured to be 15 ps. As the sample temperature increases, $T_{2\text{in}}$ decreases ($T_{2\text{in}} = 7$ ps at $T = 150$ K). Our Hanle results are in agreement with the $T_{2\text{in}}$ values measured by Lombez et al. using time-resolved photoluminescence spectroscopy [2]. The observed sharp reduction in $T_{2\text{in}}$ annealed samples is interpreted as due to the D'yakonov-Perel' spin relaxation mechanism. In annealed samples the momentum relaxation time increases, resulting in a reduction of $T_{2\text{s}}$ [2]. L. Lombez et al, Appl Phys Lett 87, 252115(2005) [3] M.I. D’yakonov and V.I. Perel’, Soviet Physics JETP, 33, 1053(1971)

Electric Field and Magnetoelectric Effects

We show that clockwise and counter-clockwise memristors can be tailored on the same sample yielding multiple resistance states. The memristive response is independent of the variation of the width or the height of the tunnel barrier. This yields a controlled sign change of the electroresistance upon polarization switching.

Heterostructure resulting from the controlled switching of polarization and/or oxygen vacancies may open new routes towards new computing architectures.

Ionized, can be manipulated by electric fields. We aim at using the strong electric fields building up in ultrathin tunnel barriers to generate and manipulate oxygen vacancies, by using the recently established model of Hanle effect taking into account the spin absorption by graphene with a large spin diffusion length, $\lambda$.

Thus $R$ in the range of 100 kOhm is generally not large enough to suppress the spin absorption, and taking into account the contacts is more important to characterize the real $r_\text{sf}$ in graphene with $\lambda$ in this range.

Electric Field and Magnetoelectric Effects

2:30PM Q32.00001 Oxygen vacancy control of a ferroelectric memristor, J. SANTAMARIA, GFMC Univ Complutense 28040 Madrid, YAOHUA LIU, S. G. E. TE VELTHUIS, Argonne National Laboratory, Illinois 60439, USA., D. HERNANDEZ-MARTIN, A. PEREZ MUNOZ, M. CABERO, G. SANCHEZ-SANTOLINO, J. TORNOS, M. VARELA, C. LEON, Z. SEFRIOUI, GFMC Univ Complutense 28040 Madrid, S. J. PENNYCOOK, University of Tennessee, Tennessee 37996-2200 — The rich phenomenology exhibited by correlated oxide interfaces can be expanded by considering the control and manipulation of point defects. In particular, oxygen vacancies can be induced by electro forming processes at redox active electrodes and, when ionized, can be manipulated by electric fields. We aim at using the strong electric fields building up in ultrathin tunnel barriers to generate and manipulate oxygen vacancies in Ag/BaTiO$_3$/La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO) micron-size structures defined by optical and electronic lithography techniques. Controlling accumulation of oxygen vacancies in the BTO or LSMO interfaces allows modification of the magnetic state of the LSMO at the interface, enabling independent variation of the width or the height of the tunnel barrier. This yields a controlled sign change of the electroresistance upon polarization switching.

We show that clockwise and counter-clockwise memristors can be tailored on the same sample yielding multiple resistance states. The memristive response is independent of the variation of the width or the height of the tunnel barrier. This yields a controlled sign change of the electroresistance upon polarization switching.

2:42PM Q32.00002 Memristive Switching and Interfacial Magnetoelectricity in LCMO/PBCO Heterostructure, XIAO SHEN, Vanderbilt University, TIMOTHY J. PENNYCOOK, Oxford University, DAVID HERNANDEZ MARTIN, ANA PÉREZ, MARIA VARELA, Universidad Complutense de Madrid, YEVGENIY S. PUZYREV, Vanderbilt University, CARLOS LEON, ZOUHAIR SEFRIOUI, JACOBO SANTAMARIA, Universidad Complutense de Madrid, SOKRATES T. PANTELIDES, Vanderbilt University — New phenomena emerge at the interfaces of transition metal oxides. Here we report memristive switching in a La$_{0.7}$Sr$_{0.3}$MnO$_3$/PrBa$_2$Cu$_3$O$_7$ bilayer structure with an On/Off ratio greater than 10$^3$ that originates from a new type of interfacial magnetoelectricity. Using DFT calculations, we show that at the LCMO/PBCO interface, a “magnetic dead layer” (MDL) can be switched on and off by a small displacement of the interfacial Mn atoms generated by an external voltage. Initially, the LCMO is ferromagnetic with no MDL. This is the Low Resistance State (LRS) as majority-spin carriers tunnel through the PBCO. A negative voltage creates an electric field that displaces the interfacial Mn atoms towards the bulk LCMO by a few hundredths of an Angstrom. In such a position, the interfacial Mn layer is coupled anti-ferromagnetically to the bulk LCMO, whereby a MDL is present, adding a barrier for the majority-spin carriers to tunnel and thus the bilayer is at High Resistance State (HRS). A positive bias drives the Mn atoms back to their original positions that favor ferromagnetic coupling, thus destroying the MDL and switching the bilayer back to LRS.

Enhanced magneto-ionic switching of interface anisotropy in Pt/Co/GdOx films, AIK JUN TAN, UWE BAUER, GEOFFREY BEACH, Massachusetts Inst of Tech-MIT, BEACH GROUP TEAM — Voltage control of magnetic anisotropy is of great interest for reducing the switching energy barrier in spintronic devices. It has recently been shown that electric field-driven oxygen ion migration near the interface of ferromagnet/oxide bilayers can lead to very large changes in magnetic anisotropy [1], but these changes required elevated temperature and a voltage dwell time on the order of minutes. Here, we examine magneto-ionic switching in ultrathin Co/GdOx films with perpendicular anisotropy, in which the GdOx gate dielectric acts as an oxygen ion conductor. We examine the switching efficiency as a function of GdOx layer thickness and electrode geometry, and show that the voltage, operating temperature, and switching timescale can be significantly reduced by optimizing the GdOx thickness and defect structure. We demonstrate reversible toggling of magnetic properties for >50 cycles, and correlate the magnetic switching behavior with changes in the electrical properties of the GdOx. 1. U. Bauer et al., arXiv:1409.1843v1(2014)
3:06PM Q32.00004 Dual field effects in spinel ferrite field effect devices: electrostatic carrier doping and redox reactions , HIDEKAZU TANAKA, Institute of Scientific and Industrial Research, Osaka University — Spinel ferrite is a good candidate as a tunable magnetic semiconductor with high $T_C$. Here, we report the gate-induced conductance modulation of $(\text{Fe}_3\text{Zn}_5\text{O}_4)\text{O}_2$ solid solution to demonstrate the dual contributions of volatile and non-volatile field effects arising from electronic carrier doping and redox reactions using field effect device structure with a ferroelectric Pb(Zr,Ti)O$_3$ and an ionic liquid DEME-TFSI. In the Pb(Zr,Ti)O$_3$/(Fe$_2$,$\text{Zn}$,$\text{O}_4$)$_2$ FET, the gate voltage dependence of channel conductance on the $(\text{Fe}_{2.2}\text{Zn}_{0.8})\text{O}_4$ layer shows the typical hysteresis behavior reflecting the ferroelectric polarization, indicating the static carrier modulation [1]. In contrast, in the DEME-TFSI/(Fe$_2$,$\text{Zn}$,$\text{O}_4$)$_2$ FET, a large hysteresis observed in the drain current vs gate voltage characteristics is not accounted for solely by electrostatic doping, strongly suggesting the presence of chemical reactions[2]. In more details, the characteristic hysteresis virtually disappears for the heavily Zn substituted system $(\text{Fe}_{2.2}\text{Zn}_{0.8})\text{O}_4$ with less carrier concentration [3]. These observations revealed the coexistence of two types of field effects in the Fe$_{3-x}$Zn$_x$O$_4$ devices, and the tuning of field-effect characteristics via composition engineering should be extremely useful for fabricating high-performance oxide field-effect devices. References; [1] Appl Phys Lett. 98 (2011) 102506, [2] Adv. Mater. Interfaces 1 (2014) 1300108, [3] Sci. Rep. 4 (2014) 5818.

3:42PM Q32.00005 Tuning magnetic and electronic properties of (La$_{1-x}$Pr$_x$)$_6$Ca$_{0.33}$MnO$_3$ thin films by composition spread deposition and electrolyte gating , XIAOHANG ZHANG, Y.G. LIANG, S. FACKLER, J.M. SHIN, ICHIRO TAKEUCHI, Department of Materials Science and Engineering, University of Maryland, A.T. N’DIAYE, E. ARENHOLZ, Lawrence Berkeley National Laboratory — The magnetic and electronic properties of mixed-valence mangetites are known to be sensitive not only to chemical doping but also to oxygenation. However, it is difficult to consistently attain exactly the same set of deposition conditions and treatment history for samples that are fabricated individually. In order to perform systematic studies on each of the two effects, we fabricated epitaxial (La$_{1-x}$Pr$_x$)$_6$Ca$_{0.33}$MnO$_3$ (LPCMO) composition spread thin films with the Pr concentration changing continuously across 1 cm to ensure that all the sample segments of interest experience the same processing history. X-ray magnetic circular dichroism (XMCD) and electronic transport measurements indicated that the Curie temperatures and the metal-insulator transition temperatures change continuously from ~ 260 K to ~ 120 K as the Pr concentration is varied from 0 to 0.33. Systematic comparison between experimental data obtained on as-grown and post-annealed samples reveals the role of oxygen in the observed magnetic and electronic transitions. Moreover, changes in the magnetic and electronic properties of LPCMO films under electrolyte-gating have also been observed. A proposed mechanism to explain the effect will be discussed.

3:54PM Q32.00006 Aspects of bulk and surface magnetism of magnetoelectric Fe$_2$TeO$_6$ , SAI MU, KIRILL BELASHCHENKO, Department of Physics and Astronomy, University of Nebraska-Lincoln — Magnetoelastic anti-ferromagnets can be used to implement voltage-controlled magnetism, but materials design for above room-temperature operation is a challenge. Here we focus on the trirutile Fe$_2$TeO$_6$ magnetoelectric and use first-principles calculations to develop several strategies for increasing its Neel temperature $T_N$ above the bulk 210 K value. We find that substitution of larger ions like Zr or Hf for Te increases $T_N$ by increasing the superexchange angles. The compensating O vacancies tend to form bound complexes with such dopants, preserving the electronic band gap. Substitution of N for O is favorable due to the decreased charge-transfer gap.

4:06PM Q32.00007 Designing asymmetric multiferroics with strong magnetoelectric coupling , XUEZENG LU, Northwestern University, HONGJUN XIANG, Fudan University, JAMES RONDINELLI, Northwestern University, MATERIALS THEORY AND DESIGN GROUP TEAM — Multiferroics offer exciting opportunities for electric-field control of magnetism. Single-phase multiferroics suitable for such applications are often exclusive or weakly coupled in bulk. In this talk, we will discuss how superlattices of perovskites can be designed from first principles to achieve high-electric field magnetism and use first-principles calculations to develop several strategies for increasing its Neel temperature $T_N$ above the bulk 210 K value. We find that substitution of larger ions like Zr or Hf for Te increases $T_N$ by increasing the superexchange angles. The compensating O vacancies tend to form bound complexes with such dopants, preserving the electronic band gap. Substitution of N for O is favorable due to the decreased charge-transfer gap.

4:18PM Q32.00008 Magnetoelectric multiferroic superlattices and interfaces: Designing spintronic materials from first principles , ZEILIA ZANOLLI, Forschungszentrum Jülich — The research challenges of the near and far future in electronics focus on the quest for new materials and novel device concepts to achieve low energy consumption, increased reliability and high device density. These can be obtained by designing active elements and interconnects whose operating principle is not (only) based on the electron charge but on the spin degree of freedom of the electron. The nanoscale size of the materials calls for atomicistic and parameter free (ab initio) simulations, which have proven to be crucial in achieving the necessary accuracy and predictive power. Materials which present a coupling between ferroelectricity and magnetism, i.e. magnetoelectric (ME) multiferroics, have been proposed as fundamental building blocks for spintronic devices [1]. However ferroelectricity and magnetism are often exclusive or weakly coupled in bulk. In this talk, we will discuss how superlattices of perovskites can be designed from first principles to achieve strong coupled MO and, hence, control the weak magnetization via an electric field [2]. Most important, advanced epitaxial techniques allow one to actually grow such magnetoelectric superlattices [3]. Another route to optimize spintronic devices is to exploit the unique electronic and transport properties of Carbon-based nanomaterials [4]. The latter present spin diffusion lengths up to 100 μm and high electron velocity. However, a large spin diffusion length comes at the price of small Spin Orbit coupling, which limits the possibility of manipulating electrons via an external applied field. Further, to achieve graphene-based devices one also needs to open its vanishing electronic gap. We use first principle techniques to show that placing graphene on a ME substrate can overcome these limitations by inducing magnetism and opening an electronic band-gap in the hybrid organic-magnetoelectric material.

4:54PM Q32.00009 Electric Field Control of the Ferromagnetic CaRuO$_3$/CaMnO$_3$ Interface
ALEXANDER GRUTTER, BRIAN KIRBY, NIST Center for Neutron Research, NIST, MATTHEW GRAY, CHARLES FLINT, Department of Materials Science and Engineering, Stanford University, YURI SUZUKI, Department of Applied Physics, Stanford University, JULIE BORCHERS, NIST Center for Neutron Research, NIST — Electric field control of magnetism has been recognized as one of the most important goals in nanoscale magnetics research. The most popular routes towards achieving magnetoelectric (ME) coupling have focused on heterostructures incorporating multiferroics or ferroelectrics. Such studies often rely on voltage induced distortion to induce strain in the magnetic film and alter the magnetic properties. However, successful attempts to induce ME coupling through interface effects or interfacial interactions remain relatively rare. The ferromagnetic interface between the antiferromagnetic insulator CaMnO$_3$ and the paramagnetic metal CaRuO$_3$ is a promising candidate for direct magnetization control. This interfacial ferroagnetism is stabilized through the competition between interfacial double exchange and antiferromagnetic superexchange between adjacent Mn$^{4+}$ so that the system is expected to be very sensitive to small changes in interfacial carrier density. Using polarized neutron reflectometry, we have probed the electric field dependence of the interfacial magnetization of CaRuO$_3$/CaMnO$_3$ bilayers deposited on SrTiO$_3$. We find that electric fields of $\pm 8$ kV/m are sufficient to switch the interfaces from largely ferromagnetic to completely antiferromagnetic.

5:06PM Q32.00010 Simultaneous Kerr and Faraday investigations of boundary magnetization and order parameter switching in voltage-controllable exchange bias films
JUNLEI WANG, WILL ECHTENKAMP, MIKE STREET, CHRISTIAN BINEK, University of Nebraska-Lincoln — Magnetoelastic oxides are of great interest for ultra-low power spintronics. A key property for the realization of electrically switchable state variables is the voltage-controlled boundary magnetization in magnetoelastic antiferromagnets. It allows electric switching of an adjacent exchange coupled ferromagnetic layer in the absence of dissipative currents. Previous surface sensitive measurements of boundary magnetization in thin films of the archetypical magnetoelastic antiferromagnet chromia lacked explicit demonstration of the predicted rigid coupling between the bulk antiferromagnetic order parameter and the boundary magnetization. We designed a magneto-optical setup allowing simultaneous measurement of Kerr and Faraday rotation. Our experiments correlate electric field induced bulk magneto-optical effects (non-reciprocal rotation), including the response on switching of the antiferromagnetic order parameter, with the boundary magnetization. Our results suggest that switching of a ferromagnetic film strongly exchange coupled to a magnetoelastic antiferromagnetic ultra-thin film allows switching of the antiferromagnetic order parameter. We investigate the possibility that this switching phenomenon might induce a voltage pulse via a generalized variation of the inverse linear magnetoelectric effect.

5:18PM Q32.00011 Voltage Controlled Exchange Bias in a Cr$_2$O$_3$ based heterostructure
WILL ECHTENKAMP, MIKE STREET, CHRISTIAN BINEK, University of Nebraska — Controlling magnetism by electrical means is a key challenge in the field of spintronics, and electric control of exchange bias is one of the most promising routes to address this challenge. Isoelectric control of exchange bias has been achieved near room temperature using bulk, single crystal, magnetoelastic Cr$_2$O$_3$, which has a voltage controlled net magnetization at the (0001) surface. Voltage control of magnetism in a Cr$_2$O$_3$ thin film system has presented significant challenges. In this study we explore the electric control of exchange bias in an all-thin-film system of decreasing chromia film thickness with significant implications for scalability of ultra-low power memory and logical devices. Cross-sectional HRTEM indicates that grain boundaries in the metallic bottom electrode propagate into the Cr$_2$O$_3$ thin film with detrimental effects on leakage currents. We address this issue via a three-step growth method for the deposition of epitaxial Pd on sapphire. The resulting microstructure of the films is analyzed by reflection high-energy electron diffraction, tunneling electron microscopy and x-ray diffraction.

2:30PM Q33.00001 Potential Utility of Non-Cognitive Constructs in Graduate Admissions
CASEY MILLER, Rochester Inst of Tech — It is becoming clear that the methods employed by many graduate admissions committees need updating. Regarding outcomes, we cannot select students that will actually graduate much better than would a coin toss. Further, the GRE is often misused. For example, the most recent GRE general test data (2006-2007) shows that for US citizens in the physical sciences, a cut-off score of ~64th percentile (700/1550 on old/new test) would eliminate from eligibility: 63% of women vs 42% of men; 76% of all under-represented minorities vs 38% of Asian and 47% of White applicants. Fortunately, Organizational Psychologists have identified and validated several “non-cognitive constructs” for admissions: aspects of personality (conscientiousness); and self-management factors. Some intriguing facts about these parameters: they are measurable with the help of social scientists; they do not show race/ethnicity/gender performance differences; they are orthogonal to cognitive metrics measured by GPA and tests scores. These are proven to enhance both validity and diversity in admissions. My goals for this talk are to overview the non-cognitive constructs with the most potential for being used in physics graduate admissions, and to suggest example admissions protocols.

2:42PM Q33.00002 Beyond detection: nuclear physics with a webcam in an educational setting
ARTHUR PALLONE, Norwich University — Nuclear physics affects our daily lives in such diverse fields from medicine to art. I believe three obstacles — limited time, lack of subject familiarity and thus comfort on the part of educators, and equipment expense — must be overcome to produce a nuclear-educated populace. Educators regularly use webcams to actively engage students in scientific discovery as evidenced by a literature search for the term webcam paired with topics such as astronomy, biology, and physics. Inspired by YouTube videos that demonstrate alpha particle detection by modified webcams, I searched for examples that go beyond simple detection with only one education-oriented result — the determination of the in-air range of alphas using a modified CCD camera. Custom-built, radiation-hardened CMOS detectors exist in high energy physics and for soft x-ray detection. Commercial CMOS cameras are used for direct imaging in electron microscopy. I demonstrate charged-particle spectrometry with a slightly modified CMOS-based webcam. When used with inexpensive sources of radiation and free software, the webcam charged-particle spectrometer presents educators with a simple, low-cost technique to include nuclear physics in science education.

2:54PM Q33.00003 Unveiling Angular Momentum
STEPHEN ROBINSON, Belmont University — Angular momentum is a notoriously difficult concept to grasp. Visualization often requires three-dimensional pictures of vectors pointing in seemingly arbitrary directions. A simple student-run laboratory experiment coupled with intuitive explanations by an instructor can clear up some of the inherent ambiguity of rotational motion. Specifically, the precessional period of a suspended spinning bicycle wheel can be related to the spinning frequency through a simple algebraic expression. An explanation of this precession apart from the concept of angular momentum will be given.

3:06PM Q33.00004 Tracking student progress in a game-like physics learning environment with a Monte Carlo Bayesian knowledge tracing model. GEY-HONG GWEON, HEE-SUN LEE, Univ of California-Santa Cruz, CHAD DORSEY, ROBERT TINKER, WILLIAM FINZER, DANIEL DAMELIN, The Concord Consortium — In tracking student learning in on-line learning systems, the Bayesian knowledge tracing (BKT) model is a popular model. However, the model has well-known problems such as the identifiability problem or the empirical degeneracy problem. Understanding of these problems remain unclear and solutions to them remain subjective. Here, we analyze the log data from an online physics learning program with our new model, a Monte Carlo BKT model. With our new approach, we are able to perform a completely unbiased analysis, which can then be used for classifying student learning patterns and performances. Furthermore, a theoretical analysis of the BKT model and our computational work shed new light on the nature of the aforementioned problems.

3:18PM Q33.00005 Quality of Undergraduate Physics Students’ Written Scientific Arguments: How to Promote Students’ Appropriation of Scientific Discourse in Physics Laboratory Reports? MEHMET AYDENIZ, KUBRA YETER-AYDENIZ, The University of Tennessee, Knoxville — In this study we challenged 18 undergraduate physics students to develop four written scientific arguments across four physics labs: 1) gravity-driven acceleration, 2) conservation of mechanical energy, 3) conservation of linear momentum and 4) Boyle’s law, in a mechanics and thermodynamics laboratory course. We evaluated quality of the written scientific arguments developed by the participants using the Claim, Evidence, Reasoning and Rebuttal (CERR) rubric. The results indicate that while students developed adequate scientific explanations that summarized the findings of their experiments, they experienced unique difficulties in using a persuasive and critical discourse in their written arguments. Students experienced the most difficulty in considering alternative explanations in formulating their written scientific arguments. We elaborate on the implications of these findings for teaching physics laboratories and assessing students’ learning in physics laboratories. We especially focus on the importance of framing in helping students to appropriate the epistemic norms of science in writing scientific arguments.

3:30PM Q33.00006 Comparison of Students’ Ability to Measure Distance using Wavelength in 1D and 2D Settings. GARY WHITE, The George Washington University — When physics students are asked to measure the distance between two fixed locations using a concrete object like a pencil, virtually all respond successfully; however, in some settings, when asked to perform a similar measurement using wavelength as a ruler, there is less success, especially if the students are first asked to note that the “ruler” to be used is not fixed in length (see “Is a Simple Measurement Task a Roadblock to Student Understanding of Wave Phenomena?”, by M. Kryjevskaia, M. Stetzer, and P. Heron, The Physics Teacher 51, 560, (2013) and references therein). I will show some data from introductory classes (algebra- and calculus-based) that replicate this latter result, and also show some interesting features when comparing particular 1D and 2D contexts.

3:42PM Q33.00007 Can you build intuition about quantum mechanics through a game? CHARLES TAHAN, None — We made an app called Meqanic for iOS. To the world, it is a pattern matching game whose rules are very unusual. In reality, it is a functional quantum simulator designed to visualize quantum states and to challenge the user to reconstruct them. The app was released on the Apple App Store in 2014. Here’s what we learned.

3:54PM Q33.00008 Facts and Methods need to be taught GEORGE ZIMMERMAN, Boston University, Emeritus — Current trends in the K-12 educational establishment tend to concentrate on “understanding”, both the “understanding” of how the student thinks and the student’s “understanding” of a concept. In many cases the teaching of facts upon which the student might base his/her “understanding” is neglected. The lack of facts is amplified in our digital age where the exposure to reality is replaced by a virtual experience. This is one of the reasons for the limitations our college students exhibit. Examples in physics and math will be discussed, as well as possible remedies.

4:06PM Q33.00009 Assessing student reasoning in upper-division electricity and magnetism at Oregon State University. JUSTYNA ZWOLAK, Florida International University, CORINNE MANOGUE, Oregon State University — Standardized assessment tests that allow researchers to compare the performance of students under various curricula are highly desirable. There are several research-based conceptual tests that serve as instruments to assess and identify students difficulties in lower-division courses. At the upper-division level, however, assessing students difficulties is a more challenging task. Although several research groups are currently working on such tests, their reliability and validity are still under investigation. We analyze the results of the Colorado Upper-Division Electrostatics diagnostic from Oregon State University and compare it with data from University of Colorado. In particular, we show potential shortcomings in the Oregon State University curriculum regarding separation of variables and boundary conditions. Our work complements and extends the previous findings from the University of Colorado by highlighting important differences in student learning that may be related to the curriculum, illuminating difficulties with the rubric for certain problems and verifying decay in post-test results over time.

Session Q34 DFD: Fluid Dynamics - General 210A - Thomas Solomo, Bucknell University

2:30PM Q34.00001 Time Transient Effects in Heterogeneous Permselective Systems. YOAV GREEN, SINOY BARK, Technion-Israel Institute of Technology — The passage of an electric current through a permselective medium (membranes/nanochannels) under an applied electric field is characterized by the formation of ionic concentration gradients which result in regions of depleted and enriched ionic concentration at opposite ends of the medium, i.e. concentration polarization (CP). In this work, we study the time-transient behavior of the concentration and electric potential distributions in a realistic two dimensional and three layered system (i.e. microchannel-permselective medium-microchannel device). We provide an analytical solution for the concentration under the simplifying assumptions of local-electroneutrality, ideal permselectivity and negligible convection while the electric potential is solved numerically. It is shown that time transient effects occur over the diffusive time scale until steady-state is achieved. The numerical steady state solution is compared with previous analytical results and good quantitative behavior is observed.

2:42PM Q34.00002 Bistability in Inhomogeneity – Effects of Flow Coherent Structures on the Fate of a Bi-stable Reaction ADITYA DHUMUNTARAO, WENBO TANG, Arizona State University — A numerical study on the mixing process of a chemical reaction model between two stable states adjacent to each other in water is presented. The two stable states are equilibriums and are homogenized by fluid stirring and diffusion, and settle into a single stable state. With all other parameters fixed, we find the dependence of the final state on the reacting speed. Interestingly, with the existence of coherent structures, at a range of intermediate speeds, the final state also depends on the flow topology. The exact dependence on flow topology is explored in detail. For this bistable reaction, the elliptic flow structures help maintain scalar concentration and preserve the small impurity. These results attribute to the fundamental connection between the underlying flow topology and the domain transitions of dynamic biogeochemical processes.

1 The authors would like to thank the NSF Grant DMS-1212144.
2:54PM Q34.00003 Convective velocity profiles as a function of applied fields in a magnetic fluid. JUN HUANG, Department of Physics, University of Central Florida, Orlando, TIANSHU LIU, Department of Mechanical and Aerospace Engineering, Western Michigan University, WEILI LUO, Department of Physics, University of Central Florida, Orlando — Natural convection occurs when there is a horizontal temperature gradient across a sample. We have found previously [1] that the convective flow in magnetic fluid responds to applied magnetic fields differently, depending on the relative direction of the gradient of temperature to that of the field. In this work we report the velocity profiles from these flows obtained from optical flow method based on images from temperature-sensitive paint technique. Results from perturbation fields show the direction change of velocity vectors and crossover from two-dimensional to three-dimensional flow for higher fields. The streamline plots indicate formation of local flow structures that could explain the slowing down of the heat transfer when the temperature gradient is anti-parallel to the field gradient. We will discuss the different responses to the applied magnetic fields for two different sample configurations in terms of relative orientation of the temperature and field gradients. [1] Jun Huang and Weili Luo “Heat Transfer Through Convection in a Quasi-One-Dimensional Magnetic Fluid.” Journal of Thermal Analysis and Calorimetry, 113, p449 (2013).

3:06PM Q34.00004 Manifolds and front propagation barriers in advection-reaction-diffusion systems. TOM SOLOMON, Bucknell University — We present experiments on the propagation of reaction fronts in laminar, vortex-dominated flows. The fronts are produced by the excitable Belousov-Zhabotinsky chemical reaction. The flows studied are driven by magnetohydrodynamic forcing techniques and are composed of a single vortex, chains or arrays of vortices, or spatially-disordered flows. In all of these cases, one-way barriers appear that either inhibit front propagation or, in some cases, pin the reactions fronts. We analyze this behavior with a recent theory of burning invariant manifolds (BIMs) that are a generalization of the theory of invariant manifolds developed in the past to characterize chaotic mixing and transport of passive impurities. We demonstrate that the BIMs are responsible for the reaction barriers observed experimentally, and we discuss the applicability of this BIM formalism to a range of flows: time-independent, time-periodic and time-aperiodic.

3:18PM Q34.00005 Tweaks to Turing Patterns, Wavelength Transitions in CDIMA. DELORA GASKINS, EMILY PRUC, MILOS DOLNIK, IRVING EPSTEIN, Brandeis University — Alan Turing predicted that stationary patterns could arise from a uniform state in a system through the processes of reaction and diffusion. Beyond the Turing instability, there exist spatially periodic states with different wavelengths. Pattern transitions, including those transitions to patterns of differing wavelengths are of interest in reaction-diffusion systems including ecological systems with patterned biomass prone to desertification. We study pattern transitions in the chlorine dioxide-iodine-malic acid (CDIMA) system which is the prototypical system for the study of Turing patterns in chemical systems. Additions of selected halides (bromides and chlorides) to the system in its patterned state have led to the observation of up to a five fold increase in wavelength. With the concentration of these halides as bifurcation parameter we observe that these large wavelength patterns are bistable with the uniform steady state. We explore the pattern wavelength selection of this system. Wavelength halving and super lattice structure formation result from transitions between patterns of different wavelengths.

3:30PM Q34.00006 Simplistic Approach to Characterize Sloshing Phenomena using CFD Simulation. MD MAHMUD, Lamar University, RAFIGUL KHAN, Cameron Corporation, QIANG XU, Lamar University — Liquid sloshing in vessels caused by forced acceleration has been the subject of intense investigations for last several decades both by experiments and numerical simulations. Many studies are done to minimize the sloshing induced forces on the vessel internals and some studies focused on different ways to describe the sloshing patterns. Most of the sloshing characterization methods are done using complex mathematical manipulation and more simplified method may be useful for better practical understanding. In this study, simple/easily understandable methods are explored to describe sloshing phenomenon through Computation Fluid Dynamics (CFD) simulation. Several parameters were varied including liquid level/tank length ratio, wave induced vessel motions, motion frequency, amplitudes in various sea state conditions. Parameters such as hydrodynamic force, pressure, moments, turbulent kinetic energy, height of the free surface, vorticity are used to quantify the sloshing intensity. In addition, visual inspections of sloshing motion are done through gas-liquid/oil-water interface fluctuation, streamlines, vector profiles. An equation connecting independent variables to resultant quantities will be established that will be established that will make it easier to describe the sloshing.

3:42PM Q34.00007 Onset of motion of a particle attached to a wall in a linearly sheared fluid flow. ARSHAD KUDROLLI, DAVID SCHEFF, BENJAMIN ALLEN, Department of Physics, Clark University — We examine the onset of motion of particle on a bumpy surface which is exposed to a linear shear fluid flow by means of moving a top surface parallel to the bottom surface on which the particle rests with a prescribed shear rate. This system can be considered as a particularly simple limit of a granular bed exposed to a fluid flow, where forces and torques acting on the particles can be clearly determined. The control parameters available to us include the relative size of the particle to the bumps, the relative size of the particle to the gap thickness, and the flow Reynolds number controlled by the density of the particle and the viscosity of the fluid. Further, the degree of exposure of the particle to the fluid flow is measured by means of adding tracer particles to the fluid and measuring the flow field around the particle. By measuring the critical shear rate at onset of motion as a function of control parameters, we estimate the relative magnitude of forces and torques acting due to drag, lift, and gravitational forces on the particle. We contrast the torque balance and force balance conditions obtained using analytical expressions and numerical simulations with those observed in our experiments.

3:54PM Q34.00008 Kelvin wake pattern and wave resistance at large Froude numbers. MICHAEL BENZAQUEN, ALEXANDRE DARMON, ELIE RAPHAËL, UMR CNRS 7083 Gulliver, ESPCI ParisTech — Recently, M. Rabaud and F. Moisy provided an analysis of airborne observations of ship wakes [1]. Their conclusion that the angle of the wake was no longer constant when varying the hull Froude number Fr drew the attention of the scientific community, as it was in contradiction with Kelvin’s century old theory of ship waves. We perform a mathematical study to understand these surprising observations [2]. Modelling the moving object by a pressure field symmetrical about a point, we analytically show that the angle delimiting the wake region outside which the surface is essentially flat actually remains constant and equal to the Kelvin angle, whereas the angle corresponding to the maximum amplitude of the waves indeed decreases to the Froude number, scaling as 1/Fr for large Froude numbers. To correctly reflect the elongated geometry of boats, we extend our calculations to anisotropic objects and show that the angle corresponding to the maximum amplitude of the waves also depends on the aspect ratio W of the object and scales as $\sqrt{W/Fr}$ for large Froude numbers [3].

Increased swimming efficiency using thickness-varying flexible fins. PETER YEH, YUANDA LI, ALEXANDER ALEKSEEV, Georgia Institute of Technology — We use three dimensional computer simulations to probe the hydrodynamics and deformation of oscillating flexible fins with varying thickness. We model the fin as an elastic rectangular plate undergoing a plunging motion at its leading edge. Since we assume that the thickest part of the fin is very small compared to its other length scales, the plate is modeled as infinitely thin. We simulate the thickness gradient by introducing an appropriate mass gradient and stiffness gradient in the plate. We characterize the steady state swimming velocity, input power, and swimming efficiency as a function of driving frequency and thickness ratio (between the thickest and thinnest part). Our simulations show that the swimming economy, the ratio between the velocity and input power, is increased when the trailing edge is thinner. These findings help to identify the physical mechanisms that allow fish to have high swimming efficiency.

Nozzle Spray Delivery Studies for High-Viscosity Shear-Thinning Fluids. SMITA AGRAWAL, MIKE CLOETER, YUXI ZHANG, JANA RAJAN, JAIME CURTIS-FISK, PUSPENDU DEO, BILLY SMITH, The Dow Chemical Company — Experiments were performed to explore the spray of shear-thinning polymer solutions through various nozzles. High speed images near the nozzle exit, drop size distributions, and spatial mass flow distributions were analyzed with the shear-thinning fluids and deionized water for comparison for seven different nozzles with pressure drops up to 40 psi. The nozzles tested include full cone, hollow cone, and flat fan nozzles. The aim was to identify suitable nozzles that would give droplet sizes in the range of 100-2000 µm for the shear-thinning fluids. It was found in general that the shear-thinning fluids led to formation of ligament like structures whereas sheet perforation was more predominant with deionized water. The spray break up was delayed with the shear-thinning fluids. The spray of the shear-thinning fluids also led to an increase in the median drop size with the extent of increase being dependent on the nozzle type. The spray angle was found to be reduced by around 20° at a distance of 12" when compared to that of distilled water. This study lends fundamental insights into spray characteristics for a wide range of spray nozzles with high viscosity shear-thinning solution as compared to spraying deionized water with the same nozzles.

Designing a Micromixer for Rolling Circle Amplification in Cancer Biomarker Detection. HAYRIYE ALTURAL, Department of Electrical and Computer Engineering, Boston University — Rolling circle amplification (RCA) is an alternative method to the Polymerase Chain Reaction based amplification for point-of-care (POC) diagnosis. In future personalized cancer diagnostic for POC applications, smaller, faster and cheaper methods are needed instead of costly and time-consuming laboratory tests. Microfluidic chips can perform the detection of cancer biomarkers within less analysis time, and provide for improvement in the sensitivity and specificity required for biochemical analysis as well. Rapid mixing is essential in the chips used in cancer diagnostic. The goal of this study is to design a micromixer for rapid RCA-based analysis and develop the assay time in cancer biomarker detection. By combining assays with micromixers, multi-step bioapplications in microfluidic chips may be achieved with minimal external control. Here, simulation results related to the micro mixer are obtained by COMSOL software.

This work was supported by the NSF grant No. DMR-1147430. E.J.T.H. acknowledges partial support by CONACYT, Mexico.

Wednesday, March 4, 2015 2:30PM - 5:30PM – Session Q35 DAMOP: Many-body Localization and Disordered Optical Lattices

Quantum computation using many-body localization. SOONWON CHOI, SARANG GOPALAKRISHNAN, Harvard Univ, NORMAN YAO, University of California Berkeley, MIKHAIL LUKIN, Harvard Univ — Conventional wisdom holds that a stable quantum bit — the building block for a quantum computer — requires an isolated degree of freedom. Here, we explore a new approach to quantum information processing based on many-body localization (MBL). In condensed-matter physics, MBL occurs when many-body interactions confine quantum dynamics to a localized phase. Unlike in other phases of matter, no emergent symmetry is realized in MBL — the quasiparticles are indistinguishable, and density matrices are highly entangled. The presence of MBL is characterized by quantum phase transitions, which can be monitored using a number of unique features of an MBL phase: a lack of thermalization, a locally gapped spectrum, and slow dephasing. We illustrate our main idea using a spin-1 model, and develop the assay time in cancer biomarker detection. By combining assays with micromixers, multi-step bioapplications in microfluidic chips may be achieved with minimal external control. Numerical simulations based on the boundary integral method showed a good agreement with the experimental findings.

Rapid mixing is essential in the chips used in cancer diagnostic. The goal of this study is to design a micromixer for rapid RCA-based analysis and develop the assay time in cancer biomarker detection. By combining assays with micromixers, multi-step bioapplications in microfluidic chips may be achieved with minimal external control. Here, simulation results related to the micro mixer are obtained by COMSOL software.

Traveling Wave Electrophoresis Due To Selective Currents At Electrodes. WILLIAM BOOTH, BOYD EDWARDS, Utah State University — Abstract Using COMSOL finite element modeling software we simulate a 2D traveling-wave electrophoresis (TWE) device for microfluidic chromatography and electrophoretic concentration. A periodic array of four electrodes each produce AC potentials shifted by a quarter-period from one another. This yields an electric wave which travels down the channel. Ions of varying mobilities in solution are carried along with the electric wave or left behind at different rates. We employ a simplified model for asymmetric reactions at the electrodes in order to solve the issue of electric double layer shielding at the electrodes. The selective reactions allow for the formation of diffusion layers of ions which attempt to follow the traveling electric wave. We examine the formation of these diffusion layers and how various system parameters affect motion of various ions through the system. With easy control over the traveling electric wave’s frequency and direction one may employ this method for concentrating or separating bands of electrolytes.

Dynamics of interacting quantum systems near the transition to a many-body localization phase. E. JONATHAN TORRES-HERRERA, Department of Physics, Yeshiva University, New York, NY 10016 and Instituto de Fisica, Benemerita Universidad Autonoma de Puebla, Puebla 72570, Mexico, LEA F. SANTOS, Department of Physics, Yeshiva University, New York, NY 10016, USA — Many-body localization (MBL) has become a very active field of research. The interest in the subject is motivated by indications of the existence of a MBL phase transition and by advances in experiments with optical lattices, which may serve as testbeds for corroborating theoretical predictions. A paradigmatic system that exhibits a MBL phase transition is the one-dimensional Heisenberg model with on-site disorder. Here, we study the dynamics of these systems. In particular, we report the observation of a power-law decay of the fidelity (survival probability) near the MBL transition. We provide numerical evidence suggesting that the exponent of this decay is related to the multifractal structure of the eigenstates through the so-called correlation dimension.

to the inclusion of interatomic interaction effects are also discussed. Hamiltonian, as well as in terms of an effective model consisting of an open quantum system with a small number of degrees of freedom. Preliminary approaches strength; and the distance over which the harmonic trap is displaced. We analyse these results in terms of the population of eigenstates of the post-quench experiment, the pre-quench potential consists of an optical lattice, a harmonic trap, and uncorrelated site disorder (produced, for example, by exposing the

We present results for the post-quench evolution of the density profile as the following parameters are varied: the pre-quench chemical potential; the disorder dependence for sample-to-sample density fluctuations. We, furthermore, examine the equilibration of the system to generalized thermodynamic statistical properties of the single-particle disordered wave functions and analyze their behavior as a function of disorder. In particular, we find a non-monotonic from a thermal environment. We relate several physical observables of the system (including their temporal as well as sample-to sample fluctuations) to the localization-delocalization transition? In particular, does the system thermalize at the transition? In this talk, I will show that certain general considerations involving the behavior of entanglement entropy close to the transition imply that at a continuous many-body localization transition, the system is fully thermalized in the sense that critical eigenstates show ergodic behavior.

Numerical data, obtained by exact diagonalization and time-evolving block decimation methods, suggests a direct transition between the two phases. Our results in terms of an extensive number of emergent local integrals of motion (LIOM), which naturally explains the spectral and dynamical properties of this phase.

PONTE, ZLATKO PAPIC, Perimeter Institute for Theoretical Physics, FRANCOIS HUVENEERS, University of Paris — We consider disordered many-body systems with periodic time-dependent Hamiltonians in one spatial dimension. By studying the properties of the Floquet eigenstates, we identify two distinct phases: (i) a many-body localized (MBL) phase, in which almost all eigenstates have area-law entanglement entropy, and the eigenstate thermalization hypothesis (ETH) is violated, and (ii) a delocalized phase, in which eigenstates have volume-law entanglement and obey the ETH. MBL phase exhibits logarithmic in time growth of entanglement entropy for initial product states, which distinguishes it from the delocalized phase. We propose an effective model of the MBL phase in terms of an extensive number of emergent local integrals of motion (LIOM), which naturally explains the spectral and dynamical properties of this phase. Numerical data, obtained by exact diagonalization and time-evolving block decimation methods, suggests a direct transition between the two phases. Our results show that many-body localization persists for sufficiently weak periodic driving, and that MBL-delocalization transition can be induced by sufficiently strong driving. [1] P. Ponte, Z. Papic, F. Huveneers, D. A. Abanin, arXiv:1410.8518 [2] P. Ponte et al., arXiv:1403.6480

PONTE, Z. Papic, Perimeter Institute for Theoretical Physics, UC Santa Barbara — It has been recently found that sufficiently disordered, isolated quantum systems may fail to thermalize leading to a ‘many-body localized’ phase. In this phase the basic tenet of equilibrium statistical mechanics, namely, the equal likelihood for all microstates with the same energy, breaks down. A fundamental question is what happens as the disorder becomes weaker so that one approaches the localization-delocalization transition? In particular, does the system thermalize at the transition? In this talk, I will show that certain general considerations involving the behavior of entanglement entropy close to the transition imply that at a continuous many-body localization transition, the system is fully thermalized in the sense that critical eigenstates show ergodic behavior.

We theoretically study a quantum quench in a fermionic lattice model that exhibits Anderson localization, in which a disorder potential is suddenly turned on in isolation from a thermal environment. We relate several physical observables of the system (including their temporal as well as sample-to-sample fluctuations) to the statistical properties of the single-particle disordered wave functions and analyze their behavior as a function of disorder. In particular, we find a non-monotonic disorder dependence for sample-to-sample density fluctuations. We, furthermore, examine the equilibration of the system to generalized thermodynamic ensembles. We relate several of the observed features to the crossover from extended to localized behavior.

In our proposed experiment, the pre-quench potential consists of an optical lattice, a harmonic trap, and uncorrelated site disorder (produced, for example, by exposing the atoms to laser speckle). The post-quench potential is the same, but with the centre of the harmonic trap shifted to one side. In the non-interacting case, we present results for the post-quench evolution of the density profile as the following parameters are varied: the pre-quench chemical potential; the disorder strength; and the distance over which the harmonic trap is displaced. We analyze these results in terms of the population of eigenstates of the post-quench Hamiltonian, as well as in terms of an effective model consisting of an open quantum system with a small number of degrees of freedom. Preliminary approaches to the inclusion of interatomic interaction effects are also discussed.
4:18PM Q35.00010 Exact mobility edge in one dimensional quasiperiodic lattices

SRIRAM GANESHAN, University of Maryland, College Park — We present localization properties of a family of nearest neighbor tight binding models with quasiperiodic onsite modulation. We prove that this family is self-dual under a generalized transformation. The self-dual condition for this general model turns out to be a closed form function of model parameters and energy. We numerically verify that this self-dual line is a mobility edge separating the localized and extended states. Our model is a first of its kind example of a nearest neighbor tight binding model with duality symmetry manifesting mobility edge. Our model provides analytical insight into the mobility edge physics of Anderson localization, a feature occurring in three or more dimensions. Quasiperiodic 1D lattices have been realized in ultracold atoms by a standing wave arrangement of two laser beams with mutually incommensurate wave vector. The quasiperiodic potentials we considered in this work can be systematically engineered by a controlled application of series of standing wave laser beams. We present a concrete schematic to realize our results in optical lattices and photonic waveguides.

4:30PM Q35.00011 Phase diagram of bosons trapped in a two-dimensional quasi-periodic lattice

CHAO ZHANG, Homer L. Dodge Department of Physics and Astronomy, The University of Oklahoma, Norman, Oklahoma, 73019, USA, ARGHAVAN SAFAVI-NAINI, JILA and Department of Physics, University of Colorado, 440 UCB, Boulder, CO 80309, USA, BARBARA CAPOGROSSO-SANSONE, Homer L. Dodge Department of Physics and Astronomy, The University of Oklahoma, Norman, Oklahoma, 73019, USA — We report on results of Quantum Monte Carlo simulations for bosons in a two dimensional quasi-periodic optical lattice. We study the ground state phase diagram at unity filling and confirm the existence of three phases: superfluid, Mott insulator, and Bose glass. At lower interaction strength, we find that sizable disorder strength is needed in order to destroy superfluidity in favor of the Bose glass. On the other hand, at large enough interaction, superfluidity is completely destroyed in favor of the Mott insulator (at lower disorder strength) or the Bose glass (at larger disorder strength). At intermediate interactions, the system undergoes an insulator to superfluid transition upon increasing the disorder, while a further increase of disorder strength drives the superfluid to Bose glass phase transition.

4:42PM Q35.00012 Superfluid - Insulator transition for bosons in disordered and quasi-periodic potentials

4:54PM Q35.00013 Characterizing the Bose Glass Phase in Disordered Optical Lattices

ERIC WELCH, ADAM CHALUPA, BYOUNGHAK LEE, Texas State Univ-San Marcos — We present a theoretical study of disordered optical lattices using a mean-field approach to the Bose-Hubbard model. Through analyses on simple disorder configurations, such as binary and ternary random disorder potentials, we find that the phase transition at each lattice site is directly between Mott insulator and superfluid, contrary to the spatially averaged phase, where the transition between Mott insulator and superfluid is through the Bose glass phase. We also discuss the instability of the Bose glass phase in uniformly disordered systems in the terms of spatially averaged pure systems with chemical potential offsets.

5:06PM Q35.00014 Searching for the Bose glass in disordered optical lattices with center-of-mass dynamics

MI YAN, VITO SCAROLA, Virginia Tech — Ultracold atomic gases placed in optical lattices realize distinct many-body phases, including superfluids and Mott insulators. The addition of controlled disorder induces an additional phase, a Bose-Glass phase, that is difficult to unambiguously identify experimentally. We apply the time-dependent Gutzwiller mean-field method to model the transport properties of interacting bosons confined in disordered optical lattices after a sudden displacement of the underlying harmonic trapping potential. The edge superfluid is used to distinguish Bose glass and Mott insulator phases in the center of the trap by different center-of-mass dynamical signatures. We find that the edge superfluid oscillates after collision with the central Mott state. But the edge superfluid only drifts through a central Bose glass with a characteristic linear signature in long-time dynamics. Our work provides a method for experimental identification of the Bose glass in cold atom systems.

5:18PM Q35.00015 Impurity-doped Bose-Einstein Condensates in Multi-mode Cavities

SHAHRIAR SHADKHOO, ROBJIN BRUINSMA, Univ of California - Los Angeles — We study impurities in a Bose-Einstein Condensate (BEC), trapped in a multi-mode cavity which is transversely laser-pumped. The pure system has been proposed to exhibit emergent crystallinity for sufficiently strong pumping, and is therefore described by the quantum version of the fluctuation-induced first order phase transitions. We address the ground state of a quantum impurity coupled to the BEC, away from and near the phase transition. We show that this model system supports various perturbative and non-perturbative excitations around the particle. Light impurities form large and small polarons, whereas solitonic solutions may appear around heavier impurities. The effects of quantum and thermal fluctuations are also investigated.

Wednesday, March 4, 2015 2:30PM - 5:18PM – Session Q36 DPOLY: Focus Session: Self-assembled Block Copolymers and Soft Nanoparticles in Solution II
2:30PM Q36.00001 Topologically Active Soft Materials for Cellular Delivery, CECILIA LEAL, University of Illinois, Urbana-Champaign — Lyotropic lipid liquid crystalline materials having nanostructures that deviate from the conventional flat bilayer arrangement such 2D hexagonally packed lipid tubes and bicontinuous channels have been increasingly recognized as relevant materials for the applications of gene and drug delivery as well as linked to the functionality of cellular organelles comprising lipid-membranes. The simple argument that non-bilayer phases such as bicontinuous cubic having 3D nanostructured interwoven channels have a higher surface-to-volume ratio enabling more point contacts with cell surfaces while having a larger encapsulation power to host drug/gene molecules might be insufficient to completely describe the experimental findings. In this work we will show our recent efforts in stabilizing topologically rich lipid-based materials incorporating drugs or nucleic acids in diverse morphologies such as: i) bulk, ii) dispersed in an aqueous solution, iii) as well as thin film coatings. We utilize a combinatorial technical approach including Small/Wide Transmission/Grazing Incidence X-ray Scattering structural characterization and Cell Culture methods to demonstrate that a judicious choice of lipid materials allows an incredibly rich phase behavior in bulk, solution, and thin film platforms. Furthermore, the systems can be tailored to be adaptive in response to a number of environmental cues. The general finding is that lipid-based materials comprising negative Gaussian curvature membranes are able to most efficiently deliver their cargo across cell membranes by lowering the energy cost of forming a membrane pore. These new materials have great potential in the particular field of responsive and self-healing materials for surface-based and systemic drug/gene delivery devices as well as bioadhesive drug delivery.

3:06PM Q36.00002 Control of Nanostructure of Block Copolymer Particles through Size and Aspect Ratio-controlled Nanoparticle Surfactants, KANG HEE KII, JAE MAN SHIN, HYUNSEUNG YANG, BUMJOON J. KIM, KAIST — Due to the high surface area of nanometer-sized colloidal particles relative to their volume, the interfacial interaction between block copolymer (BCP) chains and surfactant surrounding the emulsion droplet greatly affects the final internal morphology of BCP particles. Convex lens-like functional BCP particle with defect-free porous cylindrical channels was created via precise design of interfacial interactions between Nanoparticle (NP) surfactants and BCPs. The effect of size and aspect ratio of nanorod (NR) surfactants on the shape and internal morphology of BCP particles was systemically investigated using polystyrene-b-poly(4-vinylpyridine), Au NPs, and CuPt NPs. Both size and shape-induced segregation of NPs generated the balanced interfacial interaction between BCPs and water, and this neutralized interface combined with the directionality of solvent generated defect-free, vertically ordered porous channels within the particles. Furthermore, these particles could possess unique optical, chemical and catalytic property by loading various metal nanoparticles into the porous channels.

3:18PM Q36.00003 Multiple Phases of Binary Micellar Crystals Derived from Aqueous Solutions of Charged Block Copolymers, KOOKHEON CHAR, SEYOUNG KIM, Seoul National University, SOO-HYUNG CHOI, Hongik University, SHENG LI, DuPont Central Research and Development — Amphiphilic block copolymer containing weak polyelectrolyte blocks can induce surface-charged block copolymer micelles (BCM) in aqueous media and, at the same time, their charge densities can be finely tuned by pH of the media. Poly(styrene-block-poly(acrylic acid) and poly(styrene-block-poly(4-vinylpyridine) BCMs, whose signs of surface charges are opposite in a relevant pH window, can self-assemble together via electrostatic interactions. By mixing of these charge-tuned BCMs, we obtained binary micellar complexes showing strong crystalline habits and assigned their crystal structures with small-angle neutron scattering and other techniques. We demonstrate multiple phases of binary micellar crystals derived from a set of BCM mixtures of which size and charge ratios are varied. The dependence of the size ratio of individual phases is proven to be different from that of rigid nanoparticles such as inorganic nanocrystals. We believe that this deviation from the hard-matter superlattices is due to the deformability of BCMs based on soft building units. That is to say that BCMs can be readily deformed by good solvent and can modify their structure from spheres to other anisotropic shapes while they assemble together.

3:30PM Q36.00004 Structure and Self-Assembly of Thermoreversible Triblock Copolymer Micelles and Gels, VIVEK PRABHU, NIST, 100 Bureau Drive, Gaithersburg, Maryland, SHRINIVAS VENKATARAMAN, YI YANG, Institute of Bioengineering and Nanotechnology, 31 Biopolis Way, The Nanos Singapore, JIM HEDRICK, IBM Almaden Research Center, San Jose, California — The polymer physics of hierarchical, self-assembled block copolymer solutions remains an active area of research for both advanced materials and biomaterial applications. Of current interest is the development of aliphatic polycarbonates for biomedical applications [1]. For instance, cholesterol-functionalized aliphatic polycarbonate diblock copolymers of polyethylene glycol formed disk and stacked disk-like self-assembled morphologies that are nano-carriers for hydrophobic molecules [2]. The hydrophobic nature of the cholesterol block provides a versatile platform to form complex morphologies in solution. The presentation will describe the phase diagram, structure and dynamics of the micelles and gels formed by well-defined triblock copolymers prepared with cholesterol and fluorene hydrophobic end-groups. The hierarchical structure of these thermoreversible gels as a function of hydrophobic end-group molecular weight was studied by small-angle neutron scattering and static and dynamic light scattering covering nm-to-micron length scales and microsecond-to-second time scales. [1] F. Suriano, O. Coulembier, J.L. Hedrick, P. Dubois, Polym. Chem. 2, 528 (2011). [2] S. Venkataraman, A.L. Lee, H.T. Maune, J.L. Hedrick, V.M. Prabhu, and Y.Y. Yang, Macromolecules 46, 4839 (2013).

3:42PM Q36.00005 BREAK —

3:54PM Q36.00006 Assembly of Block Copolymer-Nanoparticles Conjugates Towards Sub-10-nm Hybrid Ordered Nanostructures, ZHIWEI LIN, PENGTAO LU, CHIH-HAO HSU, STEPHEN CHENG, Univ of Akron — Precisely controlled locations of nanoparticles (NPs) in block copolymers (BCP) and design of BCP/NPs hybrid nanostructures have attracted numerous research interests over the past several decades. In this work, two series of BC-NP conjugates, composed of a hydrophilic fullerene (AC60) NP tethered with a polystyrene-block-poly(ethylene oxide) (PS-b-PEO) at the PS chain end (AC60-b-PS-b-PEO) or the junction point (PS-AC60-b-PEO), were utilized to investigate assemblies of these two series conjugates in the bulk. It was revealed that the incorporation of AC60 NPs induces the nano-phase separation of intrinsically disordered PS-b-PEO with low molecular masses. A variety of ordered nanostructures were found including lamellae, double gyroids and cylinders with domain sizes smaller than 10 nm. The different architectures of these conjugates provided evidence of how the NPs are located and distributed within the nano-phase separated PS-b-PEO, and in turn, demonstrated significant effects of these NPs on the stabilization of these originally unstable structures.

4:06PM Q36.00007 Giant Molecules based on Precisely Functionalized POSS Nano-atoms: Tuning from Crystals to Frank-Kasper and Quasicrystal Phases, STEPHEN Z. CHENG, MINGJUN HUANG, KAN YUE, CHIH-HAO HSU, ZHIWEI LIN, University of Akron — In order to create new functional materials for advanced technologies, precisely control over functionalities and their hierarchical structures as well as orders is vital for obtaining the desired properties. Among all the giant molecules, giant surfactants and giant polyhedra draw us the special focus. Giant surfactants are constructed via tethering polymers tails to the precisely functionalized polyhedral oligomeric silsesquioxane (POSS) or fullerene (C60) molecular nano-particles (MNPs) (so called “nano-atoms”) heads. The heads and tails thus have drastic chemical differences to impart amphiphilicity. Giant polyhedra were created by integrating polyhedron framework with differently functionalized POSS nano-atoms, which further introduce the designed symmetry breaking of positional interactions. A series of novel giant surfactants with multiple polymer tails and giant tetrahedra are utilized as building blocks to construct into hierarchically ordered suprastructure systems ranging from crystals, to Frank-Kasper and quasicrystal phases in the condensed bulk state and thin films. This reveals evidently the interconnections between soft matters and hard matters in sharing their common structures and fundamental knowledge.
4:18PM Q36.00008 Kelvin Problem and Sphericity Metric in the Packing Structures of Soft Particles, SANGWOO LEE, Rensselaer Polytechnic Institute, CHRIS LEIGHTON, FRANK BATES, University of Minnesota — Attractive hard spheres are known to prefer to form close-packing structures. In contrast, soft particles develop non-close-packing structures, e.g., body-centered cubic (BCC), which Kelvin proposed a century ago as the array of densely packed monodisperse soft particles with lowest surface area per unit volume. Remarkably, nearly all packing structures by self-assembled soft particle domains in surfactants, dendrimers, and block polymers are also non-close-packed and appear a set of common symmetries. We found this commonality can be reasoned based on careful observations on the equilibration process occurring in the formation of a Frank-Kasper σ-phase in a poly(1,4-isoprene-b-DL-lactide) diblock polymer specimen. The formation of a low symmetry σ-phase occurred by statistically selective mass-exchanges between particle domains, which resulted in volume multiplicity and this process eventually lowered the surface area per unit volume, i.e., better sphericity of particle domains. This example demonstrates that the isovolume condition in the Kelvin problem, which also was assumed in the Wearn-Phelan (A15) structure is not necessary for the natural systems.

4:30PM Q36.00009 Tunable Encapsulation Structure of Block Copolymer Coated SWNTs in Aqueous Solution, YOUNGYU HAN, SUK-KYUN AHN, ZHE ZHANG, GREGORY S. SMITH, CHANGWOOD DO, Oak Ridge National Laboratory — Nano-sized and shape-tunable molecular building blocks can provide great opportunities for the fabrication of precisely controlled nanostructures. In this work, we have fabricated a molecular building block of single-walled carbon nanotubes (SWNTs) coated by block copolymers whose encapsulation structure can be controlled via temperature or addition of small molecules. The structure and optical property of SWNT-block copolymer have been investigated by small angle neutron scattering (SANS), ultraviolet-visible (UV-vis) spectroscopy, atomic force microscopy (AFM), and molecular dynamics (MD) simulation. The structure of hydrated block copolymer layer surrounding SWNT can be controlled reversibly by varying temperature as well as irreversibly by adding 5-methylsalicylic acid (5MS). Increasing hydrophobicity of the polymers with temperature and strong tendency of 5MS to interact with both block copolymers and π orbitals of SWNTs are likely to be responsible for the significant structural change of the block copolymer encapsulation layer. Our results show an efficient and simple way to fabricate and manipulate carbon-based nano building blocks in aqueous systems with tunable structure.

4:42PM Q36.00010 Pickering emulsion stabilized by highly luminescent carbon nanodots, MINXIANG ZENG, ZHENGDONG CHENG, Texas A&M Univ — Graphene quantum dots as a novel form of nanocarbons have been attracting increasing interest in the past decade owing to their low cytotoxicity, chemical inertness, cost effectiveness, and biocompatibility. However, few work has been done regarding applying carbon-based quantum dots in surfactant synthesis. The diversity and facility of surface chemistry on graphene quantum dots make them strong candidate as novel amphiphilic materials. The tunable assembly of graphene surfactant dots were synthesized and stabilized emulsions of water/oil were investigated. Also, the amphiphilicity of graphene quantum dots is tunable upon various organic functional groups. The ease synthesis of chemically modified graphene quantum dots would enable new opportunities in applying carbon-based materials on solution processing, such as enhanced oil recovery.

4:54PM Q36.00011 Preparation of uniform-sized block copolymer particles by membrane emulsification, JAE-MIN SHIN, KAIST, MINSOO KIM, GI-RA YI, Sungkyunkwan University, BUMJOON KIM, KAIST, SUNGKYUNKWAN UNIVERSITY COLLABORATION — Block copolymer (BCP) particles have been intensively studied due to their unique internal and surface structures, but their applications have been limited mainly due to inherent polydispersity in the particle size arising from the fabrication technique. Here, monodisperse polystyrene-block-polybutadiene (PS-b-PB) BCP particles with unique internal morphology were successfully prepared using Shirasu Porous Glass membrane emulsification. Systematic study on the process parameters in the membrane emulsification, such as membrane pore size, operation pressure, and surfactant concentration was performed to obtain the uniform-sized BCP particles, which generally showed coefficient of variation (CV) value under 10%. Moreover, we successfully extended our method of membrane emulsification to other polystyrene-block-poly(4-vinylpyridine) (PS-b-P4VP) particles, in which P4VP domains were selectively metallized, producing uniform-sized BCP hybrid particles.

5:06PM Q36.00012 Highly luminescent polymer particles driven by thermally reduced graphene quantum dot surfactants, HYUNSEUNG YANG, DONG JIN KANG, KANG HEE KU, HAN-HEE CHO, CHAN HO PARK, JUNHYUK LEE, DOH C. LEE, Korea Advanced Institute of Science and Technology(KAIST), PULICKEL M. AJAYAN, Rice University, BUMJOON J. KIM, Korea Advanced Institute of Science and Technology(KAIST), RICE UNIVERSITY COLLABORATION — We report the use of highly luminescent graphene quantum dot surfactants to drive Pickering emulsions and novel polymer particles. To generate the QGD surfactants, the surface properties of 10 nm sized, non-reduced QGDs (nQGDs), which have strong hydrophilicity, were synthesized and modified in a systematic manner by the thermal reduction of oxygen-containing groups at different treatment times. In stark contrast to the behavior of the nQGDs, thermally reduced QGDs (rQGDs) can produce highly stable Pickering emulsions of oil-in-water systems. To demonstrate the versatility of the rQGD surfactants, they were applied in a mini-emulsion polymerization system that requires nanoparticle surfactants to synthesize submicron-sized polystyrene particles. In addition, the use of rQGD surfactants can be extended to generating block copolymer particles with controlled nanostructures. Particularly, the polymer particles were highly luminescent, a characteristic produced by the highly fluorescent QGD surfactants, which has great potential for various applications, including bioimaging, drug delivery, and optoelectronic devices. To the best of our knowledge, this is the first report in which nanosized QGDs were used as surfactants.

Wednesday, March 4, 2015 2:30PM - 5:30PM
Session Q37 GQI: Focus Session: Semiconductor Qubits - Hybrid Systems and Electrons Floating on Liquid Helium 212A - Steve Lyon, Princeton University

2:30PM Q37.00001 Semiconductor double quantum dot micromaser, YINYU LIU, Department of Physics, Princeton University, Princeton, New Jersey 08544 — The coherent generation of light, from masers to lasers, relies upon the specific structure of the individual emitters that lead to gain. Circuit quantum electrodynamics (cQED) allows strong coupling between microwave photons and a solid-state quantum device. Photon emission has recently been observed from a cavity coupled double quantum dot. Here we demonstrate a two atom maser that is created by coupling two double quantum dots (DQDs) to a microwave cavity. Charge transport through the DQDs results in a gain as large as 1000 in the cavity transmission. With no cavity drive, the free emission spectrum has a linewidth of 34 kHz, which corresponds to a coherence length of 3 km. We verify maser action by comparing the statistics of the emitted microwave field above and below the maser threshold.

1Research was performed in collaboration with Jiri Stehlik, Christopher Eichler, Michael Guillans, Jake Taylor and Jason Petta. We acknowledge support from the Sloan and Packard Foundations, ARO, DARPA, and the NSF.

Magnetic Fields, NODAR SAMKHARADZE, PASQUALE SCARLINO, ALESSANDRO BRUNO, LEONARDO DI CARLO, LIEVEN VANDERSYPEN.

...is the typically poor performance of these resonators in high magnetic fields. We present a novel design of microwave resonators based on NbTiN nanowires, which retain intrinsic quality factors above $10^5$.

...The crossover from the strong coupling regime to the weak coupling regime is observed at 200 mK allowing for the generation of entanglement between spatially separated spin qubits [1].

...Our findings can be used to scale up spin quantum bit architectures.

...We observe a hysteretic evolution of the phase of the microwave signal as a function of the external magnetic field, stemming from the spin valve behavior of the double quantum dot (DQD) maser. In characterizing the gain of this device we find that, in addition to the direct stimulated emission of photons, there is a large contribution from transitions that involve the simultaneous emission of a photon and a phonon. This phonon assisted process controls the lasing transition because it dominates the gain in the region of large population inversion. These theoretical results are compared to experiment. The broadband nature of this phonon assisted process implies that the maser operation is robust against charge noise and fabrication imperfections. In addition, due to the sharp threshold behavior of the lasing transition, this work indicates that the maser can serve as an extremely sensitive probe of the mesoscopic environment of the DQD.

...The main goal in the recent development of hybrid circuit quantum electrodynamics with quantum dots is to find efficient means to couple single spins to cavity photons. So far though, only the coupling of photons to the charge degree of freedom could be demonstrated. Here, we demonstrate a large and coherent spin photon coupling in a cQED architecture at the single spin level. Our scheme relies on the use of a non collinear spin valve which realizes an artificial spin orbit interaction. Thanks to that interaction we are able to couple electronic states which are sensitive to the external magnetic field to cavity photons. We observe a hysteretic evolution of the phase of the microwave signal as a function of the external magnetic field, stemming from the spin valve behavior of the device. This demonstrates an efficient spin/photon coupling and illustrates a new method for manipulating the quantum mechanical spin degree of freedom. Our findings can be used to scale up spin quantum bit architectures.

...the circuit quantum electrodynamics architecture may allow for the generation of entanglement between spatially separated spin qubits [1]. This approach has introduced the challenge of fabricating high quality factor superconducting resonators on multilayered semiconductor substrates. Here we present electric field simulations which show that 30% of the resonator electric field resides in the 675 µm thick Si substrate on which the Si/SiGe heterostructure is grown, 55% resides in the 3.5 µm thick SiGe relaxed buffer and 300 nm of Si$_2$Ge$_{0.7}$ grown above the relaxed buffer, and 15% resides in the remaining Si/SiGe heterostructure. We evaluate the performance of Nb coplanar waveguide resonators fabricated on top of a strained Si/SiGe quantum well at 4.2 K and 10 mK. The tested resonators exhibit a high quality factor despite the presence of an accumulated two-dimensional electron gas beneath the resonator center pin.

4:18PM Q37.00008 Electron Spin Resonance Spectroscopy of Bismuth donors in Silicon using a Parametric Amplifier. YUIMARU KUBO, AUDREY BIENFAIT, MICHAEL STERN, DENIS VION, DANIEL ESTEVE, PATRICE BERTET, Quantumics Group, SPEC, CEA-Saclay, JARRYD PLA, CHEUK CHI LO, JOHN MORTON, London Centre for Nanotechnology, University College London, CHRISTOPH WEIS, THOMAS SCHENKEL, Accelerator and Fusion Research Division, Lawrence Berkeley National Laboratory, MICHAEL THEWALT, Department of Physics, Simon Fraser University — Bismuth donor spins in Silicon are well suited to implement a quantum memory for superconducting qubits [1], owing to their long coherence times and large hyperfine interaction leading to a zero-field splitting of 7.35GHz [2]. We report low-field electron-spin resonance spectroscopies of ensembles of Bismuth spins with a concentration of 5 \(10^{16}\) cm\(^{-3}\) in an isotopically purified 26Si sample at 10 mK, at which the electronic spin is expected to be fully polarized. The spectrometer consists of a superconducting resonator patterned on top of the substrate, with a quality factor of 10\(^7\). The signal coming from the spins is amplified using a Josephson Parametric Amplifier [3].

4:30PM Q37.00009 Entanglement of Two, Three, and Four Quantum Dots in Hybrid Quantum Dot/Plasmonic Systems. MATTHEW OTTEN, Department of Physics, Cornell University, Ithaca, NY and Mathematics and Computer Science Division, Argonne National Laboratory, Argonne, IL, RAMAN SHAH, NORBERT SCHERER, Department of Chemistry and The James Franck Institute, The University of Chicago, IL, MISUN MIN, Mathematics and Computer Science Division, Argonne National Laboratory, Argonne, IL, MATTHEW PELTON, Department of Physics, University of Maryland, Baltimore County, Baltimore, MD, STEPHÉN GRAY, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL — We use cavity quantum electrodynamics to study systems composed of two, three, and four two-state quantum dots in proximity to a plasmonic system such as a metal nanoparticle or an array of metal nanoparticles. We find that significant essential (all dot) entanglement, as measured by concurrence, in the two and four quantum dot cases is possible. At present the three quantum dot case lacks an easily applied measure of entanglement, but multiple bipartite entanglements are demonstrated. Moreover, we show that one can induce entanglement in two and three quantum dot systems starting from the ground state by use of pulsed excitations. These results represent a promising advance for the eventual use of quantum dots, coupled to one another through a dissipative structure such as a plasmonic system, in quantum computation.

4:42PM Q37.00010 Ripplonic Lamb shift for electrons on liquid helium. DENIS KONSTANTINOv, Okinawa Institute of Science and Technology, Japan, KONO KIMITOSHI, RIKEN, Japan, MICHAEL LEA, Royal Holloway, University of London, UK, MARK DUKYMAN, Michigan State University, USA — We resolve a long-standing controversy regarding the electrons on the surface of helium and their coupling to capillary waves, ripplons. The direct two-ripplon coupling to short-wavelength ripplons is strong. It leads to a strong power-law ultraviolet divergence of the shifts of the electron energy levels and to a high energy relaxation rate of the excited states. We use the Bethe-type approach to show that one-ripplon processes, taken to the higher order of the perturbation theory, compensate the divergence of the level shifts. The resulting shifts, which are ripplonic analogs of the Lamb shift, are small. The transition frequencies display characteristic temperature dependence. The calculation of this dependence with no adjustable parameters for transitions between the two lowest subbands of motion along the surface is in good agreement with our experimental data. We also show that one-ripplon processes renormalize the energy relaxation rate, which for highly excited electron states is determined by two-ripplon emission. As a result, energy relaxation is much slower than the lowest-order theory predicts. This is important for applications of electrons on helium in quantum information.

4:54PM Q37.00011 Isolating Electrons on the Surface of Superfluid Helium. MAIKA TAKITA, C. SPENCER NICHOLS, STEPHÉN LYON, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544 — Electrons on helium have been suggested as promising mobile spin qubits. Electrons floating on the surface of superfluid helium can be transferred extremely efficiently in narrow channels with underlying gates. The channels are filled with superfluid helium by capillary action and electrons on the surface can be clocked over a billion pixels in a 3-phase charge coupled device (CCD) without any detectable transfer errors. To use electrons as qubits, we need to reliably obtain a single electron per pixel. We demonstrate an electron turnstile operating across 78 parallel channels for isolating electrons. First, electrons are accumulated over wide 2.3um channels and clocked using the CCD gates into the narrow 0.8um wide turnstile regions. When large packets of electrons are clocked from the wide channels through the narrow regions, the number of electrons per pixel decreases. Using the narrow underlying gates in the turnstile region, the electron packets are repeatedly split. We find a plateau in the electron signal as a function of the applied gate voltages indicating a quantized number of electrons per pixel in each of the 78 parallel channels.

5:06PM Q37.00012 Modeling Strongly Interacting Electrons on Helium Coupled to a Microwave Resonator. GE YANG, University of Chicago, DAVID G. REES, National Chiao Tung University Institute of Physics, LEONIDAS OCOLA, DAVID CZAPLEWSKI, Argonne National Laboratory Center for Nanoscale Materials, GERWIN KOOLSTRA, DAVID MCKAY, DAVID I. SCHUSTER, University of Chicago — Electrons on helium is a unique two-dimensional electron gas system formed at the interface of a quantum liquid (superfluid helium) and vacuum. If single electrons on helium can be isolated, the motional and spin states could form the building blocks for hybrid quantum computing [1,2]. However, to trap single electrons we must start from a 2-dimensional gas of many electrons, which is a strongly interacting classical gas. In our experiment, we trap mesoscopic samples of electrons in a micron-sized trap, at the end of a centimeter-long quarter wavelength microwave cavity, and interrogate the system via the change in the microwave resonance frequency. Here, we will present a simple numeric model that we developed to understand the coupled cavity-electron on helium system in a micron-sized trap, and insights towards building a single electron quantum dot. [1] S. Lyon, Phys. Rev. A. 74, 9 (2006) [2] D.I. Schuster, et al. Phys. Rev. Lett. 105, 040503 (2010)

5:18PM Q37.00013 Entanglement dynamics of capacitively coupled spin qubits in the presence of stray inductance. MICHAEL WOLFE, SHAWN CHISHOLM, JASON KESTNER, University of Maryland, Baltimore County — A pair of spin qubits formed by electrons confined in a pair of double quantum dots can be entangled at distances on the order of microns via a floating metallic top gate that mediates capacitive coupling [1]. The double-well biasing, and hence the coupling through the top gate, can be controlled through voltage leads connected to an arbitrary waveform generator. We theoretically examine how the entanglement dynamics of the system are affected by inductance of the coupling element when the biases are driven at high frequencies. We numerically simulate the von Neumann entropy of the reduced density matrix as a function of time in various parameter regimes. In particular, we examine the behavior when the qubits are driven near the resonance frequency of the coupling element.

were calculated from a quadratic Hamiltonian that had the given ground state, and the probability that the D-Wave Two found the ground state was measured. RST problem was solved up to 100 times and the number of times the ground state energy was found was recorded. This procedure was repeated for square over all spanning trees of G. In the first study, 100 RSTs with random clusters of 8 qubits. Problem input consists of values for the fields H, for n > Hc, there is formed a local condensate of spins with nonzero z-component around the defect. It grows with further decreasing H. We then consider a point defect that corresponds to the change δJ in the coupling constant between n and n+1 spins. For δJ > Hc, there emerges a pair of localized excitations for large H. As H decreases, for some δJ-dependent H > Hc, there is formed a local cloud of spins with nonzero z-component around the defect. It grows with further decreasing H. Remote defects interact very weakly. For small but nonzero temperatures, different defects should be able to align in the opposite directions, leading to nucleation of kinks between them. We study the evolution of the system as H decreases, the possibility of forming kinks, kink tunneling, and the ultimate approach of the system to the ground state. We also study the case of antiferromagnetic defects.

4:30PM Q38.00009 Reexamining classical and quantum models for the D-Wave One processor , TAMEEM ALBASH, University of Southern California, TROELS RONNOW, MATTHIAS TROYER, ETH Zurich, DANIEL LIDAR, University of Southern California — We revisit the evidence for quantum annealing in the D-Wave One device (DW1) based on the study of random Ising instances. We consider measures that account for ground state degeneracy and the distributions of excited states, and present evidence [1] that for these new measures neither SQA nor the classical rotor model correlate perfectly with the DW1 experiments, despite both models correlating very well with the DW1 ground state success probabilities [2,3]. We thus provide evidence that SQA and the classical rotor model, both of which are classically efficient algorithms, do not satisfactorily explain all the DW1 data.

4:42PM Q38.00010 Optimal annealing in p-spin model , KOSTYANTYN KECHEDZHI, QuAIL NASA Ames Research Center Mail Stop 269-3, Moffett Field, CA 94035 and USRA RIACS, 615 National Ave, 94043 Mountain View CA, VADIM SMELYANSKIY, QuAIL NASA Ames Research Center Mail Stop 269-3, Moffett Field, CA 94035 — In this work we are looking to understand the physical mechanisms of quantum speedup in quantum annealing devices. We consider a simplified Hamiltonian that can be addressed analytically using a semiclassical approximation. The Hamiltonian models a typical potential barrier that can trap the system in a metastable state and thus prevent it from reaching the ground state. This situation is common in complex optimization problems such as a spin glass. The model we consider consists of Ising spins forming a fully connected graph with interaction energy proportional to a product of p individual spin operators (p = 2 would correspond to the pair interaction in, for example, a ferromagnet). At p > 2 this model demonstrates 1st order phase transition associated with exponential scaling of the quantum annealing computation time with the system size. We analyze the characteristics of the potential barrier that determine the efficiency of quantum annealing. We also identify the optimal regime for quantum annealing.

4:54PM Q38.00011 Isothermal quantum annealing of the 1D transverse Ising chain , DAVIDE VENTURELLI, VADIM SMELYANSKIY, ALEJANDRO PERDOMO-ORTIZ, NASA Ames Research Center, SERGEI ISAKOV, Google, SERGEY KNYSYH, NASA Ames Research Center, MARK DMYKMAN, Michigan State University — We present a quantum annealing strategy to solve optimization problems that relies on the effect of the external environment on the quantum system (isothermal protocol). We define the isothermal complexity as the scaling of the longest instantaneous relaxation time with the number of qubits in the region after the critical point where the first excitation gap equals to the temperature. We calculate this complexity for the case of 1D transverse field Ising chain coupled to the bosonic environment. We show that the quantum annealing complexity bottleneck is determined by the quantum diffusion limited recombination of the fermions that represent system excitations. We present the analytical results as well as numerical study of the system dynamics and annealing complexity.

5:06PM Q38.00012 Role of Collective Tunneling in a Quantum Annealer , HARTMUT NEVEN, Google, VADIM SMELYANSKIY, NASA, SERGIO BOIXO, ALIREZA SHABANI, SERGEI ISAKOV, Google, MARK DMYKMAN, Michigan State University, VASIL DENCHEV, Google, MOHAMMAD AMIN, ANATOLY SMIRNOV, D-Wave, MASOUD MOHSENI, Google — We show that quantum resources in the D-Wave Two processor enhance the probability to reach the global minimum of an optimization problem. We implemented a series of structural primitives on the device governed by non-convex optimization landscapes consisting of just one global and one false local minima. The quantum adiabatic evolution path over product states connects the initial global minimum with the final false minimum. The final global minimum can only be reached by traversing an energy barrier. Experimentally we found that the D-Wave Two quantum annealer returns the solution that minimizes the energy with consistently higher probability than physically plausible models of the hardware that only employ product states and thermal activation over the barrier and do not allow for multiqubit tunneling transitions. On the contrary open system quantum mechanical models are in very close correspondence with the hardware data without using any fitting parameters. We additionally performed a series of experiments in which we varied the temperature of the chip. We find that the observed correlation between the temperature and success probability is consistent only with quantum models. We also demonstrate that the success probabilities of path integral Monte Carlo are consistently low.

5:18PM Q38.00013 Collective dissipative tunneling during quantum annealing on D-Wave II device1 , VADIM SMELYANSKIY, NASA Ames Research Center, SERGIO BOIXO, ALIREZA SHABANI, SERGEI ISAKOV, Google, MARK DMYKMAN, Michigan State University, VASIL DENCHEV, Google, MOHAMMAD AMIN, ANATOLY SMIRNOV, D-Wave Systems, MASOUD MOHSENI, HARTMUT NEVEN, Google — We develop theory based on NIBA Quantum Master Equation to describe the multiqubit tunneling in the evolution of a programmable quantum annealer. We describe D-Wave II’s performance in the non-convex problems realized by frustrated networks of qubit clusters with strong intra-cluster coupling. We show that the collective effect of the environment is suppressed near the avoided crossing leading to coherent tunneling in that region. In a later stage of the annealing z-magnetizations of qubit clusters increase steeply as a manifestation of the spontaneous symmetry breaking giving rise to a substantial polaronic effect. Transition to the final solution state proceeds via tunneling of one of the qubit clusters as a whole, accompanied by the reorganization of the environmental degrees of freedom and absorption of the residual energy from the qubit system. Transition rate decreases exponentially fast with time after avoided crossing leading to the freezing of the qubit population in the local minimum. We used noise parameters from the single qubit MRT experiments taken on the same device. Model predictions for multiqubit quantum annealing on the above problems are in a very close correspondence with the data collected on D-Wave II device without using any fitting parameters.

5:30PM Q38.00014 Optimising simulated quantum annealing, simulated annealing and a mean-field algorithm to find ground states of Ising spin glasses , DAMIAN S. STEIGER, ETH - Zurich, TROELS F. RØNNOW, ETH - Zurich and Nokia Technologies, Cambridge (UK), MATTHIAS TROYER, ETH - Zurich — We report on benchmarks of finding the ground states of Ising spin glasses on chimera graphs using simulated annealing, simulated quantum annealing and a mean-field quantum annealing algorithm. We analyze the performance of these algorithms by calculating the empirical time-to-solution distribution function and extrapolating their tails, which describe the hard instances. All algorithms show an increasing fat-tail with larger system size, and therefore the average time-to-solution is dominated by the run-times of the hard instances. These tails can be significantly reduced by optimizing the annealing time and temperature. Especially the hard instances of simulated quantum annealing are solved much faster by using a shorter annealing time or higher temperature.

Session Q39 DPOLY: Focus Session: Polymer Nanocomposites - Active Particles and Dynamics
213AB - Jacinta Conrad, University of Houston

1Support from US National Science Foundation (CMMI-0800237, CMMI-106910)

Metal nanoparticles under continuous-wave (cw) optical excitation resonant with their localized surface plasmon exhibit a photothermal effect, efficiently converting the incident light into heat [1] originating from the particle. Gold nanorods (GNRs) dispersed within a transparent material are utilized as such remotely-controlled, nano-sized heaters [2], with heating properties which can be manipulated and monitored by using control of the polarization direction [3, 4] of the excitation and probe light fields. Steady-state average temperatures within a polymer matrix embedded with GNRs undergoing cw photothermal heating are determined in the immediate vicinity of the GNR by observing the rate of driven physical rotation of the nanorods, and simultaneously across the entire sample by using an independent fluorescence method. Comparing these two observations as the concentration of dispersed GNRs is varied reveals the interplay between local and global heating in these polymer nanocomposite materials.

Support from US National Science Foundation (CMMI-0800237, CMMI-106910)

Metal nanoparticles embedded within polymeric systems can be made to act as localized heat sources thereby aiding in-situ polymer processing. This is made possible by the surface plasmon resonance (SPR) mediated photothermal effect of metal (in this case gold) nanoparticles, wherein incident light absorbed by the nanoparticle generates a non-equilibrium electron distribution which subsequently transfers this energy into the surrounding medium, resulting in a temperature increase in the immediate region around the particle. Here we demonstrate this effect in polymer nanocomposite systems, specifically electrosyn polystyrene oxide nanofiber mats, which have been annealed at temperatures above the glass transition. A non-contact temperature measurement technique utilizing embedded fluorophores (perylene) has been used to monitor the average temperature within samples. The effect of annealing methods (conventional and photothermal) and annealing conditions (temperature and time) on the fiber morphology, overall crystallinity, and mechanical properties is discussed. This methodology is further utilized in core-sheath nanofibers to crosslink the core material, which is a pre-cured epoxy thermoset.

1NSF Grant CMMI-1069108

Using computer simulations, we model an array of flexible fibers that are embedded in a lower critical solution temperature (LCST) thermo-responsive gel, which swells at lower temperatures and collapses at higher temperatures. The system is immersed in a solution containing dispersed nanoparticles and this fluid is driven to flow by an imposed shear. When the gel is heated, it collapses to expose the fibers, and thereby, triggers the “catch” process. Namely, the fibers can act like “arms” that wrap around the nanoparticle and bring it from the outer solvent into the gel layer. Moreover, we show that depending on the flexibility and hydrophobicity of the fibers, as well as the imposed shear, we can position the nanoparticles at the desired height within the gel layer. Our approach can be utilized for the detection and separation of components in fluids and for the controlled insertion of nanoparticles within a hydrogel at a particular distance from the gel interface.

Support from US National Science Foundation (CMMI-0829379, CMMI-106910)

Using dissipative particle dynamics (DPD), we model a monolayer formed at the water-oil interface, which comprises stimuli-responsive nanoparticles. The solid core of the nanoparticle encompasses beads arranged in an fcc lattice structure and its surface is uniformly grafted with stimuli-responsive polymer chains. The surface-active nanoparticles adsorb to the interface by characterizing the detailed adsorption kinetics. We explore the microstructure of the monolayer at different surface coverage, including the particle crowding and ordering, and elucidate the response of monolayer to external stimuli. The collective behavior of the particles within the monolayer is demonstrated quantitatively by vector-vector autocorrelation functions. This study provides a fundamental understanding of the interfacial behavior of stimuli-responsive nanoparticles.

3:30PM Q39.00006 Using Gold Nanorods to Probe the Local Environment within Polymer Nanocomposites 1, LAURA CLARKE, SOMSUBHRA MAITY, WEI-CHEN WU, JOSEPH TRACY, JASON BOCHINSKI, North Carolina State University — Active metal nanoparticles embedded within polymeric materials can generate internal photothermal heating [1,2] to enable processing, such as shape memory actuation [3] or thermal annealing [4], with outcomes unrealizable by conventional means. When gold nanorods are utilized [5, 6], their anisotropic-shape provides additional capabilities: using the nanoparticle as an optical probe allows quantitative measurement of the local polymer environment, particularly in the melt phase. Specifically, one surface plasmon excitation can heat while the other monitors particle orientation (altered by rotational diffusion) to make a temperature measurement in the region near the nanorod [6]. We describe results from this approach with examples of the differing local environments within the polymer due to changes in processing.

1Support from US National Science Foundation (CMMI-0829379, CMMI-106910)
3:42PM Q39.00007 Contrasting nanoparticles diffusion in synthetic and biopolymer solutions
SHARMINE ALAM, INDERMEET KOHLI, ASHIS MUKHOPADHYAY, Wayne State Univ — We investigated the dynamics of gold nanospheres (AuNS) and nanorods (AuNR) in synthetic polymer (polyethylene glycol) and biopolymer (bovine serum albumin and mucin) solutions. The variables are particle size and shape, polymer volume fraction, etc. The fluctuation correlation spectroscopy (FCS) was used to measure the translational ($D_T$) and rotational diffusion ($D_R$) of gold nanoparticles. Comparison will be made for the nano-viscosities at different length scales. The nanoparticle dynamics within the mucus gel will be presented.

3:54PM Q39.00008 Embedded Gold Nanorods as Microscale Thermochromic Temperature Sensors
W. JOSHUA KENNEDY, KEITH SLINKER, Universal Technology Corporation, Air Force Research Laboratory (WPAFB), HILMAR KOERNER, GREGORY EHLERT, JEFFERY BAUR, Air Force Research Laboratory (WPAFB) — Gold nanorods (AuNRs) are known to undergo a shape transformation via surface melting at temperatures far below the bulk melting temperature of gold. Because the optical scattering by the AuNRs depends on both particle morphology and the surrounding local dielectric constant, the opto-thermal properties of polymer-AuNR nanocomposites depend strongly on the chemical and mechanical characteristics of the polymer host. We have measured the optical absorption of polymer nanocomposites consisting of AuNRs in a variety of polymer systems as a function of temperature, time, molecular weight, and crosslink density. Our results show that the shape transformation of the AuNRs is not well described by a simple kinetic model, and that multiple contributors to the surface energy play significant roles in the process. We show that the dynamics of the shape transformation may be controlled in a nanocomposite such that the optical absorption spectrum of the material may be used as a local sensor of both temperature history and degree of cure. We demonstrate the usefulness of this technique by measuring (ex situ) the temperature of an internally heated epoxy resin with a lateral spatial resolution of <10 μm.

1Principal Investigator

4:06PM Q39.00009 Supramolecular Nanocomposites Under Confinement: Chiral Optically Active Nanoparticle Assemblies and Beyond
PETER BAI, SUI YANG, WEI BAO, MIQUEL SALMERON, XIANG ZHANG, TING XU, Univ of California - Berkeley — Block copolymer-based supramolecules provide a versatile platform to direct the self-assembly of nanoparticles (NPs) into precisely controlled nanostructures in bulk and thin film geometries. A supramolecule, PS-b-P4VP(PDP), composed of the small molecule 3-pentadecylphenol (PDP) hydrogen bonded to a diblock copolymer, polystyrene-block-poly(4-vinylpyridine) (PS-b-P4VP), was subjected to 2-D volume confinement in cylindrical anodic aluminum oxide (AAO) membrane pores. TEM and 3-D TEM tomography reveal that the morphologies accessible by the supramolecule and supramolecule/NP composites, such as NP clusters, arrays, stacked rings, and single and double helical ribbons, are significantly different from those in the bulk or thin film. Furthermore, single molecule dark field scattering measurements demonstrate strong chiral optical response of single helical Au NP ribbon nanostructures in the near infrared wavelength regime. These studies demonstrate 2-D confinement to be an effective means to tailor self-assembled NP structure within supramolecule nanocomposites and pave the way for this assembly approach to be applied towards next generation chiral metamaterials and optoelectronic devices.

4:18PM Q39.00010 Harnessing Biomimetic Catch Bonds to Create Mechanically Robust Nanoparticle Networks
ANNA BALAZS, University of Pittsburgh — Using computer simulations, we investigate the mechanical properties of a network of polymer-grafted nanoparticles (PGNs) that are interlinked by labile “catch” bonds. In contrast to conventional “slip” bonds, the life time of catch bonds can potentially increase with the application of force (i.e., the rate of rupture can decrease). In effect, the bond becomes stronger under an applied force (if the strain rate is sufficiently high). Subjecting the PGN networks to a tensile deformation, we find that the networks encompassing catch bonds exhibit greater ductility and toughness than the networks interconnected by slip bonds. Moreover, when the applied tensile force is released, the catch bond networks exhibit lower hysteresis and faster relaxation of residual strain than the slip bond networks. The effects of the catch bonds on the mechanical behavior are attributed to transitions between two conformational states, which differ in their sensitivity to force. The findings provide guidelines for creating nanocomposite networks that are highly resistant to mechanical deformation and show rapid strain recovery.

4:54PM Q39.00011 Microwave Induced Welding of Carbon Nanotube-Thermoplastic Interfaces for Enhanced Mechanical Strength of 3D Printed Parts
CHARLES SWEENEY, MICAH GREEN, Texas A&M University, MOHAMMAD SAED, Texas Tech University — Three-dimensional (3D) printed parts produced by fused-filament fabrication of a thermoplastic polymer have become increasingly popular at both the commercial and consumer level. The mechanical integrity of these rapid-prototyped parts however, is severely limited by the interfiller bond strength between adjacent extruded layers. In this report we propose for the first time a method for welding thermoplastic interfaces of 3D printed parts using the extreme heating response of carbon nanotubes (CNTs) to microwave energy. To achieve this, we developed a coaxial printer filament with a pure polylactide (PLA) core and a CNT composite sheath. This produces parts with a thin electrically percolating network of CNTs at the interfaces between adjacent extruded layers. These interfaces are then welded together upon microwave irradiation at 2.45GHz. We investigated the dielectric properties of the PLA/CNT composites at microwave frequencies and performed in-situ microwave thermometry using a forward-looking infrared (FLIR) camera to characterize the heating response of the PLA/CNT composites upon microwave irradiation. Finally, computational models were developed to verify the microwave heating response of the percolating CNT composites according to their measured dielectric properties.

5:06PM Q39.00012 Smart Hybrids made of Polymer Brushes and Gold Nanospheres
STEPHANIE CHRISTAU, FELIX BROSE, TIM MOELLER, RALF KOEHLER, ZULEYHA YENICE, Technical University Berlin, JAN GENZER, North Carolina State University, REGINE VON KLITZING, Technical University Berlin — The modification of surfaces by coating with polymer brushes has attracted much interest in the past few years due to numerous potential applications in material and life science for the development of smart surfaces. They can be used as 3D matrices for the immobilization of nanoparticles, resulting in nanocomposite materials with interesting mechanical, optical, or catalytic properties with tailored functions [1]. Studying the mutual influence of the brush matrix and the attached AuNPs on the structure of the resulting brush/AuNP hybrid will allow fine-tuning of the particle loading and distribution ... this study, responsive poly-(N,N-dimethylamino)ethyl methacrylate (PDMAEMA) and poly-(N-isopropylacrylamide) (PNIPAM) brushes are used as a matrix for the attachment of spherical gold nanoparticles (AuNPs). We find that the uptake and distribution of nanoparticles in polymer brush matrices depends greatly on the brush thickness [2], brush grafting density [3], polymer chemistry, particle surface functionalization and particle size. References: [1] S. Christau et al. Z. Phys. Chem., 2014 [2] S. Christau et al. Polymers, 2014, 6, 1877. [3] S. Christau et al. Langmuir, 2014, 30, 13033

Wednesday, March 4, 2015 2:30PM - 5:30PM – Session Q41 DPOLY DMP: Focus Session: Organic Electronics and Photonics - Structure-Property Relationships
2:30PM Q41.00001 Quantifying Order in Semiconducting Polymers, CHAD SNYDER, NIST - Natl Inst of Stds & Tech — Semiconducting polymers form the basis for the burgeoning flexible electronics industry. However, quantifying their order can be challenging due to the nanophase separation induced by the side chains which are used to impart solubility, their propensity to form mesophases, and their often high levels of paracrystalline disorder. Recent successes in our laboratory in understanding these materials and quantifying their order will be presented.

2:42PM Q41.00002 Multi-scale Modeling Study of poly(3-hexylthiophene) and [6,6]-phenyl-C_61-butyric acid methyl ester Towards Organic Photovoltaic Cell Application, HANJONG YOO, KI CHUL KIM, SEUNG SOON JANG, Georgia Inst of Tech — To date, organic photovoltaic cells have gained attention due to their promising potential in the industry. Its efficiency needs to be improved through constructing better morphologies. There are three morphological quantities that affect the efficiency. The domain size of the electron donor phase has to be small and the interface-to-volume ratio of the blend must be large. The percolation ratio has to be high. To investigate the morphological properties of the active layer systems, the state-of-the-art multi-scale modeling is employed. In this study, P3HT and PCBM blends have been used as our active layer candidates. We have developed our own force field parameters to accurately describe potential energy surfaces in the layer systems. Subsequently, coarse-grained force field for P3HT and PCBM have been developed based on the improved atomistic force field parameters in order to simulate larger systems. The results from coarse-grained models are validated through the comparison with those from the full atomistic models. Using the molecular dynamics simulations, the newly developed coarse-grained models will be further used to study how the crystallinity of P3HT affects the morphological properties in the active layers.

2:54PM Q41.00003 Structure and segmental dynamics in amorphous conjugated polymers, PENGFEI ZHAN, JANNA MARANAS, ENRIQUE GOMEZ, The Pennsylvania State University — Although it is well established that the microstructure strongly affects charge transport in organic semiconductors, the role of fluctuations of the structure on charge mobilities is still not well understood. We have examined the dynamics and structure in amorphous conjugated polymers poly(3-alkylthiophene) (P3ATs) with neutron and x-ray scattering. We measured the segmental dynamics in amorphous P3ATs with quasi-elastic neutron scattering (QENS). The structure of amorphous P3ATs is measured with small-angle neutron scattering (SANS) and grazing incidence X-ray diffraction (GIXRD). Using SANS, we observe phase separation between the backbone and side-chains in all polymer samples for regiorandom P3ATs. Additionally, the analysis of the QENS data shows that longer side-chains relax faster compared with shorter side-chains and our further analysis of the elastic incoherent structure factor (EISF) suggests that the amplitude of proton motion on the thiophene rings increases by a factor of 3 as the side-chain length increases from 6 to 12, demonstrating that longer side-chains lead to enhanced motion of conjugated rings.

3:06PM Q41.00004 Pushing structural limits to reveal fundamental mechanisms of organic solar cell operation, BARRY RAND, Princeton University — Organic-based solar cells are beginning to emerge with the potential to compete with other thin film photovoltaic technologies, with efficiencies of 12% recently demonstrated. Unique to the function of organic photovoltaics are the creation of tightly bound excitons that can only be efficiently separated at a donor/acceptor (D/A) interface capable of providing the necessary energetic driving force for dissociation. The consequences of this are the need for long exciton diffusion lengths and the presence of charge transfer (CT) states, ground state complexes that exist at the D/A interface. We have that charge transfer states are more easily separated into free charge if they are delocalized; an aspect that becomes most feasible for highly ordered systems. I will discuss our recent efforts to template and control film morphology and molecular orientation. These studies allow us to understand the importance of molecular orientation, crystallite size, and crystal phase. We will show templated devices utilizing neat films as well as bulk heterojunctions, with crystallite dimensions spanning from the more standard nano-sized grains to those with highly ordered micron-sized crystalline domains revealing unprecedented thin film exciton diffusion lengths of 100s of nm. In these highly ordered films, owing to significant delocalization, we are able to directly measure photocurrent from multiple CT states, an aspect which has important consequences for the design of more efficient photocurrent generation.

3:42PM Q41.00005 Predicting X-ray absorption spectra of semiconducting polymers for electronic structure and morphology characterization, GREGORY SU, SHRAYESH PATEL, Univ of California - Santa Barbara, C. DAS PEMMARAJU, Lawrence Berkeley National Laboratory, EDWARD KRAMER, Univ of California - Santa Barbara, DAVID PRENDERGAST, Lawrence Berkeley National Laboratory, MICHAEL CHABINCY, Univ of California - Santa Barbara — Core-level X-ray absorption spectroscopy (XAS) reveals important information on the electronic structure of materials and plays a key role in morphology characterization. Semiconducting polymers are the active component in many organic electronics. Their electronic properties are critically linked to device performance, and a proper understanding of semiconducting polymer XAS is crucial. Techniques such as resonant X-ray scattering rely on core-level transitions to gain materials contrast and probe orientational order. However, it is difficult to identify these transitions based on experiments alone, and complementary simulations are required. We show that first-principles calculations can capture the essential features of experimental XAS of semiconducting polymers, and provide insight into which molecular model, such as oligomers or periodic boundary conditions, are best suited for XAS calculations. Simulated XAS can reveal contributions from individual atoms and be used to visualize molecular orbitals. This allows for improved characterization of molecular orientation and scattering analysis. These predictions lay the groundwork for understanding how chemical makeup is linked to electronic structure, and to properly utilize experiments to characterize semiconducting polymers.

3:54PM Q41.00006 Phase Separation and Development of a Scanning Time of Flight Microscope to Study Charge Transport in Structured Organic Semiconductors, SANJOY PAUL, Dept. of Physics, Kent State University, ŠUVAGATA TRIPATHI, Dept. of Chemistry, Kent State University, GAUTAM SINGH, Dept. of Physics, Kent State University, ROBERT TWIEG, Dept. of Chemistry, Kent State University, SATYENDRA KUMAR, BRETT ELLMAN, Dept. of Physics, Kent State University — A scanning time-of-flight microscope (STOFm) has been developed to study charge transport in liquid crystalline organic semiconductors (LCOSCs). The STOFm combines the well-known pulsed laser time-of-flight technique with simultaneous polarized light transmission measurements, both on length scales of ~ 10 µm. In parallel, we have fabricated devices via photopolymerization and phase separation of a monomer/LCOSC mixture. The resulting structure has the LCOSC confined to small regions separated by an insulating polymer. We will discuss fabrication of these systems, as well as their characterization using the STOFm. Finally, we will show results on position-dependent charge transport in various pure LCOSC samples.

4:06PM Q41.00007 ABSTRACT WITHDRAWN
4:18PM Q41.00008 Nanoscale Orientation Effects on Carrier Transport in a Low-Band-Gap Polymer, BAN DONG, BINGYUAN HUANG, AARON TAN, PETER GREEN, University of Michigan — We show that the out-of-plane hole mobility of the low-band-gap polymer poly[4,8-bis-(2-ethylhexyloxy)-benzo[b][1,2-b:4,5-b']dithiophene-2,6-diyl-alt-4-(2-ethylhexyloxy-l-one)thieno-[3,4-b][thiophene-2,6-diyl] (PBDDTTT-C) is film thickness dependence; and this behavior is associated with the morphology. Due to a geometric confinement and to polymer/substrate interactions, the average orientation of the chains in the thinnest films was predominantly parallel to the substrate. In this thickness range, the out-of-plane hole mobilities \( \mu \) were necessarily low and \( \beta \), a measure of the strength of the field dependence of the mobility, was largest. Within the framework of the Gaussian Disorder model, the relative value of \( \beta \) suggests that the largest effect of positional disorder on the carrier transport was most significant in the thinnest films. The hole mobility \( \mu \) increased and depended less on the electric field (\( \beta \) decreases in magnitude) with increasing thickness, due evidently to the increased degree of orientation of the domains with respect to the direction of the field (normal to the interfaces). These findings demonstrated the profound impact of the substrate on the morphology and of the morphology on the charge carrier mobility.

4:30PM Q41.00009 Directed alignment of conjugated polymers for enhanced long-range photocurrent collection, ANTON LI, DAVID BILBY, BAN DONG, JINSANG KIM, PETER GREEN, Univ of Michigan - Ann Arbor — To realize the full potential of conjugated polymers, possessing anisotropic structure and properties, it is often desirable to extend their organization to larger length scales. An epitaxy-directing solvent additive 1,3,5-trichlorobenzene was combined with an off-center spin-casting technique to produce poly(3-hexylthiophene) (P3HT) fibers with uniaxial in-plane alignment on the centimeter scale, which were incorporated into planar heterojunction solar cells with PCBM acceptor. Topography and photocurrent were mapped by photoconductive AFM; in devices with aligned P3HT, local photocurrent measured on fibers was over 4 times higher than in control devices with unaligned polymer. Even at large distances (> 200 \( \mu \)m) between laser spot (carrier excitation) and conductive probe (charge extraction), significant long-range photocurrent was measured in the aligned devices, especially when the separation was oriented parallel to the fiber alignment. Complementary TFE measurements of neat P3HT fibers revealed that the anisotropy of in-plane carrier mobilities was greater than a factor of 3. Together, these findings highlight the importance of conjugated polymer alignment for improving carrier transport and ultimately the performance of solar cells and other devices.

4:42PM Q41.00010 Modifying Photoluminescence Emission from Thin Polymer Films through Local Deformation Zones\(^1\), PO-JUI CHEN, XUAN LONG HO, JONATHON DAVID WHITE, Yuan Ze University, Taiwan — Controlling light extraction is important for applications ranging from LEDs to the weakly emissive thin films used for trace chemical detection. The commercial importance of GaN photodiodes, has resulted in the majority of work being concentrated on increasing light extraction efficiency \( (\eta) \) as GaN’s high refractive index results in up to 96% of light being trapped and reabsorbed. Various methods, such as embedding photonic crystals and surface texturing, have been proposed and employed to improve \( \eta \). Our focus is not on optimizing this quantity but rather on understanding the effect of surface modification on the angular, spatial and spectral characteristics of the emitted radiation. We do this by simulating the effect of a one-dimensional perturbation of thickness on the outputted radiation of a weakly absorbing fluorescent polymer film. While such a perturbation increases the \( \eta \) by a factor of two over a wide range of parameters, the film’s other emission properties are quite sensitive to the surface structure. For instance, adjusting the spatial period, allows the spectral peak of the emission to be tuned over a 10nm range and the output to be localized in specific regions of the film. Adjusting the edge angle, allows one to fine tune the direction of radiation escaping the film. Finally, we will discuss tradeoff between structural parameters involved in optimizing light emission for specific detector geometries.

5:44PM Q41.00011 Photocatalytically Active Oligomeric Graphitic Carbon Nitride: Conformational Flexibility, Electronic Levels, Carrier Localization, VOLKER BLUM, Department of Mechanical Engineering and Materials Science, Duke University, Durham, NC, USA, VINCENT LAU, Max Planck Institute for Solid State Research, Stuttgart, Germany, TAIJO BOTARI, WILLIAM HUHN, Department of Mechanical Engineering and Materials Science, Duke University, Durham, NC, USA, BETTINA V. LOTSCH, Max Planck Institute for Solid State Research, Stuttgart, Germany, and University of Munich (LMU), Munich, Germany — Polymers consisting of bridged heptazine units (often called “graphitic carbon nitride” or “g-C\(_3\)N\(_4\)”) show considerable promise as photocatalysts for solar hydrogen evolution. Recent experimental evidence suggests that oligomeric rather than fully polymerized “g-C\(_3\)N\(_4\)” exhibits intrinsic photocatalytic activity. Using density-functional theory (DFT; van der Waals corrected PBE functional for conformers, hybrid DFT and GW for electronic levels), we show that considerable conformational flexibility exists for the heptazine trimers and tetramers. Analysis of HOMO and LUMO locations as well as trends in photocatalytic activity among heptazine oligomers and polymers reveals the NH\(_2\) groups of the oligomers as potential charge-transfer sites. We show that conformational variations of the oligomers can lead to significant, electrostatically motivated carrier localization effects. We suggest that NH\(_2\) side groups and the intrinsic conformational variations of the oligomeric species lead to the observed enhanced catalytic activity.

5:06PM Q41.00012 ABSTRACT WITHDRAWN –

5:18PM Q41.00013 Development and Studies of Nematic Liquid Crystalline Organic Semiconductors, SALMA BEGUM, SANJOY PAUL, SUVAGATA TRIPATHI, ROBERT TWIEG, BRETT ELLMAN, Kent State Univ - Kent — A huge body of knowledge exists on the creation and alignment of films of nematic liquid crystals (LCs), raising the promise of electronic devices (OFETs, LEDs, etc.) where the structure of the semiconductor is simply controlled with major implications for device parameters. Nematic LCs, however, typically possess low mobilities due to disorder, and are also susceptible to effects due to ionic conduction and screening. We will present material classes of more practical nematic organic semiconductors as well as novel characterization techniques to measure the effects of ionic motion in the nematic phase.

Session Q42 DPOLY DCOMP: Focus Session: Theory and Simulation of Macromolecules I
214B - Lisa Hall, Ohio State University

2:30PM Q42.00001 Computation of the Gibbs free energy difference between polymorphs\(^3\), DANIEL W. SINKOVITS, SANAT K. KUMAR, Columbia University — Semi-crystalline polymers commonly crystallize into several different polymorphs; for example, the alpha and beta phases of isotactic polypropylene. While it is possible to favor particular polymorphs by kinetic means, such as with varying degrees of supercooling or through the use of different solvents in solution casting, we focus on the question of thermodynamic stability; that is, which polymorph possesses the lowest Gibbs free energy for a given temperature and pressure. We implement a version of the Bennett Acceptance Ratio method and find phase diagrams for several polymers. We also demonstrate agreement with phonon analysis in the quasi-harmonic approximation. The advantages and drawbacks of these methods will be discussed.

\(^3\)Multidisciplinary University Research Initiative (MURI)
The development of a molecular theory for dense polymer systems ranks among the most challenging problems in the statistical mechanics of complex matter. These difficulties become compounded when considering the influence of molecular details on thermodynamic properties of thin polymer films, properties deviating from those of the bulk phases. A new theory of dense polymer films is developed as a significant generalization of methods used to devise lattice cluster theory, an extension of Flory-Huggins theory that includes details of monomer structure and short range correlations (neglected in FH theory) and that has successfully been applied to a wide range of polymer systems. The new theory incorporates the essential “transport” constraints of Helfand and focuses on the strict imposition of excluded volume constraints, appropriate to dense polymer systems, rather than the maintenance of chain connectivity as appropriate for lower densities and implemented in self-consistent theories of polymer adsorption at interfaces. The theory is illustrated by presenting examples of the computed density and chain end profiles for free standing films as a function of bulk density, chain length, temperature, and chain semi-flexibility.

2:42PM Q42.00002 New Molecular Theory for Dense, Thin Polymer Films, KARL FREED, James Franck Institute, University of Chicago — The development of a molecular theory for dense polymer systems ranks among the most challenging problems in the statistical mechanics of complex matter. These difficulties become compounded when considering the influence of molecular details on thermodynamic properties of thin polymer films, properties deviating from those of the bulk phases. A new theory of dense polymer films is developed as a significant generalization of methods used to devise lattice cluster theory, an extension of Flory-Huggins theory that includes details of monomer structure and short range correlations (neglected in FH theory) and that has successfully been applied to a wide range of polymer systems. The new theory incorporates the essential “transport” constraints of Helfand and focuses on the strict imposition of excluded volume constraints, appropriate to dense polymer systems, rather than the maintenance of chain connectivity as appropriate for lower densities and implemented in self-consistent theories of polymer adsorption at interfaces. The theory is illustrated by presenting examples of the computed density and chain end profiles for free standing films as a function of bulk density, chain length, temperature, and chain semi-flexibility.

3:06PM Q42.00004 Molecular Dynamics Simulations of Homogeneous Crystallization in Polymer Melt, BIN KONG, Chinese Academy of Sci (CAS) — Molecular mechanisms of homogeneous nucleation and crystal growth from the melt of polyethylene-like polymer were investigated by molecular dynamics simulations. The crystallinity was determined by using the site order parameter method (SOP), which describes order due to the chain folding. Snapshots of the simulations showed evolution of the nucleation and the crystal growth through SOP images clearly. The isothermal crystallization kinetics was determined at different temperatures. The rate of crystallization, $K_c$, and the Avrami exponents, $n$, were determined as a function of temperature. The formation of nuclei was traced to reveal that the nuclei were formed with more ordered cores and less ordered shells. A detailed statistical analysis of the MD snapshots and trajectories suggested conformations of the polymer chains changed smoothly from random coil to chain folded lamella in the crystallization processes.

3:18PM Q42.00005 Molecular dynamics simulation of electromechanical breakdown of polyolefins under a high electric field, MAYANK MISRA, DANIEL SINKOVITS, SANAT KUMAR, Columbia University — Polymers are finding increasing use as dielectric materials. Due to their flexibility, polymer dielectrics in the presence of an electric field may undergo large deformations that result in mechanical instability, which leads to detrimental failures. We study this mechanical instability in polyolefins using all-atom molecular dynamics. We vary the simulated external electric field from 0 to 1200 V/µm to study the effect of high electric fields on polyolefins. At critical conditions, we observe a thinning effect leading to electromechanical breakdown. We also determine the critical voltage using theoretical models and relate it to the thinning effect detected in the molecular dynamics simulations.

3:30PM Q42.00006 Recovery of polymer folding landscapes from univariate time series and its dimensionality reduction using machine learning, JIANG WANG, Department of Physics, University of Illinois at Urbana-Champaign, ANDREW FERGUSON, Materials Science and Engineering, University of Illinois at Urbana-Champaign — The stable conformations and motions of polymers and macromolecules are governed by their underlying free energy surface. By integrating ideas from dynamical systems theory with nonlinear manifold learning, we have developed an approach to recover single-molecule free energy surfaces from univariate time series of a single system observable. Using the method of delays, we expand the time series into a high dimensional phase space in which, by Takens' Theorem, the dynamics are equivalent to those of the molecule in real space. We then apply nonlinear manifold learning algorithm (diffusion maps and nonlinear PCA) to extract a low-dimensional representation of the free energy surface that is diffeomorphic (i.e., a smooth transformation) to that which would have been recovered from a complete knowledge of all system degrees of freedom. We have validated our approach in molecular dynamics simulations of a C$_2$H$_4n$-alkane chain, demonstrating that the free energy surface extracted from the atomistic simulation trajectory is geometrically and topologically equivalent to that recovered from a knowledge of only the head-to-tail distance of the chain. Our approach lays the foundations to extract empirical single-molecule free energy surfaces directly from experimental data.

3:42PM Q42.00007 Flow-Induced Crystallization and Nucleation in Isotactic Polypropylenes, SCOTT MILNER, Pennsylvania State University — Flow-induced crystallization (FIC) occurs when a brief interval of strong flow precedes a temperature quench; many more nuclei form, resulting in a much more fine-grained solid morphology and better material properties. Commercial industrial polymer processing (injection molding) depends on FIC, which has been the subject of many experimental studies, most commonly on isotactic polypropylene (iPP). The prevailing hypothesis is that FIC results from flow aligning chains in the melt, increasing the melt free energy with respect to the crystal, hence acting like undercooling. Here, I combine experimental results for FIC and homogeneous nucleation with theoretical estimates for critical nuclei; to assess the prevailing hypothesis. Current best information supports the view that chain stretching (not just alignment) is necessary and sufficient to explain the observed increase in nucleation rate. Important puzzles remain: 1) shear applied at temperatures well above the equilibrium melting temperature Tm = 187 °C is effective for FIC, and 2) a shear sample may be held for hours above Tm, and still crystallize faster when quenched.

4:18PM Q42.00008 Emergent tilt order in zigzagging polymer liquids, BENJAMIN LOEWE, ANTON SOUSLOV, PAUL M. GOLDBART, Georgia Institute of Technology — We study a liquid of zigzagging two-dimensional polymers that have bending rigidity. These are directed polymers whose conformations lie along the paths followed by pieces on a checkerboard. We observe that in the continuum limit the statistical physics of one such polymer can be described in terms of the Dirac equation for a particle having an imaginary mass. We exploit this observation to study the effect of high electric fields on polyolefins. At critical conditions, we observe a thinning effect leading to electromechanical breakdown. We also determine the critical voltage using theoretical models and relate it to the thinning effect detected in the molecular dynamics simulations.

2This work was supported in part by NSF grant DMR 12 07026.
Simulations are used to study the behavior of two polymers under confinement in a cylindrical tube. We measure the free energy and the end-to-end distance of the tails. The tails do not follow the worm-like chain model and exhibit a stretched conformation. This picture for the adsorbed layer is akin to the de Gennes blob scaling model. For finite tubes, a tail and an adsorbed segment dominate the chain conformation of the adsorbed layer. Also, the mean-square end-to-end distance normal to the substrate is proportional to the normal component of the mean-square end-to-end distance to the substrate. Both quantities agree with Silberberg’s derivation for an ideal chain in the presence of a reflecting wall. We characterized the conformation near the substrate. This is demonstrated in the chain center-of-mass distribution normal to the substrate and the probability of a polymer chain ends to be the closest to the substrate. The finite element approach allows use of arbitrarily shaped systems and is ideal for studying confinement effects. We explore how this framework works on a few examples for polymers confined to a sphere.

Parallel framework for wormlike chains using self consistent field theory. The Gaussian chain model commonly used in Self Consistent Field Theory (SCFT) does not account for confinement effects. The wormlike chain model makes no assumption about the form of confinement and systems such as liquid crystals where alignment effects are critical. The orientations accounted for in a wormlike chain model can correctly capture the physics of these systems. The primary problem with a wormlike chain model is the computational cost of implementation, which far exceeds that of the Gaussian chain model. We address this problem through a parallel SCFT framework for wormlike chains incorporating orientation interactions. The framework can scale to 10s of thousands of processors using an efficient finite element (FE) approach. Orientations are treated with an FE in FE method which overlays a surface orientation mesh on top of the spatial geometry mesh. The finite element approach allows use of arbitrarily shaped systems and is ideal for studying confinement effects. We characterize the adsorbed chains and counted the number of loops and tails. For stiff chains, a tail and an adsorbed segment dominate the chain conformation of the adsorbed layer. Also, the mean-square end-to-end distance normal to the substrate is proportional to the normal component of the mean-square end-to-end distance of the tails. The tails do not follow the worm-like chain model and exhibit a stretched conformation. This picture for the adsorbed layer is akin to the polysaccharide model envisioned by Guiselin. We probe the dynamics of the segments by calculating the layer- resolved intermediate coherent collective dynamics structure factor, \( S(q,t,z) \), for values equivalent to the bond length. The segment dynamics is slower for stiffer chains. In the adsorbed layer, dynamics is slowed down and can be described by two relaxation times.
2:54PM Q43.00003 A hybrid Brownian Dynamics model for yielding, aging, and rejuvenation in deforming polymeric glasses1, WEIZHONG ZOU, RONALD LARSON, Department of Chemical Engineering, University of Michigan, Ann Arbor — We describe the rheology of polymeric glasses by combining a simple constitutive equation for the fast segmental modes, borrowed from Fielding, et al.[1], with Brownian dynamics (BD) simulations of the slow polymer modes. The BD simulations determine the polymeric stress from ensembles of finitely extensible bead-spring chains, where the bead drag coefficient is governed by solutions to the equation for segmental relaxation. Thus the model treats the short glassy segmental mode as “solvent” for the polymer modes. With rubbery modulus for the slow-relaxing polymer modes as one of our model parameters, stress-dependent relaxation, physical aging, flow rejuvenation as well as strain-hardening and recovery can be successfully accounted for in uniaxial extension and steady shear, without the use of an artificial “crinkle factor” used to account for recoil dynamics in previous work [1]. Our simulation results remarkably agree with the experimental data from Lee et al.[2] A comparison between our model and the barrier-hopping theory [3] is also made.

The authors acknowledge discussions with M. E. Cates and S. M. Fielding.

3:06PM Q43.00004 Structural Recovery of Glass-Forming Materials, SINDEE SIMON, Texas Tech University — The glass transition and structural recovery of glass-forming materials, including polymeric, small-molecule, and inorganic network glasses, have been studied in our laboratory using dilatometry and calorimetry. Of particular interest have been the relative timescales to reach equilibrium for different properties, whether the extrapolated liquid line is reached at equilibrium, the ability of phenomenological models to describe the structural recovery process, and behavior at the nanoscale. Recent work using a commercial rapid-scanning calorimeter has extended the time and temperature range to times as short as 0.01 s and temperatures up to 15 K above the nominal Tg. Our results will be discussed in the context of unanswered questions in the field.

3:42PM Q43.00005 Quantitative relaxation dynamics of supercooled liquids from first principles, LIESBETH JANSSEN, Columbia University, PETER MAYER, ThinkEco, Inc., DAVID REICHMAN, Columbia University — Understanding the liquid-to-glass transition remains one of the deepest unsolved problems in condensed matter science. Here we present a novel first-principles framework, referred to as generalized mode-coupling theory (GMCT), which can predict the microscopic dynamics of glass-forming systems with near-quantitative accuracy using only simple static information as input. The theory is based on the well-established standard mode-coupling theory (MCT) of the glass transition, but rigorously incorporates higher-order dynamic density correlations neglected in standard MCT. We demonstrate that GMCT can accurately describe the dynamics of quasi-hard spheres over an unprecedentedly large time and density domain, supporting the view that activated glassy behavior is inherently dynamic in origin. Finally, our schematic results show that GMCT is capable of predicting novel types of glass transitions, including type-A, type-B, and avoided transitions, as well as different types of relaxation-time scaling behaviors. This suggests that GMCT may constitute the first microscopic, first-principles theory that can account for different fragilities in glass-forming materials.

3:54PM Q43.00006 Using s-ensemble to probe glasses formed by cooling and aging, DAVID CHANDLER, University of California, Berkeley, JUAN P. GARRAHAN, University of Nottingham, AARON S. KEYS, University of California, Berkeley — Space-time phase transitions can be studied within the context of large-deviation formalism. Numerical implementations of this formalism to lattice models and atomistic models have demonstrated the existence of such transitions between liquid-like (i.e., dynamically active) and glassy (i.e., dynamically inactive) phases. Here, in terms of an emergent nonequilibrium correlation length and formulas derived from dynamical facilitation theory [1,2], we describe how glassy states obtained from the large-deviation formalism (i.e., the s-ensemble) are equivalent to the glassy states obtained from nonequilibrium cooling protocols. We test the formulas with lattice models, and we demonstrate that the formulas are consistent with nonequilibrium calorimetry experiments [3].

4:06PM Q43.00007 Nontrivial correlation length distinguishes melt from glass in a large-scale atomistic non-equilibrium simulation of a glass transition1, KRANTHI MANDADAPU, Lawrence Berkeley National Laboratory, ALEXANDER HUDSON, DAVID CHANDLER, University of California Berkeley — Dynamical facilitation theory [1,2] predicts the emergence of a non-trivial correlation length from the cooling process that transforms the reversible melt to the irreversible glass [3]. A decrease in cooling rate produces an increase in correlation length, and an increase in correlation length coincides with an increase in stability and aging rate of the glass. Here, we present results from a large-scale non-equilibrium numerical simulation that provide the first demonstration of the emergent nonequilibrium correlation length for an atomistic model. The study also tests the ability of the theory to predict the value of the nonequilibrium length and its corresponding glass transition temperature in terms of material properties and cooling protocols.

4:18PM Q43.00008 Thwarting Crystallization through Hydrogen Bonding in Triazine Molecular Glasses, AUDREY LAVENTURE, University of Montreal, ARMAND SOLDERA, University of Sherbrooke, OLIVIER LEBEL, Royal Military College of Canada, CHRISTIAN PELLERIN, University of Montreal — Using irregular shaped molecules interacting weakly with each other is the most intuitive choice of material properties and cooling protocols. In this presentation, we will show that variable-temperature infrared spectroscopy is a tool of choice to probe the vitreous state of these compounds. We take advantage of the selectivity of this technique to correlate their molecular features to their thermal properties. Quantitative monitoring of hydrogen bonds during vitrification will be addressed.
4:30PM Q43.00009 Theory of the Role of Attractive Forces in the Dynamics of Supercooled Liquids under Isochoric and Isobaric Conditions, ZACHARY E. DELL, KENNETH S. SCHWEIZER, University of Illinois at Urbana-Champaign — Microscopic, force-level, dynamical theories of supercooled liquids (e.g., mode-coupling, elastically cooperative nonlinear Langevin equation (ECNLE)) employ a projection approximation that replaces the real forces by a single effective force determined by the equilibrium pair structure. Recent isochoric simulations by Berthier and Tarjus suggest that under isochoric conditions such theories fail to capture the effect of attractions which might not change structure but can strongly slow relaxation. We propose a hybrid dynamical theory where the ECNLE approach with effective forces is employed for repulsions, and for attractions a new projection-less description is developed where the attractive forces directly enter. The theory is applied to the Lennard-Jones and repulsive WCA fluids in the supercooled regime. Under isochoric conditions, we find qualitative agreement with the recent simulations, where attractive forces are important depending on the specific density. Under isobaric conditions, attractive forces are found to be unimportant due to the combined effect of thermal contraction and increasing effective particle size upon cooling. The new theory exhibits density scaling, and realistically predicts the relaxation time of molecular liquids over 14 decades in time.

4:42PM Q43.00010 Relation of dynamics and local structure to glass-formability in a crystallizable bead-spring polymer model, HONG NGUYEN, TYLER SMITH, ROBERT HOY, Univ of South Florida, NIKOS KARAYIANNIS, Universidad Politecnica de Madrid, Madrid, Spain — We relate the dynamics and local structure of equilibrium and supercooled polymer melts using a model wherein a single parameter (bending stiffness) controls the morphology of the equilibrium, low-temperature crystal. The dynamical slowing down in strongly glassforming systems correlates directly to the increasing presence of microstructural features that are incompatible both with each other and with crystalline order. Systems which more readily crystallize also exhibit rich behavior since their solid-state morphology can be varied from nearly amorphous to highly crystalline by varying their thermal preparation protocol. We tie the “critical” cooling rates, across which this behavior varies, to the lifetimes of structural features such as small crystalline nuclei and stable liquid-like clusters. The role such structures play is analogous to that recently demonstrated for colloidal systems [S. R. Williams, arXiv:0705.0203, 2007], but is considerably enriched both by the dynamical constraints imposed by covalent connectivity and by the presence of a second characteristic length scale (the polymer Kuhn length) controlled by chain bending stiffness.

5:06PM Q43.00012 Dynamic Odd-Even Effects in a Network-Forming Ionic Glass Homologue, KE YANG, Univ of Illinois - Urbana, MADHUSSUDAN TYAGI, NIST Center for Neutron Research, NIST, JEFFREY MOORE, YANG ZHANG, Univ of Illinois - Urbana — Odd-even effects, the non-monicotonic dependency of physical properties on odd/even number of structural units, are widely observed in homologous series of crystalline materials. However, such alternation is not expected for amorphous molecular materials because of periodic packing. Herein, we report the synthesis and characterization of a class of stable network-forming ionic glasses with specific structure to frustrate crystallization. We performed incoherent elastic neutron scattering measurements of the nanosecond mean squared displacement and quasi-elastic neutron scattering measurements of the nanosecond relaxation time. The results indicated that the even-numbered cations showed much slower dynamics than neighboring odd-membered cations, i.e., one-methylene unit structural difference causes an abnormal difference (about five times) in cations’ diffusional dynamics. The observed difference in mobility exists both around Tg and extends to the liquid temperature regime well above Tg. The observed dynamic odd-even effect serves as another intriguing example of significant dynamic differences induced by insignificant structural changes, as is common in glass transition.

5:18PM Q43.00013 Glass formation behavior of an isolated polymer chain, WESTON MERLING, JACK MILESKI, DAVID SIMMONS, University of Akron — A single polymer chain in isolation logically represents the extreme limit of nanocoherence with respect to segmental dynamics and glass formation. Work in thin polymer films suggests that one should expect a large Tg suppression in such systems. However, recent dielectric relaxation measurements of isolated chains of P2VP in a silica substrate found bulk-like Tg in this system, apparently raising questions about the nature of observed nanocoherence effects on the glass transition. Here we describe simulations of glass formation in an isolated polymer chain, both free-floating and deposited on a substrate. Results indicate that free-floating isolated polymer chains exhibit a depression in the dynamic glass transition temperature equivalent to more than 100K in polystyrene units. However, when a chain is deposited on a substrate with sufficiently favorable surface interactions, bulk-like dynamics can be recovered due to competition between the free-surface and adsorbed interface. When this compensation effect is taken account, these results indicate that the observation of bulk-like dynamics in isolated P2VP chains on a silica substrate is consistent with observations of large Tg suppressions in polymer films supported by less attractive substrates.

This material is based upon work supported by the National Science Foundation under Grant No. DMR1310433

Wednesday, March 4, 2015 2:30PM - 5:18PM –
Session Q44 GSNP: Networks and their applications
2:30PM Q44.00001 Topological Phenotypes in Complex Leaf Venation Networks, HENRIK RONEL-LENFTITSCH, JANA LASSER, Max Planck Institute for Dynamics and Self-Organization, DOUGLAS DALY, New York Botanical Garden, ELENI KATIFORI, Max Planck Institute for Dynamics and Self-Organization — The leaves of vascular plants contain highly complex venation networks consisting of recursively nested, hierarchically organized loops. We analyze the topology of the venation of leaves from ca. 200 species belonging to ca. 10 families, defining topological metrics that quantify the hierarchical nestedness of the network cycles. We find that most of the venation variability can be described by two dimensional phenotypic space, where one dimension consists of a linear combination of geometrical metrics and the other dimension of topological, previously uncharacterized metrics. We show how this new topological dimension in the phenotypic space significantly improves identification of leaves from fragments, by calculating a “leaf fingerprint” from the topology and geometry of the higher order venation systems. Further, we present a simple model suggesting that the topological phenotypic traits can be explained by noise effects and variations in the timing of higher order venation developmental events. This work opens the path to (a) new quantitative identification techniques for leaves which go beyond simple geometric traits such as vein density and (b) topological quantification of other planar or almost planar networks such as arterial vasculature in the neocortex and lung tissue.
2:42PM Q44.00002 Nonlinear Dynamics and Control in Microfluidic Networks. DANIEL CASE, Northwestern University, JEAN-REGIS ANGILELLA, Universite de Caen et de Basse Normandie, ADILSON MOTTER, Northwestern University — Researchers currently use abundant external devices (e.g., pumps and computers) to achieve precise flow dynamics in microfluidic systems. Here, I show our use of network concepts and computational methods to design microfluidic systems that do not depend on external devices yet still exhibit a diverse range of flow dynamics. I present an example of a microfluidic channel described by a nonlinear pressure-flow relation and show that complex flow behavior can emerge in systems designed around a terminal. By controlling the flow into and out of this terminal in such a system, we demonstrate the propagation of fluid flow through intermediate channels not directly connected to the controlled terminal. I also show that adding (or removing) flow channels to a system can result in unexpected changes in the total mass flow rate, depending on the network structure of the system. We expect this work to both expand the applicability of microfluidics and promote scaling up of current experiments.

This research was funded by the National Science Foundation.

2:54PM Q44.00003 Independence of bond-level response in disordered networks. CARL GOODRICH, ANDREA LIU, University of Pennsylvania; SIDNEY NAGEL, University of Chicago — Many properties of spring networks, such as bulk elasticity, are a sum of contributions from individual bonds. For disordered systems, these contributions are often characterized by continuous distributions with tails that can be many times larger than the mean. Here, we show that these disordered networks are “stronger” or “weaker” than others. How the network responds to compression, for example, tells little about how it will respond to shear. This leads to a new principle for disordered solids: independence of bond-level response. We will show how this principle can be exploited to construct metamaterials with unique, textured, tunable and often extreme response.

3:06PM Q44.00004 ABSTRACT WITHDRAWN

3:18PM Q44.00005 Phase-space network structure of two-dimensional ±J spin glasses. XIN CAO, Hong Kong Univ of Sci & Tech, FENG WANG, Boston University, YI LONG HAN, Hong Kong Univ of Sci & Tech — We illustrate a complex-network approach to study the phase spaces of spin glasses. By exactly mapping the whole ground-state phase spaces of two-dimensional Edwards-Anderson bimodal (±J) spin glasses into networks, we discovered various phase-space properties via network analysis. The Gaussian connectivity distribution of the phase-space networks demonstrates that both the number of free spins and the visiting frequency of microstates follow Gaussian distributions. The spectra of phase-space networks are Gaussian, which is proved to be exact when the system is infinitely large. The phase-space networks exhibit community structures, which enables us to construct the entropy landscape of the ground state as a network and discover its scale-free property. The phase-space networks exhibit fractal structures, as a result of the rugged entropy landscape. Moreover, we show that the connectivity distribution, the community structure and the fractal structure drastically change at the ferromagnetic-glass transition. These quantitative measurements of the ground states provide new insight into the studies of spin glasses. On the other hand, the phase-space networks establish a new class of complex networks with unique topology.

3:30PM Q44.00006 Thermal Transport in Cayley-Tree Networks. TSAMPIKOS KOTTOS, HUANAN LI, Wesleyan Univ; BORIS SHAPIRO, Technion — In recent years there has been a lot of attention in the microscopic derivation of the laws that dictate heat current in low dimensional systems. However, many real structures are not simple one or two-dimensional structures. Rather, they are characterized by a complex connectivity that can be easily designed and realized in the laboratory. It is therefore necessary to unveil the rules that dictate thermal transport in such networks. In this contribution we present analytical results on heat current and its thermal fluctuations for a Cayley tree consisting of two types of harmonic masses: vertex masses \( M \) where phonon scattering occurs and bond masses \( m \) where phonon propagation take place. The tree is coupled to thermal reservoirs consisting of one-dimensional harmonic chain of masses \( m \). We find that the heat current is a non-monotonic function of the mass-ratio \( \mu = M/m \). In particular, there are cases when the heat current is strictly zero below some critical value \( \mu^* \). The effects of imperfections (disorder) on the heat transport are also discussed and analyzed.

This work was partly sponsored by a NSF DMR-1306984 grant and AFOSR MURI FA9550-14-0037 grant.

3:42PM Q44.00007 Fragmentation of random trees. ZIYA KALAY, Kyoto University, ELLI BEN-NAIM, Los Alamos National Laboratory — We investigate the fragmentation of a random recursive tree by repeated removal of nodes, resulting in a forest of disjoint trees. The initial tree is generated by sequentially attaching new nodes to randomly chosen existing nodes until the tree contains \( N \) nodes. As nodes are removed, one at a time, the tree resolves into an ensemble of disjoint trees, like a forest. We study the statistical properties of trees and nodes in this heterogeneous forest. In the limit \( N \to \infty \), we find that the system is characterized by a single parameter: the fraction of remaining nodes \( m \). We obtain analytically the size density \( \phi \) of trees of size \( s \), which has a power-law tail \( \phi \sim s^{-\alpha} \), with exponent \( \alpha = 1 + 1/m \). Therefore, the tail becomes steeper as further nodes are removed, producing an unusual scaling exponent that increases continuously with time. Furthermore, we investigate the fragment size distribution in a growing tree, where nodes are added as well as removed, and find that the distribution for this case is much narrower.

3:54PM Q44.00008 Cascading Failures and Stochastic Analysis for Mitigation in Spatially-Embedded Random Networks. NOEMI DERZSY, XIN LIN, ALAA MOUSSAWI, BOLESŁAW K. SZYMANSKI, GYORGY KORNISS, Rensselaer Polytechnic Institute — In complex information or infrastructure networks, even small localized disruptions can give rise to congestion, large-scale correlated failures [1], or cascades, — a critical vulnerability of these systems. Recent studies have demonstrated that driven-cascading overload failures in spatial graphs, such as the power grid, are non-self-avoiding, hence predictability is poor and conventional mitigation strategies are largely ineffective [2]. In particular, we have shown that protecting all nodes (or edges) by the same additional capacity (tolerance) can actually lead to larger global failures, i.e., “paying more can result in less”, in terms of robustness [2]. Here, we explore stochastic methods for optimal heterogeneous distribution of resources (node or edge capacities) subject to a fixed total cost. In addition to random geometric graphs, we also investigate cascading failures on the UCTE European electrical power transmission network. [1] A. Bernstein, D. Bienstock, D. Hay, M. Uzunoglu, and G. Zussman, http://arxiv.org/abs/1206.1099 (2011). [2] A. Asztalos, S. Sreenivasan, B.K. Szymanski, and G. Korniss, PLOS One 9(1): e84563 (2014).

4:06PM Q44.00009 Cooperative SIS epidemics can lead to abrupt outbreaks. FAKHTEH GHANBARNE-JAD, Max Planck Institute for the Physics of Complex Systems, Germany, LI CHEN, Robert Koch-Institute, 13353 Berlin, Germany, WEIRAN CAI, Technische Universität Dresden, Germany, PETER GRASSBERGER, Forschungszentrum Jülich, Germany. In this paper, we study spreading of two cooperative SIS epidemics in mean field approximations and also within an agent based framework. Therefore we investigate dynamics on different topologies like Erdos-Renyi networks and regular lattices. We show that cooperativity of two diseases can lead to strongly first order outbreaks, while the dynamics still might present some scaling laws typical for second order phase transitions. We argue how topological network features might be related to this interesting hybrid behaviors.

3:54PM Q44.00008 Cascading Failures and Stochastic Analysis for Mitigation in Spatially-Embedded Random Networks. NOEMI DERZSY, XIN LIN, ALAA MOUSSAWI, BOLESŁAW K. SZYMANSKI, GYORGY KORNISS, Rensselaer Polytechnic Institute — In complex information or infrastructure networks, even small localized disruptions can give rise to congestion, large-scale correlated failures [1], or cascades, — a critical vulnerability of these systems. Recent studies have demonstrated that driven-cascading overload failures in spatial graphs, such as the power grid, are non-self-avoiding, hence predictability is poor and conventional mitigation strategies are largely ineffective [2]. In particular, we have shown that protecting all nodes (or edges) by the same additional capacity (tolerance) can actually lead to larger global failures, i.e., “paying more can result in less”, in terms of robustness [2]. 4:18PM Q44.00010 Eigenvalue Separation in the Laplacian Spectra of Random Geometric Graphs¹, AMY NYBERG, KEVIN E. BASSLER, Department of Physics, University of Houston — The graph Laplacian spectra of networks are important for characterizing both their structural and dynamical properties. As a prototypical example of networks with strong correlations, we investigate the spectra of random geometric graphs (RGGs), which describe networks whose nodes have a random physical location and are connected to other nodes within a threshold distance r. RGGs model transportation grids, wireless networks, and biological processes. The spectrum consists of two parts, a discrete part consisting of a collection of integer valued delta function peaks centered about the average degree and a continuous part that exhibits the phenomenon of eigenvalue separation. We examine the behavior of eigenvalue separation for large network size N in several scaling regimes based on the parameter α such that \( N^{\alpha} = c \) is constant. We identify a transition at \( \alpha = 1/3 \), above which the separated peaks get closer together as N increases and separation is eventually lost, but below which the peaks get farther apart. Also, an approximation for the expected number of separated peaks is given in terms of N and the average degree and we show that the expected number of peaks scales as \( N^{\alpha} \).

4:30PM Q44.00011 Bounds for percolation thresholds on directed and undirected graphs¹, KATHLEEN HAMILTON, LEONID PRYADKO, University of California - Riverside — Percolation theory is an efficient approach to problems with strong disorder, e.g., in quantum or classical interest in graph theory as a tool for describing complex connections in various kinds of networks: social, biological, technological, etc. In particular, percolation on graphs has been used to describe internet stability, spread of contagious diseases and computer viruses; related models describe market crashes and viral spread in social networks. We consider site-dependent percolation on directed and undirected graphs, and present several exact bounds for location of the percolation transition in terms of the eigenvalues of matrices associated with graphs, including the adjacency matrix and the Hashimoto matrix used to enumerate non-backtracking walks. These bounds correspond to a mean field approximation and become asymptotically exact for graphs with no short cycles. We illustrate this convergence numerically by simulating percolation on several families of graphs with different cycle lengths.

4:42PM Q44.00012 Reconstructing Weighted Networks from Dynamics¹, EMILY S.C. CHING, Department of Physics, The Chinese University of Hong Kong, P.Y. LAI, Department of Physics, Graduate Institute of Biophysics, and Center for Complex Systems, National Central University, C.Y. LEUNG, Department of Physics, The Chinese University of Hong Kong — The knowledge of how the different nodes of a network interact or link with one another is crucial for the understanding of the collective behavior and the functionality of the network. We have recently developed a method that can reconstruct both the links and their relative coupling strength of bidirectional weighted networks. Our method requires only measurements of node dynamics as input and is based on a relation between the pseudo-inverse of the matrix of the correlation of the node dynamics and the Laplacian matrix of the weighted network. Using several examples of different dynamics, we demonstrate that our method can accurately reconstruct the connectivity as well as the weights of the links for weighted random and weighted scale-free networks with both linear and nonlinear dynamics.

4:54PM Q44.00013 Identification of core-periphery structure in networks, XIAO ZHANG, TRAVIS MARTIN, MARK NEWSMAN, Univ of Michigan - Ann Arbor — Many networks can be decomposed into a dense core plus an outlying, loosely-connected periphery. In this talk I will describe a method for performing such a decomposition on empirical network data using methods of statistical inference. Our method fits a generative model of core-periphery structure to observed data using a combination of an expectation-maximization algorithm for calculating the parameters of the model and a belief propagation algorithm for calculating the decomposition itself. We find the method to be efficient, scaling easily to networks with a million or more nodes and we test it on a range of networks, including real-world examples as well as computer-generated benchmarks.

5:06PM Q44.00014 Small-World Propensity: A novel statistic to quantify weighted networks, DANIELLE BASSETT, SARAH MULDOON, Univ of Pennsylvania, ERIC BRIDGEFORD, John Hopkins University — Many real-world networks have been shown to display a small-world structure with high local clustering yet short average path length between any two nodes. However, characterization of small-world properties has generally relied on a binarized representation of such graphs, neglecting the important fact that, in reality, many real-world networks are actually composed of weighted connections spanning a wide range of strengths. Hence, we present a generalization of the Watts-Strogatz formalism for weighted networks along with a novel statistic called the Small-World Propensity that quantifies both binary and weighted small-world structure. We apply this measure to real-world brain networks and show that by retaining network weights, we are able to better understand the small-world structure of these systems.

Wednesday, March 4, 2015 2:30PM - 5:30PM – Session Q45 DPOLY: Transport in Charged and Ion-Containing Polymers 216AB - Christopher Soles, National Institute of Standards and Technology

2:30PM Q45.00001 Molecular Dynamics Simulations of Ion Transport and Mechanisms in Polymer Nanocomposites¹, SANTOSH MOGURAMPPELZY, VENKAT GANESAN, Department of Chemical Engineering, University of Texas at Austin, Austin, Texas 78712, United States — Using all atom molecular dynamics and trajectory-extending kinetic Monte Carlo simulations, we study the influence of Al₂O₃ nanoparticles on the transport properties of Li⁺ ions in polymer electrolytes consisting of polyethylene oxide (PEO) melt solvated with LiBF₄ salt. We observe that the nanoparticles have a strong influence on polymer segmental dynamics which in turn correlates with the mobility of Li⁺ ions. Explicitly, polymer segmental relaxation times and Li⁺ ion residence times around polymer were found to increase with the addition of nanoparticles. We also observe that increasing short range repulsive interactions between nanoparticles and polymer membrane leads to increasing polymer dynamics and ion mobility. Overall, our simulation results suggest that nanoparticle induced changes in conformational and dynamic properties of the polymer influences the ion mobilities in polymer electrolytes and suggests possible directions for using such findings to improve the polymer matrix conductivity.

2:42PM Q45.00002 Viscoelastic Nanomechanics of Ionomically Cross-linked Polyelectrolyte Networks

 BIAO HAN, Drexel University, DAEYEON LEE, University of Pennsylvania, LIN HAN, Drexel University

Understanding the mechanics of ionically cross-linked polyelectrolyte networks is critical for applications where nm-to-um mechanics is the key to success. This study aims to reveal the roles of ionic cross-links and fixed charges in the viscoelasticity of layer-by-layer poly(allylamine hydrochloride)/poly(acrylic acid) microfilms, PAH/PAA, a complex held by pH-sensitive amine-carboxyl links. AFM-nanoindentation and force relaxation (tip R=12.5um) was performed at ion strength(IS)=0.01-1.0M, pH=5.5-2.0 (pKa of PAA=2.3). When pH changes from 5.5 to 2.0, the films swell for 4x from densely linked, net neutral state to loosely linked, positively charged one. A >100x reduction in indentation modulus was observed at all IS, suggesting the dominance of decrease in cross-link density. In most states, more than 90% force relaxation was observed, where cross-link breaking/reformation likely dominates viscoelasticity. However, at pH=2.5 and IS=0.01M, when electrical double layer repulsion is important (Debye length≈3nm), relaxation was about 60%, highlighting the contribution of fixed charges. In summary, this study revealed unique viscoelastic behaviors of PAH/PAA due to the pH- and IS-dependent cross-link and charge densities.

2:54PM Q45.00003 Charge transport and glassy dynamics of poly(ethylene oxide)-based single-ion conductors under geometrical confinement

 JAMES RUNT, CIPRIAN IACOB, Materials Science and Engineering, Penn State University

Segmental and local dynamics as well as charge transport are investigated in a series of poly(ethylene oxide)-based single-ion conductors (ionomers) with varying counters (Li+, Na+) confined in unidirectional nanoporou silica membranes. The dynamics are explored over a wide high and low temperature range by broadband dielectric relaxation spectroscopy. Slowing of segmental dynamics and a decrease in dc conductivity (strongly coupled with segmental relaxation) of the confined ionomers are associated with surface effects — resulting from interfacial hydrogen bonding between the host nanoporous silica membrane and the guest ionomers. These effects are significantly reduced or eliminated upon pore surface modification through silanization. The primary transport properties for the confined ionomers decrease by about one decade compared to the bulk ionomer. A model assuming reduced mobility of an adsorbed layer at the pore wall/ionomer interface is shown to provide a quantitative explanation for the decrease in effective transport quantities in non-silanized porous silica membranes. Additionally, the effect of confinement on ion aggregation in ionomers by using X-ray scattering will also be discussed.

3:06PM Q45.00004 High Efficiency Conduction at High Ion Contents in Ionomeric Electrolytes

 KERAN LU, JANNA MARANAS, SCOTT MILNER, Pennsylvania State University

High conductivity solid polymer electrolytes (SPEs) can open the door to safer batteries with greater capacity. Current SPEs have low conductivity, which in part is due to collective motion losses from ions diffusing as clusters. Charge is “carried” by neutral ion clusters (i.e. pairs). Using an ion-only coarse-grained molecular dynamics simulation, we show that a high ion content ionomeric electrolyte shows negligible collective motion losses due to the passing nature of ion transport. Compared to carrying, passing randomizes cation-anion motion beyond their coordination distance, resulting in greater conduction efficiency in agreement with experiments. These results suggest that well designed ion networks at higher ion contents could potentially produce highly-conductive SPEs.

3:18PM Q45.00005 Effect of molecular weight on ion diffusion and transference number in poly(ethylene oxide)

 KSENIA TIMACHOVA, NITASH BALSARA, University of California - Berkeley

Solid polymer electrolytes are of great interest for their potential use in high specific energy, solid-state batteries, however, salt transport properties in polymer electrolytes have not been comprehensively addressed over a wide range of molecular weights. Poly(ethylene oxide) (PEO) has been the most widely studied polymer electrolyte due to its high solvency of lithium salts and low glass transition temperature. This study presents measurements of the transport properties of lithium bis(trifluoromethanesulfonimide)imidide (LiTFSI) in PEO at both the high concentration present in functional electrolytes and in the dilute limit for a large range of PEO molecular weights. Individual diffusion coefficients of the Li+ and TFSI- ions were measured using pulsed-field gradient nuclear magnetic resonance and the cation transfer number was calculated. The diffusion coefficients, concentration number, and conductivity as a function of molecular weight and salt concentration provide a complete set of transport properties for PEO.

3:30PM Q45.00006 ABSTRACT WITHDRAWN

3:42PM Q45.00007 Conductivity Scaling Relationships in Nanostructured Membranes based on Proton Polymerized Ionic Liquids

 GABRIEL SANOJA, University of California, Berkeley, NATHANIEL LYND, University of Texas, Austin, RACHEL SEGALMAN, University of California, Santa Barbara

Nanostructured membranes based on proton polymerized ionic liquids are of great interest for a variety of electrochemical applications. Understanding the relationship between composition, structure, and ionic conductivity for these materials is essential for designing novel membranes with improved properties. In this work, we explore the effect of volume fraction of ionic liquid on conductivity, α using a model system composed of poly(isoprene-block-ethylene oxide-stat-histamine) glycidyl ether diblock copolymers [Pi-b-P(EO-stat-HGE)] and the resulting [Pi-b-P(EO-stat-IL)] obtained after treatment with trifluoroacetic acid. These materials self-assemble into lamellar structures with volume fractions of ionic liquid ranging from 0.50 to 0.90 as demonstrated by SAXS. Pi-b-P(EO-stat-IL) membranes exhibit conductivities up to 4 x 10^{-3} S/cm at room temperature. In addition, Pi-b-P(EO-stat-IL) based membranes have lower water uptake (λ = 8-10) in comparison with most proton conducting membranes reported elsewhere. The low λ in these membranes might translate into a stronger effect of morphology on transport properties.

3:54PM Q45.00008 Electrochemical Doping of poly[2-methoxy-5-(2-ethylhexyloxy)-1,4-phenylenevinylene] using Polymerizable Ionic Liquids

 LAYLA MASRI, JANELLE LEGER, Western Washington University

A number of emerging organic electronic technologies utilize the mixed ionic/electronic conducting character of conjugated polymeric materials. We have developed a process by which fixed doping can be achieved in conjugated polymers through the formation of covalent bonds by replacing the salt used in traditional devices with polymerizable ionic liquids (PILs). It has previously been shown that poly[2-methoxy-5-(3,7-dimethyl-actoxy)-p-phenylenevinylene (MDMO-PPV) doped with alllyltrimethylammonium allylsulfonate (ATOAAS) will produce a fixed junction light-emitting electrochemical cell due to the dissociation and subsequent immobilization of ATOAAS. We will discuss electrochemical doping of poly[2-methoxy-5-(2-ethylhexyloxy)-1,4-phenylenevinylene] (MEH-PPV) films with ATOAAS. We characterize these films via UV-Vis and cyclic voltammetry with emphasis on studying the formation of new mid-band gap energies associated with the color change observed when the film is electrochemically doped. We will discuss the mechanism for the formation of these mid-band gap energies and the applications of these films to developing technologies.
4:06PM Q45.00009 Structure and dynamics of single-ion conducting P(STFSI)-ran-P(EGMA) copolymer electrolytes, JENNIFER SCHAEFER, CHRISTOPHER SOLES, National Institute of Standards and Technology — Recently, PEO-based copolymers containing the lithiated STFSI monomer have been investigated for use as single-ion conducting electrolytes in lithium batteries. Single-ion conducting electrolytes eliminate ion concentration gradients that diminish cell performance. The low ionic conductivity of these electrolytes has limited their applicability thus far, but electrolytes based on the STFSI monomer have been shown to have sufficient conductivity to support cell operation at moderate temperatures. We will report on the characterization of the morphology and dynamics of P(STFSI)-ran-P(EGMA) copolymer electrolytes as a function of the monomer ratio (ion loading) and length of the polyethylene glycol comb. Copolymers containing sufficiently short PEG combs remain amorphous at ambient temperatures over a range of STFSI content.

4:18PM Q45.00010 Tuning the ionic conductivity in protic polymerized ionic liquid homo, random, and block copolymers, CHRISTOPHER EVANS, RACHEL SEGALMAN, University of California-Santa Barbara, UCSB TEAM — Proton conducting membranes are of interest for a number of energy applications including use in fuel cells and artificial photosynthesis systems. We have synthesized a new class of protic polymerized ionic liquids (PILs) based on imidazolium cations which exhibit high conductivities in the solid state. In contrast to previous imidazolium based PILs, the ionic liquid moity is attached via a carbon on the imidazole thus leaving the two nitrogens available to act as a proton donor/acceptor. The conductivities of these protic PILs, measured by dielectric spectroscopy, are orders of magnitude higher than the analogous non-protic PILs at a given distance above (Tg). These high conductivities are the result of a strong contribution from proton motion. A series of random and block copolymers containing the polymerized ionic liquid monomer and a non-ionic comonomer were also investigated to determine the role of comonomer on the conductivity of these materials. It was found that methyl acrylate, which has a low glass transition temperature and high dielectric constant, can result in improvements of ionic conductivity. Studies using solid state NMR are underway to understand the role of protons and mobile anions in controlling the overall conductivity of these materials.

4:30PM Q45.00011 Morphology-Conductivity Relationship in Salt-containing Diblock Copolymer/Homopolymer Mixtures, MATTHEW IRWIN, ROBERT HICKEY, TIMOTHY P. LODGE, Univ of Minn - Minneapolis — In order to unravel how ionic conductivity is affected by material morphology, a model system of polystyrene (PS), poly(ethylene oxide) (PEO), PS-block-PEO, and lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) was fabricated and characterized. These pseudo-ternary polymer blends, in which the lithium salt associates nearly exclusively with the ethylene oxide, have the potential to form a variety of morphologies such as lamellae and the three-dimensionally interpenetrating bicontinuous microemulsion by simply changing blend composition. Similar to what has been observed in salt-containing diblock copolymers, both the order-disorder transition (ODT) temperature and the ODT temperature window of these blends increase sharply with salt loading. By modulating the relative volume fraction of the homopolymers in the blend, it was shown that although less than order-of-magnitude changes in the domain spacing do not appreciably affect ion conductivity, some morphologies can result in significantly better conductivity than others. These results outline what factors matter most when designing polymer electrolytes for applications such as rechargeable lithium metal batteries and proton exchange membranes.

4:42PM Q45.00012 The Effect of Structural Modifications on Ionic Conductivity in Newly-Designed Polyester Electrolytes, DANIELLE PESKO, Univ of California - Berkeley, YUKI JUNG, GEOFF COATES, Cornell University, NITASH BALSARA, Univ of California - Berkeley — Gaining a fundamental understanding of the relationship between molecular structure and ionic conductivity of polymer electrolytes is an essential step toward designing next generation materials for battery applications. In this study, we use a systematic set of newly-designed polymers with varying side-chain lengths and oxygen functional groups to elucidate the effects of structural modifications on the conductive properties of the corresponding electrolytes. Mixtures of polyesters and lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) were characterized using ac impedance spectroscopy to measure the ionic conductivity at various temperatures and salt concentrations. The relative conductivities of these electrolytes in the dilute limit are directly comparable to results of molecular dynamics simulations performed using the same polymers. The simulations correspond well with the experimental results, and provide molecular level insight about the solvation environment of the lithium ions and how the ions transport through these polyesters.

4:54PM Q45.00013 Membranes with artificial free-volume enabled by block copolymer self-assembly, NIKOS PETZETAKIS, NITASH BALSARA, UC Berkeley — There has been considerable success towards the development of polymeric porous materials with pore sizes in the meso- or macro-scale regime. However, manipulation of polymer porosity in the micro-scale (pore diameter < 2nm) remains challenging. Previous studies relied on changes in the chemical composition and structure of the polymeric material in order to achieve the formation of larger fractional free volume. In the present report we demonstrate a methodology with which we can force a polymeric material away from structural equilibrium and then kinetically arrest it at this -out of equilibrium- state, ultimately, enabling the creation of a polymeric material with artificial free volume. Our methodology is based on block copolymer/homopolymer binary blend self-assembly where the membranes are made by first creating a heterogeneous film of a ABA type triblock copolymer containing a soluble homopolymer, B. Then in a second washing step the soluble homopolymer chains are dissolved away. The volume fraction of the composite membrane occupied initially by chains of homopolymer B is now converted to extra free volume in the microphase of block B. Key role of block A is to kinetically arrest the structure of the polymer during and after the washing step.

5:06PM Q45.00014 Noise and Ionic Conductivity in Glass Nanochannels1, BENJAMIN WIENER, Brown University, ALESSANDRO SIRIA, LYDÉRIC BOQUET, Ecole Normale Supérieure, Paris. DEREK STEIN, Brown University — Ion transport in nanochannels is relevant to processes in biology and has technological applications like batteries, fuel cells, and water desalination. We report experimental studies of the ionic conductance and noise characteristics of pulled glass capillaries with openings on the order of 50 nanometers. We employed an ac measurement technique to probe very low frequency fluctuations in the conductivity and to test a theory attributing these to chemical fluctuations in the surface charge density of the glass. We also investigate Hooge’s empirical description of the noise power spectrum and its relationship to current rectification observed in nanochannels in the surface dominated “Dukhin” regime. Finally, we test the effects of anion and cation mobility on the direction and magnitude of the observed rectification.

5:18PM Q45.00015 Structure of Nafion Thin Films on Gold1, ADAM WEBER, AHMET KUSOGLU, ALEXANDER HEXEMER, Lawrence Berkeley National Laboratory — Nafion is the prototypical ionomer in electrochemical energy devices due to its good ionic conductivity and permeselectivity. In most devices, ionomers are in contact with precious metal catalysts. When confined to nanometer-thick “thin” films (10 to 100 nm), Nafion’s morphology and associated transport properties deviate from the bulk. These changes are a function of the substrate and film thickness. In this talk, results from a systematic study of Nafion thin-film morphology on gold substrate using Grazing-incidence X-Ray Scattering (GISAXS) will be presented. GISAXS experiments carried out for a range of incident angles combined with the simulations of the electron density are used to demonstrate that the collected patterns are real and show an anisotropic long-range structural order that is strongest when the film thickness is around 50 nm and weakens for thicker and thinner films. Such ordering is not readily discernible on other substrates like carbon, nor with non-phase separated polymers like polystyrene. Results presented herein provide new insights into the key role of substrate/film interactions in inducing ordered structure in Nafion, which has implications for understanding ionomers interacting with various organic and inorganic materials in electrochemical devices.

1Supported by U. S. Department of Energy under contract number DE-AC02-05CH11231.
2:30PM Q46.00001 Dynamic force measurement of rearrangements in a 2D network of droplets, SOLOMON BARKLEY, MATILDA BACKHOLM, KARI DALNOKI-VERESS, McMaster University — The interaction between two liquid droplets in an immiscible liquid is well understood. However, the emulsions relevant to biological and industrial processes involve high concentrations of these droplets, and multi-body effects cannot be ignored. As droplets rearrange in response to a disturbance, the importance of individual pair-wise interactions between droplets changes with the geometry of neighbours. Here we report on an experimental setup consisting of a two-dimensional network of monodisperse droplets stabilized with a surfactant. The system is studied with micropipettes, which permits direct measurement of forces along with simultaneous imaging of the droplet network. One micropipette is used to apply a tensile or compressive force to the droplet cluster, while a second pipette acts as a force-transducing cantilever, deflecting in response to rearrangements of the droplets.

2:42PM Q46.00002 Precise measurements of droplet-droplet contact forces in quasi-2D emulsions, JANNA LOWENSOHN, CARLOS ORELLANA, ERIC WEEKS, Emory University — We use microscopy to visualize a quasi-2D oil-in-water emulsion confined between two parallel slides. We then use the droplet shapes to infer the forces they exert on each other. To calibrate our force law, we set up an emulsion in a tilted sample chamber so that the droplets feel a known buoyant force. By correlating the stress of the droplets and the strength of contacts with the buoyant forces, we validate our empirical force law. We improve upon prior work in our lab by using a high-resolution camera to image each droplet multiple times, thus providing sub-pixel resolution and reducing the noise. Our new technique identifies contact forces with only a 1% uncertainty, five times better than prior work. We demonstrate the utility of our technique by examining the normal modes of the droplet contact network in our samples.

2:54PM Q46.00003 Fluidization of a bubble raft under oscillatory compression, KLEBERT FEITOSA, NICHOLAS HAGANS, CHRISTINE O’DEA, James Madison University — Fluidization of two-dimensional foam is characterized by rearrangement events known as T1-events where clusters of four bubbles switch neighbors. We study rearrangement events in a bubble raft subject to periodic compression by an oscillating boundary. As the amplitude of oscillation increases, T1-events transition from being mostly reversible (elastic regime), to being increasingly irreversible (plastic regime). In addition, T1-events are found to occur most frequently right before the direction of oscillation reverses, where the stress is maximum. By contrast, the velocity field of the bubble raft shows strong dynamical heterogeneity after the direction of oscillation reverses and the stress relaxes.

3:06PM Q46.00004 Dynamical and structural transitions in periodically-driven emulsions: Reversibility loss and random hyperuniform organization, JOOST H. WEJJS, Ecole Normale Supérieure de Lyon, France, RAPHAËL JEANNERET, Warwick University, United Kingdom, REMI DREYFUS, Centre National de la Recherche Scientifique, DENIS BARTOLEO, Ecole Normale Supérieure de Lyon, France — We present experimental results and numerical simulations of a microfluidic echo process, in which a large number of droplets interact in a periodically driven viscous fluid [Jeanneret & Bartolo, Nature Comm. 5, 3474 (2013)]. Upon increasing the driving amplitude we demonstrate the collective reversibility loss of the droplet dynamics. In addition, the system undergoes a dynamical phase transition associated with a structural one: at the onset of irreversibility the droplet ensemble self-organises into a random hyperuniform state. Numerical simulations evidence that the purely reversible hydrodynamic interactions together with hard-core repulsion account for most of our experimental findings. Hyperuniformity is relevant for the production of large-band-gap materials, but are difficult to construct both numerically and experimentally. The hydrodynamic echo-process may provide a robust, fast, and simple way to produce hyper uniform structures over a wide range of packing fractions.

3:18PM Q46.00005 The Versatile Elastohydrodynamics of a Free Particle near a Thin Soft Wall, THOMAS SALEZ, PCT Lab, UMR CNRS 7083 Guillier, ESPCI ParisTech, PSL Research University, Paris, France, BAUDOUIN SAINTYVES, L. MAHADEVAN, SEAS, Harvard University, Cambridge, MA, USA — We address the free motion of a buoyant particle inside a viscous fluid, in the vicinity of a thin compressible elastic wall. After discussing the main scalings, we obtain analytically the dominant drag forces within the soft lubrication approximation. By including those into the equations of motion of the particle, we establish a general governing system of three coupled nonlinear and singular differential equations, that describe the three essential motions: sedimentation, hydroplaning, and hydrospinning, through four dimensionless control parameters. Numerical integration allows us to predict a wide zoology of exotic solutions – despite the low-Reynolds feature of the flow – including: spontaneous oscillation, Magnus-like effect, enhanced sedimentation, and boomerang-like effect. We compare these predictions to experiments. The presented elementary approach could be of interest in the description of a broad variety of elastohydrodynamical phenomena, including: landslides, ageing of cartilaginous joints, and motion of a cell in a microfluidic channel or in a blood vessel.

3:30PM Q46.00006 Dual-probe active microrheology, BENJAMIN DOLATA, ROSEANNA N. ZIA, Cornell University — Microrheology has revolutionized the study of microscopically small systems, whereby a Brownian probe particle is monitored as it travels through a complex fluid and its motion is tracked to infer properties of the embedding medium. A range of applications enables study of various materials and flow regimes: in passive microrheology probe diffusion is related to linear viscoelastic properties via a Stokes-Einstein relation, but precludes study of networked materials. Dual-probe passive microrheology overcomes this limitation in some cases. But these techniques are restricted to linear-response properties. In active microrheology a probe is driven through the medium, and reveals strongly non-equilibrium rheology, but is limited to dispersed systems. We have developed a new model for the microscale interogation of general complex fluids: Dual-probe Active Microrheology. Via a combination of asymptotic and numerical solutions to the Smoluchowski equation, we have computed the microstructural and rheological response of a colloidal dispersion to the motion of two probes driven with forces ranging from strong to weak, at arbitrary separations and orientations to their lines of centers. The interactive force between the probes and the colloids reveals a novel non-equilibrium repulsive interaction which we connect to nonlinear rheology.

3:42PM Q46.00007 The impact of hydrodynamics on stress formation, relaxation, and memory in colloidal dispersions: Transient, nonlinear microrheology, RITESH P. MOHANTY, ROSEANNA N. ZIA, Cornell University — In active microrheology, a probe is driven through a complex medium. Most work thus far has focused on steady behavior and established the relationship between the microstructure, probe speed, and rheology. But important information about structural development and relaxation are captured by startup and cessation of flows in the non-linear regime, where the structure is driven far from equilibrium. Here we study theoretically the rate of stress formation and relaxation under non-linear microrheological forcing of hydrodynamically interacting colloids. We study the behavior analytically in the double limits of weak and strong probe forcing and weak and strong hydrodynamic interactions and numerically in between. To elucidate the detailed role of hydrodynamic, Brownian, and interparticle forces in stress formation and relaxation, we employ an excluded annulus model to introduce each systematically, and study the rheological and structural response for arbitrary forcing and strength of hydrodynamic interactions. Hydrodynamics introduce an additional mode of dissipation, which manifests as a reduction in the rate of stress formation during startup. While this non-equilibrium contribution vanishes instantly upon flow shutoff, a delicate interplay between Brownian and interparticle forces influences relaxation, revealing multiple relaxation modes. The recovery of entropically stored energy is studied.
3:54PM Q46.00008 Rheology and Dynamics of Colloidal Superballs. JOHN ROYER, GEORGE BURTON, NIST, DANIEL BLAIRE, Georgetown University, STEVEN HUDSON, NIST — Relatively little is known about the role particle shape plays in the dynamics of colloidal suspensions, particularly at higher packing densities where particle interactions and changes in the microstructure become increasingly important. We examine the role of particle shape by characterizing both the bulk rheology and micro-scale diffusion in a suspension of pseudo-cubic silica superballs. Varying the packing density 0 ≤ φ ≤ 0.42, we compare the high-shear viscosity and long-time self-diffusion coefficient D2(φ) to established hard-sphere results. In dilute suspensions the superball viscosity is nearly indistinguishable from the that of hard spheres, indicating that the individual superball hydrodynamics are not dramatically different. However, there is a significant difference in the diffusion, with the superball D2(φ) decreasing faster with increasing φ. Looking at the suspension microstructure, we find that while the hard sphere pair distribution g(r) jumps to a finite value at contact r = 2a, the superball g(r) is shifted to higher distances. This suggests a simple rescaling φ → φ_{eff} defined by the minimal sphere needed to enclose the superballs, which roughly collapses the diffusion results.

4:06PM Q46.00009 Colloidal transport and diffusion over a tilted periodic energy landscape. XIAOGUANG MA, Hong Kong University of Science and Technology, PIK-YIN LAI, National Central University, Taiwan, BRUCE ACKERSON, Oklahoma State University, PENG TONG, Hong Kong University of Science and Technology — A tilted two-layer colloidal system is constructed to study force-assisted barrier-crossing dynamics over a periodic energy landscape. The energy landscape is provided by the bottom layer colloidal spheres forming a fixed crystalline pattern on a glass substrate. The corrugated surface of the bottom colloidal crystal provides a gravitational potential field for the top layer diffusing particles. By tilting the sample at an angle with respect to the direction of gravity, a tangential component of the gravitational force F is applied to the diffusing particles. The measured mean drift velocity v(F,E) and diffusion coefficient D(F,E) of the particles as a function of F and energy barrier height E agree well with the exact solution of the one-dimensional Langevin equation. From the exact solution we show analytically and verify experimentally that there exists a scaling region, in which v and D both scale as (F)_exp[E^*(F)/k_B T], where the Arrhenius pre-factor a(F) and effective barrier height E^*(F) are both modified by F. The experiment demonstrates the applications of this model system in evaluating different scaling forms of a(F) and E^*(F) and their accuracy, in order to extract useful energetic information.

4:18PM Q46.00010 Colloidal diffusion over a random landscape. YUN SU, XIAO-GUANG MA, Hong Kong University of Science and Technology, PIK-YIN LAI, National Central University, Taiwan, PENG TONG, Hong Kong University of Science and Technology — A two-dimension quenched random energy landscape is generated by using a randomly packed layer of colloidal spheres of two different sizes fixed on a glass substrate. A number of monodisperse particles diffuse on the top of the first layer particles. The diffusing particles in water feel the gravitational energy landscape U(x,y) generated by the modulated surface of the first layer particles. The trajectories of the particles are obtained by optical microscopy and particle tracking. The energy landscape U(x,y) is obtained from the measured population histogram P(x,y) of the diffusing particles via the Boltzmann distribution, P(x,y) = exp[-U(x,y)/k_B T], where k_B T is the thermal energy of the particles. The distribution of the energy barrier heights is obtained from the measured U(x,y). From the particles’ trajectories we determine the energy landscape parameters over the random landscape, such as the energy landscape over the escape energy. A quantitiative relationship between the long-time diffusion coefficient and the random energy landscape and the coordination number is good agreement with the theoretical prediction. ^Work supported in part by the Research Grants Council of Hong Kong SAR.

4:30PM Q46.00011 Inertial flow regimes of the suspension of finite size particles. IMAN LASHGARI, Linne FLOW Centre, KTH Mechanics, Stockholm, Sweden, FRANCESCO PICANO, Department of Industrial Engineering, University of Padova, Padova, Italy, LUCA BRANDT, Linne FLOW Centre, KTH Mechanics, Stockholm, Sweden — We study inertial flow regimes of the suspensions of finite size neutrally buoyant particles. These suspensions experience three different regimes by varying the Reynolds number, Re, and particle volume fraction, ϵ. At low values of Re and ϵ, flow is laminar-like where viscous stress is the dominating term in the stress budget. At high Re and relatively small ϵ, the flow is turbulent-like where Reynolds stress has the largest contribution to the total stress. At high ϵ, the flow regime is a form of inertial shear-thickening characterized by an significant enhancement in the wall shear stress not due to the increment of Reynolds stress but to the particle stress. We further analyze the local behavior of the suspension in the three different regimes by studying the particle dispersion and collisions. Turbulent cases shows higher level of particle dispersion and higher values of the collision kernel (the radial distribution function times the particle relative velocity as a function of the distance between the particles) than those of the inertial shear-thickening regimes providing additional evidence of two different transport mechanisms in the Bagnoldian regime.

1Support from the European Research Council (ERC) is acknowledged.

4:42PM Q46.00012 Flow mechanism of colloidal solutions under shear revealed by neutron scattering and simulation. XIN LI, WEI-REN CHEN, LUIS SANCHEZ-DIAZ, Oak Ridge National Laboratory, YUN LIU, National Institute of Standards and Technology, LIONEL POURCAR, Institut Laue-Langevin, WILLIAM HAMILTON, CHANGWOO DO, Oak Ridge National Laboratory, TAKUYA IWASHITA, TAKESHI EGAMI, KAO-HSIANG LIU, University of Tennessee — Using small angle neutron scattering technique and Brownian dynamics simulation we investigate the effect of external steady shear on the concentrated solutions of silica particles in the shear thinning regime. Three dimensional anisotropic structure factors are obtained as a function of shear rate. Accordingly the evolution of local topology, defined by the colloidal connectivity, is revealed by the variation of local strain. We further determine the elastic resistant length scale of the colloidal systems via characterizing the quantitative dependence of the correlation length on the strain rate.

4:54PM Q46.00013 Steady-state flow properties of amorphous materials. VIKRAM JADHAO, THOMAS O’CONNOR, MARK ROBBINS, Johns Hopkins University — Molecular dynamics (MD) simulations are used to investigate the steady-state shear flow curves of a standard glass model: the bidisperse Lennard-Jones system. For a wide range of temperatures in the neighborhood of the glass transition temperature T_g predicted by the mode coupling theory, we compute the steady-state shear stress and viscosity as a function of the shear rate \dot{\gamma}. At temperatures near and above T_g the stress crosses over from linear Newtonian behavior at low rates to power law shear-thinning at high rates. As T decreases below T_g, the stress shows a plateau, becoming nearly rate-independent at low \dot{\gamma}. There is a weak increase in stress that is consistent with Eyring theory for activated flow of a solid. We find that when the strain rate is reduced to extremely low values, Newtonian behavior appears once more. Insights gained from these simulations are applied to the computation of flow curves of a well-established boundary lubricant: squalane. In the elastohydrodynamic regime, squalane responds like a glassy solid with an Eyring-like response, but at lower rates it has a relatively small Newtonian viscosity.
5:06PM Q46.00014 X-ray photon correlation spectroscopy studies of structural irreversibility in a colloidal gel subjected to oscillatory shear flow. MU SUNG KWEON, WESLEY BURGHARDT, Northwestern University, SUBRAMANIAN RAMAKRISHNAN, GOLDA LOUIS, DANICA THOMAS, Florida State University, SURESH NARAYANAN, Argonne National Laboratory — X-ray photon correlation spectroscopy (XPCS) is used to probe the microscopic structural reversibility in a colloidal gel subjected to oscillatory shear flow. Silicon dioxide particles in decalin aggregate into a gel structure as a result of depletion interactions associated with dissolved polystyrene molecules. XPCS studies on aged quiescent gels show negligible structural dynamics on time scales of tens of seconds. Such samples were subjected to oscillatory shear with varying strain amplitude using a rheometer installed in the XPCS beam line and x-ray capable polycarbonate fixtures; this enable simultaneous rheological measurements during the XPCS experiment. In the presence of unidirectional shear flow, the decay of the XPCS autocorrelation function is dominated by the convective motion induced by the applied deformation. In oscillatory shearing of samples in the absence of significant structural relaxation, the autocorrelation function becomes periodic, returning to its initial value once every oscillation period. At higher strains, irreversible motions at the microscopic level lead to decay in the ‘echoes’ of the autocorrelation function. Interestingly, structural irreversibility is detected by XPCS only at strains that are significantly higher than those at which nonlinearity.

Session Q47 DBIO: Physics of Bacteria and Viruses 217B – Guannan Liu, Princeton University

2:30PM Q47.00001 Using Fitness Landscapes for Rational Hepatitis C Immunogen Design. GREGORY HART, ANDREW FERGUSON, University of Illinois at Urbana-Champaign — Hepatitis C virus afflicts 170 million people worldwide, 2-3% of the global population. Prophylactic vaccination offers the most realistic and cost effective hope of controlling this epidemic, particularly in the developing world where expensive drug therapies are unavailable. Despite 20 years of research, the high mutability of the virus, and lack of knowledge of what constitutes effective immune responses, have impeded development of an effective vaccine. Coupling data mining of sequence databases with the Potts model, we have developed a computational approach to systematically identify viral vulnerabilities and perform rational design of vaccine immunogens. We applied our approach to the nonstructural proteins NS3, NSA, NS, and NSB which are crucial for viral replication. The predictions of our model are in good accord with experimental measurements and clinical observations, and we have used our model to design immunogen candidates to elicit T-cell responses against vulnerable regions of these viral proteins.

2:42PM Q47.00002 Impact of cell regeneration in human respiratory tract on simultaneous viral infections. LUBINA JAHAN RASHID PINKY, HANA DOBOROVLNY, Texas Christian University — Studies have found that ~40% of patients hospitalized with influenza-like illness are infected with at least two different viruses. In these longer infections, we need to consider the role of cell regeneration. Several mathematical models have been used to describe cell regeneration in infection models, though the effect of model choice on the predicted time course of simultaneous viral infections is not clear. We investigate a series of mathematical models of cell regeneration during simultaneous respiratory virus infections to determine the effect of cell regeneration on infection dynamics. We perform a nonlinear stability analysis for each model. The analysis suggests that coexistence of two viral species is not possible for any form of regeneration. We find that chronic illness is possible, but with only one viral species.

2:54PM Q47.00003 Basic Reproduction Number of a Gamma-Distributed Within-Host Infection Model. IRMA RODRIGUEZ, HANA DOBOROVLNY, Texas Christian University — In epidemiology, the basic reproduction number (R0) is used to measure the spread potential of a disease. It is defined as the number of secondary infections produced by a first infection in a homogeneous susceptible population. Traditional ordinary differential equation infection models assume exponential transitions between different stages of cell infection. This assumption is not biologically realistic, so non-exponential models are now being investigated. The basic reproduction number of non-exponential models has yet to be calculated. Here we present an analysis of a gamma-distributed model that has allowed us to calculate R0 for this model.

3:06PM Q47.00004 Observations of Bacterial Behavior during Infection Using the ARGOS Method. A.J. CHAREST, Wentworth Inst of Techn, S. ALGARNI, G.S. IANNACCHIONE, Worcester Polytech Inst — This research employed the Area Recorded Generalized Optical Scattering (ARGOS) approach which allowed for the observation of bacterial changes in terms of individual particles and population dynamics in real time. This new approach allows for an aqueous environment to be manipulated while conducting time-specific measurements over an indefinite time period. This current study provides a more time-specific method in which the bacteria remained within the initial conditions and allows for more time precision than provided by analyzing concentrations of plaque-forming units (PFU). This study involved the bacteria (F-amp) during infection by bacteriophage T4:18. We proposed a model for flagellation of P. aeruginosa.
4:30PM Q47.00006 Seeing is believing: Direct imaging of charge flow along pili proteins reveals new mechanism for antibacterial electron transfer

RIKHIL MALVANKAR, SIBEK EBRU YALCIN, RAMESH ADHIKARI, MARK TUOMINEN, DEREK LOVLEY, University of Massachusetts Amherst — Visualization of charge flow on the nanoscale in proteins is crucial for a fundamental understanding of several life processes. Here, we report direct visualization of charge propagation along native pili of Geobacter sulfurreducens at nanometer resolution using electrostatic force microscopy. Surprisingly, charges injected at a single point into individual, untreated pili, still attached to cells, propagate over the entire filament. The charges propagate despite a lack of cytochromes on the pilus, in contrast to the dominant biochemical model that proteins are electronically insulated and must incorporate redox-active cofactors in order to achieve electron transport functionality. The mobile charge density in pili is comparable to synthetic organic conductors, increasing with proton doping, and with temperature-dependence consistent with previously discovered metallic-like transport mechanism. Conductive pili enable syntrophic bacteria to share energy by directly exchanging electrons among each other. Measurements along individual pili using nanoelectrodes showed ohmic behavior strongly dependent on the amino acid composition of pili. Electron transfer rate measurement revealed that the pilus conductivity is the decisive factor in controlling the bacterial respiration rate.

3:42PM Q47.00007 Phase separation like dynamics during Myxococcus xanthus fruiting body formation

GUANNAN LIU, SHASHI THUTUPALLI, MANON WIGBERS, JOSHUA SHAEVITZ, Princeton Univ — Collective motion exists in many living organisms as an advantageous strategy to help the entire group with predation, forage, and survival. However, the principles of self-organization underlying such collective motions remain unclear. During various developmental stages of the soil-dwelling bacterium, Myxococcus xanthus, different types of collective motions are observed. In particular, when starved, M. xanthus cells eventually aggregate together to form 3-dimensional structures (fruiting bodies), inside which cells sporulate in response to the stress. We study the fruiting body formation process as an out of equilibrium phase separation process. As local cell density increases, the dynamics of the aggregation M. xanthus cells switch from a spatio-temporally random process, resembling nucleation and growth, to an emergent pattern formation process similar to a spinodal decomposition. By employing high-resolution microscopy and a video analysis system, we are able to track the motion of single cells within motile collective groups, while separately tuning local cell density, cell velocity and reversal frequency, probing the multi-dimensional phase space of M. xanthus development.

3:54PM Q47.00008 Cell size control and homeostasis in bacteria

SERENA BRADDE, GC CUNY, SATTAR TAHERI, JOHN SAULS, UCSD, NOBERT HILL, UC Berkeley, PETRA LEVINE, Washington University, JOHAN PAULSSON, Harvard, MASSIMO VESPOLA, SUCKJOON JUN, UCSD — How cells control their size is a fundamental question in biology. The mechanisms for sensing size, time, or a combination of the two are not supported by experimental evidence. By analysing distributions of size at division and generation time of hundreds of thousands of Gram-negative E. coli and Gram-positive B. subtilis cells under a wide range of tightly controlled steady-state growth conditions, we are now in the position to validate different theoretical models. In this talk I will present all possible models in details and present a general mechanism that quantitatively explains all measurable aspects of growth and cell division at both population and single-cell levels.

4:06PM Q47.00009 Population Dynamics of the Stationary Phase Utilizing the ARGOS Method

S. ALGARNI, Worcester Polytech Inst, A.J. CHAREST, Wentworth Inst Techn, G.S. IANNACCHIONE, Worcester Polytech Inst — The Area Recorded Generalized Optical Scattering (ARGOS) approach to light scattering employs large image capture array allowing for a well-defined geometry in which images may be manipulated to extract structure with intensity at a specific scattering wave vector (I(q)) and dynamics with intensity at a specific scattering wave vector over time (I(q,t)). The ARGOS method provides morphological dynamics noninvasively over a long time period and allows for a variety of aqueous conditions. This is important because traditional growth models do not provide for conditions similar to the natural environment. The present study found that the population dynamics of bacteria do not follow a traditional growth model and that the ARGOS method allowed for the observation of bacterial changes in terms of individual particles and population dynamics in real time. The observations of relative total intensity suggest that there is no stationary phase and that the bacterial population demonstrates sinusoidal type patterns consistently subsequent to the log phase growth. These observation were compared to shape changes by modeling fractal dimension and size changes by modeling effective radius.

4:18PM Q47.00010 Nanomechanical Response of Bacterial Cells to Antimicrobial Peptides

RICHARD PARG, JOHN DUTCHE, University of Guelph — The effectiveness of antimicrobial compounds can be easily screened, however their mechanism of action is much more difficult to determine. Many compounds act by compromising the mechanical integrity of the bacterial cell envelope, and we have developed an atomic force microscopy (AFM)-based creep deformation technique to evaluate changes in the time-dependent mechanical properties of bacterial cells upon exposure to antimicrobial peptides. Measurements performed before and after exposure, as well as time-resolved measurements and those performed at different antimicrobial concentrations, revealed large changes to the viscoelastic parameters including a distinctive signature for the loss of integrity of the bacterial cell envelope. Our previous experiments have focused on Pseudomonas aeruginosa PA01 bacterial cells in Milli-Q water, for which the cells can withstand the large osmotic pressure. In our present study we have focused on performing the measurements in buffer to obtain more biologically relevant results. The AFM creep deformation measurement provides new, unique insight into the kinetics and mechanism of action of antimicrobial peptides on bacteria.

4:30PM Q47.00011 Quantifying Spatiotemporal Patterns in the Expansion of Twitching Bacterial Colonies

ERIN SHELTON, MAXIMILIANO GIULIANI, University of Guelph, LORI BURROWS, McMaster University, JOHN DUTCHE, University of Guelph — Type IV pili (T4P) are very thin (5-8 nm in diameter) protein filaments that can be extended and retracted by certain classes of Gram-negative bacteria including P. aeruginosa [1]. These bacteria use T4P to move across viscous interfaces, referred to as twitching motility. Twitching can occur for isolated cells or in a collective manner [2]. We have developed experimental and data analysis techniques to quantify the expansion of P. aeruginosa PA01 bacterial colonies at the glass-agar interface under well-controlled environmental conditions. By using particle image velocimetry (PIV) and Fourier analysis techniques, we have characterized the evolution of the advancing front of expanding colonies for a range of agar concentrations. This has allowed us to observe a transition in the collective motion of the bacterial cells as the agar concentration is increased. [1] Burrows, L.L. (2012) Annu. Rev. Microbiol. 66: 493-520; [2] Semmler, A.B., Whitchurch, C.B., Mattick, J.S. (1999) Microbiology 145: 2863-2873.
4:42PM Q47.00012 Characterization of MreB polymers in E. coli and their correlations to cell shape. JEFFREY NGUYEN, Princeton University, Dept. of Physics, NIKOLAY OUZONOV, ZEMER GITAI, Princeton University, Dept. of Molecular Biology, JOSHUA SHAEVITZ, Princeton University, Dept. of Physics — Shape influences all facets of how bacteria interact with their environment. The size of E. coli is determined by the peptidoglycan cell wall and internal turgor pressure. The cell wall is patterned by MreB, an actin homolog that forms short polymers on the cytoplasmic membrane. MreB coordinates the breaking of old material and the insertion of new material for growth, but it is currently unknown what mechanism sets the absolute diameter of the cell. With new techniques in fluorescence microscopy and imaging, we are able to quantify cell shape in 3-dimensions and access previously unattainable data on the conformation of MreB polymers. To study how MreB affects the diameter of bacteria, we analyzed the shapes and polymers of cells that have had MreB perturbed by one of two methods. We first treated cells with the MreB polymerization-inhibiting drug A22. Secondly, we created point mutants in MreB that change MreB polymer conformation and the cell shape. By analyzing the correlations between different shape and polymer metrics, we find that under both treatments, the average helical pitch angle of the polymers correlates strongly with the cell diameter. This observation links the micron scale shape of the cell to the nanometer scale MreB cytoskeleton.

4:54PM Q47.00013 Mechanism of cell alignment in groups of Myxococcus xanthus bacteria\(^1\). RAJESH BALGAM, OLEG IGOSHIN, Rice University — Myxococcus xanthus is a model for studying self-organization in bacteria. These flexible cylindrical bacteria move along. In groups, M. xanthus cells align themselves into dynamic cell clusters but the mechanism underlying their formation is unknown. It has been shown that steric interactions can cause alignment in self-propelled hard rods [1] but it is not clear how flexibility and reversals affect the alignment and cluster formation. We have investigated cell alignment process using our biophysical model of M. xanthus cell [2] in an agent-based simulation framework under realistic cell flexibility values. We observed that flexible model cells can form aligned cell clusters when reversals are suppressed but these clusters disappeared when reversals frequency becomes similar to the observed value. However, M. xanthus cells follow slime (polysaccharide gel like material) trails left by other cells and we show that implementing this into our model rescues cell clustering for reversing cells. Our results show that slime following along with periodic cell reversals act as positive feedback to reinforce existing slime trails and recruit more cells. Furthermore, we have observed that mechanical cell alignment combined with slime following is sufficient to explain the distinct clustering patterns of reversing and non-reversing cells as observed in recent experiments [3].

5:06PM Q47.00014 Magnetically-Actuated Escherichia coli System for Micro Lithography. S. LAUBACK, E. BROWN, L. PÉREZ-GUZMAN, C. PEACE, C. PIERCE, B.H. LOWER, S.K. LOWER, R. SOORYAKUMAR, Ohio State Univ - Columbus — Technologies that control matter at the nano- and micro-scale are crucial for developing new engineered materials and devices. While the more traditional approaches for such manipulations often depend on lithographic fabrication, they can be expanded upon by taking advantage of the biological systems within a living cell which also operate on the nano- and micro-scale. In this study, a system is being developed to functionalize a targeted location on the surface of a chip with the protein AmCyan from transformed Escherichia coli cells. Using established methods in molecular biology where a plasmid with the amcyan gene sequence is inserted into the cell, E. coli are engineered to express the AmCyan protein on their outer surface. In order to transport the cells to the targeted location, the transformed E. coli are labeled with superparamagnetic micro-beads which exert directed forces on the cells in an external field. Preliminary results of the protein expression on E. coli, the transport of the cells through weak magnetic fields to targeted locations and the potential to transfer protein from the cell to the chip surface will be presented.

5:18PM Q47.00015 Bactericidal Effects of Charged Silver Nanoparticles in Methicillin-resistant Staphylococcus aureus\(^1\). DULCE ROMERO-URBINA, J. JESUS VELAZQUEZ-SALAZAR, HUMBERTO H. LARA, JOSEFINA ARELLANO-JIMENEZ, EDUARDO LARIOS, The University of Texas at San Antonio, TONY T. YUAN, YOON HWANG, MAURIS N. DESILVA, Naval Medical Research Unit, JBSA Fort Sam Houston, MIGUEL JOSE-YACAMAN, The University of Texas at San Antonio — The increased number of infections due to antibiotic-resistant bacteria is a major concern to society. The objective of this work is to determine the effect of positively charged AgNPs on methicillin-sensitive Staphylococcus aureus (MSSA) and methicillin-resistant Staphylococcus aureus (MRSA) cell wall using advanced electron microscopy techniques. Positively charged AgNPs suspensions were synthesized via a microwave heating technique. The suspensions were then characterized by Dynamic Light Scattering (DLS) and Transmission Electron Microscopy (TEM) showing AgNPs size range from 5 to 30 nm. MSSA and MRSA were treated with positively charged AgNPs concentrations ranging from 0.06 mM to 31 mM. The MIC\(_{50}\) studies showed that viability of MSSA and MRSA could be reduced by 50% at a positively charged AgNPs concentration of 0.12 mM supported by Scanning-TEM (STEM) images demonstrating bacteria cell wall disruption leading to lysis after treatment with AgNPs. The results provide insights into one mechanism in which positively charged AgNPs are able to reduce the viability of MSSA and MRSA.

Wednesday, March 4, 2015 2:30PM - 5:30PM – Session Q48 DBIO: Focus Session: Physics of Proteins: Dynamics and Function III 217C - Dimitri Antoniou, University of Arizona

2:30PM Q48.00001 Investigation at the atomic level of homologous enzymes reveals distinct reaction paths.\(^1\) IOANNA ZOI, STEVEN D. SCHWARTZ, Univ of Arizona — Bacterial enzymes Escherichia coli and Vibrio cholerae 5’-Methylthioadenosine nucleosidases (MTANs) have different binding affinities for the same transition state analogue. This was surprising as these enzymes share 60% sequence identity, have almost identical active sites and act under the same mechanism. We performed Transition Path Sampling simulations of both enzymes to reveal the atomic details of the catalytic chemical step, to explain the inhibitor affinity differences. Unlike EcMTAN, VcMTAN has multiple distinct transition states, which is an indication that multiple sets of coordinated protein motions can reach a transition state. We also identified the important residues that participate in each enzyme’s reaction coordinate and explained their contribution. Subtle dynamic differences manifest in difference of reaction coordinate and transition state structure and also suggest that MTANs differ from most ribosyl transferases. As experimental approaches report averages regarding reaction coordinate information, this study offers, previously unavailable, detailed knowledge to the explanation of bacterial MTANs catalytic mechanism, and could have a significant impact on pharmaceutical design.

1We acknowledge the support of the National Institutes of Health through Grant GM068036.
2:42PM Q48.00002 Mechanistic model of sodium+/proton antiport based on X-ray crystal structures and molecular dynamics simulations, OLIVER BECKSTEIN, DAVID L DOTSON, Arizona State Univ, CHIARA LEE, SHOKO YASHIRO, Imperial College, London, POVIAS UZDAVYNYS, CHRISTOPH VON BALLMOOS, DAVID DREW, Stockholm University, Sweden, ALEXANDER D. CAMERON, University of Warwick — Na⁺/H⁺ antiporters are membrane proteins that are vital for cell homeostasis but the mechanistic details of their transport mechanism remain unclear, in particular, how Na⁺ and protons bind to the transporter. We recently solved X-ray crystal structures for two such antiporters (NhaA and NapA) in two different conformations of the transport cycle. All-atom molecular dynamics (MD) simulations (for a total simulated time > 10 µs) indicate that sodium binding is dependent on the charge states of two conserved aspartate residues. A conserved lysine forms a previously unidentified salt bridge with one of the aspartates. Under simulated physiological pH the presence of a Na⁺ ion disrupts and breaks the salt bridge in NhaA. To quantify proton binding, we then performed heuristic pKa calculations on our ensemble of simulations. The calculations support our novel hypothesis that the conserved lysine in these antiporter MD simulations protonates in a sodium-dependent manner and thus acts as part of the transport machinery. In conjunction with simulations of the conformational transition we propose a new mechanistic model of ion binding for the CPA2 class of antiporters within the larger framework of the alternating access mechanism of transmembrane transport.

2:54PM Q48.00003 Another Look at the Mechanisms of Hydride Transfer Enzymes from Quantum and Classical Transition Path Sampling¹, MICHAEL DZIERLENGA, DIMITRI ANTONIOU, STEVEN SCHWARTZ, Univ of Arizona — The mechanisms involved in enzymatic hydride transfer have been studied for years but questions remain about the participation of protein dynamics and quantum effects, especially hydrogen tunneling. In this study, we use transition path sampling (TPS) with normal mode centroid molecular dynamics (CMD) to calculate the barrier to hydride transfer in yeast alcohol dehydrogenase (YADH) and lactate dehydrogenase (LDH). Calculation of the work applied to the hydride during the reaction allows for observation of the change in barrier height due to inclusion of quantum effects. Additionally, the same calculations were performed using deuterium as the transferring particle to validate our methods with experimentally measured kinetic isotope effects. The change in barrier height in YADH upon inclusion of quantum effects is indicative of a zero-point energy contribution, and is evidence that the protein mediates a near-barrierless transfer of the rate-limiting hydride. Calculation of kinetic isotope effects using the average difference in barrier between hydride and deuteride agreed well with experimental results.

¹The authors acknowledge the support of the National Institutes of Health Grants GM068036 and GM102226.

3:06PM Q48.00004 Free energy landscape of the Michaelis complex of lactate dehydrogenase: A network analysis of atomistic simulations, XIAOLIANG PAN, STEVEN SCHWARTZ, University of Arizona — It has long been recognized that the structure of a protein is a hierarchy of conformations interconverting on multiple time scales. However, the conformational heterogeneity is rarely considered in the context of enzymatic catalysis in which the reactant is usually represented by a single conformation of the enzyme substrate complex. Lactate dehydrogenase (LDH) catalyzes the interconversion of pyruvate and lactate with concomitant interconversion of two forms of the cofactor nicotinamide adenine dinucleotide (NADH and NAD⁺). Recent experimental results suggest that multiple states exist within the Michaelis complex of LDH, and they are catalytically competent at different reaction rates. In this study, millisecond-scale all-atom molecular dynamics simulations were performed on LDH to explore the free energy landscape of the Michaelis complex, and network analysis was used to characterize the distribution of the conformations. Our results provide a detailed view of the kinetic network the Michaelis complex and the structures of the substrates at atomic scale. It also shed some light on understanding the complete picture of the catalytic mechanism of LDH.

3:18PM Q48.00005 Theory of relaxation dynamics within carotenoids via high frequency stretching modes, VYTAUTAS BALEVICIUS, DARIUS ABRAMAVICIUS, Vilnius University — Carotenoids are ubiquitous natural pigment molecules acting as light harvesters in the blue-green region of the spectrum, and at the same time ensuring the photoprotection against excessive light by quenching the triplet state of chlorophylls and singlet oxygen. However, their photophysics is still not fully understood, because the absorption takes place not into the optically dark lowest excited state S₁, but to the short-lived higher-lying state S₂. This leads to complicated intramolecular energy redistribution schemes within carotenoids. From the transient absorption experiments it is known that the S₁ state is populated shortly after the excitation of the S₂ state (on the time-scale of tens of femtoseconds). The corresponding excited state absorption signal is blue-shifting and narrowing at early times, which is attributed to the vibrational cooling of the S₁ state. We apply the secular density matrix theory to take into account both the internal conversion from the S₂ into the S₁ state and the subsequent relaxation within the manifold of high-frequency vibrational states corresponding to the carbon-carbon stretching modes (C-C and C=C). It allows us to obtain relevant pump-probe spectra in the time range from femto- to picoseconds.

3:30PM Q48.00006 Connecting thermal and mechanical protein (un)folding landscapes, LI SUN, JEFFREY NOEL, Rice University, JOANNA SULKOWSKA, University of Warsaw, HERBERT LEVINE, JOSE ONUCHIC, Rice University — Molecular dynamics simulations supplement single-molecule pulling experiments by providing the possibility of examining the full free energy landscape using many coordinates. Here, we use an all-atom structure-based model to study the force and temperature dependence of the unfolding of the protein filamin by applying force at both termini. The unfolding force-time relation τ(F) indicates that the unfolding behavior can be characterized into three regimes: barrier-limited low- and intermediate-force regimes, and a barrierless high-force regime. Slope changes of τ(F) separate the three regimes. We show that the behavior of τ(F) can be understood from a two-dimensional free energy landscape projected onto the extension X and the fraction of native contacts Q. In the low-force regime, the unfolding rate is roughly force-independent due to the small (even negative) separation in X between the native ensemble and transition state ensemble (TSE). In the intermediate-force regime, force sufficiently separates the TSE from the native ensemble such that τ(F) roughly follows an exponential relation. The TSE becomes increasingly structured with force. The high-force regime is characterized by barrierless unfolding, approaching a time limit of around 10 µs.

3:42PM Q48.00007 ABSTRACT WITHDRAWN —

3:54PM Q48.00008 Rhodopsin Photoactivation Dynamics Revealed by Quasi-Elastic Neutron Scattering, DEBSINDHU BHOWMIK, UTSAB SHRESTHA, Wayne State University, MI, SUCHHITHRANGA M. C. D. PERERA, UDEEP CHAWLA, University of Arizona, AZ, EUGENE MAMONTOV, Oak Ridge National Laboratory, TN, MICHAEL BROWN, University of Arizona, AZ, XIANG-QIANG CHU, Wayne State University, MI — Rhodopsin is a G-protein-coupled receptor (GPCR) responsible for vision. During photoactivation, the chromophore retinal dissociates from protein yielding the opsin apoprotein. What are the changes in protein dynamics that occur during the photoactivation process? Here, we studied the microscopic dynamics of state-1 rhodopsin and the ligand-free opsin using quasielastic neutron scattering (QENS). The QENS technique tracks individual hydrogen atom motion because of the much higher neutron scattering cross-section of hydrogen than other atoms. We used protein with CHAPS detergent hydrated with heavy water. The activation of proteins is confirmed at low temperature up to 300 K by mean-square displacement (MSD) analysis. The QENS experiments at temperatures ranging from 220 K to 300 K clearly indicate an increase in protein dynamic behavior with temperature. The relaxation time for the ligand-bound protein rhodopsin is faster compared to opsin, which can be correlated with the photoactivation. Moreover, the protein dynamics are orders of magnitude slower than the accompanying CHAPS detergent, which unlike protein, manifests localized motions.
4:06PM Q48.00009 Predicting side-chain conformational changes of methionine using a hard-sphere model with stereochemical constraints, A. VIRRUETA, J. GAINES, C. S. O’HERN, L. REGAN, Yale University — Current research in the O’Hern and Regan laboratories focuses on the development of hard-sphere models with stereochemical constraints for protein structure prediction as an alternative to molecular dynamics methods that utilize knowledge-based corrections in their force-fields. Beginning with simple hydrophobic dipeptides like valine, leucine, and isoleucine, we have shown that our model is able to reproduce the side-chain dihedral angle distributions derived from sets of high-resolution protein crystal structures. However, methionine remains an exception - our model yields a chi-3 side-chain dihedral angle distribution that is relatively uniform from 60 to 300 degrees, while the observed distribution displays peaks at 60, 180, and 300 degrees. Our ability to resolve this discrepancy by considering clashes with neighboring residues, and averaging the reduced distribution of allowable methionine structures taken from a set of crystallized proteins. We will also re-evaluate the electron density maps from which these protein structures are derived to ensure that the methionines and their local environments are correctly modeled. This work will ultimately serve as a tool for computing side-chain entropy and protein stability.

4:18PM Q48.00010 How can we understand an entire (super)family of proteins?, WOUTER HOFF, Oklahoma State University — Understanding how the functional properties of a protein are encoded in its amino acid sequence remains a formidable challenge. We use photoactive yellow protein (PYP) to determine how structure-function relationships can be obtained for an entire (super)family of proteins. PYP is a model system to study fundamental processes in proteins and a prototype for the PAS domain superfamily. It consists of a 100-residue PAS domain with an additional 25-residue N-terminal extension. PYP exhibits a photocycle that is initiated by pCA photosomerization, followed by proton transfer from Glu46 to the pCA and a subsequent protein quacke during formation of the pB intermediate. These structural changes are driven by the electrostatic epicenter formed by the buried ionized Glu46 side chain and involve partial protein unfolding, including the release of the N-terminal region. Deletion of the N-terminal region slows down pB decay 1,000-fold. We report results on family-wide structure-function relationships in PYP. (i) Transplanting mutations into the N-terminus of a highly studied PYP to a different PYP homolog are only partially successful, implying sequence context dependence of functional properties. (ii) We find a direct correlation between the strength of the hydrogen bonding between the pCA and Glu46 and functional properties of PYPs. The role of Glu46 as the epicenter for driving large conformational changes during pB formation is conserved. (iii) Across the PYP family the N-terminal region is negatively charged while the PAS core is positively charged. The resulting charge-charge interactions are critical for the function of the N-terminal region. (iv) We find that residues conserved in the PAS domain superfamily exert their effects through conserved patterns of side chain interactions.

4:54PM Q48.00011 A coarse-grained model to study calcium activation of the cardiac thin filament, JING ZHANG, STEVEN SCHWARTZ, University of Arizona — Familial hypertrophic cardiomyopathy (FHC) is one of the most common heart disease caused by genetic mutations. Cardiac muscle contraction and relaxation involve regulation of crossbridge binding to the cardiac thin filament, which regulates actomyosin interactions through calcium-dependent interactions in the dynamics of cardiac troponin (cTn) and tropomyosin (Tm). An atomistic model of cTn complex interacting with Tm has been studied by our group. A more realistic model requires the inclusion of the dynamics of actin filament, which is almost 6 times larger than Tm and cTn in terms of atom numbers, and extensive sampling of the model becomes very resource-demanding. By using physics-based protein united-residue force field, we introduce a coarse-grained model to study the calcium activation of the thin filament resulting from cTn’s allosteric regulation of Tm dynamics on actin. The time scale is much longer than that of all-atom molecular dynamics simulation because of the reduction of the degrees of freedom. The coarse-grained model is a good template for studying cardiac thin filament mutations that cause FHC, and reduces the cost of computational resources.

5:06PM Q48.00012 Photoduced conformational changes to porphyrin-bound albumin reduces albumin binding to Osteonectin, SARAH ROZINEK, UTSA and Air Force Research Lab., ROBERT THOMAS, Air Force Research Lab., LORENZO BRANCLEON, UTSA — Much work has shown light-induced structural changes to proteins are possible. For instance, we have previously shown that small secondary and tertiary structural changes occur to albumin when it is bound (non-covalently) to meso-tetrakis(4-sulfonatophenyl)porphyrin (TSPP) and irradiated with a low intensity laser. Further study of this light-induced protein modification could advance the understanding of albumin’s structure/function relationship. Then, this structural modification technique might be implemented to deactivate unwanted protein functions or even to bestow non-native protein properties. A necessary step toward this goal is to determine if and how protein function is affected once its structure is modified. The current study aims to explore the light-induced conformational change to TSPP-bound albumin by testing its ability to bind the biologically relevant albumin receptor, Osteonectin. In this Affinity-Depletion experiment, Osteonectin has been covalently attached to magnetic beads, forming an affinity column. TSPP-albumin will non-covalently bind the column, and we predict that the light-induced change to albumin will cause a reduction in binding to Osteonectin. This loss of binding ability would mean a deactivation of albumin’s natural cellular functions.

5:18PM Q48.00013 Probing second hydration shell of ionic solutions using Gigahertz to Terahertz spectroscopy, DEEPU GEORGE, CHOLA REGMI, SHENGFENG CHENG, NGUYEN VINH, Virginia Tech — Understanding how the functional properties of a protein are encoded in its amino acid sequence remains a formidable challenge. We use photoactive yellow protein (PYP) to determine how structure-function relationships can be obtained for an entire (super)family of proteins. PYP is a model system to study fundamental processes in proteins and a prototype for the PAS domain superfamily. It consists of a 100-residue PAS domain with an additional 25-residue N-terminal extension. PYP exhibits a photocycle that is initiated by pCA photosomerization, followed by proton transfer from Glu46 to the pCA and a subsequent protein quacke during formation of the pB intermediate. These structural changes are driven by the electrostatic epicenter formed by the buried ionized Glu46 side chain and involve partial protein unfolding, including the release of the N-terminal region. Deletion of the N-terminal region slows down pB decay 1,000-fold. We report results on family-wide structure-function relationships in PYP. (i) Transplanting mutations into the N-terminus of a highly studied PYP to a different PYP homolog are only partially successful, implying sequence context dependence of functional properties. (ii) We find a direct correlation between the strength of the hydrogen bonding between the pCA and Glu46 and functional properties of PYPs. The role of Glu46 as the epicenter for driving large conformational changes during pB formation is conserved. (iii) Across the PYP family the N-terminal region is negatively charged while the PAS core is positively charged. The resulting charge-charge interactions are critical for the function of the N-terminal region. (iv) We find that residues conserved in the PAS domain superfamily exert their effects through conserved patterns of side chain interactions.

5:20PM Q49.00001 Suppression of E. coli tumbling and wobbling in dilute polymeric fluids, ALISON PATTESON, University of Pennsylvania, ARVIND GOPINATH, Haverford College, PAULO ARRATIA, University of Pennsylvania — Bacteria commonly utilize a run-and-tumble swimming behavior to navigate through complex environments, such as mucus in the lungs or digestive system. This swimming behavior has been extensively studied in water-like fluids; yet, studies on the role of particles/polymers on the run-and-tumble technique are limited. Here, we experimentally investigate the role of polymer concentration on the swimming dynamics of E. coli. We find that small amounts of polymer drastically change the run-and-tumble behavior of E. coli cells, significantly enhancing the translational diffusion. The average cell velocity increases with polymer concentration (and viscosity) and the mean run times are enhanced. By varying polymer molecular weight, we show that enhanced translation is a result of two mechanisms: (1) suppression of cell wobbling due to elasticity and (2) enhancement of run times due to viscosity. Our results show that the transport of chemotactic cells can be independently modified by viscosity and elasticity.
2:42PM Q49.00002 Differential dynamic behaviors of undulatory nematodes in liquid vs. soft gel environment1, JIN-SUNG PARK, JENNIFER H. SHIN, Dept. of Mechanical Engineering, KAIST — Caenorhabditis elegans (C. elegans) is an undulatory nematode which exhibits two distinct locomotion types of swimming and crawling. Although in its natural habitat C. elegans lives in complex fluidic environment, our current understanding has been limited to the behavior of C. elegans in a simple Newtonian fluid. Here, we present some experimental results on the penetrating behavior of C. elegans at the interface from liquid to solid environment. Once C. elegans, which otherwise swims freely in a liquid, makes a contact to the solid gel boundary, it begins to penetrate vertically to the surface by changing its stroke motion characterized by a stiffer body shape and a slower stroke frequency. The particle image velocimetry (PIV) analysis reveals the flow streamlines produced by the stroke of worm. For the worm that crawls on a solid surface, we utilize a technique of traction force microscopy (TFM) to find that the crawling nematode forms localized force islands along the body where makes direct contacts to the gel surface.

2:54PM Q49.00003 Directed Paramagnetic Colloidal Swimmers, SIBANI LISA BISWAL, DI DU, Rice University, DEPT. CHEMICAL AND BIOMOLECULAR ENGINEERING TEAM — A novel micoscale swimmer can be generated by placing two paramagnetic colloids of different sizes in a rotating magnetic field. For propulsion at the microscale, viscous forces dominate over inertial forces. This results in the scallop theorem, where reversible displacements does not lead to any net motion. To achieve controlled swimming at the microscale, the swimmer must be able to make a sequence of deformations that are cyclic but not time reversible. Two paramagnetic bodies in a circular eccentric rotating magnetic field influence each other and propel together in a directed manne. The motion of each body tracks a half-moon course, shown in the figure below. We will describe this method and show how Brownian motion enhances this propulsion.

3:06PM Q49.00004 Mechanics of swimming at the small scale in complex fluids, THOMAS POWERS, Brown University — Recent experiments with bacteria in liquid crystalline solutions have revealed that nematic order affects the swimming behavior of bacteria. Motivated by these observations, we study a simple model of low-Reynolds-number swimming in an anisotropic fluid, that of an infinitely long two-dimensional sheet deforming via propagating transverse or longitudinal waves and immersed in a hexatic or a nematic liquid crystal. The liquid crystal is categorized by the dimensionless Ericksen number Er, which compares viscous and elastic effects. Paying special attention to the anchoring strength at the interface of the liquid crystal and the swimmer, we calculate how swimming speed depends on Er for small amplitude waves. We study both the sinusoidal steady-state problem as well as the startup problem in which the swimmer starts from rest.

3:42PM Q49.00005 Anomalous swimming behavior of bacteria in nematic liquid crystals1, ANDREY SOKOLOV, Materials Science Division, Argonne National Laboratory, Illinois 60439, USA, SHUANG ZHOU, OLEG LAVRENTOVICH, Liquid Crystal Institute, Kent State University, Kent, Ohio 44242, USA, IGOR ARANSON, Materials Science Division, Argonne National Laboratory, Illinois 60439, USA — Flagellated bacteria stop swimming in isotropic media of viscosity higher than 0.066kgm m−1s−1. However, Bacillus Subtilis slows down by only about 30% in a nematic chonicom liquid crystal (CLC, 14wt% DSCG in water), where the anisotropic viscosity can be as high as 6kgm m−1s−1. The bacteria velocity (Vb) is linear with the flagella rotation frequency. The phase velocity of the flagella Vf ≈ 2Vb in CLC, as compared to Vf ≈ 1Vb in water. The flow generated by the bacteria is localized along the bacterial body axis, decaying slowly over tens of micrometers along, but rapidly over a few micrometers across this axis. The concentrated flow grants the bacteria new ability to carry cargo particles in CLC, ability not seen in their habitat isotropic media. We attribute these anomalous features to the anisotropy of viscosity of the CLC, namely, the viscosities of splay and twist is hundreds times higher than that of bend deformation, which provides extra boost of swimming efficiency and enables the bacteria swim at considerable speed in a viscous medium. Our findings can potentially lead to applications such as particle transportation in microfluidic devices.

3:54PM Q49.00006 Propulsion and instability of flexible helical flagella, NOOR KHOURI, MOHAMMAD JAWED, Massachusetts Institute of Technology, FANG DA, EITAN GRINSPUN, Columbia University, PEDRO REIS, Massachusetts Institute of Technology — We consider a macroscopic analogue model for the locomotion of uni-flagellar bacteria in a viscous fluid. The rescaling from the original micron-scale onto the desktop-scale is made possible by the prominence of geometry in the deformation process. As a model for the flagellum, we fabricate elastomeric filaments with fully customizable geometric and material properties, and rotate them at low Reynolds number conditions in a glycerin bath. Using digital imaging, we analyze the dynamics of the geometrically nonlinear deformed configurations. Our precision experiments are compared against numerical simulations that employ the Discrete Elastic Rods (DER) method, with an emphasis on quantifying the generated propulsive force. A novel mechanical instability is uncovered, whereby the filament buckles above a critical rotation frequency and we quantify its dependence on the physical and control parameters of the system. A scaling analysis allows us to rationalize the underlying physical mechanism and informs the original biological system that motivated the study.

4:06PM Q49.00007 Does Helicobacter pylori exhibit corkscrew motion while swimming?, MAIRA CONSTANTINO, JOSEPH HARDCASTLE, RAMA Bansil, Boston University — Helicobacter pylori is a spiral shaped bacterium associated with ulcers, gastric cancer, gastritis among other diseases. In order to colonize the harsh acidic environment of the stomach H. pylori has to go across the viscoelastic mucus layer of the stomach. Many studies have been conducted on the swimming of H. pylori in viscous media however none have taken into account the influence of cell-body shape on the trajectory. We present an experimental study of the effects of body shape in the swimming trajectory of H. pylori in viscous media by a quantitative analysis of the bacterium rotation and translation in gels using phase contrast microscopy and particle tracking techniques. Preliminary microscopic tracking measurements show very well defined helical trajectories in the spiral-shaped wild type H. pylori. These helical trajectories are not seen in rod-shaped mutants which sometimes display whirling motions about one end acting as a hinge. We will present an analysis of the different trajectories for bacteria swimming in media with different viscoelastic parameters.

4:18PM Q49.00008 How does Vorticella utilize its stalk contraction-relaxation cycle?, JIAZHONG ZHOU, DAVID ADMIRAAL, SANGJIN RYU, University of Nebraska-Lincoln — Vorticella is a sessile ciliate living in water, and it coils its slender stalk to pull the cell body (zooid) towards the substrate at a maximum speed of ~ 1 cm/s. After stalk contraction is completed, the stalk slowly relaxes to its extended state. Although this ultrafast stalk contraction has been studied in terms of cell motility, it poorly understood how Vorticella utilizes its stalk contraction. Here we propose a hypothesis that Vorticella can augment transport of particles near the substrate relying on water flow induced by the stalk contraction-relaxation cycle. We investigated our hypothesis using a computational fluid dynamics (CFD) model which models Vorticella as a solid sphere moving normal to a solid surface in water. Having simulated water flow caused by Vorticella, we calculated motions of particles near Vorticella, and then quantified the transport effect of Vorticella’s stalk contraction using microfluidic mixing indices.

4:30PM Q49.00009 A steering mechanism for phototaxis in Chlamydomonas, RACHEL BENNETT, RAMIN GOLESTANIAN, University of Oxford — Chlamydomonas shows both positive and negative phototaxis. It has a single eyespot near its equator and as the cell rotates during forward motion the light signal received by the eyespot varies. We use a simple mechanical model of Chlamydomonas that couples the flagellar beat pattern to the light intensity at the eyespot to demonstrate a mechanism for phototactic steering that is consistent with observations. The direction of phototaxis is controlled by a parameter in our model and the steering mechanism is robust to noise. In the dark, our model shows emergent run-and-tumble behavior and we see switching between directed phototaxis and run-and-tumble when we switch the light on and off.

4:42PM Q49.00010 Sorting choanoflagellates, VERONICA I. MARCONI, IFEG-CONICET and FaMAF, Universidad Nacional de Cordoba, Cordoba, Argentina, GASTON L. MINO, Department of Civil and Environmental Engineering, Ralph M. Parsons Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, JAVIER SPARACINO, IFEG-CONICET and FaMAF, Universidad Nacional de Cordoba, Cordoba, Argentina, ADOLFO J. BANCHIO, CARLOS A. CONDAT, IFEG-CONICET and FaMAF, Universidad Nacional de Cordoba, Cordoba, Argentina, MIMI A.R. KOEHL, Integrative Biology, University of California, Berkeley, California 94720, USA, NICOLE KING, Department of Molecular and Cell Biology, University of California, Berkeley, California 94720, ROMAN STOCKER, Department of Civil and Environmental Engineering, Ralph M. Parsons Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139 — In freshwater environments, as well as in oceans, environmental conditions are in constant fluctuation. Some heterotrophic plankton must adapt their swimming behavior in order to survive under these conditions. In the case of the choanoflagellate, the closest animal ancestor, the ability to forage for food is given not only by its single flagellum, but also by its differentiation between fast and slow swimmers. The understanding of how these cells with different strategies to swim search for food can give us a better insight into how eukaryotes respond to different stimuli. In this work, we have designed a microfluidic device that sorts choanoflagellates by their speed. The optimal geometry was found by a numerical model using the experimentally determined motilities of each swimmer type.

5:06PM Q49.00012 Swimming of Vorticella in two-dimensional confinement, Luz Sotoelo, Young-Gil Park, University of Texas-Pan American, SungHwan Jung, Virginia Polytechnic Institute and State University, Sangjin Ryu, University of Nebraska-Lincoln — Vorticella is a ciliate observed in the stalked sessile form (trophont), which consists of an inverted bell-shaped cell body (zoid) and a slender stalk attaching the zoid to a substrate. Having circular cilia bands around the oral part, the stalkless zoid of Vorticella can serve as a model system for microorganism swimming. Here we present how the stalkless trophont zoid of Vorticella swims in two-dimensional confined geometries which are similar to the Hele-Shaw cell. Having harvested stalkless Vorticella zooids, we observed their swimming in water between two glass surfaces using video microscopy. Based on measured swimming trajectories and distributions of zooid orientation and swimming velocity, we analyzed how Vorticella’s swimming mobility was influenced by the geometry constraints.

Session Q50 GSOFT: Focus Session: Reconfiguring and Actuating Soft Matter II: Tunable Interactions 218 - Zorana Zeravcic, Rockefeller University

2:30PM Q50.00001 Magnetic field detector consisting of magnetic and semiconducting nanoparticles co-assembled in a liquid crystalline matrix, JOSÉ AMARAL, ANDREA RODARTE, JACKY WAN, CHRISTOPHER FERRI, MAKIKO QUINT, RON PANDOLFI, MICHAEL SCHEIBNER, LINDA HIRST, SAYANTANI GHOSH, University of California, Merced — An exciting area of research is using nano-constituents to create artificial materials that are multifunctional and allow for modification post-fabrication and in situ. In this work, we present the ensemble behavior of iron-oxide magnetic nanoparticles (MNP) and CdSe/ZnS quantum dots (QDs) that dispersed in an electro-optically active liquid crystalline (LC) matrix. The directed assembly of MNP's in the matrix is driven by the temperature-induced transition of the LC from the isotropic to the nematic phase as the MNP are mostly expelled into the isotropic regions, finally ending up clustered around LC defect points when the transition is complete. Our results show a two-fold intensity increase of QD photoluminescence intensity with low magnetic fields (less than 100 mT). We speculate this increase is due to MNP rearrangement which produces a compaction of the clusters, resulting in the detection of increased QD emission. The individual components work together to act as a magnetic field detector and since they are direct assembled in a LC medium, they could potentially be used in a wide range of fluid-based applications. This work was funded by NSF grants DMR-1056860 and ECC-1227034.

2:42PM Q50.00002 Computational and experimental study of magnetic colloidal assembly and martensitic transition, LIN FU, YE YANG, CATHERINE MARCOUX, JOSHUA SOCOLAR, PATRICK CHARBONNEAU, BENJAMIN YELLEN, Duke Univ — Colloidal self-assembly in external fields offers new ways to build up complex structures. Here, we study the self-assembly of a quasi-2D mixture of magnetic and non-magnetic particles immersed in a ferrofluid and under an external magnetic field. We calculate the external field strength-density-tilt angle phase diagram for the system by specialized Monte Carlo methods and compare the results with experiments. By tilting the external field away from the vertical, the system first undergoes magnetostriction, and then a martensitic phase transition between a checkerboard and a striped crystal. We find that the out-of-equilibrium transformation pathway depends strongly on the initial crystal orientation, external field strength and degree of confinement in the third dimension. Our findings suggest the possibility for improving the design of functional materials by selecting the specific type of transformation pathway to optimize either the shape change or the heat exchange properties.
phenomena are needed to describe the observed dynamics. We are especially interested in the crossover region where both phenomena can be used as a switching mechanism in "smart" fluids, i.e. fluids where properties can be tuned rapidly and reversibly by changing external parameters. We use numerical simulations to investigate the rheological properties of MR fluids close to the jamming transition as a function of the applied field and volume fraction. We use anisotropic polarizable colloidal particles and stimulate their reversible aggregation by applying a static external electric field. Through molecular dynamics simulations with a self-consistent calculation of the induced dipole moments, we demonstrate that such particles form monolayers capable of eliminating defects and dislocations, and even self-healing. Potential applications, such as tube formation, are also discussed.

3:06PM Q50.00004 Field-induced growth of self-annealing suspended colloidal monolayers. MING HAN, Northwestern University, LUIJTEN RESEARCH GROUP TEAM — Due to their reduced dimensionality, flexible sheet-like materials have numerous applications, e.g. offering the potential to serve as functional coatings or as a system for encapsulation, akin to biologic membranes. Here we report the ability to generate large ordered, flexible, and suspended monolayers via field-induced self-assembly. We use numerical simulations to investigate the rheological properties of MR thinning viscosities. They are also tunable, which means that both phenomena can be used as a switching mechanism in "smart" fluids, i.e. fluids where properties can be tuned rapidly and reversibly by changing external parameters. We use numerical simulations to investigate the rheological properties of MR fluids close to the jamming transition as a function of the applied field and volume fraction. We are especially interested in the crossover region where both phenomena are needed to describe the observed dynamics.

3:18PM Q50.00005 Directing colloidal assembly and a metal-insulator transition using quenched-disordered polymeric networks. ANH PHAN, University of Illinois at Urbana-Champaign, RYAN JADRICH, The University of Texas at Austin, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — Replica integral equation and effective medium theory methods are employed to elucidate how to massively reconfigure a colloidal assembly and realize equilibrium states of high electrical conductivity at low physical volume fractions [1]. This is achieved by employing variable mesh size networks of rigid rod or semiflexible polymers as a templating internal field. By exploiting bulk phase separation frustration and the tunable competing processes of colloid adhesion on the low dimensional network and fluctuation-driven colloid clustering in the pore spaces, distinct spatial organizations of greatly enhanced particle contacts can be achieved. As a result, a continuous, but very abrupt, transition from an insulating to metallic-like state can be realized via a small change of either the colloid-template or colloid-colloid attraction strength. Polymer conformational fluctuations are found to significantly modify the physical adhesion process and hence the ability of colloids to organize along the filamentary network strands. Qualitatively new physical behavior can emerge as the pore size approaches the colloid diameter, reflecting strong frustrating constraints of the template on colloidal assembly.

3:30PM Q50.00006 Enhanced Mechanical Properties of Nanoparticle Networks Cross-Linked by Biomimetic Catch Bonds. BADEL L. MBANGA, BALAJI V.S. IYER, VICTOR V. YASHIN, ANNA C. BALAZS, Chemical Engineering Department, University of Pittsburgh, Pennsylvania 15261, USA — The tunable behavior of cross-linked networks of Polymer-Granted Nanoparticles (PGNs) makes them excellent candidates for designing novel materials with enhanced mechanical properties. The building block of a PGN network is a nanoparticle with grafted polymer chains whose free ends' reactive groups can form bonds with the end chains on the nearby particles. We use computer modeling to study the tensile behavior of 3D samples, in which some fraction of cross-links is formed through the biomimetic "catch" bonds. In contrast to conventional "slip" bonds, the catch bonds might become stronger under an applied force due to transitions between two conformational states. The mechanical properties of the PGN networks are shown to exhibit a drastic improvement upon introduction of the catch bonds into the network. We discuss how ductility, toughness, and rate of strain recovery of the network depend on the catch bond content.

3:42PM Q50.00007 Magnetic Nano- and Micro-Particles in Living Cells: Kinetics and Fluctuations. C. PEASE, N. CHIANG, C. PIERCE, N. MUTHUSAMY, R. SOORYAKUMAR, Ohio State Univ - Columbus — Functional nano and micro materials have recently been used not only as diagnostic tools for extracellular studies but also as intracellular drug delivery vehicles and as internal probes of the cell. To realize proper cellular applications, it is important not only to achieve efficient delivery of these materials to targeted cells, but also to control their movement and activity within the confines of the cell. In this presentation, superparamagnetic nano and micro particles are utilized as probes, with their responses to weak external magnetic fields enabling them to be maneuvered within a cell. In order to generate the required local magnetic fields needed for manipulation, the fields emanating from microscopic domain walls stabilized on patterned surface profiles are used in conjunction with weak external magnetic fields to create mobile traps that can localize and transport the internalized particle. Preliminary findings on creating the mobile traps suitable for applications to probe the interior of cells, and the responses, both Brownian fluctuations and directed motion, of particles ranging in size from 200 nm to 1 micron within HS-5 cells will be presented. Future applications to probe cellular behavior within the framework of emerging biomaterials will be discussed.

3:54PM Q50.00008 Programming Directed Motion on the Micron Scale by Thermal Ratcheting. EMILY W. GEHERLS, W. BENJAMIN ROGERS, Harvard University, ZORANA ZERAVCIC, Rockefeller University, VINOTHAN N. MANOHARAN, Harvard University — We present an experimental system of DNA-functionalized colloidal particles which exhibit directed motion (“dancing”) along patterned substrates in response to temperature cycling. We take advantage of toehold exchange in the design of the DNA sequences that mediate the colloidal interactions to produce broadened, flat, or even re-entrant binding and unbinding transitions between the particles and substrate. Using this new freedom of design, we devise systems where by thermal ratcheting, we can externally control the direction of motion and sequence of steps of the colloidal dancer. We determine the maximum work that the system can perform by measuring a maximum average velocity as a function of the thermal ratcheting rate.

4:06PM Q50.00009 Tunable Thermal Switching via DNA-Based Nano Devices. MICHAEL ZWOLAK, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, CHIH-CHUN CHIEN, School of Natural Sciences, University of California, Merced, KIRILL VELIZHANIN, Theoretical Division, Los Alamos National Laboratory, YONATAN DUBI, Department of Chemistry and the Ilse Katz Center for Nano-Science, Ben-Gurion University — DNA has a well-defined structural transition – the denaturation of its double-stranded form into two single strands – that strongly affects its thermal transport properties. We show that, according to a paradigmatic model of DNA denaturation, one can engineer DNA “heattronic” devices that have a rapidly increasing thermal conductance over a narrow temperature range across the denaturation transition (∼350 K). The origin of this rapid increase of conductance, or “switching,” is the softening of the lattice and suppression of nonlinear effects as the temperature crosses the transition temperature and DNA denatures. Most importantly, we demonstrate that DNA nanojunctions have a broad range of thermal tunability due to varying the sequence and length, and exploiting the underlying nonlinear behavior. We discuss the role of disorder in the base sequence, as well as the relation to genomic DNA. These results set the basis for developing thermal devices out of materials with nonlinear structural dynamics, as well as understanding the underlying mechanisms of DNA denaturation.
4:18PM Q50.00010 Modeling the rapid de-swelling of toroidal hydrogels, SVETOSLAV NIKOLOV, YAWEN CHANG, ALEXANDER ALEXEYEV, ALBERTO FERNANDEZ DE LAS NIEVES, Georgia Institute of Technology — The utilization of synthetic hydrogel networks as 3-D cell culture platforms has allowed researchers to more effectively study how epigenetic factors affect cell growth and physiology. As a whole, this has emphasized the biomechanical role of scaffold structures and led to a number of advances in tissue engineering. Our current research focuses on modeling temperature activated shape transformations of toroidal poly(N-isopropylacrylamide) pNIPAM gels. We use dissipative particle dynamics (DPD) to simulate the steady (slow heating rates) and unsteady (fast heating rates) de-swelling behavior of these thermo-sensitive gels. Our simulations show that for slow heating rates the aspect ratio of the tori remains constant during de-swelling. For rapid heating rates we observe buckling instabilities. Our simulations agree with the experimental observations. 

Financial support by NSF CAREER Award DMR-1255288 is gratefully acknowledged.

4:30PM Q50.00011 Renewable Interfaces: Surface Topography Actuation for Complex Biological Adhesion Control, LUKA POCIVAVSEK, University of Pittsburgh Medical Center, SANGHO YE, University of Pittsburgh, KATHLEEN CAO, KA YEE C. LEE, University of Chicago, SACHIN VELANKAR, WILLIAM WAGNER, University of Pittsburgh — Controlling adhesion at biological interfaces is a complex problem with great biomedical importance. We use dynamic wrinkling, generated with PDMS/UVO chemistry under different macroscopic strains ($\epsilon_{ij} \sim 0.3$), to create a mechanical interface term that frustrates particle adhesion. This device actuates surface topography between flat (zero surface confinement $\chi_{ij}$) and wrinkled surfaces ($\chi_{ij} \sim (A/\lambda)^2$, where $A$ and $\lambda$ are wrinkle amplitude and wavelength, respectively), with a maximum rate of 0.6 Hz. Un-actuated PDMS placed in contact with whole sheep blood shows near total surface coverage with adhered platelets over 90 min. Actuation showed a nearly 100-fold decrease in platelet adhesion. Interestingly, topographic actuation is four times as effective compared to flat surface actuation in controlling platelet adhesion. Our model explores the competition between surface tension terms ($U_s = \gamma \epsilon_{ij}$) and interfacial elastic terms ($U_i = E_i(t \cdot \epsilon_{ij}^2 + t^3 \cdot (\chi_{ij}/\lambda)^2$) generated because of actuation and wrinkling, where $E_i$ is platelet modulus and $t$ is characteristic platelet length scale. The condition for de-adhesion is $U_s > U_i$.

4:42PM Q50.00012 Underwater Reversible Adhesion Between Oppositely Charged Weak Polyelectrolytes, LATIFAH ALFHAID, MARK GEOGHEGAN, NICHOLAS WILLIAMS, WILLIAM SEDDON, University of Sheffield — Force-distance data has shown that the adhesion between two oppositely charged polyelectrolytes: poly(methacrylic acid) (PMAA, a polyacid) and poly[2-(diethylamino)ethyl methacrylate] (PDEAEMA, a polybase), was controllable by varying the pH level of their surrounding. Accordingly, adhesive force at the interface between these two polymers was higher inside basic surroundings at pH 6 and 7, and then it started to decrease at pH level below 3 and above 8. Stimulating adhesion between PMAA gel and PDEAEMA brushes by adding salt to their surrounded water has only a limited effect on the adhesive force between them, contradicting previous results. Increasing the molar concentration of sodium chloride (NaCl) in the surrounded water of these two polymers from 0.1 to 1M did not decrease these adhesion forces between a PMAA gel and a grafted PDEAEMA layer (brush). The JKR equation was used to evaluate the adhesion forces between the polymer gel and the brushes and it was observed that the adhesion increased with the elastic modulus of the gel decreased.

4:54PM Q50.00013 Observing polymersome dynamics in controlled microscale flows, SUBHAKSHI KUMAR, ANISH SHENOY, CHARLES SCHROEDER, University of Illinois, Urbana Champaign — Achieving an understanding of single particle rheology for large yet deformable particles with controlled membrane viscoelasticity is a major challenge in soft materials. In this work, we directly visualize the dynamics of single polymersomes ($\sim 10 \mu m$ in size) in an extensional flow using optical microscopy. We generate polymer vesicle structures composed of polybutadiene-block-polyethylene oxide (PB-b-PEO) copolymers. Single polymersomes are confined near the stagnation point of a planar extensional flow using poly(methacrylic acid) (PMAA, a polyacid) and poly[2-(diethylamino)ethyl methacrylate] (PDEAEMA, a polybase) was controllable by varying the pH level of their surrounding. Accordingly, adhesive force at the interface between these two polymers was higher inside basic surroundings at pH 6 and 7, and then it started to decrease at pH level below 3 and above 8. Stimulating adhesion between PMAA gel and PDEAEMA brushes by adding salt to their surrounded water has only a limited effect on the adhesive force between them, contradicting previous results. Increasing the molar concentration of sodium chloride (NaCl) in the surrounded water of these two polymers from 0.1 to 1M did not decrease these adhesion forces between a PMAA gel and a grafted PDEAEMA layer (brush). The JKR equation was used to evaluate the adhesion forces between the polymer gel and the brushes and it was observed that the adhesion increased with the elastic modulus of the gel decreased.

5:06PM Q50.00014 pH-induced structural changes in aqueous CTAB/NaSal solutions, CHINEDU UMEASIEGBU, RAMANAN KRISHNAMOORTI, VEMURI BALAKOTAIAH, Department of Chemical Engineering, University of Houston — Cationic surfactants in the presence of hydrotropic salts exhibit pH-sensitive changes to rheological properties and can thus be utilized in ensuring effective stimulation of heterogeneous carbonate reservoirs. In this study, we investigate the pH-induced changes in microstructure and viscoelasticity of aqueous solutions of cetyltrimethylammonium bromide (CTAB) and sodium salicylate (NaSal), and their dependence on temperature, NaSal-to-CTAB ratio (CS/CD) and CTAB concentration (CD). It was observed that the solutions can be switched between gel-like (viscoelastic) and fluid-like (non-viscoelastic) behavior over a narrow pH range, and that the transition pH and associated change in viscoelasticity were strongly dependent on CS/CD. Dynamic light scattering and small-angle neutron scattering results revealed a hitherto unseen re-entrant transition in which micelles transition from cylindrical to spherical micelles but revert to flexible cylindrical micelles on transition pH and associated change in viscoelasticity. Our observations suggest that in addition to the well described electrostatic and hydrophobic interactions in cationic surfactant - hydrotrope interactions, the pH-induced microstructural changes are governed by complementary cation-π interactions and hydrogen bonding.

Wednesday, March 4, 2015 6:45PM - 7:45PM – Session R6 DCMP: Transformational Opportunities for Energy Sciences 006A - George Crabtree, Argonne National Laboratory
6:45PM R6.00001 Community input and update from Basic Energy Sciences Advisory Committee's Directing Matter and Energy Subcommittee, JOHN SARRAO, Los Alamos National Laboratory — BESAC has been charged to update its 2007 report Directing Matter and Energy: Five Challenges for Science and the Imagination, which depicts the science of controlling materials at the electronic, atomic, and molecular levels and represents a revolutionary view of 21st century fundamental science serving the BES community. This report outlined five grand challenges for basic science. These grand challenges, as explicated in the 2007 report, have proven to be a superb prod for the scientific community in the U.S. and beyond. The 46 Energy Frontier Research Centers, created by the Department Of Energy after acceptance of the grand challenge report, as well as the advances of the broader research community, have very effectively pursued the high bar that the five original grand challenges set. From the published results of research that was generated by the original grand challenges, we suggest new opportunities to advance our understanding and mastering of nature. These themes suggest transformational opportunities for energy science of the next decade and beyond. In this town hall, we will present the current status of this study and solicit community input in support of the effort. Additional background information is available at www.besac2014.com.

7:30PM R52.00001 Rise of the Colloidal Machines , SHARON C. GLOTZER, University of Michigan — Digital matter is a new approach in science, engineering, and medicine that uses powerful algorithms and fast computers to discover and design the materials of the future. The idea is to identify and program atoms, molecules, nanoparticles, and microparticles with the optimal shapes and interactions for forming new materials with unprecedented properties. In this talk, I’ll discuss the exciting possibilities of using nano- and micron-sized colloidal particles in the design and fabrication of functional elements for robot-like machines, such as colloidal muscles, digital colloidal bits, bionic colloidal assemblies, and colloidal swarms. These functional colloidal elements could allow researchers to make smart, shape-shifting materials, like those comprising the Terminator T-1000. I’ll also outline the fundamental physics challenges to realizing smart colloidal materials and machines.

I. Gutiérrez Lezama et al. demonstrated the possibility to achieve gate-induced ambipolar transport at the surface [1]. 2H-MoTe$_2$ band gap of around 1.0 eV. This compound shows very high mobility at room temperature and strong absorption throughout the solar spectrum. Previous studies of 2H-MoTe$_2$'s layered structure and the indirect-to-direct band gap transition when approaching the single-layer limit. 2H-MoTe$_2$ shows unique advantages in probing the quasiparticle band structures of the TMD samples with a limited lateral size. However, the STS investigations thus far have not yet consistent results even for the measurement of the quasiparticle band gap. Here we present a new comprehensive methodology of scanning tunneling spectroscopy, which contains the ability not only to probe electronic structures, but also to extract the information on their origins in the Brillouin zone. Thus, we map out, for first time, the quasiparticle energy locations in both the valence and conduction bands of TMD compounds. This capability also allows us to unravel the systematic trend in the critical point energy locations as a function of the cation-anion orbital coupling, the spin-orbital coupling, as well as the interlayer coupling. Such knowledge is critical for understanding the optical properties of TMDs emerging at the atomic scale.

8:12AM S.1.0002 Real-space methods for calculating the electronic response of 2D materials$^1$, BENJAMIN GARRETT, JAMES CHELIKOWSKY, University of Texas at Austin — We study the effects of applied fields on several 2D materials including graphene and metal dichalcogenides. We use a real space density functional method with 2D periodic boundary conditions. This negates the need for a supercell and allows us to directly simulate a transverse electric field. The dielectric properties can be calculated without layer-layer interactions. Changes in band structure in response to imposed fields are also discussed.

8:24AM S.1.0003 Scanning tunneling microscopy/spectroscopy study of graphene – MoS$_2$ heterojunction$^1$, SHIVANI RAJPUT, YAOYI LI, DUSHYANT TOMER, LIAN LI, University of Wisconsin, Milwaukee — Atomic scale topographic fluctuations are relevant to a number of graphene applications including graphene / semiconductor Schottky diodes [1,2]. In this work, we investigate the atomic structures and electronic properties of graphene-MoS$_2$ heterojunction fabricated by transferring chemical vapor deposited monolayer graphene onto mechanically exfoliated multilayer MoS$_2$. Scanning tunneling microscopy reveals the formation of Moiré patterns with corrugations $\sim 0.03$ nm, but no ripples, in contrast to graphene-SiC junctions [1,2]. Scanning tunneling spectroscopy further indicates that the periodic modulations of the Moiré pattern do not influence the electronic properties of the junction. Additional states near the Fermi level are also observed, likely due to impurities trapped at the interface during graphene transfer. These results and their impact on the properties of the van der Waals graphene-MoS$_2$ heterojunction will be discussed at the meeting.

1Supported by U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02-07ER46228.

8:36AM S.1.0004 Imaging and Manipulating Defects in Insulating Hexagonal Boron Nitride Using Scanning Tunneling Microscopy, DILLON WONG, JAIRO VELASCO, LONG JU, JIUNW LEE, SALMAN KAHN, HSINZON TSAI, CHAD GERMANY, University of California, Berkeley, TAKASHI TANIGUCHI, CHIH-KANG SHIH, Univ of Texas, Austin, KENJI WATANABE, National Institute for Material Science, ALEX ZETTL, KAUST, CHIH-KANG SHIH, Univ of Texas, Austin, MING-YANG LI, JING-KAI HUANG, IAMS, Academia Sinica, LAIN-JONG LI, IAMS, Academia Sinica; TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Material Science, ALEX ZETTL, CHIH-KANG SHIH, Univ of Texas, Austin, MING-YANG LI, JING-KAI HUANG, IAMS, Academia Sinica, LAIN-JONG LI, IAMS, Academia Sinica; KAUST, CHIH-KANG SHIH, Univ of Texas, Austin — Accurate knowledge of the electronic structures of materials is the key enabler for the advancement of science and technology based on such materials. Recent emergence of transition metal dichalcogenides (TMDs) as potentially transformative 2D electronic and photonic materials has triggered intensive research activities to investigate their electronic structures. Compared with the previous experimental efforts such as optical spectroscopies and angle resolved photoemission, the scanning tunneling spectroscopy (STS) has the unique advantages in probing the quasiparticle band structures of the TMD samples with a limited lateral size. However, the STS investigations thus far have not yielded consistent results even for the measurement of the quasiparticle band gap. Here we present a new comprehensive methodology of scanning tunneling spectroscopy, which contains the ability not only to probe electronic structures, but also to extract the information on their origins in the Brillouin zone. Thus, we map out, for first time, the critical point energy locations in both the valence and conduction bands of TMD compounds. This capability also allows us to unravel the systematic trend in the critical point energy locations as a function of the cation-anion orbital coupling, the spin-orbital coupling, as well as the interlayer coupling. Such knowledge is critical for understanding the optical properties of TMDs emerging at the atomic scale.

8:48AM S.1.0005 Electronics and atomic scale properties of defects and dopants in 2H-MoTe$_2$, MARIA LONGOBAIRDI, ALBERTO UBALDINI, ENRICO GIANNINI, University of Geneva, DPMC, DAVID R. BOWLER, London Centre for Nanotechnology and Department of Physics and Astronomy, University of London, CHRISTOPH RENNER, University of Geneva, DPMC — We present a detailed STM/STS investigation and corresponding DFT modeling of native dopants and atomic scale defects and their influence on the local electron density of states of 2H-MoTe$_2$. Semiconducting transition metal dichalcogenides (TMDs) are attracting increasing interest in the field of electronics and optoelectronics owing to their layered structure and the indirect-to-direct band gap transition when approaching the single-layer limit. 2H-MoTe$_2$ is a semiconducting TMD with a bulk band gap of around 1.0 eV. This compound shows very high mobility at room temperature and strong absorption throughout the solar spectrum. Previous studies demonstrated the possibility to achieve gate-induced ambipolar transport at the surface [1]. 2H-MoTe$_2$ is thus an attractive candidate for novel optoelectronic devices such as light-emitting diodes, photo detectors and solar cell technology. Controlling the atomic nature and density of defects and dopants is crucial for the development of the aforementioned applications and devices.

9:00AM S1.00006 Simulated scanning tunneling microscopy of few-layer phosphorus allotropes through hexagonal boron nitride, PABLO RIVERO, CEDRIC HORBATH, Univ of Arkansas-Fayetteville, ZHEN ZHU, JIE GUAN, DAVID TOMANEK, Michigan State University, SALVADOR BARRAZA-LOPEZ, Univ of Arkansas-Fayetteville — Four stable layered phosphorus allotropes that are almost degenerated in their configuration energy have been recently discussed [1]. Due to their high reactivity under ambient conditions, their exposed surfaces must be protected [2]. Here, we address the influence of a capping monolayer of hexagonal boron nitride on the scanning tunneling microscopy images of few-layered phosphorus.

9:12AM S1.00007 Scanning Tunneling Spectroscopy of Transition Metal Dichalcogenides: Quasiparticle Gap, Critical Point Energies and Heterojunction Band Offsets, CHIH-KANG SHIH, The University of Texas at Austin — As an emergent atomically thin electronic and photonic materials material, transition metal dichalcogenides (TMDs) has triggered intensive research activities toward understanding of their electronic structures. Here I will introduce a comprehensive form of scanning tunneling spectroscopy (STS) which allows us to probe details quasi-particle electronic structures of TMDs. More specifically, we show that not only the quasi-particle band gaps but also the critical point energy locations and their origins in the Brillouin Zone (BZ) can be revealed using this comprehensive form of STS. By using this new method, we unravel the systematic trend of the critical point energies for TMDs due to atomic orbital couplings, spin-orbital coupling and the interlayer coupling. Moreover, by combining the micro-beam X-ray photoelectron spectroscopy (micro-XPS) and STS, we determine the band offsets in planar heterostructures formed between dissimilar single layer TMDs (MoS2, WSe2, and WS2). We show that both commutativity and transitivity of heterojunction band off hold within the experimental uncertainty.

Other Contributors: (i) Chendong Zhang, Yuxuan Chen, and Amber Johnson at the University of Texas at Austin; (ii) Ming-Yang Li, Jing-Kai Huang, Lain-Jong Li, Chih-Piao Chuu and Mei-Yin Chou at the Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan.

9:48AM S1.00008 Structural phase transitions in monolayer molybdenum dichalcogenides, DUK-HYUN CHOE, HA JUNE SUNG, KEE JOO CHANG, Department of Physics, KAIST — The recent discovery of two-dimensional materials such as graphene and transition metal dichalcogenides (TMDs) has provided opportunities to develop ultimate thin channel devices. In contrast to graphene, the existence of moderate band gap and strong spin-orbit coupling gives rise to exotic electronic properties which vary with layer thickness, lattice structure, and symmetry. TMDs commonly appear in two structures with distinct symmetries, trigonal prismatic 2H and octahedral 1T phases which are semiconducting and metallic, respectively. In this work, we investigate the structural and electronic properties of monolayer molybdenum dichalcogenides (MoX2, where X = S, Se, Te) through first-principles density functional calculations. We find a tendency that the semiconducting 2H phase is more stable than the metallic 1T phase. We show that a spontaneous symmetry breaking of 1T phase leads to various distorted octahedral (1T') phases, thus inducing a metal-to-semiconductor transition. We discuss the effects of carrier doping on the structural stability and the modification of the electronic structure.

10:00AM S1.00009 Scanning Tunneling Microscopy study on exfoliated single-layer MoSe2, XIADONG ZHOU, ALI DADGAR, Department of Physics, Columbia University, New York, New York 10027, USA, FRANCES M. ROSS, IBM T.J.Watson Research Center, Yorktown Heights, New York 10598, USA, ABHAY N. PASUPATHY, Department of Physics, Columbia University, New York, New York 10027, USA — Monolayer transitional metal dichalcogenides (TMDs) MX2 (M = Mo, W, Ti etc; X = S, Se, Te) are a new platform for exploring new electronic and optical phenomena and functionality. However, much remains to be understood about their chemical and local electronic properties when taken to the monolayer limit. We will discuss a scanning tunneling microscopy (STM) study on exfoliated single-layer MoSe2 using a 4-probe STM system. The ability to carry out scanning electron microscopy (SEM) in our system allows us to easily locate and measure single-layer MoSe2 flakes that are mechanically exfoliated on a SiO2/Si substrate and are only a few micrometers in lateral size. Using a combination of imaging and spectroscopy, we will discuss the chemical purity and nature of defect states in this monolayer material. Using an electrostatic back gate, we will describe measurements of the single-particle electronic bandgap as a function of the chemical potential.

10:12AM S1.00010 Defect states in monolayer transition metal dichalcogenides, MAHTAB KHAN, University of Central Florida — Monolayer transition metal dichalcogenides (TMDC) have attracted considerable attention in the past few years. They are direct bandgap semiconductors, with the conduction and valence band edges at the doubly degenerate corners (± K points) of the hexagonal Brillouin zone. Recently, by using novel etching techniques, it was possible to remove a controlled number of atoms from monolayer MoS2, thereby creating a hexagonally shaped pit. By solving the Dirac equation analytically, we show that a pit gives rise to bound states with interesting properties. In particular, the optical selection rules turn out to be very strict. We confirm our analytical results by means of numerical density functional theory (DFT) calculations.

10:24AM S1.00011 Thermoelectric imaging of grain boundaries in monolayer MoS2 on the atomic scale, SANGHEE CHO, HO-KI LYEO, Korea Research Institute of Standards and Science, LAIN-JONG LI, King Abdullah University of Science and Technology, YONG-HYUN KIM, Korea Advanced Institute of Science and Technology, CHENDONG ZHANG, CHIH-KANG SHIH, The University of Texas at Austin — We used scanning thermoelectric microscopy to investigate structural defects such as point defects, edge and grain boundary in ultrathin films of MoS2 grown on graphite. Such structural changes cause the variation in local electronic states, which can be detected by thermoelectric measurement that is differentially sensitive to the Fermi electronic states. Measured thermoelectric power increased with increasing thickness of MoS2 from monolayer to multilayer, which makes a different contrast in the images of thermoelectric measurements. The changes in thermoelectric power with varying thickness can be accounted for by the changes in energy band structure. This imaging method enabled us to identify the metallic edge states, which is similar to prior measurements from tunneling spectroscopy, at the boundaries between MoS2 and graphite. Moreover, grain boundaries appear with distinct contrast in thermoelectric measurements from micrometer to atomic scale, whereas the boundaries were subtle in topographic measurements. Simultaneous measurements of topographic and thermoelectric signal revealed the structural and electronic properties of grain boundaries on the atomic scale.
10:36AM S1.00012 Occupied and Unoccupied Electronic Structure of Na doped MoS\(_2\) (0001). T. KOMESU, University of Nebraska, Lincoln, D. LE, University of Central Florida, X. ZHANG, University of Nebraska, Lincoln, Q. MA, University of California - Riverside, E. F. SCHWIER, Y. KOJIMA, M. ZHENG, H. IWASAWA, K. SHIMADA, M. TANIGUCHI, Hiroshima University, Japan, L. BARTELS, University of California - Riverside, T. S. RAHMAN, University of Central Florida, P. A. DOWBEN, University of Nebraska, Lincoln — The influence of sodium on the band structure of MoS\(_2\) (0001) and the comparison of the experimental band dispersion with density functional theory (DFT) shows excellent agreement for the occupied states (angle-resolved photoemission), and qualitative agreement for the unoccupied states (inverse photoemission spectroscopy). We will show that Na adsorption leads to charge transfer to the MoS\(_2\) surface causing an effect similar to n-type doping of a semiconductor. Moreover, results of our simulations and measurements clearly indicate that the MoS\(_2\) occupied valence band structure shifts rigidly to greater binding with little change in the occupied state dispersion and that the unoccupied states shift downward, approaching the Fermi level, yet the amount of the shift for the unoccupied states is greater than that of the occupied states, effectively causing a narrowing of the bandgap. At higher Na coverages MoS\(_2\) surface becomes metallic. Details of electronic band structure of Na/MoS\(_2\) (0001) will be discussed in light of the role of the frontier orbitals in facilitating chemical reactivity of the system.

10:48AM S1.00013 Effects of spatial averaging on the ARPES spectra of graphene. FREDERIC JOUCKEN, NICOLAS RECKINGER, University of Namur. JOSE AVILA, MARIA CARMEN ASENSIO, Soleil Synchrotron, JÉRÔME LAGOUTE, Université Paris 7 - Paris Diderot, JEAN-FRANÇOIS COLOMÉ, JACQUES GHJESSEN, ROBERT SPOKEN, University of Namur, PHYSICS DEPARTMENT, UNIVERSITY OF NAMUR COLLABORATION, ANATES BEAMLINE, SOLEIL SYNCHROTRON COLLABORATION, STM LAB, MPQ, UNIVERSITÉ PARIS 7 - PARIS DIDEROT COLLABORATION — We report on an ARPES nanoscope investigation (nano-ARPES) and demonstrate that spatial averaging of ARPES data, even on a single graphene domain, lead to apparent kinks in the dispersion relation as well as variations of the MDC widths with binding energy that do not appear in the spectra acquired on a very small spot (below 100nm X 100nm). At the same time, we show that the electronic dispersion relation of our graphene sample is perfectly linear while the MDC widths do not display a simple dependence with the binding energy.

Thursday, March 5, 2015 8:00AM - 11:00AM — Session S2 DMP: Focus Session: Beyond Graphene - Optics in 2D Semiconductors V 001B - Bernhard Urbanzek, INSA Toulouse (France)

8:00AM S2.00001 Optical and electrical responses of optically excited single layer MoS\(_2\) depending on the carrier concentration. SEONG CHU LIM, JINHEE LEE, JUNGHO KIM, HOMIN CHOI, JAESOO KIM, JUNGJOON BAE, MOHAN KUMAR, Department of Energy Science, Center for Integrated Nanostructure Physics, Sungkyunkwan University, Suwon, Republic of Korea — In this work, we study both optical and electrical responses of a single layer molybdenum disulfide (MoS\(_2\)) connecting source and drain electrodes deposited on SiO\(_2\) layer. Depending on the gate bias, the incremental rate of the photocurrent is different, implying the carrier concentration is closely involved with the observations. In semiconducting state at high negative gate bias, the increase of the number of carriers is more influential on electrical conductivity of MoS\(_2\), whereas in metallic state at high positive gate bias, the electron-electron scattering is more dominant. In addition, the photoluminescence (PL) is significantly affected by the carrier concentration as well. At low concentration, PL is stronger than that of higher carrier concentration and PL is weakened Coulomb interaction between electron-hole pairs.

8:12AM S2.00002 Electronic and optoelectronic properties of Few Layer MoS\(_2\) Flake. JIE ZHANG, SUJOY GHOSH, MILINDA WASALA, SAIKAT TALAPATRA, Department of Physics, Southern Illinois University Carbondale IL-62901, USA — We will report on the electronic and optoelectronic properties of few-layers flakes of MoS\(_2\) obtained by mechanical exfoliation of bulk MoS\(_2\) crystal. Measurements performed in field effect transistor (FET) geometry show a room temperature mobility \(\mu_{FET} \sim 40\text{cm}^2\text{V}^{-1}\text{s}^{-1}\). Temperature dependent (50K \textless T \textless 300K) photococonductivity measurements investigated using continuous laser of \(\lambda = 658\text{nm} (E=1.88eV)\), over a broad range of illuminating laser intensity, \(P (0.1\mu W < P < 2\mu W)\) indicate a fractional power dependence of steady state photocurrent on P. Room temperature responsivity obtained in these samples were found to be \(\sim 1 \text{A W}^{-1}\). Variation and/or dependence of these measured properties with respect to temperature will be presented and compared with similar measurements performed other layered 2D Transition Metal Dichalcogenides. This work is supported by the U.S. Army Research Office through a MURI grant # W911NF-11-1-0362.

8:24AM S2.00003 Optical properties of two dimensional gallium selenide. ALARIC BERGERON, Polytechnique Montreal, RICHARD LEONELLI, Université de Montréal, SEBASTIEN FRANCOEUR, Polytechnique Montreal, COPL TEAM — Gallium selenide is a layered metal chalcogenide compound with peculiar but attractive optical properties. Its very high \(d_{2g}\) coefficient, along with its optical transparency from 0.65 to 18 \(\mu m\) and high optical damage threshold, makes it an ideal material for non-linear optical applications. The band structure of GaSe presents a pseudo-direct bandgap, with the direct transition sitting \(-20\text{meV}\) above the indirect one, allowing for efficient photoconductivity and photoluminescence. This could be very interesting for various optoelectronic applications. In this study, we have analyzed the angular and polarization dependence of photoluminescence and second harmonic generation of 2D GaSe flakes of varying thicknesses, down to the monolayer. These results are examined in the light of the few-layer structure symmetry and the unusual optical selection rules forbidding light emission perpendicularly to the basal plane.

8:36AM S2.00004 Optoelectronics of Transition Metal Dichalcogenide Monolayers and Heterostructures. JOHN SCHABLEY, University of Washington — Monolayer transition metal dichalcogenides (TMDs) contain 2D valley excitons which reside in two degenerate momentum space valleys at the edges of the Brillouin zone. It is crucially important to understand fundamental 2D exciton properties in TMD monolayers and van der Waals heterostructures. By performing coherent nonlinear optical spectroscopy with high spectral resolution, we observe nanosecond decay dynamics in single monolayers of MoSe\(_2\), implying the presence of a previously unreported long-lived state that appears to trap the exciton population. In MoSe\(_2\)-WSe\(_2\) vertical heterostructures, we observe intralayer excitons, where the electron and hole are confined to different monolayers, and show evidence of strong exciton-exciton interaction effects and long lifetimes. Based on TMD monolayer excitons, we have also investigated a variety of fundamental quantum devices, including a nano-cavity laser and a second-harmonic generation transistor. Finally, we report a new type of single quantum emitter, based on single localized excitons spatially confined to defects in monolayer of WSe\(_2\). The photoluminescence from these localized excitons is spectrally narrow and shows strong anti-bunching, demonstrating the single photon nature of the emission.
9:12AM S2.00005 Strong in-plane anisotropic optical properties of monolayer, few-layer and bulk ReSe$_2$\textsuperscript{1}. HUAN ZHAO, Univ of Southern California, QIUSHI GUO, Yale University, LUHAO WANG, Univ of Southern California, FENGNIAN XIA, Yale University, HAN WANG, Univ of Southern California — Recently, there has been growing interest in the anisotropic properties of certain two-dimensional (2D) materials with reduced lattice symmetry, such as black phosphorus, for developing novel applications in nanoelectronics and infrared optoelectronics. In this work, we report the strong anisotropic optical and electronic properties of monolayer, few-layer and bulk ReSe$_2$, an emerging member of the 2D transition metal dichalcogenides (TMDs) family. With its bandgap around 1.1 eV and potentially tunable with layer number and strain, ReSe$_2$ may complement black phosphorus for optoelectronic applications utilizing its anisotropic properties in the near-infrared and visible range. Through careful investigations of the polarization-resolved Raman spectroscopy, photoluminescence (PL), polarization-resolved optical extinction spectrum, angle-resolved DC conductance and first principles calculations, we observed and explained the consistent dependence of phonon, optical and electrical properties of ReSe$_2$ on its in-plane crystal orientation. Our results reveal the interesting anisotropic properties of 2D ReSe$_2$ and shed light on its potential applications in electronics and optoelectronics.

9:24AM S2.00006 Electronic and photo-electronic transport in sputter deposited MoS$_2$ film , MILINDA WASALA, SUJOY GHOSH, JIE ZHANG, JULIANNA RICHIE, DIPANJAN MAZUMDAR, Department of Physics, Southern Illinois University Carbondale IL-62901, USA, SWASTIK KAR, Department of Physics, Northeastern University, Boston, MA-02115, USA, SAIKAIT TALAPATRA, Department of Physics, Southern Illinois University Carbondale IL-62901, USA — Here we report on the electrical transport as well as photo response of large area sputter deposited few-layers of thin MoS$_2$. Temperature dependent (55 K -275K) electronic conductivity measured on these samples show evidence of 2D Variable Range Hopping (2D-VRH) mechanism within 100K-275K. Photoconductivity measurements investigated using a continuous laser of $\lambda$ =658nm ($E=1.88eV$), over a broad range of illuminating laser intensity, P ($0.19\mu W < P < 11\mu W$). The steady state photocurrent $(I_{ph})$ indicates a fractional power dependence on laser intensity. The highest responsivities obtained in these films are found to be $\sim 0.2A/W$. The frequency (with Laser pulse frequency range 1Hz-200Hz) dependent photocurrent will be presented and discussed. This work is supported by the U.S. Army Research Office through a MURI grant # W911NF-11-1-0362 and NSF-PIRE OISE-0968405.

9:36AM S2.00007 Unusual Electrooptic Response of Colloidal 2D Transition Metal Dichalcogenide Nanodiscs , DANIEL ROSSI, Texas A&M University, DONG HEE SON, Texas A&M Univ, JINWOO CHEON, JAE HYO HANN, WONIL JUNG, Yonsei University — We have characterized an unusual electrooptic response in colloidal solutions of TiS$_2$, WSe$_2$, and ZrS$_2$ layered transition metal dichalcogenide (TMD) nanodiscs, where transient orientation order is induced by the time varying component of a square-wave electric field, giving rise to linear dichroism which decays even in the presence of the aligning field. Interestingly, identical electrooptic response were seen from both the rising and falling edges of the field, indicating that particle alignment responds to the absolute value of $\Delta E$, regardless of the DC field offset, essentially performing the optical electric field edge detection. Both the magnitude and decay time of the electrooptic response were sensitive to solvent polarity, which we believe is related to the polarity dependent interparticle interactions previously observed in colloidal TiS$_2$ nanodisc solutions. This unusual behavior appears to be a general property of colloidal TMD nanodiscs, potentially resulting from the time varying anisotropy of the induced dipole moment, in contrast to other anisotropic nanostructures with little to no dipole moment anisotropy, where the electrooptic response is dictated by the magnitude of the electric field.

9:48AM S2.00008 Biaxial Strain Engineering in Suspended MoS$_2$, DAVID LLOYD, Boston University, XINGHUI LIU, University of Colorado at Boulder, LAUREN CANTLEY, ERIC KOCH, GUANG YANG, Boston University, NARASIMHA BODDETI, University of Colorado at Boulder, MARTIN L. DUNN, Singapore University of Technology and Design, J. SCOTT BUNCH, Boston University, BUNCH TEAM — Monolayer MoS$_2$ is a direct gap semiconductor and has attracted significant interest for its potential uses in electronics and optoelectronics. It has also been shown to have a highly strain-sensitive bandgap and can sustain strains of up to 11 percent, making it ideally suited for using strain engineering to tune it’s electrical and optical properties. Herein, we fabricate pressurized MoS$_2$ blisters using single and few layer MoS$_2$ membranes suspended over cylindrical microcavities. By applying a pressure difference across the membrane and measuring the changes to its photoluminescence spectrum we study the effect of elastic biaxial strain engineering on the bandgap of MoS$_2$.

10:00AM S2.00009 Pronounced photovoltaic response from PN-junctions of multi-layered MoSe$_2$ on h-BN\textsuperscript{1}. SHAHRIAR MEMARAN\textsuperscript{2}, NIHAR PRADHAN*, ZHENGGUANG LU, DANIEL RHODES, JONATHAN LUDWIG, QIONG ZHOU, NHMF, Florida State Univ, PULICKEL AJAYAN, Rice Univ., DMITRY SMIRNOV, LUIS BALICAS, NHMF, Florida State Univ — Transition metal dichalcogenides (TMDs) such as MoS$_2$, WSe$_2$, etc., are semiconducting van der Waals bonded solids which are exfoliable down to single atomic layers. Monolayers display unique optical as well as optoelectronic properties, while heterostructures incorporating graphene and multi-layered TMDs display pronounced photovoltaic behaviour. Here, we report the observation of rectification and enhanced photocurrents as well as photovoltaic, in lateral PN junctions based on multi-layered ambipolar MoSe$_2$ crystals stacked onto h-BN. Our PN junctions composed of $\sim$10 atom layers are translucent enough to yield photoresponsivities of 1 A/W, external quantum efficiencies exceeding 30 %, short circuit currents exceeding 10$^{-3}$ A/cm$^2$, and photovoltaic efficiencies surpassing 5 % with fill factors of $\sim$70 %. These values compare favourably with those of transparent photovoltaic cells. Given that TMDs can be grown in large area, that their band gap(s) can be tuned by varying composition, and the available strategies for increasing their efficiency, our results suggest a remarkable potential for semi-transparent photovoltaic cells composed of just a few layers of TMDs.

10:12AM S2.00010 Temperature dependent photoconduction in atomically thin Layers of Indium Selenide , SUJOY GHOSH, MILINDA WASALA, JIE ZHANG, Department of Physics, Southern Illinois University Carbondale IL-62901, USA, SIDONG LEI, ROBERT VAJTAI, PULICKEL M. AJAYAN, Department of Materials Science and Nano Engineering, Rice University, Houston, Texas 77005, United States, SAIKAIT TALAPATRA, Department of Physics, Southern Illinois University Carbondale IL-62901, USA — We will report on the photo response in few-layers of thin Indium Selenide (InSe) flakes exfoliated from crystals grown using chemical vapor transport technique. Temperature dependent (20 K -300K) photoconductivity measurements investigated using a continuous laser of $\lambda$ =658nm ($E=1.88eV$), over a broad range of illuminating laser power, P ($0.1\mu W < P < 4\mu W$) indicate a power dependence of steady state photocurrent $(I_{ph})$ on P ($I \sim P^\beta$ with $\beta \sim 1$). The highest responsivity obtained in these samples were $\sim 0.5A/W$. Variation and/or dependence of these measured properties with respect to temperature will be presented. The frequency (with Laser pulse frequency range 1Hz-200Hz) dependent photocurrent will be presented and discussed. This work is supported by the U.S. Army Research Office through a MURI grant # W911NF-11-1-0362.
it through to publication. Those based at undergoing a period of rapid change, these core principles remain largely unchanged. In this talk, I will endeavour to explain how Nature editors – in particular fostering a greater appreciation of these great works of science amongst the wider public. Although the publishing landscape for scientific research is currently two-fold: facilitating the prompt communication of the most important scientific developments to the relevant research communities, while at the same time authors and the research community, the underlying principles of managing the process for journals published by IOP Publishing remain unchanged and yet the UK — Online publishing is challenging, and potentially changing, the role of publishers in both managing the peer-review process and disseminating the work communities they interact with, adapting? In this context, are alternatives to peer review on the horizon? Are these challenges unique to physics journals, or have been transformed by the internet. In particular, increasingly their role appears to be to validate research, not to disseminate it. How are journals, and the duty of scientists in the scientific community, because all scientists take turns serving either as authors, referees, and editors in the peer review process. We lack the themes of trust, where the trust is in institutions and procedures that emerge from expert communities. The practice of peer review is viewed as a citizenly objectivity by the community. The way in which this tends to be done is by peer review conducted by journals. Peer review as currently practiced touches on must be verified by someone who is not the maker of those claims, and who furthermore has no stake in the matter. In other words, claims need to be evaluated objectively, by the community. The way in which this tends to be done is by peer review conducted by journals. Peer review as currently practiced touches on the themes of trust, where the trust is in institutions and procedures that emerge from expert communities. The practice of peer review is viewed as a citizenly duty of scientists in the scientific community, because all scientists take turns serving either as authors, referees, and editors in the peer review process. We lack the resources to have a work evaluated by the entire community, so we substitute with a representative. Yet, in most examples of scientific review, the referee or referees are anonymous. This question is particularly important when the peer review process is brought to bear in order to evaluate matters beyond scientific validity, more "subjective" criteria such as relative importance, breadth of interest – criteria that do not appear to have an objective standard of comparison and validation. I will show that the anonymity of referees, far from endangering this trust, actually strengthens it. I will show that this anonymity is crucial in order to maintain any objectivity in scientific peer review, and why authors should not try to unmask the referee.

Previously, it has been recognized that scientific claims must be verified by someone who is not the maker of those claims, and who furthermore has no stake in the matter. In other words, claims need to be evaluated objectively, by the community. The way in which this tends to be done is by peer review conducted by journals. Peer review as currently practiced touches on the themes of trust, where the trust is in institutions and procedures that emerge from expert communities. The practice of peer review is viewed as a citizenly duty of scientists in the scientific community, because all scientists take turns serving either as authors, referees, and editors in the peer review process. We lack the resources to have a work evaluated by the entire community, so we substitute with a representative. Yet, in most examples of scientific review, the referee or referees are anonymous. Session S4 FEd: Physics Education Research: Course Transformation and Outreach

8:00AM S3.00001 There is no “I” in referee: Why referees should be anonymous DANIEL UCKO 1
Department of Philosophy, Stony Brook University, Stony Brook, NY — From the early days of modern science, it has been recognized that scientific claims must be verified by someone who is not the maker of those claims, and who furthermore has no stake in the matter. In other words, claims need to be evaluated objectively, by the community. The way in which this tends to be done is by peer review conducted by journals. Peer review as currently practiced touches on the themes of trust, where the trust is in institutions and procedures that emerge from expert communities. The practice of peer review is viewed as a citizenly duty of scientists in the scientific community, because all scientists take turns serving either as authors, referees, and editors in the peer review process. We lack the resources to have a work evaluated by the entire community, so we substitute with a representative. Yet, in most examples of scientific review, the referee or referees are anonymous. This question is particularly important when the peer review process is brought to bear in order to evaluate matters beyond scientific validity, more "subjective" criteria such as relative importance, breadth of interest – criteria that do not appear to have an objective standard of comparison and validation. I will show that the anonymity of referees, far from endangering this trust, actually strengthens it. I will show that this anonymity is crucial in order to maintain any objectivity in scientific peer review, and why authors should not try to unmask the referee.

1 Also at The American Physical Society (APS).

8:36AM S3.00002 Validity, not Dissemination SAMINDRANATH MITRA, American Physical Society APS — Science journals have been transformed by the internet. In particular, increasingly their role appears to be to validate research, not to disseminate it. How are journals, and the communities they interact with, adapting? In this context, are alternatives to peer review on the horizon? Are these challenges unique to physics journals, or also seen in other publication scenarios?

9:12AM S3.00003 Peer-review: An IOP Publishing Perspective TIMOTHY SMITH, IOP Publishing, Bristol, UK — Online publishing is challenging, and potentially changing, the role of publishers in both managing the peer-review process and disseminating the work that they publish in meeting contrasting needs from diverse groups of research communities. Recognizing the value of peer-review as a fundamental service to authors and the research community, the underlying principles of managing the process for journals published by IOP Publishing remain unchanged and yet the potential and demand for alternative models exists. This talk will discuss the traditional approach to peer-review placed in the context of this changing demand.

9:48AM S3.00004 Inside Nature ANDREA TARONI, Nature Physics — Since its launch in 1869, Nature has seen its mission as two-fold: facilitating the prompt communication of the most important scientific developments to the relevant research communities, while at the same time fostering a greater appreciation of these great works of science amongst the wider public. Although the publishing landscape for scientific research is currently undergoing a period of rapid change, these core principles remain largely unchanged. In this talk, I will endeavour to explain how Nature editors — in particular those based at Nature Physics — apply these principles in practice, and so determine which few of the many excellent research submissions that we receive make it through to publication.

Thursday, March 5, 2015 8:00AM - 10:00AM —
Session S3 FHP: Invited Session: Why Peer Review? 002AB - Robert Crease, Stony Brook University
8:00AM S4.00001 Assessing the Impacts of a Hybrid “Flipped” Approach to University Physics.  
CHRIS HUGHES, SCOTT PAULSON, James Madison University — Over the course of several years, the physics faculty at James Madison University has been gradually reforming the introductory calculus-based physics sequence to a hybrid model using a ‘flipped classroom’ approach. The content traditionally delivered during lecture was divided into approximately 150 short (5-10 minute) videos. For homework, students are assigned 3-5 videos to watch before each class session. These assignments are combined with in-class activities including gouger problem solving and the tutorials developed by the University of Washington group to provide the students with focused guidance on concepts and skills that students traditionally have left our classes not having mastered. For the fall semester course on mechanics, the Force Concept Inventory (FCI) was used to evaluate student outcomes. For the spring semester course on E&M and optics, the Conceptual Survey of Electricity and Magnetism (CSEM) was used. Student reaction to the course structure was generally positive though there were some complaints in the student evaluations at the end of each semester. However, a positive impact on student outcomes was observed based on the Hake gains on the FCI.

8:12AM S4.00002 Lecture capturing assisted teaching and learning experience.  
LI CHEN, MCPHS University — When it comes to learning, a deep understanding of the material and a broadband of knowledge are equally important. However, provided limited amount of semester time, instructors often find themselves struggling to reach both aspects at the same time and are often forced to make a choice between the two. On one hand, we would like to spend much time to train our students, with demonstrations, step by step guidance and practice, to develop strong critical thinking skills and problem-solving skills. On the other hand, we also would like to cover a wide range of content topics to broaden our students’ understanding. In this presentation, we propose a working scheme that may assist to achieve these two goals at the same time without sacrificing either one. With the help of recorded and pre-recorded lectures and other class materials, it allows instructors to spend more class time to focus on developing critical thinking skills and problem-solving skills, and to apply and connect principle knowledge with real life phenomena. It also allows our students to digest the material at a pace they are comfortable with by watching the recorded lectures over and over. Students now have something as a backup to refer to when they have random mistakes and/or missing spots on their notes, and hence take more ownership of their learning. Advanced technology have offered flexibility of how/when the content can be delivered, and have been assisting towards better teaching and learning strategies.

LEIGH SMITH, Dept of Physics, Univ of Cincinnati — I will describe methods used at the University of Cincinnati to enhance student success in an algebra-based physics course. The first method is to use ALEKS, an adaptive online mathematics tutorial engine, before the term begins. Approximately three to four weeks before the beginning of the term, the professor in the course emails all of the students in the course informing them of the possibility of improving their math proficiency by using ALEKS. Using only a minimal reward on homework, we have achieved a 70% response rate with students spending an average of 8 hours working on their math skills before classes start. The second method is to use a flipped classroom approach. The class of 135 meets in a tiered classroom twice per week for two hours. Over the previous weekend students spend approximately 2 hours reading the book, taking short multiple choice conceptual quizzes, and viewing videos covering the material. In class, students use Learning Catalytics to work through homework problems in groups, guided by the instructor and one learning assistant. Using these interventions, we have reduced the student DWF rate (the fraction of students receiving a D or lower in the class) from an historical average of 35 to 40% to less than 20%.

8:36AM S4.00004 Developing a Standard Based Advanced Lab Course that Fulfills COM3 Requirements.  
RUDI MICHALAK, University of Wyoming — An advanced physics lab has been developed into a course that fulfills the requirements for a university studies program ‘COM3’ course using Standard Teaching (ST) methods. The COM3 course is a capstone course under the new USP2015 study requirements for all majors. It replaces the WC writing requirement, typically filled in the English Dept., and adds the teaching of oral and digital communication skills. ST is a method that replaces typical assessments (homework / exam grades) with new assessments that measure certain specified learning outcomes. In combination with oral assessments and an oral final exam, the ST proves an efficient tool to implement the USP Learning Outcomes into a physics course. COM3 requires an unprecedented seven learning outcomes in a single course. Variety of learning outcomes: interdisciplinary goals, levels of writing (with drafting steps), organizational structure, standard language metrics, research and presentation deliverance skills, appropriate addressing of a variety of audiences, etc. With other assessment approaches than ST this variety would be difficult to meet in a physics course. An extended ST rubric has been developed for this course and will be presented and discussed in some detail.

8:48AM S4.00005 Enhancing Faculty Engagement and Student Learning in Foundational STEM Courses at a Large Public University1.  
HOWARD JACKSON, KATHLEEN KOENIG, Department of Physics, University of Cincinnati, Cincinnati, OH 45221-0011 — Enhancing student learning requires both the strong involvement of the faculty member and the student. We present preliminary efforts of an NSF-supported multi-disciplinary program to enhance learning in foundational STEM courses. A central theme, supported by evidenced-based research across the STEM disciplines, is that active learning engages students in ways that enhance student learning. A secondary theme is that sustained use of active learning techniques by faculty needs a supportive local culture. We describe our initial efforts with the use of Teaching and Learning Liaisons, faculty members trained in research-based instructional strategies in order to lower the barriers for faculty to try new (to them) active learning strategies, and to increase the probability that these faculty carry out the strategies with fidelity. We have assembled a collection of faculty across the STEM disciplines of Biology, Chemistry, and Physics to participate and will compare initial activities by these departments. Efforts to create a supportive culture for these faculty was also provided by tangible department head efforts.

1We acknowledge support from the National Science Foundation (DUE-1022563).

9:00AM S4.00006 Understanding the Spread of Research-Based Instructional Strategies: A Case Study of SCALE-UP.  
ALEXIS KNAUB, CHARLES HENDERSON, Western Michigan University, ROBERT BEICHNER, North Carolina State University, MELISSA DANCY, University of Colorado- Boulder, KATHLEEN FOOTE, North Carolina State University — Secondary implementations of research-based instructional strategies are often non-trivial and can be met with challenges. This talk will focus on lessons learned from a case study of the secondary implementations of Student-Centered Active Learning Environment with Upside-Down Pedagogies (SCALE-UP). SCALE-UP, which started in the physics department of North Carolina State University, is now used across disciplines and at institutes throughout the world. We have examined how SCALE-UP has spread within departments, between departments, and across universities. Both qualitative and quantitative data provide explanation on what has helped and hindered the spread of SCALE-UP at these various levels. We will focus on implications for faculty interested in introducing new instructional strategies at their institution.
9:12AM S4.00007 Lessons from Girl Scout Physics Outreach Day at the University of Michigan, J.T. BOURJ, J.C. WALRATH, C.A. AIDALA, University of Michigan, Ann Arbor, MI — The University of Michigan Society of Women in Physics (SWIP) has been actively collaborating in and coordinating community outreach activities since its founding in 2004. These events range from public demonstration days to high school Physics Olympiad competitions. In 2012, SWIP started an interactive demonstration day for local Girl Scout troops to specifically target an elementary and middle-school aged audience. Girl Scout Day became an annual event, and SWIP interacted with the same set of girls as they matured from 4th-6th graders to 6th-8th graders. At each event, SWIP conducted informal verbal and written surveys on their perceptions of Physics. While in all events girls of all ages asked questions regarding the experience of being a physicist and physics careers, the first event received a significant number of gendered questions. For example, “What percentage of women are physicists?” or “Are there lots of cool girls studying physics?” In following events, these questions were replaced with more technical questions about experiments from the day and questions like “Do you like your choice in jobs?” In this talk we will share our experiences from this outreach project and propose ideas on how to shape events for these age groups in the future.

9:24AM S4.00008 Rare Isotopes At Your Fingertips: a game for introducing students to nuclear science1. ZACHARY CONSTAN, National Superconducting Cyclotron Laboratory, BRIAN WINN, ANDREW DENNIS, Michigan State University, CHRIS WREDE, REMCO ZEGERS, HENDRIK SCHATZ, ALEX BROWN, National Superconducting Cyclotron Laboratory, NICHOLAS THURSTON, CHRISTOPHER BENOIT, SAHIL TANDON, WILLIAM JEFFERY, TYLER SUMMERS, ANDREW BAGDADY, PETER BURROUGHS, JOSEPH DYKSTRA, JOSHUA SHADIK, AMANDA KRUEGER, Michigan State University, MICHAEL BOWRY, CHARLES LOELIUS, MICHAEL BENNETT, National Superconducting Cyclotron Laboratory — Two units at Michigan State University, the Games for Entertainment and Learning (GEL) Lab and National Superconducting Cyclotron Laboratory (NSCL), are developing a touch-based digital game for physics outreach. Players will be able to explore the chart of the nuclides, accelerate stable nuclei, fragment them on a target, and handcraft rare isotopes from the excited protons and neutrons. Gameplay will lead them to the discovery of new isotopes, highlighting stability/instability, nucleosynthesis, radioactive decay, etc. The goal of this game is to bring an awareness and appreciation of nuclear science to a broader audience. Future funding sources will be used to further develop the game into a tool for the classroom, where students will learn about potential career paths in nuclear research.

1Work supported by grants from the American Physical Society and Michigan State University

9:36AM S4.00009 Mitchell Institute Physics Enhancement Program for High School Teachers (MIPEP)1. TATIANA ERIKHIMOVA, ALEXEY BELYANIN, BHASKAR DUTTA, Texas A&M University — The MIPEP is a two-week summer boarding school for physics teachers who had limited training in physics: usually 0-2 credit hours of college-level courses. The school was organized by the Mitchell Institute and Texas A&M Department of Physics and Astronomy during summers 2012-2014. Two weeks of intense training included lectures, physics labs, hands-on demos, tours of various campus research facilities, telescope observations, discussions and meetings with top researchers, and many other physics-related activities. Detailed assessment of the program was performed each year. We will review the results of the first three years of the school and plans for the future.

1The MIPEP has been generously supported by the Mitchell Foundation.

9:48AM S4.00010 Engaging undergraduates in interdisciplinary science during a pre-orientation camp1. JENNIFER HEATH, CATHERINE REINKE, MICHAEL CROSSER, ANNE KRUCHTEN, Linfield College — The Interdisciplinary First-Year Orientation Camp for Undergraduate Sciences (iFOCUS) was created three years ago at Linfield College. Foremost, we looked to create a supportive community to enhance the recruitment, retention, and success of science students— all students, and especially students from non-traditional backgrounds. We saw the close knit community of athletes that came together during pre-orientation practices. Could a community of science students come together with similar enthusiasm and energy? And, we were also looking for a way to expose first year students to a scientific way of thinking, embracing open-ended, research oriented, interdisciplinary problems. After the camp is over, iFOCUS students frequently join faculty research laboratories, they draw in additional students to ongoing learning communities, and a seminar series brings in outside speakers. I will discuss the program initiatives and outcomes, which have been especially useful to physics—where building an enthusiastic peer network and addressing misconceptions about science in general, and physics in particular, seem to be especially useful.

Thursday, March 5, 2015 8:00AM - 10:48AM
Session S5 DMP DCOMP: Focus Session: Spin Fluctuations and Pairing Symmetry in Fe-based Superconductors
Juan Gorman Room 005 - Wei-Cheng Lee, Binghamton University

8:00AM S5.00001 Study on the correlation between s± pairing and intra-orbital spin fluctuations in 1111 iron based superconductors with isovalent doping. HIDE TOMO USUI, KATSUHIRO SUZUKI, KAZUHIKO KUROKI, Department of Physics, Osaka University — Recently, 1111 iron based superconductors with isovalent doping have been experimentally investigated in LnFeAsO1−xFx (Ln=La, Nd, Pr) [1-4]. Interestingly, it was found that Tc takes its local maximum in the intermediate regime of arsenic/phosphorous ratio, which indicates that the superconductivity is locally optimized at a certain Fe-Pn-Fe (Pn=Pnictogen) bond angle larger than 109 deg. Given this background, we study the correlation between the local lattice structure, the orbital character of the Fermi surface, and Tc in 1111 system with isovalent doping. We calculate the band structure of LnFeAsO1−xFx and construct effective five orbital models. To our surprise, it is found that superconductivity is indeed locally optimized in the intermediate arsenic doping regime. The origin of this local optimization is traced back to the gradual variation of the orbital character and the density of states of the hole Fermi surfaces around the Γ point, which is controlled by the bond angle. The consistency with the experiment strongly indicates the importance of the spin fluctuation played in this series of superconductors.

8:12AM S5.00002 Observation of Momentum-Confined In-Gap Impurity State in Ba$_2$K$_2$Fe$_{2}As_2$: Evidence for Antiphase $s^\pm$ Pairing. PENG ZHANG, PIERRE RICHARD, TIAN QIAN, XUX SHI, JUN MA, LINGKUN ZENG, XIAOPING WANG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, EMILE RIENKELS, Helmholtz-Zentrum Berlin, BESSY, CHENGLIN ZHANG, Department of Physics and Astronomy, Rice University, PENGCHENG DAI, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, YIZHUANG YOU, ZHENGYU WENG, Institute for Advanced Study, Tsinghua University, XIANXIN WU, JIANGPING HU, HONG DING, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences — We report the observation by angle-resolved photoemission spectroscopy of an impurity state located inside the superconducting gap of Ba$_2$K$_2$Fe$_{2}As_2$ and vanishing above the superconducting critical temperature, for which the spectral weight is confined in momentum space near the Fermi wave-vector positions. We demonstrate, supported by theoretical simulations, that this in-gap state originates from weak scattering between bands with opposite sign of the superconducting-gap phase. This weak scattering, likely due to off-plane nonmagnetic (Ba, K) disorder, occurs mostly among neighboring Fermi surfaces, suggesting that the superconducting-gap phase changes sign within holelike (and electronlike) bands. Our results impose severe restrictions on the models promoted to explain high-temperature superconductivity in these materials.

8:24AM S5.00003 Anisotropic staggered magnetization in electron-doped Fe-based superconductors , HONG-YI CHEN. National Taiwan Normal University, C.S. TING, University of Houston — Based upon a two-orbital model with competing collinear antiferromagnetism and $s^\pm$ pairing superconductivity, the electronic structures are investigated by solving Bogoliubov-de Gennes equations. Our results for the optimally electron-doped compound exhibit the anisotropic staggered magnetization. The Fourier transformation of the staggered magnetization shows two uneven peaks at $Q_1 = (\pi, 0)$ and $Q_2 = (0, \pi)$. The spatial variation of the $s^\pm$ pairing superconductivity and the electronic charge distribution show a checkerboard-like pattern with $C_2$ symmetry. Finally, in the calculation of the local density of states, we found that the anisotropic staggered magnetization does not open a gap. Our results are good in agreement with the recently reported experimental results.

8:36AM S5.00004 Enhanced spin fluctuations and $s^\pm$ pairing by diagonal electron hopping in Fe-based superconductors , KAZUHIKO KUROIKA, Dept. of Physics, Osaka University — In the itinerant spin picture of the iron-based superconductors, the nesting between electron and hole Fermi surfaces is usually considered to be the origin of the spin fluctuation and thus the pairing glue. However, there have appeared some experimental observations suggesting absence of Fermi surface nesting. For instance, in the 1111 materials $Ln$FeAsO$_{1-x}$F$_x$ (Ln=La,Sm, etc.) [1], electron doping rate $x$ reaches up to 0.5, which in a rigid band picture would wipe out the hole Fermi surfaces. Still, superconductivity not only survives, but is even enhanced in the largely doped regime, in contradiction to the expectation from the bad nesting. Another example is $K_xFe_{2−y}Se_y$, where the ARPES experiments show the absence of hole Fermi surfaces[2-5]. In the present talk, we first focus on $Ln$FeAsO$_{1-x}$F$_x$, where the band structure is actually not rigid against doping, and the hole Fermi surface originating from the d$_{xy}$ orbital remains unchanged. The origin of this can be traced back to real space, where the nearest neighbor hopping $t_1$ within the d$_{xy}$ orbital is found to be strongly suppressed with doping [6]. Although the nesting itself is degraded, the spin fluctuation in the largely electron doped regime is enhanced due to $t_2 > t_1$, where $t_2$ is the second neighbor diagonal hopping. This re-enhances $s^\pm$ pairing superconductivity, and explains the double dome $\Delta T_c$ phase diagram of LaFeAsO$_{1−x}$F$_x$ [1]. From this viewpoint, it is also interesting to look into the relation between $t_1$ and $t_2$ in other materials. For instance, our first principles estimation for $K_xFe_{2−y}Se_y$ gives $t_1 = −0.008$ eV and $t_2 = 0.056$ eV, and from this strong reduction of $t_1$, both electron and hole Fermi surfaces are expected to be present around the $\Gamma$ point, in contradiction to previous experimental observations. Results of a recent ARPES experiment will be discussed from this viewpoint. References [1] S. Iimura et al., Nat. Commun. 3, 943 (2012). [2] T. Qian et al., Phys. Rev. Lett. 106, 187001 (2011). 9:12AM S5.00005 Anomalous scaling behavior of the Specific Heat jump $\Delta C$ vs. $T_c$ in the Fe-based superconductors , YUNKYU BANG, Department of Physics, Chonnam National University, Kwangju 500-757, Korea, G.R. STEWART, Physics Department, University of Florida, Gainesville, FL 32611-8440 — So called BNC scaling ($\Delta C \propto T_c$) has been observed in a wide range of the Fe-based superconducting compounds such as Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$, Ba(Fe$_{1-x}$Ni$_x$)$_2$As$_2$, BaFe$_2$As$_2$ and Ba$_2$Fe$_4$As$_2$. More recently, however, Canfield and coworkers reported that the Ba$_2$K$_2$Fe$_{2}As_2$ compound severely deviates from this scaling when $x>0.7$ and argued that this is an indication of the Lifshitz transition in the Ba$_2$K$_2$Fe$_{2}As_2$ compound at higher hole doping. In this presentation, we propose a theory that the BNC scaling as well as its strong deviation, as observed in Ba$_2$K$_2$Fe$_{2}As_2$, is an intrinsic property of the multiband superconductor mediated by a dominant interband pairing potential as realized in the sign-changing S-wave state.

9:24AM S5.00006 The effects of Coulomb interactions on the superconducting gaps in iron-based superconductors , ZHIDONG LEONG, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — Recent ARPES measurements on Co-doped LiFeAs report a large and robust superconducting gap on a band below the chemical potential. We will show that, unlike a conventional BCS theory, a multiband system with strong interband Coulomb interactions can explain the observations. We use a two-band model consisting of a superconducting electron band and a hole band that is below the chemical potential. The two bands are coupled via interband Coulomb interactions. Using Eliashberg theory, we found that superconductivity in the electron band induces a large superconducting gap in the hole band. Furthermore, the repulsive nature of the Coulomb interactions gives the induced gap an opposite sign, corresponding to an $s^\pm$ gap symmetry. Unlike other families of iron pnictides, the gap symmetry of LiFeAs has not been ascertained experimentally. The implications for the mechanism of pinning in iron pnictides will be discussed.

Z. Leong is supported by a scholarship from the Agency of Science, Technology and Research. P. Phillips is supported by the Center for Emergent Superconductivity, a DOE Energy Frontier Research Center, Grant No. DE-AC0298CH1088.

9:36AM S5.00007 Doping-induced crossover of the pairing symmetry in iron- pnictide superconductors , MAHMoud ABDEL-HAFIEZ, ZHENG HE, Center for High Pressure Science and Technology Advanced Research, Shanghai, 201203, China, XINGYE LU, HUIQIAN LUO, PENGCHENG DAI, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research, Shanghai, 201203, China, HPSTAR TEAM, CHINESE ACADEMY OF SCIENCES TEAM — Iron pnictides present a rich phase diagram and superconductivity coexists and competes with the spin density wave and the nematic order, giving unconventional pairing mechanisms. Although various efforts have put forth to clarify pairing symmetry of the Cooper pair, experimental confirmations of the precise symmetry of the superconducting (SC) order parameter and its evolution with doping remains highly controversial. Here we present the investigation results of the low-temperature specific heat down to 70 mK for high-quality BaFe$_{2−x}$Ni$_x$As$_2$ single crystals. For $x \leq 0.12$, the temperature dependence of the SC-state specific heat provides strong evidence for a two-band $s$-wave order parameter. Upon doping for $x \geq 0.15$, we find the temperature and magnetic field contributions to the specific heat in $T^2$ and $H^2$ respectively, which strongly indicate the nodes in the SC gap.
9:48AM S5.00008 Leggett modes and vortex dynamics in time-reversal symmetry breaking multiband superconductors , MIKHAIL SILAEV, EGOR BABAЕV, The Royal Institute of Technology, Stockholm, Sweden — In the framework of quasiclassical kinetic theory we study the spectrum of collective excitations and vortex dynamics in multiband superconductors. We show that the existence of mixed phase-density modes in multiband superconductors with broken time-reversal symmetry generates a new contribution to the viscosity of magnetic flux flow. Near the time reversal symmetry breaking phase transition this new contribution dominates over the usual Tinkham and Bardeen-Stephen mechanisms and provides a peculiar temperature dependence of the vortex viscosity. The results could be relevant for three band superconductor Ba$_{1-x}$K$_x$Fe$_2$As$_2$.

10:00AM S5.00009 Spontaneous currents in a superconductor with s+is symmetry , MANFRED SIGRIST, Institut fur Theoretische Physik, ETH Zurich, SAURABH MAITI, University of Florida and NHMFL, ANDREY CHUBUKOV, William I. Fine Theoretical Physics Institute, and School of Physics and Astronomy, University of Minnesota — We analyze s+ıs state proposed as a candidate superconducting state for strongly hole-doped Ba-122. Such a state breaks time-reversal symmetry (TRS) but does not break any other discrete symmetry. We address the issue whether TRS breaking alone can generate spontaneous currents near impurity sites, which could be detected in, e.g., 7SR experiments. We argue that there are no spontaneous currents if only TRS is broken. However, supercurrents do emerge if the system is put under external strain and C4 lattice rotation symmetry is externally broken.

10:12AM S5.00010 Gap structure in Fe-based superconductors with accidental nodes , ALBERTO HINOJOSA ALVARADO, ANDREY CHUBUKOV, University of Minnesota Twin Cities — We study Fe-based superconductors with s-symmetry and accidental gap nodes on electron pockets. We consider ellipticity, hybridization and an additional inter-pocket pairing interaction and analyze their effect on the gap structure and on the existence of nodal points in the quasiparticle dispersions. Depending on these parameters the gap functions at the Fermi surface may be uniform, have nodal points, or vary their phase continuously. In the quasiparticle dispersions, there exist nodal points only if the phase difference between the hybridization and inter-pocket pairing parameters is a multiple of $\pi/2$. The two parameters tend to shift the position of the nodes in the same or in opposite directions depending on their relative phases. When the parameters reach a critical value the nodes disappear.

10:24AM S5.00011 Glide plane symmetry and gap structure in the iron-based superconductors , YAN WANG, Department of Physics, University of Florida, TOM BERLJIN, Oak Ridge National Laboratory, PETER HIRSCHFELD, Department of Physics, University of Florida, DOUGLAS SCALAPINO, Department of Physics, University of California, Santa Barbara, THOMAS MAIER, Oak Ridge National Laboratory — We consider the effect of glide plane symmetry of the Fe-pnictogen/chalcogen layer in Fe-based superconductors for pairing in spin fluctuation models. Recent theories have proposed that so-called $\eta$-pairing states with nonzero total momentum can be realized and possess exotic properties such as odd parity spin singlet symmetry and time-reversal symmetry breaking. Here we show that $\eta$-pairing is inevitable when the orbital level from orbitals with even and odd mirror reflection symmetry in $z$; however, by explicit calculation, we conclude that the gap function that appears in observable quantities is identical to that found in earlier, 1 Fe per unit cell pseudo-crystal momentum calculations. P.J.H. and Y.W. were supported by Grant No. DOE DE-FG02-05ER46236 and T.B. was supported as a Wigner Fellow at the Oak Ridge National Laboratory. A portion of this research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, Office of Basic Energy Sciences, US Department of Energy.

10:36AM S5.00012 Enhanced $s^\pm$ pairing due to prioritized diagonal motion of electrons in the iron-based superconductors , KAZUHIKO KUROKI, KATSUHIRO SUZUKI, HIDETOMO USUI, Osaka University — In the itinerant spin picture of the iron-based superconductors, the nesting between electron and hole Fermi surfaces is usually considered to be the origin of the spin fluctuation. However, there are now some experimental results suggesting that the nesting is not important for superconductivity. An example is the 1111 materials LnFeAsO$_{1-x}$F$_x$ (Ln=La,Sm etc.), where over 50% of electron doping can be accomplished. Superconductivity not only survives, but is even enhanced in the largely electron-doped regime, in contradiction to the expectation from the bad nesting. In La$_2$FeAsO$_{1-x}$F$_x$ in particular, the $x$ vs. $T_c$ phase diagram exhibits a double dome feature, suggesting a possible difference in the pairing mechanism between the lightly doped and the heavily doped regimes. In the present study, we analyze the five orbital model of this system, and show that a peculiar relation among the real space hoppings is realized in the largely electron-doped regime, namely, the next nearest neighbor hopping dominates over the nearest one within the $d_{xy}$ orbitals. We argue that this enhances the $s^\pm$ pairing, which is a next nearest neighbor pairing in real space, despite the degraded nesting. We also discuss about some other materials having similar real space hoppings.
8:36AM S6.00002 Surface plasmon decay dynamics in nanostructured systems: A Feynman diagram approach1, PRINEHA NARANG, RAVISHANKAR SUNDARARAMAN, ADAM S. JERMYN, WILLIAM A. GODDARD III, HARRY A. ATWATER, California Institute of Technology, (Caltech) — The decay of surface plasmon resonances is usually a detriment in the field of plasmonics, but the possibility to capture the energy normally lost to heat would open new opportunities in photon sensors and energy conversion devices. In the context of hot-electron devices, the large extinction cross-section at a surface plasmon resonance enables nanostructures to absorb a significant fraction of the solar spectrum in very thin films. Despite the significant experimental work in this direction, a complete theoretical understanding of plasmon-driven hot carrier generation with electronic structure details has been evasive. Recently we analyzed the quantum decay of surface plasmon polaritons and found that the prompt distribution of generated carriers is extremely sensitive to the energy band structure of the plasmonic material. In this context, we use a Feynman diagram approach to describe processes involving plasmons, electrons and phonons in plasmonic hot carrier generation. Built upon this general theoretical and computational framework, we present results on higher order processes such as multi-plasmon decays in metals which are critical for plasmon-driven upconversion.

8:48AM S6.00003 Photonic pulling force in one-way waveguides, DANLU WANG, Univ of Texas, Austin, Department of Physics, CHENGWEI QIU, National University of Singapore, Department of Electrical and Computer Engineering, PETER RAKICH, Yale University, Department of Applied Physics, ZHENG WANG, Univ of Texas, Austin, Department of Electrical and Computer Engineering — Light can apply pulling force on dielectric particles through forward scattering, i.e., scattering that increases photon momentum. The forward scattering typically requires conditions in free space, e.g., large incident angle, excitation of dipole-quadrupole interaction on spherically shaped particles. Here we demonstrate photonic pulling forces on dielectric particles in photonic crystal defect waveguides supporting one-way chiral edge modes. Intuitively, momentum discrepancy between two co-existing one-way modes facilitate forward scattering on arbitrarily configured particles inside the waveguide, over a broad frequency range, upon proper choice of incident mode. The pulling forces are also topologically protected against bending of the waveguide. Moreover, we rigorously relates the direction and amplitude of photonic forces to the phase response of output modes versus the particle’s displacement. While the phase response of output modes is determined by wave functions of the involved modes.

9:00AM S6.00004 PT symmetry in optics, DEMETRIOS CHRISTODOUIDES, CREOL, The College of Optics and Photonics, University of Central Florida — Interest in complex Hamiltonians has been rekindled after the realization that a wide class of non-Hermitian Hamiltonians can have entirely real spectra as long as they simultaneously respect parity and time reversal operators. In non-relativistic quantum mechanics, governed by the Schrödinger equation, a necessary but not sufficient condition for PT symmetry to hold is that the complex potential should involve real and imaginary parts which are even and odd functions of position respectively. As recently indicated, optical systems observe the same conditions in free space, e.g., large incident angle, excitation of dipole-quadrupole interaction on spherically shaped particles. Here we demonstrate photonic pulling forces on dielectric particles in photonic crystal defect waveguides supporting one-way chiral edge modes. Intuitively, momentum discrepancy between two co-existing one-way modes facilitate forward scattering on arbitrarily configured particles inside the waveguide, over a broad frequency range, upon proper choice of incident mode. The pulling forces are also topologically protected against bending of the waveguide. Moreover, we rigorously relates the direction and amplitude of photonic forces to the phase response of output modes versus the particle’s displacement. While the phase response of output modes is determined by wave functions of the involved modes.

9:36AM S6.00005 Parity-Time Symmetric Nonlocal Metamaterials for Focusing and Image Processing, FRANCESCO MONTICONE, The University of Texas at Austin, CONSTANTINOS VALAGIANOPoulos, Aalto University, Finland, SILVIO SAVOIA, University of Sannio, Italy, ROMAIN FLEURY, ANDREA ALU, The University of Texas at Austin — Parity-Time (PT) symmetry refers to the invariance of a physical system upon reflection of space and time. An intriguing property of PT-symmetric quantum systems is the fact that they can have entirely real eigenvalue spectra, despite being non-Hermitian. Although the application of these concepts in quantum mechanics remains speculative, in classical optics non-Hermitian PT-symmetric systems can be readily realized with spatially balanced gain and loss. These systems have been shown to exhibit exotic responses, e.g., unidirectional invisibility, or anomalous scattering. Recently, negative refraction and planar focusing have been achieved by pairing a perfectly coherent absorbing metasurface with its time-reversed counterpart, i.e., a coherently lasing metasurface. Here, we generalize this idea to any pair of PT-symmetric structures, characterized by their scattering matrix, to put forward a realistic venue to PT-symmetric metamaterials for imaging. This approach allows us to design realistic structures based, e.g., on multilayered slabs, which implement the necessary nonlocality and spatial dispersion to achieve ideal all-angle negative refraction and planar focusing. We will also discuss how these concepts may realize arbitrary magnifying, focusing and image processing systems.

9:48AM S6.00006 Single-mode laser by parity-time symmetry breaking, LIANG FENG, NSF Nanoscale Science and Engineering Center, UC Berkeley and Department of Electrical Engineering, SUNY Buffalo, ZI JING WONG, NSF Nanoscale Science and Engineering Center, UC Berkeley, REN-MIN MA, NSF Nanoscale Science and Engineering Center, UC Berkeley and Department of Physics, Peking University, YUAN WANG, XIANG ZHANG, NSF Nanoscale Science and Engineering Center, UC Berkeley — Effective manipulation of cavity resonant modes is crucial for emission control in laser physics and applications. Using the concept of parity-time symmetry to exploit the interplay between gain and loss (i.e. light amplification and absorption), we demonstrate a parity-time synthetic laser with resonant modes that can be controlled at will. In contrast to conventional ring cavity lasers with multiple competing modes, our parity-time microring lasers exhibit robust broadband single-mode lasing regardless of the gain spectral bandwidth. Thresholdless parity-time symmetry breaking due to the rotationally symmetric structure leads to stable single-mode operation with the selective whispering-gallery mode order. Exploration of parity-time symmetry in laser physics may develop a new paradigm of strategically utilizing optical losses and open a door to next-generation optoelectronic devices for optical communications and computing.

10:00AM S6.00007 Hybrid chiral metamaterials by dynamic shadowing growth, JOHN GIBBS, Northern Arizona University, PEER FISCHER, ANDREW MARK, SAHAND ESLAMI, TUNG-CHUN LEE, Max Planck Institute for Intelligent Systems — Coupling optical and magnetic properties is possible in hybrid and in higher-order magnetic field induced optical activities. Here, we show that these two mechanisms can be combined in nanostructures that are simultaneously ferromagnetic, chiral, and plasmonically resonant. In this talk, a short description of the fabrication of optically active helical metamaterials will first be given, followed by the highlighting of the materials’ enhanced optical properties. Giant circular dichroism (CD) and optical rotatory dispersion (ORD) in the visible arise from helical plasmonic modes within the individual structures and can be tuned by altering the material composition, i.e. nanolayers or nanocomposites, and/or by changing the structures’ morphologies. By fabricating metamaterials which exhibit both strong CD and are ferromagnetic at room temperature, higher order terms in the generalized dielectric function in the presence of a B-field can be measured easily. In particular, magnetochiral dichroism (MChD) is a cross-term between chirality and an applied external B-field which has only been measured in crystals and molecules, but never in a metamaterial. We show that arrays of helical Ni nanostructures, due to the plasmonic nature of Ni, their chirality, as well as the fact they retain their ferromagnetism even at scales comparable to the average ferromagnetic domain size, exhibit an MChD signal that is much more pronounced in a metamaterial and can therefore be easily measured in the laboratory.
10:12AM S6.00008 Chiral Quantum Dots¹, MILAN BALAZ, University of Wyoming, Department of Chemistry, Laramie, WY, USA — Chiral optically active semiconductor quantum dots (chiral QDs) represent appealing building blocks for assembly of nanomaterials with modular structural, electronic and optical properties. Chirality in QDs can originate from several distinct phenomena that can concurrently modulate the observed chiroptical and optical properties (e.g. chiral surface, orbital hybridization). We will use our experimental and theoretical data to elaborate on the origin of capping ligand induced chirality in achiral colloidal QDs [1]. We will present a simple method to prepare chiral QDs by post-synthetic chiral ligand functionalization of achiral QDs. Importantly, capping ligands can be used not only to induce but also to control chiroptical activity of QDs. Enantiomers of chiral ligands induce mirror-image chirality in QDs, and chiroptical properties of QDs can be further modulated by the chemical structure of capping ligands as well as the size of QDs.

10:36AM S6.00010 Manipulating the polarization state of light with a metallic stereostructured layer, XIANG XIONG, SHANG-CHI JIANG, YUAN-SHENG HU, MU WANG, RU-WEN PENG, Nanjing University — Without introducing dielectric material, we report here for the first time a wave plate constructed merely by metallic stereostructured layer. With an assembly of metallic L-shaped stereostructures (LSSs), the polarization state of the reflected light can be freely manipulated within a broad frequency band. The amplitude ratio of light in two orthogonal directions and the phase difference in these two directions can be tuned accurately and independently. We suggest that our design provides a new approach in realizing broadband wave plate device to manipulate the polarization state of light.

10:48AM S6.00011 Polarisation singularities in photonic crystals for an on-chip spin-photon interface, DARYL M. BEGGS, ANDREW B. YOUNG, ARTHUR C. T. THIJSSEN, RUTH OULTON, University of Bristol — Integrated quantum photonic chips are a leading contender for future quantum technologies, which aim to use the entanglement and superposition properties of quantum physics to speed up the manipulation of data. Quantum information may be stored and transmitted in photons, which make excellent flying qubits. Photons suffer little from decoherence, and single qubit gates performed by changing photon phase, are straightforward. Less straightforward is the ability to create two qubit gates, where one photon is used to switch another’s state; inherently difficult due to the extremely small interaction cross-section between photons. The required deterministic two-qubit interactions will likely need a hybrid scheme with the “flying” photonic qubit interacting with a “static” matter qubit. Here we present the design of a photonic crystal waveguide structure that can couple electron-spin to photon path, thus providing an interface between a static and a flying qubit. We will show that the complex polarization properties inherent in the photonic crystal eigenmodes supports polarization singularities – positions in the electric field vector where one of the parameters describing the local polarization ellipse is singular – and that these singularities are ideal for a range of quantum information applications. In particular, we will show that by placing a quantum dot at one of these singularities, the electron-spin becomes correlated with the photon emission direction, creating an in-plane spin-photon interface that can transfer quantum information from static to flying qubits.

Thursday, March 5, 2015 8:00AM - 11:00AM – Session S7 DMP DCMP: Focus Session: Dirac & Weyl Semimetals 006B - Madhab Neupane, Princeton University

8:00AM S7.00001 Prediction of a strain-tunable 2D Topological Dirac semimetal in monolayers of black phosphorus, XIUWEN ZHANG, QIHANG LIU, ALEX ZUNGER, University of Colorado, Boulder, THEORY TEAM — N-dimensional Topological Nonmetals (TMN) such as N = 2D HgTe/CdTe quantum wells or N = 3D Bi2Se3 have a finite (often tiny) band gap between occupied and unoccupied bands, and show conductive Dirac cones in their N-1 dimensional geometric boundaries. On the other hand, examples of topological semimetals (TSM) are known for 3D solids (Cd3As2) where they have Dirac cones in the 3D system itself. Using density functional calculation of bands and the topological invariant Z2, we predict the existence of 2D topological Dirac semimetal in few monolayers of strain tuned black phosphorus (BP), with Dirac cones induced by band inversion. The band structures of few monolayers and bulk crystal of BP under a few percent biaxial and uniaxial strains were calculated using state-of-art electronic structure methods. The critical strain of the transition to TSM was found to decrease as the layer thickness increases. We will discuss the protection of the Dirac cones by the crystalline symmetry in the 2D TSM and the manipulation of crystalline symmetry, which induces further topological phase transitions. Supported by the NSF-DMREF-13-34170.

8:12AM S7.00002 Interaction effects of a topological Dirac semimetal Na3Bi, RUIXING ZHANG, The Pennsylvania State University, JIMMY HUTASOIT, Leiden University, CHAOXING LIU, The Pennsylvania State University — We study the interaction effects of a topological Dirac semimetal Na3Bi based on the mean field theory. The phase diagram can be classified by two kinds of chiral-symmetry-breaking order parameters: nematic orders that break rotational symmetry and charge-density-wave (CDW) order that break translational symmetry. Under strong magnetic field, gapless Landau levels will be formed and result in stabilities due to the above order parameters. These order parameters are generally complex, and are identified as complex mass terms, which introduce axioms into the low energy theory. The possible experimental consequence is also studied.
8:24AM S7.00003 Density of states and transport in Weyl semimetals with long-range disorder1
, DMYTRO PESIN, University of Utah, Salt Lake City, UT, ALEX LEVCHENKO, Michigan State University, East Lansing, MI — We consider the density of states in a Weyl semimetal with long-range Coulomb impurities. We show that at energies close to the nodal point the motion of electrons is essentially classical, and compute the density of states at low energies for the cases of self-consistent screening, and screening by non-Weyl bands. As an alternative to the recent renormalization-group calculations, we develop a diagrammatic technique that is capable of capturing quantum corrections to the classical result, and determine the applicability range of the classical treatment, as well as the energy dependence of the density of states away from the nodal points. Finally, the obtained results are contrasted with those obtained from the self-consistent Born approximation, and the implications for the electrical, thermal and thermomagnetic transport properties of the Weyl semimetal are discussed.

1The work at the University of Utah is supported by NSF Grant No. DMR-1409089, the work at MSU is supported by NSF Grant No. DMR-1401908

8:36AM S7.00004 Theory of Symmetry Protected 2D Dirac Semimetals and Derivative Topological States , STEVE YOUNG, Center for Computational Materials Science, Naval Research Laboratory, CHARLES KANE, Department of Physics, University of Pennsylvania — We present the theory of symmetry-protected 2D Dirac semimetals. These systems are distinguished from graphene by the presence of spin-orbit coupling, under which the latter becomes a quantum spin hall insulator. 2D Dirac semimetals exhibit behavior distinct from both graphene and their three-dimensional counterparts. We discuss the symmetry requirements for such systems, and using the simplest tight-binding model satisfying them, describe their properties, as well as the states that result from relaxing various constraints, including Weyl semimetal and topological insulator states. Additionally, we provide suggestions for realizing these systems based on Density Functional Theory calculations.

8:48AM S7.00005 Thermoelectric properties of Weyl and Dirac semimetals , PONTUS LAURELL, REX LUNDGREN, GREGORY FIETE, University of Texas at Austin — We study the electronic contribution to the thermal conductivity and the thermopower of Weyl and Dirac semimetals using a semiclassical Boltzmann approach. We investigate the effect of various relaxation processes including disorder and interactions on the thermoelectric properties, and also consider doping away from the Weyl or Dirac point. We find that the thermal conductivity and thermopower have a dependence on the chemical potential that is characteristic of the linear electronic dispersion, and the electron-electron interactions modify the Lorenz number. For the interacting system, we also use the Kubo formalism to obtain the transport coefficients, finding exact agreement with the Boltzmann approach at high temperatures. We also consider the effect of electric and magnetic fields on the thermal conductivity in various orientations with respect to the temperature gradient. Notably, when the temperature gradient and magnetic field are parallel, we find a large contribution to the longitudinal thermal conductivity that is quadratic in the magnetic field strength, similar to the magnetic field dependence of the longitudinal electrical conductivity due to the presence of the chiral anomaly when no thermal gradient is present.

9:00AM S7.00006 Kondo effect and non-Fermi liquid behavior in Dirac and Weyl semimetals , E. ROSSI, Physics Department, College of William and Mary, ALESSANDRO PRINCIPI, GIOVANNI VIGNALE, Physics Department, University of Missouri — We study the Kondo effect in three-dimensional (3D) Dirac materials and Weyl semimetals [1]. We find the scaling of the Kondo temperature with respect to the doping n and the coupling J between the moment of the magnetic impurity and the carriers of the semimetal. We find that when the temperature is much smaller than the Kondo temperature the resistivity due to the Kondo effect scales as the n to the -4/3. We also study the effect of the interplay of long-range scalar disorder and Kondo effect. In the presence of disorder-induced long-range carrier density inhomogeneities the Kondo effect is not characterized by a Kondo temperature but by a distribution of Kondo temperatures. We obtain the expression of such distribution and show that its features cause the appearance of strong non-Fermi liquid behavior. Finally we compare the properties of the Kondo effect in 3D Dirac materials and 2D Dirac systems like graphene and topological insulators.

Work supported by ONR-N00014-13-1-0321.

9:12AM S7.00007 Visualizing the Electronic Structure of Topological Dirac Semimetals , YULIN CHEN, Oxford University — Three-dimensional (3D) topological Dirac semimetals (TDSs) represent an unusual state of quantum matter that can be viewed as “3D graphene.” In contrast to 2D Dirac fermions in graphene or on the surface of 3D topological insulators, TDSs possess 3D Dirac fermions in the bulk. Moreover, a TDS can potentially be driven into other exotic phases (such as Weyl semimetals, axion insulators or topological superconductors), making it a unique parent compound for the study of these states and the phase transitions between them. By investigating the electronic structure of Na3Bi and Cd3As2 with angle-resolved photoemission spectroscopy including kz information, we discovered bulk (3D) Dirac fermions with linear dispersions along all three momentum directions in both materials. Furthermore, we can demonstrate the robustness of these 3D Dirac fermions against in situ surface doping, showing the protection of the bulk crystal symmetry. These findings establish both materials as model systems of 3D TDSs, which can also serve as ideal platforms for exploring exotic physical phenomena and novel applications.

9:48AM S7.00008 Tendency to Localization in Interacting Weyl Semimetals1, HAIZHOU LU, SHUNQING SHEN, The Univ of Hong Kong — Weyl semimetals are novel topological states of quantum matter, in which electrons or Weyl fermions are robust against impurity or disorder, and tend to be delocalized. In a weak external magnetic field, a negative magnetoconductivity is found to be proportional to the square root of magnetic field at low temperatures, giving the signature of the delocalization. However, here we demonstrate that the metallic and delocalization behavior of Weyl semimetals can be sabotaged by electron-electron interaction and inter-valley effects. An “insulating” tendency is therefore illustrated in disordered and interacting Weyl semimetals. Reference: Hai-Zhou Lu and Shun-Qing Shen, arXiv:1411.2686

10:00AM S7.00009 Topological Imbert-Fedorov shift in Weyl semimetals , QING-DONG JIANG, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China, HUA JIANG, College of Physics, Optoelectronics and Energy, Soochow University, Suzhou 215006, China, HAIWEN LIU, QING-FENG SUN, X.C. XIE, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — When a beam of light (photons) is reflected at an interface, the wave nature of photons can result in spatial shifts at the interface in the plane of incidence (longitudinal shift) and normal to the plane (transverse shift), which are referred as Goos-Hänchen (GH) shift and Imbert-Fedorov (IF) shift, respectively. As the massless fermionic cousin of photons, Weyl fermions are expected to share certain similar characteristics as photons. Here, we report the GH and IF effects in Weyl semimetals—a promising material harboring low energy Weyl fermions. Our results show that GH effect in WSMs is analogous to that discovered in a 2D relativistic material—graphene; however, the IF effect has no 2D counterpart, since it is genuinely a 3D effect. We emphasize that the IF shift actually originates from the topological effect of the systems, and can further lead to valley-dependent anomalous velocities. Experimentally, topological related IF shift can be utilized to characterize the Weyl semimetals and further to measure the Berry curvature. The valley-dependent anomalous velocities provide new ways for designing valleytronic devices of high efficiency.
10:12AM S7.00010 Chiral Anomaly and Diffusive Magnetotransport in Weyl Metals

ANTON BURKOV, University of Waterloo — We present a microscopic theory of diffusive magnetotransport in Weyl metals and clarify its relation to chiral anomaly. We derive coupled diffusion equations for the total and axial charge densities and show that chiral anomaly manifests as a magnetic-field-induced coupling between them. We demonstrate that a universal experimentally-observable consequence of this coupling in magnetotransport in Weyl metals is a quadratic negative magnetoresistance, which will dominate all other contributions to magnetoresistance under certain conditions.

10:24AM S7.00011 Plasmon mode as a detection of the chiral anomaly in 3D Weyl semimetals

JIANHUI ZHOU, Carnegie Mellon Univ, HAORAN CHANG, Sichuan Normal University, Chengdu, China, DI XIAO, Carnegie Mellon Univ — Weyl semimetals (WSMs) are one kind of three-dimensional gapless SMs with nontrivial topology in the momentum space. The chiral anomaly in Weyl SMs manifests as a charge imbalance between the Weyl modes of opposite chiralities induced by parallel electric and magnetic fields. We investigate the chiral anomaly effect on the plasmon mode in Weyl SMs within the RPA. We prove that the chiral anomaly gives rise to a new plasmon mode in intrinsic Weyl SMs. The chiral anomaly leads to some exotic properties in the plasmon dispersion in doped Weyl SMs. Consequently, the unconventional plasmon mode acts as a signature of the chiral anomaly in Weyl SMs, by which the spectrum of plasmon provides a proper way to detect the Lifshitz transition. Our work sheds light on the probing of the chiral anomaly in 3D Weyl SMs via the plasmon mode. The tunability of plasmons due to the chiral anomaly also makes Weyl SMs promising candidates for plasmonics. Reference: arXiv:1408.4876

10:36AM S7.00012 Terahertz conductivity study of predicted Weyl semimetal Nd$_3$Ir$_2$O$_7$ and Eu$_2$Ir$_2$O$_7$ thin films

MATTHEW T. WARREN, J.C. GALLAGHER, T.T. MAI, J. BRANCHAM, F. YANG, Center for Emergent Materials, Department of Physics. The Ohio State University. Columbus, OH 43210, C.M. MORRIS, N.P. ARMITAGE, Department of Physics & Astronomy, The Johns Hopkins University, R. VALDES AGUILAR, Center for Emergent Materials, Department of Physics. The Ohio State University. Columbus, OH 43210 — There is currently a growing interest in identifying materials with novel topological properties outside of the s- or p-orbital based bismuth chalcogenide topological insulators. One such proposal is the pyrochlore iridate materials $R$$_2$Ir$_2$O$_7$, where $R$ is a lanthanide series atom or yttrium. These have been predicted to be Weyl semimetals, containing exotic Fermi arc surface states and also an anomalous Hall effect. We have studied the temperature dependent terahertz conductivity of thin films of Nd$_3$Ir$_2$O$_7$ and Eu$_2$Ir$_2$O$_7$ grown by a novel off-axis sputtering technique. We find a close correspondence between DC transport properties and the extracted Drude parameters from fits to the THz conductivity. We will discuss these results in light of the predicted Weyl semimetal state of these materials.

10:48AM S7.00013 Coulomb disorder in three-dimensional Dirac materials

BRIAN SKINNER, Argonne National Laboratory — In three-dimensional materials with a Dirac spectrum, weak short-ranged disorder is essentially irrelevant near the Dirac point. This is manifestly not the case for Coulomb disorder, where the long-ranged nature of the potential produced by charged impurities implies large fluctuations of the disorder potential even when impurities are sparse, and these fluctuations are screened by the formation of electron/hole puddles. Here I outline a theory of such nonlinear screening of Coulomb disorder in three-dimensional Dirac systems, and present results for the typical magnitude of the disorder potential, the corresponding density of states, and the size and density of electron/hole puddles. The resulting conductivity is also discussed.

8:00AM S8.00001 Network structure of the mussel plaque and its significance for load bearing and adhesion

EMMANOUELA FILIPPIDI, JUNTAE KIM, J. HERBERT WAITE, MATTHEW HELGESON, MEGAN T. VALENTINE, University of California, Santa Barbara — Marine mussels attach to rocks, each other, and a variety of surfaces via a flat, wide plaque that is interpenetrated by the collagen fibers of a thin, long thread that connects the plaque to the mussel body. The unusually strong adhesion of the plaque has long been attributed to the molecular design of its adhesive proteins that can form a variety of strong chemical bonds. However, the molecular energies for de-adhesion are orders of magnitude smaller than the macroscopic energies measured. We propose that the mesoscopic design of the plaque is critical in enhancing load bearing and eventually adhesion. We present new results on the structure of the plaque studied via electron microscopy and neutron scattering that exhibit a plaque geometry reminiscent of structural foams. Our studies reveal a collection of pores with an inner network, further connected with an outer network. The final structure can be described by two length scales. A synthetic soft system is constructed in an effort to mimic the two-lengthscale structure of the natural plaques. The structure of the native and synthetic systems is compared with the ultimate goal of evaluating the importance of the mesoscopic structure to mechanics and adhesion.

8:12AM S8.00002 Collapse dynamics of bubble raft under compression

CHIN-CHANG KUO, Department of Physics and Astronomy, University of California, Irvine, DEVIN KACHAN, ALEXANDER LEVINE, Department of Physics and Astronomy, University of California, Los Angeles, MICHAEL DENNIN, Department of Physics and Astronomy, University of California, Irvine, DEPARTMENT OF PHYSICS AND ASTRONOMY, UNIVERSITY OF CALIFORNIA, IRVINE COLLABORATION, DEPARTMENT OF PHYSICS AND ASTRONOMY, UNIVERSITY OF CALIFORNIA, LOS ANGELES COLLABORATION — We report on the collapse of bubble rafts under compression in a closed rectangular geometry. A bubble raft is a single layer of bubbles at the air-water interface. A collapse event occurs when bubbles submerge beneath the neighboring bubbles under applied compression causing the structure of the bubble raft to go from single-layer to multi-layer. We studied the collapse dynamics as a function of compression velocity. At higher compression velocity we observe a more uniform distribution of collapse events, whereas at lower compression velocities, the collapse events accumulate at the system boundaries. We will present results that compare the distribution of collapse probability in the experiments to simulations based on a one-dimensional Ising model with elastic coupling between spin elements. Both the experimental system and simulations are excellent models for collapse in a number of complex systems. By comparing the two systems, we can tune the simulation to better understand the role of the Ising and elastic couplings in determining the collapse dynamics.

1 We acknowledge DMR-1309102
The glass-forming ability of patchy repulsive spheres requires a repulsive sphere model that includes attractive interactions between patches on each sphere to study the glass-forming ability of alloys that include non-metallic components (e.g. metal-metalloid alloys). Using molecular dynamics simulations, we quantify the GFA by measuring the critical cooling rate below which crystallization occurs as a function of the size and spacing of the patches, as well as the symmetry of the crystalline state that competes with the glass. We find that the glasses can arrest no more than 20-30% solute nonmetallic atoms (such as B, Si, and P), which explains why non-metallic elements occur at low number fractions in BMGs.

8:36AM S8.00004 Some observations on hyperuniform disordered photonic bandgap materials, from microwave scale study to infrared scale study1, SAM TSITRIN, GEEV NAHAL, San Francisco State University, MARIAN FLORESCU, University of Surrey, UK, WEINING MAN, San Francisco State University, SAN FRANCISCO STATE UNIVERSITY TEAM, UNIVERSITY OF SURREY TEAM — A novel class of disordered photonic materials, hyperuniform disordered solids (HUDDS), attracted more attention. Recently they have been experimentally proven to provide complete photonic band gap (PBG) when made with Alumina or Si; as well as single-polarization PBG when made with plastic with refract index of 1.6. These PBGs were shown to be real energy gaps with zero density of photonic states, instead of mobility gaps of low transmission due to scattering, etc. Using cm-scale samples and microwave experiments, we reveal the nature of photonic modes existing in these disordered materials by analyzing phase delay and mapping field distribution profile inside them. We also show how to extend the proof-of-concept microwave studies of these materials to proof-of-scale studies for real applications, by designing and fabricating these disordered photonic materials at submicron-scale with functional devices for 1.55 micron wavelength. The intrinsic isotropy of the disordered structure is an inherent advantage associated with the absence of limitations of orientational order, which is shown to provide valuable freedom in defect architecture design impossible in periodic structures.

10:00AM S8.00011 Disordered surface vibrations in jammed sphere packings, DANIEL SUSSMAN, ANDREA LIU, University of Pennsylvania, SIDNEY NAGEL, University of Chicago — We study the vibrational properties of networks derived from jammed packings near a free surface. We find that, in addition to the usual surface modes predicted by continuum elasticity, these systems have a surface density of disordered vibrational modes extending to arbitrarily low frequencies. The spatial profile of the surface modes shows a two-length-scale decay. The length scales diverge at the jamming transition as \( \Delta z^{-1/2} \) and \( \Delta z^{-1} \), respectively, where \( \Delta z \) is the excess coordination number above isostaticity. We speculate that these findings have implications for thin-film Lennard-Jones systems, and argue that the low-temperature jamming perspective may shed light on the physics of mobile surface layers observed in small molecule and polymeric thin films.

10:12AM S8.00012 On the Marginal Stability of Glassy Systems, LE YAN, New York University, MARCO BAITY-JESI, La Sapienza Università di Roma, MARKUS MÜLLER, The Abdus Salam International Center for Theoretical Physics, MATTHIEU WYART, New York University — In various glassy systems that are out of equilibrium, like spin glasses and granular packings, the dynamics appears to be critical: avalanches involving almost the whole system could happen. A recent conceptual breakthrough argues that such glassy systems sample the ensemble of marginal stable states, which inevitably results into critical dynamics. However, it is unclear how the marginal stability is dynamically guaranteed. We investigate this marginal stability assumption by studying specifically the critical athermal dynamics of the Sherrington-Kirkpatrick model. We discuss how a pseudo-gap in the density distribution of local fields characterizing the marginal stability arises dynamically.

10:24AM S8.00013 Critical scaling of stresses and correlations with strain rate in overdamped sheared disordered solids, JOEL CLEMMER, Johns Hopkins University, KENNETH SALERNO, Sandia National Laboratories, MARK ROBBINS, Johns Hopkins University — Like many nonequilibrium systems, disordered solids exhibit a power-law distribution of avalanches and other critical behavior when driven slowly. We extend molecular dynamics studies of quasistatic shear of 2D and 3D overdamped binary LJ glasses to finite strain rate. Finite-size scaling is used to determine the critical behavior of the shear stress and several measures of temporal and spatial correlations in non-affine displacements. With increasing strain rate, there is a power-law rise in the shear stress with exponent \( \beta \) extending to lower rates in larger systems. This behavior is governed by the rise in the dynamic correlation length with decreasing stress with exponent \( \nu \). The correlation function of non-affine displacements exhibits novel anisotropic power law scaling with \( q \), the magnitude of the wave vector. Its strain rate dependence is used to determine the scaling of the dynamic correlation length in various angular directions. In the quasistatic limit, particle diffusion in 2D is proportional to strain with a system-size dependent diffusion constant. Increasing strain rate, the dynamic correlation length drops below the system-size and the diffusion constant begins to fall.

10:36AM S8.00014 Polyamorphism in tetrahedral substances: similarities between silicon and ice, ALEX ANTONELLI, Universidade Estadual de Campinas, KARL GARCEZ, Universidade Federal do Maranhão — Tetrahedral substances, such as silicon, water, germanium, and silica, share several thermodynamical anomalies. Among them, the so-called polyamorphism, i.e., the existence of more than one amorphous state, is, perhaps, the most studied one. In this work, we study the transformations between amorphs of silicon using Monte Carlo simulations. The simulations indicate that by compressing the low density amorphous state (LDA), which is obtained by quenching the liquid at high temperature, a new denser amorphous state is formed [1]. The transformation between these two forms of amorphous silicon displays clear hysteresis, similar to the experiment reported by McMillan et al. [2]. However, analogously to the case of ice, our simulations indicate that upon annealing the unannealed high density amorphous silicon (uHDA) evolves to more stable forms. The annealing of uHDA at pressures on the order of 20 GPa gives rise to an even denser form, the very high density amorphous silicon (VHDA), while at much lower pressures, about 5 GPa, the uHDA transforms into a lower density form, the expanded high density amorphous silicon (eHDA).

10:48AM S8.00015 Thermal Transport in C60 Molecular Crystals Above Room Temperature, CAROLINE S. GORHAM, ALAN J. H. MCGAUGHEY, Department of Mechanical Engineering, Carnegie Mellon University — The thermal conductivity of solid fullerene molecular systems has garnered significant interest as an example of materials whose thermal transport is dominated by Einstein-type oscillators. Using classical molecular dynamics simulations, this study isolates the roles of intramolecular and intermolecular vibrational degrees of freedom on the bulk thermal conductivity of the face-centered cubic \( C_{60} \) molecular crystal. The Green-Kubo method is used to predict the bulk thermal conductivity. The contributions to thermal transport resulting from collective motions of the molecules, molecular rotations, and intramolecular vibrations are isolated using non-equilibrium methods. These contributions are interpreted using a Debye model, a nearest-neighbor resistance network, and Allen-Feldman theory.

Thursday, March 5, 2015 8:00AM - 11:00AM – Session S9 FIAP: Vanadium Oxides, Resistive Switching, and Interfaces with Oxides 006D - Rick Mengyan, Texas Tech University

8:00AM S9.00001 Vanadium Dioxide Phase Change Switches, MARK FIELD, CHRISTOPHER HILLMAN, PHILIP STUPAR, JONATHAN HACKER, ZACHARY GRIFFITH, KANG-JIN LEE, Teledyne Scientific & Imaging LLC — We have built RF switches using vanadium dioxide thin films fabricated within a section of inverted transmission line with integrated on chip heaters to provide local thermal control. On heating the films above the metal insulator transition we obtain record low switch insertion loss of -0.13 dB at 50 GHz and -0.5 dB at 110 GHz. We investigate the device physics of these switches including the effect of a deposited insulator on the VO2 switching characteristics, the self-latching of the devices under high RF powers and the effect of resistance change with temperature on the device linearity. Finally we show how these devices can be integrated with silicon germanium RF circuits to produce a field programmable device where the RF signal routing can be selected under external control.

8:12AM S9.00002 Interstitial hydrogen in vanadium dioxide\(^1\) —  W. B. FOWLER, M. STAVOLA, WEIKAI YIN, YING QIN, Lehigh University, L. A. BOATNER, Oak Ridge National Laboratory — It has long been recognized that VO\(_2\) has a monoclinic-to-rutile phase transition as the temperature increases through 340K, accompanied by a remarkable increase in conductivity from insulator to metal\(^{1,2}\). Recently it has been found that interstitial hydrogen can modify both the structural and the electronic phase transition\(^3\). The way hydrogen does this has only recently begun to be studied\(^4\). We are using infrared spectroscopy to study the properties of H\(_i\), and are also using the CRYSTAL06 code\(^5\) with hybridized DFT Hamiltonian to determine equilibrium positions and vibrational frequencies. IR spectroscopy finds several OH vibrational lines in hydrogenated VO\(_2\) samples. Within the monoclinic structure of VO\(_2\) there exist two non-inequivalent sites for H\(_i\), which may lead to distinct spectroscopic signatures. \(^{[1]}\) F. J. Morin, Phys. Rev. 8:24AM S9.00003 Magnetism in Bulk Vanadium Dioxide Compounds —  P. W. MENGYAN, R. L. LUCHI, B. B. BAKER, G. JAYARTHNA, Texas Tech University — Vanadium dioxide (VO\(_2\)) compounds show a metal-semiconductor transition (MST) near room temperature (stoichiometric VO\(_2\) is metallic T > \(T_{\text{MST}}\) ≈ 340 K and semiconducting T < \(T_{\text{MST}}\)) that is accompanied by a structural transition; both can be triggered by thermal, optical, electrical or barometric means. This ultrafast (sub ms) transition has been studied extensively and there is still considerable disagreement regarding the mechanism responsible for these transitions. Incorporation of a few atomic percent of H in VO\(_2\) stabilizes the metallic phase down to 200 K. Impurities such as W, Ti, Au, Cr or F lower or raise \(T_{\text{MST}}\) without significantly modifying other properties. Some effects that dopants have on the material are well known, however, the role dopants play in modifying them is far from understood. This contribution presents results of the first muon spin rotation and relaxation (MuSR) measurements on bulk VO\(_2\) compounds where we find and characterize a low temperature magnetic phase that has not yet been reported. The introduction of 2.4 at\% of W or 5 at\% of Ti raise the onset of the magnetic phase from 35 K to nearly 170 K. MuSR probes the local magnetic environment and hence provides a direct measure of the local field properties.

8:36AM S9.00004 Voltage switching of a VO\(_2\) memory metasurface using ionic gel —  M.D. GODFLAM, M.K. LIU, B.C. CHAPLER, H.T. STINSON, A.J. STERNBACH, A.S. MCLEOD, Univ of California – San Diego, M. ROYAL, Duke University, BONG-JUN KIM, ETRI, D.N. BASOV, Univ of California - San Diego. We have demonstrated large area, low voltage, non-volatile tuning of an electrolyte-based vanadium dioxide (VO\(_2\)) THz memory metasurface. Using ionic gel gating, voltage is applied to drive the insulator-to-metal transition in an underlying VO\(_2\) layer. Through application of positive and negative voltages, the metasurface resonance can be switched into the "off" or "on" state by driving VO\(_2\) into a more conductive or insulating regime, respectively. As compared to our graphene-based control devices, the longer saturation time of resonance modification in VO\(_2\)-based devices suggests that this voltage-induced switching originates primarily from electrochemical effects resulting from oxygen migration across the electrolyte-VO\(_2\) interface.

8:48AM S9.00005 Effect of doping and chemical ordering on the optoelectronic properties of complex oxide semiconductors —  IFIAT NAYYAR, CHAMBERLIN SARA, TIFFANY KASPAR. Physical Sciences Division, Pacific Northwestern National Laboratory, Pacific Northwest National Laboratory, PACIFIC NORTHWEST NATIONAL LABORATORY — It has long been recognized that VO\(_2\) has a monoclinic-to-rutile phase transition near room temperature (stoichiometric VO\(_2\) is metallic T > \(T_{\text{MST}}\) ≈ 340 K and semiconducting T < \(T_{\text{MST}}\)) that is accompanied by a structural transition; both can be triggered by thermal, optical, electrical or barometric means. 9:00AM S9.00006 ABSTRACT WITHDRAWN —

9:12AM S9.00007 Oxygen controlled bipolar switching in NiO memristor —  ZHONG SUN, YONGGANG ZHAO, DIYANG ZHAO. Tsinghua Univ, DEPARTMENT OF PHYSICS, TSINGHUA UNIVERSITY, BEIJING 100084, CHINA TEAM — As Leon Chua demonstrated, both unipolar and bipolar resistance switching devices are memristors. Over the past decade, metal/oxide/metal structure with NiO as a ReRAM functional layer has been investigated widely and in depth, due to its intrinsic unipolar resistance switching, which is attributed to the connection and rupture of nickel filament in NiO. Recently, several papers studying NiO nanowires or NiO films with C-AFM infer that bipolar switching mechanism may govern the NiO memristors on the nanoscale. However, a systematic research on the mechanism of bipolar switching in NiO memristor on the nanoscale is still lacking. Especially, the role of oxygen in a NiO memristor has never been explored. Here we carry out a comprehensive study of the mechanism of bipolar switching in NiO memristor, and uncover the dominant role of oxygen. NiO/Pt structures were measured by C-AFM equipped with 20 nm conductive tips. By controlling the inherent oxygen concentration of NiO film, film thickness, and chamber oxygen pressure, we demonstrate that it is the inner oxygen distribution, related to electric field-induced ion drift and oxygen exchange between NiO film and ambient, that acts as the state variable, whose response to applied bias results in the bipolar switching in NiO memristor.

9:24AM S9.00008 Understanding Electroforming and Resistive Switching in Silicon Dioxide Resistive Memory Devices —  YAO-FENG CHANG, The University of Texas at Austin, BURT FOWLER, PrivaTran, LLC, FEI ZHOU, KWANG-SUN KIM, JINA KANG, The University of Texas at Austin, THE UNIVERSITY OF TEXAS AT AUSTIN COLLABORATION, PRIVATRAN, LLC COLLABORATION — Electroforming and resistive switching in SiO\(_2\) materials are investigated by anneal temperature, etch time and operating ambient. Thermal anneal in reducing ambient lowers electroforming voltage to small than 10 V. Conductive filaments form within 4 nm of sidewall surfaces in devices with an etched SiO\(_2\) layer, whereas most filaments are larger than 10 nm from the electrode edge. Switching unpassivated devices fails at 1 atm air and pure O\(_2\)/N\(_2\), with recovery of vacuum switching at about 4.6 V after switching attempts in O\(_2\)/N\(_2\) and at about 9.5 V after switching attempts in air. Incorporating a hermetic passivation layer enables switching in 1 atm air. Discussions of defect energetics and electrochemical reactions lead to a localized switching model describing device switching dynamics. Low-frequency noise data are consistent with charge transport through electron-trapping defects. Low-resistance-state current is passivated by a thin oxide layer, which may lead to conductivity enhancement and band-gap reduction. In this work, the electronic and optical properties of \(\alpha-(\text{Fe}_{1-x}\text{V}_{x})\text{O}_3\) films are the electronic excitations from these levels to the unoccupied Fe 3d\(^{1}\) orbitals, reducing the onset of \(\alpha-(\text{Fe}_{1-x}\text{V}_{x})\text{O}_3\) photoconductivity by nearly 1.2 eV. Our calculated optical absorption spectra are in good agreement with the experiment. This insight into the electronic, atomic and spin ordering provides guiding principles for the design of new oxide semiconducting materials for efficient visible light harvesting, thus enabling the technological growth of alternate energy sources for solving the renewable solar energy and photo-chemical organic waste remediation problems.

9:00AM S9.00006 ABSTRACT WITHDRAWN
9:36AM S9.00009 Bio-Inspired Learning Demonstration with Synaptic Resistive Memory Devices, SEYOUNG KIM, TAYFUN GOKMEN, MARK RITTER, IBM T J Watson Res Ctr — Simple two-terminal semiconductor memory devices which can mimic the functions of biological synapses has recently opened up exciting opportunities for enabling native implementation of brain-inspired computing. Here, we demonstrate in hardware that a biologically-inspired architecture employing a novel resistive memory technology used to implement a simple learning algorithm that imitates some features of the sensorimotor stage of cognitive development of a newborn baby. Actuation and sensing were indicated by spiking neurons, and the associations between neurons were learned in a HfOx-based resistive memory array using a local rule. The system essentially realize a biased random walk algorithm using a fully connected spiking sensorimotor network and can be generalized to solve other optimization problems by redefining the input and output functions of the neurons. This demonstrates a new approach to solve classical problems with resilient, adaptive, and fault-tolerant non-Von Neumann architecture.

9:48AM S9.00010 Ab initio study of the epitaxial ZrO2/Si interface, MEHMET DOGAN, DIVINE KUMAH, CHARLES AHN, FREDERICK WALKER, SOHRAB ISMAIL-BEIGI, Yale University — Growing thin films of crystalline metal oxides on semiconductors has been of much scientific interest because of the potential applications of such systems in electronic devices. One particular research goal is to achieve ferroelectricity in a crystalline and thin oxide film that is epitaxial on a semiconductor. This would enable one to realize non-volatile field-effect transistors where the state of the system is encoded in the polarization direction of the oxide. In this work, we study oxides that are not ferroelectric in the bulk but become ferroelectric as an ultrathin film on a semiconductor such as silicon. Recent developments in epitaxial growth methods also permit fabrication of such systems. Here, we use density functional theory to study the interface between ZrO2 and Si. When the oxide is only 1 monolayer thick, we find a set of stable structures with a variety of positive and negative out-of-plane ferroelectric polarizations. We present an analysis of these structures as a function of oxide thickness and the size of interface unit cell. Furthermore, the ZrO2 can be used as a buffer layer to induce ferroelectricity in ultrathin perovskite oxides such as SrTiO3 on Si which can couple the oxide polarization to the silicon carrier density.

10:00AM S9.00011 Band alignment in metal-oxide interface Al/SiO2 and Cu/SiO2 in presence of defect, JIANQIU HUANG, CELINE HIN, Virginia Tech, VIRGINIA TECH TEAM — Semiconductors have wide use especially in electronic devices. Technological development tends to decrease the size of the electronic devices into the nanoscale. Dielectric Breakdown was an old problem which has not been fully resolved, which exponentially related to the size of electronic devices. It causes a severe and irreversible degradation on integrated circuits. Therefore, the motivation and main purpose of this research is to explore the dominant factors that will cause dielectric breakdown to occur in order to develop techniques to effectively prevent this occurrence. Density functional theory has been used to study the interface of Al/SiO2 and Cu/SiO2. Results on the investigation of atomic and charge vacancies at the interface will be presented and compared with the defect free models. The band alignment has been constructed in order to describe the behavior of the conduction band in the depletion layer. From the comparison and band alignment, a row conclusion that causes the breakdown occurrence was made.

10:12AM S9.00012 Carbon impurities in oxide dielectrics, HRAL D. TAILOR, University of California, Santa Barbara, JOHN L. LYONS, Brookhaven National Laboratory, MINSEOK CHOI, Korea Institute of Materials Science, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — The high-k oxides ZrO2 and LaAlO3 can be used as dielectrics in metal-oxide-semiconductor (MOS) devices. Dielectrics and semiconductors have very strong atomic layer deposition (ALD) often leading to unintentional incorporation of impurities such as carbon from the metal-organic precursors. Experiments indicated carbon can be a significant cause of leakage current. We investigate this problem using density functional theory with a hybrid functional. Our results show that carbon substituting on the cation site undergoes an off-site displacement and forms close bonds with oxygen in ZrO2 and LaAlO3. We calculate the corresponding defect levels, and in order to determine the impact on MOS devices we align the band structures of the dielectrics with those of the semiconductor channel materials (including GaN, Si, and GaAs). We find that carbon incorporation leads to defect levels near the conduction-band minimum of the channel materials, proving potentially detrimental for n-type devices. Intriguingly, we find that the defect levels of these carbon centers in a variety of oxides and semiconductors are aligned at roughly -3.5 eV below the vacuum level.

10:36AM S9.00014 Muonium Diffusion in In2O3, BRITTANY BAKER, ROGER LICHTI, Texas Tech University, Y. GURKAN CELEBI, Istanbul University, PATRICK MENGYAN, Texas Tech University, Y. GURKAN CELEBI, Istanbul University, PATRICK MENGYAN, Texas Tech University — Indium oxide (In2O3) is a transparent conducting oxide (TCO) commonly found in mixtures used as windows and transparent electrodes in optical semiconductor devices (i.e. LEDs and solar cells). Hydrogen diffusion in the TCO layer and across the interface between the TCO and the semiconductor device plays an important role in the degradation of the transparency of TCO windows or electrodes. Theoretical calculations show positive H as the only stable, interstitial H charge state above the neutral H ionization temperature. Muon Spin Relaxation measurements were performed to investigate positive muon (Mu+) diffusion which are an experimentally accessible analog to H+. Three distinct Mu+ states are identified between 2 K and 1000 K; a static low temperature state, a dynamic state above room temperature, and a trapping state from 400 K to 800 K. The trap component creates complex dynamics and has been modeled assuming the Mu+ transfers between the dynamic state and the trapping state. Fits of the model to the data provide information about capture and release rates and energy barriers into and out of the trap state. Here we present and discuss results from these fits, possible site locations for each state and likely diffusion paths.

10:48AM S9.00015 Group-IV Impurity Defect Levels in beta-Gallium Oxide, STEFAN BADESCU, Wyle Aerospace/US AFRL — Beta-Gallium Oxide (β-Ga2O3) is a wide-bandgap semiconductor with a significant potential as a native substrate for electronic devices. One avenue for tuning its carrier concentration and electronic properties is doping with group-IV impurity atoms. This work presents a first-principles understanding of the effects of C, Si, Ge and Sn dopants at Ga sites. C is found to act like a bistable center whereas the other dopants preserve the symmetry of the Ga site. Hybrid functionals are used to describe accurately the effects that occur mainly in the conduction band. A Brillouin zone unfolding is used that enables a direct comparison to possible spectroscopy experiments. We delineate the effects on bandgap modulation induced by charge density on the one hand, and by conduction band resonances and effective masses on the other hand.
8:00AM S10.00001 Distorted signal transport in topological insulators and its applications\textsuperscript{1}. XIAO ZHANG, Sun Yat-Sen University, CHINGHUA LEE, Stanford University — We develop a theoretical approach for studying the distorted signal transport in topological insulators. It works for arbitrarily applied electric fields and relaxation time. Exact analytic results are obtained for generic driving fields, with a particularly elegant expression for the trigonometric function case. We analytically and numerically study the effects of temperature, relaxation time etc for topological insulators in real conditions and its applications.

\textsuperscript{1}This work is supported by the National Natural Science Foundation of China through the grant No. 11404413.

8:12AM S10.00002 Current distribution in a two-dimensional topological insulator, XIAOQIAN DANG, JOHN BURTON, EVGENY TSYMBAL, Univ of Nebraska - Lincoln — Topological insulator (TI) is a bulk insulator with spin-dependent surface (edge) states that are protected by time-reversal symmetry. This property makes TIs very interesting for potential application in electronic devices. Here we report on theoretical investigations of transport properties of a model two-dimensional (2D) TI where the conductance is controlled by the topologically protected edge states. We utilize the tight-binding form of the Bernevig-Hughes-Zhang model\textsuperscript{1} and employ the Landauer-Büttiker formalism to explore the transport properties in the presence of impurities. Using the Green’s function technique we calculate the current distribution for states within the bulk band gap of the 2D TI. Interestingly, in absence of impurities we find that the current density decays into the bulk in an oscillatory fashion reflecting an oscillatory decay pattern of the local density of states as predicted from the complex band structure.\textsuperscript{2} Non-magnetic impurities disturb this picture and lead to a complex spatial distribution of current; however, the net transmission along the edge is conserved and remains a spin conductance quantum as expected from general considerations.

\textsuperscript{1}B. A. Bernevig et al., \textit{Science}, 314, 1757 (2006).

8:24AM S10.00003 Quantum geometry and stability of the fractional quantum Hall effect in the Hofstadter model. DAVID BAUER, THOMAS JACKSON, RAHUL ROY, University of California, Los Angeles — We study the correlation between the band geometry of the Hofstadter model to the limit of small flux and the stability of fractional quantum Hall states in this system. We develop a perturbative calculation of the quantum metric that agrees well with numerical calculations. In contrast to most models studied so far where the fluctuations of the Berry curvature seem to dictate the stability of any fractionalized topological phases, we find that in the Hofstadter model, the trace of the quantum metric seems to be the predominant factor.

8:36AM S10.00004 High-field charge transport on the surface of Bi$_2$Se$_3$, M.Q. WENG, M.W. WU, University of Science and Technology of China — We present a theoretical study on the high-field charge transport on the surface of Bi$_2$Se$_3$ and reproduce all the main features of the recent experimental results, i.e., the incomplete current saturation and the finite residual conductance in the high applied field regime [Costache et al., Phys. Rev. Lett. 112, 086601 (2014)]. Due to the hot-electron effect, the conductance decreases and the current shows a tendency of saturation with the increase of the applied electric field. Moreover, the electric field can excite carriers within the surface bands through interband precession and leads to a higher conductance. As a joint effect of the hot-electron transport and the carrier excitation, the conductance approaches a finite residual value in the high-field regime and the current saturation becomes incomplete. We thus demonstrate that, contrary to the conjecture in the literature, the observed transport phenomena can be understood qualitatively in the framework of surface transport alone. Furthermore, if a constant bulk conductance which is insensitive to the field is introduced, one can obtain a good quantitative agreement between the theoretical results and the experimental data [M. Q. Weng and M. W. Wu, Phys. B 90, 125306, (2014)].

8:48AM S10.00005 Dimensional crossover of transport characteristics in topological insulator nanofilms. KEN-ICHIRO IMURA, YUKINORI YOSHIMURA, Hiroshima University, KOJI KOBAYASHI, TOMI OHTSUKI, Sophia University — Recently, much effort has been made to grow thin films of a topological insulator. Naturally, its primary purpose was to reduce the contribution of the bulk to transport quantities. Here, we propose that searching for quantized transport in thin Ti films is an efficient way for probing non-trivial topological features encoded in the 3D bulk band structure. In a recent work (Kobayashi, KI, Yoshimura & Ohtsuki, arXiv:1409.1707), we have highlighted the following issues: 1) Transport characteristics of Ti thin films is well understood by studying the conductance both in the edge and slab geometries. 2) We introduce “conductance maps” for revealing the dimensional crossover in such Ti thin films. Quantization of the conductance occurs both in the edge and in the slab geometries, but not at the same time. 3) We focus on the even-odd feature in transport with respect to the number of stacked layers. We found parameter regimes in which the even-odd feature is broken by inversion of the finite-size gap associated with hybridization of the top and bottom surface wave functions. We propose that tuning the hybridization gap of a Ti thin film and make it inverted is an effective way of realizing a 2D quantum spin Hall state.

9:00AM S10.00006 Extrinsic spin-orbit coupling and density dependent weak antilocalization in three-dimensional topological insulators, WEIZHE LIU, School of Physics, The University of New South Wales, Sydney 2052, Australia, PIERRE ADROGUER, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany, XINTAO BI, ICQD, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, Hefei, Anhui 230026, China, EWELINA HANKIEWICZ, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany, DIMITRIE CULCER, School of Physics, The University of New South Wales, Sydney 2052, Australia — Topological insulators (TIs) have revolutionized our understanding of insulating behaviour. Three-dimensional TIs are insulators in the bulk but conducting along their surfaces. Much of recent researches on 3D TIs focus on overcoming the transport bottleneck, namely the fact that surface transport is overwhelmed by bulk transport stemming from unintentional doping. The key to overcoming this bottleneck is identifying unambiguous signatures of surface state transport. We will discuss on such signature: weak antilocalization, meaning that coherent backscattering increases the electrical conductivity. The features of this effect, however, are rather subtle, because in TIs the impurities have also strong spin-orbit coupling. I will show that spin-orbit coupled impurities introduce an additional time scale, which is expected to be shorter than the dephasing time, and the resulting conductivity has a distinguished part with linear dependent on the carrier number density. The result we predict is directly observable experimentally.

9:12AM S10.00007 Topological suppression of quantum tunneling, JIA-HUA GU, KAI SUN, University of Michigan, Ann Arbor — In this talk, we prove that if we bring together two band insulators with different topology, described by arbitrary topological indices, there must exist specific momentum points in the Brillouin zone where the wavefunctions of the two insulators are orthogonal and cannot hybridize. For 2D insulators, this conclusion implies that topology will prohibit tunneling of electrons between the two insulators at this momentum. This conclusion can also be generalized to some strongly-correlated topological systems. Explicit demonstration and proof will be provided for topological band insulators and fractional quantum Hall states.
9:24AM S10.00008 Charge Transport in 3D topological insulators in the presence of surface potential fluctuations, XINGYUE PENG, YIMING YANG, RAJIV SINGH, SERGEY SAVRASOV, DONG YU, Univ of California - Davis — Field effect measurements on the surface of a 3D topological insulator (TI) show a high minimum conductivity which is strongly dependent on sample details but the gate dependent conductivity also exhibits anomalous non-monotonic behavior which is not yet understood. Understanding the nature of this minimum conductivity is crucial for the design and fabrication of novel spintronic devices based on 3D TIs. We propose a theoretic model to explain this anomalous behavior, considering the existence of surface potential fluctuations as indicated by scanning tunneling spectroscopy (STS) and scanning photocurrent microscopy (SPCM) measurements on the surface of a 3D TI. Our model agrees well with preexisting experiments and our own transport measurements in field effect transistors (FETs) incorporating 5b-doped single Bi2Se3 nanoribbons.

9:36AM S10.00009 Effects of the boundary geometry on the edge current in the two dimensional topological insulator1, HYEONJIN DOH, HYOUNG JOON CHOI, Center for Computational Studies of Advanced Electronic Material Properties, Yonsei University — We study the effects of the boundary shape on the edge transport of the two dimensional topological insulator described by Kane-Mele model. The edge state is robust against all time-reversal invariant defects. However, when we consider an arbitrary sample, the edge is not straight and consists of various types of boundaries. Actually, the transport property of the edge-state in the Kane-Mele model depends on the boundary type of the edge such as zigzag and armchair edges. Therefore, the edge-transport can be affected by a corner connecting two different types of edges. Here, we investigate the energy spectrum of the various shapes of finite-size honeycomb lattice with corners along the edge. We also calculate the transport properties on the edges by applying an artificial gauge field which drives a persistent current along the edges. Although the corner of the edge seems a geometrical defects and is expected to have a little effect on the transport, our results show that the geometrical defects strongly affect the edge current depending on the corner types.

1This work was supported by NRF of Korea (Grant No. 2011-0018306) and KISTI supercomputing center (Project No. KSC-2013-C3-062).

9:48AM S10.00010 Distinctive features of transport in topological insulators, VINCENT SACKsteder, Nanyang Tech Univ, QUANSHENG WU, Institute of Applied Physics and Computational Mathematics, Beijing, KRISTIN ARNARDOTTIR, IVAN SHELYHKY, Nanyang Tech Univ, STEFAN KETTEMANN, Jacobs University Bremen — The surface states of a topological insulator in a fine-tuned magnetic field are ideal candidates for realizing a topological metal which is protected against disorder. Its signatures are (1) a conductance plateau in long wires and (2) a conductivity which always increases with sample size. We numerically show that the bulk substantially accelerates the conductance plateau’s decay in a magnetic field. It also reduces the effects of surface disorder and causes the magnitude of the surface conductivity and the magnetoconductivity to depend systematically on sample details such as doping and disorder strength. In addition, we predict a new signature of the topological state: at low temperatures the magnetoresistance will deviate strongly from the Hikami-Larkin-Nagaoka (HLN) formula. In this regime the magnetoresistance is dominated by scattering processes which wrap around the TI sample. The HLN formula’s shoulder is replaced by a feature with a larger critical field magnetic strength that is caused by wrapping. Inside the wrapping regime the magnetoconductance will lose its dependence on temperature. This new topological signature should be visible in the same samples and temperatures where the Altshuler-Aronov-Spivak (AAS) effect has already been observed.

10:00AM S10.00011 Berry-phase description of Topological Crystalline Insulators, ARIS ALEXANDRINATA, B. ANDREI BERNEVIG, Princeton University, XI DAI, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences — We study a class of translationally-invariant insulators protected by crystalline symmetries. Some of these insulators have no spin-orbit coupling, and may be realized in intrinsically spinless systems such as photonic crystals and ultra-cold atoms. Some of these insulators have no time-reversal symmetry as well, i.e., the relevant symmetries are purely crystalline. Nevertheless, topological phases exist which are distinguished by their robust surface modes. Their band topology is unveiled by the crystalline analog of Berry phases, i.e., parallel transport across certain non-contractible loops in the Brillouin zone. We also identify certain topological phases without any robust surface modes - they are uniquely distinguished by parallel transport along bent loops, whose shapes are determined by the symmetry group. Finally, we highlight recent interferometry experiments which demonstrate that these Berry phases are measurable.

10:12AM S10.00012 Majorana zero modes choose Euler numbers - revealed by full counting statistics, DONG E. LIU, Microsoft Research Station Q, ALEX LEVCHENKO, Michigan State University, ROMAN M. LUTCHYN, Microsoft Research Station Q — We consider a quantum dot (QD) coupled to a Majorana zero mode and two normal leads and study transport properties of the system. We investigate the full counting statistics of charge tunneling events which allows one to extract information about current fluctuations in the system. Using Keldysh path-integral approach, we compute the cumulant generating function for the quantum dot with Majorana and normal lead couplings. We first consider a non-interacting spinless QD, and find that for the symmetric dot-lead couplings, the zero-frequency cumulants exhibit a universal pattern (Euler polynomial), independent of the microscopic parameters. For a spinful QD, the Coulomb interaction effects are discussed for both strong interaction (single-electron occupancy regime) and weak interactions (perturbative regime). In the latter case, the interactions do not change the universal pattern at small voltage bias. Compared to the case without Majorana coupling, we show that, while the tunneling conductance might exhibit zero-bias anomaly due to Majorana or Kondo physics, the full counting statistics are qualitatively different in the presence of the Majorana coupling.

10:24AM S10.00013 Simple examples of Symmetry-Protected Topological phases and Symmetry-Enriched Topological phases of quantum lines, OLEKSI MOTORUNICH, SCOTT GERAEDTS, California Institute of Technology — We construct models realizing distinct confining phases of lattice gauge theories envisioned in a formal classification of gapped phases of gauge theories by Kapustin and Thorngren, arXiv:1309.4721. This generalizes ideas of Symmetry-Protected Topological (SPT) phases in Condensed Matter to systems where fundamental microscopic objects are quantum lines, which is of interest in High Energy Theory. Specifically, in (3+1)-D, we consider discrete ZN lattice gauge theory models, with two copies of ZN, and construct N distinct confining phases by engineering condensation of bound states of magnetic fluxes (which are quantum lines in 3d) and ZN electric field lines. In (4+1)D, we consider compact quantum electrodynamics (CQED) models, with two copies of CQED, and engineer condensation of bound states of monopoles (which are quantum lines in 4d) and U(1) electric field lines. When the bound states contain a single monopole, we find SPT-like phases of the lattice gauge theory, while when the bound states contain multiple monopoles, we find analogs of Symmetry-Enriched Topological phases, where in the present case we also have fractionalization of Faraday lines. The distinct character of these topological phases of quantum lines is revealed by unusual physics at a boundary.

10:36AM S10.00014 Interacting surface states of three-dimensional topological insulators, TITUS NEUPERT, Princeton University, STEPHAN RACHEL, Technische Universitaet Dresden, RONNY THOMALE, MARTIN GREITER, University of Wurzburg — We numerically investigate the surface states of a strong topological insulator in the presence of strong electron-electron interactions. We choose a spherical topological insulator geometry to make the surface amenable to a finite size analysis. The single-particle problem maps to that of Landau orbitals on the sphere with a magnetic monopole at the center that has unit strength and opposite sign for electrons with opposite spin. Assuming density-density and electron-electron interactions, we find superconducting and anomalous (quantum) Hall phases for attractive and repulsive interactions, respectively, as well as chiral fermion and chiral Majorana fermion boundary modes between different phases. Our setup is preeminently adapted to the search for topologically ordered surface termination that could be microscopically stabilized by tailored surface interaction profiles.
8:00AM S11.00001 A comparison of the superconducting states of Ta4Pd3Te16 and Nb3PdxSe7. QIU RUN ZHANG, BIN ZENG, DANIEL RHODES, LUIS BALICAS, NHMFL — We have measured the superconducting upper critical fields of a Ta4Pd3Te16 sample and a Nb3Pd3Se7 sample with very close values of $T_c$. The Maki parameter of Ta4Pd3Te16 ($H_{c2}(T \to 0K) \sim 5.57$) is small and hence it is an orbital limited system. However, $H_{c2}$ shows an unconventional linear $T$ dependence in the whole temperature range. Even though they have similar crystalline structures, the upper critical fields of Nb3Pd3Se7 are extremely high ($H_{c2}(T \to 0K) \sim 25T$) and much more anisotropic.

8:12AM S11.00002 High-field studies of the Pd-based Superconductor Ta4Pd3Te16. TONY HELM1, Lawrence Berkeley National Laboratory, PHILIP J.W. MOLL, ROBERT KEALHOFER, JAMES G. ANALYTIS, University of California — The layered Pd-based ternary chalcogenide Ta4Pd3Te16 (TPT) has not gotten much of attention since its first synthesis in 1997. Recently, TPT was found to turn superconducting (SC) below a critical temperature of $T_c = 4.5$K and up to 6.5K under pressure. The layered material has an orthorhombic crystal structure and the main conduction channel is suspected to run along one dimensional (1D) PdTe-chains. Band structure calculations find multiple bands at the Fermi level including 1D sheets. One of the striking features in the family of M3Pd3Q3 (M=Nb and Ta, Q=S and Se) is a very enhanced upper critical field. To understand the mechanism behind this enhancement TPT is of special interest since it has a similarly complex structure but much lower $H_{c2}$. Anomalous transport properties and a significant anisotropy in $H_{c2}$ have been interpreted in terms of an unconventional SC ground state present in TPT. Here we report studies of normal-state magnetotransport and magnetic torque in high fields that disclose details of TPTs electronic structure enabling us to speculate about the origin of SC in this compound.

3 Materials Science Division, Lawrence Berkeley National Laboratory; Department of Physics, University of California, Berkeley, California 94720, USA

8:24AM S11.00003 Anisotropic Superconducting Gap and Elongated Vortices with Caroli-De Gennes-Matricon States in the New Superconductor Ta4Pd3Te16. HUAN YANG, ZENGYU DU, DELONG FANG, ZHENYU WANG, YUFENG LI, GUAN DU, XIYU ZHU, HAI-HU WEN, Department of Physics, Nanjing University — The superconducting state is formed by the condensation of a large number of Cooper pairs. The normal state electronic properties can give significant influence on the superconducting state. For usual normal-state magnetotransport and magnetic torque in high fields that disclose details of TPTs electronic structure enabling us to speculate about the origin of SC in this compound.

8:36AM S11.00004 Tuning superconductivity in Nb2Pd0.81S5 using applied pressure and uniaxial strain. KUAN-WEN CHEN, QIU RUN ZHANG, NHMFL, Florida State Univ., DANIEL JACKSON, Univ. Florida, ANDREW GALLAGHER, NAOKI KIKUGAWA, SCOTT RIGGS, DAVID GRAF, NHMFL, Florida State Univ., JAMES HAMLIN, Univ. Florida, LUIS BALICAS, RYAN BAUMBACH, NHMFL, Florida State Univ. — Nb2Pd0.81S5 is a recently reported transition metal-chalcogenide superconductor ($T_c \sim 6.6$K) with unusually large upper critical fields ($H_c > 37 T$ for $H = b$) [1]. We present electrical resistivity measurements under applied pressure for this compound, where a piston cylinder cell was used with Daphne 7474 oil as the pressure transmitting medium. These measurements reveal that the superconducting transition temperature abruptly increases to 8.5 K for $P < 2$ kbar, but additional pressure (up to 16 kbar) has little effect on $T_c$. This result may indicate that while the electronic state of this compound is sensitive to strain, it is only weakly affected by hydrostatic pressure. This viewpoint is supported by subsequent experiments where application of Daphne oil or N-grease to the crystal surface results in an increase of $T_c$ to 8 K. In order to systematically disentangle the influence of pressure and strain, we will present results from resistivity measurements where the sample is uniaxially strained using a piezo-stack ("elastoresistance") along the b direction.

8:48AM S11.00005 MgB2 Coated Ellipsoids as an Approach to Investigate the Possible Enhancement of the Vortex Penetrating Field of SRF Cavities. TENG TAN, MATTHAEUS WOLAK, Department of Physics, Temple University, TSUYOSHI TAJIMA, Los Alamos National Lab, XIAOXING XI, Department of Physics, Temple University, LEONARDO CIVALE, Los Alamos National Lab — Superconducting rf (SRF) cavities fabricated from bulk niobium (Nb) are a key component for modern particle accelerators. The magnetic field distribution on the inner wall of an SRF cavity is inversely similar to the field distribution on top of a superconducting ellipsoid when we put it in a magnetic field parallel to its axis. By measuring the vortex penetration into the magnetized superconducting ellipsoids, we can deduce the behavior of SRF cavities. Magnesium diboride (MgB2) has potential to replace Nb as it has a higher $T_c$ of 39 K, a lower residual resistivity of ~0.1 $\mu$Omega cm (at 42 K), and a higher thermodynamic critical field $H_c$ value compared to Nb. In this work, we successfully coated uniform MgB2 layers on top of molybdenum and niobium ellipsoids. SQUID magnetometer measurements showed that the coated MgB2 layer has a $T_c$ above 38.5 K, and can provide a perfect magnetic shielding up to ~ 500 Oe at 1.8K. By coating MgB2 on Nb ellipsoids, we increased the vortex penetration field (the maximum field at which a cavity can be operated) by ~ 500 Oe at 2 K.

9:00AM S11.00006 ABSTRACT WITHDRAWN —
9:12AM S11.00007 Multiple Andreev Reflections in MgB$_2$/I/Pb Heterojunctions Cooled below 1 Kelvin$^1$, ROBERTO RAMOS, Indiana Wesleyan Univ, STEVEN CARABELLO, Drexel University, PENN STATE HARRIERSBURG, JOSEPH LAMBERT, Drexel University, WENQING DAI, QI LI, Penn State University, KE-CHEN, DANIEL CUNNANE, Temple University, C.G. ZHUANG, None, X.X. XU, Temple University — We have measured the I-V and dI/dV characteristics of two MgB$_2$/I/Pb heterojunctions below 1 Kelvin. In both junctions which were grown on c-axis substrates, we observed the characteristic pi peak corresponding to c-axis tunneling, consistent with theoretical predictions. Furthermore, we have observed sub-harmonic peaks in dI/dV that are consistent with Multiple Andreev Reflections (MAR) usually associated with high-transparency junctions. We also describe the temperature dependence of other sub-gap peaks observed. By systematically reducing noise in our setup and using sub-Kelvin temperatures, we were able to observe relatively sharp MAR peaks which are unusual for junctions with a large $R_{subgap}/R_n$ ratio.

9:24AM S11.00008 The Effect of Argon Ambient Pressure and Annealing Time on Bulk MgB$_2$ Superconductor$^1$, MURAT ERDEM, Abant Izzet Bayals University, OZGUR OZTURK, ELIF ASIKUZUN, SEYDANUR KAYA, Kastamonu University, SERAP SAFRAN, AHMET KILIC, Ankara University, CABIR TERZIOGLU, Abant Izzet Bayals University — The effects of Ar ambient pressure (vacuum, 0B, 105B and 20B) and annealing times (0.5 h and 1h) on microstructural, superconducting and mechanical properties of bulk superconducting MgB$_2$ are investigated. The samples are produced using the solid state reaction method. X-ray diffraction (XRD) and scanning electron microscopy (SEM) measurements were performed for determination of the crystal structure, and surface morphology of MgB$_2$ samples, respectively. The superconducting properties were studied by AC magnetic susceptibility and DC resistivity measurements. Increasing the Ar pressure decreased the lattice parameters and hence the average grain size. Increasing the annealing time results in larger lattice parameters and larger grain formation. The susceptibility measurements revealed two step transition which is reminiscent of granular superconductors. The intra-grain transition temperature is determined to be 38.4 K for all samples. The inter-grain transition temperatures of 37.2 K is obtained for samples produced under Ar ambient. These samples produced under Ar ambient have better superconducting properties than the ones produced in vacuum. Increasing the annealing time under vacuum further decreases the superconducting properties probably due to Mg loss.

9:36AM S11.00009 Isotropic superconducting gap and electron-boson coupling in MgB$_2$ multiband superconductor$^1$, DAIXIANG MOU, RUI JIANG, VALENETIN TAUFOUR, REBECCA FLINT, SERGUEI BUD’KO, PAUL CANFIELD, ADAM KAMINSKI, Division of Materials Science and Engineering, Ames Laboratory, U.S. DOE — MgB$_2$ is a prototype multiband BCS/Eliashberg superconductor with high transition temperature $T_c \sim 39$K. In this talk, we will present electronic properties of this compounds measured by tunable laser ARPES. Momentum dependent gap structure on two Fermi surface around $\Gamma$ is nearly isotropic with $\Delta \sim 0.5$meV, directly proving its s-wave pairing symmetry. Our data reveals a strong renormalization of the dispersion (kink) at $\sim 65$meV, which is caused by coupling of electrons to $\varepsilon_{2g}$ phonon mode. In contrast to cuprates, the 65 meV kink in MgB$_2$ does not change significantly across $T_c$. More interestingly, we observe strong coupling to a second, low energy collective mode at 10 meV. This excitation vanishes above $T_c$ and is likely a signature of the elusive Leggett mode.

9:48AM S11.00010 Measurement of the Penetration Depth and Coherence Length of MgB$_2$ in All Directions Using Transmission Electron Microscopy, JAMES LOUDON, University of Cambridge, S. YAZDI, T. KAMAS, Technical University of Denmark, N.D. ZHIGADLO, J. KARPINSKI, ETH Zurich — We demonstrate that images of flux vortices in a superconductor taken with a transmission electron microscope can be used to measure simultaneously the penetration depth and coherence length in all directions at the same temperature and magnetic field. This is particularly useful for MgB$_2$ where these quantities vary with the applied magnetic field and values are difficult to obtain at low field or in the c direction. We obtained images of flux vortices from a sample cut in the ab plane by focussed ion beam milling and compared these with simulations which accounted for flux vortices with a non-zero core in a thin, anisotropic superconductor. This gave penetration depths $\lambda_{ab} = 100 \pm 35$ nm, $\lambda_c = 120 \pm 15$ nm and coherence lengths $\xi_{ab} = 41 \pm 13$ nm and $\xi_c = 34 \pm 10$ nm at 10.8 K in a field of 4.8 mT. The implications of these values for type-1.5 superconductivity will be discussed.

10:00AM S11.00011 Superconductivity beyond the dimer model in 2D organic charge transfer salts$^1$, MICHAELA ALTMAYER, DANIEL GUTERDING, HARALD O. JESCHKE, ROSER VALENTI, Goethe-Universitaet Frankfurt. — We present a theoretical investigation of BEDT-TTF charge transfer salts containing $\kappa$-type layers. Using ab-initio density functional theory we construct realistic models with unprecedented accuracy for a broad variety of materials. We analyze the pairing symmetry and strength within random phase approximation spin fluctuation theory and interpret our findings microscopically in a tight-binding analysis. In particular we show that the minimal model for this class of materials needs to describe all BEDT-TTF molecules independently and give an example where the customary dimer model breaks down.

10:12AM S11.00012 Inhomogeneous superconducting state in $\beta''$-(BEDT-TTF)$_2$S$_2$CH$_2$CF$_2$SO$_3$, GEORGIOS KOUTROULAKIS, Univ of California - Los Angeles, H. KUHNE, Hochfeld-Magnetlabor Dresden (HLD), Helmholtz-Zentrum Dresden-Rossendorf, R. KATO, Condensed Molecular Materials Laboratory, RIKEN Advanced Science Institute, J.A. SCHLUTER, Materials Science Division, Argonne National Laboratory, J. WOSNITZA, Hochfeld-Magnetlabor Dresden (HLD), Helmholtz-Zentrum Dresden-Rossendorf, S.E. BROWN, Univ of California - Los Angeles — We present nuclear magnetic resonance (NMR) measurements on the quasi-2D organic superconductor $\beta''$-(BEDT-TTF)$_2$S$_2$CH$_2$CF$_2$SO$_3$ at ultra-low temperature ($T \sim 100$K). For a magnetic field applied precisely within the conducting layers, the field evolution of the NMR spectrum reveals a phase transition within the superconducting state ($H_F > 12$T) near to the Pauli limit $H_F \sim 9.5$T. The transition is identified by the significant line-broadening of the spectrum, associated with the electronic spin polarization distribution due to the emergence of spatially inhomogeneous superconductivity, the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state. The character of this novel SC state is studied via static and dynamic (i.e. spin-lattice relaxation) NMR measurements. Moreover, the stability of the putative FFLO phase upon rotation of the field away from the in-plane condition is investigated.

10:24AM S11.00013 Electronic structure of a dual-layered organic charge transfer salt$^1$, HARALD JESCHKE, MICHAELA ALTMAYER, ROSER VALENTI, Goethe-Universitaet Frankfurt. — We examine the electronic properties of polyorphs of (BEDT-TTF)$_{2}$Ag(CH$_3$TCE) (1:1.2-chlorotrichloroethane) within density functional theory (DFT). While a phase with low superconducting transition temperature $T_c \sim 2.6$ K exhibits a $\kappa$ packing motif, two high $T_c$ phases are layered structures consisting of $\alpha'$ and $\kappa$ packed layers. We determine the electronic structures and discuss the influence of the insulating $\alpha'$ layer on the conducting $\kappa$ layer. We find that the stripes of high and low charge in the $\alpha'$ layer correspond to a stripe pattern of hopping parameters in the $\kappa$ layer. This finding is the basis for studying the effect of the different underlying Hamiltonians on the superconducting properties.

$^1$Research funded within DFG Transregio 49.
8:00AM S12.00001 Prediction of vibration modes and thermal conductivity for amorphous ZnO-based materials, YU-TING CHENG, ANINDYA ROY, MICHAEL L. FALK, Johns Hopkins University — Amorphous materials, due to their distinct physical and chemical properties, have been widely used in photovoltaics, thermoelectrics and integrated circuits. Because the thermal conductivity is critical to the performance of such devices, the thermal transport in amorphous materials has received considerable attention in the last decade. So far, a number of experimental studies and theoretical models have reported the vibration modes and thermal conductivities for amorphous Si and SiO2. However, the applicability of these vibration mode analyses and thermal conductivity models for other amorphous materials has not been studied. In this work, we employ the molecular dynamics (MD) simulations and Allen-Feldman (AF) theory [1] to investigate the vibration modes and thermal conductivity of amorphous ZnO-based materials. ZnO is basis of a promising class of n-type semiconductors for thermoelectric application. Additionally, from this work, the contribution of individual vibrational modes to the thermal conductivity can be characterized. These results are expected to guide the interpretation of thermal transport in amorphous ZnO-based materials and the optimization for their performance with different applications. [1] P. B. Allen and J. L. Feldman, Phys. Rev. B 48, 12581 (1993).

8:12AM S12.00002 Optimization of thermoelectric properties in cross-plane superlattices - A 1D NEGF Study, MISCHA THEISBERG, MAHDI POURFARTH, Vienna Univ of Technology, NEOPHYTOS NEOPHYTOU, University of Warwick, HANS KOSINA, Vienna Univ of Technology — Thermoelectric materials utilize carrier energy filtering through potential barriers to achieve improvements in the Seebeck coefficient. Barriers, however, tend to drastically reduce the electrical conductivity, and power factor improvements are difficult to be realized. In this work we present a fully quantum mechanical simulation study of thermoelectric transport in the presence of barriers for energy filtering. For this, we use the non-equilibrium Green’s function (NEGF) method, including both acoustic and optical phonons. We show that power factor improvements can be achieved by properly adjusting a series of interrelated parameters: i) the position of the Fermi level, ii) the width, size and shape of the barriers as well as the separation between them, iii) the optical phonon energies. Our results provide insight on how to optimize superlattices and nanocomposite materials for enhanced thermoelectric properties.

8:24AM S12.00003 Sub-Band engineering through superlattice based barrier heterostructures for higher thermoelectric efficiency, MAHYAR POURHASEMI, JIVTESH GARG, Univ of Oklahoma — There is a huge desire to increase operation speeds in modern integrated circuits as they get more compact. Heat generation in such a submicron devices is a key factor limiting their performances. As a solution, thermoelectric cooling in heterostructures can address heat dissipation issue in submicron devices. Performance of single barrier heterostructures depends strongly on several parameters including barrier height, barrier width and thermal conductivity of barrier. Superlattice structures have been known to have the lowest thermal conductivities reported for crystalline materials. Low thermal conductivity is beneficial for thermoelectric cooling as it reduces the heat flow from hot end to cold junction. Moreover the band offset between the barrier and base material can be easily tuned by changing the superlattice period. By optimizing the conduction band offset (barrier height), it is possible to control the Joule heating and also optimize the amount of heat absorbed due to Peltier cooling. We investigate the feasibility of using PbSe/PbSnTe superlattices in heterostructures using Monte Carlo simulation. The effect of different parameters such as barrier height, barrier width and superlattice thermal conductivity on thermoelectric cooling of such structures will be presented.
Development of thermal rectifier using unusual electron thermal conductivity of icosahedral quasicrystals. TSUNEHIRO TAKEUCHI, Toyota Technological Inst — The bulk thermal rectifiers usable at high temperature were developed using the unusual increase of electron thermal conductivity of icosahedral quasicrystals (ICQ) at high temperature. Our previously performed analyses in terms of linear response theory suggested that the unusual increase of electron thermal conductivity of ICQ was brought about by the synergy effect of quasiperiodicity and narrow pseudogap at the Fermi level. Since the linear response theory suggests that the unusual increase of electron thermal conductivity is coupled with the small magnitude of Seebeck coefficient, the composition of Al-Cu-Fe ICQ, where the thermal conductivity shows the most significant increase with increasing temperature, was determined with a great help of Seebeck coefficient measurements. Consequently obtained $A_{11,5}Cu_{26},Fe_{12},0 ICQ, which was characterized by the small magnitude of Seebeck coefficient, possessed 9 times larger value of thermal conductivity at 1000 K than that observed at 300 K. The increasing tendency of electron thermal conductivity with increasing temperature was further enhanced by means of small amount of Re substitution for Fe. This substitution definitely reduced the lattice thermal conductivity while the electron thermal conductivity was kept unchanged. The lattice thermal conductivity was reduced by 35 % under the presence of 0.5 at. % Re, and the thermal conductivity at 1000 K consequently became about 11 times larger than that at 300 K. The thermal rectifiers were constructed using our newly developed ICQ ($A_{11,5}Cu_{26},Fe_{12},0$ or $A_{12},5Si_{10},Cu_{26},Fe_{11},0$) together with one of the selected materials (Si, Al$_2$O$_3$, Cu$_2$Te$_2$ or Ag$_2$Te) that possess thermal conductivity decreasing with increasing temperature. The heat current flowing in the rectifiers was confirmed to show significant direction dependence. The consequently obtained $TRR = |J_{\text{large}}/ |J_{\text{small}}|$ for the composite consisting of $A_{11,5}Si_{10},Cu_{26},Fe_{12},0$ or $A_{12},5Si_{10},Cu_{26},Fe_{11},0$ reached 2.24, and that is the largest value ever reported for the bulk thermal rectifiers.

9:12AM S12.00005 Thermopower measurements of atomic and molecular junctions using microheater-embedded mechanically-controllable break junctions, MAKUSU TSUTSUI, TAKANORI MORIKAWA, AKIHIDE ARIMA, MASATERU TANIGUCHI, ISIR, Osaka University — There has been growing interest in developing high-performance thermoelectric materials for realizing thermoelectric power generation. Quantum effects in low-dimensional structures are expected to provide high electronic density of states for enhanced thermopower, and thus considered as a promising approach for achieving a high figure of merit (M. S. Dresselhaus et al., Adv. Mat. 19 (2007) 1043-1053). From this respect, it is interesting to study thermoelectric properties of atomic and molecular junctions and evaluate their potential as a thermoelectric material. Recently, we have developed a heater-embedded micro-fabricated mechanically-controllable break junction (MCBJ) for investigating the thermoelectric transport in single-atom and –molecule junctions. Using the MCBJ devices, we could repeatedly form stable junctions at room temperatures via a self-breaking mechanism with one side being heated by the adjacent microheater. In my presentation, I will show the results of simultaneous measurements of the thermoelectric voltage and the electrical conductance of atom-sized Au junctions and Au-benzenedithiol-Au junctions and discuss on the geometrical dependence of thermoelectric transport.

9:24AM S12.00006 Phonon thermal conductivity of a nanowire attached to leads, SELMAN HERSHFIELD, KHANDKER MUTTALIB, Department of Physics, University of Florida — There is experimental evidence as well as theoretical proposals that nanowires can be made to have high thermoelectric efficiency by tuning the electronic properties; however, there is always a phonon contribution to the heat transport which reduces the thermoelectric efficiency. In the harmonic approximation we compute the transmission of phonons through a nanowire coupled to large leads. There is a finite thermal conductance because of the restriction provided by the nanowire. The nanowire reduces the thermal transport because of the mismatch between the leads and wire modes. We examine the effect of disorder in three places: in the wire, in the leads near the wire, and in the leads far way from the wire. In some cases disorder can increase the thermal conduction because of enhanced mode coupling. We will discuss the implications of our results for thermoelectric nanowire devices.

9:36AM S12.00007 Measurement of thermal boundary conductance at sintered Si-Si interface, MASANORI SAKATA, TAKUMA HORI, TAKAFUMI OYAKE, Department of Mechanical Engineering, The University of Tokyo, JEREMIE MAIRE, MASAHIRO NOMURA, Institute of Industrial Science, The University of Tokyo, JUNICHIRO SHIOMI, Department of Mechanical Engineering, The University of Tokyo — Performance of thermoelectric materials is enhanced by reducing thermal conductivity (TC) without appreciably decreasing electrical properties. Recently, nanocrystalline formed by compaction of nanopowder by sintering has been shown to be a promising solution for low TC and high scalability However, little is known about the thermal boundary conductance (TBC) of the grain boundaries, which dominantly affect the TC, because of the difficulty to directly measure the TBC of the local boundaries. We have therefore developed a process to fabricate a highly planar and uniform bonded-interface between Si thin film and Si substrate, which is suitable for measuring the TBC of the interfaces with time-domain thermoreflectance method. We have found that sintering temperature and HF removal of native oxide on the wafers can change the interface structures from uniform to local SiO$_x$ structures, which alter the TBC from 0.1 to 1 G$\text{W}^{-1}\text{K}^{-1}$ order. Moreover, crystal orientation mismatch can change the TBC by several times. Together with theoretical calculation that relates the TBC and TC of nanocrystalline Si, the measurement results identify the route to reduce the TC less than the state-of-art value.

9:48AM S12.00008 Tuning nanoscale thermoelectricity with electron-electron interactions, ARUNIMA COOMAR, CHARLES STAFFORD, University of Arizona — The Nonequilibrium Green’s Function (NEGF) formalism is a powerful tool that provides a microscopic theory for interacting quantum systems out of equilibrium. In this talk, I will be presenting a few results obtained using the NEGF approach combined with pi-electron effective field theory to study the thermoelectric properties such as the thermopower (S) and the dimensionless figure of merit (ZT) across single-molecule junctions with pi-conjugated molecular systems, which exhibit destructive quantum interference of the electron waves. Some interesting results showcasing the tuning of the thermoelectric properties by embedding the junctions in a dielectric medium will be presented, along with our ongoing investigations of the transmission node spectrum in these molecular junctions, and the enhanced thermoelectricity resulting from it.

10:00AM S12.00009 Thermal Transport Properties of Low Dimensional SI, GE, and SI-GE Superlattice Structures, ALI KANDEMIR, Department of Materials Science and Engineering, Faculty of Engineering, Anadolu University, CEM SEVK, Department of Mechanical Engineering, Faculty of Engineering, Anadolu University — Potential low dimensional thermoelectric materials have captured considerable attention of researchers due to their possible adaptation in power generation, energy conversion, and solid-state cooling applications. Due to enhanced electrical conductivity of these systems, researchers mainly focused on to find a way of reducing thermal conductivity of these systems to enhance their thermoelectric performance. With this intention a number of theoretical and experimental studies have been carried out. Due to their extraordinary transport properties carbon based nano materials have been studied intensively and several different researchers have pointed out their highly efficient thermoelectric properties. Furthermore, as another nanostructure material family Si, Ge, and Si-Ge based nano systems have attracted attention and ZT values larger than 2.0 have been reported for some Si nanostructures. Considering the potential of these materials, we systematically investigate the thermal transport properties of bulk and nano superlattice structures of Si, Ge and SiGe by equilibrium molecular dynamics simulations. We predicted quite low lattice thermal conductivity for some specific structures of these materials. Our results show that the thermal conductivity of these structures can be suppressed up to 75 percent of bulk superlattice or pure nanowire structures.
10:12AM S12.00010 Thermoelectric Properties of Carbon nanohybrids Incorporated Polymer Nanocomposites1, KUN ZHANG, SHIREN WANG, Texas Tech University — In this work, non-covalently functionalized graphene with fluorinated fullerene (F-C60) by π-π stacking was integrated into poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS). F-C60 as a p-type semiconducting material was used. Polylithium intercalation during growth (P(O2)) after deposition of F-C60 on SiO2. The conduction behavior which changes from strongly localized transport that fits a Variable Range Hopping (VRH) model (low P(O2)) to thermally activated transport (high P(O2)) during growth determines the conduction behavior which changes from strongly localized transport that fits a Variable Range Hopping (VRH) model (low P(O2)) to thermally activated transport (high P(O2)). The transition is observed when P(O2) increases from 0.02% to 0.2%. The single-phase STO/Si films were of high crystalline quality as verified by x-ray diffraction, transmission electron microscopy, and atomically flat. Transport measurements were performed on the STO/Si structures in a Van der Pauw configuration. The P(O2) during growth determines the conduction behavior which changes from strongly localized transport that fits a Variable Range Hopping (VRH) model (low P(O2)) to thermally activated transport (high P(O2)). The resistivity of the strongly disordered STO/Si films decreased from 1 Ohm-cm to 3x10^-2 Ohm-cm as the film thickness increased (3nm-60nm). The perpendicular magnetoresistance (MR) is positive at 300K and becomes negative at T<20K. We consider competing effects on the STO/Si heterostructure such as 1.7% compressive strain resulting in SrTiO3 nanoparticle growth, changes in the piezoelectric field, changes in the lattice constant, changes in the band gap, and changes in the occupation of the conduction and valence bands.

10:24AM S12.00011 Non-linear thermoelectricity in disordered nanowires, KHANDKER MUTTALIB, SELMAN HERSHEYFIELD, University of Florida — We consider non-linear thermoelectric transport in an effectively one-dimensional disordered semiconductor nanowire connected to a pair of three-dimensional perfectly conducting semi-infinite leads, where the impurity band of the disordered wire can be shifted relative to the conduction band of the leads by applying a gate voltage. We show how the gate voltage can be tuned to optimize a unique interplay between the microscopic parameters characterizing the transmission of electrons through the nanowire and the thermodynamic parameters that characterize the Fermi functions in the leads. Assuming a Lorentzian distribution of disorder in the wire, we calculate the full non-linear thermodynamic efficiency η as well as the power output P. We show that for a fixed set of microscopic and thermodynamic parameters η can be increased from zero to η > 0.5ηC, where ηC is the Carnot efficiency, by simply changing the gate voltage. The power output P can then be scaled by connecting many wires in parallel.

10:36AM S12.00012 Tuning the Thermoelectric Properties of a Single-Molecule Junction by Mechanical Stretching1, RENATO PONTE, Federal University of Goias, ALBERTO TORRES, Federal University of Santa Catarina, ANTONIO J.R. DA SILVA, Brazilian Synchrotron Light Laboratory (LNLS), ADALBERTO FAZZIO, Sao Paulo University — We theoretically investigate, as a function of the stretching, the behaviour of the thermoelectric properties - Seebeck coefficient (S), the electronic heat conductance (γe) - and the figure of merit (ZT) - of a molecule-based junction composed by benzene-1,4-dithiol molecule (BDT) coupled to Au(111) surfaces at room temperature. We show that the thermoelectric properties of a single molecule can be tuned by mechanical stretching. The Seebeck coefficient can be positive, indicating that it is dominated by HOMO. Furthermore, it increases as the HOMO level, which is associated to the sulphur atom, goes to energies close to the Fermi level. By modelling the transmission coefficient of the system as a single Lorentzian peak, we propose a scheme to obtain the maximum ZT of any molecular junction.

10:48AM S12.00013 First-Principles Study on Thermoelectric Properties of Carbon Nanotubes, JOUNGHEE LEE, EUI-SUP LEE, YONG-HYUN KIM, KAIST — Carbon nanotubes (CNTs) have attracted much attention because of their extraordinary material properties such as strong mechanical strength, chirality- and diameter-dependent electronic structure, and high thermal conductivity. As an electronic material, CNTs can be used as high-performance thermoelectric materials. In this work, we studied the thermoelectric properties of CNTs using first-principles calculations. We found that the thermoelectric properties of CNTs can be tuned by changing the chirality and diameter of the CNTs. The Seebeck coefficient of (9,9) metallic CNTs is 1.3 mV/K with appropriate doping level, while it is 0.8 mV/K for (10,8) semiconducting CNTs with similar diameter. When the diameter is smaller, the Seebeck coefficient of one-dimensional CNT systems based on coherent electron transport within first-principle calculations and Landauer formulation. We will also estimate a contribution from diffusive transport, comparing to experimental results. The calculated maximum Seebeck coefficient is 0.13 mV/K for (9,9) metallic CNTs, while it is 0.8 mV/K for (10,8) semiconducting CNTs with similar diameter. When the diameter is smaller, the Seebeck coefficient of semiconducting CNTs can be as big as 1.3 mV/K with appropriate doping level.

10:50AM S13.00001 Electrical characterization of n-SrTiO3δ−/p-Si(100)epitaxial diode structures1, RYAN COTTIER, DANIEL CURR, NIKOLETA THEODOROPOULOU, Texas State University — Semiconducting, single crystalline n-p (n-STO/p-Si) junctions were grown by MBE (Molecular Beam Epitaxy) using a technique that suppresses the formation of a SiOx interfacial layer. The STO layer thickness varied from 3.6 to 30 nm, and oxygen vacancies were induced during growth by controlling the background O2 pressure (P(O2)) during growth. Incorporating of STO/F-C60 nanohybrids into highly conductivity metallic PEDOT:PSS formed Schottky barrier to selectively scatter low-energy carriers. Enhanced thermoelectric power factor of rGO/F-C60/PEDOT:PSS nanocomposites were observed with the optimized power factor of 83.2 µV/m.K2, which is 19 times of that of the highly conductive PEDOT:PSS. Additionally, the F-C60 nanoparticles on rGO surfaces hinder thermal transport by phonon scattering, resulting in the synergistic effect on enhancing thermoelectric properties. As a result, a figure of merit (ZT) of 0.10 was achieved.

10:52AM S13.00002 Transport properties of SrTiO3δ−/p-Si thin films grown by Molecular Beam Epitaxy on p-Si(001) substrates1, NIKOLETA THEODOROPOULOU, DANIEL CURR, RYAN COTTIER, Physics Dpt., Texas State University, ARTURO PONCE-PEDRAZA, JESUS CANTU, OSCAR VILLARREAL, Physics, Dpt., University of Texas-San Antonio — SrTiO3 (STO) films were grown on p-Si(001) and STO(001) bulk substrates using molecular beam epitaxy (MBE). Oxygen vacancies were introduced by controlling the Oxygen pressure during growth (P(O2)): 4 × 10^-6 - 8 × 10^-7 resulting in SrTiO3δ− with δ ∼ 0.02% for the lowest P(O2). The single-phase STO/Si films were of high crystalline quality as verified by x-ray diffraction, transmission electron microscopy, and atomically flat. Transport measurements were performed on the STO/Si structures in a Van der Pauw configuration. The P(O2) during growth determines the conduction behavior which changes from strongly localized transport that fits a Variable Range Hopping (VRH) model (low P(O2)-high disorder) to thermally activated transport (high P(O2)-low disorder). The resistivity of the strongly disordered STO/Si films decreased from 1 Ohm-cm to 3x10^-2 Ohm-cm as the film thickness increased (3nm-60nm). The perpendicular magnetoresistance (MR) is positive at 300K and becomes negative at T<20K. We consider competing effects on the STO/Si heterostructure such as 1.7% compressive strain induced by lattice mismatch to Si, defects due to oxygen vacancies, the bulk STO antiferrodistortive phase transition at 105K, and structural dislocations.

9:12AM S13.00005 Continuous strain modulation of strontium titanate (SrTiO$_3$) on semiconductor interface by thermal strains LEI ZHANG, YAKUN YUAN, SHIMING LEI, BERND KABIUS, VENKATRAMAN GOPALAN, ROMAN ENGEL-HERBERT, Pennsylvania State Univ. — Strain engineering is a general strategy for tuning the desired material properties, such as enhancing carrier mobility and increasing the spontaneous polarization and Curie temperature in ferroelectric films. Control over the strain state in thin film is provided by the substrate with lattice mismatch. Although growth of strained perovskite oxides was demonstrated, the limited number of suitable substrates of high quality imposed difficulty towards utilizing the strain. We’ll discuss a novel route towards wafer-scale strain engineering of ferroelectric oxide based on large thermal mismatch between film and substrate, enabling to continuously modulate the strain state. SrTiO$_3$ films were grown on Si (001) between 400 $^\circ$C and 900 $^\circ$C above the critical film thickness. The films relaxed at growth temperature and accumulated a tensile strain ranging from 0.2% to 0.7% during cool-down, which was proportional to the temperature difference. X-ray reciprocal space maps and geometric phase analysis obtained from cross section transmission electron microscopy have been used to relate the film’s strain state to the ferroelectric properties, probed by second harmonic generation and piezo force microscopy.

9:24AM S13.00006 Switchable two-dimensional electron gas at the interface of a ferroelectric and nonpolar insulator: BaTiO$_3$/SrTiO$_3$ KURT FREDRICKSON, ALEX DEMKOV, Univ of Texas, Austin — We theoretically investigate the interface between a ferroelectric BaTiO$_3$ film and a nonpolar insulating SrTiO$_3$ substrate. We find that thin BaTiO$_3$, under 5 nm, can stabilize two polarization states. While the nonpolarized state is insulating, for the polarized heterostructure, we discovered the existence of two-dimensional gases. In this case, the heterostructure undergoes an electronic reconstruction in order to prevent the polar catastrophe. The two-dimensional gases, formed as a result, screen the polarization, leading to a substantially reduced potential drop across the ferroelectric film. We emphasize that the two-dimensional electron and hole gases are created by the polarization of the sample, and is not due to the polar nature of either material or doping.

9:36AM S13.00007 Electronic carrier transport at epitaxial oxide-semiconductor interfaces LIOR KORNBLUM, ERIC JIN, CHARLES AHN, FRED WALKER, Dept. of Applied Physics and Center for Research on Interface Structures and Phenomena, Yale University, New Haven, CT 06511, USA — The epitaxial growth of transition metal perovskite oxides on conventional semiconductors is a promising approach for integrating the wealth of electronic phenomena found in these oxides with existing devices and technologies. Some oxide functionalities require charge transport to and from the semiconductor, making the semiconductor-oxide interface an important focal point in the utilization of epitaxial oxides in electronic devices. We present our findings on electronic carrier transport in the conduction band of titanate perovskites (TiO$_x$) epitaxially grown on silicon and on germanium. Metal-semiconductor contacts were fabricated by epitaxial deposition of metallic contacts on top of epitaxially-grown oxides on semiconductors. Transport measurements show diode-like transport across the interface of some of the structures, whereas whereas leakage currents are observed in others. These results are discussed in light of the physical and electronic structure at the oxide-semiconductor interface.

8:48AM S13.00008 Growth of Dielectric SrTiO$_3$(111) Film with Atomiically Well Defined Surface1 JIANDONG GUO, YAN LIANG, WENTAO LI, SHUYUAN ZHANG, Institute of Physics, Chinese Academy of Sciences — Oxide heterointerfaces exhibit novel properties that can be controlled by external fields. The (111) surfaces of perovskite oxides are particularly interesting since the six-fold symmetry is compatible with other quantum materials, e.g., topological insulators. We grow high quality SrTiO$_3$(111) film on Nb-doped substrate by oxide molecular beam epitaxy. By adjusting the flux rates of Sr and Ti, we keep the reconstruction of film surface unchanged as that on substrate all through the growth. Thus the cation stoichiometry is achieved since the surface reconstruction is determined by Sr:Ti concentration ratio and can be monitored in real-time. Moreover reconstruction allows the stable layer-by-layer growth of the polar film. In situ scanning tunneling microscope shows the atomically well defined film surface with broadened terraces. And the C-V measurements indicate that the tunable range of the carrier density is 2E13 per cm2 for a 50 nm film. This insulator/metal homoeptaxial system provides a template for the growth of novel low-dimensional structures with flexible tunability by gate voltage.

10:00AM S13.00009 Growth of epitaxial poly-crystalline transition metal oxide thin films. SUNGMIN WOO, HOIDONG JEONG, SANG A LEE, HOSUNG SEO, Sungkyunkwan University, MORGANE LACOTTE, ADRIAN DAVID, CNRS UMR 6508, HYUN YOON KIM, Chungnam National University, WILFRID PRELLIER, CNRS UMR 6508, YUNSEOK KIM, WOO SEOK CHOI, Sungkyunkwan University — By comparing single- and poly-crystalline transition metal oxides (TMOs), one can study intriguing physical phenomena such as electronic and ionic conduction at the grain boundaries, phonon propagation, and various domain properties. In this work, we propose an approach to simultaneously fabricate single- and poly-crystalline epitaxial TMO thin films using substrate epitaxy of poly-crystalline SrTiO$_3$ (STO). In order to grow TMO thin films epitaxially with atomic precision, and to achieve a flat surface of the substrate is required. We fabricated SrTiO$_3$ (001), (110), and (111) oriented single-crystalline STO surfaces, which required different annealing conditions to achieve an atomically flat surface. A poly-crystalline STO surface was then prepared at the optimum condition for which all the domains with different crystallographic orientations could be successfully flattened. Studying the surface properties (surface potential, topography, and orientation) of poly-crystalline STO helped us to understand the formation of the atomically flat surface. Based on our research, we envision expansion of the studies regarding the epitaxial poly-crystalline TMO thin films and heterostructures.

10:12AM S13.00010 The surface of SrTiO$_3$ (111): effect of annealing in vacuum and in oxygen. MOHAMMAD SAGHAYEZHIAN, LINA CHEN, GAOMIN WANG, HANGWEN GUO, JIANDI ZHANG, EARL W. PLUMMER, Louisiana State Univ. — Baton Rouge — The surface of SrTiO$_3$ (111) have created a new playground for new physics, exhibiting novel properties such as 2DEG and topological phases such as quantum spin Hall effect. Due to the polar nature of the surface, it is very susceptible to different kinds of reconstructions which results in various terminations. There has been a fair amount of investigations on SrTiO$_3$ (111) as a function of sputtering and annealing, while less attention has been paid to its reconstruction when the surface comes in contact with oxygen or the mere effect of annealing in vacuum. We have focused on the surface reconstruction and chemical composition of SrTiO$_3$ (111) as a function of annealing temperature and oxygen pressure using LEED and ARXPS. We observed that annealing in oxygen brings more Ti to the surface in comparison with annealing in vacuum. Our data show that the SrTiO$_3$ (111) surface is highly reactive and easily absorbs carbon. Furthermore, we show that in contrast to SrTiO$_3$ (001), where carbon tends to be physisorbed and can easily be removed by low temperature annealing, on SrTiO$_3$ (111), carbon only leaves the surface after annealing to very high temperature. Also, our data show that the presence of oxygen can facilitate de-contamination of the surface and makes the surface more ordered.

10:24AM S13.00011 Influence of Strain on the Thermoelectric Properties of electron-doped SrTiO$_3$ Thin Films. ALEXANDROS SARANTOPoulos, ELIAS FERREIRO-VILA, CIQUIS, Universidad de Santiago de Compostela, Santiago de Compostela, España, CESAR MAGEN, LMA, INA, Universidad de Zaragoza, 50018 Zaragoza, Spain & Fundación ARAID, 50018 Zaragoza, Spain, MYRIAM H. AGUIRRE, LMA, INA, Universidad de Zaragoza, 50018 Zaragoza, Spain, VICTOR PARDO, Instituto de Investigaciones Tecnológicas, Universidad de Santiago de Compostela, Spain, FRANCISCO RIVADULLA, CIQUIS, Universidad de Santiago de Compostela, 50018 Santiago de Compostela, España — The discovery of a two dimensional electron gas with high mobility at the interface between insulating LaAlO$_3$/SrTiO$_3$ (LAO/STO) opened the possibility of fabricating functional devices based on this interfacial effect. Therefore, it is important to study the influence of the growth parameters on the properties of the constituent materials. Here, we demonstrate that the thermoelectric properties of epitaxial thin films of Nb:STO can be finely tuned by adjusting the growth conditions in a PLD system. By growing the sample on different substrates, we demonstrate that the amount of vacancies depends on the degree of epitaxial compressive stress. The vacancies produced lead to impurity scattering at low temperatures. We show that the magnetoresistance response, and non-linear behavior of the Hall effect, characteristic of LaO/STO interfaces, can be reproduced in thin films of Nb:STO with a controlled number of vacancies. Moreover, we show that the Seebeck coefficient is a valid tool to obtain information about the degeneracy of the electronic band structure.

1We acknowledge support from the ERC 2D Therms project.

10:36AM S13.00012 Spectroscopic ellipsometry study on doped SrTiO$_3$ superlattice films. YUNSANG LEE, Y.K. SEO, Soongsil University, CHOI, J.W. SEO, J. LEE, Sungkyunkwan University — We report on the spectroscopic ellipsometry study on the low-dimensional confinement of chemical doping in SrTiO$_3$. We fabricated superlattice films composed of the stacking of insulating SrTiO$_3$ (STO) and metallic La-doped SrTiO$_3$ (SLTO) layers. As the dimensionality is varied from three to two dimensions by changing the thickness of the SrTiO$_3$ layers, phase transition from metal to insulator occurred through interplay of charge, spin, orbital, and lattice degrees of freedom. The optical conductivity spectra obtained from the spectroscopic ellipsometry show a significant change below the charge transfer gap near 3 eV through the insulator-metal transition. We detail our research expansion of the studies regarding the epitaxial poly-crystalline TMO thin films and heterostructures.

10:48AM S13.00013 Two-dimensional electron gas at surfaces of (001), (110), and (111) oriented SrTiO$_3$ induced by Ar$^+$-irradiation. LUDI MIAO, RENZHONG DU, YUEWEI YIN, QI LI, Penn State University — Two-dimensional electron gases (2DEGs) at transition metal oxide surfaces and interfaces have attracted much attention due to their fascinating exotic properties such as superconductivity, large magnetoresistance (MR), and ferromagnetism. We have created 2DEGs at the surfaces of (001), (110), and (111) oriented SrTiO$_3$ (STO) by Ar$^+$-irradiation and measured their transport properties. The 2DEGs exhibit a fully metallic behavior with the 2D charge carrier density around $2 \times 10^{14}$ cm$^{-2}$ and the mobility as large as 5500 cm$^2$V$^{-1}$s$^{-1}$ at low temperatures, which is tunable by electric fields applied through STO back gates. We have measured MR anisotropy of the 2DEGs at surfaces of STO with all orientations. We observed combinations of two types of components in their anisotropic MR at low temperatures. While the first type is an STO-orientation-independent two-fold component results from the Lorentz force effect, the second type shows stark differences between these 2DEGs as a consequence of distinct Fermi surface symmetries with different STO orientations. Indeed, it is four-fold for STO (001), two-fold for STO (110) and six-fold for STO (111), respectively.

Thursday, March 5, 2015 8:00AM - 11:00AM — Session S14 DMP FIAP: Focus Session: Dopants and Defects in III-V and II-VI Semiconductors

008A - Kirstin Alberi, National Renewable Energy Laboratory
8:00AM S14.00001 Carrier Decay and Diffusion Dynamics in Single-Crystalline CdTe as seen via Microphotoluminescence1. ANGELO MASCARENHAS, BRIAN FLUEGEL, KIRSTIN ALBERI, NREL, YONG-HANG ZHANG, Arizona State Univ. — The ability to spatially resolve the degree to which extended defects impact carrier diffusion lengths and lifetimes is important for determining upper limits for defect densities in semiconductor devices. We show that a new spatially and temporally resolved photoluminescence (PL) imaging technique can be used to accurately extract carrier lifetimes in the immediate vicinity of dark-line defects in CdTe/MgCdTe double heterostructures. A series of PL images captured during the decay process show that extended defects with a density of 1.4x10^{-5} cm^{-2} deplete photogenerated charge carriers from the surrounding semiconductor material on a nanosecond time scale. The technique makes it possible to elucidate the interplay between nonradiative carrier recombination and carrier diffusion and reveals that they both combine to degrade the PL intensity over a fractional area that is much larger than the physical size of the defects. Carrier lifetimes are correctly determined from numerical simulations of the decay behavior by taking these two effects into account. Our study demonstrates that it is crucial to measure and account for the influence of local defects in the measurement of carrier lifetime and diffusion, which are key transport parameters for the design and modeling of advanced solar-cell and light-emitting devices.

8:12AM S14.00002 Carrier scattering mechanisms in p-type transparent copper-alloyed ZnS: Crystalline vs. amorphous, RACHEL WOODS-ROBINSON, Materials Sciences Division, Lawrence Berkeley National Laboratory, ALIREZA FAGHANINIA, Department of Energy, Environmental and Chemical Engineering, Washington University in St. Louis, JASON K. COOPER, HIEU H. PHAM, Materials Sciences Division, Lawrence Berkeley National Laboratory, CYNTHIA LO, Department of Energy, Environmental and Chemical Engineering, Washington University in St. Louis, LIN-WANG WANG, JOEL W. AGER, Materials Sciences Division, Lawrence Berkeley National Laboratory — Crystalline (wurtzite and sphalerite) and amorphous forms of copper-alloyed ZnS (Cu_{x}Zn_{1−x}S) are p-type conducting transparent thin film materials with near-record figures of merit for applications in photovoltaics and optoelectronics. Remarkably, the conductivity of amorphous Cu_{x}Zn_{1−x}S, 42 S/cm at x = 0.30, is nearly as high as crystalline Cu_{x}Zn_{1−x}S (54 S/cm at x = 0.21). This contrasts with typical observations of poorer carrier transport in amorphous materials. By combining experiment and computation, we investigate the defect physics underlying hole transport in amorphous and crystalline Cu_{x}Zn_{1−x}S. Structural probes (EXAFS, TEM and wide-angle XRD) are used to determine bonding characteristics and lattice order, and serve as inputs to ab initio hybrid functional HSE calculations of the electronic structure. Hall effect, temperature dependent conductivity (15K to 580K), and XPS valence band measurements and ab initio calculations show that hole conduction occurs in a hybridized S-3p and Cu-3d valence band for amorphous and crystalline films. The hole scattering mechanisms which limit the conductivity will be discussed in the context of theoretical carrier transport model based on Boltzmann transport equation, ab initio calculated band structure, and phonon dispersion.

8:24AM S14.00003 Diffusion of Interstitial Defects in CdTe, SU-HUI AI, JI-HUI YANG, JIE MA, JOONGOO KANG, National Renewable Energy Laboratory — CdTe is one of the most promising candidates for thin-film photovoltaic applications and it is well known that Cu and Cl diffusions play critical roles in improving the CdTe solar cell efficiency. However, the diffusion behavior of these impurities as well as the host elements in CdTe has not been clearly understood. Using first-principles calculations, we determine the diffusion behaviors of the cation atoms (Cd and Cu) and the anion atoms (Te and Cl) at different charged states is investigated. We find that, due to different electronic level occupations and level splittings, the diffusion of the cation atoms and anion atoms are very different. We explain why Cu can diffuse much faster than other elements and show that the diffusion speeds of the impurities can be controlled by tuning the Fermi level of CdTe. We have also developed a general diffusion coefficient theory for multi-barrier diffusion. Our calculated diffusivity of the interstitial impurities agrees well with available experimental measurements.

8:36AM S14.00004 ABSTRACT WITHDRAWN —

8:48AM S14.00005 First-principles study of low Σ grain boundaries in CdTe, JI-SANG PARK, Natl Renewable Energy Lab, JOONGOO KANG, DGIST, JI-HUI YANG, WYATT METZGER, SU-HUI AI, Natl Renewable Energy Lab — Grain boundaries (GBs) play critical roles in determining physical properties of polycrystalline materials. In this study, we investigate stability and electronic structure of GBs in CdTe through first-principles density functional calculations. We consider low-Σ symmetric tilt GBs including Σ=111, Σ=112, Σ=120, and Σ=130 GBs. We find that the Σ=111 GB is more stable than the other GBs considered in this study because it contains no dangling bonds and wrong bonds. The stability of the Σ=112 GBs is independent on the chemical potential of Cd and Te whereas that of the Σ=130 GBs depends on the chemical potentials. Unexpectedly, we find that the Σ=120 GBs are more stable than the Σ=112 GBs, despite that the Σ=120 GBs have often been used as a model system to study GBs in polycrystalline thin-film photovoltaic materials. The Σ=120 GBs found in this study are not electrically harmful even though the GBs contain wrong bonds.

9:00AM S14.00006 Role of phonon-assisted processes in Auger recombination in InAs, JIMMY-XUAN SHEN, DANIEL STEIAUF, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Univ of California - Santa Barbara — Auger recombination has been identified as an important loss mechanism in InAs and InAs-based alloyed thin emitters, yet the mechanisms are not fully understood. In particular, it is unclear whether direct or indirect processes dominate. The direct process involves only Coulomb interaction, while the indirect process is mediated by the absorption or emission of a phonon. We present results of first-principles calculations of the direct and indirect phonon-assisted Auger coefficients in InAs and related alloys. The direct process is usually assumed to occur in small-band-gap semiconductors. However, we find that indirect phonon-assisted processes also contribute significantly to the Auger rate. We untangle the contributions of the electron-electron-hole and hole-hole-electron processes, and pinpoint the phonon modes that are most relevant to the indirect process.

9:12AM S14.00007 Electrical characterization of GaAsN and GaAsBi single-quantum-well diodes1, JO. OCCENA, R.L. FIELD III, A.S. TERAN, T. JEN, C. KURDACK, J.D. PHILLIPS, R.S. GOLDMAN, Univ of Michigan - Ann Arbor — The highly mismatched alloys GaAsN and GaAsBi have been identified as promising candidates for the active layer of optoelectronic devices because their bandgaps can be tuned with minimal change in lattice parameter. Since the conduction band minimum (CBM) of GaAsBi and the valence band maximum (VBM) of GaAsN are approximately aligned with the CBM and VBM of GaAs, with corresponding significant valence and conduction band offsets, GaAsN/GaAsBi is expected to exhibit a staggered Type II band-offset. The resulting spatial separation of charge and optical absorption at wavelengths larger than the fundamental bandgap, on either side of the junction, is promising for both infrared detectors and solar cells. To date, few groups have grown GaAsBi alloys and the GaAsN/GaAsBi heterostructure has yet to be realized. To explore the N- and Bi-related states near the CB and VB in GaAsN(Bi) alloys, Schottky diodes containing GaAsN(Bi) quantum wells (QWs) are grown by molecular-beam epitaxy at low temperature, using Si as either an n- or p-type dopant. For both GaAsN and GaAsBi QWs, rectifying current-voltage characteristics are observed, with reasonable diode ideality factors. We will discuss the influence of increasing N and Bi fraction on the formation of N- and Bi-related states. We will also discuss progress towards measurements of the VB and CB offsets using admittance spectroscopy.

emerges as the ratio was increased from 15 to 40. As the growth temperature was decreased from 595 to 550 °C, the layers became more defective. Moreover, the layers became more defective. The strong radiative emission is concentrated in two narrow bands (~ 90 μeV width) at either 828.65 or 830.40 nm depending on the stacking fault orientation. Stacking fault defects can be imaged using far-field confocal microscopy by the narrow band photoluminescence. Polarization-resolved photoluminescence and magnetic field measurements are consistent with a theory of light-hole excitons bound to the stacking fault plane with a quantization axis normal to the plane. More recently, excitons bound to stacking faults were aligned with the temperature gradient-induced voltage, which is then converted to the local Seebeck coefficient, S. The S profile is then converted to a conduction band-

+ state to the stacking fault plane. The strong perturbation of the strain potential due to this fundamental growth defect. The narrow linewidth and high homogeneity across many defects suggests excitons are bound to a single atomically-thin stacking fault plane. This work opens the door to a novel, highly homogeneous, 2D light-hole excitonic system in the well-characterized material GaAs.

. Accurate bandgaps are included via hybrid density functionals, and spin-orbit split-offs of the valence bands as well as the d-orbitals for In are found to be crucial. Essential features such as the strong perturbation of the Luttinger Hamiltonian and the strong anticovalence between valence bands and impurity d-orbitals are captured in a zone-unfolding picture.

We find the acceptor bound-exciton lifetimes to be lifetimes for the 12-state three-carrier complex. We confirm this prediction through polarization dependent and time-resolved photoluminescence experiments. We present a convenient formalism for predicting the optical properties of k=0 excitons with an arbitrary number of charge carriers in different symmetry environments. Using this formalism, we investigate the radiative lifetime of the neutral acceptor-bound exciton (A0) and the major parameter to control cell function is of great therapeutic interest. We developed a theoretical-experimental approach to investigate the biophysical mechanisms of EF interaction with cells in electrode-free physiologically-relevant configuration. Our numerical results demonstrated that EF frequency is the fundamental tool to control cell function. In contrast, high-frequency EF penetrates the cell membrane and reaches cell cytoplasm, where it may directly activate intracellular responses. Our theoretical predictions were confirmed in our experimental studies of the effects of applied EF on vascular cell function. Results show that non-oscillating EF increases vascular endothelial growth factor (VEGF) expression while field polarity controls cell adhesion rate. High-frequency, but not low frequency, EF provides differential regulation of cytoplasmic focal adhesion kinase and VEGF expression depending on the substrate, with increased expression in cells cultured on RGD-rich synthetic hydrogels, and decreased expression for matrigel culture. A theoretical-experimental approach to investigate the biophysical mechanisms of EF interaction with cells in electrode-free physiologically-relevant configuration. Our numerical results demonstrated that EF frequency is the non-invasive tool to control cell function and highlight the importance of a unified treatment of all recombination pathways when deriving the radiative properties of multi-carrier excitons.

8:00AM S15.00001 Regulation of cellular function via electromagnetic field frequency and extracellular environment: A theoretical- experimental approach1, TOLOO TAGHIAN, Univ of Cincinnati, ABDUL SHEIKH, Yale University, DARIA NAROMEVA, ANDREI KOGAN, Univ of Cincinnati — Application of external electric field (EF) as a non-pharmacological, non-invasive tool to control cell function is of great therapeutic interest. We developed a theoretical-experimental approach to investigate the biophysical mechanisms of EF interaction with cells in electrode-free physiologically-relevant configuration. Our numerical results demonstrated that EF frequency is the major parameter to control cell response to EF. Non-oscillating or low-frequency EF leads to charge accumulation on the cell surface membrane that may mediate membrane initiated cell responses. In contrast, high-frequency EF penetrates the cell membrane and reaches cell cytoplasm, where it may directly activate intracellular responses. The theoretical predictions were confirmed in our experimental studies of the effects of applied EF on vascular cell function. Results show that non-oscillating EF increases vascular endothelial growth factor (VEGF) expression while field polarity controls cell adhesion rate. High-frequency, but not low frequency, EF provides differential regulation of cytoplasmic focal adhesion kinase and VEGF expression depending on the substrate, with increased expression in cells cultured on RGD-rich synthetic hydrogels, and decreased expression for matrigel culture.

8:12AM S15.00002 Tunnel-Current based Single-Molecule Detection Method of Biopolymer Identification, TAKAHITO OHSHIRO, MAKUSU TSUTSUI, KAZUMICHI YOKOTA, MASATERU TANIGUCHI, Osaka Univ, BIONANOTECHNOLOGY TEAM — We have been proposed a tunneling-current based identification as a single-molecule biopolymer sequencing. This methodology is based on sequentially reading the tunneling-current across the single-synthetic polymer in the sequence, resulting in a high-speed electrical discrimination of the individual nucleotides. In this study, we report on a read of nucleotide sequence by the transverse electron transport through nanogap-electrode. We measured the extent of the electron-tunneling by using nanofabricated, mechanically controllable break junction, and determined the conductance values for deoxyribo/ribo-nucleoside monophosphates. When the molecules passed between the nanoelectrodes separated by a sub-nanometer gap, the tunneling-current through the molecules was increased, relative to that in the absence of molecules. The current intensity is found to be closely related to the individual molecular energy level. We also applied this method to base-pairing in oligonucleotides. Based on the electrical conductivity for single-nucleotides, we read the fragment of sample nucleotide passing through the sensing electrode. On the basis of a reconstruction of the read fragment sequences, we successfully determined a sample nucleotide sequence.

8:24AM S15.00003 Multiplexed microfluidic quantification of proteins in serum, NITIN RAJAN, SUKUMAR RAJARIA, ANDREW CLELAND, Univ of California - Santa Barbara — Rapid and low cost immunoassays targeting proteins in blood or other bodily fluids are highly sought after for point-of-care devices and early screening of patients. Immunoturbidimetric assays utilize latex particles functionalized with antibodies, with particle aggregation in the presence of the analyte detected by a change in absorbance. Using a high throughput micro-fluidic particle analyzer based solely on electrical signals (resistive pulse sensing), we are able to accurately quantify the degree of aggregation by analyzing the changes in the particle size distribution. Thus we study the aggregation of streptavidin (SAv) coated beads in the presence of biotinylated bovine serum albumin as a proof-of-principle assay and extract the binding capacity of the SAv beads from the dose-response curve. We also use our aggregation measurement platform to characterize a commercial C-reactive protein (CRP) immunoturbidimetric assay (hsCRP, Diazyme Inc.). We obtain a linear calibration curve as well as a better limit of detection of CRP than that obtained by absorbance measurements. By using different bead sizes functionalized with different antibodies, multiplexed analyte detection is also possible. We demonstrate this by combining the commercial anti-CRP functionalized beads (0.4 microns) with biotin coated beads (1.0 microns), and carry out the simultaneous detection of SAv and CRP in a single sample.

8:36AM S15.00004 ABSTRACT WITHDRAWN –

8:48AM S15.00005 Self-Assembled DNA Structures for Molecular Force Measurement: A Magnetically Actuated Approach, M. ARMSTRONG, S. LAUBACK, C. MILLER, C. PEACE, C. CASTRO, R. SOORYAKUMAR, Ohio State Univ - Columbus — Understanding molecular forces is important to comprehend many of the underlying properties of molecular machines and biological processes. The relevant forces in these cases often lie in the piconewton range, and thus experiments on individual biomolecules must integrate techniques capable of measuring such forces. A mechanical system to measure molecular forces associated with interacting DNA strands is being developed by using self-assembled DNA nanostructures and super-paramagnetic beads. The DNA nanostructure consists of single-stranded DNA molecules which can be folded into a precise compact geometry using hundreds of short oligonucleotides, i.e., staples, via programmed molecular self-assembly. These nanostructures can be polymerized into micron-scale filaments. By functionalizing the filament ends with bispesific conjugate staples, the structure can be attached to a surface as well as labeled with magnetic beads in order to apply a force on the system. Externally magnetic fields provide the means to maneuver and manipulate the magnetically labeled DNA structures. Preliminary findings associated with the DNA constructs and their manipulation lay the groundwork to establish real-time control of DNA nanodevices with micromanipulation.
9:00AM S15.00006 Sensitization of sub 10 nm Yb\(^{3+}\)-doped NaYF\(_4\) nanoparticles with visible light through 1,2,3,4,5,6,7-heptaoctfluoro-8-hydroxyanthracene-9,10-dione chromophore. HAIZHOU LU, School of Physics and Astronomy, Queen Mary University of London, Mile End Road, London, E1 4NS, UK, YU PENG, School of Biological and Chemical Sciences, Queen Mary University of London, Mile End Road, London, E1 4NS, UK, IGNACIO HERNANDEZ, Dpto. CITIMAC, Universidad de Cantabria, Facultad de Ciencias, Avda. Los Castros, 39005, Santander, Spain, WILLIAM GILLIN, School of Physics and Astronomy, Queen Mary University of London, Mile End Road, London, E1 4NS, UK — Uniform sub 10 nm Yb\(^{3+}\)-doped NaYF\(_4\) nanoparticles were prepared using a conventional hydrothermal method. Yb\(^{3+}\) ions doped inside the NaYF\(_4\) nanoparticles can be sensitized with 1,2,3,4,5,6,7-heptaoctfluoro-8-hydroxyanthracene-9,10-dione (HL), which is bounded onto the surface of the nanoparticle, through the so-called "antenna effect." Strong sensitization is achieved with the broad visible light excitations. The overall near infrared (NIR) emission from Yb\(^{3+}\) ions is increased by a factor of 5 as a result of the broad and strong absorption of HL chromophore compared with the ytterbium's intrinsic absorption during the 980 nm regime. Interestingly, an energy migration process from Yb\(^{3+}\) ions on the surface to inner-side Yb\(^{3+}\) ions of doped nanoparticle is demonstrated by the time-resolved spectroscopy method. It gives a direct evidence that the local environment between the surface and center of the nanoparticle is different. We believe our material will contribute to the NIR emitters with a strong visible absorption for the bio-materials.

9:12AM S15.00007 Low cost sensing technology for type 2 diabetes monitoring. PRASHANT SARSWAT, MICHAEL FREE, University of Utah — Alpha-hydroxybutyrate (2-hydroxybutyrate or α-HB) is becoming more widely recognized as an important metabolic biomarker that has been shown to be highly correlated with prediabetes and other metabolic diseases. In 2012 there were 86 million Americans with prediabetes, many of whom are not aware they have prediabetes, but could be diagnosed and treated to prevent type 2 diabetes if a simple, low-cost, convenient test were available. We have developed new, low-cost, accurate α-HB detection methods that can be used for the detection and monitoring of diseases such as prediabetes, type 2 diabetes, β-cell dysfunction, and early hyperglycemia. The new sensing method utilizes a diode-connection microchip, additives, and a phototransistor to detect α-HB at levels near 1 micro g/l in the presence of serum compounds such as lactic acid, sodium pyruvate, and glucose. The objective of this research is to improve the understanding of the interactions that enhance α-HB detection to enable additional improvements in α-HB detection as well as improvements in other biosensor applications.

9:24AM S15.00008 A pH-gradient induced method for wetting metal-layer embedded nanopores. VENKAT BALAGURUSAMY, GUSTAVO STOLOVITZKY, IBM T.J. Watson Research Center, Yorktown Heights, NY — Solid-state nanopores made on a single layer of Silicon nitride are wet by a number of methods by different workers. Typically, they involve using some low-surface tension liquid like isopropanol for pre-wetting before filling with the electrolyte solution of interest e.g., a buffered KCl solution both sides of the chamber that partitions the nanopore. These methods can also be preceded by a cleaning step which may involve either oxygen plasma or piranha treatment. However we found that these methods were not successful in wetting certain batches of nanopores drilled in a stack of SiO\(_2\)/TiN/SiO\(_2\)/Si layers. We found that applying buffer solutions at different pH on the two sides of the nanopore greatly accelerated the wetting process from days to few hours and resulted in nanopores with near linear I-V behavior for high salt concentration buffer solutions. We will describe this method and the results for a number of nanopores. [1] Nanopores wet with this pH gradient method translocate DNA molecules like nanopores wet by other methods mentioned here. We believe that the actual mechanism of this wetting process is influenced strongly by the pH effect on SiO\(_2\) surface. Efforts are underway to understand the working of this wetting method by quantum computer simulation methods [2]. [1] V.S.K.Balagurusamy, US Patent 8702944 (April 2014), “A novel nanopore device wetting method ” [2] R.Zhou, Soft matter theory/simulations group, IBM Watson Research Center, personal communication

9:36AM S15.00009 Nanoribbon field-effect transistors as direct and label-free sensors of enzyme-substrate interactions. LUYE MU, Electrical Engineering, Yale University, ILIA DROUJININE, Genetics, Harvard Medical School, NITIN RAJAN, SONYA SAWTELLE, Applied Physics, Yale University, MARK REED, Electrical Engineering and Applied Physics, Yale University — The ability to measure enzyme-substrate interactions is essential in areas such as diagnostics, treatment, and biochemical screens. Many enzymatic reactions alter the pH of its environment, suggesting a simple and direct method for detection. We show the ability of Al\(_2\)O\(_3\)-coated Si nanoribbon field-effect biosensors to sensitively measure various aspects of enzyme-substrate interactions through measuring the pH. [Urea in phosphate buffered saline (PBS) and penicillinase in PBS and urine were measured to limits of -200 μM and 0.02 units/mL, respectively. We also show the ability to extract accurate kinetics from the interaction of acetylcholine and its esterase. Prior work on FET sensors has been limited by the use of surface functionalization, which not only alters enzyme-substrate affinity, but also makes enzyme activity quantification difficult. Our method involves direct detection of reactions in solution without requiring alteration to the reactants, allowing us to obtain repeatable results and sensitive limits of detection. This method is a simple, inexpensive, and effective platform for detection of enzymatic reactions, and can be readily generalized to many unrelated classes of reactants.

[1] This work was supported in part by U.S. Army Research Office and Air Force Research Laboratory

9:48AM S15.00010 ToF-SIMS Characterization of Biocompatible Silk/Poly(pyrrole) Electromechanical Actuators. NATHAN BRADSHAW, SEAN SEVERT, Western Washington Univ, ZHAOYING WANG, Pacific Northwest National Laboratory, CARLY KLEMEK, JESSE LARSON, Western Washington Univ, ZHIJIA ZHU, Pacific Northwest National Laboratory, AMANDA MURPHY, JANELLE LEGER, Western Washington University — Materials capable of controlled movements that can also interface with biological environments are highly sought after for biomedical devices such as valves, blood vessel sutures, cochlear implants and controlled drug release devices. Recently we have reported the synthesis of films composed of a conductive interpenetrating network of the biopolymer silk fibroin and poly(pyrrole). These silk-Ppy composites function as bilayer electromechanical actuators in a biologically-relevant environment, can be actuated repeatedly, and are able to generate forces comparable with natural muscle (>0.1 MPa), making them an ideal candidate for interfacing with biological tissues. Here, time of flight secondary ion mass spectrometry was used to investigate the migration of ions in the devices during actuation. These findings will be discussed in the context of the actuation mechanism and opportunities for further improvements in device stability and performance.

10:00AM S15.00011 Biocompatible Silk-Poly(Pyrrole) Composite Trilayer Electromechanical Actuators. CARLY KLEMEK, NATHAN BRADSHAW, JESSE LARSON, SEAN SEVERT, NICHOLAS OSTROVSKY-SNIDER, AMANDA MURPHY, JANELLE LEGER, Western Washington University — Biocompatible materials capable of controlled actuation are in high demand for use in biomedical applications such as dynamic tissue scaffolding, valves, and steerable surgical tools. Conducting polymers (CPs) have some desirable traits for use as an actuator, such as the ability to operate in biologically relevant fluids and responsiveness to low voltages. However CPs alone are limited due to their brittle nature and poor solubility. Recently we have shown that a composite material of silk and the CP poly(pyrrole) (Ppy) shows promising characteristics as an actuator; it is mechanically robust as well as fully biocompatible. Initial proof-of-concept experiments demonstrated that these composites bend under an applied voltage (or current) using a simple bilayer device. Here we present the development of a trilayer device, composed of two conductive layers separated by an insulating silk layer. This configuration has twice the active surface area as a bilayer, potentially increasing the amount of mechanical motion per volt applied. We will discuss the fabrication and characterization of these devices, as well as their performance and future applications of this technology.
10:12AM S15.00012 Developing a nanoscale pressure sensor utilizing the Plasmon Ruler, ALEX TAYLOR, DAVID CARROLL, Wake Forest Univ — We demonstrate a novel method for detecting pressure by utilizing the Plasmon Ruler; the effect by which the frequency of light scattered by a nanoparticle (NP) is red shifted when brought into close proximity with another NP. This distance dependent phenomenon is leveraged by a film/NP architecture, wherein silver NPs are suspended above a silver film by a polymer spacing layer. As the fluid pressure above the rigid substrate is increased, the polymer layer is compressed and the NP height is decreased, leading to a measurable redshift in the plasmon resonance frequency. Thus, by factoring in the strength of the polymer layer’s restoring force we can determine the pressure being applied. These devices were constructed onto optic wires, which allow us to probe the device using the evanescent field from light inside the glass core. This naturally leads to in vivo medical applications, such as inter-compartment or inter-cranial pressure sensing via the inserted fiber optic probe.

10:24AM S15.00013 Highly Selective and Sensitive Detection of Acetylcholine Using Receptor-Modified Single-Walled Carbon Nanotube Sensors, SHIHONG XU, BYEONGJU KIM, HYUN SEOK SONG, HYE JUN JIN, EUN JIN PARK, SANG HUN LEE, Seoul National University, BYUNG YANG LEE, Korea University, TAI HYUN PARK, SEOUNGUN HONG, Seoul National University — Acetylcholine (ACh) is a neurotransmitter in a human central nervous system and is related to various neural functions such as memory, learning and muscle contractions. Dysfunctional ACh regulations in a brain can induce several neuropsychiatric diseases such as Alzheimer’s disease, Parkinson’s disease and myasthenia gravis. In researching such diseases, it is important to measure the concentration of ACh in the extracellular fluid of the brain. Herein, we developed a highly sensitive and selective ACh sensor based on single-walled carbon nanotube-field effect transistors (swCNT-FETs). In our work, M1 muscarinic receptor protein, an ACh receptor, was expressed in E.coli and coated on swCNT-FETs with lipid membranes. Here, the binding of ACh onto the receptors could be detected by monitoring the change of electrical currents in the underlying swCNT-FETs, allowing the real-time detection of ACh at a 10 pM concentration. Furthermore, our sensor could selectively detect ACh from other neurotransmitters. This is the first report of the real-time sensing of ACh utilizing specific binding between the ACh and M1 mAChR, and it may lead to breakthroughs in various biomedical applications such as drug screening and disease diagnosis.

10:36AM S15.00014 Nanovesicle-Carbon Nanotube Hybrid Structures Mimicking Mammalian Pain Sensory System, YOUNG TAK CHO, HYE JUN JIN, Department of Physics and Astronomy, Seoul National University, JEONG MI AN, Department of Oral Biology, College of Dentistry Yonsei University, JUHUN PARK, Department of Physics and Astronomy, Seoul National University, SEOK JUN MOON, Department of Oral Biology, College of Dentistry Yonsei University, SEOUNGUN HONG, Department of Physics and Astronomy, Seoul National University — We developed a “chemical-pain sensor” based on a single-walled carbon nanotube-based field effect transistor (SWNT-FET) functionalized with rat pain sensory receptor, rat transient receptor potential vanilloid 1 (rTRPV1) mimicking a mammalian pain sensory system. The sensor can selectively detect chemical pain stimuli such as capsaicin and resiniferatoxin with a sensitivity of 1 pM detection limit. Since this sensor allows one to quantitatively measure the concentration of chemical pain stimuli just like animal sensory systems, it can be used for various practical applications such as food screening. In addition, TRP families including rTRPV1 protein used for the sensor are now suggested as potential drug targets related to nerve and circulation disorders. Thus, the capability of measuring TRP responses using our sensor platform should open up other applications such as drug screening and basic research related with nerve and circulation systems.

10:48AM S15.00015 Floating Electrode Sensor based on CNT-FET for the Detection of DNAs, MINJU LEE, BYEONGJU KIM, JOOHYUNG LEE, SEON NAMGUNG, JOEONGSU KIM, Seoul Natl Univ, JAE YEOL PARK, Doowon Technical University College, MOON-SOOK LEE, Samsung Advanced Institute of Technology, SEOUNGUN HONG, Seoul Natl Univ — DNA sensors based on carbon nanotube (CNT) networks have been drawing much attention due to their high sensitivities. In the CNT network-based DNA sensors, the modulation of the Schottky barrier by the DNA hybridization has been known to play an important role in detecting target DNAs. In such applications, many researchers have tried to enhance the sensitivity of the Schottky barrier-based sensors through various methods such as the formation of a nonsymmetrical Schottky contact or the increase of the Schottky contact area. However, these methods suffered from some limitations such as the difficulty of controlling the sensor response for applications. Here in, we developed a floating electrode-based DNA sensor with controllable responses. In this strategy, metallic floating electrodes were fabricated to form Schottky barriers between CNTs and floating electrodes. We showed that the increased number of floating electrodes could enhance the sensitivity of our sensor. We also analyzed our results based on the Langmuir isotherm theory. This efficient approach could be an important strategy to improve the sensitivity and to control the response of CNT network-based sensors. Our work should provide an important insight regarding Schottky barrier-based sensors.

Thursday, May 3, 2015 8:00AM - 11:00AM
Session S16 DMP: Focus Session: Graphene Devices: Function, Fabrication, and Characterization: van der Waals Heterostructures 101AB - Akm Nawaz, San Francisco State University

8:00AM S16.00001 Bilayer Graphene-Hexagonal Boron Nitride Heterostructure Negative Differential Resistance Interlayer Tunnel FETs, SANGWOO KANG, BABAK FALLAHZAD, KAYOUNG LEE, HEMA MOVVA, KYOUNGHWAN KIM, CHRIS CORBET, Univ of Texas, Austin, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, LUIGI COLOMBO, Texas Instruments Incorporated, LEONARD REGISTER, EMANUEL TUTUC, SANJAY BANERJEE, Univ of Texas, Austin — We present the operation of a vertical tunneling field effect transistor using a stacked double bilayer graphene (BLG) and hexagonal boron nitride (hBN) heterostructure. The device is fabricated with the so-called Van der Waals transfer method with the edges of the top and bottom BLG flakes being rotationally aligned to roughly 60°. The device shows multiple negative differential resistance (NDR) peaks which can be adjusted through the gate bias. Temperature dependent measurements show that the peak width of the differential conductance broadens and the height lowered when the temperature is increased, which is indicative of resonant tunneling. Three electron states at the Fermi level are seen, it is shown that the multiple peaks occur when the two conduction bands at the K-point of the top and bottom bilayer graphene become aligned at certain bias conditions. It is also shown that by adjusting the rotational alignment of the bands of the top and bottom BLG through an in-plane magnetic field, the conductance peaks can be broadened. In addition, utilizing the NDR characteristic of the device, one-transistor latch or SRAM operation is demonstrated.

8:12AM S16.00002 Resonant Tunneling in Double Bilayer Graphene Heterostructures, BABAK FALLAHZAD, KAYOUNG LEE, SANGWOO KANG, JIAMIN XUE, STEFANO LAURENTIS, CHRISTOPHER CORBET, KYOUNGHWAN KIM, HEMA MOVVA, Univ of Texas Austin, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, LEONARD REGISTER, SANJAY BANERJEE, EMANUEL TUTUC, Univ of Texas, Austin — We present the realization and characterization of independently contacted and rotationally aligned double bilayer graphene heterostructures, that show gate-tunable tunneling resonances and negative differential resistance in their interlayer current-voltage characteristics. Our devices are fabricated by successively stacking mechanically exfoliated bilayer graphene and hexagonal boron nitride dielectric using a layer-by-layer transfer technique. The bilayers are rotationally aligned during the device fabrication by selecting flakes with straight edges, and using them as a reference for alignment. We determine the heterostructure energy band alignment at the tunneling resonance using the individual layer carrier densities, and including the chemical potential dependence on the carrier density. Our analysis show that the tunneling resonances occur when the charge neutrality points of the two bilayer graphene flakes are energetically aligned, which suggests the resonances stem from the momentum conserving tunneling.
8:24AM S16.00003 Graphene superlattices in van der Waals heterostructures, VLADIMIR FALKO, Lancaster University — The technological development of graphene has generated new high-quality systems offer access to the earlier inaccessible extremes of quantum physics. When graphene is placed on an atomically flat substrate with hexagonal lattice with a close lattice constant, such as boron nitride (hBN), and their crystalline axes are aligned, a long-wavelength perfectly periodic moiré pattern forms for electrons in graphene. Various regimes of possible moiré minibands at zero magnetic field [Phys. Rev. B 87, 245408 (2013); Phys. Rev. B 88, 205418; Phys. Rev. B 88, 155415 (2013); New J. Phys. 15, 123009 (2013)] and strong magnetic field [Nature 497, 594 (2013), Nature Physics 10, 525 (2014); Phys Rev B 89, 075401 (2014)] will be discussed. Experimentally available graphene samples are enough to provide flux \( \psi \) through the moiré superlattice cell comparable to the magnetic flux quantum \( \phi_0 \) and reach the regime of fractal Hofstadter spectra. As a result, a single device can offer a multiplicity of two-dimensional electron systems, realised at rational flux values \( \psi = \phi_0, \phi_0/2, 2\phi_0/3, \) etc., each with its own intrinsic topological properties, including quantum Hall effect physics related to the effective Landau levels emerging from these magnetic minibands at the nearby range of magnetic fields.

9:00AM S16.00004 A boron nitride - graphene - C\textsubscript{60} heterostructure, CLAUDIA OJEDA-ARISTIZABAL, UC Berkeley, ELTON J.G. SANTOS, University of California, Berkeley, JAIRO VELASCO JR., SALMAN KAHN, UC Berkeley, AIMING YAN, UC Berkeley, JOSEF YOUNG, Lawrence Berkeley National Laboratory, KAVIENERGY, Lawrence Berkeley National Laboratory — We have fabricated a new van-der-Waals heterostructure composed by BN/graphene/C\textsubscript{60}. We performed transport measurements on the preliminary BN/graphene device finding a sharp Dirac point at the neutrality point. After the deposition of a C\textsubscript{60} thin film by thermal evaporation, we have observed a significant n-doping of the heterostructure. This suggests an unusual electron transfer from C\textsubscript{60} into the BN/graphene structure. This BN/graphene/C\textsubscript{60} heterostructure can be of interest in photovoltaic applications. It can be used to build devices like p-n junctions, where C\textsubscript{60} can be easily deposited in defined regions of a graphene junction by the use of a shadow mask. Our results are contrasted with theoretical calculations.

9:12AM S16.00005 Tunneling measurements in graphene-hexagonal boron nitride-based heterostructures\(^1\), U. CHANDNI, Institute for Quantum Information and Matter and Department of Physics, California Institute of Technology, Pasadena, California 91125, USA, K. WATANABE, T. TANIGUCHI, National Institute for Materials Science, 1-1 Namiki, Tsukuba Ibaraki 305-0044, Japan, J.P. EISENSTEIN, Institute for Quantum Information and Matter and Department of Physics, California Institute of Technology, Pasadena, California 91125, USA — Van der Waals heterostructures is an emerging field involving the study of layered materials consisting of various crystalline atomic planes exfoliated from bulk crystals and then stacked, often by hand, in custom-made patterns. Vertical tunneling structures made out of such quasi-2D crystals are potentially very interesting and may provide a new playground to observe electron-electron interaction effects in graphene and related materials. In the present work, we report the fabrication and study of several such tunnel junctions, including metal-hexagonal boron nitride (hBN)-metal, metal-hBN/graphite and metal-hBN-graphene tunneling devices. Tunneling measurements done at low temperatures and high magnetic fields reveal interesting and distinct features in each of these designs.

\(^1\)We acknowledge funding provided by the National Institute of Information and Matter, an NSF Physics Frontiers Center with support of the Gordon and Betty Moore Foundation through Grant GBMF1250.

9:24AM S16.00006 Ultra-sensitive Hall sensors based on graphene boron nitride heterostructures, JAN DAUBER, JARA-FIT and II. Institute of Physics, RWTH Aachen University, Aachen, Germany, ABHAY A. SAGADE, Advanced Microelectronics Center Aachen (AMICA), AMO GmbH, Aachen, Germany, MARTIN OELLERS, JARA-FIT and II. Institute of Physics, RWTH Aachen University, Aachen, Germany, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, 1-1 Namiki, Tsukuba, Japan, DANIEL NEUMAIER, Advanced Microelectronics Center Aachen (AMICA), AMO GmbH, Germany, CHRISTOPH STAMPFPER, JARA-FIT and II. Institute of Physics, RWTH Aachen University, Aachen, Germany — Recent developments of encapsulating graphene in hexagonal boron nitride lead to well protected graphene with very high material quality. This opens interesting possibilities for applications, such as graphene-based Hall sensors. Magnetic field sensors using Hall effect are widely used in different fields of applications, e.g. automotive and consumer electronics. Their performance benefits greatly from high room temperature mobility and low charge carrier density, which is achievable with the integrated material for the sensor and the sensor elements based on graphene boron nitride heterostructures. We show a detailed characterization including Hall effect measurements under ambient and vacuum conditions. We achieve current- and voltage-related sensitivity up to 5700 V/AT and 3V/VT, respectively, outpacing state-of-the-art silicon and III/V Hall sensor devices. Finally, we determine a magnetic resolution limited by low frequency electric noise less than 0.5 mG/Hz.

9:36AM S16.00007 Colossal Coulomb Drag in Double Bilayer Graphene Heterostructures\(^1\), KAYOUNG LEE, JAIMIN XUE, The University of Texas at Austin, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, EMANUEL TUTUC, The University of Texas at Austin — Double-layer electron systems, where charge carriers are apart into two parallel layers, have been of interest thanks to their various interlayer interaction phenomena. One of the peculiar interaction features is Coulomb drag, in which current flowing in one layer (driving layer) induces voltage drop in the opposite layer (drag layer) via interlayer momentum transfer. Recent progress in the fabrication of heterostructures consisting of atomic layer materials such as graphene and hexagonal boron nitride (hBN) has led to high mobility double layer systems. Here we probe Coulomb drag in double bilayer graphene heterostructures separated by 2 – 5 nm thick hBN dielectrics. At temperatures \( T \) lower than 30 K, we observe an anomalous Coulomb drag in the vicinity of the drag layer charge neutrality points, which increases as \( T \) is reduced. At \( T = 1.4 \) K, the lowest temperature studied here, the drag resistivity becomes comparable to the layer resistivity at a finite drag layer density \( n_{\text{drag}} \). The ratio of the drag to layer resistivity increases as the hBN thickness reduces, and also as the drag layer mobility increases. At \( T > 50K \), we observe diffusive drag, which increases with \( T \).

\(^1\)We thank ONR, NRI and Intel for support.

9:48AM S16.00008 Encapsulated Superconducting Graphene Nanodevices for Transport and Spectroscopic Studies, JOEL I-JAN WANG, Massachusetts Institute of Technology/Harvard School of Engineering and Applied Sciences, PATRICK BACK, Swiss Federal Institute of Technology in Zurich (ETHZ), YU-AN CHEN, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science (NIMS), Japan, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Through proximity effect, graphene provides an ideal platform to study mesoscopic superconductivity and other quantum phenomena as it is in contact with superconductors. The advancement in the fabrication techniques of 2-D Van der Waals heterostructures has brought the superconducting graphene nanodevice into ballistic regime and made it suitable for a variety of studies. We show superconducting graphene nanodevices encapsulated in hexagonal boron nitride (hBN) thin films. The pristine graphene can be proximitized by superconducting leads, manipulated by local gating and probed by tunneling leads in order to explore various kinds of physics.
Topological materials may exhibit Hall-like currents flowing transversely to the applied electric field even in the absence of a magnetic field. In graphene superlattices, which have broken inversion symmetry, topological currents originating from graphene’s two valleys are predicted to flow in opposite directions. This work was supported in part by the Center for Low Energy Systems Technology (LEAST), one of the six SRC STARnet Centers, sponsored by MARCO and DARPA.

1We gratefully acknowledge support for this work from ONR (N00014-13-1-0806) and AFOSR (FA9550-12-1-0268).

10:24AM S16.00011 Electric field effects in graphene-complex-oxide heterostructures1. GIRRIRAJ JNAWALI, MENGCHEN HUANG, JEN-FENG HSU, FENG BI, LU CHEN, RONGPU ZHOU, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, SANGWOO PYU, CHANG-BEOM EOM, Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, BRIAN D’URSO, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — Graphene has excellent electrical, chemical, and mechanical properties, which make it a promising material for developing nanoscale electronic devices, while complex-oxide heterostructure provide sharply confined multifunctional interfaces that can be tailored at nanodimension scales. The combination–graphene-complex-oxide heterostructures–merge the multifunctional properties of oxide interfaces such as high dielectric constant, metal-insulator-transition, magnetism, and superconductivity, with the unique electronic properties of graphene. Here we demonstrate some simple three-terminal field-effect devices that can realize the electronic properties of these two systems. Nanoscale devices are fabricated from graphene/LaAlO$_3$/SrTiO$_3$ heterostructures using c-AFM lithography. We demonstrate field effects in both the graphene and LaAlO$_3$/SrTiO$_3$ interfaces. These novel heterostructures open new avenues for creating devices that combine the most interesting and unique properties of the coupled two-dimensional electronic system.

1This work was supported in part by the Center for Low Energy Systems Technology (LEAST), one of the six SRC STARnet Centers, sponsored by MARCO and DARPA.

10:36AM S16.00012 Inelastic vertical tunneling in graphene-based heterostructures1. SERGIO DE LA BARRERA, RANDALL FEENSTRA, Carnegie Mellon University, Department of Physics — Lateral momentum conservation of tunneling states in graphene / hexagonal boron nitride / graphene heterostructures causes intriguing resonant behavior and negative differential resistance. We explain this phenomenon in terms of a simple model which includes electrostatic gating, rotational alignment between graphene layers, elastic scattering, and inelastic tunneling effects for both monolayer and bilayer graphene. We highlight recent experimental efforts to observe these effects in fabricated devices and compare with theory to validate our theoretical model. In order to improve future fabrication, we discuss disorder mechanisms, the differences between monolayer and bilayer graphene configurations, and the critical parameters which govern the characteristics of these devices.

1We gratefully acknowledge support for this work from ONR (N00014-13-1-0806) and AFOSR (FA9550-12-1-0268).

10:48AM S16.00013 Sensitive room-temperature graphene-BN atomic stack terahertz detector. JIAYUE TONG, MARTIN MUTHUE, SHAO-YU CHEN, SIGFIRD K YNGVESSON, JUN YAN, University of Massachusetts Amherst — Due to its high mobility, weak electron-phonon interaction and tunable broadband optical response, graphene is a promising material for high-speed optoelectronics such as terahertz (THz) detectors. In this presentation, we will discuss our studies of THz detection with graphene-BN heterostructure devices. Using a double-patch antenna that operates at around 1.9THz and an on-chip silicon lens, we demonstrate that asymmetrically-contacted graphene-BN heterostructure samples can efficiently detect THz laser radiation. Strong polarization dependence of our device indicates significant sensitivity improvement by antenna coupling and silicon lens coupling. We also find that responsivity can be tuned by changing the charge carrier density. Our work expands the methodology for making graphene-based THz detectors.

Thursday, March 5, 2015 8:00AM - 11:00AM – Session S17 DCMP: Graphene: Transport Properties 102AB - Inti Sodermann, Massachusetts Institute of Technology

8:00AM S17.00001 Detecting topological currents in graphene superlattices, GELIANG YU, ANDREY KRETININ, School of Physics and Astronomy, University of Manchester, Oxford Road, Manchester M13 9PL, UK, JUSTIN SONG, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139, USA, ROMAN GORBACHEV, Centre for Mesoscience and Nanotechnology, University of Manchester, Manchester M13 9PL, UK, LEONID LEVITOV, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139, USA, KONSTANTIN NOVOSELOV, ANDRE GEIM, School of Physics and Astronomy, University of Manchester, Oxford Road, Manchester M13 9PL, UK — Topological materials may exhibit Hall-like currents flowing transversely to the applied electric field even in the absence of a magnetic field. In graphene superlattices, which have broken inversion symmetry, topological currents originating from graphene’s two valleys are predicted to flow in opposite directions and combine to produce long-range charge neutral flow. We observed this effect as a nonlocal voltage at zero magnetic field in a narrow energy range near Dirac points at distances as large as several micrometers away from the nominal current path. Locally, topological currents are comparable in strength with the applied current, indicating large valley-Hall angles. The long-range character of topological currents and their transistor-like control by means of gate voltage can be exploited for information processing based on valley degrees of freedom.
8:12AM S17.00002 Quantum Spin Hall phase in multilayer graphene\textsuperscript{1}, NOEL GARCIA, JOSE LUIS LADO, JOAQUIN FERNANDEZ-ROSSIO, International Iberian Nanotechnology Laboratory (INL), THEORY OF NANOSTRUCTURES TEAM — We address the question of whether multilayer graphene systems are Quantum Spin Hall (QSH) insulators. Since interlayer coupling copes $p_z$ orbitals with $s$ orbitals of different layers and Spin-Orbit (SO) couples $p_z$ orbitals with $p_x$ and $p_y$ of opposite spins, new spins mixing channels appear in the multilayer scenario that were not present in the monolayer. These new spin-mixing channels cast a doubt on the validity of the spin-conserving Kane-Mele model for multilayers and motivates our choice of a four orbital tight-binding model in the Slater-Koster approximation with intrinsic Spin-Orbit interaction. To completely determine if the QSH phase is present we calculate for different number of layers both the $Z_2$ invariant for different stackings (only for inversion symmetric systems), and the density of states at the edge of semi-infinite graphene ribbon with armchair termination. We find that QSH systems with even number of layers are normal insulators while systems with odd number of layers are QSH insulators, regardless of the stacking.

\textsuperscript{1}We acknowledge financial support by Marie-Curie-ITN 607904-SPINOGRAPH

8:24AM S17.00003 Probing layer localization in twisted graphene bilayers via cyclotron resonance\textsuperscript{1}, CHI-KEN LU, National Taiwan Normal University, H.A. FERTIG, Indiana University Bloomington — Electron wave functions in twisted bilayer graphene may have a strong single-layer character or be intrinsically delocalized between layers, with their nature often determined by how energetically close they are to the Dirac point. We demonstrate that in magnetic fields, cyclotron resonance spectra contain signatures that may be used to distinguish the nature of these wave functions at low energies, as well as to locate low-energy critical points in the zero-field energy spectrum. Optical absorption for two different configurations–electric field parallel and perpendicular to the bilayer–is calculated, and the configurations are shown to have different selection rules with respect to which states are connected by the perturbation. Interlayer bias further distinguishes transitions involving states of a single-layer nature from those with support in both layers. For doped systems, a sharp increase in intra-Landau-level absorption occurs with increasing field as the level passes through the zero-field saddle-point energy, where the states change character from single layer to bilayer. The effects of impurity scattering will be discussed too.

\textsuperscript{1}This work was supported by the NSF through Grant No. DMR-1005035, the U.S.-Israel Binational Science Foundation, and Ministry of Science and Technology Taiwan Grant No. 103-2112-M-003-012-MY3

8:36AM S17.00004 Spin and valley polarized quantum Hall edge states in monolayer graphene, DI WEI, School of Engineering and Applied Sciences, Harvard University, JAVIER SANCHEZ-YAMAGISHI, Physics Department, Massachusetts Institute of Technology, TOENO VAN DER SAR, Physics Department, Harvard University, PABLO JARILLO-HERRERO, Physics Department, Massachusetts Institute of Technology, AMIR YACOBY, Physics Department, Harvard University — Studying edge transport in the quantum Hall regime provides insight into the nature of partially filled Landau levels. Previous reports on graphene have shown that when the four-fold degeneracy of each Landau level is lifted, spin and valley polarizations influence scattering between edges. We report progress on the fabrication of monolayer graphene devices encapsulated in hexagonal boron nitride (hBN), a technique which allows us to produce pristine graphene samples showing robust broken symmetry quantum Hall states. Additionally, graphene encapsulation allows us to create both globally and locally gated regions with sharp carrier density boundaries due to our thin hBN gate dielectrics. Here we study the transport of spin and valley polarized edge currents at these junctions.

8:48AM S17.00005 Twisting the physics in bilayer graphene, JASON LUO, JAVIER SANCHEZ-YAMAGISHI, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, Japan, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Twisted bilayer graphene is the ultimate limit of a bilayer 2DEG, where two graphene layers are stacked with an interlayer distance of only 0.34nm. The interlayer tunnel coupling can be continuously tuned by twisting the two layers, leading to different physics in the small and large twist angle limits. At small twist angles, the two layers form a large superlattice unit cell and the hybridization of the layers leads to low-energy van Hove singularities in the electronic spectrum, resulting in a strong departure from the typical monolayer graphene transport properties. At large twist angles, the system behaves as two decoupled monolayer graphene sheets, and the occupation of quantum Hall edge modes on each layer can be independently controlled. This allows for the realization of a quantum spin Hall state in twisted bilayer graphene by doping to form an electron-hole bilayer at moderate magnetic fields. I will discuss our magnetotransport measurements of high-quality twisted bilayer graphene, and how, by independently controlling the total charge density and applied electric field, we can realize different novel electronic states in this system.

9:00AM S17.00006 Ballistic transport and density of states of modulated bilayer graphene, LIUBOV ZHEMCHUZHNA, Hunter College, CUNY, DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate, GODFREY GUMBS, Hunter College, CUNY and Donostia International Physics Center (DIPC), ANDRII IUROV, University of New Mexico and Hunter College, CUNY — The magnetic band structure for electrostatically modulated bilayer graphene is calculated. We include the $K$ and $K'$ valleys. A and B sublattices as well as the bilayer crystalline structure. The energy eigenvalues are obtained as functions of wave vector as well as magnetic field. Our results are then employed in calculating density-of-states and ballistic conductance. Comparison with recent experimental results is presented.

9:05AM S17.00007 SU(4) symmetry breaking revealed by magneto-optical spectroscopy in epitaxial graphene\textsuperscript{1}, LIANG Z TAN, Univ of California - Berkeley, MILAN ORLITA, MAREK POTEMSKI, LNCMI, CNRS, MIKE SPRINKLE, CLAIRE BERGER, WALTER DE HEER, Georgia Institute of Technology, STEVEN LOUIE, University of California - Berkeley, GERARD MARTINEZ, LNCMI, CNRS — Electron-electron and electron-phonon interactions break the spin and valley degeneracies of the lowest Landau level (LL) in graphene. Multiple theoretical models have been proposed for the broken symmetry ground state. Previous tilted magnetic field transport experiments have obtained partial information on the ground state by probing the spin degree of freedom. In this work, we show that, via the valley-dependent electron-phonon interaction, symmetry breaking of the valley degree of freedom can be detected in infra-red transmission signatures close to magneto-phonon resonances. We have performed infra-red magneto-transmission experiments on multi-layer epitaxial graphene samples in magnetic fields up to 35 T. Following the main optical transition involving the lowest LL, we observe a new absorption transition increasing in intensity with magnetic fields greater than 26 T. Our theoretical calculations quantitatively explain these features, and unambiguously identify the charge density wave as the ground state in our samples.

9:12AM S17.00008 SU(4) symmetry breaking revealed by magneto-optical spectroscopy in epitaxial graphene\textsuperscript{1}, LIANG Z TAN, Univ of California - Berkeley, MILAN ORLITA, MAREK POTEMSKI, LNCMI, CNRS, MIKE SPRINKLE, CLAIRE BERGER, WALTER DE HEER, Georgia Institute of Technology, STEVEN LOUIE, University of California - Berkeley, GERARD MARTINEZ, LNCMI, CNRS — Electron-electron and electron-phonon interactions break the spin and valley degeneracies of the lowest Landau level (LL) in graphene. Multiple theoretical models have been proposed for the broken symmetry ground state. Previous tilted magnetic field transport experiments have obtained partial information on the ground state by probing the spin degree of freedom. In this work, we show that, via the valley-dependent electron-phonon interaction, symmetry breaking of the valley degree of freedom can be detected in infra-red transmission signatures close to magneto-phonon resonances. We have performed infra-red magneto-transmission experiments on multi-layer epitaxial graphene samples in magnetic fields up to 35 T. Following the main optical transition involving the lowest LL, we observe a new absorption transition increasing in intensity with magnetic fields greater than 26 T. \textsuperscript{1}This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by the NSF through XSEDE resources at NICS.
9:24AM S17.00008 Combination of conductance oscillation in the quantum Hall regime and charge trap flash memory phenomena in graphene field effect transistor, YOOJOO YUN, HAEYONG KANG, JOONG-GYU KIM, JEONCMIN PARK, THUY KIEU TRUONG, NAHEE PARK, JEONG-GYUN KIM, YOURACK LEE, CINAP, IBS, DOES, SunghyunKwanUniv., HOYEOL YUN, SANG WOOK LEE, School of Physics, Konkuk Univ., YOUNG HEE LEE, DONGSEOK SUH, CINAP, IBS, DOES, SunghyunKwanUniv., CINAP, IBS, DOES, SUNGYUNKWAN UNIV, TEAM, SCHOOL OF PHYSICS, KONKUK UNIV, COLLABORATION — We present the feature of conductance oscillation in the quantum Hall regime graphene FET on top of large gate-voltage hysteresis (up to 100 V). A mono-layer graphene was put on the hBN flake on the wet silicon oxide/silicon substrate. At 300 K, the normal conductance versus gate-voltage curve was observed showing the charge neutrality point without hysteresis. At 2 K, however, there was a huge conductance hysteresis during the sweep of gate-voltage, which could be attributed to the characteristics of charge-trap memory behavior because of defects located inside the dielectric playing a role of charge-trap sites. Even though the hysteresis during gate-voltage sweeping was enormous, in our device having hBN for graphene device preventing the deteriorating impacts from the defective SiO₂, the conductance oscillation during the gate-voltage sweep was observed from the magnetic field 4 T. In summary, the results proved that the combination of quantum Hall related transport phenomena and the charge-trap memory operation was achieved successfully without affecting each other in our graphene-on-hBN FET device.

9:36AM S17.00009 Transport in graphene on boron nitride, ASHLEY DASILVA, University of Texas at Austin, JEIL JUNG, National University of Singapore, SHAFFIQUE ADAM, Yale NUS College and National University of Singapore, ALLAN MACDONALD, University of Texas at Austin — The lattice mismatch and twist angle of graphene on boron nitride contributes to a long wavelength moire pattern in the atomic positions. This superlattice structure and the sublattice symmetry breaking in the hexagonal boron nitride layer lead to observable transport features in the graphene layer. We show a decreased conductivity at the Dirac point due to an opening of the band gap. There is also a decreased conductivity when the Fermi level is tuned to four carriers per moire unit cell, which is the position of the secondary Dirac points in perfectly matched and sublattice symmetric hexagonal bilayers. We show both intraband and interband contributions to the conductivity, the latter is peaked when the Fermi level is tuned inside the gaps, either at the Dirac point or the secondary Dirac points.

9:48AM S17.00010 Graphene-based quantum Hall resistance standards grown by chemical vapor deposition on silicon carbide, REBECA RIBEIRO-PALAU, FABIEN LAFONT, Laboratoire National de Metrologie et d’Essais, DIMITRIS KAZAZIS, Laboratoire de Photonique et de Nanostructures, ADRIEN MICHON, Centre de Recherche sur l’Hétéroépitaxie et ses Applications, OLIVIER COUTURAUD, CHRISTOPHE CONSEJO, BENOIT JOUAILT, Laboratoire Charles Coulomb, WILFRID POIRRIER, FELICIEN SCHOPFER, Laboratoire National de Metrologie et d’Essais — Replace GaAs-based quantum Hall resistance standards (GaAs-QHRS) by a more convenient one, based on graphene (Gr-QHRS), is an ongoing goal in metrology. The new Gr-QHRS are expected to work in less demanding experimental conditions than GaAs ones. It will open the way to a broad dissemination of quantum standards, potentially towards industrial end-users, and it will support the implementation of a new International System of Units based on fixed fundamental constants. Here, we present accurate quantum Hall resistance measurements in large graphene Hall bars, grown by the hybrid scalable technique of propane/hydrogen chemical vapor deposition (CVD) on silicon carbide (SiC). This new Gr-QHRS shows a relative accuracy of 1 × 10⁻¹¹ of the Hall resistance under the lowest magnetic field ever achieved in graphene. These experimental conditions surpass those of the most widely used GaAs-QHRS. These results confirm the promises of graphene for resistance metrology applications and emphasize the quality of the graphene produced by the CVD on SiC for applications as demanding as the resistance metrology.

10:00AM S17.00011 Observation of conducting edge states in graphene at zero magnetic field, MONICA ALLEN, Harvard University, ION FULGA, Weizmann Institute of Science, OLES SHTANKO, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, Massachusetts Institute of Technology, ANTON AKHMEROV, Delft University of Technology, LEONID LEVITOV, Massachusetts Institute of Technology, AMIR YACOBY, Harvard University — The electronic nature of edge states confined to the boundaries of a graphene crystal remains an outstanding question. Primarily, range from Anderson localization to chiral zero-energy edge modes, but a full microscopic picture of edge transport remains elusive. We directly image current transmission in real space by coupling superconducting electrodes to a graphene crystal and measuring quantum interference as a function of applied magnetic flux. To obtain a more quantitative picture, we employ Fourier techniques to extract the real space current distribution with nanoscale precision. We observe robust confinement of current to the edges of the crystal approaching the Dirac point and show that relative edge and bulk contributions are tunable via electrostatic gating. A strong candidate consistent with our data is the proposal of chiral edge modes that arise from sublattice symmetry breaking at the edge, sustained in all crystallographic edge orientations except atomically perfect armchair. Our techniques also open the door to fast spatial imaging of current distributions along more complicated networks of domains in larger crystals.

10:12AM S17.00012 ABSTRACT WITHDRAWN

10:24AM S17.00013 Experimental evidence of one-dimensional edge states at the line junction of two oppositely biased bilayer graphene, J. LI, Department of Physics, Penn State University, University Park, USA, K. WATANABE, T. TANIGUCHI, National Institute for Material Science, 1-1 Namiki, Tsukuba, Japan, ZHU, Department of Physics, Penn State University, University Park, USA — A one-dimensional edge (kink) state is predicted to exist at the line junction of two gapped bilayer graphene with opposite electric field bias or the stacking fault of AB-BA stacked bilayer regions. The conductance of the kink state is expected to be quantized at 4e²/h in the absence of K'-K' valley mixing, counting spin and layer degeneracy. This novel 1D system has not been realized experimentally due to fabrication challenges. Here we report evidence of the kink state in split dual-gated bilayer graphene, where the top and bottom splits are approximately 70 nm and precisely aligned. h-BN encapsulation ensures the high quality of the device, which allows us to make the bulk bilayer graphene very insulating at moderate E-fields of less than 0.3V/nm. The junction resistance RＪ exhibits drastic contrast between low resistances of several tens of KΩ when the two bilayers are oppositely biased, versus high resistances of several MΩ when the two E-fields have the same polarity. The low-resistance states are weakly insulating in temperature dependence and their resistances drop substantially in a perpendicular magnetic field. We discuss the nature of the kink state and possible reasons that RＪ deviates from the single-particle prediction of 4ℏ/π².

10:36AM S17.00014 Semiconducting transport characteristics of monolayer graphene through substrate-induced functionalization, PO-HSIANG WANG, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan, LO-YUEH CHANG, National Synchrotron Radiation Research Center, Taiwan, FU-YU SHIH, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan, PO-HSUN HO, Department of Materials Science and Engineering, National Taiwan University, Taiwan, CHIA-HAO CHEN, National Synchrotron Radiation Research Center, Taiwan, CHUN-WEI CHEN, Department of Materials Science and Engineering, National Taiwan University, Taiwan, WEI-HUA WANG, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan — We report semiconducting transport behaviors of monolayer graphene functionalized through chemically reactive substrates. In contrast to pristine graphene, graphene on activated SiO₂/Si substrates exhibits a transport gap at cryogenic temperature, nonlinear transfer characteristics, and insulating transport behaviors. Raman spectroscopy was performed to provide evidence of sp³ hybridization of graphene and confirms the presence of chemical bonding in the graphene samples. Moreover, we observe hopping transport characteristics at cryogenic temperature. Our study points toward an alternative method to control the functionalization of graphene and its transport behaviors.
10:48AM S17.00015 Tunable Optoelectronic Properties of Semiconducting Graphene1. MARC DVORAK, ZHIGANG WU, Department of Physics, Colorado School of Mines — If patterned properly, structural modifications on graphene can induce intervalley scattering between Dirac points and open a sizeable band gap. Such two-dimensional semiconductors could offer great tunability in electronic and optical properties. We performed calculations based on many-body perturbation theory using Green’s functions to obtain quasiparticle energies and optical absorption spectra for these semiconducting graphene structures, focusing on the role of defect size, type, and geometric configuration. Our results show a strong renormalization of the band gap over Kohn-Sham energy levels and exciton binding energies greater than 0.4 eV. By stacking monolayer defected graphene with various defect sizes and configurations, one could create an excellent photovoltaic absorber layer that efficiently absorbs photons with energy larger than 1.0 eV.

Thursday, March 5, 2015 8:00AM - 10:24AM –
Session S18 GSNP: Invited Session: Statistical Physics for Electric Grids Mission Room 103A - Guido Caldarelli, IMT Alti Studi Lucca

8:00AM S18.00001 Realistic modeling and analysis of synchronization dynamics in power-grid networks1. TAKASHI NISHIKAWA, Northwestern University — An imperative condition for the functioning of a power-grid network is that its power generators remain synchronized. Disturbances can prompt desynchronization, which is a process that has been involved in large power outages. In this talk I will first give a comparative review of three leading models of synchronization in power-grid networks. Each of these models can be derived from first principles under a common framework and represents a power grid as a complex network of coupled second-order phase oscillators with both forcing and damping terms. Since these models require dynamical parameters that are unavailable in typical power-grid datasets, I will discuss an approach to estimate these parameters. The models will be used to show that if the network structure is not homogeneous, generators with identical parameters need to be treated as non-identical oscillators in general. For one of the models, which describes the dynamics of coupled generators through a network of effective interactions, I will derive a condition under which the desired synchronous state is stable. This condition gives rise to a methodology to specify parameter assignments that can enhance synchronization of any given network, which I will demonstrate for a selection of both test systems and real power grids. These parameter assignments can be realized through very fast control loops, and this may help devise new control schemes that offer an additional layer of protection, thus contributing to the development of smart grids that can recover from failures in real time.

1Funded by ISEN, NSF, and LANL LDRD.

8:36AM S18.00002 Complex Dynamics of the Power Transmission Grid (and other Critical Infrastructures). DAVID NEWMAN, Univ. of Alaska Fairbanks — Our modern societies depend crucially on a web of complex critical infrastructures such as power transmission networks, communication systems, transportation networks and many others. These infrastructure systems display a great number of the characteristic properties of complex systems. Important among these characteristics, they exhibit frequent large cascading failures that often obey a power law distribution in their probability versus size. This power law behavior suggests that conventional risk analysis does not apply to these systems. It is thought that much of this behavior comes from the dynamical evolution of the system as it ages, is repaired, upgraded, and as the operational rules evolve with human decision making playing an important role in the dynamics. In this talk, infrastructure systems as complex dynamical systems will be introduced and some of their properties explored. The majority of the talk will then be focused on the electric power transmission grid though many of the results can be easily applied to other infrastructures. General properties of the grid will be discussed and results from a dynamical complex systems power transmission model will be compared with real world data. Then we will look at a variety of uses of this type of model. As examples, we will discuss the impact of size and network homogeneity on the grid robustness, the change in risk of failure as generation mix (more distributed vs centralized for example) changes, as well as the effect of operational changes such as the changing the operational risk aversion or grid upgrade strategies. One of the important outcomes from this work is the realization that “improvements” in the system components and operational efficiency do not always improve the system robustness, and can in fact greatly increase the risk, when measured as a risk of large failure.

9:12AM S18.00003 Self Healing Percolation1. ANTONIO SCALA, CNR — We introduce the concept of self-healing in the field of complex networks modelling; in particular, self-healing capabilities are implemented through distributed communication protocols that exploit redundant links to recover the connectivity of the system. Self-healing is a crucial in implementing the next generation of smart grids allowing to ensure a high quality of service to the users. We then map our self-healing procedure in a percolation problem and analyse the interplay between redundancies and topology in improving the resilience of networked infrastructures to multiple failures. We find exact results both for planar lattices and for random lattices, hinting the role of duality in the design of resilient networks. Finally, we introduce a cavity method approach to study the recovery of connectivity after damage in self-healing networks.

9:48AM S18.00004 Easily repairable networks1. THOMAS FINK, London Institute for Mathematical Sciences / CNRS — We introduce a simple class of distribution networks which withstand damage by being repairable instead of redundant. Instead of asking how hard it is to disconnect nodes through damage, we ask how easy it is to reconnect nodes after damage. We prove that optimal networks on regular lattices have an expected cost of reconnection proportional to the lattice length, and that such networks have exactly three levels of structural hierarchy. We extend our results to networks subject to repeated attacks, in which the repairs themselves must be repairable. We find that, in exchange for a modest increase in repair cost, such networks are able to withstand any number of attacks.

Thursday, March 5, 2015 8:00AM - 11:00AM –

8:00AM S19.00001 Historical Overview of 3-D Printing: Do inventors know what they are doing? . MICHAEL CIMIA, Massachusetts Institute of Technology — No abstract available.
8:36AM S19.00002 Functional Structures for System Integrity and Security . DAVID M. KEICHER, Sandia National Laboratories — The 3D printing revolution is redefining manufacturing and has given rise to a new industry segment called Additive Manufacturing (AM). Assemblies of mechanical components can now be integrated into a single printed structure. A logical next phase in this revolution is to assimilate multiple technologies to functionalize these 3D printed structures. Some applications include embedding of simple sensors for structural health monitoring and tamper protection to fully integrating electronics onto nontraditional surfaces such as the inside shell of a housing. Electronic printing technologies provide an enabling tool to this end. This talk will describe work in printing large area sensors for temperature, strain and proximity detection applications. A critical aspect will also cover improvements made to aerosol based printing technologies to provide a more robust printing solution that both demonstrates improved printing performance over existing technologies and lowers the barrier to entry for high precision conformal printing of electronics.

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:48AM S19.00004 Additive Manufacturing and High-Performance Computing: A Disruptive Latent Technology BRUCE GOODWIN, Lawrence Livermore National Laboratory — This presentation will discuss the relationship between recent advances in Additive Manufacturing (AM) technology, High-Performance Computing (HPC) simulation and design capabilities, and related advances in Uncertainty Quantification (UQ), and then examines their impacts upon national and international security. The presentation surveys how AM accelerates the fabrication process, while HPC combined with UQ provides a fast track for the engineering design cycle. The combination of AM and HPC/UQ almost eliminates the engineering design and prototype iterative cycle, thereby dramatically reducing cost of production and time-to-market. These methods thereby present significant benefits for US national interests, both civilian and military, in an age of austerity. Finally, considering cyber security issues and the advent of the “cloud,” these disruptive, currently latent technologies may well enable proliferation and so challenge both nuclear and non-nuclear aspects of international security.

10:24AM S19.00005 Additive Manufacturing and Medical Devices: Case studies, Technical Concerns and Research KATHERINE VORVOLAKOS, Food and Drug Administration — The past decade has seen a steady increase in the marketing of medical devices produced via additive manufacturing (AM). This presentation discusses the technical concerns surrounding AM in the context of medical devices. While unprecedented complexity is possible, maintaining safety and effectiveness requires a more nuanced understanding of the interdependent chemical, physical, software and process traits of creating an AM medical device. This presentation will feature historical perspective, cite specific technical concerns and describe a few medical device case studies. Additionally, it will highlight FDA research and an upcoming FDA guidance document, both of which aim to identify and help address these technical concerns.

Thursday, March 5, 2015 8:00AM - 11:00AM –
Session S20 DPOLY: Invited Session: Ion-Containing Polymers Ballroom B - Kevin Cavicchi, University of Akron

8:00AM S20.00001 Thermal and pH Transitions in Polyelectrolyte Complexes and Multilayers JODIE LUTKENHAUS, Texas A&M University — When oppositely charged polymers are mixed in water, they form a polyelectrolyte complex. Analogously at a surface, oppositely charged polymers can be assembled to form a polyelectrolyte multilayer. Complexation is entropically driven, as it results in the release of small counter ions and water molecules into the surrounding media. First, the effect of time and temperature on the formation of polyelectrolyte complexes containing model polyelectrolytes poly(diallyldimethyl ammonium chloride) and poly(styrene sulfonate) is presented. We show that complexation is a time-dependent phenomenon, which is consistent with complexes existing in a kinetically trapped state, rather than a thermodynamic equilibrium. Upon heating, a glassy-viscous transition that shows features of an LCST is demonstrated. Second, the effect of pH on polyelectrolyte multilayer microtubes is presented. The microtubes are made of poly(allylamine) and poly(acrylic acid), both of which are weak polyelectrolytes. Modulating the pH induces a nanoporous transition that results in nanoporous microtubes. These results, in summary, show that noncovalent interactions are very sensitive to external stimuli such as temperature and pH.

8:36AM S20.00002 Multicomponent transport in membranes for redox flow batteries . CHARLES MONROE, University of Michigan — Redox flow batteries (RFBs) incorporate separator membranes, which ideally prevent mixing of electrochemically active species while permitting crossover of inactive supporting ions. Understanding crossover and membrane selectivity may require multicomponent transport models that account for solute/solute interactions within the membrane, as well as solute/membrane interactions. Application of the Onsager–Stefan–Maxwell formalism allows one to account for all the dissipative phenomena that may accompany component fluxes through RFB membranes. The magnitudes of dissipative interactions (diffusional drag forces) are quantified by matching experimentally established concentration transients with theory. Such transients can be measured non-invasively using DC conductometry, but the accuracy of this method requires precise characterization of the bulk RFB electrolytes. Aqueous dissipative interactions (diffusional drag forces) are quantified by matching experimentally established concentration transients with theory. Such transients can be measured non-invasively using DC conductometry, but the accuracy of this method requires precise characterization of the bulk RFB electrolytes. Aqueous solutions containing both vanadyl sulfate (VOSO$_4$) and sulfuric acid (H$_2$SO$_4$) are relevant to RFB technology. One of the first precise characterizations of aqueous vanadyl sulfate has been implemented and will be reported. To assess the viability of a separator for vanadium RFB applications with cell-level simulations, it is critical to understand the tendencies of various classes of membranes to absorb (uptake) active species, and to know the relative rates of active-species and supporting-electrolyte diffusion. It is also of practical interest to investigate the simultaneous diffusion of active species and supports, because interactions between solutes may ultimately affect the charge efficiency and power efficiency of the RFB system as a whole. A novel implementation of Barnes’s classical model of dialysis-cell diffusion [Physics 5:1 (1934) 4-8] is developed to measure the binary diffusion coefficients and sorption equilibria for single solutes (VOSO$_4$ or H$_2$SO$_4$) in porous membranes and cation-exchange membranes. With the binary diffusion and uptake measurement in hand, a computer simulation that extends the approach of Heintz, Wiedemann and Ziegler [J. Membrane Science 137:1-2 (1997) 121-132] is used to establish Onsager resistances that describe the drag forces VOSO$_4$ and H$_2$SO$_4$ exert on each other as they interdiffuse. The ramifications of these interactions for different classes of membranes – and for RFB applications – will be discussed.

1 NSF CBET-1253544
9:12AM S20.00003 Morphology control in solid polymer electrolytes, CHRISTOPHER LI, Drexel University — Solid polymer electrolytes (SPEs) with high ionic conductivity are important for energy-related applications, such as solid state batteries and fuel cells. In this talk, I will discuss how morphology affects the properties of SPEs. In the first part of the talk, I will show quantitatively that the effect of polymer crystallization on ion transport is twofold: structural (tortuosity) and dynamic (tethered chain confinement). We decouple these two effects by designing and fabricating a model polymer single crystal electrolyte system with controlled crystal structure, size, crystallinity, and orientation. Ion conduction is confined within the chain fold region and guided by the crystalline lamellae. We show that, at low ion content, due to the tortuosity effect, the in-plane conductivity is 2000 times greater than through-plane.1. Contrary to the general view, the dynamic effect is negligible at moderate ion contents. Our results suggest that semicrystalline polymer is a valid system for practical polymer electrolytes design. In the second part of the talk, I will discuss how to use holographic photopolymerization (HP) to fabricate long-range, defect-free, ordered SPEs with tunable ion conducting pathways. By incorporating polymer electrolytes into the carefully selected HP system, electrolyte layers/ion channels with length scales of a few tens of nanometers to micrometers can be formed. Confinement effects on ion transport will be reported.

9:48AM S20.00004 Morphology and Ionic Conductivity of Block Copolymer Electrolytes Containing Ionic Liquids, MOON JEONG PARK, Pohang University of Science and Technology (POSTECH) — The global energy crisis and an increase in environmental pollution in the recent years have drawn the attention of the scientific community towards the development of efficient electrochemical devices. Polymers containing charged species have the potential to serve as electrolytes in next-generation devices and achieving high ion transport properties in these electrolytes is the key to improving their efficiency. Although the synthesis and characterization of a wide variety of ion-containing polymers have been extensively reported over the last decade, quantitative understanding of the factors governing the ion transport properties of these materials is in its infancy. In this talk, I will present the current understanding of the diverse factors affecting the thermodynamics, morphologies and ion transport of ion-containing polymers by focusing on the use of ionic liquids (ILs). Various strategies for accessing improved transport properties of IL-containing polymers are elucidated by focusing on the role of IL-polymer interactions. The major accomplishment of obtaining well-defined morphologies for these IL-containing polymers by the use of block copolymer is particularly emphasized as a novel means of controlling the transport properties. The application of IL-incorporated polymer electrolytes in high temperature fuel cells and electro-active actuators is also enclosed.

10:24AM S20.00005 Ionomer Dynamics: Insights from Broadband Dielectric Spectroscopy*1, JAMES RUNT, Pennsylvania State University — Ionomers (polymers containing ionic functionality) have been traditionally used as packaging materials and in molding applications, and are now of increasing interest as candidate single ion conductors for energy storage devices, in energy conversion, and for other electroactive materials applications. The focus of this presentation is on the insight that broadband dielectric (impedance) spectroscopy brings to our understanding of ion and polymer dynamics of this family of materials. As an example of our recent work on relatively conductive ionomers, the first portion of the presentation will focus on anion conducting polyphosphazene ionomers, in which polymer bound cations are quaternized with either short alkyl or short ether oxygen chains. The low Tg, amorphous nature, and cation-solvating backbone distinguish polyphosphazenes as promising materials for ion conduction, the iodide variants being of particular interest in solar cells. In the second part of this overview, the first findings on the molecular dynamics of linear precise polyethylene-based ionomers containing 1-methylimidazolium bromide pendants on exactly every 9th, 15th, or 21st carbon atom will be summarized. In order to develop a robust interpretation of the dynamics of these materials, it is imperative to develop a thorough understanding of microphase separation (e.g. ion aggregation), and each of the above studies is complemented by multiange X-ray scattering experiments.

1Supported by the NSF Polymers Program and DOE Basic Energy Sciences

Thursday, March 5, 2015 8:00AM - 11:00AM — Session S21 GIMS: Spectroscopic Techniques 201 - Dennis Mills, Argonne National Laboratory

8:00AM S21.00001 Nanoscale imaging of nonequilibrium polymer films, JOHN KING, STEVE GRANICK, University of Illinois, Urbana-Champaign — In recent years there have been exciting advances in sub-diffraction limited imaging based on fluorescence microscopy. While most applications of super-resolution microscopy focus on static biological imaging, we are interested in extending these techniques to the study of polymer dynamics. To this end, we couple stimulated emission depletion (STED) with spectroscopic detection, relying on spectral features of fluorescence emission to serve as the imaging contrast agent. We aim to adapt fluorescent dyes responsive to environmental properties (polarity, mobility, current, temperature, etc.) to STED imaging. Using the fluorescent spectral response as a contrast agent allows for nanoscopic environments to be directly imaged without the need for specific labeling. Rapid acquisition of images allows for slow dynamic processes in nonequilibrium polymer films to be imaged in real time. We demonstrate the power of super-resolution spectroscopic imaging by directly imaging several topical problems in materials science.

8:12AM S21.00002 Nonlinear photothermal Mid-Infrared Microspectroscopy with Superresolution1, SHYAMSUNDER ERRAMILLI, Physics department & the Photonics Center, Boston University, ALKET MERTIRI, Department of Biology, Boston University, HUI LIU, ATCHA TOTACHAWATTANA, Electrical and Computer Engineering, Boston University, MI HONG, Physics department, Boston University, MICHELLE SANDER, Electrical and Computer Engineering, Boston University — We describe a nonlinear method for breaking the diffraction limit in mid-infrared microscopy using nonlinear photothermal microspectroscopy. A Quantum Cascade Laser (QCL) tuned to an infrared active vibrational molecular normal mode is used as the pump laser. A low-phase noise Erbium-doped fiber (EDFL) laser is used as the probe. When the incident intensity of the mid-infrared pump laser is increased past a critical threshold, a nanobubble is nucleated, strongly modulating the scatter of the probe beam, in agreement with prior work. Remarkably, we have also found that the photothermal spectral signature of the mid-infrared absorption bifurcates and is strongly narrowed, consistent with an effective “mean-field” theory of the observed forkich bifurcation. This ultrasharp narrowing can be exploited to obtain mid-infrared images with a resolution that breaks the diffraction limit, without the need of mechanical scanning near-field probes. The method provides a powerful new tool for hyperspectral label-free mid-infrared imaging and characterization of biological tissues and materials science and engineering.

1We thank our collaborators H. Altug, L. D. Ziegler, J. Mertz, for their advice and generous loan of equipment.

8:24AM S21.00003 Novel Raman instrumentation for characterizing 2D nanomaterials, ANGELA HIGHT WALKER, National Institute of Standards and Technology, Gaithersburg, MD 20899 — We have designed and constructed a unique Raman microscope system to enable diffraction limited measurements of graphene and two-dimensional transition-metal dichalcogenides (TMDs). The design enables low frequency phonon measurements down to ten wavenumbers through a triple grating Raman spectrometer, as well as resonance Raman spectroscopy through multiple laser excitation lines throughout the visible region. Through coupling to a cryogen-free magnet system, Raman spectra can be collected while the sample is in fields up to 9 Tesla and at temperatures from 4 K to 400 K. Uniquely, both Farady and Voight geometries are accessible. Furthermore, multiple electronic feedthroughs permit collecting Raman scatter from devices at varying voltages. Proof of concept measurements on TMDs will highlight the full capabilities of the instrumentation. Collaborations are sought to demonstrate the utility of the new instrumentation.
9:00AM S21.00006 High Power Terahertz Conductive Antenna with Chaotic Electrodes

Christopher Kim, Benjamin Graber, Dong HO Wu, Naval Research Laboratory — Time domain terahertz spectroscopy (TDTS) is now widely adopted and being used for various purposes, including chemical and material analysis as well as detection of hazardous materials in the laboratories. While there are several different methods available to generate a wideband terahertz pulse for the TDTS, currently a terahertz photoconductive antenna may be the most popular one, as it can produce a wideband terahertz pulse very efficiently. However, our experimental investigation indicates that the conventional photoductive antenna with a pair of parallel electrodes can produce a terahertz pulse at most about 100 micro-Watts. When attempted to produce a higher power terahertz pulse, the antenna may experience irreversible failure. In order to overcome this problem, we recently redesigned the photoconductive antenna and implemented electrodes that lead to a chaotic trajectories of charged particles. With the new electrodes we have demonstrated a high power (>2 mW) coherent terahertz beam, and we found that the lifetime of the antenna is also substantially longer than that of the conventional antenna. In this talk, I will present our experimental results and disclose some of our new antenna designs.

Fidele Twagi-Rayezu, Wilhemus J. Geerts, Yubo Cui, Texas State Univ-San Marcos — The study of optical properties of Nickel (Ni) is important, given the pivotal role it plays in the semiconductor and nano-electronics technology. Ni films were made by DC and RF magnetron sputtering in an ATC Orion sputtering system of AJA on various substrates. The optical properties were studied ex situ by variable angle spectroscopic (220-1000 nm) ellipsometry at room temperature. The data were modeled and analyzed using the Woollam CompleteEase Software fitting ellipsometric and transmission data. Films sputtered at low pressure have optical properties similar to that of Palik [1]. Films sputtered at higher pressure however have a lower refraction index and extinction coefficient. It is expected from our results that the density of the sputtered films can be determined from the ellipsometric quantities. Our experiments also revealed that Ni is susceptible to a slow oxidation changing its optical properties over the course of several weeks. The optical properties of the native oxide differ from those of reactive sputtered Ni similar as found by [2]. Furthermore the oxidation process of our samples is characterized by at least two different time constants.

9:24AM S21.00008 Practical Framework for an Electron Beam Induced Current Technique Based on a Numerical Optimization Approach

Hideshi Yamaguchi, Takeshi Soeda, Fujitsu Laboratories Ltd. — A practical framework for an electron beam induced current (EBIC) technique has been established for conductive materials based on a numerical optimization approach. Although the conventional EBIC technique is useful for evaluating the distributions of dopants or crystal defects in semiconductor transistors, issues related to the reproducibility and quantitative capability of measurements using this technique persist. For instance, it is difficult to acquire high-quality EBIC images throughout continuous tests due to variation in operator skill or test environment. Recently, due to the evaluation of EBIC equipment performance and the numerical optimization of equipment items, the constant acquisition of high contrast images has become possible, improving the reproducibility. As well as field yield regardless of operator skill or test environment. The technique proposed herein is even more sensitive and quantitative than scanning probe microscopy, an imaging technique that can possibly damage the sample. The new technique is expected to benefit the electrical evaluation of fragile or soft materials along with LSI materials.

Xuetao Zhu, Yanwei Cao, Shuyuan Zhang, Xun Jia, Qinlin Guo, Fang Yang, Institute of Physics, Chinese Academy of Sciences, Linfan Zhu, University of Science and Technology of China, Larry Kessmodel, Indiana University, Bloomington, Jiandi Zhang, Ward Plummer, Louisiana State University, Jiandong Guo, Institute of Physics, Chinese Academy of Sciences — High resolution electron energy loss spectroscopy (HREELS) has been demonstrated as a powerful technique to probe vibrational and electronic surface excitations of solids. The dispersion relation of the surface excitations, i.e. energy as a function of momentum, can be obtained via the angle resolved measurements by rotating the sample or the analyzer in a conventional HREELS measurement. The sampling density in the momentum space and the detecting efficiency are restricted by the mechanical rotation. Here we introduce a new design of the HREELS system, by combining the traditional Ibach-type electron source with the mainstream hemispherical electron energy analyzer, which could simultaneously measure the energy and momentum of the scattered electrons without any mechanical rotation. The new system possesses higher efficiency and sampling density of momentum-resolved measurements by at least one order of magnitude than conventional spectrometers without deteriorating the resolution of energy and momentum. Using Bi$_2$Sr$_2$CaCu$_2$O$_{8+}$$\delta^+$ as an example, we show that an energy loss spectrum can be scanned throughout the first Brillouin zone and a momentum-dependent spectral intensity distribution could be obtained in one measurement.
10:00AM S21.00011 Measurement of the low energy spectral contribution in coincidence with valence band (VB) energy levels of Ag(100) using VB-VB coincidence spectroscopy . P.V. JOGLEKAR, R. GLADEN, Z.H. LIM, K. SHASTRY, University of Texas at Arlington, S.L. HULBERT, Photon Science Directorate, Brookhaven National Laboratory, A.H. WEISS, University of Texas at Arlington — A set of coincidence measurements were obtained for the study and measurement of the electron contribution arising from the inter-valence band (VB) transitions along with the inelastically scattered VB electron contribution. These Auger-unrelated contributions arise in the Auger spectrum (Ag 4p NVV) obtained using Auger Photoelectron Coincidence Spectroscopy (APECS). The measured Auger-unrelated contribution can be eliminated from Auger spectrum to obtain the spectrum related to Auger. In our VB-VB coincidence measurement, a photon beam of energy 180eV was used to probe the Ag(100) sample. The coincidence spectrum was obtained using two Cylindrical Mirror Analyzers (CMA’s). The scan CMA measured the low energy electron contribution in the energy range 0-70eV in coincidence with VB electrons measured by the fixed CMA. In this talk, we present the data obtained for VB-VB coincidence at the valence band energy of 171eV along with the coincidence measurements in the energy range of 4p core and valence band.

10:12AM S21.00012 High repetition rate source of narrowband extreme-ultraviolet harmonics for time-resolved ARPES . H. HE WANG, YIMING XU, STEFAN ULONSKA, PREDRAG RANITOVIC, JOSEPH ROBINSON, ROBERT KAINDL, Lawrence Berkeley National Laboratory — We present a highly efficient table-top source of extreme ultraviolet (XUV) femtosecond pulses operating at 50-kHz repetition rate. A bright XUV source flux of 3x10^13 photons/s is generated at 22.3 eV by driving high-harmonic generation with the ultraviolet second-harmonic of a laser amplifier focused tightly into Kr gas. The conversion efficiency (5x10^-12) is enhanced by two orders-of-magnitude in this cascaded scheme, exceeding dipole wavelength scaling and evidencing enhanced phase matching conditions as confirmed by simulations. Importantly, the spectral structure enables the direct, high-contrast isolation of a single, narrowband harmonic with 72 meV linewidth. The high repetition rate, narrow bandwidth, and high flux (10^{11}-10^{12} ph/s at the sample) of this source is ideal for time-resolved photoemission or nanoscale imaging. First applications in time- and angle-resolved photoemission (trARPES) will be discussed.

10:24AM S21.00013 Instrumentation for Cyclotron Resonance and Electron Spin Resonance in Pulsed Magnetic Fields . CHRISTOPHER BEEDEL, Los Alamos Natl Lab, PAUL GODDARD, Warwick University, United Kingdom, NIEL HARRISON, Los Alamos Natl Lab, JAMIE MANSON, Eastern Washington University, ROSS MCDONALD, JOHN SINGLETON, Los Alamos Natl Lab — Pulsed electron spin resonance (ESR) and cyclotron resonance (CR) are widely used in structure and magnetic resonance of materials. For example, CR can yield the strength of electron-electron correlations via the dynamic mass, and determine the Fermi surface topology. However, very high magnetic fields are required to extend CR to heavy mass and/or disordered correlated-electron systems, and to cuprate superconductors, where the upper critical field must be exceeded. Similarly, magnetic fields ~ 100 T in conjunction with high-frequency ESR could access the magnetic interactions in highly anisotropic spin-gap materials and molecular quantum magnets, probe phase transitions in f-electron systems, and examine the electronic structure of organic radicals. Pulsed magnets are therefore required for such ultra-high-field CR and ESR experiments; but the resulting extreme environment presents challenges in resonant cavity and waveguide design. In this presentation, we describe probe designs tailored to CR and ESR experiments spanning fields up to 100 T and frequencies from 40 GHz to 4 THz. These new techniques will be illustrated using experimental ESR data from organic quantum magnets.

10:36AM S21.00014 High speed nonlinear optical harmonic generation rotational anisotropy measurements for sensitive detection of crystallographic and electronic symmetry breaking . LAUREN NIU, Institute for Quantum Information and Matter, California Institute of Technology, ANTONI WOSS, University of Cambridge, JOHN HARTER, DARIUS TORCHINSKY, DAVID HSIEH, Institute for Quantum Information and Matter, California Institute of Technology — The rotational anisotropy of optical nonlinear harmonic generation (NHG) on a crystalline material can be used to probe the symmetries of both its lattice structure and underlying ordered electronic phases. Presently however, low temperature experimental setups require both optics and detectors to be mechanically rotated during measurement [1], which makes the data collection slow and thus susceptible to low frequency sources of noise. We present a new method to perform rotational anisotropy measurements based on a triple beam-splitter setup and a spatially sensitive detection scheme. This method increases the data collection frequency by over three orders of magnitude by removing nearly all rotating parts from the experiment. We will report the improved sensitivity to symmetry changes in a material and discuss the potential to carry out wavelength dependent and time-resolved NHG measurements using this method.

10:48AM S21.00015 Electron Energy-Loss Spectroscopy (EELS) Calculation in Finite-Difference Time-Domain (FDTD) Package: EELS-FDTD . NICOLAS LARGE, YANG CAO, ALEJANDRO MANJAVacas, PETER NORDLANDER, Rice University — Electron energy-loss spectroscopy (EELS) is a unique tool that is extensively used to investigate the plasmonic response of metallic nanostructures since the early works in the ’50s. To be able to interpret and theoretically investigate EELS results, a myriad of different numerical techniques have been developed for EELS simulations (BEM, DDA, FEM, GDTD, Green dyadic functions). Although these techniques are able to predict and reproduce experimental results, they possess significant drawbacks and are often limited to highly symmetrical geometries, non-penetrating trajectories, small nanostructures, and free-standing nanostructures. We present here a novel approach for EELS calculations using the Finite-difference time-domain (FDTD) method: EELS-FDTD. We benchmark our approach by direct comparison with results from the well-established boundary element method (BEM) and published experimental results. In particular, we compute EELS spectra for spherical nanoparticles, nanoparticle dimers, nanodisks supported by various substrates, and gold bowtie antennas on a silicon nitride substrate. Our EELS-FDTD implementation can be easily extended to more complex geometries and configurations and can be directly implemented within other numerical methods.

Room-Temperature Studies of Li$_{10}$Mo$_9$O$_{17}$ by Scanning Tunneling Microscopy

Michael Boyer, Ling Fu, Aaron Kraft, Clark University, Martha Greenblatt, Rutgers University — The lithium purple bronze (Li$_{10}$Mo$_9$O$_{17}$) is a quasi-1-dimensional material as evidenced by high anisotropy in resistivity and thermal conductivity measurements. The material has garnered interest due to experimental evidence for Luttinger Liquid physics from 25 K to 300 K. Here we present our room-temperature topographic and spectroscopic scanning tunneling microscopy measurements on Li$_{10}$Mo$_9$O$_{17}$. We interpret the observed topographic and spectroscopic features in the context of previous bulk and surface measurements as well as theoretical models describing the 1-dimensional physics of the lithium purple bronze.

Thermoelectric effects in the field-suppressed superconducting state of quasi-one-dimensional Li$_{10}$Mo$_9$O$_{17}$

Joshua L. Cohn, University of Miami, Carlos A. M. Dos Santos, Escola de Engenharia de Lorena - USP, Brazil, John J. Neumeier, Montana State University — We present resistivity, thermopower (S), and Nernst (ν) measurements in the range 0.4 K ≤ T ≤ 20 K on single crystals of the quasi-one-dimensional (q1D) metal, Li$_{10}$Mo$_9$O$_{17}$ (LiPB) along the q1D metallic chains. The low-T limits of S/T and ν/T, determined in the magnetic-field suppressed superconducting state (T$_{c}$ = 2 K), indicate a very small Fermi temperature (T$_{F}$ ~ 30 K), contrary to expectations from prior work including photoemission. Possible insights from these results into the nature of the mysterious density-wave order, responsible for the upturn in resistivity below ~25 K will be discussed.

Topological character and chiral solitons in double Peierls-distorted chains

Sangmo Cheon, Tae-Hwan Kim, Sung-Hoon Lee, Han Woong Yeom, Caldes, Institute for Basic Science and POSTECH, Korea — Chiral edge states have played an important role in understanding condensed matter systems such as quantum Hall systems and topological insulators. In 1D electronic systems, Peierls-distorted atomic chains such as polyacetylene have two topologically different ground states and thus have topological edge states between them. The edge states—topological solitons—show novel properties of charge-spin separation and fractional charge. Here, we present theoretical results on the topological properties of double Peierls-distorted chains with interchain coupling. The double Peierls chains support a dynamically generated topological structure with four-fold symmetric ground states and have topological solitons with a new degree of freedom, chirality, which is absent in a single chain. We also discuss experimental evidence of the chiral solitons in the 1D charge-density wave (CDW) system of indium atomic nanowires on silicon substrates.

Photoinduced Dynamics of Charge Density Waves in Mott-Peierls Systems

Yao Wang, Stanford University/Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Chen-Chien Chen, Advanced Photon Source, Argonne National Laboratory, Chunjing Jia, Stanford University/Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Michael Van Veenendaal, Advanced Photon Source, Argonne National Laboratory/Department of Physics, Northern Illinois University, Thomas Devereaux, Stanford University/Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Brian Moritz, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory — We study the time-dependent evolution of photoinduced optical excitations in a model for organic solids, using the density matrix renormalization group method. The model consists of the quarter-filled one-dimensional extended Peierls-Hubbard Hamiltonian interacting with a classical time-dependent electric field. Our main results show that the overall dynamics of the dominating $k_F\rho$ bond and charge instabilities correspond to a gigantic fluctuating behavior as a function of time, whereas the 2$k_F$ state remains largely unaffected. These results remain valid regardless of the nature of the optical excitations and whether the system is driven resonantly or not. We compare our calculations with experimental pump-and-probe ultrafast spectroscopy studies of the optical conductivity in organic compounds.

Bond patterns in 1/4-filled spin-Peierls materials

Andrew Ward, R. Torsten Clay, Mississippi State University, Niladri Comes, Sumit Mazumdar, University of Arizona — In the 1/4-filled quasi-one-dimensional molecular charge transfer solids (CTS) there exist two distinct classes of spin-Peierls (SP) transitions. The two classes are distinguished by differing bond patterns: either the pattern Strong-Medium-Weak-Medium (SMMW), or the pattern Strong-Weak-Strong-Weak’ (SWSW’). Experimentally the SP transition temperature of CTS of the first type (SMMW) is much higher than those of the second type (SWSW”). This indicates that the small change in bond patterns within the SP phase greatly affects the electronic behavior of the CTS. We show that these two bond patterns can be explained within the one dimensional Extended Hubbard Model. We use quantum Monte Carlo and finite-size scaling to create a phase diagram for the 1/4-filled 1D CTS and discuss charge order amplitude and other experimental observables.

Charge fluctuations in the metallic phase of Lithium purple bronze

Jose Alvarez, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid, Jaime Merino, Departamento de Fisica Teorica de la Materia Condensada, Universidad Autonoma de Madrid, Natalia Lera, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid — We study the role of charge fluctuations for a model of the quasi-one-dimensional Li$_{10}$Mo$_9$O$_{17}$ and study their influence in ARPES experiments. Coulomb repulsion induces a charge ordering (CO) transition in a multiorbital extended Hubbard model. The ordering pattern is different from the one present in a conventional CDW driven by Fermi surface nesting. We assume that purple bronze lays in the metallic side of this phase diagram, but still very close to the CO transition. In these regime, strong charge fluctuations manifest themselves through low-energy collective excitations softening in the proximity the transition, which may be directly visible in HRRIX experiments. We discuss specific role of quasi-one-dimensionality in this context. We argue that the electronic scattering by these charge fluctuations can lead to the upturn in the resistivity observed at 24K and the deviations of scaling observed in ARPES.
Local correlation effects on pyrochlore iridate thin films in [111] direction

QI CHEN, HSIAO-HSUAN HUNG, XIANG HU, GREGORY A. FIETE, Univ of Texas, Austin — We study the local correlation effects on topological phases of matter in pyrochlore oxide thin films of the form $A_2B_2O_7$, oriented along the [111] direction. We examine bilayer and trilayer lattice models, including an on-site Hubbard interaction, by cellular dynamical mean field theory. The local correlation effects on the topological and magnetic phases are explored in both thin film geometries. Our focus is on the stability of the interaction induced Chern Insulator phases found in mean-field (Hartree-Fock) studies. By including dynamical fluctuations and computing the topological invariants from the single-particle Greens function, we corroborate the results of the Hartree-Fock mean field study and point out the differences. We discuss the likelihood of the Chern insulator phase being experimentally realized in transition metal oxide thin films.

Perfect Metal Phases of One-Dimensional and Anisotropic Higher-Dimensional Systems

EUGENIU PLAMADEALA, Univ of California - Santa Barbara, MICHAEL MULLIGAN, Stanford University, CHETAN NAYAK, Univ of California - Santa Barbara, Microsoft Station Q — We show that a 1D quantum wire with 23 channels of interacting fermions has a perfect metal phase in which all weak perturbations that could destabilize this phase are irrelevant. Consequently, weak disorder does not localize it, a weak periodic potential need not open a gap, and contact with a superconductor also fails to open a gap. Similar phases occur for $N \geq 24$ channels of fermions, except for $N=25$, and for $k\ell$ channels of interacting bosons, with $k \geq 3$. Arrays of perfect metallic wires form higher-dimensional fermionic or bosonic perfect metals, albeit highly-anisotropic ones.

Observation of a hierarchy of modes in an interacting one-dimensional system

CHRISTOPHER FORD, MARIA MORENO, YIQING JIN, WOOI KIAT TAN, IAN GRIFFITHS, IAN FARRER, GEB JONES, University of Cambridge, ANNE ANTHORE, Universite Paris Diderot, DAVID RITCHIE, University of Cambridge, OLEKSANDR TSYPLYATYEV, ANDREW SCHOFIELD, University of Birmingham — Studying interacting fermions in 1D at high energy, we find a hierarchy in the spectral weights of the excitations theoretically and we observe evidence for second-level excitations experimentally. Diagonalising a model of fermions (without spin), we show that levels of the hierarchy are separated by powers of $\mathcal{R}^2/L^2$, where $\mathcal{R}$ is a length-scale related to interactions and $L$ is the system length. The first-level (strongest) excitations form a mode with parabolic dispersion, like that of a renormalised single particle. The second-level excitations produce a singular power-law finite size scaling of these first-level modes and multiple power-laws at the spectral edge. We measure momentum-resolved tunneling of electrons (fermions with spin) from/to a wire formed within a GaAs heterostructure, which shows parabolic dispersion of the first-level mode and well-resolved spin-charge separation at low energy with appreciable interaction strength. We find structure resembling the second-level excitations, which dies away quite rapidly at high momentum.
8:00AM S23.00001 The importance of the finite-temperature exchange-correlation for warm dense matter studies\textsuperscript{1}. \textsc{V.V. Karasiev, S.B. Trickey}, Physics and QTP, Univ. Florida — Matter at extremely elevated temperature (thousands to millions Kelvin) under a wide range of pressures usually is treated by ab initio molecular dynamics driven by free-energy DFT. Whether in the Kohn-Sham or orbital-free forms, implementation requires a reliable exchange-correlation (XC) free energy approximation. Finite-temperature Hartree-Fock calculations\textsuperscript{1} suggest strongly that the explicit T-dependence of X is important. The recently developed first rung XC free-energy functional, the finite-T local density approximation (LDA)\textsuperscript{2}, captures that explicit T-dependence for the homogeneous electron gas. We report study of the impact of explicit T-dependence in the LDA on the properties of matter in the warm dense regime and conclude that there is a need to develop a T-dependent and density gradient-dependent XC functional. Next, we analyze the finite-T gradient expansion for X and C, extract from it the appropriate reduced density gradients for X and C with explicit T-dependence, introduce the next-run GGA XC free-energy functionals, and discuss their behavior and properties.

8:12AM S23.00002 Theoretical Investigation of Differing Ion and Electron Temperatures in Hydrogen\textsuperscript{1}. \textsc{Keith Runge, Valentin Karasiev}, Department of Physics, University of Florida, Pierre Deymier, Materials Science and Engineering, University of Arizona — Andrew Ng\textsuperscript{1} has reported experimental results for silicon and gold in warm, dense matter conditions that have been modeled by use of distinct temperatures for the ions and electrons. Here we investigate the implications of such differing ion and electron temperatures for hydrogen using path-integral molecular dynamics (PIMD) for protons which interact with electrons described by orbital-free density functional theory (OF-DFT). Temperatures ranging from room temperature to many kilokelvin are considered for the protons, while the electron temperatures are fixed in the kilokelvin range. Recent advances\textsuperscript{2} in OF-DFT not only allow for faster generation of first principles forces but also include the effects of temperature on the electron density. Comparisons are made with classical molecular dynamics to allow us to quantify the quantum nuclear effects captured by PIMD.

\textsuperscript{1} Work supported by U.S. Dept. of Energy, grant DE-SC0002139.

8:24AM S23.00003 High-throughput calculations of pressure-induced phase transitions in tungsten nitride\textsuperscript{1}. \textsc{Michael Mehl}, Naval Research Laboratory, Washington DC, Daniel Finkenstadt, United States Naval Academy, Annapolis MD, Gus Hart, Brigham Young University, Provo UT, Stefano Curtarolo, Duke University, Durham NC — We have previously used high-throughput electronic structure calculations\textsuperscript{2} to determine the ground state structures of the tungsten-nitride system as a function of composition. In doing this, we found many structures with are close to the W-N convex hull and apparently metastable. The question then arises if any of these structures can be stabilized under pressure. To test this, we have determined the ground state hull as a function of pressure up to 50 GPa. We find that the structures on the hull change with pressure. We discuss some of the more interesting structures, and show how the choice of density functional changes our predictions.

\textsuperscript{1} Partial support from US-ONR and US DoD HPC.

8:36AM S23.00004 Self-diffusion and viscosity for warm dense systems by orbital-free density functional theory. \textsc{Travis Sjostrom, Jerome Daligault}, Los Alamos National Laboratory — Evaluation of transport properties requires significantly longer molecular dynamics simulations than, for example, equation of state calculations. The standard approach at lower temperatures is to use Kohn-Sham (orbital dependent) density functional theory to find the quantum electron density at every molecular dynamics step. However, the Kohn-Sham approach becomes computationally prohibited at higher temperatures for equation of state, let alone for transport properties. Our recent orbital-free approach\textsuperscript{1} has shown excellent agreement with Kohn-Sham method at lower temperatures and extends to very high temperatures. Here we evaluate self-diffusion and viscosity from low to high temperatures and compare with Kohn-Sham methods where applicable as well as with recent approaches of kinetic theory.

8:48AM S23.00005 A New Force-Matched Reactive Force Field for Bulk Water Under Extreme Thermodynamic Conditions. \textsc{Laurence Fried, Lucas Koziol}, Lawrence Livermore National Laboratory — A many-body classical force field is presented for water under dissociative thermodynamic conditions. The force field is optimized by force-matching to ab initio molecular dynamics (AIMD) simulations calculated with Density Functional Theory (DFT). The force field contains short-ranged central terms, many-body over-coordination terms, and long-range Ewald electrostatics. It is optimized and tested on water at density 1.5 g/mL and 2000 K, which is approximately 10% dissociated according to DFT. Molecular dynamics simulations closely reproduce DFT radial distribution functions, as well as the distribution of H$_2$O and dissociation products. The calculated atomic self-diffusion constants appear about 50% lower than in DFT, although precise comparison is impossible due to the short timescale accessible to AIMD (about 20 ps). The force field is also compared to ReaxFF using the CHO parameter set of Chenowith et al. ReaxFF structural and dynamical properties are in overall fair agreement with DFT, although ReaxFF water is not dissociative at these conditions.

9:00AM S23.00006 N Dependence of the Equilibrium Free Energy from the Canonical Ensemble\textsuperscript{1}. \textsc{Debajit Chakraborty, QTP}, Department of Physics, University of Florida, James Dufty, Department of Physics, University of Florida — Free-energy density functional theory conventionally is formulated in the Grand Canonical ensemble but implemented computationally in the Canonical ensemble. To investigate the effects of this disjuncture, the equilibrium free energy per particle for a uniform non-interacting gas is calculated from the Canonical ensemble for given particle number $N$ and fixed volume. The same calculation is performed from the Grand Canonical ensemble for the corresponding average $<N>$ and same volume. In dimensionless forms the latter depends only on the reduced temperature, $t = T/T_F$. In contrast, of course, the Canonical result depends on both $t$ and $<N>$. The results are compared for $1 <N> <100$. Next, the same calculations are performed for a non-uniform gas generated by an external ion using a regularized Coulomb potential. The number dependence is explored for positions near and far from the ion. The implications for free-energy density functional theory are discussed.

9:12AM S23.00007 Pressure-stabilized lithium cesides with cesium anions beyond the -1 state
, JORGE BOTANA, Beijing Computational Science Research Centre, Beijing 10084, China., MAO-SHENG MIAO, Materials Research Laboratory, University of California, Santa Barbara, California Q3 93106-5050, USA. — Main group elements usually assume a typical oxidation state while forming compounds with other species that depends on the occupation of the outermost orbital. Group I elements are usually in the +1 state in inorganic materials. Our recent work on Cs-F compounds reveals that pressure may make the inner shell 5p electrons of Cs reactive, causing Cs to expand beyond the +1 oxidation state. In our study, we have found that pressure can cause large electron transfer from light alkali metals such as Li to Cs, causing Cs to become anionic with a formal charge much beyond -1. Li and Cs only form alloys at ambient conditions, but by studying the thermodynamic stability of the intermetallic compounds Li$_m$Cs$_n$ (n=1-5, m=1; n=1,m=1-4), we have found that some Li$_m$Cs (n=1,3,4,5) compounds become stable under pressures higher than 100 GPA. Once formed, these compounds exhibit interesting structural features, including capped cuboids and dimerized icosahedra. Finally, we have also found superconductivity in metastable LiCs and that the unusual anionic state of Cs has a strong effect on the transition temperature.

9:24AM S23.00008 Bypassing the malfunction junction in warm dense matter simulations
, ATTILIA CANGI, Max Planck Institute of Microstructure Physics, AURORA PRIBRAM-JONES, University of California, Irvine — Simulation of warm dense matter requires computational methods that capture both quantum and classical behavior efficiently under high-temperature and high-density conditions. The state-of-the-art approach to model electrons and ions under those conditions is density functional theory molecular dynamics, but this method's computational cost skyrockets as temperatures and densities increase. We propose finite-temperature potential functional theory as an in-principle-exact alternative that suffers no such drawback[1]. In analogy to the zero-temperature theory developed previously[2,3], we derive an orbital-free free energy approximation through a coupling-constant formalism. Our density approximation and its associated free energy approximation demonstrate the method's accuracy and efficiency.

9:36AM S23.00009 Interaction of Short Pulse Laser Irradiation with Metal Targets under Condition of Spatial Confinement
, MAXIM SHUGAEV, EAMAN KARIM, CHENG-YU SHIH, CHENPING WU, LEONID ZHIGILEI, Univ of Virginia — While the general mechanisms of laser interactions with metals in vacuum have been broadly investigated experimentally, theoretically and computationally, the effect of strong spatial confinement by solid or liquid overlayers on the laser induced processes remains largely unexplored. In this work, the results of large-scale atomic simulations of short pulse laser irradiation of metal targets in liquid environment and in the presence of a transparent silica glass overlay are used to reveal the effect of the spatial confinement on the material response to the fast laser energy deposition. The ability of the overlayer to suppress generation of unloading tensile wave, prevent photomechanical spallation and explosive decomposition of the surface region of the target, and facilitate the formation of a high pressure and temperature supercritical state near the interface is revealed in the simulations. The results of the simulations clarify the mechanisms responsible for structural and morphological changes in the interfacial region, formation of voids and crystal defects, and generation of nanoparticles.

9:48AM S23.00010 ABSTRACT WITHDRAWN —

Thursday, March 5, 2015 8:00AM - 11:00AM –
Session S24 DCOMP: Quantum Many-Body Systems and Methods I 203AB - Chris Marianetti, Columbia University

8:00AM S24.00001 ABSTRACT WITHDRAWN —

8:12AM S24.00002 Entanglement spectrum and covalent bonding
, DAVID YANG, NORM TUBMAN, Univ of Illinois - Urbana. — We present an approach for computing the entanglement spectrum with quantum Monte Carlo for both continuum and lattice Hamiltonians. This method provides direct access to the matrix elements of the spatially reduced density matrix, using a generalization of the SWAP operator. We apply this method to several diatomic molecules and describe how the spatial entanglement spectrum encodes a covalent bond that includes all the many-body correlations. Of particular focus is the C$_2$ molecule, which has been subject to recent controversy. Our results suggest that entanglement-based methods can lead to more realistic analysis of covalent bonds than possible before.

8:24AM S24.00003 Power law violation of the area law in quantum spin chains
, RAMIS MOVASSAGH, Northeastern Univ. / MIT, PETER SHOR, MIT, Mathematics — The sub-volume scaling of the entanglement entropy with the system's size, $n$, has been a subject of vigorous study in the last decade. The area law provably holds for gapped one dimensional systems and it was believed to be violated by at most a factor of log($n$) in physically reasonable models such as critical systems. We first describe and then generalize our earlier spin-1 model [PRL 109, 207202 (2012)] to all integer spin-s chains, whereby we introduce a class of exactly solvable models that are physical yet violate the area law by a power law [arXiv:1408.1657 quant-ph]. This rules out the possibility of these models being described by a conformal field theory. We analytically show that the Schmidt rank grows exponentially with $n$ and that the half-chain entanglement entropy to the leading order scales as $\sqrt{n}$. Lastly, we introduce an external field which allows us to remove the boundary terms yet retain the desired properties of the model.
8:36AM S24.00004 Quantum criticality in “easy-plane” SU(N) spin model. JONATHAN DEMIDIO, RIBHU K. KAUL, Univ of Kentucky — We investigate a two dimensional quantum spin model with “easy-plane” SU(N) anisotropy which describes an N = 1 component superfluid of hard-core bosons. This model exhibits a transition from a magnetically ordered state, corresponding to superfluid order of the bosons, to a non-magnetic state with broken lattice translation symmetry (a valence bond solid). It has been shown previously that the fully SU(N) symmetric version of this model exhibits a continuous phase transition consistent with the scenario of deconfined quantum criticality. Using quantum Monte Carlo techniques we study the critical properties in the “easy-plane” case.

1 NSF DMR-1056536

8:48AM S24.00005 Matrix-product Ansatz for Fermions in a 1D Continuum, S.S. CHUNG, University of Cincinnati, K. SUN, University of Texas at Dallas, C.J. BOLECH, University of Cincinnati — We present a novel implementation of a matrix-product ansatz for fermions in a 1D continuum, which correctly predicts the ground state properties of a homogeneous interacting spin-1/2 system. This includes the signatures of a partially polarized regime, in agreement with a large amount of theoretical work which has guided, and/or has been inspired by, recent cold-atom experiments.

1 DOE FG02-12ER46875.

9:12AM S24.00007 Momentum-space Entanglement Spectrum of Bosons and Fermions with Interactions, REX LUNDGREN, JONATHAN BLAIR, University of Texas at Austin, MARTIN GREITER, Institue for Theoretical Physics, University of Wuerzburg, ANDREAS LAEUCHLI, Institut fuer Theoretische Physik, Universität Innsbruck, GREGORY FIEITE, University of Texas at Austin, RONNY THOMALE, Institute for Theoretical Physics, University of Wuerzburg — We study the momentum space entanglement spectra of bosonic and fermionic formulations of the spin-1/2 XXZ chain with analytical methods and exact diagonalization. We investigate the behavior of the entanglement gaps, present in both partitions, across quantum phase transitions in the XXZ chain. In both cases, finite size scaling reveals that the entanglement gap closure does not occur at the physical transition points. For bosons, we find that the entanglement gap observed in [Thomale et al., Phys. Rev. Lett. 105, 116805 (2010)] depends on the scaling dimension of the conformal field theory as varied by the XXZ anisotropy. For fermions, the infinite entanglement gap present at the XX point persists well past the phase transition at the Heisenberg point. We elaborate on how these shifted transition points in the entanglement spectra may in fact support the numerical study of the physical transitions in the momentum space density matrix renormalization group. Accepted by Physical Review Letters (arXiv:1404.7545) This work was supported by an National Science Foundation Graduate Research Fellowship

9:24AM S24.00008 Failure of the GGE for integrable models with bound states, NATAN ANDREI, GARRY GOLDSTEIN, Rutgers University — In this work we study the applicability of the local GGE to integrable one dimensional systems with bound states. We find that the GGE, when defined using only local conserved quantities, fails to describe the long time dynamics for most initial states including eigenstates. We present our calculations by studying the attractive Lieb-Liniger gas and the XXZ magnet, though similar results may be obtained for other models.

1 This research was supported by NSF grant DMR 1006684 and Rutgers CMT fellowship.

9:36AM S24.00009 Steady-state phases of the non-equilibrium Rabi-Hubbard Model, HAKAN TURECI, Princeton University, CHAITANYA JOSHI, University of St Andrews, MYKOLA BORDYUYH, Princeton University, ROSARIO FAZIO, Scuola Normale Superiore, JONATHAN KEELING, University of St Andrews, MARCO SCHIRO, Institut de Physique Theorique, CEA, CNRS-URA — We study the realization of a tunable Rabi-Hubbard Model with a coupled cavity array containing Raman-pumped 4-level qubits. This effective model is found to display a phase diagram that features a normal phase (vanishing polarization and photon coherence) and a finite-frequency ordered phase. The ordered phase may either display a “ferro-electric” order where the photon coherence is uniform through the array, or one with an alternating phase that we refer to as “anti-ferroelectric.”

9:48AM S24.00010 Local density fluctuation approach to Fermionic lattice models, ZHENGQIAN CHENG, CHRIS MARIANETTI, Columbia University — We formulate an effective action as a function of selected Hubbard operators which reproduces the local density fluctuations of a given lattice model. The relevant Hubbard operators emerge via mapping the lattice Hamiltonian to a composite system with auxiliary holes and gauge bosons which mediate the inter-cell hopping. After a mean field approximation of the gauge bosons, we get an effective local model which reproduces the expectation value of the relevant Hubbard operators. We apply our method to the one band Hubbard model in one and infinite dimensions, demonstrating good agreement between our computed static observables and the exact solutions. While our approach does not address frequency dependent observables, it has a negligible computational cost as compared to dynamical mean field theory and could be highly applicable in the context of real materials.

10:00AM S24.00011 Density-matrix renormalization group study of triangular and square Hubbard models, TAKAMI TOHYAMA, Tokyo University of Science, SHIGETOSHI SOTA, RIKEN AICS, TOMONORI SHIRAKAWA, SEIJI YUNOKI, RIKEN — We perform large-scale density-matrix renormalization group calculations for two-dimensional Hubbard models with a triangular lattice and a square lattice. In the triangular Hubbard model, we determined a boundary between metal and insulator and a boundary between spin-liquid and antiferromagnetic phases. The presence of spin-liquid phase is confirmed by spin-spin correlation function. In the square Hubbard model, we introduce a second-neighbor hopping interaction and calculate the dynamical spin correlation function to clarify the doping dependence of magnon excitations. We find a shift of a peak position toward higher energy in the electron-doped side, being consistent with recent resonant-inelastic x-ray scattering.

10:12AM S24.00012 Many-body localization edge in the random-field Heisenberg chain, DAVID J. LUITZ, NICOLAS LAFLORENCIE, FABIEN ALET, CNRS and Université Paul Sabatier de Toulouse — We present a large scale exact diagonalization study of the one dimensional spin 1/2 Heisenberg model in a random magnetic field. In order to access properties at varying energy densities across the entire spectrum for system sizes up to L=22 spins, we use a spectral transformation which can be applied in a massively parallel fashion. Our results allow for an energy-resolved interpretation of the many body localization transition including the existence of a many-body mobility edge. The ergodic phase is well characterized by Gaussian orthogonal ensemble statistics, volume-law entanglement, and a full delocalization in the Hilbert space. Conversely, the localized (non-ergodic) regime displays Poisson statistics, area-law entanglement and signs of multifractality in the Hilbert space where a true localization never occurs. We perform finite size scaling to extract the critical edge and exponent of the localization length divergence.
10:24AM S24.00013 Chiral spin density wave order on frustrated honeycomb and bilayer triangular lattice Hubbard model at half-filling, KUN JIANG, YI ZHANG, Department of Physics, Boston College, Chestnut Hill, MA 02467, USA, SEN ZHOU, State Key Laboratory of Theoretical Physics, Institute of Theoretical Physics, Chinese Academy of Sciences, Beijing 100080, CHINA, ZIQIANG WANG, Department of Physics, Boston College, Chestnut Hill, MA 02467, USA — We study the ground state properties of the Hubbard model on the honeycomb lattice with nearest-neighbor $t_1$ and second nearest-neighbor hopping $t_2$, which is isomorphic to the bilayer triangular lattice. We show that, at half-filling, chiral spin-density wave ($\chi$-SDW) order emerges due to on-site Coulomb interaction $U$ in a wide range of $t_2/t_1$ where both the two-sublattice antiferromagnetic order for small $t_2/t_1$ and the decoupled three-sublattice 120° magnetic order are strongly frustrated. For fixed $t_2/t_1$, we find that increasing $U$ leads to a continuous transition from a $\chi$-SDW semimetal with anomalous Hall effect to a topological chiral Chern insulator exhibiting quantum anomalous Hall effect, which undergoes a first order transition into a $\chi$-SDW insulator with zero total Chern number but anomalous AC Hall effect. We obtain the rich phase diagram and discuss the novel magnetic and topological properties.

10:36AM S24.00014 Summing parquet diagrams via the functional renormalization group: x-ray problem revisited, COLIN WEST, ARTUR SAEZ-GARCIA, TZU-CHIEH WEI, Yang Institute for Theoretical Physics, Stony Brook University, WEI GROUP TEAM — We present a numerical scheme for efficiently extracting the higher-order moments and cumulants of various operators on spin systems represented as tensor product states, for both finite and infinite systems. These quantities can be useful in the evaluation of phase transitions. Of particular interest is the application of this method to calculate the so-called Binder’s Cumulant, which can be used to detect critical points even with small finite numerical calculations.

Thursday, March 5, 2015 8:00AM - 11:00AM –
Session S25 DMP: Focus Session: Search for New Superconductors I 203B - Chenglin Zhang, Rice University

8:00AM S25.00001 Superconductivity in single-layer films of FeSe with a transition temperature above 100 K, JINFENG JIA, Shanghai Jiao Tong University — Recent experiments on FeSe films grown on SrTiO3 (STO) suggest that interface effects can be used as a means to reach superconducting critical temperatures (Tc) of up to 80 K. This is nearly ten times the Tc of bulk FeSe and higher than the record value of 56 K for known bulk Fe-based superconductors. Together with recent studies of superconductivity at oxides heterostructure interfaces, these results rekindle the long-standing idea that electron pairing at interfaces between two different materials can be tailored to achieve high temperature superconductivity. Subsequent angle-resolved photoemission spectroscopy measurements of the FeSe/STO system revealed an electronic structure distinct from bulk FeSe, with an energy gap vanishing at around 65 K. However, ex situ electrical transport measurements have so far only detected zero-resistance - the key superconductivity. Subsequent angle-resolved photoemission spectroscopy measurements of the FeSe/STO system revealed an electronic structure distinct from these results rekindle the long-standing idea that electron pairing at interfaces between two different materials can be tailored to achieve high temperature superconductivity. Together with recent studies of superconductivity at oxides heterostructure interfaces, these results rekindle the long-standing idea that electron pairing at interfaces between two different materials can be tailored to achieve high temperature superconductivity.

1In cooperation with Jian-Feng Ge, Zhi-Long Liu, Canhua Liu, Chun-Lei Gao, Dong Qian, Qi-Kun Xue, Ying Liu

8:36AM S25.00002 Superconducting property of Sn1-xInxTe compounds, KA-RYEONG KIM, Kyung-Hee Univ. — SnTe has been known as a topological crystalline insulator (TCI). TCI is produced by the inversion symmetry of crystal, instead of time-reversal symmetry and Z2 invariance. Recently, the superconducting properties were discovered in In-doped Sn1-xInxTe compounds, which is believed to be the first superconductor with TCI. We synthesized Sn1-xInxTe ($x = 0.1, 0.2, 0.3, 0.4, 0.5, 0.6$ and $0.7$ ) single like crystals by the flux method. From the electrical resistivity, magnetization, and heat capacity measurements, we obtained superconducting properties such as the critical temperature, upper-critical magnetic fields, coherence length, and Ginzburg-Landau parameters with respect to In-doping concentrations of Sn1-xInxTe in terms of Ginzburg-Landau and Bardeen-Cooper-Shrieffer (BCS) theory.

10:48AM S25.00003 Magnetic Structure of Superconducting FeTeOx Films by Neutron Scattering, L.K. NARANGAMMAMA, ZHIWEI ZHANG, J.I. BUDNICK, W.A. HINES, University of Connecticut, Storrs, J.W. LYNN, Center for Neutron Research, NIST, CHRISTOF NIEDERMAYER, Paul Scherrer Institut Villigen, B.O. WELLS, University of Connecticut, Storrs — We present the temperature-dependent neutron diffraction studies of superconducting FeTeOx, and non-superconducting FeTe films grown by PLD in both cases we were able to get strong elastic, magnetic neutron peaks even though we were using film samples. Both samples had magnetic scattering similar to that of bulk Fe$_{1.05}$Te, indicating the coexistence of magnetism and superconductivity in the oxidized films. We will present a detailed analysis of the differences in magnetism between the superconducting and non-superconducting samples.

9:00AM S25.00004 The local electronic structure of 1T-Ta(S_{1−x}Se_x)2 studied by scanning tunneling microscopy . XINTONG LI, PENG CAI, ZHENQI HAO, CUN YE, Tsinghua Univ, NAIZHOU WANG, XIANHUI CHEN, YAYU WANG, University of Science and Technology of China — The 1T-TaS_2 compound exhibits a series of complex charge density wave (CDW) transitions and an unexpected insulating ground state at low temperature. It is generally considered to be a Mott insulator, thus a rare example of strongly correlated transition metal dichalcogenide. When a sufficient amount of S is substituted by Se, the system becomes a superconductor. The evolution of the electronic structure and CDW order across the insulator and superconductor transition has attracted much attention. In this talk, we report scanning tunneling microscopy studies of the atomic scale electronic structure of 1T-Ta(S_{1−x}Se_x)2 with varied Se contents. In pristine 1T-TaS_2, we observe the √3 × √3 commensurate CDW order at low temperature, as well as a well-defined insulating energy gap. With increasing Se content, the commensurate CDW order becomes a nearly commensurate CDW order, and a finite electron density of state appears at the Fermi level. Spectroscopic imaging reveals close correlations between the electronic density of states at various energies. We will discuss the implications of these results on the local electronic structure of doped Mott insulators and superconductors in correlated transition metal dichalcogenides.

9:12AM S25.00005 ABSTRACT WITHDRAWN

9:24AM S25.00006 Engineering superconductivity in metal/spin ice heterostructures . JIAN-HUANG SHE, CHOONG HYUN KIM, CRAIG FENNIE, Cornell University, MICHAEL LAWLER, Binghamton University and Cornell University, EUN-AH KIM, Cornell University — How to understand and control unconventional superconductivity is among the most fundamental and pressing challenges in modern condensed matter physics. Although spin fluctuation induced pairing has long been discussed as a mechanism for unconventional superconductivity, it has been challenging to prove the mechanism or use such insight to control superconductivity. We propose an artificial heterostructure consisting of metallic layer deposited on top of quantum spin ice which could exhibit unconventional superconductivity mediated by the spin fluctuations in the spin ice. We will discuss material candidates that are amenable for film growth and their expected band structure as well as their potential for topological superconductivity.

9:36AM S25.00007 Is Sodium a Superconductor Under Pressure? . ROXANNE TUTCHTON, The Colorado School of Mines, XIAO-JIA CHEN, The Carnegie Institution of Washington, ZHI GANG WU, The Colorado School of Mines — Superconductivity has been discovered in compressed Li with a critical temperature (T_c) of 14 K. The other alkali metals are, theoretically, predicted to become superconductors under pressure. Sodium (Na) is the notable exception. Previous ab initio calculations considered superconductivity only in the BCC and FCC structures of alkali metals; however, Na goes through complicated, structural phase transitions at higher pressures until it becomes an insulator around 260 GPa. We have performed first-principles linear response calculations for four metallic phases (BCC, FCC, c116 and t119) of Na to compute lattice dynamics and the electron-phonon spectral function. The electron-phonon coupling parameter as well as T_c were then determined as functions of pressure. Our results suggest that the critical temperature for Na rises with increasing pressure to a maximum T_c of 1.2 K in the c116 phase, then it decreases rapidly to zero K at higher pressures.

9:48AM S25.00008 Searching for new superconductors using perspectives from both chemistry and physics1. ROBERT CAVA, Department of Chemistry, Princeton University — Although some may claim otherwise, the view from the lab bench is that it remains very difficult if not impossible to make reasonable predictions for what will be an entirely new superconducting material. This lends a considerable amount of drama to this field, as spectacular superconductors are periodically known to appear out of the blue sky. Nonetheless if ones business is to find new superconductors, a rational approach has to be taken to the discovery process. In our research we try both chemistry and physics-based perspectives to guide us. Mostly, our searches fail but sometimes we have discovered new superconductors, and not by accident. In this talk I will describe some examples of searches from our current work that have yielded new (Low Tc) superconductors based on both chemical and physical ideas. The postdoctoral fellows in my research group who have had primary responsibility for the searches that I will describe are Huixia Luo and Weiwei Xie.

1This research is supported by the US Department of Energy and the AFOSR MURI on superconductivity.

10:00AM S25.00009 Search for superconductivity and novel phenomena in natural minerals . REN XIONG WANG, XIANGFENG WANG, Department of Physics, University of Maryland College Park, J.R. JEFFRIES, Lawrence Livermore National Laboratory, S.R. SAHA, R.L. GREENE, J. PAGLIONE, Department of Physics, University of Maryland College Park, C. SANTELLI, J. POST, Department of Mineral Sciences, Smithsonian Museum of Natural History — In a unique venture in collaboration with the Smithsonian Institution’s National Museum of Natural History, we present ongoing work from a project focusing on the search for superconductivity in mineral specimens provided by the Department of Mineral Sciences, including magnetization and transport studies of Bornite(Cu_{5}FeS_{4}), Berthierite(FeS_{1}Te_{0.5}S_{3}), Nagyagite(Pb_{5}Au(Te,Sb){_{4}}S_{5-8}) and other related compounds, report low temperature physical properties and ab initio calculations of electronic structure of these compounds, including several unreported magnetic transitions and unconventional transport properties. We focus on an in-depth study of transport and structural properties of Sperrylite(ΠTaS_{2}) under high pressures up to 120 GPa utilizing a designer diamond anvil cell, as well as artificial synthesis using chemical substitutions to tune structural and electronic properties. We will discuss the evolution of resistivity, from semiconducting to metallic behavior as a function of applied pressure and substitution, with indications that superconductivity is induced at the highest pressures.

1This work was supported by the AFOSR under the grant number AFOSR F9550-14-1-0202.

10:12AM S25.00010 Search for Superconductivity in Extraterrestrial Materials: An Electromagnetic Phase Transition with Spin-Glass Characteristics1. S. GU ÉNON, PIT-Nano Optics, University of Tuebingen, Department of Physics and Center for Advanced Nanoscience, University of California San Diego, J.G. RAMIREZ, ALI C. BASARAN, J. WAMPLER, Department of Physics and Center for Advanced Nanoscience, University of California San Diego, S. TAYLOR, Cold Regions Research and Engineering Laboratory, Dartmouth College New Hampshire, M. THIEMENS, Department of Chemistry and Biochemistry, University of California San Diego, IVÁN K. SCHULLER, Department of Physics and Center for Advanced Nanoscience, University of California San Diego — We have established a very sensitive, selective, and non-destructive microwave absorption technique to screen a wide range of different materials for superconductivity. This technique allows for the detection of minute amounts of superconducting material in a non-superconducting matrix and it is an ideal tool for searching for superconducting phases in materials found in nature. Here, we report on electro-magnetic phase transitions in extraterrestrial materials formed under very extreme conditions difficult to replicate in a laboratory. Of particular interest is a phase with a transition temperature of 110 K. The associated field scans are characteristic of a frustrated system. Frustrated systems were reported in magnetic systems (spin glasses) as well as in granular high Tc superconductors (frustrated Josephson Junction networks). We will discuss a procedure to discriminate between those two cases.
10:24AM S25.00011 Material Specific Characterization Dataset (MSCD): A Novel Computational System for Searching for High-Tc Superconductors, MICHAEL SCHAEFFER, O’PAUL ISIKAKU-IRONKWE¹, RTS Technologies, San Diego, CA 92126 — The search for novel high-Tc superconductors, HTSCs, involves billions of potential permutations and combinations in over 80 potential elements with thousands of structures. The need arises therefore for a quick-search system with predictive power. Using correlations of superconductivity with electronegativity, valence electrons, atomic number, formula weight, number of atoms and number of elements in the stoichiometry of superconductors, we have developed a simple predictive computational system called MSCD: Material Specific Characterization Dataset. MSCD of a superconductor defines and describes its stoichiometric structure in terms of averages of electronegativity, valence electrons, atomic number, formula weight, atoms-to-element ratio, ionic radii, first ionization energy and other associated ratios. We found that when the valence electrons and atomic numbers are the same, the materials have close Tcs. Also when the electronegativity and valence electrons are the same, they share the same crystal structure. Conversely, by tuning a material’s stoichiometry to correspond to a known superconductor’s MSCD, the material will become superconducting with close enough Tc. We give many examples of MSCD of superconductors and demonstrate the quick-search predictive power of MSCD in the search for novel HTSCs.

10:36AM S25.00012 Generalized Periodic System (GPS) for Superconductors, O’PAUL ISIKAKU-IRONKWE¹, MICHAEL SCHAEFFER², RTS Technologies, San Diego, CA 92126. In the search for new superconductors, the need arises for a periodic classification system with predictive power that includes all classes, types and families of superconductors. Using the Mendeleevian model of the Periodic Table of elements, based on increasing mass per atom, we reduce all superconductors to “super-atoms, super-elements,” and classify them into the same seven periods as the periodic table. We discover that for both pure elements and multi-element superconductors, the highest Tcs occur in period 4 superconductors with an argon shell core. The key difference between low Tc and high-Tc superconductors (HTSCs) in Period 4 is the presence of anions in the HTSCs. We observe that superconductors in the other periods lacking anions have a maximum Tc of about 40K; also at least three elements, with an average electronegativity of 2.0 or higher in a material is required for Tcs above 40K. The detailed GPS for superconductors which we have developed has predictive power and should be a guide in the design and search for high-Tc superconductivity.

10:48AM S25.00013 Tunable cobalt vacancies and related properties in LaCoxAs2, GANG WANG, SHUJIE SHEN, SHIFENG JIN, Institute of Physics, Chinese Academy of Sciences, QINGZHEN HUANG, NIST Center for Neutron Research, NIST, TIANPING YING, DANDAN LI, XIAOLONG CHEN, Institute of Physics, Chinese Academy of Sciences, QINGZHEN HUANG COLLABORATION — The ThCr2Si2-type structure, composed of covalently bonded transition metal-metalloid layers and the intermediate metals, is a common structure to around 1000 compounds. However the origin of transition metal vacancies and their effects on the properties of corresponding compounds have been poorly understood. Here we will report the investigation of structure, physical properties, and electronic structure for a series of nominal LaCoxAs2 (1.6 ≤ x ≤ 2.1). It is revealed that the Co occupancy can be tuned between 1.98(1) and 1.61(1). The structural analyses show that the existence of Co vacancies results from charge balance due to the formation of bond between As-As. These Co vacancies adjust the Curie temperature from 205 K to 47 K and increase the resistivity by more than 100%. First-principles calculations indicate that the Co vacancies weaken the spin polarization and reduce the density of states at the Fermi level, resulting in decreased Curie temperature and increased resistivity, respectively. The results address the importance of transition metal vacancies in ThCr2Si2-type structure and offer a reliable route to tune the magnetism of ThCr2Si2-type structure.

Session S26 DCP: Focus Session: At the Interface of Molecules and Materials: IV

204A - Bruce Weisman, Rice University

8:00AM S26.00001 Variance Spectroscopy: A New Bridge between Ensemble and Single-Particle Studies, R. BRUCE WEISMAN, Rice University — We have developed a new experimental technique that probes variations in the spectra from small regions of heterogeneous bulk samples resulting from statistical variations in composition. The method is demonstrated using suspensions of single-walled carbon nanotubes (SWCNTs), which contain mixtures of distinct structural species emitting photoluminescence at characteristic short-wave infrared wavelengths. Using dilute SWCNT suspensions, focused excitation beams, multichannel detection, and quick data collection, we capture several thousand emission spectra representing different spatial regions of the sample. The data sets are analyzed to find emission mean and variance values as a function of wavelength. The combined mean and variance spectra contain information unavailable from conventional methods, including the abundances of different emissive species and their relative emission efficiencies. The variance data are also analyzed for correlations between intensity fluctuations at different wavelengths to give novel two-dimensional maps that reveal the spectra of homogeneous sub-populations within heterogeneously broadened bulk spectra. The off-diagonal features in these maps expose spatially correlated concentration variations for nanotubes of different types, which arise from earliest stages of aggregation. Variance spectroscopy should prove a powerful new experimental tool for characterizing nanoparticle samples.

8:36AM S26.00002 TBD, LIBAI HUANG, Notre-Dame University — No abstract available.

9:12AM S26.00003 Multiphoton Photoemission/Velocity Map Imaging Studies of Single Particle Plasmonics: A New Ultrafast Laser Microscopy Tool for Nanomaterials, DAVID NESBITT, JILA, University of Colorado — The ability to look with ultrafast laser microscopy at nanoparticles has lead to an explosion of novel research opportunities in chemistry, physics and engineering. By way of example, this talk will attempt to present recent “vignettes” from our group in ultrafast photoelectron studies of novel plasmonic nanomaterials. In particular, scanning photoionization microscopy (SPIM) and dynamics of Au, Ag plasmonic rods, cubes, nanoshells, nanostars, etc) have been investigated at the single nanoparticle level, exploiting ultrafast laser pulses tuned over the nanoparticle plasmon resonance features and monitored by time-resolved, coherent multiphoton electron photoemission and velocity map imaging methods. The focus will be on simple physical pictures that help explain and interpret the underlying chemical physics on the nanoscale level.

In collaboration with Andrej Grubisic, NASA and Jacob Pettine, JILA, University of Colorado.

9:48AM S26.00004 Femtosecond nanoplasmonic dephasing of individual silver nanoparticles, RICHA MITTAL, RACHEL GLENN, ILYAS SAYTASHEV, MARCOS DANTUS, Michigan State University — Localized surface plasmon emission from individual silver nanoparticles and cluster of 100nm silver nanoparticles are probed by 15fs laser pulse replica generated by a pulse shaper. The Fourier transform of the nanoplasmonic coherence oscillations reveals different frequency components, phases, and dephasing rates for each nanoparticle. We find broadly distributed coherence dephasing rates that correspond to the cluster size. Our results provide insight into inhomogenous and homogenous broadening mechanisms in nanoplasmonic spectroscopy.
10:00AM S26.00005 Flicker Noise as a Probe of Electronic Interaction at Metal-Organic Interfaces. OLGUN ADAK, Department of Applied Physics and Applied Mathematics, Columbia University, New York, NY, ETHAN ROSENTHAL, Department of Physics, Columbia University, New York, NY, JEFFERY MEISNER, Department of Chemistry, Columbia University, New York, NY, ERICK ANDRADE, ABHAY PASPATHY, Department of Physics, Columbia University, New York, NY, COLIN NUCKOLLS, Department of Chemistry, Columbia University, New York, NY, MARK HYBERTSEN, Center for Functional Nanomaterials, Brookhaven National Labs, Upton, NY, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics, Columbia University, New York, NY — Understanding the nature of the charge transport at metal-organic interfaces is fundamental for achieving functional organic electronic devices. The charge transport at such interfaces can be achieved by through-bond and through-space interaction. While through-bond interaction dominates the electronic coupling in most systems, through-space interaction plays important role when through-bond interaction is suppressed, for example, due to quantum interference. In this talk, we first shed light into the origin of the flicker noise phenomenon in single molecule junctions and show how it can be used to distinguish between through-bond and through-space interaction at metal-organic interfaces using a scanning-tunneling microscope based break junction technique.

10:12AM S26.00006 Dynamic Oxidation of Gallium Phosphide Surface Tracked by Near Ambient Pressure XPS1. SYLWIA PTASINSKA, XUEQIANG ZHANG, University of Notre Dame — Both from applied and fundamental points of view, it is important that we have a detailed molecular-level understanding of gas-solid interface interactions, especially under operational conditions. Recent progress in in-situ instrumentations (e.g., Near Ambient Pressure X-ray Photoelectron Spectroscopy—NAP XPS), has enabled us to explore the physicochemical processes at the gas-solid interface over a varied range of pressures (up to mbar range), bridging the gap in our knowledge of interfacial interactions. Our recent investigations have focused on dissociative adsorption of small gas-phase molecules onto III-V semiconductors, which leads to surface oxidation. In this work, we carried out a pressure- and temperature-dependent study of GaP(111) oxidation in an O2 environment. Dynamic changes in chemical evolutions at the O2/GaP(111) interface were reflected in Ga 2p, O 1s, and P 2p spectra. Different oxidation states were observed, involving Ga2O, Ga2O3 and GaPO4 formation. A “phase diagram” of GaP(111) oxidation under various O2 pressures and temperatures can help us visualize transition states and gain more insights into chemical pathways leading to the final products of GaP oxidation. Further, an estimation of work function changes of the oxidized GaP surface was obtained under near ambient conditions.

1This material is based upon work supported by the U.S. Department of Energy Office of Science, Office of Basic Energy Sciences under Award Number DE-FC02-04ER15533.

10:24AM S26.00007 One Dimensional Surface Phonon Polaritons in Boron Nitride Nanotubes: High Field Confinement and Localization1. XIAOJI XU, Lehigh University, Bethlehem, PA, USA, BEHNOOD GHAMSARI, University of Ottawa, Ottawa, Ontario, Canada, DMITRI GOLBERG, WPI-MANA Centre of National Institute for Materials Science, Tsukuba, Ibaraki, Japan, PIERRE BERINI, University of Ottawa, Ottawa, Ontario, Canada, GILBERT WALKER, University of Toronto, Toronto, Ontario, Canada — We report the direct observation of one dimensional surface phonon polaritons (SPhPs) in boron nitride (BN) nanotubes at the mid infrared frequencies. High spatial resolution infrared near-field microscopy is used to spatially map the distribution of SPhPs in BN nanotubes. The polaritonic wavelength is experimentally found to be tunable by the tubular diameter as well as the configurations of the conductive supporting substrate. Effective refractive index of the SPhPs is found to be as high as ~70 for a thin BN nanotube. Furthermore, strong field localization and mitigation of the polariton damping is achieved with the use of a rough gold substrate. The randomly spaced nanometer-sized gold grains on the substrate act as distributed reflectors for propagating SPhPs, and confined the surface waves in the one-dimension nanotube. Such geometry allows high field concentration at mid infrared frequencies for chemical sensing and nonlinear optics. Given the analogy between phonon polaritons and plasmon polaritons, BN nanotubes can be used for building blocks for nano-photonic devices in the mid infrared frequencies, with design principles learnt from well-established metallic plasmonics.

1NSERC, ONR, MEXT Japan

10:36AM S26.00008 Characterization of Size, Anisotropy, and Density Heterogeneity of Nanoparticles by Sedimentation Velocity2. BORRIES DEMELER, University of Texas Health Sciences Center San Antonio — A critical problem in materials science is the accurate characterization of the size dependent properties of colloidal inorganic nanocrystals. Due to the intrinsic polydispersity present during synthesis, dispersions of such materials exhibit simultaneous heterogeneity in density, molar mass, and particle diameter. The density increments with respect to diameter and molar mass of these nanoparticles, if known, can then provide important information about crystal growth and particle size distributions. For most classes of nanocrystals, a mixture of surfactants is added during synthesis to control their shape, size, and optical properties. However, it remains a challenge to accurately determine the amount of passivating ligand bound to the particle surface post synthesis. The presence of the ligand shell hampers an accurate determination of the nanocrystal diameter. Using CdSe and PbS nanocrystals, and the silver nanoparticle (M4Ag44(p-MBA)30), as model systems, we describe how appropriate parametrizations of the flow equation can be used to extract high resolution composition information for mixtures of solutes that are heterogeneous in two out of three hydrodynamic parameters when the third is known. We show how this approach can yield important detail to the understanding of solution composition.

10:48AM S26.00009 Design of photo-absorption properties of hybrid organic-inorganic halide perovskite photovoltaic devices by cation manipulation. OSCAR GRANAS, SEAS, Harvard University and Dept. of Physics and Astronomy, Uppsala University, DMITRY VINICHENKO, Dept. of Chemistry and Chemical Biology, Harvard University, EFTHIMIOS KAXIARAS, Dept. of Physics, Harvard University — Photovoltaic devices based on hybrid organic-inorganic halide perovskite materials have lately sailed up as one of the most promising technologies for cost effective harvest of solar energy. In just a few years the efficiency has surpassed that of both conventional dye-sensitized- and organic solar cells. In this study we investigate the influence of the size of the cationic π-system on the electronic and structural properties of the perovskite photo-absorbing material. Using theoretical simulations we investigate key quantities for photovoltaic efficiency, such as band-gap, electron- and hole mass. We show that by changing the cation the band-gap and effective masses can be controlled. Structural changes are addressed, where we can see an enhanced influence of dispersion interaction as the cation polarizability increases. The effects of spin-orbit coupling is considered for both structural and electronic properties.

2Support from VR, the Ingegerd Bergh foundation, SNIC and XSEDE is gratefully acknowledged

Thursday, March 5, 2015 8:00AM - 11:00AM — Session S27 DCP: Focus Session: Solvation of Ions and Electrons II 204B - James M. Lisy, University of Illinois at Urbana-Champaign
8:00AM S27.00001 Spectral signatures of large amplitude vibrations in solvated ions. What do the intensities tell us about structure, bonding and dynamics? ANNE MCDOY, Department of Chemistry and Biochemistry, The Ohio State University — In this talk, I will discuss recent work in our group in which we made connections between proton transfer processes and hydrogen bonding and vibrational frequencies and intensities. Due to the large amplitude motions associated with proton transfer along a hydrogen bond, the vibrational spectra of these systems contain features that cannot be understood by the usual harmonic description of molecular vibrations. The breakdown reflects both the anharmonicity along this coordinate and coupling between this mode and other low frequency modes in these systems. It also reflects changes in the electronic structure as molecules vibrate. The presentation will draw from reported vibrational spectra for systems either containing intra- or intermolecular hydrogen bonds. Both the theoretical approaches used to study these systems and the insights gained from the studies will be described. The theoretical approaches range from the introduction of higher order terms to the harmonic analysis to adiabatic treatments in which the high- and low-frequency modes are treated at different levels of approximation and diffusion Monte Carlo studies in the full dimensionality of the system of interest.

8:36AM S27.00002 Ion Microsolvation Probed by Cryogenic Ion Trap Vibrational Spectroscopy, KNUT R. ASMIS, Wilhelm-Ostwald-Institut für Physikalische und Theoretische Chemie, Universität Leipzig, Germany — How ions are solvated in solution has intrigued physical chemists since the development of the theory of electrolytic dissociation by Arrhenius at the end of the nineteenth century. A molecular-level understanding of ion solvation is not only important for understanding chemical processes in solution, but also plays an important role in understanding the surface speciation and reactivity of aerosols. Infrared photodissociation (IRPD) spectroscopy of mass-selected ions, thermalized to cryogenic temperatures, allows for a detailed characterization of the influence of the stepwise solvation of an ion on its properties, one solvent molecule at a time. Recent advances in the vibrational spectroscopy of atmospherically-relevant microsolvated ions are highlighted, with particular emphasis on using isomer-specific detection schemes and measuring IRPD spectra down into the terahertz region of the electromagnetic spectrum.

9:12AM S27.00003 Solvation of ions investigated by DFT-MD simulations: from gas phase to oxide/liquid water interfaces, MARIE-PIERRE GAIGEOT, Universite d'Evry val d'Essonne-Paris, LAMBE UMR8587 — We investigate the solvation of ions by means of DFT-based molecular dynamics simulations (DFT-MD): ions solvated in clusters and ions solvated at solid oxide/liquid water interfaces. DFT-MD simulations provide a detailed knowledge of the solution structural properties at finite temperature, and dynamical anharmonic vibrational spectra extracted from DFT-MD are used to detail the relationships between vibrational features and structures. We present recent results for ionic clusters, i.e. solvation of Li+ by water molecules in Li+(H2O)3+3, including dynamical anharmonic vibrational spectra calculations and comparisons to IR-PD (InfraRed Pre-Dissociation) experiments at different temperatures, also including the dynamical formation of these clusters as it occurs in the experiments and the understanding of how high energy conformers can be formed and probed in theses experiments. We also present solvation of electrolytes at the quartz/liquid water interfaces. Here also, not only do we use DFT-MD in order to unravel the structure of these electrolytes at the interface between the oxide and liquid water but we also extract dynamical vibrational spectra to be compared to SFG (Sum Frequency Generation) experiments. With this comparison we aim at a detailed description of the interfacial structure and its related vibrational signatures.

These works have been done in collaboration with Prof J.M. Lisy (USA), Prof M. Sprik (UK), Prof M. Sulpizi (Germany), Dr V. Brites, and M. Pfeiffer.

9:48AM S27.00004 Anomalous Vibrational Signatures of Ions and Solvation, RYAN STEELE, University of Utah — Vibrational spectroscopy has long served as one of the key experimental windows into the inner workings of molecules. Developments in recent decades have continued to expand these techniques toward exotic ions and biologically relevant systems. Such developments have unearthed a wealth of anomalous vibrational signatures, many of which challenge canonical computational approaches to the simulation of vibrational spectra. In this presentation, the vibrational spectra of particularly challenging ionic systems will be explained via new computational simulations and theoretical frameworks. Examples include (a) strongly anharmonic—yet characteristic—vibrations in protonated, misfolded DNA base pairs, as well as (b) signatures of electronic motion in the vibrational spectra of water oxidation intermediates. Both cases demonstrate strong coupling of a unique electronic structure to quantum mechanical molecular motion. New methodology to enable the interface of these two requirements will also be briefly discussed.

10:24AM S27.00005 Modeling ion solvation in ethylene carbonate and propylene carbonate, AYSE ARSLANARGIN, THOMAS BECK, University of Cincinnati — Lithium-ion batteries (LIBs) and supercapacitors are expected to have important roles in renewable energy generation and in electric vehicles as electrochemical storage systems. Non-aqueous solvents such as ethylene carbonate (EC) and propylene carbonate (PC) are widely used as liquid electrolytes in LIBs. The electrolyte structure affects the efficiency of the ion transport, and understanding the solvent structure is essential for battery performance enhancements. This work investigates the thermodynamics of ion solvation in EC and PC. Free energy and enthalpy of solvation calculations have been conducted employing different force fields. Simulated annealing calculations have been performed to fit classical ion-solvent dimer interaction energies to quantum data. Non-bonded energy parameters are altered during the fitting process. The new parameters result in good agreement with the experimental free energy of solvation values, while the enthalpy of solvation results show deviations from the experimental data. These results suggest that classical models often do not accurately predict basic interactions in ion-solvent systems.

We acknowledge the support of the NSF (Grant No. CHE-1266105) and the Ohio Computer Center for a grant of supercomputer time.

10:36AM S27.00006 Mechanisms of Li-ion transport in bulk electrolytes and through solid-electrolyte interphases (SEI), DMITRY BEDROV, ZHE LI, University of Utah, OLEG BORODIN, Army Research Laboratory — Performance of Li-ion batteries is strongly coupled to the mechanisms of Li+ transport in bulk electrolytes, its transition through electrolyte/SEI interface and its transport through glassy SEI matrix. We will discuss the results of extensive atomistic molecular dynamics (MD) simulations using APPLEP polarizable force field and that have focused on understanding of correlations between the Li+ local structure and the mechanisms of Li+ transport in these systems. Specifically, we will address: a) Li+ transport in ionic liquid based electrolytes and the influence of organic solvent additives (ethylene carbonate and acetone), b) Li-ion transport through model SEIs comprised of alkyl dicarbonate anions and the influence of SEI contamination by Mn2+ cations, and c) transition of Li+ ions through SEI/electrolyte interfaces.
10:48AM S27.00007 Understanding Complex Ion Dynamics in Lithium-Ion Battery Electrolytes from First Principles1, MITCHELL ONG, VINCENZO LORDI, Lawrence Livermore National Laboratory, TIMO BREMER, ATILLA GYULASSY, Lawrence Livermore National Laboratory, University of Utah, ERIK DRAEGER, Lawrence Livermore National Laboratory, HARSH BHATIA, Lawrence Livermore National Laboratory, University of Utah, JOHN PASK, Lawrence Livermore National Laboratory — Lithium-ion secondary batteries are commonly used to power many consumer devices such as handheld phones, laptops, portable music players, and even electric vehicles. One of the key properties that influence the performance of lithium-ion batteries is the ionic conductivity of the electrolyte. This is dependent on the mobility of the Li ion in solution and also related to their solvation structure. In this work, we have performed first-principle molecular dynamics of an LiPF6 salt solvated in different organic solvents such as ethylene carbonate (EC), ethyl methyl carbonate (EMC) and a mixture of the two. We observed that the diffusivity of Li+ is correlated to the degree of Li+ solvation. Corresponding analysis for PF6− shows greater diffusivity than Li+ associated with a weakly-bound, poorly defined first solvation shell. Using a recent analysis method to study the distribution of directional change from relative angles at successive time intervals, we also characterize the complex motion of these ions and find distinct patterns for each ion in different organic solvents. These results provide valuable insight that can be used to improve the cycling rate of Li-ion batteries and potentially lead to the design of new electrolytes for better overall battery performance.

Thursday, March 5, 2015 8:00AM - 11:00AM –
Session S28 GMAG DMP: Focus Session: Kagome Antiferromagnets I 205 - Steven White, University of California, Irvine

8:00AM S28.00001 Exotic behavior of the magnetization process of the S=1/2 kagome-lattice antiferromagnet at one-third height of the saturation, TORU SAKAI, JAEA, SPRing-8, HIROKI NAKANO, University of Hyogo — The magnetization process of the S=1/2 Heisenberg antiferromagnet on the kagome lattice is studied by the exact numerical diagonalization [1]. We successfully obtain a new result of the magnetization process of a 42-site cluster in the entire range. Our analysis clarifies that the critical behavior around one-third of the height of the saturation is different from the typical behavior of the well-known magnetization plateau in two-dimensional systems. We also examine the effect of the \( \sqrt{3} \times \sqrt{3} \)-type distortion added to the kagome lattice. We find at one-third of the height of the saturation in the magnetization process that the undistorted kagome point is just the boundary between two phases that show their own properties that are different from each other. Our results suggest a relationship between the anomalous critical behavior at the undistorted point and the fact that the undistorted point is the boundary. A similar behavior of the magnetization process was also predicted in some other frustrated systems [2,3].

8:12AM S28.00002 Measuring symmetry fractionalization in topological orders: application to Z2 spin liquids on kagome lattice, YUAN-MING LU, Ohio State Univ - Columbus, MICHAEL ZALETEL, Station Q, Microsoft Research - Santa Barbara, ASHVIN VISHWANATH, University of California - Berkeley — Mounting numerical evidence for a gapped Z2 spin liquid in the kagome Heisenberg model urges us to develop methods to measure the global and space group symmetry properties of fractional excitations. We show that the universal symmetry characterization of fractional quasiparticles, the projective symmetry group (PSG), can be measured by a dimensional reduction scheme, which relates two-dimensional (2d) symmetric topological orders to 1d symmetry protected topological phases. This general framework allows us to unify Z2 spin liquids in different slave-particle (parton) constructions on the kagome lattice. It is also directly applicable to numeric results obtained in 2d DMRG studies.

8:24AM S28.00003 Chiral and Critical Spin Liquids in Spin-1/2 Kagome Antiferromagnet1, DONGNING SHENG, WEI ZHU, SHOUSHU GONG, Department of Physics and Astronomy, California State University, Northridge, GROUP OF PROF. D. N. SHENG TEAM — The spin liquids (SL) and their phase transitions have attracted much attentions. The extended kagome antiferromagnet emerges as the primary candidate for hosting both time reversal symmetry (TRS) preserving and TRS breaking SLs based on DMRG simulations. To uncover the nature of the novel transition between them, we study a minimum XY model with the nearest-neighbor (NN) \( (J_{xy}) \), the second and third neighbor couplings \( (J_{xy} = J_{x'y} = J_{y'x}) \). We identify the chiral SL (CSL) with the turn on of a small perturbation \( J'_{xy} \approx 0.06J_{xy} \), which is characterized by topological Chern number and conformal edge spectrum as the \( \nu = 1/2 \) fractional quantum Hall state. On the other hand, the NN XY model \( (J_{yy} = 0) \) is shown to be a critical SL, characterized by the gapless spin singlet and vanishing small spin triplet excitations. The phase transition from the CSL to the critical SL is driven by the collapsing of singlet gap. By following the evolution of entanglement spectrum, we find the transition takes place through the coupling of the edge states with opposite chiralities, which merge into the bulk and become gapless neutral excitations. The effect of the NN spin-\( z \) coupling is also studied, which leads to a phase diagram with an extended regime for the gapless SL.

1 U.S. Department of Energy, Office of Basic Energy Sciences under grant No. DE-FG02-06ER46305 (W.Z., D.N.S.), the National Science Foundation through grants DMR-1408560 (S.S.G).

8:36AM S28.00004 Chiral spin liquid in the extended Heisenberg model on the Kagome lattice, WENJUN HU, WEI ZHU, California State University, Northridge, YI ZHANG, Stanford University, SHOUSHU GONG, California State University, Northridge, FEDERICO BECCA, SISSA, DONGNING SHENG, California State University, Northridge, DONNA SHENG TEAM — We investigate the extended Heisenberg model on the Kagome lattice by using Gutzwiller projected fermionic states and the variational Monte Carlo technique. In particular, when both second- and third-neighbor super-exchanges are considered, we find that a gapped spin liquid described by non-trivial magnetic fluxes and long-range chiral-chiral correlations is energetically favored compared to the gapless U(1) Dirac state. Furthermore, the topological Chern number, obtained by integrating the Berry curvature, and the degeneracy of the ground state, by constructing linearly independent states, lead us to identify this flux state as the chiral spin liquid with \( C = 1/2 \) fractionalized Chern number.
demonstrate our method on different exactly solvable quantum dimer models on the kagomé lattice, and show that it can also be applied to generic dimer and
Institute of Technology — In topological quantum spin liquid states, the crystal symmetry operations often act on fractionalized spinon excitations in a
We established a quantum phase diagram for 0 < J2 < 0.25J1 and 0 ≤ J3 ≤ J1, where we find a q = (0, 0) Neel phase, a chiral spin liquid (CSL), a cuboc1 phase that breaks both time-reversal and spin rotational
symmetries, and a valence-bond solid at the neighbor of the Heisenberg model, where a possible Z2 spin liquid has been previously identified. Interestingly, the
classical cuboc1 phase could survive in the spin-1/2 system with strong quantum fluctuations, and the CSL emerges between the q = (0, 0) and the cuboc1
phases. We discover that the CSL has the short spin correlation pattern consistent with the cuboc1 phase, but the chiral order structure is totally different. The
CSL might be understood as a result of the competition between the q = (0, 0) and the cuboc1 phases in the presence of strong quantum fluctuations. We
further studied the quantum phase transitions from the CSL to the magnetically ordered phases, and to the possible Z2 spin liquid of the Heisenberg kagome
model. Interestingly, the exotic continuous topological phase transition might be realized in the system.

Quantum dimer model for the spin-1/2 kagome Z2 spin liquid . IOANNIS
ROUSOCHATZAKIS1, Leibniz Institute for Solid State and Materials Research, IFW Dresden, and Max Planck Institute for the Physics of Complex Systems,
Dresden Germany, YUAN WAN, OLEG TCHERNYSHYOV, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, Maryland 21218,
FREDERIC MILA, Institute of Theoretical Physics, Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland — We revisit the description of
the low-energy singlet sector of the spin-1/2 Heisenberg antiferromagnet on kagome in terms of an effective quantum dimer model. With the help of exact
diagonalizations of appropriate finite-size clusters, we show that the embedding of a given process in its kagome environment leads to dramatic modifications of
the amplitudes of the elementary loop processes, an effect not accessible to the standard approach based on the truncation of the Hamiltonian to the
nearest-neighbor valence-bond basis. The resulting parameters are consistent with a Z2 spin liquid rather than with a valence-bond crystal, in agreement with the
last density matrix renormalization group results.

Novel magnetic orderings in the kagome Kondo-lattice model . GIA-WEI CHERN,
KIPFTON BARROS, Los Alamos National Laboratory, JORN VENDERBOS, Massachusetts Institute of Technology, CRISTIAN BATISTA, Los Alamos National
Laboratory — We consider the Kondo-lattice model on the kagome lattice and study its weak-coupling instabilities at band filling fractions for which the Fermi
surface has singularities. These singularities include Dirac points, quadratic Fermi points in contact with a flat band, and Van Hove saddle points. By combining
a controlled analytical approach with large-scale numerical simulations, we demonstrate that the weak-coupling instabilities of the Kondo-lattice model lead to
exotic magnetic orderings. In particular, some of these magnetic orderings produce a spontaneous quantum anomalous Hall state.

Gapless and gapped spin liquids in frustrated spin-1/2 models . FEDERICO
BECCA, Consiglio Nazionale delle Ricerche (CNR) and International School for Advanced Studies (SISSA) — We present our recent numerical calculations on the
Heisenberg model on various two-dimensional lattices, showing that gapped and gapless spin liquids may be stabilized in highly-frustrated regimes. The
magnetically disordered phases can be described by considering Abrikosov fermions coupled to gauge fields. This approach gives a flexible and transparent
representation of a myriad of states, ranging from valence-bond solids to spin liquids with different properties, including chiral order. For the Kagome lattice,
we find that a gapless U(1) spin liquid with Dirac cones is competitive with previously proposed gapped spin liquids [1,2] also when small second- (J2) and
third neighbor (J3) antiferromagnetic couplings are considered on top of the nearest-neighbor (J1) super-exchange [3-5]. For the J1 − J2 model on finite clusters, a
gapped Z2 spin liquid can be stabilized in presence of a finite J2 super-exchange, with a substantial energy gain with respect to the gapless U(1) Dirac spin
liquid. However, this energy gain vanishes in the thermodynamic limit [4]. The presence of J3 favors a chiral spin liquid with non-trivial magnetic fluxes and
C = 1/2 fractionalized Chern number [5].

Quantum Selection of Order in an XXZ Antiferromagnet on a Kagomé
Lattice1, ALEXANDER CHERNYSHEV, Univ of California - Irvine, MICHAEL ZHITOMIRSKY, CEA Grenoble — By advancing the non-linear 1/S
expansion and the real-space perturbation theory we investigate quantum order-by-disorder selection of the ground state of the nearest-neighbor XXZ
antiferromagnet on the kagomé lattice. The two methods unanimously favor q = 0 over √3 × √3 magnetic order in a wide range of the anisotropy parameter
0 ≤ Δ ≤ 0.72. We demonstrated that the order selection is generated by topologically non-trivial spin-flip processes, presented a strong evidence of the rare case
of quantum and thermal fluctuations favoring different ground states, proposed a tentative S−Δ phase diagram of the model, and suggested further studies.

Detecting crystal symmetry fractionalizations in Z2 spin liquids on kagomé
lattice — insights from quantum dimer models . YANG QI, Perimeter Institute for Theoretical Physics, LIANG FU, Massachusetts Institute of Technology — In topological quantum spin liquid states, the crystal symmetry operations often act on fractionalized spinon excitations in a
fractionalized way. These features are important for identifying the symmetry enriched topological orders of the spin liquid states. In this work we propose a
simple way to detect signatures of such crystal symmetry fractionalizations from the symmetry representations of the ground state wave function. We
demonstrate our method on different exactly solvable quantum dimer models on the kagomé lattice, and show that it can also be applied to generic dimer and
spin models. Particularly our method can be used to distinguish several proposed candidates of Z2 spin liquid states on the kagomé lattice.
10:24AM S28.00011 Chern-Simons theory for Heisenberg spins on the Kagome Lattice, KRISHNA KUMAR, University of Illinois at Urbana-Champaign, KAI SUN, University of Michigan, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We study the problem of Heisenberg spins on the frustrated Kagome lattice using a 2D Jordan-Wigner transformation that maps the spins (hard-core bosons) onto a system of (interacting) fermions coupled to a Chern-Simons gauge field. This mapping requires us to define a discretized version of the Chern-Simons term on the lattice. Using a recently developed result on how to define Chern-Simons theories on a class of planar lattices, we can consistently study spin models beyond the mean-field level and include the effects of fluctuations, which are generally strong in frustrated systems. Here, we apply these results to study magnetization plateau type states on the Kagome lattice in the regime of XY anisotropy. We find that the 1/3 and 2/3 magnetization plateaus are chiral spin liquid states equivalent to a primary Laughlin fractional quantum Hall state of bosons with (spin) Hall conductivity $\frac{1}{3} e^2/h$ and semionic excitations. The $\frac{2}{3}$ plateau is a chiral spin liquid equivalent to the first Jain descendant. We also consider the spin-1/2 Heisenberg model on the Kagome lattice with a chirality-breaking term on the triangular plaquettes. This situation also leads to a primary Laughlin bosonic fractional quantum Hall type state with filling fraction 1/2.

10:36AM S28.00012 A discretized Chern-Simons gauge theory on arbitrary graphs and the hydrodynamic theory of fraction Chern insulators, KAI SUN, University of Michigan, KRISHNA KUMAR, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — In this talk, we study how to discretize the Chern-Simons gauge theory on generic planar lattices/graphs, with or without translational symmetries, embedded on arbitrary 2D closed orientable manifolds. We show that as long as a one-to-one correspondence between vertices and faces can be defined on the graph such that each face is paired up with a neighboring vertex (and vice versa), a discretized Chern-Simons theory can be constructed. We further verify that all the essential properties of the Chern-Simons gauge theory are preserved in the discretized setup. In addition, we find that the existence of such a one-to-one correspondence is not only a sufficient condition for discretizing a Chern-Simons gauge theory, but also a necessary one, if we want the discretized theory to be nonsingular and to preserve some key properties of this topological field theory. A specific example will then be provided, in which we discretize the Chern-Simons gauge theory on a tetrahedron. In addition, as one application of our discoveries, we present a hydrodynamic theory for (discrete) fractional Chern insulators.

10:48AM S28.00013 No-go constraints on topological order in symmetric Mott Insulators, MICHAEL ZALETEL, Stanford University, ASHVINISH VISHWANATH, University of California, Berkeley — The search for anyonic excitations in Mott insulators (quantum magnets with an odd number of $S = 1/2$ spins per unit cell) has an ally in the Hastings-Oshikawa-Lieb-Schultz-Mattis theorem, which guarantees that a symmetric, gapped Mott insulator must be topologically ordered. However, this theorem is silent on which topological orders are permitted. We point out a new class of symmetry induced constraints on the topological order of a Mott insulator. For example, we show that double semion topological order cannot be realized in a symmetric Mott insulator. An application of our result is to the Kagome lattice quantum antiferromagnet where recent numerical calculations of entanglement entropy indicate a ground state compatible with either toric code or double semion topological order. Our result rules out the latter possibility.

Thursday, March 5, 2015 8:00AM - 11:00AM — Session S29 GMAG: Correlated Electron Magnetism I 206A - William Ratcliff, National Institute of Standards and Technology

8:00AM S29.00001 Investigation of magnetic order in Sm$\text{Tr}_2\text{Zn}_20$ ($\text{Tr} = \text{Fe, Co, Ru}$) and Sm$\text{Tr}_2\text{Cd}_20$ ($\text{Tr} = \text{Ni, Pd}$), DUYGU YAZICI, B. D. WHITE, UC, San Diego, P.-C. HO, California State University, Fresno, N. KANCHANA-VATEE, K. HUANG, UC, San Diego, N. R. DILLEY, Quantum Design, M. B. MAPLE, UC, San Diego — Single crystals of the cage compounds Sm$\text{Tr}_2\text{Zn}_20$ ($\text{Tr} = \text{Fe, Co, Ru}$) and Sm$\text{Tr}_2\text{Cd}_20$ ($\text{Tr} = \text{Ni, Pd}$) have been investigated by means of electrical resistivity, magnetization, and specific heat measurements. The compounds SmFe$\text{Zn}_20$, SmRu$\text{Zn}_20$, and SmNi$\text{Cd}_20$ exhibit ferromagnetic order with Curie temperatures of $T_C = 47.4$ K, 7.6 K, and 7.5 K, respectively, whereas SmPd$\text{Cd}_20$ is an antiferromagnet with a Néel temperature of $T_N = 3.4$ K. No evidence for magnetic order is observed in SmCo$\text{Zn}_20$ down to 110 mK. The Sommerfeld coefficients $\gamma$ are found to be 57 mJ/mol-K$^2$ for SmFe$\text{Zn}_20$, 79.5 mJ/mol-K$^2$ for SmCo$\text{Zn}_20$, 258 mJ/mol-K$^2$ for SmRu$\text{Zn}_20$, 165 mJ/mol-K$^2$ for SmNi$\text{Cd}_20$, and 208 mJ/mol-K$^2$ for SmPd$\text{Cd}_20$. Enhanced values of Sommerfeld coefficients $\gamma$ and a quadratic temperature dependence of the electrical resistivity at low temperature for SmRu$\text{Zn}_20$ and SmPd$\text{Cd}_20$ suggest an enhancement of the quasiparticle masses due to hybridization between localized $4f$ and conduction electron states.

8:12AM S29.00002 Non-Fermi liquid behavior and the underscreened Kondo effect in Fe$_{1-x}$Co$_x$Si, YAN WU, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, 70803, BRAD FULLER, Department of Chemistry, Louisiana State University, Baton Rouge, 70803, JULIA CHAN, Department of Chemistry, The University of Texas at Dallas, Richardson, 75080, DAVID YOUNG, JOHN DITUSA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, 70803 — Mn or Co substitutions into the narrow band-gap insulator FeSi introduce charge carriers, either holes or electrons, accompanied by an equal density of more localized magnetic moments resulting in an interesting insulator-to-metal transition (IMT). Mn doping of FeSi exhibits an IMT where the nascent metal displays intriguing field sensitive non-Fermi-Liquid (NFL) behavior due to the underscreening of $S = 1$ impurity moments by the spin-1/2 hole carriers. Here, we present the results of an investigation of Fe$_{1-x}$Co$_x$Si ($0 < y < 0.1$). Our magnetization and susceptibility measurements indicate that for $y = 0.03$ Co-impurities also introduce a $S = 1$ magnetic moment that have a tendency to form singlets whereas for larger $y$ ferromagnetic interaction that grows with $y$. We have discovered a NFL behavior for $y < 0.03$ that evolves into the standard disordered Fermi-liquid form either by applying a magnetic field or by increasing $y$. The results of specific heat measurements on Fe$_{1-y}$Co$_y$Si, performed to explore the underlying underscreened Kondo mechanism, to investigate its variation with field and composition, and to compare with our Fe$_{1-y}$Mn$_y$Si data will be presented.

8:24AM S29.00003 Kondo versus indirect exchange: the role of the lattice and the actual range of RKKY interactions in real materials, ANDREW ALLERDIT, Northeastern University, ADRIAN FEIGUIN, Department of Physics, Northeastern University, CARLOS BUSSER, Department of Physics and Arnold Sommerfeld Center for Theoretical Physics, GEORGE MARTINS, Department of Physics, Oakland University, Rochester — Magnetic impurities embedded in a metal interact via an effective Ruderman-Kittel-Kasuya-Yosida (RKKY)coupled by the conduction electrons, which is commonly assumed to be long ranged, with an algebraic decay in the inter-impurity distance. However, they can also form a Kondo screened state that is oblivious to the presence of other impurities. We study the competition mechanisms between both effects on the square and cubic lattices by introducing an exact mapping onto an effective one-dimensional problem that we can solve with the density matrix renormalization group method (DMRG). We show a dramatic departure from the conventional RKKY theory, that can be attributed to the dimensionality and different densities of states, as well as the quantum nature of the magnetic moments. In particular, for dimension $d > 1$, Kondo physics dominates even at short distances, while the ferromagnetic RKKY state is energetically unfavorable. Our findings can have clear implications in the interpretation of experiments and for tailoring the magnetic properties of surfaces.
8:36AM S29.00004 Magnetism in CeRhIn$_5$ at high fields measured by NMR$^1$. A. M. MOUCHE, F. RONNING, E. D. BAUER, J. D. THOMPSON, Los Alamos National Laboratory, A. P. REYES, P. L. KUHNS, National High Magnetic Field Laboratory, Tallahassee, FL — De Haas-van Alphen measurements$^1$ of CeRhIn$_5$ at ambient pressure show an abrupt change in the Fermi surface volume at high fields, $H^*=30$ T, and low temperatures resulting in antiferromagnetic phases with a small Fermi surface at fields below $H^*$ and a large Fermi surface at fields $H$ such that $H^* < H < 50$ T. Nuclear magnetic resonance (NMR) is the ideal probe for these magnetic states as the microscopic details are still lacking. Our preliminary NMR measurements find the magnetic order for $H \parallel c$ is incommensurate up to 30 T as opposed to $H \perp c$ which transitions from incommensurate to commensurate at $H^*=2$ T.$^2$ Furthermore, we find that the magnetic moment decreases near 17 T for $H \parallel c$. These measurements provide an insight into the magnetic anisotropy of CeRhIn$_5$ and are a crucial step to studying its high field phases. $[1]$ L. Jiao et al., arXiv 1308.0294. $[2]$ S. Raymond et al., J. Phys. Cond. Matt. 19, 242204 (2007).

$^1$Work at Los Alamos was performed under the auspices of the U.S. DOE, Office of Basic Energy Science, Division of Materials and Engineering.

8:48AM S29.00005 The Kondo Temperature of Two-dimensional Electron Gas with Rashba Spin-orbit Coupling. LIANG CHEN, Mathematics and Physics Department, North China Electric Power University, JINHUA SUN, Department of Physics, Zhejiang University, HO-KIN TANG, Department of Physics, National University of Singapore, HAI-QING LIN, Beijing Computational Science Research Centre — We use the Hirsch-Fye quantum Monte Carlo method to study the single magnetic impurity problem in two-dimensional electron gas with Rashba spin-orbit coupling. We calculate the spin susceptibilities for different spin-orbit couplings, different Hubbard interactions, and different chemical potentials. The Kondo temperatures for different parameters are estimated by fitting the universal curves of spin susceptibilities. We find that the Kondo temperature is almost a linear function of the Rashba spin-orbit energy when the chemical potential is close to the edge of the conduction band, and when the chemical potential is far away from the band edge, the Kondo temperature is independent of the spin-orbit coupling. These results demonstrate that, for single impurity problem in this system, the most important reason to alter the Kondo temperature is the divergence of density of states near the band edge, and the divergence is induced by the spin-orbit coupling.

9:00AM S29.00006 Remarkably robust and correlated coherence and antiferromagnetism in (Ce$_{1-x}$La$_x$)Cu$_2$Ge$_2$ single crystals. H. HODOVANETS, S.L. BUD’KO, W.E. STRASZHEIM, V. TAUFOUR, E.D. MUN, H. KIM, P.C. CANFIELD, Ames Laboratory and Department of Physics & Astronomy, Iowa State University, Ames, IA — We present results of transport and thermodynamic measurements on La diluted Kondo lattice compound CeCu$_2$Ge$_2$. La-substitution suppresses $T_K$ in an almost linear fashion from $\sim 4$ K, for $x=0$, to below 0.6 K, for $x>0.8$. Curiously, the system also shows low temperature coherent scattering below $T_{coh}$, up to $\sim 0.9$ of La, indicating a small percolation limit $\sim 9\%$ of Ce that separates a coherent state from a single-ion Kondo impurity state. $T_{coh}(H)$ was found to have different functional dependencies in coherent and single-ion regimes. Surprisingly, $T_{coh}$ was found to be proportional to $T_N$ over wide range of $x$. For Ce concentrations, $y=1-x$, in the range $0.01 \leq y \leq 0.08$, $T_{coh}$ in the resistivity data is proportional to $y^{0.5}$ and field-dependent thermopower shows features as expected for the single-ion Kondo impurity. This work was supported by the Department of Energy, Basic Energy Sciences. Note CORP 0207CH11358 and the AFSOR-MURI grant No. FA9550-09-1-0603.

9:12AM S29.00007 Discovery of a 3d-transition-metal-based ferromagnetic Kondo lattice system$^1$. AHMAD US SALEHEEN, TAPAS SAMANTA, DANIEL LEPKOWSKI, ALOK SHANKAR, JOSEPH PRESTIGIACOMO, Louisiana State Univ - Baton Rouge, IGOR DUBENKO, ABDIEL QUETZ. Southern Illinois University, ROY MCDougALD JR., GREGORY MCCANDLESS, JULIA CHIAN, University of Texas at Dallas, PHILIP ADAMS, DAVID YOUNG, Louisiana State Univ - Baton Rouge, NAUSHAD ALI, Southern Illinois University, SHANE STADLER, Louisiana State Univ - Baton Rouge — The formation of a Kondo lattice results in a wide variety of exotic phenomena associated with the competition between the Kondo effect and the RKKY interaction, such as heavy fermions, non-Fermi liquid behavior, unconventional superconductivity, and so on. A quantum critical point (QCP) has been frequently observed at the boundaries of competing phases for antiferromagnetic materials. However, the existence of a ferromagnetic (FM) QCP is unclear. Moreover, FM Kondo lattices are rare. Here we report the discovery of a FM Kondo lattice system Mn$_{1-x}$Fe$_x$CoGe, which is the first example of a 3d-metal-based system (i.e., not rare-earth-based). Resistivity, magnetic susceptibility, heat capacity and thermopower studies on a single crystal sample indicate that the anisotropic FM kondo lattice has formed along c-axis. The signature of a spin density wave transition was also observed above the Kondo minimum, below which the resistivity follows a log(T) behavior.

$^1$This work was supported by the U.S. Department of Energy (Grant Nos. DE-FG02-13ER46946 and DE-FG02-06ER46291).

9:24AM S29.00008 Weak hybridization and isolated localized magnetic moments in the compounds CeT$_2$Cd$_20$ (T = Ni, Pd)$^1$. BENJAMIN WHITE, DUYGU YAZICI, Department of Physics, University of California, San Diego, PEI-CHUN HO, Department of Physics, California State University, Fresno, NORAVEE KANCHANAVATEE, NAVEEN POUSE, AARON FRIEDMAN, M. BRIAN MAPLE, Department of Physics, University of California, San Diego — Large Ce-Ce distances of 6.7-6.8 Å and weak hybridization between Ce 4f and itinerant electron states act to promote stable localized magnetic moments in the compounds CeT$_2$Cd$_20$ (T = Ni, Pd), but also conspire to severely limit the strength of the Ruderman-Kittel-Kasuya-Yosida (RKKY) magnetic exchange interaction that couples them. As a consequence, measurements of electrical resistivity, performed on single-crystalline samples of these new Cd-based compounds down to 0.138 K, were unable to resolve any evidence for magnetic order. In this presentation, we will compare measurements of the physical properties of CeT$_2$Cd$_20$ (T = Ni, Pd) under ambient and applied pressures with the reported properties of the isostuctural compounds CeT$_2$X$_20$ (T = transition metal; X = Al, Zn). We will use these comparisons to discuss the interplay of unit cell volume, hybridization, and the RKKY interaction and its role in establishing the ground states of the Ce-based “1-2-20” compounds.

$^1$Sample synthesis and physical properties measurements were supported by the U.S. DOE under grant no. DE-FG02-04ER46105. Measurements of electrical resistivity below 1 K were supported by the NSF under grants no. DMR-1206553 and no. DMR-1104544.

9:36AM S29.00009 Spin zero-point fluctuations in d-metals. VLADIMIR ANTROPOV, ANDREY KUTEPOV, Ames Laboratory, Ames, USA, KAY DEWHURST, SANGEETA SHARMA, MPI for Microstructure Physics, Halle, Germany — We analyze the structure and the magnetic systems at low temperatures.

Work at Los Alamos was performed under the auspices of the U.S. DOE, Office of Basic Energy Science, Division of Materials and Engineering.
9:48AM S29.00010 Itinerant magnetism in CaMn$_2$Al$_2$$_{}^1$, JACK SIMONSON, Farmingdale State College, LUCIA STEINKE, Brookhaven National Laboratory, SHELBY ZELLMAN, JEDEDIJA KISTNER-MORRIS, AKSHAT PURI, Stony Brook University, EVON ANDREWS, Farmingdale State College, MEAGAN ARONSON, Stony Brook University and Brookhaven National Laboratory — We report the synthesis and basic properties of CaMn$_2$Al$_2$, a new itinerant magnet that is nearly isosstructural with the known quantum critical compound YFe$_2$Al$_2$. Magnetic susceptibility measurements performed on single crystals reveal a cusp at 2 K. Electrical resistivity measurements similarly have a maximum at this temperature, and heat capacity measurements show a broad peak with total entropy of ~ 10%R ln 2. These results together with those of neutron diffraction measurements suggest that CaMn$_2$Al$_2$ is weakly magnetic and potentially close to a quantum critical point.

1Research supported by a DOD National Security Science and Engineering Fellowship via the AFOSR.

10:00AM S29.00011 Complex magnetism and strong electronic correlations in Ce$_x$PdGe$_2$, ANDREW GALLAGHER, TIGLET BESARA, NHMFL, Florida State Univ., JIFENG SUN, FAMU-FSU College of Eng., Dept. Chem. & Biomed. Eng., ORNL, JOE THOMPSON, FILIP RONNING, ANDREW GALLAGHER, TIGLET BESARA, NHMFL, Florida State Univ., JIFENG SUN, FAMU-FSU College of Eng., Dept. Chem. & Biomed. Eng., ORNL, ZHAO, Max Planck Institute for Chemical Physics of Solids, Dresden, 01069, Germany — We report structure/chemical results, magnetization, heat capacity, and electrical transport data for single crystals of the new tetragonal compound Ce$_x$PdGe$_2$. Single crystal X-ray diffraction shows that this material crystallizes in the space group P4$_2$/mmc — and is related to the $\alpha$-ThSi$_2$-type structure. Complicated magnetism, with a two-part antiferromagnetic phase transition at $T_{N,1} = 10.7$ K and $T_{N,2} = 9.6$ K and subsequent ferromagnetic ordering near $T_C \approx 2.25$ K is observed. The ordered ground state emerges from a lattice of Ce ions that are hybridized with the conduction electrons, as revealed by the enhanced effective moment of the specific heat $\gamma \approx 50$ mJ/mol-Ce-K$^2$ (extrapolated to $T = 0$ for $T < T_C$). Electrical structure calculations suggest that there is significant f-electron weight in the density of states near the Fermi energy, consistent with the enhanced specific heat, and that the Fermi surface includes sheets with distinct nesting vectors. We will discuss prospects for tuning the ferromagnetism to zero temperature to produce a ferromagnetic quantum phase transition: e.g., through applied pressure and/or chemical substitution.

10:12AM S29.00012 Transport and torque magnetometry measurements on CeAuSb$_2$, LISSHAN ZHAO, Max Planck Institute for Chemical Physics of Solids, Dresden, 10069, Germany, EDWARD YELLAND, University of St Andrews, Fife, KY16 9SS, UK, JAN BRUIN, High Field Magnet Laboratory, Toemooveld 7, 6525ED Nijmegen, the Netherlands, HIDE SAKAI, Department of Applied Physics, School of Engineering, University of Tokyo, 7-3-1 Hongo Bunkyo-ku, Tokyo 113-8656 Japan, ILYA SHEIKIN, LNCMI-Grenoble (Grenoble High Magnetic Field Laboratory), CNRS, Grenoble, France, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, Dresden, 10069, Germany — The tetragonal crystal CeAuSb$_2$ has a layered structure and orders antiferromagnetically at $T < 6K$. Under a c-axis magnetic field, the Néel temperature is gradually suppressed to zero at a possible field-tuned quantum critical point at about 6 T. Within this antiferromagnetic phase, between the QCP and about 2.8 T, there is an additional, novel phase. We report transport measurements on pure single crystals of CeAuSb$_2$, in fields of up to 35 T and from room temperature down to 100 mK. We also report torque magnetometry measurements. Unlike a recent report, we find single, sharp transitions into the novel phase. We discuss the nature of the novel phase.

The work presented is supported by TOPNES(Topological Protection and Non-Equilibrium States in Strongly Correlated Electron Systems research programme), the Engineering and Physical Sciences Research Council (EPSRC, UK) and Max Planck Institute for Chemical Physics of Solids(Dresden, Germany) etc.

10:24AM S29.00013 Effects of uni-axial strain on electronic nematic state in Sr$_2$RuO$_4$, DANIEL BRODSKY, MARK BARBER, University of St Andrews, Scotland and Max Planck Institute for Chemical Physics of Solids, Germany, CLIFFORD HICKS, Max Planck Institute for Chemical Physics of Solids, Germany, ROBIN PERRY, The University of Edinburgh, Scotland, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, Germany — Sr$_2$RuO$_4$ exhibits a novel electronic phase in the vicinity of a magnetic field-tuned quantum critical point. This phase shows strong anisotropy under weak symmetry-breaking fields, so it is thought to be intrinsically nematic. We study this phase under anisotropic strain, using a piezoelectric-based device that can both compress and tension samples. We find that the phase responds strongly to anisotropic strain, and discuss this result in the context of various theoretical models for the phase.

10:36AM S29.00014 Evidence of magnetic clusters in the disordered ferromagnet Ni-V close to the quantum critical concentration, RUIZHE WANG, S. UBAID-KASSIS, A. SCHROEDER, Kent State University, Kent, OH, P.J. BAKER, F.L. PRATT, ISIS Facility, U.K., S.J. BLUNDELL, T. LANCASTER, RUIZHE WANG, S. UBAID-KASSIS, A. SCHROEDER, Kent State University, Kent, OH, T. VOJTA, Missouri University of S & T, Rolla, MO — We report the results of muon spin relaxation ($\mu$SR) experiments in zero field (ZF) and transverse field (TF) as well as magnetization (M) data of Ni$_{1-x}$V$_x$ close to the critical vanadium concentration $x_c \approx 11.6$% where the onset of the ferromagnetic (FM) order is suppressed. This material features a prototypical disordered quantum phase transition (QPT) as seen in the temperature (T) and magnetic field (H) dependence of $M(H,T)$. In the paramagnetic phase (PM) above $x_c$, $M(H,T)$ is well described by non-universal power laws characterized by an exponent $\alpha(x-x_c)$, establishing a quantum Griffiths phase. Here, we focus on the FM side of the QPT below $x_c$. After subtracting the spontaneous magnetization $M_0$, we find that $M(H,T) - M_0$ also follows a power law in $H$ at low $T$ with an analogous non-universal exponent $\alpha(x_c-x)$. This is the first evidence of a quantum Griffiths phase within the FM phase in this disordered alloy. $\mu$SR in ZF recognized a broad field distribution below $x_c$, as evidence of magnetic spatial inhomogeneties in the FM phase. Different muon depolarization rates in TF and ZF reveal magnetic clusters already in the PM regime. These observed clusters are important generic ingredients of a disordered QPT.

10:48AM S29.00015 CeCu$_2$Ge$_2$: Challenging our understanding of quantum criticality, BIN ZENG, QIU ZHANG, DANIEL RHODES, National High Magnetic Field Lab, YASUYUKI SHIMURA, Institute for Solid State Physics, University of Tokyo, Kashiwa, Japan, DAIKI WATANABE, Department of Physics, Kyoto University, Kyoto, Japan, RYAN BAUMBACH, National High Magnetic Field Lab, PEDRO SCHLOTTMANN, Department of Physics, Florida State University, Tallahassee, Florida, TAKAO EBIIHARA, Department of Physics, Graduate School of Science, Shizuoka University, Shizuoka, Japan, LUIS BALICAS, National High Magnetic Field Lab — Here, we unveil evidence for a quantum phase transition in CeCu$_2$Ge$_2$. For the H/$c$-axis, no experimental evidence for QC. But as H is rotated towards the a-axis, these $\mu$S increase considerably becoming undetectable for $\theta > 56^\circ$. Around $H \approx 30$ T the resistivity becomes $\propto T$ which, coupled to the divergence of $\mu$, indicates the existence of a field-induced QC point ($H = 0$ K). This observation, suggesting FS hot spots associated with the SDW nesting vector, is at odds with current QC scenarios for which the continuous suppression of all relevant energy scales at $H_c(\theta,T)$ should lead to a line of quantum-critical points in the H-$\theta$ plane. Finally, we show that the complexity of its magnetic phase diagram(s) makes CeCu$_2$Ge$_2$ an ideal system to explore field-induced quantum tricritical and QC end points.

8:00AM S30.00001 Magnetic properties of Ce(Fe\textsubscript{1-x}Co\textsubscript{x})\textsubscript{11}Ti and effects of H and N doping\textsuperscript{1}, LIQIN KE, VLADIMIR ANTPEROPOV, Ames Laboratory — The intrinsic magnetic properties of Ce(Fe\textsubscript{1-x}Co\textsubscript{x})\textsubscript{11}Ti related systems have been studied using electronic structure calculations. Both CeFe\textsubscript{11}Ti and CeCo\textsubscript{11}Ti have uniaxial magnetic anisotropy. Calculations of the magnetic anisotropy of Ce(Fe\textsubscript{1-x}Co\textsubscript{x})\textsubscript{11}Ti show that the easy magnetization direction changes from uniaxial to in-plane and then back to uniaxial with increasing Co content. This provides an explanation for the interesting non-monotonic behavior of coercivity observed in experiments. The effects of H and N doping on intrinsic magnetic properties are also studied. Both H and N doping increase the magnetization and Curie temperature while N doping has a stronger effect than H doping. Calculated \textit{Tc} enhancements agree well with experiments and it is found that volume and chemical effects contribute nearly equally to the \textit{Tc} enhancement with N doping. The uniaxial magnetic anisotropy decreases as N doping increases which we believe is consistent with the change in\textit{Tc}. However, a rare-earth idiosyncrasy effect is not only due to the changing of the anisotropy of Ce atom as generally believed. Instead, the decrease of MAE is a collective effect that anisotropy contributions from transition metal sites are also changed with N doping.

\textsuperscript{1}This work is supported by “Novel High Energy Permanent Magnet Without Critical Elements” project by ARPA-E of U.S. Department of Energy.

8:12AM S30.00002 First principles study of doping effects in NdFe\textsubscript{11}Ti permanent magnet compound, YOSUKE HARASHIMA, NRI, “RICS,” AIST; ESICMM, NIMS, KIYOHISA TERAKURA, NRI, “RICS,” AIST; NIMS, HIROI KINO, MANA, NIMS; ESICMM, SHOJI ISHIBASHI, NRI, “RICS.” Green-Innovative Magnetic Material Research Center, AIST , TAKASHI MIYAKE, NRI, “RICS,” ESICMM, NIMS, Green-Innovative Magnetic Material Research Center, AIST — Permanent magnet compounds are required to have large magnetization and strong uniaxial magnetocrystalline anisotropy. NdFe\textsubscript{11}Ti which is one of the ThMn\textsubscript{12}-type rare-earth 3d-transition metal compounds has large magnetic moment due to its high content of Fe. The magnetization and magnetocrystalline anisotropy of the compound can be tuned by nitrogen doping at interstitial sites. NdFe\textsubscript{11}Ti is a good candidate for a permanent magnet compound. Then, it is interesting whether there is another dopant that enhances the magnetic properties. We have investigated doping effects of NdFe\textsubscript{11}Ti X where X=B, C, N, O, and F by using first principles calculation. These dopants increase the magnetization, and the increase is especially large for N, O, and F doping. The magnetocrystalline anisotropy is estimated from the crystalline electric field parameter \textit{<r>}. NdFe\textsubscript{11}Ti has negative value of \textit{<r>} that implies the compound has in-plane anisotropy. As the atomic number of the dopant increases from B to N, \textit{<r>} is increased, and NdFe\textsubscript{11}Ti has a large positive value, suggesting strong uniaxial anisotropy. Then, \textit{<r>} turns to decrease as the dopant is changed from N to O to F, and NdFe\textsubscript{11}Ti has a large negative value. In conclusion, we found that N is the most appropriate dopant among B, C, N, O, and F.

8:24AM S30.00003 Hyperfine fields of Fe in Nd\textsubscript{2}Fe\textsubscript{14}B and Sm\textsubscript{2}Fe\textsubscript{17}N\textsubscript{3}\textsuperscript{1}, HISAZUMI AKAI, Univ of Tokyo, MASAKO OGURA, Osaka Univ — High saturation magnetization of rare-earth magnets originates from Fe and the strong magnetic anisotropy stems from f-states of rare-earth elements such as Nd and Sm. Therefore, the hyperfine fields of both Fe and rare-earth provide us with important pieces of information: Fe and rare-earth anisotropy. Nd\textsubscript{2}Fe\textsubscript{14}B and Sm\textsubscript{2}Fe\textsubscript{17}N\textsubscript{3} enable us to detect site dependence of the local magnetic moment and magnetic anisotropy (Fe sites also contribute to the magnetic anisotropy) while rare-earth NQR directly give the information of electric field gradients (EFG) that are related to the shape of the f-electron cloud as well as the EFG produced by ligands. In this study we focus on the hyperfine fields of materials used as permanent magnets, Nd\textsubscript{2}Fe\textsubscript{14}B and Sm\textsubscript{2}Fe\textsubscript{17}N\textsubscript{3} from theoretical points of view. The detailed electronic structure together with the hyperfine interactions are discussed on the basis of the first-principles calculation. In particular, the relations between the observed hyperfine fields and the magnetic properties are studies in detail. The effects of doping of those materials by other elements such as Dy and the effects of N adding in Sm\textsubscript{2}Fe\textsubscript{17}N\textsubscript{3} will be discussed.

8:36AM S30.00004 Correlations, spin-charge separation, and magnetic anisotropy, RALPH SKOMSKI, PRIYANKA MANCHANDA, Department of Physics and Astronomy and NCMN, University of Nebraska, Lincoln, NE 68588 — Much of the physics of condensed matter reflects electron-electron correlations. On an independent-electron level, correlations are described by a single Slater determinant with broken spin symmetry. This approach includes Hund’s rule correlations as well as the LSDA and LSDA+U approximations to density-functional theory (DFT). However, from Kondo and heavy-fermion systems it is known that the independent-electron approach fails to describe spin-charge separation in strongly correlated systems, necessitating the use of two or more Slater determinants. Using first-principle and model calculations, we show that spin-charge separation strongly affects the leading rare-earth anisotropy contribution in top-end permanent magnet materials such as Nd\textsubscript{2}Fe\textsubscript{14}B and SmCo\textsubscript{5}. Explicit correlation results are obtained for two limiting cases. First, we derive the density functional for tripositive rare-earth ions in a Bethe-type crystal field. The potential looks very different from the LSDA\textsuperscript{+U} potentials, including gradient corrections. Second, we use a simple model to show that Kondo-type spin-charge separation yield a rare-earth anisotropy contribution in the independent-electron approach. This research is supported by DOE (DE-FG02-04ER46152).

8:48AM S30.00005 Dy-Free Nd-Fe-B Based Permanent Magnets, ARJUN PATHAK, MAHMUD KHAN, KARL GSCHEINZENER, JR., RALPH MCCALLUM, VITALIJ PECHARSKY, The Ames Laboratory, US DOE, Iowa State University, Ames, Iowa 50011-3020, USA — Nd\textsubscript{2}Fe\textsubscript{14}B based permanent magnets are currently the state-of-the-art for high performance magnets. The prototype crystalize in the \textit{P4}_2/\text{mmm} tetragonal crystal structure, where the Nd atoms occupy the 4f and 4g sites, Fe atoms occupy six different atomic sites (16\textit{k}, 16\textit{j}, 8\textit{j}, 8\textit{j}, 4\textit{e}, 4\textit{c}), and B occupies only the 4g site. The leading contribution to the magnetocrystalline anisotropy in Nd\textsubscript{2}Fe\textsubscript{14}B energy comes from the Nd ions, which strongly prefer a \textit{c}-axis alignment at ambient temperature. Nd\textsubscript{2}Fe\textsubscript{14}B permanent magnet has excellent magnetic properties at room temperature but has poor high temperature properties (\textit{T}_{\text{Curie}}>400 K). A small amount of Dy (up to 10\%) is substituted for Nd in Nd\textsubscript{2}Fe\textsubscript{14}B to increase the high temperature performance. Although Dy containing Nd\textsubscript{2}Fe\textsubscript{14}B magnets are desired for high temperature applications, the high price and limited supply of Dy urges the development of Dy-free permanent magnets. Here, we discuss the magnetic properties of several Dy-free Nd-Fe-B based nanostructured magnets and propose alternatives for Dy-based Nd\textsubscript{2}Fe\textsubscript{14}B permanent magnets for high temperature applications such as electric drive motors and wind turbines. This work was supported by the U.S.DOE, ARPA-E, Rare Earth Alternatives in Critical Technologies for Energy (REACT). The research was performed at the Ames Laboratory which is operated for the U.S. DOE by Iowa State University under contract #DE-AC02-07CH11358.
9:00AM S30.00006 Axial Magnetic Anisotropy from Two Systems Fe$_x$B and Co$_2$B with Planar Anisotropy , VALENTIN TAUFOUR, TEJ LAMICHHANE, SERGEY L. BUDKO, ANTON JESCHE, ALAN I. GOLDMAN, KEVIN W. DENNIS, R. WILLIAM McCALLUM, VLADIMIR ANTROPOV, PAUL C. CANFIELD, Ames Laboratory / Iowa State University, Ames, IA 50011, USA — Growth of single crystals of (Fe$_{1-x}$Co$_x$)$_2$B (0 ≤ x ≤ 1) and detailed characterization of their magnetic properties will be presented. Despite the fact that both Fe$_x$B and Co$_x$B show a planar anisotropy at room temperature, we observe a uniaxial anisotropy at intermediate doping which makes (Fe$_x$Co$_{1-x}$)$_2$B a promising system for permanent magnet applications in a system without rare-earth element. Comparison with recent band structure calculations will be presented. The temperature dependence of the anisotropy measured on single crystals from 2 K to 1000 K shows some unusual variations with an increase of the magnetic anisotropy with increasing temperature at some specific substitution.

This work is supported by the Critical Materials Institute, an Energy Innovation Hub funded by the US DOE and by the Office of Basic Energy Science, Division of Materials Science and Engineering. Ames Laboratory is operated for the US DOE by Iowa State University under Contract No. DE-AC02-07CH11358.

9:12AM S30.00007 Electronic structure calculations of the temperature dependence of magnetocrystalline anisotropy in (Fe$_{1-x}$Co$_x$)$_2$B alloys$^1$, IVAN ZHURAVEV, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, Nebraska 68588, USA, LIQIN KE, VLADIMIR ANTROPOV, Ames Laboratory, Ames, Iowa 50011, USA, KIRILL BELASHCHENKO, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, Nebraska 68588, USA — A number of important magnetic systems exhibit anomalous temperature dependence of the magnetocrystalline anisotropy (MCA), such as a spin-reorientation transition or an MCA increasing with temperature. The mechanisms of such anomalies vary. In Nd-Fe-B magnets the spin-reorientation transition is likely due to the ordering of Nd spins, while in MnBi the MCA quickly increases with temperature due to thermal expansion. (Fe$_{1-x}$Co$_x$)$_2$B alloys present another example of highly anomalous temperature-dependent MCA. Our calculations show that these anomalies are not due to thermal expansion. We therefore study the effects of spin disorder on MCA and on the electronic structure of this system using our implementation of the vector disordered-local moment (DLM) method with spin-orbit coupling within the Green’s function-based linear muffin-tin orbital (LMTO) method. We also consider the influence on MCA of the spin moments of Fe and Co. The results show that the observed anomalies are associated with the effects of thermal spin fluctuations on the electronic structure.

9:24AM S30.00008 Superparamagnetism in the martensitic phase of the magnetic shape-memory alloys Ni$_{50-x}$Co$_{10}$Mn$_x$Sn$_{10}$ , SHAOJIE YUAN, Florida state univ, National High Magnetic Lab, PHILIP KUHNS, MICHAEL HOCH, NHMFL, JAMES BROOKS, Florida state univ, National High Magnetic Lab, ARNEIL REYES, NHMFL, VIJAY SRIVASTAVA, Aerospace Engineering and Mechanics, university of Minnesota, DANIEL PHELAN, Aerospace Engineering and Mechanics at university of Minnesota, RICHARD JAMES, CHRIS LEIGHTON, Chemical Engineering and Materials Science at university of Minnesota, NHMFL TEAM, UNIVERSITY OF MINNESOTA TEAM — The Ni-Mn based shape magnetic memory alloys have attracted considerable attention because of their interesting magnetic properties, including intrinsic superparamagnetism and intrinsic exchange-bias effects, which are found in the martensitic phase of these materials. Here, we report on the results of zero-field $^{59}$Mn NMR measurements made on the alloys Ni$_{50-x}$Co$_{10}$Mn$_x$Sn$_{10}$ with x=7 and x=14. The results show that Co substitution not only changes the electronic configuration of a fraction of the Mn ions but also alters the magnetic interaction among these ions, leading to marked changes in the low temperature antiferromagnetic and ferromagnetic components compared to x=0. For both x=7 and x=14 our analysis shows that the Mn ions form a new ferromagnetic nanoclusters in small Co rich regions of the sample. Based on the temperature dependence of the NMR spectral features, we propose a method to estimate the superparamagnetic cluster size distribution.

9:36AM S30.00009 Huge Magnetocrystalline Anisotropy in UMn$_2$Ge$_2$ , DAVID PARKER, Oak Ridge National Laboratory, NIRMAL GHIMIRE, Los Alamos National Laboratory, RYAN BAUMBACH, National High Magnetic Field Laboratory, Florida State Univ., Tallahassee FL, ERIC BAUER, Los Alamos National Laboratory, LING LI, DAVID MANDRUS, Univ. of Tennessee, Knoxville TN, JOHN SINGLETON, Los Alamos National Laboratory, DAVID SINGH, Oak Ridge National Laboratory — We present an experimental finding, as predicted theoretically by one of the authors, of an anomalously high uniaxial magnetic anisotropy energy - approaching 15 MJ/m$^3$ in the extremely strong Uranium spin-orbit coupling and the sizable orbital moment (approaching 2$\mu_B$) for U. This work is supported by the Critical Materials Institute, an Energy Innovation Hub funded by the US DOE and by the Office of Basic Energy Science, Division of Materials Science and Engineering. Ames Laboratory is operated for the US DOE by Iowa State University under Contract No. DE-AC02-07CH11358.

9:48AM S30.00010 Magnetic Anisotropy in UMn$_2$Ge$_2$ , MORGANN BERG, University of Texas at Austin, ALEX DE LOZANNE, RYAN BAUMBACH, JEEHOON KIM, ERIC BAUER, JOE THOMPSON, FILIP RONNING, Los Alamos National Laboratory — We present an experimental finding, as predicted theoretically by one of the authors, of an extremely high uniaxial magnetic anisotropy energy - approaching 15 MJ/m$^3$ in the 122 actinide ferromagnet UMn$_2$Ge$_2$. This large MAE appears to originate in the extremely strong Uranium spin-orbit coupling and the sizable orbital moment (approaching 2$\mu_B$) on this atom. Implications for other 122 compounds are discussed.

10:00AM S30.00011 Lattice Monte Carlo Simulation Study Atomic Structure of Alnico 5-7 Permanent Magnets , MANH CUONG NGUYEN, XIN ZHAO, CAI-ZHUANG WANG, KAI-MING HO, Ames Lab, U.S. DOE and Department of Physics and Astronomy, Iowa State University — The fluctuations and increases in price and the issues in supply recently of rare earth metals re-heated the sought for non-rare earth permanent magnets. Alnico permanent magnets have been considered as promising replacements for rare earth-based permanent magnets due to the superiors in the magnetic performance at high temperature and the abundances of the constituent elements. Using lattice Monte Carlo simulation in combination with cluster expansion method we study the atomic structure of alnico 5-7 permanent magnets. We observed the phase separation into FeCo-rich and NiAl-rich phases in alnico 5-7 at low temperature, which is consistent with experiment. The phase boundary between these two phases is quite sharp. Both FeCo-rich and NiAl-rich phases are in B2 ordering with Fe and Al sitting on 7-site and Ni and Co sitting on 7-site. The degree of order of NiAl-rich phase is quite higher than that of FeCo-rich phase and it decreases with temperature slower than that of FeCo-rich phase. We also observed a small and increasing with annealing temperature magnetic moment in NiAl-rich phase, implying that the magnetic properties of alnico 5-7 could be improved by lowering annealing temperature to diminish the magnetism in NiAl-rich phase.
applications in hybrid molecular nano-spintronics. Dip-pen nanolithography. This could open a new pathway to controlled nanoscale manipulation of magnetism in dilute magnetic semiconductors with potential preparation of the (Ga,Mn)As surface, self-assembled monolayer patterns of organic molecules with sub-75 nanometer linewidth were successfully created by molecular-beam epitaxy, and the organic molecules were deposited by solution-based self-assembly or vacuum thermal evaporation. Charge-transfer molecules coverage could modify the magnetism of the dilute ferromagnetic semiconductor thin films. Mn-doped GaAs thin films with various thicknesses were grown by We investigated the effects of electron and hole donor molecule species on the surface of (Ga,Mn)As thin films with a focus on elucidating how the molecular...magnetic properties of $\varepsilon$-$\text{Fe}_2\text{O}_3$$^1$. We acknowledged partial financial support from the Elemental Strategy Initiative Center for Magnetic Materials (ESICMM) under outsourcing project of MEXT. The computation was partly carried out on the K-computer (Grant No. hp120086).

First principles study of Al substituted strontium hexaferrite. We have studied the site occupancy and magnetic properties of Al substituted M-type Strontium hexaferrite, SrFe$_{12-x}$Al$_x$O$_{19}$ with $x = 0.5$ and $x = 1.0$ using density functional theory (DFT). For $x = 0.5$ case, an Al atom preferentially occupy the 2a site at T = 0 K, this trend endures up to 220 K beyond this temperature Al atom is more likely to occupy the 12k site. For the $x = 1.0$ case, the site preference probability is maximum when two Al atoms occupy the 2a and the 12k sites. We found that magnetic anisotropy of SrFe$_{12-x}$Al$_x$O$_{19}$ increases as the concentration of Al atoms increases, while there is a reduction in the magnetic moment per unit cell by 5µB and 10µB in the case of $x = 0.5$ and $x = 1.0$, respectively. Our results agree with the available experimental results on Al substituted hexaferrite.
8:12AM S31.00002 Different symmetry of the magnetization-direction dependence between the impurity band and valence band in GaMnAs1, IRiya Muneta, Toshiki Kanaki, Shinobu Ohya, Masaki Tanaka. The University of Tokyo — In semiconductors with heavily doped with nonmagnetic shallow acceptors, an impurity band (IB) is formed around the valence band (VB) top and merged with VB. As a result, the parabolic VB top is strongly deformed in a non-parabolic dispersion. In GaMnAs, however, the VB top keeps the parabolic dispersion though there is energy overlap between VB and IB [1-3], which is completely different from the conventional nonmagnetic semiconductors. Here, we measure tunneling anisotropic magnetoresistance on GaMnAs tunnel devices in a spectroscopic way [4-6], analyze the magnetization-direction and energy dependence of the density of states (DOS), and investigate the different symmetry between VB and IB to clarify the mysterious overlap between the two bands. We find that the magnetization-direction dependence of VB DOS is mainly four-fold symmetry along [100] which is the same as the crystal symmetry, while that of IB DOS is mainly two-fold symmetry along [110] unlike the crystal symmetry. These results reveal the unique band structures of Mn-doped III-V ferromagnetic semiconductors. [1] S. Ohya et al., Nat. Phys. (2011). [2] I. Muneta et al., APL (2013). [3] M. 8:24AM S31.00003 Anisotropic magnetic dynamics in (Ga,Mn)As film1, Xiang Li, Sinjing Dong, Tahee Yoo, Sergio Mello, Xinyu Liu, Jacek Furdyna, Margaret Dobrowolska, Department of Physics, University of Notre Dame — (Ga,Mn)As shows excellent magnetic properties which are usually described by a single-domain model. In this study, we perform a systematic investigation of ac magnetic susceptibility in (Ga,Mn)As films as a function of temperature and field carried out in parallel with dc magnetization measurements. A single ac susceptibility peak is observed close to T_C for the field along [1-10] orientation; a single peak is seen close to 22 K along [110]; and both peaks are observed along [100]. Detailed analysis indicates that the peak near T_C is related to the para-ferromagnetic transition. And the ferromagnetic domains nucleate with their easy axis aligned with [1-10] direction, involving 180° interaction along the easy axis. The peak near 22 K, on the other hand, originates from magnetization switching between two biaxial easy axes separated by a small angle, which is induced by the competition between uniaxial and cubic anisotropy. Dynamic properties emerging from the distinct frequency dependences of the ac susceptibility in these two temperature regions, such as magnetic relaxation times, have been analyzed using various models. Investigations in patterned films will be carried out as well.

8:36AM S31.00004 Theory of the Novel Mn-doped II-IV-V Dilute Magnetic Semiconductors. James Glasbrenner, NRC/NRL — A recently discovered magnetic semiconductor Ba_{1-x}K_x(Zn_{1-y}Mn_y)As_2, with its decoupled spin and charge doping, provides a unique opportunity to elucidate the microscopic origin of the magnetic interaction and ordering in dilute magnetic semiconductors (DMS). We show that (i) the conventional density functional theory (DFT) accurately describes this material, and (ii) the magnetic interaction emerges from the competition of the short-range superexchange and a longer-range interaction mediated by the itinerant As holes, coupled to Mn via the Schrieffer-Wolff ρ-d interaction representing an effective Hund’s rule coupling, J_H^{ρd}. The key difference between the classical double exchange and the actual interaction in DMS is that an effective J_H^{ρd}, as opposed to the standard Hund’s coupling J_H, depends on the Mn d-band position with respect to the Fermi level, and thus allows tuning of the magnetic interactions. The physical picture revealed for this transparent system may also be applicable to more complicated DMS systems.

9:12AM S31.00005 Annealing studies of ion-beam irradiated GaMnAs thin films, Segio L.A. Mello, M.M. Sant’Anna, C.F.S. Codeço, Universidade Federal do Rio de Janeiro, Brazil, S. Dong, T. Yoo, X. Li, X. Liu, J.K. Furdyna, University of Notre Dame — We have studied the effect of ion-beam irradiation on GaMnAs films by means of systematic transport and magnetization measurements. Both the magnetization and the conductivity of such samples decrease as a result of increase of disorder and defects in the system caused by the irradiation process. In this study we investigate the recovery of such irradiated samples, by measuring their magnetization and transport properties before and after annealing. Our preliminary transport measurements on annealed-irradiated samples show significant enhancement of the transport properties of the films (revealed by the increase of conductivity and of the critical temperature). Samples comparison of resistivity curves ρ(T) of annealed-irradiated and annealed-non-irradiated samples indicates that most defects created by low fluences of ion beams are similar to those created while growing the samples. This is evidenced by the fact that low ion-fluence irradiation ρ(T) curves of annealed-irradiated and annealed-non-irradiated samples nearly match. For high ion-fluence, however, the sample properties cannot be fully recovered by annealing. This suggests that the nature of a minor fraction of irradiation-created defects is different from those created during sample growth.

9:24AM S31.00006 Spin relaxation time dependence on optical pumping in GaAs:Mn, Veronika Burobina, University of California, San Diego, Christian Binek, University of Nebraska-Lincoln — We analyze the dependence of electron spin relaxation time on optical pumping in a partially-compensated acceptor semiconductor GaAs:Mn using analytic solutions for the kinetic equations of the charge carrier concentrations [1]. Our results are applied to previous experimental data of spin-relaxation time vs. excitation power for magnetic concentrations of approximately 10^17cm^{-3} [2]. The agreement of our analytic solutions with the experimental data supports the mechanism of the earlier-reported atypically long electron-spin relaxation time in the magnetic semiconductor.

9:36AM S31.00007 Visible-light electroluminescence in Mn-doped GaAs light-emitting diodes, Daiki Maruo, Department of Electrical Engineering and Information Systems, University of Tokyo, Pham Nam Hai, Department of Physical Electronics, Tokyo Institute of Technology, Masaaki Tanaka, Department of Electrical Engineering and Information Systems, University of Tokyo — We demonstrate visible-light electroluminescence (EL) due to d-d transitions in GaAs:Mn based LEDs. We design p-n junctions with a p^+GaAs:Mn layer, in which at a reverse bias voltage (-3 to -6 V), an intense electric field builds up in the depletion layers of the p^-n junctions. Holes are injected to the depletion layer by Zener tunneling from the conduction band or by diffusion of minority holes from the valence band of the n-type layer. These holes are accelerated by the intense electric field in the depletion layer, and excite the d electrons of Mn in the p^+ GaAs:Mn layer by impact excitations. We observe visible-light emission at E_1 = 1.89 eV and E_2 = 2.16 eV, which are exactly the same as the 4T_1 → 4A_1 and 4A_2 → 4T_1 transition energy of Mn. The threshold voltage for observation of visible-light EL is -4 V, corresponding to -(E_1 + E_2)/e. This indicates that the impact excitation is most effective for the one step excitation from the ground state 4A_1 to the highest excited state 4A_2.
10:00AM S31.00008 Magnetic Circular Dichroism (MCD) Studies on MOVPE Grown InMnSb and InMnAs 1, 2. M.A. MEEKER, B.A. MAGILL, G.A. KHODAPARAST, Virginia Tech, D. SAHA, C.J. STANTON, University of Florida, S. MCGILL, National High Magnetic Field Laboratory, Florida, B.W. WESSELS, Northwestern University — Carrier-induced ferromagnetism in magnetic III-V semiconductors has opened up several opportunities for device applications as well as for fundamental studies of a material system in which itinerant carriers interact with the localized spins of magnetic impurities. The origin of the carrier-induced ferromagnetism is still an open and exciting question. In order to understand the hole mediated ferromagnetism, probing the band structure in these material systems is crucial. Here we present magnetic circular dichroism (MCD) studies on MOVPE grown InMnSb and InMnAs, both with Curie temperatures above 300K. The measurements were performed on samples with different Mn contents, with the laser excitation energy tuned from 0.92-1.45eV, and external magnetic fields ranging up to 31 Tesla. The measurements are compared with MCD calculations based on an 8 band Pidgeon-Brown model. Comparison of the experimental results with the theoretical calculations provides a direct method to estimate the spin-polarization of the electron in the semiconductor.

10:12AM S31.00010 Ge doping of FeGa 1,2. J.C. ALVAREZ-QUICENO, M. CABRERA-BAEZ, UFABC, Brazil, J. MUNÉVAR, H. MICKLITZ, E.M. BITTAR, E. BAGGIO-SAITOVITCH, CBPF, Brazil, R.A. RIBEIRO, M.A. AVILA, G.M. DALPIAN, UFABC, Brazil, J.M. OSORIO-GUILLÉN, UdeA, Colombia — The intermetallic narrow-gap semiconductor FeGa is one of the few Fe-based diamagnetic materials. Experimentally, Ge doping induces a ferromagnetic (FM) state. The mechanism responsible for this FM response is still unestablished, but there are proposals of itinerant magnetism to explain this behavior. Our DFT simulations show that inserting holes induces a delocalized FM response, while inserting electrons induces a localized FM response around some Fe atoms. We also modeled different distributions of Ge substitution and observe that the FM response depends on the Ge concentration and also on the Ge distribution on the Ga sites. We observed that the extra electrons become localized in some specific Fe atoms, rather than delocalized over the entire crystal lattice, as expected from an itinerant model. For experimental probing of this scenario, we have performed 57Fe Mössbauer spectroscopy on flux-grown singlecrystalline samples. The resulting resonance peak shape supports a localized model for ferromagnetism, since it is possible to resolve the presence of two distinct Fe isomer shifts (despite a single crystallographic site), expected to correspond to Fe atoms with high and low magnetic moments.

10:24AM S31.00011 Ge:Mn Dilute Magnetic Semiconductor. LAILA OBIED, Brock University, SJORED ROORDA, University of Montreal, DAVID CRANDELS, Brock University — This work aims to develop Ge:Mn dilute magnetic semiconductor and study the fundamental origin of ferromagnetism in this system. Using ion implantation at 77 K, a single crystal Ge wafer was doped with magnetic Mn ions. The implantation was done at ion energy of 4.76 MeV with a fluence of 2 x 10^{15} ion/cm². X-ray diffraction (XRD) of the as-implanted sample showed that the implanted layer was amorphous. Therefore, different samples were annealed at 200 °C, 330 °C and 600 °C in a tube furnace to achieve a solid phase epitaxial regrowth of the implanted layer. XRD of the sample annealed at 330 °C for 33 hours showed a polycrystalline layer. The depth profile of Mn in the as-implanted sample and the post-annealed sample at 330 °C was determined using secondary ion mass spectroscopy (SIMS) and it was found that some Mn diffused to the surface during the annealing. XRD of the sample annealed at 600 °C for 35 minutes showed peaks corresponding to an unknown phase in addition to peaks from amorphous and polycrystalline Ge. The sample annealed at 200 °C for 168 hour showed no evidence of solid phase epitaxy. A SQUID was used to measure the magnetic properties of all samples. At low temperature, the as-implanted sample showed a paramagnetic behaviour. A magnetic hysteresis at 5K and up to 200K was observed for the samples annealed at 330 °C and 200 °C. The 600 °C annealed sample showed no ferromagnetic response and a significant reduction in the paramagnetic response at low temperature as compared to the as-implanted sample.
the strain-induced changes in spin-orbit coupling on the Re-atoms. This interplay between structural deformations and magnetism leads to a giant MCA (LSAT), SrTiO$_3$.

Magnetocrystalline anisotropy (MCA) has significant implications in a range of applications such as power generation and magnetic data storage. We report the results of using first-principles electronic structure calculations, I show how this electrostatic chemical strain (ECS) effect can be used to tune both crystal field energies and the frontier orbital structure in correlated (La, A)NiO$_3$. Oxygen ligands, which alter the M cation’s $d$-orbital occupancies and spin state, thereby imparting desirable electronic functionality. In this talk, I describe an atomistic engineering approach that makes use of long-range electrostatic interactions between atomic metal-monoxide planes ($\Lambda\Theta$ and $\Lambda\Theta'$) in naturally occurring superlattices, e.g., Ruddlesden-Popper (RP), phases, to tune interlayer atomic structure, orbital degeneracies, and magnetic properties. Using first-principles electronic structure calculations, I show how this electrostatic chemical strain (ECS) effect can be used to tune both crystal field energies and the frontier orbital structure in correlated (La, A)NiO$_3$ RP phases at fixed stoichiometry. I describe how to enhance the Ni $e_g$ orbital polarization, resulting in NiO$_6$ units that exhibit a single $d(\Delta^2 - 5\zeta^2)$ band at the Fermi level—electronic features similar to the layered superconducting cuprates. This approach is generic in construction, making it applicable to any layered topology supporting heterovalent cation substitutions. I conclude by showing it is a realistic strategy to tailor the electronic properties of known materials, and discover yet-to-be realized novel functional oxides without resorting to complex assembly of multi-component heterostructures.

8:12AM S32.00002 Effects of Ferroelectric Polarization and Strain on Magneto-Crystalline Anisotropy of SrRuO$_3$. JEEVAKA WEERASINGHE, TULA R. PAUDEL, EVGENY Y. TSYMBAL, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, Nebraska 68588, USA — Magnetoelastic properties of materials have recently been extensively investigated due to their potential application in magnetic data storage, spintronics and high-frequency magnetic devices. Among these properties is the strain effect on magneto-crystalline anisotropy (MCA) which allows the control of magnetization orientation and thus has a direct relevance to magnetic memory applications. In this work, we explore the magneto-crystalline anisotropy of ferromagnetic metal oxide SrRuO$_3$ using first-principles density functional calculations. Due to the presence of Ru atoms, this material has a relatively strong spin-orbit coupling resulting in high MCA. We investigate how epitaxial compressive and tensile strain affect the bulk anisotropy of this material. We also explore epitaxial SrRuO$_3$/BaTiO$_3$ heterostructures where ferroelectric polarization of BaTiO$_3$ affects the interface MCA energy and thus may be used as a control parameter to switch the magnetization orientation. We discuss the physical origins of the effects predicted in terms of the modulation of the electronic structure of SrRuO$_3$ by polarization strain and strain.

8:24AM S32.00003 Control strain of magnetic structure in layered iridates via strong orbital-lattice coupling. CHOONG HYUN KIM, CRAIG FENNIE, Cornell Univ — We have studied from first principles the structural, electronic, and magnetic properties of the layered-perovskite iridates $\text{A}_2\text{IrO}_3$ and $\text{A}_2\text{Ir}_2\text{O}_7$ ($\text{A}=$Sr,Ba) as a function of epitaxial strain. In most of perovkite iridates, due to their large spin-orbit coupling and cubic crystal field, ground state could be described by an effective total angular momentum state $J_{\text{tot}}=1/2$ within $I_{2g}$ manifold. In contrary to what is usually assumed, we find that $d_{2z^2-r^2}$ orbital plays a crucial role to determine a magnetic ground state of iridates if the cubic crystal field is not big enough compared to bandwidth. For instance Ba$_2$IrO$_3$ with tensile strain induces a situation in which magnetization is reversed. Our first-principles results show how A-site cation, dimensionality, and strain are correlated with the band width and crystal field to control magnetic ground states.

8:36AM S32.00004 Electrostatic Chemical Strain: An Approach to Electronic Structure Engineering in Layered Oxides. JAMES RONDONELLI, Northwestern University — Traditional approaches to create and control functional electronic materials have focused on new phases in previously unknown bulk minerals. More recently, interlayer physics has spawned interest in known materials in unexplored atomic scale geometries, especially in complex transition metal oxides (TMO), where heterostructures and superlattices with abrupt interfaces can be created on demand. The interfaces between TMOs often give rise to directional electronic features similar to the layered superconducting cuprates. This approach is generic in construction, making it applicable to any layered topology supporting heterovalent cation substitutions. I conclude by showing that it is a realistic strategy to tailor the electronic properties of known materials, and discover yet-to-be realized novel functional oxides without resorting to complex assembly of multi-component heterostructures.

9:12AM S32.00005 First principles study of the origin of Strain-tunable extraordinary magnetocrystalline anisotropy in Sr$_3$CrReO$_6$ epitaxial films. M.R. BALL, The Ohio State University. J.M. LUCY, O.D. RESTREPO, OSU, A.J. HAUSER, UC, Santa Barbara, J.R. SOLIZ, OSU, J.W. FREELAND, Argonne National Lab, P.M. WOODWARD, W. WINDL, F. Y. YANG, OSU — Magnetocrystalline anisotropy (MCA) has significant implications in a range of applications such as power generation and magnetic data storage. We report the discovery of extraordinarily large anisotropy fields and strain-tunable MCA in Sr$_3$CrReO$_6$ epitaxial films. These films grown on (LaAlO$_3$)$_{0.7}$(Sr$_2$AlTaO$_6$)$_{0.3}$(LSAT), SrTiO$_3$, and SrCr$_5$Nb$_3$O$_{17}$/LSAT substrates undergo dramatic changes in MCA shown by a shift in easy axis from in-plane to out-of-plane. To find the origin of this, we determine the strain-induced distortions and octahedral rotations by performing density functional theory (DFT) calculations using VASP. Correlation effects were treated within GGA+$U$. In DFT, the change in easy axis under strain seen in experiment can be examined through the difference in total energies for magnetic orientation along different crystal axes known as the magnetic anisotropy energy (MAE). The MAE is directly related to the moment anisotropy which is the difference between hard- and easy-axis orbital moments. When a sign change in the moment anisotropy is present, a change in easy axis is indicated. We indeed find this sign change with increasing c/a ratio which is in agreement with experiments. The origin of the MAE resides in the strain-induced changes in spin-orbit coupling on the Re-atoms. This interplay between structural deformations and magnetism leads to a giant MCA.
9:24AM S32.00006 Depth-resolved magnetic and structural analysis of relaxing epitaxial Sr$_2$CrReO$_6$ films. JEREMY LUCY, FENG-YUAN YANG, The Ohio State University, ADAM HAUSER, University of California, Santa Barbara, YAO-HUA LIU, HUA ZHOU, YONGSEONG CHOI, SUZANNE G.E. TE VELTHUIS, DANIEL HASKEL, Argonne National Laboratory — Structural relaxation in a Sr$_2$CrReO$_6$ epitaxial film, with strong spin-orbit coupling, leads to depth-dependent magnetism. We combine a couple of depth-resolved synchrotron x-ray techniques, including two-dimensional reciprocal space mapping and x-ray magnetic circular dichroism experiments, to demonstrate this effect. An 800 nm film of Sr$_2$CrReO$_6$, grown with tensile epitaxial strain on SrCr$_{0.5}$Nb$_{0.5}$O$_3$, relaxes away from the Sr$_2$CrReO$_6$/SrCr$_{0.5}$Nb$_{0.5}$O$_3$ interface. Grazing incidence x-ray diffraction measurements of the film elucidate the in-plane strain relaxation while depth-resolved x-ray magnetic circular dichroism at the Re L$_3$ edge reveals the magnetic contributions of the Re site. This demonstrates a significant change in the magnetic system. This provides an interesting and powerful way to probe the depth-varying structural and magnetic properties of a complex oxide with synchrotron-source x-ray techniques.

9:36AM S32.00007 Effects of Strain and Buffer Layer on Interfacial Magnetization in Sr$_2$CrReO$_6$ Films. YAOHUA LIU, S.G.E. TE VELTHUIS, Materials Science Division, Argonne National Laboratory, A. GLAVIC, H. AMBAYE, V. LAUTER, Quantum Condensed Matter Division, Oak Ridge National Laboratory, J.M. LUCY, F.Y. YANG, Department of Physics, The Ohio State University — Magnetic double-perovskite Sr$_2$CrReO$_6$ (SCRO) has several functional properties including a T$_C > 500$ K, high spin polarization, large spin-orbit interaction, and semiconducting behavior in highly ordered films. However, fabrication of highly ordered films is still challenging, and progress toward device applications requires an in-depth understanding of the electronic and magnetic properties, especially at interfaces. We have investigated how the Cr/Re antisite disorder and strain affect the interfacial magnetization in SCRO films via x-ray and polarized neutron reflectometry. We find that the magnetization of SCRO films is reduced near the interface with the substrate. The width of this interfacial layer weakly depends on the strain and decreases when a SrCr$_0$O$_3$ buffer layer is used to reduce the antisite disorder. Interestingly, for the SCRO film deposited on a SCNO buffer layer, the region with reduced magnetization is wider than the antisite disorder region at the SCRO/SCNO interface, suggesting that antisite disorder is not the only mechanism reducing the magnetization.

3Work at ANL was supported by the DOE-BES, MSE, at OSU by the Center for Emergent Materials, a NSF MRSEC (DMR-1420451), at ORNL by DOE-BES, Scientific User Facilities Division.

9:48AM S32.00008 Strong Enhancement of Magnetization in Fully Strained SrRuO$_3$ films on Sr$_2$RuO$_4$ single crystal substrates. SEUNGGRAN LEE, Y.J. SHIN, M.C. LEE, C.H. SOHN, S.J. KANG, CCES-IBS & Seoul Nat’l Univ., M.S. ANWAR, Y. SUGIMOTO, S. YONEZAWA, Y. MAENO, Kyoto University, T.W. NOH, CCES-IBS & Seoul Nat’l Univ. — We have investigated epitaxial growth and magnetic properties of SrRuO$_3$ (SRO113) films on single crystal Sr$_2$RuO$_4$ (SRO214) substrates. X-ray diffraction shows only SRO113(001) peaks indicating epitaxial deposition; rocking scan of SRO112(002) indicates a sharp curve with a full width at half maximum of <0.05° implying high crystallinity of our films. Transmission electron microscopy further verifies fully strained of SRO113 films with sharp interface. Surprisingly, the magnetic properties of SRO113/SRO214 show strong enhancement of magnetization (M > 3 μ$_B$/Ru), which has never found in SRO113(001) material systems. In addition, the Curie temperature of our films is identical to that of a bulk SRO113. Magnetic properties of SRO113 films are known to decrease under strain, attributed to Ru06 octahedral distortion. In comparison with varying strain of SRO113 films employing various perovskite substrates, we also found such enhancement is not coming from strain effect; M does not exceed 2 μ$_B$/Ru consistent with previous results due to the low spin configuration nature of SRO113. Possible origins of unique magnetic properties of SRO113/214 will be further discussed.

10:00AM S32.00009 Strain dependence of interfacial antiferromagnetic coupling in La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrRuO$_3$ superlattices. SUJIT DAS, Institute for Physics, MLU Halle-Wittenberg, Germany, ANDREAS HERKLOTZ, Oak Ridge National Lab., Oak Ridge, 37830 TN, USA, ECKHARD PIPPEL, Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle, Germany, EP. JIU GUO, Institute for Physics, Johannes-Gutenberg University Mainz, 55128 Mainz, Germany, DIANA RATA, KATHRIN DORR, Institute for Physics, MLU Halle-Wittenberg, Germany — We have investigated the magnetic response of La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrRuO$_3$ superlattices to biaxial in-plane strain applied in-situ. Superlattices grown on piezoelectric substrates of 0.72PbMg$_{1/3}$Nb$_{2/3}$O$_3$/0.28PbTiO$_3$ (PMN-PT) show strong antiferromagnetic coupling of the two ferromagnetic components. The coupling field of μ$_B$HAP = 1.8 T is found to change by μ$_B$δHAP/δε ~ 520 mT%$^{-1}$ under reversible biaxial strain (ε) at 80 K in a [La$_{0.7}$Sr$_{0.3}$MnO$_3$(22 Å)/SrRuO$_3$(55 Å)]$_{15}$ superlattice. This reveals a significant strain effect on interfacial coupling. The applied in-plane compression enhances the ferromagnetic order in the manganese layers which are under as-grown tensile strain. It is thus difficult to disentangle the contributions from strain-dependent antiferromagnetic Mn-O-Ru interface coupling and Mn-O-Mn ferromagnetic double exchange near the interface, since the enhanced magnetic order of Mn spins leads to a larger net coupling of SrRuO$_3$ layers at the interface. We discuss our experimental findings taken into account both the strain-dependent orbital occupation in a single-ion picture and the enhanced Mn order at the interface.

10:12AM S32.00010 Epitaxial strain induced atomic ordering in stoichiometric LaCoO$_3$ thin films. WOO SEOK CHOI, Sungkyunkwan University, JI-HWAN KWON, Seoul National University, HYOUNGJEEN JEEN, Oak Ridge National Laboratory, GEORGE A. SAWATZKY, University of British Columbia, VLADIMIR HINKOV, Max Planck-UBC Centre for Quantum Materials, MIYOUNG KIM, Seoul National University, HO NYUNG LEE, Oak Ridge National Laboratory. — Heteroepitaxial strain imposed in complex transition metal oxide thin films is recognized as an effective tool for identifying and controlling emergent physical phenomena. Stoichiometric LaCoO$_3$ is particularly interesting, since the thin film form of the material exhibits a robust macroscopic ferromagnetic ordering, while the bulk form of the material is a zero spin, nonmagnetic insulator. In this work, we show that the ferromagnetic ordering observed in LaCoO$_3$ thin films is related to a lattice modulation in the atomic scale, originating from the epitaxial strain. The possibility of oxygen vacancies have been carefully ruled out using various macroscopic and microscopic spectroscopic techniques, and an unconventional strain relaxation behavior identified by strip-like lattice modulation pattern was responsible for the non-zero spin ground state of Co$^{3+}$ ions [1,2]. We further note that the unconventional strain relaxation did not involve any uncontrolled misfit dislocations.

Effect of periodicity on order parameters of multiferroic superlattices\footnote{NSF Grant EPS-01002410}.

SHALINI KUMARI, NORA ORTEGA, Department of Physics and Institute for Functional Nanomaterials, University of Puerto Rico, San Juan, PR 00931-3334, USA — Superlattice (SL) structures with alternating perovskite oxide layers have attracted enormous attention due to their fascinating physics and technology. The half-metallic oxide La$_{0.67}$Sr$_{0.33}$MnO$_3$ (LSMO) and multiferroic Pb$_{2/3}$Zr$_{0.2}$Ti$_{0.8}$O$_{2}$ (F23) materials have been chosen to fabricate SLs by pulsed laser deposition technique on cubic LSAT substrates with LSMO or LaNiO$_3$ as bottom electrodes. X-ray diffraction studies revealed superlattice structure with satellite peaks modulated around main peaks. Atomic force microscopy studies disclosed a systematic decrease in grain size with decrease of modulation periodicity ($\Lambda$) in SLs. Piezo force microscopy studies of SL films confirmed ferroelectricity at a nanoscale level. XPS studies of SLs with $\Lambda=5$ nm confirmed the existence of all elements in the films. A relatively small reduction in saturation magnetization from 28 to 20 emu/cm$^3$ at $H=5$ kOe, remanant polarization from 21 to 10 $\mu$C/cm$^2$ and increase in dielectric constant from 530 to 743 were observed with decrease of $\Lambda$. The observed features will be explained in context of finite size, interfaces, stress, lattice distortion, and grain sizes effects.

Electric-field control of magnetization in (Co(t)/Pt)n/Pb(Mg1/3Nb2/3)$_{1-x}$TiO$_3$ multiferroic heterostructures.

YING SUN, YONGGANG ZHAO, AITIAN CHEN, YAN LIU, Department of Physics, Tsinghua University, Beijing 100084, China, LVKUAN ZOU, XIAOLI ZHENG, QINTONG ZHANG, JIANWANG CAI, XIUFENG HAN, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, WENBO WANG, WEIDA WU, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — A promising way to control magnetism via electric fields is using the converse magnetoelectric effect (CME) in heterostructures composed of ferromagnetic and ferroelectric materials. So far there are few reports on electric-field (E) control of magnetic materials with perpendicular magnetic anisotropy (PMA) which is important in information storage because of its high density and thermostability. In this work, we have systematically studied the CME in heterostructures formed by growing (Co(t)/Pt)n multilayers with different Co thicknesses and n on (011)-oriented ferroelectric Pb(Mg1/3Nb2/3)$_{1-x}$TiO$_3$ substrates. By tuning Co thickness to the vicinity of the spin reorientation critical thickness, samples with PMA, in-plane magnetic anisotropy and crossover were obtained. They showed dramatic different behaviors of E control of magnetization. The results can be understood by considering the interaction between the piezoelectric induced magnetic anisotropy and Co thickness-dependent magnetic anisotropy.

Manipulation of magnetic phase separation and orbital occupancy in manganese by strain engineering and orbital effect.

BIN CUI, CHENG SONG, FENG PAN, Tsinghua Univ, KEY LABORATORY OF ADVANCED MATERIALS (MOE) TEAM — The modification of electronic phases in correlated oxides is one of the core issues of condensed matter. We report the reversible control of ferromagnetic phase transition in manganese films by ionic liquid gating, replicating the La$_{1-x}$Sr$_x$MnO$_3$ (LSMO) phase diagram. The formation and annihilation of an insulating and magnetically hard phase in the soft magnetic matrix, which randomly nucleates and grows across the film, is directly observed under different gate voltages ($V_{G}$). The realization of reversible metal-insulator transition in colossal magnetoresistance materials can lead to the development of four-state memories. (Adv. Funct. Mater. DOI: 10.1002/adfm.201402007) The orbital occupancy and magnetic anisotropy of LSMO films are manipulated by $V_{G}$ in a reversible and quantitative manner. Positive and negative $V_{G}$ increases and reduces the occupancy of the orbital and magnetic anisotropy that were initially favored by strain (irrespective of tensile and compressive), respectively. This finding fills in the blank of electrical manipulation of four degrees of freedom in correlated system. (Adv. Funct. Mater. (revised))

Thursday, March 5, 2015 8:00AM - 11:00AM — Session S33 DBIO DPOLY: Focus Session: Conformations and Dynamics of Biopolymers I

Comparison of the Single Molecule Dynamics of Linear and Circular DNAs in Planar Extensional Flows\footnote{Texas Tech University John R. Bradford Endowment}.

YANFEI LI, Texas Tech University, KAI-YEN HSIAO, CHRISTOPHER BROCKMAN, University of Illinois at Urbana-Champaign, DANIEL YATES, GREGORY MCKENNA, Texas Tech University, CHARLES SCHROEDER, University of Illinois at Urbana-Champaign, MICHAEL SAN FRANCISCO, Texas Tech University, JULIE KORNFIELD, California Institute of Technology, RAE ANDERSON, University of San Diego — Chain topology has a profound impact on the flow behaviors of single macromolecules [1]. The absence of free ends separates circular polymers from other chain architectures, i.e., linear, star, and branched. In the present work, we study the single chain dynamics of large circular and linear DNA molecules by comparing the relaxation dynamics, steady state coil-stretch transition, and transient molecular individualism behaviors for the two types of macromolecules. To this end, large circular DNA molecules were biologically synthesized [2] and studied in a microfluidic device that has a cross-slot geometry to develop a stagnation point extensional flow [3]. Although the relaxation time of rings scales in the same way as for the linear analog, the circular polymers show quantitatively different behaviors in the steady state extension and qualitatively different behaviors during a transient stretch. The existence of some commonality between these two topologies is proposed. [1] M. Kapnistos et al., Nat. Mater. 7, 997 (2008). [2] S. Laib et al., Macromolecules 39, 4115 (2006). [3] M. Tanyeri et al., Lab Chip 11, 1786 (2011).

Ratchet rectification effect on the translocation of a flexible polyelectrolyte chain induced by spatial asymmetry of the channel.

DEBASISH MONDAL, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — We report a three dimensional Langevin dynamics simulation of a uniformly charged flexible polyelectrolyte, translocating through a symmetric narrow channel with periodically varying cross-sections, under the influence of a periodic external electric field. When reflection symmetry of the channel is broken, rectification effect is observed with a favored direction for the chain translocation. For a given volume of the channel unit and polymer length, the rectification occurs only after a threshold frequency of the external periodic driving. We also observe that the extent of the rectification depends on the length of the polyelectrolyte, geometric parameters of the channel governing the spatial asymmetry, and the strength of the external periodic driving field. The observed rectification process is interpreted in terms of an effective asymmetric periodic potential along the direction of the polymer translocation.

Comparison of Translocations of Ring and Linear Polymers.

NING OU YANG, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — We compare the translocation dynamics of ring and linear polymer chains (pertinent to circular and linear DNA) through a nanopore under a driving force, using the Fokker-Planck formalism and scaling arguments. We report qualitatively different dynamics between these topologies arising from the conformational entropy of the polymer and pore-polymer interaction.
8:36AM S33.0004 Increasing polymer diffusivity by increasing the contour length: The surprising effect of YOYO-1 on DNA dynamics

SEUNGHWAN SHIN, KEVIN DORFMAN, XIANG CHENG, Univ of Minn — Double-stranded DNA (dsDNA) labeled with cyanine dyes such as YOYO-1 has been extensively used as a model to study equilibrium and dynamic properties of semiflexible polyelectrolytes. The ability to directly visualize the polymer dynamics is an attractive feature of these experiments, but positively charged cyanine dyes affect the physical properties of dsDNA, distorting the double helix and counterbalancing the intrinsic negative charge of the backbone. A variety of studies have been conducted to reveal the effect of the dye on the contour length and the persistence length of dsDNA. However, fewer efforts have been made to directly quantify the effect of dye on the diffusion behavior of dsDNA. In order to resolve this issue, we measured the in-plane diffusion coefficient of unconfined dsDNA using confocal microscopy. Although there is widespread consensus that intercalation increases the contour length of dsDNA, we find that increasing the dye-base pair ratio for YOYO-1 actually enhances the diffusion of dsDNA. This enhancement is more significant at lower ionic strengths, which implies that the increase in the diffusion coefficient by dye-DNA intercalation is mainly due to a reduction of excluded volume effect resulting from charge neutralization on the backbone.

8:48AM S33.0005 Using an effective dimensionality to map the force-extension relation for a semi-flexible polymer in a nanoslit

HENDRICK DE HAAN, University of Ontario Institute of Technology — The force-extension relation for a semi-flexible polymer is well described by the Marko-Siggia equation in both two and three dimensions. However, while of interest for experimental systems such as DNA in nanotubes, the behaviour between these limiting dimensionalities is less understood. We will present results from simulations of a polymer subject to a stretching force \( F \) and confining geometry \( L \times 1 \times h \), with \( h \ll L \). The relevant persistence length are shown to change. This observation leads to the definition of an effective dimensionality, \( d_{eff} \), to characterize the system. At low \( F \), using \( d_{eff} \) in a generalized form of the Marko-Siggia relation provides good agreement with the simulation curves. However, at high \( F \), \( d_{eff} \) drifts back towards \( d = 3 \). The reason behind this \( F \) dependence is discussed. Semi-empirical forms for strong and weak confinement regimes will be presented and shown to give good agreement across all slit heights and stretching forces. \( d_{eff} \) is thus dependent on \( h \) and \( F \) and provides a cohesive physical picture for all regimes.

9:00AM S33.0006 Correlated Fluctuations of DNA Between Nanofluidic Traps

EXANDER KLOTZ, LYNDON DUONG, MIKHAIL MAMAEV, WALTER REISNER, McGill Univ — Nanofluidic polymer physics has been the subject of intense investigation, and experimental efforts have focused almost exclusively on quantifying equilibrium confined chain conformation in simple nanoslits (2D) and nanochannel (1D) geometries. Complex nano environments, defined as spaces composed of interlinked nanoscale regions of varying confinement and dimensionality, are also technologically significant and have qualitatively distinct physics. Here, a single DNA molecule is suspended between two adjacent nanocavities structures embedded in an open nanoflat. A portion of the molecule occupies each cavity with a third linker segment connecting the two. Contour fluctuations between the cavities give rise to novel correlations. Cross-correlation of the time-dependent cavity intensities enables a noise insensitive measurement of the relaxation times for the segmental transfer modes. We explore how these relaxation times scale with cavity width and spacing and compare our results to a simple free energy model incorporating a slend termed linker spring energy and cavity self-exclusion cost.

9:12AM S33.0007 Metastable Tight Knots in DNA

LIANG DAI, Singapore-MIT Alliance for Research and Technology, C. BENJAMIN RENNER, PATRICK DOYLE, Department of Chemical Engineering, Massachusetts Institute of Technology — Knotted structures can spontaneously occur in polymers such as DNA and proteins, and the formation of knots affects biological functions, mechanical strength and rheological properties. In this work, we calculate the equilibrium size distribution of trefoil knots in linear DNA using off-lattice simulations. We observe metastable knots on DNA, as predicted by Grosberg and Rabin. Furthermore, we extend their theory to incorporate the finite width of chains and show an agreement between our simulations and the modified theory for real chains. Our results suggest localized knots spontaneously occur in long DNA and the contour length in the knot ranges from 600 to 1800 nm.

9:24AM S33.0008 Translocation of a Polymer Chain Through a Nanopore Starting From a Confining Nanotube: The Limit of high Peclet Numbers

GARY W. SLATER, DAVID SEAN, University of Ottawa, HENDRICK DE HAAN, University of Ontario Institute of Technology — We use Langevin Dynamics simulations to study a scenario where a confining nanotube is used as a way to limit the range of conformations available to a polymer chain prior to driven translocation. We find that the tube not only reduces the variance in translocation times (a useful result for practical applications), but also that the elongated polymer conformations yield longer translocation times (also a useful result) that can be dominated by the post-propagation process when the diameter of the nanotube is smaller than a universal critical value. We adapt the tension propagation theory for this geometry and find agreement with the simulations using a single friction parameter to model the roles of both the nanotube and the modified theory for real chains. Our results suggest localized knots spontaneously occur in long DNA and the contour length in the knot ranges from 600 to 1800 nm.

9:36AM S33.0009 Dynamics of a fluctuating semi-flexible membrane

NATHANIEL TUKDARIAN, AIQUN HUANG, RAMESH ADHIKARI, ANIKET BHATTACHARYA, University of Central Florida — We report our preliminary studies of conformations and dynamics of a fluctuating semi-flexible membrane. Our membrane is a 2D lattice with linear segments (i.e., rods) of length \( L \) and \( n_b \) excluded volume beads connected by anharmonic springs. The stiffness of the membrane is controlled by adjusting the strength \( k_b \) of the bending potential \( \mathcal{U}_b = k_b (1 - n_i - n_j) \) between adjacent elementary plaquettes consisting of three beads at the corners connected by bonds and characterized by normal unit vectors \( \hat{n}_i \) and \( \hat{n}_j \). We study the conformations and dynamic fluctuations of the membrane using Brownian dynamics simulation. We show how the radius of gyration scales with \( N \) and \( k_b \), and study characteristics of the transverse fluctuations, the root-mean-square displacement of the center of mass, and the dynamics of the end monomers at each corner.

9:48AM S33.0010 Expanded experimental parameter space of semiflexible polymer assemblies through programmable nanomaterials

DAVID SMITH, CARSTEN SCHULDT, JESSICA LORENZ, TERESA TSCHIRNER, MAXIMILIEN MOEBIUS-WINKLER, Fraunhofer Institute for Cell Therapy and Immunology, JOSEF KAES, MARTIN GLASER, TINA HAENDLER, JOERG SCHNAUSS, University of Leipzig, Institute for Soft Matter Physics — Biologically evolved materials are often used as inspiration in the development of new materials as well as examinations into the physical principles governing their behavior. For instance, the biopolymer constituents of the highly dynamic cellular cytoskeleton such as actin have inspired a deep understanding of soft polymer-based materials. However, the molecular toolbox provided by biological systems has been evolutionarily optimized to carry out the necessary functions of cells, and the inability modify basic properties such as biopolymer stiffness hinders a meticulous examination of parameter space. Using actin as inspiration, we circumvent these limitations using model systems assembled from programmable materials such as DNA. Nanorods with comparable, but controllable dimensions and mechanical properties as actin can be constructed from small sets of specially designed DNA strands. In entangled gels, these allow us to systematically determine the dependence of network mechanical properties on parameters such as persistence length and crosslink strength. At high concentration of the presented attractive forces, we see a transition to highly-ordered bundled and “aster” phases similar to those previously characterized in systems of actin or microtubules.

SCHMIDT, Third Institute of Physics-Biophysics, Georg August University, Goettingen — Molecular stress generation in cells is spatially and temporally organized in complex patterns to drive meso-scale active processes such as intracellular transport, cell migration or cell division. To quantitatively understand how these processes are driven, it is necessary to map local
stresses inside cells, which is hard due to the lack of appropriate probes. We have designed a molecular-scale probe consisting of a self-assembled DNA hairpin
with a fluorophore - quencher pair that responds to small forces (pN) applied to its ends. We demonstrate the working of this force sensor in vitro and explore
possibilities for in vivo application to map local stress fields in cells.

10:12AM S33.00012 AFM Studies of Conformational Changes in Proteins and Peptides, NICOLETA
PLOS CARIU, PINA KUK SUTHANKAR, JOHN TOMICH, ROBERT SODZIEKIVCI, Kansas State University — Here, we present estimates of molecular
stiffness and mechanical energy dissipation factors for some examples of proteins and peptides. The results are obtained from AFM force spectroscopy
measurements. To determine molecular stiffness and mechanical energy dissipation factors we developed a model based on measuring several resonance
frequencies of an AFM cantilever in contact with either single protein molecule or peptides adsorbed on arbitrary surface. We used compliant AFM cantilevers
with a small aspect ratio - a ratio of length to width - in air and in liquid, including biologically relevant phosphate buffered saline medium.

8:00AM S34.00001 Computational assessment of organic photovoltaic candidate compounds,
MARIO BORUNDA, SHUO DAI, Oklahoma State University, ROBERTO OLIVARES-AMAYA, Princeton University, CARLOS AMADOR-BEDOLLA, UNAM,
ALAN ASPURU-GUZIK, Harvard University — Organic photovoltaic (OPV) cells are emerging as a possible renewable alternative to petroleum based resources
and are needed to meet our growing demand for energy. Although not as efficient as silicon based cells, OPV cells have as an advantage that their manufacturing
cost is potentially lower. The Harvard Clean Energy Project, using a cheminformatic approach of pattern recognition and machine learning strategies, has ranked
a molecular library of more than 2.6 million candidate compounds based on their performance as possible OPV materials. Here, we present a ranking of the
top 1000 molecules for use as photovoltaic materials based on their optical absorption properties obtained via time-dependent density functional theory. This
computational search has revealed the molecular motifs shared by the set of most promising molecules.

8:12AM S34.00002 Thermogravimetric, Calorimetric, and Structural Studies of the Co3O4/CoO
Oxidation/Reduction Reaction, KARL UNRUH, RONALD CICHOCKI, BRIAN KELLY, GERALD POIRIER, Univ of Delaware — To better assess the potential of cobalt oxide for thermal energy storage (TES), the Co3O4/CoO oxidation/reduction reaction has been studied by
thermogravimetric (TGA), calorimetric (DSC), and x-ray diffraction (XRD) measurements in N2 and atmospheric air environments. TGA measurements showed
an abrupt mass loss of about 6.6% in both N2 and air, consistent with the stoichiometric reduction of Co3O4 to Co and structural measurements. The onset
temperature of the reduction of Co3O4 in air was only weakly dependent on the sample heating rate and occurred at about 910 °C. The onset temperature for
the oxidation of CoO varied between about 850 and 875 °C for cooling rates between 1 and 20 °C/min, but complete re-conversion to Co3O4 could only be
achieved at the slowest cooling rates. Due to the dependence of the rate constant on the oxygen partial pressure, the oxidation of Co3O4 in a N2 environment
occurred at temperatures between about 775 and 825 °C for heating rates between 1 and 20 °C/min and no subsequent re-oxidation of the reduced Co3O4
was observed on cooling to room temperature. In conjunction with a measured transition heat of about 600 J/g of Co3O4, these measurements indicate that
cobalt oxide is a viable TES material.

8:24AM S34.00003 Electronic and Optical Properties of Novel Phases of Silicon and Silicon-
Based Derivatives, CHIN SHEN ONG, SANGKOOK CHOI, STEVEN G. LOUIE, Department of Physics, UC Berkeley and Lawrence Berkeley National Lab — Recent discoveries of two novel phases of silicon, Si320 and Si324, lead to promises of quasi-direct band gap silicon crystals that are capable
of complementing indirect-gap diamond cubic silicon for use in the solar cell industry. This work studies the quasiparticle excitations and optical spectra of
these two structures, Si320 and Si324, assessing their suitability for use as photovoltaic materials. We carry out ab initio GW and GW-BSE calculations for the
quasiparticle excitations and optical spectra, respectively, including self-energy and electron-hole interaction effects. This work was supported by NSF grant
No. DMR10-1006184 and U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at Lawrence Berkeley
National Laboratory’s NERSC facility.

8:36AM S34.00004 Accurate determination of the temperature dependent thermalization coeffi-
cient (Q) in InAs/AlAsSb quantum wells, HAMIDREZA ESMAILPOURJ, JINFENG TANG, VINCENT R. WHITESIDE, SANGEETHA VIJEYARAGUNATHAN, TETSUYA D. MISHIMA, MICHAEL B. SANTOS, IAN R. SELLERS, University of Oklahoma — We present an investiga-
tion of hot carriers in InAs/AlAsSb quantum wells as a practical candidate for a hot carrier solar cell absorber. The thermalization coefficient (Q) of the sample
is investigated using continuous wave photoluminescence (PL). The Q is accurately determined through transfer matrix calculations of the absorption, analysis
of the power density, penetration depth, diffusion, and recombination rates using a combination of simulation and empirical methods. A precise measurement of
laser spot size is important in order to determine the absorbed power density. Simulations were performed based on our PL geometry in order to calculate the
excitation spot size, which was compared with experiment by measurements using variable diameter pinholes to determine beam radius. Here, these techniques
are described, in addition to, the temperature dependent hot carrier dynamics and phonon mediated thermalization coefficient for the InAs/AlAsSb quantum
well structure.
8:48AM S34.00005 Improved performance due to selective passivation of nitrogen clusters in GaInNAs solar cells1. MIWA FUKUDA, VINCENT R. WHITESIDE, University of Oklahoma, MOHAMED AL KHALIFI, MATHIEU LEROUX, CRHEA-CNRS, France, KHALID HOSSAIN, Amethyst Research Inc., IAN R. SELLERS, University of Oklahoma — While GaInNAs has the potential to be a fourth-junction in multi-junction solar cells it has proved to be difficult to incorporate due to the low solubility of nitrogen in these materials. Specifically, mid-gap states attributed to nitrogen clusters have proved prohibitive for practical implementation of these systems. Here, we present the selective passivation of nitrogen impurities using a UV-activated hydrogenation process, which enables the removal of defects while retaining substitution nitrogen. Temperature dependent photoluminescence measurements of a GaInNAs p-n junction cell show a classic “s-shape” associated with localization prior to hydrogenation, while after hydrogenation no sign of the “s-shape” is evident. This passivation of nitrogen centers is reflected in improved performance of solar cell structures relative to reference, unpassivated devices presenting a potential route to practical implementation of GaInNAs solar cells.

9:00AM S34.00006 Amorphous carbon for photovoltaics1. FRANCESCA RISPLENDI, JEFFREY C. GROSSMAN, Massachusetts Inst of Tech-MIT, Materials Science and Engineering dept. — All-carbon solar cells have attracted attention as candidates for innovative photovoltaic devices. Carbon-based materials such as graphene, carbon nanotubes (CNT) and amorphous carbon (aC) have the potential to present physical properties comparable to those of silicon-based materials with advantages such as low cost and higher thermal stability. In particular a-C structures are promising systems in which both sp2 and sp3 hybridization coordination are present in different proportions depending on the specific density, providing the possibility of tuning their optoelectronic properties and achieving comparable sunlight absorption to aSi. In this work we employ density functional theory to design suitable device architectures, such as bulk heterojunctions (BJH) or pn junctions, consisting of a-C as the active layer material. Regarding BHJ, we study interfaces between aC and C nanostructures (such as CNT and fullerene) to relate their optoelectronic properties to the stoichiometry of aC. We demonstrate that the energy alignment between the a-C mobility edges and the occupied and unoccupied states of the CNT or C60 can be widely tuned by varying the aC density to obtain a type II interface. To employ aC in p-n junctions we analyze the p- and n-type doping of a-C focusing on an evaluation of the Fermi level and work function dependence on doping. Our results highlight promising features of aC as the active layer material of thin-film solar cells.

9:12AM S34.00007 Highly Selective Photocatalytic CO2 Reduction on TiO2-Passivated InP in Ionic Liquids1. GUANGTONG ZENG, JING QIU, SHERMIN ARAB, ZHEN LI, STEPHEN CRONIN, University of Southern California — Lowering the overpotential required to drive the photocatalytic reduction of CO2 to useful products is a very important challenge. In this article, we use an ionic liquid [EMIM][BF4] as co-catalyst to improve the selectivity and efficiency of CO2 reduction to CO on TiO2-passivated InP. Here, the InP surface is passivated using a thin film of TiO2 deposited by atomic layer deposition (ALD), which improves the photocorversion efficiency by as much as 17X compared to bare InP. We believe there are three mechanisms of enhancement in this photocatalytic system. Firstly, the TiO2 deposited by ALD is n-type due to oxygen vacancies, and forms a pn-junction with the underlying p-type InP photocathode, resulting in a built-in potential which reduces electron-hole recombination through charge separation. Secondly, the Ti4+ active sites formed on the TiO2 surface lower the energy of the CO2− intermediate through the formation of an intermediate complex. Thirdly, the [EMIM]+ ions in solution also stabilize the CO2− intermediate, further lowering the energy barrier of this reaction. Here, we use a non-aqueous ionic liquid solution, which prohibits hydrogen formation and enables highly selective CO2 reduction with a Faradaic efficiency of 46%. This general approach of passivating narrower band gap semiconductors with TiO2 and utilizing a non-aqueous ionic liquid solution allows a wide range of materials to be considered for photocatalysis, enabling more efficient photocatalysts to be developed.

9:24AM S34.00008 High-throughput search for photoabsorbers for solar fuels1. SLOBODAN MITROVIC, Caltech, Joint Center for Artificial Photosynthesis, EEARL CORNELL, Lawrence Berkeley National Laboratory, PAUL NEWHOUSE, JOEL HABER, RYAN JONES, JOHN GREGOIRE, Caltech, Joint Center for Artificial Photosynthesis — We present the suite of instrumentation developed specifically to search for light absorber materials for solar hydrogen and carbon-based fuels. A pre-screening method utilizes colorimetric image analysis to search for positive and negative metrics for electronic bandgap, isolate materials not suitable for further screening and identify phase clusters in the compositional space of combinatorial material libraries. Then, two highly-automated instruments screen for photocurrent, by performing incident-photon conversion efficiency measurement in a redox couple, and absorption properties via UV-Vis-NIR spectroscopy. Finally, we present a new instrument for multispectral microscopic imaging of material libraries. We will discuss the challenges in automated data analysis from large datasets and multispectral data-cubes.

1This material is based upon work performed by the Joint Center for Artificial Photosynthesis, a DOE Energy Innovation Hub, supported through the Office of Science of the U.S. Department of Energy under Award Number DE-SC000499.

9:36AM S34.00009 First-principles study of MnNiO3 as an alkaline oxygen-evolution photocatalyst1. JIE YU, Joint Center for Artificial Photosynthesis, Lawrence Berkeley National Laboratory, QIMIN YAN, Molecular Foundry, Lawrence Berkeley National Laboratory, WEI CHEN, ANUBHAV JAIN, Environmental Energy Technologies Division, Lawrence Berkeley National Laboratory, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, KRISTIN PERSSON, Environmental Energy Technologies Division, Lawrence Berkeley National Laboratory — We present a first-principles study of MnNiO3, a promising oxygen-evolution photocatalyst. Using density functional theory with the screened hybrid functional of Heyd, Scuseria, and Ernzerhof (HSE), we compute and analyze the ground-state geometry and electronic structure. We find that MnNiO3 is a ferrimagnetic semiconductor with an indirect band gap, consistent with experimental observations. We also predict that MnNiO3 has promising band edge positions relative to the vacuum, with potential to straddle the hydrogen evolution reaction (HER) and oxygen evolution reaction (OER) redox potentials in aqueous solution. A detailed analysis of the band structure and density of states provides a clear explanation why MnNiO3 is promising for OER. Pourbaix diagram calculations suggest that MnNiO3 is stable in alkaline solution at potentials relevant for oxygen evolution. This work was supported by the Department of Energy through the Joint Center for Artificial Photosynthesis.

9:48AM S34.00010 Energy requirements for CO2 capture from ambient air (DAC) competitive with capture from flue-gas (PCC)1. CHRISTOPH MEINRENKEN, Columbia University — Capture of CO2, whether from a flue gas source (PCC) or from distributed sources via ambient air (DAC), is a key enabling technology to provide carbon for sustainable synthetic energy carriers such as solar fuels. Based on thermodynamic minimum considerations, DAC is often expected to require about 3 times more energy (per ton CO2 captured) than PCC because CO2 in ambient air is more dilute. Here, we calculate the energy required for a humidity swing-based DAC installation that uses an anionic exchange resin as sorbent. The calculation uses recently measured equilibrium CO2 loadings of the sorbent as function of partial CO2 pressure, temperature, and humidity. We calculate the installation’s electricity consumption to be about 45 kJ per mole of pure CO2 at 1 bar (scenario-dependent). Furthermore, we estimate the amount of heat provided by ambient air and thus provide context of the overall energy and entropy balance and thermodynamic minimum views. The electricity consumption is competitive with typical parasitic loads of PCC-equipped coal-fired power plants (40-50 kJ per mole at same pressure) and significantly lower than predicted for other DAC installations such as Na(OH) sorbent-based systems. Our analyses elucidate why DAC is not always more energy-intensive than PCC, thus alleviating often cited concerns of significant cost impediments.

10:00AM S34.00011 MIS Solar Cell Devices Based on a Cu2O Substrate Utilizing h-BN as an Insulating and Passivating Layer1. ONUR ERGEN, ASHLEY GIBB, OSCAR VAZQUEZ-MENA, WILL REGAN, ALEX ZETTL, University of California at Berkeley — We demonstrate Cu2O based metal insulator semiconductor Schottky (MIS-Schottky) solar cells with efficiencies exceeding 3%. A unique direct growth technique is employed in the fabrication, and hexagonal boron nitride (h-BN) serves simultaneously as a passivation and insulation layer on the active cuprous oxide (Cu2O) layer. The devices are the most efficient of any Cu2O based MIS-Schottky solar cells reported to date.

1Department of Physics, University of California at Berkeley, Berkeley, California 94720, USA. 2Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, USA.

10:12AM S34.00012 Electronic properties of BiI3 using hybrid functionals1. PATRICK M. MCBRIDE, ANDERSON JANOTTI, CHRIS G. VAN DE WALLÉ, Univ of California - Santa Barbara — BiI3 has recently gained interest as a high-efficiency light-output scintillator material, but limited research has been done to investigate its electronic structure. Most theoretical investigations have been limited to using density functional theory (DFT) within the local density approximation (LDA) or the generalized gradient approximation (GGA), which are known to give an incorrect electronic band gap. Furthermore, these studies ignore van der Waals (vdW) interactions, even though BiI3 has a layered structure held together by vdW forces. In this talk we present results of hybrid functional calculations, including the effects of spin-orbit coupling, for the electronic and structural properties of BiI3. We will address effects of including vdW interactions and spin-orbit coupling on the nature of the band gap, electron and hole effective masses, and the band edge positions with respect to vacuum level and other relevant semiconductors. We will also discuss the suitability of BiI3 as a photovoltaic material.

10:24AM S34.00013 Quantitative model of EBIC for CdTe, PAUL HANEY, HEAYOUNG YOON, National Institute for Standards and Technology, PRAKASH KOIRALA, ROBERT COLLINS, U. Toledo, NIKOLAI ZHITENEV, National Institute for Standards and Technology — Electron beam induced current (EBIC) is a powerful characterization technique which offers the high spatial resolution needed to study polycrystalline solar cells. In an EBIC experiment, a beam of high energy electrons excites electron-hole pairs, some fraction of which are collected by contacts. Ideally, an EBIC measurement reflects the spatially resolved quantum efficiency of the device. However, experiments on polycrystalline CdTe solar cells reveal that the EBIC collection efficiency is substantially lower than the quantum efficiency of the device under optical excitation. In order to reliably extract intrinsic material properties from EBIC signals, this difference must be reconciled. Two important differences between an EBIC experiment and normal device operation are: 1. the high generation rate density associated with the electron beam, and 2. the substantial effect of the exposed surface in an EBIC experiment. By developing numerical and analytical models which account for both of these effects, the difference in the material response under EBIC and normal device operation conditions can be understood. Comparison between the model and experiment show good agreement between quantities such as maximum EBIC collection efficiency versus charge generation rate.

10:36AM S34.00014 Studying Anomalous Open-Circuit Voltage Drop-Out in Concentrated Photovoltaics Using Computational Numerical Analysis, MARGARET STEVENS, CHANDLER DOWNS, THOMAS VANDERVELDE, SCOTT MAC'LACHLAN, JAMES ADLER, Tufts University — Under high solar concentration, an anomalous open-circuit voltage drop-out has been observed experimentally, but not understood theoretically. This anomaly has often been attributed to various thermal effects, but the effect is also observed in flash testing, where thermal effects do not have time to accumulate. We discuss our theoretical examination of semiconductor performance under high optical generated carrier injection. Under these conditions, the number of optically generated charge carriers increase past the number of equilibrium charge carriers. The effect of dynamically changing charge carrier compositions on fundamental electrical properties, such as open-circuit voltage, has yet to be explored in detail. Using the Newton-Raphson method, we solved the carriers continuity equations for the optically generated charge carriers as a function of material depth in bulk III-V semiconducting materials. Ultimately, we implemented these carrier concentration functions in our simulations of the p-n band structures to characterize the impact of solar concentration on the electrical behavior of photovoltaic devices.

10:48AM S34.00015 Polymer-directed Hybrid Nanostructures for Enhanced Electrocatalytic Activity and Solar Fuel Generation, DONG HA KIM, YOON HEE JANG, JI-EUN LEE, LI NA QUAN, YU JIN JANG, EWHA Woman's Univ, POLYMER NANOHYBRID MATERIALS LAB TEAM — In this presentation, we introduce a comprehensive approach to the design and fabrication of hybrid nanostructures directed by functional polymers for photovoltaic, pholectricchemical and electrocatalytic properties. A unique strategy to generate core-shell nanoparticles based on AuNPs decorated with PANI shell with uniformly distributed alloy metal NPs in the PANI shells was developed. We systematically investigate the structural alteration during the sequential synthetic process and compared the electrocatalytic performance with respect to Pt-decorated AuNP-PANI structures in terms of the oxygen reduction reaction. Aimed for an alternative photoanodes, hierarchical mesoporous carbon-TiO2 inverse opal nanostructures were synthesized by complementary colloid and block copolymer (BCP) self-assembly, where the triblock copolymer P123 acts simultaneously as template and carbon source. Analytical studies show that incorporation of carbon moieties into TiO2 creates a new energy level above the valence band of TiO2, resulting in an effective decrease in the band gap. A significant enhanced visible light photocatalytic activity was demonstrated in terms of the degradation of p-nitrophenol (~79 %) and photoelectrochemical water splitting.

Thursday, March 5, 2015 8:00AM - 11:00AM – Session S35 DAMOP: Optomechanics, Hybrid Systems and Macroscopic Systems at the Quantum Limit 210B - Chen-Lung Hung, Purdue University

8:00AM S35.00001 Anthracene Crystals Doped with Dibenzoterrylene Molecules in Optical Fibre Microcavities, K.D. MAJOR, E.A. HINDS, ALEX S. CLARK, C. POLLISENI, S. GRANDI, Y.H. LIEN, Imperial College London, QUANTUM NANOPHOTONICS, CENTRE FOR COLD MATTER, QUANTUM OPTICS AND LASER SCIENCE GROUP TEAM — Dibenzoterrylene molecules placed in an anthracene crystal are stable emitters resistant to photobleaching and with a high quantum efficiency and low phonon coupling. Placing dibenzoterrylene doped anthracene crystals within a optical fibre microcavity can lead to enhanced emission of radiation into the modes of the optical cavity. The optical fibre microcavities are already coupled to a optical photon source. By selecting the correct cavity mirror reflectivities, the emission can be preferentially directed down the optical fibre. Excitation of the dibenzoterrylene molecules leads to the emission of single photons and can then be used as a micron-scale fibre coupled single photon source.
8:12AM S35.00002 Optomechanical Levitation of Tethered Dielectrics in a Cavity, TINA MÜLLER, CHRISTOPH REINHARDT, BODGAN PIČIU, ABEER BARASHEED, SIMON BERNARD, ALEXANDRE BOURASSA, XINYUAN ZHANG, CHRISTOPHER MCNALLY, JACK SANKEY, McGill University, MCGILL OPTOMECHANICS LAB TEAM — Optically supporting dielectric materials has the potential to increase their mechanical quality factors far beyond the limits set by material dissipation. As the mechanical frequency $\omega$ increases due to the applied optical spring, the quality factor increases as $\omega^2$, meaning that the overall dissipation rate decreases and the mass experiences less force noise from the environment. However, a major limitation when trapping weakly tethered dielectrics is the mode mixing with the low-$\omega$ mechanical modes of the tethers, occurring when the frequency of the trapped element becomes degenerate with the tether mode frequencies. In addition, the maximum trap strength is limited by the maximum optical power a dielectric can be exposed to before breakdown. Here, we describe an optimal system to overcome these limits, based on a straightforward cavity levitation scheme and controlling the position and angle of the mechanical element via its tethers. We also show progress towards trapping a SiN tethered membrane with our scheme, and discuss implementations based on other materials.

8:24AM S35.00003 Optomechanics in a Millikelvin Environment, BRADLEY HAUER, ALLISON MACDONALD, GREG POPOWICH, PAUL KIM, ARON FREDRICK, XAVIER ROJAS, JOHN DAVIS, University of Alberta — As advances in technology continue to improve the quality and reduce the size of nanofabricated devices, we edge closer and closer to the prospect of observing quantized motion of a mesoscopic mechanical resonator. Measurements of such devices, which consist of dozens to tens of nanometers, would provide an excellent test of the scales at which quantum mechanics is applicable. However, due to their relatively large effective masses, these devices must be cooled to $\text{mK}$ temperatures to reach their quantum ground state. The field of cavity optomechanics, which has already achieved quantum limited measurement sensitivity, provides a promising avenue for performing such measurements. To this end, we have designed a tapered fiber optomechanical coupling apparatus, with full 3D control and real time imaging of the coupling environment, on the base plate of a dilution refrigerator. This experiment is capable of passively cooling devices to temperatures below 10 mK, at which oscillators with resonance frequencies as low as 150 MHz will be cooled to single phonon occupancy. In this talk, I will present preliminary measurements from this cutting edge system.

8:36AM S35.00004 Optomechanical applications of optically levitated nanoparticles, LEVI NEUKIRCH, Department of Physics and Astronomy, University of Rochester, NICK VAMIVAKAS, Institute of Optics, University of Rochester — Optomechanics experiments performed in vacuum with optically levitated oscillators offer mechanical quality factors unmatched by clamped resonators. Single-beam gradient force traps have been proven capable of stably levitating nanoscale dielectric spheres in high vacuum, and parametric modulation of the trap stiffness has been demonstrated as an efficient way to cool the center of mass motion. We present our optical levitation and cooling apparatus, and characterize its performance. We discuss several applications which extend control to degrees of freedom beyond the three-dimensional translational motion of the particle.

8:48AM S35.00005 Analytic Solution of the Equation of Motion for an Optically-Torqued, Overdamped Nanorod, W.C. KERR, H. NASIF, S. RAYNOR, Wake Forest Univ. — Shelton et al.[1] performed an experiment to drive a nanorod, immersed in a viscous medium, by an optical field with rotating polarization. The nanorod had a length of about 5 microns, was held in an optical trap and placed in water, which provided a frictional torque. A linearly polarized optical beam was incident on the rod, and its polarization plane was rotated by passing it through a rotating half-wave plate. The rod’s polarization tensor was anisotropic, so its induced dipole moment was not parallel to the field; thus a driving torque was exerted on the rod. A simplified equation was written in terms of an auxiliary variable proportional to the nanorod’s angle in a rotating frame, the equation was the same as that of a damped, driven pendulum. We find that this ODE is amenable to analytic solution. The solution identifies a certain critical angular frequency such that the inertial term of the equation of motion can be ignored. When this simplified equation was written in terms of an auxiliary variable proportional to the nanorod’s angle in a rotating frame, the equation was the same as that of a damped, driven pendulum. We find that this ODE is amenable to analytic solution. The solution identifies a certain critical angular frequency, such that qualitatively different motions occur when the light polarization rotation frequency is less than or greater than the critical frequency. All features of the analytic solution agree quantitatively with the experiment.

8:00AM S35.00006 Dark-field Spectroscopy of Plasmonic Nanodevices with Nanometer Scale Features, DAVID FRENCH, STEPHEN BAUMAN, DESALEGN DEBU, CAMERON SAYLOR, JOSEPH HERZOG, University of Arkansas — Plasmonic nanodevices are metallic structures that exhibit plasmonic effects when exposed to light, causing scattering and enhancement of that light. These plasmons makes it possible for light to be focused below the diffraction limit. Dark-field spectroscopy has been used to capture scattering spectra of these structures, in order to examine the scattering and resonant frequencies of the plasmons provided by the devices. Dark-field spectroscopy is particularly well suited to this task because it is inexpensive to set up and it functions well with low signals. This paper examines the relation between the geometries of the devices and the spectral intensity of the scattered light. We study geometric parameters including device thickness and adhesion layer effects. Additionally we plan to investigate nanostructures fabricated with novel fabrication technique with device dimensions that are below 10 nm, both gap width and structure width. These devices are modeled computationally as well as manufactured and characterized experimentally.

9:00AM S35.00007 Probing emitter-cavity dressed states through environmental transitions, JAKE ILES-SMITH, Blackett Laboratory, Imperial College London, London, SW7 2AZ, UK, AHSAN NAZIR, Photon Science Institute and School of Physics & Astronomy, The University of Manchester, Oxford Road, Manchester M13 9PL, UK — In this work we explore the effect of phonons on the emission properties of a cavity QED system in several important parameter regimes — the semi-classical intermediate coupling, Fano, and strong coupling regime. Specifically, we examine the effect of phonon interactions on the emission spectrum of a quantum dot in a high-Q optical cavity, focusing in particular on a micropillar type setup. We demonstrate that the quantum mechanical nature of the phonon environment, and short timescales over which phonons processes occur, allows one to probe the joint eigenstates of the cavity and TLS even in a semi-classical regime. Not only does this demonstrate a failure of the traditional quantum optics treatment, but also challenges the notion that phonons decohere such a system to a more classical description. Furthermore, we demonstrate that the behaviour we predict may be observed in a straightforward fashion by considering the cavity reflectivity, associated phase shift, or the cavity emission spectra.

9:12AM S35.00008 Near-analytic solutions to the PMD equations in Periodically Spun Fiber using Differential Transform Method, VINOD MISHRA, US Army Research Laboratory — Periodically spun optical fibers have been found to reduce Polarization Mode Dispersion (PMD) in propagating optical modes [1]. The resulting coupled ordinary differential equations are usually solved numerically. To gain better physical understanding and dependence of PMD Change Factor (PCF) on relevant parameters, analytical solutions are to be preferred. The current work uses Differential Transform Method to derive analytical solutions to the original equations as a series and investigates their properties.

9:36 AM S35.00009 Manipulation of Light Propagation in Photonic Crystal  . ZHIYUAN YANG, Department of Physics, UNT; AMITABH JOSHI, Department of Physics and Institute for Quantum Studies, Texas A&M University, YURI ROSTOVTSEV, Department of Physics, UNT — A propagation of probe electromagnetic waves have been investigated in a heterostructure formed by linear and nonlinear layers. The appearance of a forbidden band gap for a probe electromagnetic field induced by another control electromagnetic field has been shown to lead to trapping of a probe pulse inside structure. Switching off the control field leads to resuming the propagation of the probe pulse. Implementation of nonlinear layer has been suggested.

9:48 AM S35.00010 Quantum Friction in Different Regimes1. JULIANE KLATT, STEFAN BUHMANN, Albert-Ludwig University, Freiburg, Germany — Quantum friction is the velocity-dependent force between two polarizable objects in relative motion, resulting from field-fluctuation mediated transfer of energy and momentum between them. Due to its short-ranged nature it has proven difficult to observe experimentally. Theoretical attempts to determine the precise velocity-dependence of the quantum drag experienced by a polarizable atom moving parallel to a surface arrive at contradicting results. Scheel and Barton predict a force linear in relative velocity $v$ — the former using the quantum regression theorem and the latter employing time-dependent perturbation theory. Intravaia, however, predicts a $v^3$ power-law starting from a non-equilibrium fluctuation-dissipation theorem. In order to learn where exactly the above approaches part, we set out to perform all three calculations within one and the same framework: macroscopic QED. In addition, we include contributions to quantum friction from Doppler shift and Röntgen interaction, which play a role for perpendicular motion and retarded distances, respectively, and consider non-stationary states of atom and field.

1 DFG Emmy-Noether Program

10:00 AM S35.00011 Friction forces on atoms after acceleration. DIEGO DALVIT, Los Alamos National Laboratory, FRANCESCO INTRAVAIA, Max Born Institute, Germany, VANIK MKRTCHIAN, Institute for Physical Research, Armenia, STEFAN BUHMANN, University of Freiburg, Germany, STEFAN SCHHEEL, University of Rostock, Germany, CARSTEN HENKEL, University of Postdam, Germany — We revisit the calculation of atom-surface quantum friction in the formulation based on perturbation theory. We show that the power dissipated into field excitations and the associated friction force depend on how the atom is boosted from being initially at rest to a configuration in which it is moving at constant velocity parallel to the planar interface. In addition, we point out that there is a subtle cancellation between the one-photon and part of the two-photon dissipating power, resulting in a leading order contribution to the frictional power which goes as the fourth power of the velocity.

10:12 AM S35.00012 Parametric mechanical pumping in graphene membranes , ROBERTO DE ALBA, ISAAC STORCH, THANNIYIL SEBASTIAN ABHILASH, Department of Physics, Cornell University, FRANCESCO MASSEL, Department of Physics, University of Jyväskylä, PAUL L. MCEUEN, Department of Physics, Cornell University, HAROLD G. CRAIGHED, School of Applied & Engineering Physics, Cornell University, JEEVAK M. PARPIA, Department of Physics, Cornell University — We demonstrate tension-mediated mechanical mode coupling in suspended graphene membranes. These nonlinear effects arise due to graphene’s large elastic modulus and large deflections. We show experimentally that these mode-mode interactions can be utilized to parametrically amplify or cool mechanical motion, and that the coupled system obeys similar physics to optical-cavity-coupled mechanical systems. This enables all-electrical parametric control of the resonator dynamics, including self-oscillation. Mechanical pumping can thus enhance the performance of graphene-based force sensors, or supplement traditional cooling schemes to probe coupled mechanical systems approaching the quantum regime.

10:24 AM S35.00013 Aging and annealing of ultrahigh quality factor silicon resonators1. THOMAS METCALF, XIAO LIU, Naval Research Laboratory — At liquid helium temperatures, resonators fabricated from single crystal silicon can have remarkably high quality factors, exceeding 50 million. However, the quality factors are still far from the limits predicted from known loss mechanisms, indicating the possibility of future improvement and increased sensitivity. Measurements of the baseline quality factor after a sequence of annealing and aging steps have shown that there are at least two loss mechanisms that contribute, one of which reappears with megasecond aging. The relation between these loss mechanisms and the resonator fabrication processing steps is considered, with implications for the ultimate sensitivity of resonator-based devices and in the phonon transport properties of silicon-based devices.

1 Work supported by the Office of Naval Research

10:36 AM S35.00014 Mechanical mode coupling and nonlinearity in as-grown GaAs nanowires , FLORIS BRAAKMAN, DAVIDE CADEDDU, University of Basel, GOZDE TUTUNCUOGLU, FEDERICO MATTEINI, DANIEL RÜFFER, ANNA FONTCUBERTA I MORRAL, École Polytechnique Fédérale de Lausanne, MARTINO POGGIO, University of Basel — We demonstrate coupling and nonlinear behavior of transverse mechanical modes of as-grown GaAs nanowires. Because of their small dimensions and potentially defect-free growth, nanowire cantilevers are promising as ultrasensitive force transducers for scanning probe microscopy. Furthermore, nanowire heterostructures can combine functionalities in one integrated structure which makes them attractive as hybrid systems. The observed nonlinearity is used to demonstrate mechanical mixing of two excitation frequencies, as well as to amplify a signal at a frequency close to the mechanical resonance of the nanowire oscillator. The mode coupling is observed both in a pump-probe experiment, where the resonance of one mode is shifted to higher frequencies by pumping the other mode, and in a time-resolved manner in a ringdown experiment, in which case a clear beating pattern with frequency equal to the frequency difference between the two modes is present. Sufficiently strong coupling forms the basis for phenomena such as phonon-cavity physics, mechanically induced transparency and synchronization. Furthermore, the nonlinearity and mode coupling can be used in various amplification schemes for enhancing sensitivity in force microscopy.

10:48 AM S35.00015 Room Temperature Experiments with a Macroscopic Sapphire Mechanical Oscillator . JEREMY BOURHILL, EUGENE IVANOV, MICAHEL TOBAR, UWA — We present initial results from a number of experiments conducted on a 0.53 kg sapphire “dumbbell” crystal. Mechanical motion of the crystal structure alters the dimensions of the crystal, and the induced strain changes the permittivity. These two effects frequency modulate resonant microwave whispering gallery modes, simultaneously excited within the crystal. A novel microwave readout system is described allowing extremely low noise measurements of this frequency modulation with a phase noise floor of -160 dBc/Hz at 100 kHz, near our modes of interest. Fine-tuning of the crystal’s suspension have allowed for the optimisation of mechanical Q-factors in preparation for cryogenic experiments, with a value of 8 x 10^7 achieved so far. Finally, results are presented that demonstrate the excitation of mechanical modes via radiation pressure force. These are all important steps towards the overall goal of the experiment; to cool a macroscopic device to the quantum ground state.
8:00AM S36.00001 Non-equilibrium dynamics of atomic Fermi and Bose gas under lattice geometry transformation, CHEN-YEN LAI, CHIH-CHUN CHIEN, Univ of California - Merced — The tunability of ultra-cold atom experiments has provided a new arena of exploring quantum effect in both bosonic and fermionic system in and out of equilibrium. According to recent experiments [Phys. Rev. Lett. 108, 045305 (2012)], a triangular lattice can be dynamically tuned into a square or kagome lattice by adjusting frequency and focus point of laser beams. We simulate the dynamical properties of single component fermions and weakly interacting bosons under various transformation processes, including different ramping time scales, different ramping functions, and more importantly into different types of lattice geometry. A non-equilibrium steady state, which is not thermalized, is found in single component fermion system under different particle densities in both small size system and in the thermodynamic limit. In contras, weakly interacting bosons do not exhibit observable steady state behavior. This opens new opportunities of research on dynamical multi-band effects.

8:12AM S36.00002 Spatio-temporal correlations in the Bose Hubbard model after a quantum quench1, MATTHEW FITZPATRICK, MALCOLM KENNEDY, Simon Fraser University — The dynamics of the Bose Hubbard model after a quantum quench have attracted much recent attention. Theoretically, it has proven challenging to describe spatio-temporal correlations in dimensions higher than one. We use the Schwinger-Keldysh technique and a strong coupling expansion to develop a two particle irreducible formalism that allows the study of correlations in time and space in both superfluid and Mott insulating regimes after a quantum quench. We obtain equations of motion for two-time correlation functions and relate our results to recent cold-atom experiments.

8:24AM S36.00003 Trap-induced scales in non-equilibrium dynamics of strongly interacting bosons, RAJDEEP SENSARMA, Tata Institute of Fundamental Research, ANIRBAN DUTTA, KRISHNENDU SENGUPTA, Indian Association for Cultivation of Sciences — We use a time-dependent hopping expansion technique to study the non-equilibrium dynamics of strongly interacting bosons in an optical lattice in the presence of a harmonic trap characterized by a force constant $K$. We show that after a sudden quench of the hopping amplitude $J$ across the superfluid (SF)-Mott insulator (MI) transition, the SF order parameter $\Delta$ displays a novel non-monotonic spatial profile. Both these phenomena can be explained as consequences of trap-induced time and length scales affecting the dynamics and can be tested by concrete experiments.
10:12AM S36.00010 Controlling the condensate in driven optical lattices , ALBERTO NOCERA, ADRIAN FEIGUIN, Department of Physics, Northeastern University, Boston, Massachusetts 02115, USA — We study the one-dimensional attractive Hubbard model under the influence of a periodic driving potential with the time-dependent density matrix renormalization group showing that the system can be driven in an unconventional paired state characterized by a condensate made of Cooper-pairs with a finite center-of-mass momentum similar to a Fulde-Ferrell state. We obtain results both in the laboratory and the rotating reference frames demonstrating that the momentum of the condensate can be finely tuned by changing the ratio between the amplitude and the frequency of the driving. In particular, by quenching the above ratio to the value giving suppression of the tunneling and putting the Coulomb interaction strength to zero, we are able to “freeze” the condensate. We finally study the effects of different initial conditions, and compare our numerical results to those obtained from a time-independent Floquet theory in the large frequency regime. Our work offers the possibility of engineering and controlling unconventional paired states in fermionic condensates.

10:24AM S36.00011 Dissipative effects in dipolar, quantum many-body systems 1, ARGHAVAN SAFAVI-NAINI, JILA, CU Boulder, BARBARA CAPOGROSSO-SANSONE, University of Oklahoma, ANA MARIA REY, JILA, CU Boulder — We use Quantum Monte Carlo simulations, by the Worm algorithm, to study the ground state phase diagram of two-dimensional, dipolar lattice bosons where each site is coupled, via density operators, to an external reservoir. A recent related study of the XXZ model with ohmic coupling to an external reservoir reported the existence of a bath-induced Bose metal phase in the ground state phase diagram away from half filling, and a Luttinger liquid and a charge density wave at half-filling [1]. Our work extends this methodology to higher dimensional systems with long-range interactions. In the case of hard-core bosons, our method can be applied to experimental systems featuring dipolar fermionic molecules in the presence of losses. This work utilized the Janus supercomputer, which is supported by the NSF (Award No. 1412194) and the University of Colorado Boulder, and is a joint effort with the University of Colorado Denver and the National Center for Atmospheric Research, as well as OU Supercomputing Center for Education and Research (OSCER) at the University of Oklahoma.

10:36AM S36.00012 ABSTRACT WITHDRAWN —

10:48AM S36.00013 Evolutionary games of condensates in driven and dissipative bosonic systems 1, JOHANNES KNEBEL, MARKUS F. WEBER, TORBEN KRÜGER, ERWIN FREY, Ludwig Max Univ Muenchen — Condensation is a collective behavior of particles observed in both classical and quantum physics. For example, when an equilibrated, dilute gas of bosonic particles is cooled to a temperature near absolute zero, the ground state becomes macroscopically occupied (Bose-Einstein condensation). Whether novel condensation phenomena occur far from equilibrium is a topic of vivid research. Only recently has it been proposed that a driven and dissipative gas of bosons can condense not only into a single, but also into multiple non-degenerate states. This phenomenon may occur when a system of non-interacting bosons is weakly coupled to a reservoir and is driven by an external time-periodic force (Floquet system). Coherence becomes negligible and the condensation is described by a Pauli master equation, which also arises in the evolutionary dynamics of classical agents. In our work, we apply concepts from evolutionary dynamics to determine the states that become condensates. This condensate selection is guided by the vanishing of relative entropy production. We find that the system of condensates never comes to rest: The occupation numbers of condensates oscillate, which we demonstrate for a rock-paper-scissors game of condensates.

Thursday, March 5, 2015 8:00AM - 11:00AM —

Session S37 GQI: Semiconductor Qubits - Gated Dots and Impurities I

8:00AM S37.00001 Dispersive measurement of electron spin states in Coulomb-confined silicon double quantum dots, MATTHEW HOUSE, TAKASHI KOBAYASHI, BENT WEBER, SAM HILE, SVEN ROGGE, MICHELLE SIMMONS, Centre for Quantum Computation and Communication Technology, University of New South Wales — We use radio frequency reflectometry with a resonant circuit to probe the electronic spin state. We map the ground state transition between singlet and triplet states as a function of electric and magnetic fields, which shows that the exchange energy can be tuned over an order of magnitude (about 10 to 100 eV) or more in this device. We apply high frequency pulses to induce an excited spin state and observe that the dispersive measurement can detect the excited spin state in addition to the ground state.

8:12AM S37.00002 Bias Triangles Presented in Chemical Potential Space, JUSTIN PERRON, Joint Quantum Institute, M.D. STEWART, JR, NEIL M. ZIMMERMAN, NIST - Natl Inst of Stds & Tech — Readout of spins in solid state electronic devices requires some form of spin-to-charge conversion. Through analysis of the data we are able to present spin resolvability on a single plot in chemical potential space. The presentation will allow comparisons between different biasing directions to be made in a clean and straightforward manner. This ability will be useful for investigating into PSB where these comparisons are paramount.

8:24AM S37.00003 Single-electron regime and Pauli spin blockade in a silicon metal-oxide-semiconductor double quantum dot 1, SOPHIE ROCHELLE, Université de Sherbrooke, GREGORY A. TEN EYCK, TAMMY PLUYM, MICHAEL P. LILLY, MALCOLM S. CARROLL, Sandia National Laboratories, MICHEL PIORO-LADRiÈRE, Université de Sherbrooke — Silicon quantum dots are promising candidates for quantum information processing as spin qubits with long coherence time. We present electrical transport measurements on a silicon metal-oxide-semiconductor (MOS) double quantum dot (DQD). First, Coulomb diamonds measurements demonstrate the one-electron regime at a relatively high temperature of 1.5 K. Then, the 8 mK stability diagram shows Pauli spin blockade with a large singlet-triplet separation of approximately 0.40 meV, pointing towards a strong lifting of the valley degeneracy. Finally, numerical simulations indicate that by integrating a micro-magnet to those devices, we could achieve fast spin rotations of the order of 30 ns. Those results are part of the recent body of work demonstrating the potential of Si MOS DQD as reliable and long-lived spin qubits that could be ultimately integrated into modern electronic facilities.

1 Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE’s National Nuclear Security Administration under contract DE-AC04-94AL85000.
8:36AM S37.00004 Tunable Radio-frequency Quantum Point Contact, ANNE-MARIE ROY, OLIVIER SAINT-JEAN RONDEAU, JULIEN CAMIRAND-LEMYRE, MICHEL PIORO-LADRIÈRE, Université de Sherbrooke — Manipulating the spin of single electrons in quantum dots is a promising avenue for quantum information processing. As the readout of the spins is performed via spin-to-charge conversion, establishing a charge sensing technique[1] that is fast and highly sensitive is crucial. For this reason, radio-frequency quantum point contact charge sensors have become widespread[2]. Here we present a tunable quantum point contact charge sensor using a cryogenic variable capacitor[3], tunable from 2 to 12 pF. We obtain optimal impedance matching for different quantum dot devices over a frequency range from 125 to 210 MHz. The flexibility of our setup allows the integration of radio-frequency charge sensors to a variety of nanostructures.

8:48AM S37.00005 Measurement, modeling, and simulation of cryogenic SiGe HBT amplifier circuits for fast single spin readout, TROY ENGLAND, Sandia National Laboratories, MATTHEW CURRY, CQUC and Department of Physics and Astronomy, University of New Mexico, STEVE CARR, BRIAN SWARTZENTRUBER, MICHAEL LILLY, NATHAN BISHOP, MALCOLM CARROL, Sandia National Laboratories — Fast, low-power quantum state readout is one of many challenges facing quantum information processing. Single electron transistors (SETs) are potentially fast, sensitive detectors for performing spin readout of electrons bound to Si:P donors. From a circuit perspective, however, their output impedance and nonlinear conductance are ill suited to drive the parasitic capacitance typical of coaxial conductors used in cryogenic environments, necessitating a cryogenic amplification stage. We will discuss calibration data, as well as modeling and simulation of cryogenic silicon-germanium (SiGe) heterojunction bipolar transistor (HBT) circuits connected to a silicon SET and operating at 4 K. We find a continuum of solutions from simple, single-HBT amplifiers to more complex, multi-HBT circuits suitable for integration, with varying noise levels and power vs. bandwidth tradeoffs. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

9:00AM S37.00006 Giant valley splitting in Si/oxide: discriminating Fang-Howard or Tamm-Shockley interface states, AMINTOR DUSKO, BELITA KOILLER, Instituto de Física - UFRJ, ANDRÉ SARAIVA, UFRJ / University of Wisconsin - Madison — The conduction band of silicon presents six inequivalent degenerate minima, or valleys. The presence of an abrupt interface lifts this degeneracy by a few 0.1 meV, an energy scale that may directly affect spin qubits. Experiments reporting splittings over 20 meV[1] cannot be explained by this mechanism. Extended Si/oxide interface (Tamm-Shockley) states may account for this enhancement[2]. We present a renormalization solution for the 1D tight-binding (TB) model of this interface state[2], so that the full range of TB parameters is readily accessible[3]. The renormalization language naturally reveals the role played by the chemical bond of atoms across the interface. Our approach eliminates the need for a supercell calculation[2], proving the formation of intrinsic interface states regardless of electric field. Moreover, the rectification rate of convergence provides quantitative estimates for the localization lengths of these states. We compare these interface states to the usual field-bound Fang-Howard states, suggesting capacitance measurements to differentiate them[3].

9:12AM S37.00007 Interface roughness mediated phonon relaxation rates in Si quantum dots, RIFAT FERDOUS, YULONG HSUEH, GERHARD KLIMECK, RAJIB RAHMAN, Purdue University — Si QDs are promising candidates for solid-state quantum computing due to long spin coherence times. However, the valley degeneracy in Si adds an additional degree of freedom to the electronic structure. Although the valley and orbital indices can be uniquely identified in an ideal Si QD, interface roughness mixes valley and orbital states in realistic dots. Such valley-orbit coupling can strongly influence the charge carrier relaxation. Recent experimental measurements of various relaxation rates differ from previous predictions of phonon relaxation in ideal Si QDs. To understand how roughness affects these relaxation rates, for example spin relaxation due to spin-valley coupling, which is a byproduct of spin-orbit and valley-orbit coupling, we need to understand the effect of valley-orbit coupling on valley relaxation first. Using a full-band atomistic tight-binding description for both the system's electron and electron-phonon Hamiltonians, we analyze the effect of atomic-scale interface disorder on phonon induced valley relaxation and spin relaxation in a Si QD. We find that, the valley splitting dependence of valley relaxation rate governs the magnetic field dependence of spin relaxation rate. Our results help understand experimentally measured relaxation times.

9:24AM S37.00008 Theory of 1- and 3-electron g-factors in Si quantum dots for spin-qubit manipulation, RUSKO RUSKOV, CHARLES TAHAN, Laboratory for Physical Sciences, MICHAEL E. FLATTE, University of Iowa, MENNO VELD-HORST, ANDREW DZURAK, University of New South Wales — Although the spin-orbit interaction in silicon is very weak, it is possible to map out the electron spin resonance (ESR) frequency with high precision in MOS quantum dot (QD) qubits by using isotopically purified silicon[1]. Using this method, the g-factor with 1 and 3 electrons in the dot has been measured with an in-plane magnetic field and as a function of the applied electric field perpendicular to the interface (along the growth direction [001]) [2]. Here, we present a theoretical model of the electron g-factor in Si QDs. We show that the results could be explained with the effect of an electron envelope function deformation in the confining interface region. Since the QD orbital splitting is much larger than the valley splitting at the interface, the system with 1 or 3 electrons probes the valley states at the interface, and the sign and size of the g-factor renormalization (order of tens of MHz in the chosen range of the electric field) could be explained via the spin-orbit 2D interaction induced at the interface. Electrical g-factor control opens the possibility of fast and all-electric manipulation of a few electron spin-qubit, without the need of a nanomagnet or a nuclear spin-background.

9:36AM S37.00009 Counted Sb donors in Si quantum dots, MEENAKSHI SINGH, JOSE PACHECO, EDWARD BIELEJEJ, DANIEL PERRY, GREGORY TEN EYCK, NATHANIEL BISHOP, JOEL WENDT, DWIGHT LUHMAN, MALCOLM CARROLL, MICHAEL LILLY, Sandia National Laboratories — Deterministic control over the location and number of donors is critical for donor spin qubits in semiconductor based quantum computing. We have developed techniques using a focused ion beam and a diode detector integrated next to a silicon MOS single electron transistor to gain such control. With the diode detector operating in linear mode, the numbers of ions implanted have been counted and single ion implants have been detected. Poisson statistics in the number of ions implanted have been observed. Transport measurements performed on samples with counted number of implants have been performed and regular coulomb blockade and charge offsets observed. The implications for various gates are found to be in agreement with QCAD simulations for an electrostatically defined dot. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE Office of Basic Energy Sciences user facility. The work was supported by Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.
9:48AM S37.00010 Development of Linear Mode Detection for Top-down Ion Implantation of Low Energy Sb Donors, JOSE PACHECO, MEENAKSHI SINGH, EDWARD BIELEJEIC, MICHAEL LILLY, MALCOLM CARROLL, Sandia Nat Labs — Fabrication of donor spin qubits for quantum computing applications requires deterministic control over the number of implanted donors and the spatial accuracy to within which these can be placed. We present an ion implantation and detection technique that allows us to deterministically implant a single Sb ion (donor) with a resulting volumetric distribution of <10 nm. This donor distribution is accomplished by implanting 30keV Sb into Si which yields a longitudinal straggle of <10 nm and combined with a <50 nm spot size using the Sandia Nanolplantrameter (nl). The ion beam induced charge signal is collected using a MOS detector that is integrated with a Si quantum dot for transport measurements. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE Office of Basic Energy Sciences user facility. The work was supported by Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

10:00AM S37.00011 Long-lived spin coherence and nuclear modulation effects of the silicon vacancy in 4H-SiC at room temperature, SAMUEL CARTER, ONEY SOYKKAL, SOPHIA ECONOMOU, EVAN GLASER, Naval Research Laboratory — The silicon vacancy in silicon carbide is currently being considered for applications in quantum information and sensing, with several studies showing room temperature spin polarization and manipulation. We perform room temperature optically-detected magnetic resonance and spin echo measurements on an ensemble of silicon vacancies to better characterize the nature of this system and determine the spin coherence properties. The spin coherence time is shown to be dependent on magnetic field, varying from a few ms at low fields to longer than 30 µs at 50 mT. Strong spin echo modulation that varies with magnetic field is also observed. The modulation is attributed to the interaction with nearby nuclear spins and is well-described by a theoretical model.

10:12AM S37.00012 Oxygen-Boron Vacancy Defect in Cubic Boron Nitride: A Diamond NV−Isoelectronic Center, TESFAYE ABTEW, WEIWEI GAO, University at Buffalo, State University of New York, XIANG GAO, Beijing Computational Science Foundation under Grant No. DMR-0946404. Work at Beijing CSRC is supported by the National Natural Science Foundation of China (Grant No. 11328401).

10:24AM S37.00013 Observation of a single rare-earth ion in a crystal by electric-field-modulation spectroscopy for a readout of a nuclear-spin qubit, KOUCI CHIMURA, HAYATO GOTO, SATORI KAMAKURA, MAMIKO KUJRIAKA, Frontier Research Laboratory, Corporate Research & Development Center, Toshiba Corporation — Nuclear spin states of rare-earth-metal ions in crystals are known as good candidates for qubits in solids because of their long coherence time and their good controllability by lights. In the frequency-domain quantum computer (FDQC), nuclear spin states of the ions are employed as qubits defined in a frequency domain, and interaction between the qubits is mediated by a single cavity mode. In FDQC we can use adiabatic passage with dark states to perform single-qubit gates and two-qubit gates [1], and a single-qubit gate using adiabatic passage has been demonstrated [2]. For two-qubit gates, quantum states of qubit ions need to be read out and operated individually. In order to observe a single ion in a crystal, we studied modulated signals due to ions in a cavity-mode spectrum of a monolithic optical cavity made of Pr3+:Y2SiO5. Owing to the cavity enhancement and the electric-field-modulation spectroscopy, signals which are likely due to individual ions (statistical fine structure in an inhomogeneously broadened optical transition) were observed.

10:36AM S37.00014 Wavefunction dynamics in a quantum-dot electron pump under a high magnetic field, SUNGGUEN RYU, KAIST, MASAYA KATAOKA, NPL, United Kingdom, HEUNG-SUN SIM, KAIST — A quantum-dot electron pump, formed and operated by applying time-dependent potential barriers to a two-dimensional electron gas system, provides a promising redefinition of ampereme. The pump operation consists of capturing an electron from a reservoir into a quantum dot and ejecting it to another reservoir. The capturing process has been theoretically understood by a semi-classical treatment of the tunneling between the dot and reservoirs. But the dynamics of the wavefunction of the captured electron in the ejection process has not been theoretically addressed, although it is useful for enhancing the pump accuracy and for utilizing the pump as a single-electron source for mesoscopic quantum electron devices. We study the dynamics under a strong magnetic field that leads to magnetic confinement of the captured electron, which dominates over the electrostatic confinement of the dot. We find that the wave packet of the captured electron has the Gaussian form with the width determined by the strength of the magnetic field, and that the time evolution of the packet follows the classical drift motion, with maintaining the Gaussian form. We discuss the possible signatures of the wave packet dynamics in experiments.

10:48AM S37.00015 Semiconducting nanodimer as a photonic cavity: Large and well-defined Rabi splitting, MITSUHARU UEMOTO, Graduate School of Engineering Science, Osaka University, HIROSHI AJIKI, Photon Pioneers Center, Osaka University — A metallic nanodimer acts as a photonic cavity because a strong light field appears at the gap region due to a surface plasmon resonance. In this talk, we propose a photonic cavity consisting of a semiconducting nanodimer with a small gap, and theoretically demonstrate large and well-defined vacuum Rabi splitting of a two-level emitter placed at the photonic cavity. A light field is strongly enhanced at the gap region of the semiconducting nanodimer due to an exciton resonance. The interaction between the enhanced light and the emitter is significantly larger than that in a conventional photonic cavity, because the semiconducting nanodimer has a small cavity-mode volume beyond the diffraction limit as well as the metallic nanodimer. In contrast to the metallic nanodimer, the exciton decay rate at low temperature is very small, and as a result, the quality factor reaches Q ~ 10^8 which is about 100 times larger than that of the metallic nanodimer. Consequently, the large Rabi splitting energy (~ 1.7 meV) appears for the small dipole moment (~ 25 Debye) of the emitter, and the splitting energy is two times larger than the spectral width. Such a well-defined Rabi splitting is highly suited for both fundamental researches and applications.
from the effect of mode-mode coupling. The shape of the spectrum depends on the interrelation between the nonlinear coupling strength and the decay rates of the modes. The characteristic of the coupling-induced frequency fluctuations being non-Gaussian, it is possible to average over them in a path-integral formulation and thus to find the power due to the oscillator decay. We show that the mode coupling can be easily identified from the change of the spectrum due to weak resonant driving. Despite their decay coming from the coupling to (THz) light in free-space optical cavities and to microwave (GHz) fields in superconducting circuits. Exploiting this parametric coupling to realize quantum information transfer between these domains entails construction of devices with challenging requirements. These devices must integrate the membranes with superconducting circuits operating at cryogenic temperatures in proximity of free space optical photons while meeting demands for various quantum and coupling requirements. Here we show how to construct such “hybrid quantum devices” by microfabricating and assembling chip-based structures that can be inserted into high-finesse optical cavities compatible with low temperatures. We include an overview of recent fabrication improvements of membranes mechanically isolated from environment by phononic band-gap crystals.

DAN HU, School of Natural Sciences, Univ of California, Merced. SHANG-YU HUANG, Dept. of Physics, National Taiwan Univ. JIE-QIAO ZHOU, CEMS, RIKEN, Japan. LIN TIAN, School of Natural Sciences, Univ of California, Merced. HSI-SHENG GOAN, Dept. of Physics, National Taiwan Univ. — Optomechanical systems with ultrastrong coupling could demonstrate nonlinear optical effects such as photon blockade. The system-bath couplings in these systems play an essential role in observing these effects. In this work, we use a dressed-state master equation approach to study the quantum coherence of an optomechanical system. In this approach, the system-bath couplings are decomposed in terms of the eigenbasis of the optomechanical system. The mode-dependent decay rates and mode-dependent coupling terms are included. Compared with the standard master equation, our master equation includes photon-number-dependent terms that induce dephasing. We calculate cavity dephasing, second-order photon correlation, and two-cavity entanglement using the dressed-state master equation. At high temperature, our master equation predicts faster decay of the quantum coherence than with the standard master equation. The second-order photon correlation derived with our master equation shows less antibunching than that with the standard master equation.

8:24AM S38.00003 Improving integration of high-Q silicon nitride membrane resonators into electro-opto-mechanical devices for hybrid quantum systems. 
K. CICAK, NIST - Boulder, R.W. ANDREWS, P.-L. YU, R.W. PETERSON, T.P. PURDY, P.S. BURNS, C.A. REGAL, K.W. LEHNERT, JILA: University of Colorado and NIST, Boulder, R.W. SIMMONDS, NIST - Boulder. — Macroscopic high-stress silicon nitride membranes can be implemented as ultra-high-quality-factor mechanical resonators operating in the quantum regime with average phonon occupancy below one quantum. Mechanical motion of these resonators can be engineered to simultaneously couple both to (THz) light in free-space optical cavities and to microwave (GHz) fields in superconducting circuits. Exploiting this parametric coupling to realize quantum information transfer between these domains entails construction of devices with challenging requirements. These devices must integrate the membranes with superconducting circuits operating at cryogenic temperatures in proximity of free space optical photons while meeting demands for various quantum and coupling requirements. Here we show how to construct such “hybrid quantum devices” by microfabricating and assembling chip-based structures that can be inserted into high-finesse optical cavities compatible with low temperatures. We include an overview of recent fabrication improvements of membranes mechanically isolated from environment by phononic band-gap crystals.

8:36AM S38.00004 Coherent mechanically-mediated state transfer between a superconducting qubit and a cavity. 
HUGO RIBEIRO, Department of Physics, McGill University, Montreal, Quebec H3A 2T8, Canada. YING-DAN WANG, Institute of Theoretical Physics, Chinese Academy of Sciences, Beijing 100190, China. AASHISH CLERK, Department of Physics, McGill University, Montreal, Quebec H3A 2T8, Canada. — We study coherent state transfer between a superconducting qubit and a cavity coupled via a nanomechanical resonator. There are two major challenges relating to state transfer of such systems. First, the duration of the protocol needs to be shorter than the shortest time-scale associated with dissipation (qubit relaxation, mechanical damping, cavity decay ...). This constraint implies that most of the well-known adiabatic transfer protocols cannot be used as is. Second, a fast double swap protocol, where the state of the qubit is first transferred to the mechanical degree of freedom and then to the cavity, is the most sensible scheme to mechanical dissipation. Here, we present some protocols that take into account both constraints and optimize the fidelity of the coherent state transfer.

8:48AM S38.00005 Phonon mechanisms of nonlinear decay and dephasing of mesoscopic vibro-mechanical systems. 
JUAN ATALAYA, Michigan State University. THOMAS W. KENNY, Stanford University. MARK I. DYKMAN, Michigan State University. — The frequencies and the decay rates of mesoscopic oscillators depend on vibration amplitudes. Nonlinear decay has been seen recently in various nano- and micro-mechanical systems. Here we consider a microscopic mechanism of nonlinear decay, the nonlinear coupling of the vibrational mode of interest, for example, a flexural mode, to other vibrations. Typically, the modes of interest have low eigenfrequencies \( \omega_0 \). Their decay comes from the coupling to acoustic-phonon type vibrations with much higher frequency and density of states. Thus, nonlinear decay requires quartic anharmonic coupling or cubic anharmonicity in the higher order. We find the decay rate for the inverse lifetime of the involved phonons, which is determined by the internal nonlinearity and the boundary scattering, being either much larger or smaller than \( \omega_0 \). The results extend the thermo-elastic, Akhiezer, and Landau-Rumer decay theory to nonlinear decay of mesoscopic modes and make specific predictions on the temperature and frequency dependence of the decay rate for different types of systems. We show that nonlinear decay is invariably accompanied by dephasing. We also show that in nano-electro-mechanical systems the decay rate can be electrostatically controlled.

9:00AM S38.00006 Spectra of mesoscopic oscillators with dispersive mode-mode coupling. 
YAXING ZHANG, MARK DYKMAN, Michigan State University. — Mesoscopic vibrational systems typically have several nonlinearly coupled modes with different frequencies and with long lifetime. Examples are provided by flexural modes of carbon nanotubes, graphene sheets, and nanobeams. We consider the power spectrum of one of these modes, which we call an oscillator. Thermal fluctuations of the amplitudes of the modes coupled to the oscillator lead to fluctuations of its frequency and thus to the broadening of its spectrum. However, the coupling-induced broadening is partly masked by the broadening due to the oscillator decay. We show that the mode coupling can be easily identified from the change of the spectrum due to weak resonant driving. Despite the coupling-induced frequency fluctuations being non-Gaussian, it is possible to average over them in a path-integral formulation and thus to find the power spectrum. The shape of the spectrum depends on the interrelation between the nonlinear coupling strength and the decay rates of the modes. The characteristic features of the spectrum are analyzed in the limiting cases. We also find that the spectral effect of the internal nonlinearity of the oscillator differs substantially from the effect of mode-mode coupling.

This Research is funded by AFOSR and MURI.
9:12AM S38.00007 Improving the cooling performance of a mechanical resonator with two-level-sstem defects. TIAN CHEN, XIANG-BIN WANG, Tsinghua University — We study cooling performance of a realistic mechanical resonator containing defects. The normal cooling method through an optomechanical system does not work efficiently due to those defects. We show by employing periodical $\sigma_+$ pulses, we can eliminate the interaction between defects and their surrounded heat baths up to the first order of time. Compared with the cooling performance of no $\sigma_+$ pulses case, much better cooling results are obtained. Moreover, this pulse sequence has an ability to improve the cooling performance of the resonator with different defects energy gaps and different defects damping rates.

9:24AM S38.00008 Determination of effective mechanical properties of a double-beam beam by means of a nano-electromechanical transducer. HAN HUEBL, FREDRIK HOCKE, MATTHIAS PERNPEINTNER, Walther-Meissner-Institut, Garching, Germany, XIAOQING ZHOU, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ALBERT SCHLIESDER, Niels Bohr Institute, Copenhagen, Denmark, TOBIAS J. KIPPPENBERG, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, RUDOLF GROSS, Walther-Meissner-Institut, Garching, Germany. — In the field of optomechanics, the light field in an optical resonator dynamically interacts with a mechanical degree of freedom, enabling cooling and amplification of mechanical motion. This concept of light matter interaction can be transferred to the microwave (MW) regime combining superconducting MW circuits with nanometer-sized mechanical beams, establishing the class of circuit nano-electromechanics. To Taylor the mechanical properties of a vibrational element, double and multi-layer systems are of particular interest, e.g., the combination of highly tensile stressed SiN and metallic layers allow to increase the mechanical resonance frequency while maintaining a capacitive coupling scheme. Here, we investigate the mechanical properties of a doubly-clamped, double-layer nanobeam embedded into an electromechanical system. The nanobeam consists of a highly pre-stressed silicon nitride and a superconducting niobium layer. By measuring the mechanical displacement spectral density both in the linear and the nonlinear Duffing regime, we determine the pre-stress and the effective Young’s modulus of the nanobeam corroborating the analytical double-layer model expectations.

9:36AM S38.00009 Circuit Electromechanics with a Non-Metallized Nano-beam. MATTHIAS PERNPEINTNER, Walther-Meissner-Institut, Garching, Germany, T. FAUST, Center for NanoScience and Fakultät für Physik, Ludwig-Maximilians-Universität München, München, Munich, Germany, F. HOCKE, Walther-Meissner-Institut, Garching, Germany, J.P. KOTTHAUS, Center for NanoScience and Fakultät für Physik, Ludwig-Maximilians-Universität München, München, Munich, Germany, E.M. WEIG, Department of Physics, University of Konstanz, Konstanz, Germany, H. HUEBL, R. GROSS, Walther-Meissner-Institut, Garching, Germany. — In the field of cavity optomechanics, a motional degree of freedom is coupled to an optical cavity. This approach can be transferred to the solid state environment by combining a superconducting microwave cavity with a nanomechanical resonator. Typically, metallized mechanical resonators are used, coupling capacitively to the microwave cavity. In contrast, non-metallized nanomechanical beams provide higher quality factors and have therefore been employed for mechanical sensing devices. Here, we present an approach to integrate a pure, i.e. non-metallized nanobeam, into a nano-electromechanical device, which is based on the dielectric coupling between a superconducting coplanar waveguide microwave resonator and a tensile-stressed silicon nitride nanobeam. By making use of the Duffing nonlinearity of the strongly driven beam, we calibrate the amplitude spectrum of the mechanical motion and determine the electromechanical vacuum coupling. We find a quality factor of $480,000$ at a resonance frequency of $14$ MHz and $0.5K$. We deduce a vacuum coupling of $11.5 mHz$, which is in quantitative agreement with finite element based model calculations.

9:48AM S38.00010 Temporal and spectral mode conversion of microwave signals with a mechanical resonator. ADAM REED, REED ANDREWS, University of Colorado, Boulder/JILA/NIST, TAUNO PALOMAKI, University of Washington, KATARINA CICAK, JOHN TEUFEL, NIST Boulder, KONRAD LEHNERT, University of Colorado, Boulder/JILA/NIST. — Microwave fields are a powerful means for carrying information between separate quantum devices. Different devices, however, typically emit and capture fields with distinct frequencies and temporal envelopes. This spectral and temporal mismatch presents a challenge when wigning these elements into a fully functional information processing network. Here we show that this mismatch can be overcome by using an electromechanical circuit to arbitrarily alter the temporal envelope and center frequency of microwave signals, while at the same time acting as a storage medium. We demonstrate a protocol that shifts the frequency of $7$ GHz microwave signals by $250$ MHz, and converts an exponentially decaying temporal envelope into a Gaussian envelope. To characterize our signal conditioner in the quantum regime, we inject signals with a few quanta of energy to extract the total added noise and storage lifetime of the conditioner.

10:00AM S38.00011 Reservoir engineering in microwave cavity optomechanics. FLORENT LECOCQ, JEREMY CLARK, JOSE AUMENTADO, RAYMOND SIMMONDS, JOHN TEUFEL, NIST Boulder — Microwave cavity optomechanics is an architecture in which a freely suspended membrane modulates the frequency of a superconducting microwave resonant circuit. The resulting parametric interactions influence both the mechanical degree of freedom and the microwave light emerging from the cavity. Even at cryogenic temperatures, the mechanical oscillator resonating at $10$ MHz is typically dominated by its thermal reservoir, washing out any quantum behavior. However, in the presence of coherent drives to the cavity, the bare mechanical properties can be overwhelmed by the strong opto-mechanical interactions from the light field. By choosing wisely the frequency and amplitude of the drives, one can engineer the environment seen by the mechanical oscillator, a technique known as “reservoir engineering”. From an experimentalist point of view, we will discuss how using two-tone driving schemes, we exploit correlations in the vacuum noise to: (1) eliminate the backaction imparted on the mechanical quadrature being measured, a technique so-called Back-Action Evasion, or (2) strongly couple the mechanical mode to a squeezed microwave bath.

10:12AM S38.00012 Microwave electromechanics on suspended piezoelectric membranes. G. PEAIRS, K. J. SATZINGER, A. VAINSENCHER, UC Santa Barbara, A. N. CLELAND, University of Chicago — Nanomechanical resonators with microwave frequency resonances have been operated in the quantum regime, and are attractive for hybrid electro- and opto-mechanical schemes. We characterize a class of electromechanical devices using propagating phonons in two dimensions, operating at frequencies compatible with both superconducting qubits and optomechanical resonators. We use interdigitated transducers on suspended aluminum nitride membranes to launch and detect traveling acoustic waves. We demonstrate resonances localized to the transducers, as well as transmission across membranes and extended resonances in the acoustic cavities formed by the edges of the suspended membranes. We compare these measurements to analytic as well as finite-element models to determine key parameters, including the electromechanical coupling and propagation loss.

10:24AM S38.00013 Building a quantum interface between microwave and optical photons. A. VAINSENCHER, G. PEAIRS, K.J. SATZINGER, UC Santa Barbara, A.N. CLELAND, University of Chicago — In previous work we have shown that optomechanical resonators fabricated out of piezoelectric materials may provide a means for coherent transduction between microwave and optical frequency photons. Electrical microwave signals are efficiently converted to microwave photons, and these photons in turn modulate the optical response of an optomechanical crystal. In this talk, we will describe new designs we are pursuing in this same direction, with simplified fabrication and a predicted much greater electrical-to-optical coupling strength. We will outline the current device design, simulations, fabrication, and preliminary measurements.

9:12AM S39.00005 Integrating superconducting qubit systems for improved quantum operations\(^1\). STEFAN FILIPP, SARAH SHELDON, EASWAR MAGESAN, LEV S. BISHOP, MATTHIAS STEFFEN, JERRY M. CHOW, JAY M. GAMBITTA, IBM TJ Watson Research Center, Yorktown Heights NY, USA — Recent progress in the field of superconducting circuits has led to qubit coherence times exceeding by far typical single and two-qubit gate times. In this regime, in which relaxation (T_1) and dephasing (T_2) times are above 40 and 50 microseconds, respectively, quantum gates are not limited by intrinsic noise sources. We enter this regime by optimizing the design of coplanar transmon qubits to reduce the influence of surface loss. Furthermore, we have eliminated spurious microwave resonances which we can detect by monitoring the qubit coherence while sweeping the frequency of an external microwave drive applied to the system. To improve T_2 times, we minimize dephasing caused by thermal photons in coupled resonator modes by increasing the attenuation of the readout drive lines. To maintain the ability to drive fast gates with strong microwave signals while preserving coherence, we employ weakly capacitively coupled control lines providing independent control of the qubits and allowing for improved two-qubit entangling gate operations.

\(^1\)We acknowledge support from ARO under contract W911NF-14-1-0124.

9:24AM S39.00006 Improving Superconducting Qubit Lifetimes with Broadband Filters\(^1\). NICHOLAS BRONN, ANTONIO CORCOLES, JARED HERTZBERG, SRIKANTH SRINIVASAN, JERRY CHOW, JAY GAMBITTA, MATTHIAS STEFFEN, IBM TJ Watson Research Center, YANBING LIU, ANDREW HOUCK, Princeton University — In circuit quantum electrodynamics, the state of the qubit is read out via a resonator at a different frequency than that of the qubit. Spontaneous qubit decay via the resonator may be suppressed by engineering an impedance mismatch at the qubit frequency, while still allowing a large coupling between the resonator and external environment necessary for fast, high fidelity readout. We present a stepped-impedance filter with a large stop-band in the qubit frequency range and demonstrate its effect on qubit lifetime. This filter is also effective when used in an off-chip geometry.

\(^1\)We acknowledge support from IARPA under contract W911NF-10-1-0324.

9:36AM S39.00007 Strong interaction of a transmon qubit with 1D band-gap medium\(^1\). YANBING LIU, DARIUS SADRI, ANDREW HOUCK, Princeton University, NICHOLAS BRONN, JERRY CHOW, JAY GAMBITTA, IBM — The spontaneous emission of an atom will be enhanced or suppressed in a structured vacuum, commonly known as Purcell effect. Moreover, in a frequency gap medium, an atom-photon bound state is predicted to exist in the band gap, causing the localization of light. Here using the technology of circuit quantum electrodynamics, we experimentally explore this mechanism by fabricating a microwave step-impedance filter strongly coupled to a transmon qubit. Standard transmission and spectroscopy measurements support the existence of atom-photon bound states in the system. Correlation measurement shows that the atom-photon interaction induces strong correlation of the transmitted light through the system.

\(^1\)Thanks support from IARPA

9:48AM S39.00008 Parallel Loss Channels in Superconducting Epitaxial Aluminum Resonators , CHRISTOPHER RICHARDSON, NATHAN SIWAK, LEI HE, Laboratory for Physical Sciences — Superconducting epitaxial aluminum (epi-Al) on silicon and sapphire has demonstrated low-loss performance that is desirable for linear circuit elements in quantum computing. Most often, it is process artifacts that limit the performance of devices fabricated from epi-Al. Two common artifacts are photoresist residue that is impossible to observe with optical microscopy and line edge defects on the aluminum sidewalls. Superconducting quarter-wave resonators exhibit both saturable power dependence akin to conventional two-level-systems, and power independent loss that strongly impacts yield and is fabrication process dependent. Correlations between detailed electron microscopy, and resonator quality factor measurements with values above and below 10^16 will be discussed.

10:00AM S39.00009 Characterization of Fabrication Defects in Superconducting Epitaxial Aluminum Resonators , NATHAN SIWAK, LEI HE, JUSTIN HACKLEY\(^1\), CHRISTOPHER RICHARDSON, Laboratory for Physical Sciences — A continuing challenge in superconducting quantum computing is the creation of low-loss superconducting aluminum resonators. Significant processing difficulties lie in the removal of residues resulting from conventional Cl-based plasma etching without damaging the aluminum patterns. Correlations of resist residues and corrosion pit defect densities with cleaning process variations are completed using charge contrast-enhanced imaging in a scanning electron microscope. These quantified defects provide insight into the effectiveness of specific device processing steps in reducing these artifacts which can introduce additional loss mechanisms and limit potentially high performance devices.

10:12AM S39.00010 Effects of 780 nm Optical Illumination on Loss in Superconducting Microwave Resonator\(^1\). R.P. BUDOYO, J.B. HERTZBERG, C.J. BALLARD, K.D. VOIGT, JQI and CNAM, Dept. of Physics, University of Maryland, College Park, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, JQI and CNAM, Dept. of Physics, University of Maryland, College Park — Understanding the effects of light incident on a superconducting circuit is an important step toward building a hybrid quantum system where a superconducting qubit or resonator is coupled to atoms trapped on a tapered optical fiber. We fabricated a microscale thin-film Al superconducting LC resonator (frequency 6.72GHz) on sapphire substrate and mounted it inside an Al 3d cavity (TE101 mode frequency 7.50GHz). Using an optical fiber, we illuminated the resonator with 780 nm light, and measured the change in internal quality factor and resonant frequency of the resonator as a function of applied optical power. The results suggest that the illumination causes an increase in rf drive-dependent dissipation. While optical illumination is expected to enhance dissipation due to quasiparticles, rf drive dependence is more typically seen in two-level-system dissipation. We compare the results with the change in loss from increased resonator temperature, and discuss various mechanisms of loss from optical illumination.

\(^1\)Work supported by NSF through the Physics Frontier Center at the Joint Quantum Institute (JQI), and by the Center of Nanophysics and Advanced Materials (CNAM).
The resonator has a resonance frequency of 6.14 GHz, a quality factor Q of \(2.59 \times 10^3\) and is mounted inside a superconducting aluminum 3D cavity. A tapered optical fiber enters and exits the 3D cavity through two small holes in opposite sides of the cavity, placed so that the fiber can pass close to the resonator. The 3D cavity is mounted on an x-z piezo-translation stage that allows us to change the relative position of the lumped-element resonator and fiber. When the resonator is brought near to the fiber, we observe a shift in resonance frequency due to the presence of the fiber dielectric. When light is sent through the fiber, Rayleigh scattering causes a position-dependent illumination of the resonator, generating quasiparticles and thereby affecting its resonance frequency and Q. Our model of the resonator response includes the generation, diffusion, and recombination of quasiparticles in the resonator and shows that the frequency response allows us to track the position of the fiber in situ.

**Work supported by NSF through the Physics Frontier Center, Dept. of Physics, Univ. of Maryland.**

10:36AM S39.00012 Robustness of superconducting high-Q resonators against direct quasiparticle injection, U. PATEL, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, I. NSANZINEZA, B. L. T. PLOURDE, Department of Physics, Syracuse University, Syracuse, New York 13244, R. MCDERMOTT, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706 — A longstanding goal of the superconducting qubit community is to integrate a superconducting quantum circuit with classical cryogenic digital logic based on the Single Flux Quantum (SFQ) logic family. Since the SFQ circuit transitions to the finite voltage state, care must be taken to protect the quantum circuit against quasiparticle-induced decoherence. Here we describe experiments to characterize the robustness of high-Q superconducting linear resonators against direct quasiparticle injection. We use NIS junctions to controllably inject quasiparticles into the groundplane of a superconducting resonator chip. We monitor resonator Q and frequency shift versus injection current for different device geometries. Finally, we discuss strategies to protect the resonator circuit from quasiparticle poisoning.

10:48AM S39.00013 Energy relaxation in transmons coupled to superconducting lumped-element resonators, B. SURI, S. NOVIKOV, Dept. of Physics, Univ. of MD, F.C. WELLSTOOD, JQI, CNAM, Dept. of Physics, Univ. of MD, B.S. PALMER, Lab. for Physical Sciences, Dept. of Physics, Univ. of MD, College Park, MD. — We report on the energy relaxation of a series of Al/AIOx/Al transmon qubits coupled to superconducting Al lumped-element resonators on a sapphire substrate measured at 20 mK. For some of our transmon devices, which have transition frequencies between 4 and 8 GHz, we find that the coupling of the transmon to the 50 \(\Omega\) transmission line through the lumped-element resonator is the dominant mechanism of relaxation limiting the lifetimes to 1 \(\mu\)s or smaller. By increasing the resonator’s resonant frequency from 5.4 to 7.2 GHz, increasing the loaded quality factor of the resonator, and lowering the transmon-resonator coupling, we were able to decouple the transmon from the dissipative environment by an order of magnitude. We observe an improvement in the lifetimes of the transmons, with new limits possibly set by material losses. Microwave simulations, analytical results and experimental measurements on multiple devices will be presented.

**Thursday, May 3, 2015 8:00AM - 10:48AM**

Session S41 DPOLY: New Directions in Polymer Physics 214A - Julie Albert, Tulane University

8:00AM S41.00001 Selective-Assemblies of Frank-Kasper A15 and Other Superlattices via Precisely Controlled Positional Interactions in Nano-Sized Giant Tetrahedra, MINGJUN HUANG, CHIH-HAO HSU, JING WANG, KAN YUE, STEPHEN Z.D. CHENG, University of Akron — Diverse self-assembled hierarchical structures in soft materials including small molecules, polymers, and biomacromolecules have been intensely studied. Herein, we report a class of precisely defined, rigid, nano-sized giant tetrahedra molecules, which are constructed by positioning polyhedral oligomeric silsesquioxane (POSS) molecular nanoparticles with different functional groups at the apices of a tetrahedron framework. Designed symmetry breaking of these giant tetrahedra accurately controlled the positional interactions, leading to diverse selectively assembled, highly ordered supramolecular structures. In particular, a Frank-Kasper A15 superlattice was obtained from a series of giant tetrahedra with three hydrophobic and one hydrophilic POSS cages, which resembled the essential structure of certain metal alloys, but with tunable feature sizes at much larger length scales. Formation of the A15 phase is due primarily to the deformability of the self-assembled spherical building blocks that allows size polydispersity from monodisperse giant tetrahedra.

8:12AM S41.00002 Relaxation suppression in stretched block-copolymer matrix above \(T_g\), DMITRIY ALHAZOV, MICHAEL BURMAN, ARKADII ARINSTEIN, EYAL ZUSSMAN, Technion - Israel Institute of Technology — As was shown in our recent paper [1], electrosyn polymer thermoplastic polyurethane (TPU) block-copolymer nanofiber mats start massively to contract upon heating up to \(\sim 90^\circ C\), whereas cast TPU films expand as expected. Further studies have shown that such temperature threshold is an artifact caused by process kinetics. It also turned out that cast TPU films can also massively contract upon heating, but only after the following thermo-mechanical programming: stretching the films (\(~100\%) at high temperature (\(~90^\circ C\), cooling to room temperature under constant strain, and finally, unloading the stretched films. Such behavior in films demonstrates that the contraction in electrosyn fibers cannot be attributed only to confinement. Rather, the phenomenon in question should be attributed to relaxation suppression in non-equilibrium (stretched) states of TPU polymer matrix. This conclusion is unpredicated since the temperatures of the tested samples (before heating) were much higher than the glass transition temperature of the soft phase, and the concentration of hard segments in TPU macromolecules is too low in order to form a percolated “solid” structure. In such a situation the relaxation of the non-equilibrium is expected. A possible physical explanation of the observed phenomenon, based on the blob concept, is proposed.

8:24AM S41.00003 The Influence of Interfacial Block Copolymer on the buckling and drainage of an emulsion droplet approaching a flat surface, DAMITH ROZAIRO, ANDREW B. CROLL, North Dakota State Univ — When a liquid droplet surrounded by a homogeneous fluid approaches a flat wall it can buckle and trap a thin layer of the surrounding fluid. The thin layer of trapped fluid slowly drains out, driven by the capillary forces which will eventually flatten the buckled droplet. The dynamics of these interactions are a critical stage of many industrial and biomedical applications. There is now a body of research surrounding the process and the effects of small surfactant molecules on thin film drainage. Long chain surfactants (block copolymers) are seen increasing used in emulsion stabilization, however, the unique effects of long polymer surfactants on surfactant dynamics in simple hydrodynamic processes are often ignored. In this work we experimentally study how a self-assembled diblock copolymer interface on an emulsion droplet influences the entrainment and subsequently drainage of surrounding fluid. Specifically, we investigate several different polystyrene-b-poly(ethylene oxide) (PS-PEO) molecules on toluene droplets in water as they approach an atomically flat silica surface. The film drainage rate is found to vary with the molecular weight of the PS-PEO molecules. Remarkably, we observe slower drainage rate for longer PEO chains, which can be understood with a simple hydrodynamic model.
8:36AM S41.00004 Electrostatically driven selective deposition of nanoparticles on chemically modified block copolymer patterns

1. TOM WAGNER, Institute of Physical Chemistry RWTH Aachen, LARISA TSARKOVA, DIW - Leibniz Institute for Interactive Materials, ALEXANDER BOEKER, Institute of Physical Chemistry RWTH Aachen — Targeting applications in catalysis, circuitry, molecule-recognition and optoelectronics, we selectively assembled negatively charged gold nanoparticles (AuNPs) on microphase separated poly(styrene-block-2-vinylpyridine) (PS-b-P2VP) thin films by electrostatic interactions. Chemical crosslinking of PS-b-P2VP films results in positively charged P2VP domains (qP2VP). Control of charge density of the P2VP blocks is governed by varying the degree of crosslinking. To quantify the contribution of coulombic interactions we performed combinatorial studies including micro contact printing of negatively charged AuNPs onto qP2VP-homopolymer films as well as selective AuNP deposition on PS-b-qP2VP films by immersion. During manufacture, the chemical composition of precursors and final composites has been monitored by ATR-IR and XPS-measurements whereas AFM- and FESEM-measurements revealed topographical features. XRR- and GISAXS-measurements provided information on the inner structure of the film. AuNP adsorption kinetics was followed by in-situ electrochemical impedance spectroscopy (EIS). Finally, the complementary analyses allowed for better understanding the fundamentals of electrostatically driven NP-adsorption on soft polymer surfaces.

8:48AM S41.00005 The effect of added block copolymer on oil in oil emulsions

ITAURU ASANO, TIMOTHY LODGE, Univ of Minn - Minneapolis — Oil-in-oil emulsions, formed by polymer A and polymer B in the presence of an organic solvent (A/solvent-in-B/solvent), are a unique class of emulsion, because both phases are composed of organic components. Here, the effects of PS-b-PEGs (PS: polystyrene and PEG: polyethylene glycol) on the stability of the oil-in-oil emulsions composed of PS/CHCl<sub>3</sub>-in-PEG/CHCl<sub>3</sub> were studied by varying the molecular weight (20 < M<sub>n</sub> < 200 kg/mol) and the volume fraction (0.40 < f<sub>PEG </sub> < 0.82) of the PS-b-PEG. We found that higher M<sub>n</sub> of PS-b-PEGs with low f<sub>PEG</sub> were able to stabilize the emulsions with reduced droplet size. In particular, using a large PS-b-PEG (200 kg/mol, f<sub>PEG </sub> = 0.52), the emulsion was stable for more than 2 weeks, and the droplet size decreased to the nanoscale, around 300 nm in diameter, whereas the emulsion was unstable with large droplets (>50 μm) without the PS-b-PEG. In order to reveal the mechanism of stabilization, dye-labeled PS-b-PEGs in the emulsions were directly monitored by fluorescence microscopy.

9:00AM S41.00006 Assembly of polymeric nanoparticles: Molecular dynamics study

SABINA MASKEY, DVORA PERAHIA, Clemson University, GARY S. GREST, Sandia National Laboratories — The assembly of polymeric nanoparticles or polydots has been studied using molecular dynamics simulations. These polydots are highly fluorescent and have potential applications in intracellular imaging, bio-sensors and other optoelectronic devices. Therefore their assembly is the key to their utilization. Here we probe the assembly of polydots made by para dialkyl phenyleneethynylene (PPEs) whose conformation determines their degree of conjugation and enhance their electro-optical response. As in our previous study, PPE polydots were prepared by collapsing polymer by the procedure developed. The polydots were brought together two ways. Allowing the particles to approach each other at a constant velocity of 50m/s resulted in the particles bouncing off each other which is consistent with the dense object which we have previously reported. Then polydots were brought together at constant force and interface between them has been followed. Our results show that polydots under high velocity and forces remain stable. Closer look at the interface reveals that backbones of the polymer do not inter-penetrate and side chains dominate the interface. This interfacial structure suggests that one could retain the structure of polydots upon assembly.

1 NSF CHE-1308298

9:12AM S41.00007 Assembly of Magnetite Nanoparticles Grafted with Ion-Containing Diblock Copolymers

1. YANG JIAO, PINAR AKCORA, Stevens Inst of Tech — Polystyrene (PS)-grafted iron oxide nanoparticles are shown to organize into highly ordered anisotropic nanostructures in bulk forms as of microphase separated morphologies of block copolymers. Ordered strings that are of one particle in width are created in composite films. In this work, we design a novel system of ion-containing block copolymer-grafted magnetic nanoparticles and study the effect of phase separation in grafted block copolymer on the aggregation of magnetic nanoparticles in the presence of ionic liquid, [HMIM][TFSI]. Styrene sulfonates neutralized with trietylammmonium are clicked to the thiolated ends of grafted PS through a thiol-ene click reaction. We show that the phase separated copolymer brush lead to stacking of strings of nanoparticles into planar structures. Miscibility of block-grafted nanoparticles is being enhanced by the solvation of sulfonated groups with ionic liquid. Further, we demonstrate that the copolymer-grafted particles can be easily directed under magnetic fields in liquid organic compared to their uncharged forms. The conductivity results indicate that the good miscibility between sulfonated particles and ionic liquid significantly enhances conductivity.

3We acknowledge financial support from NSF-DMR CAREER grant (#1048865).

9:24AM S41.00008 Engineer concentration gradient drug particles using microfluidic systems

JIANBIN WANG, PAVITHRA SUNDARARAJAN, ADAM PROCOPIO, LARRY ROSEN, JERRY KLINZING, PATRICK MARSAC, Merck, MERCK RESEARCH LABORATORIES TEAM — Particles designed with spatial composition gradients have attracted increasing attention in the pharmaceutical industry. The designed distributions of drug, polymer or surfactants in the concentration gradient drug particles could enable control of the drug release kinetics or targeted drug delivery. Here, we present a technique for generating concentration gradient particles from concentration gradient droplets using a microfluidic device. The concentration gradients in the liquid stream and the droplets were monitored with fluorescence microscopy and the concentration gradients were largely maintained. X-ray computed tomography was used to characterize the internal structure and concentration gradient profile in the solid particles. We successfully generated the concentration gradient particles in the coupled evaporative diffusive system by keeping the non-dimensional relative time scale for evaporation to diffusion to be 0.1 or less. Our experiments were instrumental to gaining fundamental insights into the processes controlling the concentration gradients in the particle and the droplet.

9:36AM S41.00009 Steered molecular dynamics of epoxy-amine reactions in EPON862-DETDA

YAE JI KIM, SAMUEL REEVE, ALEJANDRO STRACHAN, Purdue Univ — The combination of steered molecular dynamics (SMD) and Jarzynski’s equality has made free energy calculations for simulations of non-equilibrium pulling processes possible. This has been widely studied in protein folding and is now applied for epoxy-amine reactions for the first time using the reactive interatomic potential ReaxFF. This reaction in epoxy EPON862 and curing agent DETDA, commonly used in aerospace composite materials, is investigated in both the gas and condensed phases. The potential of mean force (PMF) is calculated during the simultaneous breaking of the epoxy ring and approach of the amine nitrogen to the terminal carbon. Minimization of the PMF is carried out by varying the timing of the reaction (e.g. delayed approach of C-N), as well as a variation of adaptive SMD via a parallel replica method. This adaptive SMD breaks the reaction into a series of time stages, reducing the necessary number of independent simulations and resulting in more rapid convergence of the PMF. Reaction completion is predicted using various initial geometric and molecular features.
10:00AM S41.00011 Chirality Transfer in Chiral Homopolymers and Chiral Block Copolymers

UMASS AMHERST, BUMJOON KIM, KAIST, RYAN HAYWARD, UMASS AMHERST — Conjugated polymer nanofibrils produced by solution assembly represent efficiently charge transporting nanostructures with promise for improving the performance of organic electronics. Despite their advantages, they have limitations that hinder their application, such as low electrical conductivity and device-to-device variations in the IETS spectra, which are possibly originated from defects in the molecular junctions and insulating wall. We also observed discrepancies and device-to-device variations in the IETS spectra, which are possibly originated from defects in the molecular junctions and insulating wall.

10:12AM S41.00012 Polydot at the interface with DPPC membrane: A Molecular Dynamics Simulation Study†, SADITH WIJESINGHE, DVORA PERAHIA, Clemson University, GARY GREST, Sandia National laboratories, CHRISTOPH JUNGHANS. Alamos National laboratories — Luminescent polymers confined into long lived polydots are of potential interest because of their tunable properties and biocompatibility. These desired properties of polydots make them potential candidates for target drug delivering agents and bio markers. The first and foremost step in such applications is introducing these polydots to biological membranes which consist of different lipids whose collective dynamics mediate the cell membrane functions. Experimental studies suggest that their ability to penetrate cells depend on the polydot morphology, charge and the environmental characteristics including the type of the cell membrane. Here we report the results of an all atom molecular dynamics simulation of a carboxylate substituted dinonyl poly para phenylene ethynylene (PPE) polydot in one-component bilayer composed 1,2-dipalmitoyl-sn-glycero-3-phosphocholine (DPPC). Introduction of a polydot into the DPPC membrane initially results in deformation of the membrane however after equilibrated, the membrane relaxes and the polydot is stable within the membrane.

10:24AM S41.00013 Investigation of a new approach for high-yield molecular electronic junctions with direct metal transfer method†, HYUNHAK JEONG, Seoul Natl Univ, HEEJUN JEONG, Hanyang Univ, TAKHEE LEE², Seoul Natl Univ — To investigate the charge transport characteristics through molecular junctions which utilize molecules as an active channel, several approaches to form molecular junctions have been demonstrated [1]. Specifically, solid state device structure-based methods have been considered, however, one of the major obstacles of this method is generation of filamentary path which results in low device yield. To overcome this, several other methods that utilize a protective interlayer have been reported [2,3]. But, it is still difficult to investigate the genuine transport characteristics through molecular junctions because of the adoption of the interlayers. Here, we propose a new approach for high-yield molecular junctions with a direct metal transfer method. With this method, we measured inelastic electron tunneling spectroscopy (IETS) characteristics of molecular junctions made with alkanethiolate. We also observed discrepancies and device-to-device variations in the IETS spectra, which are possibly originated from defects in the molecular junctions and insulating wall.

10:36AM S41.00014 Photo-crosslinking and Post-Functionalization of Solution Assembled Conjugated Polymer Nanofibers, HYEONG JUN KIM, KAIST, MATTHEW SKINNER, ALEJANDRO BRISENO, TODD EMRICK, UMASS AMHERST, RONG-MING HO, Department of Chemical Engineering, National Tsing Hua University — Herein, we deals with the chirality transfer of chiral polymers on different length scales. Helical conformation could be formed due to the stereoregularity of chiral entities in the chiral polymers and the BCPs*. Helical superstructures and phases can be fabricated by self-assembling polymer chains with helical conformation through intramolecular and intermolecular interactions. The transfer of chiral information from molecules to macroscopic level and the control of the handedness of the helical architectures are discussed. The examples of chirality transfer in the self-assembled chiral polymers and BCPs* are introduced. As found, the molecular chirality of constituted chiral entities in the chiral polymers and the BCPs* and corresponding conformational chirality plays an important role in the formation of helical architectures with exclusive handedness. Also, we deal with the chirality transfer in specific model systems, chiral polylactides and polylactide-containing BCPs*, at which homochiral evolution from chiral entity to helical phase is demonstrated. A methodology for systematic studies of the chirality transfer from molecular level to phase scale is suggested. Through the design and synthesis of macromolecules and the operation of self-assembly, the mechanisms of chirality transfer on different length scales can be understood, giving supplementary information to disclose the mysteries of morphological evolution from the molecular level.

9:48AM S41.00010 Phase Transition in a Model of Y-shaped Molecules†, DONOVAN RUTH, Lehigh University, RAUL TORAL, IFISC (CSIC-UIB), DANIELLE HOLZ, Drew University, JEFFREY RICKMAN, JAMES GUNTON, Lehigh University — Increasing attention in statistical mechanics is being given to non-spherical molecules, such as polypeptide chains and protein molecules. One example is provided by immunoglobinulin, which has a ‘Y’ shape. In this work, we determine the phase diagram of ‘Y’-shaped molecules on a triangular lattice through Monte Carlo Grand Canonical ensemble simulation, using histogram reweighting, multicanonical sampling and finite size scaling. We show that (as expected) this model is a member of the Ising universality class. For low temperatures, we implemented multicanonical sampling to induce faster phase transitions in the simulation. By studying several system sizes, we use finite size scaling to determine the two phase coexistence curve, including the bulk critical temperature, critical chemical potential and critical density.

Thursday, March 5, 2015 8:00AM - 11:00AM – Session S42 DPOLY: Electrically and Optically Active Polymers 214B - Chelsea Chen, Lawrence Berkeley National Laboratory

8:00AM S42.00001 ABSTRACT WITHDRAWN –
8:12AM S42.00002 Orthogonal Photolithography as transformative patterning technique for Organic Electronics and Photonics, ALEX ZAKHIDOV, Texas State University — Orthogonal photolithography (OP) takes advantage of the fact that the vast majority of organic semiconducting materials are either oleophilic or hydrophilic and are hence orthogonal to highly fluorinated chemicals. Therefore, appropriate fluorinated photoresists can be used to pattern organic layers without compromising performance of organic device. The availability of such orthogonal photoresists promises to enable the fabrication of complex device structures, expanding the range of possibilities for organic electronics. Particular, OP technique enables sub-pixel high-resolution patterning for OLED displays [1]. Once RGB sub-pixel structuring is realized it is expected to improve (up to 10 times) the efficiency of a display. Moreover, processing solvents used for OP can be used as encapsulation media to improve heat management of high brightness OLED devices [2]. Other applications of OP include ultra-small channel OTFTs [3]. OTFT based circuits and high voltage failure/proof organic solar cells.

8:24AM S42.00003 Self-assembled peptide nanostructure-based polymeric electronic materials1, SOMA KHANRA, SUCHI GUHA, University of Missouri, Columbia, WENDEL ALVES, THIAGO CIPRIANO, Universidade Federal do ABC, Santo Andre- Sao Paulo, Brazil — Peptide-based nanostructures derived from natural amino acids are superior building blocks for organic semiconductor-based and biocompatible devices as they can be used in a bottom-up process without the need for expensive lithography. Based on self-assembly and mimicking the strategies occurring in nature, peptide materials play a unique role in a new generation of hybrid materials for the electronics of the 21st century. In this work we functionalize diphenylalanine (FF)-containing peptides with conducting polymers, such as Poly (3-hexylthiophene) (P3HT) and polyfluorene (PF). The FF-polymer composites were synthesized by two methods: liquid-vapor and solid vapor phase. Electron microscopy images show micrometer size tubes with approximately 200 nm in diameter with homogeneous morphology. Photodiodes and light-emitting diode structures have been fabricated from FF-P3HT and FF-PF, respectively. We compare the electrical and optical properties of the FF-polymer composite devices with pristine polymer devices. Our results show that FF nanostructures with organic semiconductors could open up a new generation of bio-compatible materials in organic electronics.

8:36AM S42.00004 Investigation of Different Organic Solar Cell Active Region Structures Deposited by Resonant Infrared Matrix-Assisted Pulsed Laser Evaporation (RIR-MAPLE)1, ADRIENNE STIFF-ROBERTS, RYAN MCCORMICK, AYOMIDE ATEWOLOGUN, Department of Electrical and Computer Engineering, Duke University, STIFF-ROBERTS RESEARCH GROUP TEAM — In this work, we use RIR-MAPLE to investigate organic solar cells (OSCs) featuring different P3HT:PCBM active region structures: bulk heterojunction (BHJ), bilayer, and gradient composition. Two deposition capabilities of RIR-MAPLE, nanoscale domains in blended polymeric films and multi-layer polymeric films regardless of constituent solubility, enable the deposition of these structures. While the BHJ yields better exciton dissociation due to large donor/acceptor interfaced area, the bilayer provides better charge transport due to reduced interfacial recombination. In contrast, the gradient structure could optimize both exciton dissociation and charge transport. P3HT materials characterization includes UV-Vis absorbance for Spano analysis and grazing-incidence, wide angle X-ray scattering (GIWAXS) for structural information. The OSC device characterization includes external quantum efficiency (EQE) and current-density voltage measurements. In addition, a dynamic Monte Carlo model is used to simulate the different structures in order to generate EQE spectra for comparison to the measured device performance. This work was supported, in part, by the Office of Naval Research under Grant N00014-10-1-0481 and the National Science Foundation Triangle MRSEC on Soft Matter.

8:48AM S42.00005 Intrinsic series resistance of organic photovoltaic devices , NON THONGPRONG, PHILLIP DUXBURY , Michigan State Univ — Bilayer organic photovoltaics (OPV) are theoretically and computationally studied in order to find intrinsic physical origins of series and parallel resistances; $R_s$ and $R_p$. New current density-voltage (J-V) characteristic equations were derived in a similar manner to the work by Giebink et al., using reasoning based on hole and quasi-Fermi energies. We also developed a computational model combining previous developments by Koster et al. and Barker et al. with the interface model of Giebink et al. The computational model reveals that there are space charge regions around the donor-acceptor interface. These regions are the cause of an intrinsic $R_s$ due to their low carrier density which induces a shift of the quasi-Fermi levels from the electrode work functions. Recombination of charge transfer excitons (polaron pairs) across the interface can be viewed as a leakage path. An intrinsic origin of $R_p$ in this model is then polaron pair recombination. Both resistances are dependent on the applied voltage and these dependences are calculated using our computational model. The analysis is extended to include the presence of traps, yielding expressions for $R_s$ and $R_p$ and for the ideality factors as a function of applied voltage.

9:00AM S42.00006 Photovoltaic Cells Involving Nonconjugated Conductive Polymer, Iodine-doped Styrene-Butadiene-Rubber (SBR) , JUSTIN VAN CLEAVE, MRINAL THAKUR, Photonic Materials Research Laboratory, Auburn University, AL — Photovoltaic cells have been fabricated using titanium dioxide/ iodine-doped Styrene-Butadiene-Rubber/ carbon on indium-tin-oxide coated PET substrates. Photo-currents and photo-voltages were measured for varying intensities of light from a white light bulb, with emission from 300 to 700 nm. Iodine-doped SBR has absorption in the range of ~250 to 750 nm. The cells as fabricated were characterized and were found to show significantly higher conversion efficiencies than previously reported. For an incident light intensity of about 5 mW/cm$^2$ a maximum photo-current density of about 0.2 mA/cm$^2$ and photo-voltage of about 0.8 V were recorded. The low cost of nonconjugated conductive polymers including SBR may provide a cheaper alternative to other materials for photovoltaic applications.

9:12AM S42.00007 Polymer/solvent bicontinuous microemulsions for use as organic solar cell active layers , DYLAN KIPP, University of Texas at Austin, OLGA WODO, University at Buffalo SUNY, BASKAR GANAPATHYSUBRAMANIAN, Iowa State University, VENKAT GANESAN, University of Texas at Austin — The paradigm for the optimal morphology of an organic solar cell is characterized by cocontinuous, interpenetrating donor and acceptor domains with nanoscale dimensions and high interfacial areas. One well known equilibrium morphology that fits these characteristics is the bicontinuous microemulsion noted in the context of flexible polymeric blends. Currently, design rules are not available for producing bicontinuous microemulsion morphologies from blends of conjugated polymer + block copolymer + solvent and locate the channels of morphologies with characteristics like that of the bicontinuous microemulsion. Our theoretical analysis results in empirical design rules for producing bicontinuous microemulsion morphologies from blends of conjugated polymer + block copolymer + fullerene.

9:24AM S42.00008 Block Copolymer nanocomposite thin films for high energy-density capacitors , SAUNIL SAMANT, University of Akron, SHIMELIS HAILU, Howard University, CHRISTOPHER GRABOWSKI, MICHAEL DURSTOCK, Air Force Research Lab, DHARMARAJ RAGHAVAN, Howard University, ALAMGIR KARIM, University of Akron, UNIVERSITY OF AKRON COLLABORATION — The energy storage capacity of solid-state capacitors is governed by product of relative permittivity (ε) and square of breakdown strength (Vbd) of dielectric medium. Polymer films are widely used as the dielectric medium in capacitors due to their high Vbd and low loss but they suffer from poor permittivities. Composite dielectrics combine the high ε ceramic fillers with high Vbd polymer matrix but usually result in loss of Vbd due to aggregation induced field enhancements. For optimum enhancement of dielectric properties, it is essential to improve matrix-filler interaction and control the dispersion of fillers. To that effect we graft a BCP onto the nanofiller and disperse it within a host BCP with similar composition. Using Directed Self-assembly we fabricate BCP nanostructured films with highly dispersed functionalized nano-fillers that are not only expected to enhance the overall ε, but the well-ordered BCP nanostructures also improve Vbd by providing sharp interfacial barriers acting as charge traps. The impact of filler functionalization, BCP morphology and nanofiller loading on dispersion and capacitor performance will be reported.

9:36AM S42.00009 Theoretical Prediction of Room Temperature Thermal Superconductivity in Single Polythiophene Chains , WEI LV, ASEGUN HENRY, Georgia Inst of Tech — We used molecular dynamics simulations and a new formalism for calculating the nodal contributions to thermal conductivity to study individual polythiophene chains. The simulations suggest that it is possible to achieve divergent/infinite thermal conductivity (e.g., thermal superconductivity) in individual polythiophene chains. The new modal analysis method allowed for exact pinpointing of modes responsible for the anomalous behavior, which turned out to be transverse vibrations in the plane of the aromatic rings at frequencies ~ 0.05 THz. Within the 5 ns of integration time, one mode in particular exhibits a thermal conductivity contribution greater than 100 W m-1 K-1, which is larger than many 3D bulk materials that consist of a large multitude of modes. Further investigation showed that the divergence arises from persistent correlation between the three lowest frequency modes on chains that have exact multiples of 30 unit cells in length. Sonification of the superconducting mode heat fluxes indicated distinct patterned differences between the convergent and divergent simulations, which suggests the phenomena may differ from previous models and a new explanation of the anomalous behavior may be required for polymers.

9:48AM S42.00010 Nonvolatile 1D Photonic Films Composed of Lamellar Forming Block Copolymer/Ionic Liquid , ATSUSHI NORO, YUSUKE TOMITA, YUSHU MATSUSHITA, Nagoya University, JOSEPH WALISH, Massachusetts Institute of Technology, EDWIN THOMAS, Rice University, NAGOYA UNIVERSITY/RICE UNIVERSITY COLLABORATION — Block copolymer photonic films were prepared by infiltrating an ionic liquid (IL) into lamellar-forming polystyrene-b-poly(2-vinylpyridine) (PS-P2VP) block copolymer thin films with approximately 50/50 composition. The nonvolatile nature of IL enabled direct nanostructural observation of the films under the vacuum at room temperature by transmission electron microscopy, which revealed selective swelling of P2VP layers by the IL. Ultra-small-angle X-ray scattering also provided the quantitative nanostructure information of the photonic films, revealing the domain periodicity distance was over 100 nm. In addition to these nanostructural observations, reflectivity spectra of the photonic films were also investigated by a fiber optic spectrophotometer. The wavelength at the peak top of reflected light from the photonic films was found to increase with increasing the molecular weight of block copolymers used for film preparation. Furthermore, tunability of the wavelength was attained by infiltrating the IL into blend thin films of lamellar-forming PS-P2VP block copolymer.

10:00AM S42.00011 DNA in Nanoscale Electronics , JASON SLINKER, MARC MCMILLAN, CHRIS WOHLGAMUTH, The University of Texas at Dallas, ALON GORODETSKY, The University of California-Irvine — Functional nanoelectronics are sought for next generation integrated circuits, but several challenges limit the use of most nanoscale devices on large scales. DNA has great potential for use as a molecular wire due to high yield synthesis, near-unity purification, and nanoscale self-organization. Nonetheless, a thorough understanding of ground state DNA charge transport (CT) under biologically relevant conditions, where the double-helical structure is preserved, is lacking. We measured DNA CT through double-stranded DNA monolayers on gold by assessing 17 base pair bridges at discrete points with redox active probes. This was performed under temperature-controlled and biologically relevant conditions with cyclic and square wave voltammetry, with redox peaks analyzed to assess transfer rate and yield. We demonstrated that the yield of transport is strongly tied to the stability of the duplex, linearly correlating with the melting temperature. Transfer rate was found to be temperature-activated and to follow inverse distance dependence, consistent with a hopping mechanism of transport. These results establish the governing factors of CT speed and yield through DNA for device configurations, guiding subsequent application in nanoscale electronics.

10:12AM S42.00012 DNA-guided nickel ion chain memristive system development and characterization , CHA-CHING CHANG, HSUEH-LIANG CHU, Department of Biological Science and Technology, National Chiao Tung University, WEN-BIN JIAN, YU-CHANG CHEN, Department of Electrophysics, National Chiao Tung University — DNA is a nanowire in nature with multiple high Vbd polymer matrix but usually result in loss of Vbd due to aggregation induced field enhancements. For optimum enhancement of dielectric properties, it is essential to improve matrix-filler interaction and control the dispersion of fillers. To that effect we graft a BCP onto the nanofiller and disperse it within a host BCP with similar composition. Using Directed Self-assembly we fabricate BCP nanostructured films with highly dispersed functionalized nano-fillers that are not only expected to enhance the overall ε, but the well-ordered BCP nanostructures also improve Vbd by providing sharp interfacial barriers acting as charge traps. The impact of filler functionalization, BCP morphology and nanofiller loading on dispersion and capacitor performance will be reported.

10:24AM S42.00013 Bio-inspired peptide nanostructures for organic field-effect transistors , GRANT KNOTTS, Univ of Missouri - Columbia, THIAGO CIPRIANO, Universidade Federal do ABC, AMRIT LAUDARI, Univ of Missouri - Columbia, ROBERTA BIANCHI, WENDEL ALVES, Universidade Federal do ABC, SUCHI GUHA, Univ of Missouri - Columbia — Polymer-based nanoelectronics are used from natural amino acids. However, superior blocking blocks for biocompatible devices as they can be used in a bottom-up process without the need for expensive lithography. A dense nanostructured network of 1,1−diphenylalanine (FF) was synthesized using the solid-vapor phase technique. The formation of the nanostructures and structure-phase relationships were investigated by electron microscopy and Raman scattering. Thin films of 1,1−diphenylalanine micro/nanostructures (FF-MNs) were used as the dielectric layer in pentacene-based field-effect transistors (FETs) and metal-insulator-semiconductor diodes both in bottom-gate and top-gate structures. Bias-stress studies show that FF-MN based pentacene FETs are more resistant to degradation than pentacene FETs using FF thin film (without any nanostructures) as the dielectric layer when both are subjected to sustained electric fields. Furthermore, it is demonstrated that the FF-MNs can be functionalized for detection of enzyme-analyte interactions. This work opens up a novel and facile route towards scalable organic electronics using peptide nanostructures as scaffolding and as a platform for biosensing.

10:36AM S42.00014 Residual Stresses and Photoluminescence of Conjugated Polymer Thin Films, YA-WEI YANG, YI CHIEN, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu 300, Taiwan, TSANG-LANG LIN, Department of Engineering Science and Systems, National Tsing Hua University, Hsinchu 300, Taiwan, GUNTER REITER, Institute of Physics and Freiburg Institute for Advanced Studies, Albert-Ludwigs-Universität, Freiburg, Germany, ARNOLD CHANG-MOU YANG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu 300, Taiwan — Molecular recoiling forces (residual stress) in ultrathin polymer films (< 100 nm) were engendered by non-equilibrium chain conformations and intermolecular packing frozen from rapid solvent evaporation during film preparation. These forces when acting on conjugated macromolecules were found to contribute to large photoluminescence (PL) enhancements. The packing of the rigid-rod macromolecules into thin solid films, however, was somewhat different from that of flexible chains. As revealed by x-ray reflectivity, although the thicknesses of the solvent-trap layer (~2nm) next to substrate were almost identical, the local density was ~10 times less in MEH-PPV films than in polystyrene (PS) films (20 nm). It indicates that molecular strains induced by solvent evaporation were much smaller of conjugated polymers, hinting smaller residual stresses in the films. Concomitantly, local deformations of rubber substrate under a dewetting polymer film, a good measure of the molecular recoiling forces, were considerably smaller for MEH-PPV films than for PS. The PL dependence on residual stresses of pristine MEH-PPV films hence clearly elucidates the strong molecular stress effect on optoelectronic efficiencies.

10:48AM S42.00015 Polymeric Carbon Dioxide Capture Membranes for Artificial Photosynthesis, DANIEL MILLER, NATHANIEL LYND, Lawrence Berkeley Natl Lab — Production of carbon-rich fuels via artificial photosynthetic processes depends on the continuous availability of a carbon source. In a proposed artificial photosynthetic system, hydrogen and oxygen from solar water splitting are combined with CO$_2$ captured from the atmosphere to produce a liquid fuel such as methanol. Membrane-based processes provide advantages over other gas separation technologies, including mechanical simplicity, a relatively small footprint, and energy efficiency. We describe the synthesis and characterization of polymeric anion exchange materials for CO$_2$ concentration from gas mixtures such as the atmosphere. Transport of CO$_2$ through the membrane is promoted by an opposing flux of water, which reacts with CO$_2$ through equilibrium reactions to form charged species (bicarbonate, carbonate, and hydroxide) within the membrane. CO$_2$ transport will be discussed as a function of membrane material characteristics, including charge density, and process characteristics, including feed stream relative humidity and CO$_2$ concentration on each side of the membrane. The development of several membrane materials will be discussed. Results of experimental gas transport studies will be presented.

Thursday, March 5, 2015 8:00AM - 11:00AM
Session S43 DPOLY: Focus Session: Dynamics of Glassy Polymers Under Confinement I

8:00AM S43.00001 Structural Recovery for a Single Polystyrene Ultrathin Film Using Flash DSC, YUNG P. KOH, SIYANG GAO, SINDEE L. SIMON, Texas Tech University — The kinetic features of the glass transition under nanoconfinement of ultrathin films are studied using nanocalorimetry, with a particular focus on the cooling rate dependence of the glass transition temperature (Tg) and on the time-dependent structural recovery behavior of a 20 nm-thick polystyrene film. Measurements are performed using a commercial rapid-scanning chip calorimeter, the Mettler Toledo Flash differential scanning calorimeter (DSC). The Tg depression of the 20 nm-thick film is found to be a function of cooling rate, decreasing with increasing cooling rate, at high enough cooling rates (e.g., 1000 K/s), Tg is the same as the bulk within the error of the measurements. Structural recovery is performed as a function of aging time and temperature, and the evolution of the fictive temperature is followed. The advantages of the Flash DSC include sufficient sensitivity to measure enthalpy recovery for a single 20 nm-thick film, as well as extension of the measurements to aging temperatures as high as 15 K above nominal Tg and to aging times as short as 0.01 s. The aging behavior will be compared to that for bulk-like single thin films measured by Flash DSC, as well as to the results for stacked ultrathin films measured using conventional DSC.

8:12AM S43.00002 Dynamics of Poly(2-vinylpyridine)/Silica Nanocomposites from Brillouin and Raman Light Scattering, SHIWANG CHENG, ALEXANDER KISLIUK, Chemical Sciences Division, Oak Ridge National Lab, VLADIMIR NOVIKOV, Chemical Sciences Division, Oak Ridge National Lab; Department of Chemistry, University of Tennessee, ADAM P. HOLT, Department of Physics, University of Tennessee, ALEXEI P. SOKOLOV, Chemical Sciences Division, Oak Ridge National Lab; Department of Physics and Astronomy, Department of Chemistry, University of Tennessee — Recent studies show an interfacial layer exists between polymer matrix and nanoparticle surface in polymer nanocomposites (PNCs)[1], which could potentially explain the drastic mechanical enhancement in such materials [2]. Dynamics of this interfacial layer were captured by various techniques, where the typical dynamic range was limited to be below 1 GHz. However, the fast dynamics (above 1 GHz) of the interfacial layer is also important to the application of PNCs under severe conditions. Unfortunately, little work has been done to explore the structure and the dynamics of this layer at high frequencies. In this study, we demonstrated that Brillouin Light Scattering (BLS) can be used to estimate the thickness of the interfacial layer and its mechanical properties. By combining BLS and Raman Scattering, we probed the dynamics in the range from 1 GHz to 5 THz of the Poly(2-vinylpyridine)/Silica nanocomposites with loadings from 5% wt to 52% wt. The various features observed can also be explained in the spirit of the existence of an interfacial layer between the polymer matrix and nanoparticles. [1] Holt, A. P., et al; Macromolecules 2014, 47, 1837-1843. [2] Papon, A. et al; Soft Matter 2012, 8, 4090-4096.

8:24AM S43.00003 Improving Dielectric Breakdown Strength: Physically Aging Amorphous Polymers and Nanocomposites, RICHARD A. VAIA, CHRISTOPHER A. GRABOWSKI, HILMAR KOERNER, United States Air Force Research Laboratory — Processing conditions play a significant role in maximizing the available energy storage density of polymer dielectrics. Trapped solvents and voids act as defect sites that prematurely trigger breakdown and reduce dielectric strength. To address these issues, solvent-cast films are conventionally annealed above the glass transition and under vacuum; however these procedures can yield materials far from thermodynamic equilibrium with substantial free-volume. Here in, we demonstrate improvement in dielectric performance via controlled post-deposition annealing based on their structural relaxation characteristics. Using enthalpy relaxation studies, we quantify how local chain packing evolves in the glass during controlled cooling or physical aging, and how this impacts dielectric breakdown, complex permittivity, and energy storage density for polystyrene, poly(methyl methacrylate), and their related blended and single-component nanocomposites. These process-performance correlations, and their dependence on nanocomposite topology, provide a basis for the rational design of dielectrics for high performance capacitors.
we have recently begun investigating polymer-polymer interfaces where the magnitude of the Tg perturbation at the interface can be readily determined. Such
in systems that exhibit kinetic arrest, i.e. a glass transition. It has been applied to investigate the behavior of sample mobility at and near this transition in
which polymer chains physically adsorb to the substrate when annealed at sufficient temperature. This process, dubbed “irreversible adsorption” has been connected with changes in Tg under confinement.
model system consisting of polystyrene (PS) irreversibly adsorbed on silica. Incorporating fluorescently-labeled PS in a series of single and multi-layer films, we
selectively measure the Tg of adsorbed layers, with and without a free surface, as a function of annealing time. We then further anneal the bilayer films and
measure changes in the Tg of the irreversibly adsorbed layers to investigate chain interpenetration and its implications for the influence of irreversible adsorption on the Tg distribution throughout the film.

8:48AM S43.00005 Influence of the Free Interface on the Glass Transition Temperature of Irreversibly Adsorbed Polystyrene Thin Films. MARY BURROUGHGS, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — Polymers confined to the nanometer length scale have been shown to exhibit deviations in the glass transition temperature (Tg) from that of the bulk. Confinement effects on Tg have largely been attributed to the combined influences of the free surface and substrate interface. Recent work with polymer thin films has investigated a phenomenon at the substrate interface in which polymer chains physically adsorb to the surface. These studies also show that the deviations from bulk dynamics begin at a particular temperature (T*), providing an explanation for why some studies observe no interfacial effects in ultra-thin polymer films. A puzzling aspect of this work is that computational studies and studies on molecular
structures have largely been attributed to the combined influences of the free surface and substrate interface. Using our Limited Mobility (LM) model, we implement a new kinetic constraint such that the presence of mobility is required to facilitate local density equilibration. The LM model was developed to study dynamic heterogeneity in systems that exhibit kinetic arrest, i.e. a glass transition. It has been applied to investigate the behavior of sample mobility at and near this transition in bulk, buried slab, and supported film systems. Here we aim to probe the competition between kinetic and thermodynamic driving forces in the vicinity of the glass transition in polymer thin films. Here we use fluorescence, a technique capable of probing local dynamics, to study the Tg of a model system consisting of polystyrene (PS) irreversibly adsorbed on silica. Incorporating fluorescently-labeled PS in a series of single and multi-layer films, we selectively measure the Tg of adsorbed layers, with and without a free surface, as a function of annealing time. We then further anneal the bilayer films and measure changes in the Tg of the irreversibly adsorbed layers to investigate chain interpenetration and its implications for the influence of irreversible adsorption on the Tg distribution throughout the film.

9:00AM S43.00006 Modeling Mobility in Glassy Thin Films. JEFFREY DEFELICE, JANE LIPSON, Dartmouth College, NICHOLAS TITTO, Cambridge University, SCOTT MILNER, Pennsylvania State University — In this talk we explore the role of mobility in glassy systems and examine the effect of coupling sample mobility to system equilibration. Using our Limited Mobility (LM) model, we implement a new kinetic constraint such that the presence of mobility is required to facilitate local density equilibration. The LM model was developed to study dynamic heterogeneity in systems that exhibit kinetic arrest, i.e. a glass transition. It has been applied to investigate the behavior of sample mobility at and near this transition in bulk, buried slab, and supported film systems. Here we aim to probe the competition between kinetic and thermodynamic driving forces in the vicinity of the glass transition in polymer thin films. Here we use fluorescence, a technique capable of probing local dynamics, to study the Tg of a model system consisting of polystyrene (PS) irreversibly adsorbed on silica. Incorporating fluorescently-labeled PS in a series of single and multi-layer films, we selectively measure the Tg of adsorbed layers, with and without a free surface, as a function of annealing time. We then further anneal the bilayer films and measure changes in the Tg of the irreversibly adsorbed layers to investigate chain interpenetration and its implications for the influence of irreversible adsorption on the Tg distribution throughout the film.

9:12AM S43.00007 Perturbation of Glassy Dynamics in Thin Polymer Films due to Interfaces. CONNIE B. ROTH, Dept. of Physics, Emory University — Many confinement studies have focused on free-standing polymer films, having been historically billed as the simplest system, containing only two symmetric air-polymer interfaces with no substrate interactions. However, free-standing films have instead exhibited some of the most complex molecular weight (MW)-dependent average film glass transition temperature Tg(h) behavior with decreasing film thickness. We have previously demonstrated that high MW free-standing polystyrene (PS) films can exhibit two distinct transitions in thermal expansion on cooling, with qualitatively different MW dependencies suggesting that two separate mechanisms are acting simultaneously to propagate enhanced mobility from the free surface deeper into the material. To investigate the nature of these transitions, we present physical aging measurements below and in-between these two transitions. How the presence of a free surface alters the Tg in confined systems is complicated by the ill-defined magnitude of the perturbation in local mobility. Thus, we have recently begun investigating polymer-polymer interfaces where the magnitude of the Tg perturbation at the interface can be readily determined. Such studies provide a more well-defined system for investigating the length scales over which such perturbations are propagated, which we believe are associated with the glass transition.

9:48AM S43.00008 A Comparison of Particle Embedment and Nanoindentation: Probing the Surface Properties of Polymeric Materials. MEIYU ZHAI, HEEDONG YOON, GREGORY MCKENNA, Texas Tech Univ — In this work, we report the results from a comparison of viscoelastic surface properties of polymer obtained from two different techniques: the spontaneous particle embedment technique and nanoindentation technique. The surface compliance for polystyrene(PS) and poly(isobutyl methacrylate) (PiBMA) were determined using multi curve fitting method to extract the viscoelastic response from the experimental results. The surface layer rheological properties obtained from particle embedment experiment and indentation are compared both with each other and with the bulk properties. For both materials we observed surface softening when the test temperature is below the macroscopic glass transition temperature. This is followed by a crossover to a surface stiffening region when the test temperature is higher than the macroscopic glass transition temperature. KEYWORDS: nanoindentation, particle embedment, multi curve fitting method, viscoelastic properties

10:00AM S43.00009 Investigating the effect of chain architecture on the dynamics of thin entangled polymer films. ETHAN GLOR, ZAHRA FAKHRRAAI, Univ of Pennsylvania — Recent work in polymer physics shows that the structural relaxation time near a free surface of a thin polystyrene film is significantly different from that of the bulk polymer. This can have a large influence on their properties. For instance, studies have shown that polystyrene thin films exhibit a decreased glass transition temperature as the thickness decreases below 60 nm. A wide range of experimental techniques show that the dynamics at the free surface of polystyrene have a weaker temperature dependence than that of the bulk. Here we use cooling rate dependent Tg measurements (CR-Tg) to show that the dynamics in thin, entangled polystyrene films are directly influenced by the free surface. These studies also show that the deviations from bulk dynamics begin at a particular temperature (T*), providing an explanation for why some studies observe no interfacial effects in ultra-thin polymer films. A puzzling aspect of this work is that computational studies and studies on molecular glasses, which also exhibit enhanced surface dynamics, do not observe T*. We use CR-Tg to study thin films of various polymers to determine 1. If T* is a phenomenon common to all polymer glasses, and 2. If the value of T* is dependent on the chemistry or Tg of the polymer.
10:12AM S43.00010 Dynamic glass transition measurements on nm-thin films of low molecular mass substances using AC chip-nanocalorimetry, MATHIAS AHRENBERG, CHRISTOPH SCHICK, HEIKO HUTH, Institute of Physics, University of Rostock, Germany — We are using AC chip nano-calorimetry for the in-situ investigation of the dynamic glass transition of vapor-deposited thin films of toluene and indomethacin of thicknesses between several hundred nm down to ten nm. With these experiments on low molecular mass substances we complement our data on similar thin polymer films. Firstly, the deposition-related thermodynamic state (stable glass) of each film is erased by transforming them into ordinary glasses. Secondly, upon reheating the thin ordinary glass films a direct comparison of the subsequently measured frequency-dependent dynamic glass transition temperatures becomes possible. The frequency of temperature modulation can be varied from 1 Hz up to about 1000 Hz. Film thicknesses for indomethacin are measured ex-situ with an atomic force microscope directly on the membrane of the chip-sensors. Similar to the thin polymer films no thickness dependence of the dynamic glass transition temperature (main relaxation) is seen. The results are in agreement with the explanation given by Cangialosi et al. 1, 2. M. Ahrenberg et al., The Journal of Chemical Physics, 2013, 138, 024501-024511. 2. H. Huth et al., Eur. Phys. J. Special Topics, 2007, 141, 153-160. 3. S. Napolitano and D. Cangialosi, Macromolecules, 2013, 46, 8051-8053.

10:24AM S43.00011 Why do some diluents alter the magnitude of nanoconfinement effects on the glass transition?1, JAYACHANDRA HARI MANGALARA, NICHOLAS WEINER, MICHAEL MARVIN, DAVID SIMMONS, University of Akron — Polymers subject to nanoconfinement can exhibit large alterations in their glass transition and associated dynamic and mechanical properties. Several studies have indicated that introduction of small-molecule additives can attenuate the magnitude of nanoconfinement effects, offering a potential method of tuning the properties of nanostructured polymers in applications from microelectronics to structural nanocomposites. However, the relationship between additive molecular properties and their effects on nanoconfined glass formation remains poorly understood. A number of studies have implicated changes in the fragility of glass formation in mediating these effects; however, this remains a matter of considerable debate. Here, we report on two sets of simulations of nanoconfined polymer films: one in which we introduce several oligomeric additives with effects ranging from suppression to enhancement of bulk Tg and fragility; one in which we introduce several oligomeric additives with effects ranging from suppression to enhancement of bulk Tg and fragility; one in which we reduce the polymer’s bulk fragility via a simple, additive-free, structural modification. Results provide new insight into the impact of additives on nanoconfined glass formation as well as into the role of fragility in determining nanoconfinement effects.

10:36AM S43.00012 Tuning the Tg-Confinement Effect by Controlling the Amount of Residual Surfactant Present in Emulsion Polymerized Polystyrene Thin Films, LAWRENCE CHEN, JOHN TORKELSON, Northwestern University — The nanoconfinement effect of polystyrene (PS) ultra-thin films supported on silica has been well studied over the past two decades. In order to systematically study the influence surfactants have on the Tg-confinement effect in thin films, PS was synthesized using conventional emulsion polymerization (E-PS) using sodium dodecyl sulfate (SDS) as the surfactant. After rigorous purification, the amount of SDS remaining in the bulk E-PS sample was quantified by using a modified Epton’s Method to be 0.023 wt%. This technique not only allows us to quantitate the amount of surfactant present in bulk polymer but also allows for the fine-tuning of surfactants present in the polymer. We find that a minute amount of surfactant is capable of significantly suppressing the Tg-confinement effect as well as narrowing the Tg breadth in sufficiently thin E-PS films; the magnitude of the Tg-confinement effect is strongly dependent on the amount of residual SDS present. Interestingly, when E-PS films undergo XPS depth profiling we demonstrate that the anionic surfactant preferentially resides at the free surface layer of the film thus eliminating the free surface effect.

10:48AM S43.00013 Homogeneous nucleation of polymers under confinement and its relation to the liquid-to-glass “transition”1, YASUHITO SUZUKI, Max-Planck Institute for Polymer Research, HATICE DURAN, TOBB University of Economics and Technology, MARTIN STEINHART, Universität Osnabrück, HANS-JÜRGEN BUTT, Max-Planck Institute for Polymer Research, GEORGE FLOUDAS, University of Ioannina — The crystallization and local dynamics of model semi-crystalline polymers confined to self-ordered nanoporous alumina (AAO) were studied as a function of pore size, molecular weight and cooling/heating rate by differential scanning calorimetry, wide-angle X-ray diffraction and dielectric spectroscopy. In contrast to the bulk, polymers located inside nanoporous alumina crystallize via distinct nucleation mechanisms. Under confinement, the usual heterogeneous nucleation of bulk polymers is suppressed. Instead, within the smaller pores polymer crystallization is initiated via homogeneous nucleation. We provide the phase diagram of crystallizable polymers under confinement. We find that homogeneous nucleation is strongly coupled to the local viscosity and hence to the liquid-to-glass “transition.” Dielectric spectroscopy revealed that confinement affects both the distribution of relaxation times (much broader under confinement) and the rate of segmental motion (faster dynamics under confinement).

Thursday, March 5, 2015 8:00AM - 11:00AM – Session S44 GSNP GSOFT: Focus Session: Granular Materials and Continuum Descriptions of Discrete Media I

8:00AM S44.00001 Giant drag reduction due to interstitial air in sand, DEVARAJ VAN DER MEER, University of Twente, TESS HOMAN, Laboratoire de Physique, ENS Lyon, France — When an object impacts onto a bed of very loose, fine sand, the drag it experiences depends on the ambient pressure in a surprising way: Drag is found to increase significantly with decreasing pressure. We use a modified penetrometer experiment to investigate this effect and directly measure the drag on a sphere as a function of both velocity and pressure. We observe a drag reduction of over 90% and trace this effect back to the presence of air in the pores between the sand grains. Finally, we construct a model based on the modification of grain-grain interactions that is in full quantitative agreement with the experiments.

8:12AM S44.00002 Scattering of a legged robot in a heterogeneous granular terrain1, FEIFEI QIAN, DANIEL GOLDMAN, Georgia Institute of Technology — Many granular substrates are composed of particulates of varying size, from fine sand to pebbles and boulders. Ambulatory locomotion on such heterogeneous substrates is complicated in part due to fluctuations introduced by heterogeneities. To discover principles of movement in such substrates, we developed an automated system, the “Systematic Creation of Arbitrary Terrain and Testing of Exploratory Robots” (SCATTER), to create heterogeneous granular substrates of varying properties such as compaction, inclination, obstacle shape/size/distribution and obstacle mobility within the substrate. We investigate how the presence of a single “boulder” affects the locomotion of a 6-legged robot (15cm, 150g). The robot’s trajectory is straight before boulder interaction, and is scattered to an angle after the interaction. Surprisingly, the interactions with the boulder can lead to both negative and positive scattering angles—an effective attraction and repulsion between the robot and the boulder. The scattering pattern depends sensitively on the leg-boulder contact position and the boulder mobility within the fine sand. However, the scattering pattern dependence upon contact position on the boulder is insensitive to boulder shape (created using 3D printing), orientation and roughness.

8:24AM S44.00003 Stability of an isolated granular band in a rotating tumbler, PAUL B. UMBANHOWAR, DARIUS WHEELER, JULIO M. OTTINO, RICHARD M. LUEPTOW, Northwestern University — Granular mixtures tend to segregate into axial bands when tumbling in long, horizontal cylinders. To better understand this phenomenon we experimented and computationally studied the stability of a single band of large spherical particles initially located between two regions of small spherical particles. Unlike previous work with bidisperse particles, where the band spread axially in a diffusive-like fashion, we found that a single band can stabilize to a constant width much smaller than the cylinder length depending on the size ratio of large to small particles, R_c, and the fill fraction of the tumbler, f. Stable bands were observed for $f < 0.3$ and $1.3 < R_c < 2.5$; for $R_c$ outside this interval and $f > 0.3$, bands were unstable and grew diffusively. For $R_c < 1.3$ large particles diffuse axially in the flowing layer, while for $R_c > 2.3$ axial motion of large particles occurs mainly at the intersection of the downstream terminus of the flowing layer and the cylinder wall. Lastly, band stability was independent of initial band width for the range we tested (4-40 mm). We discuss possible band stabilization mechanisms in light of these observations.

8:36AM S44.00004 The cause of coarsening, MATTHIAS SCHROETER, MPIDS Goettingen, TILO FINGER, RALF STANARIUS, Universitaet Magdeburg — The coarsening process of bands of smaller grains in a horizontally rotated cylindrical drum is a counterintuitive process. Our X-ray tomography results point to an effective surface tension as the driving mechanism. Additionally, we report on a novel microsegregation phenomenon.

8:48AM S44.00005 Analysis of inter-event times for avalanches on a conical bead pile with cohesion, SUSAN LEHMAN, NATHAN JOHNSON, CATHERINE TIEMAN, ELLIOT WAINWRIGHT, Department of Physics, College of Wooster, Wooster, OH — We investigate the critical behavior of a 3D conical bead pile built from uniform 3 mm steel spheres. Beads are added to the pile by dropping them onto the apex one at a time; avalanches are measured through changes in pile mass. We investigate the dynamic response of the pile by recording avalanches from the pile over tens of thousands of bead drops. We have previously shown that the avalanche size distribution follows a power law for beads dropped onto the pile apex from a low drop height. We are now tuning the critical behavior of the system by adding cohesion from a uniform magnetic field and find an increase in both size and number for very large avalanches and decreases in the mid-size avalanches. The resulting bump in the avalanche distribution moves to larger avalanche size as the cohesion in the system is increased. We compare the experimental inter-event time distribution to both the Brownian passage-time and Weibull distributions, and observe a shift from the Weibull to Brownian passage-time as we raise the threshold from measuring time between events of all sizes to time between only the largest system-spanning events. These results are both consistent with those from a mean-field model of slip avalanches in a shear system [Dahmen, Nat Phys 7, 554 (2011)].

9:00AM S44.00006 Ultra-fast parallel magnetic resonance imaging of granular systems, ALEXANDER PENN, Laboratory for Energy Science and Engineering, ETH Zurich and Institute for Biomedical Engineering, University and ETH Zurich, KLAAS P. PRUESSMANN, Institute for Biomedical Engineering, University and ETH Zurich, CHRISTOPH MULLER, Laboratory for Energy Science and Engineering, ETH Zurich — Several non-intrusive techniques have been applied to probe the dynamics of two-phase granular systems, with the most prominent examples being X-ray tomography, positron emission particle tracking (PEPT), electrical capacitance tomography and magnetic resonance imaging (MRI). MRI comes with the particular advantage that by implementing suitable pulse sequences not only spin densities (i.e. voidage), but also velocity, acceleration, diffusion and chemical reactions can be measured. However, so far the investigation of two-phase granular systems has been performed on relatively small-bore systems (max. diameter 60 mm). Such systems are, however, heavily influenced by wall effects. Furthermore, largely only single-coil detection has been employed, limiting severely the temporal resolution of the data acquisition. Here, we report the acquisition of ultra-fast MRI measurements in large volume vessels using medical MRI scanners. Specifically, parallel MRI, i.e. the simultaneous use of multiple receiver coils, has been exploited to speed up the data acquisition. In combination with advanced pulse sequences, we were able to probe the rapid dynamics (voidage and velocity measurements) of gas-solid systems.

9:12AM S44.00007 3D imaging of particle-scale rotational motion in granular flows, MATT HARINGTON, MICHAEL LIN, WOLFGANG LOSERT, University of Maryland — In current granular research, many strides have been made in the characterization of three-dimensional motion and structure through the use of novel imaging techniques. In the context of measuring individual motion of spherical grains, these techniques tend to be limited to translational motion. While this is often sufficient, it neglects the rotational motion that can arise from torques that grains exert on each other, and that potentially propagate across mesososcopic structures. This has left a gap that prevents researchers from fully characterizing the behavior of real granular flows. In particular, the role of individual rotational motion has not been fully explored in the context of bulk processes such as shear-banding, segregation, and irreversibility. In our current work, the Refractive Index Matched Scanning technique is expanded to extract the orientation of near-spherical grains in a quasistatic shear flow. Particle tracking is then applied to directly measure the rotational motion of individual grains. In an initial study, the presence of rolling modes in the shear band of a circular shear cell has been confirmed. From here, we are extending the method further to determine the role of collective rotations within and across neighborhoods.

9:24AM S44.00008 Simulation of granular flows through their many phases, SACHITH DUNATUNGA, Massachusetts Inst of Tech-MIT — The material point method (MPM) is combined with a constitutive model which allows material to traverse through its many common phases during the flow process. When dense, the material is treated as a pressure sensitive elasto-viscoplastic solid obeying a yield criterion and a plastic flow rule given by the $\mu(t)$ inertial rheology of granular materials. When the free volume exceeds a critical level, the material is deemed to separate and is treated as disconnected, stress-free media. By using the MPM framework, extremely large strains and nonlinear deformations such as those common to granular flows can be represented. The method has been shown to replicate results such as Beveloo scaling in silo discharge, as well as the Bagnold profile on an inclined plane.

9:36AM S44.00009 Modeling granular inclined plane flow phenomena with Nonlocal Granular Fluidity, KEN KAMRIN, MIT, DAVID HENANN, Brown University — The continuum theory of Nonlocal Granular Fluidity (NGF) has previously been shown to predict steady granular flow fields in many different geometries, including those such as split-bottom cells, which have been historically resistant to continuum modeling. Central to NGF is a direct inclusion of a particle length-scale, which renders the rheology nonlocal, capturing the cooperatively of granular motion. In this talk we describe how the model also captures the behaviors observed in granular inclined plane flows. We show that the model predicts a quantitatively accurate “stopping curve” which indicates the conditions that determine when a flowing layer comes to a stop, which depends explicitly on the thickness of the layer. We also explore other known phenomena in this geometry, such as the dependence of the flow profile on layer thickness, the collapse of the Froude number as a function of thickness vs the stopping height, and the possibility of modeling both starting and stopping curves within the same model.

9:48AM S44.00010 Flow Profiles and Fluctuations Measured for Granular Flow in a Vertical Channel, DONALD CANDELA, KEVIN FACTO, Univ of Mass - Amherst — The average velocity profiles and the velocity fluctuations were measured for flows of a dense granular medium (corn poppy seeds) through a long vertical channel, using NMR. The flow profiles seem to be in good agreement with non-local constitutive laws that have been proposed. In particular, there is a shear band near the channel wall with width that is independent of the flow rate. However, the measured velocity fluctuations do not agree with expectations from a simple interpretation of the underpinnings of the non-local rheology. For example, there are large fluctuations in the velocity of the central portion of the flow, away from the walls. This apparent discrepancy may be due to the absence of constant-pressure boundary conditions in granular flow through a fixed-size channel.

10:00AM S44.00011 High speed impacts on a granular material\(^1\) — YUE ZHANG, Duke University, ABRAHAM CLARK, Yale University, LOU KONDIC, NJIT, BOB BEHRINGER, Duke University — When an object strikes a granular material, its momentum and energy are transferred to the grains and dissipated. When the ratio of the intruder speed, \(v_0\), to a typical granular sound speed, \(c\), is small, this energy transfer is intermittent along force-chain-like structures, leading to an inertial drag term proportional to the square of the intruder speed. However, many natural and industrial examples of granular impact occur much closer to \(M' \equiv v_0/c \sim 1\), a regime which is difficult to reach in a lab setting using many common granular materials. To address this, we perform experiments (and matching simulations) with granular materials comprised of photoelastic disks of varying stiffness (and thus, varying \(c\)), in order to probe regimes closer to \(M' \sim 1\). As \(M'\) increases, the inertial drag law fails and the material begins to behave more elastically, with a shock-like front propagating away at impact. This causes the penetration depth to be greatly reduced, and in extreme cases, the intruder can rebound temporarily. We understand this transition to damped, elastic-like behavior by comparing the grain-grain collision time to the time for the intruder to move one grain diameter.

10:12AM S44.00012 Avalanches, and evolution of stress and fabric for a cyclically sheared granular material\(^1\) — DENGMING WANG, Lanzhou University, JONATHAN BARES, DONG WANG, BOB BEHRINGER, Duke University — Granular materials yield for large enough shear stress, leading to avalanches. We seek to understand the relation between macroscopic avalanches and the microscopic granular structure. We present an experimental study of a 2D granular material subjected to cyclic pure shear, which we visualized by a photo-elastic technique. We start from a stress-free sample of frictional particles in the shear-jamming regime \((\phi_s \leq \phi < \phi_j)\). We apply multiple cycles of pure shear: shear in one direction, followed by a reversal to the original boundary configuration. The strain is made in small quasi-static steps: after each small step, we obtain polarized and unpolarized images yielding particle-scale samples and locations. Statistical measures of the avalanches are in reasonable agreement with recent mean-field avalanche models by Dahmen et al. (Nature Physics 7, 554 (2011)) The system structure evolves slowly to reduce the stress at the extremum of strain, similar to the relaxation observed by Ren et al. (Phys. Rev. Lett. 110, 018302 (2013)) in a simple shear experiment. To understand how this relaxation occurs, we track the stress and fabric tensors and measures of the strain field over many cycles of shear.

\(^1\)Supported by NASA grant NNX10AU01G, and NSF grants DMR1206351 and DMS1248071

10:24AM S44.00013 Statistics from granular stick-slip experiment\(^1\) — AGHIL ABED ZADEH, JONATHAN BARENT, ROBERT BEHRINGER, Duke Univ — We carry out experiments to characterize stick-slip for granular materials. In our experiment, a constant speed stage pulls a slider which rests on a vertical bed of circular photoelastic particles in a 2D system. The stage is connected to the slider by a spring. We measure the force on the spring as well as the slider’s acceleration by a force sensor attached to the spring and accelerometers on the slider. The distributions of energy release and time duration of avalanches during slip obey power laws. We apply a novel event recognition approach using wavelets to extract the avalanche properties. We compare statistics from the wavelet approach with those obtained by typical methods, to show how noise can change the distribution of events. We analyze the power spectrum of various quantities to understand the effect of the loading speed and of the spring stiffness on the statistical behavior of the system. Finally, from a more local point of view and by using a high speed camera and the photoelastic properties of our particles, we characterize the internal granular structure during avalanches.

\(^1\)This work is supported by NSF Grant DMR1206351 and NASA grant NNX10AU01G

10:36AM S44.00014 Force network in a three-dimensional sheared material , NICOLAS BRODU, INRIA Bordeaux, JONATHAN BARES, Duke University, JOSHUA DIJKSMAN, Wageningen UR, ROBERT BEHRINGER, Duke University — Force chains in 2D granular material have been widely studied over the past decade. However the force network evolution when a 3D granular medium is sheared remains poorly understood due to the complexity of experimental observations. We present an experimental set-up to measure interparticle forces in the case of the quasi-static deformation of a 3D sphere packing subjected to shear and compression. We perform these experiments on slightly polydispersed and los-friction soft hydrogel spheres. We measure the microscopic force network in a this three dimensional packing through imaging the entire packing at each loading steps. By resolving particle deformations via custom image analysis software, we extract all particle contacts and contact forces with a very good accuracy. We address the rising up of the Reynolds pressure from the microscopic force network and a statistical ensemble analogous to equilibrium counterpart for 3D frictionless particles.

10:48AM S44.00015 Granular dynamics under shear with deformable boundaries , DREW GELLER, SCOTT BACKHAUS, ROBERT ECKE, Los Alamos National Laboratory — Granular materials under shear develop complex patterns of stress as the result of granular positional rearrangements under an applied load. We consider the simple planar shear of a quasi-two-dimensional granular material consisting of bi-dispersed nylon cylinders confined between deformable boundaries. The aspect ratio of the gap width to total system length is 50, and the ratio of particle diameter to gap width is about 10. This system, designed to model a long earthquake fault with long range elastic coupling through the plates, is an interesting model system for understanding effective granular friction because it essentially self tunes to the jamming condition owing to the hardness of the grains relative to that of the boundary material, a ratio of more than 1000 in elastic moduli. We measure the differential strain displacements of the plates, the inhomogeneous stress distribution in the plates, the positions and angular orientations of the individual grains, and the shear force, all as functions of the applied normal stress. There is significant stick-slip motion in this system that we quantify through our quantitative measurements of both the boundary and the grain motion, resulting in a good characterization of this sheared 2D hard sphere system.

Thursday, March 5, 2015 8:00AM - 10:48AM –
Session S45 DPOLY: Focus Session: Polymer Nanocomposites: Dynamics 216AB - Laura Clarke, North Carolina State University

8:00AM S45.00001 Dynamics in Polymer Nanocomposites\(^1\) — NIGEL CLARKE, University of Sheffield — Since nanoparticles are increasingly being added to polymers to impart mechanical and functional properties, we are exploring how nanoparticles impact polymer dynamics with a focus on the diffusion coefficients. In high molecular weight polymer melts, chain diffusion is well described by the reptation model. Motion proceeds as a snake-like diffusion of the chain as a whole, along the contour of a tube that mimics the role of physical entanglements, or topological constraints, with other chains. In polymer nanocomposites there are additional constraints due to the dispersed nanoparticles in the polymer matrix. Chain motion can be altered by nanoparticle size, shape, aspect ratio, surface area, loading and the nature of the interactions between the nanoparticles and the polymer matrix. We have observed a minimum in the diffusion coefficient as a function of nanoparticle concentration when the nanoparticles are rod-like and a collapse of the diffusion coefficient onto a master curve when the nanoparticles are spherical. We are simulating the dynamics using molecular and dissipative particle simulations in order to provide physical insight into the local structure and dynamics, and have also carried out highly coarse grained Monte Carlo simulations of entangled polymers to explore how reptation is affected by the presence of larger scale obstacles.

\(^1\)We acknowledge support from the NSF/EPSRC Materials World Network Program
8:36AM S45.00002 Determination of the Tracer Diffusion Coefficient of Soft Polystyrene Nanoparticles using Neutron Reflectivity. ADAM IMEL, BRAD MILLER, University of Tennessee-Knoxville, WADE HOLLEY, Oak Ridge National Laboratory, DURAIJAI BASKARAN, JIMMY MAYS, MARK DADMUN, University of Tennessee-Knoxville — The diffusion properties of nanoparticles in polymer nanocomposites are largely unknown and depend intimately on the dispersion of the nanoparticles. We examine the diffusion of soft, organic nanoparticles, which disperse in a polymer matrix due to the interpenetration of polymer chains and particles and the reduction in the depletion entropy in the system. The impact of the presence of soft nanoparticles on the diffusion coefficient of polystyrene chains has recently been determined with neutron reflectivity. This was completed by monitoring the interdiffusion of deuterated and protonated polystyrene nanocomposite bilayers with and without the soft nanoparticles dispersed throughout both layers and extracting the diffusion coefficient from the one-dimensional solution to Fick’s second law of diffusion. In this work, we extend this method to bilayer systems with only the soft nanoparticles as one of the layers and a linear deuterated polystyrene as an adjacent layer. The development of this method allows us to determine the tracer diffusion coefficient of the soft polystyrene nanoparticles for the first time by analyzing the mutual diffusion coefficient from Fick’s second law and the fast and slow modes theories for diffusion.

8:48AM S45.00003 Viscosity of Polymer Nanocomposite with Athermal Hairy Nanoparticles. FEI CHEN, OPHELIA TSUI, Boston Univ — We studied the zero shear viscosity of polymer nanocomposites (PNC) containing silica nanoparticles grafted with polystyrene ligands blended with polystyrene homopolymer. As the ratio of the molecular weight of the homopolymer, P, to that of the ligands, N, was increased from about 0.01, we observed a transition from viscosity enforcement to viscosity reduction near P/N = 1. Interestingly, many of the samples exhibiting viscosity reduction have the dry diameter of the particles exceeding the radius of gyration of the homopolymer (i.e., 2r > Rg), making them exceptional cases according to the viscosity phase diagram published by Kalathi et al. (Phys. Rev. Lett. 109, 198301 (2012)). We discuss whether hydrodynamic effect and plasticizer effect might have caused our observations.

9:00AM S45.00004 Probing the interfacial region in polymer-graphene oxide nanocomposites. MICHAEL WEIR, Department of Physics and Astronomy, University of Sheffield, STEPHEN BOOTHROYD, DAVID JOHNSON, RICHARD THOMPSON, Durham University, NIGEL CLARKE, University of Sheffield, KARL COLEMAN, Durham University — Graphene and related two-dimensional materials are excellent candidates as filler materials in nanocomposites due to their extraordinary physical properties and high aspect ratio. We are studying graphene oxide (GO), a highly functionalized form of graphene, due to its relative ease of dispersion within polymer matrices. Interruptions to the pristine two-dimensional carbon network by oxygen-containing groups, which provide functionality, also make GO rather flexible. In this paper we show that GO is wrinkled and rough over a hierarchy of length scales from a few nanometers to a few microns, when it is incorporated in composites with poly(methyl methacrylate) (PMMA) and polystyrene (PS). Small-angle neutron scattering measurements, highlighting individual polymer chains, show a decrease in polymer radius of gyration with increasing GO concentration in PMMA/GO nanocomposites. The decrease is consistent with models of a solid interface in a polymer melt. The interface influences the polymer matrix within an interface volume stretching on the order of one polymer radius of gyration from the surface. This work is a direct measurement of the effect of the nanofiller upon the polymer matrix and progresses our understanding of interfacial interactions within nanocomposites.

9:12AM S45.00005 Polymer dynamics in PMMA-carbon nanocomposites. RANA ASHKAR, University of Maryland-College Park/NIST, MANSOUR ABDULBAKI, University of Houston, CHRISTOPHER BERTRAND, MADHUSUDAN TYAGI, ANTONIO FARAONE, PAUL BUTLER, National Institute of Standards and Technology, RAMANAN KRISHNAMOORTI, University of Houston — Particle-polymer interactions in nanocomposites can lead to significant heterogeneities in the polymer dynamics and remarkably impact the material properties. While dynamical perturbations are expected to be limited to interfacial polymer segments, for nanoparticle concentrations above percolation, however, the interfacial regions overlap. The impact of interfacial-polymer network results in a complex relaxation behavior of the polymer, that is unanticipated from dilute nanoparticle dispersions in polymer matrices. Neutron spectroscopy on C60 and SWNT composites reveals that dynamical perturbations can extend to non-interfacial polymer segments and significantly influence their local mobility and their meso-scale cooperative relaxations. In this case of attractive particle-particle interactions, a gradual decrease in the polymer mean-square displacement is observed with increasing nanoparticle loadings below the percolation threshold. However, once the nanoparticles are percolated – be it C60 or SWNT – the mean-square displacement seizes to change with increasing loading, indicating kinetic arrest of the polymer. Interestingly, upon percolation, the composites experience an order of magnitude slowdown in the structural relaxations relative to the pure matrix.

9:24AM S45.00006 Macromolecular Diffusion in Dynamic Polymer Nanocomposite1. CHIA-CHUN LIN, MATTEO CARNELLO, University of Pennsylvania, NIGEL CLARKE, University of Sheffield, KAREN WINNEY, RUSSELL COMPSTO, University of Pennsylvania — We consider diffusion of tracer particles in the presence of mobile nanoparticles in polymer nanocomposites (PNCs). These nanoparticles are mobile on the time scale of polymer dynamics and have dimensions less than the entanglement mesh size (i.e., tube diameter). The PNC consists of titanium dioxide nanorods (NR, diameter=4.5nm; length=30.1nm) grafted with phenyl groups uniformly dispersed in a polystyrene (P=650kg/mol; tube diameter=8nm) matrix up to 10 volume percent. Three deuterated polystyrenes (dPS; M=800, 1800 and 3200 kg/mol) are chosen because their diffusion relative to NR allows for investigating fixed and mobile NR by simply changing M. For all M, the reduced tracer diffusivities are observed to decrease monotonically as NR loading increases. However, the reduced diffusion of dPS (3200 kg/mol) is faster than expected compared to the fixed NR case. These findings suggest that mobile NR do not effectively slow down tracer diffusion relative to fixed particles. To test this hypothesis, dPS diffusion is investigated in a high molecular weight matrix PS (2000 kg/mol) in order to slow down NR diffusion relative to dPS (3200 kg/mol). New models are needed to incorporate these mobility dependent entanglements into a comprehensive understanding of dynamics in PNCs.

9:36AM S45.00007 Dynamics of Brush-grafted Nanoparticles in Polymer Melts1. RUSSELL COMPSTO, CHIA-CHUN LIN, Univ of Pennsylvania, KOHJI OHNO, Kyoto University, MICHAEL HORE, Case Western Reserve University, JEFFREY METH, Central Research & Development, DuPont Co., NIGEL CLARKE, Univ of Sheffield, KAREN WINNEY, Univ of Pennsylvania — Grafting a polymer brush to organic nanoparticles, which dispers in a polymer matrix due to the interpenetration of polymer chains and particles and the reduction in the depletion entropy in the system. The impact of the presence of soft nanoparticles on the diffusion coefficient of polystyrene chains has recently been determined with neutron reflectivity. This was completed by monitoring the interdiffusion of deuterated and protonated polystyrene nanocomposite bilayers with and without the soft nanoparticles dispersed throughout both layers and extracting the diffusion coefficient from the one-dimensional solution to Fick’s second law of diffusion. In this work, we extend this method to bilayer systems with only the soft nanoparticles as one of the layers and a linear deuterated polystyrene as an adjacent layer. The development of this method allows us to determine the tracer diffusion coefficient of the soft polystyrene nanoparticles for the first time by analyzing the mutual diffusion coefficient from Fick’s second law and the fast and slow modes theories for diffusion.

1Primary supports from NSF/EPSRC Materials World Network DMR 1210379 (KIW, RJC) and EP/5065373/1 (NC)
of Pennsylvania — The tracer diffusion of deuterated polystyrene (dPS; DuPont Nanocomposite Technologies, Central Research & Development, RUSSELL COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania, ADAM HOLT, Department of Physics and Astronomy, University of Tennessee, Knoxville, SHIWANG CHENG, Department of Materials Science and Engineering, Chungnam National University, NIGEL CLARKE, Department of Physics and Engineering, The University of Sheffield, KAREN WINEY, Department of Materials Science and Engineering, University of Pennsylvania, JEFFREY METH, DuPont Nanocomposite Technologies, Central Research & Development, RUSSELL COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania — The tracer diffusion of deuterated polystyrene (dPS; $M_n = 23 - 1866$ kg/mol) with a thickness (l) is measured diffusing away from hydroxyl-terminated, phenyl-terminated, and PS-grafted silicon substrates. For a hydroxyl-functionalized substrate, short polymer chains ($M_n < 23$ and 49 kg/mol; $l > >> R_g$) exhibit a diffusion coefficient that is comparable to bulk PS, whereas long polymer chains ($M_n = 532$ and 1866 kg/mol; $l < R_g$) are significantly slower than the bulk case. This slowing down is consistent with the observation by Zheng et al. [1]. In particular, bimodal diffusion coefficient was observed for intermediate molecular weight ($M_n = 168$ kg/mol; $l \sim R_g$). For phenyl-functionalized and PS-grafted substrates, no significant differences in the diffusion coefficients are observed although long polymer chains showed a moderate slowing down. These experiments demonstrate that the polymer diffusion of thin, confined films ($\sim R_g$) away from the substrate is determined by the friction due to surface-monomer contacts, and is sensitive to the chemical state of the substrate, providing a new insight into the role of the interfacial interactions on polymer dynamics.

10:00AM S45.00009 Role of the Interfacial Interactions from an Adjacent Wall on Polymer Diffusion . JIHOON CHOI, Department of Materials Science and Engineering, Chungnam National University, NIGEL CLARKE, Department of Physics and Astronomy, The University of Sheffield, KAREN WINEY, Department of Materials Science and Engineering, University of Pennsylvania, JEFFREY METH, DuPont Nanocomposite Technologies, Central Research & Development, RUSSELL COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania — The tracer diffusion of deuterated polystyrene (dPS; $M_n = 23 - 1866$ kg/mol) with a thickness (l) is measured diffusing away from hydroxyl-terminated, phenyl-terminated, and PS-grafted silicon substrates. These experiments demonstrate that the polymer diffusion of thin, confined films ($\sim R_g$) away from the substrate is determined by the friction due to surface-monomer contacts, and is sensitive to the chemical state of the substrate, providing a new insight into the role of the interfacial interactions on polymer dynamics.

10:12AM S45.00010 Length-Scale Dependent Viscosity in Semidilute Polyelectrolyte Solutions . RYAN POLING-SKUTVIK, RAMANAN KRISHNAMOORTI, JACINTA CONRAD, Univ of Houston — Using optical microscopy and particle tracking algorithms, we measured the mean-squared displacements (MSDs) of fluorescent polystyrene particles with diameters ranging from 300 nm to 2 μm suspended in semidilute solutions of high molecular weight partially hydrolyzed polyacrylamide. The solutions had polymer concentrations ranging from 0.67 to 67%, where $c^*$ is the overlap concentration, and estimated correlation lengths of $\sim 100$ to 900 nm. At short times, the particles exhibited subdiffusive behavior characterized by MSD $\sim t^\alpha$ with $\alpha < 1$. On long time scales, the particles transitioned to Fickian diffusion ($\alpha = 1$) and their diffusivity was calculated from the slope of the MSD. Whereas the large particles agreed with predictions using the Stokes-Einstein equation and bulk zero-shear viscosity, the smaller particles diffused much faster than predicted. The relative diffusivities do not collapse onto a single curve, but rather form a continuum that varies with particle size. This indicates that the particles experience a size-dependent effective viscosity mediated by the ratio of particle diameter to characteristic length scales in the polymer solution.

10:24AM S45.00011 Temperature Dependence of Rheology and Polymer Diffusion in Silica/Poly styrene Nanocomposites1, WEI-SHAO TUNG, University of Pennsylvania, NIGEL CLARKE, University of Sheffield, RUSSELL COMPOSTO, University of Pennsylvania, JEFFREY METH, DuPont Nanocomposite Technologies and DuPont Central Corporate Analytical Services, KAREN WINEY, University of Pennsylvania — Temperature-time superposition using the WLF equation is well-established for both the zero shear viscosity and the polymer diffusion coefficient in homopolymer melts. This talk will present the temperature-dependence of polymer dynamics in polymer nanocomposites comprised of polystyrene and phenyl-capped silica nanoparticles (0 – 50 vol%). The WLF equation fits the temperature dependence of the tracer polymer diffusion coefficient and the fitting parameter (B/fo) decreases smoothly with nanoparticle concentration suggesting an increase in the thermal expansion coefficient for the free volume. The WLF equation also fits the temperature dependence of the zero shear viscosity from oscillatory shear experiments, although the fitting parameter (B/fo) increases substantially with nanoparticle concentration. This discrepancy between the diffusion and rheology will be discussed with respect to the reptation model, which predicts that the temperature dependence of polymer diffusion depends predominately on the temperature dependence of local viscosity, and the elastic response in nanocomposites.

10:36AM S45.00012 Anomalous Drag Reduction and Hydrodynamic Interactions of Nanoparticles in Polymer Nanocomposite Thin Films . JAYDEEP BASU, NAIFASA BEGAM, Department of Physics, Indian Institute of Science, Bangalore, India, SIVASURENDER CHANDRAN, Department of Physics, Albert Ludwigs University of Freiburg, Germany, MICHAEL SPRUNG, PETRA-III, DESY, Germany — One of the central dogma of fluid physics is the no-slip boundary condition whose validity has come under intense scrutiny, especially in the fields of micro and nanofluidics. Although various studies show the violation of the no-slip condition its effect on flow of colloidal particles in viscous media has been rarely explored. Here we report unusually large reduction of effective drag experienced by polymer grafted nanoparticles moving through a highly viscous film of polymer, well above its glass transition temperature. The extent of drag reduction increases with decreasing temperature and polymer film thickness. We also observe apparent divergence of the wave vector dependent hydrodynamic interaction function of these nanoparticles with an anomalous power law exponent of $\sim 2$ at the lowest temperatures and film thickness. Such strong hydrodynamic interactions are not expected in polymer melts where these interactions are known to grow with increasing polymer molecular weight (MW). Our measurements reveal an opposite trend: the magnitude of the effect on segmental dynamics decreases with increasing MW. Based on detailed analysis of dielectric spectroscopy and small angle x-ray scattering measurements we provide a qualitative explanation of the unexpected observation.

Thursday, March 5, 2015 8:00AM - 11:00AM — Session S46 GMAG GQI: Invited Session: Hybrid Spin-Strained Systems in Diamond 217A - Sunil Bhave, Cornell University
8:00AM S46.00001 Coherent control over diamond nitrogen-vacancy center spins with a mechanical resonator\(^1\), GREGORY FUCHS, Cornell University — We demonstrate coherent Rabi oscillations of diamond nitrogen-vacancy (NV) center spins driven directly by a mechanical resonator without mediation by a magnetic driving field. Using a bulk-mode acoustic resonator fabricated from single crystal diamond, we exert non-axial ac stress on NV centers positioned at an antinode of a gigahertz frequency mechanical mode. When the \( \Delta m_j \approx -1 \) to +1 spin state splitting energy is tuned into resonance with a driven mechanical mode, we observe \( \Delta m_j = \pm 2 \) spin transitions, which are forbidden by the magnetic dipole selection rule. To rule out stray electric and magnetic fields as the origin of these spin transitions, we study the spin signal as a function depth within the diamond resonator. We find that the spin signal reproduces the periodicity of the acoustic standing wave, confirming the mechanical origin of the observed spin resonance \(^1\). Using single-crystal diamond mechanical resonators with \( fQ \) products of \( 2 \times 10^{12} \), we observe coherent mechanically driven Rabi oscillations up to 4 MHz. \(^2\) For ensembles of NV centers coupled to the resonator, we analyze Rabi oscillations and their dephasing with a combination of spatially inhomogeneous mechanical driving and fluctuating magnetic fields from a noisy spin environment. Additionally, we examine the coherence of mechanically controlled NV center qubits and compare it to the coherence of magnetically controlled spin qubits in the NV center ground state spin manifold. This work demonstrates direct and coherent coupling between NV center spins and resonator phonons, which has potential for NV-based metrology using hybrid spin-mechanical sensors, fundamental research into spin-phonon interactions at the nanoscale, and as a platform for hybrid spin-mechanical quantum systems. \(^1\) E. R. MacQuarrie et al., Phys. Rev. Lett. 111, 227602 (2013). \(^2\) E. R. MacQuarrie et al., arXiv:1411.5325 (2014).

8:36AM S46.00002 Strain-mediated mechanical coupling to diamond spins\(^1\), ANIA BLESZYNJSKI JAYICH, UC Santa Barbara — Nitrogen-vacancy (NV) centers in diamond are atomic-scale spin systems with remarkable quantum properties that persist to room temperature. The recent demonstration of high-quality single-crystal diamond resonators has led to significant interest in a hybrid system consisting of NV spins that interact with the resonant phonon modes of a macroscopic mechanical resonator through crystal strain. We demonstrate dynamic, strain-mediated coupling of the mechanical motion of a diamond cantilever to the spin of an embedded NV. Via quantum control of the spin, we quantitatively characterize the axial and transverse strain sensitivities of the nitrogen-vacancy ground-state spin. The nitrogen–vacancy center is an atomic scale sensor and we demonstrate spin-based strain imaging with a strain sensitivity of \( 3 \times 10^{-6} \) strain Hz\(^{-1/2} \). We discuss prospects for reaching the regime of quantum coupling between phonons and spins, and we present our results in this direction. This hybrid system has exciting prospects for a phonon-based approach to integrating NVs into quantum networks.

\(^1\) Funding from the AFOSR MURI and NSF CAREER programs are gratefully acknowledged.

9:12AM S46.00003 Dynamics of a strain-coupled, hybrid spin-oscillator system, JEAN TEISSIER, University of Basel — A single spin coupled to a mechanical oscillator forms a prototypical hybrid quantum system. With a strong and robust coupling mechanism, such devices could yield high-performance nanoscale sensors, be applied for quantum information processing tasks or ultimately be used to study macroscopic objects in the quantum regime. In this talk, I will present our recent experiments where we established a novel type of such a hybrid spin-oscillator system. Specifically, we implemented for the first time diamond nanomechanical resonators, which are coupled to embedded Nitrogen-Vacancy (NV) centre electronic spins through crystalline strain. This strain coupling mechanism is highly robust, potentially strong and leads to interesting dynamics due to the nontrivial strain coupling Hamiltonian. I will illustrate these aspects though our recent experimental results, which include the first quantitative determination of the relevant strain coupling constants and the demonstration of resolved sideband operation in our devices. I will also discuss recent experiments in which we demonstrated coherent driving of NV spins through time-varying strain fields and studied the resulting intriguing dynamics of the strain-driven NV spin system. Our results constitute first essential steps towards future experiments of our hybrid system in the quantum regime. Examples for these include spin-based oscillator sideband cooling or the recently proposed generation of spin-squeezing in nanomechanical oscillators.

9:48AM S46.00004 Phonon cooling and lasing with nitrogen-vacancy centers in diamond, PETER RABL, Institute of Atomic and Subatomic Physics, Vienna University of Technology — Diamond has emerged as a promising material for quantum applications, due in part to its optical and mechanical properties and in part to its addressable quantum defects. In this talk I will discuss the deformation potential interaction between nitrogen-vacancy (NV) centers and isolated mechanical modes in diamond nanostructures. Even on a single phonon level, this coupling can lead to significant shifts of the electronic and spin levels of the defect center and could provide a new tool to access and manipulate the quantum state of macroscopic mechanical systems. I will describe applications of this coupling mechanism for actuation (lasing) and ground state cooling of diamond nanoresonators and show how the combination of these schemes leads to PT-symmetry breaking phase transitions in coupled resonator arrays with engineered loss and gain.

Thursday, March 5, 2015 8:00AM - 10:48AM — Session S47 DBIO: Focus Session: Mechanical Structure-Function Relations in Biological Matter I 217B - Moumita Das, Rochester Institute of Technology

8:00AM S47.00001 Time evolution of cell size distributions in dense cell cultures, EVGENIY KHAIN, Oakland University — Living cells in a dense system are all in contact with each other. The common assumption is that such cells stop dividing due to a lack of space. Recent experimental observations have shown, however, that cells continue dividing for a while, but other cells in the system must shrink, to allow the newborn cells to grow to a normal size. Due to these “pressure” effects, the average cell size dramatically decreases with time, and the dispersion in cell sizes decreases, too. The collective cell behavior becomes even more complex when the system is expanding: cells near the edges are larger and migrate faster, while cells deep inside the colony are smaller and move slower. This exciting experimental data still needs to be described theoretically, incorporating the distribution of cell sizes in the system. We propose a mathematical model for time evolution of cell size distribution both in a closed and open system. The model incorporates cell proliferation, cell growth after division, cell shrinking due to “pressure” from other cells, and possible cell detachment from the interface of a growing colony. This research sheds light on physical and biological mechanisms of cell response to a dense environment and on the role of mechanical stresses in determining the distribution of cell sizes in the system.
8:12AM S47.00002 Sorting of colors in the retina . EREZ RIBAK, AMICHAI LABIN, SHADI SAFURI, IDO PERLMAN, Technion - Israel Institute of Technology — Our image of the world is detected by photoreceptors, lying at the bottom of the nearly-transparent retina. Lateral neural layers for processing the image temporally, spectrally, and spatially come in front the photoreceptors, not behind them. This reverse order is a long-standing puzzle, which we wish to explain. We found out that cone photoreceptors are attached to metabolic Muller cells which span the retina. Cones provide colour vision at day time, and are surrounded by sensitive rods which function at night. We showed by an analytical and a computational method that the Muller cells also serve as fibre optics, concentrating green-red light into the cones, while the excessive blue is scattered to the nearby rods. Spatial and spectral laboratory measurements validate that indeed the shapes and refractive index values of the Muller cells and the surrounding retina separate the colours according to the spectral sensitivities of both cones and rods. These results also explain other effects of vision acuity and colour sensitivity. References A M Labin and E N Ribak, Phys Rev Lett 104, 158102 (2010). 8:24AM S47.00003 Role of the transverse arch in stiffness of the human foot1 MARCELO A. DIAS, Aalto University, DHIRAJ K. SINGH, MAHESH M. BANDI, Okinawa Institute of Science and Technology, MOHSHUSUDHAN VENKADESAN, Yale University, SHREYAS MANDRE, Brown University — Human ancestors evolved from walking, around 6 million years (Ma) ago, to regular endurance running, around 2 Ma ago. Simultaneously, the feet evolved from a relatively flat structure like that of current day Chimpanzees (or our hands), to the modern human foot with two arches, a longitudinal and a transversal arch. The feet play a crucial role in locomotion by providing sufficient stiffness for propulsion, and being soft and pliable to absorb impacts and store energy elastically. Here we show that the transverse arch could play a central role in stiffness modulation. We first treat the foot as an elastic shell that is with intrinsically elastic. Calculations, numeric and physical experiments all show that for a foot-like shell, the stiffness has a power-law dependence on transverse curvature beyond a critical value. On the other hand, for purely longitudinally curved feet, or transverse curvature below the critical value, lead to low stiffness like a flat plate. Discrete realizations of a continuum shell, more closely resembling the human foot, also exhibit curvature induced stiffening. These results shed light on the role of the quintessentially human feature of a doubly arched foot, and suggest mechanical consequences of disorders such as a collapsed arch.

HFSR RGY0091/2013

8:36AM S47.00004 Correlating Viscoelasticity with Metabolism in Single Cells using Atomic Force Microscopy1, MATTHEW CAPORIZZO, CHARLES ROCO, CARME COLL-FERRER, Materials Science Engineering, DAVID ECKMANN, Anesthesiology and Critical Care, RUSSEL COMPOSTO, Materials Science Engineering — Variable indentation-rate rheometric analysis by Laplace transform (VIRRAL), is developed to evaluate Des-Gel drug carriers as biocompatible delivery agents. VIRRAL provides a general platform for the rapid characterization of the health of single cells by viscoelasticity to promote the self-consistent comparison between cells paramount to the development of early diagnosis and treatment of disease. By modelling the frequency dependence of elastic modulus, VIRRAL provides three metrics of cytoplasmic viscoelasticity: low frequency stiffness, high frequency stiffness, and a relaxation time. THP-1 cells are found to exhibit a frequency dependent elastic modulus consistent with the standard linear solid model of viscoelasticity. VIRRAL indicates that dextran-lysozyme drug carriers are biocompatible and deliver concentrated toxic material (rhodamine or silver nanoparticles) to the cytoplasm of THP-1 cells. The signature of cytotoxicity by rhodamine or silver exposure is a frequency independent 2-fold increase in elastic modulus and cytoplasmic viscosity while the cytoskeletal relaxation time remains unchanged independent of cytoplasmic stiffness. This is consistent with the known toxic mechanism of silver nanoparticles, where mitochondrial injury leads to ATP depletion and metabolic stress causes a decrease of mobility within cytoplasm.

8:48AM S47.00005 Linking Mechanics and Statistics in Epidermal Tissues, SANGWOO KIM, SASCHA HILGENFELDT, Univ of Illinois - Urbana — Disordered cellular structures, such as foams, polycrystals, or living tissues, can be characterized by quantitative measurements of domain size and topology. In recent work, we showed that correlations between size and topology in 2D systems are sensitive to the shape (eccentricity) of the individual domains: From a local model of neighbor relations, we derived an analytical justification for the famous empirical Lewis law, confirming the theory with experimental data from cucumber epidermal tissue. Here, we go beyond this purely geometrical model and identify mechanical properties of the tissue as the root cause for the domain eccentricity and thus the statistics of tissue structure. The simple model approach is based on the minimization of an interfacial energy functional. Simulations with Surface Evolver show that the domain statistics depend on a single mechanical parameter, properties of the tissue as the root cause for the domain eccentricity and thus the statistics of tissue structure. The model is relevant to diagnostic applications in a variety of animal and plant tissues.

9:00AM S47.00006 Cell mechanics and immune system link up to fight infections . ANDREW EKPENYONG, Dept. of Physics, Creighton University, SI MING MAN, PANAGIOTIS TOURLOMOUSIS, SARRA ACHOURI, EUGENIA CAMMAROTA, KATHERINE HUGHES, ALESSANDRO RIZZO, GILBERT NG, Univ of Cambridge, UK, JOCHEN GUCK, Technical Univ. Dresden, Germany, CLARE BRYANT, Univ of Cambridge, UK — Infectious diseases, in which pathogens invade and colonize host cells, are responsible for one third of all mortality worldwide. Host cells use special proteins (immunoproteins) and other molecules to fight viral and bacterial invaders. The mechanisms by which immunoproteins enable cells to reduce bacterial loads and survive infections remain unclear. Moreover, during infections, some immunoproteins are known to alter the cytoskeleton, the structure that largely determines cellular mechanical properties. We therefore used an optical stretcher to measure the mechanical properties of primary immune cells (bone marrow derived macrophages) during bacterial infection. We found that macrophages become stiffer upon infection. Remarkably, macrophages lacking the immunoprotein, NLR-C4, lost the stiffening response to infection. This in vitro result correlates with our in vivo data whereby mice lacking NLR-C4 have more lesions and hence increased bacterial distribution and spread. Thus, the immune-protein-dependent increase in cell stiffness in response to bacterial infection (in vitro result) seems to have a functional role in the system level fight against pathogens (in vivo result). We will discuss how this functional link between cell mechanical properties and innate immunity, effected by actin polymerization, reduces the spread of infection.

9:12AM S47.00007 Topology optimization of trabecular bone in the human spine , AHMED ELBANNA, University of Illinois Urbana Champaign — It is widely believed in the realm of biology that the trabecular structure of long bones self-optimizes in response to mechanical loads, in accordance with Wolff’s law. Here, we examine this idea by applying techniques from topology optimization the human spine. We consider different domain geometries as well as different load cases to account for the various loading conditions and changes in shape that take place within the spine during day-to-day activities and over the years. We show that the classical approach of minimizing compliance subject to a volume constraint does not yield a sponge-like architecture but results in only vertical trabeculae. Additional constraints/objective functions have to be considered simultaneously. We show that more realistic trabecular geometries may be produced by taking into consideration the function of trabecular bone as a reservoir for minerals and bone marrow production. By maximizing the surface area of the generated voids while minimizing the total volume of the trabeculae subject to a constraint on their buckling strength, we recover the sponge-like structure. Our results shed light on the optimizing conditions for bone structure beyond Wolff’s law and provide guidelines for biomimetic material design.
9:24AM S47.00008 Structure and Sequence Search on Aptamer-Protein Docking . JIAJIE XIAO, KEITH BONIN, MARTIN GUTHOLD, FREDDIE SALSBURY, Wake Forest University — Interactions between proteins and deoxyribonucleic acid (DNA) play a significant role in the living systems, especially through gene regulation. However, short nucleic acids sequences (aptamers) with specific binding affinity to specific proteins exhibit clinical potential as therapeutics. Our capillary and gel electrophoresis selection experiments show that specific sequences of aptamers can be selected that bind specific proteins. Computationally, given the experimentally-determined structure and sequence of a thrombin-binding aptamer, we can successfully dock the aptamer onto thrombin in agreement with experimental structures of the complex. In order to further study the conformational flexibility of this thrombin-binding aptamer and to potentially develop a predictive computational model of aptamer-binding, we use GPU-enabled molecular dynamics simulations to both examine the conformational flexibility of the aptamer in the absence of binding to thrombin, and to determine our ability to fold an aptamer. This study should help further de-novo predictions of aptamer sequences by enabling the study of structural and sequence-dependent effects on aptamer-protein docking specificity.

9:36AM S47.00009 Non-thermal fluctuations in living cells reveal nonlinear mechanical properties of the cytoskeleton1, H. DANIEL OU-YANG, MING-TZO WEI2, DIMITRIS VAVYLONIS, SABRINA JEDLICKA, Lehigh University — Living cells are a non-equilibrium mechanical system, largely because intracellular molecular motors consume chemical energy to generate forces that reorganize and maintain cytoskeletal functions. Persistently under tension, the network of cytoskeletal proteins exhibits a nonlinear mechanical behavior where the network stiffness increases with intracellular tension. We examined the nonlinear mechanical properties of living cells by characterizing the differential stiffness of the cytoskeletal network for HeLa cells under different intracellular tensions. Combining active and passive microrheology methods, we measured non-thermal fluctuating forces and found them to be much larger than the thermal fluctuating force. From the variations of differential stiffness caused by the fluctuating non-thermal force for cells under different tension, we obtained a master curve describing the differential stiffness as a function of the intracellular tension. Varying the intracellular tension by treating cells with drugs that alter motor protein activities we found the differential stiffness follows the same master curve that describes intracellular stiffness as a function of intracellular tension. This observation suggests that cells can regulate their mechanical properties by adjusting intracellular tension.

9:48AM S47.00010 Geometry, Mechanics, and Microstructure: Relating Structure to Function in Articular Cartilage . JESSE SILVERBERG, Wyss Institute for Biologically Inspired Engineering — Climbing cucumbers, popping pollen grains, wrinkled fingers, and curly hair. At heart, the modern revival of mechanics covers a diverse range of biological materials living at the intersection of function and form. It’s at this point, where geometry, mechanics and microstructure meet, that we find buckling instabilities, mechanical phase transitions, exotic stress responses, and fracture. While these phenomena are widely observed in many inert materials, we also find them being actively employed in biological tissues, where they have evolved as essential tools for survival. In this talk, I’ll specifically address articular cartilage, a biological material that enables smooth and painless joint motion. Using a combination of experimental techniques, an unusual structure-function relationship for this material is empirically determined, and a model based on percolating fiber networks is offered as a solution. In the end, a central theme will emerge placing this tissue in the wider context of “elastic network materials,” and a wider need for advanced imaging methods will be called for.

10:24AM S47.00011 Effect of Isotropic Assumption on Material Property Reconstructions of the Human Brain using Magnetic Resonance Elastography . AARON ANDERSON, CURTIS JOHNSON, JOSEPH HOLTROP, Univ of Illinois - Urbana, MATHEW MCGARRY, KEITH PAULSEN, Dartmouth College, BRADLEY SUTTON, Univ of Illinois - Urbana, ELIJAH VAN HOUTEN, Universite de Sherbrooke, JOHN GEORGIADES, Univ of Illinois - Urbana — Neurodegenerative diseases affect the microstructure of the brain and thus have a significant effect on the tissue mechanical properties. In vivo techniques, like magnetic resonance elastography (MRE), have shown promise as a contrast technique for disease detection. MRE is a non-invasive technique for measuring the viscoelastic mechanical properties of biological tissue by applying a low-amplitude shear wave, capturing the wave patterns with specialized magnetic resonance imaging techniques, and employing an isotropic nonlinear inversion ( NLI) material property reconstruction. When distinctly different shear wave patterns are applied, NLI reconstructs differences in the real component of the shear modulus of ~ 2 [kPa] within well ordered white matter (WM). The difference is significant due to the human brain only having a range of real shear modulus from 0 [kPa] (cerebral spinal fluid) to ~ 5 [kPa] (white matter). The focus of this investigation is to quantify the effect of propagation direction on the reconstructed material properties and examine their relationship to the underlying microstructure in a well ordered, WM regions of the brain (corpus callosum).
8:12AM S48.00002 Mixed Strategies in cyclic competition\textsuperscript{1}, BEN INTOY, MICHEL PLEIMLING, Virginia Tech — Physicists have been using evolutionary game theory to model and simulate cyclically competing species, with applications to lizard mating strategies and competing bacterial strains. However, these models assume that each agent plays the same strategy, which is called a pure strategy in game theory, until they are beaten by a better strategy which they immediately adopt. We relax this constraint of an agent playing a single strategy by instead letting the agent pick its strategy randomly from a probability distribution, which is called a mixed strategy in game theory. This scheme is very similar to multiple occupancy models seen in the literature, the major difference being that interactions happen between sites rather than within them. Choosing strategies out of a distribution also has applications to economic/social systems such as the public goods game. We simulate a model of mixed strategy and cyclic competition on a one-dimensional lattice with three and four strategies and find interesting spatial and stability properties depending on how discretized the choice of strategy is for the agents.

\textsuperscript{1}This work is supported by the US National Science Foundation through grant DMR-1205309.

8:24AM S48.00003 Spatial games with cyclic interactions: the response of empty sites\textsuperscript{1}, BART BROWN, MICHEL PLEIMLING, Virginia Tech — Predator-prey models of the May-Leonard family employ empty sites in a spatial setting as an intermediate step in the reproduction process. This requirement makes the number and arrangement of empty sites important to the formation of space-time patterns. We study the density of empty sites in a stochastic predator-prey model in which the species compete in a cyclic way in two dimensions. In some cases systems of this type quickly form domains of neutral species after which all predation, and therefore, reproduction occur near the interface of competing domains. Using Monte Carlo simulations we investigate the relationship of this density of empty sites to the time-dependent domain length. We further explore the dynamics by introducing perturbations to the interaction rates of the system after which we measure the perturbed density, i.e. the response of empty sites, as the system relaxes. A dynamical scaling behavior is observed in the response of empty sites.

8:36AM S48.00004 Critical fluctuations near the pitchfork bifurcations of period-doubling maps\textsuperscript{1}, ANDREW NOBLE, University of California, Davis, SABA KARIMEDDINY, University of Massachusetts, Amherst, ALAN HASTINGS, University of California, Davis, JONATHAN MACHTA, University of Massachusetts, Amherst — Period-doubling maps, such as the logistic map, have been a subject of intense study in both physics and biology. The period-doubling route to chaos proceeds through a sequence of supercritical pitchfork bifurcations. Here, motivated by applications to population ecology, we investigate the asymptotic behavior of period-doubling bifurcations subject to environmental or demographic noise. We demonstrate, analytically, that fluctuations in the vicinity of each noisy pitchfork bifurcation are described by finite-size mean-field theory. Our results establish an exact correspondence between the bifurcations of far-from-equilibrium systems and the mean-field critical phenomena of equilibrium systems.

8:48AM S48.00005 Population dynamics of microbial communities in the zebrafish gut, MATTHEW JEMIELITA, MICHAEL TAORMINA, Department of Physics, University of Oregon, ADAM BURNS, Institute of Ecology and Evolution, University of Oregon, JENNIFFER HAMPTON, ANNAH ROLIG, TRAVIS WILES, KAREN GUILLEMIN, Institute of Molecular Biology, University of Oregon, RAGHUVEER PARTHASARATHY, Department of Physics, University of Oregon — The vertebrate intestine is home to a diverse microbial community, which plays a crucial role in the development and health of its host. Little is known about the population dynamics and spatial structure of this ecosystem, including mechanisms of growth and interactions between species. We have constructed an experimental model system with which to explore these issues, using initially germ-free larval zebrafish inoculated with defined communities of fluorescently tagged bacteria. Using light sheet fluorescence microscopy combined with computational image analysis we observe and quantify the entire bacterial community of the intestine during the first 24 hours of colonization, during which time the bacterial population grows from tens to thousands of bacteria. We identify both individual bacteria and clusters of bacteria, and quantify the growth rate and spatial distribution of these distinct subpopulations. We find that clusters of bacteria grow considerably faster than individuals and are located in specific regions of the intestine. Imaging colonization by two species reveals spatial segregation and competition. These data and their analysis highlight the importance of spatial organization in the establishment of gut microbial communities, and can provide inputs to physical models of real-world ecological dynamics.

9:00AM S48.00006 Responses of many-species predator-prey systems to perturbations\textsuperscript{1}, SHADI ESMAILY, MICHEL PLEIMLING, Virginia Tech — We study the responses of many-species predator-prey systems, both in the well-mixed case as well as on a two-dimensional lattice, to permanent and transient perturbations. In the case of a weak transient perturbation the system returns to the original steady state, whereas a permanent perturbation pushes the system into a new steady state. Using Monte Carlo simulations, we monitor the approach to stationarity after a perturbation through a variety of quantities, as for example time-dependent particle densities and correlation functions. Different types of perturbations are studied, ranging from a change in reaction rates to the injection of additional individuals into the system, the latter perturbation mimicking immigration.

9:12AM S48.00007 Anticipating Changing in Environments: Adaptation in Fluctuating Environments in A Heterogeneous Microbial Communities, MERZU BELETE, University of Houston, GÁBOR BÁLÁZSI, Stony Brook University — The environments in which micro-organisms grow often fluctuate. To survive in temporally changing environments, cells have evolved mechanisms to survive environmental changes. One survival mechanism is generating phenotypic differences among identical cells in a given environment, with cells randomly switching between phenotypes. Such cells form subpopulations that proliferate at different rates. Optimal population fitness was attributed before to matching cellular and environmental switching rates. However, the conditions for this optimum are not well understood. In particular, it is unknown how the growth rates of the phenotypes affect the optimum. We use mathematical models to address this question. We find that the existence of the predicted optimum depends on cell growth rates in each phenotype. The predicted optimum exists for wider parameter regimes if the environmental durations are long. In addition, we study how mutants arising among such phenotypically heterogeneous cells spread in the population.

9:24AM S48.00008 The Statistical Mechanics of Zombies, ALEXANDER A. ALEMI, MATTHEW BIERBAUM, CHRISTOPHER R. MYERS, JAMES P. SETHNA, Cornell University — We present results and analysis from a large scale exact stochastic dynamical simulation of a zombie outbreak. Zombies have attracted some attention lately as a novel and interesting twist on classic disease models. While most of the initial investigations have focused on the continuous, fully mixed dynamics of a differential equation model, we have explored stochastic, discrete simulations on lattices. We explore some of the basic statistical mechanical properties of the zombie model, including its phase diagram and critical exponents. We report on several variant models, including both homogeneous and inhomogeneous lattices, as well as allowing diffusive motion of infected hosts. We build up to a full scale simulation of an outbreak in the United States, and discover that for ‘realistic’ parameters, we are largely doomed.

9:36 AM S48.00009 Mutation Accumulation and Fitness Collapse at Population Frontiers, MAXIM LAVRENTOVICH, University of Pennsylvania, DAVID NELSON, Harvard University — Rapid, deleterious mutations occurring in, e.g., viral populations and cancerous tissue, may accumulate and lead to fitness loss. Previous studies show that sufficiently rapid accumulation in one-dimensional populations leads to a fitness collapse, governed by the directed percolation (DP) universality class. We compare this situation to the collapse in effectively two-dimensional populations, such as the frontiers of three-dimensional range expansions. A phase diagram is computed as a function of the mutation rate $\mu$ and strength $s$. Relative to one-dimensional populations, we find that the collapse occurs in a smaller region of phase space. The scaling combination governing the phase diagram shape is $|\mu|/s$ for one-dimensional populations. We argue that the evolutionary dynamics is described by a set of coupled DP Langevin equations near the transition, and that the coupling terms lead to deviations from expected DP scaling.

9:48 AM S48.00010 Spiraling patterns in evolutionary models inspired by bacterial games with cyclic dominance¹, MAURO MOBILIA, University of Leeds — Understanding the mechanisms allowing the maintenance of biodiversity is a central issue in biology. Evolutionary game theory, where the success of one species depends on what the others are doing, provides a promising framework to investigate this complex problem. Experiments on microbial populations have shown that cyclic local interactions promote species coexistence. In this context, rock-paper-scissors games - in which rock crushes scissors, scissors cut paper, and paper wraps rock - are often used to model the dynamics of populations in cyclic competition. After a brief survey of some inspiring experiments, I will discuss the subtle interplay between individuals' mobility and their local interactions in two-dimensional rock-paper-scissors systems. This leads to the loss of biodiversity above a certain mobility threshold [1], and to the formation of spiraling patterns below the critical mobility rate [1-4]. I will then study a generic rock-paper-scissors metapopulation model formulated on a two-dimensional grid of patches. When these have a large carrying capacity, the model's dynamics is faithfully described in terms of the system's complex Ginzburg-Landau equation properly derived from a multiscale expansion. The properties of the ensuing complex Ginzburg-Landau equation are exploited to derive the system's phase diagram and to characterize the spatio-temporal properties of the spiraling patterns in each phase. This enables us to analyze the spiral waves stability, how these are influenced by linear and nonlinear diffusion, and to discuss phenomena such as far-field breakup [5-7].

¹Presentation mainly based on joint work with B. Szczesny and A. M. Rucklidge. Fruitful earlier collaborations with E. Frey, Q. He, T. Reichenbach, and U. C. Täuber are also acknowledged. Work supported by the UK EPSRC (grant No. EP/P505593/1).

10:24 AM S48.00011 Phase transition in predator-prey ecosystems and a connection to transitional turbulence¹, HONG-YAN SHIH, NIGEL GOLDENFELD, Department of Physics, University of Illinois at Urbana-Champaign — We suggest how the transition from laminar fluid flow to turbulence can be connected to the extinction phase transition in spatially-extended predator-prey systems. By measuring the statistics of spontaneous relaminarization, spatiotemporal intermittency and expanding turbulent puffs in hydrodynamics equations and mapping them to the corresponding states in the predator-prey model, the extinction event and the formation and propagation of spatial patterns in ecology can be interpreted as the instabilities in fluid systems. We also summarize the general phenomena of such predator-prey dynamics in a wide class of transitional turbulence systems such as magnetohydrodynamics.

10:36 AM S48.00012 Evolutionary games of condensates in coupled birth-death processes, MARKUS F. WEBER, JOHANNES KNEBEL, TORBEN KRÜGER, ERWIN FREY, Ludwig-Maximilians-Universität München — Condensation phenomena occur in many systems, both in a classical and a quantum mechanical context. Typically, the entities that constitute a system collectively concentrate in one distinct state during condensation. For example, cooling of an equilibrated bosonic gas may lead to condensation into the quantum ground state. Notably, the mathematical theory of this Bose-Einstein condensation is not limited to quantum theory but was also successfully applied to condensation in random networks. In our work, we follow the opposite path. We apply the theory of evolutionary dynamics to describe condensation in a bosonic system that is driven and dissipative. It was shown that the system may condense into multiple quantum states, but into which states has remained elusive. We find that vanishing of relative entropy production determines these states. We illuminate the physical principles underlying the condensation and show that the condensates do not need to be static but may engage in “evolutionary games” with exchange of particles. On the mathematical level, the condensation is described by coupled birth-death processes. The generic structure of these processes implies that our results also apply to condensation in other systems, ranging from population biology to chemical kinetics.

10:48 AM S48.00013 A Second Law for Markov Processes, BLAKE POLLARD, University of California, Riverside — In this talk we describe the notion of an open Markov process. An open Markov process is a generalization of an ordinary Markov process in which populations are allowed to flow in and out of the system at certain boundary states. We show that the rate of change of relative entropy in an open Markov process is less than or equal to the flow of relative entropy through its boundary states. This can be viewed as a generalization of the Second Law for open Markov processes.
8:00AM S49.00001 Collisions of deformable cells lead to collective migration1, IGOR ARANSON, Argonne National Laboratory, JAKOB LÖBER, Technical University of Berlin, Germany, FALKO ZIEBERT, Albert-Ludwig-University, Freiburg, Germany — Collective migration of eukaryotic cells plays a fundamental role in tissue growth, wound healing and immune response. The motion, arising spontaneously or in response to chemical and mechanical stimuli, is also important for understanding life-threatening pathologies, such as cancer and metastasis formation. We present a phase-field model to describe the movement of many self-organized, interacting cells. The model takes into account the main mechanisms of cell motility - actomyosin dynamics, as well as substrate-mediated and cell-cell adhesion. It predicts that collective cell migration emerges spontaneously as a result of inelastic collisions between neighboring cells. Collisions lead to a mutual alignment of the cell velocities and to the formation of coherently-moving multi-cellular clusters. Small cell-to-cell adhesion, in turn, reduces the propensity for large-scale collective migration, while higher adhesion leads to the formation of moving bands. Our study provides valuable insight into biological processes associated with collective cell motility.

8:12AM S49.00002 A self-propelled particle model with experimentally quantified cell polarization, GIUSEPPE PASSUCCI, MEGAN E. BRASCH, Syracuse University, NICHOLAS O. DEAKIN, CHRISTOPHER E. TURNER, SUNY Upstate Medical, JAMES H. HENDERSON, M. LISA MANNING, Syracuse University — Self-propelled particle (SPP) models have been used extensively to study collective cell motion, but they do not always accurately capture the long-time behavior observed in experiments. Furthermore, the equation for polarization in these models is not experimentally well-constrained. Therefore we developed a novel method for quantifying polarization in 3D breast carcinoma cells in a wound healing geometry. During cell movement, the nuclei orient toward the anterior of a cell while the Golgi body orients towards the posterior; we simultaneously imaged and tracked the Golgi and nuclei and constructed a polarization vector defined by the Golgi-nuclei axis. We find that cells in the bulk are not highly polarized, while those on the edge are highly polarized outward perpendicular to the wound edge. We also study the temporal correlations between a cell’s internal polarization determined by the Golgi-nuclei axis and the polarization of its motion determined from nuclei displacements. We incorporate these polarization dynamics into a SPP model, and compare wound healing and long-time diffusion in the model to the experiments. These SPP equations can also be coarse-grained to generate a continuum model.

8:24AM S49.00003 Modeling traction forces in collective cell migration, JULIANE ZIMMERMANN, Center for Theoretical Biological Physics, Rice University, MARKUS BASAN, Department of Physics, University of California at San Diego, RYAN L. HAYES, Center for Theoretical Biological Physics, Rice University, WOUTER-JAN RAPPEL, Department of Physics, University of California at San Diego, HERBERT LEVINE, Center for Theoretical Biological Physics, Rice University — Collective cell migration is an important process in embryonic development, wound healing, and cancer metastasis. We have developed a particle-based simulation for collective cell migration that describes flow patterns and finger formation at the tissue edge observed in wound healing experiments [1]. We can apply methods for calculating intercellular stress to our simulation model, and have thereby provided evidence for the validity of a stress reconstitution method from traction forces used in experiments [2]. To accurately capture experimentally measured traction forces and stresses in the tissue, which are mostly tensile, we have to include intracellular acto-myosin contraction into our simulation. We can then reproduce the experimentally observed behavior of cells moving around a circular obstacle [3], and suggest underlying mechanisms for cell-cell alignment and generation of traction force patterns. Sci. USA. 2013. [3] Kim, J. H., X. Serra-Picamal, D. T. Tambe, ..., J. J. Fredberg. Nature Mater. 2013.

8:36AM S49.00004 Mimicking the Interfacial Dynamics of Flowing White Blood Cells, MARIA SANTORE, University of Massachusetts — The rolling of particles on surfaces, facilitated by hydrodynamic forces combined with localized surface interactions of the appropriate strengths, spatial arrangements, and ranges, is a technologically useful means of transporting and manipulating particles. One's intuition for the rolling of a marble or a car tire cannot be extrapolated down to microparticle length scales because the microparticle interactions are dominated by electrostatic, van der Waals, and hydrogen bonding interactions rather than a friction that depends on an imposed normal force. Indeed, our microparticle rolling systems are inspired by the rolling of white blood cells on the inner walls of blood vessels and the innate immune response: Selectin molecules engage with their counterparts on the opposing surfaces to slow cell motion relative to that for freely flowing cells. In the resulting rolling signature, ligand-receptor binding and crack closing on the front of the cell are balanced with molecular dis-bonding and crack opening at the rear. The contact region is relatively static, allowing other interactions that may be present (for instance signaling) to occur for a finite duration. Thus, achieving particle rolling in synthetic systems is important because it facilitates particle-surface interactions in a continuous nonfouling fashion where the contact surface is continually renewed. In developing a synthetic model for this system, we employ polymers to modify flowing particles and/or planar collectors, producing heterogeneous interfaces which can support rolling or produce other motion signatures such as skipping, arrest, or free flow. We identify, in the synthetic system, combinations of variables that produce rolling and demonstrate how the distinction between rolling and arrest is not a simple matter of the adhesion strength between the particles and the collector. Rolling is a cooperative process and the coordination of binding in one location with dis-bonding in another requires appropriate length scales in the design of the interface and in the processing parameters as well.

9:12AM S49.00005 ABSTRACT WITHDRAWN

9:24AM S49.00006 Long Range Order of Motile Defects in Active Nematic Liquid Crystals, STEPHEN DECAMP, GABRIEL REDNER, MICHAEL HAGAN, ZVONIMIR DOGIC, Brandeis University — Active 2D nematic liquid crystals exist in a dynamical steady state in which -1/2 and +1/2 defects are spontaneously generated and annihilated at a constant rate. Active stresses in the material are thought to destroy nematic order through the generation of these defects. We present an active nematic mesophase in which motile defects of charge +1/2 spontaneously acquire long range order. The system is composed of microtubule filaments and kinesin motor protein clusters which are confined to a flat, 2D oil-water interface. The addition of ATP results in microtubule bundles which exhibit kinesin-driven extensile motion. By tuning the density of the nematic material at the 2D interface, we can tune the order parameter of the +1/2 defect ordered mesophase. Additionally, the defect alignment persists over samples at the centimeter scale.

9:36AM S49.00007 Defect-Stabilized Phases in Extensile Active Nematics, GABRIEL REDNER, STEPHEN DECAMP, ZVONIMIR DOGIC, MICHAEL HAGAN, Brandeis University — Active nematics are liquid crystals which are driven out of equilibrium by energy-dissipating active stresses. The equilibrium nematic state is unstable in these materials, leading to beautiful and surprising behaviors including the spontaneous generation of topological defect pairs which stream through the system and later annihilate, yielding a complex, seemingly chaotic dynamical steady-state. In this talk, I will describe the emergence of order from this chaos in the form of previously unknown broken-symmetry phases in which the topological defects themselves undergo orientational ordering. We have identified these defect-ordered phases in two realizations of an active nematic: first, a suspension of extensile bundles of microtubules and molecular motor proteins, and second, a computational model of extending hard rods. I will describe the defect-stabilized phases that manifest in these systems, our current understanding of their origins, and discuss whether such phases may be a general feature of extensile active nematics.
9:48AM S49.00008 Worms on a plane: simulation studies of an active nematic phase of flexible chains. MICHAEL VARGA, MOHAMMAD NAJAFI, ROBIN SELINGER, Kent State Univ - Kent — We present simulation studies of flexible nematogen “worms” composed of soft spheres assembled into flexible polymer-like chains. These elongated, flexible chains are confined to a planar substrate with periodic boundary conditions or else confined within bounding walls. We consider a variety of driving mechanisms including unidirectional gliding and gliding with random reversals. We also model actuation via kinesin motor clusters which attach and travel along a pair of neighboring chains of opposite polarity, producing inter-chain sliding forces and driving the chains in opposite directions. We examine resulting nematic order, defect nucleation, motion, and annihilation, and density fluctuations as a function of chain length, flexibility, density, and driving mechanism. In a geometry where the chains are constrained to move in tandem with tight spacing, we observe spontaneous formation of organized beating. We compare our results to experimental and theoretical studies of gliding bacteria [1] and kinesin-driven microtubules [2]. [1] Perumal et al. PRL 108, 098102 (2012), [2] Sanchez et al. Nature 491,431 (2012).

10:00AM S49.00009 Instabilities and patterns in an active nematic film. PRAGYA SRIVASTAVA, CRISTINA MARCHETTI, Physics Department, Syracuse University, NY-13244 — Experiments on microtubule bundles confined to an oil-water interface have motivated extensive theoretical studies of two-dimensional active nematics. Theoretical models taking into account the interplay between activity, flow and order have remarkably reproduced several experimentally observed features of the defect-dynamics in these “living” nematics. Here, we derive minimal description of a two-dimensional active nematic film confined between walls. At high friction, we eliminate the flow to obtain closed equations for the nematic order parameter, with renormalized Frank elastic constants. Active processes can render the “Frank” constants negative, resulting in the instability of the uniformly ordered nematic state. The minimal model yields emergent patterns of growing complexity with increasing activity, including bands and turbulent dynamics with a steady density of topological defects, as obtained with the full hydrodynamic equations. We report on the scaling of the length scales of these patterns and of the steady state number of defects with activity and system size.

1National Science Foundation grant DMR-1305184 and Syracuse Soft Matter Program.

10:12AM S49.00010 Dynamics of an overdamped active nematic liquid crystal. ELIAS PUTZIG, APARNA BASKARAN, Brandeis University — A continuum model for the dynamics of an overdamped (often termed “dry”) active nematic liquid crystal will be presented here. This talk will focus on how such a model can be used to describe the formation and self-propulsion of defects which has been seen in active liquid crystals in experiments and simulations. We will start with a general model which shows phase-separations and structure formation near the critical density (for the isotropic-nematic phase transition), and show how this model can be extended to describe extensile active nematics which are deeper within the ordered phase. The spontaneous formation of defects occurs when the contribution of the extensile stresses, to the dynamics of the order parameter, gives rise to a bend instability. This leads to a steady state of defect formation and annihilation, and the self-propulsion of defects, as is seen in experiments and simulation.

10:24AM S49.00011 The geometry and topology of turbulence in active nematics. LUCA GIOMI, Univ of Leiden — The problem of low Reynolds number turbulence in active nematic fluids is theoretically addressed. Using numerical simulations I demonstrate that an incompressible turbulent flow, in two-dimensional active nematics, consists of an ensemble of vortices whose areas are exponentially distributed within a range of scales. Building on this evidence, I construct a mean-field theory of active turbulence by which several measurable quantities, including the spectral densities and the correlation functions, can be analytically calculated. Due to the profound connection between the flow geometry and the topological properties of the nematic director, the theory sheds light on the mechanisms leading to the proliferation of topological defects in active nematics and provides a number of testable predictions. A hypothesis, inspired by Onsager’s statistical hydrodynamics, is finally introduced to account for the equilibrium probability distribution of the vortex sizes.

10:36AM S49.00012 Instabilities and boundary effects in a droplet of active polar liquid crystal. CARL WHITFIELD, RHODA HAWKINS, University of Sheffield — Using the active gel theoretical framework, we have performed analytical calculations and numerical simulations of a droplet of active polar liquid crystal at low Reynolds number. This system is a simplified model of a cytoskeletal network that generates internal stresses by converting chemical energy (in the form of ATP) into mechanical work via molecular motors. A physical understanding of these systems can give an insight into the complex and varied dynamics of eukaryotic cell migration and division. We perform a linear stability analysis on the system by separating the behaviour into two limits. One where the internal polarisation is dominated by the shape of the boundary and one where it is deformed by density fluctuations and the correlation functions, can be analytically calculated. Due to the profound connection between the flow geometry and the topological properties of the nematic director, the theory sheds light on the mechanisms leading to the proliferation of topological defects in active nematics and provides a number of testable predictions. A hypothesis, inspired by Onsager’s statistical hydrodynamics, is finally introduced to account for the equilibrium probability distribution of the vortex sizes.

10:48AM S49.00013 Interacting active elastic dimers: Two cells moving on a rigid track. MOUMITA DAS, Rochester Institute of Technology; DAVID MAYETT, J. M. SCHWARZ, Syracuse University — Cell migration in morphogenesis and cancer metastasis typically involves an interplay between different cell types. The rules governing such interplay remain largely unknown, however, a recent experiment studying the interaction between neural crest (NC) cells and placodal cells reveals an example of such rules. The study found that NC cells chase the placodal cells by chemotaxis, while placodal cells run away from NC cells when contacted by them. Motivated by this observation, we construct and study a minimal one-dimensional cell-cell model comprised of two cells with each cell represented by two-beads-connected-by-an-active spring. The active spring for each moving cell models the stress fibers with their myosin-driven contractility (and alpha-actinin extendability), while the friction coefficients of the beads describe the inter-chain sliding forces and driving the chains in opposite directions. We examine resulting nematic order, defect nucleation, motion, and annihilation, and density fluctuations as a function of chain length, flexibility, density, and driving mechanism. In a geometry where the chains are constrained to move in tandem with tight spacing, we observe spontaneous formation of organized beating. We compare our results to experimental and theoretical studies of gliding bacteria [1] and kinesin-driven microtubules [2]. [1] Perumal et al. PRL 108, 098102 (2012), [2] Sanchez et al. Nature 491,431 (2012).

8:00AM S50.00001 Self-assembly of novel molecules, VECAR1

1This research is supported by the Louisiana Board of Regents-RCS grant (LEQSF(2012-15)-RD-A-19).

8:12AM S50.00002 Self-assembly of Colloids in a Suspended Droplet: In-situ small-angle X-ray scattering

JITENDRA BAHADUR, Biology and Soft Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN, USA; DEBASHIS SEN, S. MAZUMDER, Solid State Physics Division, Bhabha Atomic Research Centre, Mumbai, India; G. SANTORO, S. YU, S.V. ROTH, Photon Science, Deutsches Elektronen-Synchrotron (DESY), Notkestr. 85 D-22607, Hamburg, Germany; Y.B. MELNICHENKO, Biology and Soft Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN, USA — An in-situ scanning SAXS experiments have been performed to probe the drying of a single suspended colloidal droplet. It has been demonstrated that shell formation can be predicted just by measuring the temporal evolution of the spatial transmission profile. The shrinkage of the droplet stops after formation of a shell. The shell thickness and droplet radius have been estimated by fitting the transmission profiles using analytical expressions. It is revealed that the evolution of volume fraction of colloids is linear during the initial stage of drying and follows a sigmoidal growth behavior at later stages. Further, the interaction between colloidal particles at different drying stages has been investigated. We provide experimental proofs of a transition from repulsive interaction between colloids into a capillary driven short range attraction for shell formation during drying. The present work demonstrates that in-situ SAXS is a very valuable technique for monitoring the dynamic processes of colloidal self-assembly and provides the opportunity to probe the drying of complex fluids without the interference from a substrate.

8:24AM S50.00003 Self-assembly of graded refractive index in squids: a patchy colloid explanation

JING CAI, PAUL HEINEY, ALISON SWEENEY, Univ of Pennsylvania — Squids have a spherical eye lens that achieves both acute and highly sensitive vision under water. The spherical shape necessitates a graded refractive index (GRIN) to form sharp images. This index variation comes from a gradient in protein packing fraction ranging from approximately 0.05 to 1.0. This presents a materials conundrum: optical transparency requires that the protein density fluctuation at length scales > 100 nm is minimized throughout the lens, something that is difficult to achieve with simple spherical particles. Here we show that squids have accomplished this by evolving a suite of proteins that can act as patchy colloids with specific low valence (M=2 or M=3). We conducted small angle X-ray scattering (SAXS) at different radial positions of the lens, and performed a Monte Carlo simulation to estimate structures consistent with the SAXS result. This analysis suggests that lens proteins may form a density gradient gel structure, with density mediated by a tightly controlled protein coordination number in each region. Patchy colloid theory may therefore explain both the GRIN and the transparency evolved in the lens.

8:36AM S50.00004 Self-assembly of tetrahedral plasmonic nanoclusters for optical metafluids

NICHOLAS SCHADE, Department of Physics, Harvard University; VINOTHAN MANOHARAN, School of Engineering and Applied Sciences and Department of Physics, Harvard University — We direct the assembly of clusters of gold nanoparticles that behave as nanoscale electromagnetic resonators. We use spherical gold nanoparticles that are exceptionally smooth, monocrystalline, and monodisperse. These particles exhibit highly reproducible scattering spectra compared with gold colloids that are available commercially. We pack these positively charged particles with negatively charged dielectric particles. The gold particles stick to the dielectric particles permanently and randomly in a process that can be modeled mathematically as “random parking,” a type of non-equilibrium self-assembly. By controlling the particles’ sizes, stoichiometry, and interactions, we maximize the yield of tetrahedral clusters, the ideal structures for isotropic metamaterials. We measure the optical properties of these structures with dark-field spectroscopy to characterize their suitability as building blocks for a bulk, isotropic, optical metafluid.

8:48AM S50.00005 Drying of Discotic Suspensions

ADITYARAM NARAYAN, ZHENGDONG CHENG, TAMU, Artie McFerrin Department of Chemical Engineering, Mary Kay O’Connor Process Safety Center — We study the evaporation driven self-assembly of exfoliated 7-Zirconium Phosphate nanoplatelets that formed continuous films at various low concentrations. These self-assembly mechanism is different from the well-known coffee-ring effect for low aspect ratio particles. The film formation can be tuned by solvent properties, temperature and concentration of the nanoparticles. By the virtue of very large surface area, these platelets can be used as flame retardant coatings after proper functionalization. These work point to a simple procedure to create uniform films by high aspect ratio nanoplates with potentially diverse applications.

9:00AM S50.00006 Self-assembly mechanism for limit-periodic structure1

CATHERINE MARCOURX, JOSHUA SOCOLAR, Duke University — Limit-periodic (LP) structures, which are the union of an infinite set of periodic lattices with ever increasing lattice constants, present a challenge for self-assembly protocols. We consider the possibility of forming a LP phase in a slow quench of a collection of colloidal particles designed to mimic the Taylor-Socolar monolite system2. A toy model with discrete tile orientations and mismatch energies yields the LP state through an infinite sequence of phase transitions. Here we present the results of Monte Carlo simulations of slow quenches of identical hard disks with embedded magnetic dipoles, allowing for continuous rotations of the close-packed disks. Surprisingly, an extremely slow quench still results in the spontaneous emergence of the LP state even when the system has a periodic ground state. The series of phase transitions preempts the formation of the periodic phase, leading to low energy states separated from the ground state by insurmountable free energy barriers.

9:12AM S50.00007 Non-additive simple potentials for pre-programmed self-assembly. CARLOS MENDOZA, IIM-UNAM — A major goal in nanoscience and nanotechnology is the self-assembly of any desired complex structure with a system of particles interacting through simple potentials. To achieve this objective, intense experimental and theoretical efforts are currently concentrated in the development of the so-called ‘patchy’ particles. Here we follow a completely different approach and introduce a very accessible model to produce a large variety of pre-programmed two-dimensional (2D) complex structures. Our model consists of a binary mixture of particles that interact through isotropic interactions that is able to self-assemble into targeted lattices by the appropriate choice of a small number of geometrical parameters and interaction strengths. We study the system using Monte Carlo computer simulations and, despite its simplicity, we are able to self assemble potentially useful structures such as chains, stripes, Kagomé, twisted Kagomé, honeycomb, square, Archimedean and quasi-crystalline tilings. Our model is designed such that it may be implemented using discotic particles or, alternatively, using exclusively spherical particles interacting isotropically. Thus, it represents a promising strategy for bottom-up nano-fabrication. Reference: Daniel Salgado-Blanco and Carlos I. Mendoza, “Non-additive simple potentials for pre-programmed self-assembly”, arXiv:1409.2916 [cond-mat.soft]

9:24AM S50.00008 Heterogeneous crystal nucleation on curved surfaces observed by real-space imaging. URS GASSER, ANDREA SCOTTI, Paul Scherrer Institut, FLORIAN ZIESE, GEORG MARET, University of Konstanz — Crystal nucleation in a supercooled liquid, i.e. the formation of critical crystal nuclei, is not well understood for both homogenous and heterogeneous nucleation. The structural transformation from the liquid to crystal precursors and finally to the structure of bulk crystal and its connection with the free energy barrier for nucleation are not well understood. The large differences between measured and calculated nucleation density rates obtained for many materials reflect this lack of understanding. We use confocal microscopy with single-particle resolution to observe heterogeneous nucleation of colloidal crystals on curved seed surfaces. The radius of curvature ranges from 4 to 40 particle diameters, allowing to observe the transition from the strong suppression of heterogeneous nucleation at small radii of curvature - an effect not captured by classical nucleation theory - to fast heterogeneous nucleation as expected from classical nucleation theory. We determine the critical nucleus size, estimate the surface tension of crystal precursors and critical nuclei, characterize their structure, and compare with expectations from classical nucleation theory. While the smallest crystal precursors are found to be almost unaffected by the curvature, the effect is significant for nuclei

9:36AM S50.00009 Computer Simulation Study of the Nucleation of Rotator Phases in Hard Polyhedral Particles. VIKRAM THAPAR, FERNANDO ESCOBEDO, Cornell University — The nucleation kinetics of the rotator phase in hard cuboctahedra, truncated octahedra, and rhombic dodecahedra is simulated via a combination of forward flux sampling and umbrella sampling. We compute the degrees of supersaturation at their corresponding pressures by improving upon the interfacial method used to estimate the liquid-rotator coexistence pressure. The nucleation rates are obtained by calculating the mean first passage time from liquid to rotator phase using forward flux sampling, and the free-energy barriers are estimated using umbrella sampling. For comparable degrees of supersaturation, the polyhedra are found to have significantly lower free-energy barriers and faster nucleation rates than hard spheres. This difference primarily stems from localized orientational ordering, which steers polyhedral particles to pack more efficiently. Orientational order hence fosters here the growth of orientationally disordered nuclei. The results are compared to preliminary data for the disorder-to-order transition for other polyhedral systems including systems pinned on a 2D interface.

9:48AM S50.00010 Interplay of isotropic and directional interactions and its role in phase behavior. DEBRA AUDUS, National Institute of Standards and Technology, FRANCIS STARR, Wesleyan University, JACK DOUGLAS, National Institute of Standards and Technology — Patchy particles, which interact through non-isotropic interactions have been studied extensively both computationally and theoretically in part because they are minimal models of protein solutions. Although proteins are inherently complicated molecules with complex shapes and interactions, when in solution, they associate and phase separate like patchy particles. However, patchy particles considered computationally are often composed of hard spheres with short-ranged attractive spots decorating the surface. Such a parameterization ignores the isotropic attractive interactions, which can potentially play an important role in phase behavior. To gain insight into this problem, we investigate patchy particles with isotropic interactions that range from purely repulsive to weakly attractive and explore how the interplay between isotropic interactions and directional interactions due to the spots affects both the phase coexistence and association in these systems. We find that for our model that even when the strength of isotropic interactions is weaker than the strength of directional interactions, the isotropic interactions can still dominate.

10:00AM S50.00011 Engineering Crystals Through Shape. GREG VAN ANDERS, University of Michigan, DAPHNE KLOTSA, University of Cambridge, SHARON GLOTZER, University of Michigan — Advances in synthesis techniques have produced colloids and nanoparticles in a diverse array of shapes that can be assembled into bulk crystals. That bulk structure is strongly affected by particle shape in idealized systems is widely established in the literature. However, this literature leaves open three key questions: (i) We know that shape affects structure, but how? (ii) Does shape matter in experimental systems where other interactions are present? (iii) How do we tailor particle shape for a target structure? In this talk we discuss recent work aimed at answering these questions.

10:12AM S50.00012 The size of the boat matters: Scale dependence in macroscopic chains thermalized by the motion of a laboratory-scale ocean. KYLE WELCH, CLAYTON KILMER, ERIC CORWIN, University of Oregon — We use a bath of chaotic surface waves in water to mechanically and macroscopically mimic the thermal behavior of various microscopic systems. The chaotic waves provide isotropic and random agitation to which a temperature can be ascribed. This allows us to passively explore the degrees of freedom of a system, in analogy to thermal motion. We report on a study of 2D macroscopic chains thermalized in this fashion. We show that the behavior of short chains is fundamentally different than the behavior of long chains in both winding angle and end-to-end distance. Furthermore, we find that short chains show anomalous compressional stiffness that rapidly softens as chain length increases. We present simulational work exploring this transition from short to long, treating the chains as self-avoiding polymers. We further apply our techniques to explorations of the evolution of a system of many interacting buoyant particles, focusing on transitions from ordered to disordered states.

10:24AM S50.00013 Directing Translational and Orientational Order of Rectangular Particle Monolayers. MARK FERRARO, THOMAS TRUSKETT, ROGER BONNECAZE, Univ of Texas, Austin — Recent advances have shown that the tunability of nanoparticle interactions can lead to a large number of thermodynamically accessible structures. The role of an external field in the assembly of particulate systems, however, is still incompletely understood. The use of larger scale patterned substrates to drive smaller scale assembly of particle monolayers can potentially expand the set of achievable lattices, and could be used in nanopatterning processes or in the manufacture of functional materials. In this presentation, grand canonical Monte Carlo (GCMC) simulations are used to assess the suitability of graphoepitaxial assembly for particle monolayers. Our prior work has shown that topographically or chemically patterned substrates can sufficiently organize hard-spheres, but many motivating applications can utilize anisotropic particle shapes (e.g. rectangular particles for bit-patterned media). Here, we describe our recent GCMC results for structures formed by rectangular particles in the presence of sparse enthalpic barriers. We examine systems of varying chemical potential, template geometry, and particle aspect ratio. Templates are evaluated by their ability to induce orientational and translational order, while maximizing pattern multiplication effects.
Thursday, March 5, 2015 8:00AM - 11:00AM – Session S51 DCMP: Invited Session: The Valley Hall Effect in van der Waals Materials  Grand Ballroom C1 - Allan MacDonald, University of Texas at Austin

8:00AM S51.00001 Detecting Topological Currents in Gapped Graphene

LEONID LEVITOV, Massachusetts Inst of Tech-MIT — The anomalous Hall effect (AHE), arising due to Berry curvature in materials with broken inversion symmetry, results in topological currents flowing in system bulk transversely to the applied electric field. We will discuss recent work on AHE in materials with several valleys, such as e.g. graphene and transition metal dichalcogenide monolayers, where these currents have been observed [Mak et al., Science 344, 1489 (2014); Gorbachev et al., Science 346, 448 (2014)]. Interestingly, these materials do not fit the paradigm of topological materials with Chern bands and associated topologically protected edge modes dominating (quantized) Hall conductivity. Here, in contrast, gapless edge states may be absent since they are not enforced by topology or symmetry. Further, even when present, these states are not protected against backscattering due to roughness on the atomic scale. Naively, this would lead one to conclude that topological currents cease to exist. If true, this would imply that the key manifestations, such as the valley Hall conductivity and orbital magnetization, vanish in the gapped state. We will argue that the opposite is true: the absence of conducting edge modes does not present an obstacle since once valley currents can be transmitted by the bulk states in the filled Fermi sea beneath the gap. This leads to an interesting behavior: rather than being vanishingly small, valley currents reach maximum value in the gapped state. Such undergap currents can also occur as persistent currents in the thermodynamic ground state and dominate orbital magnetization in valley-polarized gapped systems. We will conclude with discussing requirements for dissipationless valley transport and argue that they can be met under realistic conditions.

9:12AM S51.00003 Valley current generation by electrically induced Berry curvature in double gated bilayer graphene

SEIGO TARUCHA, Department of Applied Physics, The University of Tokyo — Valley degree of freedom is defined for an electronic system having degenerate band structure in a certain crystal configuration and can be used to generate non-dissipative current with accompanying net charge flow by breaking the spatial inversion symmetry. Graphene and transition metal dichalcogenide are two typical valley materials having K and K’ valleys due to the existence of two sub-lattices. The valley current has only recently been studied for monolayer graphene on h-BN where the spatial inversion symmetry is structurally broken by the superlattice potential. We use a double gated bilayer graphene device to electrically break the spatial inversion symmetry and control the Berry curvature. We use valley hall effect to generate a transverse pure valley current and inverse valley hall effect to detect the current. In this device the Fermi energy and the bandgap are independently varied and this allows to prove existence of valley hall effect in the insulating regime where the local resistivity increases with lowering temperature. The insulating regime is particularly interesting because the electric field to valley current conversion is less dissipative in contrast to the case for conventional spin or valley hall systems.

9:48AM S51.00004 Valley and spin currents in 2D transition metal dichalcogenides

WANG YAO, The University of Hong Kong — In two-dimensional (2D) transition metal dichalcogenides (TMDs), carriers are indexed by both the spin and the valley pseudospin (labelling the degenerate band extrema in momentum space). 2D TMDs is therefore an ideal laboratory for exploring these internal quantum degrees of freedom for new electronics, and controlling the flow of spin and pseudospin is at the heart of such applications. We will discuss two mechanisms for generating spin and valley currents of electrons in 2D group-VIB TMDs: (I) the valley and spin Hall effects arising from the Berry curvatures; and (II) the nonlinear valley and spin currents arising from Fermi pocket anisotropy. The two effects have distinct scaling with the electric field, and different dependence of the current direction on the field direction and crystalline axis. We will discuss the possibility to observe and distinguish the two effects as distinct patterns of polarized electroluminescence at p-n junction in 2D TMDs. The nonlinear current response also makes possible the generation of pure spin and valley flows without net charge current, either by an AC bias or by an inhomogeneous temperature distribution. We will also discuss the valley Hall effect of charged excitons in monolayer TMDs, which arises from the effective coupling of the excitonic valley pseudospin to its center of mass motion by the exchange interaction between the electron and hole constituents.

10:24AM S51.00005 Electron dynamics and valley relaxation in 2D semiconductors

KENAN GUNDOGU, North Carolina State University — Single layer transition metal dichalcogenides are 2D semiconducting systems with unique electronic band structure. Two-valley energy bands along with strong spin-orbital coupling lead to valley dependent career spin polarization, which is the basis for recently proposed valleytronic applications. Since the durations of valley population provide the time window in which valley specific processes take place, it is an essential parameter for developing valleytronic devices. These systems also exhibit unusually strong many body affects, such as strong exciton and trion binding, due to reduced dielectric screening of Coulomb interactions. But there is not much known about the impact of strong many particle correlations on spin and valley polarization dynamics. Here we report direct measurements of ultrafast valley specific relaxation dynamics in single layer MoS2 and WS2. We found that excitonic many body interactions significantly contribute to the relaxation process. Brixelcton formation reveals hole valley spin relaxation time. Our results also suggest initial fast intervalley electron scattering and electron spin relaxation leads to loss of electron valley polarization, which then facilitates hole valley relaxation via excitonic spin exchange interaction.
8:00AM S52.00001 Emergent Separation of Valence Bond Regimes in LiZn$_2$Mo$_2$O$_7$\cite{2}. TYREL Mc-QUEEN, Johns Hopkins University — LiZn$_2$Mo$_2$O$_7$ is a S = 1/2 triangular lattice antiferromagnet in which the basic magnetic building block is an Mo$_3$O$_13$ cluster rather than an individual ion. Rather than forming the 120° ordered magnetic state expected for a Heisenberg nearest neighbor triangular antiferromagnet, LiZn$_2$Mo$_2$O$_7$ instead favors a complex valence bond order across different energy and length scales: approximately two thirds of the spins form singlets at T ∼ 100 K, while the remainder form valence bonds at lower temperature, as indicated by inelastic neutron scattering. No static magnetic order is detected by uSR down to T = 0.05 K. What is the origin of this spontaneous separation into different regimes of magnetic fluctuations? Recent experimental data, including the impact of hole doping, will be compared to different theoretical models that have been proposed for this behavior, including an emergent honeycomb lattice by octahedral rotations and partial charge ordering driven by extra intracluster degrees of freedom.

8:36AM S52.00002 Low energy XY spin clusters in a pyrochlore antiferromagnet with weak disorder\textsuperscript{1}. KATE ROSS$^2$, Colorado State University — The spin liquid state of the Heisenberg antiferromagnet (HAFM) on the pyrochlore lattice arises from an extensive degeneracy of correlated yet disordered ground states. How this spin liquid is modified in real materials with imperfect Heisenberg exchange is a rich field of study, with many possible outcomes depending on the relevant perturbations. We have studied a single crystal of a new pyrochlore antiferromagnet, NaCaCo$_2$Fe$_2$. High spin (S = 3/2) Co$^{3+}$ forms a fully ordered pyrochlore sub lattice, while non-magnetic Na$^+$ and Ca$^{2+}$ are intermixed on the A-site. Despite isotropic magnetic properties and large antiferromagnetic coupling (\Theta_{CW} = -140 K), a freezing transition is observed at temperature much lower than the exchange energy (\Gamma \sim 3 K), thus revealing the relatively weak exchange disorder induced by the mixed ion A-site. Unexpectedly, our inelastic neutron scattering measurements reveal that the frozen state is of local XY character and supports low energy XY fluctuations. Yet the system can break free from the XY states at energies above 2.5 meV \sim 3 K; at these energy scales we observe the collinear Ising configurations expected for the weak-disorder HAFM model. The frozen state in NaCaCo$_2$Fe$_2$ provides a new outlook on the role of disorder in selecting spin configurations from the Heisenberg pyrochlore spin liquid state.

9:12AM S52.00003 Longitudinal and transverse heat transports of quantum spin liquids. MINORU YAMASHITA, ISSP, The University of Tokyo — Study of disordered states of quantum spins in two-dimensions, so-called quantum spin liquids (QSLs), has been attracting attention because 2D QSL can be a new state of matter characterized by unknown quasiparticles. Recent discoveries of materials possessing an ideal 2D triangular or a kagomé lattice have spurred a lot of experimental pursuit to identify the ground state. Especially, identifying the elementary excitation characterizing the ground state has been the central focus of attention. In this presentation, I will present our transport studies of organic insulators with ideal 2D triangular or a kagomé lattice have spurred a lot of experimental pursuit to identify the ground state. Especially, identifying the elementary excitation characterizing the ground state has been the central focus of attention.

9:48AM S52.00004 Doping and disorder in spin liquids. RODERICH MOESSNER, MPI-PKS Dresden — The question of what happens when an unconventional spin state is doped has been a central theme of the field of strongly correlated electrons since Anderson’s proposal of doping the RVB liquid state to obtain a high-temperature superconductor. Recently, there has been much progress in constructing models which exhibit topological spin liquid phases, e.g. in Kitaev’s models or in spin ice. In this talk, we address the properties of defects in such exotic spin states.

10:24AM S52.00005 Unconventional magnetic order stabilized by Kitaev interactions in the three-dimensional honeycomb polytypes of Li$_2$IrO$_3$. RADU COLDEA, University of Oxford — Materials that realize Kitaev spin models with bond-dependent anisotropic interactions have long been searched for, as the resulting frustration effects are predicted to stabilize novel forms of magnetic order or quantum spin liquids. Here we explore the magnetism of the recently-synthesized iridates \beta- and \gamma-Li$_2$IrO$_3$, which have the topology of three-dimensional Kitaev lattices of inter-connected Ir honeycombs. Using single-crystal resonant magnetic x-ray diffraction we find in both cases a surprisingly complex, yet highly symmetric, incommensurate magnetic structure with non-coplanar and counter-rotating Ir moments \cite{1,2}. Our experimental results combined with a theoretical analysis \cite{3} of candidate spin Hamiltonians provide strong evidence that both \beta and \gamma-Li$_2$IrO$_3$ realize a spin Hamiltonian with dominant Kitaev interactions. \cite{1} A. Biffin, R.D. Johnson, I. Kimchi, R. Morris, A. Bombardi, J.G. Analytis, A. Vishwanath, and R. Coldea, Phys. Rev. Lett. 113, 197201 (2014). \cite{2} A. Biffin, R.D. Johnson, Sungkyun Choi, F. Freund, S. Manni, A. Bombardi, P. Manuel, P. Gegenwart, and R. Coldea, Phys. Rev. B. 90, 205116 (2014). \cite{3} I. Kimchi, R. Coldea and A. Vishwanath, arXiv:1408.3640 (2014).

Thursday, March 5, 2015 8:00AM - 11:00AM —
Session S53 DCMP: Invited Session: Symposium on Novel Phenomena in Helium in Reduced Dimensions and Confinement —
Grand Ballroom C3 - Yoonseok Lee, University of Florida

8:00AM S53.00001 Evidence for intertwined superfluid and density wave order in two dimensional $^4$He\textsuperscript{1}. JOHN SAUNDERS, Royal Holloway University of London — We report the identification of a new state of quantum matter with intertwined superfluid and density wave order in a system of two dimensional bosons subject to a triangular lattice potential. Using a torsional oscillator we have measured the response of the second atomic layer of $^4$He adsorbed on the surface of graphite over a wide temperature range down to 2 mK. Superfluidity is observed over a narrow range of film densities, emerging suddenly and collapsing towards a quantum critical point, near to layer completion where a Mott insulating phase is predicted to form. The unusual temperature dependence of the superfluid density in the $T \rightarrow 0$ limit and the absence of a clear superfluid onset temperature are explained, self-consistently, by an ansatz for the excitation spectrum, reflecting density wave order, and a quasi-condensate wavefunction breaking both gauge and translational symmetry.

8:36AM S53.00002 Signatures of Majorana and Weyl Fermions in confined phases of superfluid $^3$He$^1$. JAMES SAULS, Northwestern Univ — The B-phase of superfluid $^3$He exhibits symmetry breaking in which separate invariance under gauge-, spin- and orbital rotations is reduced to the maximal sub-group, $SU(2)_L \otimes SU(2)_T$. Parity is broken, but time-reversal is preserved. Broken relative spin-orbit rotational symmetry implies emergent spin-orbit coupling and non-trivial topology of the ground state, both of which are encoded in the Bogoliubov-Nambu Hamiltonian: $H = (p^3 \tau_3 + c \cdot \tau_i) / \Delta / T$, where $c = \Delta / T$ is several orders of magnitude slower than the Fermi velocity. The topology of the B-phase is expressed in terms of a non-trivial winding number for the mapping between momentum space and Nambu space, $\pi_{3D} = \int \frac{d^3p}{24\pi} \epsilon_{ijk} \text{Tr} \left\{ T C (H^{-1} \partial_{\tau_j} H) \times (H^{-1} \partial_{\tau_k} H) (H^{-1} \partial_{\tau_i} H) \right\} = 2$, where $C$ is the particle-hole transformation. The physical consequence of $\pi_{3D} \neq 0$ is the emergence of a spectrum of Majorana fermions confined on any surface of $^3$He-B whose effective Hamiltonian is described $H = \sum_{p} \sum_{\alpha} \psi^\dagger_{\alpha,p} (\tau_3 + c \cdot \sigma) \psi_{\alpha,p}$. The surface excitations are self-conjugate Majorana fermions with a gapless relativistic dispersion relation $\epsilon(p) = c |p|$, and their spins locked normal to the in-plane momentum and the surface normal, $\mathbf{z}$. In this talk I describe theoretical predictions for experimental signatures based on NMR, mass flow, local ion probes and ultra-sound spectroscopy of these unique quanta that reflect the topological nature of the ground state of superfluid $^3$He.

9:12AM S53.00003 Observation of the Polar Phase of $^3$He$^1$. JEEVAK PARPIA, Department of Physics, Cornell University, Ithaca NY 14853 — Exotic pairing of Fermions into a condensed bound state is now well established in many systems. In superfluid $^3$He it is becoming evident that the nature and stability of the emergent order parameter can be altered radically by confinement in regular geometries or by providing anisotropic disorder realized in materials whose nanoscale structure is smaller than the coherence length. The temperature dependent coherence length diverges as the superfluid transition is approached from below and sets the characteristic length scale for confinement. Thus, the degree of confinement can be varied as the temperature is varied below Tc. Additionally, unlike most superconductors, the $^3$He liquid’s properties can be pressure-tuned over a large range. In bulk liquid, (in zero magnetic field) there are two equivalence phases of $^3$He: at high pressure, as the temperature is lowered there is a transition from the chiral A phase to the isotropic B phase. In bulk liquid, the relative stability of the two phases is controlled not by confinement but by strong-coupling interactions. In our highly confined system, both factors (confinement and strong coupling) come into play and depending on pressure we see a succession of two transitions (three phases) within the superfluid as the sample is cooled from the normal state. Drawing on theoretical work we identify the phases as the Polar phase near Tc, followed by a polar distorted A or B phase (depending on pressure) with the low-temperature phase being the B phase at all pressures. These observations are made with a toroidal pendulum that was used to assay the superfluid fraction and the disordered medium is the so-called “Obninsk” alumina aerogel that has highly oriented strands aligned with the torsional axis.

9:48AM S53.00004 Probing the A-B interface of superfluid helium-3. RICHARD HALEY, Lancaster University — At temperatures around 1 mK helium-3 forms a BCS spin triplet condensate. The order parameter is sufficiently complex that more than one superfluid phase coexists, each exhibiting a different broken symmetry, and there is a model first order transition between the two most stable phases, labeled A and B. The Lancaster Ultra-Low Temperature Group has developed techniques to probe the properties of the A-B interface in the deep sub-mK regime where the superfluid is in the pure condensate phase. Shaped and controllable magnetic fields are used to induce the transition, and to stabilize and move the A-B phase boundary inside the experimental volume. The latent heat of the transition has been measured, and the nucleation behavior shown to be incompatible with conventional thin film droplet nucleation dynamics. In this setup it is the most coherent two-dimensional structure in which we have experimental access. It has been proposed that this 2D surface in the surrounding 3D bulk volume is a good analog of a cosmological brane separating two distinct quantum vacuum states; experiments that simulate brane annihilation and the creation of topological defects have been carried out at Lancaster. Other investigations have included measurements of the surface tension and wetting behavior of the interface. During these studies it was discovered that a large, unpredicted frictional force was acting on the interface even though it is moving through a pure superfluid. Recent breakthrough work on the dynamics of the A-B interface has finally solved this puzzle. Current experiments include a setup where the interface region is probed directly using quartz tuning fork resonators that couple to the local density of broken Cooper pair quasiparticle excitations and thus give insight into the order parameter energy gap structure as A transforms to B.

10:24AM S53.00005 One-dimensional Quantum Fluids. GUILLAUME GERVAIS, McGill University — Fifty year ago, Joachim Mazdak Luttinger generalized the Tomonaga theory of interactions in a one-dimensional metal and show that the prior restrictions imposed by Tomonaga were not necessary. This model is now known as the Tomonaga-Luttinger liquid model (TLL) and most remarkably it does have mathematically exact solutions. In the case of electrons, it predicts that the spin and charge sector should separate, with each of them propagating with their own velocities. While there has been many attempts (some with great success) to observe TLL behavior in clean quantum wires designed on an ultra-clean semiconductor platform, overall the Luttinger physics is experimentally still in its infancy. For instance, little is known regarding the 1D physics in a strongly-interacting neutral system, whether from the point-of-view of TLL theory or even localization physics. Helium-4, the paradigm superfluid, and Helium-3, the paradigm Fermi liquid, should in principle both become Luttinger liquids if taken to the one-dimensional limit. In the bosonic case, this is supported by large-scale Quantum Monte Carlo simulations [1] which found that a lengthscale of ~ 2 nm is sufficient for the system to crossover to the 1D regime and display universal Luttinger scaling [2]. At McGill University, an experiment has been constructed to measure the liquid helium mass flow through a single nanopore. The technique consists of drilling a single nanopore in a SiN membrane using a TEM, and then applying a pressure gradient across the membrane. Previously published data in 45nm diameter hole has determined the superfluid critical velocity to be close to the limit set by the Feynman vortex rings model [3]. More recent work performed on nanopores with radii as small as 3 nm (and a length of 30nm) show that superfluid velocity for superfluid helium-3 to significantly deviate from its bulk value, 2/3. This is an important hint for the crossing over to the one-dimensional state in a strongly-correlated bosonic liquid. References:[1] Del Maestro A, Boninsegni M, Affleck I. Thursday, March 5, 2015 11:15AM - 2:15PM – Session T1 DMP: Focus Session: Beyond Graphene - Silicene and Germanene 001A - Roland Kawakami, Ohio State University

11:15AM T1.00001 Electron Energy Loss Spectroscopy Studies of Silicene and Graphene. OLEKSIV ROSLYAK, ANTONIOUS BALASSIS, Fordham University, NY, GODFREY GUMBS, Hunter College, CUNY, NY — Silicene is the silicon counterpart of graphene. However, the spin-orbit interaction in silicene opens up a substantial band gap. Consequently, there is an unambiguous low-frequency plasmon excitation originating from intra- and inter-band transitions. Both the plasmon intensity and lifetime depend on the width of the excitation gap separating electron-hole pairs. We present a formalism based on self-consistent field theory to investigates the rate of loss of energy of a beam of charged particles moving parallel and perpendicular to a silicene layer. The energy loss spectrum is presented as a function of the speed of the charged particles. We further study and compare the part of the energy absorbed by collective plasma excitation as well as by single particle excitations. We report clear spectral signatures of semi-metal to either band insulator or topological insulator. Plasmonic features of silicene flakes are also studied and compared to those of pristine graphene.
11:27AM T1.00002 Large Area Transfer and Optoelectronic Properties of Multilayer Epitaxial Germanane. VALID AMAMOU, PATRICK ODENTHAL, University of California Riverside. BETH BUSHONG, The Ohio State University, DANTE O'HARA, University of California Riverside, YUN LIU, The Ohio State University, JEREMIAH VAN BAREN, University of California Riverside, IGOR PINCHUK, The Ohio State University, YU WU, MARC BOCKRATH, HARRY TOM, University of California Riverside, JOSHUA GOLDBERGER, ROLAND KAWAKAMI, The Ohio State University — Germanane (GeH), the germanium-based analog of graphene (CH), is of particular interest due to its direct band gap and surface coherent functionalization. Furthermore, its large spin orbit coupling makes it possible to explore novel physical phenomena such as quantum spin hall effect at room temperature. Currently, large area GeH films are synthesized on Ge(111) wafers using substrate reaction or molecular beam epitaxy combined with chemical processing. This results in a high quality GeH film that is left on top of the germanium substrate. In order to perform the electrical characterization of GeH, it is required to transfer the film to an insulating substrate. Here, we demonstrate a highly efficient, nondestructive electrochemical route for the transfer of molecular beam epitaxy (MBE) GeH film from Ge(111) surfaces. This technique enables us to characterize the optoelectronic properties of epitaxial GeH after transfer such as I-V characteristics and photoconductivity wavelength dependence.

11:39AM T1.00003 Band Parameters of Two-Dimensional Materials: Phosphorene and Silicene. LOK LEW YAN VOON, The Citadel, ALEJANDRO LOPEZ BEZANILLA, Argonne National Lab, JIANWEI WANG, YONG ZHANG, U North Carolina Charlotte, MORTEN WILLATZEN, Technical University Denmark — The method of invariant is used to derive effective Hamiltonians in the presence of strain and external fields for phosphorene and silicene as examples of two-dimensional materials with and without a band gap. The band structure parameters have been obtained by fitting to density-functional theory calculations.

11:51AM T1.00004 Temperature-dependent phase transitions in epitaxial silicene on ZrB2(0001). ANTOINE FLOURENCE, YUKIKO YAMADA-TAKAMURA, Japan Advanced Institute of Science and Technology — Silicene differs from graphene, its carbon counterpart, by a mixed sp2/sp3 hybridization of the Si atoms that gives it particularly interesting mechanical and electronic properties. Silicene can form by the spontaneous and self-terminating segregation of Si atoms on the (0001) surface of zirconium diboride (ZrB2) thin films grown on Si(111) [1]. This stable form of silicene is particularly suitable for the investigation of the temperature dependence of its mechanical properties. Whereas, the amount of Si atoms does not vary, scanning tunneling microscopy and low-energy electron diffraction clearly indicate that two reversible phase transitions occur when the temperature is raised. At room-temperature, the silicene sheet is textured into one-dimensional arrays of interconnected 2.7 nm-wide ribbon-shaped stress domains [1]. Around 870 K, this ordered surface evolves into a surface made of wider domains with no ordering of the domain boundaries. At 930 K, the silicene sheet loses its structure and turns into a two-dimensional gas of Si atoms. While cooling down, silicene crystallizes reversibly. The origin of the phase transitions of epitaxial silicene will be discussed. [1] A. Fluorence et al. Phys. Rev. Lett. 108 245501 (2012).

12:03PM T1.00005 Electron confinement at the Si-MoS2 heterostructure junction. ALESSANDRO MOLLE, DANIELE CHIAPPE, CNR-IMM, Laboratorio MDM, DAVIDE RONDA, CNR-IMM, Laboratorio MDM & Universita degli studi di Milano Bicocca, ALESSIO LAMPERTI, CARLO GRAZIANETTI, EUGENIO CINQUANTA, CNR-IMM, Laboratorio MDM, MARCO FANCIULLI, CNR-IMM, Laboratorio MDM & Universita degli studi di Milano Bicocca — Two dimensional (2D) elementary materials such as silicene, germanene or phosphorene are emerging alternatives to graphene which has the consolidated class of layered metal dichalcogenides. In particular, 2D silicon nanosheets would benefit from the potential integration with the quite ubiquitous Si technology thus opening new scaling perspectives of the conventional electronic devices. In this framework we report here on the 2D epitaxy of a Si monolayer onto a MoS2 template with a locally hexagonal registry [1]. The experimental data are consistent with an ab initio calculated highly stretched silicene lattice [2]. High resolution photoemission spectroscopy investigations evidence a nearly metallic character of the Si nanosheet and a significant band bending on the MoS2 side which claims for a Si-induced electron accommodation. Integration into a bottom gated field effect transistor results in the effective transport at the Si/MoS2 heterostructure interface which is rationalized in terms of an electronic confinement. [1] Chiappe et al, Adv. Mater. 26, 2096 (2014); [2] Scalise et al, 2D Materials 1, 011010 (2014).

12:15PM T1.00006 Poisson's Ratio of Layered Two-dimensional Crystals. SUNGJONG WOO, HEE CHUL PARK, YOUNG-WOO SON, Korea Institute for Advanced Study — We have investigated the elastic properties of multilayered graphene as well as h-BN and MoS2 using a first-principles approach with up-to-date nonlocal exchange-correlation energy functional. Our analysis shows that the Poisson’s ratios of multilayered graphene, h-BN and MoS2 along out-of-plane direction are negative, near zero and positive, respectively, spanning all possibilities for signs of the ratios. While h-BN’s Poisson’s ratios are positive regardless of their disparate electronic and structural properties, the characteristic interlayer interactions as well as atomic stacking structures are shown to determine the sign of their out-of-plane ratios, highlighting their intertwined nature between elastic and electronic properties.

12:27PM T1.00007 Observation of Strong Intermode Coupling in a MoS2 Mechanical Resonator. CHANG-HUA LIU, IN SOO KIM, SPENCER PARK, KUNHO YOON, SARAH HOWELL, LINCOLN LAUHON, Northwestern University — Achieving the strong coupling regime in downscaled oscillators facilitates quantum control of macroscopic mechanics. Many approaches, including the use of dynamical backaction between mechanical resonators and photonic or superconducting cavities, require sophisticated device structures. We will describe strong mode coupling in a simple system: an ultrathin MoS2 mechanical resonator. Thermal fluctuations are exploited to study different vibrational modes of the resonator and observe avoided crossings in the vibrational spectra, indicating the entanglement of mechanical motion. Furthermore, when parametrically pumping the resonator with light, the dynamic optically induced strain leads to Stokes and anti-Stokes sidebands as well as normal-mode splitting. These signatures provide strong evidence that phonon populations can be redistributed between different vibrational modes, and also confirm that an MoS2 resonator can be operated into the strong coupling regime. These observations further suggest that 2D materials could offer a platform for developing full quantum control of nanomechanics.

12:39PM T1.00008 Measuring nanoscale friction between 2D materials and SiO2: hBN, MoS2 and Phosphorene. JASON CHRISTOPHER, Boston University, STEVEN KOENIG, National University of Singapore, ANGELO ZILETTI, Boston University, BO WEN, ZHENG HAN, Columbia University, ALEX KITT, XIANYE WANG, LOGAN KAGEORGE, Boston University, CORY DEAN, Columbia University, BARBAROS OZYILMAZ, National University of Singapore, ANNA SWAN, BENNETT GOLDBERG, Boston University — Unlike their 3D counterparts, 2D materials can be tuned with strain, leading to “strain engineering” of electrical, optical and thermal properties. Control of the precise location, magnitude and direction of a strain field depends critically on characterizing and understanding any motion or sliding between the 2D material and its anchor points. With this goal in mind, we determine the friction between three different atomically thin materials and a SiO2 substrate. Our experimental setup consists of cylindrical, micro-chambers we etch into a SiO2 substrate and seal with a 2D material membrane. We pressurize the outside of the micro-chamber, causing the 2D material to deform and slide on the substrate. The resulting strain distribution and amount of sliding is mapped using high spatial resolution Raman spectroscopy from which we determine the friction, Grüneisen and shear deformation potentials. MoS2, hBN, and Phosphorene have been chosen because they are good candidates for strain engineering applications. Additionally, in the case of MoS2 and Phosphorene we measure the photoluminescence spectrum from which we determine the strain dependence of the band gap.

\[1\] J. Christopher thanks the NDSEG program for its support.
Here we report studies of 2D layers formed by depositing Si on silicene/ZrB$_2$ going from the mono- to multi-layer regime. Recent experiments studying multiple Si layers on Ag(111) have shown that, remarkably, the multilayers are more metallic than the monolayer[2]. In the past two years, there have been quite a few experimental attempts to grow silicene on Ag(111). However, there are still controversies about whether a silicene layer with massless Dirac fermions actually exists on Ag(111). Chen et al. [1] measured the interference patterns in the differential conductance map by scanning tunneling spectroscopy and found a linear dispersion relation as the evidence for the existence of massless Dirac fermions. On the other hand, Lin et al. [2] found no Landau level sequences appearing in the tunneling spectra under a magnetic field, concluding that the Si-Ag interaction is strong enough to break the symmetry of silicene. In order to resolve these conflicting experimental findings, we have studied various Si/Ag configurations on the surface and their related electronic structures using first-principles density-functional calculations. Comparisons with experimental results will be discussed. [1] Chen et al. Phys. Rev. Lett. 109, 056804 (2012). [2] Lin et al., Phys. Rev. Lett. 110, 076801 (2013).

1:15PM T1.00011 Heterostructures by inserting Oxygen Monolayers in Si: 2D Nanolattice Growth, Electronic properties and MOSFET Device Characteristics 1, SUSEENDRAN JAYACHANDRAN, KOEN MARTENS, AUGUSTIN LU, imec / KULeuven, KENGO NISHIO, AIIST, GEOFFREY POURTOIS, imec / KULeuven, ANNELIES DELABIE, MATTY CAYMAX, imec, MARC HEYNS, imec / KULeuven — We discuss how heterostructures can be created in silicon by inserting oxygen monolayers, as well as what Density Functional Theory simulations predict in terms of electronic properties of these 2D nanolattices. We also discuss the experimental electrical characteristics of Metal-Oxide-Semiconductor Field Effect Transistors with 2D nanolattices channels. By using short (up to 500ms) low temperature O$_2$ reaction on H-terminated Si, the deposited O content can be controlled near the monolayer level, as demonstrated by SIMS measurements. Epitaxial deposition of Si on an O layer and 2D nanolattices with up to 5 periods have been achieved by CVD using SiH$_4$ at 500C. We discuss the structural and electronic properties calculated with density functional theory and give an overview of the most promising Si superlattices in terms of anticipated mobility enhancement. We report on the electrical device characteristics of 2D nanolattice Schottky diodes, MOS capacitors and MOSFETs. We discuss the impact of defectivity on electrical characteristics and the impact of the 2D nanolattices on MOSFET carrier mobility.

1:27PM T1.00012 Intrinsic magnetism, band gap opening and optical absorption in bilayer silicene 1, XINQUAN WANG, ZHIGANG WU, Department of Physics, Colorado School of Mines, WU’S CONDENSE MATTER GROUP TEAM — It has been long known to create magnetism out of simple non-magnetic materials like silicon. Here we show that intrinsic magnetism exists in bilayer silicene with no need to cut, etch, or dope. Unlike bilayer graphene, strong covalent interlayer bonds formed in bilayer silicene breaks the original π-networking of each layer, leaving the un-bonded electrons unpaired and localized to carry magnetic moments. These magnetic moments then couple ferromagnetically within each layer while antiferromagnetically across layers, giving rise to an infinite magnetic sheet with structural integrity and magnetic homogeneity. Our ab initio many-body calculations using the GW approach reveals that the unique magnetic ordering results in a fundamental band gap of 0.55 eV. Furthermore, we computed absorption spectrum by solving the Bethe-Salpeter equation, and our results suggest very strong absorption near the absorption edge. The integration of intrinsic magnetism and spontaneous band gap opening makes bilayer silicene attractive to future nanoelectronics as well as spin-based computation and data storage. This material could also be used as excellent light absorber, and its small band gap and one-dimensional confinement might be employed for efficient multi-exciton generation.

1:39PM T1.00013 Structural and electronic properties of 2D Si layers formed by deposition of Si on silicene / ZrB$_2$ 1, CYRUS F. HIRJIBEHEDIN, TOBIAS G. GILL, BEN WARNER, HENNING PRUESER, UCL, UK, KOHEI AOYAGI, RAINER FRIEDELIN, ANTOINE FLEURÉNCE, JAIST, Japan, JERZY SADOWSKI, Brookhaven National Laboratory, USA, YUKIKO YAMADA-TAKAMURA, JAIST, Japan — Silicene has been predicted to share many interesting properties with graphene. These are significantly modified by interactions with the metallic substrates in existing epitaxial silicene systems[1]. For many 2D layered materials, like graphene and MoS$_2$, these properties can change dramatically when going from the mono- to multi-layer regime. Recent experiments studying multiple Si layers on Ag(111) have shown that, remarkably, the multilayers are more metallic than the monolayer[2]. Here we report studies of 2D layers formed by depositing Si on silicene/ZrB$_2$. Using LEED, STM, and ARPES, we find that the deposition of very small amounts of Si cause structural changes to the silicene monolayer without strongly modifying its electronic properties. Additional deposition of Si causes structural changes to the first Si layer and results in a different structural domain and is more metallic. This trend continues for 3 ML up to the deposition of 10 ML. These result illustrate the rich array of properties that can be manifested in novel 2D Si nanostructures and highlight the dramatic variation in Si phases that can be seen on different substrates. [1] A. Fleurence et al., PRL 108, 245501 (2012) [2] P. Vogt et al., APL 104, 021602 (2014)

1:51PM T1.00014 Silicene on Silver: fundamental physical properties and integration in Field-Effect Transistors 1, EUGENIO CINQUANTA, Laboratorio MDM, IMM-CNR, via C. Olivetti 2, Agrate Brianza, I-20864, Italy, LI TAO, Microelectronics Research Center, The University of Texas at Austin, Texas 78758, USA, GUIDO FRATESI, ETSF and Dipartimento di Fisica, Università degli Studi di Milano, Milano, Italy, CARLO GRAZIANETTI, MARCO FANCIULLI, Laboratorio MDM, IMM-CNR, via C. Olivetti 2, Agrate Brianza, I-20864, Italy, GIOVANNI ONIDA, ETSF and Dipartimento di Fisica, Università degli Studi di Milano, Milano, Italy, DEJJ AKINWANDE, Microelectronics Research Center, The University of Texas at Austin, Texas 78758, USA, ALESSANDRO MOLLE, Laboratorio MDM, IMM-CNR, via C. Olivetti 2, Agrate Brianza, I-20864, Italy — To date, Silicene encountered different bottlenecks as reliable option in the framework of two-dimensional materials beyond graphene. Its physical properties are not completely unveiled and this, combined with its environmental instability, limits its possible integration into devices. Here we show a comprehensive characterization of Silicene by combining ab-initio calculations with optical spectroscopies. We elucidate the role of Ag in determining the electronic band structure and the optical response of differently oriented Silicene superstructures. We also show how these fundamental properties reflect in devices by presenting the experimental evidence of the ambipolar electrical transport in Silicene based field effect transistor.
The linewidth of the quasi-particle states. The impact of temperature on the exciton states is also addressed. We discuss the bandgap dependence on the temperature, and the change in the framework of the GW method we calculate the contribution of the electron-phonon coupling to the self-energy. This allows us to calculate the zero-point density of states and a step-function turn on in the density of modes. The largest radius of the ring of states occurs for a single monolayer of each material. In one to four monolayers of the group-III chalcogenides (GaS, GaSe, InS, InSe) and Bi$_2$Se$_3$ the valence band undergoes a band inversion from a parabolic to an inverted Mexican hat dispersion as the film thickness is reduced from bulk to a single monolayer. The band inversion is robust against changes in stacking order, omission or inclusion of spin-orbit coupling and the choice of functional. The Mexican hat dispersion results in a $1/\sqrt{E}$ singularity in the two-dimensional density of states and a step-function turn on in the density of modes. The largest radius of the ring of states occurs for a single monolayer of each material. The dispersion with the largest radius coincides with the maximum power factor and ZT for a material at room temperature. Ab-initio electronic structure calculations are used with a Landauer approach to calculate the thermoelectric transport coefficients. Analytical models of the Mexican hat and the parabolic dispersions are used for comparison and analysis. Vertically biased bilayer graphene could serve as an experimental test-bed for measuring this effect since the radius of the Mexican hat band edge increases linearly with vertical electric field.

**11:39AM T2.00003 Ab-initio study of the temperature effects on the optical properties of transition metal dichalcogenides** , ALEJANDRO MOLINA-SANCHEZ, Physics and Material Sciences Research Unit, University of Luxembourg — MAURIZIA PALUMMO, Dipartimento di Fisica, University of Rome Tor Vergata, Italy, ANDREA MARINI, Istituto di Struttura della Materia, Consiglio Nazionale delle Ricerche, Monterotondo, Italy, LUDGER WIRTZ, Physics and Material Sciences Research Unit, University of Luxembourg — Research on ultra-thin two-dimensional materials has been booming since the discovery of graphene along with its interesting physical properties. The transition metal dichalcogenides as MoS$_2$ are gaining considerable industrial attention due to their potential application in photovoltaics and nanoscale transistors. The optical properties of these layered materials depend strongly on the number of layers. The paradigmatic example is the transition from indirect to direct bandgap when we change from multi-layer to single-layer MoS$_2$. In this work, we study the effects of the electron-phonon interaction on the optical properties of single-layer MoS$_2$. In the framework of the GW method we calculate the contribution of the electron-phonon coupling to the self-energy. This allows us to calculate the zero-point re-normalization of the quasi-particle energies and to include temperature effects. We discuss the bandgap dependence on the temperature, and the change in the linewidth of the quasi-particle states. The impact of temperature on the exciton states is also addressed.

---

**11:51AM T2.00004 Interaction and Correlation Effects in Quasi Two-dimensional Materials$^2$** , STEVEN G. LOUIE, Univ of California - Berkeley and Lawrence Berkeley National Lab — Experimental and theoretical studies of atomically thin quasi-two-dimensional materials (typically related to some parent van der Waals layered crystals) and their nanostructures have revealed that these systems can exhibit highly unusual behaviors. In this talk, we discuss some theoretical studies of the electronic, transport and optical properties of such systems. We present results on graphene and graphene nanostructures as well as other quasi-2D systems such as monolayer and few-layer transition metal dichalcogenides (e.g., MoS$_2$, MoSe$_2$, W$_2$S$_2$, and WSe$_2$) and metal monochalcogenides (such as GaSe and FeSe). Owing to their reduced dimensionality, these systems present opportunities for unusual manifestation of concepts and phenomena that may not be so prominent or have not been seen in bulk materials. Symmetry and many-body interaction effects often play a critical role in shaping qualitatively and quantitatively their properties. Several quantum phenomena are discussed, including novel and dominant exciton effects, tunable magnetism, electron supercollimation by disorder, unusual plasmon behaviors, and possible enhanced superconductivity in some of these systems. We investigate their physical origins and compare theoretical predictions with experimental data.

**12:27PM T2.00005 Atomic model for excitons: Capturing Strongly Bound Excitons in Monolayer Transition-Metal Dichalcogenides$^3$** , FRANK TSENG, Naval Research Laboratory, ERGUN SIMSEK, George Washington University, DANIEL GUNLYCKE, Naval Research Laboratory — Monolayer transition-metal dichalcogenides form a direct bandgap predicted in the visible regime making them attractive host materials for various electronic and optoelectronic applications. Due to a weak dielectric screening in these materials, strongly bound electron-hole pairs or excitons have binding energies up to at least several hundred meV’s. While the conventional wisdom is to think of excitons as hydrogen-like quasi-particles, we show that the hydrogen model breaks down for these experimentally observed strongly bound, room-temperature excitons. To capture these non-hydrogen-like photo-excitations, we introduce an atomistic model for excitons that predicts both bright excitons and dark excitons, and as hydrogen-like quasi-particles, we show that the hydrogen model breaks down for these experimentally observed strongly bound, room-temperature excitons. For strongly bound exciton states, the lattice potential significantly distorts the envelope wave functions, which affects predicted exciton peak energies. The combination of large binding energies and non-degeneracy of exciton states in monolayer transition metal dichalcogenides may furthermore be exploited in room temperature applications where prolonged exciton lifetimes are necessary.

$^3$This work has been funded by the Office of Naval Research (ONR), directly and through the Naval Research Laboratory (NRL). F.T. and E.S acknowledge support from NRL through the SRC-NRI project 2204.001 (NSF-ECCS-1124733), FAME, one of six centers of STARnet, a SRC program sponsored by MARCO and DARPA and the use of XSEDE NSF grant # OCI-1053575.
12:39PM T2.00006 Observation of Rapid Exciton–Exciton Annihilation in Monolayer Molybdenum Disulfide, DEZHENG SUN, Departments of Physics and Electrical Engineering, Columbia University, YI RAO, Temple University, GEORG REIDER, Photonics Institute, TU Wien, GUGANG CHEN, Honda Research Institute USA, Inc., YUMENG YU, Departments of Physics and Electrical Engineering, Columbia University, LOUIS BREZIN, Laboratoire d’Optique Appliquée, ENSTA, CNRS, Ecole Polytechnique, AVETIK HARUTYUNYAN, Honda Research Institute USA, Inc., TONY HEINZ, Departments of Physics and Electrical Engineering, Columbia University — In this paper, we present ultrafast pump-probe spectroscopy results for monolayer MoS2 crystals in which we explore exciton dynamics as a function of exciton density. After a femtosecond excitation pulse of near-resonant radiation to create A excitons, we have monitored the temporal evolution of the exciton density using a continuum probe pulse. We observe a decay rate as long as 100 ps for samples at room temperature and at relatively low exciton density. The decay rate increases strongly with increasing exciton density. We are able to fit the entire set of density-dependent exciton dynamics using a simple model in which the dominant decay channel is an exciton-exciton annihilation process. From these measurements, we infer an exciton-exciton annihilation rate of \( (4.3 \pm 1.1) \times 10^7 \text{cm}^2/\text{s} \). We compare this rate with that observed in other nanostructured materials.

12:51PM T2.00007 GW-BSE calculations on two-dimensional MXene phases, ZHENGLI LI, Department of Physics, University of California at Berkeley; Materials Sciences Divisions, Lawrence Berkeley National Laboratory, LIANG HONG, Department of Physics, University of Illinois at Chicago, FELIPE JORNADA, TING CAO, Department of Physics, University of California at Berkeley; Materials Sciences Divisions, Lawrence Berkeley National Laboratory, SERDAR OGUZ, Department of Physics, University of Illinois at Chicago, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley; Materials Sciences Divisions, Lawrence Berkeley National Laboratory — MXene is a promising candidate for new useful two-dimensional (2D) crystals. Experimentally, few-layer samples have been made from the bulk, and they demonstrate many excellent properties for electric and thermal transport, as well as other novel physics. In this work, we have performed GW-BSE calculations based on first-principles calculations to study some of the MXene family. We find that monolayer Ti3C2 possesses insulating properties. Furthermore, the 2D screening effect is very strong, resulting in a GW band gap correction of almost 1 eV. Based on these initial results, we expect that optical properties of these materials will also have strong excitonic effects.

1:03PM T2.00008 Bright Interlayer Exciton Dynamics in MoSe2–WSe2 Heterostructures, PASQUAL RIVERA, KYLE SEYLER, JASON ROSS, JOHN SCHAIBLEY, UNIV OF WASHINGTON, HONGYI YU, UNIV OF Hong Kong, JON ELL, MARIE SCOTT, Uniu of Washington, JIAQIANG YAN, DAVID MANDRUS, Oak Ridge National Laboratory / Uniu of Tennessee, WANG YAO, Uniu of Hong Kong, XIAODONG XU, Uniu of Washington — Monolayer transition metal dichalcogenide heterostructures have recently demonstrated type-II band alignment, prompting great interest in characterizing the properties of this new material system. In the monolayer MoSe2–WSe2 heterostructure, bright spatially indirect excitons with dramatically extended lifetimes have been demonstrated. Since the interlayer excitons are permanent electrical dipoles, they allow for electrical and optical control. Here, we report on the investigation of interlayer exciton emission energy, lifetime, and in-plane spatial diffusion, as a function of electric field and exciton density, in the MoSe2–WSe2 heterostructure.

1:15PM T2.00009 Giant bandgap renormalization and excitonic effects in a monolayer transition metal dichalcogenide semiconductor, AARON BRADLEY, MIGUEL M. UGEDA, SU-FEI SHI, Physics Dept. UC Berkeley, FELIPE H. DA JORNADA, Physics Dept. UC Berkeley; MSD LBNL, YI ZHANG, ALS LBNL; SLAC, DIANA Y. QIU, Physics Dept. UC Berkeley; MSDLBNL, WEI RUAN, Physics Dept. UC Berkeley; Physics Dept. Tsinghua Univ., SUNG-KWAN YEH, KA HONG, ALS LBNL, ZHI-XUN SHEN, SLAC, Geballe Lab. Adv. Mater. Stanford, FENG WANG, Physics Dept. UC Berkeley; MSDLBNL, Kavli Nanosciences Inst., STEVEN G. LOUIE, Physics Dept. UC Berkeley; MSDLBNL, MICHAL F. CROMMIE, Physics Dept. UC Berkeley; MSDLBNL; Kavli Nanosciences Inst. — Reduced screening in 2D has been predicted to result in dramatically enhanced Coulomb interactions that should cause giant bandgap renormalization and exotic excitonic effects in single-layer TMD semiconductors. Here we present a direct experimental observation of extraordinarily high exciton binding energy and bandgap renormalization in a single-layer of a semiconducting MoSe2, grown on bilayer graphene, using high-resolution scanning tunneling spectroscopy and photoluminescence spectroscopy. We have measured both the quasiparticle electronic bandgap and the optical transitions, obtaining an exciton binding energy of 0.55 eV—a value orders of magnitude larger than in conventional 3D semiconductors. We have also studied the influence of external dielectric screening by repeating measurements on MoSe2/HOPG. These results are important for room-temperature optoelectronic devices involving 2D TMDs, as well as more complex layered heterostructures.

1:27PM T2.00010 Electron excitations in two-dimensional buckled honeycomb lattices, PO-HSIN SHIH, PhD. Candidate, Department of Physics, National Cheng Kung University, YU-HUANG CHIU, Professor of Department of Applied Physics, National Pingtung University, MIN-FA LIN, Professor of Department of Physics, National Cheng Kung University — The two-dimensional buckled honeycomb lattices system exhibits the rich Coulomb excitation spectra, being dominated by the free carrier density, band structure, and transferred momentum (q). There are two kinds of plasmon peaks in the energy loss spectra, calculated from the random phase approximation. They are, respectively, revealed at low and middle frequencies. The former, which arises from the free carriers, belongs to acoustic mode. It’s frequency depends on \( \sqrt{q} \) at long wavelength limit. On the other hand, the latter is due to all the \( n \)-electronic collective excitations is an optical mode. Whether such plasmon can service is mainly determined by q. The frequencies and intensities of plasmon peaks are very different among graphene, silicene, germanene, and Tin.

1:39PM T2.00011 SPEELEM Studies on the Electronic Structure of MoS2/Graphene Heterostructure, WENCAN JIN, PO-CHUN YEH, NADER ZAKI, DANIEL CHENET, GHIDEWON AREFE, YUFENG HAO, Columbia University, ALESSANDRO SALA, TEVFIK MENTES, ANDREA LOCATELLI, Elettra Sincrotrone Trieste, JAMES HONE, RICHARD OSGOOD, Columbia University, COLUMBIA UNIVERSITY COLLABORATION, — Two-dimensional layered materials have been realized through the use of van der Waals heterostructures composed of weakly interacting layers. Among them, MoS2/graphene heterostructures can combine the advantages of high carrier mobility in graphene with the direct band gap of MoS2, which leads to potential applications in nanoelectronic devices with various functionalities. In this work, we study the influence of interlayer twist angle on the electronic structure of a MoS2/graphene heterostructure using Spectroscopic Photoemission and Low Energy Electron Microscopy (SPEELEM) system. MoS2/graphene heterostructures are prepared by transferring chemical-vapor-deposition (CVD)-grown monolayer MoS2 on top of CVD-grown graphene. Twist angles are characterized using the micro-LEED and the electronic structures are directly measured using micro-ARPES.
1:15PM T2.00012 Environment-Dependent Quasiparticle Bandgap of Monolayer MoS2. YONG-SUNG KIM, Korea Research Institute of Standards and Science. JI-YOUNG NOH, HANCHUL KIM, Sookmyung Women's University, MINKYU PARK, University of Science and Technology, K.C. SANTOSH, K.J. CHO, UT Dallas — 2D semiconductors are manifested by strong Coulomb interaction inside. The strong Coulomb interaction gives remarkable effects on various properties of the 2D semiconductors, including (i) large exciton binding energy (electron-hole), (ii) large quasi-particle self-energy (electron-electron), (iii) large scattering cross section in carrier transports by charged defects (electron-charged defects), (iv) deep defect transition level (bound electron-charged defects), and (v) strong interaction between charged defects (charged defects-charged defects). The ground state, optical, and transport properties are then largely affected by the dielectric environments surrounding the 2D semiconductors, because the Coulomb interaction is effectively screened by the dielectrics. We investigate the electronic band structures of a single-layer MoS2, as a prototype 2D semiconductor, with a variety of dielectric environments by using density-functional-theory (DFT) and GW calculations.

2:03PM T2.00013 The effects of surface polarity and dangling bonds on the electronic properties of MoS2 on SiO2. HA-JUN SUNG, DUK-HYUN CHOE, KEE JOO CHANG, Korea Adv Inst of Sci & Tech — MoS2 has recently attracted much attention due to its intriguing physical phenomena and possible applications for the next generation electronic devices. In pristine monolayer MoS2, strong spin-orbit coupling and inversion symmetry breaking allow for an effective coupling between the spin and valley degrees of freedom, inducing valley polarization at the K valleys. However, the spin-valley coupling disappears in bilayer MoS2 because the inversion symmetry is restored. In this work, we investigate the effects of surface polarity and dangling bonds on the electronic properties of MoS2 on α-quartz SiO2 through first-principles calculations. In monolayer MoS2, a transition can take place from the direct-gap to indirect-gap semiconductor in the presence of O dangling bonds. In bilayer MoS2, O dangling bonds induce dipole fields across the interface and thus break the inversion symmetry, resulting in the valley polarization, similar to that of pristine monolayer MoS2. Based on the results, we discuss the origin of the valley polarization observed in MoS2 deposited on SiO2.

Thursday, March 5, 2015 11:15AM - 1:39PM –
Session T3 FPS GSNP: Invited Session: Network and Grid Resilience 002AB - Micah Lowenthal, National Academy of Science

11:15AM T3.00001 Electric Distribution Grid Resilience R&D by the U.S. DOE, DAN TON, U.S. Department of Energy — The U.S. Department of Energy’s Smart Grid Research and Development Program is undertaking R&D to modernize the distribution portion of the electricity delivery system. Key characteristics of a modernized electric distribution grid include reliability, efficiency, affordability, flexibility, and resilience of electricity delivery for all end uses. To address resilience, the Program has established a focused R&D area in FY15 aiming to reduce social consequences (economic, safety, and security) from extreme weather threats. This focus area was developed as the result of an established process in which the Program engaged national labs, universities, utilities, and other industry stakeholders to jointly envision the future state of a resilient grid, to identify R&D areas and activities of priority, and to define performance metrics and associated targets. This presentation will cover the development of the electric distribution grid R&D focus area to date, including its key elements in resilience metrics, enhanced system designs, improved preparedness and mitigation measures, and improved system response and recovery. Key findings from a stakeholder workshop and the year-one Quadrennial Energy Review (QER) report by federal agencies will be summarized presented. Further, examples of ongoing projects in this focus area supported by the Program will be featured. The presentation will conclude with highlighting some key activities planned by the Program for the near future.

11:51AM T3.00002 Designing Resilient Electrical Distribution Grids—R&D Challenges, SCOTT BACKHAUS, Los Alamos National Laboratory — Natural disaster such earthquakes, hurricanes, and other extreme weather pose serious risks to modern critical infrastructure including electrical distribution grids, as evidenced by recent events like Superstorm Sandy. To improve resilience to these events, recent U.S. government studies suggest that component and system-level hardening and resilience upgrades are needed, including adding redundant circuit segments, hardening transformers and other exposed components, adding switching and microgrid generation for flexibility. All of these upgrades are expensive. New methods are needed to design cost-efficient, high-performance combinations of upgrades. A network-centric resilience design approach is described and used to highlight several areas in need of fundamental research to improve the functionality of this and related resilience design tools.

12:27PM T3.00003 Resiliency of Distribution Systems: State-of-the-Art and the Future, CHEN-CHING LIU, Washington State University — Recent development of the smart grid significantly enhanced the level of automation in the distribution grids. With a higher level deployment of remote-controlled switches, distribution feeders can be restored more efficiently after power outages. In this presentation, computational algorithms for feeder restoration will be summarized together with their practical implementations. The traditional analytical techniques, however, are not designed for extreme events in the distribution systems. The same is true for widely adopted reliability indices. New thinking of design and operation for resilient distribution systems will be important. Resiliency for a power distribution system depends not only on the electrical and communication connectivity but also the availability and physical capability of the distribution systems to deliver power. The physical behavior of the distribution systems during an extreme operating condition will be discussed. This presentation will cover technical methods and open research issues related to resilient distribution systems. Simulation results using a 4-feeder 1069-node test system with microgrids will be used to validate the feasibility of the proposed methods.

1:03PM T3.00004 Resilience of Large-Scale Power Distribution: Modeling and Real Data, CHUANYI JI, ECE, Georgia Tech — Severe weather events are extreme but realistic scenarios of large-scale disruptions to power distribution, the last mile of our energy infrastructure. The impact of severe weather is significant: Each major disruption previously occurred caused power failures to millions of customers in large geographical areas for extended durations. A resilient power grid is called for in the nation, which poses a numerous fundamental questions. For example, how to quantify the resilience? How resilient is large-scale power distribution to severe weather? In this talk, we first discuss technical challenges for quantifying resilience that involve heterogeneous factors from power distribution to services. We then show that these factors can be modeled, in a network setting, through spatial-temporal random processes. A dynamic resilience metric is then derived from the model. The model and the metric guide us to learn resilience from real data. We will present a study, using large-scale real data on failures and recoveries, to understand how resilient power distribution is to severe-weather disruption. Joint work with Yun Wei and Henry Mei (Georgia Tech), in collaboration with utilities and policy makers, and supported by NYSEDA.

Thursday, March 5, 2015 11:15AM - 2:15PM –
Session T4 FEd FIAP: Focus Session: Building New Pathways in Physics Innovation and Entrepreneurship Education Mayor Cockrell Room 004 - Bahram Roughani, Loyola University Maryland
11:15AM T4.00001 Tinker, Thinker, Maker and CEO: Reimagining the Physics Student as Engineer, Inventor, and Entrepreneur, CRYSTAL BAILEY, American Physical Society APS — We live in an era of immense opportunity for physics graduates: their scientific training helps to make them key members of industry teams developing new technologies, or translating cutting-edge research into viable products. Physics as a discipline stands to make tremendous gains by implementing new educational approaches which provide training for success in what is increasingly the largest employment base for physicists: the private sector. In this talk, I will examine the role of physicist as innovator and how this role intersects with other similar STEM disciplines (such as engineering), and provide some insight into how implementing physics innovation and entrepreneurship (PIE) education will benefit both physics departments and the students they serve, regardless of students’ eventual career choices. I will also talk about some exciting new PIE related developments in the physics community, and provide information about how educators can get involved in this growing movement.

11:27AM T4.00002 Practical skills of the future innovator, VITALIY KAUROV, Wolfram Research — Physics graduates face and often are disoriented by the complex and turbulent world of startups, incubators, emergent technologies, big data, social network engineering, and so on. In order to build the curricula that foster the skills necessary to navigate this world, we will look at the experiences at the Wolfram Science Summer School [1] that gathers annually international students for already more than a decade. We will look at the examples of projects and see the development of such skills as innovative thinking, data mining, machine learning, cloud technologies, device connectivity and the Internet of things, network analytics, geo-information systems, formalized computable knowledge, and the adjacent applied research skills from graph theory to image processing and beyond. This should give solid ideas to educators who will build standard curricula adapted for innovation and entrepreneurship education.

11:39AM T4.00003 Fostering Innovation through Physics, 52 Technologies, and Wide Participation, RANDALL TAGG, University of Colorado Denver — We have created in a single site a workspace called the Innovation Hyperlab. It organizes 52 technologies into 3-technology work bays and houses appropriate supplies, tools, and instrumentation. Key to the operation is a supporting web site (for open release in summer 2015) with modular instruction in individual technologies. The instruction emphasizes underlying physical principles but provides direct engagement with key devices and methods in a given technology. The aim is to support learning on-demand in the midst of design projects as well as formal courses. The physical and virtual sides of the lab are designed to serve a wide range of participants, from high school students to graduate students. Most experience to date has been through using the space to support undergraduate-mentored high school student research and innovation teams pursuing projects as wide ranging as helicopter rescue and neurological rehabilitation.

11:51AM T4.00004 Your Higgs number – how fundamental physics is connected to technology and societal revolutions, SUZY LIDSTRÖM, Physica Scripta, Royal Swedish Academy of Sciences and Uppsala University, ROLAND E. ALLEN, Texas A&M University — Fundamental physics, as exemplified by the recently discovered Higgs boson, often appears to be completely disconnected from practical applications and ordinary human life. But this is not really the case, because science, technology, and human affairs are profoundly integrated in ways that are not immediately obvious. We illustrate this by defining a “Higgs number” through overlapping activities. Following three different paths, which end respectively in applications of the World Wide Web, digital photography, and modern electronic devices, we find that most people have a Higgs number of no greater than 3. Specific examples chosen for illustration, with their assigned Higgs numbers, are: LHC experimentalists employing the Worldwide Computing Grid (0) - Timothy Berners-Lee (1) - Marissa Mayer, of Google and Yahoo, and Sheryl Sandberg, of Facebook (2) - users of all web-based enterprises (3). CMS and ATLAS experimentalists (0) - particle detector developers (1) - inventors of CCDs and active-pixel sensors (2) - users of digital cameras and camcorders (3). Philip Anderson (0) - John Bardeen (1) - Jack Kilby (2) - users of personal computers, mobile phones, and all other modern electronic devices (3).

12:03PM T4.00005 Methods to Implement Innovation and Entrepreneurship in Physics, DOUGLAS ARION, Carthage College and Galileoscope LLC — The physics community is beginning to become aware of the benefits of entrepreneurship and innovation education: greater enrollments, improved students satisfaction, a wider range of interesting research problems, and the potential for greater return from more successful alumni. This talk will suggest a variety of mechanisms by which physics departments can include entrepreneurship and innovation content within their programs – without necessarily requiring earth-shattering changes to the curriculum. These approaches will thus make it possible for departments to get involved with entrepreneurship and innovation, and grow those components into vibrant activities for students and faculty.

12:15PM T4.00006 Enlarging the ‘knowledge toolbox’: helping students prepare for an innovation-driven world, ELIZABETH NILSEN, VentureWell — Physics students graduate from their course of studies to enter the “world of work.” While for many years that transition meant joining a large corporation for a life-long career, this is no longer the case. Today’s graduates will find their career with a series of organizations – often start-ups and small to mid-sized organizations – whose future depends on the ability to rapidly leverage technical knowledge into useful products and services. This session will discuss the value of preparing physics students to be innovators and entrepreneurs, both as a strategy to prepare them for future careers, as well as an opportunity to fully engage students in seeing the relevance of physics to “real world” challenges. The session will feature three case studies: 1) embedding core knowledge and skills within a technical content course; 2) building learning experiences around a team-based start-up exploration; 3) engaging an entire department in considering how to comprehensively include innovation & entrepreneurship themes in the curriculum. The session will conclude with information about how faculty members and institutions can access resources for adopting this approach to their course offerings.

12:27PM T4.00007 PANEL DISCUSSION —

Thursday, March 5, 2015 11:15AM - 2:03PM —

Session T5 DMP DCOMP: Focus Session: Disorder in Fe-based Superconductors Juan Gorman

Room 005 - Gregory Stewart, University of Florida
11:15AM T5.00001 Visualizing the atomic-scale influence on superconductivity and vortex pinning of high-energy ion irradiation in FeSeTe

PETER SPRAU, Cornell University, FREEK MASSEE, Brookhaven National Laboratory, Cornell University; YONGLEI WANG, Argonne National Laboratory; J. C. SEAMUS DAVIS, Brookhaven National Laboratory, Cornell University, University of St. Andrews, Kavli Institute at Cornell for Nanoscale Science, GENDA GU, Brookhaven National Laboratory, WAI-KWONG KWOK, Argonne National Laboratory — The maximum sustainable supercurrent density, JC, may be greatly enhanced by preventing dissipative motion of quantized vortices. Irradiation of superconductors with heavy ions is often used to create nanoscale defects with deep pinning potential for the vortices and this approach holds great promise for high current applications of iron-based superconductors. We have shown that two different atomic-scale interplay between the crystal damage from high-energy ion, the superconducting order parameter, and the vortex pinning processes. Here, we visualize the atomic-scale effects of irradiating FeSe0.45Te0.55 with 249 MeV Au ions and find two distinct forms of damage: compact regions of crystal disruption ascribable to the actual ion trajectory along with single atomic-site ‘point’ defects. We show directly that the superconducting order is virtually annihilated within the former while it is still altered by the latter. Simultaneous atomically-resolved images of the crystal defects, the superconducting density-of-states, and the vortex cores, then reveal how the vortex pinning evolves with increasing field in irradiating FeSe0.45Te0.55.

11:27AM T5.00002 Experimentally tuning the ground state of BaFe2As2 by orbital differentiation

PRISCILA ROSA, University of California at Irvine, CRIS ADRIANO, THALES GARITEZI, University of Campinas, TED GRANT, ZACHARY FISK, University of California at Irvine, RICARDO URBANO, PASCOAL PAGLIUSO, University of Campinas — The role of structural parameters in layered systems, such as iron pnictides/chalcogenides (Fe-Pn/Ch), cuprates and heavy fermions, has become crucial for the understanding of their properties. In this talk, I will discuss this subject using a combination of macroscopic and microscopic techniques to study Ba1−εEu1−εFe2−yMyAs2 single crystals (M = Co, Cu, Mn, Ni, and Ru). Interestingly, a close connection arises between the spin-density wave (SDW) phase suppression and local distortions in the structure. Furthermore, these changes in the Fermi surface by an increase of anisotropy and localization of the Fe 3d bands at the FeAs plane. Our results suggest that such increase in the planar (xσ/zw2−yγ) orbital symmetry seems to be a favorable ingredient for the emergence of superconductivity in this class of materials.

11:39AM T5.00003 FORC Evidence for Splitting of the Magnetostructural Transition in Fe1+y2 Te

MILES FRAMPTON, JOHN CROCKER, DUSTIN GILBERT, KAI LIU, RENA ZIEVE, Univ of California - Davis, GENDA GU, Brookhaven National Lab — Iron-based superconductors Fe1+y2 Te and CaFe2As2 both have simultaneous magnetic and structural transitions, at 67K and 170K, respectively. We have investigated these transitions using the First-Order Reversal Curve (FORC) method, which provides a detailed mapping of any heterogeneities and irreversible switching events. In this work, electrical resistance FORC measurements have been performed in the presence of external magnetic fields to deconvolute the phase transition. In Fe1+y2 Te the phase transition actually consists of two separate transitions, which is sensitive to the external field for H > 2T, as revealed by the FORC distribution. The different responses of these separate transitions to the magnetic field suggest that, at a minimum, the coupling to the field is different for each phase. In contrast, CaFe2As2 shows no sign of a split transition, with or without the magnetic field. In both cases the magnetic field is shown to shift the distribution, suggesting a change in the energy landscape and highlighting the coupling between the magnetic and structural transition. This work has been supported by the NSF (DMR-1008791).

11:51AM T5.00004 Unexpected impact of magnetic disorder on multiband superconductivity

DMITRI EREFROM, IWF- Dresden, Germany, MAXIM KORSHUNOV, Kirensky Institute of Physics, Krasnoyarsk, Russia, ALEXANDER GOLYUBOV, University of Twente, The Netherlands, OLEG DOLOGV, Max Planck Institute, Stuttgart, Germany — We analyze how the magnetic disorder affects the properties of the two-band s± and s±± models, which are subject of hot discussions regarding iron-based superconductors and other multiband systems like MgB2. We show that there are several cases when the transition temperature Tc is not fully suppressed by magnetic impurities in contrast to the Abrikosov-Gor’kov theory, but a saturation of Tc takes place in the regime of strong disorder. These cases are: (1) The purely interband impurity scattering, (2) impurity scattering purely in one of the bands, (3) the unitary scattering limit. We show that a transition between s±± and s± states may occur with increasing magnetic disorder.

12:03PM T5.00005 Modulation of Pairing Symmetry with Bond Disorder in Iron-based Superconductors

DAO-XIN YAO, YAO-TAI KANG, School of Physics and Engineering, Sun Yat-Sen University, WEI-FENG TSAI, Department of Physics, National Sun Yat-sen University — We study a simple two-orbital t-J1-J2 model for iron-based superconductors in the presence of a bond disorder (via nearest-neighbor bond-dilution). By using Bogoliubov-de Gennes approach, we self-consistently calculate the local pairing amplitudes and the corresponding density of states, which demonstrate a change of dominant pairing symmetry from the s+ wave to d-wave as long as J2 J1. Although the system exhibits spatially inhomogeneous pairing in weak correlations with a given realization of disorder, it is still in sharp contrast to the case with potential disorder, where the superconducting islands and the insulating sea are both present in the strong disorder regime. Moreover, from the detailed examination of the pairing gap as well as the superfluid density, the superconducting transition here is suggested to be beyond the conventional Abrikosov-Gor’kov consideration.

12:15PM T5.00006 Low-energy magnetic defects at nano- and meso-scale in Fe-based superconductors

AFTAB ALAM, Department of Physics, Indian Institute of Technology Bombay, Powai, Mumbai 400076 Maharashtra, SUFIAN N. KHAN, DUANE D. JOHNSON, Ames Laboratory, Ames, Iowa 50011, USA — In Fe-based superconductors, “ordered” moments of Fe (0.3–0.5 μB) measured by neutron scattering in the antiferromagnetic groundstate are half (∼1.6 μB) of that estimated from density-functional theory (DFT), while other experiments are closer to DFT — a puzzle not yet understood. Structural and magnetic planar defects proliferate over differing length scales, and could be key to any moment description. Thus, we study via DFT the stability and magnetic properties of antiphase and domain boundaries, twins, and nanotwins, which exhibit low-moment states confined near defect boundaries. A single local-moment picture is thus inappropriate for long-range magnetic order. While the nanoscale defects are very low in energy, twins remain so at the mesoscale, where estimated distances between twin boundaries coincide with the observed magnetic correlation length. All these defects can be weakly mobile and/or have fluctuations that will lower assessed “ordered” moments from longer spatial and/or time averaging.

1Ames Laboratory is operated for the U.S. DOE by Iowa State University under contract DE-AC02-07CH11358. A thanks startup seed grant from IIT Bombay.

12:27PM T5.00007 NMR Investigations of Inhomogeneous glassy spin fluctuations in Doped BaFe2As2

NICOLAS CURRO, University of California, Davis — We present 77As and 31P NMR data in a series of Ba(Fe1−x−yM)x+yAs2 (M=Ni, Cu, Co) and BaFe2(As1−xFes)x2 crystals that reveal the large inhomogeneous distribution of glassy spin dynamics, as well as the coexistence of frozen antiferromagnetic domains in superconducting samples. In underdoped samples, the glassy dynamics turns on below temperatures on the order of 100K, persists in magnetic fields up to 30 Tesla, and is unrelated to a competition between antiferromagnetism and superconductivity. Rather, the glassy spin dynamics are driven by inhomogeneous nematic fluctuations.
1:03PM T5.00008 Competition between the spin fluctuations and disorder in an iron-pnictide superconductor. XIAO-JIA CHEN, YONG-HUI ZHOU. Center for High Pressure Science and Technology Advanced Research, Shanghai 201203, China, ZHU-AN XU, Department of Physics, Zhejiang University, Hangzhou 310027, China, VIKTOR STRUZHKIN, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20051, USA. — The evolution path of superconductivity with pressure in an optimally doped iron pnictide BaFe$_{1.9}$Ni$_{0.1}$As$_2$ is examined by resistance measurements. We find that the superconducting transition temperature $T_c$ of this compound first increases with a maximum at around 5 GPa and then decreases with increasing pressure and eventually vanishes at around 12.5 GPa. The change of the strength of the spin fluctuations, derived from the analysis of the temperature-dependent resist ance, behaves in a similar way to $T_c$. After the destruction of superconductivity, the compound enters an insulating state due to the disorder-induced localization effect. These findings unveil that the superconductivity is controlled by the competition between the spin fluctuations and disorder and pin down the nature of the electron scattering and pairing in iron-based superconductors.

1:15PM T5.00009 Effects of Swift Particle Irradiations in (Ba,K)Fe$_2$As$_2$. TSUYOSHI TAMEGAI, TOSHIHITO TAEN, FUMIAKI OHTAKE, YUE SUN, SUNSENG PYON, MASATAKA MORIMOTO, The University of Tokyo, SATÔRÔ OKAYASU. Japan Atomic Energy Agency, HISASHI KITAMURA, National Institute of Radiological Sciences — Iron-based superconductors are believed to be good candidates for practical applications at high fields. Knowledge of the pinning mechanism of vortices is essential to achieve a large critical current density at high fields. Irradiations of swift particles are established way to introduce defects that pin vortices under the action of Lorentz force due to large current. We have systematically investigated the effects of swift particle irradiations on high-temperature superconductors (Ba,K)Fe$_2$As$_2$ family of compounds. The coherent combination of detailed structural information with an in-depth analysis of the electronic structure allows us to disentangle very sensitively “doping” effects from “substitutional” effects. This balance between substitution and doping turns out to be crucial for an understanding of magnetism and superconductivity in iron pnictides.

1:27PM T5.00010 Of substitution and doping: Spatial and electronic structure in iron pnictides. S. SCHUPPLER, P. SCHWEISS, P. NAGEL, M.-J. HUANG, R. EDER, TH. WOLF, H. V. LÖHNEYSEN, M. MERZ, Karlsruhe Institute of Technology (KIT) — A highly intriguing aspect in iron-pnictide superconductors is the composition-dependent electronic structure, in particular the question if and how charge carriers are introduced to the system upon substitution of Ba by alkali metals or of Fe by other transition metals, TM. We report on a systematic study of spatial structure and electronic states by x-ray diffraction and x-ray absorption, performed on a large number of compositions in the (Ba,K)Fe$_2$As$_2$ family of compounds. The coherent combination of detailed structural information with an in-depth analysis of the electronic structure allows us to disentangle very sensitively “doping” effects from “substitutional” effects. This balance between substitution and doping turns out to be crucial for an understanding of magnetism and superconductivity in iron pnictides.

1:39PM T5.00011 Superconductivity of Ba$_{1-x}$K$_x$Fe$_2$As$_2$ with and without artificial disorder over the entire doping range. SERAFIM TEKNOVJOYO, KYUL CHO, MAKARY A. TANATAR, RUSLAN PROZOROV, YONG LIU, THOMAS LOGRASSO, Ames Laboratory and Iowa State University, USA, MARCIN KONCZYKOWSKI, LSI, Ecole Polytechnique, France. — Effects of electron irradiation on superconducting transition temperature and in-plane London penetration depth were studied in single crystals of Ba$_{1-x}$K$_x$Fe$_2$As$_2$ ($x = 0.22, 0.34, 0.47, 0.56, 0.65, 0.80, 0.82, 0.90, 0.92, 1.0$). Electron irradiation introduces point-like disorder that gives insight into the superconducting gap structure by studying the effects of increasing scattering. We studied the entire superconducting “dome” and find distinctly different behaviours in underdoped, optimal, and overdoped compositions and unusual behaviour near $x = 0.7 - 0.8$.

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T6 DMP: Focus Session: Iridates and Osmates 006A - Saicharan Aswartham, University of Kentucky

11:15AM T6.00001 A tale of three double perovskites: Ba$_2$XOs$_6$ (X=Na,Ca,Y)¹. SHRUBA GAN-GOPADHYAY, WARREN PICKETT, University of California - Davis — High valent Os based double perovskites are one center of current interest because they display extremely large spin orbit coupling and strong electronic correlation. We present electronic and magnetic structures of three cubic Os based double perovskites with Os$^{5+}$($d^5$), Os$^{5+}$($d^4$), Os$^{6+}$($d^1$). For these first principles based calculation we used an onsite hybrid exchange only on Os(5d), as implemented in Wien2k. While Ba$_2$NaOsO$_6$ is a ferromagnetic Mott insulator, the other two show antiferromagnetic ordering. For comparison purposes we have investigated only the ferromagnetic ordered phase of these three materials. A metal-insulator transition by changing spin orbit coupling direction is found in all three materials, however each double perovskite is metallic for different magnetic directions. Surprises from looking at the radial charge densities will be discussed. We provide a resolution to the riddle: why, despite d1 configuration, does Ba$_2$NaOsO$_6$ remain cubic. This material introduces a new class of J=3/2 Mott insulator.

This balance between substitution and doping turns out to be crucial for an understanding of magnetism and superconductivity in iron pnictides.
11:39 AM T6.00003 Magnetism and anisotropy of Ir$^{5+}$ based double perovskites Sr$_2$CoIrO$_6$ and Sr$_2$FeIrO$_6$. JASMINKA TERZIC, S.J. YUAN, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA, W.H. SONG, Institute of Solid State Physics, Chinese Academy of Sciences, Hefei, China, S. ASWARTHAM, G. CAO, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA — We report on structural, thermodynamic and transport study of single-crystal double perovskites Sr$_2$CoIrO$_6$ and Sr$_2$FeIrO$_6$. The isostructural Sr$_2$CoIrO$_6$ and Sr$_2$FeIrO$_6$ feature a cubic crystal structure with pentavalent Ir$^{5+}$ (5d$^6$) which are anticipated to have J=0 singlet ground states in the strong spin-orbit coupling limit. Here we observe magnetic coupling between 5d and 3d (Co, Fe) elements, which result in antiferromagnetic order at high temperatures in both double perovskites. Of the two, Sr$_2$CoIrO$_6$ displays antiferromagnetic metallic behavior with a pronounced magnetic anisotropy; in sharp contrast, the isostructural Sr$_2$FeIrO$_6$ exhibits an antiferromagnetic, insulating ground state without discernible magnetic anisotropy. The data will be discussed and presented with comparisons drawn with similar systems.

1This work was supported by NSF via Grant DMR 1265162.

11:51 AM T6.00004 Spin-orbit coupling, magnetic anisotropy and hard magnetism in Sr$_3$NiIrO$_6$. VIVIEN ZAPF, National High Magnetic Field Laboratory, MPA-CMMS, Los Alamos National Lab — Strong spin-orbit coupling is a pre-requisite for hard magnetism with high coercive magnetic fields. Magnetic oxides containing 5d ions such as Ir$^{4+}$ should show significant spin-orbit coupling due to the high Z value. Furthermore, in 5d ions, the comparable energy scales of crystal-electric field splitting, Coulomb repulsion and spin-orbit interactions create unusual electronic ground states that can entangle spins and orbits, mix t$_{2g}$ and e$_{g}$ levels and drive magnetic exchange anisotropy. Another set of interesting electronic ground states can arise when 5d orbitals overlap 3d orbitals. In the compound Sr$_3$NiIrO$_6$, electronic structure calculations predict that the 3d orbitals of the Ni$^{3+}$ ion directly overlap 5d orbitals of the Ir$^{4+}$ ion. In addition to a “Jeff = 1/2” Ir$^{4+}$ ground state that mixes t$_{2g}$ and e$_g$ levels, the Ni$^{3+}$ should show strong single-ion anisotropy [1-3]. We present magnetization measurements of Sr$_3$NiIrO$_6$ to high magnetic fields. [4] We demonstrate magnetic hysteresis with a record 55 Tesla coercive magnetic field and long stability over time in some crystals. More generally, the A$_3$BB’O$_6$ family of compounds shows hard magnetism as B’ ion goes from 3d to 4d to 5d. Further complexities to do with evolving magnetic order and magnetic frustration also present in this family.

3 X. Ou and H. Wu, arXiv:1312.7411

12:27 PM T6.00005 Novel Magnetic and Charge Orders in Dimer-Chain Iridate Ba$_5$AlIrO$_{11}$. FENG YE, J. TERZIC, J.C. WANG, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA, W.H. SONG, Institute of Solid State Physics, Chinese Academy of Sciences, Hefei, China, S.J. YUAN, S. ASWARTHAM, G. CAO, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA — We report a novel magnetic state coexisting with a charge ordering state in a dimer-chain system Ba$_5$AlIrO$_{11}$. This newly synthesized single-crystal iridate features both tetravalent Ir$^{4+}$ and pentavalent Ir$^{5+}$ ions in each of dimers that are only linked via AlO$_4$-tetrahedra along the b-axis. Despite the evident one-dimensional characteristic, the dimer-chains undergo an unexpected long-rang order at $T_c$ = 4.5 K with a large magnetic anisotropy. The magnetic transition is unusually resilient to magnetic field up to 14 T but more susceptible to even modest hydrostatic pressure up to 10 kbar. Furthermore, a subtle structural change discerned at $T_S$ =200 K marks a charge ordering that accompanied a huge enhancement in the dielectric constant and changes in the electrical resistivity. It is evident that the strong SOC imposes a j=1/2 (Ir$^{4+}$) and singlet j=0 (Ir$^{5+}$) states in each dimer, which critically hinges on the orbital and lattice degrees of freedom.

1This work was supported by NSF via Grant DMR 1265162.

12:39 PM T6.00006 Giant spin-phonon coupling in a 5d NaOsO$_3$. STUART CALDER, JUN HEE LEE, MATTHEW STONE, MARK LUMSDEN, Oak Ridge National Lab, JONATHAN LANG, APS, MIKHAIL FEYGENSON, Oak Ridge National Lab, YOUGUO SHI, CAS, YIN SUN, YOSHIHIRO TSUGIMOTO, KAZUNARI YAMAURA, NIMS, ANDREW CHRISTIANSON, Oak Ridge National Lab — The coupling of distinct properties offers avenues to multifunctional materials. A limiting factor, however, is the degree that one parameter has to be modified to sufficiently alter the coupled property. Through a neutron scattering and first-principles density functional theory study of the 5d perovskite NaOsO$_3$ we reveal that from only a 0.1% lattice change an unprecedentedly large coupling emerges. The manifestation is a “giant” spin-phonon coupled mode shift of $\Delta J = 40$ cm$^{-1}$, the largest observed in any material. By identifying the dominant phonon as the octahedral breathing mode we show isosymmetric ordering and cooperation between the lattice and the exotic magnetically driven Slater metal-insulator transition in this material. The occurrence of the dramatic spin-phonon-electronic coupling in NaOsO$_3$ is due to a property common to all 5d materials: the large spatial extent of the 5d ion. Consequently examining 5d materials in a new light offers novel routes for multifunctional devices with enhanced coupled phenomena.

12:51 PM T6.00007 Metal-insulator transitions in effective J=1/2 insulating iridates. HONGBIN ZHANG, Rutgers University — The competition between spin-orbit coupling, crystal field splitting and electron correlations with comparable magnitude gives rise to many interesting phenomena. For instance, the so-called effective J=1/2 state has been observed in many iridates compounds, e.g., Ruddlesden-Popper (RP) Sr$_{n+1}$Ir$_n$O$_{3n+1}$ and pyrochlore RE$_2$Ir$_2$O$_7$ (RE=Bi, Pr, Nd, Sm, Eu, Y) iridates, where metal-insulator transitions occur driven by the interplay of electron correlations with magnetic ordering. Using first-principles methods, for correlated solids based on density functional theory and dynamical mean field theory (DMFT+DMFT), we have investigated the metal-insulator transitions in both classes of iridates. We explore the robustness of the effective J=1/2 state against band effects due to itineracy, structural distortion, and strain. We show how single-particle spectra, optical conductivities, and orbital and spin moments change with strain, and we demonstrate that the ground state can be well characterized in terms of an effective energy-dependent J = 1/2 state. For RP compounds, we demonstrate that the crystal field splittings induced by local structural distortions and hybridization are critical to understand previous experimental results. For pyrochlore compounds, the total energies obtained using charge self-consistent DFT+DMFT method reveal that the all-in-all-out magnetic ordering is stable at low temperature in late rare earth pyrochlores, while a bad metallic state is found in early rare earth pyrochlores, in agreement with experiments.

1:27PM T6.00008 Unquenched $e_g^1$ orbital moment in the Mott insulating antiferromagnet KOsO$_4$ $^1$, KWAN-WOO LEE, YOUNG-JOON SONG, KYO-HOON AHN, Department of Applied Physics, Graduate School, Korea Univ, Sejong, Korea, WARREN E. PICKETT, Department of Physics, Univ. of California, Davis, CA, USA — In condensed matter physics, spin-orbit coupling (SOC) has many important consequences, including some recent hot topics such as topological insulators, unconventional metal-insulator transitions, so-called relativistic Mott insulators, large orbital moments, and of course magnetic anisotropy. Whereas SOC in a $e_g$ manifold has been intensively discussed recently, SOC in an $e_g$ manifold has rarely been considered due to the conventional (usually correct) wisdom that an orbital moment is completely quenched in the $e_g$ subshell. In this presentation, using correlated band theory including SOC, we will address effects of SOC in an $e_g^1$ of KOsO$_4$, which contains OsO$_4$ tetrahedra such that the $e_g$ subshell is partially occupied. In contrast to the conventional wisdom, our results show very definite magnetocrystalline anisotropy and unquenched orbital moments of substantial size in KOsO$_4$ (half that of the Os spin moment). We have analyzed and interpreted the origin of the orbital moment on the basis of a small crystal splitting and symmetry breaking (crystalline, and additionally due to SOC itself).

1:39PM T6.00009 Hierarchical stripe phases in IrTe$_2$ driven by competition between Ir dimerization and Te bonding $^2$, WEIIDA WU, JIXIA DAI, KRISTJAN HAULE, Department of Physics and Astronomy, Rutgers University, JUNJIE YANG, Laboratory for Pohang Emergent Materials and Department of Physics, Pohang University of Science and Technology, YOON SEOK OH, SANG WOOK CHEONG, Department of Physics and Astronomy, Rutgers University — Iridium di-telluride (IrTe$_2$) belongs to the family of transition metal dichalcogenides (TMD), but it distinguishes from the traditional TMDs due to the existence of multi-step single-q charge-density wave like phase transitions. Despite of intensive studies, there is still no consensus on the physical origin of the stripe phases or even the ground state modulation for this 5d material. In this study, we present atomic-resolving images and spectroscopic measurements from scanning tunneling microscopy and spectroscopy (STM/STS). We show that the ground state of IrTe$_2$ is a q=1/6 stripe phase, identical to that of the Se-doped compound. Furthermore, our data suggest that the multi-step transitions and the stripe phases are driven by the intralayer Ir-Ir dimerization that competes against the interlayer Te-Te bonding. This competition results in a unified phase diagram with a series of hierarchical modulated stripe phases.

1:51PM T6.00010 Optical evidence for bonding-antibonding splitting in IrTe$_2$ $^3$, DIPANJAN MAZUMDAR, Southern IL Univ-Carbondale,USA, KRISTJAN HAULE, Rutgers University, Piscataway, USA, J.J. YANG, Laboratory for Pohang Emergent Materials and Department of Physics, Korea, G.L. PASCUT, Rutgers University, Piscataway, USA, B.S. HOLINSWORTH, K.R. O’NEAL, University of Tennessee, Knoxville, USA, VALERY KIRYUKHIN, SANG WOOK CHEONG, Rutgers University, Piscataway, USA, J.L. MUSFELDT, University of Tennessee, Knoxville, USA, DEPARTMENT OF CHEMISTRY, UNIVERSITY OF TENNESSEE, KNOXVILLE, USA TEAM, DEPARTMENT OF PHYSICS AND ASTRONOMY, RUTGERS UNIVERSITY, PISCATAWAY, USA TEAM, LABORATORY FOR POHANG EMERGENT MATERIALS AND DEPARTMENT OF PHYSICS, POHANG, KOREA TEAM, RUTGERS CENTER FOR EMERGENT MATERIALS, RUTGERS UNIVERSITY, USA TEAM, SOUTHERN ILLINOIS UNIVERSITY, CARBONDALE, USA TEAM — We combined optical spectroscopy with first principles calculations to reveal the electronic signatures of Ir dimer formation in the 1/5th phase of IrTe$_2$. Our measurements uncover two interband transitions into the unoccupied anti-bonding orbitals, one from mixed Iridium/Tellurium bands, the other from the dxy bonding orbital of the dimerized Ir centers. The bonding-antibonding splitting demonstrates that Iridium, not Tellurium, plays the dominant role in stabilizing the low temperature phase of IrTe$_2$ through localized bonding orbital formation.

2:03PM T6.00011 Spectroscopic evidence for negative electronic compressibility in a quasi-three-dimensional spin-orbit correlated metal $^4$, JUNFENG HE, T. HOGAN, THOMAS MION, Boston College, H. HAFIZ, Northwestern University, Y. HE, Stanford, J.D. DENLINGER, S.-K. MO, ALS, C. DHITAL, X. CHEN, QISEN LIN, Boston College, Y. ZHANG, Peking University, M. HASHIMOTO, SSRL, H. PAN, Boston College, D.H. LU, SSRL, M. ARITA, K. SHIMADA, HISOR, R.S. MARKIEWICZ, Northwestern University, Z. WANG, K. KEMPA, M.J. NAUGHTON, Boston College, A. BANSIL, Northwestern University, S.D. WILSON, RUI-HUA HE, Boston College — In quantum materials consisting of multiple mutually-coupled subsystems, the effective compressibility of one subsystem can be negative when it is countered by the positive compressibility of other subsystems. Manifestations of such negative compressibility in quantum materials have so far been limited to low-dimensional dilute electron systems. The origin of such negative compressibility has been commonly attributed to a dominance of the exchange energy over kinetic energy of electrons. Here we present evidence from ARPES for negative electronic compressibility in a quasi 3D spin-orbit correlated metal, (Sr$_{13}$Ir$_{17}$)$_2$O$_{40}$, which is driven by a dominance of the correlation energy of electrons at a relatively high density. Increased electron filling results in both an expansion of the electron Fermi pockets and an anomalous decrease of the chemical potential. This anomaly, suggestive of negative electronic compressibility, is made possible by a concomitant rapid lowering in energy of the correlated conduction band on which the chemical potential is defined, unveiling a new band picture of doping Mott insulators.

Thursday, March 5, 2015 11:15AM - 2:15PM – Session T7 DMP DCMP: Focus Session: Dirac, Weyl Semimetals, Kondo Insulators 006B - Kai Sun, University of Michigan

11:15AM T7.00001 First Principles Prediction of Topological Phases in Thin Films of Pyrochlore Iridates $^1$, Xiang HU, The University of Texas at Austin, ZHICHENG ZHONG, Vienna University of Technology, GREGORY A. FITE, The University of Texas at Austin — We make materials-specific predictions for topological phases using density functional theory combined with Hartree-Fock theory that includes the full orbital structure of the relevant iridium $d$-orbitals and the strong but finite spin-orbit coupling strength. We find $Y_2$Ir$_2$O$_7$ bilayer and trilayer films grown along the [111] direction can respectively support a $Z_2$ topological metallic phase and a Chern metallic phase with a direct gap of up to 0.02 eV. These results could potentially bring transition metal oxides to the fore as a new class of topological materials with potential applications in oxide electronics.

$^1$Funded by ARO Grant No. W911NF-09-10527, NSF Grant No. DMR-0955778, and DARPA grant No. D13AP00052. TACC provides computational resources.
Furthermore, by in-situ doping, we were able to tune its Fermi-energy, making it a flexible platform for exploring exotic physical phenomena and application potentials.

In addition, the detected Berry phase is found to vary from nontrivial to trivial at different field directions, revealing a fierce competition between the orbit-coupled field strength and the field-generated mass term. Our results demonstrate a feasible path to generate a Weyl semimetal phase based on the TDSs by breaking TRS.

Motivated by recent experiments on Pr$_2$Ir$_2$O$_7$, we provide a theory of quantum oscillations in a minimal model for pyrochlore iridates. Focusing on the conduction electron degrees of freedom with strong spin-orbit coupling and considering the electronic structure near the Fermi level, we compute quantum oscillation signals in the paramagnetic state of the model. We compare our theoretical results with existing experimental data on Pr$_2$Ir$_2$O$_7$ and discuss implication to future experiments.

In-situ synchrotron X-ray and single crystal resistance measurements find that Cd$_3$As$_2$ single crystals under high magnetic fields shows a sign change from negative to positive around 50K upon cooling. R$_H$ peaks and becomes nonlinear in field around 10K then tend to saturate in value below 10K. Two samples with different geometries (thickness and lateral dimensions) show contrasting behaviors below and above 50K, which indicates a surface origin of the low temperature carriers.

Quantum oscillations in magnetically doped SmB$_6$

I.15PM T7.00010 Quantum oscillations in magnetically doped SmB$_6$, GANG LI, COLIN TINSMAN, BENJAMIN LAWSON, FAN YU, TOMOYA ASABA, University of Michigan, XIANGFENG WANG, JOHNPIERRE PAGLIONE, University of Maryland, LU LI, University of Michigan — Quantum oscillation study on pure SmB$_6$ has revealed two-dimensional Fermi Surfaces in both crystalline (001) and (101) surface planes. On the (101) surface plane, only one area of Fermi surface is observed, consistent with theoretical prediction of surface state protected by time-reversal symmetry. It has been further predicted that for the system there is not only time reversal symmetry reservation but also crystalline mirror symmetry reservation that could give rise to protected surface states. By introducing magnetic impurities such as 1% Fe or 1% Ni into SmB$_6$, the magnetic ground state is altered and no longer has the time reversal symmetry. However, quantum oscillations are still observed for both Fe$_x$SmB$_6$ and Ni$_x$SmB$_6$ at higher field, the dispersive angular dependence of frequency will be discussed with comparison to SmB$_6$.

Electronic gap in SmB$_6$ studied by Raman spectroscopy

1:39PM T7.00011 Electronic gap in SmB$_6$ studied by Raman spectroscopy, MICHAEL VALEN'TINE, SEYED KOOPHAYEH, Johns Hopkins University, XIANGFENG WANG, YASUYUKI NAKAJIMA, JOHNPIERRE PAGLIONE, University of Maryland, COLLIN BROHOLM, WILLIAM PHELAN, TYREL MQUEEN, NATALIA DRICHKO, Johns Hopkins University — SmB$_6$ is a mixed valence compound which is suggested to be a topological Kondo insulator. Studies of insulating vs metallic properties of the bulk and the nature of the surface conduction are still ongoing. Using Raman scattering, we follow the opening of an electronic gap in samples of pure SmB$_6$ and SmB$_6$ with Al and C impurities. In all of the samples we observe an electronic gap in the range of 50-65 meV, confirming insulating state in the bulk. The gap appears in the A$_{1g}$+E$_g$ spectra as a suppression of low-frequency electronic scattering and a shift of the spectral weight to frequencies above the gap below approximately 100 K. The size of the gap and presence of electronic states in the gap depend on the method of growth (floating zone vs Al flux), and the chemical composition of the sample. We discuss a dependence of these parameters on the impurities and Sm valence.

Effect of magnetic and non-magnetic substitution in topological Kondo insulator SmB$_6$

2:03PM T7.00013 Effect of magnetic and non-magnetic substitution in topological Kondo insulator SmB$_6$, XIANGFENG WANG, YASUYUKI NAKAJIMA, SHANTA SAHA, JOHNPIERRE PAGLIONE, University of Maryland, College Park, JEFF SONIER, Simon Fraser University, PROF. JOHNPIERRE PAGLIONE TEAM, PROF. JEFF SONIER TEAM — The topological Kondo Insulator SmB$_6$ is believed to be the first realization of a topological insulator with true bulk insulating properties that coexist with a robust conducting surface state that mounting evidence suggests is non-trivial. Here we report of a systemic study of the magnetic and non-magnetic doping effect TKI SmB$_6$, in particular the effect of iron inclusion as well as both magnetic and non-magnetic rare earth substitution in Sm$_1$-RxB$_6$. We will present our careful investigations of crystal structure, transport properties and magnetization, as well as muon spin rotation studies that together suggest a very profound effect on both the bulk and surface state properties.
play an important role for smaller sizes. A. Manjavacas and F.J Garcia de Abajo, Nat. Commun. (2014).

functions. Both approaches result in an excellent agreement for nanodisks with diameters above 13 nm, although quantum confinement and nonlocal effects based on the random-phase approximation (RPA), which we compare with classical simulations obtained solving Maxwell's equations using tabulated dielectric functions. The physical reason for the above behaviors is non-conservation of optically-excited plasmonic carriers is very different in metal nanocrystals with large and small sizes. We found that the hot-electron generation is efficient only for nanocrystals with very small sizes or in nanocrystals with plasmonic hot spots. The level of smearing is controlled by external electric field. The dispersion and electromagnetic field profile of SPs is calculated numerically for different asymmetric smearings. At some point near the smeared interfaces, where dielectric constant is close to zero, strong enhancement of electric field is predicted. Asymmetry of interface smearings breaks the P-symmetry of the system that leads to frequency splitting of SPs. The dispersion and electromagnetic field profile of SPs interfaces is studied for nano-width metallic films with accounting for interface smearing. Smearing is modelled by electron cloud with density decaying exponentially from the metal surface. The level of smearing is controlled by external electric field. 11:39AM T8.00003 Tailoring the surface plasmon propagation in subwavelength cylindrical structures, HUI KIN KWOK, KIN WAH YU, Department of Physics, The Chinese University of Hong Kong — Tailoring the propagation of surface plasmon polaritons (SPPs) in waveguides is useful for subwavelength focusing in photonic circuits. We have studied the wave propagation in an array of subwavelength dielectric cylinders and hollow cylinders immersed in a metallic host. Motivated by Prodan et al.(2003) who proposed the hybridization model for the plasmonic response of cylindrical nanostructures, we extend the study to non-zero off-plane wave number to assess the effect of the hybridization of SPP modes on the wave propagation in cylindrical structures. The hybridization of SPP modes of cylindrical multi-layer or multi-array geometry allows us to tailor the SPP propagation through the proper separation of the dielectric components as well as their sizes. By means of the electro-optic effect, the tunable refractive index of the material increases the flexibility on the operating frequency range of the dispersion relation.

11:51AM T8.00004 Effect of dielectric spacer layers and substrate on SERS with Au nanoparticle arrays, XIN ZHANG, ROBERT M. BRIBER, ODED RABIN1, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742 — The optical response of a plasmonic nanostructure is often highly dependent on the nature of the underlying substrate. To study the effect of the substrate on surface enhanced Raman scattering (SERS), a series of SERS substrates were fabricated consisting of a hexagonal array of Au nanoparticles self-assembled on block copolymer films, a silicon oxide (dielectric) layer and a silicon substrate or an Au substrate. The inter-particle distance and the dielectric layer thickness were controlled. The SERS Enhancement Factors (EF) were calculated by comparing the Raman spectra of 4-aminophenol adsorbed on the surface of the Au nanoparticles and in a standard solution. The SERS EF were found to be strongly affected by the inter-particle distance and silicon oxide thickness. Changing the inter-particle spacing induced a 102 variation in the EF, changing the oxide thickness increased EF values by an factor of 10, and changing substrate from Si to Au increased EF by a factor of 10. Maximal enhancement factors were found with oxide layer thicknesses between 30 nm and 50 nm beneath the 30 nm polymer film with Au substrates. This geometry both improves the resonance condition with the probe laser and reduced the absorption by the substrate. This work illustrates that optimization of plasmonic-based sensors should consider both the metallic and the surrounding structures.

12:03PM T8.00005 Surface plasmon propagation along smeared metal-dielectric interfaces, ANDRII BOZHKO, VLADIMIR DRACHEV, ARKADII KROKHIN, University of North Texas — Propagation of surface plasmons (SPs) along metal-dielectric interfaces is studied for nano-width metallic films with accounting for interface smearing. Smearing is modelled by electron cloud with density decaying exponentially from the metal surface. The level of smearing is controlled by external electric field. The dispersion and electromagnetic field profile of SPs is calculated numerically for different asymmetric smearings. At some point near the smeared interfaces, where dielectric constant is close to zero, strong enhancement of electric field is predicted. Asymmetry of interface smearings breaks the P-symmetry of the system that leads to frequency splitting of SPs. The dispersion and electromagnetic field profile of SPs interfaces is studied for nano-width metallic films with accounting for interface smearing. Smearing is modelled by electron cloud with density decaying exponentially from the metal surface.

12:15PM T8.00006 Generation of hot plasmonic carriers, thermal effects and plasmonic photochemistry in metal nanocrystals, ALEXANDER GOVOROV, Ohio University, HUI ZHANG, Rice University, LUCAS VÁZQUEZ, Ohio University, YURI GUN’KO, University of Dublin, Ireland, MIN OUYANG, University of Maryland — We investigate the effects of generation of hot plasmonic carriers and heat in metal and hybrid nanostructures. In our approach, the problem of hot-electron generation is calculated using the quantum-mechanical approach based on the DFT method and the equation of motion of the density matrix [1], whereas the problem of heat release is treated classically. The energy distribution of optically-excited plasmonic carriers is very different in metal nanocrystals with large and small sizes. We found that the hot-electron generation is efficient only for nanoparticles with very small sizes or in nanocrystals with plasmonic hot spots. The physical reason for the above behavior is non-conservation of momentum in a nanocrystal. Using the newly-developed kinetic DFT theory, we also describe the effect of breaking of the plasmonic resonance into multiple peaks in small nanocrystals. Finally, the generation of plasmonic holes via the interband transitions leads to efficient photochemistry [2]. The results obtained in this study can be used to design a variety of plasmonic nanodevices for photocatalysis and photodetectors.

12:27PM T8.00007 Tunable plasmons in atomically thin gold nanodisks, ALEJANDRO MANJAVacas, Rice University, JAVIER GARCIA DE ABAJO, ICFO-The Institute of Photonic Sciences — The ability to modulate light at high speeds is of paramount importance for telecommunications, information processing, and medical imaging technologies. This has stimulated intense efforts to master optoelectronic switching at visible and near-infrared (vis-NIR) frequencies, although with current computer speeds in integrated architectures still remains a major challenge. Here [1] we show that atomically thin noble metal nanoslands can extend optical modulation to the vis-NIR spectral range. We find plasmons in thin metal nanodisks to produce similar absorption cross-sections as spherical particles of the same diameter. Using realistic levels of electrical doping, plasmons are shifted by about half their width, thus leading to a factor-of-two change in light absorption. These results are supported by a microscopic quantum-mechanical calculations based on the random-phase approximation (RPA), which we compare with classical simulations obtained solving Maxwell’s equations using tabulated dielectric functions. Both approaches result in an excellent agreement for nanodisks with diameter above 13 nm, although quantum confinement and nonlocal effects play an important role for smaller sizes. [1] A. Manjavacas and F.J Garcia de Abajo, Nat. Commun. (2014).

12:39PM T8.00008 Plasmon-induced Hot Carriers in Metallic Nanoparticles1, JUN LIU, ALEJANDRO MANJAVacas, VIKRAM KULKARNI, PETER NORDLANDER, Rice Univ, LANP TEAM — Plasmon-induced hot carrier formation is attracting an increasing research interest due to its potential for applications in photocatalysis, photodetection and solar energy harvesting. Here [1] we develop a theoretical model for the plasmon-induced hot carrier process and apply it to spherical silver nanoparticles and nanoshells. We show that the inclusion of many-body interactions has only a minor influence on the results. Using the model we calculate the rate of hot carrier generation, finding that it closely follows the spectral profile of the plasmon. Our analysis reveals that particle size and hot carrier lifetime play a central role in determining both the production rate and the energy distribution of the hot carriers. We characterize the efficiency of the hot carrier generation process by introducing a figure of merit that measures the number of high energy carriers generated per plasmon. Furthermore, we analyze the spatial distribution and directionality of these excitations. [1] A. Manjavacas, J. G. Liu, V. Kulkarni, P. Nordlander ACS Nano (2014)

3 We acknowledge financial support from the Welch foundation through the J. Evans Attwell-Welch Postdoctoral Fellowship Program of the Smalley Institute of Rice University (Grant No. L-C-004).

12:51PM T8.00009 Bi-anisotropy in a metallic nanoparticle ring1, LIUYANG SUN, TZUHSUAN MA, SEUNG-CHEOL YANG, The University of Texas at Austin, JINWEI SHI, Beijing Normal University, IRVING MARTINEZ, The University of Uexas at El Paso, GAEHANG LEE, Korea Basic Science Institute, GI-RA YI, Sungkyunkwan University, GENNADY SHVETS, XIAOQIN LI, The University of Texas at Austin — Optical bi-anisotropy refers to magnetoelectric coupling effect, where electric (magnetic) polarization is excited by magnetic (electric) field of the incident light, and the induced polarization and incident field are at different directions. In the field of metamaterials, bi-anisotropy effects have been previously examined in various systems with broken symmetry, such as split rings and Pi-shaped or S-shaped resonators. We investigate bi-anisotropy in the visible frequency range in an asymmetric nano-ring system consisting of four nearly identical gold nanoparticles, in which electric and magnetic dipoles interact with each other. We arrange the nanoparticles into a designed ring geometry using atomic force microscopy manipulation method. Using dark field scattering spectroscopy, we observe that the magnetic dipole is either enhanced or suppressed under different excitation conditions. These results are relevant in designing negative index metamaterials, nano-sensors and other plasmonic devices.

1:03PM T8.00010 Non-reciprocal Bands by Symmetry Breaking in One-way Magnetized Plasmonic Double Chain System, CHI WAI LING, KIN HUNG FUNG, The Hong Kong Polytechnic University — Non-reciprocity is a key component to provide one-way propagation in one dimensional (1D) optical waveguides, which enables applications like isolators and switches. Plasmonic chains, formed by spatial periodic metal nanoparticles, are subwavelength 1D optical waveguides. Coupled plasmon modes on the chains are characterized by dispersion relation ω(k), in which k is the wave vector. It has been shown that the spectral reciprocity ω(−k) = ω(k) can be protected by either time reversal (T) or inversion (P) symmetry. However, breaking of (P) and (T) symmetries are not sufficient to achieve ω(−k) ≠ ω(k). We use a magnetized plasmonic double chain system to show that breaking pi-rotation time-reversal (RT) symmetry is also a necessary condition.

1:15PM T8.00011 Controlling spontaneous emission rates of quantum dots with plasmonic nanopatch antennas, THANG HOANG, GLEB AKSELROD, CHRISTOS ARGYROPoulos, JIANI HUANG, DAVID SMITH, MAIKEN MIKKELSEN, Center for Metamaterials and Integrated Plasmonics, Duke University — The radiative processes associated with quantum emitters can be strongly controlled by intense electromagnetic fields created by plasmonic nanostructures. Here, we experimentally demonstrate large enhancements of the spontaneous emission rate of colloidal quantum dots coupled to single plasmonic nanopatch antennas. The antennas consist of silver nanocubes (75 nm) coupled to a gold film separated by a thin polyelectrolyte spacer layer (~1 nm) and core-shell CdSe/ZnS quantum dots (~6 nm). By optimizing the size of the nanopatch antenna, the plasmonic mode is tuned to be in resonance with the quantum dot emission. We show an increase in the spontaneous emission rate by a factor of 880 (Purcell factor) and a 2300-fold enhancement in the total fluorescence while maintaining a high radiative quantum efficiency of ~50 %. The nanopatch antenna, as demonstrated here, offers highly directional and broadband radiation that can be tailored for emitters from the visible to the near infrared, providing a promising approach for the spontaneous emission control of single quantum emitters.

1:27PM T8.00012 Probing plasmons in three dimensions in a scanning transmission electron microscope1, JORDAN HACHTEL, Vanderbilt University, ANAS MOUTI, Oak Ridge National Laboratory, DANIEL MAYO, CLAIRE MARVINNEY, Van- derbilt University, RICHARD MU, Fisk University, RICHARD HAGLUND, Vanderbilt University, STEPHEN PENNYCOOK, University of Tennessee, MATTHEW CHISHOLM, Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University — The optical behavior of nanostructured materials is of significant interest across many fields. Surface plasmons and their interactions with emitters in nanoscale devices allow us to control light below the coherence limit. By understanding the nature of plasmonics at the local level we can move towards unlocking the full potential of photonic devices. To this end, we examine plasmonic Ag nanoparticles suspended on insulating nanowires by combining cathodoluminescence spectroscopy, electron energy loss spectroscopy, and high resolution annular dark field imaging in a scanning transmission electron microscope. The complementary nature of CL and EELS allow us to extract optical data from a randomly shaped and oriented nanoparticle, and understand its plasmonic behavior in all three spatial dimensions.

1:39PM T8.00013 Band modulation and in-plane propagation of surface plasmons in composite nanostructures, REN-HAO FAN, DI-HU XU, KUN ZHANG, RU-WEN PENG, MU WANG, Nanjing University — In this work, we have experimentally and theoretically studied band modulation and in-plane propagation of surface plasmons (SPs) in composite nanostructures with aperture arrays and metallic gratings. It is shown that the plasmonic band structure of the composite system can be significantly modulated because of coupling between the aperture and the grating. By changing the relative positions between these optical components, the resonant modes would shift or split. And the resonant SP modes launched on the structure surface can be effectively modified by the geometric parameters. Further, we provide an experimental observation to directly show the SP in-plane propagation by using far-field measurements. Our study offers a convenient way for observing the SP propagation in far field, and provides unique composite nanostructures for possible applications in subwavelength optodevices, such as optical sensors and detectors.

1:51PM T8.00014 ABSTRACT WITHDRAWN
2:03PM T8.00015 Study on electrostatic resonance of nanoprisms with sharp corners. WAI SOEN CHAN, KA KI NG, KIN WAH YU, Department of Physics, The Chinese University of Hong Kong — We have studied the electrostatic resonance of metal nanoprisms with sharp corners numerically. We consider an infinite metal cylinder with polygonal base, e.g. square. The incident electric field lies in the plane of cross-section of the cylinder. Yu and co-workers proposed Green’s function formalism (GFF) to numerically calculate the electric potential and field distribution in plasmonic systems. We will adopt the scheme to demonstrate the effect of sharp corners, particularly on the effect of electrostatic resonance spectrum, as in the spectral analysis proposed by Bergman and Milton. Hetherington and Thorpe investigated the conductivity of a sheet containing dilute inclusion with sharp corners, they made use of a conformal mapping approach to calculate the conductivity from circular inclusions. Helsing, McPhedran and Milton also investigated the optical properties of a metamaterial lattice with inclusions having sharp corners. We study the possibility of improving numerical accuracy by combining the conformal mapping approach and GFF. We may extend similar approach to investigate the properties of plasmonic systems, for examples nanobottles and nanostars.

Session T9 FLAP: Physics and Applications of Photonics and Lasers 006D - Aleksei Zheltikov, Texas A&M University

11:15AM T9.00001 Formation of a single attosecond pulse from the resonant XUV radiation on a steep front edge of a strong IR field. TIMUR AKHMEDZHANOV, Department of Physics and Astronomy, Texas A&M University and Institute for Quantum Studies and Engineering, College Station, TX, VLADIMIR ANTONOV, Institute of Applied Physics of the Russian Academy of Sciences, Nizhny Novgorod, Russia, OLGA KOCHAROVSKAYA, Department of Physics and Astronomy, Texas A&M University and Institute for Quantum Studies and Engineering, College Station, TX — Formation of isolated attosecond pulses is one of the key aims of modern optics. Such pulses with the carrier frequency below the threshold of atomic ionization would provide a tool for studying ultrafast bound dynamics of atoms and molecules. Recently, a mechanism to form a single attosecond pulse from an incident XUV radiation via abrupt interruption of its resonant interaction with hydrogen-like atoms on a steep front edge of a strong IR field was proposed [Phys. Rev. Lett. 110, 213903 (2013)]. If the front edge of the IR field is steep enough, the atoms, essentially unaffected by the IR field during one half-period, can be completely ionized during subsequent half-period of the IR field. Thus, the transient multifrequency atomic response to the XUV radiation is limited to an ultrashort time interval, providing the possibility for attosecond pulse formation. In this contribution, we present the results of solution of time-dependent Schrodinger equation for H atoms simultaneously irradiated by the resonant XUV field and a pulse of strong IR field with steep front edge, which show the possibility to form an isolated attosecond pulse with duration on the order of few hundred attoseconds under the experimentally feasible conditions.

11:27AM T9.00002 Optical breakdown criterion for single-cycle laser pulses. PETER ZHOKHOV, ALEKSEI ZHELTIKOV, Physics & Astronomy Department, Texas A&M University — The Keldysh theory of photoionization in solids is generalized to the case of arbitrarily short driving pulses of any shape or polarization. We derive a closed-form solution for the nonadiabatic ionization rate and field-driven currents in the solid-state electron-hole plasma. Using this framework, we propose a new criterion for optical breakdown of solids that depends on the pulse shape and is applicable to laser pulses as short as a single optical cycle.

11:39AM T9.00003 Large Optical Nonlinearity Induced by Singlet Fission in Pentacene Films1, YUNLONG LIU, CHUNFENG ZHANG, Nanjing Univ, MIN XIAO, Nanjing Univ; University of Arkansas — By creating two triplet excitons from one photoexcited singlet exciton, singlet fission in organic semiconductors has drawn tremendous attention for its potential application in boosting the efficiency of solar conversion. Here, we show that this carrier-multiplication effect can be used to dramatically improve the nonlinear optical response in organic materials. With the technique of dual-wavelength optical Kerr effect (OKE), we have observed large optical nonlinearity with a magnitude of $\chi^{(3)}$ up to $10^{-9}$ esu in pentacene films, which is further shown to be a result of singlet fission as demonstrated by the detailed temporal dynamics and wavelength dependence experiment. Through the use of optical heterodyne detected OKE experiment, we have determined both the sign and value of $\chi^{(3)}$ of the pentacene film. Such efficient third order nonlinear optical response has been successfully applied to demonstrate the all-optical switching. The results observed in this work indicate that the singlet fission could be served as an effective strategy to promote the optical nonlinearity in organic molecule systems.

This work is supported by the National Basic Research Program of China (2013CB932903 and 2012CB921801, MOST), the National Science Foundation of China (91233103, 61108001, 11227406 and 11321063)

11:51AM T9.00004 Incorporation of C in Cu for the Fabrication of Transparent Electrodes1, ROMAINE ISAACS, HONG LI ZHU, COLIN PRESTON, PETER ZAVALLI, University of Maryland, AZZAM MANSOUR, Naval Surface Warfare Center, MELBS LEMIEUX, LIANGBING HU, LOURDES SALAMANCA-RIBA, University of Maryland — The incorporation of carbon nanostructures into the copper lattice has the potential to improve the current density of copper to meet the ever-increasing demands of nanoelectronic devices. We report on the structure and properties of a new material formed by the incorporation of carbon in concentrations up to 10 wt% into the crystal structure of copper that we refer to as "Cu covetic". The carbon does not phase separate after subsequent melting and re-solidification despite the absence of a predicted solid solution at such concentrations in the binary phase diagram. Bulk samples, as well as thin films grown at room temperature and high temperature are investigated. X-ray photoelectron spectroscopy (XPS) confirmed that C incorporates in the bulk of the Cu. Transmission Electron Microscopy (TEM) shows that C forms a modulated structure in the crystal lattice, and Electron Energy Loss Spectroscopy (EELS) indicates that C-K edge is graphicitic nature with sp2 bonding. Copper covetic films exhibit greater transparency, higher conductivity, and resistance to oxidation than pure copper films of the same thickness, making them a suitable choice for transparent conductors.

1Supported by DARPA/ARL under Grant No. W911NF-13-1-0058 and ONR under grant N000141410042.

12:03PM T9.00005 Reflective Optical Limiter Based on Resonant Transmission1, ELEANA MAIKRI, TSAMPIKOS KOTTOS, Department of Physics, Wesleyan University, Middletown CT-06459, USA, ILYA VITEBSKIY, Air Force Research Laboratory, Sensors Directorate, Wright Patterson AFB, OH 45433 USA — Optical limiters transmit low-level radiation while blocking electromagnetic pulses with excessively high energy (energy limiters) or with excessively high peak intensity (power limiters). A typical optical limiter absorbs most of the high-level radiation which can cause its overheating and destruction. Here we introduce the novel concept of a reflective energy limiter which blocks electromagnetic pulses with excessively high total energy by reflecting them back to space, rather than absorbing them. The idea is to use a defect layer with temperature dependent loss tangent embedded in a low-loss photonic structure. The low energy pulses with central frequency close to that of the localized defect mode will pass through. But if the cumulative energy carried by the pulse exceeds certain level, the entire photonic structure becomes highly reflective (not absorptive!) within a broad frequency range. The underlying physical mechanism is based on self-regulated impedance mismatch which increases dramatically with the cumulative energy carried by the pulse.

1AFOSR MURI FA9550-14-1-0037
12:15PM T9.00006 Coupling control based on Adiabatic elimination for densely integrated nano-photonics — MICHAEL MREJEN, HAIM SUCHOWSKI, TAIKI HATAKEYAMA, CHIH-HUI WU, LIANG FENG, KEVIN O’BRIEN, YUAN WANG, XIANG ZHANG, NSF Nanophotonics Science and Engineering Center (NSEC), 3112 Etcheverry Hall, University of California, Berkeley — The ever growing need for energy-efficient and fast communications is driving the development of highly integrated photonic circuits where controlling light at the nanoscale becomes the most critical aspect of information transfer. Here we develop a unique scheme of adiabatic elimination (AE) modulation to actively control the coupling among waveguides for densely integrated photonics. Analogous to atomic systems, AE is achieved by applying a decomposition on a three waveguide coupler, where the two outer waveguides serve as an effective two-mode system with an effective coupling of \( V_{eff} = \left[ (V_{1}^{*} + V_{2}^{*} + V_{3}^{*})^2 / 2 \right] [n_1 - V_1 + V_2]/2 \), and the middle waveguide is the equivalent to the intermediate level ‘dark state’. We experimentally demonstrate the first all optical AE modulation and its ability to control the coupling between the two waveguides by manipulating the mode index of the decoupled middle one. In addition, we show that the strong modes interactions allowed at the nano-scale offer a unique configuration of zero-coupling between all the waveguides, a phenomena that paves the way for ultra-high density photonic integrated circuits where small footprint is of crucial importance.

12:27PM T9.00007 A Moiré Cavity Plasmonic Dye Laser — ERTUGRUL KARADEMIR, Department of Physics, Bilkent University, 06800 Ankara, Turkey, SINAN BALCI, Department of Astronautical Engineering, University of Turkish Aeronautical Association, 06790 Ankara, Turkey, COSKUN KOCABAS, ATILLA AYDINLI, Department of Physics, Bilkent University, 06800 Ankara, Turkey — From its first conception [1] to its first demonstration, [2] plasmonic lasers have been an intriguing topic of research. In this work, Moiré gratings which manifest a cavity state in the SPP dispersion curve [3]. We used a reverse Kretschmann setup to decouple the amplified light component of SPPs. We employed a Moiré cavity with 250 nm periods and four period structures, respectively, with a peak wavelength of 614 nm in the four period device. Since each layer of a period has a different refractive index, constructive interference from the total reflected portion of light can be investigated to create effective reflectors. The DBR's can be made to act as optical mirrors to enhance certain wavelengths of light to be highly reflected. Due to the high refractive optical structure can be paired with a superpartner with similar guided wave and scattering properties. As a result, the guided mode spectra of these optical waveguide systems can be judiciously engineered so as to realize new families of mode filters and mode division multiplexers and demultiplexers. Here we show that the concept of supercavity can be used to synthesize scattering settings with identical scattering properties, thus giving rise to an entirely new class of transformation optics. By systematically eliminating all bound states, scattering arrangements with a low refractive index contrast can be designed to faithfully mimic the scattering behavior of high-contrast structures. Similar strategies can be used to replace negative-permittivity domains, thus avoiding unwanted optical losses.

12:39PM T9.00008 Supersymmetry and transformation optics — MOHAMMAD-ALI MIRO, MATTHIAS HEINRICH, DEMETRIOS CHRYSTODOLIDES, CRÉOL. The College of Optics and Photonics, University of Central Florida, NONLINEAR WAVE GROUP TEAM — Supersymmetry (SUSY) originated within the framework of quantum field theory as a means to treat fermions and bosons on an equal footing. While the verification of such theories remain an ongoing challenge in particle physics, some of their fundamental notions have been successfully adapted to other fields. As shown recently, optics can provide a versatile platform where the implications of supersymmetric transformations can be studied and observed. In this regard, any optical structure can be paired with any other structure with similar guided wave and scattering properties. As a result, the guided mode spectra of these optical waveguide systems can be judiciously engineered so as to realize new families of mode filters and mode division multiplexers and demultiplexers. Here we show that the concept of supercavity can be used to synthesize scattering settings with identical scattering properties, thus giving rise to an entirely new class of transformation optics. By systematically eliminating all bound states, scattering arrangements with a low refractive index contrast can be designed to faithfully mimic the scattering behavior of high-contrast structures. Similar strategies can be used to replace negative-permittivity domains, thus avoiding unwanted optical losses.

12:51PM T9.00009 Controlling modal interactions in lasers for frequency selection and power enhancement — LI GE, College of Staten Island/Graduate Center, CUNY — The laser is an out-of-equilibrium non-linear wave system where the interplay of the cavity geometry and non-linear wave interactions determines the self-organized oscillation frequencies and the associated spatial field patterns. Using the correspondence between nonlinear and linear systems, we propose a simple and systematic method to achieve selective excitation of lasing modes that would have been dwarfed by more dominant ones. The key idea is incorporating the control of modal interaction into the spatial pump profile. Our proposal is most valuable in the regime of spatially and spectrally overlapping modes, which can lead to a significant enhancement of laser power as well.

1:03PM T9.00010 Retrieval of contaminated information using random lasers — JINWEI SHI, DAHE LIU, Beijing Normal University, LIBIN CUI, Beijing Normal University and Beijing University of Technology — Data retrieval is an important information processing task. The most commonly used method in optical information processing is spatial filtering based on Fourier optics. However, these methods are very difficult to implement in practical applications. Over the last two decades, random lasers due to its cavity free property have attracted widespread attention. Some potential applications have been proposed; however, few actual applications were reported. Here we develop an information retrieval method based on random lasers, where the spatial frequency spectrum of a contaminated Fourier transform hologram can be obtained by detecting the temporal frequency spectrum information from random lasing. The hologram information can be reconstructed from an inverse Fourier transform of the spatial frequency spectrum obtained after data processing. It is shown that random lasers can be used for information retrieval, and may potentially find applications in information optics and optical data storage.

1:15PM T9.00011 Reflectivity Calculations on Hybrid-layered CdS/PVK Distributed Bragg Reflectors — JAVIER HASBUN, AJITH DESILVA, University of West Georgia — In this study we apply the Born theory [1] of wave propagation on a stratified medium to obtain the reflectivity and transmissivity of a series of distributed Bragg reflectors (DBR). The DBR's are made of pairs of identical alternating layers. Each pair of layers is referred to as a period. Thus, we grow DBR's of one, two, three, and four periods and study their reflectivity properties. Since each layer of a period has a different refractive index, constructive interference from the total reflected portion of light can be investigated to create effective reflectors. The DBR's can be made to act as optical mirrors to enhance certain wavelengths of light to be highly reflected. Due to the high refractive index difference between polyvinyl carbazole (PVK), index 1.853 and cadmium sulfide CdS (index 2.5), a greater reflectivity can be obtained from the structure for fewer periods. The constructed DBR data show theoretically fitted reflectivities with reflectances of about 27%, 51%, 64%, and 80% for the one, two, three, and four period structures, respectively, with a peak wavelength of 614 nm in the four period device.

The authors wish to thank the UWG-UWISE minigrant program for their support.
which forms a natural multilayer heterostructure consisting of a TI and an ordinary insulator. For heterostructures is a new promising strategy for manipulating the topological states and realizing exotic quantum phenomena. In this work, with recently discovered topological phase transition in (Bi$_2$Se$_3$)$_m$ and insulating bulk. If it is possible to manipulate the two coexisting states, then it should form an ideal laboratory for realizing a topologically tunable Fano system. The asymmetric Fano profile, suggesting potentials toward optically controllable topological Fano systems. By engineering the spatial overlap between surface Dirac electrons and bulk phonon, we continuously tune, abruptly switch, and dynamically modulate the sequence of layers or insert different building blocks into the crystal. We have performed angle-resolved photoemission spectroscopy on (PbSe)$_2$(Bi$_2$Se$_3$)$_3$ to test this hypothesis. The results demonstrate that utilizing of TI heterostructures is a new promising strategy for manipulating the topological states and realizing exotic quantum phenomena.

**Thursday, March 5, 2015 11:15AM - 2:15PM**

**Session T10 DCMP: Topological Insulators: Synthesis**

007A - Yasuyuki Nakajima, University of Maryland

**11:15AM T10.00001 Manipulation of topological states in a topological-insulator heterostructure** — YUSUKE TANAKA, KOSUKE NAKAYAMA, TAKAFUMI SATO, Department of Physics, Tohoku University, SEIGO SOUMA, WPI-AIMR, Tohoku University, TAKASHI TAKAHASHI, Department of Physics, Tohoku University, KAZUMA ETO, SATOSHI SASAKI, KOJI SEGAWA, YOICHI ANDO, ISIR, Osaka University — The Dirac fermions in the Topological insulators (TIs) are immune to backward scattering by nonmagnetic impurities or disorder. While experimental realizations of novel topological phenomena depend crucially on the inherent robustness of the topological surface states against perturbations, it turned out to be difficult to maintain stable surface properties under ambient atmosphere. This situation has been a hindrance for realizing novel topological phenomena and device applications of TIs. We present a novel approach to solve this problem— the heterostructure engineering where one can alter the stacking sequence of layers or insert different building blocks into the crystal. We have performed angle-resolved photoemission spectroscopy on (PbSe)$_2$(Bi$_2$Se$_3$)$_3$ to test this hypothesis. The results demonstrate that utilization of TI heterostructures is a new promising strategy for manipulating the topological states and realizing exotic quantum phenomena.

**11:27AM T10.00002 Topologically tunable ultrafast Fano interference dynamics** — SANGWAN SIM, School of Electrical and Electronic Engineering, Yonsei University, Korea, NIKESH KOIRALA, MATTHEW BRAHLEK, Department of Physics and Astronomy, Rutgers the State University of New Jersey, USA. JUN PARK, SOONYOUNG CHA, School of Electrical and Electronic Engineering, Yonsei University, Korea, SEONGSHIK OH, Department of Physics and Astronomy, Rutgers the State University of New Jersey, USA. HYUNYONG CHOI, School of Electrical and Electronic Engineering, Yonsei University, Korea — Asymmetric Fano resonance arises from interference between continuum and discrete state. The asymmetric profile has attracted strong interests in understanding light-induced optoelectronic responses and corresponding applications. In conventional solids, however, the tunability of Fano resonance is generally limited by material’s intrinsic property. Topological insulator is unique class of matters embodying both conducting Dirac surface and insulating bulk. If it is possible to manipulate the two coexisting states, then it should form an ideal laboratory for realizing a topologically tunable Fano system. In this work, with recently discovered topological phase transition in (Bi$_2$Se$_3$)$_m$, we report novel Fano interference phenomena. By engineering the spatial overlap between surface Dirac electrons and bulk phonon, we continuously tune, abruptly switch, and dynamically modulate the Fano profile. Ultrafast optical-pump terahertz-probe spectroscopy reveals that the controlled spatial overlap is responsible for the picosecond tunability of the asymmetric Fano profile, suggesting potentials toward optically controllable topological Fano systems.
11:39AM T10.00003 Adsorption and dissociation of H2O molecules on the topological insulator surface, Bi2Se3 (111)1, EUN-HA SHIN, HANCHUL KIM, Sookmyung Women’s University — Three-dimensional strong topological insulators (TIs) such as Bi2Se3, Bi2Te3 and Bi2SBi are intriguing for their surface metallicity in contrast to the insulating bulk. The metallic surface states of TI are known to be topologically protected and robust for impurities and disorders. In this work, we report first-principles calculations on the adsorption and dissociation of H2O molecules on Bi2Se3 (111) to understand the chemical reactivity and the effect of oxidation on the surface metallicity. On the pristine (111) surface, H2O molecule is found to chemisorb on a subsurface Bi atom and form two additional hydrogen bonds with neighboring surface Se atoms. The adsorbed H2O molecule can be dissociated into a hydroxyl (OH) and H. The dissociated OH takes a surface Se site, and pushes up the Se atom that is bonded with the dissociated H. We examined a subsequent dissociation reaction of OH. The final reaction products are a substitutional O (Osub) and an H2Se molecule floating in the vacuum. By examining the electronic structure, we found that the chemisorbed OH induces n-type doping. On the other hand, the Osub and the adsorbed H2O result in p-type doping. Throughout the whole chemical processes studied, the metallic surface state remains intact.

11:51AM T10.00004 Flexible Thermoelectric Fabrics Based on Layered Topological Insulator Bi2Se3 Nanoplates/Polyvinylidene Fluoride Composite1, CHAOCHAO DUN, COREY HEWITT, HUIHUI HUANG, DAVID CARROLL, Center for Nanotechnology and Molecular Materials, Department of Physics, Wake Forest University, Winston-Salem, NC 27109, U. S. — We report a highly-flexible and ultrathin thermoelectric fabrics based on topological insulator (TI) Bi2Se3 Nanoplates/PVDF Composite, which show a room temperature Seebeck coefficient, electrical conductivity, and figure of merit ZT ∼ 0.2 W/(mK), 5000 S/m, 0.02, respectively. This results demonstrate that Bi2Se3 Nanoplates/PVDF composite exhibit favorable thermoelectric characteristics, which opens a new avenue to fabricate highly-flexible and lightweight sustainable energy sources that could be compatible with portable/wearable electronic devices. The low thermal conductivity of the composites (∼ 0.42 W/(mK)) suggests the nonconducting host polymer matrix PVDF serves to bind the conducting topological insulator (TI) Bi2Se3, while still maintaining an adequate power factor and figure of merit. The flexible thermoelectric fabrics based on layered topological insulator Bi2Se3 Nanoplates/PVDF composite that with comparable thermoelctrical efficiency is only a typical example that showing the promising of the present method for further applications of 2D topological insulator like Bi2Se3, Bi2Te3 and Sb2Te3. At their current performance, if enough thermal energy is available, the composites could be used to provide sufficient thermoelectric power for low powered personal and portable electronics.

12:03PM T10.00005 Fermi level tuning and weak localization/weak antilocalization competition of bulk single crystalline Bi1−xSb2xTe compounds, WONHYUK SHON, JONGSOO RHYE, Kyung Hee Univ — In the investigation of the electrical transport properties of single crystalline Bi1−xSb2xTe (x = 0.0, 0.6, 0.8, 1.0, 1.2, and 1.4) compounds, we observed a systematic change of the Fermi level from n-type metallic (x = 0.0, 0.6) or small-gap semiconducting (x = 0.8) to p-type semiconducting (x = 1.0) and metallic (x = 1.2, 1.4), respectively, with increasing Sb-substitution concentration from the temperature-dependent electrical resistivity ρ(T) and Hall resistivity ρxy(T) measurements, respectively. The parent compound Bi2Te3 exhibits linear negative magnetoresistance measurements at low temperatures. From the Hikami-Larkin-Nagaoka analysis of the compounds (x = 0.8 and 1.0), we found that there is a competing behavior between WL and WAL in terms of Sb-doping and magnetic field strength.

12:15PM T10.00006 Emergence of Decoupled Surface Transport Channels in Bulk Insulating Bi2Se3 Thin Films, MATTHEW BRAHLEK, NIKESH KOIRALA, MARYAM SALEHI, NAMRATA BANSAL, SEONGSHIK OH, Rutgers Univ — In ideal topological insulator (TI) films the bulk state, which is supposed to be insulating, should not provide any electric coupling between the two metallic surfaces. However, transport studies on existing TI films show that the topological states on opposite surfaces are electrically tied to each other at thicknesses far greater than the direct coupling limit where the surface wave functions overlap. Here, we show that as the conducting bulk channels are suppressed, the parasitic coupling effect diminishes, and the decoupled surface channels emerge as expected for ideal TIs. In Bi2Se3 thin films with fully suppressed bulk states, the two surfaces, which are directly coupled below ∼10 QL, become gradually isolated with increasing thickness and are completely decoupled beyond ∼ 20 QL. On such a platform, it is now feasible to implement transport devices whose functionality relies on accessing the individual surface layers without any deleterious coupling effects.

12:27PM T10.00007 ABSTRACT WITHDRAWN —

12:39PM T10.00008 Epitaxial Growth of Artificial Graphene on Conventional Semiconductor Surface towards Room Temperature Topological Quantum States1, MIAO ZHOU, WENMEI MING, ZHENG LIU, ZHENGFEI WANG, FENG LIU, University of Utah — Graphene is a 2D hexagonal lattice made of sp2 hybridized carbon. Fundamental understanding of graphene has recently spurred a surge of searching for 2D topological quantum phases in solid-state materials. Here we demonstrate the epitaxial growth of artificial graphene, in which the carbon atoms are replaced by other elements, on conventional semiconductor surface to realize large-gap topological quantum phases. We show that Si(111) surface functionalized with 1/3 monolayer of halogen atoms [Si(111)-3√3×√3X (X=C1, Br, I)] exhibiting a trigonal superstructure, provides an ideal template for epitaxial growth of heavy metals, such as Bi, which self-assemble into a hexagonal lattice with high kinetic and thermodynamic stability. Remarkably, the Bi overlayer show the feature of a (Osub)2 and an H2Se molecule floating in the vacuum. By examining the electronic structure, we found that the chemisorbed OH induces n-type doping. On the other hand, the Osub and the adsorbed H2O result in p-type doping. Throughout the whole chemical processes studied, the metallic surface state remains intact.

1This research was supported by DOE (Grant No: DEF02-04ER46148).

12:51PM T10.00009 Population dynamics of Floquet-Bloch states on the surface of a topological insulator, FAHAD MAHMOOD, DILLON GARDNER, Massachusetts Inst of Tech-MIT, YEW SAN HOR, Missouri University of Science and Technology, YOUNG LEE, NUH GEDIK, Massachusetts Inst of Tech-MIT — Floquet-Bloch bands emerge in solid-state systems due to a coherent interaction between light and matter. Using time and angle resolved photoemission spectroscopy; we demonstrate that intense ultrashort midinfrared pulses hydrbide with the surface Dirac fermions of a topological insulator to form states periodic in both momentum and energy. These states exhibit band gaps at avoided crossings which are dependent on the incident light polarization and the electron momentum. Circularly polarized light induces an additional gap at the Dirac point by naturally breaking time reversal symmetry. We further characterize these bands as a function of the incident light intensity and pump-probe delay time to understand the excitation and decay mechanisms of electrons in the Floquet-Bloch states.
1:03PM T10.00010 Surface and interface states of Bi$_2$Se$_3$ thin films investigated by second harmonic generation. SUN YOUNG HAMH, SOON-HEE PARK, JONG SEOK LEE, Department of Physics and Photon Science, Gwangju Institute of Science and Technology, Gwangju 500-712, Korea, JEONG HEUM JEON, SE-JONG KHANG, Department of Physics, Korea University, 136-713, Korea, KWANGNAM YU, ENJIP CHOI, Department of Physics, University of Seoul, Seoul 130-743 Korea, SEONGSHIK OH, Department of Physics and Astronomy, Rutgers, the State University of New Jersey, Piscataway, New Jersey 08854, USA, SUNG KIM, SUK-HO CHOI, Department of Applied Physics, College of Applied Science, Kyung Hee University, Yongin 446-701, Korea, JOONBUM PARK, JUN SUNG KIM, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea — Topological insulators (TIs) behave as a charge-gapped insulator in its interior, but hosting a spin-momentum-locked Dirac state at the surface. When the Fermi level crosses over conduction/valence band, undesirable bulk charge transport disturbs to explore the surface nature, so that thin film TIs have been highlighted as a method to reduce bulk carrier effect due to large surface to volume ratio. In this presentation, we discuss surface and/or interface states for Bi$_2$Se$_3$ in form of field by exploiting second harmonic generation technique. Based on nonlinear susceptibility deduced from the model fitting, we investigate the details of band bending such as its direction and strength which were further addressed by examining terahertz field profile emitted from the sample. Finally, we discuss the evolution of these properties as a function of film thickness.

1:15PM T10.00011 Investigation of the Dirac states in a topological insulator, Bi(2)Se(3). DEEPNARAYAN BISWAS, SANGEETA THAKUR, KHADIZA ALI, Tata Institute of Fundamental Research, G. BALAKRISHNAN, University of Warwick, KALOBARAN MAITI, Tata Institute of Fundamental Research. — Topological insulators are bulk insulators with metallic surface states protected by time reversal symmetry. These surface states are spin-polarized, backscattering free and exhibit Dirac cone in their energy band structure, and thus are potential candidates for technological advances and realizing exotic phenomena. However, experiments show appearance of such topological order on the surface of metallic bulk and instability of the Dirac states in most of the materials studied. Thus, doping foreign elements to engineer the electronic states and get access to the surface states has become an outstanding problem. We studied the detailed electronic structure of Bi$_2$Se$_3$ using ARPES and DFT calculations and observe different behavior for different surface terminations. Se terminated surface exhibits an electron doping scenario with aging in contrast to the hole doped scenario in Bi terminated surface. The Dirac cone on Bi terminated surface is found to be most stable even in presence of impurities and is most suitable to observe different behavior for different surface terminations. In all devices, the upper and lower surface states are independently tunable to the Dirac point by the top and bottom gate electrodes. In thin devices, electric fields are found to penetrate through the bulk, indicating finite capacitive coupling between the surface states. A charging model allows us to use the penetrating electric field as a measure of the intersurface capacitance $C_{TT}$ and the surface state energy-density relationship $\mu(n)$, which is found to be consistent with independent angle-resolved photoemission spectroscopy measurements. At magnetic fields, increased field penetration through the surface states is observed, strongly suggestive of the opening of a surface state band gap due to broken time-reversal symmetry.

1:39PM T10.00013 A top-down approach to prepare bismuth bi-layer terminated Bi$_2$Se$_3$(0001). ROOZBEH SHOKRI, HOLGER, L. MEYERHEIM, SIMULAY ROY, KATAYÖN MOHSENEN, ARTHUR ERNST, Max-Planck-Institut für Mikrostrukturphysik, D-06120 Halle, Germany, MIKHAILO M. OTROKOV, EVGENI V. CHULKOV, Departamento de Física de Materiales UPV/EHU, Centro de Física de Materiales CFM · MPC and Centro Mixto CSIC-UPV/EHU, Spain, JÜRGEN KIRSCHNER, Max-Planck-Institut für Mikrostrukturphysik, D-06120 Halle, Germany — A bi-layer of bismuth (Bi) in the (111) plane possesses strong spin-orbit coupling and represents a prototype 2D topological insulator (TI). In this study, we propose a novel top-down approach to prepare Bi on 3D TI Bi$_2$Se$_3$(0001). Combining scanning tunneling microscopy, X-ray crystal truncation rod analysis and Auger electron spectroscopy we demonstrate that under controlled exposure of Bi$_2$Se$_3$ to atomic hydrogen flux the selenium is removed from the topmost quintuple layer and a flat Bi bi-layer terminated Bi$_2$Se$_3$, with Bi$_2$Se$_3$-terrace-size lateral extension is achieved. Our results suggest new perspectives to manipulate the electro-optical properties of both Bi and Bi$_2$Se$_3$ TIs.

1:51PM T10.00014 Efficient Dual-Gate Tuning of Fermi Level in Thin-Film Topological Insulator. ALEXEY TASKIN, FAN YANG, SATOSHI SASAKI, KOJU SEGAWA, YASUHIDE OHNO, KAZUHIKO MATSUMOTO, YOICHI ANDO, Osaka University, ISIR TEAM — Experimental studies of novel quantum phenomena predicted for three-dimensional (3D) topological insulators (TI) often require tuning of the Fermi level across the Dirac point. Both back gating and top gating techniques have been successfully applied to 3D TI thin films, however, with a single gate the chemical potential of only one surface can be controlled effectively, which is not sufficient for many applications. Recently, we have succeeded in developing a comprehensive method for fabricating dual-gated devices on TI thin films grown by molecular beam epitaxy. The method combines 1) the transfer of a high-quality bulk-insulating (Bi$_2$Se$_3$)$_x$(SiO$_2$)$_{1-x}$ thin film grown on sapphire onto a SiO$_2$/Si wafer, which serves as a back gate, and 2) the fabrication of a top gate by using a low-temperature deposition of SiN$_x$. We demonstrate that the dual gating allows effective tuning of the chemical potentials of the top and bottom surfaces across the Dirac point, which is manifested in a large peak of the sheet resistance accompanied by a sharp sign change of $R_{xy}$ upon sweeping the top and bottom gate voltages. This dual-gating method opens exciting opportunities for realization of various novel phenomena expected for 3D TIs.

2:03PM T10.00015 Air-Stable Electron Depletion of Bi$_2$Se$_3$ into the Topological Regime using Molybdenum Trioxide. JACK HELLERSTEEDT, Monash University and University of Maryland, MARK T. EDMONDS, Monash University, ANTON TADICH, Australian Synchrotron, ALAN SCHENK, Monash University, JARENE M. O’DONNELL, Australian Synchrotron, JACOB TOSADO, Monash University and University of Maryland, NICHOLAS P. BUTCH, National Institute of Standards and Technology, PAUL SYERS, JOHNPIERRE PAGLIONE, University of Maryland, MICHAEL S. FUHRER, Monash University and University of Maryland — Bismuth selenide (Bi$_2$Se$_3$) is a three-dimensional strong topological insulator of particular interest due to its relatively large bulk band gap (300 meV) and single set of topologically non-trivial surface states. However, persistent doping makes routine electronic access to the topological regime difficult. Here we explore surface transfer doping via molecular deposition as a route to bring the Fermi level into the topological regime and protect against ambient degradation. Bi$_2$Se$_3$ single crystals are cleaned in ultra-high vacuum and X-ray photoemission spectroscopy is used to measure the shifts in work function, Bi core levels, and charge state of Mo during deposition of MoO$_3$ molecules; the data indicate that MoO$_3$ can lower the Fermi level to within ∼100 meV of the Dirac point. Thin film transport measurements that ∼10$^{13}$ electrons can be depleted from the Bi$_2$Se$_3$ and that an MoO$_3$ capping layer is stable for days after exposure to ambient.

Session T11 DCMP: Superconductivity: Heavy Elements and Spin-Orbit Effects 007B - Valentin Taoufar, Ames Laboratory

11:15AM T11.00001 Fermi-surface instabilities in the presence of spin-orbit coupling  CHRISTIAN PLATT, MARIO FINK, WERNER HANKE, RONNY THOMALE, University of Wuerzburg — Besides its relevance in the formation of topological insulators, the effect of spin-orbit coupling also gives rise to novel types of superconductivity and unprecedented spin- and charge orders. Due to the progress in the fabrication of tailored materials and surfaces, these novel states-of-matter now become accessible and can be investigated by different experimental probes. Within the theoretical framework of functional renormalization group, we study the effect of spin-orbit coupling on the emergence of Fermi-surface instabilities. Starting from an ab-initio model input, we compare our results with recent experiments performed on the metallic surface states of half-Heusler compounds.

11:27AM T11.00002 Far-from-equilibrium dynamics of spin-orbit coupled superfluids  MUBARAK ALQAHTANI, MAXIM DZERO, Kent State University — We present the results of the theoretical study for the collisionless dynamics of the pairing amplitude in two-dimensional superfluid with strong spin-orbit coupling. We consider the cases when the dynamics is initiated by a sudden change of the coupling constant or an external magnetic field. Depending on the initial conditions and an amplitude of a quench, at long times the pairing amplitude dynamically vanishes, reaches a constant or periodically oscillates with time. We determine the corresponding steady state phase diagram exactly for generic quenches of the coupling constant and specific quenches of the magnetic field. We also study topological Floquet superfluidity which can be generated by the periodic oscillations of the pairing amplitude.

11:39AM T11.00003 Superconducting hyper-honeycomb lattice  ADRIEN BOUHON, ANNICA BLACK-SCHAFER, Uppsala Univ — Motivated by the recent discovery of the hyper-honeycomb β-Li2IrO3 studied in the context of Kitaev spin liquids, we investigate the possibility to realize superconductivity in the hyper-honeycomb lattice. Based on a t-J model we discuss the effect of the band structure and spin-orbit coupling on the most stable superconducting state.

11:51AM T11.00004 Superconductivity in R$_3$T$_4$Ge$_{13}$ (R = Y, Lu and T = Rh, Co, Os) single crystals  BINOD RAI, Rice University, IAIN OSWALD, University of Texas at Dallas, JIAKUI WANG, Rice University, GREGORY MCCANDLESS, JULIA CHAN, University of Texas at Dallas, EMILIA MOROSAN, Rice University — Single crystals of R$_3$T$_4$Ge$_{13}$ (R = Y, Lu and T = Rh, Co, Os) have been grown by flux methods and have been found to adopt the Fr$_3$Rh$_4$Sn$_{13}$ structure type. Magnetization and specific heat measurements confirm that all four compounds are bulk superconductors. Reduced superconducting gaps observed in the specific heat suggest that these may be multi-band superconductors. We observe an unusual increase of the electrical resistivity and a decrease of the charge carrier density on cooling in the normal state in all four reported compounds. However, band structure calculations reveal a metallic ground state in all four compounds, consistent with the emergence of superconductivity at low temperatures. We empirically show that large atomic displacement parameter ratios in R$_3$T$_4$Ge$_{13}$ compounds are correlated with the semiconducting behavior, resolving the contradiction between the experiment and the calculations.

12:03PM T11.00005 Unconventional superconductivity in U$_2$PtC$_2$  NICK WAKEHAM, ANDY MOUNCE, Los Alamos Natl Lab, NI NI, UCLA, MINGKANG KANG, Los Alamos Natl Lab, SANGYUN LEE, Sung Kyun Kwan University, ROMAN MOVSVOVICH, JIANXIN ZHU, Los Alamos Natl Lab, TUSON PARK, Sung Kyun Kwan University, ERIC BAUER, JOE THOMPSON, FILIP RONNING, Los Alamos Natl Lab — U$_2$PtC$_2$ has long been known to be a moderately heavy-fermion superconductor with transition temperature $T_c\sim 1.3$K. However, until recently little was known about the nature of the superconductivity. We will present a summary of our recent investigation into the superconductivity in this material through structural, transport, thermodynamic, and nuclear magnetic resonance measurements. Evidence for an unconventional gap structure comes from power law dependencies of the specific heat as a function of field and temperature in all four reported compounds. However, band structure calculations reveal a metallic ground state in all four compounds, consistent with the emergence of superconductivity at low temperatures. We empirically show that large atomic displacement parameter ratios in R$_3$T$_4$Ge$_{13}$ compounds are correlated with the semiconducting behavior, resolving the contradiction between the experiment and the calculations.

12:15PM T11.00006 ABSTRACT WITHDRAWN —

12:27PM T11.00007 Superconducting and normal state properties in Uranium-based materials from thermal and thermoelectric measurements  J.-PH. REID, J. BARRACLOUGH, University of St-Andrews, O. ENTWISLE, C. LITHGOW, D. SOKOLOV, W. WHITLEY, E. YELLAND, ANDREW HUXLEY, University of Edinburgh — Although it is clear that the interplay between superconductivity and magnetic or charge orders has a crucial role to the origin of superconductivity, it is not yet understood how and why that is. One of the best ways to shed light on this question is by measuring thermal conductivity and thermoelectricity. The former probes the zero-energy ($T \to 0$) quasiparticles and is very sensitive to the superconducting gap structure, whereas the latter is ideal to detect any change in the Fermi surface due to competitive orders. In this talk, a thermal and thermoelectric study will be presented and will focus on the ferromagnetic superconductor URhGe.

12:39PM T11.00008 Possible mechanism for s-wave superconductivity in heavy-fermion systems: Variational cluster study  KEISUKE MASUDA, Department of Physics, Waseda University, DAISUKE YAMAMOTO, Waseda Institute for Advanced Study, Waseda University — We study s-wave superconductivity in heavy-fermion systems, which cannot be easily understood due to the existence of the strong Coulomb repulsion between $f$ electrons. The key idea of our proposal is to consider the interorbital Cooper pairing between conduction electrons ($c$ electrons) and localized $f$ electrons, which we refer to as the “$c$-$f$ pairing.” We analyze the periodic Anderson model by means of the variational cluster approach in which all the three types of on-site pairing, namely intraorbital pairings between $c$ electrons and between $f$ electrons and the $c$-$f$ pairing, are taken into account. At half filling, the system exhibits the Kondo insulating or antiferromagnetic state, depending on the strength of the Coulomb repulsion. When electrons or holes are doped to the antiferromagnetic state, s-wave superconductivity appears coexisting with the antiferromagnetic long-range order. We also find that the magnetic order vanishes for further doping, and a pure s-wave superconducting state is formed for a certain range of doping concentration. We suggest the $c$-$f$ pairing as a possible mechanism for s-wave superconductivity in heavy-fermion systems.

12:51PM T11.00009 A comprehensive study of chemical substitution effects on superconductivity in LaPt$_4$Ge$_{12}$

E. KEVIN HUANG$^1$, DUYGU YAZICI, BENJAMIN WHITE, ALEXANDER BREINDEL, NAVEEN POUSE, Physics Department, University of Houston, LEI SHUI, Physics Department, Fudan University, BRIAN MAPLE, Physics Department, UC San Diego — The compound PrPt$_4$Ge$_{12}$ has attracted significant attention following observations of signatures of unconventional superconductivity such as time reversal symmetry breaking from μSR measurements. In contrast, LaPt$_4$Ge$_{12}$ is a conventional BCS-type superconductor, interestingly, with the same superconducting transition temperature, $T_c$, as PrPt$_4$Ge$_{12}$ ($T_c = 8$ K). To elucidate the properties of superconductivity in PrPt$_4$Ge$_{12}$, the system La$_{1-x}$Ce$_x$Pt$_4$Ge$_{12}$ was investigated and the results are compared to our previous work on Pr$_{1-x}$Ce$_x$Pt$_4$Ge$_{12}$. Measurements of magnetic susceptibility, electrical resistivity, and specific heat were performed demonstrating that $T_c$ is suppressed more rapidly in La$_{1-x}$Ce$_x$Pt$_4$Ge$_{12}$ than in Pr$_{1-x}$Ce$_x$Pt$_4$Ge$_{12}$. Specific heat measurements reveal a crossover in the temperature dependence of the superconducting state of La$_{1-x}$Ce$_x$Pt$_4$Ge$_{12}$, changing from a power law for $x = 0$ to an exponential for the Ce-substituted samples, possible evidence of a transition from a multiband to a single-band superconducting energy gap. This substitution for La did not produce the crossover.

1:03PM T11.00010 Superconductivity at 600 mK in a novel ternary platinum phosphide SrPt$_4$P$_4$ $^1$, BENMAWA JAWDAT, BING LV, ZHENG WU, MELISSA GOOCH, KUI ZHAO, LIANGZI DENG, YIYU XUE, BERND LORENZ, Texas Center for Superconductivity and Department of Physics, University of Houston, ARNOLD GULOY, Texas Center for Superconductivity and Department of Chemistry, University of Houston, CHING-WU CHU $^2$, Texas Center for Superconductivity and Department of Physics, University of Houston — In the course of our search for new superconducting materials, we have synthesized a novel, metal-rich ternary platinum phosphide superconductor with a unique structure type, and an expected transition temperature greater than 1 K. The crystal structure was determined by single crystal X-ray diffraction, and features a unique three-dimensional anionic network of vertex-shared Pt$_4$P$_4$ trigonal prisms. Furthermore, we have investigated the superconductivity in this material resistively, magnetically, and calorimetrically. The results of these studies will be presented and discussed.

$^1$Present location: Fudan University

1:15PM T11.00011 Penetration depth and point-contact spectroscopy studies of exotic superconductivity in noncentrosymmetric half-Heusler YPtBi

HYUNSOO KIM, STEVEN ZIEMAK, KEFENG WANG, YASUYUKI NAKAJIMA, JOHNPRIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD, USA, MAKARIY TANATAR, RUSLAN PROZOROV, Ames Laboratory, Department of Physics and Astronomy, Iowa State University, Ames, IA, USA — Strong asymmetric spin-orbit coupling in a noncentrosymmetric superconductor allows mixing of even and odd parity of the pairing interactions. Such an exotic pairing interaction has been suggested in some Pt-based noncentrosymmetric superconductors such as CePt$_3$Si and Li$_2$Pt$_3$B. More recently, we reported superconductivity below 0.8 K in YPtBi, a half-Heusler compound that lacks inversion symmetry. Here we present our studies of the superconducting energy gap in YPtBi using soft point contact spectroscopy and superconducting penetration depth measurements via tunnel diode resonator technique as a function of temperature and applied magnetic field. We will compare the morphology of our dI/dV energy gap spectra to previous theoretical and experimental results for triplet $p$-wave materials, and review our analysis of normalized superfluid density and theoretical current density and compare to various possible superconducting energy gap symmetries.

1:27PM T11.00012 Origins of charge density wave in novel Pt-based superconductors: SrPt$_3$As$_2$ and LaPt$_3$Si$_2$

SOORAN KIM, KYOO KIM, B.I. MIN, POSTECH — The intriguing coexistence of the charge density wave (CDW) and superconductivity in SrPt$_3$As$_2$ and LaPt$_3$Si$_2$ has been investigated by using the ab initio density functional theory band structure and phonon calculations. We have found that the local shift distortions in the [As-Pt-As] layers play an essential role in driving the five-fold supercell CDW instability as well as the phonon softening instability in SrPt$_3$As$_2$ than in LaPt$_3$Si$_2$. Specific heat measurements reveal a crossover in the temperature dependence of the superconductivity in SrPt$_3$As$_2$ and LaPt$_3$Si$_2$ different. The phonon calculations, however, suggest that the CDW and the superconductivity coexist in [X-Pt-X] layers (X = As or Si) in both cases.

1:39PM T11.00013 Superconductivity in AuBe $^1$

D.J. REBAR, J.F. DITUSA, P. ADAMS, D. BROWNE, I. VEKHTER, D. YOUNG, J. PRESTIGIACOMO, Louisiana State University — Metallic AuBe, which forms with the chiral B20 crystal structure, is a superconductor (SC) with a $T_c$ of approximately 3.2 K. Recent research on materials with this structure has revealed Skyrmion lattices, a topologically interesting magnetic state. We investigate the role the Dzyaloshinsky-Moriya interaction and spin-orbit coupling play in the superconductivity and normal state properties of this material. Samples were arc-melted in Ar atmosphere and characterized for structure and elemental composition. Magnetic susceptibility measurements revealed a full Meissner effect while the specific heat showed a sharp step at the transition temperature whose size is characteristic of a weakly-coupled SC. Measurements of the electrical resistivity at 1.8 K revealed a critical field that is five to six times that seen in the magnetization, far above the enhancement expected from a simple superconducting surface layer. In addition, we observed de Haas-van Alphen (dHvA) oscillations in these polycrystalline samples with two dominant frequencies indicating small spin-orbit split Fermi surfaces. We interpret the dHvA oscillations as emanating from a Dirac point approximately 0.4 eV below the Fermi level.

1:51PM T11.00014 Characterization of the Heavy Metal Pyrochlore Lattice Superconductor CaIr$_2$ $^1$

NEEL HALDOLAARACHCHIGE, QUINN GIBSON, LESLIE SCHOOPE, HUIXIA LUO, ROBERT CAVA, Princeton University — Compounds based on 5d transition metals are of recent interest because electron correlations and spin-orbit interactions play an important role in determining their electronic properties. Iridium oxides with the pyrochlore lattice, in particular, are predicted to host exotic electronic states, but these materials have not yet been shown to host superconductivity. A handful of Ir compounds are known to be superconducting, some more likely showing this property due to the presence of rare earths, but in other cases superconductivity is derived from Ir states at the Fermi Energy. Here we report the synthesis, experimental electronic characterization, and calculated electronic band structure of the cubic Laves phase superconductor CaIr$_2$. The inferred electron-phonon coupling constant show that CaIr$_2$ is a weakly coupled BCS-type superconductor. The electronic band structure calculations indicate that the Ir d states are dominant through the Fermi level. Given the profound effect of spin-orbit coupling on the electronic structure, it can be argued that the value of $T_c$ and possibly even the existence of superconductivity at all, is due to the heavy element character imparted to this material by the Ir pyrochlore lattice.

2:03PM T11.00015 The electron-phonon coupling and superconductivity for light-actinides on fcc structure: a first principles study\(^1\), OMAR DE LA PEÑA-SEAMAN, PAOLA GONZÁLEZ-CASTELAZO, Institute of Physics (IFUAP), Benemérita Universidad Autonoma de Puebla (BUAP), ROLF HEID, KLAUS-PETER BOHNMEN, Institute of Solid State Physics (IFP), Karlsruhe Institute of Technology (KIT) — We have studied the electronic structure, lattice dynamical properties, electron-phonon (\(\text{e-ph}\)) coupling and superconducting properties of the light-actinides (Ac, Th, Pa, U) on fcc structure. These systems have been studied within the framework of density functional perturbation theory, using a mixed-basis pseudopotential method. The electronic density of states (DOS), full-phonon dispersion as well as the Eliashberg spectral function \((\alpha^2 F(\omega))\) and the electron-phonon coupling \((\lambda)\) parameter have been calculated with and without the inclusion of spin-orbit coupling (SOC). The observed effects of SOC on \(\alpha^2 F(\omega)\) for the light-actinides under study have its roots on the changes of two quantities: the full phonon dispersion and the \(\text{e-ph}\) coupling matrix elements. The observed influence of these two ingredients is different depending of the actinide, and it is analyzed together with the contribution of the different states on the DOS at the Fermi level. The superconducting critical temperature \((T_c)\) has been analyzed solving numerically the Eliashberg gap equations on the strong-coupling regime with the information provided from \(\alpha^2 F(\omega)\) for the entire series, analyzing the superconducting behavior of the light-actinides.

11:27AM T12.00002 Artificially-Engineered III-Nitride Digital Alloy for Solar Energy Harvesting\(^1\), WEI SUN, CHEE-KEONG TAN, NELSON TANSU, Center for Photonics and Nanoelectronics, Department of Electrical and Computer Engineering, Lehigh University — The pursuit of III-Nitride based solar cell has been primarily driven by the attribute of broad solar spectrum coverage through the use of InGaN material. However, the phase separation in high In-content InGaN alloy has been one of the largest barrier in the pursuit of nitride-based solar cells. Thus, a new approach in extending the bandgap coverage in nitride-based alloy needs to be pursued. In this work, we propose a novel artificially engineered III-Nitride based digital alloy structure to overcome the limitation presented by the epitaxy of phase-separated InGaN material with high In-content. The InGaN digital alloy structure is a short period superlattice that is formed by GaN and InN thin film layers alternately in which the thickness of each layer is represented by a number of monolayer (ML). By adjusting the thickness of GaN layer (\(n\) MLs) and InN layer (\(n\) MLs), the In-content and the band structure of InGaN digital alloy can be engineered correspondingly. The use of this digital alloys demonstrated suitability of this method in extending the bandgap coverage in nitride-based semiconductors.

11:39AM T12.00003 Simulation of Epitaxial Growth of DNA-nanoparticle Superlattices on Pre-patterned Substrates\(^1\), SAIJIE PAN, TING LI, MONICA OLVERA DE LA CRUZ, Northwestern Univ — DNA self-assembly is a well-developed approach towards the construction of a great variety of nanoarchitectures. E-beam lithography is widely used for high-resolution nanoscale patterning. Recently, a new technique combining the two methods was developed to epitaxially grow DNA-mediated nanoparticle superlattices on a pre-patterned surface\(^1\). Here we use multi-scale simulations to study and predict the formation and defects of the absorbed superlattice monolayer. We demonstrate that the epitaxial growth is enthalpy driven and show that the anisotropy of the DNA-mediated substrates leads to structure defects. We develop design rules to dramatically reduce defects of the attached layer. Ultimately, with the assist of our simulation, this technique will open the door for the construction of well-ordered, three-dimensional novel metamaterials. [1] H. Atwater, et al. Nano Lett. 2013, 13, 6084.

11:51AM T12.00004 Theory of Energy Level Tuning in Quantum Dots by Surfactants, DANYLO ZHEREBETSKYY, LIN-WANG WANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, MATERIALS SCIENCES DIVISION, LAWRENCE BERKELEY NATIONAL LABORATORY TEAM — Besides quantum confinement that provides control of the quantum dot (QD) band gap, surface ligands allow control of the absolute energy levels. We theoretically investigate energy level tuning in PbS QD by surfactant exchange. We perform direct calculations of real-size QD with various surfactants within the frame of the density functional theory and explicitly analyze the influence of the surfactants on the electronic properties of the QD. This work provides a hint for predictable control of the absolute energy levels and their fine tuning within 3 eV range by modification of big and small surfactants that simultaneously passivate the QD surface.

12:03PM T12.00005 Crystalline \((\text{Al}_{1-x}\text{B}_x)\text{PSi}_3\) and \((\text{Al}_{1-x}\text{B}_x)\text{AsSi}_3\) tetrahedral phases via reaction of \(\text{Al(BH}_4)_3\) and \(\text{M(SiH}_3)_3\) \((\text{M}=\text{P, As})\)\(^1\), PATRICK SIMS, ANDREW WHITE, TOSHIHIRO AOKI, JOSE MENENDEZ, JOHN KOVETAKIS, Arizona State University — Crystalline \((\text{Al}_{1-x}\text{B}_x)\text{PSi}_3\) alloys \((x = 0.04-0.06)\) are grown lattice-matched on Si(100) by reactions of \(\text{P(SiH}_3)_3\) and \(\text{Al(BH}_4)_3\) using low-pressure CVD. The materials have been characterized by ellipsometry, XRD, XTEM, EELS and EDS, indicating the formation of single-phase monocrystalline layers with tetrahedral structures based on \(\text{AlPSi}_3\). The latter comprises interlinked \(\text{AlPSi}_3\) tetrahedra in which Al-P pairs are isolated within a Si matrix. Raman scattering of \(\text{Al}_{1-x}\text{B}_x\text{PSi}_3\) films support the presence of substitutional B in place of Al and provides evidence that B is bonded to P. The substitution of B atoms is desirable for promoting lattice matching, as required for Si-based solar cell designs. Analogous reactions of \(\text{As(SiH}_3)_3\) with \(\text{Al(BH}_4)_3\) produce \((\text{Al}_{1-x}\text{B}_x)\text{AsSi}_3\) in which the B incorporation is limited to doping concentrations at \(10^{20}\) cm\(^{-3}\). In both cases the \(\text{Al(BH}_4)_3\) efficiently delivers Al to create crystalline group IV-III-V materials comprising light, earth abundant elements with possible application in photovoltaics and light element refractory solids.

12:15PM T12.00006 Optical trends in InP polytypic superlattices¹, GUILHERME SIPAHI, TIAGO DE CAMPOS, PAULO EDUARDO DE FARIÁ JUNIOR, Universidade de São Paulo, State University of New York at Buffalo — Recent advances in growth techniques have allowed the fabrication of semiconductor nanostructures with mixed wurzite/zinc-blende crystal phases. Although the optical characterization of these polytypic structures is well reported in the literature, a deeper theoretical understanding of how crystal phase mixing and quantum confinement change the output linear light polarization is still needed. Here, we theoretically investigate the effects of these polytypic homojunctions on the interband absorption of an InP superlattice [1]. Using a single 8x8 k.p Hamiltonian that describes both crystal phases [1, 2] together with the effects of quantum and optical confinement we were able to explain the recent optical experimental results carried out on polytypic InP [3]. In summary, we have shown how the interplay of crystal phase mixing and quantum confinement can be used for light polarization engineering in polytypic homojunctions.

1FAPEP (No. 2011/19333-4, No. 2012/05618-0 and No. 2013/23993-8) and CNPq (No. 138457/2011-5, No. 245649/2012-2 and No. 149904/2013-4)

12:27PM T12.00007 Erbium doped Aluminum Nitride Nanoparticles for Nano-Thermometer Applications¹, SNEHA G. PANDYA, MARTIN E. KORDESCH, Department of Physics and Astronomy, Ohio University, Athens, OH-45701 — We have synthesized Nanoparticles (NPs) of Aluminum Nitride (AlN) doped in situ with Erbium (Er) using the inert gas condensation technique. These NPs have optical properties that make them good candidates for nanoscale temperature sensors. The Photoluminescence (PL) spectrum of Er³⁺ in these NPs shows two emission peaks in the green region at around 540 nm and 560 nm. The ratio of the intensities of these luminescence peaks is related to temperature. Using Boltzmann’s distribution, the temperature of the NP and its surrounding can be calculated. The NPs were directly deposited on (111) p-type Silicon wafers, TEM grids and glass cover slips. XRD and HRTEM study indicates that most of the NPs have crystalline hexagonal AlN structure. An enhancement of the luminescence from these NPs was observed after heating-in-air at 770 K for 3 hours. The sample was then heated in air using a scanning optical microscope laser. The corresponding change was in the range of 320-470 K. This temperature range is of interest for temperature sensors which are used for determining the potential at measure sidewall scattering. This is accomplished by acquiring spectra on a regularly spaced grid and then fitting the spectra to determine both the Schottky barrier height and the slope of the spectra. The position dependent maps of these two parameters are then related to the scattering at the interface due to the underlying pattern.

12:39PM T12.00008 Controlled formation of GeSi nanostructures on pillar-patterned Si substrate , TONG ZHOU, Fudan University, CENG ZENG, Huazhong University of Science and Technology, YONGLIANG FAN, ZUIMIN JIANG, Fudan University, JINSONG XIA, Huazhong University of Science and Technology, ZHENYANG ZHONG, Fudan University, FUDAN UNIVERSITY TEAM, HUAZHONG UNIVERSITY OF SCIENCE AND TECHNOLOGY COLLABORATION — GeSi quantum nanostructures (QNS) have potential applications in optoelectronic devices due to their unique properties and compatibility with the sophisticated Si technology. However, the disadvantages of poor quantum efficiency of the GeSi QNS on flat Si (001) substrates hinder their optoelectronic applications. Today, numerous growth strategies have been proposed to control the formation of GeSi QNS in hope of improving the optoelectronic performance. One of the ways is to fabricate GeSi QNS on patterned substrates, where the GeSi QNS can be greatly manipulated in aspects of size, shape, composition, orientation and arrangement. Here, self-assembled GeSi QNS on periodic Si (001) sub-micro pillars (SPMs) are systematically studied. By controlling the growth conditions and the diameters of the SPMs, different GeSi QNS, including circularly arranged quantum dots (QDs), quantum rings (QRs), and quantum dot molecules (QDMs), are realized at the top edge of SPMs. Meanwhile, fourfold symmetric GeSi QDMs can be also observed at the base edges of the SPMs. The promising features of self-assembled GeSi QNS are explained in terms of the surface chemical potential, which disclose the critical effect of surface morphology on the diffusion and the aggregation of Ge adatoms.

12:51PM T12.00009 ABSTRACT WITHDRAWN

1:03PM T12.00010 Utilizing Ballistic Electron Emission Microscopy to Study Sidewall Scattering of Electrons, WESTLY NOLTING, CHRIS DURCAN, ROBERT BALSANO, College of Nanoscale Science and Engineering, University at Albany, VINCENT LABELLA, Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute — Sidewall scattering of electrons in aggressively scaled integrated devices dramatically increases the resistance since the dimensions are approaching the mean free path of electrons in a metal ~ 40 nm. Ballistic Electron Emission Microscopy (BEEM) can be utilized to study hot electron scattering in metal films. In this presentation BEEM is performed on a lithographically patterned interface between a metal and a semiconductor to determine its potential at measure sidewall scattering. This is accomplished by acquiring spectra on a regularly spaced grid and then fitting the spectra to determine both the Schottky barrier height and the slope of the spectra. The position dependent maps of these two parameters are then related to the scattering at the interface due to the underlying pattern.

1:15PM T12.00011 Novel size effects on magneto-optics in the spherical quantum dots, M. KUSHWAHA, Rice University — We embark on investigating the magneto-optical absorption in spherical quantum dots completely confined by a harmonic potential and exposed to an applied magnetic field in the symmetric gauge. This is done within the framework of Bohm-Pines’ RPA that enables us to derive the Dyson equation that takes proper account of the Coulomb interactions. Intensifying the confinement or magnetic field and reducing the dot-size yields a blue-shift in the absorption peaks. However, the size effects are seen to be predominant in this role. The magnetic field tends to maximize the localization of the particle, but leaves the peak position of the radial distribution intact. The intra-Landau level transitions are forbidden.

1:27PM T12.00012 Silicene, germanene and tinene: Modeling of IR absorbance and topological states, FRIEDHELM BECHSTEDT, LARS MATTHES, Friedrich-Schiller-Universitaet Jena, OLIVIA PULCI, University Rome II Italy, PAOLA GORI, University Rome III Italy, BECHSTEDT/MATTHES TEAM, PULCI/GORI TEAM — The graphene-like but Si-, Ge- or Sn-derived group-IV honeycomb crystals [1] have attracted much attention due to their unique properties and their recent realization in experiments [2]. We study their electronic and optical properties by means of ab initio electronic-structure calculations. Conical valence and conduction bands and a vanishing electronic band gap have enormous consequences.

1:39PM T12.00013 Internal Strain in Nano-Diamond and Boron Nitride, WILLIAM MATTSON, DONALD JOHNSON, US Army Research Laboratory — Nanodiamond surfaces undergo reconstruction imposing stress on nanoparticle (NP) core and possibly storing strain energy. The unique way in which these NPs store energy may lead to useful applications, but a greater understanding of strain energy storage/release is needed. In the current work, density functional theory methods are employed to predict structural properties and energetics of C (diamond) and cubic-BN NPs. The goal is to quantify NP core stress and its relationship to surface rearrangement, particle size, and material composition. Initial results suggest different chemical factors drive surface rearrangement, leading to compressive stress in C and tensile stress in BN.

1:51PM T12.00014 Plasmon Enhanced Raman Scattering in Ag-CdTe Core-Shell Nanostructures1, SHENG WANG, DEXIONG LIU, JIANG ZENG, HUA ZHANG, DELIANG WANG, ZHENYU ZHANG, University of Science and Technology of China — Surface-enhanced Raman scattering (SERS) has been a powerful technique in investigating the properties of semiconductors. For semiconductor thin films, plasmon resonance and photoluminescence (PL) are two important factors in determining the signal of SERS. Here we carry out a combined experimental and theoretical study of the optical properties of metal-semiconductor hybrid nanosystems using SERS. First, we fabricate Ag-CdTe core-shell nanostructures by depositing CdTe on Ag nanoparticle arrays. By varying the thickness of the CdTe shell, one peak of plasmon is tuned to the wavelength of the incident light for resonant absorption, which is further verified by our finite-difference time-domain simulations. The coupling between the plasmons and excitons at the interface quenches the radiative PL process, while the non-radiative Raman scattering process is unaffected. Furthermore, the importance of multi-phonon resonance Raman scattering in these systems is investigated.

2:03PM T12.00015 Band Gaps in InN/GaN Superlattices: Polar and Nonpolar Growth Directions, NIELS CHRISTENSEN, Department of Physics and Astronomy, Aarhus University, 8000 Aarhus C, IZABELA GORCZYCA, KAMILA SKROBAS, TADEUSZ SUSKI, Institute of High Pressure Physics, UNIPRESS 01-142 Warsaw, Poland, AXEL SVANE, Department of Physics and Astronomy, Aarhus University, 8000 Aarhus C — The electronic structures of short-period superlattices (SLs) consisting of \(m\)InN/\(n\)GaN unit cells with composition \((m,n)\) have been calculated within the density-functional theory including corrections for the “LDA gap error”. The variation of the gaps with SL composition and the dependence on the growth direction, the polar \((c)\) and nonpolar \((a,m)\) directions in the wurtzite structure, are compared. The band gaps calculated for the polar SLs are much smaller than those found for non-polar SLs due to the electric polarization fields in the \((c)\) SLs. For the \((1,m)\) class of polar samples photoluminescence measurements yield energy-gap values, which are much larger than the calculated values. The reason for this is that the structure of the samples differs from the assumed ideal composition. Transmission electron microscopy studies of the assumed polar \(In_{x}Ga_{1-x}N/GaN\) SLs show that the real structure is \(In_{1-x}Ga_{x}N/GaN\) with In-content \(x<0.33\). New calculations for such SLs in perfect agreement with photoluminescence experiments.

11:15AM T13.00001 Geometry and heterointerface engineered phases of nickelates1, JAK CHAKHALIAN, University of Arkansas — Deterministic control over the spatial arrangement atoms in a crystal is the backbone of its properties that, along with the interactions, defines its ground state. Following this notion, several theoretical proposals exist to utilize a few unit cells of a correlated oxide heterostructured along the pseudo-cubic \((111)\) direction. This geometrically engineered motif relies on the presence of correlated carriers placed on a buckled honeycomb \((i.e.,\) graphene-like) lattice, or dice lattices for bilayers and trilayers of ABO\(_3\) perovskites. The guiding principle is to use strong electronic correlations combined with quantum confinement and symmetry-breaking interfaces to enable access to new electronic band structures that may activate novel or latent quantum phases. In this talk, the current status of research in this field will be reviewed. The experimental challenges in realization and characterization of such heterostructures will be exemplified by rare earth nickelates heterostructures. Several promising examples of such geometrically engineered artificial Mott materials will be discussed.

1 Work supported by DOD-ARO under the Grant number 0402-17291 and funded in part by the Gordon and Betty Moore Foundation’s EPIQS Initiative through Grant GBMF4534.

11:51AM T13.00002 Tunable Charge and Spin Order in PrNiO\(_3\) Thin Films and Superlattices, MATTHIAS HEPTING, MATTEO MINOLA, ALEX FRANO, GEORG CRISTIANI, MENG WU, MARTIN BLUSCHKE, YI LU, HANS-ULRICH HABERMEIER, GENNADY LOGVENOV, EVA BENCKISER, MATHIEU LE TACON, BERNHARD KEIMER, MPI FKF Stuttgart — The rich phase diagram of transition metal oxides such as rare-earth nickelates heterostructures. Several promising examples of such geometrically engineered artificial Mott materials will be discussed.

12:03PM T13.00003 The effect of the interface termination on the atomic and electronic structure of LaNiO\(_3\)/PbZr\(_{0.2}\)Ti\(_{0.8}\)O\(_3\)1, ANDREI MALASHCHEVICH, MATTHEW S. J. MARSHALL, ANKIT S. DISA, FREDERICK J. WALKER, CHARLES H. AHN, SOHRAB ISMAIL-BEIGI, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University — Thin film metal oxide/ferroelectric interfaces can exhibit dependence of conductivity on the polar state of the ferroelectric layer. This property has potential for technological applications in non-volatile field-effect devices. Recently, we demonstrated that ferroelectric PbZr\(_{0.2}\)Ti\(_{0.8}\)O\(_3\) (PZT) can be used to modulate conductivity of the \((001)\)-oriented LaNiO\(_3\)/PZT interface. We found that changes in conductivity result primarily from large mobility changes in the interfacial channel region. In this study, we investigate the effect of the LaNiO\(_3\) film termination \((LaO vs NiO\(_2\)) on the atomic structure and electronic properties of LaNiO\(_3\)/PZT. We present the results of the first-principles calculations of the atomic structure of the related LaNiO\(_3\)/PbTiO\(_3\) interface for both LaNiO\(_3\) terminations. For the analysis of the atomic structure and electronic properties of the ferroelectric PbTiO\(_3\) polar state and compare the results to the available experimental observations.

12:15PM T13.00004 Strain Control of Electronic Phase in Rare Earth Nickelates\textsuperscript{1}, ZHUORAN HE, ANDREW MILLIS, Dept. of Physics, Columbia Univ. — In this work, we use DFT+U methods to study the effects of strain on the electronic states and lattice structure of thin films of LuNiO$_3$. We model the effects of a substrate-induced strain by fixing the in-plane lattice parameter and relax both the c-axis lattice parameter and all internal coordinates. Both compressive and tensile strain destroy the charge order and create a metallic state. Tensile strain induces a staggered Jahn-Teller order. The staggered Jahn-Teller state is shown to compete with the charge-ordered state. The transitions are found to be first order, but the insulating gap in the charge-ordered phase varies substantially with applied strain. Implications for experiments are discussed.

\textsuperscript{1}Support: DOE ER-046169

12:27PM T13.00005 Comparative study of LaNiO$_3$/LaAlO$_3$ heterostructures grown by oxide MBE and PLD techniques\textsuperscript{1}, FRIEDERIKE WROBEL, GENNADY LOGVENOV, GEORG CHRISTIANI, EVA BENCHEKIER, Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany, ALISON F. MARK, WILFRIED SIGLE, PETER A. VAN AKEN, Max Planck Institute for Intelligent Systems, Heisenbergstr. 3, 70569 Stuttgart, Germany, BERNHARD KEIMER, Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany — The physical properties of functional oxides can be altered by, e.g., dimensionality, strain, interfacial interaction and doping. Ozone assisted molecular beam epitaxy (oxide MBE) is a technique that gives wide access to all tuning parameters while having a low deposition energy. We succeeded in growing high-quality heterostructures based on LaNiO$_3$ with oxide MBE and pulsed laser deposition (PLD) and compared crystallinity, resistivity, x-ray absorption (XAS), orbital polarization and high-resolution transmission electron microscopy (HRTEM) images. Despite the difference in growth conditions, the samples show essentially the same physical properties: By reducing the layer thickness, LaNiO$_3$ turns from a paramagnetic metal into an antiferromagnetic insulator. XAS confirms the nickel +III oxidation state and that the orbital polarization is mainly controlled through substrate strain.

12:39PM T13.00006 ABSTRACT WITHDRAWN —

12:51PM T13.00007 Orbital engineering of nickelates in three-component heterostructures, ANKIT DISA, DIVINE KUMAH, ANDREI MALASHEVICH, HANGHUI CHEN, SOHRAB ISMAIL-BEI GI, FRED WALKER, CHARLES AHN, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University, ELIOT SPECHT, Materials Science and Technology Division, Oak Ridge National Laboratory, DARIO ARENA, National Synchrotron Light Source, Brookhaven National Laboratory — The orbital configuration of complex oxides dictates the emergence of a wide range of properties, including metal-insulator transitions, interfacial magnetism, and high-temperature superconductivity. In this work, we experimentally demonstrate a novel method for achieving large and tunable orbital polarizations in nickelates. The technique is based on leveraging three-component, atomically layered superlattices to yield a combination of inversion symmetry breaking, charge transfer, and polar distortions. In the system we studied, composed of LaTiO$_3$/LaNiO$_3$/LaAlO$_3$, we use synchrotron x-ray diffraction and spectroscopy to characterize these properties and show that they lead to fully broken orbital degeneracy in the nickelate layer consistent with a single-band Fermi surface. Furthermore, we show that this system is widely tunable and enables quasi-continuous orbital control unachievable by conventional strain and confinement-based approaches. This technique provides an experimentally realizable route for accessing and studying novel orbitally dependent quantum phenomena.

1:03PM T13.00008 Soft X-ray ARPES investigation of the nickelate Fermi surface in exchange biased LaNiO$_3$-LaMnO$_3$ superlattices, FLAVIO BRUNO, S. MCKEOWN WALKER, A. DE LA TORRE, A. TAMAI, M. GIBERT, S. CATALANO, J.-M. TRISCONE, University of Geneva, Switzerland, Z. WANG, F. BISTI, V. STROCOV, Swiss Light Source, PSI, Switzerland, F. BAUMBERGER, University of Geneva, Swiss Light Source PSI Switzerland and University of St Andrews UK — We investigate (111)-oriented superlattices consisting of paramagnetic LaNiO$_3$ (LNO) and ferromagnetic LaMnO$_3$ (LMO). The field dependence of the magnetization in these heterostructures was measured at 5 K after cooling the sample in the presence of a 0.4 T field. Surprisingly, a shift of 15 mT in the magnetization loop towards negative fields along the magnetic field axis was observed [1]. If the same measurement is repeated in a (111) LMO thin film, no exchange bias is observed which implies that LNO is the driving force for the biasing effect exhibited by the heterostructures. Since LNO is a well-known paramagnetic material, the existence of exchange bias in the superlattices implies the existence of an interface-induced magnetic order. Here we use soft x-ray angle resolved photoemission spectroscopy –SX ARPES- to study the electronic band structure of LNO layers in these heterostructures. Due to the increase in photoelectron escape depth in the 500 – 1000 eV energy range, we are able to map the LNO Fermi surface below 7 u.c. of LMO. In this talk we will discuss the similarities and differences in the electronic structure between thin films of (111)-LNO and buried LNO-LMO interfaces.

1:15PM T13.00009 Advanced electron microscopy characterization of tri-layer rare-earth oxide superlattices, PATRICK PHILLIPS, University of Illinois - Chicago, ANKIT DISA, SOHRAB ISMAIL-BEI GI, Yale University, ROBERT KLEIE, University of Illinois - Chicago, UNIVERSITY OF ILLINOIS - CHICAGO TEAM, YALE UNIVERSITY TEAM — Rare-earth nickelates are known to display complex electronic band structures and will be discussed at length. By combining both energy dispersive X-ray (EDX) and electronic energy loss (EEL) spectroscopies in an aberration-corrected (STEM)-based methods, properties such as interfacial sharpness, electron transfer, O presence, and local electronic structure can be probed at the atomic scale, and the energetic ordering of Ni d orbitals and 2D conduction, the present work focuses on the experimental characterization of thin film superlattice structures consisting of alternating layers of LaNiO$_3$ and LaAlO$_3$. Sandwiched between a dull insulator, LaAlO$_3$, the superlattice film is a single-layer superlattice, LaNiO$_3$-LaMnO$_3$. Using advanced scanning transmission electron microscopy (STEM)-based methods, properties such as interfacial sharpness, electron transfer, O presence, and local electronic structure can be probed at the atomic scale, and will be discussed at length. By combining both energy dispersive X-ray (EDX) and electronic energy loss (EEL) spectroscopies in an aberration-corrected STEM, it is possible to attain energy and spatial resolutions of 0.35 eV and 100 pm, respectively. Focus of the talk will remain not only on the aforementioned properties, but will also include details and parameters of the acquisitions to facilitate future characterization at this level.

1:27PM T13.00010 Measurement of the quantum capacitance of two-dimensional vanadium dioxide films, ZHE WU, TALBOT KNIGHTON, VINICIO TARQUINI, JIAN HUANG, Department of Physics and Astronomy, Wayne State University, NELSON SEPULVEDA, Department of Electrical and Computer Engineering, Michigan State University, DEPARTMENT OF PHYSICS AND ASTRONOMY, WAYNE STATE UNIVERSITY COLLABORATION, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, MICHIGAN STATE UNIVERSITY COLLABORATION — With a homebuilt ac bridge, we have performed capacitance measurement of quasi two-dimensional vanadium dioxide films grown on silicon-dioxide/p-doped silicon substrate. The out-phase-signal, which corresponds to the resistivity variation, is superior to the four-terminal measurement result below the critical temperature by four orders of magnitude, consistent with a Mott transition influenced by Peierls transition.
1:39PM T13.00011 Carrier Localization in Confined Vanadate Superlattices, CRAIG EATON, LEI ZHANG, ROMAN ENGEL-HERBERT, Penn State University — Perovskite oxide heterostructures have attracted attention due to the wealth of phenomena emerging at the interface, as well as the presence of strong electron correlations with potential applications as active electronic material for logic application utilizing the metal-to-insulator transition. Successful monolithic integration of perovskite oxides with Si makes them an ideal material choice. Here we present the growth of cubic SrTiO$_3$/SrVO$_3$/SrTiO$_3$ heterostructures on (La$_{0.3}$Sr$_{0.7}$)(Al$_{0.5}$Ta$_{0.5}$)O$_3$ substrates and orthorhombically distorted CaTiO$_3$/SrVO$_3$/CaTiO$_3$ heterostructures on (La$_{0.3}$Sr$_{0.7}$)O$_3$ substrates by hybrid molecular beam epitaxy, where alkaline earth metals were supplied using conventional effusion cells and the transition metals from the metal-organic precursor titanium-isopropoxide and vanadium tri-isopropoxide. Here, the interfaces are non-polar and carrier confinement in the correlated vanadate metals (d$^1$ configuration, 1 electron per unit cell) is achieved using insulating titanates as barrier material. Growth challenges associated with optimizing conditions for cation and oxygen stoichiometry are discussed. Confined structures down to 2 ML have been studied to demonstrate the potential for tuning incipient 2D Mott transition from 3D correlated metal. Room temperature hall measurements revealed carrier concentration in SrVO$_3$ films are $2 \times 10^{22}$ cm$^{-3}$ in thick films and decreases to $8 \times 10^{19}$ cm$^{-3}$ at 3 ML confinement, revealing the onset of strong carrier localization. Direct comparison between SrVO$_3$ and CaTiO$_3$ structures are presented to elucidate the role of dimensional confinement and structural distortion.

1:51PM T13.00012 Emergent conductance and magnetism at metal oxide interfaces via internal charge transfer$^1$, HANGHUI CHEN, ANDREW MILLIS, CHRIS MARIANETTI, Columbia Univ — Internal charge transfer across the interface of transition metal oxides is proven to be a powerful approach to induce new electronic structure in metamaterials (PRL 111, 116403 (2013); arXiv:1408.0217 (2014)). Here we use ab initio calculations to demonstrate that while SrVO$_3$ is a paramagnetic metal and SrMnO$_3$ is an antiferromagnetic insulator, charge transfer in a SrVO$_3$/SrMnO$_3$ superlattice leads to both electronic and magnetic reconstructions on the Mn sites: the Mn $e_g$ states are electron doped and the Mn $t_{2g}$ core spins are ferromagnetically aligned. As a result, net magnetic moments are expected to emerge in the superlattice. Our work shows that charge transfer is a robust route to the design of novel two dimensional half metallic ferromagnets.

2:03PM T13.00013 DFT+DMFT study of strain and interface effects in $d^1$ and $d^2$ $t_{2g}$-perovskites, GABRIELE SCLAUZER, KRZYSZTOF DYMKOWSKI, CLAUDE EDERER, ETH Zurich — Metal-insulator transitions in thin films of early-transition metal correlated oxides are linked to both epitaxial strain and electronic reconstruction at the film/substrate interface. We separately address these two key factors for LaTiO$_3$ and LaVO$_3$ through density functional theory plus dynamical mean-field theory (DFT+DMFT). We find that mere epitaxial strain suffices to induce an insulator-to-metal transition in LaTiO$_3$ [1], but not in LaVO$_3$, in agreement with recent experiments [2]. We show that this difference can be explained by the combined effect of strain-induced changes in the crystal field splitting of $t_{2g}$ orbitals and different orbital filling in these two materials. The role of the interface is investigated through DFT+DMFT simulations of LaVO$_3$/SrTiO$_3$ heterostructures with varying superlattice periodicities and substrate terminations. Our aim is to assess whether the metallicity observed at the LaVO$_3$/SrTiO$_3$ interface could be driven by pure electronic reconstruction effects, rather than structural or stoichiometric reasons (such as, e.g., O-related defects). Thursday, March 5, 2015 11:15AM - 2:15PM — Session T14 DMP FIAP: Focus Session: Dopants and Defects in TiO2, SrTiO3, and Other Oxides 008A - Kookrin Char, Seoul National University

11:15AM T14.00001 Structural and electronic defects in SrTiO$_3$ and TiO$_2$$^1$, ANDERSON JANOTTI, Materials Department, University of California Santa Barbara, CA 93106-5050 — Control of defects and charge carriers is key to the development of metal oxide semiconductors as electronic materials. As in any semiconductor, one of the main challenges is to control the conductivity by doping as well as to reduce the concentration of native defects and unintentional impurities that act as compensation centers or sources of deep level luminescence, thus minimizing their deleterious effects. Experiments indicate that defects such as oxygen vacancies easily form and strongly affect the electronic properties of many oxide semiconductors. In SrTiO$_3$, it has been proposed that oxygen vacancies simultaneously act as a shallow donor that contribute to n-type conductivity, and as a deep center that causes luminescence well below the band-gap energy. This seemingly paradoxical behavior has remained unresolved. In rutile TiO$_2$, it has been proposed that excess electrons, either from oxygen vacancies or donor impurities, form small polarons. Although the formation of small polarons explains prominent features observed in the optical absorption spectra, charge localization seems incompatible with the high electron mobilities determined in Hall measurements of single crystals. In this talk we will discuss results of first-principles calculations for native point defects and impurities in SrTiO$_3$ and TiO$_2$, as they are prototypes of a large class of transition-metal oxide semiconductors. We will address the impact of defects and small-polaron formation on the electrical and optical properties in each material, providing a framework for interpreting similar phenomena in other complex oxides.

$^1$This work was performed in collaboration with J. B. Varley, M. Choi, N. Umezawa, P. Rinke, C. Franchini, G. Kresse, and C. G. Van de Walle. We acknowledge support from the Army Research Office under grant number W911NF-11-1-0232.

11:51AM T14.00002 Oxygen vacancy and hole conduction in “leaky” amorphous TiO2 from first-principles calculations, HIEU PHAM, LIN-WANG WANG, Lawrence Berkeley National Laboratory — In the last decade, titanium dioxide (TiO$_2$) has been one of the most studied materials due to its low cost, lightweight, eco-friendliness and long-term stability to be used in energy applications. Specifically, it was found recently that amorphous TiO$_2$ could be used as a protection layer for photo-induced water splitting. While protecting the light-absorbing photoanodes from corrosion, it can conduct hole carriers, perhaps through some defect levels. Nevertheless, the exact mechanism for such hole conductivity is not clearly understood. In this work, an amorphous TiO$_2$ model is obtained from molecular dynamics employing the melt-and-quench technique. The electronic properties, polaronic states and hole conduction mechanism in amorphous structure were investigated by means of density functional theory. The formation of oxygen vacancy was found to reduce significantly (by a few eV) upon the amorphization. Our theoretical study suggested that the oxygen vacancies and their defect states provide hopping channels which are comparable with experimental observations and could be responsible for the hole conduction in the “leaky” TiO$_2$ recently discovered for the photochemical water-splitting applications.
12:03PM T14.00003 Negative $U$ behavior of TiO$_2$- Magnéli and Corundum phases

ANTONIO CLAUDIO PADILHA, Universidade Federal do ABC, Santo André, Brazil, ALEXANDRE ROCHA, Universidade Estadual Paulista, São Paulo, Brazil, HANNES RAEBINGER, Yokohama National University, Yokohama, Japan, GUSTAVO DALPIAN, Universidade Federal do ABC, Santo André, Brazil — The isolated oxygen vacancy is known to be a negative $U$ defect in rutile TiO$_2$. This effect manifests itself by a double donor level close to the conduction band. As oxygen is further removed, TiO$_2$ no longer remains in the rutile structure and the Magnéli phases Ti$_n$O$_{2n-1}$ ($4 \leq n \leq 37$) are obtained. Those structures are characterized by ordered planes of oxygen vacancies (so-called shear planes) between rutile-like layers. Further removal of oxygen leads to the formation of Ti$_2$O$_3$ and the corundum phase Ti$_2$O$_3$. In this work, we calculated using DFT+$U$ the formation energy of several of these systems and show that these systems also have a double donor transition per oxygen vacancy. This means that these compounds as such also have negative $U$ behavior, even though the vacancies are not isolated and the donor level is a broad delocalized impurity band close to the bottom of the conduction band. The relaxation energy for the doubly ionized system is larger than that of the singly ionized one, rendering the latter unstable.

12:15PM T14.00004 Termination-specific study of oxygen vacancy transition levels on SrTiO$_3$(001) surfaces by scanning tunneling spectroscopy

WATTAYA SITAPUTRA, NIKHIKL SIVADAS, MAREK SKOWRONSKI, DI XIAO, RANDALL FEENSTRA, Carnegie Mellon University — We have studied the surface electronic structure of oxygen vacancies on SrTiO$_3$(001) surfaces using scanning tunneling spectroscopy and DFT calculations with local spin density approximation (LSDA+$U$). With high dynamic range measurements, a mid-gap level associated with the surface oxygen vacancies was observed for SrO-terminated surfaces. TiO$_2$-terminated surfaces, on the other hand, did not exhibit observable mid-gap states (this lack of signal is believed to be due to the nature of defect wavefunction involved, as well as possibly involving transport limitations in the STS measurements). Both vacuum-cleaved and MBE-grown surface have been studied. For the former, the Fermi level is pinned near mid-gap owing to disorder-induced surface states. The amount of surface disorder can be controlled in the case of epitaxially grown surfaces. Rougher MBE-grown surfaces tend to exhibit similar spectral characteristics to the cleaved surfaces, while a shift of the Fermi level toward the conduction band was observed for flattened grown surfaces. Notably, with a decreasing number of disorder-induced surface states, the Fermi level is found to be pinned within the observed band of oxygen vacancy levels.

1This research was supported by AFOSR Grant No. FA9550-12-1-0479, and it used resources of the National Energy Research Scientific Computing Center, supported by the Office of Science, US Department of Energy under Contract No. DEAC02-05CH11231.

12:27PM T14.00005 Magnetism and metal-insulator transition in oxygen deficient SrTiO$_3$

ALEJANDRO LOPEZ-BEZANILLA, Argonne Natl Lab, P. GANESH, Oak Ridge National Lab, PETER LITTLEWOOD, Argonne Natl Lab — We report new findings in the electronic structure and magnetism of oxygen vacancies in SrTiO$_3$. By means of first-principles calculations we show that the appearance of magnetism in oxygen-deficient SrTiO$_3$ is not determined solely by the presence of a single oxygen vacancy but by the density of free carriers and the relative proximity of the vacant sites. While an isolated vacancy behaves as a non-magnetic double donor, manipulation of the doping conditions allows the stability of a single donor state with emergent local moments. Strong local lattice distortions enhance the binding of this state. Consequently we find that the free-carrier density and strain are fundamental components to obtaining trapped spin-polarized electrons in oxygen-deficient SrTiO$_3$, which may have important implications in the design of switchable magneto-optic devices.

12:39PM T14.00006 The effect of oxygen vacancies and strain on the optical energy gap of strained SrTiO$_{3−δ}$ thin films

NATHAN STEINLE, BARRY KOEHNE, Undergraduate Assistant, RYAN COTTIER, Post-Doctoral, DANIEL CURRIE, Post-Graduate, NIKOLETA THEODOROPOULOU, Advisor — SrTiO$_{3−δ}$ (STO) films were grown on single crystal SrTiO$_3$ and p-Si (001) substrates using molecular beam epitaxy (MBE). The single-phase STO/Si films were of high crystalline quality as verified by x-ray diffraction (XRD) and atomic force microscopy (AFM) with an rms roughness of less than 0.5 nm. Oxygen vacancies were introduced by controlling the oxygen pressure (P(O$_2$): 10$^{-8}$ to 10$^{-7}$ torr) during growth. The lattice mismatch of STO on Si causes a 1.7% bi-axial, compressive strain. The oxygen vacancies cause a tensile strain because of the different Ti$^{4+}$ and Ti$^{3+}$ ionic radii. This agrees with our XRD measurements that show a decrease of the out of plane lattice constant as either the thickness or P(O$_2$) during growth increase. We used a Variable Angle Spectroscopic Ellipsometer M-2000 by Woolam and the VASE software to measure and model the optical properties of the films and substrates using Tauc-Lorentz and Gaussian oscillators for the STO layer. Our results show that the direct energy bandgap of STO at around 3.8 eV increases as either the thickness or P(O$_2$) decrease, in agreement with theoretical calculations. Additionally, absorption is observed in the 1.5-2 eV region for the films with increased Oxygen vacancies.

1:03PM T14.00008 Small Polaronic and Point Defects in Barium Cerate\textsuperscript{1}, MICHAEL SWIFT, ANDERSON JANOTTI, CHRIS G. VAN DE WALL, Univ of California - Santa Barbara — Barium cerate (BaCeO\textsubscript{3}) is a well-known proton-conducting material. In applications, it is frequently doped (for instance with yttrium) to increase stability and promote hydrogen uptake. However, the microscopic mechanisms of ionic conductivity and the effects of doping and native defects are still not fully understood. Many of the obstacles to the theoretical study of this material stem from the nature of the conduction band, which is made up of cerium 4f states. These states present a challenge to first-principles techniques based on density functional theory within the standard approximations for exchange and correlation. Using a hybrid functional, we investigate the effects of hydrogen impurities and native defects on the electrical and optical properties of BaCeO\textsubscript{3}. We discuss the tendency of excess electrons or holes to localize in the form of small polarons. We also explore the interactions of polarons with hydrogen impurities and oxygen vacancies, and their impact on luminescence properties.

1:15PM T14.00009 Use of nonpolar BaHfO\textsubscript{3} gate oxide for field effect on the high mobility BaSnO\textsubscript{3}. CHULKWON PARK, USEONG KIM, YOUNG MO KIM, CHANGJONG JU, KOOKRIN CHAR, Department of Physics & Astronomy, Seoul National University — Recently, BaSnO\textsubscript{3} (BSO) has attracted attentions as a transparent conducting oxide and/or a transparent oxide semiconductor due to its novel properties: the excellent oxygen stability even at high temperature and the high electrical mobility at room temperature. We fabricated field effect transistors using La-doped BSO as the semiconducting channel on undoped BSO buffer layers on SrTiO\textsubscript{3} substrates. A non-polar perovskite BaHfO\textsubscript{3} was used as the gate insulator, and 4% La-doped BSO as the source, the drain, and the gate electrodes grown by pulsed laser deposition. We have measured the optical and the dielectric properties of the epitaxial BaHfO\textsubscript{3} gate oxide layer, namely the optical band gap, the dielectric constant, and the breakdown field. Using such BaHfO\textsubscript{3} gate oxide, we observed carrier modulation in the active layer by field effect. In this presentation, we will report on the performance of such field effect transistors: the output and the transfer characteristics, the field effect mobility, the ratios, and the subthreshold swing.

1:27PM T14.00010 Field effect transistors based on BaSnO\textsubscript{3} with AlO\textsubscript{x} and HfO\textsubscript{3} gate oxides. YOUNG MO KIM, CHULKWON PARK, USEONG KIM, KOOKRIN CHAR, Department of Physics and Astronomy, Seoul National University — La-doped BaSnO\textsubscript{3} (BSO) is a transparent perovskite oxide semiconductor with high electron mobility and excellent oxygen stability. We fabricated n-type field effect transistors (FETs) on undoped BaSnO\textsubscript{3} (BSO) buffer layers on SrTiO\textsubscript{3} (STO) substrates using BLSO as the semiconducting channels and amorphous AlO\textsubscript{x} and HfO\textsubscript{3} as the gate insulators. BSO buffer layers and BLSO channels were grown by pulsed laser deposition, while the AlO\textsubscript{x} and HfO\textsubscript{3} gate insulators were grown by atomic layer deposition (ALD). Sn\textsubscript{2}O\textsubscript{3} (ITO) was used as the source, the drain, and the gate electrodes. At room temperature, we achieved the field effect mobility value of 17.8 cm\textsuperscript{2}/Vs for the AlO\textsubscript{x} FET and 19.2 cm\textsuperscript{2}/Vs for the HfO\textsubscript{3} FET. The subthreshold swing was measured to be 3.2 V/dec for the AlO\textsubscript{x} FET and 1.2 V/dec for the HfO\textsubscript{3} FET.

1:39PM T14.00011 P-type Semiconducting Behavior of BaSn\textsubscript{1−x}Ru\textsubscript{x}O\textsubscript{3} system, HYUKWOO Kwon, JUYEON SHIN, KOOKRIN CHAR, Seoul National University — BaSnO\textsubscript{3} is a promising transparent perovskite oxide semiconductor due to its high mobility and chemical stability. Exploiting such properties, we have applied BaSnO\textsubscript{3} to the field effect, the 2-dimensional electron gas, and the pn-junction devices. In spite of the success of the K-doped BaSnO\textsubscript{3} as a p-type doped, its carrier density at room temperature is rather small due to its high activation energy of about 0.5 eV. In continuation of our previous study on SrSn\textsubscript{1−x}Ru\textsubscript{x}O\textsubscript{3} system, we studied the p-type semiconducting behavior of BaSn\textsubscript{1−x}Ru\textsubscript{x}O\textsubscript{3} system. We have epitaxially grown the BaSn\textsubscript{1−x}Ru\textsubscript{x}O\textsubscript{3} (0<\textless\textless0.12) thin films by pulsed laser deposition. X-ray diffraction measurements show that the films maintain a single phase over the entire doping range and the lattice constants of the system decrease monotonously as the Ru doping increases. Transport measurements show that the films are semiconducting and their resistivities dramatically decrease as the Ru doping increases. Hall measurement data show that the charge carriers are p-type and its corresponding mobility values vary from 0.3 ~ 0.04 cm\textsuperscript{2}/Vs, depending on the doping rate. The hole carrier densities, measured to be 10\textsuperscript{17} ~ 10\textsuperscript{19} /cm\textsuperscript{3}, are larger than those of K-doped BaSnO\textsubscript{3}. Using BaSn\textsubscript{1−x}Ru\textsubscript{x}O\textsubscript{3} and Ba\textsubscript{1−y}La\textsubscript{y}SnO\textsubscript{3} as p-type and n-type semiconductors, we will fabricate np-junctions and report its performance.

1:51PM T14.00012 Effect of a Ru doped SnO\textsubscript{2−x} buffer layer on thin-film transistors based on SnO\textsubscript{2−x} channel layer, HYOSIK MUN, HYEONSEOK YANG, KOOKRIN CHAR, Seoul National University — We report on studies of transparent thin-film transistor (TFT) devices based on SnO\textsubscript{2−x} thin film. SnO\textsubscript{2−x} thin films were prepared by pulsed laser deposition with and without Ru-doped SnO\textsubscript{2−x} buffer layer on r-plane sapphire substrates to investigate the effect of a Ru-doped SnO\textsubscript{2−x} buffer layer on the electrical properties of SnO\textsubscript{2−x} channel layer. The Ru-doped SnO\textsubscript{2−x} buffer layer was found to be very crystalline and insulating at the same time. Using such Ru-doped SnO\textsubscript{2−x} buffer layer made it possible for the SnO\textsubscript{2−x} channel layer to have both low carrier density and high mobility, probably due to reduction of the threading dislocation density. AlO\textsubscript{x} gate insulator layer was deposited by atomic layer deposition and ITO was used as the source, the drain, and the gate electrodes. We will compare the TFT performances with or without the Ru-doped SnO\textsubscript{2−x} buffer layer and discuss how such buffer layer enables the necessary device parameters for TFT.

2:03PM T14.00013 Aliovalently-Doped Garnets for Li Battery Solid State Electrolytes, DEREK K. SCHWANZ, ERNESTO E. MARINERO, Purdue University — We report on a new family of fast ionic conductivity electrolytes based on the garnet LiLaZ\textsubscript{2}O. Partial substitution of Zr by aliovalent atomic species through solid state solution synthesis results in ionic conductivities 2 orders of magnitude larger than the tetragonal phase of LiLaZ\textsubscript{2}O and comparable to that of its cubic phase. The synthesis temperature is 400°C, lower than that required for the cubic stabilization of LiLaZ\textsubscript{2}O. Ongoing improvements on microstructure and film density as well as optimization of the garnet stoichiometry are expected to yield ionic conductivities surpassing the highest values reported to-date on cubic doped LiLaZ\textsubscript{2}RO (Ta, Al, W, Nb).

Thursday, March 5, 2015 11:15AM - 2:03PM
Session T15 FlAP: Nanotechnology 008B - Samir Iqbal, University of Texas at Arlington

11:15AM T15.00001 Structural aspects of TiO\textsubscript{2} nanopowders, SERGEY MAMEDOV, Horiba Scientific — TiO\textsubscript{2} nanopowders obtained using different methods with the mean size of 5, 15, 30 and 40 nm have been investigated by Raman spectroscopy in wide spectral range. Nano-size of TiO\textsubscript{2} crystals lead to a shift and broadening of the first-order Raman lines through a relaxation of the q = 0 selection rule and effects on the position, width and asymmetry of a Raman bands. The details of the evolution of the 144 cm\textsuperscript{-1} Raman line shape on the size and distributions of the nanopowders are presented and discussed in frame of confined phonons model. Analysis of Raman spectra shows that structural characteristics of nanopowders may be different even size of the nanopowders is the same. Structural features of the material depend on preparation methods/conditions and can be extracted from Raman spectra of the material.
11:27AM T15.00002 Growth and Characterization of Coherently Strained Si-Si\(_{1-x}\)Ge\(_x\) Core-Shell Nanowire Heterostructures , DAVID DILLEN, KYOUNGHWAN KIM, EMANUEL TUTUC, Univ of Texas, Austin — The large valence band offset in Ge-Si-Si\(_{1-x}\)core-shell nanowires has provided an interesting platform for the study of quasi one-dimensional hole-confined systems, and has led to the demonstration of high-performance electronic devices. Progress in the development of electron-confined systems using Group-IV core-shell structures has, however, been much slower. Coherently strained Si-Si\(_{1-x}\)Ge\(_x\)core-shell nanowires represent one possible radial heterostructure where a positive shell-to-core conduction band offset, beneficial for quantum confinement of electrons in the Si core, may be realized. We discuss the growth of strained Si-Si\(_{1-x}\)Ge\(_x\)core-shell nanowires with tunable shell composition using vapor-liquid-solid growth for the Si nanowire core, followed in-situ by Si-Si\(_{1-x}\) Ge\(_x\)shell growth. Transmission electron microscopy reveals a single crystal nanowire structure, evincing an epitaxial shell growth. Raman spectroscopy reveals a red-shift of the core Si-Si Raman mode, which depends on the shell composition and nanowire thickness, indicating coherent tensile strain in the Si core.

11:39AM T15.00003 Gold Nanorod translocations and charge measurement through solid-state nano pores , REBECCA ENGLEKE, MEHDI ZANJANI, KIM VENTA, XINGCHEN YE, GOPINATH DANDA, CHRISTOPHER MURRAY, JENNIFER LUKES, MARJIA DRNDIC, Univ of Pennsylvania — We study translocations of gold nanorods through silicon nitride nanopores and present a method for determining the surface charge of nanorods from the magnitude of the ionic current change as nanorods pass through the pore. Positively-charged nanorods with average diameters 10 nm and average nanorod lengths between 44 and 65 nm were translocated through 40 nm thick nanorods with diameters between 19 and 27 nm in 1, 10, or 100 mM KCl solutions. The presented method based on comparing simulations with experiments predicts a surface charge of 26 mC/m\(^2\) for 44 nm long gold nanorods and 18 mC/m\(^2\) for 65 nm long gold nanorods.

11:51AM T15.00004 The Effects of Nanotexturing Microfluidic Platforms to Isolate Brain Tumor Cells\(^1\) , MUHYMIN ISLAM, ADEEL SAJID, YOUNG-TAE KIM, University of Texas at Arlington, SAMIR M. IQBAL, Nano-Bio Lab, Electrical Engineering, Bioengineering, University of Texas at Arlington — Detection of tumor cells in the early stages of disease requires sensitive and selective approaches. Nanotextured polydimethylsiloxane (PDMS) substrates were implemented to detect metastatic human glioblastoma (hGBM) cells. RNA aptamers that were specific to epidermal growth factor receptors (EGFR) were used to functionalize the substrates. EGFR is known to be overexpressed on many cancer cells including hGBM. Nanotextured PDMS was prepared by micro reactive ion etching. PDMS surfaces became hydrophilic uponnanotexturing. Nanotextured substrates were incubated in tumor cell solution and density of captured cells was determined. Nanotextured PDMS provided >300% cell capture compared to plain PDMS due to increased effective surface area of roughened substrates at nanoscale as well as more focal points for cell adhesion. Next, aptamer functionalized nanotextured PDMS was incorporated in microfluidic device to detect tumor cells at different flow velocities. The shear stress introduced by the flow pressure and heterogeneity of the EGFR overexpression on cell membranes of the tumor cells had significant impact on the cell capture efficiency of aptamer anchored nanotextured microfluidic devices. Eventually tumor cells were detected from the mixture of white blood cells at an efficiency of 73% using the microfluidic device. The interplay of binding energies and surface energies was major factor in this system.

\(^1\)Support Acknowledged from NSF through ECCS-1407990

12:03PM T15.00005 Nano-Storage Wires for the Controlled Release of Biochemical Materials , HANEUL YOO, DONGJUN LEE, EUNJI KIM, DAESAN KIM, JUHUN PARK, SEUNGHUN HONG, Seoul Natl Univ — We herein report "nano-storage wires" that can store chemical species and release them at a desired moment by electrical stimulations. Here, we utilized the electrodeposition process through an anodized aluminium oxide template to fabricate multi-segmented nanowires which consisted of a polypyrrole (PPy) segment containing adenosine triphosphate (ATP) molecules, a ferromagnetic nickel segment, and a conductive gold segment. We could drive and deposit the NSWs onto desired positions on electrode surfaces via external magnetic fields. When the external electric potential was applied from the electrodes, the NSWs released ATPs from the PPy segments, and the released ATPs could change the activities of motor proteins near the NSWs. Furthermore, through direct writing or magnetic manipulation strategies, we could print NSWs onto various substrates such as flexible or three-dimensional structured substrates to build versatile chemical storage devices. Since our strategy enables the controllable storage and release of chemicals, our development should open up various applications such as drug delivery systems, biosensors and biochips for the controlled release of chemicals to biosystems.

12:15PM T15.00006 Precise Fabrication of Nanowires with Diameters of Sub-1 nm to 3 nm Using Multilevel Pulse-voltage Injection , ITARU YANAGI, RENA AKAHORI, TAKAHIDE YOKOI, KEN-ICHI TAKEDA, Central Research Laboratory, Hitachi Ltd — To date, solid-state nanowires have been fabricated primarily through a focused-electronic beam via TEM. For mass production, however, a TEM beam is not suitable and an alternative fabrication method is required. Recently, a simple nanowire-fabrication method has been reported that is based on a dielectric breakdown phenomenon of a thin membrane. In this study, to stably fabricate nanowires with diameters of 1 to 2 nm (which is an essential size for distinguishing each nucleotide) via dielectric breakdown, a technique called multilevel pulse-voltage injection (MPVI) is proposed and demonstrated. MPVI uses pulse voltages for generating the nanowires, and the generation of the nanowires is verified by measuring the current through a membrane at low voltage. This method can generate nanowires with diameters of less than 1 nm in a 10-nm-thick Si\(_3\)N\(_2\) membrane with a probability of 90%. The diameter of the generated nanowires can be widened to the desired diameters (up to 3 nm) with sub-nanometre precision. The mean effective thickness of the fabricated nanowires was 3.7 nm. These findings are derived from TEM images of the fabricated nanowires and analyses of ionic-current blockades during single-stranded DNA translocation.

12:27PM T15.00007 Electrospaying in a complex electrical field: jet formation and characteristics of final product , SHEILA KHODADADI, KIRSTEN ROVERS, GABRIEL MEESTERS, Delft University of Technology, TUDELFT-DELFT PROJECT MANAGMENT TEAM — The electrohydrodynamic atomization (EHDA) of liquid solutions is a technique developed to produce micro and nanometer size droplets. It consists of breaking a liquid jet by applying electrical forces. EHDA is one of the most suitable techniques for drug delivery and bio-nanotechnology, when precise (nm-µm) particle size and narrow size distribution is needed. However there are some challenges facing application of this technique such as limitation in flow rate, characteristics of liquids (surface tension, conductivity,…) and, the possible droplet size reduction due to evaporation of the liquid and Coulomb fission. To tackle these challenges in an EHDA-based inhalation device, we explored different possibilities to reach a stable mode in terms of jet formation, droplet-particle size and size distribution. In this contribution, we demonstrate how device configuration and operational conditions influence the electrospayed liquid and final product. We will also discuss how our approach can be used to tailor morphological properties of nanostructured materials with identical chemical compositions.
Effect of processing temperature on the properties of Fe-Hydroxyapatite: 1
VINODI KATHIRIARACHCHI, THEODORA LEVENTOURI, Department of Physics, Florida Atlantic University, ADAM RONDINONE, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, KOREY SORGE, Department of Physics, Florida Atlantic University — Multi-substituted Hydroxyapatite (HAp), Ca$_5$(PO$_4$)$_3$OH, is the main mineral phase in physiological apatite. Fe is a minor substitution element in bone and enamel substituting Ca in the HAp structure. Crystal structure, magnetic and microstructure properties of Ca$_5-x$Fe$_x$(PO$_4$)$_3$OH depend on processing parameters. We present results from our research on the Ca$_5-x$Fe$_x$(PO$_4$)$_3$OH system (x = 0.0, 0.05, 0.1, 0.2 and 0.3) prepared at 37$^\circ$C, and 80$^\circ$C. Hydroxyapatite single-phase was detected for x <0.1 in both sets of samples, while hematite and/or maghemite develops starting at x = 0.1. Rietveld refinements of XRD and NPD patterns show that the a and c lattice constants decrease with increasing Fe concentration for both sets of samples. Pure HAp is diamagnetic but as x increases, Fe-HAp transitions from paramagnetic to weak ferromagnetic behavior. TEM images show spherical particles in samples prepared at 37$^\circ$C, and elongated particles in samples prepared at 80$^\circ$C. XRF studies confirm the iron substitution and show that the Ca/P stoichiometric ratio of 1.67 decreases with increasing the Fe concentration. Further, the Fe/Ca+Fe atomic ratios of samples prepared at 37$^\circ$C are greater than those prepared at 80$^\circ$C.

1TEM and XRF data were collected at the Center for Nanophase Materials Sciences which is a DOE Office of Science User Facility. NPD data were collected at the SNS of the ORNL.

Application of near infrared sensitive multifunctional nanophosphors in optical and photoacoustic imaging . FRANCISCO PEDRAZA, AJITH KUMAR, LAWRENCE MIMUN, JING YONG YE, DHIRAJ SARDAR, Univ of Texas, San Antonio — Though there are several contrast agents available in the biomedical industry for non-invasive imaging, many of them are not capable of providing in-depth information with high signal to noise ratio. Because of the extremely high scattering processes in the biological medium, most of the optical imaging techniques fail to provide sufficient resolution in deep tissue. An alternate way to circumvent this difficulty is to integrate multiple imaging modalities such as optical, magnetic, and photoacoustic (PA) in a single contrast agent. Trivalent rare earth doped inorganic phosphors are found to be the most suitable candidates for this purpose due to their excellent NIR spectral properties. In addition, by controlling the non-radiative processes through various emission channels, it is possible to generate strong PA signals that would help us explore the wavelength dependent PA imaging features. Furthermore, magnetic imaging can be added by incorporating paramagnetic (Gd) or ferromagnetic (Fe) ions suitable lattice positions. In this work we explore the NIR sensitive optical and PA imaging features of rare-earth doped phosphors and compare their capabilities with other metallic nanoparticle-based PA imaging agents.

Fabricating quench condensed lead thin film circuits using MEMS Fab on a Chip technology . MATTHIAS IMBODEN, HAN HAN, Boston University, PABLO DEL CORRO, Instituto Balseiro, Centro Atomico Bariloche, FLAVIO PARDO, CRISTIAN BOLLE, Bell Labs, Alcatel-Lucent, DAVID BISHOP, Boston University — We have developed a MEMS Fab on a Chip consisting of micro-sources, mass sensors/heaters/thermometers, shutters and a dynamic stencil. The fab only occupies a volume of a few cubic millimeters and consumes milliwatts of power, and hence can be operated in a cryostat. Thin film patterns of arbitrary shapes using multiple materials can be manufactured, while strongly suppressing thermal annealing effects. We demonstrate deposition of quench condensed lead films with fractions of a monolayer thickness control. Furthermore, using low deposition rates it is estimated that the surface temperature of the target heats by only 1.7 K. We study the effects of growing quench condensed films with different evaporation rates to demonstrate thermal annealing effects which occur during deposition. We measure the minimum conduction thickness (insulator to metal transition) as well as the superconducting transition temperature as a function of film thickness in order to shed light on growth of amorphous films and the transition to nanocluster formations. The Fab on a Chip will allow us to build nanocircuits made of ultra-thin materials. Annealing and doping is controlled and measurements occur in situ, without exposing the fabricated circuits to thermal fluctuations or foreign contaminants. This enables new types of experiments based on quantum circuits which cannot be fabricated using standard lithography techniques.

High speed electrical measurement for roll-to-roll nanomanufacturing . NATHAN ORLOFF, CHRISTIAN LONG, JAN OBRZUT, National Institute of Standards and Technology, LAURENT MAILLAUD, National Institute of Standards and Technology — Roll-to-roll processing of nanomaterials can produce high-quality coatings and filamentous continuously, enabling materials applications for electronics, fabrics, and wires. These applications often require specific electrical properties that are correlated to the material’s nanostructure. While several high-throughput structural characterizations techniques exist, there are relatively few contactless options for quantifying the electrical properties of materials for nanomanufacturing. Here, we demonstrate a microwave method for measuring complex permittivity (or geometry for samples of known dielectric properties) in a millisecond. The demonstrated measurement times are suitable for current industrial needs, allowing real-time materials characterization and in-line control of processing variables without disrupting production.

Development Characteristics of PMMA in alternative alcohol:water mixtures . LEONIDAS E. OCOLA, Argonne National Laboratory — The most widely used resist in electron beam lithography is polymethylmethacrylate (PMMA). The standard developers used are solution mixtures of isopropanol (IPA) and methyl isobutyl ketone (MIBK) in a ratio of 3:1 and mixtures of IPA and water (H2O) in a ratio of 7:3. The Globally Harmonized System (GHS) classification entry for IPA includes: Specific target organ toxicity - single exposure (Category 3). MIBK is much more hazardous than IPA. The only GHS classification entry for Ethanol is: Flammable liquids (Category 2), i.e. more environmentally safe. Using Ethanol/H2O as a developer will therefore enable lower hazardous waste disposal costs to cleanrooms. We find Ethanol/H2O at 85% volume (2.1 molar) exhibits excellent lithography results as good as with IPA/H2O, and better contrast and sensitivity than IPA/H2O and MIBK/IPA developers. Lithographic data shows trends similar to published cosolvency data, but differ too much to be explained by it. In addition, unusual development at 50% volume concentrations for both IPA and Ethanol in H2O show dramatic pohotolite formation instead of uniform thickness loss found in standard contrast curve exposures. We believe local pockets of concentrated alcohol water molar mixtures are responsible for such behavior.

This work was supported by the Department of Energy under Contract No. DE-AC02-06CH11357. Use of the Center for Nanoscale Materials was supported by the U. S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

ABSTRACT WITHDRAWN —
of strong electron interactions within the fractal Hofstadter spectrum. Exploiting nano-scale interfacial effects between graphene and hexagonal boron nitride substrates, together with application of extremely high magnetic fields.

The discovery of the quantum Hall effect gave birth to an expansive field of research into 2D electronic systems in the presence of a magnetic field, however, direct application of such techniques and a real-space Kubo-Greenwood approach [2]. Such a breaking of the sublattice symmetry leads to the appearance of a true band gap in graphene protected by boron nitride. The device is enabled by a top-gated, solid electrochemical cell designed with calcium fluoride (CaF$_2$), which facilitates the tuning of these films by choice of substrate or chemical functionalization. Such parameters are generally selected during fabrication, and therefore remain static during device operation. However, the possibility of dynamic chemistry in a tunable solid-state system will enable the development of new devices which fully leverage the rich chemistry of graphenic materials. Here, we fabricate a novel device for localized, dynamic doping and functionalization of graphene that is compatible with CMOS processing. The device is enabled by a top-gated, solid electrochemical cell designed with calcium fluoride (CaF$_2$) substituting the oxide of a traditional MOSFET. When the CaF$_2$ is gated, F flows from cathode to anode, segregating Ca and F. In this work, one electrode is graphene. When saturated with fluorine, graphene undergoes covalent modification, becoming a wide-bandgap semiconductor. In contrast, when functionalized with calcium or dilute fluorine, graphene is electron or hole doped, respectively. With transport, Raman, and XPS, we demonstrate this lithographically localized graphene sheets encapsulated by various thicknesses of boron nitride. We discuss the implications of our work for future electrolyte gating studies of materials protected by boron nitride.

We gratefully acknowledge support from the National Science Foundation under ECCS-1232018 and DMR-1156737.

On-Chip Electrolytic Chemistry for the Tuning of Graphene Devices

Astronomy — Solid-state nanopores act as single-molecule sensors whereby passage of an individual molecule in aqueous electrolyte through a nanopore is modulated of the Fermi level on the carbon side of the junction or tunneling through the barrier due to its gate field induced thinning. Devices fabricated with a continuous layer of graphene probed principally the barrier height lowering mechanism (responsible for 2 1/2 order of magnitude current modulation) while devices fabricated with graphene into which random, micron scale holes had been created probed tunneling as well (resulting in 6 orders of magnitude current modulation). The random hole density in the latter case was limited to 20% of the graphene surface area. Here we describe the performance of devices in which ordered hole arrays permit the exploration of higher hole density G-VFETs.

DNA translocation through these nanopores, where access resistance becomes comparable to the resistance through the nanopore itself.

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T16 DMP: Focus Session: Graphene Electronic Devices

11:15AM T16.00001 Electrolyte gating of graphene protected by boron nitride, KEVIN THARRATT, PATRICK GALLAGHER, MENYOUNG LEE, Department of Physics, Stanford University, Stanford, California 94305, USA, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, 1-1 Namiki, Tsukuba, 305-0044, Japan, DAVID GOLDHABER-GORDON, Department of Physics, Stanford University, Stanford, California 94305, USA — Electrolyte gating is a technique used to induce a high carrier density at a sample surface. We have recently shown that for strontium titanate surfaces protected by boron nitride, electrolyte gating can induce high carrier densities while maintaining high electron mobility and limiting electrochemical reactions at the sample. In this talk, we describe electrolyte-gating experiments on single-layer graphene sheets encapsulated by various thicknesses of boron nitride. We discuss the implications of our work for future electrolyte gating studies of materials protected by boron nitride.

12:51PM T16.00007 Equilibration of Edge States at the Graphene P-N Junction Interface
SON LE, NIKOLAI KLIMOV, DAVID NEWELL, CURT RICHTER, NIST - Natl Inst of Stds & Tech, JUN YAN, Department of Physics, University of Massachusetts, Amherst, PRATIK AGNIOHOTRI, EVERETT COMFORT, JIUNG LEE, College of Nanoscale Science and Engineering, SUNY Pi, NY — The interaction of chiral quantized edge states at the graphene pn-junction (pnJ) interface at low temperature and high magnetic fields is topic of intense research recently [1]. It has been presumed that electron and hole edge states completely equilibrate with each other at the pnJ interface, creating an unique set of quantized longitudinal resistance values depending on the number of edge states that present in the device [2]. Experimentally, we have used a unique buried-split gate structure to electrostatically form a graphene pnJ with independent control of the number of edge state in the n- and p-regions of the device's channel. Measurement of both longitudinal and pseudo-Hall resistance shows quantized values that cannot be explained by using the complete equilibration model. We present a new “non-equilibration” model, in only the lowest Landau level’s (LLs) edge states equilibrate at the pnJ interface, while edge states arising from higher filling factor LLs propagate along the interface without equilibration. Our new model agrees with both the longitudinal and pseudo-Hall resistance results.

1:03PM T16.00008 Graphene/Lead (Pb)-based Cooper-pair splitter, IVAN BORZENETS, YUYA SHIMAZAKI, University of Tokyo, GARETH JONES, SAVERIO RUSSO, University of Exeter, MICHISHICA YAMAMOTO, SEIGO TARUCHA, University of Tokyo — We have fabricated a topological split gate structure based on a superconductor- two normal leads. (Compared to nonwire-appearing devices, the two dimensional nature of graphene allows for the normal leads to be placed arbitrarily close together and in a non-parallel arrangement.) The superconducting lead is created by contacting graphene with lead (Pb), thus inducing a supercurrent via the proximity effect. The normal metal leads are patterned into quantum dots by etching nano-constrictions with self-aligned side gates. Quantum dots strongly suppress two electron processes, allowing only one electron to pass at a time. Thus, the Cooper-pair splitting efficiency is enhanced as the split electrons must necessarily tunnel through different quantum dots. Therefore, we measure the longitudinal and transverse resistance of our graphene-based split gates, as well as the effect of graphene on the time evolution of the effect and its dependence on the number of edge state in the n- and p-regions of the device's channel.

HINNEFELD, Univ of Illinois - Urbana, RUIJUAN XU, University of California - Berkeley, STEVEN ROGERS, MOONSUB SHIM, Univ of Illinois - Urbana, LANE MARTIN, University of California - Berkeley, NADYA MASON, Univ of Illinois - Urbana — Graphene’s linear dispersion relation and the attendant implications for bipolar electronic applications have motivated a range of experimental efforts aimed at producing p-n junctions in graphene. Recent experimental results indicate that the electrical polarization in ferroelectric substrates can modify the local doping in graphene, via a hysteretic gating effect. Here, we exploit this effect to create variably doped local regions in a graphene device having a single, universal back-gate. By patterning devices on a partially shielded ferroelectric substrate, we show through electrical transport measurements that p- and n-doped regions can be induced in the system. We explore the competing effects of substrate polarization and interfacial charge-trap processes that contribute to this behavior, along with the time evolution of the effect and its dependence on the measurement conditions and device parameters.

1:15PM T16.00009 Electromechanically generating electricity with a gapped-graphene electric generator, DONALD DRESSEN, JENE GOLOVCHENKO, Harvard University — We demonstrate the fabrication and operation of a gapped-graphene electric generator (G-GE). The G-GE generates electricity from the mechanical oscillation of droplets of electrolytes and ionic liquids. The spontaneous adsorption of ionic species on graphene charges opposing electric double-layer capacitors (EDLCs) on each half of the device. Modulating the area of contact between the droplet and graphene leads to adsorption/desorption of ions, effectively charging/discharging each EDLC and generating a current. The flow of current supports a potential difference across the G-GE due to the device’s internal impedance. Both the magnitude and polarity of the induced current and voltage show a strong dependence on the type of ionic species used, suggesting that certain ions interact more strongly with graphene than others. We find that a simple model circuit consisting of an AC current source in series with a resistor and a time-varying capacitor accurately predicts the device’s dynamic behavior. Additionally, we discuss the effect of graphene’s intrinsic quantum capacitance on the G-GE’s performance and speculate on the utility of the device in the context of energy harvesting.

1:27PM T16.00010 Transport measurements of negative refractive behavior in ballistic graphene hetero junctions, GIL-HO LEE, GEON-HYOUNG PARK, MINSOO KIM, JAE HYEONG LEE, HU-JONG LEE, Pohang University of Science and Technology — We investigated the electronic current refraction at p-n junctions (PNJs) in ballistic monolayer graphene. Given a peculiar band structure of the graphene, the transmission of electrons through a PNJ is predicted to be similar to the optical refraction at the boundary of metamaterials with negative refractive index. In consequence, electrons waves injected at a point in one side of a junction can be refocused into a single point in the other side of the junction, which demonstrates Veselago lensing for the electrons. By adopting high-yield dry-transfer technique, we fabricated fully ballistic gapped graphene devices encapsulated by hexagonal boron nitrides with a local top gate. We will present the signatures of negative refractive transport behavior of electrons in PNJs and also discuss about the electronic current focusing in p-n heterojunctions in terms of Veselago lensing.

1:39PM T16.00011 A ballistic gate-tunable contact junction in graphene, QUENTIN WILMART, MICHAEL ROSTICHER, MOHAMED BOUKHICHA, ANDREAS INHOFER, PASCAL MORFIN, GWENDAL FEVE, JEAN-MARC BERROIR, BERNARD PLACAI, Laboratoire Pierre Aigrain, Ecole Normale Supérieure-PSL Research University, CNRS, EQUIPE DE PHYSIQUE MÉSOSCOPIQUE TEAM — Field-effect control of carrier is very efficient in graphene and allows controlling the doping profile with a great accuracy and high spatial resolution. This is needed if one wants to implement Dirac fermion optics experiments or simply to improve the performance of graphene devices. In this work we realize graphene transistors equipped with a set of local back-gates that provide control of local electric fields in the $10^{17}/\text{m}$ range at the 10 nanometer scale. In particular we demonstrate ballistic contact junctions using transistors with independent channel and contact back-gates. We will discuss the possibilities offered by this technology for ballistic electronic and opto-electronic applications.

1:51PM T16.00012 Enhanced OFF state resistance in reconfigurable graphene p-n junction, PRATIK AGNIOHOTRI, SURAJIT SUTAR, EVERETT COMFORT, State Univ of NY - Albany, JAMES HONE, Columbia University, PHILIP KIM, Harvard University, JI UNG LEE, State Univ of NY - Albany — Graphene, since its discovery, has proved to be a promising candidate to meet the challenges facing CMOS-based logic devices. Normal conduction modes which are perpendicular to the junction are blocked geometrically by rotating the channel with respect to the junction. "Y" shaped junction with graphene as the base material. (Compared to nonwire-appearing devices, the two dimensional nature of graphene allows for the normal leads to be placed arbitrarily close together and in a non-parallel arrangement.) The superconducting lead is created by contacting graphene with lead (Pb), thus inducing a supercurrent via the proximity effect. The normal metal leads are patterned into quantum dots by etching nano-constrictions with self-aligned side gates. Quantum dots strongly suppress two electron processes, allowing only one electron to pass at a time. Thus, the Cooper-pair splitting efficiency is enhanced as the split electrons must necessarily tunnel through different quantum dots. Therefore, we measure the longitudinal and transverse resistance of our graphene-based split gates, as well as the effect of graphene on the time evolution of the effect and its dependence on the number of edge state in the n- and p-regions of the device's channel.

The interaction of chiral quantized edge states at the graphene pn-junction (pnJ) interface at low temperature and high magnetic fields is topic of intense research recently [1]. It has been presumed that electron and hole edge states completely equilibrate with each other at the pnJ interface, creating an unique set of quantized longitudinal resistance values depending on the number of edge states that present in the device [2]. Experimentally, we have used a unique buried-split gate structure to electrostatically form a graphene pnJ with independent control of the number of edge state in the n- and p-regions of the device’s channel. Measurement of both longitudinal and pseudo-Hall resistance shows quantized values that cannot be explained by using the complete equilibration model. We present a new “non-equilibration” model, in only the lowest Landau level’s (LLs) edge states equilibrate at the pnJ interface, while edge states arising from higher filling factor LLs propagate along the interface without equilibration. Our new model agrees with both the longitudinal and pseudo-Hall resistance results.

2:03PM T16.00013 Controllable P-N Junctions in Graphene-Ferroelectric Devices, J. HENRY HINNEFELD, Univ of Illinois - Urbana, RUJUAN XU, University of California - Berkeley, STEVEN ROGERS, MOONSUB SHIM, Univ of Illinois - Urbana, LANE MARTIN, University of California - Berkeley, NADYA MASON, Univ of Illinois - Urbana — Graphene’s linear dispersion relation and the attendant implications for bipolar electronic applications have motivated a range of experimental efforts aimed at producing p-n junctions in graphene. Recent experimental results indicate that the electrical polarization in ferroelectric substrates can modify the local doping in graphene, via a hysteretic gating effect. Here, we exploit this effect to create variably doped local regions in a graphene device having a single, universal back-gate. By patterning devices on a partially shielded ferroelectric substrate, we show through electrical transport measurements that p- and n-doped regions can be induced in the system. We explore the competing effects of substrate polarization and interfacial charge-trap processes that contribute to this behavior, along with the time evolution of the effect and its dependence on the measurement conditions and device parameters.
11:15AM T17.00001 In-plane electric polarization of bilayer graphene nanoribbon by interlayer bias voltage. RYO OKUGAWA, JUNYA TANAKA, Tokyo Institute of Technology, TAKASHI KORETSUNE, RIKEN Center for Emergent Matter Science, SUSUMU SAITO, SHUICHI MURAKAMI, TIES, Tokyo Institute of Technology — Bilayer graphene nanoribbons are known to show various energy bands depending on the shapes of the edges and the width of the nanoribbons. In particular, the energy bands of the graphene nanoribbons with armchair edges become gapless or gapped when the width changes. We theoretically study a polarization along the ribbon direction induced by an external interlayer bias voltage by using a tight-binding model, when the nanoribbon is insulating. We find that a polarization is induced for armchair-edges but not for zigzag-edges. The polarization shows different behavior depending on the width as well as the bias voltage. When the interlayer bias voltage is weak, the polarization has opposite signs depending on the width modulo three. This difference can be understood by an effective two-band model from the tight-binding model. Furthermore, our ab initio calculations also agree with the results. On the other hand, under a strong bias voltage, we find that the polarization takes one-third or zero depending on the width modulo three.

11:27AM T17.00002 Characterization of graphene/metal interface and its modification by insertion of thin nano-carbon layer. AKINOBU KANDA, KENTA KATAKURA, YU ITO. Faculty of Pure and Applied Sciences and TIMS, University of Tsukuba, YOUTI OOTUKA, Faculty of Pure and Applied Sciences, University of Tsukuba — Due to high mobility and atomic thickness, graphene is a promising candidate for the next-generation electronic material. While considerable effort has been devoted to achieve higher mobility in graphene films, relatively little attention has been paid to the effect of making contact between graphene and metals, which is indispensable to the electric devices. In general, at a graphene/metal interface, mainly due to the difference in work functions, carriers are injected from the metal to graphene. The resulting shift of Dirac point is not limited at the graphene/metal interface but extends by ~1 μm into the graphene channel, which affects more significantly the performance of graphene field effect devices with shorter channel. Here, we experimentally investigate the channel length dependence of graphene transport properties and extract the effect of metal contact (i.e., strength of carrier doping). Several metal species are investigated and results are compared with numerical models. Furthermore, we try to reduce the influence of metal contact by inserting a thin nano-carbon film at the interface.

11:39AM T17.00003 Ordered Self-assembled Alkane Monolayer on Graphite and Graphene Surface. YUDAN SU, Department of Physics, Fudan University, HUILING HAN, FENG WANG, Department of Physics, University of California at Berkeley, QUN CAI, CHUANSHAN TIAN, Department of Physics, Fudan University, Y.R. SHEN, Department of Physics, University of California at Berkeley — The 2D self-assembly of long chain alkane molecule on graphite and graphene had been studied with phase-sensitive sum-frequency vibrational spectroscopy (PS-SFVS) and scanning tunneling microscopy (STM). The spectrum of Im(χ(2)) which directly characterizes the surface resonances, shows 10 cm~−1 red-shift of the symmetric-stretch frequency of the CH2 groups pointing towards graphite (or graphene) surface indicating Van der Waals interaction in between. The Gibbs adsorption energy of polyethylene (PE, n ~ 140) on graphite from chloroform solution was determined to be -42kJ/mol per molecule or -0.6 kJ/mol per CH2 unit. This large adsorption energy drives the long alkane chain to form an ordered self-assembled monolayer on graphite (or graphene). The sum frequency spectra suggest the orientation of carbon skeleton plane of alkane is predominately perpendicular to the graphite/graphene surface. Our STM result also provides clear evidence for the proposed molecular adsorption model. These results explain the large amount residual of long chain alkane on polystyrene (PS) or poly(methyl methacrylate) (PMMA) transferred graphene, and facilitate a better way to fabricate cleaner large-size graphene.

11:51AM T17.00004 Thin films of bottom-up synthesized graphene nanoribbons. MIKHAIL SHEKHIREV, ALEXEY LIPATOV, TIMOTHY VO, MOHAMMAD MEHDI POUR, ALEXANDER SINITSKII, Univ of Nebraska - Lincoln — Bottom-up solution synthetic approaches for graphene nanoribbons (GNRs) receive a great deal of attention, because they yield large quantities of atomically precise GNRs with intriguing electronic and optical properties. However, poor solubility of these GNRs in conventional solvents remains a great challenge and limits their processability for applications in nanoelectronics, photovoltaics and complementary organic electronics. We developed a protocol for thin film fabrication that could be applied for different types of bottom-up synthesized GNRs in chlorosulfonic acid and developed a protocol for thin film fabrication that could be applied for different types of bottom-up synthesized GNRs. The developed procedure also provides control over the thickness of films that can be made as thin as one GNR thick. Reactivity of the GNRs with chlorosulfonic acid and electrical properties of fabricated films will also be discussed.

12:03PM T17.00005 Electropolymerization of low-k polymer on graphene for top-gated FETs. ALEXEY LIPATOV, BENJAMIN B. WYMORE, ALEXANDRA FURSINA, TIMOTHY H. VO, ALEXANDER SINITSKII, JODY G. REDEPENNING, Univ of Nebraska - Lincoln — The most crucial step for field effect transistor (FET) fabrication is forming a thin and uniform layer of insulator on the surface of a body material to separate it from top-gate electrode. Due to hydrophobic and inert nature of graphene it has quickly become a challenge to deposit a uniform dielectric layer with atomic layer deposition (ALD). One promising method to overcome the problems associated with coating graphene is to incorporate a low dielectric constant (low-k) polymer buffer layer or an organic seed layer. This low-k dielectric layer on top of graphene provides the functional groups necessary for the ALD precursors to adhere. In our work we for the first time demonstrate electrodeposition of pinhole free thin (3-4 nm) layers of low-k polymer on monolayer graphene samples. Advantages of the technique include selectivity and scalability. It is possible to deposit the films selectively on a single graphene flake/device, and on a large number of devices simultaneously. The performance of top-gated FET devices demonstrates the utility of electrophotodeposited polymer films as a dielectric material between graphene and top-gate electrode.

12:15PM T17.00006 Processing of pristine graphene dispersions, gels, and composites. FAHMIDA IRIN, SRIYA DAS, Texas Tech University, DORSA PARVIZ, MICAH GREEN, Texas A&M University — This work focuses on the central concept of producing graphene from graphite without covalently functionalizing the graphene basal plane; such graphene may be stabilized, dispersed, and processed for use in a range of high-performance materials. In particular, we show that various dispersants such as triphenylene derivatives, polymers (polyvinylpyrrolidone), pyrene derivatives etc. can naturally adsorb to the graphene surface, create repulsive (steric and electrostatic) forces, and prevent aggregation. This allows for graphene dispersion in a wide range of organic solvents and composite precursors without compromising graphene structure. Such dispersions are stable against aggregation even when subjected to extreme temperature changes, pH changes, and freeze drying. The applications of these dispersions include the production of graphene/polymer nanocomposites, synthesis of self-healing aerogels, and electrically conductive aerogels. We fabricate graphene loaded polyvinyl alcohol (PVA) films which show enhanced modulus, strength, and electrical conductivity. We also demonstrate novel results in the area of creating graphene loaded self-healing aerogels. The hydrogels can be converted into electrically conductive aerogels that can be utilized as a template for doubly-percolated polymer composites.
12:27PM T17.00007 Facile preparation of reduced graphene oxide - ruthenium oxide nanocomposite electrodes for high-performance supercapacitors, FATIMA AMIR, Winthrop University, VIET PHAM, JAMES DICKERSON, Brookhaven National Laboratory, WINTHROP UNIVERSITY TEAM, CFN-BROOKHAVEN NATIONAL LAB TEAM. Here we report a facile approach of synthesis of graphene oxide (GO) sheets modified with ruthenium oxide (RuO₂) nanoparticles, followed by a reduction of graphene oxide in an alkaline medium. The as-prepared reduced graphene oxide (rGO)/ruthenium oxide (RuO₂) nanocomposite was used for the fabrication of a symmetric supercapacitor. The specific capacitance and charge-discharge periods of the supercapacitor were found to be dependent on both the structural and morphological properties, and the electrolytes used. Surface morphology analysis using scanning electron microscopy (SEM) shows the RuO₂ nanoparticles decorating rGO sheets, comprising a highly porous surface. Structural analysis obtained by x-ray diffraction (XRD) revealed an amorphous structure that is necessary to achieve a high cycling rate capability. The electrochemical properties of rGO/RuO₂ were measured in a two electrodes system, using two different electrolytes: H₂SO₄ and Na₂SO₄. The specific capacitance of rGO/RuO₂ in H₂SO₄ was found to be 318 F/g, and is much higher than that of Na₂SO₄ (184 F/g).
