Seebeck coefficient) of a typical heavily doped semiconductor rises with temperature until it reaches a maximum value, and then decreases due to the activation function of magnetic field orientation as well as field strength and temperature. Since the films can achieve remarkably high critical current, challenges exist in evaluating these low temperature (down to 4.2 K) properties in high magnetic fields up to 30 T. Therefore both conventional transport, and magnetization measurements in a vibrating coil magnetometer equipped with rotating sample platform were used to complement the study. Our results clearly show an evolution of pinning from strongly correlated effects seen at high temperatures to significant contributions from dense but weak pins that thermal fluctuations render ineffective at high temperatures but which become strong at lower temperatures. Support for this work is provided by the NHMFL via NSF DRM 1157490.

Session J12 DMP/DCOMP GERA FIAP: Focus Session: Thermoelectric and Coupled Phenomena 007C - Anindya Roy, John Hopkins University

2:30PM J12.00001 Colossal enhancement of the Seebeck coefficient in FeSb2 driven by nearly ballistic phonons. HIDEFUMI TAKAHASHI, RYUJI OKAZAKI, HIROKI TANIGUCHI, ICHIRO TERASAKI, Nagoya University — An unusually large S of ~ 45 mV/K (at 10 K) was discovered in FeSb2 single crystal, which prompted extensive investigations into its physical origin [A. Bentien et al., EPL 80, 17008 (2007). This compound has a small energy gap Δ ~ 5 meV, which may be caused by strong correlations of Fe 3d-electrons, as observed with Kondo insulators, and the unusually low S may be attributed to this unique band structure near the Fermi energy. However, the exceptional value of S has not been clearly explained by electron correlations, suggesting an additional contribution such as the non-equilibrium phonon-drag effect [H. Takahashi et al., JPSJ 80, 054708 (2011), H. Takahashi et al., PRB 84, 205215 (2011), and H. Takahashi et al., PRB 88, 165205 (2013)]. Here, we report on the direct investigation of this effect by measuring the transport properties of three samples with cross sections ranging from 250 × 245 µm² to 80 × 160 µm². S and ∇x show a significant size effect, indicating that nearly ballistic phonons, which have a long mean free path relative to the sample dimensions, are responsible for the colossal S.

2:42PM J12.00002 ABSTRACT WITHDRAWN —

2:54PM J12.00003 Improved Thermoelectric Performance via Piezoelectric Interaction. DAVID MONTGOMERY, Wake Forest University — Presented are the initial findings of enhanced voltage output in a hybrid thermoelectric piezoelectric generator (TPEG). We constructed TPEG by integrating insulating layers of polyvinylidene fluoride (PVDF) piezoelectric films between flexible thin film p-type and n-type thermoelectrics. The piezoelectric bound surface charge modifies the thermoelectric properties of the semiconductor electrodes which facilitates an increase in voltage. The TPEG voltage output has three contributions: traditional thermoelectric and piezoelectric terms, and a unique coupling term. A combined thermoelectric and piezoelectric model can be used to quantitate the expected coupling voltage as a function of stress and thermal gradient. The fabrication, placement, and configuration of this interface allows for different device designs and affects overall performance. Under easily achievable stress and thermal gradient this new coupling effect can increase voltage output by 20%. Because of this piezoelectric modified thermoelectric effect these hybrid generators can out preform equivalent thermoelectric or piezoelectric generators.

3:06PM J12.00004 The Role of Minority Carriers in Thermoelectrics: Why Half Heusler ZrNiSn is a good n-type but poor p-type Thermoelectric. G. JEFFREY SNYDER, California Institute of Technology — The bipolar excitation of minority carriers limits the maximum zT of a typical thermoelectric material. This is because the thermopower (absolute value of the Seebeck coefficient) of a typical heavily doped semiconductor rises with temperature until it reaches a maximum value, and then decreases due to the activation of minority carriers of opposite sign. The temperature of this thermoelectric rollover is determined largely by the band gap which acts as the activation energy of the minority carriers. Julian Goldsmid and Jeff Sharp showed that the a simple relationship, Eg = 2Sm Tm, between the maximum thermopower (Sm) the temperature where the maximum occurs (Tm) and the band gap (Ev, measured in eV) is a good approximation for many materials, particularly when both types of carriers have similar mobilities. The (T, Zr, Hf)NiSn half Heusler compounds, however, demonstrate the limits of this relationship. The Goldsmid-Sharp band-gap for n-type ZrNiSn is several times greater than that for p-type ZrNiSn that ultimately results in high thermopower at high temperature and therefore high zT for the n-type material but the p-type is not useful. We have explained this phenomena using optical band gap measurements and transport modeling. The greater mobility of the conduction band compared to the valence band suppresses the bipolar effect of the holes that enables the n-type material to retain high thermopower to high temperature. The models give quantitative guide to the accuracy of Goldsmid-Sharp band-gap by providing a correction factor that works well for Bi2Te3, and can be used to guide strategies for suppression of bipolar effects to increase the maximum zT.
The effect of thermoelectric contributions in switching dynamics and resistance drift of Phase Change Memory devices. EGECAN COGULU, IBRAHIM CINAR, AISHA GOKCE, Bogazici University, BARRY STIPE, JORDAN KATINE, HGST, A Western Digital Company, GULEN AKTAS, OZHAN OZATAY, Bogazici University — Phase Change Memory (PCM) is a promising non-volatile data storage technology that allows for multiple-bit-per-cell operation due to its high contrast in the resistance levels between 0 and 1 logic states. To visualize the complex nature and the stability of the switching dynamics in PCM devices with or without an intermediate resistance state, 3D finite element simulations were carried out in cells with a single Ge2Sb2Te5(GST) layer incorporating temperature and phase dependent thermal and electrical conductivities as well as thermoelectric effects. We compare our results with the experimental data and with our previous simulations to understand the influence of the thermo-electric effect on the phase switching. In addition, we integrated drift equations into our multiphysics simulation to get a complete picture of structural relaxation in time in amorphous and mixed phases of the GST. We compare our results with experimental resistance drift measurements to calculate a decay rate for defect concentration. Our results yield a complete picture of switching dynamics and post-switching resistance drift phenomena on the microscopic scale.

The thermopower of few-electron quantum dots with Kondo correlations. LVZHOU YE, University of Science and Tech of China — The thermopower of few-electron quantum dots is crucially influenced by on-dot electron-electron interactions, particularly in the presence of Kondo correlations. We present a comprehensive picture which elucidates the underlying relations between the thermopower and the spectral density function of two-level quantum dots. The effects of various electronic states, including the Kondo states originating from both spin and orbital degrees of freedom, are clearly unraveled. With these insights, we have exemplified an effective and viable way to control the sign of thermopower and the spectral density function of two-level quantum dots. The effects of various electronic states, including the Kondo states originating from both spin and orbital degrees of freedom, are clearly unraveled. With these insights, we have exemplified an effective and viable way to control the sign of thermopower and the spectral density function of two-level quantum dots.

Detection of Carrier Scattering Mechanism by Thermopower, SHUANG TANG, MILDRED DRESSELHAUS, Massachusetts Inst of Tech-MIT — We have developed a new method to detect the carrier scattering mechanism at different temperatures by measuring the maximum values of thermopower (Seebeck coefficient). The graphene system has been studied as a model example. The contribution of short-range interaction scattering, and long-range scattering has been inferred when the temperature varies from low temperature to room temperature. The approach to change the maximum values of thermopower (Seebeck coefficient) is also discussed. This method can not only be used in graphene, but in many novel systems, including MoS2, WS2, and black phosphorus, and other general systems.

Magnon drag thermopower and thermomagnetic properties of single-crystal iron. SARAH WATZMAN, HYUNGYU JIN, Department of Mechanical and Aerospace Engineering, The Ohio State University, Columbus, Ohio, USA, JOSEPH HEREMANS, Department of Mechanical and Aerospace Engineering and Department of Physics, The Ohio State University, Columbus, Ohio, USA — Lucassen et al. [1] demonstrate that magnon drag involves a spin-transfer mechanism closely related to the recently discovered spin-Seebeck effect. This talk will present first results of experiments mapping out the thermopower and magnetothermopower of single-crystal iron and prove that its thermopower is indeed dominated by magnon drag, as suggested by Blatt et al. in 1967 [2]. Measurements will then be presented on the magnetic field and temperature dependence of the full thermomagnetic tensor of iron’s thermopower in the xxx, xyz, and xyz geometries (the first index gives the direction of the heat flux, the second the direction of the magnetic field, and the third the applied magnetic field). Results of magneto-thermopower and Nernst coefficients will be reported for single-crystal samples oriented with α=100. The Nernst coefficients of elemental iron contain a contribution of a direct spin-transfer mechanism, which should be present in the present experiment as an interface between a ferromagnet and a normal metal. This mechanism could be put to use in high temperature ferromagnetic metallic thermoelectric alloys. 1. M. E. Lucassen et al., Appl. Phys. Lett. 99 262506 (2011) 2. F. J. Blatt et al., Phys. Rev. Lett. 18.11 (1967).

Enhancement of thermoelectric performance in composite materials through locally-modulated doping, MICHAEL J. ADAMS, HYUNGYU JIN, Department of Mechanical Engineering, The Ohio State University, JOSEPH P. HEREMANS, Department of Mechanical and Aerospace Engineering and Department of Physics, The Ohio State University — Composites of organic or inorganic constituents are often considered as a way to yield high thermoelectric figure of merit. The limit of this approach is set by the effective medium theory [1], which demonstrates formally that a composite of two materials A and B cannot have higher figure of merit than the highest of either A or B, in the absence of interaction between A and B. In this work, we show that this limit can be lifted by introducing into a host material a second phase that behaves differently vis-a-vis electrons than vis-a-vis phonons. This phase consists of electrically and thermally insulating islands of material that locally dope the semiconducting host. Doped material near the islands provides electrically conductive volumes for charge carriers. Phonons, unaffected by local doping, are scattered by the islands. Thermopower is less affected by the doped regions than electrical conductivity, by an intrinsic mathematical property of the effective medium theory [1]. We employ this concept in Bi1-xSb x alloys and in p-type (Bi2-xSb x)2Te3 compounds, which are known as good thermoelectric materials at cryogenic and room temperatures, respectively. Experimental transport data and the local microscopic characterizations of the samples are presented. 1. D. J. Bergman and L. G. Fel, J. Appl. Phys. 85 8205-8216, 1999

Enhancement of thermoelectric performance in composite materials through locally-modulated doping, MICHAEL J. ADAMS, HYUNGYU JIN, Department of Mechanical Engineering, The Ohio State University, JOSEPH P. HEREMANS, Department of Mechanical and Aerospace Engineering and Department of Physics, The Ohio State University — Composites of organic or inorganic constituents are often considered as a way to yield high thermoelectric figure of merit. The limit of this approach is set by the effective medium theory [1], which demonstrates formally that a composite of two materials A and B cannot have higher figure of merit than the highest of either A or B, in the absence of interaction between A and B. In this work, we show that this limit can be lifted by introducing into a host material a second phase that behaves differently vis-a-vis electrons than vis-a-vis phonons. This phase consists of electrically and thermally insulating islands of material that locally dope the semiconductor host. Doped material near the islands provides electrically conductive volumes for charge carriers. Phonons, unaffected by local doping, are scattered by the islands. Thermopower is less affected by the doped regions than electrical conductivity, by an intrinsic mathematical property of the effective medium theory [1]. Next Generation Electrocaloric and Pyroelectric Materials for Solid State Electrothermal Interconversion, S. PAMIR ALPAY, University of Connecticut — Storrs, JOSEPH V. MANTESE, United Technologies Research Center, SUSAN TROLIER-MCKINSTRY, QIMING ZHANG, Penn State University, ROGER W. WHATMORE, Imperial College London — Thin film electrocaloric (EC) and pyroelectric (PE) electrothermal interconversion energy sources have recently emerged as viable means for primary and auxiliary solid state cooling and power generation. This emergence is a result of two significant developments: (1) advancements in the formation of high quality polymeric and ceramic thin films with figures of merit that project system level performance as a large percentage of Carnot efficiency, and (2) the ability of these newer materials to support larger electric fields which permit operation at higher voltage; thus making the power electronic architectures more favorable for thermal to electric interconversion. Current research targets to adequately address commercial device needs, include reduction of parasitic losses, increases in mechanical robustness, and the ability to form nearly free-standing element in the range of 1 - 10 microns in thickness. This article will describe the current state-of-the-art materials, thermodynamic cycles and device losses; pointing to potential lines of research that would lead to substantially better figures of merit for electrothermal interconversion.
4:54PM J12.00011 Diameter Dependent Thermoelectric Properties of Individual SnTe Nanowires, E.Z. XU, Indiana University,  Z. LI, Indiana University; Los Alamos National Laboratory, J. MARTINEZ, New Mexico State University, N. SINITSYN, H. STITOO, N. LI, Los Alamos National Laboratory, B. SWARTZCENTRUBER, Sandia National Laboratories, J. HOLLINGSWORTH, J. WANG, Los Alamos National Laboratory, S.X. ZHANG, Indiana University — Tin telluride (SnTe), a newly discovered topological crystalline insulator, has recently been suggested to be a promising thermoelectric material. In this work, we report on a systematic study of the thermoelectric properties of individual single-crystalline SnTe nanowires with different diameters. Measurements of thermopower, electrical conductivity and thermal conductivity were carried out on the same nanowires over a temperature range of 25 - 300 K. While the electrical conductivity does not show a strong diameter dependence, we found that the thermopower increases by a factor of two when the nanowire diameter is decreased from 913 nm to 218 nm. The thermal conductivity of the measured NWs is lower than that of the bulk SnTe, which may be attributed to the enhanced phonon - surface boundary scattering and phonon-defect scattering. We further calculated the temperature dependent figure of merit ZT for each individual nanowire. This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science by Los Alamos National Laboratory (Contract DE-AC52-06NA25396) and Sandia National Laboratories (Contract DE-AC04-94AL85000).

5:06PM J12.00012 ABSTRACT WITHDRAWN —

5:18PM J12.00013 Towards a high-current triode thermoelectronic generator, GERWIN HASSINK, PATRICK HERLINGER, WOLFGANG BRAUN, CYRIL STEPHANOS, JURGEN SMET, Jochen MANNHART, Max Planck Institute for Solid State Research, Stuttgart, Germany — Thermionic power generation obtains electrical power directly from a temperature gradient by thermionic emission from a hot electrode to a cold electrode. The space charge created by the emitted electrons, however, severely reduces the efficiency of such generators. Recently, a triode setup with supporting magnetic field has demonstrated to greatly reduce the space charge [1]. Based on these results, further development has been started to reach higher output by, e.g., reducing the electrode spacing to 100 µm, and by increasing the electrode area. In addition, new gate electrode materials and geometries are investigated. The importance of the work function not only for the emitter and collector, but also for the gate, is clear from both the theory and experiment. Work function engineering through surface modification is discussed.

Tuesday, March 3, 2015 2:30PM - 5:30PM — Session J13 DMP: Focus Session: Ferroelectric and Multiferroic Oxide Heterostructures 007D - Jayakanth Ravichandran, University of Southern California

2:30PM J13.00001 Complex-oxide multilayers by design: a treasure trove of unusual ferroic functionalities, SERGE NAKHMANSOHN, University of Connecticut - Storrs — While inheriting most of the traits of their parents, layered variations of ABO₃ perovskites allow for a number of additional channels for property manipulation and fine-tuning. Their remarkable flexibility toward structural and chemical modification can be exploited for the design of new and advanced functionalities not originally present in the parent ABO₃ compounds. With the help of first-principles-based computational techniques, we have predicted intriguing electroactive behavior in layered-perovskite compounds of the Ruddlesden-Popper (RP) type. Specifically, we showed that Goldstone-like states (collective, close to zero frequency excitations, requiring practically no consumption of energy) can be induced in a PbSrTiO3-RP superlattice, manifesting themselves as easy rotations of the in-plane polarization vector. Examination of a fictitious epitaxial Bα₂ZrO₄-RP compound demonstrated that it exhibits an assortment of competing incommensurate distortions, including ones that promote in-plane polarization. In this presentation we highlight the unusual behavior of a RP Ba₂ZrO₄ structure, which has already been synthesized as a bulk ceramic. An investigation of the properties of a (fictitious) epitaxial thin-film variant of this material reveals that under compression it undergoes a transition into an incommensurate state, while under tension it shows hints of a Goldstone-like polar instability, which surprisingly occurs without the presence of a lone-pair active ions like Pb or Sn. In both cases, we observe anomalies in the planar static dielectric susceptibility of the system, with large dielectric response predicted for the phase displaying the Goldstone-like instability.

3:06PM J13.00002 Theoretical study of electronic transport properties in pillar-embedded multiferroic transition-metal oxides, YUAN-YEN TAI, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — Multiferroics show great potential in novel application to nanotechnologies based on well-established experimental techniques. Recently, vertically aligned nanocomposite (VAN) multiferroic thin films have demonstrated a significant amount of research interest owing to their promising results to give more delicate device, such as a larger interfacial area and intrinsic heteroepitaxy in this 3D structure. In order to understand the basic influence of the nano-pillar structure to the bulk multiferroics, we apply scaling theory to study the quasiparticle localization/delocalization effects of this novel nanostructure. With an effective tight-binding model, we apply the transfer matrix method to calculate the wave function behavior throughout its transverse direction. We will also show that the critical behavior varies with various disordered nano-pillar patterns. We will also give a qualitative connection of our results to the transport experiments.

3Work at the LANL was performed under the auspices of the U.S. DOE Contract No. DEAC52-06NA25396 through the LANL-LDRD program.

3:18PM J13.00003 Electric Field and Structural Phase Transition Induced Magnetization Effects in BaTiO3-FeRh Heterostructures Probed using Polarized Neutron Reflectometry, STEVEN BENNETT, THOMAS WARD, MICHAEL BIEGALSKI, Oak Ridge National Laboratory, TONY WONG, The University of Tennessee, ZHIQI LIU, HAILE AMBAYE, ARTUR GLAVIC, VALERIA LAUTER, Oak Ridge National Laboratory — The ability to change the magnetic state of a material with an electric field opens up a plethora of possible devices in spintronics and memory applications. A strong candidate material for such a control is FeRh, whose magneto-structural phase transition from antiferromagnetic (AFM) to ferromagnetic (FM) at T=350K, has shown to be controllably changed by an electric field when grown on ferroelectric BaTiO₃ (BTO). It has been suggested that this shift is largely due to the -0.47% in plane compressive strain induced by the piezoelectric BTO. Here we show a sharp repeatable change in magnetization as the system is heated/cooled through the tetragonal to orthorhombic (280-290K) and orthorhombic to rhombohedral (180-205K) crystalline phase transitions of BTO. To further characterize the effect polarized neutron reflectometry (PNR) was used to evolve the depth profile of magnetization in FeRh within the temperature vicinity of these transitions with and without the application of electric field.

3This work was carried out at the Center for Nanophase Materials Sciences (CNMS) and the Spallation Neutron Source (SNS) supported by the Scientific User Facilities Divisions, Office of Basic Energy Sciences, DOE
3:30PM J13.00004 Emergent phenomena in LaAlO3/GdAlO3 superlattices by breaking inversion symmetry , HAI-TIAN ZHANG, RYAN HAISLMAIER, JASON LAPANO, VENKAT GOPALAN, ROMAN ENGEL-HERBERT, Penn State University — Recently, tremendous interest has been focused on materials by design, where hybrid improper ferroelectricity was proposed from first principles predictions in perovskite superlattices (AB03)/(A'B03)m , which is directly coupled to the oxygen octahedral rotations [1]. Such oxygen octahedron rotations are anticipated stable at high temperatures, thus being a potential materials candidate for high temperature piezoelectric sensor and transducer applications. In this talk we will present the homeopitaxial growth of LaAlO3 and GdAlO3 by hybrid molecular beam epitaxy, where a volatile aluminium alkoxide precursor and elemental La3/Gd (flux 2 × 10−3 cm−2 s−1) were co-supplied in the presence of an oxygen plasma (RF plasma power 250 W). Growth mode, film surface morphology and defect type for films grown under La3/Gd-rich and Al-rich growth conditions will be discussed and directly related to structure and properties characterization of the LaAlO3 and GdAlO3. Changes in the octahedral tilts, probed by scanning transmission electron microscopy in the proximity of GdAlO3/LaAlO3 interface are discussed and compared to first principles predictions.

3:42PM J13.00005 Ferroelectric tunnel junctions with electron doped SrTiO3 electrodes , XIAOHUI LIU, J.D. BURTON, EVGENY TSYMBAL, University of Nebraska-Lincoln — Increasing the tunneling electroresistance (TER) is crucial for the application of ferroelectric tunnel junctions (FTJs) for electronic devices.[1] Normal FTJs are composed of a thin ferroelectric layer sandwiched by two metallic electrodes, where TER results from the ferroelectric polarization dependent electric potential height in the ferroelectric barrier. Since the resistance depends exponentially not only on potential height but also on barrier width, TER is expected to be greatly enhanced by modulation of the polarization dependent barrier width when one of the electrodes is substituted by a semiconductor.[2] Recently, experiment reported sizable (10^4) TER in a FTJ where one electrode is n-type SrTiO3, namely Pt/BaTiO3/Nb/SrTiO3.[3] To reveal the mechanism of this phenomenon, we perform theoretical studies on a representative system SrRuO3/EtaTiO3/n-SrTiO3 using on first-principles modeling. We analyze as a function of doping level the effect of ferroelectric polarization on the electronic structure near the interface, its influence on the barrier width and on the transport properties of such a system. [1] E. Y. Tsymal and H. Kohlstedt, Science, 313, 181 (2006) [2] M. Y. Zhuravlev, et al., Phys. Rev. Lett. 94, 246802 (2005) [3] Z. Wen, et al., Nat. Mater. 12, 617 (2013)

3:54PM J13.00006 Role of interface termination in SrRuO3/PbTiO3/SrRuO3 capacitors under epitaxial strain [1], SIMON DIVILOV, MARIVI FERNANDEZ-SERRA, MATTHEW DAWBER, State Univ of NY- Stony Brook — We perform a DFT analysis of (SrRuO3)/(PbTiO3)/(SrRuO3) with varying PbTiO3 using both LDA and LSDA+U. The goal of the study is to analyze the effects of symmetrical termination along the [001] plane on the magnetic and electric properties of SrRuO3 and PbTiO3, respectively. We observe the electrical polarization of the thin film is highly sensitive to the termination plane, as compared to the bulk. In addition, the termination plane determines the oxygen octahedra tilting (OOT) pattern in the thin film, although the OOT are not coupled to the polarization. Despite having a single layer of SrRuO3, we observe a magnetic polarization dependent on the termination. Our results show the importance of ab initio calculations in the presence of a magnetic parameter space to aid experiments in synthesis of superlattice and thin film capacitors.

4:06PM J13.00007 The road towards the ferroelectric-FET — Carrier density modulation by ferroelectric switching in BaTiO3/Ge , PATRICK PONATH, KURT FREDRICKSON, AGHAM POSADAS, YUAN REN, XIAOYU WU, RAMA VAŞUDEVAN, Univ of Texas, Austin, BĂRÎS OKATAN, STEPHEN JESSE, Oak Ridge National Laboratory, TOSHIHIRO AOKI, MARTHA MCCARTNEY, DAVID SMITH, Arizona State University, SERGEI KALININ, Oak Ridge National Laboratory, KEJI LAI, ALEX DEMKOV, Univ of Texas, Austin, PONATH, FREDRICKSON, POSADAS, DEMKOV TEAM, REN, WU, LAI COLLABORATION, VAŞUDEVAN, OKATAN, JESSE, KALININ COLLABORATION, AOKI, MCCARTNEY, SMITH COLLABORATION — Germanium, with its higher hole and electron mobility is a potential candidate to replace silicon as a channel material in a field effect transistor in the future. The ferroelectric high-k dielectric barium titanate (BTO) can be integrated on germanium (001) due to the small lattice mismatch between BTO and Ge and could therefore be a potential candidate for a ferroelectric memory. We report the epitaxial growth of BTO on a germanium (001) substrate with a thin STO buffer layer, which imposes compressive strain on BTO and causes it to be out of plane polarized. The BTO film crystallizes as-deposited which is monitored by RHEED. XRD measurements of the BTO film indicate an out-of-plane ferroelectric polarization of BTO on a germanium (001) substrate with a thin STO buffer layer, which imposes compressive strain on BTO and causes it to be out of plane polarized. The BTO film crystallizes as-deposited which is monitored by RHEED. XRD measurements of the BTO film indicate an out-of-plane ferroelectric polarization of BTO on a germanium (001) substrate with a thin STO buffer layer, which imposes compressive strain on BTO and causes it to be out of plane polarized. The BTO film crystallizes as-deposited which is monitored by RHEED. XRD measurements of the BTO film indicate an out-of-plane ferroelectric polarization of BTO on a germanium (001) substrate with a thin STO buffer layer, which imposes compressive strain on BTO and causes it to be out of plane polarized. The BTO film crystallizes as-deposited which is monitored by RHEED. 4:18PM J13.00008 Enhanced ferromagnetism in ferroelectric & ultrathin ferromagnetic digital superlattices[1], HANGWEN GUO, ZHENYU DIAO, WANG ZHEN, MOHAMMAD SAGHAYEZHIAN, LINA CHEN, RONGYING JIN, WARD PLUMMER, JIANDI ZHANG, Louisiana State University, SHUAI DONG, Southeast University — Electric control of magnetism has generated much activity due to both intellectual and technical interests. Epitaxial growth of transition-metal oxides with different ordering parameters offers unique platform to study magnetoelectric effect. In particular, quantum confinement of correlated electrons lead to interesting phenomena such as metal-insulator transition. In this work, we explore such effect in quantum confined regime by growing digital superlattices. We selected ferroelectric BaTiO3 (BTO) and La2/3Sr0.7MnO3 (LSMO) which exhibits ferroelectric to magnetic transition at critical thickness. We explore how confined LSMO behaves when sandwiched by BTO. Superlattices are fabricated in formula [(BTO)m/(LSMO)m]y. BTO thickness is constant & LSMO thickness are varied from 40u.c. to 2u.c. For all samples, total thickness of LSMO remains 40 u.c. Stable RHEED oscillations and sharp patterns ensure layer-by-layer growth and decent structural ordering. We find that LSMO has the ferromagnetic ground state down to 2 u.c. In addition, enhancement of ferromagnetism on ultrathin LSMO samples is observed compared to thicker films. Possible explanation involving interfacial magnetization will be discussed.

3:40PM J13.00009 Strain-mediated SrTiO3/PbTiO3 superlattice: The role of oxygen vacancy [1], MENGLEI LI, WENHUI DUAN, Tsinghua University — Using first-principle calculations, we comprehensively study the oxygen vacancy effects on the ferroelectric (FE) and antiferrodistortive (AFD) properties of the [001]-oriented SrTiO3/PbTiO3 1/1 superlattice at different epitaxial strains. Oxygen vacancies form most easily under intermediate strains while the oxygen on the PbO-plane is more difficult to lose than in other positions. Without vacancies, the superlattice is in the paraelectric phase while promote the rotations along the Ti-V-O chain by inducing local tail-to-tail polarization patterns. Furthermore, the oxygen vacancies suppress the octahedra rotations around the direction of Ti-V-O chain while promote the rotations along the other two orthogonal directions. Therefore, the mediation of the FE and AFD properties in different directions in the superlattice can be achieved by the use of the anisotropic effect of oxygen vacancies. Our results provide a theoretical ground to the various coupling effects in ferroelectric-paraelectric superlattices.

4:42PM J13.00010 The metallic screening of the interfacial dipole field in multiferroic Bi6Fe2-xCoTi3O18 thin films, XIAOFANG ZHAI, YU YUN, CHAO MA, HAOLIANG HUANG, DECHAO MENG, JIANLIN WANG, ZHENPING FU, RANRAN PENG, YALIN LU, University of Science and Technology of China — The demand for superior room-temperature multiferroic materials pushes high-quality fabrication of novel Aurivillius-type complex oxides with a goal of revealing the intrinsic room temperature multiferroic properties. We have found a new route to fabricate single-crystalline quality multiferroic Bi6Fe2-xCoTi3O18 thin-films utilizing a metallic screening effect. The films exhibit abrupt interfaces and greatly enhanced crystalline quality on conductive bottom layers while mixed types of interfaces on insulating bottom layers. The enhanced single-crystalline quality is explained by a metallic screening effect that compensates the diverging dipole field originating from the symmetry breaking at the interface. The films on the conductive bottom layers also exhibit an enhanced ferromagnetic spin coupling and a strong vertical piezoelectric polarization switching. This study demonstrates that screening the interface dipole can be crucial to fabricate high-quality thin films and then multiferroic devices.

4:54PM J13.00011 Self-modulated growth of a super-large-period BiFeCoTiO33 thin-film, YALIN LU, DECHAO MENG, XIAOFANG ZHAI, CHAO MA, HAOLIANG HUANG, YU YUN, YAN HUANG, ZHENPING FU, RANRAN PENG, University of Science and Tech of China, XIANGYU MAO, XIAOBING CHEN, Yangzhou University — The epitaxial growth of super-large-period Aurivillius thin films has been explored in order to study their period-modulated multiferroic property. BiFeCoTiO33 thin films with a pseudo-period of ten have been grown on SrTiO3 single crystal substrates using pulsed laser deposition. The films are found to be coherently strained to the substrates and atomically smooth. The X-ray diffraction indicates an average layer period of 10. While the high resolution scanning transmission electron microscopy reveals a self-modulated nanostructure in which the period changes as the thickness increases. The modulation to the period is tentatively explained by the volatile bismuth stacking difference between hetero-epitaxial growth and homo-epitaxial growth. Nonetheless, the self-modulated large period films exhibit intrinsic ferromagnetic and ferroelectric properties at room temperature.

5:06PM J13.00012 Reversible MagnetoElectric Control of Exchange Coupling in Monodomain BiFeO3 Heterostructures1, JULIAN IRWIN, W. SAENRANG, M.S. RZCHOWSKI, K.J. REIERSON, Dept. of Physics, Univ. of Wisconsin, J.E. PODKAMINER, S.B. BAEK, C.B. EOM, Dept. of Materials Sci. and Engr., Univ. of Wisconsin, J.W. FREELAND, APS, Argonne National Laboratory, B.A. DAVIDSON, CNR-Istituto Officina dei Materiali, TASC Nat. Lab, Trieste, Italy — We investigate reversible switching of the ferromagnetic properties of a monodomain thin film of the multiferroic BiFeO3 (BFO) [2] and a Co overlayer. For different electric polarization directions of the BFO film we observe changes in the Co layer magnetic anisotropy and coercive field as determined from in-plane and out-of-plane anisotropic magnetoresistance (AMR) and Magneto-Optic Kerr Effect (MOKE) measurements between 30K and 300K. The dependence of these results on BFO layer thickness is also investigated due to the thickness dependence of BFO’s cyclodial magnetic ordering. X-ray linear dichromism (XLD) measurements of the BFO layer indicate a reversible change in the BFO magnetic ordering as a result of polarization switching, verifying the presence of a magnetoelastic effect in the BFO film and suggesting a magnetic coupling between the BFO and Co layers. Weak ferromagnetism and changing surface magnetic anisotropy energy are both explored as possible mechanisms for the observed coupling [2].

5:18PM J13.00013 Spin-orbit engineering in perovskite heterostructures, BYOUNGHAK LEE, Physics Department - Texas State University, GURU KHALESA, NIST - Nati Inst of Stds & Tech — There has been a steadily increasing interest in spin-orbit effects in systems with broken inversion symmetry. These effects may have technological applicability due to recent success in inducing dynamics and switching across heavy metal/ferromagnet interfaces through spin-orbit torque. In addition, broken inversion symmetry and large spin-orbit interactions can lead to novel magnetic and superconducting properties. Little effort has focused on developing a materials platform for studying these effects systematically. The versatility of perovskites along with recent advances in their epitaxial growth may provide such a playground. In this talk we discuss our theoretical efforts to engineer spin-orbit effects in materials systems based on perovskites and contrast results with bare surfaces and interfaces.

Tuesday, March 3, 2015 2:30PM - 5:30PM — Session J14 DMP FIAP: Focus Session: Dopants and Defects in Zinc Oxide 008A - Shengbai Zhang, Rensselaer Polytechnic Institute

2:30PM J14.00001 Shallow acceptor complexes in p-type ZnO1, D.E. ASPNES2, North Carolina State University — ZnO films grown on sapphire substrates by organometallic vapor phase epitaxy exhibit p-type behavior when sufficient N is properly incorporated and followed by an appropriate annealing sequence. While substitutional N on the O sublattice is a deep acceptor, shallow acceptor complexes involving N, H and VZn, can provide useful 1015 cm−2 p-type films. Taking advantage of Raman, SIMS, and Hall-effect data, we establish a two-step growth scheme to form a metastable double donor complex, N2HZn−V(OH)−, then convert it to a single shallow acceptor complex, VZn−N2HZnH+ during in situ annealing in N2O. The VZn−N2HZnH+ complex accepts electrons at ionization energies of 134 meV, rendering it an efficient p-type dopant at room temperature.

3:06PM J14.00002 Hindered rotation of the 3326 cm−1 OH center in ZnO1, PHILIP WEISER, ELLEN FARMER, MICHAEL STAVOLA, W. BEALL FOWLER, Lehigh University — Experiments on H in ZnO have found two OH vibrational lines at 3611 and 3326 cm−1 [1,2]. The IR line at 3611 cm−1 has been assigned to isolated H+ in a bond centered configuration. The band at 3326 cm−1 has been assigned to H+ in an antibonding configuration in the vicinity of another defect, perhaps Ca [3]. The 3326 cm−1 band has a distinctive dependence on temperature, consisting of several overlapping components whose intensities show thermally activated behavior over the temperature range 4K to 50K. This behavior is reminiscent of previous results for the hindered rotation of an off-axis OD-Li center in MgO [4]. Our results suggest that the off-axis motion of OH centers in oxides might be a common occurrence.

3:18PM J14.00003 Quantum Monte Carlo models of substitutional point defects in zinc oxide and zinc selenide. JAEHYUNG YU, ELIF ERTEKIN, Univ of Illinois - Urbana — Introducing dopants into semiconductors allows manipulation of electrical and optical properties, useful for applications such as optoelectronics and photovoltaics. While first principles quantitative descriptions of the defects properties in semiconductors are critical to understanding and engineering dopants in semiconductors, obtaining accurate descriptions has proven challenging in the past. Here we demonstrate the use of quantum Monte Carlo (QMC) methods to describing the properties of point defects in zinc oxide and zinc selenide. Due to its direct treatment of electron correlation, the QMC method is capable of accurate calculation of band gaps and defect behaviors. We describe the energetics and potential barrier to forming gallium DX-center defects according to QMC in zinc selenide, and compare the description to those of conventional and hybrid DFT. We also use QMC to determine the defect transition levels for nitrogren defects in zinc oxide, and show that QMC obtains descriptions that are in agreement with GW and beyond-DFT approaches. Our results demonstrate the importance of accurate descriptions of electron correlation in the calculation of defect properties of semiconductors.

3:30PM J14.00004 Structural Stability and Ionic Defects in ZnO from Quantum Monte Carlo. JUAN A. SANTANA, Oak Ridge Assoc Univ, JARON T. KROGEL, JEONGNIM KIM, PAUL R.C. KENT, FERNANDO REBOREDO, Oak Ridge National Laboratory — An accurate method capable of describing atomic, molecular and solid-state systems is required to take a full advantage of computer-aided materials discovery and design. We have studied the atomic, molecular and solid-state properties of the Zn-O system with DMC. In particular, the equation of state of bulk Zn and ZnO in the rock salt, zinc blend and wurtzite phases and the properties of ionic defects in wurtzite ZnO were studied. The first ionization potential of O and Zn, and the atomization energy of O, ZnO dimer, and wurtzite ZnO as well as the band gap of this material were evaluated with DMC, and the results agree with experimental measurements to within 0.2 eV. The DMC atomization energy of bulk Zn, 1.00(1) eV, is also in good agreement with the experimental value, 1.35 eV, considering the complexity of this metallic system. The DMC calculated properties of Zn and ZnO under pressure, and the formation energy for the oxygen vacancy, hydrogen impurities and Zn interstitial defects in ZnO will be discussed in comparison with results from experiments and density functional theory approximations.

3:42PM J14.00005 Intrinsic point defects and their interaction with impurities in monocrystalline zinc oxide. BENGT G. SVENSSON, University of Oslo, Physics Department, Center for Materials Science and Nanotechnology, P.O. Box 1048 Blindern, N-0316 Oslo, Norway — Zinc oxide (ZnO) is a direct and wide band-gap semiconductor with several attractive features, like an exciton binding energy of ~ 60 meV, for light emitting devices, photovoltaics and spintronics. In the past decade, ZnO has received tremendous attention by the semiconductor physics community and many challenging issues have been addressed, especially the "native" n-type conductivity, the role of intrinsic point defects, and the realization of reproducible p-type doping. The latter is, indeed, decisive for a true breakthrough of ZnO-based optoelectronics. In this contribution, recent progress in our understanding of the interaction between intrinsic point defects and impurities in ZnO will be discussed. Aluminum (Al) is often introduced intentionally to accomplish high n-type conductivity since Al on Zn-site (Al\textsubscript{Zn}) acts as a shallow donor. However, Al\textsubscript{Zn}, was recently found to react strongly with Zn vacancies (V\textsubscript{Zn}) and the resulting complex (Al\textsubscript{Zn}V\textsubscript{Zn}) is energetically favorable. The Al\textsubscript{Zn}V\textsubscript{Zn} complex is a deep acceptor limiting the n-type doping efficiency and this finding is expected to hold in general for complexes between V\textsubscript{Zn} and group-III elements. Further, implantation of self-ions (Zn and O) has been demonstrated to affect radically the balance of intrinsic point defects where an excess of Zn interstitials gives rise to a dramatic depletion of residual Li impurities on Zn-site (Li\textsubscript{Zn}) whilst the opposite holds for an excess of O interstitials. In fact, this behavior appears to be of general validity and Li depletion occurs for a wide variety of implanted elements incorporated into the Zn sub-lattice while Li pile-up occurs for elements residing on O-site. Finally, the most prominent deep-level defect in ZnO, labelled E3, will be shown to involve hydrogen. E3 exists in most ZnO materials, irrespective of the growth method used, and evidence for a center formed by reaction between interstitial hydrogen and primary defects on the Zn sub-lattice will be given.

4:18PM J14.00006 Dynamical Interplay Between Intrinsic Defects and Impurity Ions in Very Dilute Ce-doped MgO Thin Films. JUNG JUI WANG, Northeastern Univ. (NU) and ALS, LBNL, MUKES KAPILASHRAMI, ALS, LBNL, XIN LI, ALS, LBNL and KTH, Royal Institute of Technology (KTH), Sweden. — A deep acceptor and donor level is observed in Ce-doped MgO thin films. 2. A strong magnetic moment is observed in high-doped films. 3. The magnetic moment is well described by a combined spin-polarized Stoner model and Hartree-Fock model. 4. The magnetic moment increases with increasing Ce concentration.

4:30PM J14.00007 Exploring Cd-Zn-O-S alloys for optimal buffer layers in thin-film photovoltaics. J. VARLEY, Lawrence Livermore National Laboratory, X. HE, University of Illinois at Urbana-Champaign, N. MACKIE, MiaSole, A. ROCKETT, University of Illinois at Urbana-Champaign, V. LORDI, Lawrence Livermore National Laboratory — The development of thin-film photovoltaics has largely focused on alternative absorber materials, while the choices for other layers in the solar cell stack have remained somewhat limited. In particular, cadmium sulfide (CdS) is widely used as the buffer layer in typical record devices utilizing absorbers like Cu(In,Ga)Se\textsubscript{2} (CIGSe) or Cu\textsubscript{x}ZnS\textsubscript{y}(Cu\textsubscript{2}ZnSnS\textsubscript{3}) (CZTS) despite leading to a loss of solar photocurrent due to its band gap of 2.4 eV. While different buffers such as Zn(S,O,OH) are beginning to become competitive with CdS, the identification of additional wider-band gap alternatives with electrical properties comparable to or better than CdS is highly desirable. Here we use hybrid functional calculations to characterize Cd\textsubscript{x}Zn\textsubscript{1-x}O\textsubscript{y}S\textsubscript{1-y} candidate buffer layers in the quaternary phase space composed by Cd, Zn, O, and S. We focus on the band gaps and band offsets of the alloys to assess strategies for improving absorption losses from conventional CdS buffers while maintaining similar conduction band offsets known to facilitate good device performance. We also consider additional criteria such as lattice matching to identify regions in the composition space that may provide improved epitaxy to CIGSe and CZTS absorbers. Lastly, we incorporate our calculated alloy properties into simulation of typical CIGSe devices to identify the Cd\textsubscript{x}Zn\textsubscript{1-x}O\textsubscript{y}S\textsubscript{1-y} buffer compositions that lead to the best performance.
4:42PM J14.00008 Impact of Mg Content on (Mg,Zn)O Native Point Defects, MOLLY BALL, OSCAR RESTREPO, LEONARD BRILLSON, WOLFGANG WINDL, The Ohio State University, DEPARTMENT OF MATERIAL SCIENCE AND ENGINEERING COLLABORATION, DEPARTMENT OF PHYSICS COLLABORATION — The two most thermodynamically stable defects in ZnO are oxygen vacancies (V\text{O}\text{\textsuperscript{2−}}) and zinc vacancies (V\text{Zn}). These native point defects are electrically charged and can contribute to free carrier densities. Experiment shows that Mg addition to ZnO significantly changes native defect densities. To better understand this dramatic decrease in V\text{Zn} \text{\textsuperscript{2−}} and V\text{O}\text{\textsuperscript{2−}}-related defects with increasing Mg content up to x=0.44 and the subsequent increase, we performed density functional theory (DFT) calculations using PAW potentials within PBE using VASP. The results showed to be very sensitive to DFT method used and potential-energy calculation. For the latter, the literature shows that one can assume that the oxygen chemical potential equals that of the atoms in the oxygen molecules at a given surrounding partial oxygen pressure. However, one can also postulate that the total defect concentrations conserve the stoichiometry, or limiting potentials from elemental equilibrium phases can be used. The experimentally observed dependence helped identify the correct way to reproduce the experimental dependence of formation energy on Mg concentration, which will be discussed in detail in this presentation.

4:54PM J14.00009 A hybrid functional study of oxygen interstitial defects in amorphous In-Ga-Zn-O semiconductors, WOO HYUN HAN, YOUNG JUN OH, KEE JOO CHANG, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Republic of Korea — Amorphous indium-gallium-zinc oxide (a-IGZO) semiconductors have attracted much attention because these materials are considered as the replacement of amorphous Si in high performance thin film transistors (TFTs). Although a-IGZO has been the subject of extensive studies due to its superior properties, problems such as threshold voltage shift have been obstacles for device applications. While O-vacancy defects were suggested to be responsible for the device instability under negative bias illumination stress (NBIS), there is no systematic study for the origin of instability under positive bias stress (PBS). In this work, we reveal the origin of PBS instability by performing hybrid density functional calculations for O interstitials in a-IGZO. The defect configuration of an O interstitial depends on its charge state. While an O-O dimer is stable in neutral state, it is easily broken by capturing electrons, acting as an electron trap. Based on the results for the formation energy and transition level of an interstitial O, we propose that excess O atoms in a-IGZO are responsible for the PBS instability.

5:06PM J14.00010 Ionic liquid gated IGZO thin film field effect transistors, PUSHPA RAJ PUDESAINI, JOO HYON NOH, ANTONY WONG, AMANDA VICTO HAGLUND, Department of Materials Science & Engineering, University of Tennessee, Knoxville, SHENG DAI, Chemical Sciences Division, ORNL, THOMAS ZAC WARD, Materials Science and Technology Division, ORNL, DAVID MANDRUS\textsuperscript{1}, PHILIP D. RACK\textsuperscript{2}, Department of Materials Science & Engineering, University of Tennessee, Knoxville — Ionic liquid gated field effect transistors have been extensively studied due to their low operation voltage, ease of processing and the realization of high electric fields at low bias voltages. Here, we report ionic liquid (IL) gated field effect transistor based on amorphous Indium Gallium Zinc Oxide (IGZO) thin film active layers. Conveniently, our device structure includes a conventional bottom gate SiO\text{\textsubscript{2}} insulator so the transfer characteristics of the IL could be directly compared to an equivalent 100 nm thick SiO\text{\textsubscript{2}} gate insulator. The transport measurement of the IL revealed the intrinsic n-channel property of the IGZO thin film with high ON/OFF ratio ~ 10\textsuperscript{4} and a large field effect electron mobility of 2.54 cm\textsuperscript{2}V\textsuperscript{−1}s\textsuperscript{−1} at 300 K and a threshold voltage of 0.1V. Comparable measurements on the bottom SiO\text{\textsubscript{2}} gate insulator revealed an ON/OFF ratio ~ 10\textsuperscript{3} and field effect electron mobility of 5.24 cm\textsuperscript{2}V\textsuperscript{−1}s\textsuperscript{−1} and a threshold voltage of 0.40V. Interestingly, temperature dependent measurements revealed that the ionic liquid electric double layer can be "frozen-in" when dropped below the glass transition temperature which could lead to new switching and possibly non-volatile memory applications.

5:18PM J14.00011 ALD growth of non-polar ZnO-based heterojunctions for UV lighting: structural, electrical and optical properties, CHANG LIU, Wuhan University — Non-polar, semi-polar, and polar ZnO films can be well controlled to epitaxially grow on different substrates such as p-Si (111), p-GaN, and sapphire substrates by atomic layer deposition at 200 °C by introducing different interlayers of Al\textsubscript{2}O\textsubscript{3}, or InGaN or AlN or even none. The electroluminescence of the n-ZnO/Al\textsubscript{2}O\textsubscript{3}/p-GaN heterojunctions was dominated by a blue emission under forward bias, whereas it was violet emission under reverse biases. Under an ultralow driven current density, a blue emission could be observed from the nanocrystalline ZnO/GaN heterojunctions. Well defined Al nanoparticles (NPs) arrays with different shapes were fabricated on the surface of ZnO by electron-beam lithography. The theoretical analysis based on the finite-difference time-domain method was carried out to show the shape dependence of the localized surface plasmon resonance wavelength. By top excitation of the Al NP arrays coupled with ZnO, a 2.6-fold enhancement in peak photoluminescence intensity was measured. Furthermore, the enhancement strongly depends on the NPs shape, revealing an important way of geometrical tuning of the UV-emission.

Tuesday, March 3, 2015 2:30PM - 5:30PM — Session J15 DMP: Focus Session: Transport and Strong Coupling in Plasmonic Nanostructures

2:30PM J15.00001 Electron and hole dynamics in the electronic and structural phase transitions of VO\textsubscript{2} — RICHARD HAGLUND, Vanderbilt University — The ultrafast, optically induced insulator-to-metal transition (IMT) and the associated structural phase transition (SPT) in vanadium dioxide (VO\textsubscript{2}) have been studied for over a decade. However, only recently have effects due to the combined presence of electron-hole pairs and injected electrons been observed. Here we compare and contrast IMT dynamics when both hot electrons and optically excited electron-hole pairs are involved, in (1) thin films of VO\textsubscript{2} overlaid by a thin gold foil, in which hot electrons are generated by 1.5 eV photons absorbed in the foil and accelerated through the VO\textsubscript{2} by an applied electric field; (2) VO\textsubscript{2} nanoparticles covered with a sparse mesh of gold nanoparticles averaging 20-30 nm in diameter in which hot electrons are generated by resonant excitation and decay of the localized surface plasmon; and (3) bare VO\textsubscript{2} thin films excited by intense near-single-cycle THz pulses. In the first case, the IMT is driven by excitation of the bulk gold plasmon, and the SPT appears on a few-picosecond time scale. In the second case, density-functional calculations indicate that above a critical carrier density, the addition of a single electron to a 27-unit supercell drives the catastrophic collapse of the coherent phonon associated with, and leading to, the SPT. In the third case, sub-bandgap-energy photons (approximately 0.1 eV) initiate the IMT, but exhibit the same sub-100 femtosecond switching time and coherent phonon dynamics as observed when the IMT is initiated by 1.5 eV photons. This suggests that the underlying mechanism must be quite different, possibly THz-field induced interband tunneling of spatially separated electron-hole pairs. The implications of these findings for ultrafast switching in opto-electronic devices — such as hybrid VO\textsubscript{2} silicon ring resonators — are briefly considered.

1Support from the National Science Foundation (DMR-1207407), the Office of Science, U.S. Department of Energy (DE-FG02-01ER45916) and the Defense Threat-Reduction Agency (HDTRA1-10-1-0047) for these studies is gratefully acknowledged.
3:06PM J15.00002 Plasmonic Hot Carrier Transport and Collection in Nanostructures, ADAM JERMYN, RAVISHANKAR SUNDARARAMAN, PRINEHA NARANG, WILLIAM GODDARD, HARRY ATWATER, California Institute of Technology. JOINT CENTER FOR ARTIFICIAL PHOTOSYNTHESIS COLLABORATION — Plasmonic resonances provide a promising pathway for efficiently capturing photons from solar radiation and improving photo-catalytic activity via hot carrier generation. Previous calculations have provided the prompt energy-momentum distributions of hot carriers, but have left open the question of their transport to collection surfaces [Accepted in Nature Communications]. As the overall efficiency of plasmonic devices is dependent not just on how many carriers are collected but also on their energy distribution, a transport model which tracks this distribution is of key importance. Here, we provide a first-principles model of this transport based upon the linearized Boltzmann equation with the diffusive and ballistic regimes handled separately, and investigate the role of geometry on plasmonic hot carrier collection.

3:18PM J15.00003 Controlling the ultrafast hot electron dynamics in hybrid plasmonic nanostructures, HAYK HARUTYUNYAN, Department of Physics, Emory University — Plasmons hold promise for applications in photonic circuitry because of their ability to squeeze light into sub-wavelength dimensions and also for their ultrafast response times. To this end, it is important to fabricate plasmonic systems that can generate large optical signals at ultrafast timescales. This goal has been accomplished using coherent harmonic generation or wave mixing in metallic nanostructures where the femtosecond plasmonic response is attributed to plasmon dephasing. However, the multi-frequency nature of these optical effects makes their practical use challenging. Plasmonic devices based on Kerr-type nonlinear optical effects, on the other hand, can operate at a single, fundamental frequency. However, the ultrafast response of gold nanostructures so far has been measured to be in the picosecond timescales attributed to electron — phonon scattering. By designing and fabricating metal-oxide hybrid nanosystems with ultra-high field enhancements we were able to demonstrate much faster, femtosecond dynamics of the optical response. Moreover, our experiments show that the nonlinear optical response can be further tuned in both electron – phonon scattering. By designing and fabricating metal-oxide hybrid nanosystems with ultra-high field enhancements we were able to demonstrate much faster, femtosecond dynamics of the optical response. Moreover, our experiments show that the nonlinear optical response can be further tuned in both time and spectral domains by tuning the material composition of our hybrid nanomaterials. Use of the Center for Nanoscale Materials was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

3:30PM J15.00004 Plasmonic Drag Effect: Toward Coupling of Electronic and Plasmonic Components in Nano-Circuits, MATTHEW LEPAIN, DAVID KEENE, Georgia Southern Univ, VINCENT RONO, NATALIA NOGINOVA, Norfolk State Univ, MAXIM DURACH, Georgia Southern Univ — Plasmonic Drag Effect (PDE) is a phenomenon of rectification of plasmonic optical fields into dc currents or dc polarization in metal nanostructures. Although being a nonlinear effect, PDE is strongly enhanced by resonance and confinement factors and can produce usable pulsed dc voltages of up to several mV in pulsed laser experiments, promising a path to long-awaited opportunities to couple electronic and plasmonic components in nano-circuits. PDE is produced via plasmonic pressure and plasmonic stricton rectification forces. In this talk we will discuss the similarities and differences between these forces and possible additional mechanisms of PDE proposed by authors. We will describe generation of DC potential profiles by photons in metal nanostructures from both theoretical and experimental perspectives.

3:42PM J15.00005 Exploring Photoswitchable Plasmon-Molecule Interactions at the Single-Molecule and Single-Nanoparticle Levels, MINGSONG WANG, Department of Mechanical Engineering, The University of Texas at Austin, BHARATH BANGALORE RAJEEVA, Materials Science and Engineering Program, The University of Texas at Austin, YUEBING ZHENG, Department of Mechanical Engineering and Materials Science and Engineering Program, The University of Texas at Austin — Through synergizing the responsiveness of functional molecules and the plasmon-assisted nanoscale localization of light, hybrid nanosystems consisting of molecules and metal nanoparticle have important applications in biochemical detection, drug delivery, and energy conversion. Single-molecule and single-nanoparticle studies of the hybrid nanosystems help eliminate the degeneracy from ensemble measurements and provide new insights into the structure-property relations. Along this line, herein, we report our recent advances in designing, measuring and controlling two types of photoswitchable metal-nanoparticle-molecule nanosystems at the single-molecule and single-nanoparticle levels: (1) azobenzene molecules on single metal nanoparticles; and (2) spiropyran molecules on single metal nanoparticles.

3:54PM J15.00006 Multifunctional Diagnostic, Nanothermometer and Photothermal Nano-devices, KORY GREEN, MEGAN O’CONNOR, PARMINDER KAUR, HONG WANG, SHUANG FANG LIM, North Carolina State University — In this study, the known therapeutic capabilities of gold nanorods (AuNRs) have been combined with the diagnostic and nanothermometer abilities of upconversion nanoparticles (UCNPs) to develop a system for simultaneous biological imaging, photothermal therapy, and nanothermal sensing. Both the excitation of UCNPs and the finely tuned longitudinal surface plasmon resonance (LSMR) mode of AuNRs lay in a window of relatively high light penetration of tissue in the infra-red. The nanothermometer property of the UCNPs allows direct quantification of the localized temperature of the photothermally heated AuNRs chemically adsorbed to their surface and is free from the bleeding problems inherent in dye thermal sensing systems, especially at high laser fluences required to kill tissue. Spectroscopy on single particles, verified by transmission electron microscopy (TEM), has been performed at varying temperatures to confirm 1) the thermal sensing properties of UCNPs and 2) to finely tune their upconversion enhancement arising from the LSMP coupling of the AuNRs. Preliminary quantification of the localized AuNR temperatures upon photothermal heating will be confirmed through single particle spectroscopy of the attached UCNPs. HeLa cell viability studies have also been performed.

4:06PM J15.00007 Plasmonic Response of Metallic Nanoparticles by Time Dependent Density Functional Theory, EMILY TOWNSEND, GARNETT BRYANT, Joint Quantum Institute, National Institute of Standards and Technology and Univ of Maryland — Plasmons in metallic nanoparticles (MNPs) hold the potential to carry quantum information. Exploiting this will require a quantum understanding of plasmons in hybrid structures of multiple MNPs and emitters/absorbers. We use real-time, real-space time dependent density functional theory (TDDFT) to examine resonances in the optical response of single and paired MNPs. We consider the character of different resonances (some occur in the core, others near the surface of the MNP) and examine the multiple excitations that constitute these resonances. In both the core and surface resonances we see both plasmon-like sloshing of electrons around the Fermi surface and single-particle-like excitation of electrons from below the Fermi surface to above it. We examine the resonances of a pair of MNPs as a function of their separation distance to see how plasmonic and single-particle excitations mix in these particles. Widely separated pairs behave similarly to individual MNPs, but at closer distances pairs behave like a single, more complicated system.

4:18PM J15.00008 Sweet Plasmonics: Sucrose Macrocryystals of Metal Nanoparticles, PEDRO LUDWIG HERNANDEZ-MARTINEZ, Nanyang Technological University, Bilken University, TALHA ERDEM, ZELIHA SORAN-ERDEM, Bilken University, VIJAY KUMAR SHARMA, Nanyang Technological University, Bilken University, HALIL AKCALI, IBRAHIM AKCALI, Bilken University, NIKOLAI GAPONIK, ALEXANDER EYCHMULLER, TU Dresden, HILMI VOLKAN DEMIR, Nanyang Technological University, Bilken University — We present a new plasmonic crystal device comprising silver nanostructures on sucrose macrocrystals. Moreover, our experiments show that the nonlinear optical response can be further tuned in both electron – phonon scattering. By designing and fabricating metal-oxide hybrid nanosystems with ultra-high field enhancements we were able to demonstrate much faster, femtosecond dynamics of the optical response. Moreover, our experiments show that the nonlinear optical response can be further tuned in both time and spectral domains by tuning the material composition of our hybrid nanomaterials. Use of the Center for Nanoscale Materials was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.
4:30 PM J15.00009 Cross-over from collective strong coupling to quenching in quantum dot-metal nanoparticles assemblies1, PRAVEENA MULLAPUDI, Indian Institute of Science, ARNAB MUKHERJEE, SAI SREESH V, student, J.K. BASU, Associate professor — The optical properties for the hybrid structures consisting of gold nanoparticles and CdSe Quantum Dots (QDs) have been widely studied. Compact hybrid monolayer films of gold nano particles (Au NPs) and cadmium selenide (CdSe QDs) with different ratios are prepared using LB method. Suitable tuning of the ratio of QDs and Au NPs at different surface densities leads to enhancement and attenuation of the emission of QDs which acts like a quantum emitters. The net emission enhancement of QDs is maximum, particularly in the case of 0.143 Au NP number fraction (ϕ) for both OFF - resonant and ON-resonant cases, and it is even more enhanced in the case of OFF- resonance i.e., when the SPR (surface Plasmon resonance) is not spectrally overlapping with the quantum dot PL maxima. We suggest that this behavior is indicative of a crossover from single particle to collective emission from quantum dots mediated by gold nanoparticles. The ability to control the radiative and non-radiative decay rates and the emission intensity from such assemblies using spectrally and spatially tuned plasmonic sources would be very crucial in the applications of photovoltaic’s and nano photonics.

1 DST grant

4:42 PM J15.00010 Controlling decay dynamics of quantum emitters with Plasmonic self assembly templates1, S.R.K. CHAITANYA INDUKURI, IISc, J.K. BASU, Department of Physics, IISc, India — Controlling the emission of quantum dots by tailoring local density of states (LDOS) in self assembled plasmonic template. Using very small diameter gold (Au) spherical nanoantenna within a polymer template randomly dispersed with quantum dots, we show how the photoluminescence intensity and lifetime anisotropy of these dots can be significantly enhanced through LDOS tuning. We also studied the effect of diameter, wider range of geometric and spectral parameters bringing out the versatility of these functional plasmonic templates. We studied the effect of nano antenna distribution on radiative and non radiative decay rates in the templates. We demonstrated that the decay dynamics in the plasmonic templates can be controlled in a facile manner by changing the filling fraction of the Au nanoparticles. This polarization dependent anisotropic decay dynamics for the quantum emitters is determined by polarization dependent LDOS of the plasmonic templates as demonstrated by FDTD simulations. Our work provides a new method to achieve spontaneous emission intensity and anisotropy enhancement with nanoscale plasmon resonators for applications from controlled photon emitters to light harvesting.

1 DST, India Nanomission

4:54 PM J15.00011 Changes of photoluminescence emission from metal/organic hybrid thin films with metal nanoparticle concentration, MEGUMI KIMURA, Japan Women’s Univ-Facul Sci, NAOKI TARUTANI, MASAHIKE TAKAHASHI, Department of Materials Science, Graduate School of Engineering, Osaka Prefecture University, ARUP NEOGI, Department of Physics, University of North Texas, RYOKO SHIMADA, Japan Women’s Univ-Facul Sci, JAPAN WOMEN’S UNIVERSITY COLLABORATION, UNIVERSITY OF NORTH TEXAS COLLABORATION — Metal nanoparticles (NPs) have been attracting research interest in the field of nanophotonics due to the localized surface plasmon (LSP) effect that enhances the electric field around metal NPs. This localization leads to enhancement of light emission from fluorescent molecules in the vicinity of the metal NPs. This study focuses on hybrid thin films consisting of metal NPs (silver: Ag-NPs), organic molecules (anthracene) and a polymer matrix (polyphenylsiloxane glass: PSS) to investigate changes of the enhancement of photoluminescence (PL) emission from anthracene molecules at various Ag-NPs concentration. The integrated PL enhancement factor was reduced at high Ag-NPs concentration due to the aggregation of Ag-NPs, and the LSP resonant energy of Ag-NPs exhibited red-shift for this case.

5:06 PM J15.00012 Coupling between Plasmonic Nanostructures and Nitrogen-Vacancy Quantum Emitters, NATHANIEL STEINSULTZ, JINXIAO GONG, MIN OUYANG, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD 20742 — In this talk, we will discuss the coupling between plasmonic nanostructures and nitrogen-vacancy (NV) center quantum emitters in diamonds at the nanoscale. We have developed a method to achieve tunable coupling between plasmonic metal nanostructures and NV centers. The effects of the metallic surface plasmon modes on the spontaneous emission rate of the NV centers can be evaluated by measuring the fluorescence lifetime of the NV centers. By coupling the NV center to the surface plasmon modes of the metallic nanoparticles, we observe an enhanced fluorescence rate of NV centers in nanodiamonds that may lead to increased sensitivity in nanoscale sensors.

5:18 PM J15.00013 XPS Observations of Crystal Field Splitting in TiO2 Thin Films in Quantum Confinement Approach, NATALYA SUSHKOVA, LAB MKS — Transition metal oxides attract increased interest due to amazing electrical and magnetic properties and their outstanding applications designated by relative d-band redistributions that are shifted in such a way that narrow bands arranged by localized electrons are situated in the vicinity of E_F. Different kinds of lattice distortions caused by doping and/or quantum size confinement of TM oxides are assigned to remarkable phenomenon Mott metal-insulator transitions, when mutual metal-oxide orbital arrangement changes dramatically. There is a widespread consensus that strong electron correlations are responsible for that change and magnetic excitation is one of manifestations of these correlations. Here we are presenting XPS study of titanium dioxide nanocrystal formations on silicon substrate with native oxide. The dynamic changes in XPS spectra were used for analysis of TiO2 thin films with mass thicknesses up to 2 monolayers formed by redox reactions of sputtered Ti on Si(100) substrate with native oxide implemented in situ under UHV conditions. XPS spectra evolution, as a traditional source of information on phase composition, was complemented by the possibility to estimate the morphology and crystal field splitting of formed precipitates. Intensity fluctuations observed for O1s, Si 2p, Ti2p spectra were accompanied by crystal field splitting in Ti2p and on second derivatives of O1s. These fluctuations were followed by noticeable changes in the vicinity of band gap indicating possible Mott metal-insulator transitions.

Tuesday, March 3, 2015 2:30PM - 5:06PM
Session J16 DMP DCOMP: Focus Session: Theory of Magnetism and Correlation in Fe-Based Superconductors
101AB - Ilya Eremin, Theory Physics III University

2:30 PM J16.00001 Itinerancy enhanced quantum fluctuation of magnetic moments in iron-based superconductors1, YU-TING TAM, DAO-XIN YAO, Sun Yat-Sen University, China, WEI KU, Brookhaven Natl Lab — We investigate the influence of itinerant carriers on dynamics and fluctuation of local moments in Fe-based superconductors, via linear spin-wave analysis of a spin-fermion model containing both itinerant and local degrees of freedom. Surprisingly against the common lore, instead of enhancing the double-exchange effect, this talk will also address the strongly asymmetric suppression of magnetic order via electron- and hole-doping.

1Supported by US DOE BES DE-AC02-98CH10886 & Chinese NBRPC-2012CB821400, NSFC-11275279.
2:42PM J16.00002 Spin fluctuations-corrected DFT for Fe-based superconductors - LUCIANO ORTENZI, Institute for Complex Systems (ISC), CNR, U.O.S. Sapienza, v. dei Taurini 19, 00185 Rome, Italy, HLYNUR GRETARSSON, Max-Planck-Institut für Festkörperforschung, Heisenbergstr. 1, D-70569 Stuttgart, Germany, S. KASAHARA, Y. MATUDA, Department of Physics, Kyoto University, Kyoto 606-8502, J. Carsill, T. SHIBAUCHI, Department of Advanced Materials Science, The University of Tokyo, Japan, K.D. FINKELESTEIN, Cornell High Energy Synchrotron Source, Cornell University, Ithaca, New York 14853, USA, W. WU, S.R. JULIAN, YOUNG-JUNE KIM, Department of Physics, University of Toronto, 60 St. George St., Toronto, Ontario, M5S 1A7, Canada, I.I. MAZIN, code 6390, Naval Research Laboratory, 4555 Overlook Avenue SW, Washington, DC 20375, USA, LILIA BOERI, Institute for Theoretical and Computational Physics, TU Graz, Austria — Alpha density functional theory (DFT) is, at the moment, the most appropriate tool for treating itinerant magnetism, its mean field implementations -local spin density approximation (LSA) with or without gradient corrections- underestimate the effect of non local spin fluctuations. As a result DFT fails in reproducing, at the same time, the crystal structure and the amplitude of local moment in near critical systems. In this talk I will present a simple method for correcting the magnetic properties of itinerant systems in LDA. The method is called reduced Stoner theory (RST). I will apply this method to study the ferromagnetic-paramagnetic transition under pressure in Ni₃Al itinerant ferromagnet and for describing the puzzling temperature behavior of the local moment found in doped-CaFe₂As₂ pnictides.

2:45PM J16.00003 Understanding the Origin of Magnetism in Various Iron-Based Superconductors from Itinerant Limit - YU-ZHONG ZHANG, MING-CUI DING, Tongji University, HAI-QING LIN, Beijing computational science research center. By investigating the band structure from first principles calculations for various iron-based superconductors we can understand the ground state of the particle-hole excitations at (\pi,\pi). Though the excitations in a few compounds show anomalous behaviors, they are not the counterexamples against the itinerant scenario. As long as the orbital degrees of freedom, which can lead to competing tendencies towards different magnetically ordered states, and the interlayer couplings are taken into account, these anomalies can be naturally accounted for from the itinerant limit. Moreover, we find that the particle-hole excitations away from the Fermi level are more relevant to the physical properties of iron-based superconductors than those close to the Fermi surfaces, which resolves the long-standing problem of why the Fermi surfaces alone can hardly explain various magnetic states observed experimentally in different iron-based superconductors. Finally, We predict based on our first principles calculations that K-doped BaFe₂P₂ and La- or Al-doped MgFeGe may be a possible iron-based superconductor.

3:06PM J16.00004 Magnetic, structural and superconducting phase diagram in bulk Fe chalcogenides: role of nematic fluctuations and biquadratic exchange - IGOR MAZIN, Naval Research Lab — It has been recently realized that even the bulk FeSe is distinctly unique, compared to “old” pnictogen-based Fe-based superconductors (FeBS), which may be a clue to understanding more exotic FeSe-derivatives. The mystery starts with the FeSe phase diagram: numerous pnictides experience an orthorhombic transition, likely of spin-"nematic" nature, followed by a magnetic transition; external pressure favors superconductivity if the starting phase is magnetic, and suppresses it otherwise, consistent with pressure suppressing spin fluctuations. FeSe, however, experiences an orthorhombic transition with no apparent sign of magnetic ordering, and its Tc raises rapidly with pressure, before switching to the usual, opposite trend. In this talk I will revisit, based on DFT calculations, magnetic fluctuations in chalcogenides, and show that, by magnetic transition, they, unlike pnictides, demonstrate unusual (and unexpected) frustration, which suppresses magnetic, but not nematic order, and fully explain the non-monotonic Tc(\rho). Specifically, after the discovery of FeBS multiple attempts have been made to map the magnetic interactions in these systems (deemed to be crucial for superconductivity) onto a set of short range pairwise exchange interactions, initially in terms of the J_{i,j},\ i\neq j, Heisenberg model. This approach failed to explain the double-stripe magnetism in FeTe, so the model was extended to include J_{i,j,k}. However, it was soon realized that this HM contradicts both ab initio calculations and neutron experiments in the magnetically ordered state of Fe pnictides. Thus the model was augmented to include a nearest neighbor biquadratic exchange K. It was also appreciated that the same interaction is essential for explaining the splitting between antiferromagnetic and orthorhombic phase transition in Fe pnictides. What has not been appreciated though was that (1) the double-stripe order is never a ground state of the HM, independent of the values of J_{i,j}, J_{i,j,k} and K; (2) the HM model has, in addition to usually considered in FeBS phases, a highly competitive novel antiferromagnetic “staggered stripes” phase, which appears to be the ground state in ab initio calculations for FeSe (but not FeTe or for FeSe under pressure). Applying the full J_{i,j,k}+ K model to the Fe(Se,Te) system demonstrates unusual frustration, not relevant for As-based FeBS, which can explain the phase diagram of the system, nonmonotonic behavior if Tc under pressure and unexpectedly large orthorhombic “nematic” region in the FeSe phase diagram.

3:42PM J16.00005 An energetically competitive \(t_3g B_{1g}\) pairing in a \(t_1g - J_1 - J_2\) model with orbital differentiated exchange couplings: implications for superconductivity in alkaline iron selenides - RONG YU, Department of Physics, Renmin University of China, Beijing 100872, China, EMILIAN MARIUS NICA, QIMIAO SI, Department of Physics and Astronomy, Rice University, Houston, Texas 77005 — The pairing state in the alkaline iron selenides remains a challenge to our understanding. We address this issue in the incipient Mott picture based on the bad-metal behavior [1] of these materials. In conjunction with this picture, the multi-orbital effect is amplified, with two studied possibilities being the orbital-selective Mott transition [2] and the orbital-dependent pairing [3]. Here we carry out calculations in a five-orbital model to the Fe(Se,Te) system demonstrates unusual frustration, not relevant for As-based FeBS, which can explain the phase diagram of the system, nonmonotonic behavior if Tc under pressure and unexpectedly large orthorhombic “nematic” region in the FeSe phase diagram.

3:45PM J16.00006 Effective Exchange Interactions for Bad Metals and Implications for Iron-based Superconductors - WENXIN DING, Rice University, RONG YU, Renmin University, QIMIAO SI, Rice University, ELIHU ABRAMANS, University of California Los Angeles — The experimentally observed bad metal behavior in parent iron pnictides and chalcogenides suggests that these systems contain strong electronic correlations and are on the verge of a metal-to-insulator transition. The magnetic excitations in this bad-metal regime mainly derive from the incoherent part of the electronic spectrum away from the Fermi energy. We present a microscopic study of the exchange interactions in such a regime within a slave rotor approach. Generalizations to the multi-orbital case are discussed, as are the implications for the strength of superconducting pairing amplitudes in the iron-based superconductors.

4:06PM J16.00007 Comparative study of pure and Co doped-BaFe₂As₂ - JACQUES SOULLARD, ILYA G. KAPLAN, Universidad Nacional Autonoma de Mexico, RAUL PÉREZ-ENRIQUEZ, Universidad de Sonora — We present a comparative study of the high critical temperature superconductor Co doped-BaFe₂As₂ at the electron correlation level by the embedded cluster method; the electron correlation is calculated through the second order Møller Plesset perturbation theory. We study successively the pure compound, the Co doped-compound in the antiferromagnetic state and in the non-magnetic state. The Co doping introduces a strong modification of the spin distribution in its neighboring atoms. The analysis of the orbital population reveals that the spin distribution of the Co impurity becomes 3 times greater than that of the central Fe of the pure compound, increase attributed to a orbital correlation increase of the \(d_{2z}\) orbital population; a local antiferromagnetic order along the b axis of the crystal structure appears. The formation mechanism of the local magnetic moments implies a spin transfer from the (n.n) and (n.n.n) atoms to the central Co and is relevant to the \(J_1 - J_2\) Heisenberg model. The orbital population analysis reveals also that, in the doped compound and in both magnetic cases, the electron charge is associated to a singlet state and may correspond to a holon.
that all three mechanisms are necessary to account for the available experimental data. We argue that the "Monte Carlo-Mean Field" (MC-MF) method, to study single and multiband Hubbard models. The focus here is on the single band case at half filling. We start with a mean-field (MF) decomposition of the Hubbard Hamiltonian and then promote the MF parameters to classical variables studied via MC simulations, while fermions are exactly diagonalized in the background of those classical variables. We present the Hubbard $U$ vs. temperature phase diagram on large three and two dimensional clusters. Our MC-MF method can capture the nonmonotonicity of $T_N$ with $U$, local moment physics above $T_N$, and the two peak behavior of specific heat, as compared with Determinantal Quantum Monte Carlo (DQMC). Results for the $t$ vs. $t'$ Hubbard model in two dimensions show that our approach can capture ground state and finite temperature properties reliably where DQMC fails due to sign problems. These one-band results set the stage for extending the MC-MF method to multiband Hubbard models of relevance to the Pnictide superconductors.

**Tuesday, March 3, 2015 2:30PM - 5:30PM – Session J17 DCMP: Transport in Graphene and its Heterostructures 102AB - Jeanie Lau, University of California, Riverside**

2:30PM J17.00001 Theoretical study of Coulomb drag in graphene, DERK HO, National University of Singapore, SHAFFIQUE ADAM, Yale-NUS College and National University of Singapore — In this theoretical work we examine the problem of Coulomb drag in graphene. We consider the common situation of heterostructures comprising graphene double layers separated by a thin sheet of hexagonal boron nitride in both zero and finite magnetic fields. We study three distinct physical mechanisms, namely the interaction induced energy-transfer between the layers, momentum transfer between the layers, and the contribution due to the hybridization of the layers to the overall transport process. We argue that all three mechanisms are necessary to account for the available experimental data.

2:42PM J17.00002 Magnetotransport in graphene and other two dimensional materials, SHAFFIQUE ADAM, Yale-NUS College, Center for Advanced 2D materials and Graphene Research Center, and Department of Physics, National University of Singapore, INDIRA YUDHISTIRA, Center for Advanced 2D materials and Graphene Research Center, and Department of Physics, National University of Singapore — In this work we address theoretically the classical and quantum magnetotransport in graphene [1] and other two dimensional materials [2]. We demonstrate that at room temperature, the largest contribution to the magnetoresistance arises from the disorder-induced carrier density inhomogeneity that gives a quadratic magnetoresistance at low magnetic fields and linear magnetoresistance at large fields. At lower temperatures, quantum phase-coherent effects can be observed in the magnetotransport, and this provides information about the dominant scattering mechanism in these materials. Castro Neto, J. Martin, S. Adam, B. Özyilmaz, and G. Eda, Nano Letters, 14, 1909 (2014).

2:54PM J17.00003 I-V characteristics of graphene quantum dots, VENKATA CHAGANTI, APALKOV VADYM, Georgia State University — Quantum dots in graphene-like materials with honeycomb crystal structures are studied numerically within tight-binding model of graphene. The energy spectra and corresponding I-V characteristics are found for both isolated graphene islands, i.e., graphene "atoms," and coupled graphene islands, i.e. graphene "molecules." The results were obtained for different sizes of graphene quantum dot and different values of the coupling constants between the dot and the contacts. The current is found to increase with increase of the size of the graphene quantum molecule and increase of the value of the coupling constant. We also study the dependence of the I-V characteristics of graphene quantum dot on the size and the placement of the contacts. For the same size of graphene quantum "atom" and graphene quantum "molecule" the I-V characteristics is almost the same.

3:06PM J17.00004 Effects of fluorination on graphene spin transport\(^1\), ZHISHENG LIN, BOWEN YANG, JING SHI, UC Riverside — Although ideal graphene has extremely weak intrinsic spin-orbit coupling (SOC), by introducing adatoms, proximity effect, hydrogenation, etc., SOC in graphene can be effectively enhanced. In this work, we study the effects of fluorination on graphene nonlocal transport which can probe the spin Hall effect and inverse spin Hall effect as SOC is introduced. The nonlocal resistance is compared between the pristine and fluorinated graphene devices. Upon fluorination, the nonlocal resistance rises clearly above the ohmic contribution and increases as the dosage increases, which is interpreted as a consequence of increased SOC in fluorinated graphene. Raman spectroscopy is used to monitor the D-peak intensity as a function of the fluorination. We find that by controlling fluorination, the magnitude of the nonlocal resistance enhancement is correlated with the D-peak in Raman spectra. We will discuss the effects of the enhanced SOC on spin diffusion length in fluorinated graphene devices. This work was supported by DOE/BES and NSF/NEB.

\(^1\)DOE/BES and NSF/NEB

3:18PM J17.00005 Spin injection and transport in graphene via spin Hall effect in Au\(^1\), BOWEN YANG, JING SHI, Department of Physics and Astronomy, Univ of California - Riverside — Graphene is a promising material for spintronics due to its negligible intrinsic spin-orbit coupling (SOC, 1-50 µeV in perfect flat graphene) derived from the light weight of carbon atoms. Experimentally, graphene shows a spin diffusion length greater than 1 µm at room temperature even though it is coupled to a substrate, as demonstrated by nonlocal spin valves. In this work, we investigate the spin injection and transport in graphene using a nonlocal Hall bar geometry with Au strips along the Hall bar arms. When a charge current flows along one Au Hall bar arm, it induces a pure spin current in Au due to the spin-Hall effect (SHE). The spin current is injected into graphene and propagates along the etched graphene channel. As it arrives at the other Au strip, the spin current is detected by the inverse spin-Hall effect (ISHE) in Au. In a 2 µm long, 0.2 µm wide Hall bar, the nonlocal resistance we obtained is 10 MΩ. Considering the small spin-Hall angle (0.01-0.02) of evaporated Au, the magnitude of the nonlocal resistance suggests efficient spin injection from metal directly into graphene. The simplicity and high injection efficiency of this method is suitable for further exploration of spin transport mechanism in graphene.

3:30PM J17.00006 Transport phenomena in deformed graphene: Magnetic field versus curvature . THOMAS STEGMANN, Instituto de Ciencias Físicas, Universidad Nacional Autónoma de México, NIKODEM SZPAK, Fakultät für Physik, Universität Duisburg-Essen, Germany — The current flow in deformed graphene nanoribbons is studied theoretically. Using a tight-binding model, we apply the nonequilibrium Green’s function (NEGF) method to investigate how a localized deformation and a perpendicular magnetic field affect the current flow. While a magnetic field acts differently on electrons and holes due to their opposite charges, the deformation treats them equivalently. Applying the eikonal approximation to the Dirac equation, which is effectively satisfied at long wavelengths, we show that the obtained geodesic lines are compatible with the current flow paths of our NEGF calculations. The solution of the Mathisson-Papapetrou equations also shows that the effect of the deformation can be subdivided in two parts. First, a pseudomagnetic field with sixfold symmetry of attractive and repulsive regions, which acts differently on electrons and holes, but changes its sign when going from the K to the K’ point. Second, an attractive force due to the curvature of the ribbon, which treats electrons and holes equivalently. We conclude with an outlook on how to use deformed graphene ribbons for geometrical focusing of the current flow.

3:42PM J17.00007 Two-dimensional metal-insulator transition in functionalized graphene . MICHAEL OSOFSKY, SANDRA HERNÁNDEZ, Naval Research Lab, ANINDYA NATH, George Mason University, VIRGINIA WHEELER, SCOTT WALTON, CLIFFORD KROWNE, KURT GASKILL, Naval Research Lab — Since its discovery, graphene has held great promise as a metal with massless carriers and thus extremely high mobility. This feature is the result of the two-dimensional character of the band structure due to the so-called Dirac cone for the ideal, perfectly ordered crystal structure. One of the implications of this ideal case is that the transport properties of this material should be immune to lattice disorder. In reality graphene, which is subject to varying amounts of disorder that depends on preparation method, environment, impurities and other extrinsic variables, has been shown to exhibit an effective mass. Thus, metallic behavior with a wide range of mobilities has been reported. This situation contradicts the prediction that all two-dimensional systems must be insulating. Furthermore, there have also been reports of damaging graphene so severely that it becomes an insulator. Therefore, graphene, with its single layer structure, is a model system for studying the two-dimensional metal-insulator transition (MIT). In this work, we systematically increase the resistivity of epitaxial graphene via the introduction of chemical moieties using very low temperature plasmas. These results reveal the existence of a two dimensional MIT in epitaxial graphene.

3:54PM J17.00008 Electronic transport in Chemically-doped Graphene . ABDOLLAH DADGAR, Columbia University — Chemical doping is a well-known technique to introduce carriers into semiconductors. Previously, we have studied the atomic and electronic structure of graphene doped with nitrogen, and have shown that the dopants primarily incorporate in the graphitic form. Such graphitic dopants are sources of strong intervalley scattering in graphene. In this work, we will describe the effect of these scattering centers on electronic transport in N-doped graphene films produced on SiO2 and BN substrates. We will discuss the mobility and charge carrier concentration inferred from field effect measurements and will discuss the temperature dependent elastic and inelastic scattering rates obtained from weak localization measurements.

4:06PM J17.00009 Near-field study in graphene/hBN heterostructures . GUANGXIN NI, Department of Physics, University of California, San Diego, La Jolla, California 92093, USA, MICHAEL GOLDFLAM, MARTIN WAGNER, ZHE FEI, ALEX SWINTON MCLEOD, MENGKUN LIU, Department of Physics, University of California, San Diego, La Jolla, California 92093, USA, FRITZ KEILMANN, Ludwig-Maximilians-Universität and Center for Nanoscience, 80539 München, Germany, BARBAROS ÖZYILMAZ, ANTONIO H. CASTRO-NETO, Graphene Research Centre and Department of Physics, National University of Singapore, 117542, Singapore, PHILIP KIM, Department of Physics, Columbia University, New York, NY 10027, USA, FRITZ KEILMANN, Ludwig-Maximilians-Universität and Center for Nanoscience, 80539 München, Germany — Graphene is proposed as one of the most promising candidates for novel plasmonic devices, owning to its versatile tunability and ultrafast operation speed. Although exciting results of graphene plasmonics have been obtained, there is keen interest in improving device quality to explore additional plasmon physics and functionalities. Here we present studies of surface plasmons in graphene/hBN devices using scanning near-field optical microscopy. We find that by using these high quality devices, plasmon dissipation rate can be greatly reduced. Moreover, we demonstrated ultrafast hot carriers induced plasmon dispersion in real space. Our study would be important for novel graphene plasmonic applications.
dependence of the critical current on the channel length, both away from and close to the charge neutrality point. The latter regime is particularly interesting work, we study several junctions of different lengths fabricated in CVD graphene, which allows for wider junctions with larger critical currents. We present the small; many of these junctions also tend to be underdamped, resulting in premature switching to the normal state before the critical current is reached. In this Josephson junctions made of graphene. These measurements are challenging, especially near the Dirac point, where the critical current of long junctions is \( \sim \) junctions as a function of the channel length and gate voltage. Previous works on normal metal SNS junctions have established that the product of the critical

| 4:18PM J17.00010 | Vertical transport through a misoriented graphene / hexagonal boron-nitride / graphene heterostructure | SUPENG GE, DARSHANA WICKRAMARATNE, ROGER LAKE, Univ of California - Riverside, UNIVERSITY OF CALIFORNIA RIVERSIDE TEAM — Hexagonal boron nitride has an atomically smooth self-passivated surface and minimal lattice mismatch with graphene, which makes it an ideal substrate material for achieving high-mobility graphene devices. There is also a growing interest in tunneling devices fabricated by vertically stacking h-BN between two layers of graphene. Mechanical stacking of these individual layers leads to interfaces that are naturally misoriented with respect to each other. Furthermore, the number of layers of h-BN between the graphene layers in such devices can also vary. The combined effect of the twist angle and the thickness of the h-BN layer on the vertical transport properties is still an open question. Using ab-initio calculations we calculate transmission across unrotated and rotated graphene/h-BN/graphene heterostructures. For a single layer of BN, misorientation increases the tunneling transmission. The transmission as a function of h-BN layer thickness and different commensurate rotation angles is discussed. |
| 4:30PM J17.00011 | Nonlinear Hall effect in h-BN/graphene on ferri-magnetic substrates | CHI TANG, BIN CHENG, ZHYONG WANG, ZILONG JIANG, MOHAMMED ALDOSARY, YAFIS BARLAS, MARC BORKRATH, JING SHI, UCR, T. TANIGUCHI, K. WATANABE, Advanced Materials Laboratory Japan — In this work, we present a magnetotransport study of fabricated graphene devices transferred on atomically flat ferri-magnetic insulator yttrium iron garnet (YIG) thin films. The graphene sheet is sandwiched between a hexagonal boron nitride (h-BN) top gate dielectric and YIG. Due to the atomically smooth surfaces of both h-BN and YIG, graphene devices exhibit high mobility. Furthermore, unlike traditional back-gated devices, the h-BN top-gated devices show negligible gate hysteresis and can achieve high carrier densities with relatively small gate voltages. To investigate the magnetotransport properties of graphene arising from the proximity-induced exchange interaction, we explore the behavior of the nonlinear Hall component over a wide range of carrier densities. The shape of nonlinear Hall part tracks the magnetization of the underneath YIG film after removal of the linear background that originates from the ordinary Hall Effect. A sign reversal of nonlinear Hall contribution is observed when graphene is tuned from electron- to hole-dominated transport regimes. The magnitude of the nonlinear Hall decreases as the density increases for both carrier types. The h-BN top gate dielectric enables us to probe the intrinsic proximity interaction of multilayered graphene heterostructures more efficiently. |
| 4:42PM J17.00012 | Controlling the electrostatic accumulation at the graphene edge, and effects on carrier transport | MENEYOUNG LEE, PATRICK GALLAGHER, Stanford University, GRACE PAN, Yale University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, DAVID GOLDBEER-GORDON, Stanford University — In graphene without doping, the local carrier density at any point is directly proportional to the net charge density induced by the electric field effect. For any finite sized sample, this induced charge distribution is inhomogeneous over macroscopic length scales and of a form determined by the actual geometry of the device. In contrast to gate-confined 2DEGs in modulation-doped semiconductor heterostructures, the carrier density accumulated at the boundary is greater than in the 2D bulk [1], and many experiments and potential applications need to take this effect into account. We will discuss experiments on boron nitride-encapsulated graphene devices (with low disorder and high mobility, which are designed to explicitly tune the electrostatic accumulation at the boundary, from over-accumulation (the situation in typical experiments) to a nearly flat band condition, and further into a regime where the 2D bulk and the edge have opposite charge. In clean devices where the mean free path exceeds the sample width and boundary scattering dominates, the effect of the electrostatic accumulation on carrier transport is pronounced. |
| 4:54PM J17.00013 | Gate-tunable Topological Pseudospin Transport in Bilayer Graphene | MENCQIAO SUI, GUORUI CHEN, LIGUO MA, Department of Physics, Fudan University, WENYU SHAN, Department of Physics, Carnegie Mellon University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, XIAOFENG JIN, Department of Physics, Fudan University, WANG YAO, Department of Physics, University of Hong Kong, DI XIAO, Department of Physics, Carnegie Mellon University, YUANBO ZHANG, Department of Physics, Fudan University — Extra quantum degree of freedom, generally referred to as pseudospin, arises in condensed matter systems when electrons from two sublattices of a crystal form degenerate bands at Fermi level. Here we describe a pseudospin system based on the “which-layer” quantum degree of freedom in bilayer graphene that is fully tuned by top and bottom gates. We detect topological pseudospin current - a result of the broken symmetry induced by the top and bottom gate electric fields - in a nonlocal geometry. The nonlocal pseudospin transport persists up to room temperature owing to the large, tunable band gap in our bilayer graphene devices. The gate-tunable pseudospin quantum degree of freedom in bilayer graphene may lead to future pseudospin-based electronic applications. |
| 5:06PM J17.00014 | All-electrical control of RKKY interaction in graphene P-N junction | SHUHUI ZHANG, WEN YANG, Beijing Computational Science Research Center, KAI CHANG, Institute of Semiconductors, Chinese Academy of Sciences — Graphene is a promising material for spintronic devices. In this development, one way is to dope graphene with magnetic impurity spins. Controllable long-range coupling between different spins is a key ingredient for these applications. The electron-mediated RKKY interaction provides a possible solution. However, there lacks efficient way to control this interaction. Here we demonstrate that by focusing the electron waves across a P-N junction, the long-range RKKY interaction can be controllably amplified by electrical gating. This provides a possible route towards scaling up graphene-based spintronic devices. |
| 5:18PM J17.00015 | Length and density dependence of the critical current in long diffusive graphene-based Josephson junctions | CHUNG-TING KE, Duke Univ. Dept. of Physics, IVAN BORZENETS, Tokyo University, Dept. of Physics, ANNE WATSON, YURA BOMZE, GLEB FINKELSTEIN, Duke Univ. Dept. of Physics — We study the critical current in graphene-based Josephson junctions as a function of the channel length and gate voltage. Previous works on normal metal SNS junctions have established that the product of the critical current, \( I_c \), and normal resistance, \( R_n \), is determined by the Thouless energy \( \Delta t \). Several recent studies have addressed the \( I_c R_n \sim \Delta t/c \) relationship in Josephson junctions made of graphene. These measurements are challenging, especially near the Dirac point, where the critical current of long junctions is small; many of these junctions also tend to be underdamped, resulting in premature switching to the normal state before the critical current is reached. In this work, we study several junctions of different lengths fabricated in CVD graphene, which allows for wider junctions with larger critical currents. We present the dependence of the critical current on the channel length, both away from and close to the charge neutrality point. The latter regime is particularly interesting because the phase coherence should be established through the electron and hole puddles on the length scales of up to 800 nm. |

2:30PM J20.00001 John H. Dillon Medal Lecture: Magnetic Field Directed Self-Assembly of Block Copolymers and Surfactant Mesophases1, CHINEDUM OSUJI, Yale University — Molecular self-assembly of block copolymers and small molecule surfactants gives rise to a rich phase behavior as a function of temperature, composition, and other variables. We consider the directed self-assembly of such soft mesophases using magnetic fields, principally through the use of in situ x-ray scattering studies. Field alignment is predicated on a sufficiently large product of magnetic anisotropy and grain size to produce magnetostatic interactions which are substantive relative to thermal forces. We examine the role of field strength on the phase behavior and alignment dynamics of a series of soft mesophases, outlining the possibility to readily create highly ordered functional materials over macroscopic length scales. We show that magnetic fields as large as 10 T have little discernable impact on the stability of block copolymer systems considered, with shifts in order-disorder transition temperatures of roughly 5 mK or smaller. Consequently, directed self-assembly in these systems proceeds by nucleation of randomly aligned grains which thereafter rotate into registry with the field. We highlight the tradeoff between decreasing mobility and increasing anisotropic field interaction that dictates alignment kinetics while transiting from a high temperature disordered state to an ordered system at lower temperatures.

3:06PM J20.00002 Directed Assembly of Block Polymers, EDWIN THOMAS, Department of Materials Science and NanoEngineering Rice University — Various types of boundary conditions and applied fields can be used to impose constraints on how the micro domain organize. In some cases the constraints serve to remove degenerate patterns which serves to eliminate defects that occur at the boundaries between energetically equivalent patterns. In other cases, either new micro domain patterns emerge or certain types of defects are created at special locations depending on the global and local symmetries of both the imposed constraints and the micro domains themselves. Addition of nano particles to a block polymer brings in additional considerations for the overall pattern of the system. Additive size, shape and surface chemistries relative to those of the block polymer influence their location in the overall pattern. By providing commensuration of block polymer period(s) as well as compatibility of the point group symmetries of both the particle(s) and domain(s), help realize systems where the equilibrium microstructure enables multifunctional physical properties.

3:18PM J20.00003 Failure of Batteries with Block Copolymer Electrolytes and Lithium Metal Anodes, NITASH BALSARA, Univ of California - Berkeley, DIDIER DEVAUX, Lawrence Berkeley National Laboratory, KATHERINE HARRY, Univ of California - Berkeley, DILWORTH PARKINSON, Lawrence Berkeley National Laboratory, RODGER YUAN, Univ of California - Berkeley, DANIEL HALLINAN, Florida A&M University/Florida State University, ALASTAIR MACDOWELL, Lawrence Berkeley National Laboratory — Solid block copolymer electrolytes are promising candidates for the development of high performance rechargeable batteries comprising a lithium metal anode due to their chemical stability toward lithium and their mechanical resistance to dendrite growth. The application of a solid polystyrene-b-poly(ethylene oxide) (SEO) block copolymer electrolyte in lithium symmetric cells permits to study the formation and growth of lithium dendrites by a non-destructive tool, hard X-ray microtomography. All solid-state batteries comprising a Li metal anode and a SEO electrolyte layer and a composite cathode were assembled and cycled. The cathode contains lithium iron phosphate as active material, SEO electrolyte as binder, and carbon black. Hard X-ray microtomography enables to visualize the microstructural changes at the Li/SEO and SEO/cathode interfaces to get insight on the battery failure mechanisms.

3:30PM J20.00004 Polymer Dynamics under Cylindrical Nano-Confinement, KAREN WINEY, WEISHAO TUNG, ROBERT RIGGLEMAN, University of Pennsylvania — Polymer melts under cylindrical confinement have previously been shown to exhibit chain conformations elongated parallel to the cylinder axis and compressed perpendicular to the cylinder. Further, simulations and theory found that the number of entanglements per chain decreases as the cylinder diameter decreases. This talk presents the local dynamics and polymer diffusion under cylindrical confinement using simulations and experiments. For the molecular dynamics simulations, an entangled polymer is confined by an amorphous cylindrical confinement. Local dynamics and local packing of monomers are affected by the cylindrical confinement and an anisotropic mean-squared displacement is observed with faster motion along the cylinder axes that increases with increasing confinement. Using elastic recoil detection experiments, polymer diffusion coefficients along cylindrical nanopores were measured for deuterated polystyrene diffusing into nanoporous membranes infiltrated with polystyrene. The tracer diffusion coefficient increased with decreasing pore size, although the increase is less pronounced than found in the simulations. Results will be discussed in terms of the reptation model.

3:42PM J20.00005 The physical aging of star-shaped macromolecules: role of functionality, PETER GREEN, BRADLEY FRIEBERG, EMMANOUIL GLYNOS, University of Michigan, GEORGIOS SAKELLARIOU, University of Athens — The phenomenon of physical aging, structural relaxations that enable the return of a polymer, quenched to a temperature $T_{eq}$ below its glass transition temperature $T_g$, to equilibrium, was investigated in a series of star-shaped macromolecules. These macromolecules possessed functionalities that varied from $f = 3$ to $f = 64$, and their degrees of polymerization per arm $N$ were all comparable ($N \approx 100$). The aging of these star-shaped macromolecules is qualitatively similar to that of linear chain polymers, with their aging rates exhibiting maxima at threshold temperatures $T_{tr}$. The aging rates of the star-shaped molecules, however, are slower than their linear analogs. Moreover, $T_{tr}$ decreased with increasing $f$, and $K$ increased with increasing $f$ for $T_{eq} < T_{tr}$. Our results are, in part, rationalized in terms of dynamic percolation models.

3:54PM J20.00006 Solvent, Thermal and Solvent-Thermal Methods on Block Copolymer Thin Films, THOMAS RUSSELL, XIAODAN GU1, University of Massachusetts, ILIA GUNKEL2, ALEXANDER HEXEMER, Lawrence Berkeley National Laboratory — Real-time grazing-incidence small-angle X-ray scattering experiments were used to study block copolymer self-assembly in thin films during thermal and solvent vapor annealing, where copolymer thin films were exposed to the vapor of a solvent having near equal interactions with the blocks and to elevated temperature in an inert gas atmosphere, respectively. Similarities between both annealing techniques were identified and advantages and disadvantages of each annealing method were discussed. We show that the product of the effective Flory-Huggins interaction parameter, $\chi$, and the degree of polymerization, $N$, determines the grain size, irrespective of the specific annealing technique. Thermal-solvent annealing, where the thin films were exposed to solvent vapors at elevated temperatures, is also discussed and compared to solvent vapor and thermal annealing.

4:06PM J20.00007 Predicting the distribution of functional nanoparticles in block polymers, ROBERT RIGGLEMAN, University of Pennsylvania — Polymer nanocomposites continue to find new applications, and it has become clear that controlling the dispersion state of the nanoparticles plays a key role in their ultimate performance. For optical properties it is crucial to control the particle spacing and mutual orientation, while mechanical properties seem to be dictated by the size and shape of any aggregates that form. However, predicting the equilibrium structure and assembly of nanoparticles as a function of their size, shape, surface functionality, and interactions with the matrix polymers remains a significant challenge. In this talk, I will describe our recent efforts to extend polymer field theory to describe the thermodynamics of polymer nanocomposite materials. Our approach does not require the mean-field approximation, and we can describe nanoparticles with a wide range of surface functionality, including grafting with various polymer architectures and strong wetting with a matrix polymer.

Physical Crosslinking and Finite Concentration

applications on directed assembly, and propose general guidelines and fabrication strategies that are likely to lead to defect-free assembly of block polymers on lithographically directed copolymer assembly processes. We examine the effects of composition, pattern characteristics, solvent concentration and general material characteristics.

highly unfavorable non-equilibrium states that are stabilized by large free energy barriers. It is therefore of interest to identify the kinetic mechanisms that may lead to elimination of such barriers. In this work we use theory and simulations to determine the pathways through which defects are annihilated or annihilated in directed copolymer assembly processes. We examine the effects of composition, pattern characteristics, solvent concentration and general material characteristics.

on directed assembly, and propose general guidelines and fabrication strategies that are likely to lead to defect-free assembly of block polymers on lithographically patterned substrates.

2:42 PM J20.00010 Polymer stability and function for electrolyte and mixed conductor applications

we have been investigating macromolecular systems that may provide acceptable ion transport properties, but withstand the harsh oxidative environment of lithium air systems. An investigation of different polymeric materials commonly examined for electrochemical applications provides insight into polymer design for these kinds of environments.

4:22 PM J20.00011 Structural evolution of polyelectrolyte-complex-core micelles and ordered-phase bulk materials

The kinetics of formation and structural evolution of novel polyelectrolyte complex materials formed by the assembly of water-soluble di- and tri-block copolymers, with one neutral block and one block either cationic or anionic, have been investigated. The mechanism and speed of the assembly process, and the organization of these domains, were probed using dynamic mechanical spectroscopy and small angle X-ray scattering (SAXS). SAXS revealed that the equilibrium morphology of both the di-block copolymer and the tri-block copolymer materials were generally qualitatively the same with some apparent quantitative differences in phase boundaries, possibly attributable to lack of full equilibration. Slow kinetics and difficulties in reaching equilibrium phase structures, especially in tri-block materials, is a principal message of this article. Detailed analysis of the SAXS data revealed that the tri-block copolymer materials formed ordered phases via a nucleation and growth pathway and that the addition of small amounts (∼20%) of corresponding di-block copolymers increased the rate of structure formation and enhanced several key physical properties.

4:43 PM J20.0010 Thermodynamics and Kinetics of Defect Annihilation in Block Copolymer Assembly

We present a coarse-grained simulation framework to study long-time dynamics of lithium ions in unentangled polymer melts. Effects of strong cation-monomer binding are modelled by formation of reversible bonds, and monomer-specific binding features enter via bond lifetime and coordination number, which can be estimated from atomistic simulations. Two competing mechanisms control the cation transport: successive replacement of dynamic bonds, and motion of the "branched" polymer cluster formed by a cation. Either channel can dominate the long-time diffusion depending on chain lengths and/or the bond lifetime relative to the Rouse time. At high concentrations, cations crosslink the polymers into a transient network, which significantly slows down the relaxation of the polymers, resulting in the non-monicotonic dependence of ion conductivity on concentration, in qualitative agreement with experiment.
2:30PM J21.00001 Multi-faceted characterization of battery reactions: the case of spinel hosts for Mg-ion batteries

JORDI CABANA, University of Illinois at Chicago — Electrochemical energy storage was an important enabler of the wireless revolution and it is touted as a key component of a society that shifts away from its dependence on fossil fuels. Batteries are the primary technology when high energy devices are required. They are complex reactors in which multiple physico-chemical phenomena are concurrent in time and space. As a result, it is increasingly clear that holistic approaches to define such phenomena require a breadth of characterization tools. I will exemplify this need in the context of our quest for hosts that are able to reversibly intercalate Mg$^{2+}$ ions. Systems based on the intercalation of multivalent ions are pushed as next generation devices because, while they can resemble systems using Li$^{+}$ ions, they can store more charge per mol of intercalated species, and adopt metals as the anode. Using a combination of characterization tools, including X-ray diffraction, spectroscopy and scattering, electron microscopy and nuclear magnetic resonance, we ascertained that spinel oxides are able to reversibly and extensively accommodate Mg$^{2+}$. The mechanisms of this reaction were also elucidated. The rationale for the choice of techniques and the key pieces they provided to complete the picture will be discussed.

This work was supported as part of the Joint Center for Energy Storage Research (JCESR), an Energy Innovation Hub funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences.

3:06PM J21.00002 Atomic-scale roughness of Li metal surface evident in soft X-ray absorption spectroscopy

DAVID PRENDERGAST, LIWEN WAN, YUFENG LIANG, YI-DE CHUANG, Lawrence Berkeley National Laboratory (LBNL), RUIMIN QIAO, LBNL and Shandong University, China, SHISHEN YAN, Shandong University, WANLI YANG, LBNL — Realizing Li metal electrodes depends on fundamental understanding and efficient control of surface properties, which requires reliable characterization of the Li metal surface. Controlled experiments of Li K-edge soft X-ray absorption spectroscopy (XAS) reveal evidence of steady oxidation of the Li metal surface even under ultrahigh vacuum (UHV) conditions. The XAS of the short-lived Li metal surface, prepared by in-situ scratching, exhibits a prominent peak at 55.6 eV, more intense and at a slightly higher energy than the first peak expected for bulk Li metal at 55 eV. First-principles XAS calculations explain the origin of both the increased intensity and energy shift. This required the use of surface structural models with under-coordinated Li atoms and an estimated 4 Å inelastic mean-free-path for Auger electrons, implying extreme surface sensitivity of the measurements to the first 2-3 atomic layers. This work provides a benchmark on both experiment and theory for further studies of Li and other reactive metal surfaces, which are currently under scrutiny for next-generation energy storage devices.

3:18PM J21.00003 Neutron Imaging of Rapid Water Imbibition in Fractured Sedimentary Rock Cores

CHU-LIN CHENG, University of Texas-Pan American, EDMUND PERFECT, BRENDAN DONNELLY, University of Tennessee-Knoxville, HASSINA BILHEUX, Oak Ridge National Laboratory, ANTON TREMSIN, University of California-Berkeley, LARRY MCKAY, VICTORIA DISTEFANO, University of Tennessee-Knoxville, JIANCHAO CAI, China University of Geosciences, LOU SANTODONATO, Oak Ridge National Laboratory — Advances in nondestructive testing methods, such as neutron, nuclear magnetic resonance, and x-ray imaging, have significantly improved experimental capabilities to visualize fracture flow in various important fossil energy contexts, e.g. enhanced oil recovery and shale gas. We present a theoretical framework for predicting the rapid movement of water into air-filled fractures within a porous medium based on early-time capillary dynamics and spreading over rough fracture surfaces. The theory permits estimation of sorptivity values for the matrix and fracture zone, as well as a dispersion parameter which quantifies the extent of spreading of the wetting front. Dynamic neutron imaging of water imbibition in unsaturated fractured Berea sandstone cores was employed to evaluate the proposed model. The experiments were conducted at the Neutron Imaging Prototype Facility at Oak Ridge National Laboratory. Water uptake into both the matrix and fracture zone exhibited square-root-of-time behavior. Both theory and neutron imaging data indicated that fractures significantly increase imbibition in unsaturated sedimentary rock by capillary action and surface spreading on rough fracture faces. Fractures also increased the dispersion of the wetting front.

3:30PM J21.00004 Tuning Fork Oscillators as Downhole Viscometers in Oilfield Applications

MIGUEL GONZALEZ, GREG BERNERO, OLIVIERO ALVAREZ, GREGORY HAM, DEFFENBAUGH MAX, Aramco Services Company; Aramco Research Center - Houston, SENSORS DEVELOPMENT TEAM — The commerciality of oil wells is greatly influenced by the physical properties of the fluids being produced. A key parameter in determining how producible the hydrocarbons are is their viscosity. Pressure and temperature changes in recovering a downhole sample to the surface can alter viscosity while accurate downhole measurement of this critical property remains a rudimentary effort in the industry. In this presentation, we describe the challenges of measuring and quantifying the viscosity of reservoir fluids in situ at downhole conditions, as well as present an overview of some of the different measurement techniques currently used. Additionally, we show our characterization of a piezoelectric tuning fork oscillator used as a viscosity sensor. In an attempt to recreate the environment found in oil wells, its mechanical and electrical properties were studied while the device was immersed in different fluids and, separately, under different conditions of pressure and temperature. This device is a first step toward the development of an inexpensive, integrated, and miniaturized sensing platform for the in situ characterization of reservoir fluids.

3:42PM J21.00005 Detecting the topographic, chemical and magnetic contrast at surfaces with nanometer spatial resolution

H. CABRERA, D.A. ZANIN, L.G. DE PIETRO, A. VINDIGNI, U. RAMSPERGER, D. PESCIA, ETH Zurich, MICROSTRUCTURE RESEARCH TEAM — Since the mid of the 1980s and over the past few decades various conventional electron spectroscopies were combined with electron spin sensitivity to investigate the magnetic properties of surfaces and thin films, evolving into the Scanning-Electron-Microscopy with Polarization Analysis (SEMPA) technique, which made it possible to directly observe the re-entrant transitions of magnetic-domain patterns in thin films of Fe on Cu(001) with several tens of nm resolution. The possibility of resolving magnetic-textures in direct space at atomic scale may trigger both fundamental understanding and efficient control of surface properties, which requires reliable characterization of the Li metal surface. Controlled experiments of Li K-edge soft X-ray absorption spectroscopy (XAS) reveal evidence of steady oxidation of the Li metal surface even under ultrahigh vacuum (UHV) conditions. The XAS of the short-lived Li metal surface, prepared by in-situ scratching, exhibits a prominent peak at 55.6 eV, more intense and at a slightly higher energy than the first peak expected for bulk Li metal at 55 eV. First-principles XAS calculations explain the origin of both the increased intensity and energy shift. This required the use of surface structural models with under-coordinated Li atoms and an estimated 4 Å inelastic mean-free-path for Auger electrons, implying extreme surface sensitivity of the measurements to the first 2-3 atomic layers. This work provides a benchmark on both experiment and theory for further studies of Li and other reactive metal surfaces, which are currently under scrutiny for next-generation energy storage devices.

3:54PM J21.00006 Multifarious apparatus for dynamic measurements in intense magnetic fields

FEDOR BALKIREV, Los Alamos Natl Lab — We describe a versatile apparatus which implements multiple types of measurement techniques suitable for intense magnetic field environment. Our approach capitalizes on recent advances in hardware/software co-design solutions to realize dynamic mapping and tracking of field-dependent phenomena in typically short time frame of pulsed measurements. The apparatus is capable of carrying out simultaneous dissimilar measurements such as resistivity, current-voltage characteristics, magnetic torque etc., both in pulse and continuous mode. The control logic can track and respond to changes in sample properties, such as onset of dissipation or changes in high-frequency oscillatory response, in sub-microsecond timescale.

This research performed under the DOE BES ’Science at 100 tesla’ and supported at the NHMFL by NSF Cooperative Agreement No. DMR-1157490
Field Laboratory to extract the carrier Hall mobility and density as a function of the temperature. We report on the integration of a custom attocube 2-axis rotary stepper positioner, with the ability to rotate a sample over the full 3D sphere with milli-degree precision. In this surface imaging technique the image intensity depends sensitively on the local electron landing energy. Specifically, we probe the in-plane potential distribution between laterally spaced electrical contacts on a layered quasi-two-dimensional (2D) sample (single to triple layer graphene). We make use of the property that incoming electrons are resonant with interlayer graphene states for well-defined (local) landing energies. Our method is straightforwardly extendable to other quasi-2D systems, most prominently to the upcoming class of layered van der Waals materials.

4:30PM J21.00009 Development of a Nonlinear Acoustic Phased Array and its Interaction with Thin Plates1. PAUL ANZEL, CARLY DONAHUE, California Institute Of Technology, CHIARA DARAI, ETH-Zurich, California Institute of Technology — Numerous technologies are based on the principle of focusing acoustic energy. We propose a new device to focus sound waves which exploits highly nonlinear dynamics. The advantages of this device are the capability of generating very highly powerful acoustic pulses and potential operation in high-temperature environments where traditional piezoelectrics may fail. This device is composed of rows of ball bearings placed in contact with a medium of interest and with an actuator on the top. Elastic spherical particles have a contact force that grows with their relative displacement to the three-halves power (Hertzian contact). When several spheres are placed in a row, the particles support the propagation of “solitary waves”—strong, compact stress-wave pulses whose tendency to disperse is counteracted by the nonlinearity of the sphere’s contact force. We present results regarding the experimental operation of the device and its comparison to theory and numerical simulations. We will show how well this system is capable of focusing energy at various locations in the medium, and the limits imposed by pre-compression. Finally, the effects of timing error on energy focusing will be demonstrated.

4:42PM J21.00010 Investigation of acoustically dead materials for resonant ultrasound spectroscopy. JONATHAN BETTS, BORIS MAIOROV, BRAD RAMSHAW, Los Alamos National Laboratory, ARKKADY SHEHTER, NHHFL, ALBERT MIGLIORE, Los Alamos National Laboratory — Resonant Ultrasonic Spectroscopy is used to excite mechanical resonances in solid samples. By precisely knowing the resonant frequency the complete elastic tensor of the sample can be calculated. In practice unwanted resonances are also created in the holder structure, these resonances are not related to the sample and can often confuse the measurement. To reduce this problem we have investigated the use of acoustically “dead” materials. We present data from various natural and synthetic materials. We also present RUS sample holder designs that can be used from <4K up to 700K and in magnet fields up to 45T. The elastic tensor of polycrystal beryllium will be presented as a demonstration of the system performance.

4:54PM J21.00011 Closed cycle refrigeration for routine magnetotransport measurements. BINUKA GUNAWARDANA, TIANYU YE, Georgia State University, WERNER WEGSCHEIDER, ETH-Zurich, RAMESH MANI, Georgia State University — Closed cycle refrigerators are an ideal solution to providing a cool environment for measurement of transport properties at low temperatures. We have developed a single-axis 14 T magnet. We discuss technical details of the rotator unit, refrigerator probe wiring and construction, and proof-of-principle measurements demonstrating precise closed loop control of magnetic field orientation.
2:54PM J22.00003 Evidence for a nematic component to the Hidden Order parameter in URu$_2$Si$_2$ from differential elastoresistance measurements. MAXWELL SHAPIRO, Stanford University, SCOTT RIGGS, National High Magnetic Field Laboratory, AKASH MAHARAJ, SRINIVAS RAGHU, Stanford University, ERIC BAUER, RYAN BAUJBACH, National High Magnetic Field Laboratory, PAULA GIRAŁDO-GALLO, Stanford University, MARK WARTENBE, National High Magnetic Field Laboratory, IAN FISHER, Stanford University — In this work, we use a novel piezo actuator technique to measure the differential elastoresistance of the unconventional heavy fermion superconductor URu$_2$Si$_2$. Prior to the onset of superconductivity ($T_c \sim 1.5$ K), URu$_2$Si$_2$ undergoes a phase transition to a novel “Hidden Order” state which has defied comprehensive understanding for over 30 years. By tracking the temperature dependence of various elastoresistivity coefficients (proportional to the Order parameter is a two-component vector oriented in the [110] crystallographic direction which breaks the underlying four-fold symmetry of the lattice (in to the Hidden Order transition. Understood within a Ginzburg-Landau framework for coupled order parameters, these measurements imply that the Hidden to high temperatures and a strong anomalous divergence (which scales as the singular contribution to the heat capacity) proximate the Hidden Order transition. Understood within a Ginzburg-Landau framework for coupled order parameters, these measurements imply that the Hidden the transition temperature over a wide range of dopings. However, the magnetic states of these dopings have not been well characterized, with only a small number of studies on polycrystalline samples reported in the literature. In this work, we present an investigation of the magnetic properties of single crystal samples of URu$_2$Fe$_x$Si$_2$ and URu$_2$Os$_x$Si$_2$. Our μSR results demonstrate that both of these dopings show an antiferromagnetic ground state between $x = 0.1$ and $x = 0.4$ that evolves with increasing temperature into the paramagnetic state by a second order transition.

3:06PM J22.00004 Optical conductivity of URu$_2$Si$_2$: gaps and electron phonon coupling. R.P.S.M LOBO, ESPCI, CNRS, UPMC — We measured the in-plane and out-of-plane optical conductivity of URu$_2$Si$_2$. The hidden order transition at 17 K shows the opening of a gap in both polarizations, with a sharp decrease in the optical scattering rate. Above the hidden order we find a redistribution of spectral weight that isoelectronic substitution of Ru with Fe acts as “chemical pressure” that evolves with increasing temperature into the paramagnetic state by a second order transition.

3:18PM J22.00005 Antiferromagnetism in Fe and Os doped URu$_2$Si$_2$ studied by μSR. M.N. WILSON, A.M. HALLAS, T. MEDINA, T.J. MUNISIE, G.M. LÜKE, Department of Physics & Astronomy, McMaster University, 1280 Main St., West Hamilton, Ontario L8P 4M1, Canada, T.J. WILLIAMS, Quantum Condensed Matter Division, Neutron Sciences Directorate, Oak Ridge National Lab, Oak Ridge, TN, 37831, USA, S.C. CHEUNG, B.A. FRANSEN, L. LIU, Y.J. UEMURA, Department of Physics, Columbia University, New York, New York 10027, USA — URu$_2$Si$_2$ is a material that has been studied extensively for almost three decades in an effort to characterize its unusual “hidden order” state. One common method used to study this compound is to perturb the ground state by doping with various metals. Such doping usually causes the transition temperature to drop, and the hidden order state to transition into an antiferromagnetic state. In contrast to this common behavior, the isoelectronic dopings Fe and Os cause a substantial increase in the transition temperature over a wide range of dopings. However, the magnetic states of these dopings have not been well characterized.

3:30PM J22.00006 Chemical pressure tuning of URu2Si2 via isoelectronic substitution of Ru with Fe. MARC JANOSCHEK, Los Alamos Natl Lab, PINAKI DAS, Ames Laboratory, NORAVEE KANCHANAVATTE, University of California San Diego, JOEL S. HELTON, National Institute of Standards and Technology, KEVIN HUANG, University of California San Diego, RYAN E. BAUJBACH, National High Magnetic Field Laboratory, Florida State University, ERIC D. BAUER, Los Alamos Natl Lab, YANIC ZHAO, WILLIAM RATCLIFF, National Institute of Standards and Technology, BEN D. WHITE, M. BRIAN MAPLE, University of California San Diego, JEFF W. LYNN, National Institute of Standards and Technology — We have used specific heat and neutron diffraction measurements on single crystals of URu$_2$Fe$_x$Si$_2$ for Fe concentrations $x \leq 0.7$ to establish that isoelectronic substitution of Ru with Fe acts as “chemical pressure” $P_{ch}$. Neutron diffraction reveals a sharp increase of the uranium magnetic moment at $x = 0.1$, reminiscent of the “hidden order” (HO) to large moment antiferromagnetic (LMAFM) phase transition in URu$_2$Si$_2$. Using the unit cell volume, and the isothermal compressibility $\kappa_T$ for URu$_2$Si$_2$, we determine $P_{ch}$ as function of $x$. The resulting temperature $T$-chemical pressure $P_{ch}$ phase diagram for URu$_2$Fe$_x$Si$_2$ is in good agreement with the established temperature $T$-external pressure $P$ phase diagram of URu$_2$Si$_2$. Thus, URu$_2$Fe$_x$Si$_2$ provides a new opportunity to study the close relationship between the HO and LMAFM phases with methods that cannot be used under pressure, and may shed some new light on the elusive order parameter of the HO.

3:42PM J22.00007 Elastoresistivity in the “Hidden Order” compound URu$_2$Si$_2$-$x$P$_x$. CAMILLA MOIR, Florida State University, National High Magnetic Field Laboratory, RYAN BAUJBACH, National High Magnetic Field Laboratory, ANDREW GALLAGHER, KUAN-WEN CHEN, Florida State University, National High Magnetic Field Laboratory, ARKADY SHEKHTER, GREG BOEBINGER, SCOTT RIGGS, National High Magnetic Field Laboratory — The intermetallic compound URu$_2$Si$_2$ undergoes a phase transition near 17.5 K, with clear thermodynamic and transport signatures. However, despite nearly 30 years of research, the nature of the order parameter remains unknown. This “hidden order” phase, and its relationship to the superconductivity that appears below 1.4 K, remains a central puzzle in the physics of correlated electron materials. In order to unfold the phenomena that are nascent in pure URu$_2$Si$_2$, we recently developed a flux growth technique that allows us to grow dopings through Si→P. This technique is unique because it enables the use of high vapor pressure elements. We find that phosphorous substitution suppresses the hidden order transition temperature until, at roughly 1.5% doping, a quantum phase transition is reached. We measure the doping evolution of the temperature dependent elastoresistivity focusing on the behavior of the nematic component ($b_{2g}$) as the Hidden Order transition is approached.

3:54PM J22.00008 Unfolding the physics of URu$_2$Si$_2$ through chemical substitution (Si → P). RYAN BAUJBACH, ANDREW GALLAGHER, KUAN-WEN CHEN, NHMF, Florida State Univ., FUMITAKE KAMETANI, ASC, NHMF, Florida State Univ., NAOKI KIKUGAWA, Natl. Inst. Mat. Sci., Tsukuba, Japan, NHMF, Florida State Univ., SAMANTHA CARY, THOMAS ALBRECHT-SCHMITT, Dept. Chem. and Biochem., Florida State Univ. — URu$_2$Si$_2$ features all of the major phenomena that are at the focus of current research in correlated electron materials, including an exotic ordered state ("hidden order"), unconventional superconductivity, and anomalous metallic behavior. We recently undertook to study URu$_2$Si$_2$ using the novel tuning parameter Si → P substitution which, in a simple picture, simply adds electrons to the conduction band. Substitution of high vapor pressure elements in URu$_2$Si$_2$ is unprecedented, and is enabled by our new molten metal flux technique [1]. We find a rich phase diagram that includes two quantum phase transitions that are associated with hidden order and antiferromagnetism, respectively. In the hidden order region, the superconducting transition temperature is initially enhanced with P, after which it approaches zero before hidden order is destroyed, suggesting that URu$_2$Si$_2$ might be electronically displaced from the optimal doping. The high order and antiferromagnetic regions are distant from each other, indicating that their origins are quite different. We will discuss these results and implications for understanding hidden order, superconductivity, and quantum criticality.

4:06PM J22.00009 Ultrasound in a Metamagnet and the Single Energy Scale Model. B. SHIVARAM, University of Virginia, VERNON ULRICH, Grove City College, PRADEEP KUMAR, University of Florida, V. CELLI, University of Virginia — Ultrasound velocity measurements in the heavy electron compound UPt$_3$ for magnetic fields up to 33 T are reported. We show that the single energy scale model (B.S.Shivaram et al., Phys. Rev. B, 89, 241107(R), 2014) captures the observed key features of the field dependence in the sound velocity shift, $\Delta v_s$. The shift $\Delta v_s$ at $H_c$ is inversely dependent on temperature above a certain “Dingle Temperature” and assumes a fixed value at very low T. This “saturation” in $\Delta v_s$ is accounted for by level broadening in the single energy scale model.
4:18PM J22.00010 Thermal and Transport properties of $U_2Pt_{1-x}\text{Ir}_xC_2$, MIN GU KANG, CALDES, Institute of Basic Science, Pohang, Korea, Department of Physics, POSTECH, Pohang, Korea, NICK WAKEHAM, Los Alamos National Laboratory, Materials Physics and Applications Division, Los Alamos, New Mexico 87545, USA, NI NI, Department of Physics & Astronomy, UCLA, Los Angeles, California 90024-1769, USA, ERIC BAUER, Los Alamos National Laboratory, Materials Physics and Applications Division, Los Alamos, New Mexico 87545, USA, JEEHOON KIM, CALDES, Institute of Basic Science, Pohang, Korea, Department of Physics, POSTECH, Pohang, Korea, FILIP RONNING, Los Alamos National Laboratory, Materials Physics and Applications Division, Los Alamos, New Mexico 87545, USA — We report thermal and transport properties of $U_2Pt_{1-x}\text{Ir}_xC_2$ from which a magnetic phase diagram is obtained. Pure $U_2IrC_2$ is an antiferromagnet at 6.5 $K$, whose Neel temperature initially rises to 13.2 $K$ at $x=0.8$ and subsequently is suppressed to zero temperature with increasing Pt content near $x=0.4$. Heat capacity data at $x=0.4$ shows an upturn at low temperature, which is consistent with proximity to a quantum critical point and considered as non-Fermi liquid behavior. The entropy after the phonon contribution has been subtracted has a value of 0.18 $R\ln 2$ at the Neel temperature of $U_2IrC_2$, revealing an itinerant nature of the 5f electrons in this compound. On the Pt rich side of the phase diagram, superconductivity is suppressed by $x=0.15$. The residual resistivity increases by a factor of 10 from pure Pt ($x=0$) to $x=0.15$ where superconductivity is suppressed to zero. The phase diagram is compared to pressure tuned and Rh doped $U_2PtC_2$ demonstrating the role of electronic tuning in this system.

4:30PM J22.00011 Single crystal growth and study the physical properties of non-centrosymmetric $UIrSi_3$, SHANTA SAHA, JOHNPIERRE PAGLIONE, Center for Nano Physics and Advanced Materials, Dept. of Physics, University of Maryland, College Park, Maryland — Heavy-fermion superconductivity in the non-centrosymmetric crystal structure has drawn much attention [1]. It is theoretically argued that the order parameter contains not only a spin-singlet part, but also an admixture of a spin-triplet state. The compound $UIrSi_3$ crystallizes in the non-centrosymmetric BaNiSn$_2$ structure which is closely related to the well-known ThCr$_2$Si$_2$-type [2]. Preliminary study on polycrystalline $UIrSi_3$ shows antiferromagnetic order below Neel temperature $T_N = 42 K$ [2]. Its lanthanide analog CeIrSi$_3$ shows heavy-fermion superconductivity under pressure [1]. Therefore, further investigation on $UIrSi_3$ would be meaningful. We will present our attempt to grow single crystal of $UIrSi_3$ by Czochralski method in a tetra-arc-furnace and study of its physical properties.

4:42PM J22.00012 Tuning the ground state of the Kondo lattice in $UTBi_2$ ($T = Ag, Au$) single crystals, PRISCILA ROSA, University of California, Irvine, YONGKANG LUO, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, PASCOAL PAGLIUSO, University of Campinas, ERIC BAUER, JOE THOMPSON, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, ZACHARY FISK, University of California, Irvine — Motivated by the interesting magnetic anisotropy found in the Ce-based heavy fermion family CeTX$_2$ ($T = \text{transition metal}, X = \text{pnictogen}$), here we study the novel U-based parent compounds $UTBi_2$ ($T = Ag, Au$) by combining magnetization, electrical resistivity, and heat-capacity measurements. The single crystals, synthesized by the self-flux method, also crystallize in the tetragonal HfCuSi$_2$-type structure (space group P4/nmm). Interestingly, although $UAuBi_2$ is a low-$\gamma$ antiferromagnet below $T_N = 181 K$, $UAuBi_2$ is a moderately heavy uniaxial ferromagnet below $T_C = 22 K$. Nevertheless, both compounds display the easy-magnetization direction along the c-axis and a large magnetocrystalline anisotropy. Our results point out to an incoherent Kondo behaviour in the paramagnetic state and an intricate competition between crystal field effects and two anisotropic exchange interactions, which lead to the remarkable difference in the observed ground states.

4:54PM J22.00013 Direct Observation of a Superconducting Spin Resonance in the Heavy Fermion Antiferromagnetic Superconductor $UNi_2Al_3$, JERO D WAGMAN, JONATHAN GAUDENT, McMaster University, COLLIN BROHOLM, JOSE RODRIG\'EZ, National Institute of Standards and Technology, BARRY WINN, MELISSA GRAVES-BROOK, Oak Ridge National Laboratory, JIM GARRETT, Brockhouse Institute for Materials Research, BRUCE GAULIN, McMaster University — We present neutron scattering data identifying a superconducting spin resonance in the heavy fermion, antiferromagnetic superconductor $UNi_2Al_3$. This resolves a longstanding issue in the comparison of $UNi_2Al_3$ to its isostructural sister $UPd_2Al_3$. These material both undergo antiferromagnetic phase transitions at relatively high temperatures, $T_N = 4.6 K$ and 14.5 $K$ respectively, before respectively superconducting below 1.2 and 2 $K$(B. D. Gaulin, et al, PRB 66, 174520 (2002)). However, previous reports suggest that only the magnetic fluctuations in $UPd_2Al_3$ display sensitivity to superconductivity via a superconducting spin resonance - the build up in the superconducting ground state of excess scattered intensity at a well defined resonance energy centered on a magnetic wave-vector. We resolve this disparity by clearly identifying a superconducting spin resonance in $UNi_2Al_3$ at the incommensurate wavevector $Q = (\frac{1}{2} \pm 0.11 0 \frac{1}{2})$. This re-establishes the relationship between these sister compounds and further evidences the intimate correlation of magnetism and superconductivity. 

Tuesday, March 3, 2015 2:30PM - 5:30PM – Session J23 DCOMP: Theory and Simulation of Excited-State Phenomena in Semiconductors and Nanostuctures II

2:30PM J23.00001 Accurate effective masses from first principles, JONATHAN LAFLAMME JANSSEN, XAVIER GONZE, Université catholique de Louvain, Institute of Condensed Matter and Nanosciences, Nanoscopic Physics — The accurate ab initio description of effective masses is of key interest in the design of materials with high mobility. However, up to now, they have been calculated using finite-difference estimation of density functional theory (DFT) electronic band curvatures. To eliminate the numerical noise inherent to finite-difference and obtain an approach that is more suitable for material design using high throughput computing, we develop a method allowing to obtain the curvature of DFT bands using Density-Functional Perturbation Theory (DFPT), taking a change of wavevector as a perturbation. Also, the inclusion of $G_0W_0$ corrections to DFT bands in our method will be presented.
dependent density-functional theory (TDDFT) is more efficient, but standard functionals do not produce excitons in extended systems. We present a new, approach the nanosecond time scale, suggesting the possibility of engineering a phonon bottleneck through geometry modification.

to the ground state by an order of magnitude. GQDs with zigzag edges demonstrate a significantly longer hot carrier lifetime in low-lying excited states that using time-dependent density functional theory to calculate nonadiabatic coupling between excitations. Employing the reduced density matrix method geometry dependence in these systems. We examine hot carrier relaxation due to lattice vibrations in GQDs of varying size and edge type (armchair or zigzag),

Electronic and optical properties of a metal-organic framework with ab initio many-body perturbation theory. KRISTIAN BERLAND, Univ. of Oslo, Dept. Physics, SMN, KYUHO LEE, Lawrence Berkeley National Lab., Molecular Foundry, SAHAR SHARIFZADEH, Dept. of Electrical and Computer Engineering, Boston University, JEFFREY B. NEATON, Dept. of Physics, UC Berkeley — With their unprecedented surface area, and their structural and chemical tunability, metal-organic frameworks (MOFs) are being thoroughly explored for applications related to gas storage. Less studied are their electronic, excited-state, and optical properties. Here we explored such properties of Mg-MOF-74 using a combination of density functional theory (DFT) and many-body perturbation theory (MBPT) within the GW approximation and the Bethe-Salpeter equation (BSE) approach. The near-gap electronic conduction states were found to fall into two distinct categories: molecular-like and 1d-dispersive. Further, using the BSE approach, we predict a strongly anisotropic absorption spectrum, which we link to the nature of its strongly-bound excitons. Our calculations are found to be in good agreement with experimental absorption spectra, validating our theoretical approach.

Polarization-dependent force driving the Eg mode in bismuth under optical excitation: comparison of first-principles theory with ultra-fast x-ray experiments. STEPHEN FAHY, EAMONN MURRAY. Tyndall National Institute, University College Cork — Using first principles electronic structure methods, we calculate the induced force on the Eg (zone centre transverse optical) phonon mode in bismuth immediately after absorption of a ultrafast pulse of polarized light. To compare the results with recent ultra-fast, time-resolved x-ray diffraction experiments, we include the decay of the force due to carrier scattering, as measured in optical Raman scattering experiments, and simulate the optical absorption process, depth-dependent atomic driving forces, and x-ray diffraction in the experimental geometry. We find excellent agreement between the theoretical predictions and the observed oscillations of the x-ray diffraction signal, indicating that first-principles theory of optical absorption is well suited to the calculation of initial atomic driving forces in photo-excited materials following ultrafast excitation.

Nonadiabatic coupling and hot carrier relaxation in graphene quantum dots. JONATHAN TRINASTIC, Quantum Theory Project, University of Florida, IEK-HENG CHU, University of California-San Diego, HAI-PING CHENG, Quantum Theory Project, University of Florida — Graphene quantum dots (GQDs) have many possible applications in a variety of research areas, including photovoltaics, catalysis, and sensors. Experimental research has suggested the existence of long hot carrier relaxation times on the order of 100-200 ps due to carrier-phonon interactions, however little theoretical work has examined phonon-induced relaxation and its size or geometry dependence in these systems. We examine hot carrier relaxation due to lattice vibrations in GQDs of varying size and edge type (armchair or zigzag), using time-dependent density functional theory (TDDFT) to calculate nonadiabatic coupling between excitations. Employing the reduced density matrix method to calculate relaxation rates, we find a 100 ps relaxation time constant for low-lying excited states in a GQD with 132 carbon atoms, matching experiment. We also find that carbon-chain ligands attached to the QD edges significantly change the nonadiabatic recombination rates to the ground state by an order of magnitude. GQDs with zigzag edges demonstrate a significantly longer hot carrier lifetime in low-lying excited states that approach the nanosecond time scale, suggesting the possibility of engineering a phonon bottleneck through geometry modification.

Excitons in solids with non-empirical hybrid time-dependent density-functional theory. CARSTEN ULLRICH, University of Missouri, ZENG-HUI YANG, Temple University, FRANCESCO SOTTILE, ETSF, Ecole Polytechnique, Palaiseau — The Bethe-Salpeter equation (BSE) accurately describes the optical properties of solids, but is computationally expensive. Time-dependent density-functional theory (TDDFT) is more efficient, but standard functionals do not produce excitons in extended systems. We present a new, non-empirical hybrid TDDFT approach whose computational cost is much less than BSE, while the accuracy for both bound excitons and the continuum spectra is comparable to that of the BSE. Good performance is observed for both small-gap semiconductors and large-gap insulators.

Electron Excitation Dynamics of Molecules Induced by Optical Near-Field. KATSUYUKI NOBUSADA, MASASHI NODA, Institute for Molecular Science — Optical response of molecules is undoubtedly essential for understanding their physicochemical properties. In conventional theoretical approaches to the optical response, far-field light and matter interaction has been discussed. However, recent advanced nano fabrication allows us to produce very precise nanostructures and optical response in a nanometer region plays a crucial role in developing functional materials. To understand the nano-optical response, we must explicitly treat the light-matter interaction, i.e., optical near field and matter interaction, occurred in a nanometer region. Very recently, we have developed an original TDDFT computational method with the aim of understanding optical-near-field excitation dynamics in nanostructures. Our computed results clearly show interesting phenomena that are completely absent in the conventional optical response under a dipole approximation. We will discuss some computed results of unusual electron excitation dynamics such as two-photon excitation and dissociation of molecules by an optical near field.

We further combine the electron dynamics calculation in the TDDFT with the Maxwell’s equation for electromagnetic fields so as to achieve simultaneous
time-dependent Kohn-Sham equation in real-time, it is possible to describe nonperturbative nonlinear electron dynamics induced by intense laser fields.

We have been developing a theoretical and computational method to describe electron dynamics in crystalline solids irradiated by laser pulses. Our method is based on the time-dependent density functional theory (TDDFT), which enables us to treat quantum electron dynamics in the first principles level. By solving the time-dependent Kohn-Sham equation in real-time, it is possible to describe nonperturbative nonlinear electron dynamics induced by intense laser fields. We further combine the electron dynamics calculation in the TDDFT with the Maxwell’s equation for electromagnetic fields so as to achieve simultaneous
descriptions of both micro-meter-scale laser-field propagation and nanometer-scale electron dynamics induced by the fields. We call it “Maxwell + TDDFT multiscale simulation.” As an application of the method, we show calculated transferred energy distribution from a laser pulse to a bulk SiO2 sample. We evaluated the laser damage threshold and the ablation depth from the distribution. We found that the calculation nicely reproduced measured results of both threshold and depth.

4:18PM J23.00010 Optical properties of alkali halide crystals from all-electron hybrid-exchange TD-DFT calculations , ROSS WEBSTER, Imperial College, LEONARDO BERNASCONI, STFC Rutherford Appleton Laboratory, NICHOLAS HARRISON, Imperial College — I will present a study of the electronic and optical properties of a series of alkali halide crystals, based on a recent implementation of hybrid TD-DFT in the all-electron Gaussian basis set code CRYSTAL [1]. This TD-DFT implementation includes on-site correlation and long range electron-hole interactions by including non-local Fock exchange in the functional. I will examine in particular, the impact of the Gaussian basis set size and quality on the prediction of the band gap, optical gap, and exciton binding energy of these systems, expanding on our previous work [2]. I will show that the polarisability criterion proposed by Rappoport and Furche for molecular systems [3], can be used to converge calculated excited-state properties with the basis set size for periodic systems. I will compare results from CRYSTAL calculations with GW+BSE calculations, previous plane-wave pseudopotential estimates and with experimental data. Finally, I will explore the potential for development of this method, including choice of exchange-correlation kernel, and our current work on a wide range of systems.

4:30PM J23.00011 A fast real time time-dependent density functional theory simulation method , LIN-WANG WANG, Lawrence Berkeley National Laboratory, ZHI WANG, Lawrence Berkeley National Laboratory, Berkeley; Institute of Semiconductors, Chinese Academy of Sciences, SHU-SHENG LI, Institute of Semiconductors, Chinese Academy of Sciences — We have developed an efficient real time, time-dependent density functional theory (TD-DFT) method that can increase the effective time step from 1 attosecond to 10 femtosecond, or 0.1. 0.5 femtosecond. Our algorithm, which carries out the non-adiabatic molecular dynamics TDFT simulations, can have comparable speed to the Born-Oppenheimer (BO) ab initio molecular dynamics (MD). As an application, we simulated the process of an energetic CI particle colliding onto a monolayer of MoSe2. Our simulations show a significant energy transfer from the kinetic energy of the CI particle to the electronic energy of MoSe2, and the result of TDFT is very different from that of BO MD simulations. This new algorithm will enable the use of real-time TD-DFT for many new simulations involving carrier dynamics and electron-phonon couplings.

4:42PM J23.00012 Correlated Light-Matter Interactions in Cavity QED , JOHANNES FLICK, Fritz-Haber-Institut, Berlin, CAMILLA PELLEGRINI, Universidad del Pais Vasco, San Sebastian, MICHAEL RUGENTHALER, Institut fur Theoretische Physik, Universitat Innsbruck, HEIKO APPEL, Fritz-Haber-Institut, Berlin, ILYA TOKATLY, Universidad del Pais Vasco, San Sebastian, ANGEL RUBIO, Universidad del Pais Vasco San Sebastian — In the last decade, time-dependent density functional theory (TDDFT) has been successfully applied to a large variety of problems, such as calculations of absorption spectra, excitation energies, or dynamics in strong laser fields. Recently, we have generalized TDDFT to also describe electron-photon systems (QED-TDDFT) [1,2]. Here, matter and light are treated on an equal quantized footing. In this work, we present the first numerical calculations in the framework of QED-TDDFT. We show exact solutions for fully quantized prototype systems consisting of atoms or molecules placed in optical high-Q cavities and coupled to quantized electromagnetic modes. We focus on the electron-photon exchange-correlation (xc) contribution by calculating exact Kohn-Sham potentials using fixed-point inversions and present the performance of the first approximated xc-potential based on an optimized effective potential (OEP) approach.

3:54PM J23.00008 First-principles calculation for electron dynamics in dielectrics induced by intense laser pulses , SHUNSUKE A. SATO, KAZUHIRO YABANA, University of Tsukuba, YASUSHI SHINOHARA, Max Planck Institute, KYUNG-MIN LEE, Center for Relativistic Laser Science, TOMOHITO OTOBE, Japan Atomic Energy Agency, GEORGE F. BERTSCH, University of Washington — We have been developing a theoretical and computational method to describe electron dynamics in crystalline solids irradiated by laser pulses. Our method is based on the time-dependent density functional theory (TDDFT), which enables us to treat quantum electron dynamics in the first principles level. 4:54PM J23.00113 Fast Integral method for the calculation of Hartree and Exchange terms in DFT and TDDFT$^1$, MICHAEL ZUZOFSKI, AMIR BOAG, AMIR NATAN, Dept. of Physical Electronics, Tel-Aviv University, Israel — The Hartree and Exchange terms can become a computational intensive task in DFT and TDDFT calculations of large structures. Existing methods use either iterative solvers such as conjugate gradient or multi-grid methods or use FFT for the calculation of those terms via the solution of the Poisson equation. With iterative solvers, the problem of setting the boundary conditions is often time consuming by itself as approximations such as the multipole expansion might not converge easily for structures with high aspect ratio. With FFT one needs to use a larger box for the calculation of finite systems. We present an alternative integral method to calculate the Hartree and Exchange terms in DFT and TDDFT. We first describe the algorithm and show that this has $O(N)$ scaling for elongated structures. We then show some examples of long 1D chains ground state and time dependent calculations that use this algorithm. Finally we discuss some possible applications for more advanced functionalities that include the Fock exchange or screened exchange.

5:06PM J23.00114 Band Gap Studies in Density Functional Theory$^1$, THOMAS E. BAKER, Department of Physics & Astronomy, University of California, Irvine, California 92697 USA, LUCAS WAGNER, Department of Theoretical Chemistry and Amsterdam Center for Multiscale Modeling.FEW, Vrije Universiteit, De Boelelaan 1083, 1081HV Amsterdam, The, MILES STOUDENMIRE, Perimeter Institute for Theoretical Physics, Waterloo, Ontario, N2L 2Y5 Canada, KIERON BURKE, Department of Chemistry and of Physics, University of California, Irvine, California 92697 USA, STEVEN WHITE, Department of Physics & Astronomy, University of California, Irvine, California 92697 USA — We examine the exact properties of Density Functional Theory (DFT) in one dimension and compare it with the numerically exact answer provided by Density Matrix Renormalization Group. Using the exact answers, we can compare exact Density Functional Theory quantities against commonly used approximations. Approximations tend to underestimate the band gap of the material. We compare the exact DFT quantities with the approximations to explore the band gap problem and provide numerical proofs of principle.

5:18PM J23.00115 Real-time quantum electron-phonon dynamics$^1$, VALERIO RIZZI, TCHAVDAR TODOROV, JORGE KOHANOFF, Queen’s University Belfast, ALFREDO CORREA, Lawrence Livermore National Laboratory — Electrons and atomic motion out of equilibrium exchange energy and momentum. Physical processes that involve this exchange include Joule heating, inelastic electron tunneling, and thermalization of hot electrons in an irradiated material. An explicit dynamical treatment of both subsystems is essential to model such non-adiabatic phenomena and requires the ability to describe the interaction of the coupled electrons and nuclei without enforcing equilibration a priori. Therefore, being able to describe an electronic system in real time together with the underlying ionic system is a key feature for first-principles electron-phonon methods. We have developed an approach for real-time phonon-assisted electron transfer in nanowires, explicitly tracking out-of-equilibrium systems that exchange energy. Our model is fully quantum mechanical: it overcomes the limitations of the Ehrenfest (quantum-classical) approximation and doesn’t require thermostats, or the treatment of either subsystem as a bath. We can probe a range of timescales: from attoseconds (electronic timescale) to picoseconds (typical of atomic vibrations). The comparison with exact simulations of systems with a single phonon and a single electron has proved an invaluable validation tool for our method. We are able to describe the population inversion of an excited electronic system coupled to phonons and phonon-assisted conduction in systems with Anderson localization.

Session J24 Quantum Monte Carlo Simulations of Fermion and Boson Systems I 203AB - Juana Moreno, Louisiana State University

2:30PM J24.00001 Quantum phases of dipolar bosons in multi-layered optical lattice geometries, BARBARA CAPOGROSSO-SANSONE, Homer L. Dodge Dept. of Physics and Astronomy, University of Oklahoma — Dipolar interactions are responsible for stabilizing novel quantum many-body states in ultracold systems. In this talk we consider dipolar bosons trapped in $N \geq 2$ optical lattice layers. These configurations provide an ideal setup to explore novel physics resulting from the long range and anisotropic character of the dipolar interaction. We present results based on Path Integral Quantum Monte Carlo by the two-worm and a novel N-worm algorithm for dipolar hard-core bosons whose dipole moments are aligned perpendicularly to the optical lattice layers. Several non-trivial phases are stabilized. For two-dimensional bi-layer geometries these phases include pair-superfluidity, pair-supersolidity, and solid phases. For stacks of one-dimensional layers (tubes) superfluidity of multimers, solids, countersuperfluids are stabilized and they have a threshold-less nature with respect to the dipolar interaction.

3:06PM J24.00002 Detecting Goldstone Modes Using Entanglement Entropy in Quantum Monte Carlo, BOHDAN KULCHYTSKYY, CHRIS HERDMAN, University of Waterloo, STEPHEN INGLIS, Ludwig Maximilian University of Munich, ROGER MELKOV, University of Waterloo, Perimeter Institute — Bipartite entanglement entropy has emerged as a multifunctional tool in the study of condensed matter systems. In the context of systems with a spontaneously broken continuous symmetry, the scaling of this quantity has been predicted by Metlitski and Grover to have logarithmic subleading universal contribution to the boundary [1]. To test this, we conduct large-scale Quantum Monte Carlo simulations for a two-dimensional spin-1/2 XY-model at temperatures below the finite-system energy gap. Based on the predicted Renyi entropy scaling form, we are able to extract the number of Goldstone modes through the coefficient of the subleading logarithm. Further, we confirm that an additional subleading geometrical constant is present, which can be expressed in terms of a quantity in a free scalar field theory. This work illustrates the striking quantitative agreement that can be achieved between analytical continuum theory and lattice numerics, through calculations of Renyi entanglement entropies. [1] M. Metlitski and T. Grover arXiv:1112.5166 (2011)

3:18PM J24.00003 ABSTRACT WITHDRAWN —

3:30PM J24.00004 Solving fermion sign problem in quantum Monte Carlo by Majorana representation, HONG YAO, ZI-XIANG LI, YI-FAN JIANG, Institute for Advanced Study, Tsinghua University — We discover a new quantum Monte Carlo (QMC) method to solve the fermion sign problem in interacting fermion models by employing Majorana representation of complex fermions. We call it Majorana QMC (MQMC). Especially, MQMC is fermion sign free in simulating a class of spinless fermion models on bipartite lattices at half filling and with arbitrary range of (unfrustrated) interactions. To the best of our knowledge, MQMC is the first auxiliary field QMC method to solve fermion sign problem in spinless (more generally, odd number of species) fermion models. MQMC simulations can be performed efficiently both at finite and zero temperatures. We believe that MQMC could pave a new avenue to solve fermion sign problem in more generic fermionic models. (Zi-Xiang Li, Yi-Fan Jiang, and Hong Yao, arXiv:1408.2269).
3:42PM J24.00005 Quantum Monte Carlo simulations of bosons with complex interactions

VALERY ROUSSEAU, Louisiana State University — Many of the most exciting materials and phenomena being studied today, from oxide heterostructures to topological insulators or iron-based superconductors, are the ones in which an understanding of how quantum particles interact with each other is essential. In the last decade, the development and the improvement of quantum Monte Carlo algorithms combined with the increased power of computers has opened the way to the exact simulation of Hamiltonians that include various types of interactions, such as inter-species conversion terms or ring-exchange terms. Simultaneously, developments made in the field of optical lattices, laser cooling and magneto/optical trapping techniques have led to ideal realizations of such Hamiltonians. A wide variety of phases can be present, including Mott insulators and superfluids, as well as more exotic phases such as Haldane insulators, supersolids, counter-superfluids, or the recently proposed Feshbach insulator. These experimental realizations of the various forms of the Hubbard model can have interesting applications, in particular they provide a possible way of performing quantum computing, and have also given rise to a new field known as Atomtronics, the equivalent of Electronics where the carriers are replaced by atoms. I will illustrate these ideas with examples of Hamiltonians that have been studied and some results. In order to study these systems, it is crucial to identify the various phases that are present, which can be characterized by a set of order parameters. Of particular importance in this task is the superfluid density. It is well known that the superfluid density can be related to the response of the free energy to a boundary phase twist, or to the fluctuations of the winding number. However, these relationships break down when complex interactions are involved. To address this problem, I will propose a general expression of the superfluid density, derived from real and thought experiments. I will discuss two interesting applications of my method to the SF transition of softcore bosons with 2nd neighbor hopping and to atom-molecule mixtures.

We study charge- and spin-ordered states in the two-dimensional extended Hubbard model on a triangular lattice with a triangular lattice filling of 1/3 filling. While the nearest-neighbor Coulomb repulsion $V$ induces charge-ordered states, the competition between on-site $U$ and nearest-neighbor $V$ interactions lead to quantum phase transitions to an antiferromagnetic spin-ordered phase with honeycomb charge order. In order to avoid the fermion sign problem and handle frustrations here we use quantum Monte Carlo methods with the string-bond tensor network ansatz for fermionic systems in two dimensions. We determine the phase boundaries of the several spin- and charge-ordered states and show a phase diagram in the on-site $U$ and the nearest-neighbor $V$ plane. The numerical accuracy of the method is compared with exact diagonalization results in terms of the size of matrices $D$. We also test the use of lattice symmetries to improve the string-bond ansatz.

Viable mouse liver. We use an SJL mouse model to study liver inflammation in vivo using the spatially and spectrally resolved nIR signature of the localized d(AAAT). An advancement in biosensor development is the use of near infrared fluorescent carbon nanotube sensors for in-vivo detection [2]. Here, we show that PEG-ligated SWNT sensors.

Another area of phase that exhibits highly selective recognition for specific molecules. To prove the generality of this phenomenon, we report three examples of heteropolymers—MoRe or corona phase molecular recognition [1] as a method of discovering synthetic antibodies, or nanotube-templated recognition sites from a heteropolymer 2D electronic structures of carbon nanotubes and graphene respectively can be utilized to advance new concepts in molecular detection. We introduce CoPh-Nanosensor Interfaces

Wang, University of Maryland

Cornell University — Graphene channel field-effect biosensors are demonstrated for detecting the binding of double-stranded DNA and poly-l-lysine. Sensors based on CVD graphene transferred using a clean, etchant-free transfer method. The presence of DNA and poly-l-lysine are detected by the change in the Dirac mobility, such as the ternary alloy CuAlNi, are metals that have the fascinating ability to “remember” their original shape: Once deformed, the simple act of heating can thermomechanically return them to their original configuration. At the heart of this process is a martensitic phase transition, a solid-solid transition that can be induced by either a temperature change or by external stress. Cycling between phases of SMAs reveals hysteresis in their stress-strain relationships and transformation temperatures. Moreover, these characteristics evolve over many transformation cycles. We report on in-situ X-ray Photon Correlation Spectroscopy (XPCS) measurements of the microstructural evolution of a CuAlNi alloy that underlies these hysteresis effects. By simultaneously monitoring changes in X-ray speckle patterns from the two solid phases as the alloy was thermally cycled through both partial and full transformations, we have seen reversible microstructural hysteresis loops and irreversible loops that reveal mesoscopic plastic deformation in the material.

Wang, University of Maryland

2:30PM J26.00001 Corona Phase Molecular Recognition (CoPhMoRe) or corona phase molecular recognition [1] as a method of discovering synthetic antibodies, or nanotube-templated recognition sites from a heteropolymer library. We show that certain synthetic heteropolymers, once constrained onto a single-walled carbon nanotube by chemical adsorption, also form a new corona phase that exhibits highly selective recognition for specific molecules. To prove the generality of this phenomenon, we report three examples of heteropolymers—nanotube recognition complexes for riboflavin, L-thyroxine and estradiol. The platform opens new opportunities to create synthetic recognition sites for molecular detection. We have also extended this molecular recognition technique to neurotransmitters, producing the first fluorescent sensor for dopamine. Another area of advancement in biosensor development is the use of near infrared fluorescent carbon nanotube sensors for in-vivo detection [2]. Here, we show that PEG-ligated d(AAAT)_{n} DNA wrapped SWNT are selective for nitric oxide, a vasodilator of blood vessels, and can be tail vein injected into mice and localized within the viable mouse liver. We use an SJL mouse model to study liver inflammation in vivo using the spatially and spectrally resolved nIR signature of the localized SWNT sensors.

3:06PM J25.00007 ABSTRACT WITHDRAWN —

4:18PM J25.00008 Strength and Dislocation Structure Evolution of Small Metals under Vibrations . ALFONSO NGAN, University of Hong Kong — It is well-known that ultrasonic vibration can soften metals, and this phenomenon has been widely exploited in industrial applications concerning metal forming and bonding. In this work, we explore the effects of a superimposed small oscillatory load on metal plasticity, from the nano- to macro-size range, and from audible to ultrasonic frequency ranges. Macroscopic and nano-indentation were performed on aluminum, copper and molybdenum, and the results show that the simultaneous application of oscillatory stresses can lower the hardness of these samples. Moreover, in situ TEM and EELS observations show that subgrain formation and reduction in dislocation density generally occurred when stress oscillations were applied. These findings point to an important knowledge gap in metal plasticity — the existing understanding of ultrasound softening in terms of the vibrations either imposing additional stress waves to augment the quasi-static applied load, or heating up the metal, whereas the metal’s intrinsic deformation resistance or dislocation interaction processes are assumed unaltered by the ultrasound, is proven wrong by the present results. Furthermore, in the case of nonindentation, the continuous stress-deformation measurement technique for nanoindentation measurement assumes that the imposed signal-carrier oscillations do not intrinsically alter the material properties of the specimen, and again, the present results prove that this can be wrong. To understand the enhanced subgrain formation and dislocation annihilation, Discrete Dislocation Dynamics (DDD) simulations were carried out and these show that when an oscillatory stress is superimposed on a quasi-static applied stress, reversals of motion of dislocations may occur, and these allow the dislocations to revisit repeatedly suitable configurations for annihilation. DDD, however, was unable to predict the observed subgrain formation presumably because the number of dislocations that can be handled is not large enough. Subgrain formation was directly predicted by a new simulation method of dislocation plasticity based on the dynamics of dislocation density functions.

4:54PM J25.00009 To Slip or Snap: Finite Length Chains and Yield Mechanisms in Polyethylene Fibers1 . THOMAS O’CONNOR, MARK ROBBINS, Johns Hopkins University, Physics and Astronomy — Understanding the microscopic mechanisms of yield in oriented polymer fibers is a long-standing problem. Advances in polymer processing have produced highly ordered polyethylene (PE) fibers with tensile strengths between 4-7 GPa, but these values are far less than the theoretical limiting strength of 25 Gpa due to C-C bond scission. This reduction in strength is caused by the presence of defects within the fiber. The simplest type of defect is chain ends which reflect the finite length of polymer chains. The presence of chain ends allows a polymer fiber to yield by chain slip without scission of covalent bonds. Here we present extensive united atom (UA) and all atom (AA) molecular dynamics simulations of crystalline PE fibers subjected to uniaxial tension. The fibers are fully aligned crystals constructed from chains of finite length N, with N spanning 3 orders of magnitude (10^2 – 10^4 monomers). We explore the yield behavior of these systems and relate it to the dynamics of the underlying chain end defects. UA tensile strengths are systematically smaller than AA by a factor of about 3. Both show a saturation in tensile strength as N rises above 500 monomers. This reflects a saturation in the stress for chain ends to slip and implies a maximum tensile strength of 6 Gpa.

Subgrain formation was directly predicted by a new simulation method of dislocation plasticity based on the dynamics of dislocation density functions.

3:06PM J25.00006 Detection of DNA and Protein using CVD Graphene-channel FET Biosensors . ABHILASH SEBSTIAN, ANIKET KAKATKAR, ROBERTO DE ALBA, HAROLD CRAIGHEAD, JEEVAK PARPIA, Centre for Materials Research, Cornell University — Graphene channel field-effect biosensors are demonstrated for detecting the binding of double-stranded DNA and poly-l-lysine. Sensors consist of CVD graphene transferred using a clean, etchant-free transfer method. The presence of DNA and poly-l-lysine are detected by the change in the Dirac Voltage (the voltage at which the graphene’s resistance peaks) of the graphene transistor. Sensors show large shifts in the Dirac voltage ~ 17 V after exposure to ~ 580 pM of poly-l-lysine and ~ 14 V upon exposure to 300 pM of DNA. The polarity of the response changes to positive direction with poly-l-lysine and negative direction with DNA. Sensors show detection limits of 8 pM for 48.5 kbp DNA and 11 pM for poly-l-lysine. The biosensors are easy to fabricate, reusable and are promising as sensors of a wide variety of charged biomolecules.
of how the molecular orbital is renormalized is addressed. Photosynthesis. In this work we report density functional theory (DFT) and many-body GW calculations to investigate CO2 adsorption on III-nitride semiconductor surfaces.

YING-CHIN CHEN, HONG GUO, McGill Univ — Photon-induced chemical transformation of CO2 is a very interesting direction of green-house gas reduction. LAY-SENG CHONG, PHILIPPE GUYOT-SIONNEST, UNIL Geneva — While much research on colloidal quantum dots is focused on their potential as visible emitter or light harvester, this talk will cover our investigations of the mercury chalcogenide colloidal quantum dots in the thermal mid-infrared ranges of 3-5 microns and 8-12 microns where the atmosphere is transparent. HgTe is a zero-gap semiconductor. As a result, colloidal quantum dots (QD) of sizes between 10 and 20 nm readily lead to infrared gaps tuning between 3 and 12 microns respectively. It is also very promising that infrared photodetection using dried films of these QDs has now been demonstrated up to 12 microns. Further improvement through chemistry are likely and will be required to raise the detectivity to the level required to transform thermal infrared detection technology. In contrast to HgTe QDQDs which tend to be intrinsic, beta-HgS and HgSe QDQDs are naturally n-doped, in the first such instance with QDQDs. Furthermore, the doping is modulated by modifying the surface composition, and this effect is attributed to the tuning of the energy level with respect to the environment, via the surface electrostatics. With controlled doping, both HgSe and HgS QDQDs have now led to the first operation of mid-infrared QD photodetector based on the intraband absorption. This is a breakthrough in the field of colloidal quantum dots where interband transitions had been exclusively used for the past 30 years. One challenge with both interband and intraband infrared QDQDs will be to reduce the nonradiative recombination, which will improve the detectivity as well as allow to use their infrared luminescence.

3:30PM J26.00004 Infrared detection with colloidal quantum dots based on interband and intraband transitions , PHILIPPE GUYOT-SIONNEST, University of Chicago — While much research on colloidal quantum dots is focused on their potential as visible emitter or light harvester, this talk will cover our investigations of the mercury chalcogenide colloidal quantum dots in the thermal mid-infrared ranges of 3-5 microns and 8-12 microns where the atmosphere is transparent. HgTe is a zero-gap semiconductor. As a result, colloidal quantum dots (QD) of sizes between 10 and 20 nm readily lead to infrared gaps tuning between 3 and 12 microns respectively. It is also very promising that infrared photodetection using dried films of these QDs has now been demonstrated up to 12 microns. One challenge with both interband and intraband infrared QDQDs will be to reduce the nonradiative recombination, which will improve the detectivity as well as allow to use their infrared luminescence.

4:06PM J26.00005 Unraveling Molecular Structure in Stern Layer at Charged Water Interface using sum-frequency vibrational spectroscopy , YU-CHIEH WEN, Institute of Physics, Academia Sinica, SHUAI ZHA, SHANSHAN YANG, CHUANSHAN TIAN, Department of Physics, Fudan University, Y. RON SHEN, Department of Physics, University of California, Berkeley, California — Charged aqueous interfaces, such as membrane/water and electrochemical interfaces, are essential in many chemical, biological, and environmental processes. Interactions between heterogeneous interfacial molecules and the consequent molecular network dictate properties and functions of the interfaces; however, the microscopic-level picture of the charged water interfaces remains substantially unclear. Here we demonstrate probing of the molecular structure in Stern layer at aqueous interfaces using sum-frequency vibrational spectroscopy. We show that at anionic surfactant/water interfaces, the hydrogen-(H)-bonding strength and network in the Stern layer depend sensitively on conformation and ionization of the surfactants, suggesting a relevant influence of the surfactant-water charge transfer. In addition, ion adsorption to the interface is shown to distort the interfacial water structure. Our study offers exciting opportunities to acquire microscopic insights into interfaces for catalytic and electrochemical applications.

4:18PM J26.00006 Mind the Entropy: Electronic and Thermal Fluctuations of Large Molecules on Metals , REINHARD MAURER, Yale University, WEI LIU, IGOR POLTAVSKYI, Fritz-Haber Institute of the Max-Planck Society, HARALD OBERHOFER, THOMAS STECHER, Technische Universitaet Muenchen, ALEXANDRE TKATCHENKO, Fritz-Haber Institute of the Max-Planck Society, KARSTEN REUTER, Technische Universitaet Muenchen — The prevailing working hypothesis in vacuum surface science is that equilibrium properties of adsorbed molecules are largely altered by finite temperature effects. In this work we illustrate that this is not the case for the adsorption geometry, energetics, and desorption temperature of the molecular switch Azobenzene adsorbed to Ag(111). Comparing with X-ray standing wave measurements and temperature programmed desorption experiments we find strong discrepancies to static Density-Functional Theory calculations. Anharmonic corrections and ab-initio molecular dynamics simulation of the free energy of desorption account for the thermal fluctuations and inclusion of many-body dispersion effects accounts for the electronic fluctuations. In addition, we demonstrate that finite temperature effects lead to an incorrect prediction of the correct desorption temperature. This implies that an accurate description of adsorbate interactions and entropies of adsorption in most realistic functional hybrid metallic organic systems necessitates a full account of the inherent anharmonicity of adsorbate and substrate in addition to an accurate description of dispersion interactions.

4:30PM J26.00007 Stressed and Compressed Polymersomes , ROBERT HAYES, CHANGQIAN YU, STEVE GRANICK, Univ of Illinois - Urbana — Polymersomes are well-defined vesicular structures that have been studied extensively for encapsulation, controlled release and as cell mimics, inter alia. While polymersomes at ambient conditions are reasonably well-understood, comparatively little is known about how structure and properties change when subject to variations in their local environment. In this talk, atomic force microscopy is used to probe PEO-PBD polymersomes adsorbed at a solid liquid interface under osmotic pressure. We reveal interesting changes in shape and solvation not captured by classical theory.

4:42PM J26.00008 Effect of CO2 on a polystyrene adsorbed nanolayer1 , DEBORAH BARKLEY, NAISHENG JIANG, LEVENT SENDOGLUAR, XIAOYU DI, MANI SEN, MAYA K. ENDOH, TADANORI KOGA, Stony Brook University, Stony Brook, NY, BULENT AKGUN, Center for Neutron Research, National Institute of Standards and Technology and Bogazici University, Bebek, Istanbul, Turkey, MICHAEL DIMITRIOU, SUSIL SATIJA, Center for Neutron Research, National Institute of Standards and Technology — We report the role of compressed carbon dioxide (CO2) in a mobility gradient of polymer chains near a planar solid substrate. A series of bilayers of bottom hydrogenated polystyrene and top deuterated polystyrene layers were prepared on Si substrates, and high pressure neutron reflectivity (NR) was used to study diffuse motion at the polymer/polymer interface. The interdiffusion is hindered when the distance is less than 3Rg (Rg, radius of polymer gyration). This reduced chain diffusivity is attributed to CO2-induced polymer adsorption on the substrate, transforming the 0.6Rg thick region from the substrate interface into an irreversibly adsorbed polymer layer. The cohesion strength is attributed to loops in the adsorbed chains with which the neighboring chains can entangle.

1T. K. acknowledges the partial financial support from NSF Grants (CMMI-084826 and CMMI-1332499).

4:54PM J26.00009 First-principles investigation of CO2 absorption on III-nitride surfaces , YING-CHIN CHEN, HONG GUO, McGill Univ — Photon-induced chemical transformation of CO2 is a very interesting direction of green-house gas reduction. An accurate description of electronic structure at the interface between CO2 and the photocatalysts is important for understanding the process of artificial photosynthesis. In this work, we present density functional theory (DFT) and many-body GW calculations to investigate CO2 adsorption on III-nitride semiconductor surface. The adsorption geometry is determined at the DFT level and the electronic structure is investigated at both DFT and GW levels. A detailed illustration of how the molecular orbital is renormalized is addressed.
5:06PM J26.00010 Ab initio molecular-dynamics study of EC decomposition process on Li$_2$O$_2$ surfaces, YASUNOBU ANDO$^1$, Department of Materials Engineering, The University of Tokyo, TAMIO IKESHOJI, MINORU OTANI$^2$, Nanosystem Research Institute, AIST — We have simulated electrochemical reactions of the EC molecule decomposition on Li$_2$O$_2$ substrate by ab initio molecular dynamics combined with the effective screening medium method. EC molecules adsorb onto the peroxide spontaneously. We find through the analysis of density of states that the adsorption state is stabilized by hybridization of the sp$^2$ orbital and the surface states of the Li$_2$O$_2$. After adsorption, EC ring opens, which leads to the decomposition of the peroxide and the formation of a carboxy group. This kind of alkyl carbonate formed on the Li$_2$O$_2$ substrate was found in experiments actually

5:18PM J26.00011 Understanding 3C-SiC/SiO$_2$ interfaces in SiC-nanofiber based solar cells from ab initio theory$^1$, TAUFIK ADI NUGRAHA, STEFAN WIPPERMANN, Max-Planck-Institute for Iron Research — Nanostructured materials — such as e. g. hybrid nanocomposites consisting of inorganic semiconductor nanofibers and organic surfactants — provide genuinely novel pathways to exceed the Shockley-Queisser limit for solar energy conversion. The synthesis of such functionalized nanofibers can be performed completely using only inexpensive wet chemical solution processing. However, the synthesis conditions often lead to complex interfacial structures involving thin oxide layers between the nanofiber and surfactants, whose atomic details are poorly understood at best. Here we present a combined density functional theory and tight binding investigation of interfaces between 3C-SiC nanofiber surfaces and SiO$_2$. Considering a wide variety of possible interfacial structures we utilize a grand canonical approach to generate a phase diagram and predict the structural details of the interface as a function of the chemical potentials of Si, O and H. This study provides directions about how the synthesis conditions lead to specific types of interfacial structures and their impact on the electronic properties of the interface.

$^1$The authors wish to thank U. Gerstmann, S. Greulich-Weber and W. G. Schmidt for helpful discussions. S. W. acknowledges BMBF NanomatFutur Grant No. 13N12972.

Session J27 DCP: Focus Session: Chemical Physics of Clusters: Bridging from Angstrom-scale Clusters to Micron-scale Aerosol Particles III

2:30PM J27.00001 Solvation Effects on Structure and Charge Distribution in Anionic Clusters$^3$, J. MATHIAS WEBER, JILA and Department of Chemistry & Biochemistry, University of Colorado at Boulder — The interaction of ions with solvent molecules modifies the properties of both solvent and solute. Solvation generally stabilizes compact charge distributions compared to more diffuse ones. In the most extreme cases, solvation will alter the very composition of the ion itself. We use infrared photodissociation spectroscopy of mass-selected ions to probe how solvation affects the structures and charge distributions of metal-CO$_2$ cluster anions.

$^3$We gratefully acknowledge the National Science Foundation for funding through Grant CHE-0845618 (for graduate student support) and for instrumentation funding through Grant PHY-1125844.

2:30PM J27.00002 Proton transfer in acetaldehyde and acetaldehyde-water clusters: Vacuum ultraviolet photoionization experiment and theoretical calculations, OLEG KOSTKO, TYLER P. TROY, BISWAJIT BANDYOPADHYAY, MUSAHID AHMED, Lawrence Berkeley National Lab — Acetaldehyde, a probable human carcinogen and of environmental importance, upon solvation provides a test bed for understanding proton transfer pathways and catalytic mechanisms. In this study, we report on single photon vacuum ultraviolet photoionization of acetaldehyde and acetaldehyde-water clusters. Appearance energies of protonated clusters are extracted from the experimental photoionization efficiency curves and compared to electronic structure calculations. The comparison of experimental data to computational results provides mechanistic insight into the fragmentation mechanisms of the observed mass spectra. Using deuterated water for isotopic tagging, we observe that proton transfer is mediated via acetaldehyde and not water in protonated acetaldehyde-water clusters.

3:18PM J27.00003 Does the 18-Electron Rule Apply to CrSi$_{12}$?$^1$, MARISSA BADDICK ABREU,VIKAS CHAUHAN, ARTHUR REBER, SHIV KHANNA, Virginia Commonwealth University — Understanding the bonding between silicon and transition metals is valuable for devising strategies for incorporating magnetic species into silicon. CrSi$_{12}$ is the standard example of a cluster whose apparent high stability has been explained by the 18-electron rule. We critically examine the bonding and nature of stability of CrSi$_{12}$ and show that its electronic structure does not conform to the 18-electron rule. Through theoretical studies we find that CrSi$_{12}$ has 16 effective valence electrons assigned to the Cr atom and an unoccupied 3d$^3$ orbital. We demonstrate that the cluster’s apparent stability is rooted in a crystal field-like splitting of the 3d orbitals analogous to that of square planar complexes. CrSi$_{12}$ is shown to follow the 18-electron rule and exhibits all the conventional markers characteristic of a magic cluster. We will also present results on the stability and electronic structure of FeSi$_{12}$ clusters and in particular examine the valence configuration of FeSi$_{12}$ since Fe has two additional valence electrons compared to Cr.

$^1$We acknowledge support from the Department of Energy (DOE) under Award Number DE-SC0006420.

3:30PM J27.00004 Effect of N- and P-Type Doping on the Oxygen-Binding Energy and Oxygen Spillover of Supported Palladium Clusters$^3$, ARTHUR C. REBER, SHIV N. KHANNA, Virginia Commonwealth University — The oxygen-binding energy is one of the primary factors determining catalytic activity in oxidation reactions. One strategy for controlling the binding of a reactant to a surface is to dope the surface to create complementary donor–acceptor pairs. As oxygen is an acceptor, we have investigated the effect of doping on the oxygen-binding energy on Pd atoms and clusters supported on a rutile TiO$_2$(110) surface. We find that the P-type doping of the TiO$_2$ surface dramatically reduces the O-binding energy to Pd. When extended to Pd$_2$-supported clusters, we find that the P-type dopant decreases the energy for the oxygen to bind at spillover sites directly to the TiO$_2$ surface. In Pd$_2$O$_2$, the oxygen-binding energy is reduced with P-type doping, suggesting that this strategy may be used to control the oxygen-binding energy to supported catalysts.

3:42PM J27.00005 Cluster Study of Anion Specificity in Solutions: From Molecular-Like Species to Nano-Sized Droplets1, XUE-BIN WANG, Pacific Northwest National Lab — In this talk, I will present our cluster approach using size-selected, low-temperature photoelectron spectroscopy and ab inito calculations to study a variety of complex anion solvation across the Hofmeister series. Pronounced anion specific effects and rich solute-solvent interactions have been discovered en-route to solvation evolution from molecular species to nano-sized droplets. We found significant solute anisotropy effects in preferably selecting solvent network to align solute permanent dipole with the solvent electric field in hydrated neutral clusters. Thermodynamic advantage of organic acids in facilitating formation of bisulfate ion clusters, an important issue related to atmospheric chemistry and aerosol particle formation will also be discussed.

4:18PM J27.00006 Ligand-modulated interactions between charged monolayer-protected Au144(SR)60 gold nanoparticles in physiological saline1, OSCAR VILLARREAL, LIAO CHEN, ROBERT WHETTEN, MIGUEL YACAMAN, Univ of Texas, San Antonio — We studied the interactions of functionalized Au144 nanoparticles (NPs) in a near-physiological environment through all-atom molecular dynamics simulations. The AuNPs were coated with a homogeneous selection of 60 thiolates: 11-mercapto-1-undecanesulfonate, 5-mercapto-1-pentanesulfonate, 5-mercapto-1-pentane-amine, 4-mercapto-benzoate or 4-mercapto-benzamide. These ligands were selected to elucidate how the aggregation behavior depends on the ligands’ sign of charge, length, and flexibility. Simulating the dynamics of a pair of identical AuNPs in a cell of saline of 150 mM NaCl in addition to 120 Na+/Cl- counter-ions, we computed the aggregation affinities from the potential of mean force as a function of the pair separation. We found that NPs coated with negatively charged, short ligands have the strongest affinities mediated by multiple Na+ counter-ions residing on a plane in-between the pair and forming “salt bridges” to both NPs. Positively charged NPs have weaker affinities, as Cl counter-ions form fewer and weaker salt bridges. The longer ligands’ large fluctuations disfavor the forming of salt bridges, enable hydrophobic contact between the exposed hydrocarbon chains and interact at greater separations due to the fact that the screening effect is rather incomplete.

4:30PM J27.00007 Structural and charge inhomogeneity in supported Pt clusters1, F.D. VILA, J.J. REHR, U. of Washington, A.I. FRENKEL, Yeshiva U. — Nanoparticle materials are ubiquitous in heterogeneous catalytic processes and there is broad interest in their physical and chemical properties. However, global probes such as XAS and XPS reveal their ensemble properties, missing details of their local electronic and structural changes upon desorption. For example, upon single CO adsorption, the Pt-Pt bonds formed by coordinated Pt atoms are locally expanded by 5%, with little change in the rest of the particle. Coordination also has a large effect on the net charge of the Pt atoms, with a net loss of charge upon adsorption. Finally, we show how high coverage inverts the charge distribution in the clusters.

4:42PM J27.00008 New Insights into the Structure of Multimetallic Nanoparticles and their Advanced Characterization, SUBARNA KHANAL, NABRAJ BHATTARAI, JESUS VELÁZQUEZ-SALAZAR, GREGORY GUISBIERS, MIGUEL JOSE-YACAMAN, University of Texas at San Antonio — Noble multimetallic nanoparticles have led to exciting progress in a versatile array of applications. For the purpose of better tailoring of nanoparticles activities and understanding the correlation between their structures and properties, control over the composition, shape, size and architecture of bimetallic and multimetallic nanomaterials plays an important role on revealing their new or enhanced functions for potential applications. Advance electron microscopy techniques were used to provide atomic scale insights into the structure-properties of different materials: Pt-Pd, Au-Au, Cu-Cu, Pt-AgPd-Pt, and AuCu/Pt nanoparticles. These multimetallic nanoparticles have raised interest for their various applications in fuel cells, ethanol and methanol oxidation reactions, hydrogen storage, and so on. The nanostructures were analyzed by transmission electron microscopy (TEM) and aberration-corrected scanning transmission electron microscopy (Cs-corrected STEM), in combination with high angle annular dark field (HAADF), bright field (BF), energy dispersive X-ray spectroscopy (EDS), and electron energy loss spectroscopy (EELS) detectors. These techniques allowed us to probe the structure at the atomic level of the nanoparticles revealing new structural information and elemental composition of the nanoparticles.

Tuesday, March 3, 2015 2:30PM - 5:30PM – Session J28 GMAG DMP FIAP: Focus Session: Spin-Hall Effect I 205 - Ken-Ichi Uchida, Tohoku University

2:30PM J28.00001 The Spin Hall Effect in Rare Earth Thin Films, NEAL REYNOLDS, JONATHAN GIBBONS, JOHN HERON, Cornell University Physics Department, DARRELL SCHLOM, Cornell University Materials Science and Engineering, DANIEL RALPH, Cornell University Physics Department — The spin Hall effect results in a spin current which flows transverse to an applied electric field in heavy metals, and which can be used to apply an efficient spin transfer torque to the ferromagnetic layer in heavy metal/ferromagnet bilayer structures. We report experimental investigations of the strength of the spin Hall effect in lanthanide rare earth materials. To ensure trustworthy results, we compare the results of several complementary measurement techniques: off-resonant second harmonic detection of current-induced magnetic tilting, spin-torque ferromagnetic resonance, and spin pumping. We report on both the anti-damping and effective-field components of the spin torque generated by the spin Hall effect.

2:42PM J28.00002 Nonequilibrium spin polarization induced charge Hall effect, DAZHI HOU, Z. QIU, WPI Advanced Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, R. IGUCHI, Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan. K. SATO, WPI Advanced Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, K. UCHIDA, G. W. BAUER, EIJII SAITO, Tohoku University, Sendai 980-8577, Japan — The nonequilibrium spin polarization lies at the heart of information processing in spin-based devices. The generation and manipulation of the spin polarization have been realized by various approaches, however, the spin polarization is usually considered to have negligible effect on the electric transport property, especially for systems of high electron concentration like metals (e_F ~ eV). Here we show that the nonequilibrium spin polarization can cause a novel Hall voltage in a conventional metallic alloy at room temperature, which is due to a new mechanism and closely related to the spin Nernst effect.
2:54PM J28.00003 Spin Hall effect by surface roughness1. LINGJUN ZHOU, VAHRAM GRIGORYAN, Fudan University, China. SADAMICHI MAEKAWA, Japan Atomic Energy Agency, Japan. XUHUI WANG, King Abdullah University of Science and Technology, Saudi Arabia. JIANG XIAO, Fudan University, China — spin Hall effect and its inverse effect, caused by the spin orbit interaction, provide the interconversion between spin current and charge current. Since the effects make it possible to and manipulate spin current electrically, how to realize the large effects is an important in both physics and applications. To do so, materials with heavy elements, which have strong spin orbit interaction, have been examined so far. Here, we propose a new mechanism to enhance the spin Hall effect without heavy elements, i.e. surface roughness in metallic thin films. We examine Cu and Al thin films with surface roughness and find that they give the spin Hall effect comparable to that in bulk Au. We demonstrate that the spin Hall effect induced by surface roughness has the side jump direction but not skew scattering.

3:06PM J28.00004 Optical detection of spin Hall effect in metals1. OLAF VAN T ERVE, AUBREY HANBICKI, KATHY MCCREARY, CONNIE LI, BERRY JONKER, Naval Research Lab — Here we present room temperature measurements of the spin Hall effect in non-magnetic metals such as Pt and β-W using a standard bench top magneto-optic Kerr effect (MOKE) system2. With this system, one can readily determine the angular dependence of the induced polarization on the bias current direction, the orientation of the spin Hall induced polarization, and the sign of the spin Hall angle. When a bias current is applied, the spin Hall effect causes electrons of opposite spin to be scattered in orthogonal directions, resulting in a spin accumulation at the surface of the film. The MOKE signal tracks the applied square wave bias current with an amplitude and phase directly related to the spin Hall angle. Using this technique, we show that the spin Hall angle of β-W is opposite in sign and significantly larger than that of Pt, and follow the structural phase transition from β-W to α-W as the film is annealed through the dependence of the spin Hall angle on crystal structure. We also use this technique to detect spin diffusion from β-W into Al thin films.

3:18PM J28.00005 Extremely large, gate tunable spin Hall angle in 3D Topological Insulator pn junction1, 2. K M MASMUS HABIB, REDWAN SAJJAD, AVIK GHOSH, Univ of Virginia — The band structure of the surface states of a three dimensional Topological Insulator (3D TI) is similar to that of graphene featuring massless Dirac Fermions. We show that due to this similarity, the chiral tunneling of electron in a graphene pn junction also appears in 3D TI. Electrons with very small incident angle (modes) are allowed to transmit through a TI pn junction (TIPNJ) due to the chiral tunneling. The rest of the electrons are reflected. As a result, the charge current in a TIPNJ is suppressed. Due to the spin momentum locking, all the small angle modes are spin-down states. Therefore, the transmitted end of the TIPNJ becomes highly spin polarized. On the other hand, the spin of the reflected electron is flipped due to spin momentum locking. This enhances the spin current at the injection end. Thus, the interplay between the chiral tunneling and spin momentum locking reduces the charge current but enhances the spin current at the same time, leading to an extremely large (~20) spin Hall angle. Since the chiral tunneling can be controlled by an external electric field, the spin Hall angle is gate tunable. The spin current generated by a TIPNJ can be used for energy-efficient switching of nanoscale ferromagnets, which is an essential part of spintronic devices.

3:30PM J28.00006 Growth of β-Tungsten Films Towards a Giant Spin Hall Effect Logic Device, AVAYA JAYANTHINARASIMHAM, MANASA MEDIKONDA, AKITOMO MATSUBAYASHI, State University of New York, Albany, PRASANNA KHARE, HYUNCHER CHONG, RICHARD MATYI, ALAIN DIEBOLD, VINCENT LABELLA, SUNY, Polytechnic Institute — Spin-orbit coupling in metastable β-W generates spin transfer torques strong enough to flip magnetic moment of an adjacent magnetic layer. In a MTJ stack these torques can be used to switch between high and low resistive states. This technique can be used in designing efficient magnetic memory and non-volatile spin logic devices. Deposition conditions selective to β-W need to be understood for the large scale fabrication of such devices. The transition from β to α phase of Tungsten is strongly governed by thickness of W layer, base pressure and oxygen availability for example, above 5 nm β film relaxes and forms an α phase. Resistivity measurements as well as x-ray photoelectron spectroscopy and x-ray diffraction and reflectivity analysis are performed to determine the phase and thickness of tungsten films. We show that β phase is influenced by ultrathin thermal oxide of Si layer and the amount of oxygen flow during the growth. These results demonstrate a reliable technique to fabricate β-W film up to 20 nm on bare Si and silicon dioxide, while providing insight to growing it anywhere in the device stack.

3:42PM J28.00007 Spin polarized tunneling study on spin Hall effect metals and topological insulators1. LUQIAO LIU, IBM TJ Watson Research Center — Spin orbit interactions give rise to interesting physics phenomena in solid state materials such as the spin Hall effect (SH) and topological insulator surface states. Those effects have been extensively studied using electrical detection techniques so far. However, to date most experiments focus only on characterizing electrons near Fermi surface, while the spin-orbit interaction is expected to be dependent on electrons’ energies. Here we develop a tunneling spectroscopy technique to measure spin Hall materials and topological insulators under finite bias voltages. By electrically injecting spin polarized current into spin Hall metals or topological insulators through nonmagnetic material/oxide/ferromagnet (FM) junctions and measuring the induced transverse voltage, we are able to quantify the magnitude of the SHE in typical 5d transition metals and the spin momentum locking in topological insulators. The obtained spin Hall angles in Ta, Pt, W and Ir at zero bias are consistent with the results from spin torque experiments, and measuring the induced transverse voltage, we are able to quantify the magnitude of the SHE in typical 5d transition metals and the spin momentum locking in topological insulators. The obtained spin Hall angles in Ta, Pt, W and Ir at zero bias are consistent with the results from spin torque experiments, and measuring the induced transverse voltage, we are able to quantify the magnitude of the SHE in typical 5d transition metals and the spin momentum locking in topological insulators. The obtained spin Hall angles in Ta, Pt, W and Ir at zero bias are consistent with the results from spin torque experiments. Using this technique, we show that the spin-Hall angle of α-W into Al thin films.

Role of transparency of platinum-ferromagnet interface in determining intrinsic magnitude of spin Hall effect

Weifeng Zhang, Stanford Univ, Wei Han, International Center for Quantum Materials, Peking University, Xin Jiang, Western Digital, See-Hyun Yang, Stuart Parkin, IBM Research - Almaden — The spin Hall effect (SHE) converts charge current to pure spin currents in orthogonal directions in materials that have significant spin-orbit coupling. The efficiency of the conversion is described by the spin Hall angle (SHA). The SHA can most readily be inferred by using the generated spin currents to excite or rotate the magnetization of ferromagnetic films or nano-elements via spin-transfer torques. Some of the largest spin torque derived spin Hall angles (ST-SHA) have been reported in platinum. By using spin torque ferromagnetic resonance (ST-FMR) measurements, we show that the transparency of the Pt-ferromagnet interface to the spin current plays a central role in determining the magnitude of the ST-SHA. We measure a much higher ST-SHA in Pt/cobalt (0.11) compared to Pt/permalloy (0.05) bilayers when the interfaces are assumed to be completely transparent. Taking into account the transparency of these interfaces, as derived from spin-mixing conductivities, we find that the intrinsic SHA in platinum has a much higher value of 0.19 as compared to the ST-SHA. The importance of the interface transparency is further exemplified by the insertion of atomically thin magnetic layers at the Pt/permalloy interface that we show strongly modulates the magnitude of the ST-SHA.

Spin Hall effects from mesoscopic Pt films with high resistivity

Chuan Qin, Department of Physics and Astronomy, University of Delaware, Yongming Luo, Chao Zhou, Department of Physics, Fudan University, YunJiao Cai, Shuhuan Chen, Department of Physics and Astronomy, University of Delaware, Yizheng Wu, Department of Physics, Fudan University, Yi Ji, Department of Physics and Astronomy, University of Delaware — The spin Hall effect (SHE) and inverse spin Hall effect (ISHE) are explored in mesoscopic lateral structures. Each structure consists of a Pt stripe, a Cu channel and a Py spin injector/detector. Low-resistance AlOx layers are placed at all interfaces. Two groups of structures are made with different sizes of the Pt/AlOx/Cu interfaces. The average resistance values of interfaces are 80 ohm in one group and 4 ohm in the other. Despite the resistance difference by a factor of 20, the average SHE signals only differ by a factor of 1.8 with the low-resistance structures showing higher signals. For a low-resistance interface, the ISHE signal is enhanced due to a more efficient absorption of the pure spin current but at the same time the signal reduction due to current shunting is also more severe. We are able to estimate the effect of shunting and the rate of spin absorption and obtain the product of spin Hall angle and the Pt spin diffusion length. It is noteworthy that the resistivity of the Pt stripe is substantially larger than that of an extended film. The large Pt resistivity contributes positively to the size of the signals but also implies short Pt spin diffusion length (<2nm). A sizable Pt spin Hall angle of >0.09 is estimated.

The Enhancement of spin Hall torque efficiency and Reduction of Gilbert damping in spin Hall metal/normal metal/ferromagnetic trilayers

Minh-Hai Nguyen, Chi-Feng Pai, Daniel C. Ralph, Robert A. Buhrman, Cornell Univ — The spin Hall effect (SHE) in ferromagnet/heavy metal bilayer structures has been demonstrated to be a powerful means for producing pure spin currents and for exerting spin-orbit damping-like and field-like torques on the ferromagnetic layer. Large spin Hall (SH) angles have been reported for Pt, beta-Ta and beta-W films and have been utilized to achieve magnetic switching of in-plane and out-of-plane magnetized nanomagnets, spin torque auto-oscillators, and the control of high velocity domain wall motion. For many of the proposed applications of the SHE it is also important to achieve an effective Gilbert damping parameter that is as low as possible. In general the spin orbit torques and the effective damping are predicted to depend directly on the spin-mixing conductance of the SH metal/ferromagnet interface. This opens up the possibility of tuning these properties with the insertion of a very thin layer of another metal between the SH metal and the ferromagnet. Here we will report on experiments with such trilayer structures in which we have observed both a large enhancement of the spin Hall torque efficiency and a significant reduction in the effective Gilbert damping. Our results indicate that there is considerable opportunity to optimize the effectiveness and energy efficiency of the damping-like torque through engineering of such trilayer structures.

Phase diagram and optimal switching induced by spin Hall effect

Shu Yan, Ya. B. Bazaliy, Department of Physics and Astronomy, University of South Carolina — In a ferromagnet/heavy-metal bilayer device with strong spin Hall effect, an in-plane current excites magnetic dynamics through spin-torque transfer. We analyze bilayers with a perpendicularly magnetized ferromagnet and calculate three-dimensional phase diagrams describing switching due to application of external magnetic field at a fixed current. For fields applied in the plane formed by the film normal vector and the current direction, we find the location of the additional equilibria created by the spin torque and give analytic expressions for two different destabilization boundaries. We further discuss the nature of switching at each boundary and qualitatively describe the magnetic state evolution. By analyzing the phase portraits of the system we give the condition at which switching from “up” to “down” state proceeds through this intermediate state. Using numeric simulations we analyze the switching time and compare it to that of a spin valve with a perpendicular polarizer.

Enhanced anti-damping torque in double-Spin-Hall trilayers

Satoru Emori, Tianxiang Nan, Carl Boone, Trevor Oxholm, David Budil, Northeastern University, John Jones, Brandon Howe, Gail Brown, Air Force Research Laboratory, Nian Sun, Northeastern University — In magnetic thin-film heterostructures, current-induced anti-damping torque can switch magnetization [1], drive domain walls [2], and induce precessional dynamics [3]. The spin Hall effect in ferromagnet/normal-metal bilayers is an especially promising mechanism for generating a robust anti-damping torque. We report on enhanced tuning of resonant magnetization dynamics in in-plane magnetized Ta/CoFeB/Pt trilayers, where both the Ta and Pt layers serve as spin-Hall sources. The change in resonant linewidth induced by in-plane DC current is measured using spin-torque ferromagnetic resonance (FMR) [4] and cavity-based FMR [5]. With optimized Ta and Pt layer thicknesses, we observe in 4-nm thick CoFeB a damping modification of >3 x 10^-3 per 10^{11} A/m^2 of DC current, effectively more than doubling the anti-damping torque compared to conventional spin-Hall bilayers. This finding provides a new possibility for increasing the efficiency of spin-Hall driven devices.

Tuesday, March 3, 2015 2:30PM - 4:54PM — Session J29 GMAG DMP FIAP: Focus Session: Ultrafast Spin-Dynamics 206A - Charlie Karis, University of Uppsala
2:30PM J29.00001 All-Optical Control of Magnetization in various Ferromagnetic Structures

RAJASEKHAR MEDAPALLI, University of California San Diego, VINCENT JOLY, Universite de Lorraine, YUKIKO TAKAHASHI, NIMS, Japan, STEPHANE MANGIN, Institut Jean Lamour, Universite de Lorraine, YESHAIHUA FAINMAN, ERIC FULLERTON, University of California San Diego — Until recently, the only class of material that demonstrated all-optical switching (AOS) is a narrow range of rare-earth (RE) and transition-metal (TM) alloy compositions. However, recent experimental investigations have broadened the choice of materials for AOS and showed that optical control of magnetization is a much more general phenomenon. These materials include wide variety of ferrimagnetic RE-TM alloys, RE-free synthetic ferrimagnets and, moreover, ferromagnetic thin films, multi-layers and even their granular films. By employing a magnetization sensitive microscopy technique we investigated the AOS in various ferromagnetic materials like Co/Pt multi-layers as a function of material composition, structure, laser pulse fluence, and multi-layer thickness and also in FePt granular thin films, as a function of grain sizes. Our results show the optimal material conditions in ferromagnets and highlight pathways for reducing possible energy consumption for the AOS in these materials. Moreover, our time-resolved pump-probe measurements on CoPt thin films and their multi-layers reveal the ultrafast magnetization response to the 100 fs laser pulses and its role in AOS.

2:42PM J29.00002 Ultrafast Dynamics near the M-edge in Chromium

GERARD SALVATELLA, RAFAEL GORT, THOMAS MICHLMAYR, ANDREAS VATERLAUS, YVES ACREMANN, None — Upon excitation by a femtosecond laser pulse a ferromagnet can be demagnetized on a sub-picosecond timescale. During the demagnetization both energy and angular momentum are exchanged between the electron gas and the lattice. However, the mechanisms and the characteristic times through which such exchanges occur are still controversial. A strong debate remains on whether bulk spin-flips or spin-currents are the primary cause of momentum transfer. To shed light on this topic two types of experiments are undertaken. First, demagnetization is studied in a pump-probe experiment in Ni for different pump-pulse durations. It is observed that shorter laser pulses demagnetize nickel more efficiently than longer pulses. The experiment reveals two processes: a fast process demagnetizes the sample within less than a picosecond and causes a remagnetization on the same timescale. Simultaneously, a slower process causes a magnetization loss that lasts tens of picoseconds. For long pulses only the slow remagnetization process is relevant. Second, a delayed double pulse experiment is performed in which the induced heat from the first pump pulse influences the demagnetization caused by the second through the increase of either the lattice or the electron temperatures.

3:06PM J29.00004 Ultrafast demagnetization: A transport effect?

GERARD SALVATELLA, RAFAEL GORT, THOMAS MICHLMAYR, ANDREAS VATERLAUS, Laboratory for Solid State Physic, ETH Zurich — The ultrafast loss of magnetization caused by a femtosecond laser pulse is still not well understood. One of the important contributions is spin flip scattering in the bulk of the magnetic material, mediated by the presence of phonons. The second contribution is the creation of spin currents, which transport spin angular momentum from the magnetic film into the substrate, where spin slips can take place outside of the view of the observer. Spin currents have been predicted by Battiato et al., PRL p.105, 027203 (2010). Here, we discuss a simple thermodynamic model describing laser induced spin currents as a cause of the temperature dependent shift of the chemical potentials. Experiments are discussed, which may be able to separate the effect of the lattice temperature from spin transport effects.

3:18PM J29.00005 Ultrafast spin switching in a canted antiferromagnetic YFeO3 driven by pulsed THz radiations

KIM TAEHEON, HAN SUN YOUNG, HAN JEONG WOO, HAN Gwangju Institute of Science and Technology (GIST), CHUL KANG, CHUL-SIK KEE, Advanced Photonics Research Institute, Gwangju Institute of Science and Technology, SEOHONG JUNG, JAEHUN PARK, Pohang Accelerator Laboratory, POSTECH, YUSUKE TOKUNAGA, RIKEN Center for Emergent Matter Science (CEMS), YOSHINORI TOKURA, University of Tokyo, LEE JONG SEOK, Gwangju Institute of Science and Technology (GIST) — We investigate the precessional motion of the magnetic moment in the canted antiferromagnetic YFeO3 which is excited by a linearly polarized terahertz (THz) pulse at room temperature. By tuning the spectral component of the input THz pulse around the quasi-ferromagnetic mode located near 0.3 THz, we have experimentally clarified the resonance effect of the magnetic moment in the canted antiferromagnet. Furthermore, we demonstrate that the spin state can be switched all-optically on a picosecond time-scale using THz spectral component of the input THz pulse around the quasi-ferromagnetic mode located near 0.3 THz, we have experimentally clarified the resonance effect.

3:30PM J29.00013 Ultrafast magnetization dynamics in heterogeneous granular FePt media

GRAF PIERRE, GRANITZKA PATRICK, ALEXANDER REID, SIMES/SLAC, WILLIAM SCHLOTTER, GEORGI DAKOVSKII, ANKUSH MITRA, LCLS/SLAC, PADRAIC SHAFFER, LBNL, MEHTA VIRAT, OLAV HELLWIG, HGST, ANDREAS SCHERZ, XFEL, JOACHIM STÖHR, HERMANN DÜRR, NIMS, Japan, STEPHANE MANGIN, Institut Jean Lamour, Universite de Lorraine, YESHAIHUA FAINMAN, ERIC FULLERTON, University of California San Diego — Ultrafast magnetization dynamics in heterogeneous granular FePt media have recently been studied with fs laser pump-probe techniques[Becker, et al APL 104, 152412 (2014)]. Large 400 GHz eigenfrequencies are observed due to the huge FePt magnetic anisotropy. However, such optical techniques only measure the collective spin precession of all grains without spatial resolution. Here we investigate the nanoscale magnetization dynamics in FePt with fs pump-probe pulses from the Linac Coherent Light Source at Stanford. We show that optical excitation leads to distinctly different magnetic responses due to the size distribution of FePt grains. While part of the laser-excited magnetic grains demagnetize nickel more efficiently than longer pulses. The experiment reveals two processes: a fast process demagnetizes the sample within less than a picosecond and causes a remagnetization on the same timescale. Simultaneously, a slower process causes a magnetization loss that lasts tens of picoseconds. For long pulses only the slow remagnetization process is relevant. Second, a delayed double pulse experiment is performed in which the induced heat from the first pump pulse influences the demagnetization caused by the second through the increase of either the lattice or the electron temperatures.
3:42PM J29.00007 Laser-induced ultrafast spin dynamics in di-, tri- and tetranuclear nickel clusters, and the M process, DEBAPRIYA CHAUDHURI, Department of Physics and Research Center OPTIMAS, University of Kaiserslautern, Germany, HONGPING XIANG, Department of Physics and Astronomy, California State University Northridge, California, USA, GEORGIOS LEFKIDIS, WOLFGANG HÜBNER, Department of Physics and Research Center OPTIMAS, University of Kaiserslautern, Germany — We present a theoretical investigation of the ultrafast magneto-optical dynamics in clusters with 2, 3 and 4 Ni atoms. We study cooperative effects by increasing both the number of active centers and the multiplicities (up to quintets) in our Hilbert space. In the dinuclear cluster Ni2 a novel spin-flip scenario based on the M process is established. This process is highly operative in case the standard M process fails. In the trinuclear cluster Ni3Na2 simultaneous spin-flip and spin-transfer is observed. Local spin-switch is also achieved via a non-linear M process which involves two off-resonant transitions. Finally, in the tetranuclear cluster (Ni4)2 the use of quintets provides an insight into an irreversible demagnetization scenario. We believe that our systematic investigation allows us to establish a relation between the magnetic centers and the multiplicities. Our research represents an important step towards the miniaturization of spintronic devices and functionalization of various logic elements based on molecular structure.

3:54PM J29.00008 A look at the Dynamics of Ultrafast Magnetization Reversal1, CHRIS RODGERS, GUOPING ZHANG, Indiana State University — There is an ever pressing need to figure out ways to store more data at a faster rate. The implementation of All Optical Magnetization Reversals is a potential step in this direction. There is a strong experimental understanding of the phenomenon. However, a clear theoretical model doesn’t exist. The theoretical model presented here is a potential step towards an understanding of this phenomenon. Through a computer simulation, we show that magnetization reversal could potentially occur through the interaction of the circular polarization of an ultrafast laser pulse, and the orbital angular momentum of a bound spin particle.

4:06PM J29.00009 Optimal Control of Magnetization Dynamics in Ferromagnetic Materials using TDDFT1, PETER ELLIOTT, KEVIN KRIEGER, E.K.U GROSS, Max Planck Institute of Microstructure Physics — Recently [1] intense laser-field induced ultrafast demagnetization was observed in ab-initio simulations using Time-Dependent Density Functional Theory (TDDFT) for various ferromagnetic materials (Fe,Co,Ni). From a practical and technological viewpoint, it is useful if the induced dynamics (e.g. of the total magnetic moment) are controllable. In this talk we apply optimal control theory together with TDDFT calculations to tailor the intense laser pulses so as to achieve a particular outcome (e.g. maximize the total moment lost) while also including any required constraints (e.g. pulse duration, pulse frequencies, maximum fluence, etc).

1Supported by U.S. Department of Energy and Indiana State University

4:18PM J29.00010 Thermal spin torque driven by ultrafast heat current in metallic spin-valve structures, GYUNG-MIN CHOI, University of Illinois, BYOUNG-CHUL MIN, Korea Institute of Science and Technology, KYUNG-JIN LEE, Korea University, DAVID CAHILL, University of Illinois — Spin transfer torque (STT), coupling of the angular momentum of the spin of electrons and the magnetization of a ferromagnet, enables the manipulation of nanomagnets with spin currents rather than magnetic fields. STT has been most often realized by passing electrical currents through magnetic layers. Generation of STT by passing a heat current through magnetic layers has been theoretically predicted. This so-called “thermal STT” relies on the transport of thermal energy, as opposed to the transport of electrical charge, and provides new functionality for device applications. Here, we provide direct evidence of thermal STT generated by ps time-scale heat currents on the order of 100 GW m⁻². In metallic spin valve structures, the physical mechanism for thermal STT is the spin-dependent Seebeck effect (SDSE). We create ultrafast heat currents using ps duration pulses of laser light in the NM1/FM1/NM2/FM2 structure: FM1 acts as a spin generation layer by SDSE and FM2 acts as a spin detection layer by STT; NM1 acts as a heat absorbing layer and NM2 acts as a heat sink layer. The magnetization dynamics of FM2 are probed by time-resolved magneto-optic Kerr effect with a time resolution of 1 ps. By incorporating different ferromagnetic layers, which have different signs for SDSE, and varying the thickness of the heat sink layer, we are able to control the sign and magnitude of thermal spin torque.

4:30PM J29.00011 Spin accumulation in out of equilibrium mesoscopic superconductors, DENIS CHEVALLIER, Univ de Leiden, CLEMENT DUTREIX, Univ Paris-Sud 11, MARINE GUICOU, IPHT Saclay, CHARIS QUIAY, MARCO APRILI, Univ Paris-Sud 11, CRISTINA BENA, IPHT Saclay — We study the spin accumulation in a junction between a superconductor and a ferromagnet or a normal metal in presence of a Zeeman magnetic field applied to the superconductor, and when the junction is taken out of equilibrium by applying a voltage bias. We first apply a DC voltage on the junction and show that the spin relaxation time (ns) is larger than the charge relaxation time (ps) inducing a spin-charge separation in the superconductor. Then we calculate the time-dependence of the spin accumulation for an applied AC voltage. We find that the measured spin accumulation depends on the frequency of the applied bias. This dependence allows one to extract directly the spin relaxation time in the superconductor which is in complete agreement with the experimental result.

4:42PM J29.00012 Spin-dependent Otto quantum heat engine based on a molecular substance, WOLFGANG HÜBNER, GEORGIOS LEFKIDIS, CHUANDING DONG, DEBAPRIYA CHAUDHURI, University of Kaiserslautern and Research Center OPTIMAS, LEVAN CHOTORLISHVILI, JAMAL CHATORLISHVILI, J. BERAKDAR, Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Germany — We explore the potential of single molecules for thermodynamic cycle[2]. To this end we propose two molecular heat engines based on the realistic Ni₄ dimer: a quantum Otto engine and a modified quantum Otto engine for which laser-induced optical excitations substitute for one of the heat-exchange points. For reliable predictions and to inspect the role of spin and electronic correlations we perform fully correlated ab initio calculations of the electronic states and the excited states. We analyze the efficiency and the word output of the derived engines and find an enhancement when the spin degree of freedom is included. We also use the von Neumann entropy to describe correlations and entanglement of the engines during the cycles. Furthermore, we link our results to previous results regarding an isobaric stroke[3] and a magnetic quantum Diesel engine on the same substance[4].

Tuesday, March 3, 2015 2:30PM - 5:30PM – Session J30 GMAG DMP: Focus Session: Magnetic Imaging and Characterization 206B - Yves Idzerda, Montana State University
2:30PM J30.00001 Moment Mapping of bcc Fe$_{1-x}$Mn$_x$ Alloy Films on MgO(001) YVES IDZERDA, HARSH BHATIKAR, Montana State Univ, ELIKE ARENHOLZ, Advanced Light Source — The magnetic moments of ~20 nm single crystal films of compositionally graded Fe$_{1-x}$Mn$_x$ films (0.1 ≤ x ≤ 0.2) grown on MgO(001) are determined by spatially resolved moment mapping using X-ray absorption spectroscopy (XAS) and magnetic circular dichroism (MCD). RHEED measurements confirmed that the growth of Fe$_{1-x}$Mn$_x$ films remained epitaxial and in the bcc phase up to x=0.35 but, like Fe growth, is rotated 45 degrees with respect to the MgO(001) surface net. This is beyond the bulk bcc stability limit of x=0.12. Both magnetometry and XMC measurements show that the net magnetic moment of these alloy films behave similarly to the bulk behavior, with a gradual moment reduction at low Mn concentrations followed by an abrupt departure from the Slater-Pauling curve and disappearance of the moment at x=0.15. By generating a compositional dependence of the reflection total electron yield cross section, we show that the spin polarization is present in the 5nm thick alloy film. In conclusion, we are able to map the Fe spin moment using linear and circular polarized soft X-rays, the local composition and elemental moments can be simultaneously mapped across the surface of the sample. The Fe moment is found to gradually reduce with increasing Mn content with a very abrupt decline at x=0.15. Surprisingly, the Mn moment shows a very small net moment (<0.1 m$_{B}$) at all compositions, suggesting a complicated Mn spin structure.

2:42PM J30.00002 Spectroscopically Resolved Imaging of Spin Dynamics in Ferromagnets Using Nitrogen-Vacancy Centers in Diamond JASON LIU, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, MA SAKI NAGATA, Institute for Chemical Research, Kyoto University, R.D. MCMICHAEL, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — During the past decade, research into nitrogen-vacancy (NV) centers, a known defect in diamonds, has increased in popularity. This popularity is due to the ability to optically prepare and measure the magnetic state of the spin triplet associated with the NV center. Optically, the ground state electrons can be excited by a 532 nm wavelength laser and the fluorescence results in the emission of red photons. Optically detected magnetic resonance (ODMR) is possible because the $m_s = ± 1$ states create weaker fluorescence. Magnetometers with detectivity on the order of 10$^3$ nT/Hz$^{1/2}$ have been demonstrated. In this talk, the design and performance of a scanning diamond NV center magnetometer for magnetization dynamics in ferromagnetic samples will be presented. In this instrument, a microwave magnetic field is used to excite precession in magnetic nanostructures and resulting shifts in the stray field are detected by changes in the ODMR of the diamond NV centers.

2:54PM J30.00003 A nitrogen-vacancy center magnetometer for measuring magnetization dynamics in ferromagnetic nanostructures JASON LIU, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, MA SAKI NAGATA, Institute for Chemical Research, Kyoto University, R.D. MCMICHAEL, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — During the past decade, research into nitrogen-vacancy (NV) centers, a known defect in diamonds, has increased in popularity. This popularity is due to the ability to optically prepare and measure the magnetic state of the spin triplet associated with the NV center. Optically, the ground state electrons can be excited by a 532 nm wavelength laser and the fluorescence results in the emission of red photons. In this instrument, a microwave magnetic field is used to excite precession in magnetic nanostructures and resulting shifts in the stray field are detected by changes in the ODMR of the diamond NV centers.

3:06PM J30.00004 Imaging Magnetic Vortices Dynamics Using Lorentz Electron Microscopy with GHz Excitations JYING WANG, CHUNHUI DU, TING TANG, JASON LIU, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — Magnetic vortices in thin films are naturally formed spiral spin configurations with a core polarization pointing out of the film plane. They typically represent ground states with high structural and thermal stability as well as four different chirality-polarity combinations, offering great promise in the development of spin-based devices. For applications to spin oscillators, non-volatile memory and logic devices, the fundamental understanding and precise control of vortex excitations and dynamic switching behavior are essential. The compact dimensionality and fast spin dynamics set grand challenges for direct imaging technologies. Recently, we have developed a unique method to directly visualize the dynamic magnetic vortex motion using advanced Lorentz electron microscopy combined with GHz electronic excitations. It enables us to map the orbit of a magnetic vortex core in a perpendicular square with <5nm resolution and to reveal subtle changes of the gyrotropic motion as the vortex is driven through resonance. Further, in multilayer spin-valve disks, we probed the strongly coupled coaxial vortex motion in the dipolar- and indirect exchange-coupled regimes and unraveled the underlying coherence and modulation. Our approach is complementary to X-ray magnetic circular dichroism and is of general interest to the magnetism community as it paves a way to study fundamental spin phenomena with unprecedented resolution and accuracy. Collaborations with S.D. Pollard, J.F. Pulecio, D.A. Arena and K.S. Buchanan are acknowledged.

3:18PM J30.00005 Direct imaging of interacting vortex orbits and deformations with Lorentz transmission electron microscopy SHAWN POLLARD, State Univ of NY- Stony Brook, Department of Physics and Astronomy, JAVIER PULECIO, YIMEI ZHU, Brookhaven National Laboratory, Condensed Matter Physics and Materials Science Department — Understanding the interactions between confined, interacting magnetic quasiparticles, such as magnetic vortices, is essential towards developing both an understanding of their mutual coupling, as well as limitations for a variety of spintronic devices. However, due to a lack of spatial resolution afforded by traditional techniques, direct observation of the changes of vortex orbits in real space has been lacking. Utilizing high resolution Lorentz TEM, we image the time averaged vortex trajectories in multi-vortex permalloy rectangular and elliptical planes while applying an oscillating in-plane field tuned to the vortex gyrotropic mode. Using an additional in-plane DC field, we observe a transition of the vortex orbits from circular to heavily distorted as the vortices are driven together, a result of increased interaction strength in laterally coupled vortex pairs. Furthermore, in closely spaced vortex pairs, the strong coupling results in a single resonance frequency. As the vortices are moved apart, pinning effects begin to dominate, and the peak frequency is no longer singular. Micromagnetic simulations are utilized to further elucidate the coupled behavior and obtain time-resolved information of the dynamic process.

1Work supported by DOE-BES, Materials Sciences and Engineering Division, under Contract No. DE-AC02-98CH10886.
Using the tip of a low temperature scanning tunneling microscope (STM), we position Fe atoms on a Cu surface. This allows for the study of magnetic lattices built on surfaces, exploring the transition from individual quantum spins to classical magnetism. We report the first three-dimensional mapping of charge-density wave domains in bulk polycrystalline chromium samples using differential-aperture x-ray microdiffraction at the Advanced Photon Source.

NRMFM probe uses a magnet-on-cantilever geometry and is equipped with dual x-y-z piezoelectric motion stages, for micron-step coarse positioning and sub-nanometer fine positioning of both the laser interferometer and the sample with respect to the cantilever, permitting three-dimensional scanning-mode detection of nuclear magnetism. The probe keeps the cantilever detector in high vacuum, maintaining a high Q-factor, while the local NMR properties of nearby aqueous samples in glass microtubes are measured. The entire probe head fits in either a 3.5-cm bore magnet or in an electromagnet with a similarly small gap.

This research used resources of the Advanced Photon Source, a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory under Contract No. DE-AC02-06CH11357

5:06PM J30.00012 Nucleation and Control of Magnetic Quasi-particles via Extrinsic and Intrinsic Energies1, JAVIER PULECIO, Dept. CMPMS, Brookhaven National Laboratory, PETER WARNICKE, SLS, Paul Scherrer Institute, DARIO ARENA, NSLS, Brookhaven National Laboratory, MI-YOUNG IM, CXRO, LBNL and Dept. Emerging Mater. Science, DGIST, SHAWN POLLARD, Dept. of Phys. and Astro., Stony Brook University, PETER FISCHER, CXRO, LBNL and Dept. Phys., UC Santa Cruz, YIMEI ZHU, Dept. CMPMS, Brookhaven National Laboratory — Magnetic quasi-particles present an excellent opportunity to study fundamental magnetic properties and dynamics. The fine balance of energies including demagnetization, direct exchange, external perturbations, crystalline anisotropy, indirect exchange, and DMI, allows for the nucleation of a diverse ensemble of spin textures such as vortices, merons, and skyrmions, all of which demonstrate unique behavior. We present our investigations of single vortex symmetry breaking under external perturbations and demonstrate a method to determine the core polarity using Lorentz Transmission Electron Microscopy [1]. We also discuss how to tailor the high-frequency dynamics of coupled coaxial vortices using indirect exchange interactions [2]. We conclude by discussing the nucleation of unconventional chiral spin textures in nano-disc heterostructures using a complementary multi-technique approach, i.e. micromagnetic modeling, FMR, MFM, MTXM, and LTEM.

5:18PM J30.00013 Single spin relaxometry of spin noise from a ferromagnet, FRANCESCO CASOLA, 1) Harvard-Smithsonian Center for Astrophysics, 60 Garden St., Cambridge, MA 02138, USA, 2) Department of Physics, Harvard University, TOEND DER SAR, Department of Physics, Harvard University, 17 Oxford St., Cambridge, MA 02138, USA, RONALD WALSWORTH, 1) Harvard-Smithsonian Center for Astrophysics, 60 Garden St., Cambridge, MA 02138, USA, 2) Department of Physics, Harvard University, AMIR YACOBY, Department of Physics, Harvard University, 17 Oxford St., Cambridge, MA 02138, USA — The introduction of new schemes for the measurement of spatially resolved dynamic magnetic properties of strongly correlated electrons is essential for the study of condensed matter magnetism and the development of novel spintronic devices. Here we show the possibility to detect the magnetic spin noise produced by a thin (~30 nm) layer of a patterned micro-sized ferromagnet (Ni81Fe19) by optical initialization and read-out of the single spin state of a nearby nitrogen vacancy center (NV) in diamond. For the interpretation of our results, we develop a general framework describing single-spin stray field detection in terms of a filter function sensitive mostly to spin fluctuations with wavevector \( \sim 1/d \), where \( d \) is the NV-ferromagnet distance. Our results pave the way towards quantitative and non-perturbative detection of spectral properties in nanomagnets, establishing NV center magnetometry as an emergent probe of collective spin dynamics in condensed matter [1].

Tuesday, March 3, 2015 2:30PM - 5:30PM —
Session J31 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors: Probing Spins in 2D Materials and Semiconductors 207A - Aubrey Hanbicki, Naval Research Laboratory

2:30PM J31.00001 Tightly bound excitons in monolayer transition metal dichalcogenides, JIE SHAN, Penn State University — Atomically thin transition metal dichalcogenides (TMDs) MX2 (M = Mo, W, X = S, Se, Te) have emerged as a new class of two-dimensional (2D) semiconductors. Monolayer TMDs possess a honeycomb lattice structure with broken inversion symmetry that permits interesting valley dependent optical selection rules and Berry curvature effects. Yet, another very distinctive feature of electrons in 2D semiconductors is the significantly reduced dielectric screening of Coulomb interactions. An important consequence of strong Coulomb interactions is the formation of tightly bound excitons. They significantly modify the optical response of the material and play a defining role in the optoelectronic processes. In this talk, I will discuss our recent experiments on the binding energy of excitons and trions and their spin-valley properties in TMDs.

3:06PM J31.00002 Direct observation of spin-to-charge conversion in MoS2 monolayer with spin pumping, CHENG CHENG, VIKTORIA IVANOVS’KAJA, JUAN-CARLOS ROJAS SANCHEZ, BRUNO DLUBAK, PIERRE SENEOR, Unité Mixte de Physique CNRS/Thales and Université Paris Sud, YOUNG HEE LEE, GANZHEN HAN, CINAP Institute for Basic Science; Department of Energy Science, Sungkyunkwan University, HYUN KIM, CINAP Institute for Basic Science, Sungkyunkwan University, HEEJUN YANG, CINAP Institute for Basic Science; Department of Energy Science, Sungkyunkwan University, ABDELMAJID ANANE, Unité Mixte de Physique CNRS/Thales and Université Paris Sud — Unlike graphene, layered transition-metal dichalcogenides are 2D wide bandgap semiconductors with large intrinsic spin-orbit coupling (SOC) and valley-spin coupling, which makes them a unique playground for spintronics. We present here the first demonstration of spin injection into monolayer MoS2 with spin pumping from a 3D ferromagnetic (FM) film, circumventing the impedance mismatch at the metal-semiconductor interface. We measured the transverse voltage generated by spin-to-chARGE current conversion in MoS2 with broadband (3 GHz-9 GHz) ferromagnetic resonance (FMR) setup. The observed symmetric Lorentzian signals are in \( \mu \)V range under small rf excitations well below 1 Oe. This voltage magnitude is unexpected for inverse spin Hall effect and is interpreted in the frame of inverse Rashba-Edelstein effect (iREE) due to strong SOC in MoS2. By applying a moderate gate voltage (up to 10 V) on the MoS2/FM multilayer, we observe clear modulation (up to 30%) of the linewidth and amplitude of the iREE signal, indicating electrical tuning of the spin mixing conductance.

3:18PM J31.00003 Proximity Induced Exchange Splitting in Graphene1, SHANSHAN SU, Department of Electrical and Computer Engineering, University of California, Riverside, YAPIS BARLAS, Department of Physics and Astronomy, University of California, Riverside, ROGER LAKE, Department of Electrical and Computer Engineering, University of California, Riverside — We perform an ab-initio study of the proximity effect in a two-dimensional (2D) heterostructure composed of graphene and a thin film ferromagnetic insulator (europium oxide, EuO). Two different structures are considered i) graphene on a EuO layer and ii) graphene sandwiched between two EuO layers. Both structures show two-fold degenerate low-energy bands at the \( \Gamma \) point in the Brillouin zone, however, the former heterostructure shows a clear energy gap in the spectrum whereas the latter exhibits degenerate band crossings. The two different spectra result from a competition of proximity induced exchange splitting on the graphene sheet and sub-lattice mass induced due to the crystal field effect. Addition of spin-orbit coupling in the sandwiched structure indicates lifting of this two-fold degeneracy leading to band anti-crossings if the inversion symmetry perpendicular to the graphene plane is broken.

3:30PM J31.00004 Gate-voltage controlled spin pumping effects: spin injection from YIG and Co into metal and graphene based 2D materials. ALAN KALITSY, MINT Center, University of Alabama, Tuscaloosa, AL, USA. MAIRBEK CHSHIEV, SPINTEC, UMR (8191) CEA/CNRS/UJF/Grenoble INP, INAC, 17 rue des Martyrs, 38054 Grenoble Cedex, France. OLEG MRYASOV, MINT Center, University of Alabama, Tuscaloosa, AL, USA. — Spin current injection into nonmagnetic semiconductors and oxides is crucial component of spintronics. The spin pumping mechanism free from the impedance mismatch is a promising way to inject spin current into nonmagnetic materials [1]. Here we present theory of spin current injected into non-magnetic films which arises from magnetization precession. We apply this theory to two cases: (i) insulating yttrium iron garnet ferromagnet/nonmagnetic metal interfaces and (ii) hcp-Co/single layer graphene interface. The electron transport calculations are based on the non-equilibrium Green Function formalism within the tight binding Hamiltonian model [2]. We show that magnitude of the pumped spin current can be efficiently controlled by the gate voltage.

3:42PM J31.00005 Cross-correlation spin noise spectroscopy of interacting multi-component spin systems. LUI YANG, DIBYENDU ROY, SCOTT CROOKER, NIKOLAI SINITSYN, Los Alamos National Laboratory — Interacting multi-component spin systems are ubiquitous in semiconductor spintronics; e.g. carrier-mediated ferromagnetism in magnetic semiconductors, or electronic spin coupling to nuclear spin baths. Traditionally, inter-species spin interactions are studied by experimental methods that are necessarily perturbative; e.g. by intentionally polarizing or depolarizing one spin species and detecting the response of the other. Here, we show that multi-probe spin noise spectroscopy can reveal interspecies spin-spin interactions — under conditions of strict thermal equilibrium — by cross-correlating the stochastic fluctuation signals exhibited by each of the constituent spin species. We develop a theory for such noise cross-correlations in thermal equilibrium. As a proof of principle, we compare the results with an experimental study of a well-understood interacting spin system — a mixture of warm Rb and Cs vapors — by applying a new type of two-color spin noise spectroscopy [1,2]. Noise correlations directly reveal the presence of inter-species spin-spin interactions. Such non-invasive and noise-based techniques should be generally applicable to any multi-component spin system in which the fluctuations of the constituent components are detectable.

3:54PM J31.00006 A method for wide-bandwidth spin noise measurements without a large background1, BRENNAN C. PURSLEY, XINLIN SONG, Applied Physics Program, University of Michigan, Ann Arbor, MI, USA, VANESSA SIH, Department of Physics, University of Michigan, Ann Arbor, MI, USA — Spin noise measurements have rapidly evolved over the last few decades to become a class of highly sensitive characteristic tools [1,2]. Presently used methods, though quite sensitive, suffer from large backgrounds. We report on an experiment that yields signal proportional to the spin noise, without further processing. Our demonstration utilizes ultrafast optical techniques, but the signal processing could also be applied to pulsed electrical measurements. We will discuss the experiment, necessary equipment, and data sets from a GaAs sample.

4:06PM J31.00007 Detection of quantum entanglement using cross-correlation spin noise spectroscopy. DIBYENDU ROY, Max Planck Institute for the Physics of Complex Systems, NIKOLAI A. SINITSYN, Theoretical Division, Los Alamos National Laboratory — Nature of spin-spin correlations between two interacting spin subsystems in thermal equilibrium can be probed using cross-correlation spin noise spectroscopy [1] with two linearly polarized off-resonant laser beams of different wavelength. Here we propose to use such cross-correlator of spins to detect and quantify quantum correlations such as quantum entanglement between the spin subsystems. We demonstrate our proposal for interacting quantum dots.

4:18PM J31.00008 Effects of Strain and Quantum Confinement in Optically Pumped Nuclear Magnetic Resonance in GaAs: Interpretation Guided by Spin-Dependent Band Structure Calculations, CLIFFORD BOWERS, RYAN WOOD, SAHA DIPTA, JOHN TOKARSKI, LAUREN MCCARTHY, GARY SANDERS, CHRISTOPHER STANTON, Univ of Florida - Gainesville, STEPHEN MCGILL, ARNEIL REYES, PHIL KUHNS, National High Magnetic Field Laboratory FSU, JOHN RENO, Sandia National Laboratories. — Magnetic Resonance in GaAs: Interpretation Guided by Spin-Dependent Band Structure Calculations — A combined experimental-theoretical study of optically pumped NMR (OPNMR) has been performed in a GaAs/AlGaAs quantum well film bonded to a Si substrate with thermally induced biaxial strain. The photon energy dependence of the Ga OPNMR signal was recorded at magnetic fields of 4.9 and 9.4 T at a temperature of 4.8-5.4 K. The data were compared to the nuclear spin polarization calculated from the differential absorption to spin-up and spin-down states of the electron conduction band using a modified Pidgeon Brown model. Comparison of theory with experiment facilitated the assignment of features in the OPNMR energy dependence to specific interband Landau level transitions. The results provide insight into how effects of strain and quantum confinement are manifested in optical nuclear polarization in semiconductors.

4:30PM J31.00009 Orbital Angular Momentum Imprints Studied Using Optical Vortex Pumpprobe Spectroscopy1, M. A. NOYAN, A. L. EXARHOS, J. M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania — We introduce a second generation magneto-optical spectroscopy based on orbital angular momentum of light. Our technique is analogous to methods such as time resolved Faraday/Kerr rotation, but instead of utilizing photon spin, we use holographic gratings to pump and probe materials using photons carrying orbital angular momentum (OAM). We will discuss our first time resolved experiments studying pump-induced OAM dichroism in bulk semiconductors. 100 fs pump pulses with alternating orbital angular momentum ±h create OAM imprints whose momentum distributions resemble right- or left-handed “whirlpools” or vortices. The OAM memory of the sample is then measured using a probe beam whose ±h OAM components are detected in a balanced photodiode bridge. We find that in n-GaAs, the dynamical OAM signal shows a unique timescale when compared to population and spin dynamics and, surprisingly, lasts considerably longer than the momentum scattering time. This method should be of further interest for studying non-equilibrium dynamics in a variety of orbitally coherent systems.

1 We gratefully acknowledge support from NSF DMR-1206270.
4:42PM J31.00010 Room-Temperature Magneto-Optical Phenomena in Organo-Metal Halide Perovskites. — TING WU, YU-CHE HSIAO, MINGXING LI, Department of Materials Science and Engineering, University of Tennessee, Knoxville, Tennessee, 37996, USA, NAM-GOO KANG, JIMMY MAYS, Department of Chemistry, University of Tennessee, Knoxville, Tennessee, 37996, USA, BIN HU, Department of Materials Science and Engineering, University of Tennessee, Knoxville, Tennessee, 37996, USA — Organo-metal halide perovskites have become extremely interesting light-emitting, photovoltaic and lasing materials. The first magneto-optical phenomena, namely magneto-absorption effects, were reported in 1994 for very low temperature and high field (20 Tesla). Here, we report room-temperature magneto-optical phenomena at low field (<200 mT) from such perovskites. We find that room-temperature magneto-optical effects require high excitation intensity. At high excitation intensities we can observe magnetic field effects on photoluminescence, photocurrent, and electroeluminescence. The magneto-optical phenomena indicate that both light-emitting and photovoltaic responses undergo a spin-dependent process. Furthermore, at low excitation intensities organo-metal halide perovskites exhibit negligible magnetic field effects. Therefore, we can conclude that the magneto-optical phenomena are from spin-dependent charge recombination in light-emitting and photovoltaic processes. This presents a new mechanism to control the light-emitting and photovoltaic functions in organo-metal halide perovskites by using spins. This presentation will discuss the key parameters in controlling magneto-optical phenomena in organo-metal halide perovskites.

4:54PM J31.00011 Laser-induced ultrafast spin dynamics and ERASE functionality on quasi-linear molecular ions. — GEORGIOS LEFKIDIS, University of Kaiserslautern and Research Center OPTIMAS, CHUN LI, SHAOBIN ZHANG, Northwestern polytechnical University, Xi’an, China, WOLFGANG HÜBNER, University of Kaiserslautern and Research Center OPTIMAS — We present an ab initio investigation of the A-process-based ultrafast spin manipulation on positively charged two-magnetic-center molecular ions bridged by non-magnetic oxygen [1]. Multiple derived spin-switching and spin-transfer scenarios on the quasi-linear structure [Fe-O-Co]⁺ are used to build two closed, reversible spin-dynamics cycles with respect to the spin localization and orientation. A mechanism addressing the “ERASE” functionality is proposed by properly exploiting the irreversibility of some laser-induced spin-manipulation scenarios, and the resulting Shannon entropy change is analyzed. We compare with a previously suggested mechanism based on chirped laser pulses [2]. Such controllable spin-dynamics cycles and logic functionality demonstrate promising applications in the design of spintronic devices on isolated magnetic molecule [3].

3:06PM J32.00002 Influence of structural asymmetries on LaNiO$_3$-LaMnO$_3$ interfaces, MARTA GIBERT, University of Geneva, MICHEL VIRET, CEA Saclay, PAULO ZUBKOF, UCL London, SARA CATALANO, University of Geneva, CINTHIA PIAMON-TEZE, SLS-PSI, NICOLAS JAOUEN, SOLEIL, JEAN-MARC TONNERRE, CNRS, Instiut Neel, ALMUDENA TORRES-PARDO, Complutense University of Madrid, ALEX GLOTER, ODILE STEPHAN, University of Paris-Sud, JEAN-MARC TRISCONE, University of Geneva — Complex electronic reconstruction at interfaces between transition metal oxides play a key role on the emergence of novel functionalities in these materials. In this context, we reported on the observation of exchange bias in superlattices composed of nominally paramagnetic metallic LaNiO$_3$ and semiconducting ferromagnetic LaMnO$_3$ ultrathin layers [1], which exemplifies how interface engineering can induce a magnetic structure in LaNiO$_3$. Here, we investigate the properties of LaNiO$_3$-LaMnO$_3$ bilayers, i.e. SrTiO$_3$/LaNiO$_3$/LaMnO$_3$. TEM images have shown that the interface LaNiO$_3$/LaMnO$_3$ is sharper than the LaMnO$_3$/LaNiO$_3$ one, which displays two monolayers intermixing. This structural asymmetry results in very distinct properties: enhanced conductivity and extremely reduced magnetization is observed for the "sharp interface" samples in contrast to the rough ones. State-of-the-art synchrotron techniques reveal differences in interfacial charge transfer and induced magnetic moments in the Ni atoms, and allow us to reproduce the magnetic profile of each LMO layer. The role of orbital occupation will also be explored.

3:18PM J32.00003 ABSTRACT WITHDRAWN

3:30PM J32.00004 Charge and Strain Control of Interface Magnetism, M.R. FITZSIMMONS, LANL, K. DUMESNIL, Institut Jean Lamour, N. JAOUEN, Synchrotron SOLEIL, T. MAROUTIAN, G. AGNUS, Université Paris-Sud, J.-M. TONNERRE, Université Grenoble Alpes, B. KIRBY, NIST, E. FOHTUNG, NMSU, B. HOLLADAY, E.E. FULLERTON, O. SHPYRKO, S.K. SINHA, UCSD, Q. WANG, A. CHEN, Q.X. JIA, LANL — We studied the influence of an electric field applied to an La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO) layer in a LSMO/Pb$_{2/3}$Sr$_{1/3}$TiO$_3$ (PZT)/Nb-doped SrTiO$_3$ (STO) heterostructure by measuring its magnetization depth profile using resonant x-ray magnetic reflectivity. The saturation magnetization of the ferromagnetically-ordered LSMO was not affected by the direction of the polarization of the PZT. However, the ferromagnetic thickness and magnetization of the LSMO film at remanence were reduced for hole-charge accumulation at the LSMO/PZT interface. To understand the independent roles of strain and hole-doping, we performed neutron scattering experiments of La$_{1-x}$Sr$_x$MnO$_3$ films grown on Nb-doped STO in which bending strain (via 4-point bending jig) or electric field (via parallel plate capacitor) was applied to the films. We observed that bending strain affects the saturation magnetization of the LSMO film, whereas electric field affects the remnant magnetization of the film. These observations suggest strain may be a more effective means to control magnetism than charge.

3:42PM J32.00005 Mapping magnetism with atomic resolution using aberrated electron probes, JUAN IDROBO, Oak Ridge National Laboratory, JAN RUSZ, Uppsala University, MICHAEL A. MCGUIRE, CHRISTOPHER T. SYMONS, RANGA RAJU VATSAVAI, ANDREW R. LUPINI, Oak Ridge National Laboratory — In this talk, we report a direct experimental real-space mapping of magnetic circular dichroism with atomic resolution in aberration-corrected scanning transmission electron microscopy (STEM). Using an aberrated electron probe with customized phase distribution, we reveal with electron energy-loss (EEL) spectroscopy the checkerboard antiferromagnetic ordering of Mn moments in La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO)/La$_{0.7}$Sr$_{0.3}$FeO$_3$ (LSFO) heterostructures. The results in a magnetic circular dichroic signal with intrinsically larger signal-to-noise ratios than those obtained via nanodiffraction techniques (where most of the transmitted electrons are discarded). The novel experimental setup presented here, which can easily be implemented in aberration-corrected STEM, opens new paths for probing dichroic signals in materials with unprecedented spatial resolution.

3:54PM J32.00006 Insight into spin transport in oxide heterostructures from interface-resolved magnetic mapping, M.N. GRISOLIA, F.Y. BRUNO, C. VISANI, Unite Mixte de Physique CNRS/Thales, 91767 Palaiseau (FRANCE) and Université Paris-Sud, 91405 Orsay (FRANCE), S. VALENCIA, R. ABRUDAN, A.A. UNAL, Helmholtz-Zentrum Berlin, 12489 Berlin (GERMANY), M. VARELA, J. TORNOS, A. RIVERA-CAZALDA, Z. SFEIRIOUI, C. LEON, J. SANTAMARIA, U. Complutense 28040 Madrid (SPAIN), S. J. PENNYCOOK, The University of Tennessee, TN 37996 (USA), J.E. VILLEGES, A. BARTHELEMY, M. BIBES, Unite Mixte de Physique CNRS/Thales, 91767 Palaiseau (FRANCE) and Université Paris-Sud, 91405 Orsay (FRANCE) — At interfaces between complex oxide materials, orbital and magnetic reconstructions may produce states of matter absent from the materials involved, offering novel possibilities for electronic and spintronic devices. Here we show that magnetic reconstruction has a strong influence on spin transport. In epitaxial heterostructures combining layers of antiferromagnetic LaFeO$_3$ (LFO) and ferromagnetic La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO), we find that a net magnetic moment is induced in the first few unit planes of LFO near the interface with LSMO. Using X-ray photoemission electron microscopy, we show that the ferromagnetic domain structure of the LMO electrodes is imprinted into the antiferromagnetic tunnel barrier, endowing it with spin selectivity. Finally, we find that coexisting ferromagnetic and antiferromagnetic interactions strongly influence the tunnel magnetoresistance of LSMO/LFO/LSMO junctions through competing spin polarization and spin filtering effects.

4:06PM J32.00007 Exchange coupling in (111)-oriented La$_{0.7}$Sr$_{0.3}$MnO$_3$/La$_{0.7}$Sr$_{0.3}$FeO$_3$ superlattices, YUE JIA, RAJESH CHOPDEKAR, Department of Chemical Engineering and Materials Science, Univ. of California, Davis, ELKE ARENHOLZ, ANTHONY YOUNG, MATTHEW MARCUS, ANDREAS SCHOLL, Advanced Light Source, Lawrence Berkeley National Laboratory, YAYOI TAKAMURA, Department of Chemical Engineering and Materials Science, Univ. of California, Davis — Epitaxial La$_{0.7}$Sr$_{0.3}$MnO$_3$/La$_{0.7}$Sr$_{0.3}$FeO$_3$ (LSFO) superlattices serve as ideal systems to explore the magnetic structure and exchange coupling in (111)-oriented perovskite oxides. The (111) orientation offers a buckled honeycomb structure resembling that of graphite with the stacking of highly polar layers. Furthermore, the bulk LSFO magnetic structure predicts that the (111) interface should have fully uncompensated antiferromagnetic (AF) moments leading to exchange bias interactions. Detailed soft x-ray magnetic spectroscopy and microscopy reveal that interfacial effects and the ultrathin nature of the sublayers of the superlattices can stabilize orientations of the LSFO AF spin axis which differ from that of LSFO films and LSMO/LSFO bilayers. A portion of the interfacial AF moments can be reoriented to an arbitrary direction by a moderate external magnetic field through spin-flop coupling with the ferromagnetic LSMO sublayers with low magnetocrystalline anisotropy in the (111) plane.

4:30PM J32.00009 ABSTRACT WITHDRAWN
4:42PM J32.00010 Signatures of a Two-Dimensional Ferromagnetic Electron Gas at the La$_{0.5}$Sr$_{0.5}$MnO$_3$/SrTiO$_3$ Interface Arising From Orbital Reconstruction$^3$, MARIA J. CALDERON, IMCM-CSIC, NORBERT NEMES, JUAN IGNACIO BELTRAN, FLAVIO BRUNO, JAVIER GARCIA-BARRIOCANAL, ZOHAIR SEFRIOU, CARLOS LEON, Universidad Complutense de Madrid, MAR GARCIA-HERNANDEZ, CARMEN MURGZ, LUIS BREY, IMCM-CSIC, JACOBO SANTAMARIA, Universidad Complutense de Madrid — The interface between two different oxides has properties different from the ones corresponding to the constituent layers in bulk. Different orders can arise due to the complexity of these materials in which the orbital degree of freedom, magnetism and lattice are strongly interdependent. Here we present a joint theoretical-experimental effort to understand the properties of a multilayer formed by a metallic ferromagnetic manganese oxide (La$_{0.5}$Sr$_{0.5}$MnO$_3$) and the insulating SrTiO$_3$. Magnetoresistance measurements as a function of the relative angle between the magnetic field and the interface plane have shown an unexpected in-plane peak. Calculations of resistivity in a model system including spin-orbit coupling reveal that the unexpected in-plane maximum is due to transport through a two-dimensional ferromagnetic electron gas formed by orbital reconstruction at the manganite interface. These orbital and magnetic reconstructions are supported by X-ray linear dichroism and ab-initio calculations. Advanced Materials DOI:10.1002/adma.201402829.

5:06PM J32.00012 Observation of a Three-Dimensional Quasi-Long-Range Charge Order in YBa$_2$Cu$_{3-x}$O$_7-/La$_{0.7}$Ca$_{0.3}$MnO$_3$ Heterostructures, THOMAS MION, JUNFENG HE, Boston College, PADRAIC SHAFER, Lawrence Berkeley National Laboratory, VU THANH TRA, National Chiao Tung University, QING HE, JIUNN-YUAN LIN, Lawrence Berkeley National Laboratory, YING-HAO CHU, Academia Sinica, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory, RUIHUA HE, Boston College — Heterostructures with strong interfacial effects can exhibit novel physical properties non-existent in either of the constituent materials alone. In particular, striking phenomena are observed when materials with mutually incompatible order parameters are put together by interface control on the atomic level. YBa$_2$Cu$_{3-x}$O$_7-/La$_{0.7}$Ca$_{0.3}$MnO$_3$ (YBCO/LCMO) heterostructures, which are high temperature superconducting and a ferromagnet, respectively, have been observed to exhibit novel phenomena not present in either material alone. The proximity effect between superconductivity and ferromagnetism is a three-dimensional quasi-long-range charge order that is generated exclusively at the interface. Here, we report on a new electronic order in this system which competes with superconductivity. It is a three-dimensional quasi-long-range charge order, distinct from the recently observed two-dimensional charge order in bulk YBCO. Our finding contributes to establishing YBCO/LCMO heterostructures as a unique material platform in which superconductivity, charge order and ferromagnetism coexist and interact with each other.

4:54PM J32.00011 Emergent ferromagnetism in NdMnO$_3$/SrMnO$_3$ superlattices, ARTUR GLAVIC, STUART CALDER, Quantum Condensed Matter Division; Oak Ridge National Laboratory, VALENTINO COOPER, HEMANT DIXIT, Materials Science and Technology Division; Oak Ridge National Laboratory — The phenomenon of ferromagnetism evolving in digital superlattices of two antiferromagnets LaMnO$_3[n]$/SrMnO$_3[n]$ has been well established [1-2]. We show that this interface effect can be observed in systems with different rare earth manganites as well, exemplified in the Nd system grown on LSAT and TBsO$_3$ substrates. With polarized neutron reflectometry we prove that not only 2/1 unit cell samples become ferromagnetic but that interface ferromagnetism can be induced whenever a single layer of SrMnO$_3$ is introduced in the NdMnO$_3$ system. These results show that the strain state of the superlattice system is of much less importance for the induced magnetization then the Mn$^{3+}$/Mn$^{4+}$ electronic state.

5:18PM J32.00013 The Electrophoretic-like Mechanism of Huge Current effect in Electronically Phase Separated Manganite Wires, LIFENG YIN, WENGANG WEL, JIAN SHEN, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai 200433, China — Electronically phase separated (La, Pr)CaMnO$_3$ manganite wires are found to exhibit huge current effect. As the current density increase, the resistivity of wires decreases dramatically, and the metal-insulator transition temperatures get enhanced. However, the superconducting Quantum Interference Device measurements show that the magnetizations with current on and off are almost identical. It is further confirmed by magnetic force microscope measurements, i.e. the current only changes the shape of ferromagnetic domain, while not the volume of ferromagnetic domain. The results conform to a phenomenological model in which the inherent nanoscale insulating and metallic domains are rearranged through electrophoretic-like processes to open and close percolation channels.
2:54PM J33.00003 Input spike trains suppress chaos in balanced neural circuits, RAINER ENGELKEN, MICHAEL MONTEFORTE, FRED WOLF, Max Planck Institute for Dynamics and Self-Organization — A longstanding hypothesis claims that structured input in neural circuits enhances reliability of spiking responses. While studies in single neurons well support this hypothesis [Mainen, Sejnowski 1995] the impact of input structure on the dynamics of recurrent networks is not well understood. Earlier studies of the dynamic stability of the balanced state used a constant external input [van Vreeswijk, Sompolinsky 1996, Monteforte, Wolf 2010] or white noise [Lajoie et al. 2014]. We generalize the analysis of dynamical stability for balanced networks driven by input spike trains. An analytical expression for the Jacobian enables us to calculate the full Lyapunov spectrum. We solved the dynamic equations using the fixed point attractor method to extract the production rate and attractor dimension. We examined the transition from constant to stochastic input in various scenarios. We find a suppression of chaos by input spike trains. We also find that both independent bursty input spike trains and common input more strongly reduces chaos in spiking networks. Our study extends studies of chaotic rate models [Molgedey et al. 1992] to spiking neuron models and opens a novel avenue to study the role of sensory streams in shaping the dynamics of large networks.

3:06PM J33.00004 Low-dimensional stochastic dynamics underlie the emergence of spontaneous movement in electric fish1, ALEXANDRE MELANSON, Univ of Ottawa, JAMES J. JUN, Janelia Farm, JORGE F. MEJIAS, New York University, LEONARD MALER, ANDRE LONGTIN, Univ of Ottawa — Observing unconstrained animals can lead to simple descriptions of complex behaviours. We apply this principle here to infer the neural basis of spontaneous movements in electric fish. Long-term monitoring of fish in freely swimming, stimuli-free conditions has revealed a sequence of behavioural states that alternate randomly between periods of activity, movement, high active sensing rate) and inactivity (no movement, low active sensing). We show that key features of this sequence are well captured by a 1-D diffusion process in a double well energy landscape, where we assume the existence of a slow variable that modulates the relative depth of the wells. Model validation is two-fold: i) state duration distributions are well fitted by exponential mixtures, indicating non-stationary transition rates in the switching process. ii) Monte Carlo simulations with progressive tilting of the double well is consistent with the observed transition triggered average. We interpret the stochastic variable of this dynamical model as a decision-like variable that, upon reaching a threshold, triggers the transition between states. Thus we identify threshold crossing as a possible mechanism for spontaneous movement initiation and offer a dynamical explanation for slower behavioural changes.

3:18PM J33.00005 Millisecond-Scale Motor Encoding in a Cortical Vocal Area1, ILYA NEMENMAN, Emory University, CLAIRE TANG, University of California, San Francisco, DIALA CHEHAYEB, Emory University, KYLE SRIVASTAVA, Georgia Institute of Technology and Emory University, SAMUEL SOBER, Emory University — Studies of motor control have almost universally examined firing rates to investigate how the brain shapes behavior. In principle, however, neurons could encode information through the precise temporal patterning of their spike trains as well as (or instead of) through their firing rates. Although the importance of spike timing has been demonstrated in sensory systems, it is largely unknown whether timing differences in motor areas could affect behavior. We tested the hypothesis that significant information about trial-by-trial variations in behavior is represented by spike timing in the songbird vocal motor system. We found that neurons in motor cortex convey information via spike timing far more often than via spike rate and that the amount of information conveyed at the millisecond timescale greatly exceeds the information available from spike counts. These results demonstrate that information can be represented by spike timing in motor circuits and suggest that timing variations evoke differences in behavior.

3:30PM J33.00006 Mechanical Surface Waves Accompany Action Potential Propagation, BERNAMIN MACHTA, Lewis Sigler Institute, Princeton University, AHMED EL HADY, Princeton Neuroscience Institute, Princeton University — The action potential (AP) is the basic mechanism by which information is transmitted along neuronal axons. Although the excitability nature of axons is understood to be primarily electrical, many experimental studies have shown that a mechanical displacement of the axonal membrane co-propagates with the electrical signal. While the experimental evidence for co-propagating mechanical waves is diverse and compelling, there is no consensus for their physical underpinnings. We present a model in which these mechanical displacements arise from the driving of mechanical surface waves, in which potential energy is stored in elastic deformations of the neuronal membrane and cytoskeleton while kinetic energy is stored in the movement of the axoplasmic fluid. In our model these surface waves are driven by the traveling wave of electrical depolarization that characterizes the AP, altering the electrostatic forces across the membrane as it passes. Our model allows us to predict the shape of the displacement that should accompany any traveling wave of voltage, including the well-characterized AP. We expect our model to serve as a framework for understanding the physical origins and possible functional roles of these AWs in neurobiology. See Arxiv/1407.7600

3:42PM J33.00007 Stimulation reveals structural drivers of dynamic brain reorganization, SARAH MULDOON, Univ of Pennsylvania and US Army Research Laboratory, JEAN VETTEL, US Army Research Laboratory, DANIELLE BASSETT, Univ of Pennsylvania — Understanding the brain as a complex network of interacting components can provide insight into cognitive function. From this perspective, one can study two types of networks: the anatomical network composed of physical connections between neurons or brain regions, and the functional networks constructed from coherent neurophysiological activity. However, the relationship between these two types of networks is far from understood. Do underlying anatomical networks drive functional networks and if so how? Theoretical predictions from linear models suggest that stimulation of certain brain regions can more easily move the brain into different states, forming a type of “control.” Yet, the brain is far from a linear system. Using a nonlinear model of brain activity derived from diffusion spectrum imaging of white matter connectivity and Wilson-Cowan dynamics, we test the relationship between regional connectivity patterns and the ability of regional stimulation to impart change in functional network configurations. We find that local regional connectivity relates to network controllability and that the system is sensitive to perturbations in the underlying network structure.

3:54PM J33.00008 Cell fate variation of neural stem cells treated with carbon nanotubes1, MASSOOMA GIRBHAI, SABRINA JEDLICKA, Lehigh University, MING ZHENG, National Institute of Standards and Technology, SLAVA V. ROTKIN, Lehigh University — Delivery of materials, such as drug compounds or imaging agents for treatment or diagnosis of disease still presents a biomedical challenge. Nanotechnological advances have presented biomedicine with a number of agents that possess the appropriate size and chemistry to pass through the blood brain barrier. Functionalized carbon nanotubes are one such agent, which can potentially aid in drug and gene delivery to the central nervous system. In addition, carbon nanotubes have already been applied in several areas of nerve tissue engineering to probe and augment cell behavior, and to track subcellular components, and to study the growth and organization of neural networks. Although the production of functionalized carbon nanotubes has escalated in recent years, knowledge of cellular changes associated with exposure to these materials remains unclear. In this study, cellular phenotypes such as proliferation, growth and differentiation in C17.2 neural stem cells have been tested when treated with single-walled carbon nanotubes functionalized with synthetic ssDNA and RNA. The research has shown irregular behavior in the cell fate which could be due to changes in the cytoskeletal filaments. These results would be worth considering when developing strategies to deliver components to the central nervous system.

4:06PM J33.00009 Chimera States in a Hodgkin-Huxley Model of Thermally Sensitive Neurons , TERA GLAZE, SCOTT LEWIS, University of Missouri at St. Louis, KENNETH SHOWALTER, West Virginia University, SONYA BAHAR, University of Missouri at St. Louis — Chimera states, in which identically coupled groups of nonlinear oscillators exhibit very different dynamics, with one group performing synchronized oscillations and the other group showing desynchronized behavior, have recently been studied in computational models. Chimera states have also been demonstrated experimentally in optical and chemical systems. The behavior is particularly relevant in the context of neural synchronization, given the phenomenon of unihemispheric sleep in many animal species, including some mammals, and the recent observation of asymmetric sleep in human patients with sleep apnea. Here, we characterize chimera states using the Huber-Braun neural model, a Hodgkin-Huxley-like model of thermally sensitive neurons. We identify parameter regimes which exhibit chimera behavior and phase cluster states, both in a system with Abrams-Strogatz (mean field) coupling and in a system with Kuramoto (distance-dependent) coupling.

4:18PM J33.00010 Coordinated encoding between cell types in the retina: insights from the theory of phase transitions1 , TATYANA SHARPEE, Salk Institute for Biological Studies — In this talk I will describe how the emergence of some types of neurons in the brain can be quantitatively described by the theory of transitions between different phases of matter. The two key parameters that control the separation of neurons into subclasses are the mean and standard deviation of noise levels among neurons in the population. The mean noise level plays the role of temperature in the classic theory of phase transitions, whereas the standard deviation is equivalent to pressure, in the case of liquid-gas transitions, or to magnetic field for magnetic transitions. Our results for the form of a fusion, two recent discoveries of new types of ON and OFF ganglion cells, as well as the absence of multiple types of ON cells. We further show that, across visual stimulus contrasts, retinal circuits continued to operate near the critical point whose quantitative characteristics matched those expected near a liquid-gas critical point and described by the nearest-neighbor Ising model in three dimensions. Because the retina needs to operate under changing stimulus conditions, the observed parameters of cell types corresponded to metastable states in the region between the spinodal line and the line describing maximally informative solutions. Such properties of neural circuits can maximize information transmission in a given environment while retaining the ability to quickly adapt to a new environment.

4:54PM J33.00011 Optogenetic stimulation of a meso-scale human cortical model , PRASHANTH SELVARAJ, ANDREW SZERI, UC Berkeley, JAMIE SLEIGH, Waikato Clinical School, HEIDI KIRCH, UC San Francisco — Neurological phenomena like sleep and seizures depend not only on the activity of individual neurons, but on the dynamics of neuron populations as well. Meso-scale models of cortical activity provide a means to study neural dynamics at the level of the population of neurons. Additionally, they offer a safe and economical way to test the effects and efficacy of stimulation techniques on the dynamics of the cortex. Here, we use a physiologically relevant meso-scale model of the cortex to study the hypersynchronous activity of neuron populations during epileptic seizures. The model consists of a set of stochastic, highly non-linear partial differential equations. Next, we use optogenetic stimulation to control seizures in a hyperexcited cortex, and to induce seizures in a normally functioning cortex. The high temporal resolution this method offers makes a strong case for the use of optogenetics in treating meso scale cortical disorders such as epileptic seizures. We use bifurcation analysis to investigate the effect of optogenetic stimulation in the meso scale model, and its efficacy in suppressing the non-linear dynamics of seizures.

5:06PM J33.00012 Pore opening dynamics in the exocytosis of serotonin1 , GUILLERMO RAMIREZ-SANTIAGO, Universidad Nacional Autonoma de Mexico, MONTSERRAT C. CERCON, Consejo Nacional de Ciencia y Tecnologia, ALEJANDRO MARTINEZ-VALENCIA, ISRAEL SALINAS HERNANDEZ, LEONARDO RODRIGUEZ-SOSA, FRANCISCO F. DE-MIGUEL, Universidad Nacional Autonoma de Mexico — The current view of the exocytosis of transmitter molecules is that it starts with the formation of a fusion pore, which is a transient channel that connects the intravesicular and the extravesicular spaces, and is completed by the release of the rest of the transmitter contained in the vesicle upon the full fusion and collapse of the vesicle with the plasma membrane. However, under certain circumstances, a rapid closure of the pore before the full vesicle fusion produces only a partial release of the transmitter. Here we show that whole release of the transmitter occurs through fusion pores that remain open for tens of milliseconds without vesicle collapse. This was demonstrated through amperometric measurements of serotonin release from electrodense vesicles in the axon of leech Retzius neurons and mathematical modelling. By modeling transmitter release with a diffusion equation subjected to boundary conditions that are defined by the experiment, we showed that those pores with a fast half time constant remained opened and allowed the full quantum release without vesicle collapse, whereas pores with a slow rise time constant closed rapidly, thus producing partial release. We conclude that a full transmitter release may occur through the fusion pore in the absence of vesicle collapse.

5:18PM J33.00013 Synaptic connectivity and spatial memory: a topological approach , RUSSELL MILTON, UT Houston, ANDREY BABICHEV, Rice University, YURI DABAGHIAN, Rice University, Baylor College of Medicine — In the hippocampus, a network of place cells generates a cognitive map of space, in which each cell is responsive to a particular area of the environment — its place field. The peak response of each cell and the size of each place field have considerable variability. Experimental evidence suggests that place cells encode a topological map of space that serves as a basis of spatial memory and spatial awareness. Using a computational model based on Persistent Homology Theory we demonstrate that if the parameters of the place cells spiking activity fall inside of the physiological range, the network correctly encodes the topological features of the environment. We next introduce parameters of synaptic connectivity into the model and demonstrate that failures in synapses that detect coincident neuronal activity lead to spatial learning deficiencies similar to the ones that are observed in rodent models of neurodegenerative diseases. Moreover, we show that these learning deficiencies may be mitigated by increasing the number of active cells and/or by increasing their firing rate, suggesting the existence of a compensatory mechanism inherent to the cognitive map.

2:30PM J34.00001 Wetting on surfaces with tailored nano-scale defects , KRISTINA DAVITT, ROMAIN LHERMEROULT, ETIENNE ROLLEY, Laboratoire de Physique Statistique de l’ENS Paris — Surface heterogeneity is acknowledged as a cause of contact angle hysteresis. More recently, it has also been recognized as having an important effect on contact line dynamics [1]. However, it has proven difficult to design quantitative experiments [2]. There are two fundamental difficulties: (i) to control the heterogeneity and (ii) to fabricate a true reference surface. In many methods, additional well-controlled defects may be added to a surface, however, the untreated substrate itself already presents some chemical or topographical disorder (typically nano-scale). This is illustrated by the fact that even on a purportedly defect-free surface the hysteresis is non-negligible (>a few degrees).
We report on the use of adsorbed short-chain polymer surfaces as nearly ideal reference surfaces (H < 0.01°). Topographical defects of controlled size, shape and density are then added using nanosphere lithography with dilute colloidal suspensions, and the dependence of the hysteresis and low-velocity dynamics on the defect parameters are determined.

2:42PM J34.00002 Contact line dynamics on a pseudo-brush, Romain Lhermetout, Kristina Davitt, Etienne Rolley, Laboratoire de Physique Statistique de l’ENS, 24 rue Lhomond 75005 Paris, France. Hugo Perrin, Bruno Andreotti, Laboratoire de Physique et Mecanique des Milieux Heterogenes de l’ESPCI, 10 rue Vauquelin 75005 Paris, France — Polymer brushes are nanometric layers of polymers that are attached to a solid surface. They are well-known for strongly modifying the mechanical properties of the surface. Although friction and slippage experiments have been performed on such systems [1], the impact of brushes on wetting dynamics has not yet been investigated. We report measurements of contact line dynamics of simple liquids over so-called pseudo-brushes adsorbed on silicon. We will show that this system exhibits (i) a surprisingly low hysteresis, a feature of great utility when studying the impact of added defects on the contact angle, (ii) a specific contribution to the dissipation, which is localized at the contact line, in addition to the viscous dissipation in the liquid wedge. The pseudo-brush contribution can be isolated from the total dissipation [2] and a simple model is used to explain the role of the pseudo-brush.

2:54PM J34.00003 Deformation of Nanoscale Elastomeric Free-Standing Films by Sessile Liquid Droplets, Rafael Schulman, Kari Dalnoki-Veress, McMaster University — The study of liquid droplets on soft, deformable substrates has recently garnered a great deal of attention. In particular, it has been found that droplets deform elastic surfaces at the contact line, and that this deformation can yield contact angles that do not obey Young’s law. Rather, the microscopic contact line geometry is dictated by a force balance between the three surface stesses, akin to the Neumann construction for droplets on liquid substrates. In our experiment, we place liquid droplets atop elastomeric free-standing films with thicknesses of hundreds of nanometers. Using optical microscopy, as well as atomic force microscopy, we directly measure the contact line geometry and induced deformation of the free-standing film.

3:06PM J34.00004 A thermodynamic model for the wetting characteristics of hierarchical physically-patterned surfaces, Michael Bell, Department of Physics, Penn State University, University Park, PA 16802, Azar Shahraz, Kristen Fichthorn, Ali Borhan, Department of Chemical Engineering, Penn State University, University Park, PA 16802 — An understanding of wetting is important for many applications, including superhydrophobic self-cleaning and low-drag surfaces. Many natural examples of such surfaces exist, including insect legs, bird feathers, and plant leaves. The mechanism of superhydrophobicity on these surfaces is known to be related to their hierarchical roughness (i.e., roughness on micro and nano length scales), though the precise role of hierarchical roughness is not yet well understood. We present a two-dimensional thermodynamic model of the wetting of a hierarchically-grooved surface for droplets with variable Bond number. By investigating wetting phenomena on a roughened interface, we are able to isolate different effects that contribute to the contact angle hysteresis. We find that the presence of microgrooves can yield contact angles that do not obey Young’s law. Rather, the microscopic contact line geometry is dictated by a force balance between the three surface stesses, akin to the Neumann construction for droplets on liquid substrates. In our experiment, we place liquid droplets atop elastomeric free-standing films with thicknesses of hundreds of nanometers. Using optical microscopy, as well as atomic force microscopy, we directly measure the contact line geometry and induced deformation of the free-standing film.

3:18PM J34.00005 Wetting ridge growth and contact line pinning on viscoelastic solid, Su Ji Park, Pohang Univ of Sci & Tech, Joshua B. Bostwick, Northwestern Univ., Jung Ho Je, Pohang Univ of Sci & Tech — Dynamic wetting behaviors on soft viscoelastic solids are potentially important to interpret complex biological processes resulted from cell-substrate interactions. When a droplet sits on a soft surface, its surface tension deforms the contact line, creating a “wetting ridge,” which causes characteristic spreading behaviors. The key to understand the underlying mechanisms is to investigate wetting ridge dynamics during spreading. However, it is challenging to explore wetting ridge dynamics, mostly due to limitations in observation. Here, we directly visualize wetting ridges in real-time during spreading using x-ray microscopy with a high spatio-temporal resolution. We reveal that the growth of wetting ridges is dominated by their broadening in early stage and by their heightening in later stage. The two growth mechanisms control the ridge-geometry and determine the spreading behaviors. Most importantly, we find that the contact line pinning is enhanced by increased flexibility of the ridge crest. Finally, we clarify two different mechanisms of pinning/depinning transitions: “stick-slipping” and “stick-breaking.”

3:30PM J34.00006 Self-pinning of a Nanosuspension Drop: MD Simulations, Baiou Shii, Edmund Webb, Lehigh University — The behavior of nano-fluids, or fluid suspensions containing nano-particles, has garnered tremendous attention recently for applications in advanced manufacturing. Contact line pinning by the particles or self-pinning has been extensively considered during contact line retreat due to solvent evaporation. Here we will present our results from MD simulations on self-pinning of an advancing contact line. For a wetting system of identical low viscosity, highly wetting drops. We reveal that the growth of wetting ridges is dominated by their broadening in early stage and by their heightening in later stage. The two growth mechanisms control the ridge-geometry and determine the spreading behaviors. Most importantly, we find that the contact line pinning is enhanced by increased flexibility of the ridge crest. Finally, we clarify two different mechanisms of pinning/depinning transitions: “stick-slipping” and “stick-breaking.”

3:42PM J34.00007 Inertial Wetting Kinetics for Nanometer Scale Droplets, Edmund Webb III, Baiou Shii, Lehigh University — Inertial spreading occurs immediately following contact between a droplet and solid surface. For low viscosity liquids with high wettability, high contact line velocities are observed during this stage. A counterintuitive result from atomic scale simulations is that even nanometer sized metallic drops exhibit a regime of wetting that is governed by inertial effects. Using a Tolman length corrected surface tension to account for liquid/vapor interface curvature effects that manifest in small drops, inertial spreading data from molecular dynamics simulations for varying drop size (down to a few nm diameter) can be collapsed onto a single curve using otherwise continuum scale inertial capillary flow theory. In addition, for inertial spreading on a low advancing contact angle surface, a second nanoscale effect is observed, which is related to curvature gradients that manifest along a significant portion of the liquid/vapor interface in the smallest drops. This is caused by rapid advancement of a precursor wetting film. The duration of the inertial regime is computed and shown to scale with the inertial/capillary time scale. Evidence is presented that capillary waves play a role in determining the duration of the inertial wetting regime for low viscosity, highly wetting drops.

3:54PM J34.00008 Inertia-driven droplet depinning on textured surfaces, Sungyoon Lee, Department of Mechanical Engineering, Texas A&M University, Benjamin Wilcox, Department of Aerospace Engineering, Texas A&M University, Ali Reza Hooshanginejad, Department of Mechanical Engineering, Texas A&M University, Alex Berger, Department of Aerospace Engineering, Texas A&M University, Feng Xu, Department of Mechanical Engineering, Texas A&M University, Edward White, Department of Aerospace Engineering, Texas A&M University — The stability of drops on surfaces subject to forcing by wind and gravity is relevant to heat exchangers, fuel cells, and aircraft icing, and it lacks understanding in a high Reynolds number regime. To experimentally investigate this phenomenon, water drops are placed on the rough aluminum floor of a tiltable wind tunnel and brought to critical conditions for varying drop sizes, inclination angles, and flow speeds. In particular, the evolving 3D droplet shapes under flow are reconstructed based on a laser-speckle interface measurement tool, while the critical flow rates of droplet depinning are also noted. By accounting for the contact angle hysteresis and the pressure build-up in a nearly turbulent boundary layer, the critical depinning flow rate is theoretically predicted and is compared to the experimental results. We also observe and explain the transition of the drop depinning behavior from inertia-dominated to gravity-dominated regimes at non-zero inclination angles.

3:54PM J34.00008 Contact line dynamics on a pseudo-brush, Romain Lhermetout, Kristina Davitt, Etienne Rolley, Laboratoire de Physique Statistique de l’ENS, 24 rue Lhomond 75005 Paris, France. Hugo Perrin, Bruno Andreotti, Laboratoire de Physique et Mecanique des Milieux Heterogenes de l’ESPCI, 10 rue Vauquelin 75005 Paris, France — Polymer brushes are nanometric layers of polymers that are attached to a solid surface. They are well-known for strongly modifying the mechanical properties of the surface. Although friction and slippage experiments have been performed on such systems [1], the impact of brushes on wetting dynamics has not yet been investigated. We report measurements of contact line dynamics of simple liquids over so-called pseudo-brushes adsorbed on silicon. We will show that this system exhibits (i) a surprisingly low hysteresis, a feature of great utility when studying the impact of added defects on the contact angle, (ii) a specific contribution to the dissipation, which is localized at the contact line, in addition to the viscous dissipation in the liquid wedge. The pseudo-brush contribution can be isolated from the total dissipation [2] and a simple model is used to explain the role of the pseudo-brush.

4:06PM J34.00009 Electrowetting on Semiconductors, CESAR PALMA, ROBERT DEEGAN, University of Michigan — In traditional electrowetting-on-dielectric (EWOD) a sessile drop rests on a thin dielectric separating it from a conductor. A voltage applied between the droplet and the conductor causes an increase in the solid-liquid interface area and a concomitant reduction of the contact angle. The change in the contact angle is well modeled by the Young-Lippmann equation. Here we report experiments where the conductor is replaced by lightly-doped, single-crystal silicon. We observe contact angle changes that are polarity-dependent as well as a non-reversible light-induced wetting transition. As suggested previously we assume that the charge distributions in the system have a direct analogue with the charges states of a metal-oxide-semiconductor capacitor. We calculate the free energy of the system taking into account both capillary and electrostatic contributions. By minimizing this result we derive a modified form of the Young-Lippmann equation. We further enhance our model to include the effect of pinning and well known semiconductor surface effects including interface charges and work function differences. We find that this model works well with experimental results.

4:18PM J34.00010 How cats and dogs drink differently?, SUNGHWAN JUNG, SEAN GART, JAKE SOCHA, Virginia Tech, PAVLOS VLACHOS, Purdue University — Drinking is defined as the animal action of taking water into the mouth, but to fluid mechanists, it is simply one kind of fluid transport phenomena. Classical fluid mechanics show that fluid transport can be achieved by either pressure-driven or inertia-driven processes. In a similar fashion, animals drink water using pressure-driven or inertia-driven mechanisms. For example, domestic cats and dogs lap water by moving the tongue fast, thereby developing the inertia-driven mechanism. We will investigate how cats and dogs drink water differently and discuss the underlying fluid mechanics.

4:30PM J34.00011 How droplets nucleate and grow on liquids and liquid impregnated surfaces1, SUSHANT ANAND, Massachusetts Inst of Tech-MIT, KONRAD RYKACZEWSKI, Arizona State University, SRINIVAS PRASAD BENGALURU SUBRAMANIAM, Massachusetts Inst of Tech-MIT, DANIEL BEYSENS, ESPCI-PMM, KRIPA VARANASI, Massachusetts Inst of Tech-MIT — Condensation on liquids has been studied extensively in context of breath figure templating, materials synthesis and self-cleaning surfaces. However, the mechanics of nucleation and growth on liquids remains unclear, especially on liquids that spread on the condensate. By examining the energy barriers of nucleation, we provide a framework to choose liquids that can lead to enhanced nucleation. We show that due to limits of vapor sorption within a liquid, nucleation is most favoured at the liquid–air interface and demonstrate that on spreading liquids, droplet submergence within the liquid occurs thereafter. We provide a direct visualization of the thin liquid profile that cloaks the condensed droplet on a liquid impregnated surface and elucidate the vapour transport mechanism in the liquid films. Finally, we show that although the viscosity of the liquid does not affect droplet nucleation, it plays a crucial role in droplet growth.

4:42PM J34.00012 Phase-Field Modeling of the Buoyancy-Driven Detachment of a Wall-Bound Pendant Drop1, ANDREA LAMORGESE, ROBERTO MAURI, DICI/University of Pisa, LABORATORY OF MULTIPHASE REACTIVE FLOW TEAM — We investigate numerically the critical conditions for detachment of an isolated, wall-bound emulsion droplet acted upon by surface tension and wall-normal buoyancy forces alone using a simple extension of a diffuse interface model for partially miscible binary mixtures that was previously employed for simulating several two-phase flow phenomena far and near the critical point ["Phase-Field Approach to Multiphase Flow Modeling," Milan J. Math. 79, 597 (2011)] to allow for static contact angles other than 90°. We use the same formulation of the Cahn boundary condition as first proposed by Jacqmin ["Contact-line dynamics of a diffuse fluid interface," J. Fluid Mech. 402, 57 (2000)] which accommodates a cubic (Heitmeier) interpolation of surface tensions between the wall and each phase at equilibrium. We show that this model can be successfully employed for simulating three-phase contact line problems in stable emulsions with nearly immiscible components. We also show the first numerical determination of critical Bond numbers as a function of static contact angle by phase-field simulation.

4:54PM J34.00013 Asymptotic model for three-dimensional coating flow of nematic liquid crystal on an inclined substrate1, MICHAEL LAM, New Jersey Institute of Technology, LIN TE-SHENG, National Chiao Tung University, LINDA CUMMINGS, LOU KONDIC, New Jersey Institute of Technology — We consider a coating flow of nematic liquid crystal (NLC) film on an inclined substrate. Exploiting the large aspect ratio in the geometry of interest, an asymptotic approach is utilized to derive a fourth order nonlinear partial differential equation governing the evolution of the free surface. Previous results have shown that there exist two-dimensional traveling wave solutions that translate down the substrate. In contrast to the analogous Newtonian flow, such solutions may be unstable to streamwise perturbations. Extending well-known results for Newtonian flow, we analyze the stability of the front with respect to transverse perturbations. Particular attention is paid to the interplay between the bulk elasticity and the anchoring conditions at the substrate and free surface. Using full numerical simulations, we validate the linear stability theory and present examples of downslope flow of NLC in the presence of both transverse and streamwise instabilities.

5:06PM J34.00014 Contact Angle: Consequence of minimized Casimir Energy, SUDDARSON SHIVAKUMAR, Southern IL Univ-Carbondale — In 1805, T. Young, in his classic work, expressed the cosine of the angle subtended by the surface of a liquid droplet on a solid surface in terms of the surface energies of the respective mediums-solid, liquid and gas. More recently, London derived the van der Waals interaction energy using the then recent advent of quantum mechanics. Later, in 1937, H. C. Hamaker attempted to derive the interaction energies between two interacting mediums in contact. But, the van der Waals interaction energies for two bodies diverges as the bodies come in contact. To circumvent this undesired divergence, Hamaker introduced a cut-off distance parameter in his analysis, which typically is argued to be of atomic length. All future work on contact angles, since Hamaker, to our knowledge, has never been discussed without relying on this cut-off parameter. We here show that the contact angle is independent of the cut-off parameter, and free of divergence. Thus, contact angle is a measurable physical quantity.

5:18PM J34.00015 Sub-nanometric substrate structural changes enhance the solid/liquid slip boundary condition1, JOSHUA MCGRAW, ANTOINE BRIDET, SAMUEL GRANDTHYLL, KARIN JACOBS, Saarland University, Experimental Physics, 66041 Saarbrücken — Alkylsilane self-assembled monolayers (SAMs) have long been used as model substrates for their ease of preparation and hydrophobic properties. We have long observed that these monolayers also provide a slip boundary condition for dewetting polymer films, and that the slip condition is switchable if the alkyl chain length is changed (from 12 to 18 backbone carbons, for example). Typically, this change is affected in a quantized way, using one or the other chain length, thus obtaining one or the other slip condition. It has been suggested that the specific structure of the resulting SAM controls the slip condition. Here, we present results in which this structure is changed in two continuous ways. First, we prepare SAMs containing bimode mixtures of alkylsilanes, with the composition as a control parameter. Second, we thermally anneal the SAMs, resulting in an irreversible loss of carbon from the monolayer. In both cases, we find an enhanced slip condition which is tuneable over a certain range.

2:30PM J35.00001 Self-energy of a Cold Atom Interacting with an Elastic Membrane

SANGHITA SENGUPTA, University of Vermont, WEI-SHIUANG XU, MIT, DENNIS CLOUGHERTY, University of Vermont — The interaction of an atom with an elastic membrane is studied using Feynman-Dyson perturbation theory. The self-energy $\Sigma(E)$ of an atom with incident energy $E$ is calculated analytically to second-order in the atom-membrane interaction. We explicitly show that while the first-order contribution to the self-energy is well-behaved, the second-order contribution is divergent in the limit of infinite membrane size, and we identify the various divergent contributions. These results are discussed in the context of the “quantum sticking” and scattering of cold atoms from two dimensional materials such as graphene and monolayer transition metal dichalcogenides.

2:42PM J35.00002 Effects of quantum coherence and interference in atoms near nano-particle

SUMAN DHAYAL, YURI ROSTOVTSEV, University of North Texas — Optical properties of ensembles of realistic quantum emitters coupled to plasmonic systems are studied using a self-consistent model. In particular, the coherent effects such as forming “dark states,” optical pumping, coherent Raman scattering, and the stimulated Raman adiabatic passage (STIRAP) are revisited in the presence of metallic nanoparticles. It is shown that the “dark states” are still formed but have more complicated structure, the optical pumping and the STIRAP cannot be employed in the vicinity of plasmonic nanostructures. The STIRAP technique should be used carefully, because it may not work or has at least new features in the presence of nanoparticles. We have also found difference of the local atomic polarization and the atomic polarization averaged over ensemble of atoms homogeneously spread near nanoparticles. The averaged polarization is strongly related to the polarization of the external field, meanwhile the local polarization can be very different from the one induced by the external field. The obtained results are important for excitation of single molecules, e.g. new components of scattering from single molecules can be used for efficient detection of nanoparticles.

2:54PM J35.00003 Observations of parity-time symmetry in optical systems: microtoroid resonators and moving hot atoms

JIANNING WEN, LIANG JIANG, Department of Applied Physics, Yale University, USA, YANHONG XIAO, Department of Physics, Fudan University, China, XIAOSHUN JIANG, National Laboratory of Solid State Microstructures and College of Engineering and Applied Sciences, Nanjing University, China, MIN XIAO, College of Engineering and Applied Sciences, Nanjing University, China; Physics, Univ of Arkansas, USA — Compound-photonic systems with gain and loss provide a powerful platform for testing various theoretical proposals on non-Hermitian parity-time (PT)-symmetric quantum mechanics and initiate new possibilities for shaping optical beams and pulses beyond conservative structures. Such systems can be designed as optical analogues of complex PT-symmetric potentials with real spectra. However, the beam dynamics can exhibit unique features distinct from conservative systems due to non-trivial wave interference and phase-transition effects. Here, we report two of our recent experiments on the realizations of PT-symmetric optics in two different systems: one uses two directly coupled high-Q silica-microtoroid resonators with balanced effective gain and loss [1]; while the other is the first experimental implementation in an optical system using moving atoms, in which the coupling of two optical modes is realized by coherent diffusion of atomic coherence [2]. In both studies, our theories show excellent agreements with the experimental observations. [1] L. Chang, X. Jiang, S. Hua, C. Yang, J. Wen, L. Jiang, G. Li, G. Wang, and M. Xiao, Nature Photonics 8, 524 (2014). [2] P. Peng, W. Qu, W. Cao, L. Zheng, S. Shen, J. Wen, L. Jiang, and Y. Xiao (submitted).

3:06PM J35.00004 Thermodynamic considerations of mechanical oscillations

CHIAO-HSUAN WANG, JQI/UMD, JACOB TAYLOR, JQI/NIST/QuICS — Recent experimental efforts in large-scale optomechanical systems have been made to observe coherent superpositions of macroscopic oscillators. However, the quantum harmonic oscillator treatment of macroscopic optomechanics may need further verification due to the presence of enormous numbers of internal degrees of freedom. We examine models of a mechanical oscillator coupled to many degrees of freedom in thermal contact with a bath, and find that spring-like classical oscillations can occur even if there is no underlying quantum mechanical oscillator. We provide a microscopic description of this thermal oscillator mechanism, and consider methods for distinguishing between quantum harmonic oscillations and other oscillatory behaviors.

3:18PM J35.00005 Measurement and control of a mechanical oscillator at its thermal decoherence rate

DALZIEL WILSON, VIVISHEK SUDHIR, NICOLAS PIRO, RYAN SCHILLING, AMIR GHADIMI, TOBIAS KIPPNBERG, Swiss Federal Institute of Technology in Lausanne — In real-time (Markovian) quantum feedback protocols, the outcome of a continuous measurement is used to stabilize a desired quantum state. Extending such protocols to macroscopic systems is a significant challenge, as the measurement must in this case compete with rapid environmental decoherence. We report on the realization of an interferometric sensor that approaches the requirements of quantum feedback for a solid-state, 4.3 MHz nanomechanical oscillator: namely, the ability to resolve its zero-point motion in the timescale of its thermal decoherence. The sensor is based on near-field cavity-optomechanical coupling, and realizes a measurement of the oscillator’s displacement with an imprecision 40 dB below that at the standard quantum limit, while maintaining an imprecision-backaction product within a factor of 5 of the Heisenberg uncertainty limit. As a demonstration of its utility, we use the measurement to feedback cool the oscillator to an phonon occupation of 5.4±0.7 (i.e., a ground state probability of 16%). Our results establish a new benchmark for the performance of a linear position sensor, and signal the emergence of engineered mechanical oscillators as practical subjects for measurement-based quantum control.

3:30PM J35.00006 Non-equilibrium quantum heating effects in driven, strongly-interacting optomechanics

AASHISH CLERK, MARC-Antoine LEMONDE, Department of Physics, McGill University — We study the influence of weak, nonlinear single-photon optomechanical interactions in a strongly driven cavity, focusing on the regime where these interactions become resonant due to the formation of optomechanical polaritons. We extend the Keldysh field-theory approach to this problem formulated in our previous work[1] to now consider how zero-point fluctuations give rise to effective temperatures in this driven, interacting system. We show that this quantum heating has distinct signatures in the effective temperature of both the photonic and phononic degrees of freedom, and can in principle be detected by looking at the spectrum of the light leaving the cavity.

that the study of the pulsations leads to interesting observations of the optical, thermal, and mechanical properties of the device.

The precise waveform and frequency of these pulsations can be tuned by altering the laser detuning and input power, and we have found that the mechanical properties of the device can be altered by changing the laser parameters.

Our experiments probing the properties of ripplons and thermal vibrations of the helium are expected to have high quality factors [1]. Here we report on progress towards coupling microwave photons in a superconducting microwave cavity with ripplons on superfluid helium. [1] P. Roche et al., Phys. Rev. Lett. 75, 3316 (1995)

The coupling of our device on the order of 5 kHz per nm of ripplon wave amplitude. In this talk, we will discuss the study of the pulsatons leading to interesting observations of the optical, thermal, and mechanical properties of the device.

4:06PM J35.00009 Regenerative Pulsations in Optomechanical Devices , HUGH RAMP, MOHAMMAD BITARAFAN, BRAD HAUER, XAVIER ROJAS, RAY DECORBY, JOHN DAVIS, Univ of Alberta — In optomechanical devices, the presence of a strong cavity field is often desired to observe mechanical motion. In this case it becomes important to consider the effects of non-linear optical processes occurring in the device medium, which alter the effective refractive index and absorption coefficient of the device. We study the example of the buckled-dome Fabry-Perot microcavity, in which light is trapped in a spherical cap formed by two Si-SiO₂ Bragg mirrors of radius 125 µm. In the presence of strong optical fields the silicone in the device undergoes a combination of (3) non-linear processes resulting in periodic shifts of the cavity optical resonance known as regenerative pulsations. We have found that the precise waveform and frequency of these pulsations can be tuned by altering the laser detuning and input power, and found that the study of the pulsations leads to interesting observations of the optical, thermal, and mechanical properties of the device.

4:18PM J35.00010 Optomechanics with ripplons on superfluid helium , GERWIN Koolstra, David Mckay, Ge Yang, University of Chicago, David Czaplewski, Argonne National Laboratory, Center for Nanoscale Materials, David Schuster, University of Chicago — Superfluid helium has arisen as a promising candidate for optomechanics systems. Due to extremely low loss well below the lambda point, vibrations on the helium – ripplons – are expected to have high quality factors [1]. Here we report on progress towards coupling microwave photons in a superconducting LC resonator (riplon-traps in Si chip) can be manipulated and detected using superconducting resonators. We estimate the coupling of our device on the order of 5 kHz per nm of ripplon wave amplitude. In this talk, we will discuss our experiments probing the properties of ripplons and thermal vibrations, forming a gram-scale, sideband resolved, optomechanical system. We demonstrate the detection of a series of acoustic modes with high quality factors as high as 3 x 10⁷. The lowest dissipation modes are limited by an intrinsic three phonon process at higher temperatures, which leads to a 7° dependent attenuation. In isotopically purified samples at temperatures below 10 mK, acoustic quality factors over 10¹⁰ may be possible. A system of this type may be utilized to study macroscopic quantized motion and as a frequency tunable, ultra-sensitive sensor of extremely weak displacements and forces, such as continuous gravity wave sources.

4:42PM J35.00012 Strong single-photon nonlinearities in a multimode optomechanical system in the weak coupling regime , Kjetil Borkje, Department of Physics, University of Oslo, Stefán Walter, Department of Physics, University of Basel — We theoretically study the dynamics of two optomechanical cells, where each cell consists of an optical cavity mode whose resonance frequency is modulated by the position of a mechanical resonator. The two cells are furthermore coupled via photon and phonon tunneling, such that both the photon and the phonon modes hybridize to form symmetric and antisymmetric supermodes. This setup can for example be implemented in an optomechanical crystal. We show that by laser driving one of the optical supermodes with appropriately chosen power and frequency, the system can display strong single-photon effects already when the optomechanical single-photon cooperativity becomes larger than unity. This means that single-photon nonlinearities become important at significantly smaller coupling rates than in a single-mode system. We study how this system can be used to manipulate light at the single-photon level and to realize interactions between individual photons.

5:06PM J35.00014 Quantum synchronization of two dissipatively coupled Van der Pol oscillators , Stefan Walter, University of Basel, University of Erlangen-Nürnberg, Andreas Nunnennkamp, University of Basel, University of Cambridge, Christoph Bruder, University of Basel — Synchronization is a universal phenomenon that is important both in fundamental studies and in technical applications. Here we study synchronization of two dissipatively coupled Van der Pol oscillators in the subthreshold regime and analyze the transition in terms of frequency entrainment and frequency locking. Due to quantum noise strict frequency locking is absent and replaced by a crossover from weak to strong frequency entrainment. The differences to the behavior of one quantum Van der Pol oscillator subject to an external drive are discussed. Moreover, a possible experimental realization of two coupled quantum Van der Pol oscillators in an optomechanical setting is described.

3.42PM J35.00007 Simulating a Parametric Oscillator-Based Dynamical Casimir Effect , Enrique Guererro, Humboldt State University, Alessandro Castelli, Luis A. Martínez, Raymond Chiao, Jay E. Sharping, University of California, Merced — We present simulations of a cavity for use in demonstrating the dynamical Casimir effect (DCE). The successful demonstration of the DCE gives rise to interesting opportunities to study questions in Quantum Mechanics and General Relativity. Crucial to this experiment is attaining resonant cavities with a high Q, a measurement of how purely our system resonates. Necessary Q values can and have been achieved using superconducting cavities, and the low losses in these cavities allows above threshold amplification of vacuum fluctuations. Simulations of the system are crucial to optimize cavity design parameters. Using COMSOL Multiphysics, we simulate a set of three resonant cavities to create and amplify radio frequency (11 GHz) electromagnetic wave. Coupling between different cavities is achieved via a membrane which is driven into motion by electromagnetic radiation pressure. The simulation is being conducted concurrently with preliminary cavity experiments.

3:54PM J35.00008 Optomechanical cooling in a correlated emission laser , WenChao Ge, M. SuHail Zubairy, Argonne National Laboratory, Center for Nanoscale Materials, David Schuster, University of Chicago — In optomechanical devices, the presence of a strong cavity field is often desired to observe mechanical motion. In this case it becomes important to consider the effects of non-linear optical processes occurring in the device medium, which alter the effective refractive index and absorption coefficient of the device. We study the example of the buckled-dome Fabry-Perot microcavity, in which light is trapped in a spherical cap formed by two Si-SiO₂ Bragg mirrors of radius 125 µm. In the presence of strong optical fields the silicone in the device undergoes a combination of (3) non-linear processes resulting in periodic shifts of the cavity optical resonance known as regenerative pulsations. We have found that the precise waveform and frequency of these pulsations can be tuned by altering the laser detuning and input power, and found that the study of the pulsations leads to interesting observations of the optical, thermal, and mechanical properties of the device.

4:30PM J35.00011 Superfluid Helium-4 as an Ultra-low Loss Optomechanical Element , Laura de Lorenzo, Keith Schwab, Caltech — We investigate the low loss acoustic motion of superfluid He-4 parametrically coupled to a high Q, superconducting niobium Te₁₀₁₁ microwave resonator, forming a gram-scale, sideband resolved, optomechanical system. We demonstrate the detection of a series of acoustic modes with high quality factors as high as 3 x 10⁷. The lowest dissipation modes are limited by an intrinsic three phonon process at higher temperatures, which leads to a 7° dependent attenuation. In isotopically purified samples at temperatures below 10 mK, acoustic quality factors over 10¹⁰ may be possible. A system of this type may be utilized to study macroscopic quantized motion and as a frequency tunable, ultra-sensitive sensor of extremely weak displacements and forces, such as continuous gravity wave sources.

5:06PM J35.00014 Quantum synchronization of two dissipatively coupled Van der Pol oscillators , Stefan Walter, University of Basel, University of Erlangen-Nürnberg, Andreas Nunnennkamp, University of Basel, University of Cambridge, Christoph Bruder, University of Basel — Synchronization is a universal phenomenon that is important both in fundamental studies and in technical applications. Here we study synchronization of two dissipatively coupled Van der Pol oscillators in the subthreshold regime and analyze the transition in terms of frequency entrainment and frequency locking. Due to quantum noise strict frequency locking is absent and replaced by a crossover from weak to strong frequency entrainment. The differences to the behavior of one quantum Van der Pol oscillator subject to an external drive are discussed. Moreover, a possible experimental realization of two coupled quantum Van der Pol oscillators in an optomechanical setting is described.
density turns out to be anisotropic which reveals its tensorial property. Counterintuitively, the bias of the anisotropy is alternating between $x$- and $y$-directions due to the nature of anisotropic interactions.

Simulating the loading of a bosonic quantum gas into a one-dimensional optical lattice with and without a trap, we find that the redistribution of atomic density non-adiabatically during lattice loading are one of the limiting factors that prevent the same low temperatures to be reached as in experiments without lattice.

Theoretical Physik, ETH Zurich, 8093 Zurich, Switzerland — In the quest to reach lower temperatures of ultra-cold gases in optical lattice experiments, we derive an extended mean-field formalism to study the thermodynamical properties of the Bose-Hubbard model. The framework can be viewed as the zero-frequency limit of bosonic dynamical mean-field theory (B-DMFT), but equally well and less accurately than in B-DMFT.

Department of Physics, Virginia Tech, Blacksburg, Virginia 24061, USA — Optical lattices can be tailored to realized a variety of different geometries. We model bosons confined to a bilayer configuration to allow a pseudospin degree of freedom in the layer index. Specifically, we model the Bose-Hubbard model on a bilayer square lattice with variable inter-layer hopping. Without the presence of interlayer hopping, the phase diagram only presents well known superfluid or Mott insulating phases. But interlayer hopping allows coupling of these two states. We find that an interesting incompressible phase emerges at half filling as we increase the interlayer hopping strength. We study the low temperature physics of the new phase and address the nature of pseudospin correlations in observables. We pair our effective theory with a quantum Monte Carlo study.

Department of Applied Science and Technology, Politecnico di Torino, I-10129 Torino, Italy, BARBARA CAPOGROSSO SANSONE, H. L. Dodge Department of Physics and Astronomy, The University of Oklahoma, Norman, Oklahoma, USA, VITTORIO PENNA, MARCO FEDELE DI LIBERTO, Utrecht University — The control of transport properties is a key tool at the basis of many technologically relevant effects in condensed matter. The clean and precisely controlled environment of ultracold atoms in optical lattices allows one to prepare simplified but instructive models, which can help to better understand the underlying physical mechanisms. Here we show that by tuning a structural deformation of the unit cell in a bipartite optical lattice, one can induce a phase transition from a superfluid into various Mott insulating phases forming a shell structure in the superimposed harmonic trap. The Mott shells are identified via characteristic features in the visibility of Bragg maxima in momentum spectra. The experimental findings are explained by Gutzwiller mean-field and quantum Monte Carlo calculations. Our system bears similarities with the loss of coherence in cuprate superconductors, known to be associated with the doping induced buckling of the oxygen octahedra surrounding the copper sites.

Theor. Physik, ETH Zurich, 8093 Zurich, Switzerland, ADRIAN KANTIAN, DPMC-MaNEP, University of Geneva, 24 Quai Ernest-Ansermet, CH-1211 Geneva, Switzerland, BELA BAUER, Microsoft Research, Station Q, University of California, Santa Barbara, CA 93106, USA, MATTHIAS TROYER, DIETER JOSWICK, DARIO HUEGEL, Ludwig Maximilian University Munich, LODE POLLET, Department of Physics, Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Ludwig-Maximilians-University Munich — We derive an extended mean-field formalism to study the thermodynamical properties of the Bose-Hubbard model. The framework can be viewed as the zero-frequency limit of bosonic dynamical mean-field theory (B-DMFT), but equally well and less accurately than in B-DMFT.

Single-photon optomechanics in the strong coupling regime is promising to play a key role in the realization of superpositions of macroscopic objects (for testing the foundations of quantum theory) and enhancing the nonlinear optomechanical interactions (for possible applications in quantum information processing). The stationary/time-independent spectrum of a single-photon interacting with a tiny movable mirror (in the context of cavity quantum optomechanics) can exhibit the signatures of optomechanical interaction as the appearance of multiple side bands in the spectrum. Strong optomechanical coupling and the good cavity limit are the two main conditions that need to be satisfied in order to observe all resonances in the spectrum [J.-Q. Liao et. al., Phys. Rev. A, 85,025803 (2012)]. We investigate the time-dependent (TD) version of the spectrum in the weak mechanical damping limit [Single-photon time-dependent spectrum in quantum optomechanics, I. M. Mirza, S. van Enk, to appear in Phys. Rev. A (2014)], which reveals some novel effects that are not possible to observe otherwise. For instance, the TD spectrum indicates that a sufficient amount of time has to pass before one can observe the fully resolved spectrum, even if the strong coupling and good cavity conditions are respected. Moreover, the TD spectrum also exhibits the order (in time) in which different side bands appear, thus further explaining the different photon-phonon interactions responsible for the distinct resonances.

Optical lattices can be tailored to realized a variety of different geometries. We model bosons confined to a bilayer configuration to allow a pseudospin degree of freedom in the layer index. Specifically, we model the Bose-Hubbard model on a bilayer square lattice with variable inter-layer hopping. Without the presence of interlayer hopping, the phase diagram only presents well known superfluid or Mott insulating phases. But interlayer hopping allows coupling of these two states. We find that an interesting incompressible phase emerges at half filling as we increase the interlayer hopping strength. We study the low temperature physics of the new phase and address the nature of pseudospin correlations in observables. We pair our effective theory with a quantum Monte Carlo study.

5:18PM J35.00015 Single-photon time-dependent spectrum in quantum optomechanics, IMran M. MIRZA, STEVEN J. VAN ENK, Oregon Center for Optics, Department of Physics, University of Oregon, USA — Single-photon optomechanics in the strong coupling regime is promising to play a key role in the realization of superpositions of macroscopic objects (for testing the foundations of quantum theory) and enhancing the nonlinear optomechanical interactions (for possible applications in quantum information processing). The stationary/time-independent spectrum of a single-photon interacting with a tiny movable mirror (in the context of cavity quantum optomechanics) can exhibit the signatures of optomechanical interaction as the appearance of multiple side bands in the spectrum. Strong optomechanical coupling and the good cavity limit are the two main conditions that need to be satisfied in order to observe all resonances in the spectrum [J.-Q. Liao et. al., Phys. Rev. A, 85,025803 (2012)]. We investigate the time-dependent (TD) version of the spectrum in the weak mechanical damping limit [Single-photon time-dependent spectrum in quantum optomechanics, I. M. Mirza, S. van Enk, to appear in Phys. Rev. A (2014)], which reveals some novel effects that are not possible to observe otherwise. For instance, the TD spectrum indicates that a sufficient amount of time has to pass before one can observe the fully resolved spectrum, even if the strong coupling and good cavity conditions are respected. Moreover, the TD spectrum also exhibits the order (in time) in which different side bands appear, thus further explaining the different photon-phonon interactions responsible for the distinct resonances.

Session J36 DAMOP: Bosons in Optical Lattices 211 - Randall Hulet, Rice University

2:30PM J36.00001 Phase diagram of the Bilayer Bose Hubbard Model, YANFEI TANG, VITO SCAROLA, Department of Physics, Virginia Tech, Blacksburg, Virginia 24061, USA — Optical lattices can be tailored to realized a variety of different geometries. We model bosons confined to a bilayer configuration to allow a pseudospin degree of freedom in the layer index. Specifically, we model the Bose-Hubbard model on a bilayer square lattice with variable inter-layer hopping. Without the presence of interlayer hopping, the phase diagram only presents well known superfluid or Mott insulating phases. But interlayer hopping allows coupling of these two states. We find that an interesting incompressible phase emerges at half filling as we increase the interlayer hopping strength. We study the low temperature physics of the new phase and address the nature of pseudospin correlations in observables. We pair our effective theory with a quantum Monte Carlo study.

2:42PM J36.00007 Tunable anisotropic superfluidity in optical Kagome superlattice, AXEL PELSTER, XUE-FENG ZHANG, Univ. of Kaiserslautern, Germany, TAO WANG, Harbin Institute of Technology, China, SEBASTIAN EGGERT, Univ. of Kaiserslautern, Germany — We study the extended Bose-Hubbard model for the optical Kagome superlattice generated by enhancing the long wavelength laser in one direction. By combining Quantum Monte Carlo simulations with the Generalized Effective Potential Landau Theory, we find not only the Mott insulator—superfluid phase transition, but also striped solid phases with non-integer filling factors. Furthermore, we determine with high accuracy the quantum phase diagram for different trap potential offsets. Due to the delicate interplay between onsite repulsion and artificial symmetry breaking, the superfluid density turns out to be anisootropic which reveals its tensorial property. Counterintuitively, the bias of the anisotropy is alternating between $x$- and $y$-direction while tuning the particle number or the hopping strength. Finally, we discuss how to observe such phenomenon experimentally, in particular via time-of-flight absorption measurements.

3:30PM J36.00006 Minimizing Non-Adiabaticities In Optical Lattice Loading, MICHELE DOLFI, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland, ADRIAN KANTIAN, DPMC-MaNEP, University of Geneva, 24 Quai Ernest-Ansermet, CH-1211 Geneva, Switzerland, BELA BAUER, Microsoft Research, Station Q, University of California, Santa Barbara, CA 93106, USA, MATTHIAS TROYER, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland — In the quest to reach lower temperatures of ultra-cold gases in optical lattice experiments, we derive an extended mean-field formalism to study the thermodynamical properties of the Bose-Hubbard model. The framework can be viewed as the zero-frequency limit of bosonic dynamical mean-field theory (B-DMFT), but equally well and less accurately than in B-DMFT.

3:18PM J36.00005 ABSTRACT WITHDRAWN
progress on magnetic effects in 2+1 dimensions will be discussed. We propose to implement the quantum rotors which appear in the Hamiltonian formulation using Bose mixtures or p-orbitals. Recent perturbation theory effective Hamiltonian for various Bose-Hubbard models. This correspondence can be exploited for building a lattice gauge theory simulator coupled regime. We discuss the plaquette corrections to the effective theory where link variables are integrated out. We discuss matching with the second-order WEN TSAI, ALEXEI BAZAVOV, JIN ZHANG, UC Riverside — We study the Lattice Gauge Theory of the U(1)-Higgs model in 1+1 dimensions in the strongly density fluctuations, current correlation functions, and excitation spectra are measurable in ultracold atom experiments. 

As the superfluid is rotated it moves with a supercurrent until it develops phase slips which generate vortices. We use a finite temperature strong-coupling approximation on an optical lattice in the presence of an annular trap and a barrier across the annular region which acts as a Josephson junction. In addition, we show how even more complex Josephson junction structures spontaneously arise if the filling is increased to generate Mott regions within the system.

3:54PM J36.00008 Spin Meissner Effect and Chiral Mott Insulators in Quantum Ladders . ALEXANDRU PETRESCU, Yale University USA and Center for Theoretical Physics, Ecole Polytechnique, France, KARYN LE HUR, Center for Theoretical Physics, Ecole Polytechnique and CNRS, France — We introduce generic bosonic models exemplifying that chiral Meissner currents can persist in insulating phases of matter. We first consider interacting bosons on a two-leg ladder. The total density sector can be gapped in a bosonic Mott insulator at odd-integer filling, while the relative density sector remains superfluid due to interchain hopping. Coupling the relative density to gauge fields yields a pseudospin Meissner effect [1]. We show that the same phase arises if the bosons are replaced by spinful fermions confined in Cooper pairs, and find a dual fermionic Mott insulator with spinon currents [2]. We propose two experimental realizations, one with ultracold atoms in the setup of [3], and another with Josephson junction arrays. Finally, we discuss the possibility to explore Laughlin phases in these systems by tuning the magnetic flux and the density of bosons [4].

4:06PM J36.00009 ABSTRACT WITHDRAWN —

4:18PM J36.00010 P-orbital Condensations of Two-species Bose Mixture in Optical Lattice1, JHIH-SHIHI YOU, Department of Physics, National Tsing Hua Univ, I-KANG LIU, Department of Physics and Graduate Institute of Photonics, National Changhua University of Education, DAW-WEI WANG, Department of Physics, National Tsing Hua Univ, SHIH-CHUAN GOU, Department of Physics and Graduate Institute of Photonics, National Changhua University of Education, CONGJUN WU, Department of Physics, University of California, San Diego — We investigate the p-orbital Bose-Einstein condensations (BECs) of two-species mixture in a bipartite optical lattice. A new imaginary-time propagation method is developed to numerically solve the Gross-Pitaevskii equation with truncating states below the p bands, which can be applicable to even higher orbital bands. Our study confirms that the intra-species interactions favor complex time-reversal broken BECs with staggered orbital currents. However, when the inter-species interaction increases, the complex condensate state undergoes a quantum phase transition toward a real-valued TR invariant condensate with staggered spin density structure. We discuss the origin and properties of such phase transition and its implication in the experimental setup.

4:42PM J36.00012 Cold-atom quantum simulation of U(1) lattice gauge-Higgs model , KENICHI KASAMATSU, Dept. of Phys. Kinki Univ., YOSHIHITO KUNO, Dept. of Appl. Phys., Nagoya Inst. of Tech., YOSHIRO TAKAHASHI, Dept. of Phys. Kyoto Univ., IKUO ICHINOSE, Dept. of Appl. Phys., Nagoya Inst. of Tech., TETSUO MATSUI, Dept. of Phys. Kinki Univ. — We discuss the possible methods to construct a quantum simulator of the U(1) lattice gauge-Higgs model using cold atoms in an optical lattice. These methods require no severe fine tunings of parameters of atomic-interactions in contrast with the other previous literature. We propose some realistic experimental setups to realize the atomic quantum simulator of the U(1) lattice gauge-Higgs model in a two-dimensional optical lattice. Our target gauge-Higgs model has a nontrivial phase structure, i.e., existence of the phase boundary between confinement and Higgs phases, and this phase boundary is to be observed by cold-atom experiments. As a reference to such experiments, we make numerical simulations of the time-dependent Gross-Pitaevskii equation and observe the real-time dynamics of the atomic simulators. Clarification of the dynamics of this gauge-Higgs model sheds some lights upon various unsolved problems including the inflation process of the early universe.

4:54PM J36.00013 Chiral Bosonic Phases on the Haldane Honeycomb Lattice , IVANA VASIC, Institut fuer Theoretische Physik, Goethe-Universitaet, 60438 Frankfurt/Main, Germany, ALEXANDRU PETRESCU, Department of Physics, Yale University, New Haven, CT 06520, USA and Centre de Physique Theorique, Ecole Polytechnique, CNRS, 91128 Palaiseau, France, KARYN LE HUR, Centre de Physique Theorique, Ecole Polytechnique, CNRS, 91128 Palaiseau Cedex, France, WALTER HOFSTETTER, Institut fuer Theoretische Physik, Goethe-Universitaet, 60438 Frankfurt/Main, Germany — Motivated by its recent realization in an ultracold atom experiment [1], we investigate the honeycomb lattice tight-binding model introduced by Haldane [2], for bosons with local interactions at the average filling of one boson per site [3]. We uncover in the ground state phase diagram three phases: a uniform superfluid (SF), a chiral superfluid (CSF) and a plaquette Mott insulator with local current loops (PMI). Nearest-neighbor and next-nearest neighbor currents distinguish CSF from SF, and the phase transition between them is first order. We apply bosonic dynamical mean field theory and exact diagonalization to obtain the zero temperature phase diagram, complementing numerics with calculations of excitation spectra in strong and weak coupling perturbation theory. Furthermore, we explore the possibility of chiral Mott insulating phases at the average filling of one boson every two sites. The characteristic density fluctuations, current correlation functions, and excitation spectra are measurable in ultracold atom experiments. [1] G. Jotzu et al., arXiv:1406.8784 [2] F. D. M. Haldane, Phys. Rev. Lett. 61, 2015 (1988). [3] Ivana Vasic, Alexandru Petrescu, Karyn Le Hur, Walter Hofstetter, arXiv:1408.1411

5:06PM J36.00014 Strong-coupling theory approach to describe an atomtronic josephson junction on an optical lattice , MANJARI GUPTA, H.R. KRISHNAMURTHY, Center For Condensed Matter Theory, Department of Physics, Indian Institute of Science, Bangalore 560012, India, J.K. FREERICKS, Department of Physics, Georgetown University, Washington, D.C. 20057, USA — We examine the behavior of a boson superfluid on an optical lattice in the presence of an annular trap and a barrier across the annular region which acts as a Josephson junction. As the superfluid is rotated it moves with a supercurrent until it develops phase slips which generate vortices. We use a finite temperature strong-coupling (t/U) expansion about the mean-field solution of the Bose Hubbard model, as described in our earlier paper Ref. [1] to characterize the device. Although our formalism is in equilibrium, it allows us to study the superfluid current flow and the generation of phase slips. This theory should aid in the further development of atomtronic circuits [2]. In addition, we show how even more complex Josephson junction structures spontaneously arise if the filling is increased to generate Mott regions within the system.

with numerical modelling of the readout process. We have determined the band structure of the BCC optical lattice for all theoretically possible couplings, and find that the band structure for lattices realizable in the lab, differs significantly from that expected for a BCC crystal. As coupling is increased, the lattice becomes increasingly chaotic [1] and it becomes possible to produce band structures that have qualitative similarity to a BCC.

Tuesday, March 3, 2015 2:30PM - 5:18PM —
Session J37 GQI: Focus Session: Quantum Dynamics with Phonons and Photons 212A - Ken Brown, Georgia Institute of Technology

2:30PM J37.00001 Quantum Information Experiments with Trapped Ions at NIST, ANDREW WILSON, National Institute of Standards and Technology, 325 Broadway, Boulder CO 80305 — We present an overview of recent trapped-ion quantum information experiments at NIST. Advancing beyond few-qubit “proof-of-principle” experiments to the many-qubit systems needed for practical quantum simulation and information processing, without compromising on the performance demonstrated with small systems, remains a major challenge. One approach to scalable hardware development is surface-electrode traps. Micro-fabricated planar traps can have a number of useful features, including flexible electrode geometries, integrated microwave delivery, and spatio-temporal tuning of potentials for ion transport and spin-spin interactions. In this talk we report on a number of ongoing investigations with face trapped ions. Experiments feature a multi-zone trap with closely spaced ions in a triangular arrangement (a first step towards 2D arrays of ions with tunable spin-spin interactions), a scheme for smooth transport through a junction in a 2D structure based on switchable RF potentials, and a micro-fabricated photodetector integrated into a trap. We also give a progress report on our latest efforts to improve the fidelity of both optical and microwave 2-qubit gates. This work was supported by IARPA, ONR and the NIST Quantum Information Program. The 3-ion and switchable-RF-junction traps were developed in collaboration with Sandia National Laboratory.

3:06PM J37.00002 Trapped Ion Quantum Computing with Microwaves, JOE RANDALL, University of Sussex, Imperial College, SEBASTIAN WEIDT, MARGARET STERLING, RALPH HANSON, University of Sussex, ANDREW RODRIGUEZ, ANNA WEBB, University of Sussex, HWAJUN TANASANTHI, PRASANNA SRINIVASAN, MICHAEL KRAFT, University of Southampton, JESSICA MACLEAN, CHRIS MELLOR, University of Nottingham, WINFRIED HENSINGR, University of Sussex — To this point, entanglement operations in trapped ion qubits have been predominantly performed with lasers. However, this becomes problematic when scaling to large numbers of qubits due to the challenging engineering required. The use of stable and easily controllable microwaves to drive entanglement gates can overcome this problem. We will present our work towards implementing multi-qubit entanglement gates using microwaves in an experimental setup that produces a static magnetic field gradient of 24 T/m over an ion string. We will first present a scheme for preparing and manipulating dressed-state qubits and qutrits that are highly robust to decoherence from magnetic field fluctuations. We will also present our work experimentally demonstrating motional sideband transitions and Schrödinger cat states using microwaves in conjunction with the magnetic field gradient, as well as sideband cooling to the ground state of motion using dressed-states. Furthermore, we will show our latest results in creating microfabricated ion trap chips towards large scale quantum computing and simulation.

3:18PM J37.00003 Non-Hermitian magnetism and entanglement in dissipative atomic systems, TONY LEE, CHING-KIT CHAN, Harvard/ITAMP, FLORENTINET REITER, Niels Bohr Institute, NIMROD MOISEYEV, Technion — Quantum phase transitions are usually studied in terms of Hermitian Hamiltonians. However, cold-atom experiments can implement non-Hermitian Hamiltonians via weak measurements. We show that the non-Hermitian XY model exhibits quantum phase transitions beyond the framework of Hermitian physics. There is a phase transition already for two atoms. In a 1D chain, the ordered phase is frustrated and has quasi-long-range order despite the absence of a continuous symmetry [1]. The non-Hermitian phase transition also has a lot more entanglement than the Hermitian one [2]. We discuss experimental implementation with trapped ions, cavity QED, and optical lattices. [1] Phys. Rev. X 4, 041001 (2014). [2] arXiv:1409.7067.

3:30PM J37.00004 Entanglement Transfer in a Double Jaynes-Cummings Model, SAMINA MASOOD, University of Houston Clear Lake, Houston TX, ALLEN MILLER, Syracuse University, Syracuse, NY — We compute and analyze the atom-atom entanglement, the entanglement between the two photon modes, and also the entanglement between each atom and each photon mode. The measure of entanglement is the von Neumann entropy. For the case in which the two photon-atom systems have identical properties, but allowing for non-resonant conditions, the sum of the von Neumann entropy. For the case in which the two atom-photon systems have identical properties, but allowing for non-resonant conditions, the sum of the

4:18PM J37.00006 ABSTRACT WITHDRAWN —

4:30PM J37.00007 On Readout of Vibrational Qubits using Quantum Beats, DMYTRO SHYSHLOV, DMITRI BABIKOV, Marquette Univ — Readout of the final states of qubits is a crucial step towards implementing quantum computation in experiment. In this theoretical work we explore the process of readout from vibrational qubits in thiophosphene molecules, SCC12, using quantum beat oscillations. The quantum beats are measured by first exciting the superposition of the qubit-encoding vibrational states to the electronically excited readout state with variable time delay pulses. The resulting oscillation of population of the readout state is then detected as a function of time delay. In principle, fitting the quantum beat signal by an analytical expression should allow extracting the values of probability amplitudes and the relative phases of the vibrational qubit states. However, we found that if this procedure is implemented using the standard analytic expression for quantum beats, a non-negligible phase error is obtained. We discuss the origin and properties of this phase error, and propose a new analytical expression to correct the phase error. The corrected expression fits the quantum beat signal very accurately. We now have a practical approach to read out the final state of vibrational qubits in experiments by combining the analytic expression for fitting with numerical modelling of the readout process.
We study the properties of this generalized entropy and generalized mutual information, and apply this framework to the exact mutual information is complex-valued and the space-like distance and time-like one are determined by the amplitude and the phase of the generalized mutual information between two generic regions of the system which do not have to be space-like separated. We study the generalized mutual information defined using this quantum gravity and condensed matter physics. Based on the proposal of arxiv:1309.6282, we would like to use quantum entanglement between two regions to construct the partially transposed reduced density matrix ρA2 := ρA1 ⊗ ρA2, and correspondingly. We study the process of selective construction of invariants to obtain physically meaningful polynomial invariants for three and four qubit pure states. In this article, we report the exact relations between the concurrence of a two qubit reduced state and corresponding three or four qubit pure state invariants. Firstly, we obtain an analytical expression for concurrence of a given mixed state of two qubits in terms of determinants of negativity fonts in the three or four qubit pure state. For three qubits, a comparison with three angle and squared negativity expressed in terms of determinants of negativity fonts leads to three relations. These three conditions satisfied by the two-way and three-way correlations sum together and lead to well known CKW inequality. When a qubit pair is part of a four qubit pure state, it may be entangled to the rest of the system through two-way, three-way and four-way correlations. Monogamy equalities, satisfied by two-way, three-way and four-way non-local quantum correlations are presented for states belonging to classes of four qubit pure states with distinct entanglement types.

### Session J38 GQI: Focus Session: Entanglement and Mathematics of Quantum Information 212B
- Sean Carroll, California Institute of Technology

2:30PM J38.00001 Entanglement negativity in free-fermion systems, PO-YAO CHANG, XUEDA WEN, SHINSEI RUY, University of Illinois at Urbana-Champaign — We derive a general formula of the logarithmic negativity in free-fermion systems, using the overlap matrix to construct the partially transposed reduced density matrix ρA12 of a subsystem A := A1 ⊃ A2. In particular, we consider the negativity between two adjacent or disjoint regions in three systems: a homogeneous one-dimensional chain, the dimerized Su-Schrieffer-Heeger model, and the integer Quantum Hall state. For the negativity of two adjacent intervals in a homogeneous one-dimensional gas, we find agreement with the conformal field theory [P. Calabrese et al. Phys. Rev. Lett. 109, 130502 (2012)]. On the other hand, the negativity for the integer quantum Hall states satisfies the area law. Our method is applicable to the study of the negativity in any free-fermion systems.

2:42PM J38.00002 Fidelity of recovery and geometric squashed entanglement, KAUSHIK SEHADREESAN, MARK WILDE, Louisiana State University — We define the fidelity of recovery of a tripartite quantum state on systems A, B, and C as a measure of how well one can recover the full state on all three systems if system A is lost and a recovery operation is performed on system A alone. The surprisal of the fidelity of recovery (its negative logarithm) is an information quantity which obeys nearly all of the properties of the conditional quantum mutual information I(A:B|C), including non-negativity, monotonicity under local operations, duality, and a dimension bound. We then define an entanglement measure based on this quantity, which we call the geometric squashed entanglement. We prove that the geometric squashed entanglement is an entanglement monotone, that it vanishes if and only if the state on which it is evaluated is unentangled, and that it reduces to the geometric measure of entanglement if the state is pure. We also show that it is sub-additive, continuous, and normalized on maximally entangled states. Our results for the bipartite case can easily be extended to a multipartite fidelity of recovery and a multipartite geometric squashed entanglement.

### Session J38 212B — Generalized Entanglement Entropy and Space-Time Geometry of Quantum System
- ZHAO YANG, PATRICK HAYDEN, XIAOLIANG QI, Stanford Univ — Entanglement entropy plays a key role in relating quantum information with gravitational wave observables. Based on the proposal of arxiv:1309.6282, we would like to use quantum entanglement between two regions of a quantum system as a measure of the geometrical distance between them. However, since entanglement entropy can only be defined between space-like separated regions, we are forced to treat space and time inhomogeneously. In this work, we propose a generalized entanglement entropy (GEE) which is defined between two generic regions of the system which do not have to be space-like separated. We study the generalized mutual information defined using this generalized entanglement entropy, and demonstrate for several different systems that this provides a reasonable measure of space-time distance. The generalized mutual information is complex-valued and the space-like distance and time-like one are determined by the amplitude and the phase of the generalized mutual information, correspondingly. We study the properties of this generalized entropy and generalized mutual information, and apply this framework to the exact holographic mapping of free fermions in various conditions.
3:18PM J38.00005 Entanglement Spectrum of a Random Partition: Connection with the Anderson Transition, SAGAR VIJAY, LIANG FU, Massachusetts Inst of Tech-MIT — The entanglement spectrum of a topologically-ordered ground-state that is obtained by partitioning the system under consideration into two subsystems which extend throughout the bulk, has been recently shown to be a probe of the quantum critical behavior of the topological phase at the transition to a direct-product state \([1]\). Here, we generalize this notion of a bulk entanglement spectrum to extract universal information about disorder-driven topological phase transitions, by performing an extensive, random partition into two subsystems with probability \(p \in [0, 1]\). We apply our random partitioning procedure to a one-dimensional topological superconductor (TSC), and demonstrate that the phase diagram of the resulting entanglement Hamiltonian describes disorder-driven transitions to a Griffiths phase. \([1]\) T. H. Hsieh and L. Fu, Phys. Rev. Lett. 118, 106801 (2014).

3:30PM J38.00006 The existence of maximally multipartite entangled states of \(N\) particles may depend on their spin, JAY LAWRENCE, University of Chicago and Dartmouth College, MARIO GAETA, ANDREI KLIMOV, University of Guadalajara, Jal., Mexico — Maximally multipartite entangled states (MMES) are defined \([1]\) as pure states of \(N\) particles for which all subsystems consisting of up to half the particles \((k=\lfloor N/2\rfloor)\) are maximally mixed \((\rho_k \sim \frac{1}{2^k})\). Such states exist for two- or three-particle systems (Bell states for \(N=2\) and GHZ states for \(N=3\)), and this holds for any spin. The situation changes for four particles, where MMES states do not exist for spin-1/2 \((\text{dimension } d=2)\), but they do exist for all odd prime dimensions \(d\) or spin states \(s=(d-1)/2\). The latter systems exhibit three types of graph states, the GHZ and cluster states accessible to qubits, which are not MMES, but also a third type, called \(P\) states \([2]\), which are MMES but are not accessible to qubits. We show how the \(P\) states succeed while GHZ and cluster states fail by comparing (i) the reduced states of subsystems, and (ii) the measurement-induced pathways which project Bell states of any two particles. We discuss the possibilities that similar transitions exist for larger systems, for which it is known \([1]\) that MMES do not exist for eight or more qubits. \(1.\) L. Aaroud and N.J. Cerf, Phys. Rev. A 87, 012319 (2013). \(2.\) J. Lawrence, Phys. Rev. A 84, 022338 (2011).

3:42PM J38.00007 Entanglement and coherence in many-body dipolar systems, SUSANNE YELIN, University of Connecticut — The presence of dipoles in atoms and molecules can nonlinearly change the coherent dynamics and entanglement structure in many-body situations. I will present examples for atomic and molecular systems.

4:18PM J38.00008 Entanglement-Assisted Transformations of W-Type States, JIYANG XIAO, ERIC CHITAMBAR, Southern Illinois University - Carbondale — In multipartite systems, it is usually impossible to transform one entangled state into another via local operations and classical communication (LOCC). However, the transformation may become possible with the help of some extra entanglement. This kind of transformation is called entanglement-assisted LOCC (eLOCC). Beyond the bipartite setting, very little is known about eLOCC. We prove the optimal eLOCC probability for transforming a tripartite W-type state \(\frac{1}{\sqrt{2}}(x_{000} + x_{100} + x_{010} + x_{110})\) into a GHZ state \(\sqrt{(x_{011} + x_{101} + x_{110})}\) and a Bell state \(\frac{1}{\sqrt{2}}(x_{000} + x_{100} + x_{010})\) (which is not a GHZ state). We consider eLOCC transformations of a more general W-type state \(\frac{1}{\sqrt{2}(x_{011} + x_{101} + x_{110})}\) into GHZ and cluster states. We demonstrate that the phase diagram of the resulting entanglement Hamiltonian describes disorder-driven transitions to a Griffiths phase. \([1]\) T. H. Hsieh and L. Fu, Phys. Rev. Lett. 118, 106801 (2014).

4:42PM J38.00010 Jordan Algebraic Quantum Categories, MATTHEW GRAYDON, Perimeter Institute, HOWARD BARNUM, University of New Mexico, COZMIN UDULEC, Invenia Technical Computing Corporation, ALEXANDER WILCE, Susquehanna University — State cones in orthodox quantum theory over finite dimensional complex Hilbert spaces enjoy two particularly essential features: homogeneity and self-duality. Orthodox quantum theory is not, however, unique in that regard. Indeed, all finite dimensional formally real Jordan algebras — arenas for generalized quantum theories with close algebraic kinship to the orthodox theory — admit homogeneous self-dual positive cones. We construct categories wherein these theories are unified. The structure of composite systems is cast from universal tensor products of the universal C*-algebras enveloping ambient spaces for the constituent state cones. We develop, in particular, a notion of composition that preserves the local distinction of constituent systems in quaternionic quantum theory. More generally, we explicitly derive the structure of hybrid quantum composites with subsystems of arbitrary Jordan algebraic type.

4:54PM J38.00011 Jacobi – type identities and the underlying quantal algebra, SAMIR LIPOVACA, None — Reference \([1]\) introduced two identities written in terms of single commutators and anticommutators for any three elements of an arbitrary associative algebra where one is a consequence of other which is called the fundamental identity. From the fundamental identity a set of four other identities, represented in terms of double commutators and anticommutators is derived. We will show that three of these identities are in fact the defining identities of the quantal algebra. In this light, \([1]\) did actually derive an underlying quantal algebra for an arbitrary associative algebra from the fundamental identity. Remarkably, the proof of the Theorem 2 showed that the existence of this underlying quantal algebra is equivalent to the associativity condition. A generalization to the super case of the quantal algebra is, in essence, derived in the section 3 of \([1]\).

5:06PM J38.00012 Quantum Bochner’s theorem for phase spaces built on projective representations\(^1\), NINNAT DANGNIAM, CHRISTOPHER FERRIE, Univ of New Mexico — Bochner’s theorem gives the necessary and sufficient conditions on a characteristic function such that it corresponds to a true probability density function. In the Wigner phase space picture, quantum Bochner’s theorem gives the necessary and sufficient conditions on the quantum characteristic function such that it corresponds to a valid quantum state and such that its Fourier transform is a true probability density. We extend this theorem to discrete phase space representations which possess enough symmetry to define a generalized Fourier transform.

5:18PM J38.00013 Galois-unitary operators that cycle mutually-unbiased bases1. HOAN DANG, Perimeter Institute for Theoretical Physics & University of Waterloo, MARCUS ALPÉBÉY, University of Sydney, INGEMAR BENGTSSON, Stockholms University — Wigner’s theorem states that probability-preserving transformations of quantum states must be either unitary or anti-unitary. However, if we restrict ourselves to a subspace of a Hilbert space, it is possible to generalize the notion of anti-unitaries. Such transformations were recently constructed in search of Symmetric Informationally-Complete (SIC) states. They are called Galois-unitaries (g-unitaries for short), as they are unitaries composed with Galois automorphisms of a chosen number field extension. Despite certain bizarre behaviors of theirs, we show that g-unitaries are indeed useful in the theory of Mutually-Unbiased Bases (MUBs), as they help solve the MUB-cycling problem and provide a construction of MUB-balanced states.

Tuesday, March 3, 2015 2:30PM - 5:30PM –

2:30PM J39.00001 Implementing fault tolerance in a superconducting quantum circuit, RAMI BARENDS, Google, Santa Barbara — The surface code error correction scheme is appealing for superconducting circuits as the fundamental operations have been demonstrated at the fault-tolerant threshold. Here, we present experimental results on the repetition code, a one-dimensional primitive of the surface code which can detect bit-flip errors, implemented on a device consisting of nine Xmon transmon qubits. We discuss the basic mechanics of error detection, show preservation of a Greenberger-Horne-Zeilinger state, and show suppression of environmentally-induced error.

3:06PM J39.00002 Performing repetitive error detection in a superconducting quantum circuit, J. KELLY, UC Santa Barbara, R. BARENDS, A. FOWLER, Google, Santa Barbara, A. MEGRANT, UC Santa Barbara, E. JEFFREY, Google, Santa Barbara, T. WHITE, UC Santa Barbara, D. SANK, J. MUTUS, Google, Santa Barbara, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara, Z. CHEN, B. CHIARO, A. DUNSWORTH, I.-C. HOI, C. NIEL, P. J. O’MALLEY, UC Santa Barbara, P. ROUSHAN, Google, Santa Barbara, C. QUINTANA, A. VAINSENCHER, J. WENNER, A. N. CLELAND, UC Santa Barbara, J. M. MARTINIS, University of California and Google, Santa Barbara — Recently, there has been a large interest in the surface code error correction scheme, as gate and measurement fidelities are near the threshold. If error rates are sufficiently low, increased systems size leads to suppression of logical error. We have combined high fidelity gate and measurements in a single nine qubit device, and use it to perform up to eight rounds of repetitive bit error detection. We demonstrate suppression of environmentally-induced error as compared to a single physical qubit, as well as reduced logical error rates with increasing system size.

3:18PM J39.00003 A Leakage-Resilient Approach to Fault-Tolerant Quantum Computing with Superconducting Elements1. JOYDIP GHOSH, University of Calgary, AUSTIN FOWLER, University of California, Santa Barbara — Superconducting qubits, while promising for scalability and long coherence times, contain more than two energy levels, and therefore are susceptible to errors generated by the leakage of population outside of the computational subspace. Such leakage errors are currently considered to be a prominent roadblock towards fault-tolerant quantum computing with superconducting qubits. Fault-tolerant quantum computing using topological codes is based on sequential measurements of multi-qubit stabilizer operators. In this talk, I propose a leakage-resilient scheme to perform repetitive measurements of multi-qubit stabilizer operators, and then discuss how to use this scheme as an ingredient to develop a leakage-resilient approach for surface code quantum error correction with superconducting circuits. Our protocol is based on SWAP operations between data and ancilla qubits at the end of every cycle, requiring read-out and reset operations on every physical qubit in the system, and thereby preventing persistent leakage errors from occurring.

3:30PM J39.00004 Characterization of superconducting qubits in a planar lattice1. SRIKANTH SRINIVASAN, ANTONIO CORCOLES, EASWAR MAGESAN, NICHOLAS BRONN, JARED HERTZBERG, JAY GAMBITTA, MATTHIAS STEFFEN, JERRY CHOW, IBM T.J. Watson Research Center — The surface code is a promising implementation for quantum computing because of its relatively lenient thresholds for fault tolerance. The physical layout contains two general classes of qubits, code and syndrome, arranged in a planar lattice. In this talk we present complete characterization of a four qubit planar lattice and discuss the experimental challenges for achieving high fidelity. This includes integrating four independent readouts using parametric amplifiers, gate calibration procedures, and sample design. Careful device design is required for efficient signal delivery without deleterious microwave crosstalk. The low crosstalk is validated through measurements of simultaneous randomized benchmarking on both single and two-qubit entangling gates. This work is a step towards realizing the surface code on a planar lattice.

1 We acknowledge support from IARPA under contract W911NF-10-1-0324.

3:42PM J39.00005 Arbitrary error detection in a planar lattice of the surface code1. ANTONIO CORCOLES, EASWAR MAGESAN, SRIKANTH SRINIVASAN, NICHOLAS BRONN, JARED HERTZBERG, ANDREW CROSS, MATTHIAS STEFFEN, JAY GAMBITTA, JERRY CHOW, IBM T J Watson Res Ctr — We detect arbitrary single-qubit errors on a system of four superconducting qubits arranged in a planar lattice, amenable to the surface code. The error detection protocol is based on the stabilizer formalism and protects a codeword encoded on an entangled two-qubit state by quantum non-demolition parity measurements, ZZ and XX. These parity measurements are performed using the other two qubits acting as syndromes. We introduce a bit- or phase-flip single-qubit error applied to the codeword and show that this error can be revealed uniquely in the syndromes. The -non-trivial- geometric arrangement of the qubits is essential to the surface code algorithm and is therefore extendable throughout the two-dimensional plane, encoding progressively larger logical Hilbert spaces towards a fully scaled fault-tolerant quantum computer.

1 We acknowledge support from IARPA under contract W911NF-10-1-0324.
3:54PM J39.00006 Characterizing Quantum Gates with Iterated Randomized Benchmarking on Superconducting Qubits1. SARAH SHELDON, LEV S. BISHOP, STEFAN FILIPP, MATTHIAS STEFFEN, JERRY M. CHOW, JAY M. GAMBETTA, IBM T.J. Watson Research Center, Yorktown Heights, NY, USA — With coherence times exceeding 40us and single qubit gate fidelities of 0.9996, we find our current calibration schemes and DRAG pulse shaping fall short of the coherence limit. It is therefore necessary to develop new methods of finding and addressing errors in the qubit control. We present a method for characterizing small errors using a variation of interleaved randomized benchmarking to identify sources of systematic errors. Our new scheme, iterative randomized benchmarking, interleaves repetitions of gates in a randomized benchmarking sequence to determine the type of error on the target gate. The scaling of the fidelity with the number of interleaved gates reveals if the gate errors are coherent or incoherent. Experimental data indicates that our system is sensitive to an over-rotation by an angle of \( \pi/128 \). We also apply this technique to identify sources of coherent errors that may be reducing our randomized benchmarking error rates.

---

4:06PM J39.00007 Detecting and Reducing Gate Leakage in Superconducting Qubits using Randomized Benchmarking. ZHAN, J. KELLY, UC Santa Barbara, R. BAREND, Google, Santa Barbara. B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara. B. CHIARO, A. DUNSWORTH, UC Santa Barbara, A. FOWLER, Google, Santa Barbara. I.-C. HOI, UC Santa Barbara. E. JEFFREY, Google, Santa Barbara. A. MGRANT, UC Santa Barbara, J. MUTUS, Google, Santa Barbara. C. NEILL, P.I.J. O’MALLEY, C. QUINTANA, UC Santa Barbara, P. ROUSHAN, D. SANK, Google, Santa Barbara. A. VAINSENCHER, J. WENNER, T. WHITE, UC Santa Barbara. A. N. KOROTKOV, UC Riverside, A.N. CLELAND, UC Santa Barbara, J.M. MARTINIS, University of California and Google, Santa Barbara. — Superconducting qubits are a promising platform for building a quantum computer due to their scalability and ease of control. One potential drawback is the existence of more than two energy levels, which can allow the qubit to leak out of the computational subspace when performing operations. This leakage error is particularly detrimental in the surface code scheme, which leads to correlated errors. We will present a method for characterizing gate leakage rates using randomized benchmarking, and present strategies based on these results for reducing leakage.

4:18PM J39.00008 Efficient State Tomography for Continuous Variable Systems. CHAO SHEN, LUYAO JIANG, STEFAN KRASTANOV, VICTOR V. ALBERT, REINIER HEÈRES, BRIAN VLASTAKIS, ROB SCHOLEKOPF, LIANG JIANG, Yale University — We propose an efficient and error robust scheme for state tomography of a continuous variable system, which is dispersively coupled to a two-level system. Our adaptive tomography protocol offers a significant speed up compared to the conventional Wigner tomography for a practically interesting class of states, such as Schrodinger cat states. In the presence of typical experimental errors, the number of measurements required is still close to the information theoretic limit. Our proposals can be readily implemented in platforms such as superconducting transmon qubit inside a microwave cavity.

4:30PM J39.00009 Implementing gates in a fluxonium-like qubit with suppressed wavefunction overlap. NATHAN EARNEST, YAO LU, DAVID MCKAY, University of Chicago, DAVID CZAPLEWSKI, LEONIDAS OCOLA, Argonne National Lab, DAVID SCHUSTER, University of Chicago. — Superconducting Josephson junction qubits are a promising technology for quantum information processing, but are limited by finite lifetimes. The lifetime of the qubit, according to Fermi’s golden rule, is dictated by the overall overlap of the |0> and |1> wavefunctions and so a long lived qubit may be constructed from states with well-isolated wavefunctions. A “double-well” fluxonium-like qubit [1] with well-separated degenerate ground states is obtained by increasing the qubit energy EJ and decreasing the charging energy EC. This qubit implementation is expected to have T2s similar to a tunable transmon qubit but, due to the isolated wavefunctions, has promise for long T1s that are insensitive to arbitrary forms of noise. This isolation, however, makes performing arbitrary quantum gates more difficult as wavefunction overlap also allows for arbitrary qubit operations. In this presentation, we will discuss methods for performing arbitrary quantum gates, the implications for decoherence due to flux noise, and discuss experimental progress.

4:42PM J39.00010 High-fidelity single-shot Toffoli gate with superconducting elements via quantum control. EHSAN ZAHEDINEJAD, JOYDIP GHOSH, BARRY SANDERS, University of Calgary — A single-shot Toffoli, or controlled-controlled-NOT, gate is desirable for classical and quantum information processing. The Toffoli gate alone is universal for reversible computing and, accompanied by the Hadamard gate, forms a universal gate set for quantum computing. The Toffoli gate is a key ingredient for (non-topological) quantum error correction. Currently Toffoli gates are achieved by decomposing into sequentially implemented single- and two-qubit gates, which requires much longer times and yields lower overall fidelities compared to a single-shot implementation. We develop a quantum-control procedure to directly construct single-shot Toffoli gates and devise a scheme for three nearest-neighbor-coupled superconducting transmon systems that should operate with 99.9% fidelity under realistic conditions. The gate is achieved by a non-greedy quantum control procedure using our enhanced version of the Differential Evolution algorithm.

4:54PM J39.00011 The Design of Control Pulses for Heisenberg Always-On Qubit Models. RUDOLPH MAGYAR, Sandia National Laboratories. — One model for a universal quantum computer is a spin array with constant nearest neighbor interactions and a controlled unidirectional site-specific magnetic field to generate unitary transformations. This system can be described by a Heisenberg spin Hamiltonian and can be simulated for on the order of 50 spins. It has recently been shown that time-dependent density functional inspired methods may be used to relate various spin models of qubits to ones that may be easier to compute numerically allowing potentially the efficient simulation of greater numbers of spins. One of the challenges of such an agenda is the identification of control pulses that produce desired gate operations (CNOT and single qubit phase gates). We apply control theory to design a universal set of pulses for a Heisenberg always-on model Hamiltonian for a few qubits and compute to known pulses when available. We suggest how this approach may be useful to design control pulses in other realistic designs. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Security Administration under contract DE-AC04-94AL85000.

5:06PM J39.00012 Demonstrated control of a Transmon using a Reciprocal Quantum Logic digital circuit - Part 1. MICHA STOUTMORE, JAMES MEDFORD, QUENTIN HERR, OFER NAAMAN, HAROLD HEARNE, JOEL STRAND, ANTHONY PRZYBYSZ, AARON PESETSKI, JOHN PRZYBYSZ, Northrop Grumman Corporation. — We report on experiments in which we used a Reciprocal Quantum Logic circuit to perform Z rotations on a Transmon qubit. Reciprocal Quantum Logic (RQL) [1] is a low-power superconducting digital technology based on paired single-flux quantum voltage pulses. Here we discuss the RQL hardware used in these experiments - an RQL output amplifier [2] whose output is non-return-to-zero (NRZ) encoded 3 mV differential signal, and is primarily intended for transmitting RQL data signals to standard room temperature CMOS hardware. We demonstrate the circuit operation at both 4 K and 20 mK with wide circuit operating margins. [1] J. Appl. Phys. 109, 103903 (2011) [2] Supercond. Sci. Technol. 23, 022044 (2010)
5:18PM J39.00013 Demonstrated control of a Transmon using a Reciprocal Quantum Logic digital circuit - Part 2. JAMES MEDFORD, MICAH STOUTIMORE, QUENTIN HERR, OFER NAAMAN, HAROLD HEARNE, JOEL STRAND, ANTHONY PRZYBYSZ, AARON PESETSKI, JOHN PRZYBYSZ, Northrop Grumman Corporation — We demonstrate coherent manipulation of a 2D asymmetric Transmon qubit using a Reciprocal Quantum Logic (RQL) [1] distributed output amplifier mounted at 20 mK. The RQL amplifier provided active isolation and amplification for signals generated by room temperature equipment. We measured a 30% suppression of the Transmon lifetime when connected to the RQL circuit, which we primarily attributed to static power dissipation associated with the on-chip 50 Ohm source termination of the amplifier. [1] J. Appl. Phys 109, 103903 (2011)

Tuesday, March 3, 2015 2:30PM - 5:30PM – Session J41 DPOLY: Focus Session: Organic Electronics and Photonics, Optical and Electrical Properties 214A - Michael Chabinyc, University of California, Santa Barbara

2:30PM J41.00001 BREAK –

3:06PM J41.00002 Measuring Exciton Diffusion in Conjugated Polymer Films with Super-resolution Microscopy1. SAMUEL PENWELL, LUCAS GINSBERG, RODRIGO NORIEGA MANEZ, NAOMI GINSBERG, UC Berkeley — Conjugated polymers are highly tunable organic semiconductors, which can be solution processed to form thin films, making them prime candidates for organic photovoltaic devices. One of the most important parameters in a conjugated polymer solar cell is the exciton diffusion length, which depends on intermolecular couplings, and is typically on the order of 10 nm. This mean exciton migration can vary dramatically between films and within a single film due to heterogeneities in morphology on length scales of 10’s to 100’s nm. To study the variability of exciton diffusion and morphology within individual conjugated polymer films, we are adapting stimulated emission depletion microscopy, STED is typically used in biology with well-engineered fluorescent labels or on NV-centers in diamond. I will, however, describe how we have demonstrated STED in conjugated polymer films of MEH-PPV and CN-PPV by taking care to first understand the film’s photophysical properties. This new approach provides a way to study exciton diffusion by utilizing subdiffraction optical excitation volumes. In this way, we will obtain a spatiotemporal map of exciton distributions that will help to correlate the energetic landscape to film morphology at the nanoscale. This research is supported in part by the Department of Energy Office of Science Graduate Fellowship Program (DOE SCGF), made possible in part by the American Recovery and Reinvestment Act of 2009, administered by ORISE-ORAU under contract no. DE-AC05-06

3:18PM J41.00003 Probing the exciton coherent size in organic crystals and the effect of polar bonds1. WAI-LUN CHAN, TI WANG, Univ of Kansas — Exciton transport in organic crystals is commonly described by a series of incoherent hopping. This is no longer valid if the transport range is on the order of the exciton coherent size. Recently, it has been proposed that exciton delocalization is responsible for ultrafast charge separation found in bulk heterojunction (BHJ) photovoltaics. However, the coherent exciton transport range has not been measured. Here, by using time-resolved photoemission and zinc phthalocyanine crystals as a model system, we observe a transition from coherent to incoherent transport while the exciton coherent size is decreasing. The electron-vibration interaction is found to be the main driving force that reduces the exciton coherent size. Furthermore, by using phthalocyanine molecules with a polar bond, e.g. titanyl phthalocyanine, we observe an upshift in electron energy as a function of time after photo-excitation. Our observation can be explained by spontaneous exciton dissociation after photoexcitation, which produces a more delocalized charge transfer state. This would explain why BHJ made by ‘push-pull’ polymers or small molecules, which consist of electron-rich and electron-deficient units, often have a better charge separation efficiency.

3:30PM J41.00004 Fully three dimensional calculations of c-AFM current flow patterns, including space charge effects, traps and fibrous morphologies, KANOKKORN PIMCHAROEN, PHILLIP DUBURY. Department of Physics and Astronomy, Michigan State University — Organic semiconductors are promising materials for many optoelectronic devices due to their versatile applications and low-cost fabrication, including organic photovoltaics (OPV), light-emitting diodes (OLED), and thin-film transistors (OTFT). The performance of these devices is controlled by charge transport which primarily depends on the nanoscale morphology. Unlike other microscopies, conductive Atomic Force Microscope (c-AFM) is capable of characterizing both nanoscale morphology and local electronic properties simultaneously. With this unique ability, c-AFM has been used extensively to characterize these organic semiconductor devices in the past decade, however the spreading of current from the tip geometry in the presence of traps, which are ubiquitous in these materials, is not well understood. We have developed a fully three dimensional device simulation tool enabling treatment of inhomogeneous systems including c-AFM tip geometry, spatially varying trap distributions, and fibrous morphologies. Results characterizing charge transport in the fibrous morphologies and in the presence of traps will be discussed, including the effect of traps and space charge effects on current spreading from the c-AFM tip.

3:42PM J41.00005 Interface structure of P3HT/SWNT blend and charge separation process on it. KATSUHIKO NISHIMURA, RYOTA JONO, MIKIYA FUJII, KOICHI YAMASHITA, Department of Chemical System Engineering, University of Tokyo and JST, CREST — We investigated the mechanism that suppression of charge recombinations takes place in blends of regioregular Poly-3-HexylThiophene (rrP3HT) and semiconducting Single Walled Carbon Nanotube (scSWNT) only if excess P3HT exists. The rrP3HT/scSWNT blend seems to be suitable for OPV application because rrP3HT is common acceptor material and also can be used for purifying scSWNT and removing metallic one. The suppression of charge recombinations is attributed to unique helical supramolecular structure at P3HT/SWNT interfaces. However, the detailed mechanism of the suppression has not been clarified yet. In this presentation, we show that side chains of P3HT are important in formation of the helical structure rather than alignment of main chains with graphene lattices of SWNT by using semi-empirical quantum chemistry method. Moreover, HOMO levels of P3HT molecules at the interfaces estimated to be lower than those in crystalline domain because of disordered stacking due to formation of the helical structure. This difference in HOMO levels can act as the driving force for escape of charge carriers from the interfaces and can result to the suppression of charge recombinations. [1] S. D. Stranks et. al., Nano. Lett. 11, 66
The conversion of excitons into charge within organic solar cells is complicated by bound electronhole pairs, or charge transfer states at donor/acceptor interfaces. The solar cell requires generating an efficient current. Thus it is necessary that charge transfer is further separated into free charge carriers to be transported to electrode. We focus on the improved the conversion efficiency of bulk-heterojunction organic solar cells. We use dependent density functional theory with CAM-B3LYP/6-31G(d) to study the oscillator strengths, electronic structure, HOMO-LUMO band gap and energy level in several polymer (donor): fullerene (acceptor) blends, such as MDMO-PPV, PCDDBT, PCPDDBT, PBDB3, PTB7 and PTBF2 with PC70BM. To determine the effective physical factor in light energy conversion, we consider (i) charge transfer type excitation generated directly by photoinduced electron transition in the donor/acceptor interface (ii) the factors for controlling the conversion efficiency such as short-circuit current density and closed circuit voltage.

On the theory of Carrier's Electrostatic Interaction near an Interface.

Micheal Watters, Hossein Hashemi, John Kieffer, Univ of Michigan - Ann Arbor  Heterojunction interfaces are common in non-traditional photovoltaic device designs, such as those based on small molecules, polymers and carbon nanotubes [1]. We have developed a number of the effective Hamiltonians for the heterojunction interface region on carrier/exciton energetics using a mixture of both semi-classical and quantum electrostatic methods, ab initio methods, and statistical mechanics. Our theoretical analysis has yielded several useful relationships and numerical recipes that should be considered in device design regardless of the particular materials system. As a demonstration, we highlight these formalisms as applied to carriers and polaron pairs near a C60/subphthalocyanine interface [1]. On the regularly ordered areas of the heterojunction, the effect of the interface is a significant set of corrections to the carrier energies, which in turn directly affects device performance.

2:30PM J42.00001 Phase Transitions on Random Lattices: How Random is Topological Disorder?1, HATEM BARGHATHI, THOMAS VOJTA, Missouri Univ of Sci & Tech — We study the effects of topological (connectivity) disorder on phase transitions. We identify a broad class of random lattices whose disorder fluctuations decay much faster with increasing length scale than those of generic random systems, yielding a wandering exponent of $\omega = (d - 1)/(2d)$ in $d$ dimensions. The stability of clean critical points is thus governed by the criterion $(d + 1)\nu > 2$ rather than the usual Harris criterion $d\nu > 2$, making topological disorder less relevant than generic randomness. The Imry-Ma criterion is also modified, allowing first-order transitions to survive in all dimensions $d > 1$. These results explain a host of puzzling violations of the original criteria for equilibrium and nonequilibrium phase transitions on random lattices. We discuss applications, and we illustrate our theory by computer simulations of random Voronoi and other lattices.

2:42PM J42.00002 Shear Jamming in Frictionless Particulate Media1, THIBAULT BERTRAN, COREY S. O’HERN, Yale University, R.P. BEHRINGER, Duke University, BULBUL CHAKRABORTY, Brandeis University, MARK D. SHATTUCK, City College of the City University of New York — We numerically study two-dimensional packings of frictionless bidisperse disks created using compressive and simple shearing protocols. To create jammed packings by compression, we start $N$ particles from random positions and grow their diameters followed by relaxation of particle overlaps using energy minimization. These compressed packings exist over a range of packing fractions $\phi$. As a result, during compression the system may reach a $\phi$ above the minimum value before jamming. If this unjammed packing is then sheared by a strain $\gamma$, it can jam. Using a combination of compression and shearing, we can define jamming protocols as trajectories in the $(\phi, \gamma)$ plane that yield jammed packings. In this plane, we can reach a particular point $(\phi_n, \gamma_n)$ in many ways. We will focus on two protocols: (1) shearing to $\gamma_n$ at $\phi = 0$ followed by compression to $\phi_n$ at $\gamma = \gamma_n$, and (2) compression to $\phi_n$ at $\gamma = 0$ followed by shearing to $\gamma_n$ at $\phi = \phi_n$. For protocol 1, we find that the probability of finding a jammed packing at $\phi$ and $\gamma$, $P(\phi, \gamma) = Q(\phi)$ is independent of $\gamma$. For protocol 2, we use a simple theory to deduce $P(\phi, \gamma)$ from $Q(\phi)$.

2:54PM J42.00003 Three Dimensional Characterization of Quantum Vortex Dynamics in Superfluid Helium. DAVID MEICHEL, DANIEL LATHROP, University of Maryland — Vorticity is constrained to line-like topological defects in quantum superfluids, such as liquid Helium below the Lambda transition. We have invented a novel method to disperse fluorescent nanoparticles directly into the superfluid which become trapped on the vortex cores, providing optical tracers. Using a newly constructed multi-camera stereoscopic microscope, we present data dynamically characterizing vortex reconnections and the subsequent emission of Kelvin waves fully in three dimensions. Statistics of thermally driven counterflow will be compared in 3D to previous measurements in projection.

3:06PM J42.00004 Defect-Stabilized Phases in Extensible Active Nematics. GABRIEL REDNER, STEPHEN DECAMP, ZVONIMIR DOGIC, MICHAEL HAGAN, Brandeis University — Active nematics are liquid crystals which are driven out of equilibrium by energy-dissipating active stresses. The equilibrium nematic state is unstable in these materials, leading to beautiful and surprising behaviors including the spontaneous generation of topological defect pairs which stream through the system and later annihilate, yielding a complex, seemingly chaotic dynamical steady-state. In this talk, I will describe the emergence of order from this chaos in the form of previously unknown broken-symmetry phases in which the topological defects themselves undergo orientational ordering. We have identified these defect-ordered phases in two realizations of an active nematic: first, a suspension of extensible bundles of microtubules and molecular motor proteins, and second, a computational model of extending hard rods. I will describe the defect-stabilized phases that manifest in these systems, our current understanding of their origins, and discuss whether such phases may be a general feature of extensible active nematics.

3:18PM J42.00005 Jamming Percolation in Three Dimensions. EIAL TEOMY, Tel Aviv University, ANTIMA GHOSH, Weizmann Institute, YAIR SHOKEF, Tel Aviv University — We introduce a three-dimensional kinetically-constrained model for jamming and glasses [1], and prove that the fraction of frozen states is continuous at the directed-percolation critical density. In agreement with the accepted scenario for jamming- and glass-transitions, this is a mixed-order transition; the discontinuity is accompanied by diverging length- and time-scales. Because one-dimensional directed-percolation paths comprise the backbone of frozen particles, the unfrozen rattlers may use the third dimension to travel between their cages. Thus the dynamics are diffusive on long-time scales even above the critical density for jamming. Our new model is a non-trivial extension of the two-dimensional spiral model [2].

3:30PM J42.00006 Diffuse globally, compute locally: a cyclist approach to modeling long time robot locomotion. TINGNAN ZHANG, DANIEL GOLDMAN, PREDRAG CVITANOVIĆ, Georgia Institute of Technology — To advance autonomous robots we are interested to develop a statistical/dynamical description of diffusive self-propulsion on heterogeneous terrain. We consider a minimal model for such diffusion, the 2-dimensional Lorentz gas, which abstracts the motion of a light, point-like particle bouncing within a large number of heavy scatters (e.g. small robots in a boulder field). We present a precise computation (based on exact periodic orbit theory formula for the diffusion constant) for a periodic billiard wall. For small inter-disk separations, with periodic orbits up to $10^6$, our method is efficient and accurate. For other parameter choices, the boundaries become simple at sufficiently small but widely different scales across the phase space, despite the observed sensitive dependence on initial conditions. However, such scales are often far below the current computational resolution even for low-dimensional dynamical systems.

3:42PM J42.00007 Fractal Geometry of Undriven Dissipative Systems. XIAOWEN CHEN, TAKASHI NISHIKAWA, ADILSON E. MOTTER, Department of Physics and Astronomy, Northwestern University — Traditional studies of chaos in conservative or driven dissipative systems have established a correspondence between sensitive dependence on initial conditions and fractal basin boundaries. Here, I will present on a new type of chaos due to transient interactions with transient chaotic saddles in undriven dissipative systems. I will show that such systems can develop complicated trajectories, but only exhibit fractality and the Wada property at all scales for specific parameter choices at which the dynamics have a degenerate fixed point. For other parameter choices, the boundaries become simple at sufficiently small but widely different scales across the phase space, despite the observed sensitive dependence on initial conditions. However, such scales are often far below the current computational resolution even for low-dimensional dynamical systems.
3:54PM J42.00008 On Path Attractors, Stochastic Bifurcation and Dephasing In Genetic Networks, DAVIT POTOYAN, Rice University — Gene regulatory networks are driven stochastic systems with the noise having two distinct components due to the to birth and death of metabolite molecules and dichotomous nature of gene state switching. Presence of dichotomous gene noise alone has the capacity to significantly perturb the optimal transition paths and steady state probability distributions compared to the macroscopic models and their weak noise approximations. Most importantly dichotomous gene noise can also lead to multimodal distributions due to stochastic bifurcation of the underlying nonlinear dynamical system, which underlies the mechanism of formation of population heterogeneity. In this note we derive approximate path based expression of the time dependent probability of gene circuits which enables deeper exploration of the role of gene noise in formation of epigenetic states and dephasing-like phenomena.

4:06PM J42.00009 Model reduction by manifold boundaries, MARK TRANSTRUM, Brigham Young University — Mathematical models of physical systems can be interpreted as manifolds of predictions embedded in the space of data. For models of complex systems with many parameters, the corresponding model manifold is very high-dimensional but often very thin. This “low effective dimensionality” has been described as a hyper-ribbon and is characteristic of systems exhibiting simple, emergent behavior. I discuss a new model reduction method, the manifold boundary approximation method, which constructs a series of models by iteratively approximating the high-dimensional, thin manifold by its boundary. This model reduction method unifies many different model reduction techniques, such as renormalization group and continuum limits, while greatly expanding the domain of tractable models. I demonstrate with a model of a complex signaling network from systems biology. The method produces a series of approximations which reveal how microscopic parameters are systematically “compressed” into a few macroscopic degrees of freedom, effectively building a bridge between the microscopic and the macroscopic descriptions.

4:18PM J42.00010 Saturation in coupled oscillators, AHMED ROMAN, JAMES HANNA, Virginia Polytechnic Institute and State University — We consider a weakly nonlinear system consisting of a resonantly forced oscillator coupled to an unforced oscillator. It has long been known that, for quadratic nonlinearities and a 2:1 resonance between the oscillators, a perturbative solution of the dynamics exhibits a phenomenon known as saturation. At low forcing, the forced oscillator responds, while the unforced oscillator is quiescent. Above a critical value of the forcing, the forced oscillator’s steady-state amplitude reaches a plateau, while that of the unforced oscillator increases without bound. We show that, contrary to established folklore, saturation is not unique to quadratically nonlinear systems. We present conditions on the form of the nonlinear couplings and resonance that lead to saturation. Our results elucidate a mechanism for localization or diversion of energy in systems of coupled oscillators, and suggest new approaches for the control or suppression of vibrations in engineered systems.

4:30PM J42.00011 Regular and Chaotic Motion of a Piecewise Smooth Bouncer, CAMERON LANGER, BRUCE MILLER, Texas Christian University — The dynamical properties of a particle in a gravitational field colliding with a rigid wall moving with piecewise constant velocity are studied. The linear nature of the wall’s motion permits further analytical investigation than is possible for the system’s sinusoidal counterpart. We consider three distinct collision models: elastic, inelastic with either a constant or velocity dependent restitution coefficient. We confirm the existence of unbounded orbits (Fermi acceleration) in the elastic model, and find regular and chaotic behavior in the inelastic cases. We also examine trajectories wherein the particle experiences an infinite number of collisions in a finite time i.e., the phenomenon of inelastic collapse. We address these “sticking solutions” and their relation to both the overall dynamics and the phenomenon of self-reanimating chaos. Additionally, we investigate the long-term behavior of the system as a function of both initial conditions and parameter values. We find novel bifurcation phenomena not seen in the sinusoidal model. Our investigations reveal that, although the piecewise linear bouncer is a simplified version of the sinusoidal model, it captures essential features of the latter and also exhibits behavior unique to the discontinuous dynamics.

4:42PM J42.00012 Nonlinear Dynamics and Thermodynamics of a One-Dimensional Plasma in Simulation, PANKAJ KUMAR, BRUCE MILLER, Texas Christian Univ — We report on the results of a simulation study of the nonlinear dynamics and the thermodynamics of a single-component one-dimensional plasma with periodic boundary conditions. For a system of the plasma with three particles, we plot the Poincare maps and calculate the largest Lyapunov exponents. The results indicate that the three-particle system exhibits interesting dynamics with the phase-space containing periodic, quasiperiodic, as well as chaotic regions for different initial conditions. Special periodic orbits have been identified and their stabilities have been examined for the three-particle system. The behavior of the system in the thermodynamic limit has been simulated using large versions of the system and the dependences of the pressure, the coupling strength and the largest Lyapunov exponent on the average per-particle kinetic energy are presented. The results of the thermodynamic-limit simulations indicate that the net pressure is equal to the kinetic pressure for all temperatures and there is no phase transition.

4:54PM J42.00013 Evolution of a One-dimensional, Two Component, Universe, YUI SHIOZAWA, BRUCE MILLER, Texas Christian Univ, JEAN-LOUIS ROUET, Universite d’Orleans — While the universe we observe today exhibits local filament-like structures, with stellar clusters and large voids between them, the primordial universe is believed to have been nearly homogeneous with slight variations in matter density. To understand how the observed hierarchical structure was formed, researchers have developed a one-dimensional analogue of the universe that can simulate the evolution of a large number of matter particles. Investigations to date demonstrate that this model reveals structure formation that shares essential features with the three-dimensional observations. In the present work, we have expanded on this concept to include two species of matter, specifically dark matter and luminous matter. In our simulation, luminous matter is treated in a way that loses energy in interaction with itself. The results of the simulations clearly show the formation of a Cantor set like multifractal pattern over time in configuration space as well as in phase space. In contrast with most earlier studies, mass-orientation methods for computing the multifractal dimensions were performed on various subsets of the matter distribution in order to understand the bottom-up structure formation.

5:06PM J42.00014 Cosmology in One Dimension: Fractal Dimensions from Mass Oriented Partitions, BRUCE MILLER, Texas Christian University, JEAN-LOUIS ROUET, Universite d’Orleans, YUI SHIOZAWA, Texas Christian University — The distribution of visible matter in the universe has its origin in the weak fluctuations of density that existed at the epoch of recombination. The hierarchical distribution of the present universe, with its galaxies, clusters and super-clusters of galaxies indicates the absence of a natural length scale. Numerical simulations of a one-dimensional system permit us to closely follow the evolution stage with an initial perturbation in the Hubble flow. The limitation to one dimension removes the necessity to make approximations in calculating the gravitational field and the system dynamics. It is then possible to accurately follow the trajectories of particles for a long time. The simulations show the emergence of a self-similar hierarchical structure in both the phase space and the configuration space and invite the implementation of a multifractal analysis. Here we apply four different methods for computing generalized fractal dimensions Dq of the distribution of particles in configuration space. We first employ the conventional methods based on partitions of equal size and then less familiar methods based on partitions of equal mass. We show that the latter are superior for computing generalized dimensions for indices q < −1 which characterize regions of low density.

Tuesday, March 3, 2015 2:30PM - 5:18PM
Session J43 DPOLY GSOFT: Focus Session: Manipulating Glasses: Mechanics 214C - Daniel Sussman, University of Pennsylvania
Creep experiments were performed for the temperatures ranging from Tg,macroscopic−14°C to Tg,macroscopic+19°C. Time temperature superposition and time thickness superposition were applied to create reduced creep curves, and those were compared with macroscopic data [J. Non-Cryst. Solids. 2002, 307, 790-801]. The results showed that the time temperature superposition was applicable in the glassy relaxation regime to the steady-state plateau regime. However in the long time response of the creep compliance, time thickness superposition failed due to the thickness dependence on the steady-state plateau.

It was observed that the steady state compliance increased with film thickness. The thickness dependence on the plateau stiffening followed a power law of $D_{\text{plateau}} \propto h^{4.16}$, which is greater than observed in organic polymers where the exponents observed range from 0.83 to 2.0 [Macromolecules. 2012, 45 (5), 2453-2459].

1 National Science Foundation Grant No. CHE 1112416 and John R. Bradford Endowment at Texas Tech

3:18PM J43.00003 Effect of temperature on segmental mobility is reduced, but not eliminated during constant strain rate deformation of poly(methyl methacrylate) glasses1. KELLY HEBERT, BENJAMIN BENDING, JOSH RICCI, M.D. EDIGER, Univ of Wisconsin, Madison — Deformation of polymer glasses is typically nonlinear and not understood at a molecular level. During deformation, segmental motion in polymer glasses can be accelerated by over a factor of 1000. While temperature has a big impact on the segmental motion of polymer glasses in the absence of deformation, some workers suggest that segmental mobility in polymer glasses undergoing deformation should be independent of temperature. We have measured segmental mobility in poly(methyl methacrylate) glasses during constant strain rate deformation at four different temperatures using a probe reorientation method. We find that during deformation, the dependence of segmental mobility on temperature is significantly reduced, though not eliminated. This is in qualitative agreement with the work of Chen and Schweizer. We also find that the KWW $\beta$ parameter increases during deformation, indicating a narrower distribution of segmental relaxation times. At a given strain rate, this increase of the KWW $\beta$ parameter is larger at lower temperature.

1 We thank the National Science Foundation (DMR-1404614) for support of this research.

3:30PM J43.00004 Thermally Induced Deformation in Metallic Glass: the Activations and Relaxations1. YUE FAN, Oak Ridge National Laboratory, TAKUYA IWASHITA, TAKESHI EGAMI, University of Tennessee — Thermally induced deformation in metallic glasses was investigated by sampling the potential energy landscape (PEL) and probing the changes in the atomic properties (e.g. energy, displacement, stress). The complete deformation processes consist of two stages: the activation (i.e. trigger, from initial minima to nearby saddle states on PEL), and relaxation (i.e. from saddle states to final minima on PEL). We show that the activation stages are triggered by local rearrangements of a small number of atoms, typically 5 atoms in average. Surprisingly, the individual triggers are invariant of the cooling history or elastic structure of the system. However, the organizations between different trigger centers can be varied and are related to the overall stability of the system. On the other hand, relaxation stages consist of two branches, a localized branch, and a cascade branch. While the localized branch is insensitive to the cooling history the system, the cascade branch is highly related with the processing conditions. In particular, for a faster quenched system, the cascade relaxation is found more prominent than in a slowly quenched system.

1 The work is supported by Department of Energy.

3:42PM J43.00005 An energy landscape description of the mechanical response of model glassy materials1. MINGLEI WANG, KAI ZHANG, MENG FAN, YANHUI LIU, JAN SCHROERS, Yale Univ., MARK SHATTUCK, The City College of the City University of New York, COREY O’HERN, Yale Univ., CENTER FOR RESEARCH ON INTERFACE STRUCTURES AND PHENOMENA TEAM — We perform molecular dynamics simulations of binary Lennard-Jones glasses to determine their mechanical response over a range of cooling rates spanning more than three orders of magnitude. To quantify the mechanical response, we measure the shear and bulk moduli using pure shear and compression deformation modes. To correlate the mechanical response to properties of the energy landscape, we also perform zero-temperature quasistatic pure shear simulations and measure the energy per particle as a function of strain. We show that glasses quenched at slower rates possess more brittle response since they exist in deeper energy minima with wider basins. In contrast, rapidly quenched glasses possess ductile response since they exist in shallow, narrow energy minima, which are easily overcome through applied shear.

1 NSF MRSEC Grant No. DMR-1119826 (K.Z.)
In this talk, I will explore the origin of rigidity of granular solids, and present a new paradigm for emergence of order in these athermal systems. thermal motion provides the mechanism for organization by allowing particles to explore the space of configurations. This well-established paradigm of emergent behavior breaks down for collections of macroscopic objects ranging from grains of sand to asteroids. In this macro-world of particulate systems, thermal motion is absent, and mechanical forces are all important. We lack understanding of the basic, unifying principles that underlie the emergence of order in this world. Behringer, Duke University — Particle systems self-assemble in ways that are sensitive to their environments. Proteins fold, polymers crosslink, and molecular systems form crystals. Granular materials, unlike proteins, polymers or molecules, are not sensitive to temperature, and will only form new structures when they are driven. This raises the question of how a granular state depends on the preparation protocol, and an even more basic question of what is needed to specify a granular state. I will focus on granular systems near jamming, where key state variables include the density and stresses. Systems of frictionless grains are jammed for \( \phi > \phi^* \). For frictional grains the picture changes. For a given strain amplitude, the deformation of the material involves localized plastic events that were identified based on the relative displacement of atoms before and after the shear transformation. We found that the density profiles of cage jumps decay away from the inclusion, which correlates well with the radial dependence of the local deformation of the material. At the same strain amplitude, the plastic deformation becomes more pronounced in the cases of weakly damped dynamics or large time scales of the shear transformation. We showed that the density profiles can be characterized by the universal function of the radial distance multiplied by a dimensionless factor that depends on the friction coefficient and the time scale of the shear event.

**2:30PM J44.00001 Self-assembly and the Formation of Structure in Granular Materials**

ROBERT BEHRINGER, Duke University — Particle systems self-assemble in ways that are sensitive to their environments. Proteins fold, polymers crosslink, and molecular systems form crystals. Granular materials, unlike proteins, polymers or molecules, are not sensitive to temperature, and will only form new structures when they are driven. This raises the question of how a granular state depends on the preparation protocol, and an even more basic question of what is needed to specify a granular state. I will focus on granular systems near jamming, where key state variables include the density and stresses. Systems of frictionless grains follow the Liu-Nagel\(^1\) scenario of jamming, with a lowest packing fraction, \( \phi_J \), such that any system with \( \phi < \phi_J \) is unjammed, and all isotropic states (shear stress \( \tau = 0 \)) are jammed for \( \phi > \phi_J \). For frictional grains the picture changes. For a given \( \phi \) in the range \( \phi_S < \phi < \phi_J \) it is possible to have stress-free (un jammed) states, highly anisotropic fragile states, and robustly jammed states. The fragile and strongly jammed states form spontaneously in response to shear. By inference, \( \phi_S \) is not a state variable, but recent experiments\(^2\) indicate that the non-rattler fraction, \( J_{NR} \), is. In \( \phi_S < \phi < \phi_J \) the system response is inherently non-linear; under cyclic shear, the system self-organizes to new steady states via a process that resembles thermal activation, with shear stress replacing energy\(^3\). The activation is provided by shear strain. We observe similar relaxation under cyclic compression. An important question is, what is (are) the organizing principle(s) which govern jamming by shear, and systematic reorganization under cyclic driving? 1. Liu, A. & S. Nagel, Nature 396, 21 (1998). 2. **3:06PM J44.00002 Emergent Behavior in the Macro-World: Rigidity of Granular Solids**

BULBUL CHAKRABORTY, Brandeis Univ — Diversity in the natural world emerges from the collective behavior of large numbers of interacting objects. The origin of collectively organized structures over the vast range of length scales from the subatomic to colloidal is the competition between energy and entropy. Thermal motion provides the mechanism for organization by allowing particles to explore the space of configurations. This well-established paradigm of emergent behavior breaks down for collections of macroscopic objects ranging from grains of sand to asteroids. In this macro-world of particulate systems, thermal motion is absent, and mechanical forces are all important. We lack understanding of the basic, unifying principles that underlie the emergence of order in this world. In this talk, I will explore the origin of rigidity of granular solids, and present a new paradigm for emergence of order in these athermal systems.

3:30PM J45.00006 Bulk Elastic Fingering in Soft Materials, BAUDOUIN SANTYVES, Harvard University, JOHN BIGGINS, Cambridge University, ZHIYAN WEI, Stanford University, SERGE MORA, Montpellier 2 University, L. MAHADEVAN, Harvard University, ELIS-ABETH BOUCHAUD, ESPCI-PARISTECH, HARVARD UNIVERSITY TEAM, ESPCI-PARISTECH COLLABORATION, CAMBRIDGE UNIVERSITY COLLABORATION — Systematic experiments have been performed in purely elastic polycrylamide gels in Hele-Shaw cells. We have shown that a bulk fingering instability arises in the highly deformable confined elastomers. A systematic study shows that surface tension is not relevant. This instability is sub-critical, with a clear hysteretic behavior. Our experimental observations have been compared very favorably to theoretical and finite element simulations results. In particular, the instability wavelength and the critical front advance have been shown to be proportional to the distance between the two glass plates constituting the cell. A very important feature is that elasticity doesn’t influence this lengthscale, making this instability very generic. We will also show some new results on an elastic counterpart experiment of the famous Saffman-Taylor experiment, where we push a soft gel in a stiff one.

3:42PM J45.00007 Mechanical properties of 3D printed warped membranes, ANDREJ KOSMRLJ, KECHAO XIAO, JAMES C. WEAVER, JOOST J. VLASSAK, DAVID R. NELSON, Harvard University — We explore how a frozen background metric affects the mechanical properties of solid planar membranes. Our focus is on a class of "warped membranes" with a preferred random height profile characterized by random Gaussian variables \( h(q) \) in Fourier space with zero mean and variance \( \langle |h(q)|^2 \rangle \propto q^{-4} \). It has been shown theoretically that in the linear response regime, this quenched random disorder increases the effective bending rigidity, while the Young’s and shear moduli are reduced. Compared to flat plates of the same thickness \( t \), the bending rigidity of warped membranes is increased by a factor \( \sim h_0/t \) while the in-plane elastic moduli are reduced by \( \sim 1/h_0 \), where \( h_0 = \sqrt{\langle |h(x)|^2 \rangle} \) describes the frozen height fluctuations. Interestingly, \( h_0 \) is system size dependent for warped membranes characterized with \( m > 2 \). We present experimental evidence of these predictions, using warped membranes prepared via high resolution 3D printing.

3:54PM J45.00008 Localization in an Idealized Heterogeneous Elastic Sheet, BEKELE GURMESSA, ANDREW B. CROLL, North Dakota State Univ — Localized deformation is ubiquitous in many natural and engineering materials. Often times such deformations are associated to non-homogeneous strain fields in the materials. In this work we demonstrate the response of idealized non-homogeneous elastic sheets to uniaxial compression. The idealized patterned surface layers are created selective ultraviolet/ozone (UVO) treatment of the top surface of polydimethylsiloxane (PDMS) using TEM grid mask. By controlling the exposure time of the UVO, samples ranging from continuous thin films to sets of isolated small plates were created. We show how local strains vary with location in a patterned sample, leading to a complex localization process even at low strains. We also see that continuous regions form isotropic undulations upon compression which persist to high strains, well beyond where localization is observed in the patterned regions. Despite the complexity, the localized deformation profile can be adequately described with a simple elastic model when appropriate local boundary conditions are considered.

4:06PM J45.00009 Primary and secondary bifurcations in compressed elastomeric bilayers with small modulus contrast, ANESIA AUGUSTE, University of Massachusetts Amherst, LIUHUA JIN, ZHIGANG SUO, Harvard University, RYAN C. HAYWARD, University of Massachusetts Amherst — Elastic materials undergo various kinds of elastic instabilities when subjected to compression. The primary bifurcation behavior for a stiff thin film on a thick soft substrate is wrinkling, whereas for a homogeneous material it is creasing. While ideal bilayered systems with large contrasts in modulus and thickness are well understood, many system in nature and engineering contexts are far from this simple case. We have developed an experimental system to systematically vary the modulus contrast, complemented by finite element simulations, to study the primary and secondary bifurcations in compressed bilayers. We find that below a certain strain threshold bilayers can be stable to both wrinkles and creases. For slightly larger contrasts, the primary bifurcation is wrinkling but there are two distinct types of secondary bifurcations: (1) wrinkles that transition into creases without period-doubling; and (2) wrinkles to creases preceded by period doubling. Understanding surface instabilities in such non-ideal bilayer systems provides important insights on the behavior of biological tissues and other systems with a small modulus contrast.

4:18PM J45.00010 The Structural Change of Buckling Depending on the Directional Mechanical Heterogeneity of Top Thin Films, DOKYEONG KWON, Seoul Natl Univ, HYOSEON SUH, University of Chicago, DOMIN KIM, KOOKHEON CHAR, Seoul Natl Univ — Buckling of thin films on elastomeric substrates such as polydimethylsiloxane (PDMS) is the well-known phenomenon in buckling instability originating from the moduli mismatch between a substrate and a thin film placed on the top. Recently, many studies on the microstructure created by the buckling with flat top films have been reported and physics behind them has almost been well received. However, only a few work has been done on the buckling structure with micropatterned top films and buckling mechanics for patterned top films-PDMS bilayers has not yet been studied in detail. Here, we present the buckling of mechanically heterogeneous, patterned top films placed on top of elastomeric PDMS substrates. Mechanically heterogeneous top films were prepared by polystyrene (PS) films with topographic patterns. Buckling instability was induced by applying mechanical stresses to the PS-PDMS bilayer. Resulting buckling structure showed the structural change depending on the alignment of the top films with respect to the buckling direction. The structural change was analyzed with finite element method calculation, giving insights on the buckling mechanics of top film with complicated patterns placed on PDMS substrates.

4:30PM J45.00011 High Aspect Ratio Wrinkles, YU-CHENG CHEN, ALFRED CROSBY, University of Massachusetts Amherst — Buckling-induced surface undulations are widely found in living creatures, for instance, gut villi and the surface of flower petal cells. These undulations provide unique functionalities with their extremely high aspect ratios. For the synthetic systems, sinoidal wrinkles that are induced by buckling a thin film attached on a soft substrate have been proposed to many applied applications. However, the impact of the synthetic wrinkles have been restricted by limited aspect ratios, ranging from 0 to 0.35. Within this range, wrinkled aspect ratio is known to increase with increasing compressive strain until a critical strain is reached, at which point wrinkles transition to localizations, such as folds or period doublings. Inspired by the living creatures, we propose that wrinkles be stabilized in high aspect ratio by manipulating the strain energy in the substrate. We experimentally demonstrate this idea by forming a secondary crosslinking network in the wrinkled surface and successfully achieve aspect ratio as large as 0.8. This work not only provides insights for the mechanism of high aspect ratio structures seen in living creatures, but also demonstrates significant promise for future wrinkle-based applications.

4:42PM J45.00012 Competition between adhesion and inertia during stick-slip peeling of Pressure Sensitive Adhesives, M.-J. DALBE, Laboratoire de Physique de l’ENS de Lyon, CNRS, Université de Lyon, France, R. VILLE, Laboratoire FAST, CNRS, Université Paris-Sud, Orsay, France, M. CICCOTTI, Laboratoire PPMD/SIMM, CNRS, ESPCI ParisTech, Paris, France, P.-P. CORTET, FAST, S. SANTUCCI, Laboratoire de Physique de l’ENS de Lyon, L. VANEL, Institut Lumière Matière, CNRS, Université de Lyon, France — We consider the classical problem of the unstable stick-slip dynamics often observed when peeling a pressure sensitive adhesive, quantifying for the first time experimentally the influence of the peeling angle. This instability is known to be the consequence of a decreasing fracture energy of the adhesive-substrate joint over a certain range of driving velocity: we focus here on the important case where the instability develops at large driving velocity. We show that below a certain rate of film slip, the instability is sub-critical, with a clear hysteretic behavior. Our experimental observations have been compared very favorably to a theoretical model and finite element simulations results. In particular, the instability wavelength and the critical front advance have been shown to be proportional to the distance between the two glass plates constituting the cell. A very important feature is that elasticity doesn’t influence this lengthscale, making this instability very generic. We will also show some new results on an elastic counterpart experiment of the famous Saffman-Taylor experiment, where we push a soft gel in a stiff one.
4:54PM J45.00013 Influence of large strain rheology on the peeling performances of Pressure Sensitive Adhesives. Richard Villey, Matteo Ciccotti, Costantino Creton, Laboratoire SIMM, CNRS, ESPCI ParisTech, Université Pierre et Marie Curie, PSL Research University, Paris, France; Pierre-Philippe Cortet, Laboratoire FAST, CNRS, Université Paris-Sud, Orsay, France; David J. Yarusso, 3M Company, 3M Center, 230-1D-15, St. Paul, MN, 55144-1000, USA — The dependence of adhesion energy of Pressure Sensitive Adhesives (PSA) on peeling velocity reduces to a master curve using a time-temperature superposition principle, usually verified by the linear rheology of polymers. This result has guided models predicting peeling energy of PSA to consider the small strain rheology of the glue only, despite it can experience very large strains before debonding. The argument of the time-temperature superposition principle can actually also be applied to large strains and is thus not a stringent one. To clarify the role of large strain rheology during the peeling of PSA, we present experiments on commercial and custom-made tapes supplied by 3M Company. Small and large strain rheology differences are obtained by changing the glass transition temperature, the cross-linking density and the density of entanglements, yet remaining close to commercial PSA. The rheology influence is decoupled from geometrical effects, by examining the nontrivial dependence of the adhesion energy on the peeling angle. Finally, adhesion energy measurements and visualizations of the process zone, over a large range of peeling velocities, are discussed, in the perspective of building a model for the adherence considering the complete rheology of the glue.

5:06PM J45.00014 What can cracked polymer do? Kexin Jiao, Chuanhong Zhou, Punit Kohli, Department of Chemistry and Biochemistry, Southern Illinois University Carbondale, Anish Pou德尔, Tsuchin Chi, College of Engineering, Southern Illinois University Carbondale — Buckling, delamination, and cracking are very well-known phenomena observed in most thin films. They were theoretically explained by the existence of mechanical instability due to the residue stress generated when a thin film is deposited on substrates or undergoing environmental stress. Buckled structures at micro- or nano-scale have been of great interests and have been used extensively in many applications including particles self-assembling, surface wettability modification, and micro-electronic device fabrication. However, peeling of a layer from a substrate due to delamination or fractures on a thin film due to cracking is mostly taken as an undesirable result. Therefore, strategies are inspired for preventing or removing these often undesired structures. We found that after being heated above its decomposition temperature and then cooled to room temperature, a PDMS thin film showed micro-fibers of 100μm width and up to 1.5 cm in length. By studying the formation mechanism, control of the dimensions and of the growth pattern on a substrate for PDMS micro-fibers were realized. Giving credit to their high flexibility and optical transparency, a PDMS micro-fiber was utilized in high resolution near field imaging achieved by attaching a micro-lens on the fiber. Interestingly, a surface covered by PDMS micro-fibers will turn from superhydrophobic into superhydrophilic by further heating providing potential applications in surface wettability modification. In future, we will investigate and simulate the growth of PDMS micro-fiber and look for more possible applications.

5:18PM J45.00015 Formation of 3He droplets in dilute 3He-4He solid solutions. Chaohuan Huan, University of Florida, Gainesville, USA; Don Canoletta, University of Massachusetts, Amherst, USA; Sung Kim, Liang Yin, Jiang-Sheng Xia, Neil Sullivan, University of Florida, Gainesville, USA — We review the different stages of the formation of 3He droplets in dilute 3He-4He solutions. The studies are interesting because the phase separation in isotopic helium mixtures is a first-order transition with a conserved order parameter. The rate of growth of the droplets as observed in NMR studies [1] is compared with the rates expected for homogeneous nucleation followed by a period of coarsening known as Ostwald ripening.

Session J46 DBIO: Invited Session: Physics of Proteins: Integrating Computation with Experiment 217A - Wouter Hoff, Oklahoma State University

2:30PM J46.00001 Protein Folding Transition Paths: Single Molecule Experiments, Theory and Simulations. William Eaton, Laboratory of Chemical Physics, NIDDK, NIH, Bethesda, MD — The transition-path is the tiny fraction of an equilibrium, single-molecule trajectory when the transition over a free-energy barrier occurs between two states. In the case of protein folding, the distribution of transition paths contains all of the mechanistic information on how a protein folds and unfolds. Transition path distributions can now be predicted for fast folding proteins by all-atom molecular dynamics simulations and by an Ising-like theoretical model [1,2]. Experimental information on transition paths should provide the most demanding test of both simulations and theoretical models. However, transition-paths for barrier crossings have never been observed experimentally for any molecular system in solution. Because it is a single molecule property, even determining the average transition-path time is challenging. In this presentation, I will discuss how we use measurements of Förster resonance energy transfer in single molecule fluorescence experiments and a photon-by-photon analysis to measure average transition path times for proteins of different topology and folding rate coefficients using the Gopich/Szabo maximum likelihood method [3,4]. These results, which are surprisingly interesting, are just the first, but important, steps toward measuring intra-molecular distances during individual transition paths. 3:06PM J46.00002 Exploring the active site structure of photoreceptor proteins by Raman optical activity. Masashi Unno, Saga University — Understanding protein function at the atomic level is a major challenge in a field of biophysics and requires the combined efforts of structural and functional methods. We use photoreceptor proteins as a model system to understand in atomic detail how a chromophore and a protein interact to sense light and send a biological signal. A potential technique for investigating molecular structures is Raman optical activity (ROA), which is a spectroscopic method with a high sensitivity to the structural details of chiral molecules. However, its application to photoreceptor proteins has not been reported. Thus we have constructed ROA spectrometer using near-infrared (NIR) laser excitation at 785 nm. The NIR excitation enables us to measure ROA spectra for a variety of biological samples, including photoreceptor proteins, without fluorescence from the samples. In the present study, we have applied the NIR-ROA to bacteriorhodopsin (BR) and photoactive yellow protein (PYP). BR is a light-driven proton pump and contains a protonated Schiff base of retinal as a chromophore. PYP is a blue light receptor, and this protein has the 4-hydroxycinnamyl chromophore, which is covalently linked to Cys69 through a thiolester bond. We have successfully obtained the ROA spectra of the chromophore within a protein environment. Furthermore, calculations of the ROA spectra utilizing density functional theory provide detailed structural information, such as data on out-of-plane distortions of the chromophore. The structural information obtained from the ROA spectra includes the positions of hydrogen atoms, which are usually not detected in the crystal structures of biological samples.

experimental and computational approach to discover novel chemoceptor molecules and compare their binding features, as well as the conformational changes they produce. We first used molecular docking to computationally screen a large chemical library and tested binding strengths of the top-ranking molecules for the E. coli chemoreceptor Tar. Chemotactic properties of the binding molecules were then studied using a specially designed microfluidic device. Novel attractant and antagonist molecules were identified that bind directly with the E. coli chemoreceptor Tar. Molecular dynamics simulations showed that attractant and antagonist binding result in distinct conformational changes in Tar. Differences of antagonist and attractant binding suggest that molecules lacking triggering interaction with the receptor behave as antagonist. For Tar, the triggering interaction is mediated by the hydrogen bonds formed between a donor group in the attractant and the main-chain carbonyls in the fourth helix of Tar. This "bind-and-trigger" mechanism of receptor signaling is verified experimentally by converting an antagonist into an attractant when introducing an NH group into the antagonist compound. Similar conformational changes were also observed in the E. coli Tar system.

cells can be reprogrammed to become pluripotent stem cells [1]. The possible cell fates can be modeled as attractors in a dynamical system, the "epigenetic

both cellular differentiation and reprogramming can be described in the landscape picture as motion from one attractor to another attractor. We perform Monte Carlo simulations in a simple model of the landscape [2]. This model is based on spin glass theory and it can be used to construct a simulated epigenetic landscape starting from the experimental genomic data. We re-analyse data from several cell reprogramming experiments [3-6] and compare with our simulation results. We find that the model can reproduce some of the main features of the dynamics of cell reprogramming.

Collective Calcium Signaling of Defective Multicellular Networks , GARRETT POTTER, BO SUN, Oregon State University — A communicating multicellular network processes environmental cues into collective cellular dynamics. We have previously demonstrated that, when excited by extracellular ATP, fibroblast monolayers generate correlated calcium dynamics modulated by both the stimuli and gap junction communication between the cells. However, just as a well-connected neural network may be compromised by abnormal neurons, a tissue monolayer can also be defective with cancer cells, which typically have down regulated gap junctions. To understand the collective cellular dynamics in a defective multicellular network we have studied the calcium signaling of co-cultured breast cancer cells and fibroblast cells in various concentrations of ATP delivered through microfluidic devices. Our results demonstrate that cancer cells respond faster, generate singular spikes, and are more synchronous across all stimuli concentrations. Additionally, fibroblast cells exhibit persistent calcium oscillations that increase in regularity with greater stimuli. To interpret these results we quantitatively analyzed the immunostaining of purigenic receptors and gap junction channels. The results confirm our hypothesis that collective dynamics are mainly determined by the availability of gap junction communications.

Microfluidic study of environmental control of genetic competence in Strept-
coccus mutans1. MINJUN SON, SEYEDEHDELARAM GHOREISHILANGROUDI, Department of Physics, University of Florida, SANG-JOON AHN, ROBERT BURNE, Department of Oral Biology, University of Florida, STEPHEN HAGEN, Department of Physics, University of Florida — The bacterial pathogen Streptococcus mutans has the ability to enter a transient state of genetic competence in which it can integrate exogenous DNA. It regulates the competent state in response to several environmental inputs that include two quorum sensing peptides (CSP and XIP) as well as pH and other variables. However the interplay of these variables in regulating the competent state is poorly understood. We are using microfluidics to isolate and control environmental inputs and examine how the competence regulatory circuit responds at the single cell level. Our studies reveal that the pH of the growth environment plays a critical role in determining how cells respond to the quorum sensing signals: The response to both peptides is sharply tuned to a narrow window of near-neutral pH. Within this optimal pH range, a population responds unimodally to a XIP stimulus, and bimodally to CSP; outside this range the response to both signals is suppressed. Because a growing S. mutans culture acidifies its medium, our findings suggest that the passage of the pH through the sensitivity window transiently activates the competence circuit. In this way a sharply tuned environmental response gives S. mutans fine control over the duration of its competent state.

3:30PM J47.00004 Discovering novel ligands for understanding molecular mechanism of bacteria chemotaxis , LUHUA LAI, Peking University — In order to understand the molecular mechanism of bacteria chemotaxis, we used a combined experimental and computational approach to discover novel chemoceptor molecules and compare their binding features, as well as the conformational changes they produce. We first used molecular docking to computationally screen a large chemical library and tested binding strengths of the top-ranking molecules for the E. coli chemoreceptor Tar. Chemotactic properties of the binding molecules were then studied using a specially designed microfluidic device. Novel attractant and antagonist molecules were identified that bind directly with the E. coli chemoreceptor Tar. Molecular dynamics simulations showed that attractant and antagonist binding result in distinct conformational changes in Tar. Differences of antagonist and attractant binding suggest that molecules lacking triggering interaction with the receptor behave as antagonist. For Tar, the triggering interaction is mediated by the hydrogen bonds formed between a donor group in the attractant and the main-chain carbonyls in the fourth helix of Tar. This "bind-and-trigger" mechanism of receptor signaling is verified experimentally by converting an antagonist into an attractant when introducing an NH group into the antagonist compound. Similar conformational changes were also observed in the E. coli Tar system.

3:42PM J47.00005 Dynamic information routing in complex networks, Center for Physics and Biology, Rockefeller University, MARC TIMME, Max-Planck Institute for Dynamics and Self-Organization, DEMIAN BATTLAGLIA, Institute of Systems Neuroscience, Aix-Marseille University — Flexible information routing fundamentally underlies the function of many biological and artificial networks. Yet, how information may be specifically communicated and dynamically routed in these systems is not well understood. Here we demonstrate that collective dynamical states systematically control patterns of information sharing and transfer in networks, as measured by delayed mutual information and transfer entropy between activities of a network’s units. For oscillatory networks we analyze how individual unit properties, the connectivity structure and external inputs all provide means to flexibly control information routing. For multi-scale, modular architectures, we resolve communication patterns at all levels and show how local interventions within one sub-network may remotely control the non-local network-wide routing of information. This theory helps understanding information routing patterns across systems where collective dynamics co-occurs with a communication function.

3:54PM J47.00006 Strain induced critical behavior in athermal biopolymer networks, ABHINAV SHARMA, Georg August University, Gottingen, ALBERT LICUP, ROBBIE RENS, MICHAEL SHEINMAN, Vrije Universiteit Amsterdam, KARIN JANSSEN, GIJSE KOENDERINK, AMOLF, Amsterdam, FRED MACKINTOSH, Vrije Universiteit Amsterdam — Biopolymer networks exhibit highly interesting mechanical behavior. An instructive model system is that of a network composed of rope-like filaments—zero resistance to compression but finite resistance to stretching. For networks with connectivity below Maxwell point, there is no elastic modulus for small deformations. However, when networks are subjected to an external strain, stiffness emerges spontaneously beyond a critical strain. We demonstrate that the spontaneous emergence of elasticity is analogous to a continuous phase transition. The critical point is not fixed but depends on the geometry of the underlying network. The elastic behavior near the critical point can be described analogous to that of Magnetization in ferromagnetic material near the curie temperature. Surprisingly, the critical exponents are independent of the dimensionality and depend only on the average connectivity in the network. By including bending interactions in the rope network, we can capture the mechanical behavior of biologically relevant networks. Bending rigidity acts as a coupling constant analogous to the external magnetic field in a ferromagnetic system. We show that nonlinear mechanics of collagen are successfully captured by our framework of regarding nonlinear mechanics as a critical phenomenon.

4:06PM J47.00007 Pattern Learning, Damage and Repair within Biological Neural Networks, THEODORE SIU, KATE FITZGERALD O’NEILL, TROY SHINBROT, Rutgers Univ — Traumatic brain injury (TBI) causes damage to neural networks, potentially leading to disability or even death. Nearly one in ten of these patients die, and most of the remainder suffer from symptoms ranging from headaches and nausea to convulsions and paralysis. In vitro studies to develop treatments for TBI have limited in vivo applicability, and in vitro therapies have even proven to worsen the outcome of TBI patients. We propose that this disconnect between in vitro and in vivo outcomes may be associated with the fact that in vitro tests assess indirect measures of neuronal health, but do not investigate the actual function of neuronal networks. Therefore in this talk, we examine both in vitro and in vivo neuronal networks that actually perform a function: pattern identification. We allow the networks to execute genetic, Hebbian, learning, and, additionally, we examine the effects of damage and subsequent repair within our networks. We show that the length of repaired connections affects the overall pattern learning performance of the network and we propose therapies that may improve function following TBI in clinical settings.

4:18PM J47.00008 In silico evolution of oscillatory dynamics in biochemical networks, MD ZULFIKAR ALI, Clark University, NED S. WINGREEN, Princeton University, RANJAN MUKHOPADHYAY, Clark University — We are studying in silico evolution of complex, oscillatory network dynamics within the framework of a minimal mutational model of protein-protein interactions. In our model we consider two different types of proteins, kinase (activator) and phosphatase (inhibitor). In our model, each protein can either be phosphorylated (active) or unphosphorylated (inactive), represented by binary strings. Active proteins can modify their target based on the Michaelis-Menten kinetics of chemical equation. Reaction rate constants are directly related to sequence dependent protein-protein interaction energies. This model can be studied for non-trivial behavior e.g. oscillations, chaos, multiple stable states. We focus here on biochemical oscillators; some questions we will address within our framework include how the oscillatory dynamics depends on number of protein species, connectivity of the network, whether evolution can readily converge on a stable oscillator if we start with random initial parameters, neutral evolution with additional protein components and general questions of robustness and evolvability.

4:30PM J47.00009 Uncertainty of Prebiotic Scenarios: The Case of the Non-Enzymatic Reverse Tricarboxylic Acid Cycle, DMITRY ZUBAREV, DMITRIJ RAPPOPORT, ALAN ASPURU-GUZIK, Harvard University — We consider the much discussed hypothesis of the primordial nature of the non-enzymatic reverse tricarboxylic acid (rTCA) cycle and describe a modeling approach that quantifies the uncertainty of this hypothesis due to the combinatorial aspect of the constituent chemical transformations. Our results suggest that a) rTCA cycle belongs to a degenerate optimum of auto-catalytic cycles, and b) the set of targets for the investigations of the origin of the common metabolic core should be significantly extended.

This work was supported by a grant from the Simons Foundation (SCOL 291937, Dmitry Zubarev).

4:42PM J47.00010 Extracting Hidden Hierarchies in 3D Distribution Networks, CARL MODES, MARCELO MAGNASCO, Rockefeller University, ELÉNI KATIFORI, Max Planck Institute for Dynamics and Self-Organization — Natural and man-made transport webs are frequently dominated by dense sets of nested cycles. The architecture of these networks—the topology and edge weights—determines how efficiently the networks perform their function. Yet, the set of tools that can characterize such a weighted cycle-rich architecture in a physically relevant, mathematically compact way is sparse. In order to fill this void, we have developed a new algorithm that rests on an abstraction of the physical ‘tiling’ in the case of a two dimensional network to an effective tiling of an abstract surface in space that the network may be thought to sit in. Generically these abstract surfaces are richer than the plane and upon sequential removal of the weakest links by edge weight, neighboring tiles merge and a tree characterizing this merging process results. The properties of this characteristic tree can provide the physical and topological data required to describe the architecture of the network and to build physical models. This new algorithm can be used for automated phenotypic characterization of any weighted network whose structure is dominated by cycles, such as mammalian vasculature in the organs, the root networks of clonal colonies like quaking aspen, or the force networks in jammed granular matter.

4:54PM J47.00011 Dynamic maintenance of stochastic molecular clusters on cell membranes, ANDREW MUGLER, Purdue University, MARTIJN WEHRENS, PIETER REIN TEN WALDE, FOM Institute AMOLF — Clustering of molecules on cell membranes is a widely observed phenomenon. A key example is the oncoprotein Ras. Maintenance of Ras clusters has been linked to proper Ras signaling. Yet, the mechanism by which Ras clusters are maintained remains unclear. Recently it was discovered that activated Ras promotes further Ras activation. We show using particle-based simulation that this positive feedback link is sufficient to produce persistent clusters of active Ras molecules via a dynamic nucleation mechanism. The particle statistics are consistent with experimental observations. Interestingly, our model does not support a Turing regime of macroscopic reaction-diffusion patterning. This means that the clustering we observe is a purely stochastic effect, arising from the coupling of the positive feedback network with the discrete nature of individual molecules. These findings underscore the importance of stochastic and dynamic properties of reaction diffusion systems for biological behavior.
5:06PM J47.00012 Sensing multiple ligands with single receptor1. VIJAY SINGH, ILYA NEMENMAN, Emory University — Cells use surface receptors to measure concentrations of external ligand molecules. Limits on the accuracy of such sensing are well-known for the scenario where concentration of one molecular species is being determined by one receptor [Endre]. However, in more realistic scenarios, a cognate (high-affinity) ligand competes with many non-cognate (low-affinity) ligands for binding to the receptor. We analyze effects of this competition on the accuracy of sensing. We show that maximum-likelihood statistical inference allows determination of concentrations of multiple ligands, cognate and non-cognate, by the same receptor concurrently. While it is unclear if traditional biochemical circuitry downstream of the receptor can implement such inference exactly, we show that an approximate inference can be performed by coupling the receptor to a kinetic proofreading cascade. We characterize the accuracy of such kinetic proofreading sensing in comparison to the exact maximum-likelihood approach.

5:18PM J47.00013 Dynamic phases in control and information processing biological circuits . SURIYANARAYANAN VAIKUNTHANATHAN, University of Chicago — Recent work using the mathematical framework of large deviation theory has shown that fluctuations about the steady state can have a particularly rich structure even in extremely simple non-equilibrium systems [Phys. Rev. E. 89, 062108, 2014]. In certain instances the fluctuations can encode the presence of a dynamical phase with properties distinct from those of the steady state of the system. The transition between these two regimes is akin to a first order thermodynamic phase transition. Specifically, it implies an extreme sensitivity of the system to changes in certain sets of parameters. I will show that such dynamical phase transitions can serve as a general organizing principle to understand biological circuits that are involved in information processing and control. I will focus on two specific examples: adaptation control in E. coli chemotaxis and ultra sensitive response of the E. coli flagella motor, to illustrate these calculations. This work also elucidates the role played by energy dissipation in ensuring control and suggests general guidelines for the construction of robust non-equilibrium circuits that perform various specified functions.

Session J48 DBIO: Focus Session: Physics of Cellular Organization

2:30PM J48.00001 Collective Dynamics of Dividing Chemotactic Cells , ANATOLII GELIMSON, RAMIN GOLESTANIAN, Rudolf Peierls Centre for Theoretical Physics, University of Oxford — The large scale behaviour of a population of cells that grow and interact through the concentration field of the chemicals they secrete is studied using dynamical renormalization group methods. The combination of the effective long-range chemotactic interaction and lack of number conservation leads to a rich variety of phase behaviour in the system, which includes a sharp transition from a phase that is controlled by a weakly coupled perturbatively accessible fixed point to a phase controlled by a nonaccessible strong coupling fixed point. For a range of parameters, the perturbatively accessible fixed point has nontrivial critical exponents.

2:42PM J48.00002 Nature’s rheologists: Lymphatic endothelial cells control migration in response to shear stress , GERALD FULLER, ALEX DUNN, VINAY SURYA, Stanford University — Endothelial cells (ECs) line the inner surface of blood and lymphatic vessels and are sensitive to fluid flow as part of their physiological function. EC organization, migration and vessel development are profoundly influenced by shear stresses, with important implications in cardiovascular disease and tumor metastasis. How ECs sense fluid flow is a central and unanswered question in cardiovascular biology. We developed a high-throughput live-cell flow chamber that models the gradients in wall shear stress experienced by ECs in vivo. Live-cell imaging allows us to probe cellular responses to flow, most notably EC migration, which has a key role in vessel remodeling. We find that most EC subtypes, including ECs from the venous, arterial, and microvascular systems, migrate in the flow direction. In contrast, human lymphatic microvascular ECs (hLMVECs) migrate against flow and up spatial gradients in wall shear stress. Further experiments reveal that hLMVECs are sensitive to the magnitude, direction, and the local spatial gradients in wall shear stress. Lastly, recent efforts have aimed to link this directional migration to spatial gradients in cell-mediated small molecule emission that may be linked to the gradient in wall shear stress.

2:54PM J48.00003 Obstructions Inhibit Long-range Motor Motility in Microtubule Bundles . M.W. GRAMLICH, University of Massachusetts - Amherst — Efficient cellular transport along the cytoskeletal network is essential for cell growth and maintenance. Everything from microtubules to plasma membrane components are transported along the cytoskeletal network. Long-range transport is accomplished by molecular motors carrying cargo along a microtubule network. Recently, the role of the microtubule bundle geometry has begun to be explored. Microtubules bundle together in order to efficiently direct transport. Consequently, bundled microtubules introduce a new set of parameters which affect cellular transport, such as bundle spacing or microtubule polarity. Even previously tested parameters need to be re-considered, such as the role of obstructions. In this talk I will focus on the relationship between obstructions and microtubule polarity, and their affects on long-range transport. Microtubule polarity varies from completely uniform, with all plus-ends pointing in the same direction, to completely random. I will quantitatively show how obstructions inhibit long-range motor motility in any bundle, regardless of the distribution of microtubule polarity within the bundle. However, inhibition of long-range transport is greater in mixed polarity bundles. This result has implications for how cells use microtubule polarity to accommodate obstructions in order to efficiently direct transport.

3:06PM J48.00004 Tackling the single molecule counting problem1. STEVE PRESSE, Indiana University - Purdue University Indianapolis — Protein-protein interactions – that give rise to spatiotemporal organization in the cell – are the basis for most biological processes. Quantitatively understanding these interactions is an essential prerequisite for developing mechanistic models of cell biology. However there is currently no routine answer to “how many proteins of type X are in this complex?” in living cells. Here we discuss methods developed in our group (Geoff Rollins, Kostas Tsekovs) for tackling this “single molecule counting problem” starting from photobleaching data and data from a superresolution microscopy technique called PALM (PhotoActivated Localization Microscopy).

3:18PM J48.00005 C. elegans uses Liquid-Liquid Demixing for the Assembly of Non-Membrane-Bound Compartments. CHRISTOPH A. WEBER, FRANK JUELICHER, Max Planck Institute of the Physics of Complex Systems, ANDRES FELIPE DIAZ DELGADILLO, LOUISE JAWERTH, ANTHONY A. HYMAN, Max Planck Institute of Molecular Cell Biology and Genetics , DEPARTMENT BIOLOGICAL PHYSICS TEAM, HYMAN LAB COLLABORATION — P granules are liquid cytoplasmic RNA/Protein condensates known to determine the germ lineage in Caenorhabditis elegans. They resemble striking similarities with liquid droplets, such as dripping, shearing and wetting. Assuming that P granules are liquid-like we consider how they form in the crowded cytoplasm. Using confocal and light-sheet microscopy, P granule formation in vivo and in vitro is shown to share all hallmarks with a liquid-liquid phase-separation. Specifically, demixing is determined by temperature and concentration, the droplet formation is reversible with respect to temperature quenches and there is evidence for droplet growth due to coalescence and Ostwald-ripening. Liquid-liquid demixing in vivo breaks the paradigmatic view that a molecular machinery is necessary to build up organelles through complex biological pathways. Instead we propose that P granules form following a Flory-Huggins model. Liquid-liquid demixing could also serve as a mechanism for the assembly of non-membrane-bound compartments in other living organisms.
polymerization rate can increase the polymerized-actin content of the patch. We present data for NPF dynamics budding yeast, which confirm some of the
reduced, there is a discontinuous transition from protein pulses to persistent patches. We also find, surprisingly, that in some parameter regimes reducing the
“nucleation-promoting factors” (NPFs) that catalyze actin polymerization, and curvature-generating proteins. We model the dynamics of protein patches in
to bend it, and finally disassemble. The patches contain an initial coat that establishes the endocytic site and binds cargo, polymers of the protein actin,
under Grant R01-GM107667.

5:06PM J48.00012 Pulse Dynamics in Endocytic Protein Patches1, ANDERS CARLSSON, XINXIN WANG, Washington University in St Louis — During the process of endocytosis in yeast, submicron-sized protein patches assemble, exert forces on the membrane
to bend it, and finally disassemble. The patches contain an initial coat that establishes the endocytic site and binds cargo, polymers of the protein actin,
“nucleation-promoting factors” (NPFs) that catalyze actin polymerization, and curvature-generating proteins. We model the dynamics of protein patches in
4:54PM J48.00011 Exploration of locomotion in the ParA/ParB system, LAVISHA JINDAL, ELDON EMBERLY, Simon Fraser University — In many bacteria the ParA/ParB system is responsible for actively segregating DNA during replication. ParB precessively
moves by hydrolyzing DNA bound ParA-ATP forming a depleted ParA region in its wake. Recent in-vitro experiments have shown that a ParB covered bead can
traverse a ParA bound DNA substrate. It has been suggested that the formation of a gradient in ParA leads to diffusion-ratchet like motion of the ParB bead
but its origin and potential consequences requires investigation. We have developed a deterministic model for the in-vitro ParA/ParB system and show that
any amount of spatial noise in ParA can lead to the spontaneous formation of its gradient. The velocity of the bead is independent of this noise but depends
on the scale over which ParA exerts a force on the bead and the scale over which ParB hydrolyzes ParA from the substrate. There is a particular ratio of these
scares at which the velocity is a maximum. We also explore the effects of cooperative vs independent rebinding of ParA to the substrate. Our model shows
how the driving force for ParB originates and highlights necessary conditions for directed motion in the in-vitro system that may provide insight into the in-vivo
behaviour of the ParA/ParB system.

3:54PM J48.00008 Viscoelastic properties of actin networks influence material transport1, SAMANTHA STAM, Biophysical Sciences Graduate Program, University of Chicago, KIMBERLY WEIRICH, James Franck Institute, University of Chicago, MARGARET GARDEL, Department of Physics and James Franck Institute, University of Chicago — Directed flows of cytoplasmatic material are important in a variety of biological processes including assembly of a mitotic spindle, retraction of the cell rear during migration, and asymmetric cell division. Networks of cytoskeletal polymers and molecular motors are known to be involved in these events, but how the network mechanical properties are tuned to perform such functions is not understood. Here, we construct networks of either semiflexible actin filaments or rigid bundles with varying connectivity. We find that solutions of rigid rods, where unimpeded sliding of filaments may enhance transport in comparison to unmoving tracks, are the fastest at transporting network components. Entangled solutions of semiflexible actin filaments also transport material, but the entanglements provide resistance. Increasing the elasticity of the actin networks with crosslinking proteins slows network deformation further. However, the length scale of correlated transport in these networks is increased. Our results reveal how the rigidity and connectivity of biopolymers allows material transport to occur over time and length scales required for physiological processes.

4:06PM J48.00009 Regulation of kinesin-transport by microtubule age and polymerization conditions, JING XU, WINNIE LIANG, Physics, UC Merced, STEPHEN KING, U Central Florida, K. FAYSAL, Physics, UC Merced — Microtubules are fundamental biopolymers in cells, formed via self-assembly (“polymerization”) of tubulin dimers. Microtubule polymerization conditions have been shown to alter the presence of defects in microtubule lattices, including point defects (missing tubulin dimers) and line defects (protofilament disruption). Potential impact of these lattice defects on molecular motor-based transport is not yet understood. Here we investigate the impact of microtubule polymerization conditions on multiple-kinesin transport, using single-molecule-type optical trapping experiments. We find that kinesin-based cargoes pause preferentially at specific locations along individual microtubules, and that the pause frequency and duration is strongly dependent on microtubule age and polymerization condition. Within each polymerization condition and for fresh microtubules, we also observe significant variations in multiple-kinesin travel distances, depending on which microtubules the motors travel along. Taken together, our study suggests an important role of microtubule lattice defect in regulating intracellular transport.

4:18PM J48.00010 Heterogeneity in motor driven transport, ALI TABEL, University of Northern Iowa — I will discuss quantitative analysis of particle tracking data for motor driven vesicles inside an insulin secreting cell. We use this method to study the dynamical and structural heterogeneity inside the cell. I will discuss our effort to explain the origin of observed heterogeneity in intracellular transport. Finally, I will explain how analyzing directional correlations in transport trajectories reveals self-similarity in the diffusion media.

4:54PM J48.00011 Exploration of locomotion in the ParA/ParB system, LAVISHA JINDAL, ELDON EMBERLY, Simon Fraser University — In many bacteria the ParA/ParB system is responsible for actively segregating DNA during replication. ParB precessively
moves by hydrolyzing DNA bound ParA-ATP forming a depleted ParA region in its wake. Recent in-vitro experiments have shown that a ParB covered bead can
traverse a ParA bound DNA substrate. It has been suggested that the formation of a gradient in ParA leads to diffusion-ratchet like motion of the ParB bead
but its origin and potential consequences requires investigation. We have developed a deterministic model for the in-vitro ParA/ParB system and show that
any amount of spatial noise in ParA can lead to the spontaneous formation of its gradient. The velocity of the bead is independent of this noise but depends
on the scale over which ParA exerts a force on the bead and the scale over which ParB hydrolyzes ParA from the substrate. There is a particular ratio of these
scares at which the velocity is a maximum. We also explore the effects of cooperative vs independent rebinding of ParA to the substrate. Our model shows
how the driving force for ParB originates and highlights necessary conditions for directed motion in the in-vitro system that may provide insight into the in-vivo
behaviour of the ParA/ParB system.

5:06PM J48.00012 Pulse Dynamics in Endocytic Protein Patches1, Supported by NIH under Grant R01-GM107667.
at higher ant densities. In comparison, dead ants are always solid-like. oppose the applied stress. In the linear regime, the dynamics is fractal-like with both storage and shear moduli that overlap for over three orders of magnitude to drip and spread like simple liquids, but that can also store energy and maintain a shape like elastic solids. They are an active material where the constituent MICHAEL TENNENBAUM, ZHONGYANG LIU, DAVID HU, Georgia Institute of Technology — Fire ants, and Avalanches, CHARLES REICHARDT, CYNTHIA OLSON REICHARDT, Los Alamos National Laboratory — We examine the mobility and velocity fluctuations of a driven particle moving through an active matter bath of self-mobile particles for varied system densities and activities. The driven particle mobility is strongly non-monotonic and is correlated with distinct spatial-temporal structures that arise in the active media. We identify an activity-induced crystallization regime that is distinct from the higher activity-induced phase-separated cluster regime. The probe particle velocity fluctuation distributions exhibit specific features in the different dynamic regimes. In the cluster phase, we observe telegraph noise, while in the denser active jamming regimes, the probe particle moves in intermittent jumps or avalanches of power-law distributed sizes. 2:42PM J49.00002 Using artificial microswimmers for controlling the motion of passive colloidal particles in straight and asymmetric channels, VYACHESLAV R. MISKO, University of Antwerp — Artificial self-propelled microswimmers capable of autonomous navigation through complex environments provide appealing opportunities for localization, pick-up and delivery of micro- and nanoscopic objects. Such self-driven microswimmers show not only the ability to navigate through the environment but also modify the environment. Using numerical simulations, we investigate active Brownian motion of self-propelled overdamped microswimmers, i.e., Janus spheres illuminated by light, in straight and corrugated channels. We demonstrated that a small fraction of active microswimmers injected in a system of passive colloids are capable of rectifying the passive species (i.e., in asymmetric channels [1]) or separating various species (i.e., in a mixture of passive species [2]). We analyze the effect of autonomous pumping of passive species by active microswimmers in various corrugated channels. [1] Pulak K. Ghosh, Vyacheslav R. Misko, Fabio Marchesoni, and Franco Nori, Phys. Rev. Lett. 110, 268301 (2013). [2] W. Yang, V.R. Misko, K. Nelissen, M. Kong, and F.M. Peeters, Soft Matter 8, 5175 (2012).

2:54PM J49.00003 Visco-elastic Dynamics of an Active Polar Dynamic System, HARALD PLEINER, Max Planck Institute for Polymer Research, Mainz, Germany, DANIEL SVENSEK, Department of Physics, Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia, HELMUT R. BRAND, Theoretische Physik III, Universität Bayreuth, Germany — We study the dynamics of systems with a polar dynamic preferred direction that are embedded in visco-elastic media. Examples include the pattern-forming growth of bacteria and molecular motors. Because the ordered state only exists dynamically, but not statically, the macroscopic variable of choice is the velocity of the active units. The passive visco-elastic medium is described by a relaxing strain tensor. We derive the macroscopic equations for such a system and discuss novel static, reversible and irreversible cross-couplings connected to this two-fluid (velocity-shear) system. The dynamics is rather different compared to the case of passive, static polar order. In particular, we find a complicated normal mode structure that reflects the broken time-reversal symmetry due to the non-equilibrium situation, anisotropy of first sound and a possible second sound excitation due to the active velocity, and various manifestations of the visco-elastic relaxation. We discuss critically the role of the so-called active term in the stress tensor as well as the thermodynamically correct description of the hydrodynamic transport velocities.

3:06PM J49.00004 ABSTRACT WITHDRAWN —

3:18PM J49.00005 Long range self-organization in bacterial swarms, CHONG CHEN, YI LIN WU, The Chinese University of Hong Kong, WU YILIN TEAM — When grown on air-semisolid interface, many bacteria are able to move in groups and expand rapidly, in a manner called swarming. Bacteria swarming displays rich collective behavior. In this work, we focus on the interaction between swarm cells of E. coli and their fluid environment. Using novel tracers, we discovered large scale self-organization in E. coli swarming colonies that spans a distance of millimeters. This long range self-organization most likely results from local interactions. The results provide new insights into the collective behavior in active matter systems.

3:30PM J49.00006 Dynamic Clustering in Suspension of Motile Bacteria, HEPENG ZHANG, XIAO CHEN, XIANG YANG, Shanghai Jiao Tong Univ, China, MINGCHENG YANG, Beijing National Laboratory for Condensed Matter Physics and Key Laboratory of Soft Matter Physics, Institute of Physics, Chinese Academy — Bacteria suspension exhibits a wide range of collective phenomena arising from interactions between individual cells. Here we investigate dynamic clusters of motile bacteria near an air-liquid interface. Cell in a cluster orient its flagella perpendicular to the interface and generate attractive radial fluid flow that leads to cluster formation. Rotating cell also creates tangential forces on neighbors that sets clusters into counter-clockwise rotation. We construct a numerical model of self-propelled particles that interact via pair-wise forces extracted from hydrodynamic calculations; such a model reproduces many properties of observed cluster dynamics.

3:42PM J49.00007 Dynamics and elasticity of fire ant aggregations, ALBERTO FERNANDEZ-NIEVES, MICHAEL TENNENBAUM, ZHONGYANG LIU, DAVID HU, Georgia Institute of Technology — Fire ants, Solenopsis invicta, form aggregations that are able to drip and spread like simple liquids, but that can also store energy and maintain a shape like elastic solids. They are an active material where the constituent particles constantly transform chemical energy into work. We find that fire ant aggregations shear thin and exhibit a stress cutoff below which they are able to oppose the applied stress. In the linear regime, the dynamics is fractal-like with both storage and shear moduli that overlap for over three orders of magnitude and that are power law with frequency. This dynamic behavior, characteristic of polymer gels and the gelation point, gives way to a predominantly elastic regime at higher ant densities. In comparison, dead ants are always solid-like.
Capillary foams: highly stable bubbles formed by synergistic action of particles and immiscible liquid. CARSON MEREDITH, YI ZHANG, SVEN BEHRENS, Georgia Tech — Liquid foams are a familiar part of everyday life from beer and frothed milk to bubble baths; they also play important roles in enhanced oil recovery, lightweight packaging, and insulation. We report a new class of foams, obtained by frothing a suspension of colloidal particles in the presence of a small amount of an immiscible secondary liquid. A unique aspect of the new foams, termed capillary foams, is that suspended particles mediate spreading of a minority liquid around gas bubbles. The resulting mixed particle/liquid coating can stabilize bubbles against coalescence even when the particles alone cannot. We demonstrate the generality of capillary foams by forming them from a diverse set of particle/liquid combinations and rationalize the results with a simple free energy model. In addition to many applications as liquid foams, capillary foams can serve as precursors for hierarchically-structured solids with porosity on different length scales and with significant application potential.
3:06PM J50.00004 Hyperuniformity Length in Experimental Foam and Simulated Point Patterns, ANTHONY CHIECO, ADAM ROTH, University of Pennsylvania, REMI DREYFUS, CNRS-Solvay-UPenn, SALVATORE TORQUATO, Princeton University, DOUGLAS DURIAN, University of Pennsylvania — Systems without long-wavelength number density fluctuations are called hyperuniform (HU). The degree to which a point pattern is HU may be tested in terms of the variance in the number of points inside randomly placed boxes of side length L. If HU then the variance is due solely to fluctuations near the boundary rather than throughout the entire volume of the box. To make this concrete we introduce a hyperuniformity length $\eta$, equal to the width of the boundary where number fluctuations occur. Thus $\eta$ helps characterize the disorder. We show how to deduce $\eta$ from the number of particles, $n$, so that Poisson and Einstein patterns plus those made by the vertices and bubble centroids in 2D foams. A Poisson pattern is one where points are totally random. These are not HU and $\eta$ equals L/2. We coin “Einstein patterns” to be where points in a lattice are independently displaced from their site by a normally distributed amount. These are HU and $\eta$ equals the RMS displacement from the lattice sites. Bubble centroids and vertices are both HU. For these, $\eta$ is less than L/2 and increases slower than linear in L. The centroids are more HU than the vertices, in that $\eta$ increases more slowly.

3:18PM J50.00005 The Response of a 2D Emulsion to Local Perturbations, XIA HONG, CARLOS ORELLANA, ERIC WEEKS, Department of Physics, Emory University, Atlanta, GA — We experimentally perturb a quasi-two-dimensional emulsion packing by inflating an oil droplet into the system in a controlled way. Our samples are oil-in-water emulsion confined between two close-spaced parallel plates, so that the droplets are deformed into pancake shapes. In this system, there is only viscos friction and no static friction between droplets. By imaging the droplets with a video microscopy, we observe rearrangement events induced by the local perturbation. Simultaneously, we measure droplet-droplet contact forces by analyzing the outlines of each droplet in our movies. These allow us to study how the packings with varying degrees of spatial order have different responses to the local perturbation.

3:30PM J50.00006 Simulations of Soft Glassy Matter with Ripening, HYUN JOO HWANG, ROBERT RIGGLEMAN, JOHN CROCKER, University of Pennsylvania — Soft glassy matter (SGM) such as foams, emulsions, and colloids, exhibit interesting rheological properties that have long defied explanation. In particular, the shear modulus of these materials displays weak power law frequency dependence. To understand the origin of this property in more depth, we have built a three-dimensional, modified Bubble Dynamics model. The bubbles interact with a purely repulsive harmonic potential and ripen according to diffusion-based governing equations. An energy minimizer is implemented to quasi-statically relax topological rearrangements in the system as ripening proceeds. Preliminary results show that the model displays expected intermitten particle rearrangements and a weakly frequency-dependent shear modulus behaving like a power law fluid. We find that the anomalous relaxation properties and avalanche-like nature of the rearrangements can be related to different measures of the systems potential energy landscape.

3:42PM J50.00007 Arresting relaxation in Pickering Emulsions, TIM ATHERTON, CHRIS BURKE, Tufts University — Pickering emulsions consist of droplets of one fluid dispersed in a host fluid and stabilized by colloidal particles absorbed at the fluid-fluid interface. Everyday materials such as crude oil and food products like salad dressing are examples of these materials. Particles can stabilize non spherical droplet shapes in these emulsions through the following sequence: first, an isolated droplet is deformed, e.g. by an electric field, increasing the surface area above the equilibrium value; additional particles are then adsorbed to the interface reducing the surface tension. The droplet is then allowed to relax toward a sphere. If more particles were adsorbed than can be accommodated by the surface area of the spherical ground state, relaxation of the droplet is arrested at some non-spherical shape. Because the energetic cost of removing adsorbed particles exceeds the droplet deformation energy, these structures can remain stable over long timescales. In this presentation, we will discuss new results on how chemical reactions can be used to stabilize emulsions and to control their properties in technology and nature.

3:54PM J50.00008 Suppression of Ostwald Ripening by Chemical Reactions, DAVID ZWICKER, Harvard University, ANTHONY A. HYMAN, Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany, FRANK JÜLICH, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — Emulsions consisting of droplets immersed in a fluid are typically unstable and coarsen over time. One important coarsening process is Ostwald ripening, which is driven by the surface tension of the droplets. Ostwald ripening must thus be suppressed to stabilize emulsions, e.g. in cosmetic, pharmaceutical, or food products. To study Ostwald ripening, we use microemulsions, which contain stable liquid-like compartments, e.g. germ granules, Cajal-bodies, and centrosomes. Such systems are often driven away from equilibrium by chemical reactions and can thus be called active emulsions. Here, we show that non-equilibrium chemical reactions can suppress Ostwald Ripening, leading to stable, monodisperse emulsions. We derive analytical approximations of the typical droplet size, droplet count, and time scale of the dynamics from a coarse-grained description of the droplet dynamics. We also compare these results to numerical simulations of the continuous concentration fields. Generally, we thus show how chemical reactions can be used to stabilize emulsions and to control their properties in technology and nature.

4:06PM J50.00009 Membrane-mediated colloidal interactions, CASPER VAN DER WEL, DORIS HEINRICH, DANIELA KRAFT, Leiden University — Membrane proteins are known to play a key role in inducing curvature in biological membranes. This curvature leads to interactions between the proteins through minimization of the bending energy of the membrane. Simulations have shown a wide variety of interesting phenomena, for example how curvature influences protein sorting, but little is understood about the underlying physics. We study these membrane-mediated interactions using an experimental model system consisting of micro-sized polymer particles linked to a freestanding lipid membrane (GLV). The particles locally distort the membrane curvature and by that exhibit an attraction. The influence of the curvature distortion on the pairwise interaction is studied systematically by tracking the particles with confocal microscopy.

4:18PM J50.00010 Contact-line deformation around a spherical particle at an anisotropic liquid interface, NESRIN SENBIL, WEI HE, ANTHONY DINSMORE, University of Massachusetts, Amherst — The shape of the contact line around a particle determines its interaction with other particles at liquid interfaces. Thus, the shape of the interface and contact line is significant for self-assembly and many other applications of colloids. In our experiments, we used PDMS-coated millimeter-sized glass spheres to avoid pinning. The contact line around the sphere is observed at initially flat, cylindrical-like and saddle-like shapes with a camera placed perpendicular to the plane of the initially flat interface. Unlike flat interfaces, at anisotropic interfaces, the contact line around the sphere is not circular. Our results demonstrate that the quadrupolar deformation of the contact line ($z_2$) increases with deviatoric curvature (anisotropy) of the interface (D_H). For instance, for a PDMS-coated glass sphere with a diameter 3.2mm, $z_2$ increases from 0 to 0.12mm$^{-1}$, $z_0$ increases from 0 to about 0.3mm. We will discuss the relation among $z_2$, $D_H$, mean contact radius, particle radius, and contact angle and compare to theory. Our results are important to understand the assembly of particles at anisotropically curved interfaces. This work is funded by the NSF through CBET-0967620 and by the Gulf of Mexico Research Initiative through the C-MEDS consortium.

4:30PM J50.00011 The influence of protein aggregation on adsorption kinetics, JOEL ROVNER, NIST — When proteins adsorb to an air-water interface they lower the surface tension and may form an age-dependent viscoelastic film. Protein adsorption to surfaces is relevant to both commercial uses and biological function. The rate at which the surface tension decreases depends strongly on temperature, solution pH, and protein structure. These kinetics also depend on the degree to which the protein is aggregated in solution. Here we explore these differences using Chymotrypsinogen as a model protein whose degree of aggregation is adjusted through controlled heat treatment and measured by chromatography. To study these effects we have used a micropipette tensiometer to produce a spherical-cap bubble whose interfacial pressure was controlled — either steady or oscillating. Short heat treatment produced small soluble aggregates, and these adsorbed faster than the original protein monomer. Longer heat treatment produced somewhat larger soluble aggregates which adsorbed more slowly. These results point to complex interactions during protein adsorption.
Crystal nucleation and structural relaxation, transient domains and dynamic heterogeneity, grain boundaries and polycrystallinity. A stochastic model from which University of California, Berkeley — Materials undergoing glass transitions are often materials that can also crystalize. The qualities of the solid that forms

Grand Ballroom C1 - Eli Ben-Naim, Equilibrium Statistical Mechanics of Liquids, Glasses and Biomolecules

Irwin's knowledge and understanding of the subject were breathtaking.

Some portion of the cold Boston winter in warm La Jolla, and we would always get together during these visits. For a period of a number of years we decided a family (he was a sworn bachelor...until he met his wife) until shortly before his death. For many years, first alone and then with family, Irwin would spend

LINDENBERG, Univ of California - San Diego — Irwin Oppenheim's early work on Langevin equations, master equations, and Brownian motion was one of the

We consider the problem of constructing dynamic CG models within the context of the Multi-Scale Coarse Graining (MS-CG) method of Voth and coworkers.

Coarse grained (CG) models of molecular systems, with fewer mechanical degrees of freedom than an all-atom model, are used extensively in chemical physics. It is generally accepted that a coarse grained model that accurately describes equilibrium structural properties (as a result of having a well constructed CG potential energy function) does not necessarily exhibit appropriate dynamical behavior when simulated using conservative Hamiltonian motion by stochastic but Markovian dynamics on that surface, such as Langevin or Brownian dynamics. However, depending on the nature of the system and the extent of the coarse graining, a Markovian dynamics for the CG degrees of freedom may not be appropriate.

Dynamic surface tension measurements carried out with conventional methods like pendant drop analysis, Wilhelmy plate, etc are limited in their temporal resolution (>50 ms). In this study, we describe design and application of maximum bubble pressure tensiometry for the measurement of dynamic surface tension effects at extremely short (1-50 ms) timescales. We discuss the ramifications of this nearly unprecedented capability for unraveling physics underlying high speed printing and foaming with small molecule surfactant solutions.

Janus nanoparticles for stable microemulsions with ultra-low IFT values: ILSE NAVA, AGUSTIN DIAZ, YI-HSIEN YU, ZHENDONG CHENG, Texas A&M University — Janus particles are an influential type of materials used in foams, detergents, surfactants and cosmetics. Due to their demonstrated flexibility and non-toxicity, they have the potential to replace molecular surfactants, and thanks to their amphiphilic nature, they can stabilize immiscible biphasic systems. Disk-based Janus particles best perform this stabilization. Graphene has been used to manufacture this class of particles; however, their fabrication in high yield by short and atomically economic syntheses remains a challenge. In this project we report the first synthesis of monolayer disks by a one pot reaction under microwave energy. Using a scalable method, these disks were synthesized, emulsified (in an oil/water system), and chemically reacted to obtain the Janus nanodisks with an efficient method. Our nanosheets production technique is a promising approach for the fabrication of Janus nanodisks via emulsification as it produces IFT (interfacial tension) values in a lower range than that of the molecular surfactants. These ultra-low values, in conjunction with the sheets' salt resistance, temperature resistance, and non-toxicity position Janus particles as the next generation of nanosurfactants.

Maximum bubble pressure tensiometry and foamability: THEODORE WALKER, WILLIAM ABBOTT-KLOSTERMANN, PRASANTH NARAYANAN, VIVEK SHARMA, Chemical Engineering, University of Illinois Chicago — The stability of a freshly created foam is intimately linked with the rate of mass transfer of a surfactant from liquid sub-phase to the interface, and this diffusion- or adsorption-limited mass transfer dictates the so-called foamability. The time dependent variation in surface tension can also become a factor in controlling response to dilational deformations, as kinetic effects due to mass transfer also enter into the description of Gibbs-Marangoni elasticity of surfaces. Dynamic surface tension measurements carried out with conventional methods like pendant drop analysis, Wilhelmy plate, etc are limited in their temporal resolution (>50 ms). In this study, we describe design and application of maximum bubble pressure tensiometry for the measurement of dynamic surface tension effects at extremely short (1-50 ms) timescales. We discuss the ramifications of this nearly unprecedented capability for unraveling physics underlying high speed printing and foaming with small molecule surfactant solutions.

Competing dynamics of vitrification and crystal coarsening: DAVID CHANDLER, University of California, Berkeley — Materials undergoing glass transitions are often materials that can also crystallize. The qualities of the solid that forms depend upon the system's dynamics and experimentalist's protocols. This lecture describes some of the associated phenomena, including competition between crystal nucleation and structural relaxation, transient domains and dynamic heterogeneity, grain boundaries and polycrystallinity. A stochastic model from which all of these phenomena emerge will be presented.

Brownian motion, old and new, and Irwin's role in my academic life: KATJA LINDENBERG, Univ of California - San Diego — Irwin Oppenheim's early work on Langevin equations, master equations, and Brownian motion was one of the earliest and strongest reasons for my change of direction from my PhD work in condensed matter theory to my later and lifelong interest in Brownian motion and, more broadly, statistical mechanics. I will talk about some of my most recent work on subdiffusion, a form of anomalous diffusion that describes random motions in crowded or disordered media where motions are hindered by the medium. On a personal note, I knew Irwin for decades, from the time before he had a family (he was a sworn bachelor...until he met his wife) until shortly before his death. For many years, first alone and then with family, Irwin would spend some portion of the cold Boston winter in warm La Jolla, and we would always get together during these visits. For a period of a number of years we decided to take advantage of these visits to write the definitive text in traditional Thermodynamics. We did not make it past about 2/3 of the project, but it was a great learning experience for me while it lasted. Irwin's knowledge and understanding of the subject were breathtaking.

 session J50.00012: Gravitational Drainage of Anionic and Nonionic Surfactant Mixtures: THEODORE WALKER, UNIVERSITY OF ILLINOIS AT CHICAGO — The stability of a freshly created foam is intimately linked with the rate of mass transfer of a surfactant from liquid sub-phase to the interface, and this diffusion- or adsorption-limited mass transfer dictates the so-called foamability. The time dependent variation in surface tension can also become a factor in controlling response to dilational deformations, as kinetic effects due to mass transfer also enter into the description of Gibbs-Marangoni elasticity of surfaces. Dynamic surface tension measurements carried out with conventional methods like pendant drop analysis, Wilhelmy plate, etc are limited in their temporal resolution (>50 ms). In this study, we describe design and application of maximum bubble pressure tensiometry for the measurement of dynamic surface tension effects at extremely short (1-50 ms) timescales. We discuss the ramifications of this nearly unprecedented capability for unraveling physics underlying high speed printing and foaming with small molecule surfactant solutions.

 session J50.00013: ZrP nanoparticles based fire-fighting foams: LECHENG ZHANG, ZHENDONG CHENG, HAI LI, TEXAS A&M UNIVERSITY — Firefighting foam, as a significant innovation in fire protection, greatly facilitates extinguishments for liquid pool fire. Recently, with developments in LNG industry, high-expansion firefighting foams are also used for extinguishing LNG fire or mitigating LNG leakage. Foam stabilizer, an ingredient in fire-fighting foam, stabilizes foam bubbles and maintains desired foam volume. Conventional foam stabilizers are organic molecules. In this work, we developed a inorganic based ZrP (Zr(HPO4)2·H2O, Zirconium phosphate) plate functionalyzed as firefighting foam stabilizer, improving firefighting foam performance under harsh conditions. Several tests were conducted to indicate performance. The mechanism for the foam stabilization is also proposed.

 session J50.00014: Maximum bubble pressure tensiometry and foamability: THEODORE WALKER, WILLIAM ABBOTT-KLOSTERMANN, PRASANTH NARAYANAN, VIVEK SHARMA, Chemical Engineering, University of Illinois Chicago — The stability of a freshly created foam is intimately linked with the rate of mass transfer of a surfactant from liquid sub-phase to the interface, and this diffusion- or adsorption-limited mass transfer dictates the so-called foamability. The time dependent variation in surface tension can also become a factor in controlling response to dilational deformations, as kinetic effects due to mass transfer also enter into the description of Gibbs-Marangoni elasticity of surfaces. Dynamic surface tension measurements carried out with conventional methods like pendant drop analysis, Wilhelmy plate, etc are limited in their temporal resolution (>50 ms). In this study, we describe design and application of maximum bubble pressure tensiometry for the measurement of dynamic surface tension effects at extremely short (1-50 ms) timescales. We discuss the ramifications of this nearly unprecedented capability for unraveling physics underlying high speed printing and foaming with small molecule surfactant solutions.

 Session J51 GSNP GSOFT: Invited Session: Irwin Oppenheim Memorial Session: Non-Equilibrium Statistical Mechanics of Liquids, Glasses and Biomolecules

 Brownian motion, old and new, and Irwin's role in my academic life: KATJA LINDENBERG, Univ of California - San Diego — Irwin Oppenheim's early work on Langevin equations, master equations, and Brownian motion was one of the earliest and strongest reasons for my change of direction from my PhD work in condensed matter theory to my later and lifelong interest in Brownian motion and, more broadly, statistical mechanics. I will talk about some of my most recent work on subdiffusion, a form of anomalous diffusion that describes random motions in crowded or disordered media where motions are hindered by the medium. On a personal note, I knew Irwin for decades, from the time before he had a family (he was a sworn bachelor...until he met his wife) until shortly before his death. For many years, first alone and then with family, Irwin would spend some portion of the cold Boston winter in warm La Jolla, and we would always get together during these visits. For a period of a number of years we decided to take advantage of these visits to write the definitive text in traditional Thermodynamics. We did not make it past about 2/3 of the project, but it was a great learning experience for me while it lasted. Irwin's knowledge and understanding of the subject were breathtaking.
4:18PM J51.00004 Ion Atmosphere Near Nucleic Acids1, UDAYAN MOHANTY, Department of Chemistry, Boston College — We will discuss allatom structure based model that explicitly includes ionic effects, i.e., electrostatic interactions with explicit magnesium ions and implicit KCl that allow us to carry out explicit solvent molecular dynamics simulations of adenine riboswitch and SAMI riboswitch. Our predictions for the excess ions around the riboswitch, and the magnesiumRNA interaction free energy will be compared with experimental data. We will provide upper and lower bounds for preferential interaction coefficient, a statistical mechanical quantity that is a measure of excess ion atmosphere around a polyelectrolyte. We will discuss the role of surface charge density of mobile ions from added salt in determining the counterion release entropy associated with chain collapse. Finally, the Poisson’s ratio of oligomeric DNA will be determined. (Work done in collaboration with R. Hayes, J. Noel, P. Whithford, S. Hennelly, J. Onuchic, and K. Sanbonmatsu.)

1Work supported by fellowship from John Simon Guggenheim Memorial Foundation.

4:54PM J51.00005 The Typical Lengthscale Characterizing the Glass Transition at Lower Temperatures, ITAMAR PROCACCIA, The Weizmann Institute of Science — The existence of a static length scale that grows in accordance with the dramatic slowing down observed at the glass transition is a subject of intense interest. A recent publication compared two proposals for this length scale, one based on the point-to-set correlation technique and the other on the scale where the lowest eigenvalue of the Hessian matrix becomes sensitive to disorder. The conclusion was that both approaches lead to the same length scale, but the former is easier to measure at higher temperatures and the latter at lower temperatures. But even after using both methods together, the range of increase in the observed length scales was limited by the relaxation times reachable by standard molecular dynamics techniques (i.e. about 4-5 orders of magnitude). In this paper we therefore attempt to explore the typical scale at even lower temperatures, testing for this purpose two approaches, one based on the idea of vapor deposition and the other on a swap Monte Carlo technique. We conclude that the first approach does not help in getting to lower temperatures, but the second one does so quite effectively. We can reach a typical lengthscale that grows in accordance with at least 18 orders of magnitude increase in the relaxation time, coming close to the best experimental conditions. We conclude by discussing the relationship between the observed lengthscale and various models of the relaxation time.

Tuesday, March 3, 2015 2:30PM - 5:30PM —
Session J52 Buckley Prize / Apker Award Session Grand Ballroom C2 -

2:30PM J52.00001 Buckley Prize Talk: Electrostatic Control of the Superconductor-Insulator Transition1, ALLEN GOLDMAN, Univ of Minnesota - Minneapolis — The superconductor-insulator transitions (SITs) of ultra-thin films are among the simplest quantum phase transitions. The ground states of systems that have been studied are usually changed by adjusting the level of disorder, by the application of perpendicular and parallel magnetic fields, by altering the chemical composition, and by the seeding of the surface with pair-breaking magnetic impurities. More recently, realizations of the electric field effect have been used to tune SITs. This has been done with devices employing high dielectric constant gate insulators, as well as with electric double layer transistor devices employing ionic liquids as gate insulators. In addition to disordered ultrathin films, cuprates, and metallic interfaces between insulators have also been studied. The SITs of selected systems will be reviewed with particular attention being paid to the results of finite size scaling analyses of the transitions, and the nature of the insulating states found. In the case of the cuprates, the extent to which their phase diagrams can be traversed will be explored. Finally the potential value of electrostatic gating as a tool in the search for new superconductors will be discussed.

3:06PM J52.00002 Buckley Prize Talk: Bosons on the Boundaries: The magnetic field driven superconductor-insulator quantum phase transition . ARTHUR HEBARD, University of Florida — Experiments probing the competition between superconductivity and disorder in two-dimensional (2D) thin-film systems have provided fascinating glimpses into the physics of superconductor-insulator (S-I) quantum phase transitions (QPTs). This talk will address the use of externally applied magnetic fields to tune through the S-I transition of amorphous composite indium oxide (α-InOx) thin films prepared at different stages of disorder. Air-stable α-InOx films are particularly advantageous for these studies: the disorder parameter as measured by the sheet resistance can be reproducibly controlled during deposition and the films are uniformly homogeneous out to macroscopic length scales. Temperature-dependent resistance and current-voltage measurements confirm the power-law decay of the order-parameter correlation function appropriate to a Kosterlitz-Thouless description of phase transitions in 2D systems. Accordingly, the superconducting phase transition temperature Tc is related to the unbinding of vortex-antivortex pairs either by temperature and/or disorder. The application of magnetic fields unveils fundamentally different physics in which, rather than a vortex unbinding transition, a field-tuned QPT emerges with the signature of a disorder-dependent critical field Bc that identifies the delocalization and Bose condensation of field-induced vortices. The concomitant pronounced divergence in resistance, which becomes increasing sharp as the temperature is lowered, marks the boundary between a superconductor harboring both Bose condensed Cooper pairs and localized vortices and an insulator harboring both Bose condensed Cooper pairs and localized Cooper pairs. The data for this putative QPT are well described by finite temperature scaling theory with critical exponent values accurately determined. At higher fields there is a second critical field where the transverse resistance appears to diverge, signaling the unbinding of pairs with the superconducting energy gap simultaneously going to zero and localized single electrons dominating to form a Fermi glass insulator.

3:42PM J52.00003 Buckley Prize Talk: The Superconductor-(Metal)-Insulator Transition . AHARON KAPITULNIK, Stanford University — While the classical theory of phase transitions has been extraordinarily successful, there are several reasons to exercise caution when applying this approach to the zero temperature superconducting transition. First, experimental identification of the relevant phases requires extrapolation to zero temperature, which becomes complicated, especially when one needs to identify sources of dissipation. In addition, since superconductivity may be highly inhomogeneous as appreciable superconducting order parameter may be concentrated in “superconducting puddles” due to disorder and/or spontaneous phase separation, the nature of the quantum phase transition to a superconducting state may be highly anomalous, where the system attempts to optimize the formation of puddles with the Josephson coupling among them to obtain global superconductivity. In this talk we will review some of the consequences of these considerations, emphasizing the possible emergence of anomalous metallic phases close to the superconductor-insulator transition.

4:18PM J52.00004 Buckley Prize Talk: Theory of Quantum Phase Transitions: A 25 year purview . MATTHEW FISHER, UC Santa Barbara — A 25 Purview of Quantum Phase Transitions
4:54PM J52.00005 Leroy Apker Award Talk: Transport measurements of a model cuprate superconductor. MICHAEL VEIT, Univ of Minn - Minneapolis — High-temperature superconductivity in the cuprates has been the subject of intense research since its discovery in 1986 by J. G. Bednorz and K. A. Müller. The fundamental challenge posed by these materials is that they exhibit strong electronic correlations, giving rise to anomalous properties, such as the observation that the resistivity in optimally hole-doped samples is linear in temperature from the superconducting transition temperature up to very high temperatures. The scope of this work was to explore the phase diagram through transport measurements of a model compound. Specifically, the resistivity, magneto-resistance, Hall effect and thermoelectric power were measured for single-crystal samples of HgBa2CuO4+δ (Hg201). The outcome of these measurements is highly surprising. Despite the complexity of the phase diagram, conventional Fermi-liquid metallic behavior is observed in the pseudogap regime below optimal doping.

Tuesday, March 3, 2015 2:30PM - 5:30PM — Session J53 DCMP: Invited Session: Progress in Electrically-Gated Quantum Dot Qubits Grand Ballroom C3 - HongWen Jiang, University of California, Los Angeles

2:30PM J53.00001 Control and Measurement of an Exchange-Only Spin Qubit. JAMES MEDFORD, Harvard University — Gate-defined semiconductor quantum dots have proven to be a versatile testbed for exploring quantum systems and quantum information. We demonstrate the fast all-electrical control of a spin qubit using the two coherent exchange interactions in a triple quantum dot. Our measurements identify the role of nuclear spins from the host GaAs in this system as a mechanism for both dephasing and leakage out of the qubit subspace. We also show that by increasing both exchange interactions in a balanced fashion, we enter a second regime of operation. In this regime, leakage from the subspace has been suppressed, resulting in a spin qubit with a tunable electric dipole moment, which we refer to as the resonant exchange qubit.

3:06PM J53.00002 Silicon based quantum dot hybrid qubits1. DOHUN KIM, University of Wisconsin — The charge and spin degrees of freedom of an electron constitute natural bases for constructing quantum two level systems, or qubits, in semiconductor quantum dots. The quantum dot charge qubit offers a simple architecture and high-speed operation, but generally suffers from fast dephasing due to strong coupling of the environment to the electron’s charge. On the other hand, quantum dot spin qubits have demonstrated long coherence times, but their manipulation is often slower than desired for important future applications. This talk will present experimental progress of a ‘hybrid’ qubit, formed by three electrons in a Si/SiGe double quantum dot, which combines desirable characteristics (speed and coherence) in the past found separately in qubits based on either charge or spin degrees of freedom. Using resonant microwaves, we first discuss qubit operations near the ‘sweet spot’ for charge qubit operation. Along with fast (>GHz) manipulation rates for any rotation axis on the Bloch sphere, we implement two independent topographic characterization schemes in the charge qubit regime: traditional quantum process tomography (QPT) and gate set tomography (GST). We also present resonant qubit operations of the hybrid qubit performed on the same device, DC pulsed gate operations of which were recently demonstrated. We demonstrate three-axis control and the implementation of dynamic decoupling pulse sequences. Performing QPT on the hybrid qubit, we show that AC gating yields π rotation process fidelities higher than 93% for X-axis and 96% for Z-axis rotations, which demonstrates efficient quantum control of semiconductor qubits using resonant microwaves. We discuss a path forward for achieving fidelities better than the threshold for quantum error correction using surface codes.

3:42PM J53.00003 Electrical control of a long-lived spin qubit in a Si/SiGe quantum dot. ERIKA KAWAKAMI, Kavli Institute of Nanoscience, TU Delft — Electron spins in Si/SiGe quantum dots are one of the most promising candidates for a quantum bit for their potential to scale up and their long dephasing time. We realized coherent control of single electron spin in a single quantum dot (QD) defined in a Si/SiGe 2D electron gas. Spin rotations are achieved by applying microwave excitation to one of the gates, which oscillates the electron wave function back and forth in the gradient field produced by cobalt micromagnets fabricated near the dot. The electron spin is read out in single-shot mode via spin-to-charge conversion and a QD charge sensor. In earlier work [1], both the fidelity of single-spin rotations and the spin echo decay time were limited by a small splitting of the lowest two valleys. By changing the direction and magnitude of the external magnetic field as well as the gate voltages that define the dot potential, we were able to increase the valley splitting and also the difference in Zeeman splittings associated with these two valleys. This has resulted in considerable improvements in the gate fidelity and spin echo decay times. Thanks to the long intrinsic dephasing time T2* ~ 900 ns and Rabi frequency of 1.4 MHz, we now obtain an average single qubit gate fidelity of an electron spin in a Si/SiGe quantum dot of 99 percent, measured via randomized benchmarking. The dephasing time is extended to 70 us for the Hahn echo and up to 400 us with CPMG80. From the dynamical decoupling data, we extract the noise spectral density in the range of 30 kHz-3 MHz. We will discuss the mechanism that induces this noise and is responsible for decoherence. In parallel, we also realized electron spin resonance and coherent single-spin control by second harmonic generation, which means we can drive an electron spin at half the Larmor frequency. Finally, we observe not only single-spin transitions but also transitions whereby both the spin and the valley state are flipped. Altogether, these measurements have significantly increased our understanding and raised the prospects of spin qubits in Si/SiGe quantum dots.

This work has been done in collaboration with T.M. J. Jullien, P. Scarlino, V.V. Dobrovitski, D.R. Ward, D. E. Savage, M. G. Lagally, Mark Friesen, S. N. Coppersmith, M. A. Eriksson, and L. M. K. Vandersypen. This work was supported in part by the Army Research Office (ARO) (W911NF-12-0607), the Foundation for Fundamental Research on Matter (FOM) and the European Research Council (ERC). Development and maintenance of the growth facilities was supported by the Department of Energy (DOE) (DE-FG02-03ER46028). E.K. was supported by a fellowship from the Nakajima Foundation. This research utilized NSF-supported shared facilities at the University of Wisconsin-Madison.

4:18PM J53.00004 Control of Spin States in Triple Quantum Dots. ANDREW SACHRAJDA, National Research Council of Canada — A brief review will be given on coherent behaviour in serial triple quantum dots in AlGaAs/GaAs heterostructure related to multi-spin states. One series of experiments involves the application of coherent superpositions of multi-electron states to the transfer of single spins and two-spin states non-locally between edge quantum dots while maintaining the center quantum dot occupation fixed at one or zero electrons. A second series of experiments involves the identification of coherent leakage mechanisms away from targeted encoded three-spin states qubits. Finally, results will be shown which reveal an unexpected control of the gap at the S-T+ anticrossing by taking advantage of different nuclear dynamic polarization pumping rates.
One- and two-qubit logic using silicon-MOS quantum dots

Andrew Dzurak, UNSW - Australia — Spin qubits in silicon are excellent candidates for scalable quantum information processing [1] due to their long coherence times and the enormous investment in silicon MOS technology. While our Australian effort in Si QC has largely focused on spin qubits based upon phosphorus dopant atoms implanted in Si [2,3], we are also exploring spin qubits based on single electrons confined in SiMOS quantum dots [4]. Such qubits can have long spin lifetimes $T_1 = 2 \text{s}$, while electric field tuning of the conduction-band valley splitting removes problems due to spin-valley mixing [5]. In isotopically enriched Si-28 these SiMOS qubits have a control fidelity of 99.6% [6], consistent with that required for fault-tolerant QC. By gate-voltage tuning the electron $g^*$-factor, the ESR operation frequency can be Stark shifted by >10 MHz [6], allowing individual addressability of many qubits. Most recently we have coupled two SiMOS qubits to realize CNOT gates [7] via either controlled rotation (CROT) or controlled phase (CZ) operations. The speed of the two-qubit CZ-operations is controlled electrically via the detuning energy and over 100 two-qubit gates can be performed within a two-qubit coherence time of 8 $\mu$s.

8:00AM L1.00001 Toward Air-Stable Multilayer Phosphorene Thin-Films and Transistors

Joon-Seok Kim, Yingnan Liu, Weinan Zhu, Seohye Kim, Di Wu, Li Tao, Ananth Dodabalapur, Keji Lai, Deji Akinwande, The University of Texas at Austin — Few-layer black phosphorus, also known as phosphorene, has recently rose into scientific limelight due to its promising characteristics for flexible device and optoelectronic applications, such as high mobilities beyond what is achievable in other 2D dichalcogenides. In addition, its direct thickness-dependent bandgap enables optoelectronics from the infrared to visible regions. However, a fundamental challenge lies on its lack of air stability, which is of paramount importance for practical device application. Physical degradation of unprotected phosphorene in a matter of hours in air was obvious from optical and atomic force microscopy (AFM). Moreover, microwave impedance microscopy (MIM) revealed that samples with thin capping layers, though more air-stable, began to degrade from the edges inward within a few days, where the degradation was primarily electronic with minor physical changes. Statistics from phosphorene field-effect transistors (FETs) have shown that double capping with dielectric and hydrophobic fluoropolymer films afford further improved and robust weeks-long air-stability. The simple capping methods represent a facile route for achieving air-stable phosphorene devices that can enable basic studies and potential applications.

8:12AM L1.00002 Weak Localization in Bulk Black Phosphorus and Few-Layer Phosphorene

YUCHEN DU, ADAM NEAL, HONG ZHOU, PEIDE YE, Purdue University — Most of the recent experimental research on black phosphorus (BP) or phosphorene has been focused on device applications with few systematic studies on electrical transport properties of single-layer or few-layer phosphorene. Here, we report on the magnetotransport experiments on thick BP films and few-layer phosphorene at low temperatures. The observed weak localization is well fitted by the Hikami-Larkin-Nagaoka model where the temperature dependence of the phase coherence length has demonstrated to be a power-law behavior of $T^{-0.7}$. In addition, the temperature dependence of Hall mobility as a function of the film thickness is also examined to uncover the limitation of mobility in few-layer phosphorene with different mechanisms.

8:24AM L1.00003 Passivation of Exfoliated Black Phosphorus Transistors Against Ambient Degradation1

SPENCER WELLS, JOSHUA WOOD, DEEP JARIWALA, KAN-SHENG CHEN, EUNKYUNG CHO, VINOD SANGWAN, XIAOLONG LIU, LINCOLN LAUHON, TOBIN MARKS, MARK HERSAM, Northwestern University — Unencapsulated exfoliated black phosphorus field-effect transistors are found to rapidly degrade upon exposure to ambient conditions, causing large increases in threshold voltage after only 6 h in ambient, followed by a $\sim 10^3$ decrease in FET on/off ratio and mobility after 48 h. Careful investigation into the cause of this degradation suggests that $H_2O$ irreversibly reacts with unprotected, exfoliated BP to form oxidized phosphorus species, as observed by AFM, TEM, XPS, Fourier transform infrared spectroscopy, and electrostatic force microscopy. This interpretation is further supported by the observation that BP degradation occurs more rapidly on hydrophobic octadecyltrichlorosilane self-assembled monolayers as opposed to hydrophilic SiO$_2$, implicating an edge-based intercalation of O$_2$ saturated H$_2$O in BP as the cause of degradation. Atomic layer deposited AlO$_x$ overlayers were found to suppress ambient degradation, allowing encapsulated BP FETs to maintain high on/off ratios of $\sim 10^3$ and mobilities of $\sim 100$ cm$^2$/Vs for over one month in ambient, demonstrating the effective passivation of BP flakes against ambient degradation [1].

8:36AM L1.00004 Imperfect 2D phosphorus, yet an almost perfect semiconductor, EVGENI PENEV, YUANYUE LIU, FANGBO XU, ZHANG ZHANG, BORIS YAKOBSON, Rice Univ — The deep gap states created by defects in semiconductors typically deteriorate the performance of (opto)electronic devices. This has limited the applications of two-dimensional (2D) metal dichalcogenides (MX$_2$) and underscored the need for a new 2D semiconductor without defect-induced deep gap states. The talk will discuss why a 2D mono-elemental semiconductor can be a promising candidate. This is exemplified by a first-principles study of 2D phosphorus (“phosphorene”) [1], a recently fabricated high-mobility semiconductor. Most of the defects, including intrinsic point defects and grain boundaries, are electronically inactive, thanks to the homoelemental bonding, which is not preferred in heterogeneous system such as MX$_2$. Unlike MX$_2$, where the edges create deep gap states and cannot be eliminated by passivation, the edge states of 2D P can be removed from the band gap by hydrogen termination. It is further found that both the type and the concentration of charge carriers in 2D P can be tuned by doping with foreign atoms. The work sheds light on the role of defects on the electronic structure of low-dimensional materials in general.

8:48AM L1.00005 Single/Bi-layer Silicene Field-Effect Transistors and their Air-Stability. LI TAO, Microelectronics Research Laboratory, The University of Texas at Austin, Texas 78758, USA, EUGENIO CINQUANTA, CARLO GRAZIANETTI, ALESSANDRO MOLLE, Laboratorio MDM, IMM-CNR, via C. Olivetti 2, Agrate Brianza, I-20864, Italy, DEJI AKINWANDE, Microelectronics Research Center, The University of Texas at Austin, Texas 78758, USA — Silicene, the Si analogue of graphene, has the potential to be a widely tunable 2D material for novel nanoelectronics. Air-stability is a major issue for experimental investigation on siliconene devices, which per this study has been greatly addressed by our encapsulated delamination with native electrodes (SEDNE) approach. SEDNE process preserves silicene/Ag interface during transfer and fabrication, and real-time Raman spectroscopy observes a short time window for Ag-removed silicene device stays intact and gradually degrades. In our predefined experiments, silicene devices exhibit an ambipolar charge transport behavior, corroborating theories on Dirac band in Ag-free silicene. Monolayer silicene device has extracted field-effect mobility within the theoretically predicted range and ON/OFF ratio greater than graphene, whereas bilayer silicene device shows lower mobilities and gate modulation similar to graphene. This work suggests a realistic prospect for improving air-stability of silicene devices and its tunable performance, which can be leveraged for other air-sensitive 2D materials. *Support from U.S. Army Research Office (W911NF-13-0364) and Future Emerging Technologies (270749) under European Commission are appreciated.

9:00AM L1.00006 Black Phosphorus RF Transistor

HAN WANG, Ming Hsieh Dept. EE, USC, XIAOMU WANG, FENGNIAN XIA, Dept. EE, Yale, LUHAO WANG, Ming Hsieh Dept. EE, USC, HAO JIANG, QIANGFEI XIA, Dept. ECE, U Mass, MATTHEW L. CHIN, MADDAN DUBEY, Sens & Elec. Dev. Directorate, US ARL, SHU-JEN HAN, IBM T.J. Wason Cent. — Few-layer and thin film form of layered black phosphorus (BP) has recently emerged as a promising material for applications in high performance thin film electronics and infrared optoelectronics. Layered BP offers a $\sim 0.3\text{ eV}$ bandgap and high mobility, leading to transistor devices with decent on/off ratio and high on-state current density. Here, we demonstrate the GHz frequency operation of black phosphorus field-effect transistor for the first time. BP transistors demonstrated here show excellent current saturation with an on-off ratio exceeding $2 \times 10^{10}$. The S-parameter characterization is performed for the first time on black phosphorus transistors, giving a 12 GHz short-circuit current-gain cut-off frequency and 20 GHz maximum oscillation frequency in 300 nm channel length devices. A current density in excess of 270 mA/mm and DC transconductance above 180 mS/mm are achieved for hole conductions. The results reveal the promising potential of black phosphorus transistors for enabling the next generation thin film transistor technology that can operate in the multi-GHz frequency range and beyond.

9:12AM L1.00007 Phosphorene as a new 2D material for nanoelectronic and optoelectronic applications. PEIDE YE, Purdue University — Phosphorus is one of the most abundant elements preserved in earth, constructing with a fraction of 0.1% of the earth crust. In general, phosphorus has several allotropes including white, red, and black phosphorus. Black phosphorus, though rarely mentioned, is a layered semiconductor and have great potentials in optical and electronic applications. Remarkably, this layered material can be reduced to one single atomic layer in the vertical direction owing to the van der Waals structure, dubbed phosphorene, where the physical properties can be tremendously different from its bulk counterpart and needed to be further explored. In this talk, we trace back to the 100 years research history on black phosphorus from the synthesis to material properties, and extend the topic from black phosphorene to phosphorene. The physical and transport properties are highlighted, aiming at further applications in electronic and optoelectronic devices.
9:48AM L1.00008 The Effect of Gas Absorption on Multilayer Black Phosphorus Field Effect Transistor. XUE LIU, JIN HU, CHUNLEI YUE, NICHOLAS DELLA FERA, ZHIQIANG MAO, JIANG WEI, Tulane University — Multilayer black phosphorus (BP) is drawing much attention recently due to its reported high mobility (up to 1000 cm²/V·s) and on/off ratio (up to 10⁵) as the channel material for field effect transistor (FET). We investigated the interplay between the electrical response of high performing BP-FET and gas adsorbate introduced to its surrounding environment. Different type of gas including CO₂, H₂O, Ethanol, CO, NO, NH₃, etc. has been tested. We observed that the absorption of gas molecules generally reduces the overall on-state conductance of the device with an order of 10 − 100. And such reduction can be fully recovered by purging with inert gas or baking at mild temperature (about 100°C). The absorption dynamics and detailed mechanism are also been investigated. We conclude that multilayer black phosphorus is an excellent material for chemical sensing.

10:00AM L1.00009 Stability and Passivation of Phosphorene Field Effect Transistors. YEXIN DENG, ZHE LUO, Purdue University; XIANFAN XU, Purdue University; PEIDE YE, Purdue University — Phosphorene is a new 2D semiconducting material which has been intensively studied for its physical properties and potential device applications. Its high carrier mobility and thickness-dependent direct band gap make its promising for high-performance field effect transistors and optoelectronic devices. However, even few layer phosphorene films are gradually degraded in air due to its irreversible chemical reactions with oxygen and water in ambient. In order to make stable phosphorene films for real device applications, we systematically studied the different passivation methods including PMMA, 2D hBN, and atomic layer deposited (ALD) dielectrics at different growth conditions. A combination of hBN and ALD could be one of the final solutions for realizing the environmentally stable phosphorene devices.

10:12AM L1.00010 Electrical characterization of fully encapsulated ultra thin black phosphorous-based heterostructures with graphene contacts. AHMET AVSAR, Graphene Research Center, National University of Singapore; IVAN JESUS VERA-MARUN, Graphene Research Center, National University of Singapore; Zernike Institute for Advanced Materials, University of Groningen, The Netherlands; JUN YOUN TAN, Graphene Research Center, National University of Singapore, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan; ANTONIO HELIO CASTRO NETO, BARBAROS ÖZYILMAZ, Graphene Research Center, National University of Singapore — The presence of finite bandgap and high mobility in semiconductor few-layer black phosphorous offers an attractive prospect for using this material in future two-dimensional electronic devices. Here we present for the first time fully encapsulated ultrathin (down to bilayer) black phosphorous field effect transistors in Van der Waals heterostructures to preclude their stability and degradation problems which have limited their potential for applications. Introducing monolayer graphene in our device architecture for one-atom-thick conformal source-drain electrodes enables a chemically inert boron nitride dielectric to tightly seal the black phosphorous surface. This architecture, generally applicable for other sensitive two-dimensional crystals, results in stable transport characteristics which are hysteresis free and identical both under high vacuum and ambient conditions. Remarkably, our graphene electrodes lead to contacts not dominated by thermionic emission, solving the issue of Schottky barrier limited transport in the technologically relevant two-terminal field effect transistor geometry.

10:24AM L1.00011 High Mobility Two-Dimensional Electron Gas in Black Phosphorus. LIKAI LI, Fudan University, GUO JUN YE, University of Science and Technology of China; VY TRAN, Washington University in St. Louis; St. Louis, GUORUI CHEN, Fudan University; HUICHAO WANG, JIAN YANG, Washington University in St. Louis, St. Louis, XIANHUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Fudan University — Black phosphorus has recently emerged as a new member in the family of two-dimensional (2D) atomic crystals. It is a semiconductor with a tunable bandgap and high carrier mobility — material properties that are important for potential opto-electronic and high-speed device applications. In this work, we achieve a record-high carrier mobility in black phosphorus by placing it on hexagonal boron nitride (h-BN) substrate. The exceptional mobility of the 2D electron gas created at the interface allows us to observe quantum oscillations for the first time in this material. The temperature and magnetic field dependence of the oscillations yields crucial information about the black phosphorous 2DEG, such as cyclotron mass of the charge carriers and their lifetime. Our results pave the way to future research on quantum transport in black phosphorus.

10:36AM L1.00012 Oxidation pathways in Phosphorene: an ab-initio investigation. MATHEUS PAES LIMA, ADALBERTO FAZZIO, ANTONIO JOSÉ ROQUE DA SILVA, University of São Paulo — Phosphorene is a recently isolated single layer of Black Phosphorus. In this 2D material, the combination of a direct band gap with a high charge carrier mobility opens up the possibility of its use in nano devices. However, the exposure of Black Phosphorus to air leads to its fast degradation, which indicates the relevance to understand its oxidation processes. In the present work we investigate the initial steps of the oxidation process, focusing on the interaction of a single O₂ molecule with the phosphorene layer. We show that the existence of oxidation pathways having only a single barrier of 0.13eV occurring between the free O₂ (triplet) and the triplet-singlet potential energy surface (PES) crossing point. We estimate a room temperature triplet-singlet transition probability of P₁→₀ = 0.015, using the Landau-Zener model. Once the O₂ switches to the singlet PES, there is an oxygen incorporation with an energy gain of 4.2eV with respect to the PES crossing point, with the O₂ molecule spontaneously dissociating without any barrier. In this process, the final geometry has one O bonded to a P lone pair, and the other located between two P atoms. Our investigations were performed with DFT calculations at the GGA level as implemented in the VASP code.

10:48AM L1.00013 Tunability of Band Gap in Multilayer Phosphorene by External Electric Fields and Electron Dopings. SEUNG SU BAIK, HYOU NG JOON CHOI, Center for Computational Studies of Advanced Electronic Materials (CCSAEMP) and Department of Physics, Yonsei University, Korea — Black phosphorus (BP) and its two-dimensional derivative phosphorene are rapidly emerging nanoelectronic materials with potential applicability to field effect transistors and optoelectronic devices. Unlike the gapless semiconductor graphene, multilayer BP has a substantial band gap of ~ 0.2 eV and the band-gap size is reportedly varied by external electric fields. To explore the extensibility of such band-gap modulation, we have investigated electronic band structures of multilayer BP by using the first-principles density-functional method as implemented in the SIESTA code. By controlling the electron doping concentrations and the resultant electric fields therefrom, we examine the manageability of the band-gap size and the anisotropic carrier mobility. This work was supported by NRF of Korea (Grant No. 2011-0018306) and KISTI supercomputing center (Project No. KSC-2013-C3-062).

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L2 DMP: Focus Session: Beyond Graphene - Spin and Magnetic Properties 001B - Jun Zhu, Pennsylvania State University
8:00AM L2.00001 Indirect exchange interaction in 3D Dirac semimetals, A. Mellnik, J. S. Lee, A. Richardella et al.; NANCY SANDLER, SERGIO ULLOA, Ohio University — 3D Dirac semimetals are new three-dimensional materials with linear band crossings —Dirac points— at distinctive locations in the Brillouin zone. They are predicted to have fascinating properties such as the chiral anomaly and surface Fermi arcs. Na$_2$Bi and Cd$_3$As$_2$ are two prototypical examples that have been characterized experimentally [1]. Breaking of time reversal symmetry splits the Dirac points into Weyl points, which are protected by the underlying crystal symmetry. We study the indirect exchange interaction, between two magnetic impurities in these materials. We present results on the behavior of the interaction as a function of the inter-impurity separation in the Dirac phase. We also analyze the transition into the Weyl phase, by introducing perturbations that can be induced by external fields. [1] Science 343, 864; arXiv:1312.7624; Nat. Commun. 5, 3786; PRL 113, 027603.

8:12AM L2.00002 First-principles study of magnetic properties of two-dimensional semi conductors ABX$_3$\(^3\), A. Kandala, A. Richardella, S.-Y. Xu, M. Neupane, A. Mellnik, A. Kandala, J. S. Lee, D. M. Zhang, M. Z. Hasan and D. C. Ralph. We acknowledge funding from the DARPA Meso program, ONR and C-SPIN (under sponsorship of MARCO and DARPA).

8:24AM L2.00003 Structure and magnetism of the van der Waals bonded ferromagnet CrI$_3$, M. Neupane, A. Richardella, S.-Y. Xu, M. Neupane, A. Mellnik, A. Kandala, J. S. Lee, D. M. Zhang, M. Z. Hasan and D. C. Ralph. We acknowledge funding from the DARPA Meso program, ONR and C-SPIN (under sponsorship of MARCO and DARPA).

8:36AM L2.00004 Topological Spintronics: Materials, Phenomena and Devices, NITIN SAMARTH, Penn State University — The two-dimensional surface states of three-dimensional topological insulators such as Bi$_2$Se$_3$ and (Bi,Sb)$_2$Te$_3$ possess a spin texture that can potentially be exploited for spintronics applications. We provide a perspective on the emergence of “topological spintronics,” demonstrating how this spin texture can be engineered using either quantum tunneling between surfaces [1] or by breaking time-reversal symmetry [2]. We then discuss recent experiments that show striking spintronic phenomena useful for proof-of-concept devices, including a spin-orbit torque of record efficiency at room temperature [3] and an electrically-gated “giant anisotropic magnetoresistance” at low temperature [4].

This work was carried out in collaboration with A. Richardella, S.-Y. Xu, M. Neupane, A. Mellnik, A. Kandala, J. S. Lee, D. M. Zhang, M. Z. Hasan and D. C. Ralph. We acknowledge funding from the DARPA Meso program, ONR and C-SPIN (under sponsorship of MARCO and DARPA).

9:00AM L2.00005 Thermodynamic Stability of Topological Insulators, DEMET USANMAZ, PINKU NATH, JOSE J. PLATA, Department of Mechanical Engineering and Materials Science, Duke University, Durham, North Carolina 27708, USA, GIUS L.W. HART, Department of Physics and Astronomy, Brigham Young University, Provo, UT 84602, MARCO B. NARDELLI, Department of Physics and Department of Chemistry, University of North Texas, Denton, Texas 76203, USA, STEFANO CURTAROLO, Materials Science, Electrical Engineering, Physics, and Chemistry, Duke University, Durham, North Carolina 27708, USA, CENTER FOR MATERIALS GENOMICS TEAM, G. L. W. HART COLLABORATION, M. B. NARDELLI COLLABORATION — Well known three-dimensional TIs such as Bi$_2$Te$_3$, Bi$_2$Se$_3$, Bi$_2$Te$_2$Se, Sb$_2$Te$_3$Se have been the subject of research due to potential application for spintronic devices. TIs have large bulk band gap and metallic surface states at the special time-reversal-invariant momentum (TRIM) points of the Brillouin zone. These fascinating properties constitute the current carry along the surface and not conduct current through the bulk. Creating heterostructures of TIs has recently been demonstrated to be advantageous for controlling electronic properties. In addition to the importance of the electronic properties of materials, thermodynamic stability is the key for manufacturability of materials. Guided by cluster expansion, we have investigated the thermodynamic stability of TI interfaces.

9:24AM L2.00006 A Field-effect Transistor based on Two-dimensional Topological Insulators, WOLfgang Vandenbergh, MASSIMO FISCHETTI, The University of Texas at Dallas — Monolayer tin functionalized with iodine (iodostannanane) is a two-dimensional topological insulator and iodostannanane ribbons have a very high mobility when the Fermi level is in the bandgap. For wide ribbons, the mobility and the conductivity decrease by several orders of magnitude when the Fermi level is in the conduction or valence band[1]. We show how this property can be exploited to make a topological-insulator field-effect transistor (TIFET) by gating the iodostannanane. We simulate the TIFET's electrical characteristics invoking a drift-diffusion like approximation and introducing a simplified model for the conductivity of the topological insulator. The TIFET is shown to have input and output characteristics similar to those of conventional field-effect transistors with an on/off ratio exceeding three orders of magnitude. Furthermore, the on-current is very high enabling high-speed operation and the amount charge in the channel is small making TIFETs interesting for low-power applications.

9:36AM L2.00007 Magneto-optical studies of MoS$_2$\textsuperscript{1}, MUMTAZ MURAT ARIK, ALOK MUKHERJEE, PAYAM TAHERI, HUI XING, HAO ZENG, JOHN CERNE, State Univ of NY - Buffalo — We report infrared and visible (0.100 – 2.75 eV) magneto-optical measurements on high quality monolayer MoS$_2$ prepared by sulfurizing MoO$_3$ films. Reflection, photoluminescence, and magneto-optical Kerr spectra of MoS$_2$ on different substrates are measured at magnetic fields up to 7 T and temperatures down to 10 K. In the visible reflection spectrum we observe the A1 and B1 excitonic transitions. While the A1 strength is independent of magnetic field, the B1 amplitude increases by a factor of 1.5 at 5 T. This work is supported by NSF-DMR1006078.

9:48AM L2.00008 Valley contrasting chiral phonons in monolayer hexagonal systems\textsuperscript{1}, LIFA ZHANG, QIAN NIU, Univ of Texas, Austin — In monolayer hexagonal lattice systems, two inequivalent valleys appear in the reciprocal lattice space. With inversion symmetry breaking, we find valley dependent chiral phonons which are circularly polarized with carrying spin angular momentum and ionic magnetic moment. At valleys, light and heavy phonons are found and evolve in intervallley electronic scattering. Under three-fold rotation operation, phonons have pseudo angular momentum, which include spin and orbital parts. From conservation of pseudo angular momentum, momentum and energy, the selection rules in valleytronics are obtained. Due to chiral valley phonons, one can observe polarized infrared photoluminescence and phonon valley coherence by infrared excitation. There is also a valley dependent phonon Berry curvature which can result a valley phonon Hall effect. The valley-dependent chiral phonon, together with its spin angular momentum, pseudo angular momentum, infrared polarized photoluminescence, phonon valley coherence and valley Hall effect, will form a basis for valley-based phonics applications.

\textsuperscript{1}We acknowledge support from DOE-DMSE (DE-FG03-02ER45958), NBRPC (2012CB-921300), NSFC (91121004), and the Welch Foundation (F-1255)

10:00AM L2.00009 Thickness dependence of spin polarization and electronic structure of ultra-thin films of MoS$_2$ and related transition-metal dichalcogenides, TAY-RONG CHANG, National Tsing Hua U., Taiwan, HSIN LIN, National University of Singapore, HORNG-TAY JENG, National Tsing Hua U., Taiwan, ARUN BANSIL, Northwestern U. — Thickness dependence of electronic structures of transition-metal dichalcogenides (TMDs) MX$_2$ (M=Mo or W, X=S, Se or Te) is investigated using first-principles calculations. When spin-orbit coupling (SOC) is included in the computations, the electronic structure of monolayer MX$_2$ films exhibits significant band splittings due to the breaking of spatial inversion symmetry. In particular, spin-split states appear around the valence band maximum with nearly 100% out-of-the-plane spin polarization with the spin oriented oppositely at the K and K’ symmetry points in the Brillouin zone. For bilayer films, the spin-polarization can be tuned by an out-of-the-plane electric field, and the spin-polarized states are weakly coupled between the layers with small $\xi_{\perp}$ dispersion. We confirm a transition from an indirect to a direct band gap as the thickness is reduced to a monolayer in MoX$_2$, in agreement with recent experimental findings. Our study provides insights into the thickness dependence of electronic structure and the degree of spin polarization of the valence bands in ultra-thin TMD films and their viability for spintronics applications.

10:12AM L2.00010 RKKY interaction in transition-metal dichalcogenide nanoflakes\textsuperscript{1}, OSCAR AVALOS-OVANDO, DIEGO MASTROGIUSEPPE, SERGIO ULLOA, Ohio University — Transition metal dichalcogenides (TMDs) are layered crystals with unique electronic and optical properties, and are promising candidates for a new generation of semiconductor-based devices, mainly when exfoliated to one or a few layers. The process of exfoliation often produces nanoscale samples – flakes – with different shapes and boundaries. These flakes might have applications as quantum dots with novel characteristics. One interesting topic relates to the presence of magnetic impurities and their interaction. In combination with strong spin-orbit coupling and valley degrees of freedom, TMDs might have a great impact in the field of spintronics. Using an effective low-energy two-orbital tight-binding model, we study the Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction between two magnetic impurities in 2D TMD nanoflakes. We consider different geometries and terminations, analyzing the effect of the sample size. Our results show the behavior of the interaction for impurities sitting at different positions in the flake, and its possible tunability with the electron/hole concentration. The magnetic impurities can be intrinsic to the sample production process or can be introduced extrinsically. Our results can be tested with local probes, such as spin-polarized STM.

10:24AM L2.00011 Two-dimensional Mineral [Pb$_2$Bi$_3$][AuTe$_2$]: High mobility Charge Carriers in Single-atom-thick Layers\textsuperscript{1}, LEI FANG, Department of Chemistry, Northwestern University, J. IM, C. STOUMPOS, F. SHI, V. DRAVID, Northwestern University, M. LEROUX, Argonne National Laboratory, A. FREEMAN, Northwestern University, W.-K. KWOK, D.-Y. CHUNG, Argonne National Laboratory, M. KANATZIDIS, Northwestern University — We report that [Pb$_2$Bi$_3$][AuTe$_2$], known as a naturally occurring mineral buckhornite, hosts 2D carriers in single-atom-thick layers. The structure is composed of stacking layers of weakly coupled [Pb$_2$Bi$_3$] and [AuTe$_2$] sheets. The insulating [Pb$_2$Bi$_3$] sheet inhibits interlayer charge hopping and confines the carriers in the basal plane of the single-atom-thick [AuTe$_2$] layer. Magneto-transport measurements and theoretical calculations show a property of multiband semimetal with compensated density of electrons and holes, which exhibit high hole carrier mobility of 1360 cm$^2$/Vs. This material possesses an extremely large anisotropy $10^4$, comparable to benchmark materials graphite. The electronic structure features linear band dispersion at the Fermi level and ultrahigh Fermi velocities of 10$^4$ m/s which are virtually identical to that of graphene. The weak interlayer coupling gives rise to the highly cleavable property of single crystal specimens, indicating a prospect for monolayer system.

10:36AM L2.00012 Giant spin-splitting and orbital angular momentum in triangular lattice, SEHOON OH, HYOUNG JOON CHOI, Department of Physics, IPAP, and Center for Computational Studies of Advanced Electronic Material Properties, Yonsei University, Seoul, Korea — We study the spin-splitting in triangular-lattice materials including Au (111) surface and transition-metal dichalcogenides quantitatively as well as qualitatively using tight-binding calculations and first-principles calculations. To analyze the spin-splitting of the bands, we calculate the orbital angular momentum (OAM) and consider the symmetry of the system. We confirm that the giant spin-splitting results from the presence of significant local OAMs and strong spin-orbit interactions in the vicinity of high-atomic number elements. This work was supported by NRF of KOREA (Grant No. 2011-0018306) and KISTI supercomputing center (Project No. KSC-2013-C3-062).
10:48AM L2.00013 Excitonic and marginal Fermi liquid instabilities in 2D and 3D Dirac semimetals, JOSE GONZALEZ, Instituto de Estructura de la Materia (CSIC), Madrid, Spain — We study the quantum electrodynamics of 2D and 3D Dirac semimetals by means of a self-consistent resolution of the Schwinger-Dyson equations, aiming to obtain the respective phase diagrams in terms of the relative strength of the Coulomb interaction and the number N of Dirac fermions. In this framework, 2D Dirac semimetals have just a strong-coupling instability characterized by exciton condensation (and dynamical generation of mass) that we find at a critical coupling well above the estimates made with RPA screening (large-N approximation), thus explaining the absence of that instability in free-standing graphene samples. On the other hand, we show that 3D Dirac semimetals have a richer phase diagram, with a strong-coupling instability leading to dynamical mass generation up to N = 4 and a line of critical points for larger values of N characterized by the vanishing of the electron quasiparticle weight in the low-energy limit. Such a marginal Fermi liquid boundary marks the transition to a kind of strange metal that can still be defined in terms of electron quasiparticles, but with parameters that have large imaginary parts implying an increasing deviation at strong coupling from the conventional Fermi liquid picture.

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L3 GSNP: Topics in Statistical Physics II

8:00AM L3.00001 Concept of Linear Thermal Circulator Based on Coriolis forces1, HUANAN LI, TSAMPIKOS KOTTOS, Wesleyan University — Directional transport and the creation of non-reciprocal devices that control the flow of energy and/or mass at predefined directions have been posing always fascinating challenges. In this contribution, we show that the presence of a Coriolis force in a rotating linear lattice imposes a non-reciprocal propagation of the phononic heat carriers. Using this effect we propose the concept of Coriolis linear thermal circulator which can control the circulation of a heat current. A simple model of three coupled harmonic masses on a rotating platform allow us to demonstrate giant circulating rectification effects for moderate values of the angular velocities of the platform.

8:12AM L3.00002 Magnetically driven quantum heat engine1, ENRIQUE MUNOZ, Pontificia Universidad Catolica de Chile, FRANCISCO PENA, Pontificia Universidad Catolica de Valparaiso — In analogy with classical thermodynamics, a quantum heat engine generates useful mechanical work from heat, by means of a reversible sequence of transformations (trajectories), where the “working substance” is of quantum mechanical nature. Several theoretical implementations for a quantum heat engine have been discussed in the literature, such as entangled states in a qubit, quantum mechanical versions of the Otto cycle, and photocells. In this work [1], we propose yet a different alternative by introducing the concept of a magnetically driven quantum heat engine. We studied the efficiency of such system, by considering as the “working substance” a single nonrelativistic particle trapped in a cylindrical potential well, as a model for a semiconductor quantum dot, in the presence of an external magnetic field. The trajectories are driven by a quasistatic modulation of the external magnetic-field intensity, while the system is in contact with macroscopic thermostats. The external magnetic field modulation allows to modify the effective geometric confinement, in analogy with a piston in a classical gas.

8:24AM L3.00003 ABSTRACT WITHDRAWN —

8:36AM L3.00004 Why are all dualities conformal? Theory and practical consequences, SEYYED MOHAMMAD SADEGH VAEZI, ZOHARN NUSSINOV, Washington University, GERARDO ORTIZ, Indiana University, Bloomington — We relate duality mappings to the “Babbage equation” F(F(z)) = z with F a map linking weak to strong coupling theories. Under fairly general conditions F may only be a specific conformal transformation of the fractional linear type. This deep general result has enormous practical consequences. For example, one can establish that weak and strong coupling expansions are trivially related, i.e., one needs to generate only one of them while the other is automatically determined through a set of linear constraints. The latter partially solve or, equivalently, localize the computational complexity to a simple fraction of the coefficients, and as a bonus those relations encode non-trivial equalities between different geometric constructions. We illustrate our findings by examining various models including, but not limited to, ferromagnetic and spin-glass type Ising models on hypercubic lattices.

8:48AM L3.00005 ABSTRACT WITHDRAWN —

9:00AM L3.00006 Quantifying the Effects of Noise on Diffuse Interface Models: Cahn-Hilliard-Cook equations, SPENCER FIEFER, BASKAR GANAPATHYSUBRAMANIAN, Iowa State Univ — We present an investigation into the dynamics of phase separation through numerical simulations of the Cahn-Hilliard-Cook (CHC) equation. This model is an extension of the well-known Cahn-Hilliard equation, perturbed by an additive white noise. Studies have shown that random fluctuations are critical for proper resolution of physical phenomena. This is especially true for phase critical systems. We explore the transient behavior of the solution space for varying levels of noise. This is enabled by our massively scalable finite element-based numerical framework. We briefly examine the interplay between noise level and discretization (spatial and temporal) in obtaining statistically consistent solutions. We show that the added noise accelerates progress towards phase separation, but retards dynamics throughout subsequent coarsening. We identify a scaling exponent relating morphology metrics with the level of noise. We observe a very clear scaling effect of finite domain size, which is observed to be offset by increasing levels of noise. Domain scaling reveals a clear microstructural asymmetry at various stages of the evolution for lower noise levels. In contrast, higher noise levels tend to produce more uniform morphologies.
9:12AM L3.00007 Definitions of temperature in non-extensive systems¹, SERGIO DAVIS, GONZALO GUTIERREZ, Departamento de Física, Facultad de Ciencias, Universidad de Chile — Superstatistics (Beck and Cohen, 2003) is a proposed formalism for explaining the presence of non-Boltzmann distributions in Nature for systems out of equilibrium. The superstatistical ensemble is a superposition of canonical ensembles according to

\[ P(\vec{r}, \vec{p} | H) = \int dB P(\beta | H) \exp(-\beta H(\vec{r}, \vec{p})) Z(\beta), \] 

with \( P(\beta | H) \) the probability density for the inverse temperature parameter \( \beta \). In this work we show that, in order for this formalism to be internally consistent, it is impossible to have a definition of \( \beta \) as an observable which is valid across all “superstatistical” ensembles. In other words, the shape of the ensemble cannot be determined by measuring temperature, only by measuring energy. Our results also reveal that energy and temperature are not in the same footing as observables for non-canonical ensembles.

¹Funding from FONDECYT 1140514

9:24AM L3.00008 Non-reciprocal acoustic transport in media with spectral asymmetry and losses, ANDREA KLEEMAN, RAHUL DEORA, HUANAN LI, FRED ELLIS, TSAMPIKOS KOTTOS, Department of Physics, Wesleyan University, Middletown CT-06459, USA, ILYA VITEBSKIY, The Air Force Research Laboratory, Sensors Directorate, Wright Patterson AFB, OH 45433 USA — We propose a novel scheme for acoustic isolators, which rely on the interplay of spectral asymmetry and distributed losses. The spectral asymmetry is imposed to the system via a flow, which is moving inside a corrugated waveguide with a constant velocity. A result of this asymmetry is that left and right moving acoustic waves have different group velocities. Then, depending on the direction of the incident acoustic signal, inherent losses result in different level of attenuation of the transmitted signal. The outgoing acoustic wave has the same frequency characteristics as the incoming one. An experimental realization of our proposal is also discussed.

9:36AM L3.00009 Density reconstruction via maximum entropy method, AUSTIN MCDONALD, RAYMOND ATTA-FYNN, Department of Physics, University of Texas at Arlington, PARTHAPRATIM BISWAS, Department of Physics and Astronomy, The University of Southern Mississippi — We demonstrate an application of the maximum entropy principle by employing the Shannon entropy functional to reconstruct functions that are otherwise non-trivial to reproduce by existing reconstruction techniques. Specifically, we present the reconstruction of the Dirac comb by maximizing the Shannon entropy subject to the moment constraints using Monte-Carlo type and population-based approaches. The results are compared with the existing results in the literature and the convergence properties of the resulting distributions are examined in relation to the number of input moments.

9:48AM L3.00010 Density of Yang-Lee zeros in the thermodynamic limit using Tensor RG¹, ARTUR GARCIA-SAEZ, TZU-CHIEH WEI, Yang Institute for Theoretical Physics and Department of Physics and Astronomy, Stony Brook University — The partition function of ferromagnets in a lattice is represented as a Tensor Network and efficiently contracted using an iterative RG process. The density of Yang-Lee zeros on the complex field plane is obtained from accurate calculations of the free energy and local observables in an effective thermodynamic limit. We illustrate this approach studying the distribution of Yang-Lee zeros for the Ising model in 2D and 3D square lattices.

¹This work was supported in part by the National Science Foundation.

10:00AM L3.00011 Entanglement Thermalization and Local Conservation Laws, LIANGSHENG ZHANG, Princeton University, HYUNGWON KIM, Rutgers University, DAVID HUSE, Princeton University — We study the thermalization of entanglement entropy in one-dimensional spin chains under the unitary dynamics of a nonintegrable Hamiltonian or periodic driving by Floquet operators. Using full diagonalization of the Hamiltonian matrix and the Floquet operators, we analyze the time evolution of entanglement entropy starting from various initial conditions, including initial states with entanglement in excess of the thermal equilibrium value. It is found that the thermalization of entanglement entropy is coupled to local conservation laws when approaching equilibrium, and the absence of conservation laws in the Floquet system allows the entanglement entropy to thermalize more rapidly than it does in the corresponding Hamiltonian.

10:12AM L3.00012 Phase transitions in a confined monolayer of magnetized beads, JULIEN SCHOCK-MEL, Univ de Liege — We present experimental results obtained with a model experimental system dedicated to the study of 2D phase transitions. The system is composed of millimetric beads interacting through magnetic dipole-dipole interaction. Due to the confinement, repulsive interactions tend to order the system. In addition, the system is submitted to a controlled mechanical agitation which produce an erratic motion of the beads and thus creates disorder. Controlling the competition between interaction energy and entropy, allows us to explore different structures of 2 dimensional systems. At first, the melting of a two dimensional crystal is studied. As predicted by the KTHNY theory, a two stage melting is observed, including the so-called hexatic phase (see results in Phys. Rev. E.87, 062201 (2013)). Afterward, the behavior of binary systems is studied. In particular, the effect of the grains polydispersity on the order is analyzed.

10:24AM L3.00013 Complex Pole Approach in Thermodynamic Description of Fluid Mixtures with Small Number of Molecules, TIMUR ASLYAMOV, Moscow Inst of Phys & Tech, OLEG DINARIEV, Schlumberger Moscow Research Center — Physically consistent description of equilibrium small molecular systems requires the extension of thermodynamics. The reason is the absence of thermodynamic limit, which is mandatory for the applicability of classical thermodynamics. New theoretical method of complex pole decomposition for the statistical description of small multicomponent molecular systems is implemented. Similar approach has been previously developed and applied in nuclear physics for finite systems of nucleons. We have significantly transformed and extended the original formulation to make it work for multicomponent molecular mixtures in small systems. The aim of this research is to provide new comprehensive description of small equilibrium molecular systems with numerous scientific and industrial applications for artificial and natural materials with nanopores. Several cases for molecular systems in small cavities are studied. In particular size-dependent additional pressure for small systems is evaluated analytically and numerically. The obtained results are in correspondence to published experimental data and molecular dynamics simulations.
Heterogeneous dynamics and stretched exponential decay of spatio-temporal correlations for Coulomb-interacting particles in confined geometries, AMIT GHOSAL, BISWARUP ASH, Indian Institute of Science Education and Research-Kolkata, Mohanpur Campus, India-741252, JAYDEEP CHAKRABORTI, S. N. Bose National Centre for Basic Sciences, Kolkata, India-700098 — We investigate the dynamics of Coulomb-interacting confined particles over a range of temperatures capturing the crossover from a Wigner molecule to a liquid-like phase. Dynamical signatures, derived from the Van-Hove correlations, develop pivotal understanding of the phases as well as the intervening crossover, which are inaccessible from the study of static correlations alone. The motion of the particles shows frustrations, produces heterogeneities depending on the observation time-scales and temperatures and results into a non-Gaussian behavior. The extent and nature of the departure of the behavior of spatio-temporal correlations from the conventional wisdom depends crucially on the symmetry of the confinements. In particular, we find that the decay of correlations follow a stretched-exponential form in traps that lack any symmetry. Our data offers a broad support to a theoretical model that integrates the non-Gaussian behavior arising from the convolution of Gaussian fluctuations weighted by appropriate diffusivities, consistent with local dynamics. The richness of information from the dynamic correlation will be shown to improve the understanding of melting in confined systems in a powerful manner.

Current-driven complex dynamics of single-layer epitaxial islands on substrates, DWAIPAYAN DASGUPTA, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — We study theoretically the current-driven dynamics of isolated single-layer epitaxial islands on crystalline substrates, which provides important guidance toward surface nanopatterning approaches based on the current-driven assembly of such islands. We develop and validate a fully nonlinear model for the islands’ driven morphological evolution on elastic substrates of face-centered cubic crystals in the regime where diffusional mass transport is limited to the island edge. For islands on (110)-, (100)-, and (111)-oriented substrate surfaces, we report a transition in the asymptotic states reached by such driven island dynamics from steady to oscillatory, mediated by Hopf bifurcation. We characterize the bifurcation and explore the dependence of the stable time-periodic state beyond the Hopf point on the misorientation angle between the applied electric field and fast edge diffusion directions, the strength of the edge diffusional anisotropy, and the island size. For islands larger than a critical size, depending on the orientation of the substrate surface, we observe fingering and necking instabilities in the island morphology. We carry out a comprehensive numerical simulation study and explore the complexity of the driven island dynamics with the variation of the problem parameters.

Experimental Signatures of Orbital Fluctuations in Iron Based Superconductors, WEI-CHENG LEE, Binghamton University - SUNY — Understanding the high temperature superconductivity has been one of main subjects in the condensed matter physics. The discovery of new classes of high-temperature superconductors, iron pnictides in 2008, launched an international wave of research in the past few years. While the magnetic interactions are certainly important in these materials, there have been significant evidences suggesting that the orbital degrees of freedom could play an important role as well. In this talk, I will demonstrate that the orbital degrees of freedom do play a significant role in physical properties of iron-based superconductors. At the level of single particle properties, while the orbital order in the quasi-1D dxy and dzy bands has been proposed to be a possible driving mechanism for the structural phase transition, our study shows that the fluctuations associated with the orbital order could further drive a non-Fermi liquid behavior in the critical region of the orbital ordering phase transition. I will show that this non-Fermi liquid behavior could induce a zero-bias anomaly in the point contact spectroscopy, which has been observed in a variety of iron based superconductors. As for the magnetic properties, we also find that the orbital order and fluctuations can qualitatively change the nature of the spin excitation spectrum, giving rise to the novel incommensurate-to-commensurate transformation observed in a recent neutron scattering measurement. In the superconducting state, we predict that a new collective excitation, termed as orbital resonance mode, could exist generally in the iron-based superconductors, which in principle can be measured by Raman spectroscopy. Our findings offer a new perspective on the pairing mechanism of iron based superconductors, and suggest that orbital degrees of freedom could provide a new route to high temperature superconductivity.

Orbital-selective Correlation Effects in Alkali Metal Iron Pnictides, WEICHENG LV, Rice University, RONG YU, Renmin University of China, JIAN-XIN ZHU, Los Alamos National Laboratory, QMIAO SI, Rice University — There is growing evidence for the substantial electronic correlations in the iron based superconductors. In particular, recent experiments have revealed strong orbital-selective correlation effects in the series of alkali metal iron pnictides AFe2As2 (A = K, Rb, Cs). Among the important questions is how these systems, with a 3d-electron filling n = 5.5 per site, differs from the parent iron pnictides, which has n = 6. Here, we address these issues in a five-orbital Hubbard model with filling n = 5.5, using the U(1) slave-spin method. As the lattice parameters increase from K to Rb, then to Cs, we are able to identify the systematics in the orbital-selective Mott behavior as the correlation effects are enhanced due to the reduced bandwidth. We discuss the implications of our results for the quasiparticle mass as well as for the spin spectral weight.

Spin and Orbital Nematic Susceptibility of Iron Based Superconductors. CHRISTOPHER BISHOP, SHUHUA LIANG, ANAMITRA MUKHERJEE, NIRAVKUMAR PATEL, ELBIO DAGOTTO, ADRIANA MOREO, Univ of Tennessee, Knoxville — The spin and orbital nematic susceptibility of the iron-based superconductors are calculated in the undoped limit using a three-orbital (xz, yz, xy) spin-fermion model that includes spin, orbital, and lattice degrees of freedom [1]. The results are in very good agreement with experiments by J-H. Chu et al., Science 337, 710 (2012). Recently, Raman scattering experiments[2] indicate a Curie-Weiss behavior of the orbital nematic susceptibility in BaFe2As2 and Sr(Fe1−xCox)2As2. This behavior is observed in our numerical simulations after considering the coupling between the spin and orbital nematic order parameters. A Landau-Ginzburg formalism is used to analytically derive equations for both the spin and orbital susceptibility that fit well the numerical data. [1] S. Liang et al., arXiv:1405.6395 (2014), to appear in PRB. [2] Y.-X. Yang, et al., “Raman scattering as a probe of charge nematic fluctuations in iron based superconductors,” JPS Conf. Proc. 3, 015001, 2014.

1National Science Foundation Grant No. DMR-1104386
9:00AM L.00004 Diverging Nematic Susceptibility, Physical Meaning of $T^*$ scale, and Pseudogap in the Spin Fermon Model for Pnictides, SHUHUA LIANG, ANAMITA MUKHERJEE, NIRVUKUMAR PATEL, CHRIS BISHOP, ELBIO DAGOTTO, ADRIANA MOREO, Univ of Tennessee, Knoxville — Using Monte Carlo simulations including the lattice degree of freedom [1], for the first time the nematic susceptibility of the spin fermion model for the pnictides is calculated [2]. The results are in very good agreement with experiments by J.-H. Chu et al., Science 337, 710 (2012). Our study suggests a nematicity in the spin fermion model primarily originating on magnetism, but with the lattice/orbital also playing an important role by boosting up critical temperatures and separating the structural $T_S$ and Néel $T_N$ transitions. At $T > T_S$, Curie-Weiss behavior is observed with a characteristic temperature $T^*$ being the $T_N$ of the purely electronic system. In this regime, a pseudogap in the density of states and short-range magnetic order is observed.

9:12AM L.00005 Symmetry of reentrant tetragonal phase in Ba$_{1-x}$Na$_x$Fe$_2$As$_2$: Magnetic versus orbital ordering mechanism, DMITRY KHAYALIYIN, ISIS facility, Rutherford Appleton Laboratory, STEPHEN LOVESEY, Diamond Light Source Ltd, PASCAL MANUEL, ISIS facility, Rutherford Appleton Laboratory, FRANK KRUGER, London Centre for Nanotechnology, University College London, STEPHAN ROSENKRANZ, JARED ALLRED, OMAR CHMAISSEM, RAY OSBORN, Materials Science Division, Argonne National Laboratory — Magneto-structural phase transitions in Ba$_{1-x}$Fe$_2$As$_2$ ( $A$ = K, Na) materials have been analyzed for both magnetically and orbitally driven mechanisms, using symmetry methods formulated within the Landau theory of phase transitions. Both mechanisms predict identical orthorhombic space group symmetries for the magnetic and nematic phases observed over much of the phase diagram, but they predict different tetragonal space-group symmetries for the newly discovered reentrant tetragonal phase in Ba$_{1-x}$Na$_x$Fe$_2$As$_2$ ($x \sim 0.25$). In a magnetic scenario, magnetic order with moments along the $c$-axis, as found experimentally, does not allow any type of orbital order, but in an orbital scenario, we have determined two possible orbital patterns, specified by $P4/mnc1$ and $H221$ space groups, which do not require atomic displacements relative to the parent $H/mmm$1 symmetry and, in consequence, are indistinguishable in conventional diffraction experiments. We demonstrate that the three possible space groups are however, distinct in resonant X-ray Bragg diffraction patterns created by Templeton & Templeton scattering. This provides an experimental method of distinguishing between magnetic and orbital models.

9:24AM L.00006 The phase diagram of Sr$_{1-x}$Na$_x$Fe$_2$As$_2$: evidence of magnetic C4 phase universality, K.M. TADDEI, Northern Illinois University, J.M. ALLRED, Argonne National Laboratory (ANL), D.E. BUGARIS, ANL, M. KROGSTAD, Northern Illinois University, S. ROSENKRANZ, R. OSBORN, H. CLAUS, D.Y. CHUNG, ANL, S.H. LAPIDUS, ANL Advanced Photon Source. M.G. KANATZIDIS, ANL and Northwestern University, O. CHMAISSEM, ANL and Northern Illinois University — Determination of the nature of superconductivity in the high $T_c$ iron based superconductors requires understanding the material’s magnetic behavior out of which superconductivity arises. The apparent competition between superconductivity and magnetism in these materials and the appearance of superconductivity upon suppression of magnetism suggests magnetic fluctuations as a possible superconducting pairing mechanism. A recent study of the sodium doped barium 122 system which established the existence of a new magnetic phase near the Fermi level of the electron and hole bands and is determined by the electron filling. We find that within an itinerant approach the magnetic susceptibility introduces the anisotropy of the magnetization of the striped antiferromagnetic state by lifting the degeneracy of all three components of the magnetization.

9:36AM L.00007 Enhancement of superconductivity near a nematic quantum critical point, SAMUEL LEDERER, Stanford Univ, YONATAN SCHATTNER, EREZ BERG, Weizmann Institute of Science, STEVEN KIVELSON, Stanford Univ — In both the hole-doped cuprate and iron-based high temperature superconductors, there is evidence of a nematic quantum critical point at a critical doping near the “optimal doping” at which the superconducting $T_c$ is maximal. Thus motivated by experiments, but without pretense that the theory is directly applicable to these materials, we consider a low $T_c$ metallic superconductor weakly coupled to the soft fluctuations associated with proximity to a nematic quantum critical point. We show that a dynamical Efros-Slatkin model remains valid outside of a parametrically narrow interval about the nematic quantum critical point; 2) in 2D, the symmetry of the superconducting state (d-wave, s-wave) is typically determined by the non-critical interactions, but $T_c$ is enhanced by the nematic fluctuations in all channels; 3) in 2D, this enhancement grows rapidly upon approach to criticality up to the point at which the weak coupling approach breaks down, but in 3D the enhancement is much weaker. Finally, we note some consequences of the nematicity-mediated pairing interaction, such as highly anisotropic gap functions and non-local collective modes.

9:48AM L.00008 Manifestation of nematic degrees of freedom in the Raman response function of iron pnictides, UNA KARAHASANOVIC, JOERG SCHMALIAN, Karlsruhe Institute of Technology — The electronic nematic phase in pnictides, characterized by the broken C4 symmetry, is believed to be generated by the presence of magnetic fluctuations associated with the striped phase, and occurs as a thin sliver in the phase diagram, above the magnetic transition temperature. Detecting the presence of nematic degrees of freedom in iron-based superconductors is a difficult task, since it involves measuring four spin correlation functions. We show that the nematic degrees of freedom manifest themselves in the experimentally measurable Raman response function, which is a density-density correlation weighted by an appropriate form factor. We calculate the Raman response function in the large $N$ limit by considering Aslamazov-Larkin type of diagrams that contain series of inserted boxed-like diagrams that resemble the nematic coupling constant of the theory. These diagrams effectively account for collisions between spin fluctuations. We demonstrate that the Raman response function diverges at the structural phase transition.

10:00AM L.00009 Magnetic and orbital ordering in the iron-based superconductors: role of spin-orbit coupling, FELIX AHN, Institut für Theoretische Physik III, Ruhr-Universität Bochum, Bochum, Germany, JOHANNES KNOlle, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, RAFAEL FERNANDES, School of Physics and Astronomy, University of Minnesota, Minneapolis, USA, ILYA EREMIN, Institut für Theoretische Physik III, Ruhr-Universität Bochum, Bochum, Germany — We analyze the magnetic ordering in the iron-based superconductors in presence of spin-orbit coupling. Based on several tight-binding parametrizations of the 3d electron states we show how the spin-orbit coupling introduces the anisotropy of the magnetization of the striped antiferromagnetic state by lifting the degeneracy of all three components of the magnetization $m_x$, $m_y$, and $m_z$. The orientation of the magnetic moment is determined by the contribution of the xy, zz, and yz orbitals to the electronic states near the Fermi level of the electron and hole bands and is determined by the electron filling. We find that within an itinerant approach the magnetic ordering is most favorable along the wavevector of the striped AF state. This appears to be a natural consequence of the spin-orbit coupling in the striped AF state where the ferro-orbital order of the $xz$ and $yz$ orbitals is only a consequence of the striped AF order. We further analyze the role of spin-orbit coupling for the C4 magnetic structure where SDW order parameters with both wavevectors, $Q_{x} = (\pi, 0)$ and $Q_{y} = (0, \pi)$, coexist.

Session L6 DMP: Focus Session: Phononic And Mechanical Phenomena In Nanostructures
006A - Michael Scheibner, University of California, Merced

8:00AM L6.00001 Coherent phonon modulation by nanoscale acoustically mismatched interface
SHANGJIE YU, MIN QING. Univ of Maryland-College Park — Precise engineering of phonon spectrum by material design is essential for in-depth understanding of fundamental physical phenomena as well as new technology breakthrough. When phonons propagate through two different constituents, their mismatched interface can coherently modulate phonon spectrum. In this talk, we will demonstrate the phonon characteristics can be precisely tailored through nanoscale interfacial coupling by investigating acoustically mismatched core-shell hetero-nanostructures with ultrafast pump-probe technique. Coherent phonon coupling between core and shell through their interface has been experimentally revealed, which agrees well with theoretical simulation. This interfacial phonon coupling also represents a unique fingerprint of complex nanostructures.

8:12AM L6.00002 Acoustic vibrations of complex metal nanostructures
AFTAB AHMED, Argonne National Laboratory, ANNA KLJINKOVA, EUGENIA KUMACHEVA, University of Toronto, Canada, JEFFREY GUEST, Argonne National Laboratory — Coherent acoustic vibrations of plasmonic nanoparticles modulate light at ultra-high frequencies. Plasmonic nanoparticles are of particular interest because of their high absorption cross sections, and offer wide range of applications including sensing and nano-mechanical devices. Here we show acoustic vibrations of complex metal nanostructure using a femtosecond pump-probe technique. The studied nanostructure is composed of an octahedral core (Au) and cubic shell (Ag). Unique elastic properties and complex geometries of the two metals provide a richer transient absorption spectrum than that of a simple nanocube of similar dimensions. Further, two different vibrational modes are detected as compared to the single-probe wavelengths. Numerical simulations were carried out to explain our experimental findings and to study the dynamics of the complex structure. Dependence of the excited modes on the pump wavelength is also investigated. These oscillations provide insights into the mechanical properties of the material at nanoscale.

8:24AM L6.00003 Slow light using crystal lattice vibrations in coupled quantum dots
ANDREW JACOBS, JOSHUA CASARA, CAMERON JENNINGS, MARK KERFOOT, MICHAEL SCHEIBNER, University of California, Merced — Phonons can induce an optical transparency in crystal structures, as was recently shown in an experimental study of asymmetric coupled quantum dots [1]. This transparency occurs due to Fano-type quantum interference between the discrete interdot exciton and continuum single dot-like polariton states. Here, we study this phonon-induced optical transparency as an avenue for slowing light. We find that slowdown factors up to 80,000 are possible, corresponding to a time delay of order 1 ps for a photon passing through a single coupled quantum dot pair. The optical slowdown is sensitive to both the Fano asymmetry factor and the homogeneous linewidth of the interdot exciton–we discuss the tunability of the slowdown factor using either parameter. Lastly, we investigate the effect of charge fluctuations, which are found to decrease the amount of optical slowdown. The experimentally measured interdot exciton linewidth is then used to theoretically infer the maximum possible optical transparency and slowdown factor without fluctuations present. [1] M. L. Kerfoot et al., Nat. Commun. 5, 3299 (2014).

8:36AM L6.00004 Phononic frequency combs through nonlinear resonances
RU-WEN PENG, Nanjing University, LU-SHUAI CAO, Universitat Hamburg, DONG-XIANG QI, MU WANG, Nanjing University, PETER SCHMELCHER, Universitat Hamburg — It is well known that optical frequency combs have become important coherent optical sources with diverging applications, ranging from optical frequency metrology to ultracold gases. In this work, we explore an analogue of optical frequency combs in driven nonlinear phononic systems, and present a mechanism for generating phononic frequency combs through nonlinear resonances. In the underlying process, a set of phonon modes is simultaneously excited by the external driving which yields frequency combs with an array of discrete and equidistant spectral lines of each nonlinearly excited phonon mode. Frequency combs through nonlinear resonance of different orders are investigated, and in particular the possibility of correlation tailoring in higher-order cases is revealed. We suggest that our results can be applied in various nonlinear acoustic processes, such as phonon harvesting, and can also be generalized to other nonlinear systems. Reference: L. S. Cao, D. X. Qi, R. W. Peng, Mu Wang and P. Schmelcher, Phys. Rev. Lett. 112, 075505 (2014).

8:48AM L6.00005 Low Frequency Thermal Conductivity in Micro Phononic Crystals
VIRGILIO ANJOS, ALISON ARANTES, Univ Federal de Juiz de Fora — We study theoretically the cumulative thermal conductivity of a micro phononic crystal at low temperature regime. The phononic crystal considered presents carbon microtubes inclusions arranged periodically in a two-dimensional square lattice embedded in soft elastic matrix. Moderate and high impedance mismatch are considered concerning the material composition. The low frequency phonon spectra (up to tens of GHz) are obtained solving the generalized wave equation for inhomogeneous media within the Plane Wave Expansion method. We consider low temperatures in order to increase the participation of GHz thermal phonons. We observed suppression in the cumulative thermal conductivity at the band gap region and thus a reduction of thermal conductivity of the phononic crystal when compared with the bulk matrix.

9:00AM L6.00006 ABSTRACT WITHDRAWN —
9:12AM L6.00007 How intermixing and anharmonicity enhances interfacial thermal conductance?1 CARLOS POLANCO, JINGJIE ZHANG, NAM LE, ROUZBEH RASTGARKAFSGHARKOLAEI, PAMELA NORRIS, AVIK GHOSH, Univ of Virginia — The thermal conductance at an interface, whether ballistic or diffusive, can be expressed as a product of the number of conducting channels (M) and their average transmission (T). The common expectation is that interfacial defects reduce T and thus hurt the conductance. This is however at odds with recent simulations showing that a thin intermixing layer can in fact enhance the conductance. We argue that such an enhancement occurs when the increase in number of modes outweighs the reduction in their average transmission. The new channels open as a result of (a) the random interfacial structure that relaxes the conservation rules for the transverse momentum and promotes transitions between formerly symmetry disallowed channels; and (b) inelastic scattering through phonon-phonon interactions that allow modes beyond the contact cut-off frequency to contribute to transport. We use these results to build a back of the envelope model for interfacial conductance that depends on the mixing distribution, the anharmonic strength, the phonon polarization and wavelength. Non-Equilibrium Green’s Function (NEGF) as well as Molecular Dynamics (MD) simulations on Si/mixed layer/Ge, as well as simpler FCC crystals support our results.

9:24AM L6.00008 Interfacial thermal transport and phonon-phonon conversion at the graphene-boron nitride lateral interface, ZHUN-YONG ONG, GANG ZHANG, YONG-WEI ZHANG, Inst of High Perform Comp — Using the nonequilibrium Green’s function method, we compute the thermal boundary conductance of a monolayer graphene-boron-nitride (Gr-BN) lateral heterostructure with an armchair interface. At 300 K, the thermal conductance of the Gr-BN interface is computed to be 3.5 nW/nm² or equivalent to approximately 200 nm of BN. The application of a strain, parallel or normal to the interface, also reduces the interfacial thermal resistance by improving the transmission of acoustic phonons. We do a modal decomposition of the phonon transmission spectrum and identify the phonon scattering channels responsible for heat transfer at the interface. We show that at low frequencies, interfacial heat transfer is dominated by the longitudinal, transverse and flexural acoustic phonons while at higher frequencies, it is mostly by longitudinal acoustic and optical phonons. Our work sheds light on the mechanism of phonon-phonon conversion at the interface of 2D lateral heterostructures and how it can be modified via the application of strain.

9:36AM L6.00009 Thermoelectric transport through a quantum nanoelectromechanical system and its backaction, HANGBO ZHOU, Natl Univ of Singapore, JUZAR THINGNA, University of Augsburg, JIAN-SHENG WANG, BAOVEN LI, Natl Univ of Singapore — In recent years, nanoelectromechanical systems (NEMS) have been in the limelight of intense experimental and theoretical investigation due to their potential applications in quantum-controlled devices. In this work we study the thermoelectric transport through a single electron transistor (SET) coupled to a quantum nano mechanical resonator (NR). The effects of the quantum NR on the thermoelectric current are investigated with special emphasis on how the SET-NR coupling strength plays a role in such a NEMS. We find that the SET-NR coupling is not only able to suppress or enhance the thermoelectric current but can also switch its direction. The effect of the NR on the thermoelectric coefficients of the SET are studied and we find that even a small SET-NR coupling could dramatically suppress the figure of merits 2ZT. Lastly, we investigate the backaction of electronic current on the NR and possible routes of heating or cooling the NR are discussed. We find that by appropriately tuning the gate voltage the backaction can be eliminated, which could find possible applications to enhance the sensitivity of detection devices.

9:48AM L6.00010 Emergence of Chaos in nano-electromechanical shuttles with hard-wall collision: Nonanalytic charge transport1 HEE CHUL PARK, Korea Institute for Advanced Study, KANG-HUN AHN, Department of physics, Chungnam National University — We develop a theory for charge transport in nano-electromechanical shuttles in the presence of hard-wall collision. We show that, in certain regimes, the time-averaged charge current is not predictable and is not an analytic function of applied voltage. The rectified electric current and its non-analyticity emerge from a non-Markovian process in the presence of the hard-wall collision, which causes chaotic motion of the shuttle.

10:00AM L6.00011 Nonlinearity-induced synchronization enhancement in micromechanical oscillators, JEFFREY R. GUEST, DARIO ANTONIO, DAVID A. CZAPLEWSKI, DANIEL LÓPEZ, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL, USA, SEBASTIÁN I. ARROYO, DAMIAN H. ZANETTE, Centro Atómico Bariloche and Instituto Balseiro, 8400 Bariloche, Río Negro, Argentina — An autonomous oscillator synchronizes to an external harmonic force only when the forcing frequency lies within a certain interval around the oscillator’s natural frequency. Under ordinary conditions, the width of this “synchronization range” decreases when the oscillator’s self-sustained amplitude grows, constraining synchronized motion of micro- and nanomechanical resonators to narrow frequency and amplitude bounds. In this talk, we will show that nonlinearity in the oscillator can be exploited to manifest a regime where the synchronization range increases with increasing oscillation amplitude. We demonstrate this regime experimentally with a self-sustained micromechanical oscillator, revealing an increase in the synchronization range by orders of magnitude over that expected for a linear oscillator. We provide analytical results which show that nonlinearities are the key determinants of this enhancement. Our results suggest a new strategy to enhance synchronization of micromechanical oscillators by capitalizing on their intrinsic nonlinear dynamics.

10:12AM L6.00012 Fluctuation Reduction in a Si Micromechanical Resonator Tuned to Nonlinear Internal Resonance, B. SCOTT STRACHAN, Michigan State Univ, DAVID CZAPLEWSKI, CHANGYAO CHEN, Argonne National Labs, MARK DYKMAN, Michigan State Univ, DANIEL LÓPEZ, Argonne National Labs, STEVEN SHAW, Michigan State Univ — We describe experimental and theoretical results on an unusual behavior of fluctuations when the system exhibits internal resonance. We study the fundamental flexural mode (FFM) of a Si microbeam. The FFM is electrically actuated and detected. It is resonantly nonlinearly coupled to another mode, which is not directly accessible and has a frequency nearly 3 times the FFM frequency. Both the FFM and the passive mode have long lifetimes. We find that the passive mode can be a “sink” for fluctuations of the FFM. This explains the recently observed dramatic decrease of these fluctuations at nonlinear resonance [1]. The re-distribution of the vibration amplitudes and the fluctuations is reminiscent of what happens at level anti-crossing in quantum mechanics. However, here it is different because of interplay of the dependence of the vibration frequency of the FFM on its amplitude due to internal nonlinearity and the nonlinear resonance with the passive mode. We study both the response of the system to external resonant driving and also the behavior of the system in the presence of a feedback loop. The experimental and theoretical results are in good agreement. [1] D. Antonio, Nat. Comm., 3, 806 (2012).
10:24AM L6.00013 Dynamical properties of single crystalline 4H-SiC micro-cantilevers and determination of Poisson’s ratio and density of 4H-SiC thin film. FENG ZHAO, ALLEN LIM, QUAN TRAN, School of Engineering and Computer Science, Washington State University Vancouver — As a wide bandgap semiconductor, single crystalline 4H-polytype silicon carbide (4H-SiC) is a very attractive material for microelectromechanical systems (MEMS) with operation in harsh environments such as high temperature, radiation, chemical/biomedical, etc. Fabrication and performance prediction of 4H-SiC MEMS require releasing of thin films as well as an accurate value of its important material properties including density and Poisson’s ratio. However, releasing single crystal 4H-SiC microstructures is extremely challenging due to the very inert chemical resistance of 4H-SiC (practically only etched by molten KOH above 600 °C). Although density and Poisson’s ratio in bulk 4H-SiC form have been known, they may not be the same in thin film with the thickness in the order of micrometers for MEMS systems. In this paper, we successfully released single crystal 4H-SiC to fabricate suspended micro-cantilever structures using a recently developed surface micromachining technique. The dynamical properties of these cantilevers including resonant frequency and force-distance were characterized, from which the density and Poisson’s ratio of 4H-SiC thin film were determined.

10:36AM L6.00014 Structural and Mechanical Properties of (Co/Cu) Co-doped Nano ZnO1. OZGUR OZTURK, ELIF ASIKUZUN, Kastamonu University, DOGAN AKCAY, LUTFI ARDA, Bahcesehir University, AHMET TOLGA TASC1, ABDULKADIR SENOL, Kastamonu University, SEVIM SENOL, CABIR TERZIOGLU, Abant Izzet Baysal University — Zn1−xCoxCoxO (x=0.0, 0.01, 0.02, 0.03, 0.04, and 0.05) solutions were prepared by co-precipitation method with subsequent calcination at 800 °C. The crystal structures, phases, sizes and microstructure of Zn1−xCoxCoxO powder samples were characterized by using X-Ray Diffraction (XRD) and Scanning Electron Microscopy (SEM). Microhardness values of all B doped ZnO powders were measured by using Vickers hardness tester. The experimental microhardness data were used to determine elastic modules, yield strength, and fracture toughness value of the samples. Additionally, the experimental results were analyzed using the various theoretical models namely, Kick’s Law, Elastic/Plastic Deformation (EPD) models, Proportional Specimen Resistance (PSR), and Hays-Kendall (HK) approach. The Vickers microhardness measurements revealed that hardness of Zn1−xBxO powder samples increased with B doping.

1This research has been partially supported by Scientific and Technological Council of Turkey (Project No. 114F259) and partially supported by Kastamonu University Scientific Research Projects Coordination Department under the Grant No. KUBAP-03/2013-41.

10:48AM L6.00015 The structural and mechanical behaviours of Boron-doped ZnO nanostructures1. ABDULKADIR SENOL, Department of Physics, Abant Izzet Baysal University, 14280 Bolu, Turkey, SEVIM DEMIROZU SENOL, Department of Chemistry, Abant Izzet Baysal University, 14280 Bolu, Turkey, OZGUR OZTURK, ELIF ASIKUZUN, AHMET TOLGA TASC1, ABDULKADIR SENOL, Kastamonu University, 37100 Kastamonu, Turkey, CABIR TERZIOGLU, Department of Physics, Abant Izzet Baysal University, 14280 Bolu, Turkey — Undoped and Boron (B)-doped Zinc Oxide (ZnO) nanoparticles were synthesized by Hydrothermal method. The structural and mechanical behaviours of B doped ZnO (Zn1−xBxO, x=0, 0.05, 0.07, 0.11) were systematically examined. The crystal structure, phases, sizes and microstructure of Zn1−xBxO powder samples characterized by using X-Ray Diffraction (XRD) and Scanning Electron Microscopy (SEM). Microhardness values of all B doped ZnO powders were measured by using Vickers hardness tester. The experimental microhardness data were used to determine elastic modules, yield strength, and fracture toughness value of the samples. Additionally, the experimental results were analyzed using the various theoretical models namely, Kick’s Law, Elastic/Plastic Deformation (EPD) models, Proportional Specimen Resistance (PSR), and Hays-Kendall (HK) approach. The Vickers microhardness measurements revealed that hardness of Zn1−xBxO powder samples increased with B doping.

Wednesday, March 4, 2015 8:00AM - 10:48AM – Session L7 DMP DCMP: Focus Session: Topological Superconductivity and Majorana Fermions

8:00AM L7.00001 Multiple signatures of topological phase transitions in a finite superconducting nanowire with intrinsic interactions1. Y.-H. CHAN, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei 10617, Taiwan, CHING-KAI CHIU, Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, Canada V6T 1Z1, KUEI SUN, Department of Physics, The University of Texas at Dallas, Richardson, Texas 75080-3021, USA — We study a finite chain model with spinless fermions that describes a pair wave superconductor with intrinsic interactions. By systematically tracking various physical quantities such as ground state energy, compressibility, entanglement spectrum, Cooper pair size, and pair condensate density, we obtain multi-signature of topological phase transitions between strong and weak pairing states. Some of the signatures are stable against finite-size effects. In addition, we explore the possibility of the topological transition at fixed volume, number of particles, and number of condensed pairs. The results would help explore a fundamental question: whether or not must a topological phase transition accompany with the change of extensive thermodynamic quantities?

8:12AM L7.00002 Effect of coupling to Majorana bound states on Kondo physics in a strongly correlated quantum-dot device1. TATHAGATA CHOWDHURY, KEVIN INGERSENT, Univ of Florida - Gainesville — Majorana bound states in spinless fermions is an intriguing possibility that is a key ingredient of Majorana bound states in Kondo physics. In order to test the theory, we have designed a quantum dot model with spinless fermions interacting with a Majorana bound state. We have studied the ground state structure of the system and found that the Majorana bound state, when added to the system, changes the ground state energy and the entanglement spectrum.

8:24AM L7.00003 Classification of reflection symmetry protected topological semimetals and nodal superconductors, CHING-KAI CHIU, University of British Columbia, ANDREAS SCHNYDER, Max Planck Institute Stuttgart — The topological classification of insulators, semimetals, and superconductors in terms of nonspatial symmetries is well understood, less is known about topological states protected by crystalline symmetries, such as mirror reflections and rotations. In this work, we systematically classify topological semimetals and nodal superconductors that are protected, not only by nonspatial (i.e., global) symmetries, but also by a crystal reflection symmetry. We find that the classification crucially depends on (i) the codimension of the Fermi surface (nodal line or point) of the semimetal (superconductor), (ii) whether the mirror symmetry commutes or anticommutes with the nonspatial symmetries and (iii) how the Fermi surfaces (nodal lines or points) transform under the mirror reflection and nonspatial symmetries. The classification is derived by examining all possible symmetry-allowed mass terms that can be added to the Bloch or Bogoliubov-de Gennes Hamiltonian in a given symmetry class and by explicitly deriving topological invariants.
8:36AM L7.00004 Signatures of topological phase transition from fluctuating vortices in superconducting doped topological insulators. PEDRO LOPES, UNICAMP-Univ de Campinas, POUYAN GAHEMI, Physics Department, City College of the City University of New York — We study the interplay between low energy vortex bound modes in superconducting doped topological insulators and dynamical fluctuations of the vortex position. We show how this interaction leads to corrections in the local density of states close to the vortex core, signaling a topological vortex phase transition. We also present a detailed analysis of the low energy vortex bound modes, with analytic and numerical approximations, which may be used to access the quantities of physical interest.

8:48AM L7.00005 Quantum interference of edge supercurrents in a two-dimensional topological insulator1. GRIGORY TKACHOV, PABLO BURSET, BJOERN TRAUZETTEL, EWELINA HANKIEWICZ, Wurzburg University — Josephson weak links made of two-dimensional topological insulators (TIs) exhibit magnetic oscillations of the supercurrent that are reminiscent of those in superconducting quantum interference devices. We propose a microscopic theory of such a TI SQUID effect1. The key ingredient of our model is the exact treatment of the influence of an external magnetic field on the edge supercurrents. We show that this effect has the form of a 1D Doppler effect that describes the flux-controlled interference of the edge currents with superimposed suppression of Andreev reflection. Both long and short junctions are discussed. In particular, for long junctions the theory shows a temperature-driven crossover from the normal $\Phi_0$-periodic SQUID pattern to a $2\Phi_0$-quasiperiodic pattern consisting of a series of alternating even and odd peaks (where $\Phi_0=hc/2e$ is the magnetic flux quantum). The predicted even-odd effect is the signature of gapless (protected) Andreev bound states with a sawtooth dependence on the magnetic flux. Our findings may shed some light on the recently observed even-odd interference pattern in InAs/GaSb-based TI Josephson junctions, suggesting new operation regimes for nano-SQUIDs.

9:00AM L7.00006 Topologically stable gapless phases in nonsymmorphic superconductors. SHINGO KOBAYASHI, MASATOSHI SATO, Department of Applied Physics, Nagoya University — Nontivial node structures are a salient feature in the unconventional superconductors (SCs), providing valuable clues to an understanding of the symmetry of Cooper pairs. In the presence of spin-orbital coupling, the node structures are determined by the group theory [1] where the symmetry operation in a crystal lattice is followed by spin. Such a node is stabilized by crystal symmetry. Especially, as the counterexample of the Blount’s theorem, Micklitz and Norman indicated that there exists a stable line node in nonsymmorphic SCs with odd parity [2]. In our previous study [3], we found that the topological classification not only includes the Blount’s theorem but also updates the instability of line node via the bulk-boundary correspondence. In this talk, taking into account the nonperiodic boundary condition on a tight-binding Hamiltonian, we extend the topological node stability to nonsymmorphic SCs and show that the stable line node suggested by Micklitz and Norman is also the topological object.

9:12AM L7.00007 Dynamical Generation of Floquet Majorana Flat Bands in s-Wave Superconductors. AMRIT POUDIL, Dartmouth College, GERARDO ORTIZ, Indiana University, Bloomington, LORENZA VIOLA, Dartmouth College — We present techniques to dynamically engineer flat bands of symmetry-protected Majorana edge modes in s-wave superconductors. Specifically, we show how time-dependent periodic control may be employed for designing time-independent effective Hamiltonians, which support Floquet Majorana flat bands, starting from topologically trivial equilibrium conditions. In the first approach, a suitably chosen modulation of the chemical potential simultaneously induces Majorana states with strong Rashba spin-orbit coupling. We focus, in particular, on the role of confinement effects in long ballistic junctions. In the normal regime, scattering at the two contacts gives rise to two distinct features in conductance, Fabry-Perot resonances and Fano dips. The latter arise in the presence of a strong Zeeman field $B$ that removes a spin sector in the leads (helical leads), but not in the central region. Conversely, a helical central region between non-helical leads exhibits helical gaps of half-quantum conductance, with superimposed helical Fabry-Perot oscillations. These normal features translate into distinct subgap states when the leads become superconducting. In particular, Fabry-Perot resonances within the helical gap become parity-protected zero-energy states (parity crossings related to Yu-Shiba-Rusinov bound states), well below the critical field $B_c$, at which the superconducting leads become topological. As a function of Zeeman field or Fermi energy, these zero-modes oscillate around zero energy, forming characteristic loops, which evolve continuously into Majorana bound states as $B$ exceeds $B_c$.

9:24AM L7.00008 Superconducting States in Doped Topological Materials. MASATOSHI SATO, Department of Applied Physics, Nagoya University — There are considerable interests in topological superconductivity in condensed matter physics. In this talk, we will present our recent works on topological superconductors and the related phenomena. In particular, I will discuss how topological non-trivial structures in normal states may provide non-trivial quantum phenomena in the superconducting states. As examples, I will discuss odd parity superconductors, superconducting states in doped topological insulators and Weyl semi-metals. In the latter case, I will show how synergy effects of symmetry and surface states in the normal states may provide non-trivial quantum phenomena in the superconducting states.

9:36AM L7.00009 SNS junctions in nanowires with spin-orbit coupling: role of confinement and helicity on the sub-gap spectrum. JORGE CAYAYO, Consejo Superior de Investigaciones Científicas (CSIC) - Spain, ELSA PRADA, Universidad Autónoma de Madrid (UAM) - Spain, PABLO SÁNCHEZ-RODRÍGUEZ, CONSEJO Superior de Investigaciones Científicas (CSIC) - Spain — We study normal transport and the sub-gap spectrum of superconductor-normal-superconductor (SNS) junctions made of semiconducting nanowires with strong Rashba spin-orbit coupling. We focus, in particular, on the role of confinement effects in long ballistic junctions. In the normal regime, scattering at the two contacts gives rise to two distinct features in conductance, Fabry-Perot resonances and Fano dips. The latter arise in the presence of a strong Zeeman field $B$ that removes a spin sector in the leads (helical leads), but not in the central region. Conversely, a helical central region between non-helical leads exhibits helical gaps of half-quantum conductance, with superimposed helical Fabry-Perot oscillations. These normal features translate into distinct subgap states when the leads become superconducting. In particular, Fabry-Perot resonances within the helical gap become parity-protected zero-energy states (parity crossings related to Yu-Shiba-Rusinov bound states), well below the critical field $B_c$, at which the superconducting leads become topological. As a function of Zeeman field or Fermi energy, these zero-modes oscillate around zero energy, forming characteristic loops, which evolve continuously into Majorana bound states as $B$ exceeds $B_c$.

9:48AM L7.00010 Observation of topologically protected surface states in a Bi-Pd superconductor. MASATO SAKANO, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, The University of Tokyo, KENJIRO OKAWA, MANABU KANOU, Materials and Structures Laboratory, Tokyo Institute of Technology, HARUHIKO SANJO, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, The University of Tokyo, TAICHI OKUDA, Hiroshima Synchrotron Radiation Center, Hiroshima University, TAKAO SASAGAWA, Materials and Structures Laboratory, Tokyo Institute of Technology, KYOKO ISHIZAKA, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, The University of Tokyo — A layered Bi-Pd superconductor is investigated by spin- and angle-resolved photoemission spectroscopy. Beside the spin-degenerate bulk bands, several spin-polarized surface bands, some of which crossing the Fermi level, are clearly observed. These surface states are evaluated to be topologically protected, based on the $Z_2$ invariant analysis in analogy to 3-dimensional strong topological insulators. It indicates that this material is likely to be a topological superconductor realized without any carrier doping or applying pressure.
10:00AM L7.00011 Surface transport coefficients for three-dimensional topological superconductors\textsuperscript{1}, HONG-YI XIE, YANG-ZHI CHOU, MATTHEW FOSTER, Rice Univ — We argue that surface spin and thermal conductivities of three-dimensional topological superconductors are universal and topologically-quantized at low temperature. For a bulk winding number $\nu$, there are $|\nu|$ “colors” of surface Majorana fermions. Localization corrections to surface transport coefficients vanish due to time-reversal symmetry (TRS). We argue that Altshuler-Aronov interaction corrections vanish because TRS forbids color or spin Friedel oscillations. We confirm this within a perturbative expansion in the interactions, and to lowest order in a large-$|\nu|$ expansion. We suggest that 3D topological superconductors are a closer analog of the 2D quantum Hall effect than 3D topological insulators.

10:12AM L7.00012 Majorana fermion from weak topological superconductivity: application to SrTiO\textsubscript{3} and KTaO\textsubscript{3}, SUK BUM CHUNG, Seoul Natl Univ, CHEUNG CHAN, HONG YAO, Institute for Advanced Study, Tsinghua University — Much of the current experimental efforts for detecting Majorana zero modes centered on probing the boundary of quantum wires with strong spin-orbit coupling. It is possible to realize the same type of Majorana zero mode at crystalline dislocation in the 2D superconductor, which has non-zero weak topological indices. Unlike at an Abrikosov vortex, at such a dislocation, there will not be midgap states other than the Majorana zero mode that can complicate the experimental detection. We will show that, using the anisotropic dispersion of the Ti / Ta t2g orbitals, such a weak topological superconductivity can be realized when the surface 2DEG of SrTiO\textsubscript{3} or KTaO\textsubscript{3} becomes superconducting.

10:24AM L7.00013 Probing Majorana-like states in quantum dots and quantum rings\textsuperscript{1}, IGOR ZUTIC, BENEDIKT SCHARF, Department of Physics, University at Buffalo, SUNY, Buffalo, NY 14260, USA — Engineering topological superconductivity in semiconductor structures offers fascinating ways to obtain and study Majorana modes in a condensed matter context. Here, we theoretically investigate topological superconductivity in quantum dots and quantum rings [1]. Using both analytical as well as numerical methods, we calculate the quasiparticle excitation spectra in these structures and the corresponding excitation amplitudes and charge densities. In the topological regime, we can observe the chiral edge modes localized at the boundaries and possessing finite energy in quantum dots and quantum rings. By applying a magnetic field which is expelled from the quantum ring, but which creates a flux that is an odd integer multiple of $\Phi_0/2 = \hbar/2e$, Majorana modes, that is, (approximately) degenerate edge modes with zero energy and zero charge density, become possible in the topological regime. Furthermore, we investigate finite-size effects that split these degenerate edge modes as well as the effect of a magnetic field penetrating into the superconducting region that can under certain circumstances still support edge modes with approximately zero energy and charge.

10:36AM L7.00014 Superconducting tunneling studies on thin film gold nanowires coupled to a BCS superconductor\textsuperscript{1}, PENG WEI, Department of Physics and Francis Bitter Magnet Lab, MIT, FERHAT KATMIS, CUI-ZU CHANG, Francis Bitter Magnet Lab, MIT, PATRICK LEE, Department of Physics, MIT, JAGADEESH MOODERA, Department of Physics and Francis Bitter Magnet Lab, MIT — The nanowire patterned out of (111)-oriented gold thin film is an excellent candidate for hosting Majorana bound states (MBS) when it is coupled to an s-wave superconductor [1]. The robust MBS is guaranteed by the large Rashba spin-orbit coupling (SOC) of gold surface state, as well as by large spatial separations between the two MBS in fabricated micrometer size long nanowires. In addition, being able to produce complex nanowire circuit, our approach is better streamlined for achieving the braiding circuit of Majorana fermions. We present our experimental approach of growing high quality hetero-layers consisting of epitaxial (111)-oriented gold thin film on vanadium using molecular beam epitaxy (MBE). Unique lithography processes are developed to pattern the top gold thin film into nanowires with a width around 100nm without damaging the hetero-layers such as its topography or superconducting behavior. Superconducting tunneling studies are performed over the gold nanowire using lithographically fabricated planar tunnel junctions. These tunneling characteristics will be discussed.

Session L8 DCMP: Modeling and Measurement of Surface Morphology 006C - Mina Yoon, Oak Ridge National Laboratory

8:00AM L8.00001 A Computational Investigation of Random Angle Grain Boundaries for CdTe Solar Cells, CHRISTOPHER BUURMA, University of Illinois at Chicago, MARIA CHAN, Argonne National Laboratory, ROBERT KLIE, SIVALINGAM SIVANANTHAN, University of Illinois at Chicago, DOE BRIDGE COLLABORATION — Grain boundaries (GB) in poly-CdTe solar cells play an important role in species diffusion, segregation, defect formation, and carrier recombination. Many studies on GBs in CdTe focus on either entire grain-boundary networks found in complete poly-CdTe devices, those exhibiting high symmetry such as the coincident site lattice (CSL) or symmetric tilt or twist, or on very small scale Scanning-Tunneling Electron Microscope (STEM) viewable interfaces and dislocations. The topic of this talk is a comprehensive survey of the grain boundary parameter space regardless of the degree of symmetry found and whether the STEM channeling condition is satisfied. Our survey encompasses both near-CSL or vicinal grain boundaries decorated with nearby dislocations, as well as mixed tilt and twist interfaces with all possible symmetrically inequivalent grain boundary planes. Atomistic calculations using a Stillinger-Weber potential will be presented on a large representative sample of random-angle GBs. Trends in interfacial energies and atomistic structures as a function of tilt/twist/displacement parameters will be investigated. First principles density functional theory (DFT) calculations will be performed on a subset of these GBs to reveal their electronic structures and their implications towards PV performance. DoE Sunshot program contract DOE DEEE005956. Use of the Center for Nanoscale Materials was supported by the USDoE, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.
8:12AM L8.00002 The surface morphology of CuFeS$_2$: A hybrid-exchange density functional study$^{1}$, VICENT HUAIR-YU CHEN, Department of Physics, Imperial College London, London SW7 2AZ, United Kingdom, RUTH MARTINEZ CASADO, Department of Theoretical Condensed Matter Physics, Autonomous University of Madrid, 28049 Madrid, Spain, GIUSEPPE MALLIA, NICHOLAS HARRISON, Thomas Young Centre, Department of Chemistry, Imperial College London, London SW7 2AZ, United Kingdom — The surface morphology of CuFeS$_2$ has been determined using hybrid-exchange density functional theory calculations. The (110) surface is identified to be the most stable non-polar surface with a surface energy of 0.58 Jm$^{-1}$. The polar (112)/(112) surface pair is shown to be remarkably stable and thermodynamically preferred to the (110) surface if certain defects are included. The stability of the polar (112)/(112) surface pair is attributed to a combination of geometric and electronic mechanisms localised to the (112) surface which combine to neutralise the electrostatic dipole perpendicular to the surface. The former entails a partial reversal of the surface atomic layer sequence while the latter involves dispersion of charge from the subsurface anions to neighbouring cations. Because of its stability, (112) and (112) facets always form a significant portion of the Wulff construction regardless of the growth conditions.

8:24AM L8.00003 Characterizing Submonolayer Growth of 6P on Mica: Capture Zone Distributions vs. Growth Exponents and the Role of Hot Precursors$^{1}$, T.L. EINSTEIN, JOSUE MORALES-CIFUENTES, Univ of Maryland-College Park, ALBERTO PIMPINELLI, Rice Quantum Institute — Analyzing capture-zone distributions (CZD) using the generalized Wigner distribution (GWD) has proved a powerful way to access the critical nucleus size$^{2}$. Of the several systems to which the GWD has been applied, we consider 6P on mica, for which Winkler’s group found $i \approx 3$. Subsequently they measured the growth exponent $\alpha$ (island density $\propto F^\alpha$, for flux $F$) of this system and found good scaling but different values at small and large $F$, which they attributed to DLA and ALA dynamics, but with larger values of $i$ than found from the CZD analysis. We investigate this result in some detail. The third talk of this group describes a new universal relation between $\alpha$ and the characteristic exponent $\beta$ of the GWD. The second talk reports the results of a proposed model that takes long-known transient ballistic adsorption into account, for the first time in a quantitative way$^{3}$. We find several intermediate scaling regimes, with distinctive values of $\alpha$ and an effective activation energy. One of these, rather than ALA, gives the best fit of the experimental data and a value of $i$ consistent with the CZD analysis.

8:36AM L8.00004 How Hot Precursor Modify Island Nucleation: A Rate-Equation Model$^{1}$, JOSUE MORALES-CIFUENTES, T.L. EINSTEIN, Univ of Maryland-College Park, ALBERTO PIMPINELLI, Rice Quantum Institute — We describe the analysis, based on rate equations, of the hot precursor model mentioned in the previous talk$^{4}$. Two key parameters are the competing times of ballistic monomers decaying into thermalized monomers vs. being captured by an island, which naturally define a “thermalization” scale for the system. We interpret the energies and dimensionless parameters used in the model, and provide both an implicit analytic solution and a convenient asymptotic approximation. Further analysis reveals novel scaling regimes and nonmonotonic crossovers between them. To test our model, we applied it to experiments on parahexaphenyl (6P) on sputtered mica$^{5}$. With the resulting parameters, the curves derived from our analytic treatment account very well for the data at the 4 different temperatures. The fit shows that the high-flux regime corresponds not to ALA (attachment-limited aggregation) or HMA (hot monomer aggregation) but rather to an intermediate scaling regime related to DLA (diffusion-limited aggregation). We hope this work stimulates further experimental investigations.

$^{1}$Work at UMD supported by NSF CHE 13-05892

8:48AM L8.00005 Scaling and Exponent Equalities in Island Nucleation: Novel Results and Application to Organic Films Alberto Pimpinelli, Levent Tumbek, and Adolf Winkler$^{1}$, ALBERTO PIMPINELLI, Rice Quantum Institute, LEVENT TUMBEK, ADOLF WINKLER, Graz Univ of Technol. — As discussed in the first talk, the scaling of the island density with the flux $F$ and/or the capture zone distribution (CZD) can be used to determine the size of the critical nucleus $i$, but so far an analytic function for CZD exists only for diffusion-limited aggregation (DLA). For CZD the scaling function is $P_i(s) = a_i s^\beta \exp(-b_i s^2)$, with $\beta = i + 2$. We have extended the analytic description of the CZD in terms of $P_i$ also to attachment-limited aggregation (ALA); in this case we obtain $\beta = (i + 3)/2$. Furthermore, we could demonstrate that the general relationship $\alpha \beta = i$ holds, independent of the aggregation mechanism$^{6}$. This important exponent equality should help to better characterize nucleation and growth of thin films.

9:00AM L8.00006 A spatio-temporal model of wrinkling in photopolymerised networks, MATTHEW HENNESSY, ALESSANDRA VITALE, PAUL STAVRINOU, OMAR MATAR, JOAO CABRAL, Imperial College London — Photopolymerisation is a common solidification process whereby crosslinked polymer networks are created by illuminating a monomer-rich bath with collimated light. In addition, photopolymerisation is extensively employed industrially and shows exceptional promise for advanced three-dimensional patterning of functional surfaces. Under conditions of strong optical attenuation and limited mass and thermal diffusion, photopolymerisation occurs in a localised region which propagates from the illuminated surface into the bulk as a travelling wave with a planar wavefront. Under specific conditions that we set out to map, this planar wavefront may become unstable and the surface of the resulting gel can acquire a wrinkled morphology. We believe this instability is mechanical in nature and arises from compressive stresses that are generated during frontal photopolymerisation. In this talk, we will present a novel mathematical model that captures both the photopolymerisation with wrinkling processes. We show that by coupling photopolymerisation with wrinkling in a controlled manner, a number of interesting and industrially relevant patterns can be achieved.
9:12AM L8.00007 Ginzburg-Landau theory of the bcc-liquid interface kinetic coefficient. KUO-AN WU, Department of Physics, National Tsing-Hua University, Hsinchu, Taiwan, JEFFREY HOYT, Department of Materials Science and Engineering and Brockhouse Institute for Materials Research, McMaster University, Hamilton, Canada, ALAIN KARMA, Physics Department and Center for Interdisciplinary Research on Complex Systems, Northeastern University, Boston, USA — We extend the Ginzburg-Landau (GL) theory of atomically rough bcc-liquid interfaces outside of equilibrium to derive an analytical expression for the kinetic coefficient $\mu_i$. The kinetic coefficient is expressed as a spatial integral along the normal direction of a sum of gradient square terms corresponding to different nonlinear density wave profiles. Anisotropy arises naturally from the dependence of those profiles on the angles between the principal reciprocal lattice vectors $\mathbf{K}$ and $\mathbf{n}$. Values of the kinetic coefficient for the (100), (110) and (111) interfaces are compared quantitatively to the prediction of linear Mikhail-Chernov (MC) theory and previous MD simulation studies of crystallization kinetics for a classical model of Fe. The GL theory predicts a similar expression for $\mu$ as the MC theory but yields a better agreement with MD simulations for both its magnitude and anisotropy due to a fully nonlinear description of density wave profiles across the solid-liquid interface. In particular, the overall magnitude of $\mu$ predicted by GL theory is an order of magnitude larger than predicted by the MC theory. GL theory is also used to derive an inverse relation between $\mu$ and the solid-liquid interfacial free-energy.

9:24AM L8.00008 Island Dynamics Model for Mound Formation: Effect of a Step-Edge Barrier. CHRISTIAN RATCSCH, UCLA, DIONISIOS MARGETIS, University of Maryland, FREDERIC GIBOU, UCSB — We have developed an island dynamics model for epitaxial growth with the level-set technique, where islands are treated as continuous in the x-y-plane, while individual atomic layers are resolved in the z-direction. Atoms are treated as a mean field quantity by solving a diffusion equation. We will discuss an analytic derivation for the proper expression for the equilibrium adatom density at the step edge in the presence of a step-edge barrier. The effect of an additional step-edge barrier is incorporated via a mixed Robin-type boundary condition for the diffusion equation. We will present a numerical scheme to solve such a boundary condition on a fixed grid with moving boundaries. We will show how the inclusion of the step-edge barrier leads to the formation of mounds that become progressively steeper as the step-edge barrier increases. Finally, we will discuss how we can include the effect of downward funneling in our model, and how it leads to the stabilization of the slope of the mounds.

9:36AM L8.00009 In-situ probing and modeling atomic layer deposition processes on Ge surface. YUANXIA ZHENG, SUNGWOOK HONG, Penn State Univ, BRUCE RAYNER, Kurt J. Lesker Company, SUMAN DATTA, ADRI VAN DUIN, ROMAN ENGEL-HERBERT, Penn State Univ — Germanium (Ge) is a promising CMOS compatible channel material with a low effective-mass of holes. One of the major challenges in developing Ge-FETs is integrating a high-quality gate stack on Ge. A direct high-k dielectric deposition like HfO$_2$ on Ge has resulted in poor electrical characteristics of the semiconductor-dielectric interface. 1 GeO$_2$/Ge interface has been found low in interface-trap density, but its quality rapidly degrades when deposited with high deposition rates. Ultrathin GeO$_2$ layers on Ge(001) are known to enhance dopant incorporation. 2 This work focuses on deposition of GeO$_2$ on Ge(001) by atomic layer deposition (ALD) processes. We use (a) in-situ spectroscopic ellipsometry for real-time monitoring of atomic-layer-deposition (ALD) processes on Ge, (b) ex-situ X-ray photoelectron spectroscopy (XPS) to probe the interface chemistry, and (c) reactive force field (ReaxFF) simulations to directly model the growth kinetics and interface formation. A strong surface-chemistry dependence (hydrogenated Ge vs oxidized Ge) has been found in the Al$_2$O$_3$-ALD nucleation (Trimethylaluminum+H$_2$O), which is well reproduced by ReaxFF simulation. Furthermore, both experiments and simulations revealed that the Al$_2$O$_3$ capping on GeO$_2$/Ge interface prevents oxygen diffusion into Ge, and therefore stabilizes the interface. 1 [1] Appl. Phys. Lett. 87, 032107 (2005). 2 J. Appl. Phys. 106, 104117 (2009). 3 2012 Symp. VLSI Technol. 2011~2012 (2012).

9:48AM L8.00010 Structural evolution of Ag nanoparticles during electron driven synthesis of Ag filaments on Ag$_2$WO$_4$. In situ observation and theoretical supporting evidence. EDISON Z. DA SILVA, Institute of Physics, University of Campinas, Unicamp, WYLLAMANIEY DA SILVA PEREIRA, INCTMN-UFScar, Universidade Federal de Sao Carlos, JUAN ANDRES, LOURDES GRACIA, Departament de Quimica Fisica i Analítica, Universitat Jaume I, MIGUEL SAN-MIGUEL, Instituto of Chemistry - University of Campinas, ELSON LONGO, INCTMN-UNESP, Universidade Estadual Paulista, VALERIA M. LONGO, INCTMN-USP, Universidade de Sao Paulo, Instituto de Fisica de Sao Carlos — $\alpha$-Ag$_2$WO$_4$ crystals irradiated by an electron beam from an electron microscope under high vacuum, nucleate metallic Ag, and form Ag metallic nanowires on the $\alpha$-crystals surface. In order to understand this interesting and complex behavior of the formation and growth of Ag nanowires on $\alpha$-Ag$_2$WO$_4$ we investigated by detailed in situ transmission electron microscopy (TEM), field emission scanning electron microscopy (FE-SEM) studies, density functional theory calculations and ab initio molecular dynamics (MD) simulations. First principle calculations point out that Ag-3 and Ag-4 atoms, located on the (100) surface, are the most energetically favorable to undergo the diffusion process to form metallic Ag. Ab initio MD simulations and nudged elastic band (NEB) method were used to investigate the minimum energy pathways for diffusion of Ag atoms to outward sites on the (100) surface. The results point out that the injection of electrons decreases the activation barrier for this diffusion step and this unusual behavior results from the presence of a lower energy barrier process.

10:00AM L8.00011 Kinetic Transition of Crystal Morphology from Nanoparticles to Dendrites during Electron Beam Induced Deposition of Gold. JEUNG HUN PARK, Univ of California Los Angeles and IBM T. J. Watson Research Center, NICHOLAS SCHNEIDER, HAIM BAU, Univ of Pennsylvania, SUNEEL KODAMBAKA, Univ of California Los Angeles, FRANCES ROSS, IBM T. J. Watson Research Center — We studied the kinetic transition from compact nanoparticle to dendritic morphology during electron beam-induced Au deposition using in situ liquid cell-based transmission electron microscopy. Radiolysis of water by electrons generates radicals and molecular species. Hydrated electrons and hydrogen and hydroxide radicals can act as reducing agents and initiate the reduction of the water-soluble precursor, HAuCl$_4$, resulting in the precipitation of Au as nanostructures. We tracked nucleation, growth, and morphological transition of Au from movies recorded in situ, as a function of irradiated dose and liquid thickness. We identified several distinct regimes that depend on the irradiation time: (1) nucleation; (2) linear volumetric growth; (3) formation of dendritic structures; (4) coalescence and dissolution. A diffusion and reaction model for the radiolytic species and metal ions in the confined geometry of the irradiated volume is used to understand the nucleation sites and morphological transitions. We finally describe how nanoparticles can be made to grow in a stepwise manner by switching the supply of Au ions on and off electrochemically, and discuss possibilities for creating more complex nanostructures.

10:12AM L8.00012 Possible detection of surface melting on solid hydrogen by TOF-SIMS. TAKU SUZUKI, National Institute for Materials Science — The molecular hydrogens form the simplest of all molecular solids. Thus, the irradiation effect of ion beams on quench-condensed hydrogen film is conceptually the simplest of all molecular condensed systems and therefore is an ideal benchmark system for testing theories. However, the number of studies concerning ion beam irradiation effect on solid hydrogen is quite limited. In the present study, we have investigated secondary ion emission from quench-condensed hydrogen films under ion beam irradiation. To prepare the quench-condensed hydrogen films, we developed ultra-high vacuum (UHV) – compatible cryostat, which enables such heating to 4 K. The UHV chamber was equipped with an ion gun with an electrostatic deflector for chopping and an electrostatic energy analyzer. The continuous 2 keV He$^+$ ion beam was utilized for ion scanning spectroscopy (ISS), while the ion beam was chopped for time-of-flight secondary ion mass spectroscopy (TOF-SIMS). The sample was prepared by the exposure of a polycrystalline H$_2$. We found the enhancement of the H$^+$ ion emission with decreasing the sample temperature. The enhancement of the secondary H$^+$ ion emission is most likely related with the solid-liquid phase transition.
10:24AM L8.00013 Surface nanopatterning using electric-field-driven assembly of single-layer epitaxial islands, ASHISH KUMAR, DWAIYEAR DASGUPTA, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — We report a systematic simulation study of an approach to surface nanopatterning based on electric-field-driven assembly of single-layer epitaxial islands on face-centered cubic crystalline substrates. We have developed and validated a fully nonlinear driven island evolution model with diffusional mass transport limited to the island edges and accounting for edge diffusional anisotropy and island coalescence and break-up. For islands on (110), (100), and (111)-oriented substrate surfaces, we report formation of complex nanomodels starting from two different types of initial configurations: a single island with larger-than-critical size and an assembly of relatively small islands, which undergo a sequence of coalescence and break-up events. For both initial configurations, we study the dependence of the nanopattern features on the duration of application of the electric field, the strength of edge diffusional anisotropy, and the misorientation angle between a fast edge diffusion direction and the applied electric field direction. For assemblies of islands, we also study the resulting nanopattern dependence on the intrinsic geometrical parameters of the assembly. We report entire classes of complex patterns formed as the above parameters are varied.

10:36AM L8.00014 Nonlinear Analysis of Secondary Ripple Formation on Surfaces of Stressed Crystalline Solids, LIN DU, DWAIYEAR DASGUPTA, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — The competition between surface energy and elastic strain energy in surfaces of stressed crystalline solids is responsible for Asaro-Tiller/Grinfeld (surface cracking) morphological instabilities. Using linear stability theory (LST), we have predicted that properly directed and sufficiently strong electric fields and thermal gradients can inhibit such instabilities; we validate the LST predictions based on self-consistent dynamical simulations according to a fully nonlinear surface evolution model. The simulations also reveal that long-wavelength perturbations from the planar surface morphology can trigger a tip-splitting instability, which causes formation of a pattern of secondary ripples that is beyond the scope of LST. Based on weakly nonlinear analysis, we have developed a theory that can explain the occurrence of such rippling instabilities and predict the number of ripples that form on the surface as a function of perturbation wavelength. The theory predicts the critical wavelength for the onset of secondary ripple formation and the external field strength requirement for planar surface stabilization. The conclusions of the theory are validated by comparisons with the results of the self-consistent numerical simulations.

Session L9 DCMP: Semiconductor Atomic Structure, Lattice Properties, and Phase Transitions
006D - Matthew Stone, Oak Ridge National Laboratory

8:00AM L9.00001 Structure and dynamics of CdTe studied by X-ray and neutron scattering, MATTHEW STONE, JENNIFER NIEDZIELA, Oak Ridge National Laboratory — We present x-ray diffraction and inelastic neutron scattering studies of the structure and lattice dynamics of commercial CdTe. We also present complementary density functional theory calculations. The X-ray data show a subtle structural transition is present near 80 K, which manifests also in the measured phonon density of states. Refinement of the structure above and below the transition temperature shows no change to the long-range ordered structure. The inelastic neutron scattering studies were performed using an isotopically un-enriched sample of CdTe, which possesses a high cross section for thermal neutron absorption. The neutron portion of the study was performed with a thin-plate geometry in the reflection condition at the ARCS instrument at the SNS, showing the high flux of the instrument makes possible lattice dynamics studies of materials with high thermal neutron absorption. Single crystal and powder inelastic neutron scattering measurements will be presented. Current interpretation of the nature of the transition and future studies will be discussed.

8:12AM L9.00002 First-principles calculations of phonons and Raman spectra in monoclinic CsSnCl$_3$, LING-YI HUANG, WALTER LAMBRECHT, Case Western Reserve Univ — Halide perovskites have recently attracted attention for photovoltaic applications. While CsSnCl$_3$ in the perovskite structure is less suitable for solar cells because of its higher band gap than the iodides, it is still of interest as the end member of mixed CsSn(I$_{1-x}$Cl$_x$)$_3$ and addition of Cl has been found to increase solar cell efficiencies. The other reason this material is interesting is that at 390 K it undergoes a phase transition to a monoclinic structure with even larger band gap, which differs from the yellow phase occuring for CsSnI$_3$. Understanding the various possible phase transitions and structures in the trihalides is important for the long-term stability of these materials in solar cells. Raman data exist on monoclinic CsSnCl$_3$ material since the late 80s but have in the past not been compared with first-principles calculations of the phonons in this material. We present calculations of the phonons at the Γ point using density functional perturbation theory using the abinit program. A symmetry analysis is presented and the calculated phonon modes are compared with experimental data and previous attempts to classify the modes as internal to the SnCl$_3$ tetrahedra and lattice modes. Supported by DOE.

8:24AM L9.00003 Application of Quantum Monte Carlo Methods to Describe the Properties of Manganese Oxide Polymorphs, JOSHUA SCHILLER, ELIF ERTEKIN, Univ of Illinois - Urbana — First-principles descriptions of the properties of correlated materials such as transition metal oxides has been a long-standing challenge. Manganese oxide is one such example: according to both conventional and hybrid functional density functional theory, the zinc blende polymorph is predicted to be lower in energy than the rock salt polymorph that occurs in nature. While the correct energy ordering can be obtained in density functional approaches by careful selection of modeling parameters, we present here an alternative approach based on quantum Monte Carlo methods, which are a suite of stochastic tools for solution of the many-body Schrodinger equation. Due to its direct treatment of electron correlation, the QMC method offers the possibility of parameter-free, high-accuracy, systematically improvable analysis. In manganese oxide, we find that the QMC methodology is able to accurately reproduce relative phase energies, lattice constants, and band gaps without the use of adjustable parameters. Additionally, statistical analysis of the many-body wave functions from QMC provides some diagnostic assessments to reveal the physics that may be missing from other modeling approaches.

8:36AM L9.00004 ABSTRACT WITHDRAWN
8:48AM L9.00005 ABSTRACT WITHDRAWN
Harmonic Approximation was applied successfully to determine the Gibbs free energy of MnFeSi, which is linearly proportional to the Latent heat \( L \) of magnetization. Experimentally \( L \) can be determined with techniques such as Differential Scanning Calorimetry. In our study we use VASP in addition to the Phonopy package, to determine the finite temperature properties of the system. Quasi Harmonic Approximation was applied successfully to determine the Gibbs free energy of MnFeSi-P, \( \text{P}_{0.66} \). Hence we show a phase transition around 425 K. From the temperature derivative of \( G \), the specific heat was obtained and finally the latent heat was obtained.

Institude for Basic Sciences, Kyung Hee University, Seoul, Korea — Using ab initio density functional calculations, we investigate the structural and electronic properties of the ordered crystalline and disordered amorphous phases of a GeTe material, which would be used for phase change random access memory. In order to understand the mechanism of shear-induced phase transition and the key factors effecting the transition, we performed molecular dynamics simulations on a GeTe material. The shear-induced phase transition would not occur without change of lattice structure — contrarily to Ce. Our study of Pu shows that the most important effect originating the differentiation between the equilibrium densities of its allotropes is the competition between the Peierls effect and the Madelung interaction. However, the proper treatment of electron correlation effects is crucial to reach good agreement with experiment. A similar interplay between kinetic and elastic interactions in the formation of Si-IV. Combining nanoscratching and micro-Raman spectroscopy, shear effect on Si-I to Si-IV phase transition has been studied qualitatively and quantitatively. A clear evolution of phase transition of silicon has been recorded. The stability of Si-IV has been analyzed by analyzing an in-situ Raman measurement under various temperatures.

8:36AM L10.00044 Tuning the Fermi level through the Dirac point of giant Rashba semiconductor BiTeI*1, DERRICK VANGENNEP, D.L. MASLOW, J.J. HAMLIN, Dept. of Physics, Univ. of Florida, S. MAITH, Dept. of Physics, Univ. of Florida and NHMFL, Tallahassee, FL, D. GRAFT, S.W. TOZER, NHMFL, Tallahassee, FL, C. MARTIN, Dept. of Physics, Univ. of Florida and Ramapo Coll., NJ, H. BERGER, Inst. of Cond. Mat. Physics, École Poly. Féd. de Lausanne — We report measurements of Shubnikov-de Haas oscillations in the giant Rashba semiconductor BiTeI under pressure. We observe one high frequency oscillation at all pressures and one low frequency oscillation that emerges between ~0.3 - 0.7 GPa indicating the appearance of a second small Fermi surface. BiTeI has a conduction band bottom that is split into two sub-bands due to the strong Rashba coupling, resulting in a “Dirac point.” Our results suggest that the chemical potential starts below the Dirac point in the conduction band at ambient pressure and moves upward across it as pressure is increased. We present a simple model that captures this effect and can be used to understand the pressure dependence of our sample parameters. The parameters extracted via our model support the notion that pressure brings the system closer to the predicted topological quantum phase transition.

8:48AM L10.00005 Magnetic field-induced breakdown of helical conduction in an InAs/GaSb bilayer, DMITRY PIKULIN, Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, Canada V6T 1Z1, TIMO HYART, Department of Physics and Nanoscience Center, University of Jyväskyla, P.O. Box 35 (YFL), FI-40014 University of Jyväskyla, Finland, SHUO MI, Instituut-Lorentz, Universiteit Leiden, P.O. Box 9506, 2300 RA Leiden, The Netherlands, JAKUB TWORZYDLO, Institute of Theoretical Physics, Faculty of Physics, University of Warsaw, Hoza 69, 00-681 Warsaw, Poland, MICHAEL WIMMER, Kavli Institute of Nanoscience, Delft University of Technology, P.O. Box 5046, 2600 GA Delft, The Netherlands, CARLO BEENAKKER, Instituut-Lorentz, Universiteit Leiden, P.O. Box 9506, 2300 RA Leiden, The Netherlands — We calculate the conductance of a two-dimensional bilayer with inverted electron-hole bands, to study the sensitivity of the quantum spin Hall insulator (with helical edge conduction) to the combination of the perpendicular magnetic field in presence of disorder. The characteristic breakdown field for helical edge conduction splits into two fields with increasing disorder, a field $B_\tau$ for the transition into a quantum Hall insulator (supporting chiral edge conduction) and a smaller field $B_\sigma$, for the transition to bulk conduction in a quasi-massless state. The spatial separation of the inverted bands, typical for broken-gap InAs/GaSb quantum wells, is essential for the magnetic-field induced bulk conduction — there is no such regime in HgTe quantum wells.

9:00AM L10.00006 HgTe/CdTe heterostructure under perturbations preserving time-reversal symmetry: a density functional theory study, PAULO PIQUINI, JONAS ANVERSA, Universidade Federal de Uberlândia, ADALBERTO FAZZIO, Universidade de São Paulo — The Dirac-like spin states at the interfaces of HgTe/CdTe heterostructures are predicted to be robust against perturbations preserving time-reversal symmetry. However, these perturbations will certainly affect these interface states. In this work we use the density functional theory to study the behavior of these interface states under external pressure and electric fields. Differently from the three-dimensional topological insulators, the HgTe/CdTe interface states present fully in-plane Rashba-like spin texture. Further, biaxial external pressures and electric fields perpendicular to the interfaces are seen to change the energetics and dispersion of the protected states, modifying the energy ordering of the crossing of the polarized interface states inside the band structure, and altering their Fermi velocities while not changing the topological phase.

9:12AM L10.00007 Search for emergent superlattice dispersion in a topological insulator heterostructure*1, ILYA BELIOPOLSKI, Princeton Univ, NIKESH KOIRALA, Rutgers University, SUYANG XU, MADHAB NEUPANE, GUANG BIAN, NASSER ALIDOUSS, Princeton University, SEONGSHIK OH, Rutgers University, ZAHID HASAN, Princeton University — Crystals are typically offered to us by nature and we must search among them to find ones with useful properties. Here, we consider a more aggressive approach to materials engineering whereby we build nanometer-scale periodic arrays of different crystal lattices. Such a lattice of lattices mimics the behavior of ‘directly engineered’ electronic properties in an emergent superlattice band structure. To our knowledge, no such superlattice dispersion has yet been observed. However, the discovery of topological insulators offers a natural route to engineering a superlattice band structure. Moreover, a topological insulator superlattice has immediate relevance to supporting chiral edge conduction and a Kramer’s pair of counter propagating 1D helical edge states. Since the topological quantum Hall effect, characterized by an insulating 2D bulk and a Kramer’s pair of counter propagating 1D helical edge states. The characteristic breakdown field for helical edge conduction splits into two fields with increasing disorder, a field $B_\tau$ for the transition into a quantum Hall insulator (supporting chiral edge conduction) and a smaller field $B_\sigma$, for the transition to bulk conduction in a quasi-massless state. The spatial separation of the inverted bands, typical for broken-gap InAs/GaSb quantum wells, is essential for the magnetic-field induced bulk conduction — there is no such regime in HgTe quantum wells.

9:36AM L10.00009 Role of Coulomb Interaction in the Bulk Gap of Inverted InAs/GaSb bilayers*1, LINGJIE DU, RUI-RUI DU, Rice Univ, GERARD SULLIVAN, Teledyne Scientific and Imaging — Inverted InAs/GaSb bilayers have been shown to support the quantum spin Hall effect, characterized by an insulating 2D bulk and a Kramer’s pair of counter propagating 1D helical edge states. Since the Fermi energy of electrons and that of holes can be individually turned by gates, the degree of band inversion can be readily controlled in experiments. Here we perform the inplane field magneto-measurement of InAs/GaSb samples, in the two limits of band inversion. In the deeply inverted regime where electron and hole density exceed 10e11/cm2, we found that the bulk gap closes under several Tesla field, consistent with previous results in the same regime (M. J. Yang et al, Phys. Rev. Lett. 78, 4613). On the other hand, in the shallowly inverted regime close to inverted-normal band transition we find that the bulk gap remains open to very high fields (up to 35T). These results suggest that the nature of the bulk gap in InAs/GaSb in the shallowly inverted regime is not well understood. We will discuss the possible role of Coulomb interaction in this regime, where dilute electron-hole gases are unstable against the formation of bilayer excitation.

We study dynamics of vortices in superconductors using the molecular dynamics simulation. Motion of vortices causes a heat generation and also decreases amplitude of the superconducting order parameter on their trail because of quasi-particle relaxation time. We incorporate these effects into the Molecular dynamics methods. In a superconducting corbino-disk, where vortices move along concentric circles, vortex motion is more rapid around the center of the disk than that around the edge. Therefore the heat generation is not uniform and there appears heat transport from the center to the edge. In such case, our simulation shows that vortices move toward the edge of the disk. Also vortices show some dynamical spiral structures depend on the pinning impurity sites and heat resistance between the superconductor and a substrate. We show details of these motions and analyze the effects of the heat transport to the vortex dynamics.

8:12AM L11.00002 ThermoElectric Measurements of Electronic Diffusivity in Bad Metals1, JIECHENG ZHANG, ELI LEVENSON-FALK, AHARON KAPITULNIK, Stanford University — Many interesting materials, including cuprate superconductors and heavy-fermion systems, exhibit “bad metal” behavior at high temperatures, where the electronic mean free path is shorter than the de Broglie wavelength. Recent theory [1] postulates that conduction in such systems is best described by collective incoherent transport, instead the standard quasiparticle model. This has implications for the temperature dependence of electronic diffusivity in these materials. We present a setup for measuring electronic diffusivity: a laser beam is focused onto a material surface and chopped, creating a periodic, concentrated heat source. The resulting thermoElectric signal is measured at various positions on the same surface with sharp voltage probes. By sweeping temperature in the range 10-450 K, we are able to measure the temperature dependence and anisotropy of the electronic diffusivity of the material. We discuss experimental improvements and measurements of cuprate superconductors.

8:24AM L11.00003 Heat Transport in non-uniform superconductors, CAROLINE RICHARD, ANTON B. VORONTSOV, Department of Physics, Montana State University, Bozeman, Montana — Thermal transport in superconductors is used as an experimental probe of both quasiparticles states and order parameter structure. Although thermal properties of uniform superconductors have been studied a lot, much less is known about details of the transport in non-uniform phases such as vortex states or the speculative Fulde-Ferrell-Larkin-Ovchinnikov state. Using the quasi-classical Keldysh technique, we theoretically investigate the heat transport in a inhomogeneous superconducting state where the order parameter contains a domain wall. We study the effect of Andreev states, bound to the domain wall, on thermal conductivity, and find the response to be strongly non-local. In linear response, we determine the density of states, impurity self-energy and the effective local temperature gradient required to sustain a stationary heat current through the sample.

8:36AM L11.00004 Heat transport along domain walls and surfaces of superconductors1, ANTON VORONTSOV, CAROLINE RICHARD, Montana State University — We calculate thermal transport in non-uniform states of unconventional superconductors, that appear near pairbreaking surfaces, or due to formation of domain walls in the order parameter. The spectrum of the quasiparticles states in these regions is dominated by the Andreev bound states, including topologically protected modes. We investigate how these states contribute to the heat transport, using non-equilibrium quasiclassical theory in linear response. We report self-consistent calculation of the order parameter, impurity self-energies, density of states and vertex corrections. Particular attention is paid to the non-local nature of the response. We show differences and similarities between domain walls in d-wave materials, and surfaces of multi-component chiral superconducting states. We describe results for Born and unitary impurity scattering limits, and effects of the Zeeman magnetic field on thermal transport.

8:48AM L11.00005 Vortex relaxation in type-II superconductors following current quenches1, HARSH CHATURVEDI, HIBA ASSI, Virginia Tech, ULRICH DOBRAMYSYL, Mathematical Institute, University of Oxford, UK, MICHEL PLEIMLING, UWE TÄUBER, Virginia Tech — The mixed phase in type-II superconductors is characterized by the presence of mutually repulsive magnetic flux lines that are driven by external currents and pinned by point-like or extended material defects. We represent the disordered vortex system in the London limit by an elastic directed line model, whose relaxation dynamics we investigate numerically by means of Langevin Molecular Dynamics. We specifically study the effects of sudden changes of the driving current on the time evolution of the mean flux line gyration radius and the associated transverse displacement correlation functions. Upon quenching from the moving into the pinned glassy phase, we observe algebraically slow relaxation. The associated two-time height-autocorrelations display broken time translation invariance and can be described by a simple aging scaling form, albeit with non-universal scaling exponents.

1Research supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02-09ER46613.

9:00AM L11.00006 Ordered Pinning Arrays with Tunable Geometry via Thermal Effects1, JUAN TRASTOY, ROZENN BERNARD, JAVIER BRIATICO, JAVIER E. VILLEGAS, Unite Mixte de Physique CNRS/Thales, France, MAXIME MALNOU, NICOLAS BERGAL, JEROME LESUEUR, LPEM, CNRS-ESPCI, France, CHRISTIAN ULYSSE, GIANCARLO FAINI, CNRS, LPN, France — We have used geometrically frustrated pinning arrays to create artificial vortex-ice [1]. The pinning arrays are fabricated via ion irradiation of high-Tc superconducting films. These arrays break time translation invariance and can be described by a simple aging scaling form, albeit with non-universal scaling exponents. Upon quenching from the moving into the pinned glassy phase, we observe algebraically slow relaxation. The associated two-time height-autocorrelations display broken time translation invariance and can be described by a simple aging scaling form, albeit with non-universal scaling exponents.

9:12AM L11.00007 Controlling Superconductivity in Thin Film with an External Array of Magnetic Nanorods, WONBAE BANG, K.D.D. RATHNAYAKA, I.F. LYUKSYUTOV, Department of Physics and Astronomy, Texas A&M University, College Station, Texas 77843, USA, W. TEIZER, Department of Physics and Astronomy, Texas A&M University; WPI-Advanced Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, D.G. NAUGLE, Department of Physics and Astronomy, Texas A&M University, College Station, Texas 77843, USA — We have fabricated a novel type of magnet-superconductor hybrid: an ordered array of magnetic nanorods on top of a superconducting film which is electrically insulated from the array. We have studied the transport properties of this magnet-superconductor hybrid including the R(T) and R(H) dependences for temperatures 0.96<T<1.06Tc and magnetic fields H<700 Oe (Tc denotes the critical temperature of the hybrid system). We compare these results with those for a superconducting film on top of alumina template with an array of magnetic nanowires.
9:24AM L11.00008 Effects of heavy ion irradiation on the thermodynamic and transport properties of YBCO1

9:48AM L11.00010 Single vortex pinning and penetration depth in superconducting NdFeAsO$_{1−x}$F$_x$. JESSIE T. ZHANG, Massachusetts Institute of Technology. JEEHOO KIM, MAGDALENA HUEFNER, Harvard University, CUN YE, Tsinghua University, STELLA KIM, PAUL CANFIELD, RUSLAN PROZOROV, Iowa State University, OPHIR M. AUSLÄNDER, Technion - Israel Institute of Technology. JENNIFER E. HOFFMAN, Harvard University — We use a magnetic force microscope (MFM) to investigate single vortex pinning and penetration depth in NdFeAsO$_{1−x}$F$_x$, one of the highest-$T_c$ iron-based superconductors. In fields up to 20 Gaus, we observe a disordered vortex arrangement, implying that the pinning forces are stronger than the vortex-vortex interactions. By manipulating the vortices using the MFM tip, we obtain single vortex depinning forces for vortices in NdFeAsO$_{1−x}$F$_x$. Moreover, our MFM measurements allow the first local and absolute measurement of the superconducting penetration depth in NdFeAsO$_{1−x}$F$_x$ to nanometer scale resolution.

10:00AM L11.00011 Structural and Ground State Vortex Lattice Domains in MgB$_2$2

10:12AM L11.00012 Enhancement of critical current through oxygen irradiation in optimized 2G superconducting coated conductors. KAREN KIHLMSTROM, Argonne National Laboratory, University of Illinois at Chicago, M. LEROUX, U. WELP, W-K. KWOK, A.E. KOSELEV, Argonne National Laboratory, G.W. CRABTREE, Argonne National Laboratory, University of Illinois at Chicago, M.W. RUPICH, S. FLESHER, A.P. MALÖZEMOFF, American Superconductor Corp, A. KAYANI, Western Michigan University, CES COLLABORATION — We demonstrate the strong suppression of the critical current density, $J_c$, of commercial coated conductors (CC) in high magnetic fields using 3 MeV oxygen irradiation. The rapid suppression of $J_c$ of coated conductors in magnetic fields remains a barrier for application of CCs in motors, generators, transformers, solenoids, and MRI systems. Using TRIM simulations, we determined that 3-MeV O-ions produce an essentially uniform defect distribution in bare CC at a rate that is $\sim$ 2500 faster than that achieved with proton irradiation. Irradiating with 3 MeV O-ions to a dose of 1x10$^{13}$ O-ions/cm$^2$ generates a near doubling of the critical current at low temperatures: at 5K, 5T, we enhanced the critical current from 6.4 MA/cm$^2$ to 12.2 MA/cm$^2$. This dose can be achieved in a couple of seconds, thus this irradiation technique could be incorporated into a viable reel-to-reel production process. This work supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. D.O.E., Office of Science, Office of Basic Energy Sciences (K.K., M.L., A.K) and by the D.O.E, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357 (U.W., W.K.).

10:24AM L11.00013 Magnetic Levitation Force Measurement System at Any Low Temperatures From 20K To 300K1

10:36AM L11.00014 Controlling microwave driven vortex avalanches by superconductivity stimulation. ANTONIO LARA, FARKHAD G. ALIEV, Universidad Autonoma de Madrid, Spain, ALEJANDRO V. SILHANEK, Université de Liège, Belgium, VICTOR V. MOSCHCHALOV, Katholieke Universiteit Leuven, Belgium — The response of superconducting devices to electromagnetic radiation is a core concept implemented in diverse applications, ranging from the currently used voltage standard to single photon detectors in astronomy. Surprisingly, a sufficiently high power subgap radiation may stimulate superconductivity itself. Recently we have demonstrated the possibility of stimulating also type II superconductors, in which the radiation may cause nonlinear response of the vortex core [1]. This effect opens the possibility of effective control over vortex avalanches. Here we report on a detailed study of superconductivity enhancement and avalanche control by GHz radiation in type II superconducting Pb films in the presence of vortices. The magnetic field dependence of the vortex related microwave losses in a film with periodic pinning reveals a reduced dissipation of mobile vortices in the stimulated regime due to a reduction of the core size. Results of numerical simulations support the validity of this conclusion. Moreover, we demonstrate that microwave stimulated superconductivity induces a notable increase of microwave depinning power needed to trigger avalanches in the proximity of vortex depinning frequencies. Our findings open new ways to control the vortex dissipation and depinning induced avalanches by using superconductivity stimulation.

10:48AM L11.00015 Observation of Sinusoidal – Like Regular Voltage Oscillations in Silver Doped YBa2Cu3O7−δ1, ATILGAN ALTINKOK, Giresun University, MURAT OLUTAS, ATILLA KILIC, KIVILCIM KILIC, Abant Izzet Baysal University — The influence of bi-directional square wave (BSW) current was investigated on the evolution of the $V−t$ curves at different periods ($P$), temperatures and external magnetic fields. It was observed that slow transport relaxation measurements result in regular sinusoidal voltage oscillations which were discussed mainly in terms of the dynamic competition between pinning and depinning. The symmetry in the voltage oscillations was attributed to the elastic coupling between the flux lines and the pinning centers along grain boundaries and partly inside the grains. This case was also correlated to the equality between flux entry and exit along the YBCO/Ag sample during regular oscillations. It was shown that the voltage oscillations can be described well by an empirical expression $V(t) ∼ \sin(\omega t + \phi)$. We found that the phase angle $\phi$ generally takes different values for the repetitive oscillations. Fast Fourier Transform analysis of the $V−t$ oscillations showed that the oscillation period is comparable to that ($P$) of the BSW current. This finding suggests a physical mechanism associated with charge density waves (CDWs), and, indeed, the weakly pinned flux line system in YBCO/Ag resembles the general behavior of CDWs. At certain values of $P$, amplitude of BSW current, $H$ and $T$, the YBCO/Ag sample behaves like a double-integrator, since it converts the BSW current to sinusoidal voltage oscillations in time.

Wednesday, March 4, 2015 8:00AM - 11:00AM –
Session L12 DMP GERA FIAP DCOMP: Focus Session: Oxide and Chalcogenide Thermoelectric Materials 007C - Zhifeng Ren, University of Houston

8:00AM L12.00001 Theoretical survey of doped sodium cobaltate and strategies for enhancing the thermoelectric performance1, M. HUSSEIN N. ASSADI, HIROSHI KATAYAMA-YOSHIDA, Osaka University — Doped Na$_x$CoO$_2$ is suitable for highly efficient thermoelectric conversion at $\approx 1000$ K. However, due to complex lattice structure and strong correlation effects, atomistic understanding of dopant’s influence is challenging to resolve experimentally. We examined a wide range of dopants’ electronic structures using density functional method. We found that dopants like Mg, Ba, Sr, Au and Eu always substitute Na for all Na concentrations. In contrast, dopants like Ni, Bi, W, Sb and Sn always substitute Co regardless of Na concentration. Furthermore, there is a third class of dopants like Cu and Y that substitute Na for $x \leq 0.5$, but for higher Na concentrations, they substitute Co. In the case of Mg$_x$Na$_{1-x}$, we could experimentally verify Mg’s local chemical environment using Raman spectroscopy therefore validating the theoretical results. The implication of Na-substituting dopants on thermoelectric performance is the immobilization of Na ions which behave similar to ionic liquid in pristine Na$_x$CoO$_2$. This immobilization reduces the resistivity by improving the mobility of carriers and thus enhancing the thermopower.

8:12AM L12.00002 Anisotropic transport in single-crystal molybdenum bronze, Li$_{0.33}$MoO$_3$. SAEED MOSHEFYEGAN, JOSHUA L. COHN, University of Miami, JOHN J. NEUMEIER, Montana State University — We present transport measurements (resistivity, thermopower, thermal conductivity) on single crystals of the quasi-one-dimensional semiconductor Li$_{0.33}$MoO$_3$ in the temperature range 200-500 K. First synthesized and studied long ago[2] the thermal and thermoelectric properties for this compound have not been previously reported. We find extreme anisotropy in the Seebeck coefficient within the $\alpha−c$ planes, with $S_\alpha − S_\beta \approx 300 \mu$V/K near room temperature. The thermal conductivity at room temperature in the $a−c$ planes was $\sim 1.5−2$ W/mK and 7-8 times smaller along $b^*$. We also report x-ray studies of the out-of-plane ($b^*$) lattice constants indicating a small structural transition at $T \approx 350$ K that coincides with anomalies in the transport properties.

8:24AM L12.00003 Thermoelectric properties of amorphous ZnO-based materials using ab initio methods. ANINDYA ROY, YU-TING CHENG, MICHAEL L. FALK, Johns Hopkins Univ — We use a combination of computational methods - molecular dynamics and density functional theory, to predict thermoelectric properties of amorphous ZnO-based materials. We use BoltzTraP[1] to calculate properties such as Seebeck coefficient and electrical conductivity within semiclassical Boltzmann transport theory, and compare with available experimental results. Additionally, we investigate the change in the thermoelectric parameters caused by alloying amorphous ZnO with tin and other elements. Our preliminary calculations suggest that the thermoelectric performance of amorphous ZnO is on par with the crystalline counterpart. This is encouraging - since amorphous materials are yet to be studied in depth for their potential as thermoelectric materials, and they could see much improvement with sustained effort. Also, while ab initio methods are routinely used to predict properties of crystalline systems, their application in amorphous systems is a less-explored area.

8:36AM L12.00004 Perovskite- and Heusler based materials for thermoelectric converters. ANKE WEIDENKAFF, University of Stuttgart — The broad application of thermoelectric converters in future energy technologies requires the development of active, stable, low cost and sustainable materials. Semiconductors based on perovskite and heusler structures show substantial potential for thermoelectric energy conversion processes [1-3]. Their good performance can be explained based on their suitable band structure, adjusted charge carrier density, mass and mobility, limited phonon transport, electron filtering possibilities, strongly correlated electronic systems, etc. These properties are widely tunable by following theoretical concepts and a deep composition-structure-property understanding to change the composition, structure and size of the crystallites in innovative scalable synthesis procedures. Improved thermoelectric materials are developed, synthesised and tested in diverse high temperature applications to improve the efficiency and energy density of the thermoelectric conversion process. The lecture will provide a summary on the field of advanced perovskite-type ceramics and Heusler compounds gaining importance for a large number of future energy technologies.

9:12AM L12.00005 Thermoelectric properties of Cl-doped In$_2$Pb$_{0.01}$Sn$_{0.03}$Se$_{2.9}$Cl$_x$ polycrystalline compounds. JIN-HEE KIM, MIN JAE. KIM, SUEKYUNG OH, JONG-SOO RHYEE, Kyung Hee Univ - Sawon Campus, SU-DONG PARK, Advanced Materials Group, Korea Electrotechnology Research Institute. We investigated thermoelectric properties of Cl-doped polycrystalline compounds of In$_2$Pb$_{0.01}$Sn$_{0.03}$Se$_{2.9}$Cl$_x$ ($x = 0.02$, $0.04$ and $0.06$). The x-ray diffraction measurement shows gradual change of lattice volume for $x < 0.04$ without any impurity phases indicating systematic change of Cl-doping. The Cl-doping in the compounds has an effect of increasing carrier concentration and effective mass of carrier resulting in the increase of power factor near 700 K than In$_2$Pb$_{0.01}$Sn$_{0.03}$Se$_{2.9}$. Because of the increased electrical conductivity near 700 K, the thermoelectric figure-of-merit $ZT$ is 1.25 at 723 K for $x = 0.04$ Cl-doped compound which is relatively high value as n-type polycrystalline materials.

9:24AM L12.00006 Effects of Ge replacement in GeTe by Ag or Sb on the Seebeck coefficient and carrier concentration modified by local electron imbalance. E.M. LEVIN, A. HOWARD, U.S. DOE Ames Laboratory and Iowa State University, W.E. STRASZHEIM, Iowa State University. Variation in carrier concentration in Ag$_{2-x}$Ge$_{2-x}$Te$_5$ and Sb$_{2-x}$Ge$_{2-x}$Te$_5$ was found for Sb$_2$Ge$_2$Te$_5$ and Ag$_2$Ge$_2$Te$_5$. Interplay between the Seebeck coefficient and electrical resistivity in these alloys results in variation of power factor; the value of 45 mW/cm K° at 300 K and 873 K, respectively, if matched with appropriate p-type legs.

9:36AM L12.00007 Raman Spectroscopy of the Thermoelectric Sr$_{0.6}$Ba$_{3.8}$Nb$_2$O$_6$. MICHAEL PRIMROSE, JEAN TOULOUSE, Physics Department, Lehigh University. JONATHAN BOCK, CLIVE RANDALL, Center for Dielectric Studies, Materials Research Institute, Pennsylvania State University — Strontium Barium Niobate (SBN) has recently been shown by Lee et al. [1] to exhibit high thermoelectric power factor and electrical resistivity of Ag$_2$Ge$_2$Te$_5$ and Sb$_2$Ge$_2$Te$_5$ can be attributed to different electron configurations of valence electrons of Ag (4d$^{10}$5s$^1$) and Sb (5s$^2$5p$^3$) compared to that of Ge (4s$^2$4p$^3$) resulting in local electron imbalances and changing the concentration of charge carriers (holes) generated by Ge vacancies. In contrast, our $^{125}$Te NMR and Seebeck coefficient data for Ag$_2$Sb$_2$Ge$_4$Te$_8$ are similar to those observed for GeTe. This shows that effects from Ag and Sb compensate each other and indicates the existence of [Ag$_x$Sb$_y$] pairs. The effects of Ge replacement in GeTe by Ag, Sb, or [Ag$_x$Sb$_y$] on rhombohedral lattice distortion also have been analyzed. Interplay between the Seebeck coefficient and electrical resistivity in these alloys results in variation of power factor; the value of 45 mW/cm K°, the highest among known tellurides, was found for Sb$_2$Ge$_2$Te$_5$.

9:48AM L12.00008 Bulk oxides: asymmetry between p- and n-type transport properties. ANTOINE MAIGNAN, LABORATOIRE CRISMAT / CNRS / ENSICAEN / UCBN. The thermoelectric power (TEP) of transition metal oxides shows large difference depending on the sign of the charge carriers. In electron-doped oxides, the best TEs in terms of the figure of merit are heavily doped transparent conductors (as doped ZnO). The physics is very similar to that of semiconductors, though the defects chemistry differs: the existence of planar defects created by the dopants (in the conduction band) and the p-doping induced via the formation of oxygen vacancies (in the valence band). In contrast, the best n-types are layered cobaltites (CdI$_2$-type layers with edge-shared Co$_{12}$ octahedra). The Co cations adopt a low spin state. Both electronic correlations and spin entropy have to be considered to explain the S(T) curve for T < 150K, whereas for T > 150K, the spin/orbital configurations and the doping level in the generalized Heikes formula are dominating. This description supported by the results obtained for perovskite ruthenates was recently unvalidated for the quadruple perovskite AC$_2$Ru$_4$O$_{12}$, showing very different S(T) with S saturation at 900K. Their Pauli paramagnetism enlights the role of the spins upon thermopower. Similarly, searching for other n-types, interesting TE properties have been found in Ba$_2$Mn$_2$O$_{12}$; the S(T) evidences a charge/orbital ordering in this manganite ($y_{Mn}=3.7$) coupled to an abrupt change in the unit-cell volume. Ba$_2$Mn$_2$O$_{12}$, although of n-type, exhibits a cst. ($S_{Mn}=-240$ cm$^{-1}$) T-400K, explained by the generalized Heikes formula rather used for p-type. This difference with other n-type oxides is related to the Mn$^{4+}$/Mn$^{3+}$ magnetism and the contribution of e$_g$ orbitals for the transport properties. In this presentation, the richness of the TE properties of metal transition oxides will be emphasized focusing on the important role of the spins.

10:24AM L12.00009 Enhancement of Thermoelectric Performance in n-type PbTe$_{1−y}$Se$_y$ by Cr Doping. EYOBS CHERE, QIAN ZHANG, Univ of Houston. KENNETH MCEANLEY, MIT. MENG LIANG YAO, Boston Collage, FENG CAO, Univ of Houston, CYRIE OPEIL, Boston Collage. We investigated the thermoelectric properties of PbTe$_{1−y}$Se$_y$ with $y = 0.25$, $0.5$, $0.75$, $0.85$, and $1$. We found the peak $ZT$ temperature increased with increasing concentration of Se. A highest $ZT$ of $≈ 0.6$ at room temperature in Te-rich Cr$_{0.015}$Pb$_{0.985}$Te$_{0.75}$Se$_{0.25}$ was obtained due to a lowered thermal conductivity and enhanced power factor resulted from high Seebeck coefficient of about -220 $\mu$V K$^{-1}$ and high Hall mobility $≈ 1120$ cm$^2$ V$^{-1}$ s$^{-1}$ at room temperature. A room temperature $ZT$ of $≈ 0.5$ and peak $ZT$ of $≈ 1$ at about 573 K to 673 K is shown by Se-rich sample Cr$_{0.01}$Pb$_{0.99}$Te$_{0.25}$Se$_{0.75}$. This improvement of the room temperature $ZT$ improved the average $ZT$ over a wide temperature range and could potentially lead to a single leg efficiency of thermoelectric conversion for Te-rich Cr$_{0.015}$Pb$_{0.985}$Te$_{0.75}$Se$_{0.25}$ up to $≈ 11 \%$ and Se-rich Cr$_{0.01}$Pb$_{0.99}$Te$_{0.25}$Se$_{0.75}$ up to $≈ 13 \%$ with cold side and hot side temperature at 300 K and 873 K, respectively, if matched with appropriate p-type legs.

10:36AM L12.00010 Phonon Dispersions of Thermoelectric SnSe$^{1}$. CHEN LI, JIAWANG HONG, ANDREW MAY, JIE MA, TAO HONG, SONGXUE CHI, GEORG EHLERS, OLIVIER DELAIRE, Oak Ridge National Laboratory — SnSe has recently attracted significant interest as a thermoelectric material with very high $ZT$ > 2 along two crystallographic axes. A favorable property of SnSe is its very low thermal conductivity, which is below 1$W/m$ K$^{-1}$ along all axes even at ambient temperature, and decreases with temperature. However, the degree of anisotropy of the thermal conductivity remains somewhat controversial. We present our results of detailed inelastic neutron scattering measurements of the phonon dispersions and their temperature dependence. The results are compared with first-principles calculations to investigate the origin of the low thermal conductivity and its anisotropy.

10:48AM L12.00011 Ultrafast investigation of photo-excited carrier-lattice dynamics in PbTe using Fourier-transform inelastic X-ray scattering, MASON JIANG, CRYSTAL BRAY, JESSE CLARK, TOM HENIGHAN, MIKE KOZINA, AARON LINDENBERG, MARIANO TRIGO, PETER ZALDEN, DAVID REIS, PULSE Institute, Stanford University, MATTHIEU CHOLLET, JAMES GLOWNIA, MATTHIAS HOFFMANN, DILING ZHU, LCLS, SLAC National Accelerator Laboratory, OLIVIER DELAIRE, ANDREW MAY, BRIAN SALES, Oak Ridge National Laboratory, STEPHEN FAHY, EAMONN MURRAY, IVANA SAVIC, Tyndall National Institute — We report with fine temporal and momentum resolution non-equilibrium electron-phonon and phonon-phonon dynamics in the widely-used thermoelectric material PbTe. The measurements are made possible by both the intense, ultrafast X-ray pulses of the Linac Coherent Light Source instrument and the recently developed Fourier-transform inelastic X-ray scattering (FT-IXS) technique. We demonstrate experimentally the various effects of impulsive optical photo-excitation on the lattice dynamics of the material as carriers are dramatically redistributed in the system. Specifically, coupled two-phonon states are excited throughout various Brillouin zones and possible plasmon-phonon modes are observed very near zone center. Coupled with calculations from density functional theory (DFT), an analysis of these photo-excited modes yields new insight into the origins of the incipient ferroelectricity and zone center anomalies noted in past measurements on PbTe.

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L13 DMP: Focus Session: Nanostructured LaAlO$_3$/SrTiO$_3$ Heterostructures 007D - Jeremy Levy, University of Pittsburgh

8:00AM L13.0001 Ultrafast Optical Response of Graphene/LaAlO$_3$/SrTiO$_3$ Nanostructures$^1$, LU CHEN, GIRRIRAJ JNAWALI, MENCHENG HUANG, JEN-FENG HSU, FENG BI, University of Pittsburgh, HYUNGWOO LEE, SANGWOO RYU, CHANG-BEOM EOM, University of Wisconsin-Madison, BRIAN D’URSO, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — The exceptional electronic and optical properties of graphene make it promising for tunable plasmonic device applications in the terahertz regime. Plasmons can be induced in graphene by femtosecond laser excitation and its resonance frequency can be tuned over a broad terahertz range by varying the graphene pattern size or gate voltage. Recently, generation, and detection of broadband terahertz (around 10 THz) radiation from 10-nm-scale LaAlO$_3$/SrTiO$_3$ nanostructures created by conductive atomic force microscope (c-AFM) lithography has been demonstrated. This unprecedented control of THz radiation at 10 nm length scales creates a pathway toward hybrid THz functionality in graphene/LaAlO$_3$/SrTiO$_3$ nanostructures. We will discuss efforts to probe graphene plasmonics and its tunability by using this nanoscale THz spectrometer.

8:12AM L13.0002 Probing the nanoelectromechanical properties of LaAlO$_3$/SrTiO$_3$ Sketch-SETs, A. GAUTHIER, F. BI, Department of Physics and Astronomy, University of Pittsburgh, H. LEE, S. RYU, C. B. EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, P. IRVIN, J. LEVY, Department of Physics and Astronomy, University of Pittsburgh — The LaAlO$_3$/SrTiO$_3$ (LAO/STO) interface is reversibly achieved using a locally-tunable metal-insulator transition. This property can be applied to create nanoscale electronic devices such as sketched single-electron transistors (Sketch-SETs) at the LAO/STO interface. A Sketch-SET consists of a quantum dot coupled to source, drain, and gate electrodes. LAO/STO possesses a coupling between lattice distortion and carrier density; mechanical strain applied to the surface can tune the conductance at the interface. Leveraging this property may allow for strain-based control over the electron occupancy of a Sketch-SET. We use a cryogenic scanning probe microscope to create (at room temperature) and measure (at low temperature) the electronic properties of Sketch-SET devices and probe their unique nanoelectromechanical properties.

8:24AM L13.0003 CVD-grown graphene on LaAlO$_3$/SrTiO$_3$: transferring, patterning and c-AFM lithography$^1$, MENGCHENG HUANG, GIRRIRAJ JNAWALI, JEN-FENG HSU, Univ of Pittsburgh, HYUNGWOO LEE, SANGWOO RYU, Univ of Wisconsin-Madison, FENG BI, UNIV of Pittsburgh, FERESHTHE GHAHARI, JAYAKANTH RAVICHANDRAN, PHILIP KIM, Harvard Univ, CHANG-BEOM EOM, Univ of Wisconsin-Madison, BRIAN D’URSO, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — Interesting properties are anticipated when graphene is integrated with complex-oxide heterostructures. To create these structures, single-layer graphene is grown by chemical vapor deposition and transferred onto LaAlO$_3$/SrTiO$_3$, following a deep UV exposure method, the size and position of the graphene can be patterned to be compatible with the c-AFM lithography technique applied on LaAlO$_3$/SrTiO$_3$. Local control of metal-insulator transition at LaAlO$_3$/SrTiO$_3$ interface is reversibly achieved using the c-AFM lithography technique without observable graphene degradation. The graphene layer can also serve as a top gate to modulate the LaAlO$_3$/SrTiO$_3$ interface conductance.

8:36AM L13.0004 High-energy photoemission studies of oxide interfaces$^1$, RALPH CLAESSEN, Physikalisch-Institut und Rontgen Center for Complex Material Systems (RCCM), Universitat Wuerzburg, Germany — The interfaces of complex oxide heterostructures can host novel quantum phases not existing in the bulk of the constituents, with the high-mobility 2D electron system (2DES) in LaAlO$_3$/SrTiO$_3$ (LAO/STO) representing a prominent example. Despite extensive research the origin of the 2DES and its unusual properties — including the supposed coexistence of superconductivity and ferromagnetism — are still a matter of intense debate. Photoelectron spectroscopy, recently extended into the soft (SX-ARPES) and hard (HAXPES) X-ray regime, is a powerful method to provide detailed insight into the electronic structure of these heterostructures and, in particular, of the buried interface. This includes the identification of the orbital character of the 2DES as well as the determination of vital band surface information, such as band alignment, band bending, and even k-resolved band dispersions and Fermi surface topology. Moreover, resonant photoemission at the Ti-L edge reveals the existence of two different species of Ti 3d states, localized and itinerant, which can be distinguished and identified by their different resonance behavior. The role of oxygen vacancies is studied by controlled in-situ oxidation, which allows us to vary the composition from fully stoichiometric to strongly O-deficient. By comparison to free STO surfaces we can thus demonstrate that the metallicity of the heterointerfaces is intrinsic, i.e., it persists even in the absence of O defects. I will discuss our photoemission results on LAO/STO heterostructures in both (100) and (111) orientation as well as on the related system γ-Al$_2$O$_3$/STO(100), which also hosts a 2DES with an even higher mobility. Work in collaboration with J. Mannhart (MPI-FKF, Stuttgart), T. Prbyd (TU Denmark), N. Rijnders (U Twente), S. Saga (U Osaka), M. Giorgoi (BESSY, HZB), W. Drube (DESY Photon Science), V.N. Strocov (Swiss Light Source), J. Denlinger (Advanced Light Source, LBNL), and T.-L. Lee (Diamond Light Source).

$^1$Support by DFG and BMBF is gratefully acknowledged.
we present the investigation of ballistic transport in LaAlO$_3$ of electronic device density is key for any material system to be considered as potential for electronics, which demands ballistic devices at the nanoscale. Here, we gratefully acknowledge financial support from the following agencies and grants: AFOSR (FA9550-12-1-0057 and FA9550-10-1-0524) AFOSR FA9550-12-1-0342 (CBE) and DMR-1234096 (CBE).

Astronomy, University of Pittsburgh, HYUNGWOO LEE, SANGWOO RYU, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Pittsburgh — Weak anti-localization is a macroscopic observation of a quantum transport phenomenon in two-dimensional systems with spin-orbit coupling in which destructive self-interference of carrier trajectories leads to an enhanced conductivity at low magnetic fields. Characterizing spin-orbit coupling at the LaAlO$_3$/SrTiO$_3$ (LAO/STO) interface is important in realizing this system’s potential as a principal host for oxide nanoelectronics. Previously, the spin-orbit coupling at the 2D LAO/STO interface was shown to be gate-tunable. Here, we study a crossover from 2D to 1D regimes using nanowires at the LAO/STO interface using weak anti-localization measurements. Transport measurements were performed on nanowires with widths varying from 200 nm down to 10 nm. A series of magnetoresistance measurements were performed at various backgate voltages to study carrier-density dependence. The results are fit to both 2D and 1D models of a weak anti-localization conductance correction due to Rashba spin-orbit coupling.

2We gratefully acknowledge financial support from ARO (W911NF-08-1307), AFOSR (FA9550-10-1-0524 and FA9550-12-1-0342), and NSF (DMR-1104191, DMR-1124131 and DMR-1234096).

3We gratefully acknowledge support for this work from ARO (W911NF-08-1307), AFOSR (FA9550-10-1-0524 and FA9550-12-1-0342), and NSF (DMR-1104191, DMR-1124131 and DMR-1234096).

LaAlO$_3$/SrTiO$_3$ nanowires

investigating dimensional crossover of spin-orbit coupling in

LaAlO$_3$/SrTiO$_3$ nanowires

RONGPU ZHOU, MICHELLE TOMCZKYK, GUANGLEI CHENG, SHICHENG LU, MENGCHEN HUANG, PATRICK IRVIN, Univ of Pittsburgh, HYUNGWOO LEE, SANGWOO RYU, CHANG-BEOM EOM, Univ of Wisconsin-Madison, JEREMY LEVY, Univ of Pittsburgh — Scaling of electron device density is key for any material system to be considered as potential for electronics, which demands ballistic devices at the nanoscale. Here we present the investigation of ballistic transport in LaAlO$_3$/SrTiO$_3$ nanowire devices that act as quantum point contacts. In these devices, electron transport shows quantized conductance up to 3rd sub-band energy levels. We also observe odd integer conductance in the units of $e^2/h$ at high magnetic fields, further indicating spin-resolved quantum transport. We analyze the strength of the Zeeman spin-splitting for various sub-bands induced by magnetic field, where 1D sub-bands show a linear Zeeman splitting for out of plane magnetic field. From the transconductance and magnetic field dependence measurements we extract a g-factor for each of these sub-bands. We discuss the various factors related to spin-resolved transport in these devices. Acknowledgements: We gratefully acknowledge financial support from the following agencies and grants: AFOSR (FA9550-10-1-0524 and FA9550-12-1-0268), NSF (DMR-1124131 and DMR-1104191), AFOSR FA9550-12-1-0342 (CBE), and DMR-1234096 (CBE).

Quantized conductance through quantum point contacts in LaAlO$_3$/SrTiO$_3$ nanowires

Quantized conductance through quantum point contacts in LaAlO$_3$/SrTiO$_3$ nanowires

ANIL ANNADI, SHICHENG LU, GUANGLEI CHENG, MICHELLE TOMCZKYK, MENGCHEN HUANG, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, SANGWOO RYU, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — Abstract: Scaling of electronic device density is key for any material system to be considered as potential for electronics, which demands ballistic devices at the nanoscale. Here we present the investigation of ballistic transport in LaAlO$_3$/SrTiO$_3$ nanowire devices that act as quantum point contacts. In these devices, electron transport shows quantized conductance up to 3rd sub-band energy levels. We also observe odd integer conductance in the units of $e^2/h$ at high magnetic fields, further indicating spin-resolved quantum transport. We analyze the strength of the Zeeman spin-splitting for various sub-bands induced by magnetic field, where 1D sub-bands show a linear Zeeman splitting for out of plane magnetic field. From the transconductance and magnetic field dependence measurements we extract a g-factor for each of these sub-bands. We discuss the various factors related to spin-resolved transport in these devices. Analysis of local conductance switching by AFM-writing at the LaAlO$_3$/SrTiO$_3$ interface

MARGHERITA BOSELLI, DANFENG LI, WEI LIU, ALEXANDRE FÉTE, STEFANO GARIGLIO, JEAN-MARC TRISCONE, DQMP, University of Geneva — A two dimensional electron liquid is present at the interface between LaAlO$_3$ and SrTiO$_3$; this system exhibits several interesting physical properties, including tunable superconductivity. In heterostructures with 3 unit cells of LaAlO$_3$, an insulator to metal transition can be induced by the electric field effect. We report here on the use of the atomic force microscopy writing technique developed in the group of J. Levy [1] to locally switch on and off conductivity at the interface. Our results show that a quatz resonator AFM sensor is particularly suitable for this purpose. In this configuration, the measurements can be performed in the dark, strongly reducing photo-doping. Electronic nanostructures are found to be particularly sensitive to the writing procedure and to the ambient humidity. We discuss how these parameters can be optimized to confine electrons in regions down to tens of nanometers. Simulations of the conductance changes upon AFM writing are compared to experiments. The temperature evolution of the conductance shows that nanowires are metallic.

Anisotropic superconducting properties of nanowires at the LaAlO$_3$/SrTiO$_3$ (110) interface

PATRICK IRVIN, MENGCHENG HUANG, ANIL ANNADI, GUANGLEI CHENG, JEREMY LEVY, University of Pittsburgh, KALON GOPINADHAN, THIRUMALAI VENKATESAN, ARIANDO ARIANDO, National University of Singapore — The superconducting properties of nanowires created on anisotropic SrTiO$_3$ (110) surfaces were investigated. Nanowires are created using conductive AFM (c-AFM) lithography at the LaAlO$_3$/SrTiO$_3$ (110) interface along the (001) and (110) crystallographic directions. In these devices we observe anisotropic superconductivity. The upper critical magnetic field along the (001) and (110) directions are found to be markedly different with a superconducting dome that is shifted for the two orientations. These observations can be explained by anisotropic orbital binding of Ti and O atoms or the differences in the spin-orbit coupling along the two different directions.

1We gratefully acknowledge support for this work from NSF (DMR-1124131, DMR-1104191), AFOSR (FA9550-12-1-0057, FA9550-12-1-0268), and CRP-NRF (Tailoring Oxide Electronics).

One-dimensional Quantum Wire Formed at the Boundary Between Two Insulating LaAlO$_3$/SrTiO$_3$ Interfaces

ALON RON, Tel Aviv University, YORAM DAGAN, Tel Aviv Univ — We grow a tiled structure of insulating two dimensional LaAlO$_3$/SrTiO$_3$ interfaces composed of alternating one and three LaAlO$_3$ unit cells. The boundary between two tiles is conducting. At low temperatures this conductance exhibits quantized steps as a function of gate voltage indicative of a one dimensional channel. The step size of half the quantum of conductance is an evidence for absence of spin degeneracy.
10:24AM L13.00011 Metal-insulator transition in nanostructured SrTiO$_3$/LaAlO$_3$\textsuperscript{1} — HOULONG ZHUANG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, VALENTINO R. COOPER, Materials Science and Technology Division, ORNL, P. GANESH, Center for Nanophase Materials Sciences, ORNL, HAIXUAN XU, Department of Materials Science and Engineering, The University of Tennessee, Knoxville, P. R. C. KENT, Computer Science and Mathematics Division; Center for Nanophase Materials Sciences, ORNL — It is well known that an insulator-to-metal transition occurs at SrTiO$_3$/LaAlO$_3$ epitaxial heterostructures when the number of LaAlO$_3$ layers reaches a critical value of four. With first-principles calculations, we show that instead of requiring the threshold number of layers to trigger metallicity, the so-called 1+2 overlayer heterostructure also exhibits metallic states. Interestingly, we demonstrate that these metallic states form a two-dimensional electron gas at the overlayer heterostructure. We understand that these fascinating phenomena originate from a modified “polar catastrophe” model, where the overlayer heterostructure accumulates an electrostatic potential more rapidly than regular heterostructures, leading to the reduction of number of LAO layers. Using this model, we further show that the thinner 1+1 overlayer heterostructure exhibits a similar 2DEG. Our work provides a novel approach of inducing 2DEGs in oxide heterostructures, which are beneficial for modern electronics applications.

\textsuperscript{1}HZ, PRCK, VRC and PG were sponsored by the LDRD at ORNL for the U.S. DOE and HX by the University of Tennessee JDRD and UT/ORNL-JIAM programs.

10:36AM L13.00012 Nanoscale Electrostatic Confinement at Oxide Interfaces — SRIJIT GOSWAMI, EMRE MULAZIMOGLU, LIEVEN VANDERSYPEN, ANDREA CAVIGLIA, Delft University of Technology — We develop a robust and versatile platform to define nanostructures at oxide interfaces via patterned top gates. Using LaAlO$_3$/SrTiO$_3$ as a model system, we demonstrate controllable confinement of electrons to nanoscale regions in the conducting interface. The excellent gate response, ultra-low leakage currents, and long term stability of these gates allows us to perform a detailed study of devices in a split-gate geometry. Electrical transport through such devices displays a distinct threshold associated with depletion directly below the gates, resulting in the formation of a narrow conducting channel even at room temperature. We examine the effects of cross-talk between the gates, and also show that a combination of top gates and back gate can be used to efficiently modulate charge transport through these nanostructures.

10:48AM L13.00013 Lateral probing of the LaAlO$_3$/SrTiO$_3$ two-dimensional electron liquid\textsuperscript{1} — M.P. STEHNO, A.E.M. SMINK, H. HILGENKAMP, A. BRINKMAN, MESA+ Institute for Nanotechnology, University of Twente, The Netherlands — The 2-dimensional electron liquid (2DEL) at the interface between the insulating oxides lanthanum aluminate and strontium titanate (LAO/STO) has a complex band structure and hosts novel electronic phases with magnetism and superconductivity. Electrical characterization of the 2DEL has focused mainly on magnetotransport in films or confined geometries, and on z-axis tunneling. We contacted the LAO/STO interface laterally and obtained a gate-tunable barrier between the 2DEL and the metallic electrode. Features in the differential conductance spectra are spaced by energies similar to the confinement energy at the oxide interface and may thus yield information on the (sub-) band structure of 2DEL and barrier region.

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L14 DMP FIAP: Focus Session: Dopants and Defects in Group IV Semiconductors

8:00AM L14.00001 BSE calculations of color center defects in diamond\textsuperscript{1} — S. VIMOLCHALAO, U. of Washington, W.H. LIANG, UC Merced, F.D. VILA, J.J. KAS, J.J. REHR, U. of Washington, F. FARGES, Muséum National d’Histoire Naturelle, Paris — Colored diamonds are both of fundamental and commercial interest. Several recent efforts have focused on determining the origin of their colors. For example, experiments show that the color of blue diamonds is associated with isolated boron impurities\textsuperscript{2}, while nitrogen impurities are responsible for yellow diamonds. It has previously been shown\textsuperscript{3} that theoretical Bethe-Salpeter Equation (BSE) simulations of boron-doped diamond yield a dark-blue diamond in good agreement with that observed. However, the structure of the nitrogen defects is not well understood. Here we present BSE calculations of the optical response of nitrogen-doped diamonds using relaxed 64-atom unit cells. We focus on N$_{Vb}$ defect sites, where $x$ is the number of substitutional nitrogen atoms and $y$ is the number of carbon vacancies. We find that the most likely candidates are the N$_x$V$_y$ and N$_{Vb}$ defects, which show absorption in the 2.5-3.2 eV range, consistent with yellow color. Our results also rule out the N$_{Vb}$ and N$_x$V$_y$ defect types as possible yellow centers.

\textsuperscript{1}Supported by DOE grant DE-FG03-97ER45623.

8:12AM L14.00002 Structure and electronic properties of nanodiamond and its fluorination effect, KAZUYUKI TAKAI, KENTA KOGANE, Hosei University, HIDEKAZU TOUHARA, YOSHIIYUKI HATTORI, Sinshu University — Fluorination of nano-sized diamond (ND) is expected not only to stabilize the surface structure, but also to introduce functional groups on the surface, the conduction carriers, and so on. In this study, we evaluate the structure and magnetic properties of ND and fluorinated ND (FND) in order to consider the change in the electronic state and the surface structure by fluorination. Fluorination of ND was carried out by the direct reaction between gaseous fluorine (1 atm) and commercially available detonation diamond at 623 — 873 K. X-ray Diffraction study reveals the structural stability of core part of ND during fluorination. X-ray photoemission spectroscopy exhibits F1s peak at the lower binding energy region than that for physisorbed molecular fluorine, indicating the formation of the chemical bonding between C and F in the sample. The Electron Paramagnetic Resonance results suggest that fluorination induces not only changes in the surface structure but also relaxation of defects in the core part.

8:24AM L14.00003 Determine the number of nitrogen vacancy color centers in the nanodiamond particles with large size difference, JUI-HUNG HSU, National Sun Yat-sen University, LONG-JYUN SU, HUAN-CHENG CHANG, Academia Sinica — The number of emitters in a nano-particle is usually determined by the photon correlation using the Hanbury Brown and Twiss configuration. However, limited to the photon statics, this method is only valid for the small numbers. It would be difficult to measure the number of emitters, if individual nano-particles contain more than several tens or hundreds of emitters. In this contribution, we present a work to quantitatively determine the number of nitrogen-vacancy (NV) centers in the individual nano-diamond (ND) particles. Our previous work (nanotechnology 24, 315702) suggests that the density of NV centers would be significantly decreased while reducing ND particle size from 100 nm to 30 nm. It thus motivates us to measure the number of NV centers of individual ND particles with large size difference. Under saturated the pulse excitation, the emission intensity from individual ND particle is proportional to the number of NV centers and the fluorescence quantum yield, which are able to be determined independently.
8:36AM L14.00004 Designing shallow donors in diamond1
1. JONATHAN MOUSSA, Sandia National Laboratories — The production of n-type semiconducting diamond has been a long-standing experimental challenge. The first-principles simulation of shallow dopants in semiconductors has been a long-standing theoretical challenge. A desirable theoretical goal is to identify impurities that will act as shallow donors in diamond and assess their experimental viability. I will discuss this identification process for the LiN4 donor complex. It builds a scientific argument from several models and computational results in the absence of computational tools that are both trustworthy and computationally tractable for this task. I will compare the theoretical assessment of viability with recent experimental efforts to co-dope diamond with lithium and nitrogen. Finally, I discuss the computational tools needed to facilitate future work on this problem and some preliminary simulations of donors near diamond surfaces.

1Sandia National Laboratories is a multi-program lab managed and operated by Sandia Corp., a wholly owned subsidiary of Lockheed Martin Corp., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:12AM L14.00005 Carbon-antisite vacancy defect in 4H silicon carbide for realizing solid state qubit1
1. ADAM GALI, KRISZTIAN SZASZ, VIKTOR IVADI, Wigler Research Centre for Physics, Hungarian Academy of Sciences, IGOR ABRIKOSOV, Linköping University, MICHEL BOCKSTETDE, University of Erlangen-Nürnberg, ERIK JANZEN, Linköping University — Dopants in solids are promising candidates for implementations of quantum bits for quantum computing. Silicon carbide (SiC) with engineered point defects is considered as very promising material for the next generation devices, with applications ranging from electronics and photonics to quantum computing. Employing density functional theory and many body perturbation theory, we show that the neutral carbon antisite-vacancy pair (CAV) has high spin ground state, and that its spin may be coherently manipulated by optical excitation in n-type 4H SiC. As the positively charged CAV defect in 4H SiC has been recently engineered to act as single photon source [1], our finding brings a hope that optically addressed quantum bits can be realized by the neutral CAV defects in 4H SiC, and provide an additional target for researchers seeking for solid state single color centers for quantum information processes and metrology. The calculated zero-phonon line of the optically excited state is about 1550 nm (0.8 eV) which perfectly fits to the telecom wavelengths, that makes this qubit candidate very promising for integration of quantum optics devices with existing fiber optics technology. 9:24AM L14.00006 Determining exact location of Group V dopants below the Si(001):H surface from scanning tunnelling spectroscopy and density functional theory1
1. VERONIKA BRAZDOVA, KITIPHAT SINTHITHARAKOON, PHILIPP STUDER, DAVID R. BOWLER, ADAM RAHNEJAT, NEIL J. CURSON, STEVEN SCHOFIELD, ANDREW J. FISHER, University College London — Group V impurities in silicon provide a way to tailor properties of electronic materials. The magnetically quiet environment that silicon provides for the impurity spins has also led to new applications in coherent quantum devices. In both the ultimate classical devices and in future quantum computers the exact position of the dopants near surfaces and interfaces will determine the functionality: the ability to control and monitor those positions is key in these technologies. We precisely determine the substitutional sites of neutral As dopants that lie between 4.2 A and 15.0 A below the hydrogenated Si(001) surface, using a combination of density functional theory and low-temperature scanning tunnelling microscopy. We describe the interaction of the donor-electron state with the surface.

9:36AM L14.00007 Towards bipolar atomic scale dopant devices defined by STM-lithography1
1. ANDREAS FUHRER, SIGRUN KOSTER, NIKOLA PASCHER, IBM Research – Zurich, Säumerstrasse 4, 8803 Rüschlikon — Dopant device fabrication with hydrogen resist lithography has been demonstrated only for n-type dopants. The reason for this is the ease with which phosphorus can be incorporated and activated after gas phase doping with phosphine. Specifically, incorporation on the silicon (001) surface can be achieved at 350°C while keeping the hydrogen resist intact and thus avoiding surface diffusion of the dopants. Here, we present new results on p-type δ-doping of silicon, towards the fabrication of bipolar dopant devices with hydrogen resist lithography. Using diborane as a gas-phase dopant source, Hall bar devices were fabricated to extract hole densities and mobilities in cryogenic magnetooptical transport experiments. Furthermore, the dependence of these parameters on diborane dose and dopant activation temperatures is investigated. We find that gas-phase doping with diborane is compatible with hydrogen resist lithography and dopant structures can be patterned using the STM. However, activation of the boron dopants currently still leads to significant diffusion and therefore blurring of the patterned devices. We will discuss the prospects of further optimising this and present a possible path forward towards bipolar atomic scale device fabrication with the STM.

9:48AM L14.00008 Suppressed Complete Ionization of Shallow Donors in Germanium1
1. JOSE MENENDEZ, CHI XIU, CHARUTHA SENARATNE, JOHN KOUVETAKIS, Arizona State Univ — For doping levels Nd > 10¹⁷ cm⁻³, an elementary analysis demonstrates that shallow donors should not be completely ionized in germanium at room temperature. The predicted degree of incomplete ionization (I.I.) represents a fundamental limitation in the quest for ultra-low sheet resistances, as required in Ge-based nMOS devices. Unfortunately, the experimental verification of the predictions is made difficult by the possible presence of inactive dopants, which also lead to free carrier concentrations n < Nd. In this work, we prepared n-type Ge films on Ge-buffered Si substrates using novel synthetic approaches that are expected to minimize the presence of inactive dopants. Higher-order germanes (Ge₂H₆ and Ge₃H₁₀) were used as the source of Ge for growth at low temperatures. Phosphorus atoms were furnished via P(MH₂)₃ (M = Ge, Si) compounds in which the P atom is already bonded to three group-IV atoms in a way that is expected to promote substitutional incorporation. Spectroscopic ellipsometry and SIMS were used to determine n and Nd, respectively. The results indicate no observable I.I. Within experimental error, n ≈ Nd in contradiction with the elementary theory. These findings are compatible with the model developed by Altermatt et al. to explain I.I. phenomena in silicon.

10:00AM L14.00009 Band Structure and Optical Properties of Dilute Ge:C Alloys1
1. CHAD STEPHENSON, WILLIAM O'BRIEN, MENG QI, Department of Electrical Engineering, University of Notre Dame, MICHAEL PENNINGER, WILLIAM SCHNEIDER, Department of Chemical and Biomolecular Engineering, University of Notre Dame, MIIRIAM GILLET-KUNNATH, JAROSLAV ZAJICEK, Department of Chemistry and Biochemistry, University of Notre Dame, MARK WISTEY, Department of Electrical Engineering, University of Notre Dame — The last major missing piece to achieving integrated Si photonics is an efficient light emitter. Dilute Ge:C alloys offer a new route to create efficient lasers directly within conventional CMOS electronics. Although neither Ge nor C emits light, Ge:C is a highly mismatched alloy, similar to GaAsN, in which band anticrossing is expected to create a direct bandgap. We have performed ab initio band structure simulations using hybrid functionals and spin-orbit coupling that show a sharp decrease in bandgap at the direct conduction band valley with C incorporation, turning Ge:C into a direct bandgap semiconductor and even a semi-metal. We report on the optical properties, highlighting the strength of free carrier absorption due to the changes in the band structure. Some of its potential applications include integrated light emitters, modulators, and photodetectors. With the three-band system, Ge:C also has potential for use in upconverting structures. We also report successful incorporation of C in Ge using hybrid gas-solid source molecular beam epitaxy (MBE) using a precursor gas, tetra(germyl)methane (4GeMe), that prevents undesirable C-C bonds and interstitial incorporation.
10:12AM L14.00010 GeSn pin diodes: from pure Ge to direct-gap materials\textsuperscript{1}, JAMES GALLAGHER\textsuperscript{2}, CHARUTHA SENARATNE\textsuperscript{1}, CHI XU\textsuperscript{1}, TOSHIHITO AOYI\textsuperscript{1}, JOHN KOUVETAKIS\textsuperscript{1}, JOSE MENENDEZ\textsuperscript{1}, Arizona State Univ — Complete n−i−p Ge\textsubscript{1−y}Sn\textsubscript{y} diode structures (y=0-0.09) were fabricated on Si substrates with Sn concentrations covering the entire range between pure Ge and direct-gap materials. The structures typically consist of a thick (＞1 \(\mu\)m) \(n+p\) Ge buffer layer grown by Gas Source Molecular Epitaxy using Ge\textsubscript{1−x}H\textsubscript{x} and either P(SiH\textsubscript{4})\textsubscript{3} or P(GeH\textsubscript{3})\textsubscript{3}, followed by a GeSn intrinsic layer (≈500 nm), grown by Chemical Vapor Deposition (CVD) using Ge\textsubscript{3}H\textsubscript{8} and SnD\textsubscript{4}, and a GeSn \(p\)-type top layer (≈200 nm) grown by CVD using Ge\textsubscript{3}H\textsubscript{4}, SnD\textsubscript{4} and B\textsubscript{2}H\textsubscript{6}. Temperature-dependence of the \(I−V\) characteristics of these diodes as well as the forward-bias dependence of their electroluminescence (EL) signal were investigated, making it possible for the first time to extract the compositional dependence of parameters such as band gaps, activation energies, and dark currents. The EL spectra are dominated by direct-gap emission, which shifts from 1.59 nm to 2.30 nm, in agreement with photoluminescence results.

10:24AM L14.00011 Doping and strain dependence of the electronic band structure in Ge and GeSn alloys\textsuperscript{1}, CHI XU, JAMES GALLAGHER, CHARUTHA SENARATNE, CHRISTOPHER BROWN, Arizona State Univ,NALIN FERNANDO, STEFAN ZOLLNER, New Mexico State Univ, JOHN KOUVETAKIS, JOSE MENENDEZ, Arizona State Univ — A systematic study of the effect of dopants and strain on the electronic structure of Ge and GeSn alloys is presented. Samples were grown by UHV-CVD on Ge-buffered Si using Ge\textsubscript{3}H\textsubscript{8} and SnD\textsubscript{4} as the sources of Ge and Sn, and B\textsubscript{2}H\textsubscript{6}/P(GeH\textsubscript{3})\textsubscript{3} as dopants. High-energy critical points in the joint-density of electronic states were studied using spectroscopic ellipsometry, which yields detailed information on the strain and doping dependence of the so-called \(E_1\), \(E_1 + \Delta_1\), \(E_0\) and \(E_2\) transitions. The corresponding dependencies of the lowest direct band gap \(E_0\) and the fundamental indirect band gap \(E_{ind}\) were studied via \(\mu\)-room-T photoluminescence spectroscopy. Of particular interest for this work were the determination of deformation potentials, band gap renormalization effects, Burstein-Moss shifts due to the presence of carriers at band minima, and the dependence of other critical point parameters, such as amplitudes and phase angles, on the doping concentration. The selective blocking of transitions due to high doping makes it possible to investigate the precise \(k\)-space location of critical points. These studies are complemented with detailed band-structure calculations within a full-zone \(k\)-dot-\(p\) approach.

10:36AM L14.00012 First-principles Study of the NiGe/Ge Schottky Barrier Height under Dopant Segregation\textsuperscript{1}, CHIANG-YUAN LIN, Department of Electronics Engineering and Institute of Electronics, National Chiao Tung University, HAN-CHI LIN, R&D, Taiwan Semiconductor Manufacturing Company — Traditional Si-based MOSFETs are approaching its fundamental scaling limits, and Ge has been comprehensively explored as a potential channel material to replace Si due to its high intrinsic carrier mobility for further performance enhancement. Nevertheless, strong Fermi-level pinning near the valence band edge of Ge leads to high electron Schottky barrier height. Dopant segregation technique has been proposed to achieve shallower junction depth and heavier dopant concentration for NiGe/Ge. However, the role of dopants at the NiGe/Ge interface is not clear. In this study, first-principles calculations are employed to nail down the most stable dopant position and to obtain the physical Schottky barrier height (by HSE06 hybrid functional) of the NiGe/Ge contact. For the conventional n-type dopant such as phosphorous and arsenic, our calculations show that those two elements may be segregated at the interface, while the reduction of the Schottky barrier height is insignificant. This implies that the experimental improvement of the NiGe/n-type Ge junction by dopant are mainly attributed to the increased dopant concentration around the interface.

8:12AM L15.00002 Ellipsometric Study of NbO$_2$ Grown by MBE on LSAT from 77 to 800 K †
T.N. NUNLEY, S. ZOLLNER, NMSU, T. HADAMEK, A.B. POSADAS, A. O’HARA, A.A. DEMKOV, UT Austin — NbO$_2$ is a transition metal oxide that has been of interest for several decades. Like other complex oxides it has a metal-insulator transition provoked by external stimuli such as temperature, pressure, and electric fields. Our study shows the dielectric function of NbO$_2$ grown by molecular beam epitaxy, optical axis in-plane, on (LaAlO$_3$)$_{0.3}$(Sr$_2$TiAlO$_6$)$_{0.7}$ (LSAT) substrates. The ellipsometric angles were measured from 0.76 to 6.52 eV using a UV/VIS variable-angle spectroscopic ellipsometer and from 250 to 1200 cm$^{-1}$ using an FTIR ellipsometer. By using regression analysis we modeled our optical spectra with one model over the entire range from the mid-infrared to the near UV. For the LSAT substrate, we used optical constants from a previous study. A sum of Tauc-Lorentz oscillators describes the dielectric function of the NbO$_2$ film. We have measured the dielectric function of the sample from 77-800 K. This has allowed us to see that the absorption peaks sharpen/broaden with decreasing/increasing temperature. We have also plotted the direct and indirect band gaps as a function of temperature.

8:24AM L15.00003 Lyddane-Sachs-Teller Analysis of Electronic Transitions†
WILLIAM KARSTENS, Saint Michaels College, DAVID Y. SMITH, University of Vermont and Argonne National Laboratory — We have explored the use of the Lyddane-Sachs-Teller (LST) relation for analysis of electronic optical spectra. This relation originated in the theory of IR lattice absorption and, in analogy with the high IR reflectivity of polar crystals, we demonstrate a substantial region of almost-metallic UV reflectivity above the fundamental electronic absorption in selected solids; it is especially pronounced in group IV elements. This electronic Reststrahlen is terminated by a well-defined longitudinal plasmon and may be understood within LST theory. The original LST formulation neglects dissipation; we show it reflects the geometric symmetry of a normalized dispersion curve based on relative frequencies and polarizabilities. If dissipation is included, absorption widths enter only in second order, so the original LST relation applies to optical spectra that can be approximated by the Lorentz model. The Kramers-Kronig based moments formulation of Noh and Sievers [1] holds generally. The normalized curve is specified by a single strength parameter that may be used as an approximate index to characterize optical response. The dielectric response of covalent semiconductors will be discussed as examples of the LST relation and the dependence of energy-loss spectra on electronic properties. [1] T. W. Noh and A. J. Sievers, Phys. Rev. Lett. 63, 1800 (1989).

8:36AM L15.00004 Correlation between heavy-hole and light-hole Mahan Excitons in a two-dimensional electron gas†
J. PAUL, P. DEY, C.E. STEVENS, Dept. of Physics, University of South Florida, Tampa, Florida 33620, USA, T. TOKUMOTO, Dept. of Physics, University of Alabama at Birmingham, Birmingham, Alabama 35294, USA, J.L. RENO, CINT, Sandia National Laboratories, Albuquerque, New Mexico 87185, USA, D.J. HILTON, Dept. of Physics, University of Alabama at Birmingham, Birmingham, Alabama 35294, USA, D. KARAISKAJ, Dept. of Physics, University of South Florida, Tampa, Florida 33620, USA, D. J. HILTON COLLABORATION, J. L. RENO COLLABORATION — We present the coherent two-dimensional Fourier transform (2DFT) spectra of Mahan Excitons associated with the heavy-hole and light-hole resonances observed in a modulation doped GaAs/AlGaAs single quantum well. These resonances are observed to be strongly coupled through many-body interactions. The 2DFT spectra were measured using co-linear, cross-linear, and co-circular polarizations and reveal striking differences. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. Department of Energy, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

8:48AM L15.00005 Optical Properties of LaVO$_3$ and YTiO$_3$\footnote{Supported in part by the US Department of Energy, Office of Science, Office of Nuclear Physics under contract DE-AC02-06CH11357}
JOHN COULTER, EFSTRATIOS MANOUSAKIS, Florida State University & NHMFL — Motivated by recent experimental efforts to fabricate p-n junctions from transition metal oxides (TMOs) and recent theoretical and computational work illustrating that strongly correlated insulators can produce more than one electron-hole pair from a single solar photon through impact ionization, we study the optical properties of LaVO$_3$ and YTiO$_3$ by \textit{ab initio} methods. We apply the Bethe-Salpeter equations (BSE) to calculate the optical properties, starting from quasi-particle energy levels and states found at the level of the GW approximation. We present comparisons of the exciton binding energy to experimental data. We examine the extent to which these materials might be promising for efficient carrier multiplication, as has been shown previously in VO$_2$.

9:00AM L15.00006 FT-IR and Raman Spectroscopic Study of Cobalt Oxides, YANG LI, FAN QIN, WENLAN QIU, Department of Electrical and Computer Engineering, University of Houston, HUI FANG, Department of Physics, Sam Houston State University, VIKTOR G. HADJIEV, Texas Center for Superconductivity and Department of Mechanical Engineering, University of Houston, DMITRI LITVINOV, JIMING BAO, Department of Electrical and Computer Engineering, University of Houston — Fourier transform infrared (FTIR) and Raman spectroscopy are studied on cobalt monoxide (CoO) and cobalt dicobalt oxide (Co$_3$O$_4$) in the presented work. We can experimentally detect the transverse and longitudinal optical modes of Co$_3$O$_4$ using transmittance and diffuse reflectance (DRIFTS) spectra in FTIR, which showed good agreement with theoretical calculation. DRIFTS results also proved that Co$_3$O$_4$ with smaller particle size will lead to an increase in the LO-TO ratio. During the oxidation process from CoO to Co$_3$O$_4$, this ratio is gradually raised. CoO can be identified with a broad band near 500cm$^{-1}$. For the first time, we clearly demonstrate that Co$_3$O$_4$ exhibits only the second order Raman scattering near 1070cm$^{-1}$ at room temperature and ambient pressure (excited by 473nm laser).

9:12AM L15.00007 Infrared magneto-spectroscopy of narrow bandgap metamorphic InAs$_{1-x}$Sb$_x$†
JONATHAN LUDWIG, Florida State University and National High Magnetic Field Laboratory, S. SUCHALKIN, State University of New York at Stony Brook, Y. JIANG, School of Physics, Georgia Institute of Technology, G. KIPSHIDZE, Y. LIN, L. SHTERENGAS, S. LURYI, G. BELENKY, State University of New York at Stony Brook, D. SMIRNOV, National High Magnetic Field Laboratory — Metamorphic InAsSb alloys are a promising narrow gap semiconductor with bandgaps as low as 0.12eV, corresponding to approximately 10um, much smaller eithe InAs or InSb. The effect of bowing on the reduction in the bandgap over its binary counterparts is not completely understood. Here, we report on the systematic low-temperature infrared magneto- absorption study of a series of InAs$_{1-x}$Sb$_x$ layers with varying Sb concentration performed in magnetic fields up to 17.5 T. Several cyclotron resonance series, including interband transitions, are observed. These results allow us to extract and compare the bowing coefficients for the effective mass and bandgap.
Magnetic Field-Induced Direct-Indirect Bandgap Crossover in Al\textsubscript{1-x}Ga\textsubscript{x}As

KIRSTIN ALBERI, ALEKSEJ MIALITSIN, BRIAN FLUEGEL, National Renewable Energy Laboratory, SCOTT CROOKER, National High Magnetic Field Lab, Los Alamos National Laboratory, ANGELO MASCARENHAS, National Renewable Energy Laboratory — Determining the exact alloy composition and energy at which a direct-indirect bandgap crossover occurs in semiconductor alloys is important for engineering optoelectronic materials. However, some amount of error is usually introduced when establishing the crossover from the extrapolation of the direct and indirect bandgap energy trends measured with a discrete set of alloyed samples. We use high magnetic fields up to 58 T to induce the crossover in a single Al\textsubscript{1-x}Ga\textsubscript{x}As sample, thereby allowing us to precisely identify the crossover energy at low temperature \cite{1}. The onset of the crossover is marked by a reduction in the photoluminescence peak energy and the emergence of an asymmetric peak lineshape resulting from the competition between the radiative lifetime and carrier migration times in the indirect regime. Analysis of the lineshape progression through the crossover confirms that the crossover can be classified as an alloy disorder broadened, first order phase transition. \cite{1} K. Alberi, et al, Appl. Phys. Express, 7, 111201 (2014)

Transient Infrared Studies of Carrier Injection Effects on the Reststrahlen Band of SiC

BRYAN SPANN\textsuperscript{3}, RYAN COMPTON\textsuperscript{2}, ADAM DUNKELBERGER\textsuperscript{3}, JAMES LONG, Naval Research Laboratory, PAUL KLEIN, Sotera Defense Solutions Inc., JOSH CADOWELL, JEFF OWRUTSKY, Naval Research Laboratory — Sub-diffraction light confinement has led to advances in imaging, metamaterials, and plasmonics among other fields. A phenomenon that can provide sub-diffraction light is the surface phonon polariton (SPhP). SPhPs couple infrared photons with optical phonons. Because SPhPs are coupled directly to phonons, lifetimes can be longer than that of surface plasmon polaritons (SPPs) whose lifetimes are dominated by electron scattering. SiC is one material that exhibits SPhPs. SIC SPhPs are activated by photons with energies near the Reststrahlen band. In this study we investigate aspects of carrier dynamics by photo-injecting free carriers into the SiC conduction band using a pulsed 355 nm pump laser and probe the resulting dynamics near the Reststrahlen band using a tunable CO\textsubscript{2} laser. Variable pump fluences provided free carrier densities of 1x10\textsuperscript{17} to 1x10\textsuperscript{19}. Probing the excited state dynamics near the Reststrahlen band revealed complex transient behavior resulting in positive and negative changes in transient reflectance depending on the photo-injection level and the probe energy. Numerical simulations were carried out to mimic the initial photo-injection level provided by the transient experiment and resulted in qualitative agreement with the experiment.

Lifetime investigations of recombination in CdTe heterostructures using time-resolved photoluminescence

BOBBY L. HANCOCK, CRAIG H. SWARTZ, MADHAVIE EDIRISOORIYA, ELIZABETH B. LEBLANC, O. NORIEGA, P. A. R. D. JAYATHILAKA, OLANREWAJU S. OGEDEGBE, MARK HOLTZ, THOMAS H. MYERS, Texas State University — Free photocarrier lifetimes are critical parameters in semiconductors used in photovoltaics, such as cadmium telluride (CdTe). However, CdTe is historically plagued by short photocarrier lifetimes due to competing non-radiative recombination attributed to surfaces and interfaces. One consequence of this is an elusive lifetime for the bulk material. We report progress in mitigating the effects of surfaces and interfaces using a CdTe/Mg\textsubscript{1-x}Cd\textsubscript{x}Te double heterostructure grown by molecular beam epitaxy. Photocarrier lifetimes are measured using time-resolved photoluminescence (TRPL). Lifetimes as high as 240 ns are measured at room temperature with barriers having approximately \( \alpha = 35\% \). The results of these studies will be presented along with a discussion of the radiative, surface, and interfacial recombination.

1. U. S. Department of Energy (DEAC36-08GO28308 FPACE II Sub. ZEJ-4-2007-0)

Phonon dispersion relations of Sb\textsubscript{2}S\textsubscript{3} and Bi\textsubscript{2}S\textsubscript{3} using the supercell force-constant method

CHEE KWAN GAN, Institute of High Performance Computing, KUN TING EDDIE CHUA, Harvard-Smithsonian Center for Astrophysics, 60 Garden Street, Cambridge, MA 02138, USA, YUN LIU, Institute of High Performance Computing — We present a lattice dynamical study on the orthorhombic antimony telluride sulphide (Sb\textsubscript{2}S\textsubscript{3}) \cite{1} and bismuth sulphide (Bi\textsubscript{2}S\textsubscript{3}) \cite{2} using the supercell force-constant method. We find that the slow decay of the interatomic force constants for these compounds in the Pnma setting critically demand the use of a large supercell of \( 2 \times 4 \times 2 \) that consists of 320 atoms. To enable a practical calculation the space group information is fully utilized where only inequivalent atoms within the primitive cell are displaced for the force calculations. The effect ofBorn effective charges is incorporated into the method. We compare our results with that obtained from the density-functional perturbation theory. We found that smaller supercells could lead to unphysical acoustic phonon softening and lifting of the degeneracies along high symmetry directions. Our results provide a proper guideline for the use of the supercell force-constant method: the supercell size must be carefully be tested along with other parameters such as the kinetic energy cutoff, the Brillouin zone sampling or the self-consistent convergence criteria. \cite{1} Y. Temperature dependent band gaps of GeSiSn alloys grown on Ge buffered Si substrates

NALIN FERNANDO, T.N. NUNLEY, S. ZOLLNER, NMSU, C. XU, J. MENENDEZ, J. KOUVETAKIS, ASU — Band gap engineering of Ge by controlling tensile strain and alloying with Si and Sn has attracted great interest. Ge\textsubscript{1-x}Si\textsubscript{x}Sn\textsubscript{y} ternary alloy with two compositional degrees of freedom allows decoupling lattice constant and electronic structures. Hence it is important to determine the temperature and compositional dependence of optical properties of these materials. The complex pseudodielectric functions of Ge films grown on Si(100) and GeSiSn grown on buffered Ge were measured using spectroscopic ellipsometry in the 0.76-6.6 eV energy range between 77-800 K to investigate the E\textsubscript{1} and E\textsubscript{1} + \Delta\textsubscript{1} critical point (CP) energies. CP energies and related parameters were obtained by analyzing the second-derivative \( d^{2}e/d\omega^{2} \) of the dielectric function. Our experimental results are in good agreement with the theoretics. The predicted E\textsubscript{1} CP energy shift of Ge on Si due to strain generated by thermal expansion mismatch. We will discuss the compositional dependence of the E\textsubscript{1} and E\textsubscript{1} + \Delta\textsubscript{1} CP energies of GeSiSn alloys and effects of temperature on shifting CP energies.

10:24 AM L15.00013 Optoelectronic properties of Ta$_3$N$_5$: A joint theoretical and experimental study$^1$, JULIANA MORBEC, Institute for Molecular Engineering, University of Chicago, USA, IEVA NARKEVICIUTE, THOMAS JARAMILLO, Department of Chemical Engineering, Stanford University, USA, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago, USA — A joint theoretical and experimental study of the optoelectronic properties of Ta$_3$N$_5$ was conducted by means of ab initio calculations and ellipsometry measurements [1]. Previous experimental work on Ta$_3$N$_5$ has not been conclusive regarding the direct or indirect nature of light absorption. Our work found excellent agreement between the optical spectrum computed using the Bethe-Salpeter equation and the measured one, with two prominent features occurring at 2.1 and 2.5 eV assigned to direct transitions between N and Ta states. The computed optical gap, obtained from the $G^0W_0$ direct photoemission gap, including spin-orbit coupling, electron-phonon interaction, and exciton binding energy, was found to be of excellent agreement with measurements. Our results also showed that Ta$_3$N$_5$ is a highly anisotropic material with heavy holes in several directions, suggesting low hole mobilities, consistent with low measured photocurrents in the Ta$_3$N$_5$ literature. Work is in progress to compute polaronic contributions to the hole and electron mobilities and to investigate the effect of substitutional doping on the electronic structure of Ta$_3$N$_5$.

10:36 AM L15.00014 Electrically Tunable Hot-Silicon Terahertz Attenuator$^1$, MINJIE WANG, Department of Electrical and Computer Engineering, Rice University, ROBERT VAJTAI, PULICKEL AJAYAN, Department of Materials Science and NanoEngineering, Rice University, JUNICHIRO KONO, Department of Electrical and Computer Engineering, Rice University — We have developed a continuously tunable, broadband terahertz attenuator with a transmission tuning range greater than 10$^3$. Attenuation tuning is achieved electrically, by simply changing the DC voltage applied to a heating wire attached to a bulk silicon wafer, which controls its temperature between room temperature and 550 K, with the corresponding free-carrier density adjusted between 10$^{14}$ cm$^{-3}$ and 10$^{17}$ cm$^{-3}$. This 'hot-silicon'-based terahertz attenuator works most effectively at 450–550 K (corresponding to a DC voltage variation of only 7 V) and completely shields terahertz radiation above 550 K in a frequency range of 0.1-2.5 THz. Both intrinsic and doped silicon wafers were tested and demonstrated to work well as a continuously tunable attenuator, but they exhibited slightly different behaviors before a dramatic transmission drop at 450–550 K: intrinsic silicon wafers showed a monotonic transmission decrease with temperature while doped wafers showed a slight increase in transmission before the drop. All behaviors can be understood quantitatively via the free-carrier Drude model taking into account thermally activated intrinsic carriers.

10:48 AM L15.00015 Photoluminescence measurements of high Sn-content Ge$_{1-x}$Sn$_x$ and Ge$_{1-x-y}$Si$_x$Sn$_y$ grown on Ge-buffered Si, YUNG KEE YEO, THOMAS R. HARRIS$^1$, Department of Engineering Physics, Air Force Institute of Technology, Wright-Patterson AFB, OH 45433, USA, BUGUO WANG, Department of Physics, Wright State University, Dayton, OH 45435, USA, MEE-YI KYU, Department of Physics, Kangwon National University, Chuncheon 200-701, Korea, JOHN KOUVETAKIS, Department of Chemistry and Biochemistry, Arizona State University, Tempe, Arizona 85287, USA — The optical properties of newly developed, high Sn-content Ge$_{1-y}$Sn$_y$ and Ge$_{1-x-y}$Si$_x$Sn$_y$ thin films grown on Ge-buffered Si have been characterized using temperature-dependent and laser power-dependent photoluminescence (PL) measurements. The results show two distinct PL peaks related to both the direct (Γ) and indirect (L) bandgap transitions. Furthermore, the measured separation energy between the direct and indirect bandgap related PL peaks for Ge$_{0.945}$Sn$_{0.055}$ sample is only about 30 meV compared to the value of 140 meV for bulk Ge. This study shows a very encouraging result toward producing Ge- and Si-based direct bandgap semiconductors, whose predicted indirect-to-direct bandgap crossover could be near 6% Sn. Clear competition between the two transitions is also observed as a function of temperature and laser power. Overall, this work represents an extensive PL characterization of Ge$_{1-y}$Sn$_y$ and Ge$_{1-x-y}$Si$_x$Sn$_y$ materials over a wide compositional range and should be useful for the development of next-generation optoelectronic devices.

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L16 DMP: Focus Session: van der Waals Bonding in Advanced Materials: Molecular Systems and Interfaces 101AB - Noa Marom, Tulane University

8:00AM L16.00001 Effect of Substrate Chemistry on the Adsorption of Olympicene Radical: A vdW inclusive DFT study$^1$, JERONIMO KARA, University of Central Florida, HANAND YILDIRIM, Purdue University, ABDELKADER KARA, University of Central Florida — We investigate the effects of surface chemistry on the adsorption characteristics of the Olympicene radical on Au and Pt(111) surfaces using vdW inclusive density functional theory (DFT) employing the optimized vdW-DF and vdW-DF2 methods. Adsorption characteristics such as adsorption energy, adsorption geometry, electronic structure, charge transfer, and charge redistribution will be presented. The effect of substrate electronic structure on the nature of bonding will be discussed. Comparison on the nature of bonding will be presented with our previously reported results on the adsorption of Olympicene radical on Cu(111) to provide a more complete picture.

8:12 AM L16.00002 First Principles Investigation of the C3 Coefficients for Molecular Adsorption on Transition Metal Surfaces$^1$, ABDELKADER KARA, JERONIMO MATOS, University of Central Florida, HANAND YILDIRIM, Purdue University — C6 coefficients are used to investigate the strength of the long-range interactions for weakly interacting dimers as a function of separation distance. These coefficients are useful both as a measure for the accuracy of the various van der Waals (vdW) inclusive methods. In the case of molecule-surface interaction, the C3 coefficient is the counterpart to the C6 coefficient that is used for testing the interaction of dimers. We will present the results of the vdW inclusive density functional theory (DFT) calculations evaluating the C3 coefficients for the adsorption of M/X(110) and X(111), with X: Ag, Au, Cu, Pt, Pd, Ni, Rh and M: Benzene, Thiophene, Selenophene, Pentacene and Olympicene, as described by the PBE exchange-correlation functional and the self-consistent vdW-DF, optimized vdW-DFs and vdW-DF2 functionals.

8:24AM L16.00003 Phonon dispersion of acene molecular crystals using van der Waals-corrected density functional theory. FLORIAN ALTVAETER, University of California, Berkeley, TONATIUH RANGEL, Lawrence Berkeley National Laboratory, JEFFREY B. NEATON, University of California, Berkeley, Lawrence Berkeley National Laboratory — Acene molecular crystals are interesting testbeds for the study of phenomena relevant to organic optoelectronics, including charge separation and carrier transport. In such processes, scattering from lattice vibrations is an important dissipation mechanism. Despite their central role in dissipation processes, there are few calculations of phonon spectra in acene crystals. Here, we carry out van der Waals-corrected density functional theory calculations of the ground-state structure and phonon band structure of acene molecular crystals, using neutron diffraction data where applicable. We use a finite-differences method, and compare the performance of several approaches — including standard generalized gradient approximations (GGA) such as PBE, PBE plus pair-wise vdW corrections, and vdW density functionals — to experiments for solid naphthalene and pentacene.

8:36AM L16.00004 Probing Molecule-Molecule Interactions Through Atomic Force Spectroscopy. ANDRAS MAGYARKUTI, Department of Applied Physics and Applied Mathematics, Columbia University, COLIN NUCKOLLS, Department of Chemistry, Columbia University, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics, Columbia University — We investigate the role of molecule-molecule interactions at the single-molecule level using a custom high-resolution atomic force microscope (AFM). We perform break-junction measurements using a gold substrate and gold-coated AFM cantilever on a series of methyl-sulfide terminated alkane chains. We measure, simultaneously, two independent quantities for each junction: force and conductance. This gives us insight into junction elongation and rupture processes. We use conductance as a signature of the junction structure and electronic characteristics and use the measured force to understand its mechanical properties. We find that molecular junctions form with one or two molecules bridging the gap between the cantilever and substrate, with the two-molecule junction having roughly twice the conductance of the one-molecule junction. More importantly, we find that the probability to form a two-molecule junction is higher for alkanes with an odd number of carbon atoms indicating that the van der Waals interactions between the two molecules might be important in forming these junctions. We discuss the implications of these results and compare to those obtained for conjugated molecules.

8:48AM L16.00005 Forces and Dynamics in Aromatic Overlayers on Metal Surfaces. SHAFA T MUBIN, KRISTEN FICHTHORN, Pennsylvania State University — Organic thin films have been the subject of intense research because of their suitability for applications in molecular electronics. The beneficial properties of these films are sensitive to the structure of the film. However, predicting and controlling organic thin-film structures is still a significant challenge. Owing to computational requirements, first-principles calculations cannot probe the link between thin-film deposition conditions and film structure. In this talk, we will discuss a multi-scale approach applied to quantify structures and dynamics of a thin film of benzene on Ag(111). Based on first-principles calculations, we developed a force field to describe the interaction of benzene with Ag(111). We applied this force-field to describe several aspects of this system, including its order-disorder phase transition and its desorption kinetics. Despite the apparent simplicity of this vdW dominated system, it exhibits surprising complexity in binding site preference and in ordering, leading to an interesting interplay between pi-conjugated electrons of benzene and surface-state electrons of Ag(111).

9:00AM L16.00006 Quantifying molecule-surface interactions using AFM-based single-molecule manipulation. F.S. TAUTZ, C. WAGNER, R. TEMIROV, N. FOURNIER, M. GREEN, T. ESAT, P. LEINEN, Forschungszentrum Juelich GmbH, Germany, A. GROETSCH, Federal Institute for Occupational Safety and Health, Dortmund, Germany, V.G. RUIZ, A. TKATCHENKO, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany, C. LI, K. MUELLEN, Max-Planck-Institut fuer Polymerforschung, Mainz, Germany, M. ROHFLING, Universitaet Muenster, Germany — Scanning probe microscopy plays an important role in the investigation of molecular adsorption. Promising is the possibility to probe the molecule-surface interaction while tuning its strength through AFM tip-induced single-molecule manipulation. Here, we outline a strategy to achieve quantitative understanding of such manipulation experiments [1]. The example of qPlus sensor based PTCDA molecule lifting experiments is used to demonstrate how different aspects of the molecule-surface interaction, namely the short-range adsorption potential [2], the asymptotic van der Waals potential [3], local chemical bonds which are the source of the surface corrugation [4], and molecule-molecule interactions [5] can be measured with SPM and interpreted by the help of force-field simulations.

9:12AM L16.00007 Many-Body Dispersion Interactions in Molecular Materials. ROBERT A. DISTASIO JR., Princeton University — In this work, we have developed an efficient method for obtaining an accurate theoretical description of van der Waals (vdW) interactions that includes both long-range Coulomb electrodynamic response screening effects as well as treatment of the many-body vdW energy to infinite order. This method goes beyond the standard C_6/R^6 pairwise additive approximation and can easily be coupled to a wide array of theoretical methods, ranging from classical force fields to higher-level quantum chemical calculations. To demonstrate the increasingly important role played by many-body vdW interactions in large, structurally complex molecular systems, we use this method to investigate several pertinent molecular properties, such as binding energies/affinities in gas-phase molecular dimers and supramolecular complexes, relative conformational energetics in small polypeptides, and thermodynamic stabilities among competing molecular crystal polymorphs.

9:48AM L16.00008 Predicting Elastic Properties of β-HMX from First-principles Calculations. QING PENG, ROBERT A. DISTASIO, FLORIAN ALTVAETER, University of California, Berkeley, TONATIUH RANGEL, Lawrence Berkeley National Laboratory, JEFFREY B. NEATON, University of California, Berkeley, Lawrence Berkeley National Laboratory — We investigate the performance of the van der Waals (vdW) functions in predicting the elastic constants of the β-polymorph of cycloctetramethylene tetranitramine (HMX) energetic molecular crystal using density functional theory (DFT) calculations. We confirm that the accuracy of the elastic constants is significantly improved using the vdW corrections with environment dependent C_6 together with PBE and revised PBE exchange-correlation functionals. The elastic constants obtained using PBE-D3(0) calculations yield the most accurate mechanical response of β-HMX, with respect to the experimental stress-strain data. The PBEsol without vdW corrections can also predict the elastic constants well. Our results suggest that PBE-D3 calculations are reliable in predicting the elastic constants of this material.
10:00AM L16.00009 Quantitative bond energetics in atomic-scale junctions with significant van der Waals character, LATHA VENKATARAMAN, Columbia Univ, SRIHARSHA ARADHYA1, Columbia University, Applied Physics, MARK HYBERTSEN, CFN, Brookhaven National Labs. — A direct measurement of the potential energy surface that characterizes individual chemical bonds in complex materials has fundamental significance for many disciplines. Here, we demonstrate that the energy profile for metallic single-atom contacts and single-molecule junctions can be mapped by fitting ambient atomic force microscope measurements carried out in the near-equilibrium regime to a physical, but simple, functional form.[1] In particular we are able to extract bond energies for metal-molecule link bonds in cases where the interaction has significant contribution from nonspecific interactions attributed to van der Waals (vdW) interactions at short length scale in addition to specific donor-acceptor bonds.[2] Our approach significantly expands the quantitative information extracted from these measurements, allowing direct comparisons to density functional theory (DFT) calculations instead of relying on trends in bond rupture forces alone. [1] S.V. Aradhya, A. Nielsen, M.S. Hybertsen, L. Venkataraman, ACS Nano 8, 7522–7530 (2014) [2] S.V. Aradhya, M. Frei, M.S. Hybertsen, L. Venkataraman, Nature Materials, 11, 872-876, (2012)

10:12AM L16.00010 Charge transfer from first principles: self-consistent GW applied to donor-acceptor systems , VIKTOR ATALLA, Fritz Haber Institute, Berlin, FABIO CARUSO, University of Oxford, ANGEL RUBIO, Universidad del Pais Vasco, San Sebastián, Spain, MATTHIAS SCHEFFLER, Fritz Haber Institute, Berlin, PATRICK RINKE, Aalto University, Helsinki, Finland — Charge transfer in donor-acceptor systems (DAS) is determined by the relative alignment between the frontier orbitals of the donor and the acceptor. Semi-local approximations to density functional theory (DFT) may give a qualitatively wrong level alignment in DAS, leading to unphysical fractional electron transfer in weakly bound donor-acceptor pairs. GW calculations based on first-order perturbation theory (G0W0) correct the level alignment, but leave unaffected the electron density. We demonstrate that self-consistent GW (scGW) provides an ideal framework for the description of charge transfer in DAS. Moreover, scGW seamlessly accounts for many-body correlations and van der Waals interactions. As in G0W0, the scGW level alignment is in agreement with experimental reference data. However in scGW, also the electron density is treated at the GW level and, therefore, it is consistent with the level alignment between donor and acceptor leading to a qualitatively correct description of charge-transfer properties.

10:24AM L16.00011 Van der Waals Interactions in Aspirin , ANTHONY REILLY, Cambridge Crystallographic Data Centre, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG — The ability of molecules to yield multiple solid forms, or polymorphs, has significance for diverse applications ranging from drug design and food chemistry to nonlinear optics and hydrogen storage. In particular, aspirin has been used and studied for over a century, but has only recently been shown to have an additional polymorphic form, known as form II. Since the two observed solid forms of aspirin are degenerate in terms of lattice energy, kinetic effects have been suggested to determine the metastability of the less abundant form II. Here, first-principles calculations provide an alternative explanation based on free-energy differences at room temperature. The explicit consideration of many-body van der Waals interactions in the free energy demonstrates that the stability of the most abundant form of aspirin is due to a subtle coupling between collective electronic fluctuations and quantized lattice vibrations. In addition, a systematic analysis of the elastic properties of the two forms of aspirin rules out mechanical instability of form II as making it metastable [A. M. Reilly and A. Tkatchenko, Phys. Rev. Lett. 113, 055701 (2014).]

10:36AM L16.00012 Determination of Surface-Substrate Adsorption Energy using the Exchange-Hole Dipole Moment , MATTHEW CHRISTIAN, Univ of California - Merced, ALBERTO OTERO DE LA ROZA, National Institute for Nanotechnology, ERIN JOHNSON, Univ of California - Merced — Calculated surface-substrate binding energies are usually underestimated because conventional density functionals do not include dispersion, which is necessary to capture the van der Waals interactions that lead to weak physisorption. The exchange-hole dipole moment (XDM) model is a non-empirical density-functional approach to model dispersion. Adsorption energies for several aromatic molecules and nucleobases on noble metal surfaces were calculated using B86bPBE-XDM. In this talk, I compare the calculated adsorption energies with experiment and present implications for future applications to modeling surface interactions.

10:48AM L16.00013 Van der Waals Dispersion Interactions and Excited States of Oligoacene Molecular Crystals , TONATIUVIANGELGORDILLO, SAHARSHARIFZADEH, Molecular Foundry, LBNL, KRISTIAN BERLAND, Chalmers University of Technology, Sweden, FLORIAN ALTVATER, Molecular Foundry, LBNL; UC-Berkeley, KYUHO LEE, Molecular Foundry, LBNL, PER HYLDGAARD, Chalmers University of Technology, Sweden, LEEDORONEN, Weizmann Institute of Science, Israel, JEFFREY B. NEATON, Molecular Foundry, LBNL; UC-Berkeley — Molecular crystals are a prototypical class of van der Waals (vdWs)-bound organic materials with novel excited state properties relevant for photovoltaics applications. Predicting the structure and excited state properties of oligoacene crystals presents a challenge for standard density functional theory (DFT), as standard functionals do not have long-range dispersion, and DFT does not yield excited-state properties. In this work, we use a combination of vdW-corrected DFT both pair-wise correction methods and correlation functionals and many-body perturbation theory to study the geometry and excited states of oligoacene crystals. We find that vdWs methods can predict lattice constants up to 1% of the experimental measurements. Low lying excited states computed with MBPT compare well with experiments, and are found to be quite sensitive to geometry. Our study reveals the importance of vdWs dispersion interactions to the determination of excited states; moreover, our work suggests routes for predictive calculations, in which both structures and excited states are calculated entirely from first-principles.

3We thank DOE for external funds, and NERSC for computational resources.

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L17 DCMP: Graphene: Optical Properties 102AB - Hua Chen, University of Texas at Austin
8:00AM L17.00001 Graphene in Ultrafast and Ultrastrong Laser Pulses1. HAMED KOOCHEK KELARDEH, VADYM APALIKOV, MARK STOCKMAN, Georgia State Univ — We have shown that graphene subjected to an ultrafast (near-single-oscillation pulse) and strong (F ~ 1-3 V/Å) pulse exhibits fundamental behavior dramatically different from both insulators and metals. In such an ultrafast and ultrastrong field, the electron dynamics is coherent, in contrast to relatively long pulses (τ > 100 fs) where the electron’s dephasing becomes important leading to incoherent dynamics. Electron transfer from the valence band (VB) to the conduction band (CB) is deeply irreversible i.e., non-adiabatic, in which the residual CB population (after pulse ends) is close to the maximum one. The residual CB population as a function of wave vector is nonuniform with a few strongly localized spots near the Dirac points, at which the CB population is almost 100%. Furthermore, it is shown the direction of charge transfer depends on the pulse amplitude. Namely, at small pulse amplitude, <1V/Å, the charge is transferred in the direction of the pulse maximum (positive transferred charge), while at large amplitude, >1 V/Å, it is in opposite direction of the pulse maximum (negative transferred charge). Consequently, in terms of charge transport, graphene at small pulse intensities behaves as a dielectric while at large intensities acts as a metal. These femtosecond currents and charge transfer in graphene may provide fundamental basis for detection and calibration of ultrashort intense laser pulses and are promising for petahertz information processing.

8:12AM L17.00002 Giant mid-infrared Kerr enhancement from films on SiC1. ALOK MUKHERJEE, M. MURAT ARIK, State Univ of NY - Buffalo, CHASE T. ELLIS, Electronics Science & Technology Division Code 6800, U.S. Naval Research Laboratory, Washington, DC, USA., PAYAM TAHERI, ANDREAS V. STIER, MYOUNG HWAN KIM, HAO ZENG, JOHN CERNE, State Univ of NY - Buffalo, JOSEPH G. TISCHLER, EVAN R. GLASER, RACHEL L. MYERS WARD, JOSEPH L. TEDDSCO, CHARLES R. EDDY JR, D. KURT GASKILL, Electronics Science & Technology Division Code 6800, U.S. Naval Research Laboratory, Washington, DC, USA., YU LIU, SHUNCHONG WANG, GANG WANG, Institute of Physics, Chinese Academy of Sciences, China — We report an enhancement of over an order of magnitude in the complex Kerr angle at photon energies near 121 meV in a variety of films on SiC substrates. The change in the reflected polarization in the presence of an out-of-plane magnetic field (polar magneto-optical Kerr effect, PMOKE) is measured in films ranging from graphene on SiC, aluminum doped SiC and iron oxide deposition on SiC. We model the PMOKE signal using multilayer analysis and find that the main contributor to this enhancement is the index of SiC becoming unity near 121 meV, at the edge of the Reststrahlen band of SiC. This result not only increases our sensitivity to PMOKE in a wide range of materials but also suggests that choice of substrate plays an important role in enhancing Kerr signal. This work is supported by NSF-DMR1006078.

8:24AM L17.00003 Graphene thermal transport studies via radio-frequency, cross-correlated Johnson noise thermometry. JESSE CROSSNO, XIAOMENG LIU, KE WANG, ACHIM HARZHEIM, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, THOMAS OHKI, KIN CHUNG FONG, Raytheon BBN Technologies, PHILIP KIM, Harvard University — The electronic temperature of a dissipative, mesoscale device can be determined and monitoring the Johnson noise power emitted over a wide frequency range. Using radiometry techniques, we have developed a high-frequency, wide bandwidth, cross-correlation Johnson noise thermometer operating from room temperature to cryogenic levels that is compatible with strong magnetic fields. Precisions ranging from 2 to 25 mK are demonstrated over the temperature range of 3 to 300 K with 1 second of integration time. This non-invasive thermometer has enabled us to perform sensitive electronic thermal transport studies in boron nitride encapsulated monolayer graphene over two orders of magnitude in temperature. This versatile technique also enables precision Fano factor measurements as well as studies of correlated noise phenomena, such as those found in layered Van der Waals heterostructures.

8:36AM L17.00004 Valley polarized transport through irradiated graphene. ARIJIT KUNDU, HERB FERTIG, BABAK SERAYDJEH, Indiana Univ - Bloomington — Graphene under the application of circularly polarized light can go through Floquet topological transitions between various topological phases. With a drive protocol that breaks the valley symmetry, such transitions can occur at different points in the drive parameter space for different valleys. This may lead to valley polarized transport. We apply this concept to propose geometries for valleytronics devices like valves and transistors, which we theoretically analyze.

8:48AM L17.00005 Interaction of Dirac Fermion excitons and biexciton-exciton cascade in graphene quantum dots. ISIL OZFIDAN, University of Ottawa, MAREK KORKUSINSKI, National Research Council Canada, PAWEL HAWRY-LAK, University of Ottawa — We present a microscopic theory of interacting Dirac quasi-electrons and quasi-holes confined in graphene quantum dots. The single particle states of quantum dots are described using a tight binding model and screened direct, exchange, and scattering Coulomb matrix elements are computed using Slater pₓ orbitals. The many-body ground and excited states are expanded in a finite number of electron-hole pair excitations from the Hartree-Fock ground state and computed using exact diagonalization techniques. The resulting exciton and bi-exciton spectrum reflects the degeneracy of the top of the valence and bottom of the conduction band characteristic of graphene quantum dots with C3 symmetry. We study the interaction of multi-electron and hole complexes as a function of quantum dot size, shape and strength of Coulomb interactions. We identify two degenerate bright exciton (X) states and hole complexes as a function of quantum dot size, shape and strength of Coulomb interactions. We identify two degenerate bright exciton (X) and hole complexes as a function of quantum dot size, shape and strength of Coulomb interactions. We next calculate the exciton to bi-exciton transitions and hole complexes as a function of quantum dot size, shape and strength of Coulomb interactions. We identify two degenerate bright exciton (X) and hole complexes as a function of quantum dot size, shape and strength of Coulomb interactions. We next calculate the exciton to bi-exciton transitions and hole complexes as a function of quantum dot size, shape and strength of Coulomb interactions.

9:00AM L17.00006 Optical limiting and nonlinear optical properties of gold-decorated graphene nanocomposites. RAMAKRISHNA PODILA, Clemson University, PRABIN PRADHAN, MURALIKRISHNA MOLLI, Sri Sathyai Sai Institute of Higher Learning, DARSHASH KANIVIYOR, Indian Institute of Technology Madras (IITM), SAI MUTHUKUMAR V. S. SIVA SANKARA SAI, Sri Sathyai Sai Institute of Higher Learning, S. RAMAPRABHU, Indian Institute of Technology Madras (IITM), APPARAO RAO, Clemson University, DEPARTMENT OF PHYSICS, SRI SATHYA SAI INSTITUTE OF HIGHER LEARNING TEAM, ALTERNATIVE ENERGY AND NANOTECHNOLOGY LABORATORY (AENL), INDIAN INSTITUTE OF TECHNOLOGY MADRAS TEAM, DEPARTMENT OF PHYSICS AND ASTRONOMY, CLEMSON NANOMATERIALS CENTER, CLEMSON UNIVERSITY TEAM — Although metal nanoparticle-decorated nanomaterials exhibit excellent optical limiting (OL) performance at a relatively higher fluence (>9 J/cm²), there is a dearth of OL materials for protecting low damage threshold (<1 J/cm²) photonic devices. The rehybridization of some metal d-orbitals and graphene p-orbitals often leads to undesirable changes in graphene’s electronic structure, which adversely affects OL. Here, we demonstrate that d-orbitals of Au nanoparticles exhibit little or no rehybridization with graphene, and result in an enhanced OL behavior even at a low fluence of ~0.4 J/cm² due to the excellent photo-absorption of Au combined with rapid carrier thermalization by graphene.
9:12AM L17.00007 Background-Free Ultrafast Pump-Probe Transmission Spectroscopy of Graphene. JOSEPH R. MURPHY, Department of Physics, University at Buffalo, State University of New York, TIANMU ZHANG, TIM THOMAY, ALEXANDER N. CAVALIERI, Department of Electrical Engineering, University at Buffalo, State University of New York, SAIMA HUSAINI, ROBERT G. BEDFORD, Sensors Directorate, Air Force Research Laboratory, Wright-Patterson Air Force Base — Graphene and graphene-related materials exhibit properties of interest for optical applications. Time-resolved pump-probe spectroscopy has been proven an effective tool to measure the time scales of carrier dynamics of materials with adequate absorption. Ultrafast measurements are challenging to conduct due to graphene’s low absorption of 2.3% per layer and time scales of the carrier dynamics in the sub-picosecond range. To perform these experiments, laser pulses with a duration of 200 fs from the 800 nm beam from an amplified Ti:sapphire laser system with a repetition rate of 250 kHz were used with energy densities as low as 4 μJ/cm². The difficulty of the detection of the low absorption in this single-color experiment is further exacerbated by the need to distinguish the signal in the probe beam from the noise present in the two beams used. We present the results from a background-free technique used in our ultrafast pump-probe measurements; these results reveal the presence of electronic processes with time scales on the order of 500 to 700 fs in multilayer graphene. This background-free technique uses optical chopping to modulate the pump and probe beams at different frequencies and we have found that this method significantly improves the signal to noise ratio.

9:24AM L17.00008 Photocurrent Generation in the Fractional Quantum Hall Regime of Graphene. SANFENG WU, Department of Physics, University of Washington, LEI WANG, Department of Electrical Engineering, Columbia University, YOU LAI, National High Magnetic Field Laboratory, GRANT AIVAZIAN, HELIN CAO, Department of Physics, University of Washington, CORY DEAN, Department of Physics, Columbia University, JAMES HONE, Department of Mechanical Engineering, Columbia University, ZHIQIANG LI, National High Magnetic Field Laboratory, XIAODONG XU, Department of Physics, University of Washington — Significant understanding toward fractional quantum Hall effects has been made through probing the quantum transport of carriers at the Fermi surface. However, little is known about the non-equilibrium behavior of the carriers that are excited above the Fermi Sea. In this talk, we will discuss the transport phenomena of photo-excited carriers in the quantum Hall regime of graphene. By probing the photocurrent generation through the edge channels of a graphene field effect transistor under high magnetic field and low temperature, we observe chiral edge transport of photo-excited carriers. The observed photocurrent can directly resolve both integer and fractional quantum Hall states. Our measurements may provide a new experimental approach to uncover the rich and exotic physics related to fractional quantum Hall effects.

9:36AM L17.00009 Study of photocurrent response in bilayer graphene. LONG JU, University of California, Berkeley, LEI WANG, JAMES HONE, Columbia University, FENG WANG, University of California, Berkeley — Bilayer graphene is a unique system where the electronic band structure can be controlled by external electric field. The transition between semimetal to semiconductor with a bandgap up to 250 meV can be achieved by applying voltages on top and bottom gates. In this talk I’ll show our photocurrent measurement in dual-gated bilayer graphene devices. Different mechanisms of photocurrent generation will be discussed. I’ll also talk about its implications for potential opto-electronic applications of bilayer graphene.

9:48AM L17.00010 Photoresponse in Graphene Boron Nitride Vertical Heterostructures. TROND ANDERSEN, GIONG MA, CHUN-HUNG LUI, Massachusetts Inst of Tech-MIT, NITYAN NAIR, University of California, Berkeley, NATHANIEL GABOR, University of California, Riverside, ANDREA YOUNG, WENJING FANG, Massachusetts Inst of Tech-MIT, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, Japan, JING KONG, NUH GEDIK, PABLO JARILLO-HERRERO, Massachusetts Inst of Tech-MIT — Combining two-dimensional materials into vertical heterostructures reveals diverse, intriguing phenomena and provides a novel way of engineering materials with desired electronic properties. Placing graphene on hexagonal boron nitride (hBN) has given particularly interesting results, including enhanced mobility, opening of a band gap, and highly controllable photo-induced doping. We explore the photoresponse of vertical graphene-hBN-graphene heterostructures in a high electronic temperature regime where thermonic emission dominates. Near the charge neutral point, we observe a pronounced conductance peak, which we attribute to a cooling bottleneck that appears at low carrier density, thus suggesting hot carrier enhanced thermonic emission. To further investigate the mechanism by which current is generated, we conduct two-pulse correlation measurements and study the temporal dynamics of the system. We observe a positive correlation, implying that the hot carriers thermalize before crossing the hBN barrier. Finally, we propose an advanced, modified two-temperature model, which allows for numerical simulations that are consistent with our measurements.

10:00AM L17.00011 Scanning photocurrent microscopy in Graphene mediated by photo-Nernst effect. ZAIYAO FEI, HELIN CAO, GRANT AIVAZIAN, Department of Physics, University of Washington, JASON ROSS, Department of Materials Science and Engineering, University of Washington, DAVID COBDEN, Department of Physics, University of Washington, XIAODONG XU, Department of Physics, Department of Material Science and Engineering, University of Washington — We have performed scanning photocurrent microscopy on monolayer graphene devices in a perpendicular magnetic field of up to 7 T. At zero field we observe photocurrent generated only near the contacts, but for a finite magnetic field an additional edge magnetophotocurrent contribution appears far from the contacts which is odd in magnetic field. The edge photocurrent also has opposite polarities for opposite edges. At low field this contribution can be well explained by the photo-Nernst effect combined with the nonlocal current generation mechanism described by Son and Levitov (ref. Phys. Rev. B 90, 075415, 2014). The effect persists to room temperature. At higher fields Landau quantization effects are seen along with oscillations of the magneto-photocurrent. The theory remains inadequate to explain all the features in this regime.

10:12AM L17.00012 Altshuler-Aronov-Spivak Oscillation in Graphene Antidot lattice. YAGI, RYOJI SAKAKIBARA, JUNPEI ONISHI, ADSM, Hiroshima University, YAGI LAB. TEAM — We have observed the Altshuler-Aronov-Spivac (AAS) oscillation in triangular antidot lattice of single layer graphene. Low temperature magnetoresistance exhibited h/2e periodic oscillations near zero magnetic field, negative magnetoresistance, and h/e periodic (AB-type) oscillations at higher magnetic fields. Phase of the AAS oscillation was the same as those for conventional 2D electrons with negligible spin orbit interaction, showing that inter-valley scattering averaged the Berry phase effect which results in anti-localization. (Yagi et al. J. Phys. Soc. Jpn. 81, 064707 (2012).)

10:24AM L17.00013 Low-gate-biased edge-state manipulation for tunable spin-polarized current source in zigzag graphene ribbon. LI CHANG, CHON-SAAR CHU, Department of Electrophysics, National Chiao-Tung University — In this work, we investigate the spin transport through a region with inhomogeneous edge-potential generated by split gates in a zigzag graphene ribbon (ZGNR). The split gates (each covers the lower and upper edges of the ribbon) actively modify the coupling between the pair of edge states and electrically generate the tunable edge-sate gap (ESG). With a homogeneous exchange field in the whole background, the ESGs of opposite spins are separated. We utilize these separated gaps to realize the tunable spin-polarized current source. Specifically, the split gates are placed in the middle segment of the ZGNR and we numerically study the spin transport through the potential region. With the exchange field strength of 5 meV and the on-site energy uncertainty within ±4 meV, we still get nearly 100% spin polarized current.
**10:36AM L17.00014 Temperature-dependent Transport Properties of CVD grown Graphene with Pd Functionalization**, BOCHEN ZHONG, Department of Physics and Astronomy, University of South Carolina, AHSAN UDDIN, AMOL SINGH, Department of Electrical Engineering, University of South Carolina, GOUTAM KOLEY, Department of Electrical and Computer Engineering, Clemson University, RICHARD WEBB, Department of Physics and Astronomy, University of South Carolina — We have investigated the temperature dependence of carrier density and mobility of CVD grown graphene before and after 2nm Pd deposition by Hall effect measurement. In our samples, Hall mobility increases as temperature increases, indicating that Coulomb scattering is the most important scattering mechanism. The Pd functionalization layer scattering limited carrier mobility is modeled as a function of temperature, and a least-square fit is done. Furthermore, Hall mobility of the Pd-functionalized graphene enhances significantly after exposure to H2 and the dominant scattering mechanism switches to thermal excited substrate optical phonon scattering.

**10:48AM L17.00015 Toward High Performance Graphene-based Solar Cells: Spectroscopic Study on Doped Graphene**, JAN-KAI CHANG, Department of Physics, Caltech; Graduate Institute of Photonics and Optoelectronics, National Taiwan University, CHEN-CHIH HSU, WEI-HSIANG LIN, Department of Physics, Caltech, CHIH-I WU, Graduate Institute of Photonics and Optoelectronics, National Taiwan University, NAI-CHANG YEH, Department of Physics, Caltech — We have investigated the temperature dependence of graphene-based devices: Spectroscopic study on doped graphene. The proposed facile strategy led to a tunable work function from 3.25 eV to 5.10 eV, enabling graphene anode and cathode for solar cell devices. Both hybrid and organic photovoltaics using graphene electrodes have been carried out with a series of optimization based on spectroscopic characterizations. Since aging of doped graphene is crucial to the lifetime of graphene-based solar cells, the doping-induced electronic state variation with time has been investigated via X-ray and ultra-violet photoemission spectroscopy analysis to gain insight in its electronic properties and stability. The doping effect developed in graphene has also been studied via Raman spectroscopy, including time evolution of the Raman D, G and 2D bands under normal and humid conditions for up to 30 days. This systematic investigation of aging effect provides better understanding and helps optimize the stacking of doped graphene films for achieving high performance graphene-based devices.

Wednesday, March 4, 2015 8:00AM - 11:00AM

**Session L18 DPOLY FIAP GSOFT: Invited Session: Industry Day: Dynamics and Non-Equilibrium Processes of Colloids and Filled Polymer Blends** Mission Room 103A - Valeriy Ginzburg, Dow Chemical

**8:00AM L18.00001 Structure-Property Relationships of Architectural Coatings by Neutron Methods**, ALAN NAKATANI, The Dow Chemical Company — Architectural coatings formulations are multi-component mixtures containing latex polymer binder, pigment, rheology modifiers, surfactants, and colorants. In order to achieve the desired flow properties for these formulations, measures of the underlying structure of the components as a function of shear rate and the impact of formulation variables on the structure is necessary. We have conducted detailed measurements to understand the evolution under shear of microstructure and larger scale mesoscale in model architectural coatings formulations by small angle neutron scattering (SANS) and ultra small angle neutron scattering (USANS), respectively. The SANS results show an adsorbed layer of rheology modifier molecules exist on the surface of the latex particles. However, the additional hydrodynamic volume occupied by the adsorbed surface layer is insufficient to account for the observed viscosity by standard hard sphere suspension models (Krieger-Dougherty). The USANS results show the presence of latex aggregates, which are fractal in nature. These fractal aggregates are the primary structures responsible for coatings formulation viscosity. Based on these results, a new model for the viscosity of coatings formulations has been developed, which is capable of reproducing the observed viscosity behavior.

**8:36AM L18.00002 Thermal Imaging Processes of Polymer Nanocomposite Coatings**, JEFFREY METH, CR&I, DuPont Co. — Laser induced thermal imaging (LITI) is a process whereby infrared radiation impinging on a coating on a donor film transfers onto an adjacent film to produce a pattern. This talk describes how LITI patterning can print color filters for liquid crystal displays, and details the physical processes that are responsible for transferring the nanocomposite coating in a coherent manner that does not degrade its optical properties. Unique features of this process involve heating rates of 10^7 K/s, and cooling rates of 10^4 K/s, which implies that not all of the relaxation modes of the polymer are accessed during the imaging process. On the microscale, the polymer flow is forced by devolatilization of solvents, followed by deformation akin to the constrained blister test, and then fracture caused by differential thermal expansion. The unique combination of disparate physical processes demonstrates the gamut of physics that contribute to advanced material processing in an industrial setting.

**9:12AM L18.00003 Dynamics of Polyelectrolyte Chains within Layer-by-Layer Assemblies**, SVETLANA SUKHISHVILI, Department of Chemistry, Chemical Biology and Biomedical Engineering, Stevens Institute of Technology, Hoboken 07030 — Layer-by-layer (LbL) assembly of charged polymers/nanoparticles finds diverse industrial applications ranging from NIR reflective heat-reduction to multi-stage drug delivery. Internal layering of film components lies at the heart of their performance. I will discuss experiments aimed to unravel relationships between center-of-mass diffusion of polyelectrolyte (PE) chains within LbL films, PE molecular characteristics, environmental conditions (salt concentration), and film structure. Upon film annealing in salt solutions, chain diffusion is highly anisotropic (as probed by fluorescence recovery after photobleaching and neutron reflectometry), and is strongly coupled with film structure. For layered LbL films, PE diffusion in the direction parallel to the substrate reveals quasi-Rouse scaling with molecular weight (D ~ M^−1), even for long chains, suggesting that chains disentangle upon adsorption. Finally, I will discuss quantitative aspects of salt-induced PE chain diffusion in directions parallel and perpendicular to the substrate, and their consequences for persistent layering within LbL films.

**9:48AM L18.00004 Field responsive shear thickening fluids for personal protective equipment and MMOD shielding for spacecraft and astronauts**, NORMAN WAGNER, University of Delaware / STF Technologies LLC — Shear thickening fluids (STFs) are novel, field responsive materials and have been shown to provide enhanced ballistic and puncture resistance when integrated into nanocomposites. In this talk, I will review the basic principles of shear thickening in colloidal dispersions by introducing new, recent results describing the unique material functions of the shear thickened state and how these material functions relate to those observed in simulation and experiments, as well as models for these material functions and their dependence on particle concentration. Next, performance data for STF-Armor(TM) nanocomposites (STF intercalated with aramid and other textiles) in puncture, ballistic and hypervelocity impact experiments, as well as energy absorbing impact experiments, will be shown and related back to the material properties of the STF fluids. Finally, advances in product development to achieve suitable puncture resistance for novel applications such as puncture resistant surgical gloves (STF Technologies LLC) will be presented along with challenges for the future product development.

9:12AM L19.00003 3D Printing, Additive Manufacturing, and Solid Freeform Fabrication:
The Technologies of the Past, Present and Future . JOSEPH BEAMAN, University of Texas at Austin — Starting in the
late 1980’s, several new technologies were created that have the potential to revolutionize manufacturing. These technologies are, for the most part, additive
processes that build up parts layer by layer. In addition, the processes that are being touted for hard-core manufacturing are primarily laser or e-beam based
processes. This presentation gives a brief history of Additive Manufacturing and gives an assessment for these technologies. These technologies initially grew
out of a commercial need for rapid prototyping. This market has a different requirement for process and quality control than traditional manufacturing. The
relatively poor process control of the existing commercial Additive Manufacturing equipment is a vestige of this history. This presentation discusses this history
and improvements in quality over time. The emphasis will be on Additive Manufacturing processes that are being considered for direct manufacturing, which
is a different market than the 3D Printing “Makerbot” market. Topics discussed include past and present machine sensors, materials, and operational methods
that were used in the past and those that are used today to create manufactured parts. Finally, a discussion of new methods and future directions of AM is
presented.

9:48AM L19.00004 Additive Manufacturing Enabled Ubiquitous Sensing in Aerospace and
Integrated Building Systems1 . JOSEPH MANTESE, United Technologies Research Center — Ubiquitous sensing is rapidly emerging as
a means for globally optimizing systems of systems by providing both real time PHM (prognostics, diagnostics, and health monitoring), as well as expanded
in-the-loop control. In closed or proprietary systems, such as in aerospace vehicles and life safety or security building systems; wireless signals and power must
be supplied to a sensor network via single or multiple data concentrators in an architecture that ensures reliable/secure interconnectivity. In addition, such
networks must be robust to environmental factors, including: corrosion, EMI/RFI, and thermal/mechanical variations. In this talk, we describe the use of
additive manufacturing processes guided by physics based models for seamlessly embedding a sensor suite into aerospace and building system components; while
maintaining their structural integrity and providing wireless power, sensor interrogation, and real-time diagnostics. We detail this approach as it specifically
applies to industrial gas turbines for stationary land power.

10:24AM L19.00005 Manufacturing of Wearable Sensors for Human Health and Performance
Monitoring . AZAR ALIZADEH2, GE Global Research — Continuous monitoring of physiological and biological parameters is expected to improve
performance and medical outcomes by assessing overall health status and alerting for life-saving interventions. Continuous monitoring of these parameters
requires wearable devices with an appropriate form factor (lightweight, comfortable, low energy consuming and even single-use) to avoid disrupting daily
activities thus ensuring operation relevance and user acceptance. Many previous efforts to implement remote and wearable sensors have suffered from high
cost and poor performance, as well as low clinical and end-use acceptance. New manufacturing and system level design approaches are needed to make the
performance and clinical benefits of these sensors possible while satisfying challenging economic, regulatory, clinical, and user-acceptance criteria. In this talk we
will review several recent design and manufacturing efforts aimed at designing and building prototype wearable sensors. We will discuss unique opportunities and
challenges provided by additive manufacturing, including 3D printing, to drive innovation through new designs, faster prototyping and manufacturing, distributed
networks, and new ecosystems. We will also show alternative hybrid self-assembly based integration techniques for low cost large scale manufacturing of single
use wearable devices.

9:12AM L20.00003 Probing Quantum Magnetism in 2D with an Array of Hundreds of Trapped Ions\(^1\). JOHN BOLLINGER, NIST, Boulder CO 80305 — Quantum simulations using AMO systems promise a new way to experimentally study emergent quantum phenomena, but few systems have demonstrated the capability to control ensembles in which quantum effects cannot be directly computed. The 2D array of 100s of \(^{9}\)Be\(^+\) ions in a Penning trap, crystallized in a triangular lattice when laser cooled, is a promising platform for intractable quantum simulations using the \(^{9}\)Be\(^+\) valence electron spin as a qubit \([1]\). Spin-dependent forces are employed to modify the strong Coulomb interaction of the ions, mimicking a quantum magnetic interaction. The range of the magnetic interaction can be tuned from infinite to a dipole-dipole like coupling. Combining the application of the spin-dependent force with a transverse magnetic field should lead to the development of quantum correlations between the spins, which can be measured through optical readout of the spin state, both globally and with site-resolved imaging. In this way, trapped atomic ions can be used to probe novel and intractable aspects of quantum magnetism, including the effects of long-range interactions and simulations of quantum non-equilibrium phenomena \([2]\). In addition to a general overview, I will discuss recent work from a new Penning trap set-up at NIST.

9:48AM L20.00004 Quantum atom optics with BEC: Fisher information for entangled non-Gaussian many particle states, MARKUS OBERTHALER, Kirchhoff Institute for Physics, Heidelberg University, 69120 Heidelberg/Germany — Our results build on the successful generation of spin squeezed states utilizing the quantum dynamics in an interacting two component Bose gas. The initial state is close to an unstable fixed point of the underlying classical system and thus the dynamics leads to squeezing for the initial time (harmonic regime) but generates non-Gaussian states for longer times. With this new method we generate 6dB spin squeezed states on a short time scale. The novel way of squeezing generation also allows the exploration of over-squeezed states i.e. transient non-Gaussian states towards the generation of cat states. We will report on our results preparing and characterizing these transient non-Gaussian states. They reveal variances which are larger than the classical shot noise limit thus suppression of fluctuations cannot be employed as an entanglement witness. We therefore developed a novel method for detecting the presence of entanglement by extracting from the experimentally detected distribution functions a bound of the Fisher information present in the system. With that we confirm that the entanglement is still present although the states are not spin squeezed. Furthermore interferometry beyond classical limits with these novel states is demonstrated by employing maximum likelihood estimation of the interferometric phase. We will also present a general approach which allows the upscaling of squeezed states to large atom numbers by employing the concept – divide and conquer. We explicitly demonstrate 5dB squeezing for more than 13000 particles. We use this resource and combined this with swapping the squeezing to magnetically sensitive states for demonstration of quantum enhanced magnetometry with high spatial resolution.

10:24AM L20.00005 SU(N) orbital magnetism and synthetic dimensions with two-electron fermions, LEONARDO FALLANI, LENS / Florence — I will report on recent experiments performed at LENS with ultracold 173Yb Fermi gases. These two-electron atoms offer a range of new opportunities for quantum simulation with ultracold gases, since they grant the access to two stable degrees of freedom—nuclear spin and electronic state—that can be manipulated independently and coherently. By controlling the electronic state via an ultranarrow clock transition, we have obtained the first demonstration of fast, coherent spin-exchange oscillations between fermionic atoms trapped in two different long-lived electronic orbitals [1]. This result paves the way to the observation of exotic quantum magnetism and of paradigmatic condensed-matter effects in a fermonic system exhibiting SU(N)-invariant interactions. Finally, I will present the results of a very recent experiment, where we have used Raman transitions between different 173Yb nuclear spin states to synthesize an effective lattice dynamics in a finite-sized “extra dimension.” By using this innovative approach, we have realized synthetic magnetic fields for effectively-charged fermions and we have demonstrated the emergence of chiral edge states propagating along the edges of the system, thus providing a direct evidence of a prominent feature of quantum Hall physics in condensed-matter systems [2].

Wednesday, March 4, 2015 8:00AM - 11:00AM –

8:00AM L21.00001 Design and performance of a cryogenic scanning tunneling microscope in high magnetic field for 2D layered materials study\(^1\). TIEN-MING CHUANG, FEI-FANG CHUNG, SYU-YOU GUAN, SHAN-AN YU, CHE-AN LIU, CHIA-SHENG HSU, CHIH-CHUAN SU, Institute of Physics, Academia Sinica, Nankang, Taipei 11529, Taiwan, RAMAN SANKAR, FANG-CHENG CHOU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan — We will describe the design and performance of a cryogenic scanning tunneling microscope (STM) system in a high magnetic field. A Pan-type STM is mounted on a homemade low vibration 4He pot refrigerator, which can be operated in continuous flow mode at \(T \sim 1.6\)K and in a magnetic field of up to 9 Tesla. A cleavage device at \(T=4.2\)K stage is used to cleave the 2D layered materials before inserting into STM as well as functioning as the radiation shield. The liquid helium boil rate of 4.6 liters per day is achieved due to our careful design, which allows the measurement at base temperature up to 10 days. We will demonstrate its capability of measuring atomically registered energy resolved spectroscopic maps in both real space and momentum space by our recent results on Rashba BiTeI.

8:12AM L21.00002 ABSTRACT WITHDRAWN –
8:24AM L21.00003 Quantum Interference between Energy Absorption Processes of Molecular Exciton and Interface Plasmons on Luminescence Induced by Scanning Tunneling Microscopy

KUNIKIYUKI MIWA, HIROSHI IMADA, RIKEN, MANORI SAKAUE, HIDEAKI KASAI, Graduate School of Engineering, Osaka University, YOUSOO KIM, RIKEN — Luminescence induced by the tunneling current of a scanning tunneling microscope (STM) from molecule-covered metal surfaces is attributed to radiative decays of molecules and interface plasmons localized near the tip-substrate gap region. Since the dynamics of molecule and interface plasmons strongly influence each other, the interplay between these dynamics gives rise to peculiar phenomena originating from quantum many-body effects. In this study, we develop the effective model of the system and investigate the luminescence properties using the nonequilibrium Green’s function method. The results show that, in addition to the dynamic spectrum of molecular, energy reabsorption by interface plasmons have a critical role in determining the luminescence spectral profile of interface plasmons. The additional peak structure arises owing to the interference between these energy absorption processes. Origin of prominent peak and dip structures observed in recent experiments are identified by the developed theory. The details of the interference effects on the luminescence properties will be discussed.

8:36AM L21.00004 Image Distortions of Molecules in Atomic Force Microscopy with Carbon Monoxide Terminated Tips

NIKOLAJ MOLL, LEO GROSS, BRUNO SCHULER, ALESSANDRO CURIONI, GERHARD MEYER, IBM Research - Zurich — Using functionalized tips, the atomic resolution of a single organic molecule can be achieved by atomic force microscopy (AFM) operating in the regime of short-ranged repulsive Pauli forces while the van-der-Waals and electrostatic interactions only add a diffuse attractive background. The underlying mechanisms of image distortions with CO-terminated tips are identified and studied in detail. Parts of a molecule appear different in size, which primarily originates from the charge density. Further, tilting of the CO at the tip, induced by van der Waals forces, enlarges the apparent size of parts of the molecule by up to 50%. Moreover, the CO tilting in response to local Pauli repulsion causes a significant sharpening of the molecule bonds in AFM imaging. With these image distortions it is possible to distinguish different bond orders of individual carbon-carbon bonds in organic molecules by AFM.

8:48AM L21.00005 Three-Dimensional Imaging of Complex Molecular Electronic States via Atomic Manipulation Reconstruction

ERIC CHATTERJEE, DOMINIK RASTAWICKI, ALEX CONTRYMAN, YAN SUN, DYLAN RUETER, HARI MANOHARAN, Stanford Univ — We describe a method based on STM atomic manipulation for experimentally capturing the complete three-dimensional electronic structure of complex molecules. Using techniques we have recently developed for assembling molecular graphene and related materials, we vary specific site potentials, intersite hopping amplitudes, and Fermi energy in 2D nanostructures which when wrapped into a 3D container represent a new probe molecule. Here we present the design methods and analyses of a number of such molecules, focusing on those containing rotational symmetry. We show how various types of fullerenes, of interest due to their electronic and vibrational properties, can be unwrapped on a 2D surface, reprogrammed, and rewrapped to 3D. Examples of the unwrapping methods include cutting selected bonds in order to sever adjacent faces or sites. Analysis of the local density of states for 2D correspondents to fullerenes yields the presence of peaks at the highest occupied molecular orbital and lowest unoccupied molecular orbital, with an energy gap between these levels. The replication of these properties of fullerenes in 2D space serves as evidence of the significant potential of STM assembly and spectroscopy in studying the applicability of exotic 3D molecules in electronics.

9:00AM L21.00006 Gauge Fields and Topological Confinement in Synthetic Nanomaterials Assembled via Atomic Manipulation

DOMINIK RASTAWICKI, ERIC CHATTERJEE, YAN SUN, ALEX CONTRYMAN, DYLAN RUETER, HARI MANOHARAN, Stanford Univ — The assembly of molecular graphene and related nanostructures demonstrated that atomic manipulation can be used to build functional quantum nanomaterials site by site and bond by bond. This level of precise control lets one tune the potential of each site, the hopping strength of each bond, and—by adjusting lattice size—the Fermi energy and relative interaction strength inside and between sites. Here we present examples of new molecular materials assembled and characterized by STM/STS exploiting these techniques. We show that lattices with varying site potential across six sites of a unit cell show signatures of non-abelian gauge fields. We will contrast observed behavior with conventional abelian gauge fields built into the same structures. We will also show that boundaries between patterned mass domains can induce topological edge states and topological charge confinement. We will also discuss the engineering of flat bands into more complex materials, and show effects of the resulting quenching of kinetic energy.

FABIAN DONAT NATTERER, NIST, Center for Nanoscale Science and Technology — In graphene, phonons are important agents for a wide range of phenomena; they mediate relaxation rates for hot carriers, they lead to van-Hove singularities, and they induce a renormalization of the Fermi velocity due to electron-phonon coupling and many-body interactions [1]. The previous observations of phonons [2-4] by inelastic electron tunneling spectroscopy (IETS) have been expandable in terms of detail and resolution due to weak signals and other spectral features which inhibit a clear distinction between phonons and miscellaneous excitations. We find that utilizing a back gated graphene device, where the graphene charge carrier density can be varied in magnitude and sign, allows all the critical point graphene phonons with large density of states to be sampled by IETS with the scanning tunneling microscope, and in good agreement with density functional calculations. In addition, a strong overtone excitation at 360 meV is observed. Quite surprisingly, we observe all the graphene excitations are resonantly enhanced when the charge carrier type is switched, indicating that this amplification occurs whenever the inelastic transition allows a change in the graphene chirality. The chiral enhancement is observed to follow a linear trend with energy and reaches almost an order of magnitude for the highest transition. Our averaging technique suppresses charge carrier dependent excitations, while it improves the signal for inelastic transitions. This approach can be employed as a guide in advanced studies that are relying on gate tunable graphene devices, such as for the detection of spin, vibrational, or rotational excitations in adsorbates.

9:48AM L21.00008 Probing the Hydrogen Bond Strength at Single Bond Limit1, JING GUO, International Center for Quantum Materials, School of Physics, Peking University, JING-TAO LU, School of Physics, Huazhong University of Science and Technology, JI CHEN, JINBO PENG, XUANGZHI MENG, ZIHANG WANG, International Center for Quantum Materials, School of Physics, Peking University, XIN-ZHE LI, School of Physics, Peking University; Collaborative Innovation Center of Quantum Matter, Beijing, ENGE WANG, YING JIAOQING, International Center for Quantum Materials, School of Physics, Peking University; Collaborative Innovation Center of Quantum Matter, Beijing — Many extraordinary physical, chemical and biological properties of water are determined by hydrogen-bonding interaction between the water molecules. So far, the routine way to determine the hydrogen-bonding strength of water is probing the frequency shift of O—H stretching mode using various spectroscopic techniques, which all suffer from the difficulty of spectral assignment and the broadening of vibrational signals due to the lack of spatial resolution. In this talk, we show the ability to probe the hydrogen-bonding strength of interfacial water at single bond limit using resonantly enhanced inelastic electron tunneling spectroscopy (IETS) with a scanning tunneling microscope (STM). The conventional IET signals of water molecules are extremely weak and far beyond the experimental detection limit due to the negligible molecular density of states (DOS) around the Fermi level. This difficulty can be surmounted by turning on the tip-water coupling, which shifts and broadens the frontier molecular orbitals of water to the proximity of Fermi level, resulting in a resonantly enhanced IET process.

10:12AM L21.00010 Elemental Fingerprinting of Materials with Sensitivity at the Atomic Limit1, MARVIN CUMMINGS, NOZOMI SHIRATO, Argonne Natl Lab, HEATH KERSELL, YANG LI, Ohio U., BENJAMIN STRIPE, DANIEL ROSEN-MANN, Argonne Natl Lab, SAW-WAI HLA, Argonne Natl Lab — Variants of scanning probe microscopes have proven tremendously valuable for extracting detailed information about the nature of a sample’s surface (atomic, electronic, magnetic), however it has proven difficult to yield chemical information utilizing scanning probe techniques alone. At Argonne National Laboratory’s Advanced Photon Source, a new in-situ high-resolution microscopy technique, the synchrotron x-ray scanning tunneling microscopy (SXSTM), utilizes x-rays as a chemical, electronic and magnetic probe and the nanofabricated tips of a scanning tunneling microscope as the chemical detector to take full advantage of the sub-nm spatial resolutions that STM provides. Utilizing the new SXSTM technique, chemical fingerprinting of individual nickel clusters on a Cu(111) surface has been demonstrated with a 2 nm lateral resolution and a sensitivity confined to the first atomic surface layer. In addition, the photoionization cross-section from a single nm-scale Ni cluster has been successfully measured. SXSTM could be proved to be a powerful new surface characterization technique, enabling exciting areas of opportunity and discovery in the chemical and materials sciences.

10:24AM L21.00011 Direct elemental and magnetic contrast of magnetic thin films and nanoparticles measured by synchrotron X-ray scanning tunneling microscopy and spectroscopy, ANDREW D’IULLO, Argonne National Laboratory, IL 60439, USA, N. SHIRATO, M. CUMMINGS, Argonne National Laboratory, Lemont, IL 60439, USA, H. KERSELL, Ohio University, Athens, OH 45701, USA, S.-W. HLA, V. ROSE, Argonne National Laboratory, IL 60439, USA — Synchrotron X-ray scanning tunneling microscopy (SX-STM) combines two of the most robust characterization instruments of materials science in a single setting and it can provide elemental fingerprinting of materials down to the atomic limits [1]. Here, we show that the SX-STM can also be useful for the magnetic measurements with elemental specificity by combining tunneling microscopy and spectroscopy with the X-ray magnetic circular dichroism (XMCD) technique. The experiments are performed in the Advanced Photon Source beam line 4-ID-C using a custom-built SX-STM system. During the experiment, the circularly polarized synchrotron light is projected onto iron nanoclusters adsorbed on a cobalt thin film on Cu(111) surface, and the resulting photo-current is collected by a nano-fabricated SX-STM tip. The photocurrent intensity clearly reveals major and minority spin states when measured at L2 and L3 edges of the magnetic materials.

10:36AM L21.00012 Schottky Barrier mapping of the W/Si diode using ballistic electron emission microscopy, CHRISTOPHER DURCAN, ROBERT BALSANO, NICHOLAS PIENIAZEK, College of Nanoscale Science and Engineering, State University of New York at Albany, VINCENT LABELLA, Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute — The Schottky barrier of the W(001)/Si(001) diode was investigated and spatially mapped at the nanoscale using ballistic electron emission microscopy (BEEM) and ballistic hole emission microscopy (BHEM). The miscibility of tungsten and silicon creates a thin silicide upon deposition with transmission electron microscopy (TEM) and Rutherford backscattering spectrometry (RBS) showing the changes in the silicide over several weeks. Using standard current voltage measurements there is no change in the charge transport across the diode during this time period. However, BEEM measurements do show dramatic changes to the transport of ballistic electrons over time with nanoscale resolution. Time dependent Schottky barrier maps are generated over a 1 µm x 1 µm area and provide valuable insight to the barrier height homogeneity, defect formation, and interfacial effects occurring in the diode.

10:48AM L21.00013 Obtaining reliable friction data at the nanoscale by tuning AFM parameters1, SUNG HYUN KIM, SUENNIE KIM, Hanyang University — Carefully devised experimental study of friction at the nanoscale in dry system is desired for proper mathematical modeling or for quantitative research. Experimentally, contact mode atomic force microscope (AFM) which is able to perform lateral force microscopy (LFM) can be used for acquiring frictional data. To obtain reliable LFM information, we have investigated the effect of scanning parameters, especially gain and scanning rate, on the LFM measurements. Depending on the parameters selected, the relative ratio of the friction force obtained from graphene to that of SiO2 varies greatly from about 1 to 0.1. We will discuss, here, firstly how to understand this behavior and secondly the parameter-optimization procedure for the LFM imaging, which is different from the height imaging, eventually to aid quantitative LFM studies.

8:00AM L22.00001 New Phases Stabilized by Anisotropic Impurity in $^{3}$He , A.M. ZIMMERMAN, J.I.A. LI, Northwestern University, J. POLLANEN, California Institute of Technology, C.A. COLLETT, W.P. HALPERIN, Northwestern University — We have introduced anisotropic impurity into superfluid $^{3}$He using well-characterized silica aerogel samples negatively strained by mechanical compression along the cylinder axis by $\approx 10\%$, $20\%$, and $30\%$. Using NMR measurements, we determined the temperature-magnetic field phase diagrams for these amounts of strain. In previous work it was found that in the presence of negative strain of $\approx 20\%$ the superfluid A-phase is only stable above a critical magnetic field, $H_{c}^{A}$. We have found that $H_{c}^{A}$ increases linearly with strain. By comparing the measured NMR longitudinal resonance frequency to results from unstrained isotropic aerogel, we have determined that in the presence of negative strain the B-phase evolves into a new anisotropic phase. This new anisotropic phase is more stable than the A-phase for fields below $H_{c}^{A}$. This work was supported by the National Science Foundation, DMR-1103625.

8:12AM L22.00002 Puddles of Helium on graphite surfaces , USHNISH RAY, NORMAN TUBMAN, University of Illinois at Urbana-Champaign — The ground state of $^{3}$He in 2D has long been theoretically suspected to be in a non-binding gaseous state. Recent experiments with ultra low density $^{3}$He adsorbed on Grafoil have shown, however, that below a critical density ($0.6 - 0.9\ nm^{-2}$) this 2D system becomes a self bound liquid. Subsequent numerical studies with an idealized graphite potential indicate that such a state is forbidden, but can possibly form on other alkali substrates. A key aspect not taken into consideration in such studies are the details of the anisotropic graphite potential. Our studies with finite temperature Path-Integral Monte-Carlo and ground state Diffusion Monte-Carlo techniques that use the full anisotropic graphite potential, on the other hand, reveals an alternate picture. We find that although the effective mass induced by the graphite surface is not enough to induce a macroscopic liquid, the system can still form ultra low density liquid puddles composed of a few $^{3}$He atoms. This picture is in agreement with experimental findings and illuminates a novel phase of Helium on graphite surfaces

8:24AM L22.00003 Confinement effect on Anderson-Higgs modes in superfluid $^{3}$He-B , T. MIZUSHIMA, Osaka University, J.A. SAULS, Northwestern Univ — Superfluid $^{3}$He is a prototype to observe the spectrum of Anderson-Higgs (AH) modes associated with spontaneous symmetry breaking. In bulk superfluid $^{3}$He, AH modes have been observed experimentally through attenuation of zero sound, propagation of transverse sound and its acoustic Faraday rotation. Starting from a Lagrangian formulation, we examine the AH modes of $^{3}$He-B confined in a restricted geometry. For bulk $^{3}$He-B this formalism leads to the well known spectrum of bosonic collectives modes of the bulk B-phase labelled by the quantum numbers for total angular momentum, $J = 0, 1, 2, ...$, the projection along an axis, $J_{z} = -J, ... , J$, and the parity under particle-hole conversion, $K = \pm 1$. For the equilibrium phases of $^{3}$He confinement induces pair breaking and leads to symmetry breaking, giving rise to a rich topological phase diagram. In terms of the bosonic excitations, we find that confinement induces symmetry breaking and leads to mixing of modes with different $J$, as well as to level splittings of the AH modes that are otherwise degenerate in bulk $^{3}$He-B. We find a new spectrum of Bosonic modes is generated that are bound to the surface of superfluid $^{3}$He in a restricted geometry. We also report on the coupling of the AH modes to ultra-sound.

8:36AM L22.00004 Topological quantum phases of helium-4 confined to nanoporous materials , LODE POLLET, LMU Munich, Germany, ANATOLY KUKLOV, College of Staten Island, City University of New York, New York — The ground state of $^{4}$He confined in a system with the topology of cylinder can display properties of solid, superfluid, and liquid crystal. This phase, which we call a compactified supersolid (CSS), originates from wrapping the basal planes of the bulk hcp solid into concentric cylindrical shells, with several central shells exhibiting superfluidity along the axial direction. Its main feature is the presence of a topological defect which can be viewed as a disclination with Frank index $\pi$. For the equilibrium phases of $^{4}$He confinement induces pair breaking and leads to symmetry breaking, giving rise to a rich topological phase diagram. In terms of the bosonic excitations, we find that confinement induces symmetry breaking and leads to mixing of modes with different $J$, as well as to level splittings of the AH modes that are otherwise degenerate in bulk $^{3}$He-B. We find a new spectrum of Bosonic modes is generated that are bound to the surface of superfluid $^{3}$He in a restricted geometry. We also report on the coupling of the AH modes to ultra-sound.

8:48AM L22.00005 $^{3}$He Condensation and Dissolution at Layer Completion in $^{3}$He-$^{4}$He Mixtures Adsorbed on Carbon Nanotubes , GARY WILLIAMS, EMIN MENACHEKIAN, JOHN ABRAHAM, BOB CHEN, VITO IAIA, ANDREW LI, SERGEY SUSHCHIKH, UCLA — The condensation and then dissolution of $^{3}$He has been observed at layer completion in $^{3}$He-$^{4}$He mixtures adsorbed on multiwall carbon nanotubes. With an initial fill of 3.5 layers of $^{3}$He, the addition of $^{3}$He in five steps of 0.07 layers uniformly reduces $T_{K}/c^{2}$, showing that the $^{3}$He is uniformly distributed. With the final 0.35 layer of $^{3}$He still present, additional $^{4}$He is then added at low temperature (225 mK). An abrupt transition is observed in the third sound signal very near the total-thickness 4.0 layer completion, where the Q factor suddenly drops by two orders of magnitude and the sound speed becomes constant. With the addition of another 0.1 layer of $^{4}$He the sound speed starts to decrease again and the Q climbs back to its initial value. We postulate that this behavior marks the formation of condensed $^{3}$He “islands” induced by the layer completion, and then the $^{3}$He dissolves back to uniform coverage past that point.

9:00AM L22.00006 Dissipative neutral mass flow and quantum phase slips in one dimension , ADRIAN DEL MAESTRO, Univ of Vermont — Motivated by experimental progress towards confining bosonic quantum fluids inside nanoscale constrictions, we have determined how quantum phase fluctuations of the superfluid order parameter modify neutral mass transport through a one dimensional channel open to vacuum. In the one dimensional limit, dissipation occurs in the guise of phase slips which may be nucleated due to the presence of impurity scattering, disorder, or a periodic potential. By combining equilibrium quantum Monte Carlo simulations with non-equilibrium calculations in the framework of Luttinger liquid theory, we have computed the relationship between the applied pressure and resistive mass flow for a one dimensional quantum fluid of neutral bosons. Understanding the temperature dependence of the resulting nonlinear pressure-flow behavior may be essential for the interpretation of quasi-1D superfluid flow experiments on helium-4.

9:24AM L22.00008 Pressure driven flows of superfluid helium-4 through a single nanopipe. ANGEL VELASCO, ZUZANNA SIWY, PETER TABOREK, University of California, Irvine — We have measured flow rates of helium-4 through a single etched nanopore of 31 nm diameter with a mass spectrometer. Flow rates were measured as a function of pressure at constant temperature and at saturated vapor pressures along the coexistence curve between 0.5 K and 3.5 K. Due to the constraint of the mass spectrometer the low pressure side was maintained at P=0 creating an intrinsic superfluid/vapor interface which forms inside the pipe and at its exit. We observed two flow regimes at low temperatures with velocities in the range of 6 and 11 m/s consistent with Feynman’s vortex critical velocity and a thermal vortex nucleation model respectively. The velocity in a laminar, viscous flow is proportional to the pressure drop while in superfluid flows to zeroth order the velocity is independent of the pressure. A first order correction shows a linear dependence on the pressure with the slope continuously varying from a positive to a negative value near the lambda point. We have also measured flow rates in the normal state and found rates in exact agreement with conventional viscous theory that incorporates the Laplace pressure and a zero slip length[1]. Supported by NSF DMR-0907495. [1] Velasco et al. Appl. Phys. Lett. 105, 2014

9:36AM L22.00009 A titanium transition-edge sensor for the in-situ detection of individual He3* excimers in superfluid helium 1. FAUSTIN CARTER, SCOTT HERTEL, CATHERINE MATULIS, MICHAEL ROCKS, DANIEL MCKINSEY, DANIEL PROBER, Yale University — Incident radiation can excite superfluid helium into a diatomic He3* excimer, which decays through the emission of a 15 eV photon. Such excimers have been used as tracers to measure the superfluid’s quantum turbulence, thanks in part to the long half-life of the He3* triplet state (~13 seconds). However, the efficient detection of single or a few excimers remains a challenge. We present a detector capable of in-situ detection of the He3* excimers either directly (the excimer collides with the detector), or by collecting the 15 eV photon emission upon decay. This detector is based on a titanium superconducting transition-edge sensor (TES), with an energy resolution of 1.5 eV fwhm, coupled to an aluminum absorber. The TES is designed to operate from 20-300 mK in a dilution refrigerator. We will discuss operating characteristics of the detector and present preliminary data for detection of individual excimers.

9:48AM L22.0010 Interaction of Ions, Atoms and Small Molecules with Quantized Vortex Lines in Superfluid 4He1. JUSSI ELORANTA, DAVID MATTEO, Chemistry Dept., Calif. State University Northridge, GARY WILLIAMS, UCLA — The interaction of a number of impurities (H2, Ag, Cu, Ag2, Cu2, Li, He3+, He4+, He5 (5S), He3 (5S1/2)) with quantized rectilinear vortex lines in superfluid 4He is calculated using density functional methods at 0 K. The technique yields the impurity radius as well as the vortex line core parameter. The core parameter at 0 K (0.74 Å) obtained either directly from the vortex line geometry or from the trapping potential fitting is smaller than previously suggested but is compatible with a re-analysis of the Rayfield-Reif experiment. All of the impurities have significant binding energies to the vortex lines below 1 K where the thermally assisted escape process becomes very inefficient. Even at higher temperatures the trapping times, especially for larger clusters, are sufficiently long that the observed metal nanowire assembly in superfluid helium can take place at vortex lines. The binding energy of the electron bubble is predicted to decrease as a function of both temperature and pressure, which allows adjusting the trap depth for either permanent trapping or thermally assisted escape. A new scheme for determining the trapping of impurities on vortex lines by optical absorption spectroscopy is outlined and demonstrated for He3*.

10:12AM L22.00012 Helium-3 Confined to a 1.08 Micron Deep Cavity1, NIKOLAY ZHELEV, ABHILASH SEBASTI, Cornell University, LEV LEVITIN, BEN YAGER, ANDREW CASEY, JOHN SAUNDERS, Royal Holloway University London, JEEVAK PARPIA, Cornell University — We describe measurements of superfluid Helium-3 confined to a high-aspect ratio cavity within the head of a high quality factor torsion pendulum. The 1.08 μm deep, rotationally symmetric cavity (11 mm diameter) is defined into a 14 mm diameter silicon disk. The silicon disk is anodically bonded to a matching octagonal glass piece to complete the torsion head. The thickness of 1 mm for both the glass and the silicon ensures minimal distortion of the cavity up to a few bars of pressure. We observe that the normal fluid component stays coupled to the smooth walls of the cavity down to the lowest measured temperatures. By tracking the torsion pendulum frequency and quality factor, we can identify a well defined superfluid transition in the fluid within the pendulum head. We plan to map out the phase diagram for the highly confined Helium-3 at low pressures and observe whether a “stripe phase” is realized in the vicinity of the transition between the A and B superfluid phases.1

10:24AM L22.00013 The Fermionic spectrum, phase transition and domain walls of confined 3He-A film

HAO WU, J. A. SAULS, Northwestern University — The edge states of a 3He film are Weyl Fermions propagating on the edge in a direction determined by the chirality of the bulk phase. Under lateral confinement, the wave functions for counter-propagating Weyl Fermions on opposing edges overlap. We show that the edge states hybridize and form a band, and the continuum states exhibit band gaps. We report self-consistent calculations of the reduction in the spontaneous edge mass currents due to hybridization as a function of lateral confinement, $D$. Strong lateral confinement leads to a sequence of quantum phase transitions. The phase undergoes a transition to a pair density wave (PDW) phase with broken translational symmetry at $D_{c1} \approx 13\xi_0$, and a transition to a polar state at $D_{c2} \approx 9\xi_0$. The PDW phase for $D < D_{c1}$ is periodic array of chiral domains separated by domain walls with currents that conflict with the direction of edge currents. We report self-consistent calculations of the PDW phase near $D_{c2}$ that resolves the competition in energy between edge states and Fermions bound to the domain wall. The resulting pattern of circulating currents also resolves the apparent violation of current conserved $\xi_0$.

10:36AM L22.00014 A Variable Path Length Cell for Transverse Acoustic Studies of Superfluid 3He

C.A. COLLETT, M.D. NGUYEN, J.I.A. LI, A.M. ZIMMERMAN, W.P. HALPERIN, Northwestern University, Evanston, IL 60208, USA, J.P. DAVIS, University of Alberta, Edmonton, AB, Canada T6G 2R3 — Transverse sound has recently emerged as an effective probe of the order parameter of superfluid 3He. It has allowed for the study of quantum fluids. Our study in 3He-B showed that the temperature dependence of the damping in this device was consistent with a damping model derived from thermal quasi-particles and demonstrated its potential as a sensitive quasi-particle flux detector. It is natural to conceive a scheme to build angle-resolved or space-momentum resolved 3He quasi-particle detectors in the form of array of resonators. This type of detectors could play an important role in revealing detailed structure of excitations or visualizing vortices in quantum fluids. A prototype detector is composed of 4 x 4 or 6 x 6 array of comb-drive resonators with strategically dispersed resonance frequencies. In this paper, We will discuss the working principle and design of the detector array.

10:48AM L22.00015 Micromachined Angle Resolved 3He Quasi-particle Detector1, YOONSEOK LEE, C.S. BARQUIST, P. ZHENG, W.G. JIANG, Department of Physics, University of Florida, Gainesville, FL, T.R. SCHUMANN, Y.K. YOON, Department of Electrical and Computer Engineering, University of Florida, Gainesville, FL — Micromachined comb-drive mechanical resonators have been developed for the study of quantum fluids. Our study in 3He-B showed that the temperature dependence of the damping in this device was consistent with a damping model derived from thermal quasi-particles and demonstrated its potential as a sensitive quasi-particle flux detector. It is natural to conceive a scheme to build angle-resolved or space-momentum resolved 3He quasi-particle detectors in the form of array of resonators. This type of detectors could play an important role in revealing detailed structure of excitations or visualizing vortices in quantum fluids. A prototype detector is composed of 4 x 4 or 6 x 6 array of comb-drive resonators with strategically dispersed resonance frequencies. 8:00AM L23.00001 First Principles Simulations of P-V-T Unreacted Equation of State of LLM-1051, RIAD MANAA, I-FENG KUO, LAURENCE FRIED, Lawrence Livermore National Laboratory — Equations of states (EOS) of unreacted energetic materials extending to high-pressure and temperatures regimes are of particular interest since they provide fundamental information about the associated thermodynamic properties of these materials at extreme conditions. Very often, experimental and computational studies focus only on determining a pressure-volume relationship at ambient to moderate temperatures. Adding elevated temperature data to construct a P-V-T EOS is highly desirable to extend the range of materials properties. Atomic scale molecular dynamics simulations are particularly suited for such a construct since EOSs are the manifestation of the underlying atomic interactions. In this work, we report dispersion-corrected density functional theoretical calculations of unreacted equation of state (EOS) of the energetic material 2,6-diamino-3,5-dinitropyrazine-1-oxide (LLM-105). We performed large-scale constant-volume and temperature molecular dynamics simulations for pressures ranging from ambient to 35 GPa, and temperatures ranging from 300 K to 1000 K. These calculations allowed us to construct an unreacted P-V-T EOS and obtain bulk modulus for each P-V isotherm. We also report the thermal expansion coefficient of LLM-105 in the temperature range of this study.

8:24AM L23.00003 Dynamic response of matter heated by ultrafast laser pulses¹. ELISEO GAMBOA, LUKE FLETCHER, SEBASTIAN GOÈDE, ULF ZASTRAU, HAE-JA LEE, ERIC GALTIER, WILL SCHUMAKER, ROHINI MISHRA, PHILIPP SPERLING, MAXENCE GAUTHIER, ALESSANDRA RAVASIO, MICHAEL MACDONALD, SIEGFRIED GLENZER, SLAC National Accelerator Laboratory — The material properties of the light elements at extreme conditions are of utmost importance to a diverse set of fields, from astrophysics and cosmology to research into controlled nuclear fusion energy production. These high-energy density states, defined as solid density plasmas with $T > 10$ eV, may be produced in the laboratory by irradiation of materials with high-energy or high-power lasers. Characterizing these material conditions using optical means is challenging because the plasma is above critical density and the experimental conditions are maintained over only very brief timescales. We present a preliminary analysis of x-ray scattering data from ultrafast, isochorically-heated hydrogen and carbon in experiments conducted at the Matter in Extreme Conditions endstation at the Linac Coherent Light Source (LCLS) x-ray free electron laser, SLAC National Accelerator Laboratory. By observing the collective and non-collective x-ray scattering of the LCLS beam at multiple pump-probe delays, we infer the time-history of the electron and ion temperatures and thus the equilibration rate.

8:36AM L23.00004 Micron-scale Reactive Atomic Simulation of Void Collapse and Hotspot Growth in PETN¹. Tzu-Ray Shan, Ryan Wixom, Aidan Thompson, Sandia National Laboratories, SANDIA NATIONAL LABORATORIES TEAM — Material defects and other heterogeneities such as dislocations, micro-porosity, and grain boundaries play key roles in the shock-induced initiation of detonation in energetic materials. We performed non-equilibrium molecular dynamics simulations to explore the effect of nanoscale voids on hotspot growth and initiation in micron-scale pentahexitrol tetranitrate (PETN) crystals under weak shock loading (Up = 1.25 km/s; Us = 4.5 km/s). We used the ReaxFF potential implemented in LAMMPS. We built a pseudo-2D PETN crystal with dimensions 0.3 μm × 0.22 μm × 1.3 nm containing a 20 nm cylindrical void. Once the initial shockwave traversed the entire sample, the shock-front absorbing boundary condition was applied, allowing the simulation to continue for ~0.5 nanoseconds. Results show an exponentially increasing hotspot growth rate. The hotspot morphology is initially symmetric about the void axis, but strong asymmetry develops at later times, due to strong coupling between exothermic chemistry, temperature, and divergent secondary shockwaves emanating from the collapsing void.

1Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s NNSA under contract DE-AC04-94AL85000.

8:48AM L23.00005 Post-stishovite transition in hydrous aluminum SiO$_2$¹. RENATA WENTZCOVITCH, Department of Chemical Engineering and Materials Science, U of Minnesota, Twin Cities, KOICHIRO UMEMOTO, Department of Earth Sciences, U of Minnesota, Twin Cities, MN, USA and Earth and Life Sciences Institute, Tokyo-Tech, Tokyo, Japan, KATSUYUKI KAWAMURA, Department of Sustainable Resource Science, Okayama University, Okayama, Japan, KEI HIROSE, Earth and Life Sciences Institute, Tokyo-Tech, Tokyo, Japan — Incorporation of aluminum and some water into SiO$_2$ significantly reduces the post-stishovite transition pressure in SiO$_2$. This behavior suggests that the ferroelastic post-stishovite transition in subducted Earth’s crust could be the source of seismic anomalies with low shear velocities observed in the mid to upper lower mantle. Using ab initio static calculations and molecular dynamics with inter-atomic potentials, we show that hydrogen bonds play a crucial role in lowering the transition pressure. A cooperative redistribution of hydrogen atoms is the main mechanism responsible for the transition pressure reduction in hydrous aluminium stishovite. The effect is enhanced by increasing the water content and suggests a relationship between the depth of these seismic anomalies and degree of hydration of stishovite in the subducted crust.

9:00AM L23.00006 The Dilemma of the High-Spin Persistence Into the Mbar Range of Some Ferric-Metal Oxides¹. MOSHE P. PARTENAK, GREGORY KH. ROZENBERG, ERAN GREENBERG, WEIMING XU, MARK NIKOLAEVSKY, Tel Aviv University, School of Physics & Astronomy — The fate of the strongly correlated $d-d$ Mott-Hubbard (MH) insulators at extreme conditions of pressure is determined by two main reactions: (i) correlation breakdown due to broadening leading to bands overlap of the empty-filled band resulting in metallization consequently loss of magnetic moment and, (ii) spin crossover due to the augmented crystal-field (10Dq ~ r$^{-5}$) which in the case of the Fe$^{3+}$ - oxides results in $S=5/2 > S=1/2$ transition. The experimental observation of these high pressure phenomena using Diamond-Anvils-Cells and the experimental methods of resistance and $^{57}$Fe Mössbauer effect at varying (P,T) and Synchrotron XRD at RT. This presentation will focus on the recent discovered cases of some Fe$^{3+}$ M/O where the high-spin state prevails into the Mbar region; showing no signs of correlation breakdown. The persistence of correlated, HS states to such pressures cannot be explained. This will be preceded by a short introduction to the experimental methods and cases of pressure-induced spin-crossover or MH transitions.

9:12AM L23.00007 Semi-empirical equations of state for NaCl¹. MICHEL SANTOS, University of Sao Paulo, RENATA WENTZCOVITCH, University of Minnesota — Despite diamond anvil cell experiments having reached pressures of hundreds of GPa, measuring high pressures is still a challenge. One of the strategies adopted in high pressure measurements is to measure the lattice spacing, via x-ray diffraction, of a calibrant pressurizer. This behavior suggests that the ferroelastic post-stishovite transition in subducted Earth’s crust could be the source of seismic anomalies with low shear velocities observed in the mid to upper lower mantle.

¹Research supported by NSF/EAR and CAPES of Brazil.

9:24AM L23.00008 Phase stability and elasticity of CaSiO$_3$ perovskite, FAWEI ZHENG, Department of Chemical Engineering and Materials Science, U of MN -Twin cities, MN, USA, TAO SUN. Key Laboratory of Computational Geodynamics, University of the Chinese Academy of Sciences, Beijing, China, RENATA WENTZCOVITCH, Department of Chemical Engineering and Materials Science, and Minnesota Supercomputing Institute, U of MN -Twin cities, MN, USA — CaSiO$_3$ perovskite (CaPv) is the third most abundant mineral in the Earth’s lower mantle and is a major component of mid-ocean ridge basalt (MORB). This perovskite is stable only at high pressures, it is highly anharmonic, and undergoes a tetragonal to cubic transition at conditions that are still debated. We have used a recently developed hybrid method combining ab initio molecular dynamics with vibrational normal mode analysis to compute its free energy, thermal equation of state, and phase boundary at relevant geophysical conditions. These results are essential for understanding several aspects of mantle convection.
The idea that fossil fuel emissions might cause global warming was first proposed nearly a century ago. In the 1980s, nearly all experts recognized that civilization faced a monumental challenge. By around 2000 the major likely impacts were well understood. Now the task was to pin down the specific risks in each of the many different regions, ecosystems, and human systems. Meanwhile actual impacts began to appear, such as changes in species ranges and unprecedented deadly heat waves. Two common energetic materials, PETN and RDX, were studied wherein we have found unique emission peaks in the frequency range of 0-10THz that arise from select carrier frequencies.

10:00AM L23.00011 Thermoelasticity of Al$^{3+}$- and Fe$^{3+}$-bearing bridgemanite$^1$, JUAN VALENCIA-CARDONA, GAURAV SHUKLA, University of Minnesota Twin cities, MATTEO COCCOCIIONI, Ecole Polytechnique Federale de Lausanne, Switzerland, RENATA WENTZCOVITCH, University of Minnesota Twin cities — We present LDA+U calculations of high temperature elastic properties of (Mg$_{1-x}$Fe$_{x}$$^{3+}$)SiO$_3$, bridgemanite ($0 \leq x \leq 0.125$), the most abundant constituent of Earth’s lower mantle. Calculations of aggregate elastic moduli and acoustic velocities for the Mg-end member ($x=0$) are in excellent agreement with the latest high pressure and high temperature experimental measurements. In the iron bearing system, we particularly focus on the change in thermoelastic parameters across the state change that occurs in ferrous iron above ~30 GPa, often attributed to a high-spin (HS) to intermediate spin (IS) crossover but explained by calculations as a lateral displacement of substitutional iron in the bridgemanite cage. We show that the measured effect on the equation of state of this change in the state of iron can be explained by the lateral displacement of substitutional iron, not by the HS to IS crossover. Calculated elastic properties of (Mg$_{0.475}$Fe$_{0.525}$)SiO$_3$ along an adiabatic mantle geotherm, somewhat overestimate longitudinal velocities but produce densities and shear velocities consistent with Preliminary Reference Earth Model data throughout most of the lower mantle.

10:12AM L23.00012 Molecular modeling of high-pressure ramp waves in tantalum, J. MATTHEW D. LANE, HOJUN LIM, Sandia National Laboratories, JUSTIN L. BROWN, Sandia National Labs — Ramp wave compression experiments of bcc metals under extreme conditions have produced differing measurements of material strength response. These variations are often attributed to differing experimental techniques, and varying material factors such as microstructure, and strain-rate. We present non-equilibrium molecular dynamics simulations of tantalum for single crystal and two polycrystalline nanostructures out to 250 GPa, over strain states ranging from 10$^{10}$ to 10$^{11}$ 1/s. Results will be compared to recent Z-machine strength experiments, meso-scale crystal plasticity models and continuum-scale polycrystalline model. Sandia National Laboratories is a multi program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

10:24AM L23.00013 Singly Bonded Layered Polymeric Nitrogen (LP-N)$^1$, CHOONG-SHIK YOO, DANE TOMASINO, MINSEOB KIM, Washington State Univ, JESSE SMITH, HPCAT/APS, Geophysical Laboratory — We report the discovery of novel nitrogen phase synthesized using laser-heated diamond anvil cells at pressures well above the stability field of cg-N. This new phase is characterized by its singly bonded, layered polymeric (LP) structure similar to the predicted Pba2 and two colossal Raman bands, arising from two groups of highly polarized nitrogen atoms in the bulk and surface of the layer, respectively. The present result also provides a new constraint for the nitrogen phase diagram, highlighting an unusual symmetry breaking of the layered polymeric structure.

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L24 FHP FPS: Invited Session: Pais Prize Session: Physics at the Intersection of History, Technology and Society 203AB - Catherine Westfall, Michigan State University

8:00AM L24.00001 Abraham Pais Prize Lecture: Understanding the Impacts of Global Warming: a History, SPENCER WEART, American Institute of Physics — The idea that fossil fuel emissions might cause global warming was first proposed around the end of the 19th century, and for the following half century it sounded like a good thing. In the 1950s, confirmation that warming really might be coming leading to more varied speculations. Scientists could only state possible problems in vague terms. First on the list were sea-level rise and a threat to food supplies. New ideas were added through the 1960s and 1970s, ranging from the degradation of natural ecosystems to threats to human health. Experts in fields from forestry to economics, even national security, pitched in to assess a variety of possible consequences. It turned out to be impossible to make solid predictions, given the differences from one region to another and the ways human society itself might try to adapt to the changes. In the 1990s, lengthy technical studies abandoned specific predictions of impacts to address “vulnerabilities” under different likely “scenarios.” Researchers also began to explore the risks and consequences of extreme weather events like droughts and floods. By around 2000 the major likely impacts were well understood. Now the task was to pin down the specific risks in each of the many different regions, ecosystems, and human systems. Meanwhile actual impacts began to appear, such as changes in species ranges and unprecedented deadly heat waves. Nearly all experts now understood that civilization faced a monumental challenge.
8:36AM L24.00002 Burnt by the Sun: Jack Kilby and the ’70s Solar Boom . CYRUS MODY, Rice University — Much has been written, by both scientists and historians, about the contributions of Jack Kilby (co-winner of the 2000 Nobel Prize in Physics) to the invention of the integrated circuit and semiconductor microelectronics more generally. The story goes that Kilby conceived of the integrated circuit in 1958 during his first weeks working for Texas Instruments. Considerably less well known, however, is that Kilby took a leave of absence from TI in 1970 to become a consultant and independent inventor. The projects Kilby chose to pursue — from teaching machines to electronic checkwriters to offering advice to the military — offer insights into how establishment scientists and engineers thought about science’s role in solving America’s social and economic problems in the dreary 1970s. I focus in particular on Project Illinois, a residential solar energy system that Kilby and two colleagues proposed in the wake of the OPEC embargo, and which Texas Instruments developed almost to the point of large-scale manufacturing. The cancelation of Project Illinois in 1983 — which precipitated Kilby’s final resignation from TI and retreat from active research — tells us a great deal about the frustrations of doing “socially relevant” science and engineering in the 1970s, and possibly also today.

9:12AM L24.00003 Optimistic Dangers: Views of Radium Therapy During the American Radium Craze , AIMEE SLAUGHTER, Los Alamos Historical Society — 1903 marked the beginning of intense and widespread popular interest in and curiosity about the newly-discovered element radium. This American radium craze was marked by an outpouring of media attention. Radium captured the public’s attention because of its strange properties, which could not be fully explained by scientists: it remained warmer than its surroundings, it glowed in the dark, and it emitted energy from an unknown internal source. The radioactivity emitted by radium also had marked effects on the body. In this talk I will focus on views of these physiological effects of radium during the height of the American radium craze, 1903–1907. Physicists experimented with radium as a therapy, and newspapers reported on radium treatments of ailments ranging from acne to whooping cough. When applied to superficial cancers, radium seemed to melt the tumor away, to be replaced by healthy tissue. Newspapers were quick to report that radium had cured cancer. At the same time, radium was also understood to be a dangerous substance: newspapers discussed the possibility of weaponizing its internal stores of energy, patients were often burned in the course of treatment, and it was speculated that radium in large amounts might blind, maim, or kill someone exposed to it. These dangers were well known but were never mentioned in the uniformly optimistic reports on the potentials of radium therapy. The modern expectation that beneficial applications of science may have a hidden darker side was not part of American culture at the beginning of the twentieth century. The early radium clinic was a unique site where non-scientists physically experienced a new scientific discovery, an element that was both familiar and unknown. At the height of the radium craze, the dangers of radium were optimistically set aside as physicians and physicists were tamed the new element.

9:48AM L24.00004 To Rule the Waves: Cable Telegraphy and the Making of “Maxwell’s Equations” , BRUCE HUNT, University of Texas — How and why did Maxwell’s theory of the electromagnetic field come to be cast into the now familiar form of four vector equations? In particular, how and why was this done not by James Clerk Maxwell himself, but by Oliver Heaviside in a series of articles published in a London electrical trade journal in 1885, several years after Maxwell’s death? The answer, I will argue, lies in the demands and opportunities presented by the global network of submarine telegraph cables, one of the characteristic technologies of the Victorian British Empire. Heaviside, himself a former telegrapher, was steeped in the problems confronting cable telegraphy, particularly the distortion or “retardation” that signals suffered in passing along a cable. It was Heaviside’s search for an effective tool with which to tackle such problems that led him to take up Maxwell’s theory and then to recast it into the four “Maxwell’s equations.”

10:24AM L24.00005 The Social Appropriation of Quantum Language and Imagery , ROBERT CREASE, Stony Brook University — Planck introduced ‘quantum’ as a technical term in 1900 in connection with studies of the emission and absorption of light. Following the development of quantum mechanics in 1925-1927, quantum terminology and imagery – including ‘quantum leap,’ ‘Heisenberg’s Uncertainty Principle,’ and ‘complementarity’ – began appearing in ever-widening cultural spheres, including journalism, literature, philosophy, television, and coffee cups and t-shirts. Later, these terms and images were joined by others, including ‘Schroedinger’s Cat’ and ‘parallel worlds.’ As a result, numerous quantum terms and images have become popular and powerful metaphors in the public imagination. Each of these terms and images followed a different trajectory in moving from their original scientific context into popular culture. This talk explores the trajectories and popular meanings of these terms, as well as their uses and misuses.

Wednesday, March 4, 2015 8:00AM - 10:48AM — Session L25 DCMP: Superconductivity: Miscellaneous Experiments 203B - Eric Palm, High Magnetic Field Laboratory

8:00AM L25.00001 Studying Superconductivity and Magnetism in Y₀₃Co₇ with a Tunnel Diode Resonator Circuit , R.T. GORDON, Western Illinois University, M.D. VANNETTE, Saginaw Valley State University, J. STRYCHALSKA, T. KLIMCZUK, Gdansk University of Technology, R.J. CAVA, Princeton University, R. PROZOROV, Ames Laboratory and Iowa State University — I will discuss recent tunnel diode resonator (TDR) circuit measurements on a single crystal of the material Y₀₃Co₇. This material displays a superconducting transition at Τ_c = 2.5 K and an unusual magnetic state at temperatures just above this transition, up to 8 K. The exact nature of this magnetic state is a point of contention. Following the development of quantum mechanics in 1925-1927, quantum terminology and imagery – including ‘quantum leap,’ ‘Heisenberg’s Uncertainty Principle,’ and ‘complementarity’ – began appearing in ever-widening cultural spheres, including journalism, literature, philosophy, television, and coffee cups and t-shirts. Later, these terms and images were joined by others, including ‘Schroedinger’s Cat’ and ‘parallel worlds.’ As a result, numerous quantum terms and images have become popular and powerful metaphors in the public imagination. Each of these terms and images followed a different trajectory in moving from their original scientific context into popular culture. This talk explores the trajectories and popular meanings of these terms, as well as their uses and misuses.

8:12AM L25.00002 Polaronic high-temperature superconductivity in optimally doped bismuthate Ba₁₋ₓKₓBiO₃ , NICHOLAS DERIMOW, JACOB LABRY, ARMOND KHODAGULIAN, Department of Physics & Astronomy, California State University, Los Angeles, JUN WANG, Department of Physics, Faculty of Science, Ningbo University, Ningbo, P. R. China, GUO-MENG ZHAO, Department of Physics & Astronomy, California State University, Los Angeles — Magnetic measurements have been carried out in the superconducting and normal states of the optimally doped nonmagnetic bismuthate superconductor Ba₁₋ₓKₓBiO₃. The magnetic data along with previous µSR, resistivity, and tunneling data consistently show that there is a large polaronic enhancement in the density of states and effective electron-phonon coupling constant. The first-principle calculation within the density-functional theory indicates a small electron-phonon coupling constant of about 0.3-0.4, which can only lead to about 1 K superconductivity within the conventional phonon-mediated mechanism. Remarkably, the polaronic effect increases the electron-phonon coupling constant to about 1.4, which is large enough to lead to 32 K superconductivity. The present work thus uncovers the mystery of high-temperature superconductivity in bismuthate superconductors, which will also provide important insight into the pairing mechanism of other high-temperature superconductors.

²Derimow acknowledges NIH Grant R25 GM 061331-13.
8:24AM L25.00003 Search for electron-phonon coupling in superconducting BKBO  D. PARSHALL, NIST Center for Neutron Research, Gaithersburg MD 20899, J.L. NIEDZIELA, Oak Ridge National Laboratory, Oak Ridge TN 37831, S. BARILO, Institute of Solid State and Semiconductor Physics, Minsk, 220072, Belarus, J.W. LYNN, NIST Center for Neutron Research, Gaithersburg MD 20899 — Ba0.6K0.4BiO3 is a superconductor with a Tc = 30 K. While generally regarded as a BCS superconductor, previous work searching along the high-symmetry directions did not find characteristic signatures of electron-phonon coupling near the energy gap of ~9 meV. Making use of the new Multizon Phonon Refinement technique, we are able to examine the phonon spectrum at all symmetry points and look for signatures of electron-phonon coupling.

8:36AM L25.00004 Pressure effects on static and dynamic spin properties in CrAs1  M. MATSUDA, M. B. STONE, Quantum Condensed Matter Division, Oak Ridge National Laboratory, J.-G. CHENG, W. WU, F. LIN, J. L. LUO, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, K. MATSUBAYASHI, Y. UWATOKO, Institute for Solid State Physics, University of Tokyo, Japan — CrAs is an antiferromagnetic metal, which shows a helical spin structure accompanied by an abrupt lattice expansion at T\textsubscript{N} ~ 260 K in ambient pressure. With applying pressure, this material shows superconductivity with a maximum transition temperature of ~2 K. Since Cr has the spin degree of freedom, elucidating the magnetic contribution to the superconductivity is crucial to understand the pairing mechanism. Our neutron diffraction studies have revealed that the static magnetic order as well as the structural anomaly is suppressed with applying external pressure. Chemical pressure effect was also studied by substituting As by P, which is found to be almost the same as the external pressure. We also plan to show the magnetic excitations in undoped and P-doped CrAs measured by inelastic neutron scattering experiments, which will give useful information on a coupling between the magnetism and the superconductivity.

8:48AM L25.00005 Chemical doping and pressure effects on the noncentrosymmetric superconductors ZrRe\textsubscript{6} and BiPd1  MOJAMMEL ALAM KHAN, DAVID P. YOUNG, AHMAD US SALEHEEN, AMAR KARKI, DANA BROWNE, P.W. ADAMS, TAPAS SAMANTA, Louisiana State University — Polycrystalline samples of ZrRe\textsubscript{6} doped with Ti, W and Os and BiPd doped with Te and Ni were made using arc melting and RF - induction furnaces. Variation of the superconducting transition temperature with different types of doping was observed. Small suppression of T\textsubscript{c} was observed for both hole and electron doping in ZrRe\textsubscript{6} samples. Suppression in T\textsubscript{c} was also observed for BiPd. The effect of hydrostatic pressure on T\textsubscript{c} was determined for both compounds. Effect of Re depreciation on T\textsubscript{c} for ZrRe\textsubscript{6} were observed by synthesizing samples, ZrRe\textsubscript{5.95} ~ 5.85. In addition, small diameter wires (0.0005" ~ 0.004") of BiPd were synthesized for critical current density measurements. The critical temperature of the wires was found to be slightly higher (~4.07 K) than that reported for bulk samples (~3.78 K).

9:00AM L25.00006 Giant Two-Phonon Raman Signal from NbC Coherent Precipitates in Niobium  JOHN ZASADZINSKI, CHAOYUE CAO, Illinois Institute of Technology, RUNZHE TAO, ROBERT KLIB, University of Illinois Chicago, LANCE COOLEY, Fermi National Accelerator Laboratory — High purity Nb, subjected to the processing steps used in SRF cavity fabrication, has been shown to reveal nanoscale NbC precipitates near the surface that are coherent with the host Nb matrix. Raman backscattering from such regions reveal spectra similar to the earlier work on bulk NbC but with a strongly enhanced two-phonon signal. The unprecedented strength and sharpness of the two phonon response has allowed a direct comparison to \textit{ab initio} calculations of the phonon dispersion curves of NbC under uniform compression where it is shown directly that the two phonon signal originates in the regions of strong electron-phonon renormalization. The strong two phonon signal may indicate an enhancement of the electron phonon spectral function, α\textsuperscript{2}F(ω).

9:12AM L25.00007 Experimental demonstration of superconducting critical temperature increase in electromagnetic metamaterials1  VERA SMOLYANINOVA, BRADLEY YOST, KATHRYN ZANDER, THOMAS GRESSOCK, Towson University, MICHAEL O'SOFSKY, HEUNGOOSO KIM, NRL, SHANTA SAHA, RICHARD GREENE, IGOR SMOLYANINOV, University of Maryland — A recent proposal that the metamaterial approach to dielectric response engineering may increase the critical temperature of a composite superconductor-dielectric metamaterial has been tested in experiments with compressed mixtures of tin and barium titanate nanoparticles of varying composition. An increase of the critical temperature of the order of 0.15 K compared to bulk tin has been observed for 40% volume fraction of barium titanate nanoparticles. Similar results were also obtained with compressed mixtures of tin and strontium titanate nanoparticles.

9:24AM L25.00008 Magneto-transport near a quantum critical point  IAN HAYES, NICHOLAS BREZNAY, University of California Berkeley, ARKADY SHEKHTER, ROSS MCDONALD, National High Magnetic Field Lab, Los Alamos, JAMES ANALYTIS, University of California Berkeley — The physics of quantum critical phase transitions connects to some of the most difficult problems in condensed matter physics, including metal-insulator transitions, frustrated magnetism and high temperature superconductivity. Near a quantum critical point (QCP) a new kind of metal emerges, whose thermodynamic and transport properties do not fit into the unified phenomenology with which we understand conventional metals — the Landau Fermi liquid (FL) theory - characterized by a low temperature limiting T-linear specific heat and a T\textsuperscript{2} resistivity [1]. Studying the evolution of the T\textsuperscript{2} dependence of these observables as a function of a control parameter leads to the identification both of the presence and the nature of the quantum phase transition in candidate systems. In this study we measure the transport properties of basp, at T < T\textsubscript{c} by suppressing superconductivity with high magnetic fields. At sufficiently low temperatures, the resistivity of all compositions (x ≥ 0.31) crosses over from a linear to a quadratic temperature dependence, consistent with a low temperature FL ground state. As compositions with optimal T\textsubscript{c} are approached from the overdoped side, this cross-over becomes steeper, consistent with models of quantum criticality where the effective Fermi temperature T\textsubscript{F} goes to zero.

1NSF DMR No.1306392

9:36AM L25.00009 Low-temperature STM Measurements of Granular Pb films\textsuperscript{1}, S.A. MOORE, J. FEDOR, Department of Physics, Temple University, Philadelphia, PA 19122, J. CURTIS, G. KARAPETROV, Department of Physics, Drexel University, Philadelphia, PA 19104, I. BEŁBORODOV, Department of Physics, California State University Northridge, Northridge, CA 91330, M. IAVARONE, Department of Physics, Temple University, Philadelphia, PA 19122 — Using low-temperature scanning tunneling microscopy and spectroscopy (LT-STM/STS) we have investigated the electronic properties of granular Pb films grown on HOPG at low temperature. Films grown under these conditions form a two-dimensional array of disconnected grains with a similar distribution of sizes. Local spectroscopic measurements as a function of field and temperature reveal a grain size dependent competition between the repulsive electron-electron interaction and the attractive superconducting pairing interaction. Our results show the presence of an increased depletion of states around the Fermi energy for all grain sizes, with a complete suppression of the superconducting state below a critical grain size. We compare these results to those found on 9ML and 100ML continuous films also grown on HOPG, where the superconducting state completely dominates the electronic properties.

\textsuperscript{1}Work at Temple University was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-SC0004556.

9:48AM L25.00010 Paramagnetic Meissner effect in electrochemically doped Indium-Tin Oxide films, ALI ALIEV, Alan G. MacDiarmid NanoTech Institute, University of Texas at Dallas, Richardson, TX, 75083 — Transparent conductive indium tin oxide (ITO) thin films, electrochemically intercalated with alkali (Li\textsuperscript{+}, Na\textsuperscript{+}, K\textsuperscript{+}, Rb\textsuperscript{+}, Cs\textsuperscript{+}), alkali earth (Mg\textsuperscript{2+}, Ca\textsuperscript{2+}), or complex NH\textsubscript{4}\textsuperscript{+} ions show tunable superconducting transition with dome shape behavior of $T_c$ versus electron density around the maximum at 5 K. The zero resistance transition in superconducting state is accompanied with paramagnetic Meissner response to the applied external magnetic field, i.e. the increase of magnetization in field cooling regime. We provide extensive evidences of flux trapping using dc SQUID, ac susceptibility and transport measurements. In particular, we present evidence that the paramagnetic response results from the lower $T_c$ on the center of disk samples than on the edges leading to the trapping of magnetic flux in the center, and that change of $T_c$ profile to opposite removes the paramagnetic response. The flux trapped state is metastable. An alteration of external magnetic field destroys the giant vortex.

10:00AM L25.00011 Novel fabrication process for all-MgB\textsubscript{2} Josephson junctions and circuits\textsuperscript{1}, THOMAS MELBOURNE, ELIAS GALAN, XIAOXING XI, KE CHEN, Temple University — A novel process for fabricating high-quality MgB\textsubscript{2}/Mo/MgB\textsubscript{2} Josephson junctions and circuits is reported. A 100 nm-thick bottom electrode of MgB\textsubscript{2} was grown on SiC (0001) substrate by hybrid physical-chemical vapor deposition (HPCVD) and then coated by a 1 – 5 nm-thick MgO junction barrier layer and a 20 nm-thick TiO\textsubscript{2} protection layer. After the bottom MgB\textsubscript{2} layer was patterned an 80 nm-thick MgO etch-stop layer was then deposited on the sample with a pattern created by photo- or e-beam lithography and lift-off, followed by reactive ion etching in SF\textsubscript{6} to form TiO\textsubscript{2} from the Josephson junction areas. Finally, a 100 nm-thick MgB\textsubscript{2} serving as both the top electrode and wiring layer was deposited and patterned by photolithography and ion mill. The advantage over previously reported process is that this process combines the MgB\textsubscript{2} top electrode and the wiring layer, which simplifies fabrication and allows for an additional layer of MgB\textsubscript{2} to be dedicated to a ground plane in circuits. Characteristics of all-MgB\textsubscript{2} Josephson junctions fabricated by this process are shown.

\textsuperscript{1}This work is supported by the U.S Office of Naval Research under grant N00014130052.

10:12AM L25.00012 Electrical transport property of nano carbon superconductors, YUKI MATSUDA, Department of Physics, Tohoku Univ, SATOSHI HEGURI, WPI-AIMR, Tohoku Univ, YOICHI TANABE, Department of Physics, Tohoku Univ, KATSUHIRO NAKAGAWA, WPI-AIMR, Tohoku Univ, MARUKO KOBAYASHI, Kitami Institute of Technology, Asahidai, Kitami, Japan, KAZUYUKI OKAJIMA, Department of Physics, Tohoku Univ, TATSUO TOMITA, Department of Electrical Engineering, Tohoku Univ, YUKI HAYABUSA, Department of Physics, Tohoku Univ — Using low-temperature scanning tunneling microscopy and spectroscopy (LT-STM/STS) we have investigated the electronic properties of granular Pb films grown on HOPG at low temperature. Films grown under these conditions form a two-dimensional array of disconnected grains with a similar distribution of sizes. Local spectroscopic measurements as a function of field and temperature reveal a grain size dependent competition between the repulsive electron-electron interaction and the attractive superconducting pairing interaction. Our results show the presence of an increased depletion of states around the Fermi energy for all grain sizes, with a complete suppression of the superconducting state below a critical grain size. We compare these results to those found on 9ML and 100ML continuous films also grown on HOPG, where the superconducting state completely dominates the electronic properties.

10:24AM L25.00013 Confinement of superconducting fluctuations due to emergent electronic inhomogeneities in ultrathin films, CLÉMENCE CARBILLET, Sorbonne Universités, UPMC, UMR 7588, Institut des Nanosciences de Paris, F-75005, Paris, France, SERGIO CAPRARA, MARCO GRILLI, Department of Physics, University of Rome “La Sapienza,” Piazzale A. Moro 5, I-00185 Rome, Italy, CHRISTOPHE BRUN, TRISTAN CREN, FRANCOIS DEBONTRIDDER, Sorbonne Universités, UPMC, UMR 7588, Institut des Nanosciences de Paris, F-75005, Paris, France, BAPTISTE VIGNOLLE, CNRS/INCM, 143 Avenue de Rangueil, 31400 Toulouse, France, KONSTANTIN ILIN, MICHAEL SIEGLER, Institute of Micro- and Nano-electronic Systems, Karlsruhe Institute of Technology, Hertzstrasse 16, D-76187 Karlsruhe, Germany, DIMITRI RODITCHEV, BRIGITTE LERIDON, LPEM-CNRS/ESPCI-ParisTech/UPMC/PSL, 10 rue Vauquelin, 75005 Paris, France — The question of homogeneity, granularity, or glassiness of materials on the verge of a superconductor/insulator transition is fundamental and hotly debated. Here, by combining macroscopic and nano-scale studies of superconducting ultrathin NbN films, we reveal some nanoscopic electronic inhomogeneity that emerges when the film thickness is reduced. While thicker films display a purely two-dimensional behavior in electrical transport measurements, we demonstrate a seemingly zero-dimensional regime in the superconducting thermal fluctuations for the thinner samples. This regime corresponds to a longer survival and anomalous local diffusion of the Cooper pair fluctuations. Remarkably, the typical length scale, 20-40 nm, extracted from the fluctuation conductivity coincides with the correlation length of the electronic inhomogeneities directly revealed by local scanning tunneling spectroscopy.

10:36AM L25.00014 Hall coefficient of ultrathin niobium in Si/Nb/Si trilayers, MARTA Z. CIEPLAK, I. ZAYTSEVA, O. ABAL’OSHEV, P. DLUZEWSKI, W. PASZKOWICZ, Institute of Physics, PAS, Warsaw, Poland, L.Y. ZHU, C.L. CHIEN, Johns Hopkins University, M. KONCZYKOWSKI, Ecole Polytechnique, Palaiseau, France — We study the structural and magnetotransport properties of ultrathin Nb layers in Si/Nb/Si trilayers, grown by magnetron sputtering at room temperature. The thickness of Nb, d, is in the range from 1.1 nm to 50 nm, with a fixed Si thickness of 10 nm. With decreasing d the superconductivity is suppressed for d < 1.2 nm, and the structure of the Nb layers evolves, from polycrystalline at d > 6 nm, to amorphous at d < 3.3 nm. The Hall coefficient, positive in thick Nb layers, initially increases with decreasing d, but starts to diminish at d < 6 nm, and eventually changes sign into negative at d < 2 nm. In the thinnest Nb layers the dependence of the Hall voltage on magnetic field becomes non-linear at lower temperatures, indicating that two types of carriers contribute to transport. The influence of boundary scattering on the relaxation rate of carriers, and band broadening in the amorphous films, may be responsible for this effect. We discuss the correlation between the superconductivity suppression and the appearance of the electron contribution to the conductance, observed in the present films; we also compare our results to the properties of other previously studied ultrathin Nb films.

\textsuperscript{2}Supported by: Polish NSC Grant No. 2011/01/B/ST3/00462, NSF Grant No. DMR 1262253, French-Polish Program PICS 2012; partially performed in laboratories co-financed by the ERDF Projects POIG.02.01-04-032/08 and POIG.02.01-00-005/09.
8:00AM L26.00001 Exciton Dynamics in Quantum Dot Films and Interfaces1, WILLIAM TISDALE, Massachusetts Inst of Tech-MIT — Colloidal quantum dots (QD) are a promising material platform for solution-processable optoelectronics, devices such as solar cells, light-emitting diodes, thermoemodules, and flexible electronics. Central to the operation of these devices is the formation, transport, and conversion of free charges and excitons. In the first part of the talk, I will present a comprehensive study of exciton diffusion in inhomogeneously broadened QD assemblies, including spectrally-resolved transient photoluminescence spectroscopy, transient photoluminescence quenching, time-resolved optical imaging, and kinetic Monte Carlo simulations. In the second part of the talk, I will show how nanoscale dielectric screening phenomena in atomically thin semiconductors such as MoS_2 can lead to counterintuitive energy transfer behavior from QD donors.

8:36AM L26.00002 Ligand Chemistry and the Low-Frequency Vibrations of Semiconductor Nanocrystals2. ANNA JOLENE MORK, WILLIAM TISDALE, Massachusetts Institute of Technology — A variety of phonon-mediated processes can lead to counterintuitive energy transfer behavior from QD donors.

8:48AM L26.00003 Evolution of “waterproof” photoluminescent complexes of rare earth ions in crowded environment1. MICHAEL BLADES, Lehigh University, TETYANA IGNAITOVA, UC Irvine, JUAN DUQUE, STEPHEN DOORN, Los Alamos National Lab, IVAN BIAGGIO, SLAVA V. ROTKIN, Lehigh University — Understanding behavior of rare-earth ions (REI) in crowded environments is crucial for several nano- and bio-technological applications. Evolution of REI photoluminescence in small compartments inside a silica hydrogel, mimic to a soft matter bio-environment, has been studied and explained within a solvation model. The model uncovered the origin of high rare earth photoluminescence efficiency to be the formation of REI complexes, surrounded by sodium deoxycholate molecules. Comparative study of these REI-deoxycholate complexes in bulk water solution and those enclosed inside the hydrogel revealed a strong correlation between an up to 5 times longer photoluminescence lifetime of REIs and appearance of the deoxycholate ordered phase, further confirmed by dynamics of REI solvation shells, REI diffusion experiments and morphological characterization of microstructure of the hydrogel.

9:00AM L26.00004 Nanointerfaces in InAs-SnxS6 nanocrystal-ligand networks: atomistic and electronic structure from first principles1. EMILIO SCALISE, STEFAN WIPPERMANN, Max-Planck-Institute for Iron Research, GIULIA GALLI, University of Chicago — Semiconducting nanocomposites – consisting of nanocrystals (NCs) embedded in a host matrix – offer exciting prospects for solar energy conversion, light emission and electronic applications. Recent advances in wet chemical techniques allow for the synthesis of NCs, their assembly into superlatices and embedding into a host matrix using only inexpensive solution processing. However, the atomicistic details of such composites are poorly understood, due to the complexity of the synthesis conditions and the unavailability of robust experimental techniques to probe nanointerfaces at the microscopic level. Here we present a density functional theory investigation of the interaction of SnSx ligands with InAs NCs. Employing a grand canonical approach, we considered a multitude of structures possibly realized at the NC-ligand interface, such as surface termination, reconstructions, passivation, substitution of subsurface atoms, ligand dissociation, NC core-shell formation and the adsorption of the ligands on NCs with different structures. This study provides guidance about the experimental conditions which lead to specific structural motifs and highlights the impact of structural details on the composite’s electronic properties.

9:12AM L26.00005 Defect Chemistry of Nanocarbon. YUHUANG WANG, University of Maryland — Defects can rule the properties of a crystal. This effect is particularly intriguing in atom-thick materials such as single-walled carbon nanotubes and graphene, where electrons, excitons, phonons, and spin may strongly couple at the defects due to reduced dimensionality. In this talk, we will discuss our recent progress in fundamental understanding and molecular control of sp3 defects in sp2 carbon lattices, and their applications. An sp3 defect (tetrahedral bonding, diamond-like) is created by covalently attaching a functional group to the sp2 carbon lattice (trigonal planar, honeycomb-like) of a carbon nanotube or graphene. The beauty of this type of defect is its well-defined structure and chemical tunability at the molecular level. Our experimental results have unraveled a series of intriguing and surprising roles of defects. Specific examples will be given to illustrate how defects may be used to drive reaction propagation on sp2 carbon lattices, brighten carbon nanotube photoluminescence, and create selective chemical sensors.

9:48AM L26.00006 Localized Excitons in Carbon Nanotubes. LYUDMYLA ADAMSKA, STEPHEN K. DOORN, SERGEI TRETIAK, Los Alamos National Lab — It has been historically known that unintentional defects in carbon nanotubes (CNTs) may fully quench the fluorescence. However, some dopants may enhance the fluorescence by one order of magnitude thus turning the CNTs, which are excellent light absorbors, in good emitters. We have correlated the experimentally observed photoluminescence spectra to the electronic structure simulations. Our experiment reveals multiple sharp asymmetric emission peaks at energies 50-300 meV red-shifted from that of the lowest bright exciton peak. Our simulations suggest an association of these peaks with deep trap states tied to different specific chemical adducts. While the wave functions of excitons in undoped CNTs are delocalized, those of the deep-trap states are strongly localized and pinned to the dopants. These findings are consistent with the experimental observation of asymmetric broadening of the deep trap emission peaks, which can result from scattering of acoustic phonons on localized excitons. Our work lays the foundation to utilize doping as a generalized route for wave function engineering and direct control of carrier dynamics in SWCNTs toward enhanced light emission properties for photonic applications.
10:00AM L26.00007 Understanding the effect of surface defects on sp2 carbon and HOPG . ANDREW KOZBIAL, VAHID VAHDAT, HAITAO LIU, LEI LI, Univ of Pittsburgh, DEPARTMENT OF CHEMICAL & PETROLEUM ENGINEERING TEAM, DEPARTMENT OF CHEMISTRY TEAM — Basal planes of graphite are traditionally believed to be inert and electrochemical activity of graphitic materials was thought to occur at high energy defect sites, i.e., step edges. However, recent studies have shown the basal surface of graphite to be highly active and these results have significant implication on design of graphitic electrodes along with numerous other graphite, graphene, and carbon nanotube-based products. The mildly hydrophobic surface of fresh graphite subsequently adsorbs airborne contaminants causing the surface to transition towards hydrophobic behavior. A missing link between electrochemical activity and wettability requires elucidation of basal plane behavior and answering whether defect density on a graphite surface affects wettability. We have quantified defect density on various grades of highly ordered pyrolytic graphite (HOPG) through AFM imaging and contrasted wettability results to describe the effect of defect sites on wettability and surface contamination.

10:12AM L26.00008 Calculating exciton downconversion rates in Coulombically coupled chromophores , CRAIG CHAPMAN, GEORGE SCHATZ, Northwestern University — Exciton downconversion is a second order energy transfer process that splits a high energy exciton in a donor chromophore into multiple lower energy excitons in acceptor chromophores. Downconversion has been seen in a variety of materials including rare-earth doped glassy matrices, organic crystals, and semiconductor nanocrystals, and has the potential to efficiently convert a single high energy photon into a broad distribution of lower energy excitons. A comprehensive mechanistic understanding of the energy conversion process will allow for the rational engineering of materials that can control the flow of energy in a guided fashion. To this end we formulate and implement a method for calculating multi-chromophore Förster-like exciton transfer rates using transition charges obtained from time-dependent density functional theory.

10:24AM L26.00009 Raman spectroscopy of electric-field-tuned molecule-semiconductor interface1 , ALEXEY ZAYAK, FLOYD HILTY, ANDREW KUHLMAN, Bowling Green State University — In the search for methods of studying chemical properties of surfaces and atomic-scale heterogeneous interfaces, Raman scattering promises significant potential for measuring physical and chemical properties that vary on the scale of a few chemical bonds, reporting not only about a particular chemical species, but also about the immediate chemical environment. In this work we use first-principles (DFT) computations to investigate the chemical modification of Raman spectra of organic species after being chemically absorbed on semiconductor surfaces. We examine the binding of a trans-1,2-twot(4-pyridyl) ethylene molecule to the PbSe semiconductor surface and show that we can control the degree of the interfacial chemical coupling by means of an external electric field, and at the same time, observe the induced changes in Raman spectra. In the process of applying electric bias, we observed a crossover between two regimes of the interfacial electron-vibron coupling: with vibration-induced charge transfer, and without it.

We acknowledge BGSU for financial support and TACC and OSC for computing time.

Wednesday, March 4, 2015 8:00AM - 10:36AM — Session L27 DCP: Focus Session: Solvation of Ions and Electrons I 204B - Mary T. Rodgers, Wayne State University

8:00AM L27.00001 Comprehensive thermochromoscopy for the hydration of copper ions . PETER ARMENTROUT, University of Utah — Cross sections for the threshold collision-induced dissociation (TCID) of Cu2+(H2O)n+, where n = 8 – 10, and of CuOH+(H2O)n+, where n = 1 – 4, are measured using a guided ion beam tandem mass spectrometer. In both cases, the primary dissociation pathway is found to be loss of a single water molecule followed by the sequential loss of additional water molecules. In the Cu2+ complexes, charge separation to form CuOH+(H2O)2 and H+(H2O)7 is also observed and CuOH+(H2O) competitively loses both H2O and OH. The data are analyzed using a statistical model after accounting for internal and kinetic energy distributions, multiple collisions, and kinetic shifts to obtain 0 K bond dissociation energies (BDEs). In addition, BDEs for the loss of OH from CuOH+(H2O)n, where n = 0 – 4 are derived using the experimental BDEs for dissociation of CuOH+(H2O)n and literature values for Cu+(H2O)n. Experimental BDEs are compared to theoretical BDEs determined at several levels of theory with reasonable agreement. Structural information regarding complexes of CuOH+(H2O)n+, where n = 2 – 9, are also obtained using infrared photodissociation spectroscopy (IRPD) in the OH stretching region and comparison to theoretical spectra. The IRPD spectra of all complexes where n ≥ 3 are consistent with structures generally having a coordination number (CN) of 4 although CuOH+(H2O)7 exhibits bands characteristic of both CN = 4 and CN = 5 isomers.
Nano Lett. [1] V. K. Voora, and K. D. Jordan, systems. The model potentials are used to study nonvalence correlation-bound anion states of large water clusters as well as “superatomic” states of fullerene to characterize nonvalence correlation-bound anion states of a variety of systems including C

Following the completion of the molecule or cluster being dominated by long-range correlation effects. Failure of conventional Hartree-Fock reference based approaches for treating these noncovalent interactions, as electrostatic interactions can be adjusted by introducing different monovalent cations and hydrogen bonding interactions can be adjusted by varying the level of hydration. IRPD spectra with isotopic (H/D) analysis helped unravel the overlapping N-H and O-H stretching modes, a major challenge of earlier studies. Thermodynamic analysis using relative Gibbs free energies, for energy ordering, together with spectral analysis provided unambiguous assignment of spectral features and structural configurations. A systematic hydration model with an in-depth account of noncovalent interactions is presented.

8:48AM L27.00003 Hydration Structures and Thermodynamic Properties of Cationized Biologically Relevant Molecules, M+(Indole)(H2O)n, (M = Na, K; n = 3-6). HAOCHEN KE, JAMES LISY, Univ of Illinois - Urbana — The balance between various noncovalent interactions plays a key role in determining the hydration structures and thermodynamic properties of biologically relevant molecules in biological mediums. Such properties of biologically relevant molecules are closely related to their often unique biological functionalities. The indole moiety is a basic functional group of many important neurotransmitters and hormones and has been used as tractable model for more complex biomolecules. The cationized indole water cluster is a perfect system for the quantitative and systematic study of the competition and cooperation of noncovalent interactions, as electrostatic interactions can be adjusted by introducing different monovalent cations and hydrogen bonding interactions can be adjusted by varying the level of hydration. IRPD spectra with isotopic (H/D) analysis helped unravel the overlapping N-H and O-H stretching modes, a major challenge of earlier studies. Thermodynamic analysis using relative Gibbs free energies, for energy ordering, together with spectral analysis provided unambiguous assignment of spectral features and structural configurations. A systematic hydration model with an in-depth account of noncovalent interactions is presented.

8:48AM L27.00003 Hydration Structures and Thermodynamic Properties of Cationized Biologically Relevant Molecules, M+(Indole)(H2O)n, (M = Na, K; n = 3-6). HAOCHEN KE, JAMES LISY, Univ of Illinois - Urbana — The balance between various noncovalent interactions plays a key role in determining the hydration structures and thermodynamic properties of biologically relevant molecules in biological mediums. 9:00AM L27.00004 How big is the hydrated electron? Thermodynamics of electron solvation and its partial molar volume. DAVID BARTELS, Notre Dame Radiation Laboratory — Several models for the hydrated electron solvation structure have been proposed, which all can do a reasonable job of reproducing the room temperature optical spectrum. As Larsen, Glover and Schwartz [1] demonstrated, tweaking the electron-water pseudopotential can completely change the structure from a cavity to a non-cavity geometry. Deciding between the competing models then requires comparison with other observables. The resonance Raman spectrum and the temperature dependence of the optical spectrum can be cited as evidence in favor of a non-cavity structure [2]. In the present work we will re-examine the thermodynamics of hydration [3]. In particular, we will present new experimental and simulation results for the partial molar volume, which can bear directly on the cavity vs. non-cavity controversy.

9:36AM L27.00005 Theoretical studies of nonvalence correlation-bound anions. VAMSEE VOORA, KENNETH JORDAN, University of Pittsburgh — Nonvalence correlation-bound anion states have been investigated using state-of-the-art ab initio methodologies as well as by model potential approaches. In nonvalence correlation-bound anion states the excess electron occupies a very extended orbital with the binding to the molecule or cluster being dominated by long-range correlation effects. Failure of conventional Hartree-Fock reference based approaches for treating these anionic states is discussed. Ab initio approaches that go beyond Hartree-Fock orbitals, such as Green’s function, and equation-of-motion methods are used to characterize nonvalence correlation-bound anion states of a variety of systems including C60 and C60F6. Edge-bound nonvalence correlation-bound anionic states are established for polycyclic aromatics. Accurate one-electron model potential approaches, parametrized using the results of ab initio calculations, are described. The model potentials are used to study nonvalence correlation-bound anion states of large water clusters as well as "superatomic" states of fullerene systems.

10:24AM L27.00007 Mapping the UV Photophysics of Platinum Metal Complexes Bound to Nucleobases\(^1\), ANANYA SEN, CAROLINE DESSENT, University of York — We report the first UV laser spectroscopic study of isolated gas-phase complexes of Platinum metal complexes bound to a nucleobase as model systems for exploring at the molecular level the key photophysical processes involved in photodynamic therapy. Spectra of the Pt\(^{IV}\) (CN)\(_2^−\) • Uracil and Pt\(^{II}\) (CN)\(_2^−\) • Uracil complexes were acquired across the 220–320 nm range using mass-selective photodepletion and photofragment action spectroscopy. The spectra of both complexes reveal prominent UV absorption bands that we assign primarily to excitation of the Uracil \(\pi - \pi^*\) localized chromophore. Distinctive UV photofragments are observed for the complexes, with Pt\(^{IV}\) (CN)\(_2^−\) • Uracil photooxidation resulting in complex fission, while Pt\(^{II}\) (CN)\(_2^−\) • Uracil photooxidation initiates a nucleobase proton-transfer reaction across 4.4–5.2 eV and electron detachment above 5.2 eV. The observed photofragments are consistent with ultrafast decay of a Uracil localized excited state back to the electronic ground state followed by intramolecular vibrational relaxation and ergodic complex fragmentation. In addition, we present recent results to explore how the photophysics of the Platinum complex-nucleobase clusters evolves as a function of nucleobase. Results are presented for Pt\(^{II}\) (CN)\(_2^−\) • Uracil complexed to Cytosine, Thymine and Adenine, reveal distinctive decay dynamics which we attribute to the intrinsic decay dynamics of the nucleobase.

Session L28 GMAG DMP: Focus Session: Spin Liquids I

8:00AM L28.00001 Thermodynamic properties of magnetic strings on a square lattice\(^1\), LUCAS MOL, DENIS DA MATA OLIVEIRA, Departamento de Física, Universidade Federal de Minas Gerais, MICHAEL BACHMANN, The University of Georgia — In the last years, spin ice systems have increasingly attracted attention by the scientific community, mainly due to the appearance of collective excitations that behave as magnetic monopole like particles. In these systems, geometrical frustration induces the appearance of degenerated ground states characterized by a local energy minimization rule, the ice rule. Violations of this rule were shown to behave like magnetic monopoles connected by a string of dipoles that carries the magnetic flux from one monopole to the other. In order to obtain a deeper knowledge about the behavior of these excitations we study the thermodynamics of a kind of magnetic polymer formed by a chain of magnetic dipoles in a square lattice. This system is expected to capture the main properties of monopole-string excitations in the artificial square spin ice. It has been found recently that in this geometry the monopoles are confined, but the effective string tension is reduced by entropic effects. To obtain the thermodynamic properties of the strings we have exactly enumerated all possible string configurations of a given length and used standard statistical mechanics analysis to calculate thermodynamic quantities. We show that the low-temperature behavior is governed by strings that satisfy ice rules.

\(^1\)Financial support from FAPEMIG and CNPq (Brazilian agencies) are gratefully acknowledged.

8:12AM L28.00002 Dimer liquid state in the quantum dimer-pentamer model on the square lattice, OWEN MYERS, University of Vermont, C.M. HERDMAN, University of Waterloo — We study the ground state of the quantum dimer-pentamer model (QDPM) on the square lattice. This model is a generalization of the square lattice quantum dimer model (QDM) as its configuration space comprises fully-packed hard-core dimer coverings as well as configurations containing pentamers, where four dimers touch a vertex. Thus in the QDPM, the fully-packed, hard-core constraint of the QDM is relaxed such that the local dimer number at each vertex is fixed modulo 3; correspondingly, the local U(1) gauge symmetry of the QDM Hilbert space is reduced to a local Z\(_3\) gauge symmetry in the QDPM. We construct a local Hamiltonian for which the Rokhsar-Kivelson (RK) state (the equal superposition of all configurations in a topological sector) is the exact ground state and has a 9-fold topological degeneracy on the torus. Using Monte Carlo calculations, we find no spontaneous symmetry breaking in the RK wavefunction and that its dimer-dimer correlation function decays exponentially. Additionally, we discuss the possibility of \(Z_3\) topological order in the ground state of the QDPM.

8:24AM L28.00003 Breakdown of antiferromagnetism and the Coulomb phase for RVB states on anisotropic three-dimensional lattices, K.S.D. BEACH, University of Mississippi — Nearest-neighbor (NN) resonating-valence-bond (RVB) wave functions often serve as prototype ground states for various frustrated models in two dimensions because of their lack of long-range magnetic correlations. In three dimensions, these states are generally not featureless, and their tendency is toward antiferromagnetic order. On the cubic and diamond lattices, for example, the NN RVB state exhibits both antiferromagnetism and power law dimer correlations characteristic of the “Coulomb phase” (in analogy with classical hardcore dimer models). The introduction of strong spatial anisotropy, however, leads to the destruction of these long-range and algebraic correlations, leaving behind an apparent short-range spin liquid state. We characterize the critical exponents at the phase boundaries for wave functions built from products of SU(2) singlets as well as their SU(N) generalizations and discuss attempts to construct a field theory that describes the transitions.

8:36AM L28.00004 Topological defects in quantum spin-nematics, YUTAKA AKAGI, HIROAKI T. UEDA, NIC SHANNON, Okinawa Institute of Science and Technology — Topological defects play an important role in the theory of nematic phases in liquid crystals. However, relatively little is known about their role in quantum spin nematic phases which have no long-range dipole order and break only spin-rotational symmetry [1-3]. Here, we consider the topological defects in these nontrivial states. The model is the spin-1 bilinear biquadratic model on the triangular lattice [4-6]. We classify the defects by homotopy theory and numerical optimization approach, simulated annealing. We also discuss new type defects at particular point, which has global SU(3) symmetry.

8:48AM L28.00005 Singlet-triplet excitations and long range entanglement in the spin-orbital liquid candidate FeSc$_2$S$_4$\(^1\). N. J. LAURITA, Institute of Quantum Matter, Johns Hopkins University, J. DEISENHOFER, University of Augsburg, LIDONG PAN, C.M. MORRIS, Institute of Quantum Matter, Johns Hopkins University, M. SCHMIDT, University of Augsburg, M. JOHNSSON, Stockholm University, V. TSURKAN, University of Augsburg, Academy of Sciences of Moldova, A. LOIDL, University of Augsburg, N.P. ARMITAGE, Institute of Quantum Matter, Johns Hopkins University — Theoretical models of the spin-orbital liquid (SOL) FeSc$_2$S$_4$ have predicted it to be in close proximity to a quantum critical point separating a spin-orbital liquid phase from a long-range ordered magnetic phase. Here, we examine the magnetic excitations of FeSc$_2$S$_4$ through time-domain terahertz spectroscopy under an applied magnetic field. At low temperatures an excitation emerges that we attribute to a single-triplet excitation from the SOL ground state. A three-fold splitting of this excitation is observed as a function of applied magnetic field. Using experimentally obtained parameters, we compare to existing theoretical models to determine FeSc$_2$S$_4$’s proximity to the quantum critical point and establish FeSc$_2$S$_4$ as a SOL with long-range entanglement.

\(^1\)Work at Johns Hopkins was supported by the Gordon and Betty Moore Foundation through Grant GBMF2628, the DOE-BES through DE-FG02-08ER46544, and the ARCS Foundation.

9:00AM L28.00006 Probing hidden orders in frustrated magnets, LUCILE SAVARY, T. SENTHIL, Massachusetts Institute of Technology — We propose a new direct way to experimentally probe some hidden orders, in particular, spin nematic order in magnets. Both the general formulation and particular applications to possible materials with specific hidden orders will be discussed.

9:12AM L28.00007 A continuous Mott transition between a metal and a quantum spin liquid, RYAN V. MISHMASH, Caltech and UCSB, IVAN GONZALEZ, CESGA, ROGER G. MELKO, Waterloo and Perimeter Institute, OLEXEI I. MOTRÜNICH, Caltech, MATTHEW P. A. FISHER, UCSB — More than half a century after first being proposed by Sir Nevill Mott, the deceptively simple question of whether the interaction-driven electronic metal-insulator transition may be continuous remains enigmatic. Recent experiments on two-dimensional materials suggest that when the insulator is a quantum spin liquid, lack of magnetic long-range order on the insulating side may cause the transition to be continuous, or only very weakly first order. Motivated by this, we study a half-filled extended Hubbard model on a triangular lattice strip geometry. We argue, through use of large-scale numerical simulations and analytical bosonization, that this model harbors a continuous (Kosterlitz-Thouless-like) quantum phase transition between a metal and a gapless spin liquid characterized by a spinon Fermi sea, i.e., a “spin Bose metal”. These results may provide a rare insight into the development of Mott criticality in strongly interacting two-dimensional materials and elucidate a mechanism by which spin-liquid phases are stabilized in the vicinity of such transitions.

9:24AM L28.00008 The phase diagram of the XXZ model and the extended Hubbard model on the triangular lattice\(^1\), SEBASTIAN EGGERT, XUE-FENG ZHANG, DANIEL SELLMANN, Univ. of Kaiserslautern, Germany, CLAUDIUS GROS, LUCA TOCCHIO, Univ. of Frankfurt, Germany — The Heisenberg model on the triangular lattice was proposed as the first example of a spin-liquid by Anderson in the early 70’s. Even though the isotropic Heisenberg model is by now well understood and known not to be a spin-liquid in the modern sense, so far the full phase diagram of the xxz model on the triangular lattice has received little attention. We now present DMRG calculations on order parameters and entanglement measures in order to establish the quantitative phase diagram as a function of both field and Ising anisotropy. We then also discuss the effect of introducing spin and charge degrees of freedom by considering the extended Hubbard model on the triangular lattice as a function of filling. In this case there is a very rich phase diagram with several different phases, where a stable charge order coexists with conducting behavior.

9:36AM L28.00009 Possible spin liquid phase of the $S = 1/2$ J1-J2 triangular Heisenberg model\(^1\), ZHENYUE ZHU, UC Irvine, DAVID HUSE, princeton University, STEVEN WHITE, UC Irvine — We study the $S = 1/2$ Heisenberg model on the triangular lattice with nearest neighbor interaction $J_1$ and next nearest neighbor interaction $J_2$ with the density matrix renormalization group. We are able to study long open cylinders with width up to 9 lattice spacings. At $J_2/J_1 = 0.1$, we find a possible spin liquid (SL) state with short range spin-spin, bond-bond and chiral correlation lengths, bordered by a classical $120^\circ$ Need order pattern at small $J_2$ and a two sub-lattice collinear magnetic ordered state at $J_2 > 0.17$. We identify two quasi-degenerate ground states in the SL phase on long even cylinders, with an energy gap that decreases exponentially with the cylinder width. We also observe a dimerization effect on odd cylinders. We further find a large spin triplet gap. Our evidence supports a fully gapped SL state for the intermediate phase.

\(^1\)Supported by NSF Grant No. DMR-1161348 and Simon foundation on the Many Electron Problem

9:48AM L28.00010 Quantum spin liquid in a $\pi$ flux triangular lattice Hubbard model, STEPHAN RACHEL, Technical University Dresden, MANUEL LAUBACH, University of Wuerzburg, JOHANNES REUther, Dahlem Center for Complex Quantum Systems and Freie Universitaet Berlin, RONNY THOMALE, University of Wuerzburg — We propose the $\pi$ flux triangular lattice Hubbard model ($\pi$-THM) as a prototypical setup to stabilize magnetically disordered quantum states of matter in the presence of charge fluctuations. The quantum paramagnetic domain of the $\pi$-THM which we identify for intermediate Hubbard $U$ is framed by a Dirac semi-metal for weak coupling and by $120^\circ$ Néel order for strong coupling. Generalizing the Klein duality from spin Hamiltonians to tight-binding models, the $\pi$-THM maps to a Hubbard model which corresponds to the $(J_1, J_3) = (-1, 2)$ Heisenberg-Kitaev model in its strong coupling limit. The $\pi$-THM provides a promising microscopic testing ground for exotic finite-$U$ spin liquid ground states amenable to numerical investigation.

10:00AM L28.00011 Quantum Antiferromagnets and Emergent Orders on Spatial Anisotropic Triangular Lattices, JIAN-JIAN MIAO, DONG-HUI XU, YI ZHOU, FU-Chun ZHANG, Zhejiang Univ — Schweniger boson representation and large $N$ expansion technique is applied to the quantum antiferromagnetic Heisenberg model on triangular lattices with spatial anisotropic nearest-neighbor and next-nearest-neighbor coupling. In the large $N$ limit, we found several degenerate ground states with different magnetic ordering on sub-lattices, where the non-zero bonds form honeycomb lattice or dice lattice. Large $\kappa = (N^{-1})$ expansion is used to lift the degeneracy and to obtain the phase diagram. Possible applications to recent discovered compound LiZnMo$_3$O$_8$ are discussed.
10:12AM L28.00012 Magnetism in $S = 1/2$ Double Perovskites with Strong Spin-Orbit Interactions, HIROAKI ISHIZUKA, LEON BALENTS, University of California, Santa Barbara — Motivated by recent studies on heavy-element double-perovskite (DP) compounds, we theoretically studied spin models on a FCC lattice with anisotropic interactions. In these systems, competition/cooperation of spin, orbital, and the lattice degrees of freedoms in the presence of the strong-spin orbit coupling is of particular interest. In a previous theoretical study, the magnetic phase diagrams of DP compounds with $S_1$ electron configuration was studied using a model with four-fold degenerated single-ion state. On the other hand, a recent experiment on a DP material, Ba$_2$Na$_2$OsO$_6$, reported that the compound is likely to be an effective $S = 1/2$ magnet. Inspired by the experimental observation, we considered spin models with symmetry-allowed anisotropic nearest-neighbor interactions. By a combination of various analytical and numerical techniques, we present the magnetic phase diagram of the model and the effect of thermal and quantum fluctuations. In particular, we show that fluctuations induce $(110)$ anisotropy of magnetic moments. We also discuss a possible “nematic” phase driven by spin-phonon couplings.

10:24AM L28.00013 A liquid-gas transition in a 3D Kitaev model, JOJI NASU, Tokyo Institute of Technology — Quantum spin liquid (QSL) is an exotic quantum state of matter in insulating magnets, where long-range ordering is suppressed down to the lowest temperature. Several experimental candidates of QSL have been recently nominated thus far. In their characterization, the absence of thermodynamic anomalies, namely, adiabatic connection from the high-temperature paramagnet (spin gas), is regarded as a hallmark of QSL. Although adiabatic connection between liquid and gas is allowed by bypassing the critical end point in conventional fluids, it is highly nontrivial whether a thermodynamic transition between QSL and paramagnet exists or not in quantum spin systems. The issue is crucial not only for theoretical understanding of QSLs but also for the interpretation of existing and forthcoming experiments. To clarify this problem, we investigate a three-dimensional extension of the Kitaev model [1,2,3]. This model is relevant to the recently found Ir oxides Li$_2$IrO$_3$. The Kitaev model is one of the soluble quantum spin models, where the ground state is given by gapped and gapless QSLs, depending on the anisotropy of the interactions. This model can be rewritten as a free Majorana fermion system coupled with $Z_2$ variables. Using this representation, we perform the Monte Carlo simulation and analyze the thermodynamic properties. We find that the model exhibits a finite-temperature phase transition between the QSLs and paramagnet in the whole parameter range. This result indicates that both gapless and gapped QSL phases at low temperatures are always distinguished from the high-temperature paramagnet by a phase transition. We also find that the difference between QSL and paramagnet comes from the topological nature of the excitations. This work has been done in collaboration with Y. Motome and M. Udagawa in Univ. of Tokyo. [1] J. Nasu, M. Udagawa, and Y. Motome, Phys. Rev. Lett. 113 197205 (2014). [2] J. Nasu et al., Phys. Rev. B 89 115125 (2014). [3] J. Nasu, M. Udagawa, and Y. Motome, preprint (arXiv:1409.4865).

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L29 GMAG DMP FIAP: Focus Session: Spin Transport and Voltage Control 206A — Ronny Knut, National Institute of Standards and Technology

8:00AM L29.00001 Voltage controlled magnetism in 3d transitional metals, WEIGANG WANG, Univ of Arizona — Despite having attracted much attention in multiferroic materials and diluted magnetic semiconductors, the impact of an electric field on the magnetic properties remains largely unknown in 3d transitional ferromagnets (FMs) until recent years. A great deal of effort has been focused on the voltage-controlled magnetic anisotropy (VCMA) effect where the modulation of anisotropy field is understood by the change of electron density among different d orbitals of FMs in the presence of an electric field. Here we demonstrate another approach to alter the magnetism by electrically controlling the oxidation state of the 3d FM at the FM/oxide interface. The thin FM film sandwiched between a heavy metal layer and a gate oxide can be reversibly changed from an optimally-oxidized state with a strong perpendicular magnetic anisotropy to a metallic state with an in-plane magnetic anisotropy, or to a fully-oxidized state with nearly zero magnetization, depending on the polarity and time duration of the applied electric fields. This is a voltage controlled magnetism (VCM) effect, where both the saturation magnetization and anisotropy field of the 3d FM can be reversibly controlled by voltage in a non-volatile fashion. We will also discuss the impact of this VCM effect on magnetic tunnel junctions and spin Hall switching experiments. This work, in collaboration with C. Bi, Y.H. Liu, T. Newhouse-Illige, M. Xu, M. Rosales, J.W. Freeland, O. Mryasov, S. Zhang, and S.G.E. te Velthuis, was supported in part by NSF (ECCS-1310338) and by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA.

8:36AM L29.00002 Field-dependent perpendicular magnetic anisotropy and interfacial metal-insulator transition in CoFeB/MgO systems, IGOR BARSUKOV, University of California, Irvine, YU FU, INAC/CEA, Grenoble, France, C. SAFRANSKI, YU-JIN CHEN, B. YOUNGBLOOD, University of California, Irvine, A. GONCALVES, L. SAMPAYO, CBPF, Rio de Janeiro, Brazil, R. ARIAS, Universidad de Chile, Santiago, Chile, M. SPASOVA, M. FARLE, CeNIDE, University Duisburg-Essen, Duisburg, Germany, I. KRIVOROTOV, University of California, Irvine — The CoFeB/MgO interface is a central role in magnetic tunnel junction devices due to the high tunneling magnetoresistance ratio. A strong perpendicular anisotropy (PMA) and voltage-controlled anisotropy are beneficial for spintronics application. We study PMA in thin films of Ta$_2$/Co$_{20}$Fe$_{60}$B$_{20}$/MgO in the thickness range of 0.9-2.5 nm and find that it can be best described by the first two order terms. Surprisingly, we find PMA to be strongly field-dependent [1]. Our results show that the field dependence has significant implications for determining and customizing magnetic anisotropy in spintronic applications. Our data suggest that it can be caused by an inhomogeneous interfacial spin pinning with a possibly ferrimagnetic phase at the CoFeB/MgO interface. We perform magnetometry and transport measurements and find a magnetization peak and resistance transitions at 160K, which are consistent with the presence of an interfacial oxide phase undergoing a Morin-like [2] transition. [1] I. Barsukov et al., 105, 152403 (2014) [2] F. J. Morin, Phys. Rev. Lett. 3, 34 (1959)

8:48AM L29.00003 Electric Polarization Controllable Magnetoresistance of Magnetic Ferroelectric Tunnel Junctions, MEI FANG, YANMEI WANG, Fudan University, DAL SUN, University of Utah, XIAOSHAN XU, University of Nebraska at Lincoln, WENTING YANG, LIFENG YING, Fudan University, JIANG LU, HO NYUNG LEE, Oak Ridge National Laboratory, JIAN SHEN, Fudan University, FUDAN UNIVERSITY TEAM, UNIVERSITY OF UTAH COLLABORATION, UNIVERSITY OF NEBRASKA AT LINCOLN COLLABORATION — The tunneling of electrons through ferroelectric material sandwiched by ferromagnetic electrodes, dubbed magnetic ferroelectric tunnel junctions (MFTJs), can be affected by not only the magnetic alignments between the two ferromagnetic electrodes, but also the electric polarization of the ferroelectric layer, which is right for multi-functional device applications. In this work, we investigate the TMR response during the switching process of electric polarization of the ferroelectric layer. Using a parallel connection mode for polarized up and polarized down domains of the PZT layer, the percentage of switched domain and its corresponding TMR are determined. The calculation results agree well with the experiments data.

Voltage controlled magnetocrystalline anisotropy at the Fe/MgO (001) interface. Pavel Lukashev, University of Northern Iowa, Evgeny Tsymbal, University of Nebraska - Lincoln — The effect of electric fields on magnetocrystalline anisotropy energy (MAE) is a promising way to control the magnetization orientation purely by voltage (rather than by current required for a spin transfer torque), which can potentially alleviate the energy dissipation bottleneck of the existing magnetic memory technology. Here we perform density-functional calculations to explore the voltage controlled magnetic anisotropy (VCMA) of a thin film Fe stacked along the [001] direction when an external electric field is applied across an adjacent epitaxial MgO layer. The results are analyzed by evaluating layer and orbital resolved contributions to MAE. We find that MAE is confined to a depth of few atomic layers near the interface, as determined by the metal screening length, indicating that the VCMA is an interface effect. The applied electric field leads to a nearly linear change in the interface MAE due to a change in the 3d-orbital occupancy of the interfacial Fe atoms and is enhanced, as compared to the clean Fe (001) surface, due to a relatively large dielectric constant of MgO. In addition to the electric field screening, there is a notable effect of atomic displacements driven by an applied electric field, when atomic relaxations are taken into account.

First-principles study of electric field and structural strain impact on perpendicular magnetic anisotropy of Fe/MgO interfaces. Fatima Ibrahim, Hongxin Yang, Bernhard Dieny, Mairbek Chshiev, Spintec, CEA/BRGM/Institut Néel, INAC, 38054 Grenoble, France — Electric-field (EF) control of magnetic anisotropy is promising in the context of establishing low-energy consumption memory devices [1] since it allows EF-assisted switching of magnetization in magnetic tunnel junctions with perpendicular magnetic anisotropy (PMA) [2]. Using first-principles calculations, we demonstrate that both the EF and structural strain induce changes of the PMA in Fe/MgO interfaces which originally exhibit strong PMA [3]. Namely, we find that the PMA change in response to strain is much larger than that induced by applied EF. This suggests that the EF control of PMA is caused not only by charge accumulation and depletion mechanism but rather mediated by structural modifications occurring at the interface in agreement with recent experimental reports [4,5]. In addition, using atomic and orbital-resolved analysis of PMA, we elucidate the effect of both the EF and structural strain on PMA showing in particular that it extends beyond the interfacial layer.

Voltage-controlled magnetic tunnel junctions with Gd$_2$O$_3$ barriers. Ty Newhouse-Illige, Charles Stanford, Matthew Gamble, Chong Bi, Hamid Almasi, Weigang Wang, University of Arizona — It is of great importance to investigate magnetic tunnel junction (MTJ) with high-k barriers, with the premise that a large voltage-controlled magnetic anisotropy (VCMA) can be achieved due to the increased charge transfer effect. Gd$_2$O$_3$ has a dielectric constant of 22, which is substantially larger than that of MgO (∼ 9). It is critical to achieve crystalline barrier with cubic phase in order to obtain symmetry-conserved tunneling as in MgO-based MTJs. We have demonstrated that cubic Gd$_2$O$_3$ can be grown on amorphous CoFeB by reactive sputtering under proper conditions. In exchanged-biased MTJs with in-plane anisotropy, magnetotunneling anisotropy (MTA) up to 20 K has been obtained. The sharp switching at near zero field and exchange-bias field higher than 800 Oe indicate the magnetic properties of the CoFeB in these junctions are nearly as good as in MgO-based MTJs. MTJs with interfacial perpendicular magnetic anisotropy (PMA) has been created with TMR ∼ 10%. A very interesting VCMA effect in these Gd$_2$O$_3$-based MTJs has been observed and will be discussed. This work was supported in part by NSF (CCF-1310338) and by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA.

A transition in the magneto-transport in the L1$_0$ MnAl thin films. Linqiang Luo, Jiwei Lu, Nian Diao, Yishen Cui, Stuart A. Wolf, University of Virginia — In this talk we will report on L1$_0$ MnAl thin films with perpendicular magnetic anisotropy prepared on single crystal MgO substrates by co-sputtering Mn and Al targets. A Cr seed layer enabled the epitaxial growth of the MnAl films. The magneto-resistance (MR) of these films was measured using a Hall bar structure. When the external electric field was applied perpendicular to the thin film surface, a change in the magnetic state of the MR was observed as will be discussed below. Above 175K, a negative magneto-oresistance was observed with two maxima occurring at the coercivity fields of the MnAl thin films. Below 175K, the MR became positive, and the MR ratio increased with decreasing temperature. The possible mechanisms for the transition in the MR will be discussed in detail in this talk. They include the effects of inhomogeneity, chemical ordering and the underlying domain structure.

Voltage-controlled magnetocrystalline anisotropy at the Fe/MgO (001) interface. Pavel Lukashev, University of Northern Iowa, Evgeny Tsymbal, University of Nebraska - Lincoln — The effect of electric fields on magnetocrystalline anisotropy energy (MAE) is a promising way to control the magnetization orientation purely by voltage (rather than by current required for a spin transfer torque), which can potentially alleviate the energy dissipation bottleneck of the existing magnetic memory technology. Here we perform density-functional calculations to explore the voltage controlled magnetic anisotropy (VCMA) of a thin film Fe stacked along the [001] direction when an external electric field is applied across an adjacent epitaxial MgO layer. The results are analyzed by evaluating layer and orbital resolved contributions to MAE. Near Room Temperature Kondo-Suppression of Spin Accumulation in Cu-Based Non-Local Spin Valves. Justin Watts, University of Minnesota, Liam O’Brien, University of Minnesota, University of Cambridge, Paul Crowell, Chris Leighton, University of Minnesota — Recent studies on metallic non-local spin valves have focused on the anomalous temperature dependence of the spin accumulation signal, $\Delta R_{NL}$, which unexpectedly decreases at low temperatures. O’Brien et al. (Nat. Commun. 5, 3927, 2014) advanced an explanation, based on interdiffusion-induced local moments suppressing injected spin polarization via a manifestation of the Kondo effect. Here we extend this work to devices based on Co/Cu, a combination for which the Kondo temperature can exceed 300 K. Non-magnetic channel thicknesses, $L_y$, from 50 to 200 nm have been explored, along with annealing temperatures up to 100 °C. The decrease in spin diffusion length in Cu from 300 nm for $L_y = 50$ nm to 20 nm for $L_y = 200$ nm, and its change upon annealing, will be discussed in detail. Most importantly we find that, despite the limited miscibility of Co in Cu, a significant decrease in $\Delta R_{NL}$ occurs with decreasing temperature as the Cu channel thickness is reduced. In the thinnest channels we find the maximum in $\Delta R_{NL}$ occurs near room temperature. This result implies that local moment formation and the associated Kondo physics can impact the performance of spin transport devices at ambient temperature in a very common and technologically important materials system.

10:12AM L29.000010 Asymmetric spin absorption into a nonlocal spin detector. SHUHAN CHEN, CHUAN QIN, YI JJ, University of Delaware — Nonlocal spin detection measures a spin-dependent chemical potential difference associated with a spin accumulation in a nonmagnetic channel. Typically a ferromagnetic spin detector is in contact with the nonmagnetic channel. A spin-dependent voltage is developed between the detector and the channel when a fraction of the spin current in the channel is absorbed into the detector. We explore an unconventional approach for nonlocal spin detection by probing the voltage between the two ends of the ferromagnetic spin detector. The nonlocal spin valves with 150 nm wide Cu channels are fabricated by e-beam lithography. The ferromagnetic Py spin injectors are 250 nm wide and Py spin detectors are 120 nm wide. Low-resistance AlOx barriers are placed between the Py and the Cu. Since the spin absorption across the Cu/AlOx/Py detector interface is not spatially uniform, a net emf is formed near the junction and a net voltage develops between the two ends of the spin detector. This spin-dependent voltage is clearly detectable at room temperature and suggests an unconventional method of detecting nonlocal spin accumulation.

10:24AM L29.00011 Transport properties of $\text{RPtBi (R = Gd, Dy, Tm, and Lu)}$ under applied magnetic fields. EUNDEOK MUN, Simon Fraser University, SERGEY BUD’KO, PAUL CANFIELD, Iowa State University, Ames Laboratory — It has been suggested that the combination of strong spin-orbit coupling and noncentrosymmetric crystal structure make ternary Heusler compounds a strong candidate for 3D topological materials. The crystal structure of rare-earth platinum bismuth ($\text{RPTBi}$) half-Heusler compounds lacks an inversion symmetry, hence the material is a noncentrosymmetric. The earlier electrical resistivity data of $\text{RPTBi}$ revealed a systematic change from a small gap semiconductor for lighter rare-earth to metallic for heavier rare-earth compounds. The angle resolved photoemission spectroscopy showed a clear spin-orbit splitting of the surface bands that cross the Fermi surface. Here we present very large magnetic field dependencies of transport properties in single crystals of $\text{RPTBi}$ ($R =$ Gd, Dy, Tm, and Lu). Successfully grown the high quality $\text{RPTBi}$ single crystals reveal that a large non-saturating magnetoresistance (MR) of as high as 800 % at 2 K and over 300 % at 300 K under a moderate magnetic field of 14 T. In addition to the large MR, the samples exhibit pronounced temperature and magnetic field dependences of Hall coefficient and thermoelectric power. Obtained transport data suggest that the high hole and electron mobility dominate the magnetotransport.

10:36AM L29.00012 Effect of thickness and strain on the metamagnetic transition temperature of ultra-thin epitaxial FeRh films$^1$. ALEJANDRO CEBALLOS, CATHERINE BORDEL, Univ of California - Berkeley, OLIVER SCHNEIDER, Julius-Maximilians-Universitat Wurzburg, FRANCES HELLMAN, Univ of California - Berkeley — The antiferromagnetic to ferromagnetic transition in ultra-thin epitaxial FeRh films was studied as a function of film thickness and substrate-induced strain. The lattice mismatch from MgO, STO and KTO was used to provide different strain states on FeRh films with thicknesses spanning 5 to 22 nm. The interplay of these parameters was studied using magnetometry, diffractometry, atomic force microscopy and energy dispersive spectroscopy. Our results provide insight into the growth mechanisms of FeRh and how the onset of the magnetic transition can be controlled via strain engineering.

10:48AM L29.00013 Temperature-dependent spin scattering in Pt and at its interfaces. RYAN FREEMAN, ANDREI ZHOLUD, SERGEI URAZHIDIN, Emory Univ — Pt is an important material for spintronic devices, as it exhibits a significant spin Hall effect, enabling its applications as an efficient source of spin currents. Among key parameters describing spin-transport properties are the spin diffusion length (SDL) and the interfacial spin-scattering $\delta$. The reported values of SDL in Pt range from 0.5 to 15nm, likely due to the differences in the measurement approaches and material purity. Little is presently known about $\delta$. We utilized current-perpendicular-to-plane giant magnetoresistance (CPP-GMR) and magnetic nanopillar structures to determine the dependence of $\delta$ and SDL in Pt on temperature T. Both $\delta$ and SDL increase by almost a factor of two between 300K and 7K, implying that the bulk spin scattering decreases while the interfacial spin scattering increases with decreasing T. These opposite trends result in a nonmonotonic dependence of GMRT on T for thin Pt layers. We discuss the possible mechanisms for the unexpected dependence of $\delta$ on T. We also show that the SDL is within a factor of 2 of the mean free path, implying that almost every scattering event is spin flipping. This result provides a simple approach to estimate SDL in Pt and other materials with strong spin-orbit interaction.

Wednesday, March 4, 2015 8:00AM - 11:00AM – Session L31 GMAG DMP FIAP: Focus Session: Spin Dependent Phenomena in Semiconductors: Spin Orbit and Spin Relaxation 207A - Hanan Dery, University of Rochester

8:00AM L31.00001 Spin-orbit coupling in bulk and low dimensional III-V zinc-blende and wurtzite semiconductors from first principles$^1$. MARTIN GMITRA, JAROSLAV FABIAN, University of Regensburg, Germany — We have performed systematic investigations, using first-principles methods, of spin-orbit coupling effects in bulk III-V zinc-blende and wurtzite GaAs, GaSb, InAs, and InSb semiconductors. We have investigated the spin-orbit effects of the surface states of these semiconductors in different technologically important growth directions. Based on symmetry-derived Hamiltonians we have extracted realistic spin-orbit parameters important for spin relaxation, spin transport, optical orientation, and semiconductor-based Majorana states studies.

8:12AM L31.00002 ABSTRACT WITHDRAWN —

8:24AM L31.00003 Spin Relaxation in III-V Semiconductors in various systems: Contribution of Electron-Electron Interaction. FATIH DOGAN, HASAN KESSERWAN, AURELIEN MANCHON, King Abdullah University of Science and Technology (KAUST) — In spintronics, most of the phenomena that we are interested happen at very fast time scales and are rich in structure in time domain. Our contribution, on the other hand, is mostly based on energy domain calculations. Many of the theoretical tools use approximations and simplifications that can be perceived as oversimplifications. We compare the structure, material, carrier density and temperature dependence of spin relaxation time in n-doped III-V semiconductors using Elliot-Yafet (EY) and D’yakonov-Perel’ (DP) with real time analysis using kinetic spin Bloch equations (KSBE). The EY and DP theories fail to capture details as the system investigated is varied. KSBE, on the other hand, incorporates all relaxation sources as well as electron-electron interaction which modifies the spin relaxation time in a non-linear way. Since el-el interaction is very fast ($\sim$ fs) and spin-conserving, it is usually ignored in the analysis of spin relaxation. Our results indicate that electron-electron interaction cannot be neglected and its interplay with the other (spin and momentum) relaxation mechanisms (electron-impurity and electron-phonon scattering) dramatically alters the resulting spin dynamics. We use each interaction explicitly to investigate how, in the presence of others, each relaxation source behaves. We use GaAs and GaN for zinc-blend structure, and GaN and AIN for the wurtzite structure,
8:36AM L31.00004 Spin Relaxation in Materials Lacking Coherent Charge Transport$^1$. NICHOLAS HARMON, University of Iowa — As semiconductor spintronics research extends to materials beyond intrinsic or lightly doped semiconductors (e. g. organic materials, amorphous semiconductors, and impurity bands), the need is readily apparent for new theories of spin relaxation that encompass highly disordered materials, where charge transport is incoherent. We describe a broadly applicable theory of spin relaxation in materials with incoherent charge transport. The theory is based on continuous-time-random-walk theory and can incorporate many different relaxation mechanisms. We focus primarily on spin relaxation caused by spin-orbit and hyperfine effects in conjunction with carrier hopping. Analytic and numerical results from the theory are compared in various regimes with Monte Carlo simulations. Three different systems were examined: a polymer (MEH-PPV) $^1$, amorphous silicon $^2$, and heavily doped n-GaAs. In the organic and amorphous systems, we predict spin relaxation and spin diffusion dependences on temperature and disorder for three different mechanisms (hyperfine, hopping-induced spin-orbit, and intra-site spin relaxation). The resulting unique experimental signatures predicted by the theory for each mechanism in these disordered systems provide a prescription for determining the dominant spin relaxation mechanism. We find our theory to be in agreement with available measurements in these materials. We also predict that large disorder modifies certain mechanisms to be algebraic instead of exponential in time. Our results should assist in evaluating the suitability of various disordered materials for spintronic devices. All work done in collaboration with Michael E. Flatté. Timothy Peterson and Paul Crowell collaborated as well on the n-GaAs study.

9:12AM L31.00005 Electron spin flips due to scattering off substitutional donors in multivalley semiconductors$^1$. YANG SONG, Department of Electrical and Computer Engineering, University of Rochester, Rochester, New York, 14627, OLEG CHALAEV, Department of Electrical and Computer Engineering, University of Rochester, HANAN DERY, Department of Electrical and Computer Engineering, Department of Physics and Astronomy, University of Rochester — We elucidate the physical origin of donor-driven spin relaxation in multivalley semiconductors with an emphasis on silicon. This spin flip is dominated by intervalley scattering between non time-reversal related valleys and by spin-orbit interaction from the core region of the donors. By a concise and intuitive explanation, we will present how the crystal symmetries and the multivalley nature of the conduction band set the selection rules for spin flips, and how to decisively associate the microscopic contributions with the empirically found strong dependence of the spin relaxation on the donor identity. These analyses and results are quite general for various other materials with multivalley conduction bands, and they are crucial for optimizing spintronics devices especially in the highly doped region near semiconductor-ferromagnet interfaces.

9:24AM L31.00006 Spin relaxation in strained n-type silicon$^1$. OLEG CHALAEV, YANG SONG, HANAN DERY, University of Rochester — The impurity-induced spin-relaxation mechanism in heavily doped n-type silicon has been recently reported in Phys. Rev. Lett. 113, 167201. The leading contribution to the spin-relaxation rate occurs due to electron transitions between momentum-space valleys that reside on different crystallographic axes (the so-called f-process). This spin relaxation mechanism can be suppressed by applying uniaxial compressive strain that lifts the valley degeneracy. By calculating the next-order contribution to the spin-relaxation rate due to intravalley scattering and intervalley scattering between opposite valleys (the so-called g-process), we find a significant enhancement of the spin lifetime.

9:36AM L31.00007 Theory of copper induced spin-orbit coupling in graphene: substrate, clusters, and adatoms$^1$. TOBIAS FRANK, Univ Regensburg, SUSANNE IRMER, DENIS KOCHAN, MARTIN GMITRA, JAROSLAV FABIAN, University of Regensburg — We present a DFT study of graphene functionalized by copper adatoms and clusters, as well as of graphene on the (111) Cu surface, focussing on spin-orbit coupling effects. In the single copper adatom limit we study two energetically favored adsorption positions: the top and bridge positions and their corresponding diffusion barrier. Based on symmetry arguments we propose an effective tight-binding model Hamiltonian to describe low energy electronic states and determine realistic orbital and spin-orbit coupling parameters. We consider also copper clusters adsorbed on graphene and graphene on the Cu (111) surface, for which we as well fit to a model Hamiltonian to extract Rashba and intrinsic spin-orbit coupling strengths.

9:48AM L31.00008 Intervalley mixing and skew scattering in graphene systems$^1$. MAHMOUD M. ASMAR, SERGIO E. ULLOA, Ohio University — The scattering of electrons in graphene from impurities that preserve the point symmetries of the lattice is known to be anisotropic, with a transport to elastic time ratio $\xi \approx 2$ at low energies [1]. In systems in which the spin orbit interactions (SOI) are locally enhanced and do not lead to K-K' intervalley mixing, we have shown that the scattering becomes isotropic, and can be experimentally detected through the drop in $\xi \approx 1$ at low carrier concentrations [2]. These systems have been also shown to exhibit skew scattering and associated spin Hall Effect (SHE) [3]. In this study we extend our analysis to defects described by time reversal invariant interactions (TRIs) that reduce the lattice symmetries of graphene and may cause intervalley scattering. We show that the presence of such defects also leads to the suppression of $\xi$, with carrier concentration dependence similar to those produced by the intrinsic SOI, but qualitatively different from the effects of Rashba SOI, allowing their simultaneous determination. Finally, we show the effects of such defects on skew scattering, and the dependence of the SH angle on the relative strength of such disorder.

10:00AM L31.00009 Extrinsic Spin Hall Effect Induced by Resonant Skew Scattering in Graphene

1. AÑES FERREIRA², Graphene Research Centre and Department of Physics, National University of Singapore, 2 Science Drive 3, Singapore 117546, Singapore. TATIANA G. RAPPOPORT, Instituto de Física, Universidade Federal do Rio de Janeiro, CP 68.528, 21941-972 Rio de Janeiro, RJ, Brazil, MIGUEL A. CAZALILLA, Department of Physics, National Tsing Hua University, and National Center for Theoretical Sciences (NCTS), Hsinchu City, Taiwan. A.H. CASTRO NETO, Graphene Research Centre and Department of Physics, National University of Singapore, 2 Science Drive 3, Singapore 117546, Singapore. — We show that the extrinsic spin Hall effect can be engineered in monolayer graphene by decoration with small doses of adatoms, molecules, or nanoparticles originating local spin-orbit perturbations. The analysis of the single impurity scattering problem shows that intrinsic and Rashba spin-orbit local couplings enhance the spin Hall effect via skew scattering of charge carriers in the resonant regime. The solution of the transport equations for a random ensemble of spin-orbit impurities reveals that giant spin Hall currents are within the reach of the current state of the art in device fabrication. The spin Hall effect is robust with respect to thermal fluctuations and disorder averaging.

10:12AM L31.00010 Weyl Nodes in Trigonal Tellurium and Selenium

MOTOAKI HIRAYAMA, Nanosystem Research Institute, AIST, RYO OKUGAWA, Department of Physics, Tokyo Institute of Technology, SHOJI ISHIBASHI, Nanosystem Research Institute, AIST, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology, TIES, Tokyo Institute of Technology, TAKASHI MIYAKE, Nanosystem Research Institute, AIST. — Singular points in the momentum space (Dirac nodes) have been under intensive investigation recently. Among various Dirac systems, materials having three-dimensional Dirac nodes without spin degeneracy (Weyl nodes) are of particular interest because of their topological nature. We study trigonal Te and Se as systems having both strong spin-orbit interaction (SOI) and broken inversion symmetry, which is necessary for the Weyl node. We calculate the electronic structure by using QMAS [1] based on relativistic density functional theory, and add the self-energy correction in the GW approximation. Te and Se are insulating at ambient pressure. The conduction bands have a spin splitting similar to the Rashba splitting around the H points, but unlike the Rashba splitting the spin directions are radial, forming a hedgehog spin texture. The energy gap decreases with increasing pressure. In the metallic phase, the spin rotates twice around H on the k₉ = ±π/c plane, which can be explained by the motion of the Weyl nodes under pressure [2]. We also find that trigonal Te shows the Weyl semimetal phase with time-reversal symmetry under pressure [2].

10:24AM L31.00011 Spin relaxation and transport mechanisms in ZnO thin films

MEGAN PRESTGARD, GENE SIEGEL, University of Utah. Department of Materials Science and Engineering, ROBERT ROUNDY, MIKHAIL RAIKH, University of Utah, Department of Physics, ASHUTOSH TIWARI, University of Utah, Department of Materials Science and Engineering — Zinc oxide has been widely used in optoelectronic and lasing application due to its wide-bandgap and large exciton binding energy. In recent studies, it has also been studied for spintronic device applications due to its relatively large spin-orbit coupling and potential as a dilute magnetic semiconductor. However, a fundamental understanding of spin transport and relaxation mechanisms has not yet been reached. Knowledge of these mechanisms is required in order to accurately explain and enhance spin-based effects in ZnO. To study spin transport and relaxation in ZnO, four-probe non-local Hanle measurements were performed on thin film samples. These samples were grown using a pulsed laser deposition technique under low ambient oxygen pressure. Under these conditions, the films grown are degenerately doped, with a carrier concentration on the order of 10¹⁹ cm⁻³. Taking this into account, the spin lifetime results can be explained by Dyakonov-Perel (DP) relaxation mechanisms using Fermi-Dirac statistics.

10:36AM L31.00012 Hyperfine-induced spin relaxation of a hopping carrier: implications for spin transport in 1-D vs 3-D organic semiconductors

1. VAGHARSH MKHITARYAN, VIATCHESLAV DOBOVITSKI, Ames Laboratory, Iowa State University, Ames, Iowa 50011. 0 TEAM — The hyperfine coupling of a carrier spin to a nuclear spin bath is a predominant channel for the carrier spin relaxation in organic semiconductors. We investigate the hyperfine-induced spin relaxation of a carrier performing a random walk on a d-dimensional regular lattice theoretically, in a transport regime typical for organic semiconductors. We show that in d=1 and d=2 the time dependence of spin polarization, P(t), is dominated by a superexponential decay, crossing over to an exponential tail at long times. The faster decay is attributed to multiple self-intersections (returns) of the random walk trajectories, which occur more often in lower dimensions. We also show, analytically and numerically, that the returns lead to sensitivity of P(t) to external electric and magnetic fields, and this sensitivity strongly depends on dimensionality of the system (d = 1 vs. d = 3). Furthermore, we consider the coordinate dependence of spin polarization, σ(r), in a hypothetic lateral or vertical organic spin-valve device. We demonstrate that, while σ(r) is essentially exponential, the effect of multiple self-intersections can be identified in transport measurements from the specific field-dependence of spin relaxation length.

10:48AM L31.00013 Dissecting the mechanisms of magnetocrystalline anisotropy in alloys: Electronic structure analysis tools and applications to (Feₓ₋₀₂ Coₓ)₀₂₋₀₂, Liₓ₋₀₂, Feₓ, N alloys

KIRILL BELASHCHENKO, University of Nebraska - Lincoln, VLADIMIR ANTRPOPOV, Ames Laboratory — We describe a first-principles code and a set of tools providing detailed information about the mechanisms of the magnetocrystalline anisotropy (MCA) in alloys. The spin-orbit coupling (SOC) is included in the Green’s function-based linear muffin-tin orbital (LMTO) method combined with the coherent potential approximation. Third-order correspondence with the LMTO Hamiltonian is formally demonstrated. The analysis tools include the identification of contributions from different spin channels, single-ion and two-ion terms and alloy components by computing the SOC energy with scaled SOC parameters, as well as a full reciprocal-space resolution of MCA in the Brillouin zone. Application of these tools is illustrated for the (Feₓ₋₀₂ Coₓ)₀₂₋₀₂ system, where the complicated non-monotonic concentration dependence of MCA is attributed to the combination of band filling and SOC selection rules. For Liₓ₋₀₂, Feₓ, N we demonstrate the interplay between chemical disorder, orbital polarization, and correlation effects in a doubly degenerate impurity band.

8:00AM L32.00001 Huge spin-driven polarizations at room temperature in bulk BiFeO₃. JUN HEE LEE, RANDY FISHMAN, Oak Ridge National Laboratory — Although BiFeO₃ is one of the most investigated multiferroics, its magnetoelectricity and spin-driven polarizations are barely understood on an atomistic level. By combining a first-principles approach with a spin-cyclod model, we report hidden but huge spin-driven polarizations at room temperature in bulk BiFeO₃. One of the polarizations reaches \( \sim 0.03 \text{ C/m}^2 \), which is larger than any other spin-driven polarization in a bulk material by one order of magnitude. By comparing our results with intrinsic measurements such as neutron scattering, Raman spectroscopy, IR directional dichroism, and high magnetic-field measurements, we disentangle all the hidden spin-driven polarizations due to exchange-striction, spin-current, and single-ion-anisotropy. We find that the broken inversion symmetry of the J3c structure of BiFeO₃ induce the strong response of the magnetic couplings to an electric field and are responsible for the associated huge spin-driven polarizations.

8:12AM L32.00002 Theory for the Spectroscopic Mode Frequencies and THz Absorption of Multiferroic BiFeO₃. RANDY FISHMAN, JUN HEE LEE, Oak Ridge National Laboratory — A microscopic model for BiFeO₃ that includes two Dzyaloshinskii-Moriya interactions and easy-axis anisotropy along the ferroelectric polarization predicts both the zero-field spectroscopic modes as well as their splitting and evolution in a magnetic field [1]. Due to simultaneously broken time-reversal and spatial-inversion symmetries, the absorption of light changes slightly as the magnetic field or the direction of light propagation is reversed. We discuss three sets of physical mechanisms that contribute to the THz absorption and directional dichroism (DD) of BiFeO₃: spin current, magnetostriction, and anisotropy. First-principles calculations are used to obtain relationships among some of the polarization matrix elements induced by broken inversion symmetries in J3c structure. While our model nicely describes the DD along the magnetic field direction [1-1,0], it fails to predict the weak DD observed for field along [1,1,0].

8:24AM L32.00003 Atomic-Scale Tunneling Spectra across BiFeO₃/La₄/3Sr₇/3MnO₃ Heterointerfaces. YA-PING CHIU, Department of Physics, National Taiwan Normal University, Taipei, 116, Taiwan, BO-CHAO HUANG, Institute of Physics, Academia Sinica, Taipei 105, Taiwan, PU YU, State Key Laboratory of Low-Dimensional Quantum Physics, Department of Physics, Tsinghua University, CHIA-SENG CHANG, YING-HAO CHU, Institute of Physics, Academia Sinica, Taipei 105, Taiwan. — Atomic-level evolution of electronic structures across BiFeO₃/La₄/3Sr₇/3MnO₃ complex oxide heterointerfaces has been demonstrated by cross-sectional scanning tunneling microscopy and spectroscopy in this work. Analysis of scanning tunneling spectroscopy results exploits how the change in the terminated interface brings the influence to the electrostatic configurations across the BiFeO₃/La₄/3Sr₇/3MnO₃ heterointerfaces. Spatially unit-cell-by-unit-cell resolved electronic states at the atomic level reveal that the control of material interfaces at the atomic level determines the ferroelectric polarization in BiFeO₃. The precise electronic information therefore provides a clear realization about the electronic state at these complex-oxide heterointerfaces, which is crucial to understand and design a host of novel functionalities at complex oxide heterointerfaces.

8:36AM L32.00004 Structural evolution from Bi₄/3K₀.8Fe₂O₉₋δ nanobelts to BiFeO₃ nanochains and their multiferroic properties. SINING DONG, Univ of Notre Dame, XIAOGUANG LI, Univ of Sci and Tech of China, XINYU LIU, MALGORZATA DOBROWOLSKA, JACEK FURDYNA, Univ of Notre Dame — In this study, we reported the structural evolution of Bi₄/3K₀.8Fe₂O₉₋δ nanobelts to BiFeO₃ nanochains and the related variations of multiferroic properties. By using in-situ transmission electron microscopy with comprehensive characterization, it was found that the layered perovskite multiferroic Bi₁₄/3K₀.8Fe₂O₉₋δ nanobelts were very unstable in a vacuum environment with Bi being easily removed. Based on this finding, a simple vacuum annealing method was designed which successfully transformed the Bi₁₄/3K₀.8Fe₂O₉₋δ nanobelts into one-dimensional BiFeO₃ nanochains. Both the Bi₁₄/3K₀.8Fe₂O₉₋δ nanobelts and the BiFeO₃ nanochains showed multiferroic behaviors, with their ferroelectric and ferromagnetic properties clearly established by piezoresponse and magnetic measurements, respectively. Interestingly, the BiFeO₃ nanochains exhibited a surprisingly large exchange bias with small training effects. This one-dimensional BiFeO₃ multiferroic nanostructure characterized by a relatively stable exchange bias offers important functionalities that may be attractive for device applications.

8:48AM L32.00005 Correlated Switching Dynamics in the Nanoscale Proximity of 90° Ferroelectric Domain Walls. SHIMING LEI, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA, United States., XUEYUN WANG, S.W. CHEONG, Department of Physics and Astronomy and Rutgers Center for Emergent Materials, Rutgers University, Piscataway, NJ, United States., L.Q. CHEN, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA, United States., SERGEE KALININ, The Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, Tennessee, VENKATRAMAN GOPALAN, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA, United States. — Ferroelectrics are materials which have a built in polarization in their crystal structure even in the absence of an electric field. Domain walls themselves can possess dramatically different properties than the bulk ferroelectrics themselves. Previously we discovered that the universally present 180° walls have an order of magnitude lower domain switching threshold field than the bulk. This effect extends up to many microns around a wall, though the wall itself is unit cell thick. Here we present new results on 90° walls in PbTiO₃ single crystals that show similar proximity effect and correlated switching. Our SSSPFM imaging across the a/c/a domain walls suggests a strong correlated switching behavior in the proximity of the inclined 90° domain walls, even at a small AC driving voltage of 1V without DC bias on the tip. Consistent with phase-field modeling results, the inclined extended domain walls is found to act as nucleation sites in ferroelectric materials, and give rise to the domain wall asymmetrical broadening across the domain wall.

9:00AM L32.00006 Magnetic-induced polarization in charge-ordered CaMnO₁₂₋δ system. DIOMEDES SALDANA-GRECO, JIN SOO LIM, ANDREW M. RAPPE, University of Pennsylvania — The electronic properties of CaMnO₁₂₋δ yield interesting physical phenomena including charge-ordering, non-collinear magnetism, and improper ferroelectricity. The charge-ordered CaMnO₁₂₋δ is a complex quadruple perovskite whose chemical formula is (CaM₃₋δ)₃(Mn⁺³₋δMn⁺⁹/₁₂)O₁₂ where three Mn⁺³ are on the A-site (Mn₁), three Mn⁺³ on the B-site (Mn₂), and one Mn⁺³ on the B-site (Mn₃). Three parallel c-chains with alternating Mn₁ and Mn₂ form a Kagome lattice with either Mn₃ or Ca at the center of the hexagonal rings. The non-collinear magnetic structure consists of spin moments lying on the ab-plane, forming a helical pattern along the c-axis. Our DFT+U+J study shows that the Mn₃ spins adopt a (90°-30°) spin configuration with respect to the surrounding (Mn₁,Mn₂) spins, breaking the inversion symmetry and generating a Berry-phase computed ferroelectric polarization of 2975 μC/m² along the c-axis. We demonstrated that when the magnetic helicity of the system is reversed, the ferroelectric polarization flips. This study aims to explore how the electronic and magnetic properties are intertwined to give rise to a multiferroic, charge-ordered state.
9:12AM L32.00007 Giant spin-driven ferroelectric polarization and magnetoelectric effect in perovskite rare-earth maganifies under high pressure. TSUYOSHI KIMURA, Osaka University — The discovery of ferroelectricity in TbMnO$_3$ triggered extensive studies on a type of multiferroics, “spin-driven ferroelectrics.” Unlike conventional ferroelectrics such as BaTiO$_3$, spin-driven ferroelectrics exhibit remarkable magnetoelectric (ME) effects. However, the ferroelectric polarization $P$ in spin-driven ferroelectrics ever reported ($< 10^{-3}$µC/cm$^2$) is much smaller than that in conventional ferroelectrics (typically $10^0 - 10^3$µC/cm$^2$). Thus, the quest for robust magnetically-controllable $P$ comparable to that in conventional ferroelectrics is still a major challenge in the research on multiferroics. In this study, we utilized the “high-pressure” to attain a magnetically-controllably spin-driven $P$ with its magnitude being comparable to that in conventional ferroelectrics [T. Aoyama et al., Nature Commun. 5, 4927 (2014)]. With a home-made high-pressure measurement system with a diamond anvil cell, we investigated high-pressure effects on ME properties of perovskite TbMnO$_3$ ($R =$ Gd, Tb, and Dy). Our study revealed that these magnanites exhibit a pressure-induced ME phase transition and that the high-pressure phase shows the largest $P$ (e.g., 1 µC/cm$^2$ in TbMnO$_3$) among spin-driven ferroelectrics ever reported. Moreover, $P$ is further enhanced by applying a magnetic field. Our study demonstrates that it is possible to attain giant spin-driven ferroelectric polarization which comes close to that in conventional ferroelectrics, and to control it magnetically.

This work has been done in collaboration with T. Aoyama, K. Yamauchi, A. Iyama, S. Picozzi, A. Miyake, and K. Shimizu.

9:48AM L32.00008 Terahertz electromagnons in spin-diluted cupric oxide: dynamics of twisted spin states. JAMES LLOYD-HUGHES, University of Warwick, SAMUEL JONES, University of Oxford, NICOLA WURZ, MICHELE FAILLA, CHRIS MCCONVILLE, University of Warwick, DHARMALINGHAM PRABHAKARAN, University of Oxford — Understanding the physics of magnetoelectric materials may lead to their application in actuators, sensors and solid state memories. Improper multiferroics also have novel quasiparticle excitations: electromagnons form when spin-waves become electric-dipole active. We investigated magnons, electromagnons and spin-lattice coupling in Cu$_{1-x}$Zn$_x$O (0<x<0.05), an improper ferromagnet. Terahertz time-domain spectroscopy demonstrated electromagnons only in the multiferroic phase, and established the selection rule and that the oscillator strength tracks the static polarisation [1]. The impact of non-magnetic Zn-substitution on lattice dynamics was elucidated by Raman and Fourier-transform spectroscopy, showing strong spin-lattice coupling in Cu$_{1-x}$Zn$_x$O. While the phonon and magnon modes broaden and shift as a result of alloy-induced disorder, the electromagnon was found to be insensitive to Zn substitution and the induced disorder in the local spin structure. The results demonstrate that electromagnon excitations and dynamic magnetoelectric coupling can be maintained even in disordered spin systems, and at elevated temperatures [2]. [1] Nature Communications 5, 3787 (2014). [2] Physical Review B 90, 064405 (2014).

10:00AM L32.00009 Terahertz study of potential multiferroic materials Sr$_2$FeSi$_2$O$_7$ and BaFe$_2$O$_4$[1], THUC T. MAI, M.T. WARREN, J. BRANGHAM, Center for Emergent Materials, Department of Physics. The Ohio State University. Columbus, OH 43210, T-H. HWAN, POSTECH, South Korea, S-W. CHEONG, Department of Physics, Rutgers University. J. YAN, Oak Ridge National Laboratory and University of Tennessee Knoxville. R. VALDES AGUILAR, Center for Emergent Materials, Department of Physics. The Ohio State University. Columbus, OH 43210 — We present data on the complex dielectric function of two iron-based quantum magnets in the terahertz frequency range. We study the phase transitions in Sr$_2$FeSi$_2$O$_7$ at low temperature when it becomes a collinear antiferromagnet, in contrast with the canted antiferromagnetic state of iso-structural multiferroic Ba$_2$CoGe$_2$O$_7$. We compare the terahertz response of these two materials in light of the recent observation of electromagnon excitations in Ba$_2$CoGe$_2$O$_7$. We have also studied BaFe$_2$O$_4$, a hexagonal ferromagnet that is predicted to have an antiferroelectric state. We will report experiments at terahertz frequencies probing this predicted state.

10:12AM L32.00010 Enhancement of Magnetoelectric Coupling in CoGa$_2$Fe$_{2-x}$O$_4$/BaTiO$_3$ Composite[1], YAN NI, ZHEN ZHANG, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University, CAJETAN NLEBE-DIM, Ames Laboratory, U.S. Department of Energy — Multiferroic materials exhibit magnetoelectric coupling and promise new device applications including magnetic sensors, generators and filters. An effective method for developing magnetoelectric (ME) materials with enhanced ME effect is achieved by the coupling through the interfacial strain between piezoelectric and magnetostrictive materials. In this study, enhancement of magnetoelectric coupling was found by systematically studying the electrical and magnetic properties of CoGa$_2$Fe$_{2-x}$O$_4$/BaTiO$_3$ composite. It is found that Ga doping not only stabilizes the magnetic phase of composites but also increases the sensitivity of magnetoelastic response by 30%. Moreover, Ga doping reduces the electrical conductivity and the dielectric loss of composite. An enhancement of magnetoelectric coupling was found to be significant in the composite as compared to the constituent materials. The results indicate that the interfacial strain can significantly enhance the magnetoelectric coupling.

10:24AM L32.00011 Ultrafast Optical Spectroscopy of BiFeO$_3$-BaTiO$_3$ Based Structures[1], B.A. MAGILL, M.A. MEEKER, G.A. KHODAPARAST, S. PRIYA, Y. ZHOU, HYUN-CHEOL SONG, Virginia Tech. M. BISHOP, S. MCGILL, National High Magnetic Field Laboratory, Florida — Ultrafast optical spectroscopy can provide insight into fundamental microscopic interactions, dynamics and the coupling of several degrees of freedom. Pump/ probe studies can reveal the answer to questions like “What are the achievable switching speeds in multiferroics?” In this talk, we report on two color (400/800nm) pump-probe differential reflectance spectroscopy of BiFeO$_3$-BaTiO$_3$ based structures to probe the coupling between optical and acoustic phonons to spin waves, in these material systems. We present the results of several different time resolved transient reflectivity measurements to probe both the carrier and spin dynamics.

10:36AM L32.00012 Linear to quadratic magnetoelectric effect in Fe langasite, SERGEY ARTYUKHIN, DAVID VANDERBILT, SANG-WOOK CHEONG, Rutgers University — Materials with coexisting and interacting switchable ferroic orders – multiferroics – are the subject of intense investigations due to their existing and potential applications in spintronics and information storage technology. Here we investigate the much debated magnetically induced polarization and magneto-electric effect in the hexagonal Fe-langasite Ba$_3$NbFe$_3$Si$_2$O$_{11}$ with distorted triangular layers of magnetic Fe ions. We propose a simple model for these phenomena, and discuss how application of the magnetic field induces a toroidal moment, responsible for the peculiar magnetoelectric effect in this material.
Euglena’s diverse perspectives led. I will demonstrate how this process led to improved curricular design, refined assessment objectives, and new design heuristics.

at multiple-time scales. In this presentation I will detail our process of collecting systematic data, listening to and valuing students’ reasoning, and bridging in instructor to teaching in a large lecture hall with multiple instructors. We have used a design-based research approach to support critical reflection of the course learning environment that bridges the disciplinary domains of biology and physics. Across the three years we have gone from teaching in a small class with one — but they often see these courses as disconnected. Over the past three years the NEXUS/Physics course has been working to develop an interdisciplinary — and charge screening in fluids. We also introduce the students to research-grade equipment and modern physics analysis tools in contexts relevant to biology, — via construction and via play – and it provides an engaging theme for a formal biophysics devices class as well as to be presented in informal outreach activities; its low cost requirements make it especially suitable for use in resource-limited settings.

This work is supported by NSF-TUES DUE 11-22818, the HHMI NEXUS grant, and a NSF Graduate Research Fellowship (DGE 0750616).

Session L33 DBIO FED: Focus Session: Undergraduate Teaching at the Intersection of Physics and Biology

8:00AM L33.00001 Rethinking Physics for Biologists: A design-based research approach

8:18AM L33.00002 Introductory Physics Laboratories for Life Scientists – Hands on Physics of Complex Systems

8:48AM L33.00003 A biotic video game smart phone kit for formal and informal biophysics education

9:00AM L33.00004 Hands-on-Entrophy, Energy Balance with Biological Relevance

9:36AM L33.00005 A Low-Cost, Hands-on Module to Characterize Antimicrobial Compounds Using an Interdisciplinary, Biophysical Approach
9:48AM L33.00006 An undergraduate course, and new textbook, on “Physical Models of Living Systems”
PHILIP NELSON, Univ Pennsylvania — I’ll describe an intermediate-level course on “Physical Models of Living Systems.” The only prerequisite is first-year university physics and calculus. The course is a response to rapidly growing interest among undergraduates in several science and engineering departments. Students acquire several research skills that are often not addressed in traditional courses, including: basic modeling skills, probabilistic modeling skills, data analysis methods, computer programming using a general-purpose platform like MATLAB or Python, dynamical systems, particularly feedback control. These basic skills, which are relevant to nearly any field of science or engineering, are presented in the context of case studies from living systems, including: virus dynamics; bacterial genetics and evolution of drug resistance; statistical inference; superresolution microscopy; synthetic biology; naturally evolved cellular circuits. Publication of a new textbook by WH Freeman and Co. is scheduled for December 2014.

1Supported in part by EF-0928048 and DMR-0832802.

10:00AM L33.00007 Teaching Optics to Biology Students Through Constructing a Light Microscope
JENNIFER ROSS, Univ of Mass - Amherst — The microscope is familiar to many disciplines, including physics, materials science, chemistry, and the life sciences. It demonstrates fundamental aspects of ray and wave optics, making it an ideal system to help students in the basic concepts of optics and in measurement principles and techniques. We present an experimental system developed to teach students the basics of ray and wave optics. The students design, build, and test a light microscope made from optics components. We describe the equipment and the basic measurements that students can perform to develop experimental techniques to understand optics principles. Students measure the magnification and test the resolution of the microscope. The system is open and versatile to allow advanced projects such as epi-fluorescence, total internal reflection fluorescence, and optical trapping. We have used this equipment in an optics course, an advanced laboratory course, and graduate-level training modules.

8:00AM L34.00001 Hybrid Perovskite Solar Cells with Copper Iodide as Hole Transportlayer
ROSS HAROLDSON, ZANE OLDS, ALEXANDER B COOK, ANVAR ZAKHIDOV, Univ of Texas - Dallas — Hybrid organo-metallic solar cells based on perovskite-structured nanocrystals have had steadily improving power conversion efficiencies over the past several years, and within this short period of time are capable of achieving efficiencies over 19%. In our work we show that dopants thin layer of Copper iodide (Cul) on top of a hole transport layer such as PEDOT:PSS increases the open circuit voltage, of the devices. Cul is a p-type hole conducting material with a large band gap that has been used before for hole transport layers by itself. We demonstrate that Cul as the working hole transport layer increases the Voc about 10% increase.

8:12AM L34.00002 Morphological Optimization of Perovskite Thin Films via Dynamic Zone Annealing
YAN SUN, KAI WANG, XIONG GONG, ALAMGIR KARIM, University of Akron — Organolead Halide Perovskites have been proved to be excellent candidates for application in low-cost high-efficient solar cells owing to their superior desired optical and electrical properties, as well as compatibility with low-temperature solution-processed manufacturing. However, most perovskites applications in photovoltaics require high quality perovskite films. Although tremendous works on tuning perovskite film morphology have been reported previously, it is still a challenge to realize high quality perovskite film with controllable film uniformity and surface coverage, neither the mechanisms in the formation of perovskite. To address the issues above, here we demonstrate the effect of Dynamic Zone Annealing (DZA) on perovskite morphologies, which is proved as an efficient method to control the structure and morphology in crystalline polymer and block copolymers. Via applying the DZA method, the mechanism in perovskite film formation is studied. Furthermore, by optimizing DZA parameter such as maximum temperature, temperature gradient and zone velocity to control dendritic morphology and the grain growth, enhanced device performance was realized eventually.

equal contribution

8:24AM L34.00003 Photovoltaic properties of low band gap ferroelectric perovskite oxides
XIN HUANG, Southeast University, TULA PAUDEL, University of Nebraska-Lincoln, SHUAI DONG, Southeast University, EVGENY TSYMBAL, University of Nebraska-Lincoln — Low band gap ferroelectric perovskite oxides are promising for photovoltaic applications due to their high absorption in the visible optical spectrum and a possibility of having large open circuit voltage. Additionally, an intrinsic electric field present in these materials provides a bias for electron-hole separation without requiring p-n junctions as in conventional solar cells. High quality thin films of these compounds can be grown with atomic layer precision allowing control over surface and defect properties. Initial screening based on the electronic band gap and the energy dependent absorption coefficient calculated within density functional theory shows that hexagonal rare-earth manganites and ferrites are promising as photovoltaic absorbers. As a model, we consider hexagonal TbMnO_3. This compound has almost ideal band gap of about 1.4 eV, very high ferroelectric Curie temperature, and can be grown epitaxially. Additionally hexagonal TbMnO_3 offers possibility of coherent structure with transparent conductor ZnO. We find that the absorption is sufficiently high and dominated by interband transitions between the Mn d-bands. We will present the theoretically calculated photovoltaic efficiency of hexagonal TbMnO_3 and explore other ferroelectric perovskite oxides.

8:36AM L34.00004 Infrared spectrum and normal-mode assignment in methyl-ammonium lead halide perovskite CH_3NH_3PbI_3
MIGUEL ANGEL PEREZ OSORIO, MARINA FILIP, Department of Materials, University of Oxford, Parks Road, Oxford, OX1 3PH, UK — CALLUM DOCHERTY, LAURA HERZ, MICHAEL JOHNSTON, Clarendon Laboratory, Department of Physics, University of Oxford, Parks Road, Oxford, OX1 3PU, UK — FELICIANO GIUSTINO, Department of Materials, University of Oxford, Parks Road, Oxford, OX1 3PH, UK — Solar cells based on MAPbI_3 (MA=CH_3NH_3) have attracted enormous attention during the past two years owing to their high energy-conversion efficiency, reaching up to 19.3% in record devices. A detailed understanding of the structure/property relations of this compound may help us explain its extraordinary performance. Here, we investigate the vibrational modes and infrared (IR) absorption spectrum of MAPbI_3 by combining first-principles calculations and experiment. Our calculations indicate that the normal modes at high frequency, 400-3100 cm^{-1}, correspond to internal vibrations of the MA cations, whereas those at low frequency, up to 180 cm^{-1}, can be assigned either to vibrations of the PbI network or to the libration and spinning of the cations. Using a factor group analysis we establish the symmetry of the normal modes and predict which mode will be IR or Raman active. In order to confirm these assignments we explicitly calculate the IR spectrum of the MAPbI_3. The calculated spectrum is in good agreement with experiment, therefore we now have a complete characterization of the vibrational properties of MAPbI_3. This work will serve as a solid reference for future structural and characterization studies of hybrid organic-inorganic perovskites.
8:48AM L34.00005 Nanoscale charge localization induced by random orientations of organic molecules in hybrid perovskite CH₃NH₃PbI₃. JIE MA, LIN-WANG WANG, Lawrence Berkeley National Lab — Perovskite-based solar cells have achieved high solar-energy conversion efficiencies and attracted wide attentions nowadays. Despite the rapid progress in solar-cell devices, many fundamental issues of the hybrid perovskites have not been fully understood. Experimentally, it is well known that in CH₃NH₃PbI₃, the organic molecules CH₃NH₃ are randomly oriented at the room temperature, but the impact of the random molecular orientation has not been investigated. Using linear-scaling ab-initio methods, we have calculated the electronic structures of the tetragonal phase of CH₃NH₃PbI₃ with randomly oriented organic molecules in large supercells up to ~ 20,000 atoms. Due to the dipole moment of the organic molecule, the random orientation creates a novel system with long-range potential fluctuations unlike alloys or other conventional disordered systems. We find that the charge densities of the conduction-band minimum and the valence-band maximum are localized separately in nanoscales due to the potential fluctuations. The charge localization causes electron-hole separation and reduces carrier recombination rates, which may contribute to the long carrier lifetime observed in experiments. We have also proposed a model to explain the charge localization.

9:00AM L34.00006 Dynamics of CH₃NH₃PbI₃ from first principles simulations1, ALI KACHMAR, MARCELO CARIGNANO, Qatar Environment and Energy Research Institute, Qatar Foundation, PO Box 5825, Doha, Qatar — We study the dynamical and optical properties of CH₃NH₃PbI₃ using density functional calculations based on forces calculated with density functional theory. We have studied the three stable phases of CH₃NH₃PbI₃ but most of the effort was dedicated to the intermediate tetragonal phase, which is stable at standard ambient conditions. In this case, two different system sizes have been considered, one with 8 unit cells (384 atoms) and a larger one with 27 unit cells (1296 atoms). The total simulated time reached 40 ps. Our findings reveal the interplay between the thermal energy of the system and the electronic degrees of freedom. For example, the organic molecule undergoes relatively fast rotations and the energy band gap, approximated by the LUMO-HOMO energy difference, fluctuates around the equilibrium value of ~1.5 eV with a width of 0.2 eV. The rotation of the CH₃NH₃ molecule is not isotropic, and more importantly, it is quite sensitive to the size of the simulation box. Our study also provides a quantitative measure for the finite size effects affecting the calculated properties and provides a contextual scenario in which to analyze the more typical density functional theory studies based on static calculations on optimal structures.

1The authors acknowledge the HPC resources of Texas A&M University at Qatar.

9:12AM L34.00007 Bandstructure, optical spectra, and mean free paths in the room-temperature structure of CH₃NH₃PbI₃ from many-body perturbation theory1, DEREK VIGIL-FOWLER, MARCO BERNARDI, STEVEN G. LOUIE, University of California at Berkeley and Lawrence Berkeley National Lab — The organometallic halide perovskites have generated enormous interest due to the rapidly increasing efficiency of solar cells fabricated from these materials. Most research on the organometallic halide perovskites has been experimental due to the challenges posed by these materials to theoretical study, including the size of the unit cell, the presence of many defects, the orientational disorder in of the methyammonium (MA) cation, and the heavy atoms involved with the corresponding large spin-orbit coupling (SOC). We study the room-temperature tetragonal structure of CH₃NH₃PbI₃ using density functional theory (DFT) and a many-body Green’s functions approach. We use DFT to study the effect of the dependence of the bandstructure on the orientation of the MA cation, while we perform GW and GW plus Bethe-Salpeter equation (GW-BSE) calculations to study the quasiparticle bandstructure and optical spectra, respectively, paying close attention to convergence and the effect of SOC. We particularly investigate the existence of a proposed charge-transfer state in this material. We also briefly discuss the mean free paths due to electron-photon and electron-electron scattering in the ideal structure.

1This work was supported by NSF Grant No. DMR10-1006184, and U.S. DOE Contract No. DE-AC02-05CH11231 and the DOE SciDAC program. Computational resources were provided by NERSC. D.V.-F. acknowledges funding from the NSF’s Blue Waters Fellowship.

9:24AM L34.00008 Exciton Binding energies and effective masses in Organo-lead Tri-Halide Perovskites, OLIVER PORTUGALL, ATSUKIKO MIYATA, ANATOL MITIOGLU, PAULINA PLOCHOCKA, LNCMI TOULOUSE, JACOB TSE-WEI WANG, SAMUEL STRANKS, HENRY SNAITH, ROBIN NICHOLAS, Oxford University, LNCMI TOULOUSE TEAM, OXFORD UNIVERSITY TEAM — Solid-state perovskite-based solar cells have made a dramatic impact on emerging PV research with efficiencies of over 17% already achieved. However, to date the basic electronic properties of the perovskites such as the electron and hole effective masses and the exciton binding energy are not well known. We have measured both for methyl ammonium lead tri-iodide using magneto absorption in very high magnetic fields up to 150T showing that the exciton binding energy at low temperatures is only 16 meV, a value three times smaller than previously thought and sufficiently small to completely transform the way in which the devices must operate. Landau level spectroscopy shows that the reduced effective mass of 0.104 me is also smaller than previously thought. In addition by using a fast pulse 150T magnet we measure the band structure change due to the structural phase transition that occurs in this system at around 160K. We also observe Landau levels in the high temperature phase as used for device production, which has a very similar effective mass and the analysis suggests an exciton binding energy which is even smaller than in the low temperature phase.

9:36AM L34.00009 Ferritin-based nanocrystals for solar energy harvesting1, JOHN COLTON, STEPHEN ERICKSON, CAMERON OLSEN, JACOB EMBLEY, TREVOR SMITH, RICHARD WATT, Brigham Young University — Ferritin is a 12 nm diameter hollow protein with an 8 nm cavity that can be filled with a variety of nanocrystals (ferrihydrite being native). We report on several experiments with ferritin-based nanocrystals designed to utilize ferritin for solar energy harvesting. First, we have shown that the native band gap can be altered by controlling nanocrystal size, by replacing the native iron oxide core with other metal oxides, and by depositing halides and oxo-anions with the iron oxide core. This gives available band gaps of 1.6 to 2.3 eV. Theoretical efficiency calculations based on these band gaps show that the efficiency of a multi-junction solar cell based on layered structures using a fast pulse 150T magnet we measure the band structure change due to the structural phase transition that occurs in this system at around 160K. We also observe Landau levels in the high temperature phase as used for device production, which has a very similar effective mass and the analysis suggests an exciton binding energy which is even smaller than in the low temperature phase.

9:48AM L34.00010 Tuning Fermi Level Beyond the Intrinsic Equilibrium Doping Limit through Quenching: the Case in CdTe1, JI-HUI YANG, JI-SANG PARK, JOONGOO KANG, WYATT METZGER, TERESA BARNES, SU-HUAI WEI, National Renewable Energy Lab — The ability to tune the Fermi levels is of great importance for many electronic device applications. However, the Fermi level is often limited to a certain range in the band gap due to the existence of certain intrinsic compensating defects. Here, we demonstrate that quenching can be used as an effective way to overcome this limit and tune the Fermi levels in a much wider range. Taking a photovoltaic material, CdTe, as a prototype example, we analyzed the physical origin behind the Fermi level pinning and explain why growing the sample at high temperature and then rapidly quenching it to room temperature can overcome the self-compensation limit. We show that for CdTe, quenching can enlarge the Fermi level range from only 0.6 eV to 1.1 eV, which has a great potential in improving CdTe solar cell performance. Our proposed strategy of tuning Fermi level positions beyond intrinsic equilibrium doping limit is general and can be applied to other semiconductor systems.

10:00AM L34.00011 Photovoltaic efficiency of an indirect bandgap material, MICHELLE TOMASIK, NÍALL MANGAN, JEFFREY GROSSMAN, MIT — Photovoltaic materials with direct band gap transitions absorb light more readily than those with indirect gaps, allowing for thinner devices. However, direct bands also suffer faster rates of radiative recombination than indirect bandgap materials. Some novel photovoltaic absorber materials, such as tin sulfide, have both direct and indirect gaps. Such materials raise the question of whether the multiple energy states benefit or harm device efficiency. We develop a model for current in a device with direct and indirect band gaps using detailed balance, similar to the Shockley-Queisser model for direct band photovoltaics. We explore the effects of the following on device performance: transition probability of carriers between the direct and indirect state, and relative transport rate in each band.

10:12AM L34.00012 Ab initio modeling of the optical properties in organometallic halide perovskites for photovoltaic applications1, AMANDA NEUKIRCH, WAN YI NEI, Los Alamos National Laboratory, LAURENT PEDESSEAU, JACKY EVEN, Université Européenne de Bretagne, CLAUDINE KATAN, CNRS, Institut des Sciences Chimiques de Rennes, ADITYA MOHITE, SEGREGI TRETIAK, Los Alamos National Laboratory — The need for an inexpensive, clean, and plentiful source of energy has generated large amounts of research in an assortment of solution processed organic and hybrid organic-inorganic solar cells. A relative newcomer to the field of solution processed photovoltaics is the lead halide perovskite solar cell. In the past 5 years, the efficiencies of devices made from this material have increased from 3.5% to nearly 20%. Despite the rapid development of organic-inorganic perovskite solar cells, a thorough understanding of the fundamental photophysical processes driving the high performance of these devices is not well understood. I am using state-of-the-art ab initio computational techniques in order to characterize the properties at the interface of perovskite devices in order to aid in materials design and device engineering. I will present an in-depth analysis of the electronic and optical properties of bulk and surface states of pure and mixed halide systems. The high-level static quantum mechanical calculations, including spin-orbit-coupling and the many body GW approach, identify the key electronic states involved in photinduced dynamics. This knowledge provides important information on how the optical properties change with variations to the system.

1Supported by the DOE, the LANL LDRD program XW11, and CNLS.

10:24AM L34.00013 Band-Gap Tuning in Perovskite-type Ferroelectric ZnSnO₃ by Doping and Core-Shell Approach for Solar Cell Applications, CORISA KONS, ANUJA DATTA, Florida Cluster for Advanced Smart Sensor Technologies and Department of Physics, University of South Florida, PRITISH MUKHERJEE, Center for Integrated Functional Materials and Department of Physics, University of South Florida — Ferroelectric (FE) perovskite materials are an emerging class of potential absorbers in next generation solar cells due to their spontaneous polarization which facilitates electron-hole separation and drive charge carriers at opposite ends. With a large remnant polarization of \( \approx 59 \ \mu \text{C/cm}^2 \), perovskite-type LiNbO₃ (LN)-ZnSnO₃, containing earth abundant elements is of much interest as a high performance solar absorber. However, the wide band-gap in ZnSnO₃ (\( \sim 3.7 \) eV) is unsuitable to absorb the broad solar range, which can be overcome by band-gap engineering. Here, we discuss band-gap tuning through substitutional doping (Sb, Cu, Ca, Ba) in LN-type ZnSnO₃ nanorods, synthesized by a facile solvothermal process. A band-gap as low as 2.5 eV was obtained in 5 at.% Ca doped ZnSnO₃ nanorods showing superior FE properties. The current-voltage (\( I-V \)) measurements under light revealed multiple orders of enhancement as compared to the dark. The band-gap in ZnSnO₃ is also found to be a strong function of the lattice constant which is tuned by introducing a slight strain through lattice mismatching using a core shell approach. A detailed structural, optical, and FE analyses are predicted to predict the future of this technologically important material in next generation FE photovoltaics.

10:36AM L34.00014 Nanoscale optimization of quantum dot solar cells, YANSHU LI, ANDREI SERGEEV, NIZAMI VAGIDOV, VLADIMIR MITIN, State Univ of NY - Buffalo, KIMBERLY SABLON, Army Research Laboratory, STATE UNIV OF NY - BUFFALO TEAM, ARMY RESEARCH LABORATORY TEAM — Quantum dots (QDs) offer possibilities for nanoscale control of photoelectron processes via engineering the band structure and potential profile. Nanoscale potential profile (potential barriers) and nanoscale band engineering (AlGaAs atomically thin barriers) effectively suppress the photoelectron capture to QDs. QDs also increase conversion efficiency of the above-bandgap photons due to extraction of electrons from QDs via Coulomb interaction with hot electrons that excited by high-energy photons. To study the effects of the band structure engineering and nanoscale potential barriers on the photovoltaic performance we fabricated 3-\( \mu \text{m} \) base GaAs devices with various InAs quantum dot media and selective doping. All quantum dot devices show improvement in conversion efficiency compared with the reference cell. Quantum efficiency measurements allow us to associate the spectral characteristics of photoresponse enhancement with nanoscale structure of QD media. The dark current analysis provides valuable information about recombination in QD solar cells. The two-diode model well fit the scope of data and recovers the measured open circuit voltage.

10:48AM L34.00015 Theoretical study on single-phase stability and intrinsic defects in different Cu₂ZnSn(Se₁₋ₓSₓ)₄ (x = 0.25, 0.5, 1) alloys, PRANAB SARKER, MUHAMMAD N. HUDA, Department of Physics University of Texas at Arlington, Texas 76019 — Cu₂ZnSn(Se₁₋ₓSₓ)₄ (CZTSSe) alloy has been emerged as a potential next generation commercialized photovoltaic cell because of its higher solar-to-current efficiency (12.6 %) over parent compounds Cu₂ZnSnS₄ (CZTS) and Cu₂ZnSnSe₄ (CZTSe). However, the values of composition \( x \) in higher efficient CZTSSe (>1%) are not known yet. It has been inferred from the recent theoretical and experimental evidences that 0.375 \( \leq x \leq 0.625 \) (\( x = \text{alloy ratio per unit cell} \)) could be the range that poses to ensure higher PV efficiency in CZTSSe. The crystal structure of CZTSSe at those \( x \) values were determined using density functional theory. In addition, the probability of forming different intrinsic defects in those different CZTSSe alloys were evaluated at various growth conditions determined from chemical potential landscape analysis for the first time. Chemical potential landscape analysis further reveals that CZTSSe alloys have higher single phase stability than that of their parent structures.

Wednesday, March 4, 2015 8:00AM - 10:36AM
Session L35 DFD: Turbulence and Instabilities

8:00AM L35.00001 Information theory used to study the turbulent cascade, RORY CERBUS, Okinawa Institute of Science and Technology, Fluid Mechanics Unit, WALTER GOLDBURG, University of Pittsburgh, Department of Physics and Astronomy — The simplest picture of turbulence is the one imagined by Richardson and Kolmogorov. In their theory there is a cascade of energy from large scales to small scales. Here we present a new tool to study this picture using simple ideas borrowed from information theory. We use the conditional entropy (conditioned uncertainty) of velocity fluctuations on one scale conditioned on another larger or smaller scale. By varying the scale of the velocity fluctuations used in the conditioning, we can test both direction and locality. The ideas are tested on both experimental and numerical simulation data. This tool can be applied to 3D turbulence or 2D turbulence and because it has nothing to do with the Navier-Stoke’s equation, it can be used for any other system where there is a similar cascade-like phenomenon.

1This work is supported by NSF Grant No. 1044105 and by the Okinawa Institute of Science and Technology (OIST).
8:12AM L35.00002 Mutually independent cascades in anisotropic soap-film turbulence, CHIEN-CHIA LIU, GUSTAVO GIOIA, PINAKI CHAKRABORTY, Okinawa Institute of Science and Technology — Computational, experimental and field data amassed to date indicate that in 2D turbulence the spectrum of longitudinal velocity fluctuations, \( E_1(k_1) \), and the spectrum of transverse velocity fluctuations, \( E_2(k_1) \), correspond always to the same cascade, consistent with isotropy, so that \( E_1(k_1) \propto k^{-5/3} \) and \( E_2(k_1) \propto k^{-5/3} \). The "spectral exponent" \( \alpha \) is either 5/3 (for the inverse-energy cascade) or 3 (for the enstrophy cascade). Here, we carry out experiments on turbulent 2D soap-film flows in which \( E_1(k_1) \propto k^{-5/3} \) and \( E_2(k_1) \propto k^{-5/3} \), as if two mutually independent cascades were concurrently active within the same flow. To our knowledge, this species of spectrum has never been observed or predicted theoretically. Our finding might open up new vistas in the understanding of turbulence.

8:24AM L35.00003 The spectral link in mean-velocity profile of turbulent plane-Couette flows, DONGRONG ZHANG, GUSTAVO GIOIA, PINAKI CHAKRABORTY, Okinawa Institute of Science and Technology — In turbulent pipe and plane-Couette flows, the mean-velocity profile (MVP) represents the distribution of local mean (i.e., time-averaged) velocity on the cross section of a flow. The spectral theory of MVP in pipe flows (Gioia et al., PRL, 2010) furnishes a long-surmised link between the MVP and turbulent energy spectrum. This missing spectral link enables new physical insights into an imperfectly understood phenomenon (the MVP) by building on the well-known structure of the energy spectrum. Here we extend this theory to plane-Couette flows. Similar to pipe flows, our analysis allows us to express the MVP as a functional of the spectrum, and to relate each feature of the MVP relates to a specific spectral range: the buffer layer to the dissipative range, the log layer to the inertial range, and the wake (or the lack thereof) to the energetic range. We contrast pipe and plane-Couette flows in light of the theory.

8:36AM L35.00004 Reinforcement of steady streaks for consecutive transition delay\(^1\), SOHRAB S. SATTARZADEH, JENS H. M. FRANSSON, Linnaeus Flow Centre, KTH Mechanics — Miniature vortex generators (MVGs) are recently proven efficient as passive control devices to delay the transition to turbulence on a flat plate boundary layer by modulating the base flow in the spanwise direction, through generating steady streamwise elongated streaks, and hence reducing the skin-friction drag. As the MVGs are localized in the streamwise direction, a shortcoming of the passive laminar control is the recovery of the two-dimensional boundary layer which force the control effects to fade away. In the present study we show that by placing a second array of MVGs downstream of the first one the streamwise extent of the control can be prolonged by reinforcing the steady streaks in the streamwise direction. The reinforced passive control strategy results in consecutive turbulence transition delay with obtaining a net skin-friction drag reduction of 65\%, for the present measurement conditions, compared to the smooth plate boundary layer.

\(^1\)Support from the European Research Council (ERC) is acknowledged.

8:48AM L35.00005 Numerical study of turbulent transport at high Reynolds number in Richtmyer-Meshkov instability in an ICF like geometry, POOJA RAO, JEREMY MELVIN, RYAN KAUFMAN, HYUNKYUNG LIM, YAN YU, JAMES GLIMM, Stony Brook University, DAVID SHARP, Los Alamos National Lab — We study mixing in high Reynolds (Re) number flows in numerical simulations of a Richtmyer-Meshkov instability in an idealized ICF geometry. We propose that LES simulations of these turbulent flows have an underlying dependence on the numerical algorithm and this possible non-uniqueness emphasize the need for parameter free models to allow extrapolation from validation of Re in the experimental range. Using the front-tracking code FronTier (validated for Rayleigh-Taylor data at Re=35k) in combination with the dynamic subgrid-scale models proposed by Germano, we achieve a parameter free model to allow for this extrapolation step. Under this simulation framework, we discuss the properties of the mixing and document the sensitivity of the subgrid terms to the numerical algorithm.

9:00AM L35.00006 Measuring the orientation and rotation rate of 3D printed particles in turbulent flow, GREG VOTH, Wesleyan Univ, STEFAN KRAMEL, BRENDAN COLE, Wesleyan University — The orientation distribution and rotations of anisotropic particles plays a key role in many applications ranging from icy clouds to papermaking and drag reduction in pipe flow. Experimental access to time resolved orientations of anisotropic particles has not been easy to achieve. We have found that 3D printing technology can be used to fabricate a wide range of particle shapes with smallest dimension down to 300 \( \mu \)m. So far we have studied rods, crosses, jacks, tetrads, and helical shapes. We extract the particle orientations from stereoscopic video images using a method of least squares optimization in Euler angle space. We find that in turbulence the orientation and rotation rate of many particles can be understood using a simple picture of alignment of both the vorticity and a long axis of the particle with the Lagrangian stretching direction of the flow.

9:12AM L35.00007 Lattice-Boltzmann Simulation of Tablet Dissolution in Complex Hydrodynamic Environment, JIAOLOONG JIANG, NING SUN, Materials Science and Engineering Department, Stony Brook University, Stony Brook, NY, 11794, USA, TAESHN PARK, GLEN H. KO, RES Group Inc., 1 Broadway, Cambridge, MA, 02142, USA, DILIP GERSAPPE, Materials Science and Engineering Department, Stony Brook University, Stony Brook, NY, 11794, USA — Using the Lattice-Boltzmann method, we developed a 3D model to study the tablet dissolution process in a complex hydrodynamic environment involving spatially varying velocity and shear forces. The results show that a turbulent flow is formed in the region above the tablet, which has been obtained by visualization experiments. The dissolution profiles were obtained by incorporating detailed kinetics, showing good agreement with case studies from literature. After studying the influence of the paddle speed and the size of the system, we simulated the dissolution process for multicomponent tablets. Our results indicate how the hydrodynamic environment would affect the dissolution process by changing the local concentration of components near the tablet as well as by the particle erosion under high fluid velocity. Since the code was successfully parallelized, the simulation for comparatively large systems is possible now.

9:24AM L35.00008 Three Dimensional Characterization of Quantum Vortex Dynamics in Superfluid Helium, DAVID MEICHLE, DANIEL LATHROP, University of Maryland — Vorticity is constrained to line-like topological defects in quantum superfluids, such as liquid Helium below the Lambda transition. We have invented a novel method to disperse fluorescent nanoparticles directly into the super-fluid which become trapped on the vortex cores, providing optical tracers. Using a newly constructed multi-camera stereographic microscope, we present data dynamically characterizing vortex reconnections and the subsequent emission of Kelvin waves fully in three dimensions. Statistics of thermally driven counterflow will be compared in 3D to previous measurements in projection.

9:36AM L35.00009 The Importance of Nonlocal Terms in Superfluid Turbulence, RENA ZIEVE, OWEN DIX, University of California, Davis — Simulations of vortex motion in superfluid helium based on the Biot-Savart law plus vortex reconnections can model homogeneous superfluid turbulence. However, the quantitative properties of the turbulent tangle are disturbingly sensitive to details of how the computations are carried out, and in some cases the tangle degenerates unphysically into an arrangement of parallel straight vortices. These problems have been attributed to the reconnection procedure, to the periodic boundary conditions used for most calculations, and to the localized induction approximation (LIA) which often replaces the (non-local) Biot-Savart integral. Previous work using numerical calculation of the complete Biot-Savart integral does not show the same issues as the LIA calculations, but these are time-consuming calculations. We show here that numerical integration over a relatively small region can suffice, as long as the size of the region exceeds the typical intervortex spacing. This result explains why the non-local contribution has a strong effect. It contributes an attraction between nearby vortices that ultimately leads to reconnections, which prevent the vortices from settling into an array of parallel lines.
9:48AM L35.00010 Study of Grid Turbulence in Superfluid He\textsuperscript{4} in a Large Square Channel\textsuperscript{1}.

JHIEE YANG, GARY C. IHAS, University of Florida, WILLIAM F. VINE, University of Birmingham — Studying quantum turbulence in superfluid helium can lead us to a deeper understanding in classical turbulence. We study grid-generated turbulence in liquid helium in the temperature range 1.4 K-2.1 K for homogeneous and isotropic turbulence (HIT). Using a conventional second sound attenuation method, the decay of vorticity ($\omega$) is observed in a long, square cross-section channel. Theories assume that energy is injected on the scale of the grid mesh size, and predict that when the energy containing eddies are growing, the vorticity decays as $\omega \sim t^{-11/6}$ for $\omega \sim t^{-17/14}$. When they saturate at the channel size, the vorticity begins decaying as $\omega \sim t^{-11/2}$. Previous experiments have been performed in 1 cm$^2$ square channels, with a limited range of mesh sizes. We have used a larger channel and various mesh sizes to investigate grid mesh size effects and decay before saturation. A novel phase and amplitude locked feedback system ensures fast, stable attenuation data without disturbances from temperature fluctuations.

\textsuperscript{1}US NSF DMR #1007937 and EPSRC EP /H04762X/1.

10:00AM L35.00011 Observation of the Stratorotational Instability in Flow between Rotating Concentric Cylinders\textsuperscript{1}.

RYU IBANEZ, HARRY L. SWINNEY, University of Texas at Austin, BRUCE RODENBORN, Centre College — We study the stratorotational instability in a Taylor-Couette system with a radius ratio $\eta = r_o/r_i = 0.877$. The system is vertically stratified with a constant buoyancy frequency, $N = \sqrt{-g/(\rho_o/\rho_i)(\partial \rho/\partial z)}$. We determine when the flow becomes unstable as the ratio of the outer to inner cylinder rotation rates, $\mu = \Omega_o/\Omega_i$, is decreased from unity (solid body rotation), for Reynolds numbers $Re = \Omega_i r_i (r_o - r_i)/\nu$ ranging from 450 to 4000 and $N/2r = 0.3$ to 1.0 Hz. The axial and azimuthal frequencies, obtained from spatiotemporal spectral analysis of digital movies, yield the observed modes at different Re and $\mu$ for fixed $N$. We find for sufficiently large buoyancy frequency, $N/2r > 0.5$ Hz, the stratorotational instability occurs even above the $\mu = \eta$ stability limit obtained from theory developed in the Boussinesq (small $N$) approximation [cf. the review by D A Shalybkov, \textit{Physics Uspekhi} 52, 915 (2009)]. The frequencies we obtain for the azimuthal modes are close to multiples of the average frequency of rotation of the cylinders, while the axial wavelengths are found to vary linearly with Froude number, $Fr = \Omega_i/N$.

\textsuperscript{1}Supported by The Sid W. Richardson Foundation

10:12AM L35.00012 Stability analysis of an electrified liquid jet in the presence of an externally coflowing liquid. VENKAT GUNDABALA, VIKRANT MODI, Indian Institute of Technology Bombay, GUNDABALA MICROFLUIDICS GROUP TEAM — Traditionally, electrospraying and electrospaying are carried out with either air or vacuum as external medium. Recently, it has been shown that electrospRAY can be successfully implemented in the presence of an external flowing liquid. We envisage that implementation of electrospraying process in the presence of an external liquid coflowing with the electrospraying solution will allow greater control on the fiber deposition and morphology. In the present work, to gain fundamental understanding on the behaviour of an electrified liquid jet in the presence of an externally coflowing liquid, we perform stability analysis on the system. The classical Rayleigh-Plateau instability and an electrically induced axisymmetric instability were identified. The effect of the viscosity, velocity, and permittivity of the ambient liquid on the stability of the two instabilities was studied. It was found that both the growth rate and the critical wavenumbers were strongly influenced by the above parameters. An operating diagram predicting the transition from drop generation mode to fiber generation mode as a function of external liquid properties is generated.

10:24AM L35.00013 An adaptive selective frequency damping method\textsuperscript{1}. BASTIEN JORDI, COLIN COTTER, SPENCER SHERWIN, Imperial College London — The selective frequency damping (SFD) method is used to obtain unstable steady-state solutions of dynamical systems. The stability of this method is governed by two parameters that are the control coefficient and the filter width. Convergence is not guaranteed for arbitrary choices of these parameters. Even when the method does converge, the time necessary to reach a steady-state solution may be very long. We present an adaptive SFD and show that by modifying the control coefficient and the filter width along the solver execution, we can reach an optimum convergence rate. This method is based on successive approximations of the dominant eigenvalue of the flow studied. We design a one-dimensional model to select SFD parameters that enable us to control the evolution of the least stable eigenvalue of the system. These parameters are then used for the application of the SFD method to the multi-dimensional flow problem. We apply this adaptive method to a set of classical test cases of computational fluid dynamics and show that the steady-state solutions obtained are similar to what can be found in the literature. Then we apply it to a specific vortex dominated flow (of interest for the automotive industry) whose stability had never been studied before.

Wednesday, March 4, 2015 8:00AM - 11:00AM – Session L36 GSOFT: Focus Session: Reconfiguring and Actuating Soft Matter I: Metamaterials

8:00AM L36.00001 Buckling in a topological metamaterial. ANINE MEEUSSEN, JASYN PAULOSE, VINCENZO VITTELLI, Univ of Leiden — Controlling the nonlinear response of mechanical metamaterials paves the way toward designing materials with adaptive and tunable mechanical properties. Buckling, a change in load-bearing state from axial compression to off-axis deformation, is a ubiquitous nonlinear instability that is often exploited to change the local or global mechanical response in metamaterials composed of slender elements. We create localized buckling regions in cellular metamaterials by engineering states of self-stress, regions where the response is dominated by stretching or compression of the constituent beams rather than bending at the stiff hinges connecting them. Unique to our approach is the use of topological states of self-stress, which originate in a topological invariant that characterizes the vibrational spectrum of the repeating unit cell. Unlike typical states of self-stress which result from additional geometric constraints induced by excess beams in a region, these topological states do not change the number of beams at each hinge. We demonstrate the phenomenon through numerical calculations of the linear response of the proposed metamaterial, and through experiments probing the nonlinear regime including localized buckling at specific regions.

8:12AM L36.00002 Holey Sheet! A Programmable Mechanical Metamaterial. BASTIAAN FLORIJN, CORENTIN COULAI, MARTIN VAN HECKE, Leiden University — We probe the mechanics of BiHolar metamaterials, 2D elastic media with a square lattice of circular holes of two different sizes. Biaxial loading of these BiHolar structures leads to a wealth of mechanical responses, including mechanically switchable hysteresis and memory effects. We show that we can program the mechanical response with the loading force and the hole size ratio\textsuperscript{[1]}

\textsuperscript{[1]}Bastiaan Florijn, Corentin Coulais, and Martin van Hecke, Phy. Rev. Lett. 113, 175503 (2014)
Tunable acoustic metamaterials

D. ZEB ROCKLIN, University of Michigan, Department of Physics, BRYAN CHEN, Instituut-Lorentz, Leiden University, MARTIN FALK, Massachusetts Institute of Technology, TOM LUBENSKY, University of Pennsylvania, Physics and Astronomy, VINCENZO VITELLI, Instituut-Lorentz, Leiden University — Mechanical lattices under periodic boundary conditions with coordination $z = 2d$, where $d$ is the spatial dimensionality, and with a gapped phonon spectrum at all wavenumbers not equal to zero are isostatic. When cut, these lattices with $N$ sites in two dimensions necessarily have of order $N^{1/2}$ zero modes on their boundaries. Recently, Kane and Lubensky showed that these systems can be described by a super-symmetric Hamiltonian analogous to that of the Su-Schrieffer model for polyacetylene and they identified a topological invariant, the topological polarization, that determines on which edges zero modes lie in finite systems. We show that a family of two-dimensional four-site-per-unit-cell isostatic lattices possess topologically protected bulk zero modes. These “Weyl modes” are novel, tunable low-energy mechanisms of the mechanical lattice. They are the analogs of the zero-energy electronic modes of topological semimetals. We discuss how adjusting the lattice parameters induces Weyl modes and alters their wavevectors (generally incommensurate with the lattice) and how they can transport zero modes from one edge to an opposite one as surface wavenumber varies. An accompanying talk discusses the novel dynamical properties of the system.

Reversible Shape Memory Optical Gratings

QIAOXI LI, CARY TIPPETS, YULAN FU, Univ of NC - Chapel Hill, EUGENE DONEV, Seawee: The University of the South, SARA TURNER, VALERIE ASHBY, RENE LOPEZ, SERGEI SHEIKO, Univ of NC - Chapel Hill — Recent advancements in the understanding of the mechanisms that control shape memory in semi-crystalline polymers, has led to the development of protocols that allow for reversibility in complex shape transformations. The shift between two programmable shapes is reversible without applying any external force. This is made possible by thermodynamically driven relaxation of extended polymer chains on heating is then inverted by kinetically preferred pathways of polymer crystallization on cooling. Reversible shape-shifting was applied to modulation of photonic gratings to create hands-free reversibly tunable optical elements. We have fabricated a sub-micron ratio optical square grating that presents reversible magnitude changes of its diffraction intensity (up to about 38% modulation) when subject to changes in temperature. This result is attributed to programmable changes in the grating height due to reversible shape memory and is repeatable over multiple cycles. Besides, roughness-induced variations in scattering signal observed upon heating-cooling cycles may offer another way to monitor kinetics of polymer melting and crystallization. Grants: NSF DMR-1407645, A. CHEN, R. SOORYAKUMAR, Ohio State Univ - Columbus — Photonic crystals and diffraction gratings are key components in color displays, bio/chemical sensors and security coded documentation, among others. Most magnetically responsive photonic crystals rely on electrostatic repulsion and magnetic attraction between constituent particles to tune the inter-particle spacing and thus, their resulting optical signatures. We present a 2D tunable diffraction device based on an all magnetic confinement and manipulation scheme previously developed for fluid borne magnetic dipoles (Scientific Reports 3, 3124 (2013)). The confinement platform consists of thin-film permanent magnets patterned on a silicon surface and a precessing magnetic field. By adjusting the orientation of the field, inter-particle dipolar and trap confinement forces are tuned, thereby enabling the confined magnetic beads to repel or attract one another. A bench top epi-illumination microscope delivers a narrow incident light cone that is diffracted and subsequently imaged. We investigate the white light diffraction from beads in various overall confining potentials, as a function of the orientation of the magnetic field. The presence of the confining potential and field-tunable inter-particle spacing gives rise to a wide range of tunable diffraction patterns.

Effects of graphene on electro-optic switching and spontaneous polarization of a ferroelectric liquid crystal

RAJ TARANT BASU, US Naval Academy — A small quantity of graphene flakes was doped in a ferroelectric liquid crystal (FLC), and the field-induced ferroelectric electro-optic switching was found to be significantly faster in the FLC+graphene hybrid than that of the pure FLC. Further studies revealed that the suspended graphene flakes enhanced the FLC’s spontaneous polarization by improving smectic-C ordering resulting from the pi-electron stacking, and reduced rotation viscosity by trapping some of the free ions of the FLC media. These effects coherently impacted the FLC-switching phenomenon, enabling the FLC molecules to switch faster on reversing an external electric field.

Effects of graphene on electro-optic response and ion-transport in a nematic liquid crystal

DANIEL KINNAMON, ALFRED GARVEY, RAJ TARANT BASU, US Naval Academy — A small quantity of graphene flakes was doped in a nematic liquid crystal (LC), and the nematic electro-optic switching was found to be significantly faster in the LC+graphene hybrid than that of the pure LC. Additional studies revealed that the presence of graphene reduced the free ion concentration in the nematic media by ion-trapping process. The reduction of mobile ions in the LC was found to have subsequent impacts on the LC’s conductivity and rotational viscosity, allowing the nematic director to respond faster on switching the electric field on and off.
10:00AM L36.00011 Sound and Noisy Light: Optical Control of Phonons in Photo-switchable Structures. SOPHIA SKLAN, JEFFREY GROSSMAN, Massachusetts Inst of Tech-MIT. We present a novel means of controlling phonons via optical tuning. Taking as a model an array of photoresponsive materials (photowitches) embedded in a matrix, we numerically analyze the vibrational response of an array of bistable harmonic oscillators with stochastic spring constants. Changing the intensity of light incident on the lattice directly controls the composition of the lattice and therefore the speed of sound. Furthermore, modulation of the phonon bandstructure at high frequencies results in a strong confinement of phonons. The applications of this regime for phonon wave-guides, vibrational energy storage, and phononic transistors is examined.

10:12AM L36.00012 Meta-Atom Interactions and Coherent Response in rf SQUID Metamaterials. MELISSA TREPANIER, DAIMENG ZHANG, University of Maryland, OLEG MUKHANOVA, Hynes, PHILIPP JUNGSUSANNE BUTZ, Karlsruhe Institute of Technology, V.P. KOSELETS, IEEE, ALEXEY USTINOVA, Karlsruhe Institute of Technology, STEVEN ANLAGEA, University of Maryland. An rf SQUID (radio frequency superconducting quantum interference device) metamaterial can be modeled as an array of coupled nonlinear oscillators with resonant frequencies that are extremely tunable with temperature, dc magnetic field, and rf current. The metamaterial is driven by an external rf field and its response to that field defines its metamaterial characteristics. In the presence of disorder (nonuniform applied dc magnetic flux for instance) the SQUIDs may or may not oscillate coherently in response to the external rf field. Since we are interested in metamaterial applications, a strong coherent response is desirable. The coherence is affected by a variety of factors including flux uniformity, array size, degree of coupling, strength of the driving field, and uniformity in SQUID parameters. In this talk we will present experimental and simulation results exploring the effect of these parameters on coherence.

10:24AM L36.00013 ABSTRACT WITHDRAWN —

10:36AM L36.00014 Combinatorial 3D Mechanical Metamaterials. CORENTIN COULAIS, Univ of Leiden, EIAL TEOMY, Tel-Aviv University, KOEN DE REUS, Univ of Leiden, YAIR SHOKEF, Tel-Aviv University, MARTIN VAN HECKE, Univ of Leiden / AMOLF. We present a class of elastic structures which exhibit 3D-folding motion. Our structures consist of cubic lattices of anisotropic unit cells that can be tiled in a complex combinatorial fashion. We design and 3d-print this complex ordered mechanism, in which we combine elastic hinges and defects to tailor the mechanics of the material. Finally, we use this large design space to encode smart functionalities such as surface patterning and multistability.

10:48AM L36.00015 Mechanical topological matter. LISA NASH, DUSTIN KLECKNER, University of Chicago, VINCENTO VITHELLI, Instituut-Lorentz, Leiden University, ARI M. TURNER, Johns Hopkins University, WILLIAM T.M. IRVINE, University of Chicago. Topologically protected states can arise in electronic systems with broken time-reversal symmetry. We present a classical mechanical model for a solid in which broken time-reversal symmetry gives rise to topologically protected edge-modes, analogous to the edge modes in the quantum Hall effect. We will discuss numerical and experimental observations of these chiral edge-modes, their topological characterization, robustness and broader phenomenology.

Wednesday, March 4, 2015 8:00AM - 11:00AM –
Session L37 GQI: Focus Session: Semiconductor Qubits - Electrically Controlled Quantum Dots 212A - Charles Marcus, University of Copenhagen

8:00AM L37.00001 Addressable single-spin control in multiple quantum dots coupled in series. TAKASHI NAKAJIMA, RIKEN Center for Emergent Matter Science – Electron spin in semiconductor quantum dots (QDs) is promising building block of quantum computers for its controllability and potential scalability [1]. Recent experiments on GaAs QDs have demonstrated necessary ingredients of universal quantum gate operations: single-spin rotations by electron spin resonance (ESR) which is virtually free from the effect of nuclear spin fluctuation [2], and pulsed control of two-spin entanglement [3]. The scalability of this architecture, however, has remained to be demonstrated in the real world. In this talk, we will present our recent results on implementation of single-spin-based qubits in triple, quadruple, and quintuple QDs based on a series coupled architecture defined by gate electrodes. Deterministic initialization of individual spin states and spin-state readout were performed by the pulse operation of detuning between two neighboring QDs. The spin state was coherently manipulated by ESR, where each spin in different QDs is addressed by the shift of the resonance frequency due to the inhomogeneous magnetic field induced by the micro magnet deposited on top of the QDs. Control of two-spin entanglement was also demonstrated. We will discuss key issues for implementing quantum algorithms based on three or more qubits, including the effect of a nuclear spin bath, single-shot readout fidelity, and tuning of multiple qubit devices. Our approaches to these issues will be also presented. This research is supported by Funding Program for World-Leading Innovative R&D on Science and Technology (FIRST) from JSPS, IARPA project “Multi-Qubit Coherent Operations” through Copenhagen University, and Grant-in-Aid for Scientific Research from JSPS.

8:36AM L37.00002 Multi-qubit read-out of spin qubits in GaAs in a CCD like manner: the Spin qubit CCD. TIM BAART, MOHAMMAD SHAFIEI, JULES VAN OVEN, Kavli Institute of Nanoscience, Delft University of Technology, CHRISTIAN REICHL, WERNER WEGSCHEIDER, Solid State Physics Laboratory, ETH Zurich, LIENEN VANDERSYPEN, Kavli Institute of Nanoscience, Delft University of Technology. Efficient implementation and characterization of quantum information protocols requires the ability to measure multiple qubits individually and in a single-shot manner. We reported a succesful demonstration of two-qubit read-out in [1]. We now demonstrate the next step by reading out three individual spin qubits formed by a linear array of three quantum dots where each electron forms a single spin qubit. We introduce several strategies for multi-qubit measurements in dot arrays and demonstrate and implement the following protocol experimentally. We first read-out the right qubit using standard spin-to-charge conversion [2]. Next we shuttle the centre electron to the right dot and read out its spin state. Afterwards we shuttle the left qubit through the centre dot to the right, and complete the three-qubit read-out. Due to its resemblance with reading out a CCD, we coin this the Spin qubit CCD. This is the first demonstration of reading out multiple qubits through the same reservoir and allows scaling to larger arrays of qubits.

Biasing modes, the Hamiltonian has an especially simple form, which can directly generate a wide range of different entangling gates including the iSWAP gate. In which the system can be biased, and use the representation of its nonlocal properties in terms of local invariants. We find that, in one of the possible trajectories. Furthermore, we prepare different states using these gates and determine their fidelities. In our experiment this calibration routine succeeds in removing systematic gate errors to a high degree while increasing the pulses’ decoherence. We extract the Bloch sphere trajectories of the resulting gate sequences using self-consistent state tomography and find good agreement with the theoretically predicted trajectories. 

Fernando Calderon-Vargas, Jason Kestner, University of Maryland Baltimore County — In view of recent experimental demonstration of entanglement in capacitively coupled singlet-triplet qubits, we address the open question of what type of entangling gates the system’s Hamiltonian can produce directly via a single square pulse. In the analysis we consider the system’s Hamiltonian from first principles, incorporating the three different ways in which the system can be biased, and use the representation of its nonlocal properties in terms of local invariants. We find that, in one of the possible biasing modes, the Hamiltonian has an especially simple form, which can directly generate a wide range of different entangling gates including the iSWAP gate. 

Moreover, using the complete form of the Hamiltonian we find that, for any biasing mode, a CNOT gate can be generated directly.

Xin Wang, Condensed Matter Theory Center, University of Maryland, College Park, Edwin Barnes, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park — Precise execution of quantum gates acting on two or multiple qubits is essential to quantum computation. For semiconductor spin qubits coupled via capacitive interaction, the best fidelity for a two-qubit gate demonstrated so far is around 70%, insufficient for fault-tolerant quantum computation. In this talk we present control protocols that may substantially improve the robustness of two-qubit gates against both nuclear noise and charge noise. Our pulse sequences incorporate simultaneous dynamical decoupling protocols and are simple enough for immediate experimental realization. Together with existing control protocols for single-qubit gates, our results constitute an important step toward scalable quantum computation using spin qubits.

This work is done in collaboration with Sankar Das Sarma and supported by LPS-NSA-CMTCT and IARPA-MQCO.

Jeroen Danon, Mark Rudner, Niels Bohr Inst. — We study multi-photon resonances in a strongly-driven three-level quantum system, where one level is periodically swept through a pair of levels with constant energy separation $E$. Near the multi-photon resonance condition $n \omega_0 = E$, where $n$ is an integer, we find qualitatively different behavior for $n \geq 2$. We explain this phenomenon in terms of families of interfering trajectories of the multi-level system. Remarkably, the behavior is insensitive to fluctuations of the energy of the driven level, and survives deep into the strong dephasing regime. The setup can be relevant for a variety of solid state and atomic or molecular systems. In particular, it provides a clear mechanism to explain recent puzzling experimental observations in strongly-driven double quantum dots.

Peter Stano, Riken Center for Emergent Matter Science, Wako, Saitama, Japan, Jelena Klinovaja, Floris Braakman, Department of Physics, Kinglerbergstrasse 82, University of Basel, Switzerland, Lieven Vandersypen, Kavli Institute of Nanoscience, TU Delft, 2600 GA Delft, The Netherlands, Daniel Loss, Department of Physics, Kinglerbergstrasse 82, University of Basel, Switzerland — We investigate theoretically the long-distance coupling and spin exchange in an array of quantum dot spin qubits in the presence of microwaves. We find that photon assisted tunnelling is boosted at resonances between photon and energy of virtually occupied excited states and show how to make it spin selective. We identify configurations that enable fast switching and spin echo sequences for efficient and non-local manipulation of spin qubits. We devise configurations in which the near-resonantly boosted tunnelling provides non-local coupling which, up to certain limit, does not diminish with distance between the manipulated dots before it decays weakly with inverse distance.

9:48AM L37.00008 Efficient suppression of Overhauser field fluctuations with DNP. Robert McNeil, Tim Botzem, Stefanie Tenberg, JARA Institute for Quantum Information, RWTH-Aachen University, Sebastian Rubbert, Kavli Institute of Nanoscience Delft, Delft University of Technology, Hendrik Bluhm, JARA Institute for Quantum Information, RWTH-Aachen University — In certain spin-qubit schemes the Overhauser field is a tuned control parameter and in many spin qubits this fluctuating nuclear field is a significant factor limiting coherence. Nuclear spins can be driven via dynamic nuclear polarisation (DNP) to a chosen field and selective feedback applied narrowing the distribution of nuclear Overhauser field fluctuations[1]. The achievable narrowing of the Overhauser field is related to the maximum pump rate and previous experiments on gated GaAs quantum dots were limited by the pump rate of the pumping mechanism used. We present a method to reduce nuclear fluctuations by increasing the maximum achievable pump rate. Sequentially applying two ac electric fields with frequencies slightly detuned from the desired Larmor frequency results in a pump curve with a stable fixed point. In the absence of spin-orbit interaction, driving electron spin flips via electric dipole spin resonance (EDSR)[2] will also drive nuclear spin flips and this scheme is expected to result in stronger pumping and efficient suppression of the Overhauser field fluctuations. We will present experimental evidence of this driven nuclear polarization including tracking of EDSR resonances. 1. Bluhm, et al. PRL 105, 216803 ('10) 2. Laird, et al. PRL 99, 246601 ('07)

10:00AM L37.00009 Anisotropy and quadrupolar effects on dephasing in two-electron spin qubits in GaAs. Tim Botzem, Robert McNeil, Hendrik Bluhm, JARA-Institute for Quantum Information, RWTH Aachen University. D-52074 Aachen, Germany — Understanding the dynamics of nuclear spins causing decoherence of gate-defined two-electron spin qubits in GaAs is a crucial prerequisite for a potential use in quantum computation. We present B-field dependent Hahn echo measurements giving new insight on the mechanism causing dephasing due to the nuclear spin bath of the host material GaAs. By rotating the magnetic field inplane we discover two effects ultimately limiting coherence times. We find that the anisotropy of the nuclear spins and electrical fields contributes to broadening of the nuclear Lamor frequencies, which in turn degrades electron coherence. By rotation the magnetic field towards the [100] direction, we can minimize this effect, but an additional envelope modulation that can be attributed to a electron g-factor anisotropy occurs.
Pumping of Dynamic Nuclear Polarization in GaAs Double Quantum Dots

Wednesday, March 4, 2015 8:00AM - 11:00AM
Session L38 GQI: Focus Session: Quantum Algorithms 212B - Nathan Wiebe, Microsoft Research
8:48AM L38.00005 Quantum learning robust to noise1, JOHN SMOLIN, ANDREW CROSS, GRAEME SMITH, IBM T J Watson Res Ctr — Noise is often regarded as anathema to quantum computation, but in some settings it can be an unlikely ally. We consider the problem of learning the class of n-bit parity functions by making queries to a quantum example oracle. In the absence of noise, quantum and classical parity learning are easy and almost equally powerful, both information-theoretically and computationally. We show that in the presence of noise this story changes dramatically. Indeed, the classical learning problem is believed to be intractable, while the quantum version remains efficient. Depolarizing the qubits at the oracle’s output at any constant nonzero rate does not increase the computational (or query) complexity of quantum learning more than logarithmically. However, the problem of learning from corresponding classical examples is the Learning Parity with Noise (LPN) problem, for which the best known algorithms have superpolynomial complexity. This creates the possibility of observing a quantum advantage with a few hundred noisy qubits. The presence of noise is essential for creating this quantum-classical separation.

9:00AM L38.00006 Quantum algorithm for topological and geometric analysis of data, SETH LLOYD, MIT, PAOLO ZANARDI, University of Southern California, SILVANO GARNERONE, IQC University of Waterloo — Topological methods for analyzing data sets provide a powerful technique for extracting useful information from data. Data that represents geometric features of the world typically gives a distorted picture of those features, if only because the devices and systems that sense the world and that generate the data by their very nature induce distortions. By definition, topological features are those that persist under continuous distortions of the data. Topological methods can therefore identify features of the real system from which the data was collected, but that have been distorted by the data collection process. Persistent homology is a sophisticated tool for identifying such topological features—connected components, holes, or voids—and for determining how such features persist as the data is viewed at different scales. This talk presents quantum machine learning algorithms for calculating Betti numbers in persistent homology, and for finding eigenvectors and eigenvalues of the combinatorial Laplacian (the quantities that famously allow one to “hear the shape of a drum”). The algorithms provide an exponential speedup over classical algorithms for topological and geometrical data analysis.

9:12AM L38.00007 On the Chemical Basis of Trotter-Suzuki Errors in Quantum Chemistry Simulation, RYAN BABBUSH, JARROD MCCLEAN, Harvard University, DAVE WECCKER, Microsoft Research, ALÁN ASPURU-GUZIK, Harvard University, NATHAN WIEBE, Microsoft Research — Although the simulation of quantum chemistry is one of the most anticipated applications of quantum computing, the scaling of known upper bounds on the complexity of these algorithms is daunting. Prior work has bounded errors due to Trotterization in terms of the norm of the error operator and analyzed scaling with respect to the number of spin-orbitals. However, we find that these error bounds can be loose by up to sixteen orders of magnitude for some molecules. Furthermore, numerical results for small systems fail to reveal any clear correlation between ground state error and number of spin-orbitals. We instead argue that chemical properties, such as the maximum nuclear charge in a molecule and the filling fraction of orbitals, can be decisive for determining the cost of a quantum simulation. Our analysis motivates several strategies to use classical processing to further reduce the required Trotter step size and to estimate the necessary number of steps, without requiring additional quantum resources. Finally, we demonstrate improved methods for state preparation techniques which are asymptotically superior to proposals in the simulation literature.

9:24AM L38.00008 Simulating Hamiltonian Dynamics with a Truncated Taylor Series, ROLANDO SOMMA, Los Alamos National Laboratory — One of the main motivations for quantum computers is their ability to efficiently simulate the dynamics of quantum systems. Since the mid-1990s, many algorithms have been developed to simulate Hamiltonian dynamics on a quantum computer, with applications to problems such as simulating spin models and quantum chemistry. While it is now well known that quantum computers can efficiently simulate Hamiltonian dynamics, ongoing work has improved the performance and expanded the scope of such simulations. In this talk, I will describe a very simple and efficient algorithm for simulating Hamiltonian dynamics on a quantum computer by approximating the truncated Taylor series of the evolution operator. This algorithm can simulate the time evolution of a wide variety of physical systems. The cost of this algorithm depends only logarithmically on the inverse of the desired precision, and can be shown to be optimal. Such a cost also represents an exponential improvement over known methods for Hamiltonian simulation based on, e.g., Trotter-Suzuki approximations. Roughly speaking, doubling the number of digits of accuracy of the simulation only doubles the complexity. The new algorithm and its analysis are highly simplified due to a technique for implementing linear combinations of unitary operations to directly apply the truncated Taylor series. This is joint work with Dominic Berry, Andrew Childs, Richard Cleve, and Robin Kothari.

10:00AM L38.00009 Scaling of Quantum Walks on Complex Networks1, STEFAN BOETTCHER, STEFAN FALKNER, Physics Dept., Emory University, RENATO PORTUGAL, Laboratório Nacional de Computação Científica — I will describe the renormalization group method (RG) as applied to master equations with a unitary propagator. It allows to determine many asymptotic properties of quantum walks, although I will focus here on the walk dimension d_w, which describes the similarity solution, p(x,t) ∼ f(|x|/d_w)^t, for the probability density function p. We can calculate d_w to arbitrary accuracy for a number of networks, such as the dual Sierpinski gasket, small-world Hanoi networks, or Migdal-Kadanoff lattices, which we have verified with direct simulations. However, due to unitarity, the asymptotic solution of the RG equations as well as procedures to implement RG approximately for arbitrary walks remain elusive. Yet, based on the exact RG for the nearest neighbor walk, we can conjecture a few general conclusions, for instance, that d_w for a discrete-time quantum walk is always half of that for the random walk on the same r-regular network, when driven with the Grover coin. (This talk summarizes our work in http://dx.doi.org/10.1103/PhysRevA.90.032324 and http://arxiv.org/abs/1410.7034.)

10:12AM L38.00010 An Easy Method for Finding the Scattering Coefficients of Quantum Graphs and Some Applications, SETH COTTRELL, New York Univ NYU — Quantum walks are roughly analogous to classical random walks, and like classical walks they have been used to find new (quantum) algorithms. When studying the behavior of large graphs or combinations of graphs it is often useful to find the response of a subgraph to signals of different frequencies. In this talk I’ll be presenting a simple technique for quickly finding the scattering coefficients of any quantum graph. This is done by imitating the scattering states using normalizable states on a modified version of the graph. These scattering coefficients can be expressed entirely in terms of the characteristic polynomial of the graph’s time-step operator. With these coefficients in hand we can replace an entire subgraph with a single vertex whose behavior is frequency dependent. This gives us a powerful set of tools for rapidly understanding the behavior of more complex structures. Time permitting, I will apply these tools to several types of graphs (star, complete, tree) demonstrating how we can gain information about the structure of these graphs by bouncing signals off of them, describing the limitations on what information cannot be accessed, and even show how to construct some computations using quantum walks that can be run in faster than classical time.

10:24AM L38.00011 Variational Quantum Eigensolver: How to Use Any Quantum Device in Your Lab to Perform Quantum Simulation, JARROD MCCLEAN, Harvard University — Quantum devices offer a way to simulate and study states that currently cannot be efficiently stored or manipulated on classical computers. Unfortunately, many quantum algorithms designed to simulate such states are prohibitively expensive in terms of quantum resources such as coherence time. In this talk I will review a recently introduced technique, the Variational Quantum Eigensolver, that has minimal coherence and can utilize any quantum device capable of basic state preparation and measurement for a quantum advantage in the simulation of physical quantum states. I will also introduce the problem of simulation of molecular systems in quantum chemistry and discuss recent advances in understanding and reducing the costs associated with this problem in our and related algorithms.
HENDRIK MEIER, RICHARD T. BRIERLEY, ANGELA KOU, STEVEN M. GIRVIN, LEONID I. GLAZMAN, Yale University — We investigate a long chain of inductively coupled Josephson junctions penetrated by an external magnetic field. In the limit of infinite junction capacitances, we determine the classical ground state and find that the competition between Josephson and inductive forces leads to a rich phase diagram as a function of magnetic flux per plaquette $\phi_0$ and the ratio $F = E_J/E_L$ of Josephson ($E_J$) and inductive ($E_L$) energies. At large $\ell$, kinks in the superconducting phase set in as a function of $\phi_0$, similarly to vortices in type-II superconductors. Upon further increasing $\phi_0$, the interplay between kink-kink interaction and pinning on the lattice leads to a Frenkel-Kontorova-type (devil’s) staircase of phases distinguished by different rational kink densities. At $\phi_0$, equal to half a flux quantum, the system bears similarity to a classical Ising antiferromagnet, possibly with a long-ranged exchange. Inclusion of a finite junction capacitances is similar to placing the Ising chain in a transverse magnetic field (the quantum Ising model). Using this similarity, we investigate the quantum dynamics of a chain of fluxonium qubits.

8:12AM L39.00002 Ground states and excitations of inductively coupled fluxonium qubits, R.T. BRIERLEY, H. MEIER, A. KOU, I.I. GLAZMAN, S.M. GIRVIN, Yale University — We consider fluxonium qubits arranged in a one dimensional array, where the inductors are shared between neighboring qubits. For an infinite system with small charging energies, there are a series of different phases that depend on the applied magnetic flux and the ratio of the inductive and Josephson energies. For small flux and large Josephson energy, the behavior of the classical ground state is similar to the Frenkel-Kontorova model, while when the flux is half a flux quantum it is similar to an Ising antiferromagnet. A realistic finite system will not exhibit a phase transition but some features of the infinite-size limit should persist. We investigate theoretically the ground and low-lying excited states for experimentally relevant parameters. We discuss how the nature of the ground state changes, and what experimental signatures would be expected.

8:24AM L39.00003 Reentrant Behavior in A Multi-connected Superconducting Jaynes-Cummings Lattice, LIN TIAN, KANGJUN SEO, School of Natural Sciences, University of California, Merced, CA 95343, USA — Superconducting quantum devices have excellent connectivity, tunable coupling and long decoherence time as demonstrated by recent experiments. These devices provide a powerful platform for constructing analog quantum simulators to study novel many-body effects. Here we present a multi-connected Jaynes-Cummings lattice model, where the qubits and the resonators are connected alternately. In a one-dimensional configuration, this model bears an intrinsic symmetry between the left and the right qubit-resonator couplings under a mirror reflection. Different from the coupled cavity array (CCA) model, the qubit-resonator couplings in this model induce both onsite Hubbard nonlinearity and hopping of the excitations along the lattice. By analyzing this model in the limiting cases of very different couplings, we show that this model demonstrates a Mott insulator–superfluid–Mott insulator transition at commensurate fillings with symmetric critical points. The reentry to the Mott insulator phase originates from the symmetry between the couplings.

8:36AM L39.00004 Phase Diagram of A Multi-connected Superconducting Jaynes-Cummings Lattice at Commensurate and Incommensurate Fillings, KANGJUN SEO, LIN TIAN, School of Natural Sciences, University of California, Merced, CA 95343, USA — A multi-connected superconducting Jaynes-Cummings lattice can be constructed with alternatively-connected superconducting qubits and resonators. In a one-dimensional configuration, this model bears an intrinsic symmetry between the left and the right qubit-resonator couplings. Here we study the quantum phase transition of this model using the exact diagonalization method. At commensurate fillings, the off-diagonal long range order of the single-particle density matrix and the energy gap are calculated. We obtain the phase diagram of this model, which demonstrates a symmetry between the couplings and a reentry to the Mott insulator phase. For a system with given chemical potential, the density of the excitations contains integer-valued plateaus between critical chemical potentials that define the boundaries of different many-body phases and indicate the phase transition. We also discuss the implementation of this model with superconducting devices, including the state preparation and detection schemes.

8:48AM L39.00005 Simulating an Interacting Quantum Gas with Superconducting Circuits, CHRISTOPHER EICHLER, JONAS MLYNEK, JONAS BUTSCHER, PHILIPP KURPIERS, ETH Zurich, TOBIAS OSBORNE, Gottfried Wilhelm Leibniz Universität Hannover, ANDREAS WALLRAFF, ETH Zurich — The high level of control achievable over quantized degrees of freedom have turned superconducting circuits into one of the prime physical architectures for quantum computing and simulation. While conventional approaches towards quantum information processing mostly rely on unitary time evolution, more recently open-system dynamics are considered for quantum simulations. In this talk, I will present experiments in which we use an open cavity QED system with tunable interactions to simulate the ground state of an interacting Bose gas confined in one dimension [1,2]. These experiments rely on the ability to efficiently measure higher order photon correlations of the cavity output field. For this purpose we have developed a quantum limited amplifier achieving phase-preserving amplification at large bandwidth and high dynamic range [3]. Our results explore a different path towards the simulation of complex quantum many-body physics based on the controlled generation and detection of nonclassical radiation in an open quantum system.

9:00AM L39.00006 Many-body localization in a quantum system subject to a local periodic drive, CANRAN XU, MAXIM VAVILOV, Univ of Wisconsin, Madison — We consider a one dimensional spin chain system with quenched disorder and in the presence of a local harmonic drive. We study the time evolution of the system in the Floquet basis and evaluate the Bures displacement of the system in the Hilbert space caused by the drive per one period. This displacement can be used to identify two phases of the system: (1) the many-body localized phase, in which the distribution of the distance exhibits long tails while its average value decreases rapidly as disorder increases; and (2) the ergodic phase, in which the displacement distribution is narrow and its average value weakly depends on disorder. This distinction in the average value of the displacement between the two phases develops readily for system with ten or more spins. Therefore, recently built networks of superconducting qubits subject to a local microwave drive can simulate dynamics of a system in the many-body localization regime.

9:12AM L39.00007 Localization vs. delocalization of waves in circuit QED. BRUNO G. TAKETANI, FRANK K. WILHELM, Saarland University — Wave localization in disordered media is an important phenomenon arising from the destructive interference of waves from the many scatterers in the medium. However, interaction between localized modes may counteract this effect and lead to a localization-delocalization transition. Understanding this interplay between disorder and interaction is of great importance. We investigate this interplay using quasiperiodic JJA.

9:24AM L39.00008 Site-wise manipulations induced phase transitions of interacting photons using superconducting circuit simulators1, XIUHAO DENG, School of Natural Sciences, University of California Merced, CHUNJING JIA, Department of Applied Physics, Stanford University, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator, CHIH-CHUN CHIEN, School of Natural Sciences, University of California Merced — The Bose Hubbard model (BHM) of interacting bosons in a lattice has been a paradigm in many body physics. Here a quantum simulator of the BHM using a superconducting circuit is proposed. Specifically, a superconducting transmission line resonator supporting microwave photons is coupled to a charge qubit to form one site of the BHM, and adjacent sites are connected by a tunable coupler. To obtain a mapping from the superconducting circuit to the BHM, we focus on the dispersive regime where the excitations remain photon-like. Standard perturbation theory is implemented to locate the parameter range where the BHM can be simulated. This simulator allows single-site manipulations and we illustrate this feature by considering two scenarios where a single-site manipulation can drive a Mott insulator-superfluid transition. The critical point of the transition can be located by mean-field analyses and the exact diagonalization method was implemented to provide accurate results. The variance of the density and the fidelity metric clearly show signatures of this transition. Experimental realizations and other possible applications of this simulator are also discussed.

9:36AM L39.00009 Classical chaos and its correspondence in superconducting qubits. C. NEILL, B. CAMPBELL, Z. CHEN, B. CHIARO, A. DUNSWORTH, M. FANG, I. HOI, J. KELLY, A. MEGRANT, P. O’MALLEY, C. QUINTANA, A. VAINSENCHER, J. WENNER, T. WHITE, UC Santa Barbara, R. BARENDRES, YU CHEN, A. FOWLER, E. JEFFREY, J. MUTUS, P. ROUSHAN, D. SANK, J.M. MARTINIS, Google, Santa Barbara — Advances in superconducting qubits have made it possible to experimentally investigate quantum-classical correspondence by constructing quantum systems with chaotic classical limits. We study the quantum equivalent of a classical spinning top using three fully coupled qubits that behave as a single spin-3/2 and subject the spin to a sequence of non-linear rotations. The resulting entanglement bears a striking resemblance to the classical phase space, including bifurcation, and suggests that classical chaos manifests itself as quantum entanglement. Studying the orientation of the spin-3/2 reveals that the rotations which generate chaos and entanglement are at the same time the source of disagreement between the quantum and classical trajectories. Our experiment highlights the correspondence between classical non-linear dynamics and interacting quantum systems.

9:48AM L39.00010 Quantum simulation with arrays of transmon qubits: Ising dynamics1. VINAY RAMASESH, SHAY HACOHEN-GOURGY, QNL, University of California, Berkeley, THOMAS KIENDL, FLORIAN MARQUARDT, Institut for Theoretical Physics, Universität Erlangen-Nürnberg, Staudtstraße 7, D-91058 Erlangen, Germany, NATHAN SIWAK, CHRISTOPHER RICHARDSON, Laboratory for the Physical Sciences - University of Maryland, College Park, IRFAN SIDDIQI, QNL, University of California, Berkeley — Chains of coupled qubits are known to realize the transverse-field Ising Hamiltonian in the two-level approximation. In this model, the qubit transition frequencies map onto the external magnetic field, so the ground and excited states play the role of spin-up and spin-down atoms. We implement this structure in a planar, on-chip architecture, with a one dimensional linear array of capacitively-coupled transmon qubits, where the two terminal qubits are dispersively coupled to microwave independent resonators for state readout. We present spectroscopic data and describe coherent manipulations in the array.

1This work is supported by the AFOSR.

10:00AM L39.00011 Quantum simulation with an array of transmon qubits: Bose-Hubbard model1. SHAY HACOHEN-GOURGY, VINAY RAMASESH, QNL, University of California, Berkeley, CLAUDIA DE GRANDI, STEVEN GIRVIN, Departments of Physics and Applied Physics, Yale University, IRFAN SIDDIQI, QNL, University of California, Berkeley — Chains of capacitively-coupled transmons can emulate the Bose-Hubbard Hamiltonian when one considers the full level-structure of the circuit. Here, each individual transmon plays the role of a lattice site, with the excitation level of each transmon corresponding to the number of bosons occupying that particular site. The transmon’s anharmonicity gives rise to the attractive contact-interaction term, while the capacitive coupling realizes the hopping amplitude. We implement such a chain of 3 capacitively-coupled transmons in a single 3D microwave cavity. In our parameter regime, the ground state of the 3-excitation subspace is one in which all excitations lie on a single qubit. Using cavity-assisted bath engineering, it should be possible to cool from an initial state in this subspace to the ground state. We present the current status of this goal.

10:12AM L39.00012 Perturbative scanning probe microscopy on a Kagome lattice of superconducting microwave resonators, DEVIN UNDERWOOD, Princeton University, WILL SHANKS, IBM, ANDY C.Y. LI, JENS KOCH, Northwestern University, ANDREW HOUCK, Princeton University — Microwave photons confined to a lattice of coupled resonators, each coupled to its own superconducting qubit have been predicted to exhibit matter like quantum phases. Realizing such a lattice-based quantum simulator presents a daunting experimental challenge; as such, new tools and measurement techniques are a necessary precursor. Here, we present measurements of the internal mode structure of microwave photons on a 49-site Kagome lattice of capacitively-coupled coplanar waveguide resonators without qubits. By scanning a probe with a sapphire tip over the surface of a single lattice site, the resonant frequency was detuned, thus forming a local defect in the lattice. This perturbation resulted in measurable shifts in the lattice spectrum, which were used to extract the mode weights at the perturbed site. By perturbing each lattice site it was possible to reconstruct a complete map of different normal mode weights within the entire lattice. Additionally we present experimental evidence of a frustrated flat band that arises from the Kagome lattice geometry.

10:24AM L39.00013 Perturbative study of interacting photons in open lattices, ANDY C.Y. LI, Northwestern University, FRANCESCO PETRUCCIONE, University of KwaZulu-Natal and National Institute for Theoretical Physics, JENS KOCH, Northwestern University — Quantum simulation realized in the circuit QED architecture is an emerging direction to study many-body physics in open lattice systems. Among several models of interacting photons, the driven-dissipative Jaynes-Cummings (JC) lattice is commonly employed to investigate the steady-state and dynamical behavior. While there is a wealth of analytical and numerical tools applicable to closed lattice systems in thermal equilibrium, the number of methods to treat open lattice systems is rather limited. Hence, many properties of open lattices remain an open question. Here, we formulate a general perturbation theory and an infinite-order resummation scheme applicable to open lattices. We then apply this theory to the driven-dissipative JC lattices to predict steady-state expectation values. This allows us to explore the rich features due to photon-qubit interaction and compare results obtained for finite chains and infinite lattices.
10:36 AM L39.00014 Experimental Study of a Disordered Jaynes-Cummings Lattice , MATTIAS FITZPATRICK, DEVIN UNDERWOOD, DARIUS SADRI, Princeton University, JENS KOCH, Northwestern University, ANDREW HOUCK, Princeton University — Circuit quantum electrodynamics (cQED) is an exciting testbed for simulation of open quantum systems. Effective photon-photon interactions can be mediated by a superconducting qubit strongly coupled to a microwave transmission line cavity. Many-body quantum simulators can be realized using Jaynes-Cummings systems, where a competition is induced between onsite interactions and hopping between sites. In this experiment, we present measurements of a Kagome lattice consisting of 49 microwave cavity resonators and 49 transmon qubits. We fabricate each qubit with random area superconducting quantum interference devices (SQUIDs) to create qubits with different sensitivity to magnetic field. This allows us to simultaneously tune all of the qubits randomly with the application of a single external magnetic field, enabling a systematic study of the effects of disorder. We will present preliminary experimental results from this Kagome lattice as well as future directions of quantum simulation using Jaynes-Cummings lattices.

Wednesday, March 4, 2015 8:00AM - 11:00AM – Session L41 DPOLY DMP: Focus Session: Organic Electronics and Photonics - Transport in Polymer Thin Films 214A - Barry Rand, Princeton University

8:00 AM L41.00001 Changes in the Solution Behavior of Conjugated Polymers with Light Absorption , MARK DADMUN, BRIAN MORGAN, University of Tennessee — Conjugated polymers are well established as functional materials in a broad range of applications including organic photovoltaics, chemical sensors, and organic light emitting diodes. This functionality is mainly derived from their ability to create electron-hole pair excitons through photoexcitation. The presence of these entities on the polymer chains may alter the chain conformation, solution behavior, and ultimately macroscopic morphology, of the conjugated polymer. Previous studies have shown significant changes in properties such as viscosity and photooluminescence upon exposure of select conjugated polymer films to white light. In order to expand upon these preliminary findings, we have performed small angle neutron scattering experiments on solutions of several semiconducting, conjugated polymers in both the presence and absence of incident light. Substantial differences are observed between the light vs dark samples, the magnitude of which are dependent on polymer dispersion, solvent choice, and solution concentration. Analysis of the neutron curves shows real difference in Kuhn lengths and radius of gyration of the polymer, suggesting possible rearrangement of polymer chain conformation or alteration of polymer chain-solvent interactions.

8:12 AM L41.00002 Correlating Transport with Nanostructure and Chemical Identity in Radical Polymer Conducting Glasses , BRYAN BOUDOURIS, LIZBETH ROSTRO, ADITYA BARADWAJ, MARTHA HAY, Purdue University — Radical polymers are an emerging class of macromolecules that are composed of non-conjugated backbones which bear stable radical groups at the pendant positions. Because of these stable radical sites, these glassy materials are able to conduct charge in the solid state through a series of oxidation-reduction (redox) reactions. Importantly, the redox-active behavior is controlled by both the local chemical environment of the radical polymer groups and by the nanoscale structure of the materials. Here, we demonstrate that proper control of the pendant group chemical functionality allows for the fabrication of transparent and conducting amorphous thin films which have solid-state hole mobility and electrical conductivity values on the same order as those seen in common conjugated, semicrystalline polymer systems [e.g., poly(3-hexylthiophene) (P3HT)]. Furthermore, we show that control of the nanostructure of the materials aids in facilitating transport in these radical polymer thin films. In turn, we implement simultaneous spectroscopic and electrical characterization measurements in order to elucidate the exact mechanism of charge transport in radical polymers. Finally, we demonstrate that, because there is ready control over the molecular properties of these materials, developing bendable and stretchable transparent conducting thin films is relatively straightforward with this unique class of organic electronic materials.

8:24 AM L41.00003 Using NEXAFS spectroscopy to probe the Biaxial Orientation of a Pyridal[2,1,3]thiadiazole-containing Donor-Acceptor Polymer , SHRAYESH PATEL, GREG SU, CHAN LUO, MING WANG, ALAN HEEGER, GUILLERMO BAZAN, MICHAEL CHABINYC, EDWARD KRAMER, UC Santa Barbara; Mitsubishi Chemical - Center for Advanced Materials — Near Edge X-ray Absorption Fine Structure (NEXAFS) spectroscopy is a powerful tool to probe the molecular orientation of conjugated polymer thin films. Here, we report on the biaxial orientation of a high mobility donor-acceptor copolymer coated on uniaxial nanogrooved substrates. The polymer system under investigation is regioregular PCDTPT based on cyclopenta[2,1-b:3,4-b]dithiophene (CDT) and pyridal[2,1,3]thiadazole (PT) structural units. In partial electron yield mode, NEXAFS spectroscopy is a surface sensitive technique (~2-3 nm). This is particularly useful as we are interested in probing the orientation near the interface between the polymer and the substrate. While the carbon K-edge is commonly used for NEXAFS experiments, we can take advantage of the PT unit and use the nitrogen K-edge to probe the biaxial orientation of our films. We will present the biaxial orientation of films coated on substrates with and without uniaxial nanogrooves. The results indicate that the presence of uniaxial nanogrooves are important in obtaining films with high level of orientation. Lastly, anisotropic field-effect transistor mobility values will be presented for various coating conditions.

8:36 AM L41.00004 Percolation, tie-lines, and the microstructural determinants of charge transport in semicrystalline conjugated polymers , ANDREW SPAKOWITZ, Stanford University — Semiconducting polymers play an important role in a wide range of optical and electronic material applications. It is widely accepted that the polymer ordering impacts charge transport in such devices. However, the connection between molecular ordering and device performance is difficult to predict due to the current need for a mathematical theory of the physics that dictates charge transport in semiconducting polymers. Here, we present a new analytical and computational description in which the morphology of individual polymer chains is dictated by well-known statistical models and the electronic coupling between units is determined using Marcus theory. This effort combines our research group’s modeling efforts in polymer conformational properties and reaction-diffusion phenomena to address the multiscale dynamics of charge transport in a heterogeneous material. The resulting model is capable of bridging molecular-level charge transport mechanisms to large scale transport behavior, thus facilitating direct comparison with experiments. The multiscale transport of charges in these materials (high mobility at short length scales, low mobility at long length scales) is naturally described with our framework. Additionally, the dependence of mobility with electric field and temperature is explained in terms of conformational variability and spatial correlation. Our model offers a predictive approach to connecting processing conditions with transport behavior.
9:12AM L41.00005 Charge motion in Poly(3-hexylthiophene-2,5-diyl) studied with Scanning Probe Microscopy1, JASON MOSCATELLO, CHLOE CASTANEDA, KATHERINE AIDALA, Mount Holyoke College — Organic semiconductors like poly(3-hexylthiophene-2,5-diyl) offer the promise of solution-processable, flexible electronics, but the charge motion in these disordered films is not fully understood. We use Kelvin Probe Force Microscopy (KPFM) to study trapped charges in the channel of inverted field effect transistors and have developed a technique to measure real time screening. The tip of the AFM is placed at a specific location above the sample with grounded source and drain electrodes, and the potential of the surface is recorded using KPFM. When a voltage is applied to the back gate, charges will move to screen this potential. For materials with relatively low charge density and mobility, it will take some time of amount to fully screen. The tip will initially measure the potential of the voltage applied to the back-gate, which will decrease as charges enter the film. The shape and timescales of this decrease reveal information about injection barriers and traps in the material. Our data suggest that we are observing holes entering and exiting trap states as the gate voltage is turned on and off. Other factors, such as aging, increase the timescales of the screening.

9:24AM L41.00006 Probing charge delocalization in a semi-crystalline supramolecular polymer, KEEHOON KANG, SHUN WATANABE, KATRINA BROCH, Cavendish Laboratory, University of Cambridge, Cambridge, U.K., DAIUSKE MATSUMOTO, KAZUHIRO MARUMOTO, Division of Materials Science, University of Tsukuba, Japan, HISAAKI TANAKA, SHIN-ICHI KURODA, Department of Applied Physics, Nagoya University, Japan, MARTIN HEENEY, Department of Chemistry, Imperial College, London, U.K., HENNING SIRRINGHAUS, Cavendish Laboratory, University of Cambridge, Cambridge, U.K. — Various doping methods have achieved metallic conductivity in π-conjugated polymer but most of them suffer from dopant-induced disorder. We developed a simple and effective method of doping a high mobility semi-crystalline polymer, poly(2,5-bis(3-hexadecylthiophen-2-yl)-thieno[3,2-b]thiophene) (pBTBT) by forming a bi-layer with a small-molecule acceptor, 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F4-TCNQ). The doping realizes an efficient charge transfer between pBTBT and F4-TCNQ (conductivity over 150 S/cm), while preserving the structural order of a pristine pBTBT. The charges are discovered to be sufficiently delocalized to give rise to a nearly-ideal Hall effect, and therefore, a coherent transport in a wide temperature range. Graphene was used as the back contact material, and the charge density was measured to be approximately 8 cm-2 per room temperature. The combination of a Pauli magnetic susceptibility and magnetococonductance signatures strengthen the evidence of weak localization in the supramolecular system. Comparison with other amorphous conducting polymers elucidates the role of structural order as an indicator of the degree of charge delocalization.

9:36AM L41.00007 A Blend Approach to P3HT Based Field Effect Transistor Performance Enhancement via Inclusion of 2,5-bis(3-dodecylthiophen-2-yl)thieno[3,2-b]thiophene: PING-HSUN CHU, Georgia Institute of Technology, LEI ZHANG, University of Massachusetts, Amherst, JUNG OK PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology, ALEJANDRO L. BRISEÑO, University of Massachusetts, Amherst, ELSA REICHMANIS, Georgia Institute of Technology — Improved OFET performance through a polymer-small molecule semiconductor blend approach was demonstrated. However, a number of serious issues remain. For example, the threshold voltage (Vth) of the blend OFETs is still at a relatively high value (Vth) > 10V), which is incompatible with most of portable electronics. Moreover, electrode treatment or thermal annealing is required to avoid a sacrifice in the device performance. However, a small molecule, 2,5-bis(3-dodecylthiophen-2-yl)thieno[3,2-b]thiophene (BTTT), is proposed to be incorporated within poly(3-hexylthiophene) (P3HT) polymer thin-films and is demonstrated to lead to over 50% improvement in charge carrier mobility. The resultant blend OFETs exhibit approximately 5-fold increase in charge carrier mobility, 10-fold increase in on-off current ratio and concomitantly, controlled the Vth as low as 1.7 V. It is worth noting that no pre- or post-treatment is required during the blend OFET fabrication process. Further, the thin-film deposition was conducted under ambient conditions using a volatile low boiling point solvent, suggesting a promising method for low-cost, high-throughput, large-area flexible device fabrication under non-stringent conditions.

9:48AM L41.00008 Probing electric fields within organic transistors by nonlinear optics1, PAULO B. MIRANDA, SILVIA G. MOTTI, DOUGLAS J. C. GOMES, Instituto de Fisica de Sao Carlos, Universidade de Sao Paulo, Brazil — Organic field-effect transistors (OFETs) are important building blocks in many organic devices, but further improvements in their performance will require a detailed knowledge of their operation mechanism. Thus mapping the electric fields in OFETs, both in the active organic layer and inside the gate dielectric, will allow a direct comparison with theoretical OFET models and guide advances in device engineering. The nonlinear optical processes of sum-frequency generation (SFG) and second-harmonic generation (SHG) may be used to probe electric fields in OFETs. With a proper choice of pump wavelength, SHG can selectively probe the field component along the OFET channel, inside the organic semiconductor. In contrast, SFG may probe the field within any organic material by selecting a specific molecular vibration and monitoring the field-enhanced SFG signal. Here we investigate OFETs fabricated with a polythiophene derivative (P3HT) on silicon substrates and with the insulating polymer PMMA for the dielectric layer. Both the strength and sign of the electric field in PMMA can be determined, yielding a direct probe of charge accumulation along the OFET channel. An extension of this technique to map the spatial distribution of accumulated charge along the channel will also be discussed.

1Work funded by FAPESP and CNPq (Brazil)

10:00AM L41.00009 Sub-threshold charge transport in polymer transistors, SEOHEE KIM, The University of Texas at Austin, TAE-JUN HA, Kwangwoon University, PRASHANT SONAR, Queensland University of Technology, ANANTH DODABALAPUR, The University of Texas at Austin — Research on polymer transistors has taken center stage due to their promise for use in displays, large-area electronics, and sensors. Most transistors with disordered semiconductor active layers such as amorphous silicon and polymers, have a large density of bulk trap states. Sub-threshold conduction in such transistors is very important. In particular, charge transport in the drift-limited sub-threshold regime is important and has not been adequately investigated. In this work, we will present an analysis of sub-threshold charge transport in polymer transistors with active layers based on the diketopyrrolopyrrole (DPP) core. Such transistors possess room temperature field-effect mobilities of over 2 cm2/Vs. We present an analysis of both above threshold and below threshold charge transport and show how the transport mechanisms change with temperature and charge density. We will also discuss a method to correctly calculate the density of trap states by sub-threshold modeling.

10:12AM L41.00010 High Performance Short-Channel Organic Field-Effect Transistors with Graphene Electrodes1, NARAE KANG, SAIFUL I. KHONDAKER, NanoScience Technology Center and Department of Physics, University of Central Florida — Organic Field-Effect Transistors (OFETs) have received a great deal of attention due to their easy-processing, low-cost, flexibility, and transparency that can lead to future electronic applications such as flexible display, solar cell, and sensors. One of the major challenges in fabricating high-performance OFETs is to reduce a large injection barrier formed at metal/organic interface, which results in poor electrical transport performance. In order to overcome this issue, graphene has been suggested as a promising electrode material for OFETs due to its unique electronic properties as well as strong π-π interaction with organic molecular, which can reduce the injection barrier at the electrode/organic interface. In this study, we fabricated short-channel OFETs using mechanically exfoliated graphene electrodes, and performed temperature dependent transport studies. We will present the detailed temperature dependent data and discuss the charge carrier injection mechanism at graphene/organic interface.

1US NSF Grant No. ECCS 1102228
10:24AM L41.00011 Charge transport in ion-gel gated IDTBT transistors. SHUN WANG, BEI BAO, XIANYI SHAO, LIU TAN, YUESHEN WU, LIBIN WEN, XUXU BAI, XIAOJUN GUO, YING LIU, Shanghai Jiao Tong University — Ionic liquids (ion gels) have been employed as the gate dielectric for polymer transistors due to its ultra-high capacitance. At high charge carrier density provided by ionic liquid gating, polymers like P3HT and PBTTT can exhibit very high mobility. We have fabricated ion-gel gated IDTBT transistors and measured its charge transport properties. We found that the mobility of ion-gel gated IDTBT transistors is greatly suppressed compared to the Cytop gated devices. At carrier density on the order of $10^{14}/$cm$^2$, IDTBT shows mobility of about 0.05 cm$^2$/V/s. Detailed analysis of the temperature dependence of resistivity shows 3D Mott variable range hopping in IDTBT at such carrier density, indicating a different charge transport mechanism from Cytop gated device.

10:36AM L41.00012 Conditions for the Formation of P3HT Organogels During Spin-Coating: Tuning Electrical Properties in Thin Films. CAMERON S. LEE, WEN YEN, Department of Chemistry, University of Texas, Austin — Development of hole-transporting copolymers for use in bulk heterojunctions (BHJs) has significantly improved organic solar cell performance. Despite advances on the materials side, the physics of charge carrier transport remains unsettled. Intrigued by its ability to maintain high fill factors in thick active layers, we studied the copolymer poly[(5-(4,4-diocytyl-4H-silolo)[3,4-b:5,6-b']dithiophen-2yl)-3-tetradecylthiophen-2-yl)] blended with P3HT:BM. Results show mobilities which are carrier-concentration-dependent and characterized by a negative Poole-Frenkel effect. Such behavior is not described by current carrier transport models. Established transport mechanisms like multiple-trap-and-release or variable range hopping yield dependence of mobility on carrier concentration. However, a more basic model like Gaussian distribution model (GDM) is needed to produce the negative Poole-Frenkel effect, though GDM cannot describe carrier-concentration-dependent mobility. We have combined key aspects of existing models to create a unified transport model capable of describing phenomena observed in P3TSiTzTz:PC$_7$BM. This model can be used to address open questions about transport physics of organic BHJ materials.

10:48AM L41.00013 Insights from transport modeling of unusual charge carrier behavior of PDTSiTzTz:PC$_7$BM bulk heterojunction materials. OLEKSIY SLOBODYAN, SARAH MOENCH, KELLY LIANG, ERIC DANIELSON, BRADLEY HOLLIDAY, ANANTH DODABALAPUR, Univ of Texas, Austin — Development of hole-transporting copolymers for use in bulk heterojunctions (BHJs) has significantly improved organic solar cell performance. Despite advances on the materials side, the physics of charge carrier transport remains unsettled. Intrigued by its ability to maintain high fill factors in thick active layers, we studied the copolymer poly[(5-[(4,4-diocytyl-4H-silolo)[3,4-b:5,6-b']dithiophen-2yl)-3-tetradecylthiophen-2-yl)] blended with P3HT:BM. Results show mobilities which are carrier-concentration-dependent and characterized by a negative Poole-Frenkel effect. Such behavior is not described by current carrier transport models. Established transport mechanisms like multiple-trap-and-release or variable range hopping yield dependence of mobility on carrier concentration. However, a more basic model like Gaussian distribution model (GDM) is needed to produce the negative Poole-Frenkel effect, though GDM cannot describe carrier-concentration-dependent mobility. We have combined key aspects of existing models to create a unified transport model capable of describing phenomena observed in P3TSiTzTz:PC$_7$BM. This model can be used to address open questions about transport physics of organic BHJ materials.

Session L42 DPOLY: Focus Session: Renewable and Sustainable Polymers 214B - Megan Robertson, University of Houston

8:00AM L42.00001 Ecobionanocomposites: Hierarchical supramolecular materials incorporating stereocomplexation. JOHN DORGAN, Colorado School of Mines — Polyactides (PLAs) are a leading class of renewable plastics with several favorable sustainability metrics. However, for many applications basic PLA has insufficient properties. The combination of nanoscopic filler particles can be combined with the phenomena of stereocomplexation to create a new class of hierarchically structured materials. Recent progress on the development of these novel ecobionanocomposites is discussed.

8:12AM L42.00002 Insights from transport modeling of unusual charge carrier behavior of PDTSiTzTz:PC$_7$BM bulk heterojunction materials. OLEKSIY SLOBODYAN, SARAH MOENCH, KELLY LIANG, ERIC DANIELSON, BRADLEY HOLLIDAY, ANANTH DODABALAPUR, Univ of Texas, Austin — Development of hole-transporting copolymers for use in bulk heterojunctions (BHJs) has significantly improved organic solar cell performance. Despite advances on the materials side, the physics of charge carrier transport remains unsettled. Intrigued by its ability to maintain high fill factors in thick active layers, we studied the copolymer poly[(5-[(4,4-diocytyl-4H-silolo)[3,4-b:5,6-b']dithiophen-2yl)-3-tetradecylthiophen-2-yl)] blended with P3HT:BM. Results show mobilities which are carrier-concentration-dependent and characterized by a negative Poole-Frenkel effect. Such behavior is not described by current carrier transport models. Established transport mechanisms like multiple-trap-and-release or variable range hopping yield dependence of mobility on carrier concentration. 8:36AM L42.00002 Positive effect of biaxial stretching on the mechanical behavior of PLA-Talc nanocomposites. SAADIA OUCHIAR, GREGORY STOCLET, Université de Lille 1 - UMET, CYRILLE CABARET, Ecomeris, VINCENT GLOAGUEN, Université de Limoges - LCSN, JEAN-MARC LEFEBVRE, Université de Lille 1 - UMET, UMET - ENGINEERING POLMER SCIENCE TEAM, UMET / ECMERIS COLLABORATION, UMET / LCSN COLLABORATION — Poly (Lactic acid) (PLA), a biodegradable polyester issued from renewable resources, appears as a good candidate for the replacement of petrochemical-based materials due to its good combination of physical properties. However, major drawbacks of PLA are its brittle behavior and its low thermal stability. One way to outclass these lacks consists in adding nanofillers into PLA. It is also recognized that the mechanical and barrier properties can be improved by biaxial drawing process. Consequently, this study deals with the enhancing effect of biaxial stretching on mechanical properties of Talc based PLA nanocomposites. The Talc content was varied between 0 to 30 wt%. This high level of talc results in a decrease in material cost, in addition to the enhancement of various physical properties. A main result is that neat PLA, which initially exhibit a brittle behavior upon uniaxial stretching at room temperature, become ductile after being biaxially stretched under appropriate conditions. More surprising is that the same behavior is observed for the filled samples. The origin of these enhancing properties will be also discussed.

8:48AM L42.00003 Manipulating Interactions in Cellulose Nanocrystal/Waterborne Epoxy Composites through Physical Mixing. MEISHA L. SHOFNER, School of Materials Science and Engineering, Georgia Institute of Technology, NATALIE M. GIROUARD, J. CARSON MEREDITH, School of Chemical and Biomolecular Engineering, Georgia Institute of Technology, GREGORY T. SCHUENEMAN, Forest Products Laboratory, USDA Forest Service — The objective of this research is to more fully understand the relationships between component interactions and processing pathways in cellulose nanocrystal (CNC)/polymer composite materials. Specifically, wood-derived CNC/waterborne epoxy composites with CNC loadings up to 15 wt.% were produced using two different protocols. Through relatively simple changes in processing, significant differences in CNC dispersion and composite physical properties were seen, and these changes were attributed to an association between the CNCs and the epoxy emulsion, similar in nature to colloidal halogen. Considering literature results available for CNC nanocomposites, as well as other types of polymer nanocomposites, these results support the assertion that the processing-structure-property relationships in such nanocomposites are diverse and can be used to design materials for a range of applications. Additionally, these results put into context the properties that can be expected in composites containing wood-based CNCs produced at a pilot scale facility as compared to CNCs from other cellulose sources produced a few grams at a time, making these results relevant to the production of CNC-based composites at larger volumes.

9:00AM L42.00004 Epoxy thermost set networks derived from vegetable oils and their blends1  
CHANG RYU, MATTHEW RAVALLI, Rensselaer Polytechnic Institute — Epoxidized vegetable oils (EVOs), such as epoxidized soybean oil and linseed oils were prepared by the partial oxidation of the unsaturated double bonds in vegetable oils and used as monomers for preparing epoxy thermost set materials based on the cationic polymerization. These EVOs have been used to prepare epoxy thermost sets of different network densities by cationic polymerization using onium salt catalyst. The crosslinked epoxy thermost sets provide an ideal platform to study the structure-property-relationships of networked polymers. In particular, rheological studies on the epoxidized vegetable oil thermost sets have been performed to measure the molecular weights between crosslinks (Mx) in the epoxy thermost sets and to ultimately elucidate the role of functionality of epoxy groups in EVO on the mechanical and thermophysical properties of the epoxy thermost set materials.

1 NSF DMR POLYMERS 1308617

9:12AM L42.00005 Structure-Property Relationships in Thiol-Ene Networks Composed of Plant-Derived Chemistry Ac. GUOZHEN YANG, HIRUY TESEFAY, MEGAN ROBERTSON, Univ of Houston — Polymer films prepared through thiol-ene chemistry are attracting increasing attention due to their ease of preparation and superior physical properties. We are investigating the properties of thiol-ene films which contain plant-derived allylated phenolic acids as substitutes to traditional petroleum-derived ene-bearing components. Phenolic acids are readily available through a variety of plant sources and contain rigid aromatic rings which contribute mechanical strength to the resulting polymer films. In this study, the properties of polymer films containing four phenolic acids were explored: salicylic acid, 4-hydroxybenzoic acid, gentisic acid and gallic acid. The allylated phenolic acids vary in the relative number and placement of the allyl groups used in the preparation of the polymer films, which impacts the resulting crosslinking density, glass transition temperature, and mechanical behavior of the polymer films. We have developed relationships between the chemical structures of the phenolic acids and the thermal and mechanical behavior of the polymer films.

9:24AM L42.00006 Polyester Vitrimers from Biosourced Lactones1  
JACOB BRUTMAN, PAULA DELGADO, MARC HILLMYER, University of Minnesota - Twin Cities — Crosslinked polymers with controllable healing characteristics have received significant attention over the last decade. However, there is still much to be developed with these materials in the sustainability arena. Herein, we studied the healing capabilities of crosslinked bioderived poly(lactones) through Lewis acid catalyzed transesterification reactions. Materials that use isodesmic reactions (e.g., transesterification) for healing are termed vitrimers and have been reported using a diverse range of chemistries. Our initial studies focused on the healing properties of amorphous star-shaped poly((±)-lactide) crosslinked with methylenediphenyl disocyanate in the presence of stannous(II) octoate. These materials exhibited remarkably fast stress relaxation rates when compared with previously reported polyester-based vitrimers, and exhibited similar stress relaxation rates at temperatures 140°C lower. Furthermore, the materials were able to recover their original tensile strengths post-healing by heating the system at 140°C for only 30 min. These results will be described in this presentation, as well as our ongoing research efforts on utilizing renewable crosslinkers, a variety of Lewis acid catalysts, and other amorphous polyesters derived from substituted lactates.

1 We acknowledge the Center for Sustainable Polymers at the University of Minnesota, a National Science Foundation supported Center for Chemical Innovation (CHE-1136607).

9:36AM L42.00007 Short-Range Correlation of Successive Helical Jump Motions of Poly(L-Lactic Acid) Chains as Revealed by Solid State NMR1  
WEI CHEN, TOSHIKAZU MIYOSHI, Department of Polymer Science, the University of Akron — Polylactide (i.e. Polyactic acid, PLA) is a renewable and biocompatible thermoplastic material, owning the largest market share among all biodegradable polymeric materials. Thus, understanding of microscopic structure and dynamics are definitively important subjects in further application. The helical jump motion in semi-crystalline polymers was proposed by Hoffmann et al to explain the αc relaxation in the crystalline region. So far, solid-state NMR proved that several semi-crystalline polymers such as polyethylene, isotactic-polypropylene, etc, show large amplitude motions in the crystalline regions. Additionally, successive helical jump motions may lead to long-range chain diffusions. Actually, chain diffusions are determined in terms of combinations of the overall jump rates and coupling degree of the jumps. Thereby, elucidations of correlations of the individual helical jump motions are also scientifically and practically important in further understanding dynamic nature of the crystalline chains and the structural evolutions of polymer crystals. Here, we utilize enter-bands only detection of exchange (CODEX) and 2D exchange NMR to characterize molecular dynamics of the crystalline chains in PLLA α phase. Dynamic geometry, correlation time, and short-range correlation of individual chain dynamics of PLLA in the crystalline region are for the first time reported.

9:48AM L42.00008 Rayleigh-Taylor Instability Analysis at Biobased Composite Interfaces1  
RICHARD WOOL, XINTIAN SU, Univ of Delaware — The Rayleigh-Taylor (RT) instability occurs when a light fluid (such as a gas) of density ρL forms an unstable interface with a heavy fluid of density ρH due to gravitational forces g in the heavy-over-light unstable configuration. The RT instability produces bubbles and spikes which grow with amplitude H ~ [gkM]1/2 in the linear region (Hk<<1) which evolves in a complex manner in the non-linear region (Hk>>1). Here, the wavenumber k = 2π/λ, λ = wavelength between instabilities, t = time, and the Atwood number A = (ρL−ρH)/(ρL+ρH). The RT instability is common in Inertial Confinement in Fusion reactions, Super Novas and for the first time reported here, in the interface of natural fibers with a liquid molding resin (soyoil) where the gas emitted from the natural fibers at T > 100°C explicitly forms and traps the bubbles and spike instabilities in the curing resin. The non-equilibrium spikes that form with A = 0.999 (Hk=1) are self-similar and behave as H = H0 + βtλ, where the initial instability height H0 = 11.6 micron and β = 1.0 (50 µm/s) for soy-based resins (ρL = 1.1 g/cm3). The RT spikes are typical of natural fibers less than 50 µm in diameter. The RT instability is a well-known phenomenon in other fields: the eco-leather is substantially lower viscosity compared to natural leather, polyurethane and PVC (Funded by EPA).

10:00AM L42.00009 Thermodynamic Interactions and Shear Alignment of Sustainable Tri-block Copolymers  
SHU WANG, MEGAN ROBERTSON1  
University of Houston, SAMEER VAJJALA KESAVA, ENRIQUE GOMEZ, Pennsylvania State University — Fatty acid-derived acrylates, lauryl acrylate (LAc) and stearyl acrylate (SAc), were utilized in the preparation of polystyrene-b-(LAc-co-SAc)-b-styrene) triblock copolymers. The thermodynamic interactions between polystyrene and the polycrylates were probed through rheology (determination of the order-disorder transition), cloud point measurements, and small angle neutron scattering. The Flory-Huggins interaction parameter was independent of the alkyl side-chain length when the side-chain contained greater than 10 carbon atoms. The thermal and mechanical properties of the triblock copolymers, which behave as thermoplastic elastomers, could be readily tuned by varying the acrylate composition, without changing the order-disorder transition temperature. Structural analysis revealed non-equilibrium spherical morphologies of the triblock copolymers, which transformed to highly-ordered cylindrical microstructures under large amplitude oscillatory shear at a temperature well below the order-disorder transition.

10:12 AM L42.00010 Structure and phase behavior of aqueous methylcellulose solutions, JOHN MCALLISTER, PETER SCHMIDT, TIMOTHY LODGE, FRANK BATES, University of Minnesota — Cellulose ethers (CE) constitute a multi-billion dollar industry, and have found end uses in a broad array of applications from construction materials, food products, personal care products, and pharmaceuticals for more than 80 years. Methylcellulose (MC, with the trade name METHOCEL TM) is a CE in which there is a partial substitution of –OH groups with –O–CH3 groups. This results in a polymer that is water-soluble at low temperatures, and aqueous solutions of MC display gelation and phase separation at higher temperatures. The nature of MC gelation has been debated for many years, and this project has made significant advances in the understanding of the solution properties of CEs. We have characterized a fibrillar structure of MC gels by cryogenic transmission electron microscopy (cryo-TEM) and small angle neutron scattering (SANS). Using light scattering, turbidity measurements, and dynamic mechanical spectroscopy (DMS) we report that MC microphase separates by nucleation and growth of fibril aggregates, and is a different process from LCST phase separation.

10:24 AM L42.00011 Water in Renewable Polymers: Nonequilibrium Thermodynamics1, YOSSEF ELABD, Texas A&M University — The design of polymers derived from sustainable resources (renewable plastics) as replacements to nonrenewable plastics for various applications will require an accurate assessment and fundamental understanding of the dynamics water sorption in glassy polymers. In this work, water sorption and diffusion in a number of glassy polymers (including the renewable polymer poly(lactide)) were measured using gravimetric and spectroscopic techniques. Non-Fickian diffusion was observed in all polymers studied, which was indicated by rapid, initial water uptake (driven by a concentration gradient), followed by continuous, gradual uptake of water at later experimental times (driven by slow polymer relaxation). Additionally, water sorption in these glassy polymers was predicted using two nonequilibrium thermodynamic models, where excellent agreement between the model prediction and experimental data was achieved for both models. Furthermore, contrasting physical pictures of water clustering were obtained between the Zimm-Lundberg theory and direct measurements.

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L43 DPOLY GSOFT GSNP: Focus Session: Stable Glasses, Fluids Under Confinement and at Interfaces 214C - Zahra Fakhraui, University of Pennsylvania

8:00AM L43.00001 Observation of Charge Inversion and Divalent Ion Transport in Nanochannels1, XIN LI, Department of Physics, Yale University, WEIHUA GUAN, Department of Electrical Engineering, Penn State University, BEN WEINER, Department of Physics, Yale University, MARK REED, Department of Electrical Engineering, Department of Applied Physics, Yale University — Ion transport in nanochannels has attracted increasing attention in recent years, with potential applications ranging from ionic control and biosensing to energy storage and conversion. Exciting phenomena occur from the nanoscale confinement of fluids and new models are expected. While most of the previous work in the field has focused on simple monovalent electrolytes, we report a systematic study of divalent ion transport in a well-defined nanochannel fabricated via standard semiconductor methods. Inversion of net surface charge at the fluid/solid interface has been observed by a novel method of open potential work in the field. Moreover, the relation of this charge inversion phenomena with the strong correlated liquid (SCL) theory has been deeply discussed. Intriguing observations from conductance measurement reveal ion-surface interactions and ion-ion correlations.

8:12AM L43.00002 Electrostatic effects of dielectric interfaces on confined electrolyte1, YUFEI JING, Applied Physics Program, Northwestern University, Evanston, IL 60208, VIKRAM JADHAO, Department of Physics & Astronomy, Johns Hopkins University, Baltimore, MD 21218, JOS W. ZWANIKKEN, MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University, Evanston, IL 60208 — The behavior of ions in liquids confined between interfaces characterized by different dielectric permittivities is crucial to many nanoscale assembly processes in synthetic and biological materials. The presence of multiple interfaces and associated dielectric heterogeneities often complicates the desired ionic distributions via simulations or theory. Electrostatic correlation effects in a system with electrolyte confined by two planar dielectric interfaces are systematically studied by Car-Parrinello molecular dynamics simulations and liquid state theory. Results for ionic density profiles for various electrolyte concentrations, stoichiometric ratios and dielectric contrasts are presented. We also investigate the interactions between two planar surfaces and effects of the dielectric interfaces on the double layer structure near the interfaces which lies at the heart of soft matter physics.

8:24AM L43.00003 Squeezeout of a model ionic liquid under confinement and charging1, ERIO TOSATTI, SISSA and ICTP, Trieste, Italy, ROSARIO CAPOZZA, SISSA, Trieste, Italy, ANDREA BENASSI, Empa, Duibendorf, Switzerland, ANDREA VANOSSI, CNR-IOM Democritos and SISSA, Trieste, Italy — Electrical charging of parallel plates confining a model ionic liquid down to nanoscale distances yields a variety of charge-induced changes in the structural features of the confined film, including even-odd switching of the structural layering, and important changes of planar ordering within layers. By means of molecular dynamics simulations, we explore this variety of phenomena in the simplest charged Lennard-Jones coarse-grained model including the effect a neutral tail attached to one of the model ions. Using open, grand-canonical-like conditions which allow the flow of ions in and out of the interplate gap, we simulate the liquid squeezeout and obtain the distance dependent forces between the plates during their adiabatic approach under load. Effective free energy curves obtained by integration of these forces versus interplate distance show the local minima that correspond to layering, and predict the switching between one and another under squeezing and charging.

8:36AM L43.00004 Electrical charging effects on sliding lubrication properties of a model confined ionic liquid, ROSARIO CAPOZZA, International School for Advanced Studies (SISSA), Via Bonomea 265, 34136 Trieste, Italy, ANDREA BENASSI, Empa, Materials Science and Technology, Überlandstrasse 129, 8600 Dübendorf, Switzerland, ANDREA VANOSSI, CNR-IOM Democritos National Simulation Center. Via Bonomea 265, 34136 Trieste, Italy, ERIO TOSATTI, International School for Advanced Studies (SISSA), Via Bonomea 265, 34136 Trieste, Italy — Ionic liquids lubricants, used under conditions of nanometric confinement between parallel plates or tip-surface gaps, explore the dependence of friction upon charging, suggestive of some electrical control of friction. Using a simple ionic liquid model, we first study by molecular dynamics the friction between parallel plates under conditions of successive layering reached by squeezeout under an increasing inter-plate force. We then simulate the frictional changes brought about by different charging states of the plates, related to charging-induced switches corresponding to squeezeout (or suck-in) transitions between different layering states as predicted by local minima in the charge-dependent enthalpy curves. Although the actual frictional behavior obtained does depend upon the assumed features and parameters of the model liquid and its interaction with the plates, the broader scenario obtained for charging effects, its relationship to the equilibrium layering and its enthalpy characterization appear of general value.
8:48AM L43.00005 Crossover in the local diffusive dynamics of equilibrium and supercooled confined fluids, JONATHAN BOLLINGER, THOMAS TRUSKETT, University of Texas at Austin — Confined fluids are ubiquitous in natural and technological contexts, and relating emergent structural motifs to dynamics is critical to facilitate the inverse design of nano- and micro-fluidic systems. Crucially, such thin film systems are frequently tuned between equilibrium and glassy states, as during, e.g., processing of polymer thin films. We use molecular dynamics simulations and a Fokker-Planck equation based method to examine the position-dependent diffusive dynamics of binary hard-sphere fluids confined to slit pores that are designed to mimic realizable thin films [Nugent et al. PRL 2007, 99]. At moderate densities, local single-particle mobilities normal to the direction of confinement are higher in regions of high local packing fraction. However, as the average packing fraction is increased into the supercooled regime, this local positive correlation between packing fraction and mobility is reversed. We discuss the outlook for a universal mechanistic framework that can unite these disparate local correlations between packing and mobility and also predict average diffusivities of the inhomogeneous fluids. Auxiliary measurements of the simulated films suggest that this behavioral dichotomy should also emerge in structurally similar experimental colloidal suspensions.

9:00AM L43.00006 Geometrical frustration and correlated capillary instabilities among concentric polymer toroids, ZHENG ZHANG, Univ of Colorado - Boulder, GENE HILTON, National Institute of Standards and Technology, YIFU DING, Univ of Colorado - Boulder — We present the first study on the simultaneous capillary instability among concentric viscous toroids. An array of concentric polystyrene (PS) toroids were lithographically fabricated with a constant radial spacing between neighboring toroids. The toroids were confined in a poly (methyl methacrylate) (PMMA) matrix. PS and PMMA were used because of their immiscibility and well-characterized physical properties. The glass transition temperature ($T_g$) of the pattern are well above room temperature. We found that the radial contraction mode of toroids (Pairam & Fernández-Nieves, PRL 2009) was depended due to substrate confinement. Upon further annealing, the toroids ruptured along the circumferential direction at a finite wavelength. Depending on the relative value of PS, the rupture behavior of each toroid (with different aspect-ratios) can be non-correlated or correlated radially. In the correlated case, geometric frustration due to the toroidal curvature was observed, which led to an intriguing branching behavior in the correlated instability and closely resembles a Cayley tree with fractal coordination number of 3.

9:12AM L43.00007 Ultrastable Glasses and the Random First Order Transition Theory of Glasses, PETER WOLYNES, Rice University — I will discuss the implications of the RFOF theory for the dynamics of ultrastable glasses focusing on the achievable limits to stability and the heterogeneous and homogenous mechanisms of their rejuvenation.

9:48AM L43.00008 Probing the Dynamics of Thin TPD Glass Films via Dewetting$^1$, YUE ZHANG, ETHAN GLOR, TIANYI LIU, CHEN LI, ZAHRA FAKHRAEI, Department of Chemistry, University of Pennsylvania — Enhanced mobility of surface layer has been observed in both polymer glasses and small molecule organic glasses. In polymers, the mobile surface layer is believed to have great effects on the properties of thin films. Similar studies in small molecule glasses are significantly more challenging due to dewetting. Understanding the dynamics of this mobile layer, and its effect on thin film dynamics can be important in understanding heterogeneous dynamics in glassy systems. In this work, we investigate the properties of the mobile layer and its effect on the overall properties of thin glass films of small molecule organic glasses. We show that thin (thickness below 30nm) TPD (N,N’-Bis(3-methylphenyl)-N,N’-diphenylbenzidine) films prepared by physical vapor deposition (PVD), can be unstable and dewet in a hole growth manner due to enhanced mobility at temperatures as low as Tg-35K. By following the kinetics of dewetting, we investigate the mobility changes with temperature and film thickness. These studies can elucidate the relation between the enhanced mobility and the stability of thick films of the same materials prepared at similar deposition temperatures and thus the formation mechanisms and unique properties of physical vapor deposited glasses.

10:00AM L43.00009 Dewetting of a Liquid-Liquid System, STEFAN BOMMER, NIKOLAS BECKER, Experimental Physics, Saarland University, 66041 Saarbruecken, Germany, SEBASTIAN JACHALSKI, DIRK PESCHKA, Weierstrass Institute for Applied Analysis and Stochastics, 10117 Berlin, Germany, BARBARA WAGNER, Institute for Mathematics, Technical University Berlin, 10623 Berlin, Germany, RALF SEEMANN, Experimental Physics, Saarland University, 66041 Saarbruecken, Germany — In recent years a thorough understanding of thin film dewetting from solid substrates was developed. However, the understanding of a thin liquid film dewetting from another liquid remained scarce. By in situ AFM studies we explore the dewetting dynamics and the morphologies of liquid polystyrene (PS) dewetting from liquid polymethyl-methacrylate (PMMA). Using a selective solvent allows to remove the dewetted PS layer and to image the liquid/liquid interface at selected times. Combining the PS/air and the PS/PMMA interfaces we obtain the full three dimensional shape of the dewetting morphologies. The characteristic shapes of the rim profiles, the equilibrating droplets and their dewetting dynamics depend not only on the ratios of viscosity and surface tension of the two liquids but also on the relative height of the underlying layer. The latter originates from the flow field of the dewetting liquid which penetrates surprisingly deep into the lower liquid it is dewetting from.

10:12AM L43.00010 Coupling the coffee-ring effect to phase separation in drying polymer-nanocrystal deposits. ERIK K. HOBIE, NDSU, JOSEPH B. MILLER, Rice University, AUSTIN C.P. USSELMAN, NDSU, REBECCA J. ANTHONY, UW E. KORTSHAGEN, UMN, ALEXANDER J. WAGNER, ALAN R. DENTON, NDSU — The coupling between the coffee-ring effect and liquid-liquid phase separation is examined for ternary mixtures of solvent, polymer and colloidal nanocrystal. Using real-space imaging and spectroscopic techniques, we resolve the kinetic morphology of the drying front for varied molecular weight of the polymer. Our results demonstrate that the size of the polymer chain has a significant impact on the nature of the coupling between the two instabilities, and we relate these observations to simulations, measured and predicted binodal curves, and the observed shape of the flow field in the confined region at the contact line. The results inform a blade coating process that we exploit to print homogeneous or periodically patterned microscopic wires of nanocomposite material.

8:00AM L44.00001 Extremes in systems with linear and nonlinear memory by the return-interval approach\textsuperscript{1} , ARMIN BUNDE, Institute of Theoretical Physics, Giessen University — The occurrence of extreme events above a certain threshold $Q$ in time series can be characterized by their return intervals $r$. Here we review recent work on the distribution $P_Q(r)$ of the return intervals and their correlation properties (i) in systems with linear long-term memory and (ii) in systems with non-linear memory. Examples for (i) are temperature records, examples for (ii) are financial records. The distribution of the return intervals is an important quantity in risk estimation since it enables one to calculate the probability that an extreme event occurs in the next period of time. We discuss the different functional forms of $P_Q(r)$ that range from simple exponential (random systems) to stretched exponentials (systems with long-term memory) and $q$-exponentials (systems with non-linear memory). We show that both linear and non-linear memory lead to return intervals in the return time series, which then results in a clustering of the extreme events. Both the distribution of the return intervals and their correlation properties can be used as a test bed for computer models.

8:36AM L44.00002 Rare Event Extinction on Stochastic Networks\textsuperscript{1} , IRA SCHWARTZ\textsuperscript{2}, Naval Research Lab, LEAH SHAW, College of William and Mary, BRANDON LINDLEY, R. D. Wagner Associates, Inc. — We consider the problem of extinction processes on random networks with a given structure. For sufficiently large well-mixed populations, the process of extinction of one or more state variable components occurs in the tail of the quasi-stationary probability distribution, thereby making it a rare event. Here we show how to extend the theory of large deviations to random networks to predict extinction times. In particular, we use the theory to find the most probable path leading to extinction. We apply the methodology to epidemic models and discover how mean extinction times scale with epidemiological and network parameters in Erdos-Renyi networks. The results are shown to compare quite well with Monte Carlo simulations of the network in predicting both the most probable paths to extinction and mean extinction times.

8:48AM L44.00003 Revealing non-Gaussian noise through noise-induced switching in a parametric oscillator , PAVEL POLUNIN, Michigan State University, PANPAN ZHOU, Hong Kong University of Science and Technology, NICHOLAS MILLER, SiTime, STEVEN SHAW, Michigan State University, HO BUN CHAN, Hong Kong University of Science and Technology, MARK DYKMAN, Michigan State University — Rates of noise-induced switching between coexisting states of dynamical systems exponentially strongly depend on the noise characteristics. We use the related sensitivity to reveal the deviation of the noise from Gaussian. We study a parametrically driven nonlinear oscillator, which has two stable stationary states. One of the consequences is that, in the space of two or more observable quantities ($q_i$), the average “angular momentum” ($\langle L_{ij} \rangle \equiv \langle q_i q_j \rangle$) is typically non-trivial. In addition, the full distribution of $L$ often display remarkable properties. We will provide a general framework for the study of noise-induced switching and extinction in delayed systems modeling population dynamics. In the weak noise limit, the rates of inter-attractor switching and extinction are associated with the membrane potential while the second is associated with membrane ionic permeability. Noise-induced switching times correspond to the rate at which spontaneous action potentials occur. The fast-slow nature of this system allows us to derive analytical expressions for both the MPEPs and mean switching times as functions of the relative noise intensity. Derived expressions are found to be in good agreement with both computational minimization of the geometric action as well as direct simulation of the underlying stochastic differential equations. [1] P. H. Dannenberg, J. C. Neu, and S. W. Teitsworth, Phys. Rev. Lett. 113, 020601 (2014).

9:00AM L44.00004 Dependence of mean switching times on relative noise intensity in fast-slow dynamical systems , STEPHEN TEITSWORTH, PAUL DANNENBERG, JOHN NEU, Duke University — Recently, we used a geometric minimum action method to analytically and numerically study the dependence of most probable escape paths (MPEPs) on relative noise intensities in a generic two-dimensional fast-slow dynamical system [1]. In this talk, we apply and extend this approach to study MPEPs and associated mean switching times in a quadratic integrate-and-fire model of single neuron dynamics as a function of relative noise intensity in the two dynamical variables. Here, one variable is associated with the membrane potential while the second is associated with membrane ionic permeability. Noise-induced switching times correspond to the rate at which spontaneous action potentials occur. The fast-slow nature of this system allows us to derive analytical expressions for both the MPEPs and mean switching times as functions of the relative noise intensity. Derived expressions are found to be in good agreement with both computational minimization of the geometric action as well as direct simulation of the underlying stochastic differential equations. [1] P. H. Dannenberg, J. C. Neu, and S. W. Teitsworth, Phys. Rev. Lett. 113, 020601 (2014).

9:12AM L44.00005 Noise Induced Switching and Extinction in Systems with Delay\textsuperscript{1} , LORA BILLINGS, Montclair State University, IRA SCHWARTZ, US Naval Research Laboratory, TOM CARR, Southern Methodist University, MARK DYKMAN, Michigan State University — We consider the rates of noise-induced switching between multiple attractors of dynamical systems with delay, and the rates of noise-induced extinction in delayed systems modeling population dynamics. In the weak noise limit, the rates of inter-attractor switching and extinction are exponentially small. To logarithmic accuracy, the formulation of the rates is reduced to variational problems, which give the most probable paths followed by both switching or extinction dynamics. We show that the equations for the most probable paths are acausal and formulate the appropriate boundary conditions. Explicit general results of the rates are obtained for small delay compared to the relaxation rate, and verified using a direct variational method to find the rates. We find that the analytical results agree well with the numerical simulations for both switching and extinction rates.

9:36AM L44.00007 Experimental Observation of Dynamic Phase Transitions in uniaxial Co-Films, ANDREAS BERGER, OLATZ IDIGORAS, CIC nanoGUNE, PAOLO VAVASSORI, CIC nanoGUNE and IKERBASQUE Foundation — We studied the time dependent magnetic reversal behavior of uniaxial films in the vicinity of the dynamic phase transition (DPT) as a function of the period \( P \) and bias \( H_b \) of an oscillating magnetic field. For our experiments, we have used Co-films with in-plane orientation of the uniaxial magneto-crystalline anisotropy axis to avoid complications due to long-range magneto-static interactions. Correspondingly, we have grown 30 nm thick Co-films that exhibit (10-10) surface orientation by means of suitable growth sequences and deposition conditions [1]. For the dynamic field response experiments, we utilized a home-built high-sensitivity magneto-optical Kerr effect set-up, which allowed for real-time low-noise hysteresis loop measurements with \( P \) as small as 0.580 ms. Our experiments reveal in addition to the DPT at a critical period \( P_c \), the occurrence of transient dynamic behavior for \( P < P_c \). [2]. Our data are consistently explained by a phase line at \( H_b = 0 \) for \( P < P_c \), which causes a first order phase transition in between two antiparallel dynamic order states, thus indicating far-reaching similarities of the DPT to equilibrium phase transitions [2]. However, we also observe anomalies, such as unusual fluctuation pattern in the \( P-H_b \) plane, which might be related to the recently suggested occurrence of dynamically “dead” surfaces [3]. References: [1] O. Idigoras et al., J. Appl. Phys. 115, 083912 (2014); [2] A. Berger et al., Phys. Rev. Lett. 111, 190602 (2013); [3] H. Park and M. Pleimling, Phys. Rev. Lett. 109, 175703 (2012).

9:48AM L44.00008 Effects of magnetic field quenches on the relaxation dynamics of vortex lines in disordered type-II superconductors\(^1\), HIBA ASSI, HARSHWARDHAN CHATURVEDI, MICHEL PLEIMLING, UWE C. TÄUBER, Department of Physics, Virginia Tech, ULRICH DOBRAMYSL, Mathematical Institute, University of Oxford — Understanding the relaxation dynamics of vortex matter in disordered type-II superconductors from experimentally realizable initial conditions may improve material characterization and optimization for technological applications. We model magnetic flux lines in the London limit as interacting directed elastic lines subject to uncorrelated point-like or extended columnar pinning centers. We employ a Langevin Molecular Dynamics algorithm to simulate the vortex dynamics. We analyze the vortex relaxation kinetics following sudden magnetic field changes by instantaneously adding or removing lines from the system at random. By studying two-time correlation functions such as the mean-square displacement and height autocorrelation function, as well as one-time observables such as the ratio of pinned line elements and radius of gyration, we disentangle the effects of the competing repulsive vortex interaction and pinning and we compare the distinct relaxation properties due to the type of disorder. We discovered some universal features regardless of the type of quench and the presence of vortex interactions, and others that are dependent on the type of disorder and the system’s initial conditions.

10:00AM L44.00009 Pinning time statistics for vortex lines in disordered environments\(^1\), UWE C. TÄUBER, Department of Physics, Virginia Tech, ULRICH DOBRAMYSL, University of Oxford, MICHEL PLEIMLING, Department of Physics, Virginia Tech — We study the pinning dynamics of magnetic flux (vortex) lines in a disordered type-II superconductor. Using numerical simulations of a directed elastic line model, we extract the pinning time distributions of vortex line segments. We compare different model implementations for the disorder in the surrounding medium: discrete, localized pinning potential wells that are either attractive and repulsive or purely attractive, and whose strengths are drawn from a Gaussian distribution; as well as continuous Gaussian random potential landscapes. We find that both schemes yield power law distributions in the pinned phase as predicted by event-extreme statistics, yet they differ significantly in their effective scaling exponents and their short-time behavior.

---

10:12AM L44.00010 Dead magnetic surface layers near dynamic phase transitions, PATRICIA RIEGO, ANDREAS BERGER, CIC nanoGUNE Consolider — We have performed a detailed study of the dynamic phase transition (DPT) for a magnetic layer system with surfaces subjected to an oscillatory external magnetic field in mean field approximation (MFA). Specifically, we focused our study on bulk-terminated surfaces, i.e., we deal with multilayer systems that have the same exchange coupling strength between nearest neighbors everywhere, including at the surface. We are able to reproduce within the MFA the absence of a surface phase transition at the bulk critical point that was previously reported by Tauscher et al. utilizing Monte-Carlo simulations [1]. In addition, we observe that the DPT is also absent or at least severely suppressed for several layers below the surface, which exhibit susceptibility peaks that are four orders of magnitude smaller than the one corresponding to the bulk. Most importantly, we identify the reason for this “dead” surface behavior. The oscillatory magnetization \( M(t) \) response to the external magnetic field is not synchronous in between the surface and the bulk near the DPT. This lack of correlation prevents the layers from sufficiently supporting each other’s dynamic ordering, so that the surface and the layers close to it cannot follow the bulk DPT.

10:24AM L44.00011 Spherical surface growth models, XAVIER DURANG, Korean Institute for Advanced Study, MALTE HENKEL, Universite de Lorraine, France — We study several surface growth models obtained by treating and replacing the non-linear term in the noisy Burgers equation or the KPZ equation by a mean spherical condition. We want to explore the consequences of such constraints on the Edwards-Wilkinson (EW) equation and the KPZ equation by a mean spherical condition. We study the pinning dynamics of magnetic flux (vortex) lines in a disordered type-II superconductor. Using numerical simulations of a directed elastic line model, we extract the pinning time distributions of vortex line segments. In those exactly solvable models, one has to solve the spherical conditions and then we can derive the two-time quantities (the correlation function and the response function). Therefore, we have access to the non-equilibrium exponents and compare them to those of the EW model or the KPZ model.

10:36AM L44.00012 Failure of Steady State Thermodynamics\(^1\), RONALD DICKMAN, Universidade Federal de Minas Gerais — To be useful, steady state thermodynamics (SST) must be self-consistent and have predictive value. Consistency of SST was recently verified for driven lattice gases under global weak exchange. Here, I verify consistency of SST under local (pointwise) exchange, but only in the limit of a vanishing exchange rate; for a finite exchange rate the coexisting systems have different chemical potentials. I consider the lattice gas with nearest-neighbor exclusion on the square lattice, with nearest-neighbor hopping (NNE dynamics), and with hopping to both nearest and next-nearest neighbors (NNE2 dynamics). I show that SST does not predict the coexisting densities under a nonuniform drive, or in the presence of a nonuniform density provoked by a hard wall or nonuniform transition rates. The steady state chemical potential profile is, moreover, nonuniform at coexistence, contrary to the basic principles of thermodynamics. Finally, I discuss examples of a pair of systems possessing identical steady states, but which do not coexist when placed in contact. These results cast serious doubt on the consistency and predictive value of SST.

Self-organization in non-equilibrium systems

Jodie Lutkenhaus, Texas A&M University

The question about why complex systems self-organize to reach more efficient and robust states is still without a satisfactory answer. We approach it from a physics perspective, where energy gradients lead to change in the structure of systems to ensure the most efficient energy transport. This approach stems from fundamental variational principles in physics, such as the principle of least action, which determine the motion of particles. We compare energy transport through a cell which has random motion of its molecules, and a cell which can form convection cells. We examine the sign of change of entropy, and the action needed for the motion inside those systems. The system in which convective motion occurs, reduces the time for energy transmission, compared to random motion. For more complex systems, this convection cells become a network of transport channels, for the purpose of obeying the equations of motion in this geometry. Those transport networks are an essential feature of complex systems in biology, ecology, economy and society in general. This approach can help explain some of the features of those transport networks, and how they correlate with the level of complexity of systems.

Ion transport and softening in a polymerized ionic liquid

RAJEEV KUMAR, Center for Nanophase Materials Science & Computer Science and Mathematics Division, Oak Ridge National Laboratory, Oak Ridge, TN, VERA BOCHAROVA, Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN, EVGHENI STRELCOV, Center for Nanophase Materials Science, Oak Ridge National Laboratory, Oak Ridge, TN, VERONIKA STREHMEL, Hochschule Niederrhein University of Applied Sciences, Krefeld, Germany, JOSHUA SANGORO, Department of Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, TN, ALEXEI SOKOLOV, Department of Chemistry, University of Tennessee, Knoxville, TN, SERGEI KALinin, BOBBY SUMPTER, Center for Nanophase Materials Science, Oak Ridge National Laboratory, Oak Ridge, TN — Polymerized ionic liquids (PolyILs) are promising materials for various solid-state electronic applications such as dye-sensitized solar cells, lithium batteries, actuators, and field-effect transistors. However, fundamental understanding of interconnection between ionic transport and mechanical properties in PolyILs is far from complete. In this work, local charge transport and structural changes in films of a PolyIL are studied using an integrated experiment-theory based approach. Kinetics of charging, steady state current-voltage relations and softening of the PolyIL films beyond certain threshold voltages are studied by applying electric field through a scanning probe microscopy (SPM) tip. All of the experimental data can be explained by a modified Poisson-Nernst-Planck formalism for the charge transport, which takes into account the dissociation of ions under applied electric field (the Wien effect).

Formation of ion clusters in the phase separated structures of neutral-charged polymer blends

HA-KYUNG KWON, MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208, United States — Polyelectrolyte blends, consisting of at least one charged species, are promising candidate materials for fuel cell membranes, for their mechanical stability and high selectivity for proton conduction. The phase behavior of the blends is important to understand, as this can significantly affect the performance of the device. The phase behavior is controlled by χ, the Flory-Huggins parameter multiplied by the number of mers, as well as the electrostatic interactions between the charged backbone and the counterions. It has recently been shown that local ionic correlations, incorporated via liquid state (LS) theory, enhance phase separation of the blend, even in the absence of polymer interactions. In this study, we show phase diagrams of neutral-charged polymer blends including ionic correlations via LS theory. In addition to enhanced phase separation at low χ, the blends show liquid-liquid phase separation at high electrostatic interaction strengths. Above the critical strength, the charged polymer phase separates into ion-rich and ion-poor regions, resulting in the formation of ion clusters within the charged polymer phase. This can be shown by the appearance of multiple spinodal and critical points, indicating the coexistence of several charge separated phases.

Diffusional Response of Assembled Polyelectrolyte Chains to Salt Annealing

VICTOR SELIN, Department of Chemistry, Chemical Biology and Biomedical Engineering, Stevens Institute of Technology, Hoboken, New Jersey 07030, JOHN F. ANKNER, Spallation Neutron Source, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, Svetlana Sukhishvili, Department of Chemistry, Chemical Biology and Biomedical Engineering, Stevens Institute of Technology, Hoboken, New Jersey 07030 — We report on the effect of salt on the diffusion of polyelectrolyte (PE) chains within electrostatically assembled polyelectrolyte multilayers. Layer-by-layer (LbL) films were assembled using poly(methacrylic acid) (PMAA) as a polyanion and quaternized poly-2-(dimethylamino)ethyl methacrylate as a polycation. Fluorescence recovery after photobleaching and neutron reflectometry were used to monitor the center-of-mass diffusion of PMAA chains in directions parallel and perpendicular to the substrate (D// and D⊥, respectively). In both directions, the diffusion coefficient was exponentially dependent on salt concentration, with significantly faster diffusion in the direction parallel to the substrate. At the same time, D// dramatically decreased with salt annealing time as the films became increasingly intermixed, reflecting strong coupling between internal layering and PE chain dynamics within LbL films.

Characterization of diblock copolymer lamellar structure from neutron scattering measurements and molecular dynamics simulations

CHEOL JEOng, JENNY KIM, SANGCHEOL KIM, NIST - Natl Inst of Stds & Tech, TSUNG-HAN TSAI, E. BRIAN COUGHLIN, University of Massachusetts Amherst, CHRISTOPHER SOLES, NIST - Natl Inst of Stds & Tech — The Nanoscale structure of block copolymers (BCP) with lamellar morphology plays an important role in transport properties for fuel cell and battery application. We develop a paracrystalline model to interpret small angle neutron scattering (SANS) and X-ray scattering (SAXS) data of hydrated amphiphilic BCP lamellar phase in order to elucidate water distribution as well as hydrophilic and hydrophobic domain spacing. We assume Gamma distribution for the fluctuation of lamellar thickness instead of Gaussian. It is observed that BCP can deswell upon hydration along lamellar normal direction due to chain collapse of hydrophobic domain overcoming expansion of hydrophilic domain, which has been compared with coarse-grained molecular dynamics simulation (CGMD). CGMD results show that the variation of interfacial area per chain is strongly correlated to the conformation of hydrophobic chains, domain spacing and water distribution in the hydrophilic domain, compatible with the observation from SANS and SAXS.
compare the conductivity of SbMMA/IL with the homopolymer/IL mixture, and to discuss the ion transport mechanism.

lamellar morphology with long-range order. Slower rates of solvent evaporation produce films with lamellae preferentially oriented to be in the plane. In-plane

membranes. Herein we demonstrate a novel approach of fabricating block copolymer electrolyte membranes, by inducing pores in the proton-conducting phase. We examine morphology of these membranes with contrast-matched resonant soft X-ray scattering (RSAXS) and high-angle annular dark field scanning transmission electron microscopy (HAADF STEM). These materials show excellent charge transport behavior and water vapor transport properties, surpassing commercially available materials. These results and efforts to improve other important physical characteristics for membrane applications will be presented.

Morphology and Proton Transport in Porous Block Copolymer Electrolyte Membranes, CHELSEA CHEN, University of California, Berkeley. JEFFREY KORTRIGHT, Lawrence Berkeley National Lab, DAVID WONG, Exponent, NITASH BALSAURA, University of California, Berkeley — Block copolymer electrolyte membranes consisting of a proton-conducting block and an uncharged structural block are attractive due to their potential in clean energy applications. Herein we demonstrate a novel approach of fabricating block copolymer electrolyte membranes, by inducing pores in the proton-conducting phase. We examine morphology of these membranes with contrast-matched resonant soft X-ray scattering (RSAXS) and electron tomography. Proton conductivity as a function of porosity and water activity is also investigated. By tuning the porosity of the membranes, we are able to adjust the water uptake of the membranes for improved proton conductivities, in both humid air and liquid water.

Morphology-structure-property relationships in polymerized ionomeric liquids, JOSHUA SANGORO, MAXIMILIAN HERES, JOSEPH MINUTOLO, JACOB SHAMBULN, MAIR LANG, Univ of Tennessee, KNOXVILLE, STEFAN BORDZINSKI, VERONIKA STREHMEHL, Hochschule Niederrhein University of Applied Sciences, STEPHEN PADDISON, Univ of Tennessee, Knoxville — Charge transport and structural dynamics in systematic series of polymerized ammonium- and imidazolium-based ionic liquids are investigated by broadband dielectric spectroscopy, temperature-modulated differential scanning calorimetry, and X-ray as well neutron scattering techniques. Detailed analysis reveal strong decoupling of these processes in the polymerized ionic liquids, implying failure of the classical theories in describing charge transport and molecular dynamics in these systems. In addition, a strong correlation is observed between the ionic conductivity at the respective calorimetric glass transition temperatures and the morphologies revealed by the scattering experiments. In this talk, a physical explanation of the origin of the observed decoupling of ionic conductivity from structural dynamics will be proposed.

Controlling ion aggregation and conduction in PEO-based ionomers, DAVID CALDWELL II, JANNA MARANAS, Pennsylvania State Univ — PEO-based ionomers are ideal for reducing concentration polarization found in typical solid polymer electrolytes. This is achieved by binding the anion to the polymer backbone, significantly reducing the anions mobility. Ion aggregation is prevalent in these systems, but their influence on SPE performance is difficult to study experimentally. We present results of molecular dynamics simulations that explore the relationship between ion content and temperature on ion aggregation, polymer motion, and ion conduction. An unforeseen result of ionomers is the creation of string-like aggregates that form conduction pathways in the amorphous region. These conduction pathways allow for a partial decoupling of ion conduction with polymer dynamics. The improvement in conductivity through the use of ion aggregates can be quantified by calculating the inverse of the Haven Ratio, dubbed $f$-value. Typical SPEs have an $f$-value less than 0.2, while the ionomers of study exhibit $f$-values near unity or higher. Understanding what properties influence the development and use of these conduction pathways will provide insight for further development of solid polymer electrolytes.

Dynamics of Polymerized Ionic Liquids and their Monomers, RALPH H. COLBY, Materials Science and Engineering, Penn State University — Dielectric spectroscopy determines the static dielectric constants ($\varepsilon_s$) of polymers with imidazolium pendant structures containing a combination of alkyene and ethyleneoxy units as spacers between the backbone and the imidazolium cation. All monomers and their polymers exhibited two dipolar relaxations, assigned to the usual segmental motion ($\alpha_s$) associated with the glass transition and a lower frequency stronger relaxation ($\alpha_g$), attributed to ions rearranging. While pairs in conventional (smaller) ionic liquids prefer antiparallel alignment [Kirkwood $g \approx 0.1$ with $\varepsilon_s \approx 15$], because their polarizability volumes strongly overlap, ion pair dipoles in the larger ionic liquid monomers display $g$ of order unity and $50 \leq \varepsilon_s \leq 110$. Longer spacings lead to higher static dielectric constant, owing to a significant increase of the relaxation strength of the $\alpha_g$ process, which is directly reflected through an unanticipated increase of the static dielectric constant with ionic liquid molecular volume. The ionomers consistently exhibit 1.5 - 2.3 times higher static dielectric constants than the monomers from which they were synthesized, suggesting that polymerization encourages the observed synergistic dipole alignment ($g > 1$). Comparison of dielectric and linear viscoelastic responses reveals a strong connection between the time scales of polymer segmental motion ($\alpha_s$), ion rearrangements ($\alpha_g$) and the viscoelastic softening associated with the glass transition. For all polymers with imidazolium side chains and a wide variety of counter-ions, a single strong low molecular volume. Large side chains have low $T_g \approx -50$ °C and their ionic conductivity increases as ethylene oxide repeats are incorporated into the side chains.

Morphology and Ionic Conductivity of Oriented Block Copolymer/Ionic Liquid Mixtures, SHARON SHARICK, KAREN I. WINEY, University of Pennsylvania — Ion-containing block copolymers with increased continuity and long-range order of ion-containing microdomains were prepared to probe the impact of grain boundaries and microdomain orientation on ion transport. We studied poly(styrene-b-methyl methacrylate) diblock copolymers swollen with 1-ethyl-3-methyl-imidazolium bis(trifluoromethylsulfonylimide) (SBMMA/IL), and characterized the thermal transitions, morphologies, and ionic conductivities by differential scanning calorimetry, small-angle X-ray scattering, and electrochemical impedance spectroscopy over a range of compositions. Two glass transition temperatures ($T_g$) are observed, corresponding to PS and PMMA/IL microdomains, and $T_{DP-PMMMA/IL}$ is modeled well by the Gordon-Taylor expression. SBMMA/IL films prepared by solvent evaporation exhibit strongly microphase-separated lamellar morphology with long-range order. Slower rates of solvent evaporation produce films with lamellae preferentially oriented to be in the plane. In-plane conductivities increased with both increasing ionic liquid content and with better parallel alignment of lamellae. The Sax and Ottino model will be used to compare the conductivity of SBMMA/IL with the homopolymer/IL mixture, PMMA/IL, and to discuss the ion transport mechanism.
10:36 AM L45.00012 Effect of Lithium Ion Concentration of a Single-Ion-Conducting Block Copolymer Electrolyte on the Morphology-Conductivity Relationship. ADRIANA A. ROJAS, University of California, Berkeley, SEBNEM İNCEOGLU, Lawrence Berkeley National Laboratory, GREG STONE, Malvern Instruments, NITASH BALSARA, University of California, Berkeley — Single-ion-conducting block copolymer electrolytes are desirable for lithium metal batteries because they enable the sole conduction of lithium ions, the reacting species in lithium batteries; hence, they avert detrimental battery limitations due to salt concentration gradients. A single-ion-conducting block copolymer electrolyte, poly(ethylene oxide)-b-poly(styrenesulfonfyl lithium) (trifluoromethyl sulfonyl) imide (PEO-b-PSSLiTFSI), was characterized in-situ and ex-situ for its ionic conductivity and morphology using AC impedance spectroscopy and small angle x-ray scattering, respectively. This work is the first to elucidate the relationship between the two properties in a single-ion block copolymer electrolyte. The transference number for the copolymers was determined to be greater than or equal to 0.87, indicating that to a good approximation, the block copolymers are single-ion conducting electrolytes. It was found that increasing the molecular weight of the PSSLiTFSI block led to an increase in the extent of block copolymer block-mixing and a change in the conductivity profile from discontinuous to continuous. These effects can be attributed to the disruption of PEO crystallization, which was shown to drive microphase separation.

10:48 AM L45.00013 Role of Constituent Hard Polymer in Enhancing Lithium Transfer Number of Lithium Salt-Polymer Complexes. GYUHA JO, MOON JEONG PARK, Pohang Univ of Sci & Tech — Lithium polymer batteries have been projected as promising energy storage systems, owing to their unique advantages such as long cycle life, high specific capacity, and high cell potential. While the polymer electrolytes such as poly(ethylene oxide) (PEO) employed in lithium polymer batteries have high ionic conductivity and low volatility, the PEO-lithium salt complexes indicated immense shortcomings of concentration polarization, ascribed to the motion of free anions within PEO. This has limited charge/discharge rate of lithium batteries. In this study, we present a new methodology for improving the ionic conductivity and lithium transference number of PEO, by block copolymerization with a hard polymer, namely poly(dithiooxamide) (PDTOA). Compared to a simple PEO/PDTOA blend, lithium-salt doped PEO-b-PDTOA block copolymers exhibited significantly improved ionic conductivity values. Further, lithium transference numbers as high as 0.66 were observed, which are much higher than the corresponding values for conventional PEO-salt electrolytes (∼0.25).

Wednesday, March 4, 2015 8:00 AM - 11:00 AM — Session L46 DBIO DCMP: Invited Session: Design Principles in Synthetic Biology

217A - Ned Wingreen, Princeton University

8:00 AM L46.00001 Enzyme clustering can induce metabolic channeling. MICHELE CASTELLANA, Lewis-Sigler Institute for Integrative Genomics, Princeton University, Princeton, NJ, United States — Direct channeling of intermediates via a physical tunnel between enzyme active sites is an established mechanism to improve metabolic efficiency. In this talk, I will present a theoretical model that demonstrates, that co-clustering enzyme active sites can yield the full efficiency benefits of direct channeling if the enzyme active sites are close enough in proximity. The model predicts the separation of the size of clusters that maximize metabolic efficiency, and this prediction is in agreement with the spacing between co-clusters in yeast and mammalian cells. The model also predicts that enzyme agglomerates can regulate steady-state flux division at metabolic branch points: we experimentally test this prediction for a fundamental branch point in Escherichia coli, and the results confirm that enzyme colocalization within an agglomerate can accelerate the processing of a shared intermediate by one branch. Our studies establish a quantitative framework to understand co-clustering-mediated metabolic channeling and its application to both efficiency improvement and metabolic regulation.

8:36 AM L46.00002 Programming Biology for Health and Sustainability. PAMELA SILVER, Harvard Medical School — Biology presents us with an array of design principles. From studies of both simple and more complex systems, we understand some of the fundamentals of how Nature works. We are interested in using the foundations of biology to engineer cells in a logical and predictable way to perform certain functions. By necessity, the predictable engineering of biology requires knowledge of quantitative behavior of individual cells and communities. By building and analyzing synthetic systems, we learn more about the fundamentals of biological design as well as engineer useful living devices with myriad applications. For example, we are interested in building cells that can perform specific tasks, such as remembering past events and thus acting as biological computers. Moreover, we design cells with predictable biological properties that serve as cell-based sensors, factories for generating useful commodities and improved centers for carbon fixation. We have recently engineered natural gut bacteria that can non-invasively report on the dynamics of the animal gut. In doing so, we have made new findings about how cells interact with and impact on their environment. These principles can be applied to problems of all natural environments.

9:12 AM L46.00003 Signaling Mechanisms of Proteins and Protein Complexes. WENDELL LIM, University of California, San Francisco — No abstract available.

9:48 AM L46.00004 Synthetic networks in microbial communities. GUROL SUEL, UCSD — While bacteria are single celled organisms, they predominantly reside in structured communities known as biofilms. Cells in biofilms are encapsulated and protected by the extracellular matrix (ECM), which also confines cells in space. During biofilm development, microbial cells are organized in space and over time. Little is known regarding the processes that drive the spatio-temporal organization of microbial communities. Here I will present our latest findings that utilize synthetic biology approaches to uncover the organizational principles that drive biofilm development. I will also discuss the possible implications of our recent findings in terms of the cost and benefit to biofilm cells.

10:24 AM L46.00005 Metabolite Valves: Dynamic Control of Metabolic Flux for Pathway Engineering. KRISTALA PRATHER, Massachusetts Institute of Technology — Microbial strains have been successfully engineered to produce a wide variety of chemical compounds, several of which have been commercialized. As new products are targeted for biological synthesis, yield is frequently considered a primary driver towards determining feasibility. Theoretical yields can be calculated, establishing an upper limit on the potential conversion of starting substrates to target compounds. Such yields typically ignore loss of substrate to byproducts, with the assumption that competing reactions can be eliminated, usually by deleting the genes encoding the corresponding enzymes. However, when an enzyme encodes an essential gene, especially one involved in primary metabolism, deletion is not a viable option. Reducing gene expression in a static fashion is possible, but this solution ignores the metabolic demand needed for synthesis of the enzymes required for the desired pathway. We have developed Metabolite valves to address this challenge. The valves are designed to allow high flux through the essential enzyme during an initial period where growth is favored. Following an external perturbation, enzyme activity is then reduced, enabling a higher precursor pool to be diverted towards the pathway of interest. We have designed valves with control at both the transcriptional and post-translational levels. In both cases, key enzymes in glucose metabolism are regulated, and two different compounds are targeted for heterologous production. We have measured increased concentrations of intracellular metabolites once the valve is closed, and have demonstrated that these increased pools lead to increased product yields. These metabolite valves should prove broadly useful for dynamic control of metabolic flux, resulting in improvements in product yields.
be approximated by a drift-diffusion model for which we calculate diffusion and drift coefficients as functions of the CTRW model parameters. We also show that, in the limit of slowly-varying (long-wavelength) density perturbations, the time-dependent linear density response can whereas stability indicates absence of aggregation. We show that a broadening of CTRW distributions of the random speed and/or random runtimes strongly aggregation, individual bacteria follow random walk paths determined by randomly selected runtimes, turning angles, and speeds. We have simulated this

0 whether a uniform cell density \( R(r, t, \theta) \). By way of a linear stability analysis, we investigated the instabilities in the subset of a single cell. We aim to characterise growth cone navigation in defined nano-dot guidance cue environments, by using the tools of computational neuroscience to conduct “molecular psychophysics.” We start with a generative model of growth cone behaviour and we characterise sensory and internal sources of noise contributing to behavioural variables, by combining knowledge of the underlying stochastic dynamics in cue sensing and the growth of the cytoskeleton. This enables us to produce bottom-up lower limit estimates of behavioural response reliability and visualise it as probability distributions over axon growth trajectories. Given this information we can match our in silico model’s “psychometric” decision curves with empirical data. Finally we use a Monte-Carlo approach to predict response distributions of axon trajectories from our model.

1 Work funded by the United States National Science Foundation.

8:36AM L47.00002 Motor Switching Rates in Caulobacter Crescentus Follow First Passage Time Distribution1
JAY TANG, MICHAEL MORSE, JORDAN BELL, GUANGLAI LI, Brown University — The flagellar motor of uni-flagellated bacterium Caulobacter crescentus switches stochastically between clockwise (CW) and counterclockwise (CCW) rotation. We performed measurements of the time intervals between switches in order to gain insight on motor dynamics and regulation. Our measurements were performed both on free swimming cells and tethered cells with their flagella attached to a glass slide. A peak time of approximately one second was observed in both motor directions with counterclockwise intervals more sharply peaked. The distributions of switching times can be fitted using biased first passage time statistics. We present a model of motor switching dynamics, which is controlled by the binding of CheY-P to motor subunits FliM. A lower threshold number of FliM with CheY-P bound triggers a switch in motor rotation from CW to CCW, whereas a higher threshold triggers an opposing switch from CCW to CW. The time intervals between alternating switches may be increased or decreased by regulating CheY-P concentration, resulting in biased directional motion in the cells swimming trajectory over many motor cycles under external spatial or temporal gradients.

STUART SEVIER, HERBERT LEVINE, Rice University — The ability to watch biochemical events play out at the single-molecule level has led to the discovery that transcription occurs in a noisy, “bursty” manner. Recently, as the single-molecule lens is placed over a larger number of organisms and genes, relationships between mean expression and noise beyond the “bursty” paradigm have emerged. Through a master-equation formulation of transcription we have found that many powerful physical principles relating to irreversibility seem to play a central role in the newly uncovered trends. Specifically, the relationships between mean expression and noise appears to be a direct consequence of network currents. We discuss how emphasizing the underlying principles in the models can explain recent experimental data and lead to a generalized view of transcription.

8:48AM L47.00003 Consequences of Irreversibility in Fundamental Models of Transcription
STUART SEVIER, HERBERT LEVINE, Rice University — The ability to watch biochemical events play out at the single-molecule level has led to the discovery that transcription occurs in a noisy, “bursty” manner. Recently, as the single-molecule lens is placed over a larger number of organisms and genes, relationships between mean expression and noise beyond the “bursty” paradigm have emerged. Through a master-equation formulation of transcription we have found that many powerful physical principles relating to irreversibility seem to play a central role in the newly uncovered trends. Specifically, the relationships between mean expression and noise appears to be a direct consequence of network currents. We discuss how emphasizing the underlying principles in the models can explain recent experimental data and lead to a generalized view of transcription.

9:00AM L47.00004 Variability and Reliability in Axon Growth Cone Navigation Decision Making
MARTA GARNELO, Imperial College London, SÉBASTIEN G. RICOULT, DAVID JUNCKER, TIMOTHY E. KENNEDY, McGill University, ALDO A. FAISAL, Imperial College London — The nervous system’s wiring is a result of axon growth cones navigating through specific molecular environments during development. In order to reach their target, growth cones need to make decisions under uncertainty as they are faced with stochastic sensory information and probabilistic movements. The nervous system’s wiring therefore exhibits features of both organisms (perception–decision–motor) and the axon. We aim to characterise growth cone navigation in defined nano-dot guidance cue environments, by using the tools of computational neuroscience to conduct “molecular psychophysics.” We start with a generative model of growth cone behaviour and we characterise sensory and internal sources of noise contributing to behavioural variables, by combining knowledge of the underlying stochastic dynamics in cue sensing and the growth of the cytoskeleton. This enables us to produce bottom-up lower limit estimates of behavioural response reliability and visualise it as probability distributions over axon growth trajectories. Given this information we can match our in silico model’s “psychometric” decision curves with empirical data. Finally we use a Monte-Carlo approach to predict response distributions of axon trajectories from our model.

9:12AM L47.00005 Stability of a Random Walk Model for Fruiting Body Aggregation in M. xanthus1
G.C. MCKENZIE-SMITH, Bowdoin College, H.B. SCHÜTTLER, C. COTTER, L. SHIMKETS, University of Georgia — Myxococcus xanthus exhibits the social starvation behaviour of aggregation into a fruiting body containing myxospores able to survive harsh conditions. During fruiting body aggregation, individual bacteria follow random walk paths determined by randomly selected runtimes, turning angles, and speeds. We have simulated this behavior in terms of a continuous-time random walk (CTRW) model, re-formulated as a system of integral equations, describing the angle-resolved cell density, \( R(r, t, \theta) \), at position \( r \) and cell orientation angle \( \theta \) at time \( t \), and angle-integrated ambient cell density \( \rho(r, t) \). By way of a linear stability analysis, we investigated whether a uniform cell density \( R_0 \) will be unstable for a small non-uniform density perturbation \( \Delta R(r, t, \theta) \). Such instability indicates aggregate formation, whereas stability indicates absence of aggregation. We show that a broadening of CTRW distributions of the random speed and/or random runtimes strongly favors aggregation. We also show that, in the limit of slowly-varying (long-wavelength) density perturbations, the time-dependent linear density response can be approximated by a drift-diffusion model for which we calculate diffusion and drift coefficients as functions of the CTRW model parameters.

1 Funded by the Fungal Genomics and Computational Biology REU at UGA.
9:24AM L47.00006 Single-cell analysis of transcription kinetics across the cell cycle , SAMUEL SKINNER, HENG XU, Department of Biochemistry and Molecular Biology, Baylor College of Medicine; CENTER FOR THEORETICAL BIOLOGICAL PHYSICS, RICE UNIVERSITY, SONAL JAISWAL, PABLO FREIRE, Baylor College of Medicine, THOMAS ZWAKA, Department for Developmental and Regenerative Biology, Icahn School of Medicine at Mount Sinai, IDO GOLDING, Department of Physics and Center for the Physics of Living Cells, University of Illinois at Urbana-Champaign — Transcription is a highly stochastic process. A common way of inferring transcription kinetics is to measure mRNA abundance in individual cells and compare the observed copy-number statistics to the prediction of a theoretical stochastic model. However, the reliability of this procedure is hampered by the fact that the measured mRNA numbers represent integration over the finite lifetime of mRNA, over multiple copies of the same gene, and the mixing of cells from different phases of the cell cycle. Here we address these limitations by simultaneously quantifying nascent and mature mRNA in individual cells, and incorporating gene-copy and cell-cycle effects in the analysis of mRNA statistics. We demonstrate this approach on Oct4 and Nanog, two key players in the mouse pluripotency network. We find that both genes are well described by a two-state stochastic model for transcription initiation. The difference in their expression characteristics is attributed to a 2.6-fold difference in the probability of switching to an active transcriptional state. Early in the cell cycle, the two copies of each gene exhibit independent activity. However, after gene replication, the probability of each gene copy to be active diminishes, resulting in dosage compensation.

9:36AM L47.00007 Inference of protein diffusion probed via fluorescence correlation spectroscopy , KONSTANTINOS TSEKOURAS, IUPUI — Fluorophores are an inherent part of single molecule or few particle biophysical data sets. Traditionally, "noise" fluctuations have been viewed as a nuisance, to be eliminated or minimized. Here we look on how statistical inference methods — that take explicit advantage of fluctuations — have allowed us to draw an unexpected picture of single molecule diffusional dynamics. Our focus is on the diffusion of proteins probed using fluorescence correlation spectroscopy (FCS). First, we discuss how — in collaboration with the Bustamante and Marqusee labs at UC Berkeley — we determined using FCS data that individual enzymes are perturbed by self-generated catalytic heat (Riedel et al, Nature, 2014). Using the tools of inference, we found that distributions of enzyme diffusion coefficients shift in the presence of substrate revealing that enzymes performing highly exothermic reactions dissipate heat by transiently accelerating their center of mass following a catalytic reaction. Next, when molecules diffuse in the cell nucleus they often appear to diffuse anomalously. We analyze FCS data — in collaboration with Rich Day at the IU Med School — to propose a simple model for transcription factor binding-unbinding in the nucleus to show that it may give rise to apparent anomalous diffusion. Here inference methods extract entire binding affinity distributions for the diffusing transcription factors, allowing us to precisely characterize their interactions with different components of the nuclear environment. From this analysis, we draw key mechanistic insight that goes beyond what is possible by simply fitting data to "anomalous diffusion" models.

10:12AM L47.00008 Simple models do not explain early dynamics of H. influenzae bacteremia , XINXIAN SHAO, Department of Physics, Emory University, BRUCE LEVIN, Department of Biology, Emory University, ILYA NEMENMAN, Department of Physics, Emory University — There is an abundance of largely qualitative information about the physiological and molecular mechanisms of bacterial pathogenesis. However, little is known about population dynamic processes by which bacteria colonize hosts and invade cells and tissues and thereby cause disease. Classic experiment of Moxon and Murphy[1] observed that, when inoculated intranasally with a mixture of equally virulent strains of Haemophilus influenzae type b(Hib), neonatal rats develop a bacteremic infection that often is dominated by only one random competing strain. A common qualitative explanation for this phenomenon is that the bacteria must switch stochastically into a rapidly growing phenotype to start the full-fledged invasion. Then the first bacterium to switch activates the host immune response, which in turn shuts the door in front of the second strain. We implemented this model computationally and analytically, and we conclude that the data do not support the hypothesis that the observed dependence of the rate of infections on the inoculum size. New experiments are needed to identify mechanisms underlying the dependence.

10:24AM L47.00009 The Dynamics in Epithelial Cell Intercalation in Drosophila Morphogenesis1, FRED WOLF, LARS REICHL, Max Planck Institute for Dynamics and Self-Organization, DEQING KONG, YUJUN ZHANG, Institute for Developmental Biochemistry, Medical School, University of Göttingen, STEPHAN EULE, JAKOB METZGER, Max Planck Institute for Dynamics and Self-Organization, JÖRG GROßHANS, Institute for Developmental Biochemistry, Medical School, University of Göttingen — Epithelial cell rearrangement is important for many processes in morphogenesis. During germband extension in early gastrulation of Drosophila embryos, exchange of neighbors is achieved by junction remodeling that follows a topological T1 process. Its first step is the constriction of dorsal-ventral junctions and fusion of two 3x vertices into a 4x vertex: a process believed to be junction autonomous. We established a high throughput imaging pipeline, by which we recorded, segmented and analysed more than 1000 neighbor exchanges in drosophila embryos. Characterizing the dynamics of junction lengths we find that the constriction of cell contacts follows intriguingly simple quantitative laws. (1) The mean contact length decreases approximately as a square root of time to collapse. (2) The time dependent variance of contact lengths is proportional to the square of mean. (3) The time dependent probability density of the contact lengths remains close to Gaussian during the entire process. These observations are sufficient to derive a stochastic differential equation for contact length that captures the non-equilibrium statistical mechanics of contact collapse. 1Supported by the German Research Foundation.

10:36AM L47.00010 Stochastic Terminal Dynamics in Epithelial Cell Intercalation , STEPHAN EULE, JAKOB METZGER, LARS REICHL, Max Planck Institute for Dynamics and Self-Organization, DEQING KONG, YUJUN ZHANG, JOERG GROSSHANS, Institute for Developmental Biochemistry, Medical School, University of Göttingen, FRED WOLF, Max Planck Institute for Dynamics and Self-Organization — We found that the constriction of epithelial cell contacts during intercalation in germ band extension in Drosophila embryos follows intriguingly simple quantitative laws. The mean contact length (Λ) follows (Λ(t)) ∼ (T − t)α , where T is the finite collapse time; the time dependent variance of contact length is proportional to the square of the mean; finally the time dependent probability density of the contact lengths remains close to Gaussian during the entire process. These observations suggest that the dynamics of contact collapse can be captured by a stochastic differential equation analytically tractable in small noise approximation. Here, we present such a model, providing an effective description of the non-equilibrium statistical mechanics of contact collapse. All model parameters are fixed by measurements of time dependent mean and variance of contact lengths. The model predicts the contact length covariance function that we obtain in closed form. The contact length covariance function closely matches experimental observations suggesting that the model well captures the dynamics of contact collapse.

10:48AM L47.00011 Methods for reconstructing sets of ordinary differential equations from time series data , MANUEL MAI, Department of Physics, Yale University, NEW HAVEN, CT, USA, COREY O’HERN, Department of Physics, Department of Computational Biology and Bioinformatics, Yale University, NEW HAVEN, CT, USA, MARK D. SHATTUCK, Benjamin Levich Institute and Physics Department, The City College of New York, NEW YORK, NY, USA — We propose a novel method for reconstructing the underlying non-linear ordinary differential equations (ODE) for a physical system from time series data. Common methods for ODE reconstruction generate suitable candidate equations for the system and then fit the ODE parameters to the time series data. Candidate sets of ODEs are evolved using genetic programming methods and candidates that poorly fit the data are discarded. Such schemes are computationally expensive. We develop an alternative more efficient approach to ODE reconstruction. In the first step, we identify key features of the set of ODEs (such as the number and stability of fixed points) from the data. In the second step, we develop functional forms for the right-hand sides of the ODEs that interpolate between fixed points and saddles. We will show a number of examples where we can reconstruct nonlinear ordinary differential equations that capture the equivalent dynamics as that found in the original time series data.
8:00AM L48.00001 Genetic networks specifying the functional architecture of orientation domains in V1. JOSCHA LIEDTKE, FRED WOLF, Max Planck Institute for Dynamics and Self-Organization — Although genetic information is critically important for brain development and structure, it is widely believed that neocortical functional architecture is largely shaped by activity dependent mechanisms. Here we show theoretically that mathematical models of genetic networks of principal neurons interacting by long range axonal morphogen transport can generate morphogen patterns that exactly prescribe the functional architecture of the primary visual cortex (V1) as experimentally observed. We analyze in detail an example genetic network that encodes the functional architecture of V1 by a dynamically generated morphogen pattern. We use analytical methods from weakly non-linear analysis [Cross & Hohenberg 1993] complemented by numerical simulations to obtain solutions of the model. In particular we find that the pinwheel statistics are in quantitative agreement with high precision experimental measurements [Kaschube et al. 2010]. This theory opens a novel perspective on the experimentally observed robustness of V1’s architecture against radically abnormal developmental conditions such a dark rearing [White et al. 2001]. Furthermore, it provides for the first time a scheme how the pattern of a complex cortical architecture can be specified using only a small genetic bandwidth. 

8:12AM L48.00002 Numerical simulations on active rod like particles as a model for the collective behavior of Myxococcus xanthus, MANON WIGBERS, Department of Physics and Astronomy, Vrije Universiteit, Amsterdam, 1081HV. The Netherlands, SHASHI THUTUPALLI, JOSHUA SHEAVITZ, Department of Physics, Princeton University, Princeton, NJ, 08544, USA — We study collective behavior of Myxococcus xanthus using numerical simulations. Under starvation conditions, these social bacteria organize into multi-cellular structures, called “fruited bodies,” within which cells sporulate. During the process of fruiting body formation, cells show various collective motion patterns. One of the most striking of these patterns is the so called rippling motility, characterized by standing density waves of reversing bacteria. Similar rippling behaviour is also observed during predatory feeding of the bacteria. Until now, the principles underlying this rippling behavior are not fully elucidated. Analogous to the well studied liquid crystalline phases in condensed matter physics, the ordering of the baceria within these rippling waves resembles a smectic like layered structure. In contrast to active nematic liquid crystalline phases widely studied in recent times, this represents the first known empirical example of an active smectic phase. Inspired by single-cell resolution experimental data of the bacteria, we develop a model of active rod like particles and use numerical simulations to study the organizing principles that drive the transitions between the various active liquid crystalline phases in the myxobacterial collective behavior.

8:24AM L48.00003 Non-ergodic diffusion on quenched, scale-free disorder in two dimensions, GERALD J. LAPEYRE, JR., PIETRO MASSIGNAN, CARLO MANZO, JUAN A. TORRENTO-PINA, MARIA F. GARCÍA-PARAJO, MACIEJ LEWENSTEIN, ICF0-The Institute of Photonic Sciences — We discuss our recently introduced models of diffusion on media with random diffusivity [1] and their application to transport in cell membranes [2]. We find that the diffusion shows weak ergodicity breaking, and compute the anomalous exponents as a function of model parameters. We also report recent results on criteria for predicting weak ergodicity breaking in random walks on specific models of quenched, scale-free, random media.

8:36AM L48.00004 Growth Kinetics of Intracellular RNA/Protein Droplets: Signature of a Liquid-Liquid Phase Transition?, JOEL BERRY, STEPHANIE C. WEBER, NILESH VAIDYA, LIAN ZHU, MIKKO HAATAJA, CLIFFORD P. BRANGWYNNE, Princeton University — Nonmembrane-bound organelles are functional, dynamic assemblies of RNA and/or protein that can self-assemble and disassemble within the cytoplasm or nucleoplasm. The possibility that underlying intracellular phase transitions may drive and mediate the morphological evolution of some membrane-less organelles has been supported by several recent studies. In this talk, results from a collaborative experimental-theoretical study of the growth and dissolution kinetics of nucleoli and extranucleolar droplets (ENDs) in C. elegans embryos will be presented. We have employed Flory-Huggins solution theory, reaction-diffusion kinetics, and quantitative statistical dynamic scaling analysis to characterize the specific growth mechanisms at work. Our findings indicate that both in vivo and in vitro droplet scaling and growth kinetics are consistent with those resulting from an equilibrium liquid-liquid phase transition mediated by passive nonequilibrium growth mechanisms—simultaneous Brownian coalescence and Ostwald ripening. This supports a view in which cells can employ phase transitions to drive structural organization, while utilizing active processes, such as local transcriptional activity, to fine tune the kinetics of these phase transitions in response to given conditions.

8:48AM L48.00005 External stimulation strength controls actin response dynamics in Dicyostelium cells, HSIN-FANG HSU, Max Planck Institute for Dynamics and Self-Organization, CHRISTIAN WESTENDORF, Institut für Pflanzenwissenschaften, Universität Graz, MARCO TARANTOLA, VLADIMIR ZYKOV, EBERHARD BODENSCHATZ, Max Planck Institute for Dynamics and Self-Organization, CARSTEN BETA, Institute of Physics and Astronomy, University of Potsdam — Self-sustained oscillation and the resonance frequency of the cytoskeletal actin polymerization/depolymerization have recently been observed in Dicyostelium, a model system for studying chemotaxis. Here we report that the resonance frequency is not constant but rather varies with the strength of external stimuli. To understand the underlying mechanism, we analyzed the polymerization and depolymerization time at different levels of external stimulation. We found that polymerization time is independent of external stimuli but the depolymerization time is prolonged as the stimulation increases. These observations can be successfully reproduced in the frame work of our time delayed differential equation model.

10:36AM L48.00012 Terasaki Ramps in the Endoplasmic Reticulum: Structure, Function and Formation, GREG HUBER, Kavli Institute of Theoretical Physics, UCSB, JEMAL GUVEN, DULCE-MARIA VALENCIA, Instituto de Ciencias Nuclareas, UNAM, Mexico City — The endoplasmic reticulum (ER) has long been considered an exceedingly important and complex cellular organelle in eukaryotes (like you). It is a membrane structure, part folded lamellae, part tubular network, that both envelopes the nucleus and threads its way outward, all the way to the cell’s periphery. Despite the elegant mechanics of bilayer membranes offered by the work of Helfrich and Canham, as far as the ER is concerned, theory has mostly sat on the sidelines. However, refined imaging of the ER has recently revealed beautiful and subtle geometrical forms – simple geometries, from the mathematical point of view – which some have called a “parking garage for ribosomes.” I’ll review the discovery and physics of Terasaki ramps and discuss their relation to cell-biological questions, such as ER and nuclear-membrane re-organization during mitosis. Rather than being a footnote in a textbook on differential geometry, these structures suggest answers to a number of the ER’s structure-function problems.

Session L49 GSOFT GSNP: Focus Session: Mechanics of Defects and Discontinuities 217D - James Hanna, Virginia Polytechnic Institute and State University

8:00AM L49.00001 Fracture of brittle coatings on soft plastic substrates, JOEL MARTHELOT, Massachusetts Institute of Technology, DAVY DALMAS, JEREMIE TEISSEIRE, SVI, CNRS, Saint-Gobain, JOSE BICO, BENOIT ROMAN, PMMH, ESPCI ParisTech — Mechanics of stiff and electrically conductive films deposited on soft plastic substrates have recently gain interest due to the development of stretchable electronics applications. When submitted to tensile stress, such films tend to fail with the apparition of arrays of parallel channel cracks transverse to the direction of deformation, with fatal consequences for electrical conductivity. We study the propagation of such fractures in oxide monolayers coated on a polymer substrate under uniaxial stretching. We show how the crack density undergoes a transition from a statistic failure distribution of brittle material to a deterministic failure set by the elastic mismatch between the film and the substrate. A two-dimensional model of a film bonded to an elastic substrate fails to describe the saturation observed at high strain. We present experimental evidences of the localization of strain in the substrate by in-situ AFM imaging of the fracture process. We propose an increment of the model to account for the plasticity of the substrate. This description allows to pass continuously from the elastic to the plastic regime and to predict the saturation of the fragmentation as observed experimentally at large deformation.

8:12AM L49.00002 ABSTRACT WITHDRAWN —

8:24AM L49.00003 Effect of topological defects and curvature on anisotropic crystal growth, AMIR AZADI, Department of Physics, University of Massachusetts, Amherst, GREGORY M. GRASON, Department of Polymer Science and Engineering, University of Massachusetts, Amherst — The equilibrium shapes and symmetries of crystals are vestiges of the physical principles underlying their formation. We perform particle-based simulations guided by analytical analysis to investigate the structure of crystalline domains on curved substrates, a focus on the impact of topological defects on domain morphology. We find at low area fraction, as has been argued previously, that isotropic crystal growth with relatively compact domains generates large curvature-induced strains accommodated by relative ductile interactions, while the formation of anisotropic ribbon-like structures with lower-curvature induced stresses, introduces a larger line tension cost, and is thus favored for brittle crystals. Our results show that for ductile crystals with large surface coverage, appearance of stable topological defects precludes the formation of anisotropic, ribbon-like structures. However branch-like structures with large interfacial area are stable for certain values of intermediate curvature and crystalline ductility. These processes are guided by the interplay between elastic shape instability, defects, and curvature, where pattern formations are not related to kinetic instabilities.

8:36AM L49.00004 Energy Barriers for Defects in Disordered Solids, SVEN WIJTMANS, LISA MANNING, Syracuse University — In solids, defects govern flow and failure. In crystals, defects are easily-identified dislocations, while in disordered solids, defects can be found by analyzing the vibrational modes of the system, which are eigenvectors of the matrix describing the linear response. The low frequency modes are typically quasi-localized hybrids of excitations localized at the defects and plane-wave like modes. Additional analysis can separate these components, giving the location of a defect or a point of particle along a defect. Together, the energy barrier for each defect, we place particles along an isolated defect mode and calculate the energy at which the system transitions to a new energy basin. Different definitions of a new basin, such as a change in the particle contact network or particle displacements above a specific threshold, give different results. We identify several criteria that are consistent and provide a reasonable, robust definition of an energy barrier. Somewhat surprisingly, we find that energy barriers for isolated defects are generally higher than energy barriers for typical quasi-localized modes in the system.

8:48AM L49.00005 Tuning a material’s properties through the excitation of localized defect modes, MARC SERRA GARCIA, ETH Zurich, JOSEPH LYDON, California Institute of Technology, CHIARA DARAIO, ETH Zurich — Technological applications such as acoustic super-lenses and vibration mitigation require materials with extreme mechanical properties (Very high, zero, or negative stiffness). These properties can be achieved through buckling instabilities, local resonances and phase transitions, mechanisms that are limited to particular frequencies, strains or temperatures. In this talk I will present an alternative mechanism to tune the stiffness of a lattice. The mechanism is based on the excitation of a nonlinear localized defect mode. The oscillation of the defect mode affects the bulk properties of the lattice. This is due to the thermal expansion of the defect mode and the nonlinear coupling between the mode amplitude and the strain of the lattice. Due to the singular properties of nonlinear systems near bifurcation points, the lattice can achieve an arbitrarily large stiffness. It is possible to select point of the force-displacement relation that is being tuned by selecting the defect’s excitation frequency and amplitude. Depending on the nonlinear interaction potential at the defect site, the stiffness can be tuned to extremely positive or extremely negative values. While our theoretical and experimental results have been obtained in a granular crystal, the analysis suggests that an equivalent effect should be present in other lattices with localized modes and nonlinearity.

9:00AM L49.00006 Scars and the stability of crystalline shells under external pressure1, DUAN-DUAN WAN, MARK BOWICK, Syracuse University, RASTKO SKNEPNEK, University of Dundee — While continuum elastic theory predicts the mechanical properties of ideal spherical shells under external pressure, on microscopic scale the response of shells to pressure may be affected by their crystalline order and defect structure. Here we compare the stability, under external pressure, of shells with a minimal set of topologically-required defects to shells with extended defect arrays (grain boundary “scars”). In particular, we perform Monte Carlo simulations to compare how shells with and without scars deform quasi-statically under external hydrostatic pressure. We find that the critical pressure at which shells collapse is lowered when the scar distribution breaks icosahedral symmetry and raised when symmetry is preserved. The particular shapes resulting from collapses which break icosahedral symmetry depend crucially on the Föppl-von Karman number.

1We thank the Soft Matter Program of Syracuse University for support.
9:12AM L49.00007 Dynamics and geometry of interacting fractures in torn elastic sheets: convergent, divergent, and multiple swirling cracks, EUGENIO HAMM, Universidad de Santiago de Chile — I will present some recent results on the dynamics of multiple interacting cracks in torn elastic sheets. Specifically, I will consider a peeling - like configuration, in which two cracks converge in a robust fashion, and a “concertina” configuration in which two cracks systematically diverge. Based on experiments, I will discuss the non-trivial aspects of both problems, namely the way in which elasticity and fracture mechanics are concomitant when it comes to predict crack paths. Besides, I will show cases in which the trajectory of a crack is dictated by the path followed by another crack. This delayed interaction of cracks allows the construction of multiple crack configurations in which each crack recursively interacts with a nearby crack, giving rise to divergent self-similar spiral trajectories. Finally, I will discuss the effects of material anisotropy on the propagation of cracks. If time permits, I will also present a concise review of a second example of defect dynamics: the motion of conical singularities in thin elastic sheets, subjected to external forcing, and their mutual interaction. Specifically I will consider the gliding, climbing, annihilation and rotation of such structures.

9:48AM L49.00008 Untangling Superfluid Vortices, DUSTIN KLECKNER, MARTIN W. SCHEELER, University of Chicago, DAVIDE PROMENT, University of East Anglia, WILLIAM T. M. IRVINE, University of Chicago — What is the role of topology, or knottedness, in superfluid phase defects (quantum vortices)? In ideal classical fluids, vortex knots may never untie, and so there is an associated conserved quantity – helicity – which measures how tangled a flow is. One might expect a similar robustness for superfluid defects, however, simulations of the Gross-Pitaevskii equation demonstrate that vortex knots and links spontaneously untie and unlink. Nonetheless, the topology dramatically affects the vortex evolution, and a component of the initial helicity is transferred to helical coils as the knots unravel. These effects are remarkably similar to the behavior of tangled vortices in viscous fluids, suggesting they are universal features of non-ideal fluids.

10:00AM L49.00009 Dynamics of vacancies in two-dimensional Lennard-Jones crystals, ZHENWEI YAO, MONICA OLVERA DE LA CRUZ, Northwestern University — Vacancies represent an important class of crystallographic defects, and their behaviors can be strongly coupled with relevant material properties. We report the rich dynamics of vacancies in two-dimensional Lennard-Jones crystals in several thermodynamic states. Specifically, we numerically observe significantly faster diffusion of the 2-point vacancy with two missing particles in comparison with other types of vacancies; it opens the possibility of doping 2-point vacancies into atomic materials to enhance atomic migration. In addition, the resulting dislocations in the healing of a long vacancy suggest the intimate connection between vacancies and topological defects that may provide an extra dimension in the engineering of defects in extensive crystalline materials for desired properties.

10:12AM L49.00010 Jump conditions for thin bodies from an action principle, JAMES HANNA, Virginia Polytechnic Institute and State University — Thin, flexible bodies such as strings, sheets, and rods often sustain kinky geometric features, or experience discontinuous contact forces in their interactions with obstacles. The physics of dynamic and static versions of these phenomena differ. Kink/shock propagation, impact, peeling, unwrapping, tearing and cracking all occur at geometric locations in a body that do not correspond to material points. I will discuss how the jump conditions for momentum and energy across such moving discontinuities may be derived from an action principle for an extended body with time-dependent, non-material boundaries.

10:24AM L49.00011 ABSTRACT WITHDRAWN —

10:36AM L49.00012 Nonlinear optical probing of electric field induced oxygen migrations in Fe doped SrTiO$_3$, HAOCHEH YUAN, DAVID ASCIENZO, ONUR KURT, ZEHRA CEVHER, STEVE GREENBAUM, CUNY-Hunter Coll, RUSSELL MAIER, CLIVE RANDALL, the Pennsylvania State University, YUHANG REN, CUNY-Hunter Coll, CENTER FOR DIELECTRIC STUDIES, MATERIALS RESEARCH INSTITUTE TEAM — We report on our recent study of the electric field induced oxygen migration dynamics and defect states near the interface in Fe-doped SrTiO$_3$ single crystals by optical second harmonic generation (SHG) using a femtosecond Ti:sapphire laser at 800 nm wavelength. By varying both the incidence and the output angles, we identified a strong correlation between the measured SHG signals and the microscopic defect textures of the samples. Significant changes in SHG intensities and phases are explained by the formation and extension of oxygen vacancies and crystalline distortions near Fe defect centers. Our results show that the SHG technique is a powerful tool for detecting local environment near interfaces and oxygen migrations in ferroelectric structures.

10:48AM L49.00013 Positron beam spectroscopy of defect kinetics in highly oriented pyrolytic graphite, VARGHESE ANTO CHIRAYATH, AMARENDRA G, IGCAR, Kalpakkam, India - 603102 — We report here slow positron beam spectroscopy of thermally activated defect annealing mechanisms in highly oriented pyrolytic graphite (HOPG) which has been implanted with 200 keV carbon ions. The HOPG samples were irradiated to a dose of 10$^{14}$ and 10$^{15}$ ions/cm$^2$ which are just below the dose required for amorphization. The open volume defect-sensitive positron studies have clearly shown a defect annealing mechanism at temperatures close to the Wigner energy release peak for both the lower and higher dose irradiated samples. The sample irradiated to higher dose has also shown a second defect annealing step at 723K from near the end of range of the implanted ions. This step however was not visible in the lower dose sample and has not been previously reported. Positron beam spectroscopy could also detect the presence of interstitial defects trapped at the inter-planar regions after the open volume defect recovery by 973 K. These results will be compared to the present understanding of the open volume defect structures and their migration in graphite as well as in other sp$^2$ hybridized nanostructures like graphene.

8:00AM L50.00001 ABSTRACT WITHDRAWN —
8:12AM L50.00002 Switchable End-Linking of Gold Nanorods Induced by a Computationally Designed, Metal-Binding Peptide, ROBERT C. FERRIER, MATTHEW EIBLING, University of Pennsylvania, CHRISTOPHER MACDERMAID, Temple University, CHRISTOPHER LANCHI, JEFFERY G. SAVEN, RUSSELL J. COMPOSTO, University of Pennsylvania — Gold nanorods (AuNRs) possess unique optical properties that depend on the local orientation and separation of the individual rods. Previously, our group has explored the ‘permanent’ end-linking of AuNRs with alkane diethiols. The present work investigates the switchable end-linking of AuNRs via a computationally designed peptide. AuNRs are end-functionalized with a peptide designed in silico to bind a specific metal-ion. AuNRs end-to-end assemble when this metal-ion is present in solution above a particular concentration. The effect of metal-ion concentration on AuNR assembly is probed via UV/Visible spectroscopy and electron microscopy. A chelating agent is added to disassemble the AuNRs, returning the AuNRs to their original, unlinked, state. AuNRs can then be assembled again by adding more metal-ions, thereby allowing the solution optical properties to be switched between two states.

8:24AM L50.00003 Electrical anisotropy in coatings of aligned silver nanowires1, YE XU, Department of Physics and Astronomy, University of Pennsylvania. GABRIEL GÄLDERON-ORTIZ, Department of Physics and Astronomy, University of Puerto Rico at Humacao, ANNEMARIE EXARHOS, Department of Physics and Astronomy, University of Pennsylvania, AHMED ALSAYED, Complex Assemblies of Soft Matter, CNRS-Rhodia-UPenn UMI 3254, KAREN WINEY, Department of Materials Science and Engineering, University of Pennsylvania, JAY KIKKAWA, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — Conductive and transparent coatings consisting of silver nanowires (AgNWs) have been suggested as a promising candidate to replace traditional ITO coatings for emerging flexible electronics applications. The electrical properties of such AgNW coatings depend strongly on the structure of nanowire networks formed by various processing methods. In this work, we study how the alignment of nanowires affects the electrical anisotropy in AgNW coatings. Specifically, we introduce a robust method to prepare coatings of well-aligned AgNWs on glass substrates; the method utilizes the rapid flow of AgNW suspensions through a confined geometry. The angle-dependent sheet resistance of the coatings was measured, and large anisotropy in surface conductivity was found to characterize the aligned AgNW networks. We also explore the degree of alignment and surface coverage of AgNWs in the networks, thereby establishing connections between microscopy network structures and macroscopic electrical anisotropy.

8:36AM L50.00004 Molecular simulations of PEGylated lipids at interfaces: size selective dispersion of nanoscale objects, MARIA SAMMALKORPI, SAMPSA VIERROS, Department of Chemistry, Aalto University, Finland, PAUL R. VAN TASSEL, Department of Chemical & Environmental Engineering, Yale University, USA, JUKKA MÄTTÄ, Department of Chemistry, Aalto University, Finland — Phospholipids and phospholipid derivatives offer efficient, noncovalent functionalization and dispersion of hydrophobic objects, e.g., therapeutic molecules and nanoparticles including carbon nanotubes (CNTs). However, the relation of lipid aggregates in bulk solution and in the presence of the object, and the resulting dispersion remain important questions. We employ here molecular dynamics simulations to explore PEGylated lipid aggregates at interfaces and the resulting dispersion efficiency. By varying lipid and substrate curvature, and the PEG chain length, we find 1) lipid-CNT and PEGylated lipid-CNT aggregation behavior consistent with recent experiments, 2) the assembled morphology to vary from micellar-like to tubular coating (phospholipids) and micellar to monolayer-like (PEGylated lipids) with the transition depending on lipid curvature and for PEGylated lipids also on the PEG chain length and CNT diameter, 3) aggregation morphology dependent CNT dispersion ability, and 4) good agreement between simulation and scaling theories of a brush-type PEG [1,2]. Finally, we discuss the implications to size-selective separation of hydrophobic particles and experimental observations.

8:48AM L50.00005 Designing entropy-driven binary ordered superlattices from polyhedral nanoparticles, MIHIR KHADILKAR, FERNANDO ESCOBEDO, Cornell University — While ordered multicomponent structures of nanoparticles are certainly desirable in view of multiple potential applications, their self-assembly often requires highly tuned enthalpic interactions between the different constituents. We present simulation results on binary mixtures of hard polyhedral nanoparticles that form ordered superlattices without any enthalpic interaction, with the help of shape anisotropy alone. We also identify a rule that maximizes packing compatibility and hence promotes the formation of ordered superlattices based on the order-disorder transition pressures of the pure components. Results show formation of plastic solid solutions in the case of binary mixtures involving nanoparticle shapes from the truncated cube family, whose pure-components also form plastic crystals. Preliminary results for 2D systems will also be presented.

9:00AM L50.00006 Computer simulation study on the self-assembly structure of soft Janus particles, ZHAO-YAN SUN, ZHAN-WEI LI, Stete Key Laboratory of Polymer Physics and Chemistry, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences, MULTI-SCALE SIMULATION TEAM — Soft and deformable Janus particles have received more attention due to their unique properties and enormous potential applications in recent years. Here we present a mesoscale model for soft Janus particles, which successfully reflects their physical nature by directly mapping onto experimentally measurable particle properties. By properly tuning Janus balance and the strength of attraction between attractive patches, soft Janus particles can reversibly self-assemble into a number of fascinating hierarchical superstructures in dilute solutions, such as micelles, wormlike strings, single helices, double helices, bilayers, tetragonal bilayers, complex supermicelles, and in bulk systems, such as the hexagonal columnar structure and the body-centered tetragonal structure. We also introduce a new concept in achieving template-free fabrication of diverse 2D ordered nanostructures by utilizing anisotropic characteristics of soft triblock Janus particles. Our work demonstrates that soft Janus particles with the deformable and non-centrosymmetric characteristics hide many surprises in the design and fabrication of hierarchically self-assembled superstructures.

9:12AM L50.00007 Self-organization in periodically sheared granular materials, SAM WILKEN, GARY L HUNTER, PAUL M CHAIKIN, New York University — Self-organization as a result of periodic shear is becoming a feature observed in an increasing number of systems. In our experiments, we enforce cyclic shear on a three dimensional system of non-Brownian particles to investigate the global packing behavior of the granular assembly. By starting with a diluted, loosely packed system and measuring the packing fraction after each shear cycle, we find the system compacts to reach a steady state with a well defined packing fraction. The shear amplitude determines the steady state packing fraction, where large amplitude shear produces a lower packing density and small amplitude shear produces a higher packing density. We also study the phase diagram of this system which exhibits caged motion and a transition to vorticity.
9:24AM L50.00008 Bio-inspired Structural Colors from Deposition of Synthetic Melanin Nanoparticles by Evaporative Self-assembly. MING XIAO, Univ of Akron, YIWEN LI, University of California, San Diego, DIMITRI DEHEYN, Scripps Institution of Oceanography, University of California, San Diego, XIULIJUN YUE, NATHAN GIANNESCHI, University of California, San Diego, MATTHEW SHAWKEY, ALI DHINOJWALA, Univ of Akron — Melanin, a ubiquitous black or brown pigment in the animal kingdom, is a unique but poorly understood biomaterial. Many bird feathers contain melanosomes (melanin-containing organelles), which pack into ordered nanostructures, like multilayer or two-dimensional photonic crystal structures, to produce structural colors. To understand the optical properties of melanin and how melanosomes assemble into certain structures to produce colors, we prepared synthetic melanin (polypodamine) particles with variable sizes and aspect ratios. We have characterized the absorption and refractive index of the synthetic melanin particles. We have also shown that we can use an evaporative process to self-assemble melanin films with a wide range of colors. The colors obtained using this technique is modeled using a thin-film interference model and the optical properties of the synthetic melanin nanoparticles. Our results on self-assembly of synthetic melanin nanoparticles provide an explanation as why the use of melanosomes to produce colors is prevalent in the animal kingdom.

1National scientific foundation, air force office of scientific research, human frontier science program

9:36AM L50.00009 Mobility and diffusion of bound DNA-coated colloids. ETIENNE DUCROT, JEREMY S. YODH, Center for Soft Matter Research, New York University, YU WANG, Molecular Design Institute, New York University, YUFE WANG, Center for Soft Matter Research, New York University, XIAOLONG ZHENG, MARCUS WECK, Molecular Design Institute, New York University, DAVID J. PINE, Center for Soft Matter Research, New York University — DNA coatings have been proposed as a versatile means for programming the self-assembly of micrometer and nanometer size particles. Progress in achieving this goal for particles larger than about 100 nm, where the DNA coatings are typically much thinner than the particle diameter, has been impeded because such DNA-coated colloids stick to each other like Velcro; they collide and bind but fail to anneal into their preprogrammed structure. Most notably, they generally fail to assemble into colloidal crystals but form random aggregates. We have prepared micrometer-size colloids coated with single stranded DNA that are mobile even after they bind, so that the particles can rapidly rearrange. Here we report measurements of the mean square displacement of one ssDNA particle on a second ssDNA particle immobilized on a substrate, when the temperature is quenched to just below the melting temperature (near 40°C). For shallow quenches of ΔT ≈ 0.5°C, the mean square displacement is proportional to time, Δr^2~At, indicating diffusive motion. For deeper quenches of ΔT ≈ 1°C, Δr^2~At^n, where n ≈ 1, indicating subdiffusive motion. This behavior is discussed in terms of a random distribution of traps.

9:48AM L50.0010 High-yield production of stable colloidal clusters and their use in hierarchical DNA-directed assemblies. JAMES MCGINLEY, YIFAN WANG, IAN JENKINS, TALID SINNO, JOHN CROCKER, University of Pennsylvania, CROCKER RESEARCH GROUP COLLABORATION, SINNO RESEARCH GROUP COLLABORATION — Our goal is to produce and purify high yields of stable DNA-coated colloidal clusters by using crystal templates and reprogrammable DNA interactions. First, we incorporate “impurity” particles into a host colloidal crystal made up of DNA-coated polymer microspheres, and ensure that the only bonds that are preserved are those between the impurity particles’ DNA strands and those of their nearest neighboring host particles. After dispersing the host crystal and making all DNA bonds permanent using a DNA-reactive enzyme, we are left with stable colloidal clusters, each comprised of a single impurity particle surrounded by a number of particles dictated by the host crystal structure. The clusters can be made withicosahedral, Cuboctahedral, Tetrahedral, Cubic, and Octahedral symmetries, and can then be purified using density gradient fractionation. We will demonstrate that the scalable production of purified, well-oriented and stable DNA-coated colloidal clusters allows for the exploration of hierarchical assemblies with asymmetric building blocks and directional bonding.

10:00AM L50.0011 Using Microfluidics to Measure the Equation of State for a 2D Colloidal Membrane. ANDREW BALCHUNAS, RAFAEL CABANAS, SETH FRADEN, ZVONIMIR DOGIC, Brandeis Univ — In the presence of non-adsorbing polymer, monodisperse filamentous viruses assemble into colloidal membranes, which are 2D liquid-like one-rod-length-thick monolayers of aligned rods. Colloidal membranes are of particular interest because their properties are accounted for by the same theoretical models that are used to describe the biophysics of conventional lipid bilayers. However, bulk membrane formation only occurs over a very limited range of depletant concentrations and ionic strengths. In order to explore the properties of the colloidal membranes under a much wider range of molecular parameters, we have developed a microfluidic technique that allows for in-situ exchange of the enveloping polymer suspension. This allows us to access the region of phase space where membranes are metastable. Using our technique we can measure how the colloidal membrane area depends on applied osmotic pressure, allowing us to determine its equation of state. We also characterize the dynamics of the constituent rods by using single molecule tracking techniques.

10:12AM L50.00012 Assembly and interactions of achiral rafts in colloidal membranes. JOIA MILLER, Brandeis University, PRERNAA SHARMA, Indian Institute of Science Bangalore, ZVONIMIR DOGIC, Brandeis University — Two-dimensional colloidal membranes composed of rods of different lengths display rich phase behavior. In particular, chirality of constituent rods stabilizes assembly of colloidal rafts, micron sized droplets enriched in one type of rod floating in the background membrane. Colloidal rafts interact via long-range repulsive interactions that are mediated by local rod twisting due to their rods’ inherent chirality. We explore the behavior of an achiral bidisperse mixture of colloidal rods. Even in the achiral limit we observe assembly of stable or meta-stable finite-sized rafts. However, in contrast to the chiral limit, the long-range interactions between achiral rafts are attractive. These rafts are embedded in a host membrane that has nearly critical fluctuations in composition. We correlate the attractive domain interactions with these critical fluctuations.

10:24AM L50.00013 Patchy particles using colloidal caps. CHRISTINE MIDDLETON, DAVID PINE, New York University — We present a method for making patchy particles functionalized with single stranded sticky end DNA only on their patches. This is done by adding “spherical cap” particles as patches to single stranded DNA-coated colloids. The caps are single stranded DNA using copper-free click chemistry. Due to being attached only by depletion, the patches diffuse on the surface of the particle. The patchy particles can then interact with each other in a specific, directional way through the mobile, DNA functionalized patches.

10:36AM L50.00014 Temperature controlled nanoparticle stability in concentrated polymer solutions. SO YOUN KIM, Ulsan Natl Inst of Sci & Tech, CHARLES F. ZUKOSKI, University at Buffalo — Polyethylene glycol (PEG) in water is known to display a lower critical solution temperature (LCST) and a closed loop at high temperature. When silica nanoparticles are suspended in concentrated PEG solution, we observe temperature dependent phase separation even below the 60°C which is much lower than the LCST for the lowest PEG reported. Depending on the conditions, nanoparticles form clusters and show gelation and both can be reversible. Small angle x-ray scattering (SAXS) is used to characterize microstructure of nanoparticle dispersion and diffusing wave spectroscopy (DWS) and other light scattering techniques are employed to understand particle correlations in dense systems. Polymer dynamics near particle substrate is discussed with NMR Free Induction decay experiment. These combined experimental studies help to understand the detailed mechanism of nanoparticle gelation in polymer solutions.
10:48AM L50.00015 A Directional Entropic Force Approach to Assemble Anisotropic Nanoparticles into Superlattices1, BYEONGDU LEE, Argonne Natl Lab, TAO LI TEAM, KAYLIE YOUNG, GEORGE C. SCHATZ, CHAD A. MIRKIN COLLABORATION2, MICHAEL ENGEL, PABLO F. DAMASCENO, SHARON C. GLOTZER COLLABORATION3 — We introduce a directional entropic force approach (DEFA) for controlling the assembly of anisotropic nanoparticles into crystalline lattices. The method relies on surfactant micelle-induced depletion interactions to assemble anisotropic gold nanoparticles into reconfigurable, non-close-packed (open) superlattices in solution. The anisotropic nanoparticles align along their flat facets to maximize entropy, and therefore minimize the free energy of the system, leading to assemblies with long-range order. Importantly, our experimental work complements recent theoretical work that proposes directional entropic forces between nanoparticle facets as a viable means for thermodynamically assembling nanoparticle superlattices. The experimental work herein uses depletants to create strong attractive forces that can drive assembly of reversible superlattices with tunable spacing in solution. These directional entropic forces are analogous to the directional bonding between atoms in molecules. The resulting crystalline superlattices are therefore shape-dependent. We show that the electrostatic and depletion interactions combine to determine the lattice spacing, and can be tuned independently with surfactant concentration and ionic strength to reconfigure the lattice constant.

Wednesday, March 4, 2015 8:00AM - 11:00AM –
Session L51 DCMP: Invited Session: Topological Superconductors
Grand Ballroom C1 - Ady Stern, Weizmann Institute of Science

8:00AM L51.00001 Time reversal invariant topological superconductors in one dimension: how to realize them and what can they do for you, EREZ BERG, Weizmann Institute of Science — Time-reversal invariant (TRI) topological superconductors are exotic superconductors that support anomalous protected edge states. These states are electronic analogues of the B phase of superfluid $^3$He. In one spatial dimension, a TRI superconductor carries a Kramers pair of Majorana zero modes at each end. In this talk, I will discuss setups to realize this phase in spin-orbit coupled quantum wires, in proximity to conventional superconductors. The topologically non-trivial phase can be stabilized either by coupling the wire to two superconductors with a phase difference of $\pi$ between them, or spontaneously, due to repulsive interactions in the wire. In the former case, the system is a natural realization of a fermion parity pump, switching the local fermion parity of both edges when the relative phase between the superconductors is changed adiabatically by $2\pi$. I will show that a gapless TRI topological phase with exponentially localized edge states can exist even if the superconductor used to induce pairing is one-dimensional, and superconducting long-range order is destroyed by long-wavelength fluctuations. If time allows, I will talk about the signatures of the TRI phase in noise correlation experiments, and compare it to the the case of a time reversal breaking phase with a single Majorana zero mode at the ends.

8:36AM L51.00002 Induced superconductivity in the quantum spin Hall edge, SEAN HART, Harvard University — The quantum spin Hall insulator is an example of a two-dimensional topological insulator, a phase of matter in which protected gapless surface states surround a gapped bulk. Inducing superconducting pairing within the helical edge states of the quantum spin Hall effect has been proposed as an avenue towards topological superconductivity. In this talk we present measurements of superconductivity induced in two-dimensional HgTe/HgCdTe quantum wells, a material which becomes a quantum spin Hall insulator when the well width exceeds $d_C = 6.3$ nm. In wells that are 7.5 nm wide, we find that supercurrents are confined to the one-dimensional sample edges as the bulk density is depleted. However, when the well width is decreased to 4.5 nm the edge supercurrents cannot be distinguished from those in the bulk. Our Josephson interferometry measurements provide evidence for supercurrents carried by the helical edges of the quantum spin Hall effect, one of the crucial ingredients for one-dimensional topological superconductivity. These results also directly yield information about the microscopic structure of the edge modes. In particular we find that the widths of the edge channels range from 180 nm to 408 nm.

9:12AM L51.00003 Local Adiabatic Mixing of Kramers Pairs of Majorana Bound States, KARSTEN FLENSBERG, Center for Quantum Devices, The Niels Bohr Institute, Univ of Copenhagen, Denmark — In this talk adiabatic time evolution of Kramers pairs of Majorana bound states and the prospects of using such bound states as parity qubits are discussed. It is shown that local adiabatic perturbations can cause a rotation in the space spanned by the Kramers pair and that the quantum information is therefore unprotected against local perturbations. This is in contrast to the case of single localized Majorana bound states in systems with broken time reversal symmetry. However, under certain conditions such mixing does not occur. A general scheme for determining when these conditions are satisfied is explained and exemplified with a quasi-1D model of a time reversal symmetric topological superconductor.

9:48AM L51.00004 Phase coherent transport in hybrid superconductor-topological insulator devices1, AARON FINCK, University of Illinois at Urbana-Champaign — Heterostructures of superconductors and topological insulators are predicted to host unusual zero energy bound states known as Majorana fermions, which can robustly store and process quantum information. Here, I will discuss our studies of such heterostructures through phase-coherent transport, which can act as a unique probe of Majorana fermions. We have extensively explored topological insulator Josephson junctions through SQUID and single-junction diffraction patterns, whose unusual behavior give evidence for low-energy Andreev bound states. In topological insulator devices with closely spaced normal and superconducting leads, we observe prominent Fabry-Perot oscillations, signifying gate-tunable, quasi-ballistic transport that can elegantly interact with Andreev reflection. Superconducting disks deposited on the surface of a topological insulator generate Aharonov-Bohm-like oscillations, giving evidence for unusual states lying near the interface between the superconductor and topological insulator surface. Our results point the way towards sophisticated interferometers that can detect and read out the state of Majorana fermions in topological systems. This work was done in collaboration with Cihan Kurter, Yew San Hor, and Dale Van Harlingen.

1We acknowledge funding from Microsoft Project Q.
weakly coupled to a heat bath. I will conclude with a brief discussion of how these phenomena may best be detected in experiments.

Wednesday, March 4, 2015 8:00AM - 11:00AM — Session L52 DCMP: Invited Session: Many Body Localization and Entanglement  Grand Ballroom

C2 - Chandran Anushya, Perimeter Institute for Theoretical Physics

10:24AM L51.00005 Selective Equal Spin Andreev Reflections induced by Majorana Fermions

KAM TUEN LAW, Hong Kong Univ of Sci & Tech — The search for Majorana fermions has become an important subject in recent years. Zero-bias conductance peaks (ZBCPs) possibly induced by Majorana fermions have been reported in tunneling spectroscopy experiments. However, the origin of these ZBCPs is still under debate. In this talk, I would like to point out that Majorana fermions induce a special type of Andreev reflection processes called selective equal spin Andreev reflections (SESARs) [1]. For SESAR processes at a normal lead/topological superconductor interface, incoming electrons with certain spin polarization in the lead are reflected as counter-propagating holes with the same spin. The spin polarization direction of the electrons of this Andreev reflected channel is selected by the Majorana fermions. Moreover, electrons with opposite spin polarization are always reflected as electrons with unchanged spin. We show that the tunneling current from a ferromagnetic lead to a topological superconductor is strongly affected by the spin polarization direction of the lead due to SESARs. This property can be used to detect Majorana fermions in several candidate topological superconductors. The application of SESARs in generating giant spin currents in nodal topological superconductors will also be discussed.

8:00AM L52.00001 Renormalization group studies of many-body localization

EHUD ALTMAN, The Weizmann Institute of Science — Quantum correlations do not usually persist for long in systems at finite energy density and disappear once the system thermalizes. But many-body localization offers an alternative paradigm, whereby quantum matter can evade the usual fate of thermal equilibrium and retain retrievable quantum correlations even at high energies. I will survey a dynamical renormalization group (RG) approach used to characterize the novel dynamics and entanglement structures, which develop in the localized phase in lieu of classical thermalization. Then I will present a theory of the transition between the ergodic and the many-body localized phase based on a novel RG framework. Here eigenstate entanglement entropy emerges as a natural scaling variable; the RG describes a change from area-law to volume law entanglement through an intriguing critical point, where the distribution of entanglement entropy becomes maximally broad. The ergodic phase established near the critical point is a Griffiths phase, which exhibits sub-diffusive energy transport and sub-ballistic entanglement propagation. The anomalous diffusion exponent vanishes continuously at the critical point. Before closing I will discuss recent progress in confronting the emerging theoretical understanding of many-body localization with experimental tests.

8:36AM L52.00002 Evidence for Many-Body Localization in an Ultracold Fermi-Hubbard Gas

BRIAN DEMARCO, University of Illinois at Urbana-Champaign — Many-body localization (MBL) is a promising new paradigm for understanding disorder-induced localization in interacting quantum systems at non-zero temperature. We observe the emergence of an insulating state consistent with MBL in a strongly correlated atomic Fermi gas trapped in a disordered optical lattice, a closed system that realizes the disordered Fermi-Hubbard model. In measurements of disorder-induced localization obtained via mass transport, we detect three phenomena characteristic of MBL. We measure localization of this strongly interacting system at non-zero temperature, and we observe interaction-driven delocalization. We also observe localization that persists as the temperature and energy density of the gas are increased.

9:12AM L52.00003 Entanglement and universal dynamics in many-body localized systems

DMITRY ABANIN, Perimeter Institute for Theoretical Physics — We are used to describing systems of many particles by statistical mechanics. However, the basic postulate of statistical mechanics – ergodicity – breaks down in so-called many-body localized systems, where disorder prevents particle transport and thermalization. In this talk, I will describe a phenomenological theory of the many-body localized (MBL) phase, based on new insights from quantum entanglement [1]. I will argue that, in contrast to ergodic systems, MBL eigenstates are not highly entangled, but rather obey so-called area law, typical of ground states in gapped systems. I will use this fact to show that MBL phase is characterized by an infinite number of emergent local conservation laws, in terms of which the Hamiltonian acquires a universal form. Turning to the experimental implications, I will describe the behavior of MBL systems following quantum quenches: surprisingly, entanglement shows logarithmic in time growth [1,2], reminiscent of glasses, while local observables exhibit power-law approach to ‘equilibrium’ values [3]. I will support the presented theory with the results of numerical experiments. I will close by discussing experimental implications and other directions in exploring ergodicity and its breaking in quantum many-body systems, including many-body localization in periodically driven systems.

---

9:48AM L52.00004 Localization protected quantum order

RAHUL NANDKISHORE, Princeton University — Many body localization occurs in isolated quantum systems, usually with strong disorder, and is marked by absence of dissipation, absence of thermal equilibration, and a memory of the initial conditions that survives in local observables for arbitrarily long times. The many body localized regime is a non-equilibrium, strongly disordered, non-self averaging regime that presents a new frontier for quantum statistical mechanics. In this talk, I point out that there exists a vast zoo of correlated many body localized states of matter, which may be classified using familiar notions of spontaneous symmetry breaking and topological order. I will point out that in the many body localized regime, spontaneous symmetry breaking can occur even at high energy densities in one dimensional systems, and topological order can arise even without a bulk gap. I will also discuss the phenomena of perfectly isolated many body localized systems, which are weakly coupled to a heat bath. I will conclude with a brief discussion of how these phenomena may best be detected in experiments. References: Phys. Rev. B 88, 014206 (2013), Phys. Rev. B 90, 195115 (2014), Phys. Rev. ---

Infinite dimensions has emerged. However, it is an understatement to say that large, exactly isostatic packings approach to other open issues in the theory of glasses. With a recently developed scaling theory of the jamming transition, and with numerical simulations. Finally, I will briefly discuss some possible extensions of this impact on the critical properties of the jamming transition and allows one to obtain analytic predictions for the critical exponents. The predictions are consistent in the solution: as in the SK model, the glassy states turn out to be marginally stable, and are described by a Parisi equation. Marginal stability has a deep based on the exact solution of the hard sphere model in infinite dimension. An unexpected analogy with the Sherrington-Kirkpatrick spin glass model emerges independent of spatial dimension, suggesting that a mean field theory can correctly predict their values. I will discuss a mean field approach to the problem.

FRANCESCO ZAMPONI, LPTENS and CNRS, Ecole Normale Superieure, Paris — The jamming transition marks the emergence of rigidity in a system of many-body localized phases—the interacting analogs of the Anderson insulator. In this talk I will discuss in detail three observations related to the entanglement properties of many-body localized systems: (i) A global quench within the many-body localized phase gives rise to a slowly (logarithmically) increasing entanglement entropy. This is due to interaction induced dephasing that is absent in the Anderson insulator and therefore serves as a unique signature of the many-body localized phase. (ii) A local quench from an eigenstate leads to an extensive increase in the entanglement entropy only at the many-body localization transition itself. And (iii) at the many-body localization transition the distribution of entanglement entropies becomes extensively broad, while it vanishes both in the extended metallic phase and in the localized phases. The width of the entanglement distribution, like the long time limit of the local quench, is therefore a useful diagnostic for a many-body localization transition. I explicitly demonstrate how all these features are observed in microscopic spin chain models of many-body localization, and, in particular, discuss how they can be used to detect a many-body mobility edge.

Wednesday, March 4, 2015 8:00AM - 11:00AM –
Session L53 DCMP GSOFT: Invited Session: Advances in Glassy Systems Across Many Scales
Grand Ballroom C3 - Andrea Liu, University of Pennsylvania

8:00AM L53.00001 Thermodynamic glass transitions in three dimensional glasses, LUDOVIC BERTHIER, CNRS & University Montpellier 2 — The physics associated to the glass transition controls the dramatic evolution of transport coefficients in systems as diverse as dense liquids, polymers, colloids, but also granular particles and active matter. The experimental liquid-glass transition in equilibrium fluids is characterized by several phenomenological crossovers, but glasses can form without crossing any sharp singularity. I will present multiple evidences suggesting that the glass formation process is underlied by equilibrium phase transitions. Combining numerical tools developed to study ordinary phase transitions to recent theoretical analytical progress I will demonstrate that studies of the glass transition have entered a new phase, where the relevant order parameter, thermodynamic fluctuations and phase transformations can be directly analysed in finite dimensional model glasses.

8:36AM L53.00002 Exact computation of the critical exponents of the jamming transition, FRANCESCO ZAMPONI, LPTENS and CNRS, Ecole Normale Superieure, Paris — The jamming transition marks the emergence of rigidity in a system of amorphous and athermal grains. It is characterized by a divergent correlation length of the force-force correlation and non-trivial critical exponents that are independent of spatial dimension, suggesting that a mean field theory can correctly predict their values. I will discuss a mean field approach to the problem based on the exact solution of the hard sphere model in infinite dimension. An unexpected analogy with the Sherrington-Kirkpatrick spin glass model emerges in the solution: as in the SK model, the glassy states turn out to be marginally stable, and are described by a Parisi equation. Marginal stability has a deep impact on the critical properties of the jamming transition and allows one to obtain analytic predictions for the critical exponents. The predictions are consistent with a recently developed scaling theory of the jamming transition, and with numerical simulations. Finally, I will briefly discuss some possible extensions of this approach to other open issues in the theory of glasses.

9:12AM L53.00003 Revealing the critical behavior of jamming: high precision simulations of large, exactly isostatic packings1, ERIC CORWIN, Univ of Oregon — Recently, an exact first-principle theory of jamming criticality in infinite dimensions has emerged. However, it is an understatement to say that it is far from the physically relevant dimensions of d = 2 and 3. In this work we probe how meaningful these infinite-dimensional predictions are in low dimensions by examining the scaling of the weak contact forces at jamming. We use a combination of 1) newly developed GPU techniques implementing quad-precision simulations and 2) an algorithm to calculate extremely accurate interparticle forces for isostatic packings to probe the behavior of systems of very-many-particles in dimensions d = 2 – 6. We find that the weak forces arise from two populations, one associated with localized excitations and the other with extended excitations. We find that the fraction of localized excitations decreases with increasing dimension. Surprisingly, the infinite-dimensional predictions hold exactly all the way down to d = 2 for the extended excitations.

10:24AM L53.00005 Seeking Quantum Speedup Through Spin Glasses: Evidence of Tunneling?, HELMUT G. KATZGRABER, Texas A&M University — Quantum annealing machines use a non-mainstream method known as adiabatic quantum annealing to perform optimization tasks. Very recently, tests performed by different research teams on the D-Wave Two quantum annealer using spin glasses as a benchmark have shown that, although the machine indeed appears to tap into quantum effects, it shows no speedup over traditional computing architectures. We present results that suggest that the benchmark instances used are too simple to detect quantum speedup and based on insights from spin-glass physics outline strategies to develop hard instance classes. With our choice of benchmark strategy, we show that the D-Wave Two quantum annealer does not outperform current computer technologies, mainly due to noise and calibration errors of the device. However, our results do indicate that quantum tunneling might be present.

Work done in collaboration with F. Hamze (D-Wave Systems, Inc.), Zheng Zhu (Texas A&M University) and Andrew J. Ochoa (Texas A&M University). H.K.K. acknowledges support from the NSF (Grant No. DMR-1151387).
11:15AM M1.00001 Tunable layer-by-layer oxidation of atomically thin WSe$_2$. MAHIRO YAMAGAMI, MASAHIRO ISHIHAMA, Department of Physics, University of Tokyo, JAPAN. — The ability to tailor the properties of a material nanoscale heterostructures is limited by the intrinsic crystalline quality of the TMDs. Our research group has focused on the intrinsic properties of BN, which is considered to be an ideal substrate for graphene devices. However, many intrinsic properties of BN have not been clarified yet, since many researchers have focused on the electrical properties of BN. In this study, we demonstrate that the layer-by-layer dielectric breakdown of BN is systematically studied using the conductive atomic force microscopy. We find that the obtained field strength is about 12 MV/cm, which is comparable to the conventional SiO$_2$. After the dielectric breakdown, BN fractured like a flower with equilateral triangular fragments. However, when an applied voltage is stopped just in the middle of the dielectric breakdown, the formation of holes is clearly observed, which does not penetrate to the bottom metal electrode. Subsequent IV measurement at the hole indicates that the remaining BN layer in the hole is still electrically inactive. A possible explanation is presented.

11:27AM M1.00002 Layer-by-layer Dielectric Breakdown of Hexagonal Boron Nitride Film in Conductive AFM Measurement. YOSHIKI HATTORI, The University of Tokyo, JAPAN, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, JAPAN. — We have investigated the structural and electronic properties of fluorinated (MoS$_2$), WS$_2$, MoTe$_2$, and WTe$_2$. We have demonstrated the feasibility of conducting the measurements in situ conductance and crystalline properties of graphene and MoS$_2$ monolayers. We realized back or side gated electrical devices from monolayer MoS$_2$ or graphene crystals (trigonals respectively hexagons) suspended on a 50nm SiNx m. The devices are exposed to electron irradiation inside a 200kV transmission electron microscope (TEM) and we perform in situ conductance measurements. The number of defects and the quality of the graphene and MoS$_2$ monolayers is strongly affected by monolayer MoS$_2$ and the binding leads to p-doping. Fluorine atoms are strongly bound on molydisulfide and the binding leads to p-type conductivity. As such, fluorination can be useful for chemical doping of monolayer MoS$_2$.

11:39AM M1.00003 Fluorinating Single Layer Molydisulfide. MASAHIRO ISHIHAMA, JYOTI KATOCH, Department of Physics and Nanoscience Technology Center, University of Central Florida — We have investigated the structural and electronic properties of fluorinated (MoS$_2$) using electron microscopy, scanning tunneling microscopy and spectroscopy, photoluminescence and ultraviolet photoelectron spectroscopy. Fluorine atoms are strongly bound on molybdenum disulfide and the binding is p-type. As such, fluorination can be useful for chemical doping of monolayer molybdenum disulfide. We will discuss our experimental results in light of our recent ab-initio calculations.

11:51AM M1.00004 The effect of defects produced by electron irradiation on the electrical properties of graphene and MoS$_2$. JULIO ALEJANDRO RODRIGUEZ-MANZO, ADRIAN BALAN, CARL NAYOR, WILL PARKIN, MATTHEW PUSTER, A.T. CHARLIE JOHNSON, MARIJA DRNDIC, Univ of Pennsylvania — We present a study of the effects of the defects produced by electron irradiation on the electrical and crystalline properties of graphene and MoS$_2$ monolayers.

12:03PM M1.00005 Intrinsic disorder in graphene on transition metal dichalcogenide heterostructures. MATTY KANTZ, MATTHEW PUSTER, University of Texas at Austin, DEVIN MCKENZIE, SHENGQIANG HUANG, MARINA PAGGEN, University of Arizona, MAZHAR ALI, ROBERT CAVA, Princeton University, EMMANUEL TANG, University of Texas at Austin, BRIAN L. LEROY, University of Arizona. — Recently, semiconducting materials in the transition metal dichalcogenide (TMD) family have gained great popularity for use in novel graphene-based heterostructure devices such as tunneling transistors, highly efficient flexible photovoltaic devices, and nonvolatile memory cells. TMDs have also been explored as alternatives to hexagonal boron nitride (hBN) as substrates for pristine graphene devices. Their quality has thus far been significantly worse than comparable hBN devices. We examine graphene on numerous TMD substrates (MoS$_2$, WS$_2$, WSe$_2$, MoTe$_2$) with scanning tunneling microscopy and spectroscopy and find that point and line defects intrinsic to all TMD crystals (both of natural and synthetic origin) result in scattering of electrons in graphene. Our findings suggest that the quality of graphene on TMD heterostructures is limited by the intrinsic crystalline quality of the TMDs.

12:15PM M1.00006 Tailoring the properties of two dimensional molybdenum disulfide. SAIFUL I. KHONDAKER, MUHAMMAD R. ISLAM, NARAE KANG, UDAI BHANU, HARI P. PAUDEL, MIKHAIL EREMENCHOUK, LAURENCE TETARD, MICHAEL N. LEUENBERGER, NanoScience Technology Center and Department of Physics, University of Central Florida — The ability to tailor the properties of a material is essential to optimize device functionality. In this talk, we will present evidence that the electrical and optical properties two-dimensional (2D) molybdenum disulfide (MoS$_2$) can be tuned by controlled exposure to plasma oxygen plasma. We find that the mobility, on-current and resistance of 2D MoS$_2$ FETs vary exponentially by up to four orders of magnitude with respect to the plasma exposure time. Photoluminescence (PL) study show a decrease of PL intensity leading a complete quenching. Raman studies show a significant decrease of intensity of MoS$_2$ peaks with the creation of new oxidation induced peak, while X-ray photoelectron spectroscopy (XPS) study show peaks associated with MoO$_3$ after plasma exposure. We suggest that during exposure to oxygen plasma, the energetic oxygen molecules interact with MoS$_2$ and create MoO$_3$ rich defected-regions, which are insulating. MoO$_3$ defected-regions act as a tunnel barrier for the injected conduction electrons, giving rise to the exponential increase in resistivity as a function of plasma exposure time. Bandstructure calculation shows that the PL quenching upon plasma exposure is due to the creation of MoO$_3$ defected-regions which causes a direct to indirect bandgap transition in monolayer MoS$_2$. This work is based on research supported by the National Science Foundation under Grant No. 0955625.
12:27PM M1.00007 Synthesis and Characterizations of Two-Dimensional Atomic Layers and Their Heterostructures, YI-HSIEN LEE, National Tsing Hua University — Monolayers of van der Waals (vdW) materials, including graphene, h-BN, and MoS$_2$, have been highlighted regarding both scientific and industrial aspects due to novel physical phenomenon inherited from the reduced dimensionality. Layered transition metal dichalcogenides (TMD) atomic layers, being considered as the thinnest semiconductor, exhibit great potential for advanced nanodevices. Monolayer in the class of offered a burgeoning field in fundamental physics, energy harvesting, electronics and optoelectronics. Recently, atomically thin heterostructures of TMD monolayer with various geometrical and energy band alignments are expected to be the key materials for next generation flexible optoelectronics. The individual TMD monolayers can be aligned vertically or laterally to construct diverse heterostructures which are difficult to reach with the laborious pick up-and-transfer method of the exfoliated flakes. The ability to produce copious amounts of high quality layered heterostructures on diverse surfaces is highly desirable but it has remained a challenging issue. Here, we have achieved a direct synthesis of various heterostructures of monolayer TMDs. The synthesis was performed using ambient-pressure CVD with aromatic molecules as seeding promoters. We discuss possible growth behaviors, and we examine the symmetry and the interface of these heterostructures using optical analysis and atomic-resolution scanning TEM. Our method offers a controllable synthesis of to obtain high-quality heterogeneous of TMD atomic layers with diverse interface geometry.

1:03PM M1.00008 Spatial Progression of Thermal Oxidation in Layered WSe$_2$ Nano-sheets, YINGNAN LIU, Department of Physics, University of Texas at Austin, CHENG TAN, Microelectronics Research Center, University of Texas at Austin, HARRY CHOU, Department of Mechanical Engineering, University of Texas at Austin, AVINASH NAYAK, Microelectronics Research Center, University of Texas at Austin, DI WU, Department of Physics, University of Texas at Austin, JONYEOK KIM, Microelectronics Research Center, University of Texas at Austin, RODNEY RUOFF, Department of Mechanical Engineering, University of Texas at Austin, KEJI AKINWANDE, Microelectronics Research Center, University of Texas at Austin, KEJI LAI, Department of Physics, University of Texas at Austin — Owing to the extremely different bonding strengths between intralayer covalent bonds and interlayer van der Waals interaction, many physical and chemical properties of layered transition metal dichalcogenides are expected to be highly anisotropic in nature. Using a number of compositional, structural, and electrical characterization tools, we have studied the spatial progression of the thermal oxidation of exfoliated WSe$_2$ nano-sheets, which primarily starts at the sample edges and propagates laterally towards the center. As revealed by microwave impedance microscopy and transport measurements, the partially oxidized regions show much higher conductivity than either the WSe$_2$ itself or the completely oxidized WO$_3$. The ability to electrically map out how chemical reactions are taking place in the nanoscale could be of particular importance for 2D materials that hold promise for future applications.

1:15PM M1.00009 Bulk Direct Band Gap MoS$_2$ by Plasma Induced Layer Decoupling, ROHAN DHALL, University of Southern California, MAHESH NEUPANE, DARSHANA WICKRAMARATNE, University of California-Riverside, MATTHEW MECKLENBURG, ZHEN LI, University of Southern California, CARLON MOORE, XEI SCIENTIFIC, ROGER LAKE, University of California-Riverside, STEPHEN CRONIN, University of Southern California — We report a robust method for engineering the optoelectronic properties of few layer MoS$_2$ using low energy oxygen plasma treatment. Gas phase treatment of MoS$_2$ by an upstream N$_2$-O$_2$ plasma is shown to enhance the photoluminescence (PL) of few layer MoS$_2$ flakes by up to 20 times, without reducing the layer thickness. A blue shift in the photoluminescence spectra and narrowing of linewidth is consistent with a transition of MoS$_2$ from indirect to direct band gap material. Atomic force microscope and Raman spectra reveal that the flake thickness actually increases as a result of the plasma treatment, indicating an increase in the interlayer separation in MoS$_2$. Ab-initio calculations reveal that the increased interlayer separation is sufficient to decouple the electronic states in individual layers, leading to a transition from an indirect to direct gap semiconductor. With optimized plasma treatment parameters, we observed enhanced PL signals for 32 out of 35 few layer MoS$_2$ flakes tested, indicating this method is robust and scalable. Monolayer MoS$_2$, while direct band gap, has a small optical density, which limits its potential use in practical devices. The results presented here provide a material with the direct band gap of monolayer MoS$_2$, without reducing sample thickness, and hence optical density.

1:27PM M1.00010 High-Throughput Screening of Substrates for Synthesis of Two-Dimensional Materials, ARUNIMA K. SINGH, NIST - Natl Inst of Stds & Tech, HOULONG L. ZHUANG, Oak Ridge National Laboratory, FRANCESCA TAVAZZA, NIST - Natl Inst of Stds & Tech, RICHARD G. HENNIG, University of Florida, Cornel University — Since the discovery of graphene, several two-dimensional (2D) materials have been synthesized experimentally, but many theoretically predicted 2D materials are yet to be synthesized. Common synthesis techniques such as chemical-vapor deposition and molecular-beam epitaxy require suitable substrates. We are developing a strategy to enable high-throughput searches for suitable substrates for 2D materials by automatically identifying suitable substrate candidates and characterize their stabilizing properties and doping effects using density-functional theory. As first steps, we have found that several transition-metal, rare-earth-metal, and refractory-diboride substrates sufficiently reduce the formation energies of 2D group-III-V materials, making them thermodynamically stable on these substrates [1,2]. Additionally, these substrates lead to variable amount of doping of the 2D materials depending on the work functions of the 2D materials and the substrates. We observe large adsorption energies and strong doping of the 2D materials which indicates that these substrates can provide good electrical contact to enable transport measurements and electronic applications.

1:39PM M1.00011 Direct patterning and characterization of large area, single layer MoS$_2$ film synthesized by chemical vapor deposition, WOANSEO PARK, Seoul Natl Univ, JAEEYOUN BAIK, Pohang Accelerator Laboratory, TAE-YOUNG KIM, KYUNGJUNE CHO, Seoul Natl Univ, WOONG-KI HONG, Korea Basic Science Institute, HYUN-JOON SHIN, Pohang Accelerator Laboratory, TAKHEE LEE, Seoul Natl Univ — Molybdenum disulfide (MoS$_2$) has gained a significant amount of attention due to a great potential for atomic-film electronics. Recently chemical vapor deposition (CVD) method has been utilized to synthesize MoS$_2$ films, however, the synthesis of large area MoS$_2$ films still remains a challenge for practical device development. For the further utilization, existing synthetic approaches that can be used to fabricate large-area MoS$_2$ films require additional patterning processes, which may introduce unintentional contamination from other chemicals during the various processes. Therefore, it is required to directly prepare patterned, MoS$_2$ films during the CVD synthesis. In this presentation, we report a simple method for the synthesis of MoS$_2$ films that can be directly patterned during the synthesis, so that post-patterning processes can be avoided and device fabrication can be made simultaneously. This study suggests that large-area, single-layer MoS$_2$ films can be synthesized by CVD and directly patterned for atomic-film electronic devices.
1:15PM M1.00012 Chemical Exfoliation of Layered Superconductors: An Avenue to Synthesize Boron-rich Quasi Two Dimensional Nanostructures, SAROJ KUMAR DAS, ASHA LIZA JAMES, KABEER JASUJA, Indian Institute of Technology Gandhinagar — Zero-dimensional and one-dimensional boron based nanostructures have presented excellent avenues in the past for utilizing the fascinating science of boron at the atomic level. The research on synthesizing two-dimensional (2-D) boron-based nanostructures is currently in its incipient stages. In this talk, we demonstrate two chemical approaches that yield quasi 2-D boron-rich nanostructures by enabling an exfoliation of a layered boron-based superconductor. While one approach employs the simple tool of ultrasonication in an aqueous phase, the other approach utilizes a chelation mediated strategy based on coordination of metal ions and organic ligands. Both these synthetic routes are shown to result in a processable colloidal dispersion of boron-rich nanostructures. This talk will present details of the two exfoliation approaches and a comprehensive study of the morphological, chemical and optical properties of the dispersed nanosheets. We will demonstrate that the exfoliated nanosheets undergo an in-situ chemical modification with ionizable functional groups derived from solvent that enable electrostatic stabilization. We will further shown that this functionalization modifies the band structure of the nanosheets which gives rise to photoluminescence and result in physico-chemical properties distinct from the parent superconductor. This ability to synthesize quasi 2-D boron rich nanostructures significantly adds to the current state of literature on boron-based quasi-planar nanostructures.

2:03PM M1.00013 The formation of Colloidal 2D/3D MoS2 Nanostructures in Organic Liquid Environment1, ENGIN DURGUN, H. SENER SEN, TUGBA OZTAS, BULEND ORTAC, Bilkent University - UNAM — 2D MoS2 nanosheets (2D MoS2 NS) and fullerene-like MoS2 nanostructures (3D MoS2 NS) with varying sizes are synthesized by nanosecond laser ablation of hexagonal crystalline 2H-MoS2 powder in methanol. Structural, chemical, and optical properties of MoS2 NS are characterized by optical microscopy, SEM, TEM, XRD, Raman and UV/VIS/NIR absorption spectroscopy techniques. Results of structural analysis show that the obtained MoS2 NS mainly present layered morphology from micron to nanometer scale. Detailed analysis of the product also proves the existence of inorganic polyhedral fullerene-like 3D MoS2 NS generated by pulsed laser ablation in methanol. The possible factors which may lead to formation of both 2D and 3D MoS2 NS in methanol are examined by ab initio calculations and shown that it is correlated with vacancy formation. The hexagonal crystalline structure of MoS2 NS was determined by XRD analysis. The colloidal MoS2 NS solution presents broadband absorption edge tailoring from UV region to NIR region. Investigations of MoS2 NS show that the one step physical process of pulsed laser ablation-bulk MoS2 powder interaction in organic solution opens doors to the formation of “two scales” micron- and nanometer-sized layered and fullerene-like morphology MoS2 structures.

11:15AM M2.00001 Ultrafast generation of pseudo-magnetic field for valley excitons in WSe2 monolayers, JONGHWAN KIM, XIAOPING HONG, CHENHAO JIN, SU-FEI SHI, Univ of California - Berkeley, CHIH-YUAN S. CHANG, Academia Sinica, MING-HUI CHIU, LAIN-JONG LI, King Abdullah University of Science, FENG WANG, Univ of California - Berkeley — The valley pseudospin emerges as a new degree of freedom in atomically thin two-dimensional transition metal dichalcogenides (MX2). In analogy to the control of spin in spintrons, the capability to manipulate the valley pseudospin can provide exciting opportunities in valleytronics. Here we present that femtosecond pulses with circular polarization can generate ultrafast and ultrahigh valley pseudomagnetic field in a monolayer MX2. Our polarization-resolved transient absorption measurement shows that the degeneracy of valley exciton transitions at K and K’ valley in WSe2 monolayers can be lifted by optical Stark effect from the non-resonant pump. Energy splitting due to the optical Stark effect is linear with both the pump intensity and the inverse of pump detuning. We observe that valley-selective optical Stark effect can create an energy splitting more than 10 meV which corresponds to a pseudomagnetic field over 60 Tesla. Our study demonstrates efficient and ultrafast control of the valley excitons with optical light which can open up the possibility of coherent manipulation of the valley polarization in MX2.

11:27AM M2.00002 Valley splitting and polarization by the Zeeman effect in monolayer MoSe2, YEILE LI, Columbia Univ, JONATHAN LUDWIG, National High Magnetic Field Lab, TONY LOW, ALEXEY CHERKIKOV, XU CUI, GHIDEWON AREFE, YOUNG DUCK KIM, AREND VAN DER ZANDE, ALBERT RIGOSI, HEATHER HILL, SUK HYUN KIM, JAMES HONE, Columbia Univ, ZHIQIANG LI, DMITRY SMIRNOV, National High Magnetic Field Lab, TONY HEINZ, Columbia Univ — We have measured circularly polarized photoluminescence in monolayer MoSe2 under perpendicular magnetic fields up to 10 T. At low doping densities, the neutral and charged excitons shift linearly with field strength at a rate of $\pm 0.12$ meV/T for emission arising, respectively, from the K and K’ valleys. The opposite sign for emission from different valleys demonstrates lifting of the valley degeneracy. The magnitude of the Zeeman shift agrees with predicted magnetic moments for carriers in the conduction and valence bands. The relative intensity of neutral and charged exciton emission is modified by the magnetic field, reflecting the creation of field-induced valley polarization. At high doping levels, the Zeeman shift of the charged exciton increases to $\pm 0.18$ meV/T. This enhancement is attributed to many-body effects on the binding energy of the charged excitons.

11:39AM M2.00003 Nonlinear Optical and Excitonic Effects in Two-Dimensional Transition Metal Dichalcogenides, WANG-KONG TSE, Los Alamos National Laboratory — We present a theory for coherent optics in two-dimensional transition metal dichalcogenides. Using the density matrix formalism, we derive the kinetic equations for the interband polarization and band population distributions, and study the regime of strong optical fields where Coulomb interaction effects are small and the regime of weak optical fields where excitonic effects are important. In particular, the influence of the optical Stark effect on the excitonic properties is studied within our theory. We also address the excitonic effects of Coulomb interaction on the optical conductivity and compare our results with that of graphene.

11:51AM M2.00004 Direct observation of spin-valley-layer locking in centrosymmetric bulk WSe2 by spin- and angle-resolved photoemission, PHIL KING, School of Physics and Astronomy, University of St Andrews, UK — Methods to generate spin-polarized electronic states in non-magnetic solids are strongly desired to enable all-electrical manipulation of electron spins for new quantum devices. This is generally accepted to require breaking global structural inversion symmetry. In contrast, I will report our observation from spin- and angle-resolved photoemission spectroscopy of spin-polarized bulk states in the centrosymmetric transition-metal dichalcogenide 2H-WSe2 [1]. Mediated by a lack of inversion symmetry in constituent Se-W-Se monolayers of the bulk crystal where the electronic states are localized, we show how enormous spin splittings up to $\approx 0.5$ eV result, with a spin texture that is strongly modulated in both real and momentum space. Through this, our study provides direct experimental evidence for a putative locking of the spin with the layer and valley pseudospins in transition-metal dichalcogenides, of key importance for using these compounds in proposed valleytronics devices.

12:27PM M2.00005 Topological induced valley polarization in bilayer graphene/Boron Nitride

LEONARDO BASILE, Escuela Politecnica Nacional, JUAN C IDROBO, Oak Ridge National Laboratory — Novel electronic devices relay in our ability to control internal quantum degrees of freedom of the electron e.g., its spin. The valley number degree of freedom is a pseudospin that labels degenerate eigenstates at local maximum/minimum on the valence/conduction band. Valley polarization, that is, selective electronic localization in a momentum valley and its manipulation can be achieved by means of circular polarized light (CPL) in a system with strong spin-orbit coupling (SOC). In this talk, we will show theoretically that the fact that neither graphene nor BN have a strong SOC, a bilayer of graphene on BN oriented at a twist angle has different absorption for right- and left- CPL. This induced polarization occurs due to band folding of the electronic bands, i.e., it has a topological origin.

This research was supported EPN multidisciplinary grant and by DOE SUFD MSED

12:39PM M2.00006 Anomalous temperature dependence of charged exciton photoluminescence polarization in monolayer WSe$_2$

A.T. HANBICKI, Naval Research Laboratory, G. KIOSEOGLOU, University of Crete, M. CURRIE, C.S. HELBERG, A.L. FRIEDMAN, K.M. MCCREARY, B.T. JONKER, Naval Research Laboratory — Monolayer WSe$_2$ is a direct-gap transition metal dichalcogenide semiconductor. Its low-dimensional hexagonal structure leads to two inequivalent K-points in the Brillouin zone. The valley index and spin are intrinsically coupled with spin-dependent selection rules that enable populating and interrogating each valley using circularly polarized light. Here, we probe the degree of circular polarization of the emitted photoluminescence (PL) as function of the photo-excitation energy and temperature to elucidate spin-dependent inter- and intra-valley relaxation mechanisms. Monolayer WSe$_2$ flakes have PL emission from the free and charged exciton near 2.0 eV. We reproductively isolate these excitons via appropriate sample preparation. With excitation using positive helicity light, we analyze the PL for positive and negative helicities to determine polarization. Unlike MoS$_2$, we measure significant polarization from the charged exciton for high excitation energies, even at room temperature. There is also an enhancement of polarization of the charged exciton at intermediate temperatures. We discuss the polarization behavior in terms of phonon assisted intervalley scattering processes.

12:51PM M2.00007 First-Principles Calculations of LEEM Reflectivity Spectra of Molybdenum Disulfide

JOHN MCCLAIN, Integrated Applied Mathematics, University of New Hampshire, KARSTEN POHL, Department of Physics and Materials Science Program, University of New Hampshire, JIAN-MING TANG, Department of Physics, University of New Hampshire — We present calculations of the low-energy electron specular reflectivity spectra of systems of a few layers of molybdenum disulfide at general angles of incidence using a newly modified algorithm within our first-principles theoretical approach, which leverages the self-consistent scattering potentials produced by density-functional theory [1]. Our calculated normal-incidence spectra for MoS$_2$ reveal layer-dependent features around 7-8 eV and 15 eV, allowing for a characterization of the number of layers via LEEM reflectivity and thus an in-situ technique for growth monitoring. We have previously described the application of our approach to the off-normal spectra of few-layer graphene, but the lack of mirror symmetry in MoS$_2$ requires a new algorithm for finding degenerate pairs of solutions for the matching procedure. The computed off-normal spectra illustrates the complexity of the electronic structure of MoS$_2$. We also present the way in which our new off-normal algorithm leads naturally to an approach to higher-order diffraction intensity calculations with the wave-matching scheme, along with our results for higher-order diffraction in model systems and progress towards results for real systems. [1] McClain et al., arXiv.1311.2917.

1:03PM M2.00008 Spin-orbit coupling in the band structure WSe$_2$ monolayers

IORI TANABE, Univ of Nebraska - Lincoln, Dept. of Physics and Astronomy, ALEXEI BARINOV, Elettra Experimental Division, Sincrotrone Trieste, DUY LE, University of Central Florida, EDWIN PRECIADO, MIGUEL ISARRARAZ, LUDWIG BARTELS, University of California Riverside, Department of Chemistry, TALAT RAHMAN, University of Central Florida, Dept. of Physics, PETER DOWBEN, Univ of Nebraska - Lincoln, Dept. of Physics and Astronomy — We have mapped the occupied band structure of monolayer WSe$_2$ by small spatial spot angle resolved photoemission and have found significant spin-orbit coupling in excess of 500 meV, far larger than for MoS$_2$. The experimental band mapping is consistent with theoretical expectations with the top of the valence band is seen at K, not Γ, thus distinct from the band structure for the bilayer and bulk single crystals. This shift of the top of the valence band in monolayer WSe$_2$, from Γ to K, is also predicted in density functional theory. In general the wave vector dependent experimental band structure confirms the expectations of density functional theory.

1:15PM M2.00009 Intrinsic circular polarization in centrosymmetric stacks of transition-metal dichalcogenide

QIHANG LIU, XIUWEN ZHANG, ALEX ZUNGER, University of Colorado, Boulder — The circular polarization (CP) that the photoluminescence inherits from the excitation source in n monolayers of transition-metal dichalcogenides (MX)$_n$ has been previously explained as a special feature of odd values of n, where the inversion symmetry is absent. This valley polarization effect results from the fact that in the absence of inversion, charge carriers in different band valleys could be selectively excited by different circular polarized light. Such restriction to non-centrosymmetric systems poses a limitation on the material selection for achieving CP. Although several experiments observed CP in centrosymmetric MX$_2$ systems e.g., for bilayer in MX$_2$, they were dismissed as being due to some extrinsic sample irregularities. Here we show that for n = even where inversion symmetry is present and valley polarization physics is strictly absent, such intrinsic selectivity in CP is to be expected on the basis of fundamental spin-orbit physics. First-principles calculations of CP predict significant polarization for n = 2 bilayers: from 69% in MoS$_2$ to 93% in WSe$_2$. This realization could broaden the range of materials to be considered as CP sources.

1:27PM M2.00010 Electric field and spin-orbit coupling effects on the band structure of monolayer WSe$_2$

TTITPONG FONGKAEW, School of Physics, Suranaree University of Technology, Nakhon Ratchasima 30000, Thailand, WALTER R.L. LAMBRECHT, Department of Physics, Case Western Reserve University, Cleveland, OH, USA 44106 — Transition metal dichalcogenides are known to switch from indirect to direct gap between bulk and monolayer form. Here we show that in WSe$_2$, an electric field perpendicular to the layer of order a few 0.1 MV/cm has strong effects on the conduction band and can convert the material back to an indirect gap. The competing minima at different points in the Brillouin zone undergo different shifts with electric field because of their different orbital character. Using first-principles GGA calculations in the presence of an electric field with and without spin-orbit coupling, we determine the critical field at which the minimum between Γ and K (where the gap occurs in bulk) becomes back the lowest conduction band minimum. For even stronger electric fields we find the CBM to shift to the Γ-point. While the electric fields considered here are much larger than the fields obtained in gated structures, they may be possible using electric double layers using an electrolyte. Such measurements have already been done on bulk WSe$_2$, [Nature Physics 9, 563 (2013)] but focused on the valence band and Rashba effects instead of the conduction band.

This work was supported by Development and Promotion of Science and Technology Talents Project (DPST).
1:39PM M2.00011 Spin-dependent refraction at the atomic step of transition-metal dichalcogenides. MIKITO KOSHINO, TETSURO HABE, Tohoku Univ. — We theoretically propose a spin-dependent electronic transport mechanism in the transition metal dichalcogenide, in which the spin-opposed electron beam is split into different directions depending on spins at an atomic domain boundary. Specifically, we calculate the electronic transmission across a boundary between monolayer and bilayer of the transition metal dichalcogenide, and demonstrate that up-spin and down-spin electrons entering the boundary are refracted and collimated to opposite directions. The phenomenon is attributed to the strong spin-orbit interaction, the trigonally-warped Fermi surface, and the different crystal symmetries between the monolayer and bilayer systems. The spin-dependent refraction suggests a potential application for a spin splitter, which spatially separates up-spin and down-spin electrons simply by passing the electric current through the boundary.

1:51PM M2.00012 Two dimensional valley electrons and excitons in the noncentrosymmetric 3R MoS2. RYOSUKE AKASHI1, MASAYUKI OCHI, Riken Center for Emergent Matter Science, Japan, SANDOR BORDACS, Budapest University of Technology and Economics, Hungary, RYUJI SUZUKI, The University of Tokyo, Japan, YOSHINORI TOKURA, Riken Center for Emergent Matter Science, Japan, YOSHIHIO IWA, The University of Tokyo, Japan, RYOTARO ARITA, Riken Center for Emergent Matter Science, Japan — Possible control of the valley-dependent spin polarization in transition-metal dichalcogenides has been a hot topic as the valleytronics. Through the recent great progress based on the monolayer systems, people’s interest is shifting to multilayered polytypes. The centrosymmetric 2H-stacked systems have been much studied for switching of the valley-dependent spin polarization. On the other hand, some of the authors [Suzuki et al., Nat. Nanotechnol. 9, 611 (2014)] have successfully fabricated the noncentrosymmetric 3R-stacked MoS2 multilayer and demonstrated the valley polarization independent of the number of layers. On the basis of this success, we further examined the valley electronic states in the 3R-MoS2 and found their novel two-dimensional properties utilizable for the valleytronics [Akashi et al., submitted]. Namely, interlayer hopping of the valley electrons was proved to be zero as a consequence of a quantum-interference effect caused by the 3R-stacking geometry. In the talk, we report the results of the reflectivity measurement and analysis with an anisotropic hydrogen atomic model and show that the zero hopping causes 2D-hydrogen-like spectroscopic and confinement of the wave function within a single layer of the valley exciton.

2:03PM M2.00013 Electrical Control of Exciton-Enhanced Second-Harmonic Generation in Monolayer WSe2. KYLE SEYLER, JOHN SCHAIBLEY, University of Washington, RUI GONG, University of Hong Kong, PASQUAL RIVERA, AARON JONES, SANFENG WU, University of Washington, JIAQIANG YAN, DAVID MANDRUS, Oak Ridge National Laboratory, WANG YAO, University of Hong Kong, XIAODONG XU, University of Washington — Nonlinear optical frequency conversion, in which optical fields interact with a nonlinear medium to produce new field frequencies, is ubiquitous in modern photonic systems. However, the nonlinear electric susceptibilities that give rise to such phenomena are often challenging to tune in a given material, and so far, dynamical control of optical nonlinearities remains confined to research labs. In this talk, we report a new mechanism to electrically control second-order optical nonlinearities in monolayer WSe2. We show that the intensity of second-harmonic generation (SHG) at its lowest exciton resonance is widely tunable through electrostatic doping in a field-effect transistor device. Such remarkable tunability arises from the strong exciton charging effects in monolayer semiconductors, which allow for exceptional control over the exciton and trion oscillator strengths. Our study paves the way for a new platform of chip-scale, electrically tunable nonlinear optical devices based on two-dimensional semiconductors.

11:15AM M3.00001 The Future of (Artificial) Intelligence. STUART RUSSELL, Professor of Computer Science, University of California, Berkeley — No abstract available.

11:51AM M3.00002 Cognitive Computing: From Breakthroughs in the Lab to Applications in the Field. GURUDUTH BANAVAR, IBM TJ Watson Research Center — In the last decade, the availability of massive amounts of new data, and the development of new machine learning technologies, have augmented reasoning systems to give rise to a new class of computing systems. These “Cognitive Systems” learn from data, reason from models, and interact naturally with us, to perform complex tasks better than either humans or machines can do by themselves. In essence, cognitive systems help us penetrate the complexity of big data, reason using rich models, and enable each of us to perform like the best. We believe this will transform every industry for the better. Artificial Intelligence (AI) has a rich history, dating back to 1950’s. The desire to build a Turing machine that would imitate a human dominated the psyche of the AI researchers for many decades [1]. The complex reality of human beings and the limitations of early symbolic approaches narrowed the success of early AI technology to a few specialized and small-scale applications [2, 3]. Over the last decade, new kinds of unstructured data from social networks, streaming data, and online publications, as well as massive data emitted from sensors from the physical world have outpaced traditional forms of structured data. This will continue to grow exponentially. The insights embedded in this massive amount of data can provide unprecedented opportunities for business and social value. Data has indeed become one of our most precious resources, and with its accelerated pace of evolution, it will determine the future trajectory of business and society [4]. New tools are being developed to extract insights out of the big data, which is abundant, unstructured, noisy, and unreliable. These tools have not relied on the same techniques that helped us exploit clean, structured data of the past, using small-scale models of the world and explicitly specified reasoning mechanisms. The new tools are using more automated statistical pattern-matching techniques, called machine learning, that have come of age in the last decade [ref]. In addition to reasoning from explicitly specified models of the world, these new machine learning techniques have given rise to a new class of systems that effectively learn from patterns in big data, and simultaneously augment their world models. Such systems can also interact naturally with us, on human terms, through natural language (i.e., unstructured text data), speech (i.e., unstructured audio data), vision (i.e., unstructured video data), and other modalities. We call this emerging class of systems that reason, learn, and interact naturally with us “Cognitive Systems”. IBM’s Watson is a family of cognitive systems targeted to a variety of domains. The first Watson system was capable of answering factoid questions as effectively as the best professionals in that field (as demonstrated by the Jeopardy! exhibition match, see illustration). Follow-on systems answer other types of questions, e.g., those that require passage answers, as well as other domains, e.g., healthcare, insurance, and education. Yet other cognitive systems in the Watson family go beyond question answering to support discovery of insights hidden in big data, such as in huge repositories of scientific literature, reasoning with evidence to support or refute topics of discussion, and to go beyond textual data to images and videos.

1:03PM M3.00004 Beneficial Smarter-than-human Intelligence: the Challenges and the Path Forward. BENJA FALLENSTEIN, Machine Intelligence Research Institute — Today, human-level machine intelligence is still in the domain of futurism, but there is every reason to expect that it will be developed eventually. A generally intelligent agent as smart or smarter than a human, and capable of improving itself further, would be a system we’d need to design for safety from the ground up: There is no reason to think that such an agent would be driven by human motivations like a lust for power; but almost any goals will be easier to meet with access to more resources, suggesting that most goals an agent might pursue, if they don’t explicitly include human welfare, would likely put its interests at odds with ours, by incentivizing it to try to acquire the physical resources currently being used by humanity. Moreover, since we might try to prevent this, such an agent would have an incentive to deceive its human operators about its true intentions, and to resist interventions to modify it to make it more aligned with humanity’s interests, making it difficult to test and debug its behavior. This suggests that in order to create a beneficial smarter-than-human agent, we will need to face three formidable challenges: How can we formally specify goals that are in fact beneficial? How can we create an agent that will reliably pursue the goals that we give it? And how can we ensure that this agent will not try to prevent us from modifying it if we find mistakes in its initial version? In order to become confident that such an agent behaves as intended, we will not only want to have a practical implementation that seems to meet these challenges, but to have a solid theoretical understanding of why it does so. In this talk, I will argue that even though human-level machine intelligence does not exist yet, there are foundational technical research questions in this area which we can and should begin to work on today. For example, probability theory provides a principled framework for representing uncertainty about the physical environment. It seems certain to be helpful to future work on beneficial smarter-than-human agents, but standard probability theory assumes omniscience about logical facts; no principled framework for representing uncertainty about the outputs of deterministic computations exists as yet, even though any smarter-than-human agent will certainly need to deal with uncertainty of this type. I will discuss this and other examples of ongoing foundational work.

Wednesday, March 4, 2015 11:15AM - 1:51PM
Session M5 DMP DCOMP: Focus Session: Intercalated FeSe and Other Fe-chalcogenide Superconductors
Juan Gorman Room 005 - Stephen Wilson, University of California, Santa Barbara

11:15AM M5.00001 High transition temperatures in molecular intercalates of FeSe$^1$. STEPHEN BLUNDELL, University of Oxford — Molecular groups can now be intercalated into iron-based superconductors with dramatic consequences on the superconducting properties. These species act as charge reservoirs, sources of electrical polarization, and also make subtle structural modifications to superconducting layers, all of which can make novel adjustments to the band structure that in turn can control superconducting properties. By synthesizing the compound $\text{Li}(\text{NH}_2)\text{y}(\text{NH}_3)_{1−y}\text{Fe}_2\text{Se}_2$ ($x \approx 0.6; y \approx 0.2$), in which lithium ions, lithium amide and ammonia (NH$_3$) act as the spacer layer between FeSe layers, we have turned a 9 K superconductor into a 43 K superconductor [1]. Further chemical modification allow us to produce a range of new superconducting materials which we have studied using a variety of techniques including muon-spin rotation. Recently, we have used hydrothermal reactions to produce layered lithium iron selenide hydroxides with chemical formula $\text{Li}_x\text{Fe}_y(\text{OH})\text{Fe}_{1−y}\text{Se}$ and thereby producing compounds whose transition temperature can be tuned from zero up to about 40 K [2]. Minimizing the concentration of iron vacancies in the iron selenide layer and simultaneously increasing the electron count on iron in the selenide layers enhance the superconducting properties in this family. Future prospects for new superconducting materials using these novel synthetic routes will be discussed, as will also our current understanding of the superconductivity in these materials. (Work performed in collaboration with S. J. Clarke and coworkers at Oxford, RAL and Durham, UK.)

1Work supported by EPSRC(UK).

11:51AM M5.00002 Unified picture of the doping dependence of superconducting transition temperatures in alkali metal/ammonia intercalated FeSe$^1$. DANIEL GUTERDING, HARALD JESCHKE, Institute for Theoretical Physics, University of Frankfurt, Frankfurt a.M., Germany, PETER HIRSCHFELD, Department of Physics, University of Florida, Gainesville, FL, ROSEN VALENTI, Institute for Theoretical Physics, University of Frankfurt, Frankfurt a.M., Germany — We present a theoretical investigation of alkali metal/ammonia intercalated FeSe$^1$. Using ab-initio density functional theory we unravel how charge doping and dimensionality of the electronic structure can be controlled through the chemical composition of the intercalated molecules. Within random phase approximation spin fluctuation theory we analyze the impact of intercalation on the superconducting pairing strength. We find that high $T_c$, does not exceed 40 K in the iron selenide layer and simultaneously increasing the electron count on iron in the selenide layers enhance the superconducting properties in this family. Future prospects for new superconducting materials using these novel synthetic routes will be discussed, as will also our current understanding of the superconductivity in these materials. (Work performed in collaboration with S. J. Clarke and coworkers at Oxford, RAL and Durham, UK.)

12:03PM M5.00003 Neutron scattering studies on semiconductor Rb$_8$Fe$_{1.5}$Se$_2$. MENG WANG, PATRICK VALDIVIA, ROBERT BIRGENEAU, University of California, Berkeley, WEI TIAN, SONQUXE CHI, Oak Ridge National Laboratory, PENGCHENG DAI, Rice University, EDITH BOURRET-COURCHESNE, Lawrence Berkeley National Laboratory — We report neutron scattering and transport measurements on semiconductor Rb$_8$Fe$_{1.5}$Se$_2$, a compound isostuctural and isoelectronic to the well-studied A$_4$Fe$_2$Se$_4$($A =$ K, Rb, Cs, TI/K) superconducting systems. Both resistivity and dc susceptibility measurements reveal a magnetic phase transition at $T_c = 275$ K. Neutron diffraction studies show that the 275 K transition originates from a phase with rhombohedral iron vacancy order which exhibits an in-plane stripe antiferromagnetic ordering below 275 K. Based on the close similarities of the in-plane antiferromagnetic structures, moments sizes, and ordering temperatures in semiconducting Rb$_8$Fe$_{1.5}$Se$_2$ and K$_8$Fe$_{1.5}$Se$_2$ we argue that the in-plane antiferromagnetic order arises from strong coupling between local moments. The spin waves of the stripe AF order will also be presented.

12:15PM M5.00004 Block magnetic excitations in the orbitally-selective Mott insulator BaFe$_2$Se$_3$. M. MOURIGAL, Johns Hopkins University and Georgia Institute of Technology, SHAN WU, Johns Hopkins University, M.B. STONE, Oak Ridge National Laboratory, J.R. NEILSON, Johns Hopkins University and Colorado State University, J.M. CARON, Johns Hopkins University and Cornell University, T.M. MCQUEEN, Johns Hopkins University, C.L. BROHOLM, Johns Hopkins University and Oak Ridge National Laboratory — We investigate the spectrum of magnetic excitations in the Fe-based two-leg ladder material BaFe$_2$Se$_3$ by means of broad-band inelastic neutron scattering. BaFe$_2$Se$_3$ garnered recent attention due to its quasi-1D structure and as hosting an exotic block magnetic ground-state where 4 Fe spins co-align to form Fe$_4$ plaquettes. Our neutron results provide a detailed understanding of magnetic excitations originating from the Fe$_4$ block ground-state. Consisting of a 50 meV wide band of quasi-1D acoustic spin-waves and three high-energy modes around 100 meV and 200 meV, the spin fluctuations and the static moment carry a total squared magnetic moment of 16 $\mu_B$ per Fe, indicative of orbital selectiveness for localized spins. We develop an effective Heisenberg model that accounts for the observed spectrum and provides a set of exchange interactions to understand how magnetic magnetism stems from strong lattice, orbital and electronic correlations in iron chalcogenides.
12:27PM M5.00005 Neutron investigation of possible (ferro)magnetic order in the new superconductor \( \text{Li}_{1-x}\text{Fe}_x\text{OD} \) \((\text{Fe}_{1-y}\text{Se})\). JEFFREY LYNN, NIST Center for Neutron Research, Gaithersburg, MD 20899, XIUQUAN ZHOU, CHRISTOPHER K. H. BORG, EFRAIN RODRIGUEZ, Department of Chemistry and Biochemistry, University of Maryland 20742 — The system \( \text{Li}_{1-x}\text{Fe}_x\text{OD} \) \((\text{Fe}_{1-y}\text{Se})\) has recently been reported to become superconducting at \( T_c \approx 43 \) K and then developing ferromagnetism in terms of a spontaneous vortex lattice below \( T_{\text{f}} \approx 10 \) K [1]. We have prepared the tetragonal \((\text{Li}_{1-x}\text{Fe}_x\text{OD})\) \((\text{Fe}_{1-y}\text{Se})\) phase by hydrothermal synthesis in \( \text{D}_2\text{O} \) to reduce the neutron incoherent scattering cross section. We also prepared the samples using isotopically purified \( ^7\text{LiOD} \) as a starting material to reduce the neutron adsorption cross section. The lattice parameters according to neutron and X-ray diffraction varied with 3.79 \( \pm 0.02 \) \( \text{Å} \) for the neutron incoherent scattering cross section. The lattice parameters according to neutron and X-ray diffraction varied with 3.79 \( \pm 0.02 \) \( \text{Å} \) and 9.16 \( \pm 0.02 \) \( \text{Å} \) for the neutron incoherent scattering cross section. We have also prepared the samples using isotopically purified \( ^7\text{LiOD} \) as a starting material to reduce the neutron adsorption cross section. The lattice parameters according to neutron and X-ray diffraction varied with 3.79 \( \pm 0.02 \) \( \text{Å} \) and 9.16 \( \pm 0.02 \) \( \text{Å} \). We have carried out bulk magnetization, high resolution powder diffraction measurements to determine the crystal structure, high intensity diffraction measurements for the magnetic structure, and small angle scattering measurements to elucidate the interaction between the magnetism and superconductivity. The results of the neutron and bulk measurements will be discussed in detail.

12:39PM M5.00006 Multiband transport and nonmetallic low-temperature state of \( \text{K}_{0.50}\text{Na}_{0.25}\text{Fe}_{1.52}\text{Se}_2 \). HYEJIN RYU, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973, USA, F. WOLFF-FABRIS, Hochfeld-Magnetlab Dresden (HLD), Helmholtz-Zentrum Dresden-Rossendorf, D-01314 Dresden, Germany, J.B. WARREN, Instrument Division, Brookhaven National Laboratory, Upton, New York 11973, USA, M. UHLARZ, J. WOSNITZA, Hochfeld-Magnetlab Dresden (HLD), Helmholtz-Zentrum Dresden-Rossendorf, D-01314 Dresden, Germany, C. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973, USA — We report evidence for multiband transport and an insulating low-temperature normal state in superconducting \( \text{K}_{0.50}\text{Na}_{0.25}\text{Fe}_{1.52}\text{Se}_2 \) with \( T_c \approx 20 \) K. The temperature-dependent upper critical field \( H_{\text{c2}} \) is well described by a two-band model. After the superconductivity is suppressed by applying magnetic field at low temperature, the normal-state resistance is found to increase logarithmically as \( T \to 0 \). This indicates that high-\( T_c \) copper oxides and granular superconductors, suggesting that the superconductor-insulator transition is related to intrinsic nanoscale phase separation. Work at Brookhaven is supported by the U.S. DOE under Contract No. DE-AC02-98CH10886 and in part by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. DOE, Office for Basic Energy Science (C.P.). We acknowledge the support of the HLD at HZDR, member of the European Magnet Field Laboratory (EMFL). C.P. acknowledges support by the Alexander von Humboldt Foundation.

12:51PM M5.00007 First-principles theory of electron-spin fluctuation coupling and superconducting instabilities in iron selenide1. JOHANNES LISCHNER, UC Berkeley and Lawrence Berkeley National Lab, TIMUR BAZHIROV, UC Berkeley, ALLAN H. MACDONALD, UT Austin, MARVIN L. COHEN, STEVEN G. LOUIE, UC Berkeley and Lawrence Berkeley National Lab — We present first-principles calculations of the coupling of quasiparticles to spin fluctuations in iron selenide and discuss which types of superconducting instabilities this coupling gives rise to. We find that strong antiferromagnetic stripe-phase spin fluctuations lead to large coupling constants for superconducting gaps with \( \pi \) symmetry, but these coupling constants are significantly reduced by other spin fluctuations with small wave vectors. An accurate description of this competition and an inclusion of band structure and Stoner parameter renormalization effects lead to a value of the coupling constant for an \( s \) wave superconductor. This is similar as for high-\( T_c \) copper oxides and granular superconductors, suggesting that the superconductor-insulator transition is related to intrinsic nanoscale phase separation.

---

1:03PM M5.00008 “Forbidden” phonon in the iron chalcogenide series1. DAVID M. FOBES, IGOR A. ZALIZNYAK, ZHIJUN XU, GENDA GU, JOHN M. TRANQUADA, CMPMSD, Brookhaven National Lab, Upton, NY 11793-5000, USA — Recently, we uncovered evidence for the formation of a bond-order wave (BOW) leading to ferro-ordinal order at low temperature, acting to stabilize the bccillinear AFM order, in the iron-rich parent compound, \( \text{Fe}_{1+y}\text{Te}\). [D. Fobes et al., Phys. Rev. Lett. 112, 187202 (2014)]. Investigating the inelastic spectra centered near (100) in \( \text{Fe}_{1+y}\text{Te}\), a signature peak for the BOW formation in the monoclinic phase, we observed an acoustic phonon dispersion in both tetragonal and monoclinic phases. While a structural Bragg peak accompanies the mode in the monoclinic phase, in the tetragonal phase Bragg scattering at this \( Q \) is forbidden by symmetry, and we observed no elastic peak. This phonon mode was also observed in superconducting \( \text{Fe}_{60}\text{Se}_{40} \), where structural and magnetic transitions are suppressed. LDA frozen phonon calculations suggested that this mode could result from a spin imbalance between neighboring Fe atoms, but polarized neutron measurements revealed no additional magnetic scattering. We propose that this “forbidden” phonon mode may originate from dynamically broken symmetry, perhaps related to the strong dynamic spin correlations in these materials.

1 Work at BNL was supported by BES, US DOE, under Contract No. DE-AC02-98CH12883. Research at ORNL’s HFIR and SNS sponsored by Scientific User Facilities Division, BES, US DOE. We acknowledge the support of NIST, in providing neutron research facilities.

1:15PM M5.00009 Synthesis and superconductivity in spark plasma sintered pristine and graphene-doped \( \text{FeSe}_{0.5}\text{Te}_{0.5} \). POOJA PUNEET, RAMAKRISHNA PODILA, JIAN HE, APPARAO RAO, Clemson University, AUSTIN HOWARD, NICHOLAS CORNELL, ANVAR A. ZAKHIDOV, University of Texas at Dallas, DEPARTMENT OF PHYSICS AND ASTRONOMY, CLEMSON NANOMATERIALS CENTER, CLEMSON UNIVERSITY TEAM, NANOABET, UNIVERSITY OF TEXAS AT DALLAS TEAM — Replace this text with your abstract body. Here, we present a new ball-milling and spark plasma sintering based technique for the facile synthesis of \( \text{FeSe}_{0.5}\text{Te}_{0.5} \) superconductors (SC) without the need for pre-alloying. This method is advantageous since it is quick and flexible for incorporating other dopants such as graphene for vortex pinning. We observed that \( \text{FeSe}_{0.5}\text{Te}_{0.5} \) exhibits a coexistence of ferromagnetic (FM) and SC signature plausibly arising from a FM core-SC shell structure. More importantly, the \( H_{\text{c2}} \) values observed from resistivity data are higher than 7 T indicating that SPS process synthesized \( \text{FeSe}_{0.5}\text{Te}_{0.5} \) samples could lead to nextgeneration superconducting wires and cables.

1:27PM M5.00010 An ab-initio Quantum Monte Carlo analysis of pressure and magnetism in the unconventional superconductor, \( \text{FeSe} \). BRIAN BUSEMEYER, LUCAS K. WAGNER, University of Illinois, Urbana-Champaign Physics Department — We report the results of many-body ab-initio fixed-node diffusion Monte Carlo calculations performed on the unconventional superconductor, \( \text{FeSe} \). \( \text{FeSe} \) shows a strong pressure-dependent critical temperature, and because magnetism is generally expected to play an important role in understanding unconventional superconductivity, for pressures ranging from ambient to 11 GPa, we investigate the single and many-body properties of three ordered magnetic configurations, including the two found in similar iron-based superconductors. Our calculations find that at least two magnetic orders (collinear and bicollinear) are nearly degenerate in energy, becoming closer in energy as pressure increases. We also analyze how correlations between the electrons change as a function of pressure, and discuss what this could mean for superconductivity.

This study demonstrates an efficient approach to tune the multiferroicity in the manganite system. Polarized state intimately correlates with the lower temperature ferroelectric state that is induced by the incommensurate spiral magnetic order of Mn spins. We report the formation of a highly polarized state in multiferroic DyMnO$_3$ via pressure and temperature conditions. BRANDON WILFONG, Washington College, 300 Washington Ave. Chestertown, MD 21620, USA — Recent experiments demonstrate that isovalent doping studies give the similar phase diagram as the heterovalent doped cases: with the P-doping, the magnetic order is suppressed and the superconductivity emerges. With the help of tight-binding model calculation and self-consistent lattice Bogoliubov-de Gennes (BdG) equation calculation, we choose a minimal two-orbital model and obtain the phase diagram of BaFe$_2$(As$_{1-x}$P$_x$)$_2$ against the P content x, which could be qualitatively comparable with the experimental results. Besides, we will compare these results with the recent experiments shown QCP in this system.

Session M6 DMP DCOMP: Focus Session: Coupling Polarization and Magnetism I

11:15AM M6.00001 In-situ Raman Spectroscopic Investigation of Relaxor Multiferroic Pb(Fe$_{0.5}$Nb$_{0.5}$)$_3$O$_3$ under High Pressure and Temperature Conditions
BRANDON WILFONG, Washington College, 300 Washington Ave. Chestertown, MD 21620, USA — The vibrational and structural properties of lead ferroanate, Pb(Fe$_{0.5}$Nb$_{0.5}$)$_3$O$_3$, have been investigated using Raman spectroscopy up to 40 GPa and up to 415 K at selected pressures. Three phase transitions were noted via the pressure evolution at 5.5, 8.7 and 24 GPa at room temperature, respectively. The temperature dependencies of the Raman spectra indicated two phase transitions at 1.5 GPa, 335 and 365 K, which support the appearance of an intermediate tetragonal P4mm phase between the ferroelectric R3m and paraelectric Pm-3m phases. At 2.5, 3.9 and 7.4 GPa, the system showed one phase transition with temperature evolution at 337, 348 and 332 K respectively. With this set of data, a $P-T$ phase diagram was compiled to provide further insight into the magnetoelectric coupling and allow comparison to other systems in order to elucidate the impact of magnetic order on relaxor systems.

11:27AM M6.00002 Investigation of the multiferroic behavior in FeVO$_4$ single crystals
EHAB ABDELHAMID, Wayne State University, KENTA KIMURA, TSUYOSHI KIMURA, Osaka University, ONATTU D. JAYAKUMAR, Bhabha Atomic Research Centre, VAMAN M. NAIK, University of Michigan-Dearborn, RATNA NAIK, GAVIN LAWES, Wayne State University — For FeVO$_4$ is considered as a model system for understanding the magnetoelectric interaction mechanisms in low symmetry multiferroics. Bulk FeVO$_4$ exhibits two antiferromagnetic phase transitions at $T_{N1} = 22$ K and $T_{N2} = 15$ K. Below $T_{N2}$, a noncollinear magnetic order develops, breaking the space inversion symmetry that induces ferroelectric order. Earlier measurements on polycrystalline samples of FeVO$_4$ doped with magnetic (e.g.: Chromium) as well as non-magnetic (e.g.: Zinc) ions, indicate the stability of the two antiferromagnetic transition temperatures, with a change of only 2% corresponding to the doping concentration of 20%. It also shows the ability of the FeVO$_4$ trilinic structure to accommodate such high doping levels. Working along the same line, we have prepared both doped and undoped single crystals of FeVO$_4$ by a flux method. Samples were characterized using XRD and Raman spectroscopy to track the changes in lattice parameters induced by different dopants. The magnetic and ferroelectric properties were investigated in order to understand the origin of magnetoelectric coupling in low symmetry multiferroics.

11:39AM M6.00003 Near Room-Temperature Magnetism and Enhanced Magnetic Moments in Multiferroic (LuFeO$_3$)$_{1-x}$/(LuFe$_2$O$_3$)$_x$ Superlattices
JARRETT MOYER, University of Illinois at Urbana-Champaign, JULIA MUNDY, CHARLES BROOKS, MEGAN HOLTZ, DAVID MULLER, DARRELL SCHLOM, Cornell University, PETER SCHIFFER, University of Illinois at Urbana-Champaign — The development of room-temperature multiferroics is necessary to realize the potential of these materials in low-power energy, memory, and logic applications. Currently, there are only four potential single-phase multiferroics that exist at room-temperature, all of which have either antiferromagnetic or weakly ferromagnetic magnetic orderings. Here, we report on the magnetic properties of epitaxially grown superlattices composed of the ferroelectric, weakly ferromagnetic LuFeO$_3$ and the paraelectric, ferrimagnetic LuFe$_2$O$_3$. By inserting layers of $x$-LuFeO$_3$ ($T_N = 147$ K) into LuFe$_2$O$_3$, we increase $T_C$ from 219 K for single-phase LuFe$_2$O$_3$ to 270 K for (LuFeO$_3$)$_{1-x}$(LuFe$_2$O$_3$)$_x$. Additionally, while the magnetic moment on the LuFe$_2$O$_3$ layers remains constant for $m/(m+2n)<0.5$, it increases rapidly for $m/(m+2n)>0.5$, resulting in magnetic moments orders of magnitude larger than the weak ferromagnetic room-temperature multiferroics. We will discuss the potential mechanisms for these enhanced transition temperatures and magnetic moments and the potential to increase $T_C$ to above room temperature.

This research is primarily supported by DOE Award No. DE-SC0002334.

11:51AM M6.00004 RMO3 perovskite oxides with magnetic and ferroelectric polar structures
WEI REN, SHUNBO HU, YABEI WU, Shanghai University — Enhancing the electrical polarization and the magnetic ordering transition temperatures constitutes a current research focus in multiferroics of fundamental and technological importance. Here we report on some progress on the RMO3 perovskites for novel routes to realize multiferroics, giving specific examples of rare earth and transition metal oxide materials. First principles calculations, either supported by experimental results or awaiting for experimental verifications, are shown to offer useful guidance for the research of unconventional multiferroics. We hope to stimulate more efforts from experimentalists and theorists to work together for the future developments in fundamental science and device applications. These experimental and theoretical approaches will open up new possibilities for exploring, modeling, and exploiting novel electromagnetism and multiferroic materials.

12:03PM M6.00005 Excess-hole induced high temperature polarized state and its correlation with the multiferroicity in single crystalline DyMnO$_3$
TAO ZOU, Michigan State University, ZHILING DUN, University of Tennessee, HUIBO CAO, Oak Ridge National Lab, MENGZE ZHU, DANIEL COULTER, Michigan State University, HAIDONG ZHOU, University of Tennessee, XINQILIN K. J. Michigan State University — Controlling the ferroelectricity and magnetism in multiferroic materials has the ferroelectric R3m and paraelectric Pm-3m phases. We report the formation of a highly polarized state in multiferroic DyMnO$_3$ single crystals which develops well above the magnetic transition temperatures, and we attribute it to the thermally stimulated depolarization current effect of excess holes forming Mn$^{4+}$ ions in the system. We also show that this high temperature polarized state intimately correlates with the lower temperature ferroelectric state that is induced by the incommensurate spiral magnetic order of Mn spins. This study demonstrates an efficient approach to tune the multiferroicity in the manganite system.
12:15PM M6.00006 Colossal Directional Dichroism in a Multiferroic CuB$_2$O$_4$  SHINO GO YODA, NOBUYUKI ABE, Univ of Tokyo, SHOJIRO KIMURA, Tohoku University, YASUHIRO H. MATSUDA, TOSHIHIRO NOMURA, AKIHITO IKEDA, SHOJIRO TAKEYAMA, TAKA-HISA ARIMA, University of Tokyo — In multiferroic materials, electric and magnetic responses to light can interfere with each other, resulting in novel optical phenomena. One typical example is directional dichroism, where the absorption coefficient changes with the reversal of the propagating direction of light. It has been reported that CuB$_2$O$_4$ shows giant directional dichroism at 1.40 eV, which corresponds to the intratomic transition of Cu$^{2+}$ hole. The optical absorption coefficient changes by a factor of three at low magnetic fields. In this study, we investigated magnetic field dependence of directional dichroism up to 52 T. We have observed colossal directional dichroism where the ratio of the optical absorption coefficient is as large as 1000% at 52 T. The observed extraordinary large directional dichroism is explained by a modification of the electric and magnetic dipole transition moments due to the canting of the spin direction of Cu$^{2+}$ hole by the application of a high magnetic field.

12:27PM M6.00007 Magneto-orbital helices as a route to coupling magnetism and ferroelectricity in multiferroic CaMn$_7$O$_{12}$  ROGER JOHNSON, University of Oxford — In compounds with long-range ferromagnetic or antiferromagnetic ordering, the magnetic and structural degrees of freedom may couple through orbital ordering. It has long been hoped that this type of coupling could be exploited to create high-temperature multiferroics - materials in which both ferroelectricity and long-range magnetism coexist in a single phase, and may couple to give rise to spontaneous magneto-electric functionality. In this talk I will report a detailed experimental study of the multiferroic oxide CaMn$_7$O$_{12}$. Our complementary data from pyroelectric current, magnetometry, single crystal x-ray diffraction, and powder neutron diffraction experiments show that CaMn$_7$O$_{12}$ couple to give rise to spontaneous magneto-electric functionality. In this talk I will report a detailed experimental study of the multiferroic oxide CaMn$_7$O$_{12}$.

1:03PM M6.00008 Ultraviolet Raman spectroscopy of hexagonal LuFeO$_3$ films 1, 2  D.M. A. TENNES, D.A. HILLSBERRY, E.L. THIES, Department of Physics, Boise State University, Boise, ID 83725, USA, J.A. MUNDY, D.A. MULLER, School of Applied and Engineering Physics, Cornell University, Ithaca, NY 14853, USA, C.M. BROOKS, D.G. SCHLOM, Department of Materials Science and Engineering, Cornell University, Ithaca, NY 14853, USA — Hexagonal LuFeO$_3$ films grown by molecular-beam epitaxy on yttria-stabilized zirconia substrates were studied by variable temperature ultraviolet Raman spectroscopy. Hexagonal LuFeO$_3$ is a multiferroic that is isostructural to YMnO$_3$ at room temperature. LuFeO$_3$ spectra at room temperature are consistent with the polar hexagonal $P6_3/mmc$ structure. The temperature evolution of the Raman spectra of a LuFeO$_3$ film measured in the range 10–1250 K indicate a transition to a non-polar (likely $P6_3/mmc$) phase; fitting of the temperature dependence of the Raman intensities yields a transition temperature of 1020 ± 50 K. We also observed a change in the slope of Raman intensity vs. temperature dependence of the most intense phonon peak around 400–450 K, which might indicate another structural transition, possibly to a structure with space group $P6_3/mmc$ (also polar).

1:15PM M6.00009 Pressure induced spin-flop transition in multiferroic Mn$_{1-x}$Co$_x$WO$_3$ 1, 2  FENG YE, JINCHEN WANG, SONGXUE CHI, JAIME FERNANDEZ-BACA, Oak Ridge National Lab, M. GOOCH, BERND LORENZ, K.-C. LIANG, Y.-Q. WANG, Y.Y. SUN, C.W. CHU, University of Houston — The effect of cobalt substitution in Mn$_{1-x}$Co$_x$WO$_3$ results in the most complex multiferroic phase diagram with multiple polar phases. We have examined the spin-flop transition in Co$_{40}$Fe$_{40}$B$_{20}$/Pb(Mg$_{1/3}$No$_{2/3}$)$_{1-x}$Ti$_x$O$_3$ (1-x)TixO3 multiferroic heterostructures, of which Pb(Mg$_{1/3}$No$_{2/3}$)$_{1-x}$Ti$_x$O$_3$ structure varies with increasing x from rhombohedral (R) phase, through tetragonal (T) phase, to tetragonal phase. We found that the samples with Pb(Mg$_{1/3}$No$_{2/3}$)$_{1-x}$Ti$_x$O$_3$ in R phase and MBP both display large and nonvolatile behavior, while it shows volatile behavior in tetragonal phase. These results indicate that it is not MPB but R phase that is vital for the nonvolatile behavior. We also studied the temperature effect of electric-field-controlled magnetization by varying temperatures from 200 K to 340 K and found that the magnetic-field dependence of the optical absorption shows a hysteresis like the magnetization curve, which indicates that the change in optical absorption should originate from the rotation of the magnetic moments of Co$^{2+}$.
In this present work, using first-principles density-functional theory, we have investigated the effect of strain on previously reported MOFs, such as hybrid crystalline compounds composed of an extended ordered network made up of organic molecules, organic linkers and metal cations. In particular, MOFs with the same topology as inorganic ABO$_3$ perovskites, have been shown to have interesting properties, i.e. coexistence of ferroelectric and magnetic ordering [1]. Session M7 DMP DCMP: Focus Session: Topological Crystalline Insulators

11:15AM M7.00001 Electron and spin properties of topological crystalline insulator (Pb,Sn)Se

TOMASZ STORY, Institute of Physics, Polish Academy of Sciences — Topological crystalline insulators (TCIs) constitute a new class of quantum materials with the Dirac-like metallic surface states that cross the bulk semiconductor band gap and are topologically protected by crystalline mirror plane symmetry. The TCI states have recently been experimentally observed in PbSe, SnTe, and PbSnTe for both (001) and (111) crystal surfaces. These IV-VI semiconductors undergo (at a specific tin content, temperature, and pressure) a band structure inversion driven by strong relativistic effects. The investigations of the surface electronic states by angle- and spin-resolved photoemission spectroscopy will be presented for bulk (Pb,Sn)Se monocrystals with tin content up to 37 at. %, also doped with magnetic Mn$^{2+}$ ions. In the inverted band structure regime we found the Dirac-like topological in-gap states in the vicinity of four X points of the (001) surface Brillouin zone and observe a temperature-driven topological phase transition from a trivial insulator to a TCI state below the band inversion point. In crystals with Mn ions we demonstrate very efficient tuning of the topological transition temperature by band gap engineering effect. The spin-resolved ARPES experiments revealed a characteristic vortical electron spin polarization texture at the Dirac points. Based on spectroscopic observation we construct the composition - temperature topological phase diagram of (Pb,Sn)Se and compare it with tight-binding band structure calculations. P. Dziawa et al., Nat. Mat. 11, 1023 (2012); B.M. Wojek et al., Phys. Rev. B 87, 115106 (2013); C.M. Polley et al., Phys. Rev. B 89, 075317 (2014); B.M. Wojek et al., Phys. Rev. 11:51AM M7.00002 Topological crystalline insulator states in layered materials

YOUNGKUK KIM, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, CHARLES KANE, EUGENE MELE, Department of Physics and Astronomy, University of Pennsylvania, ANDREW RAPPE, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania — Topological crystalline insulator (TCI) is a topological state of materials whose topological property relies on generic crystalline symmetries. Based on first-principles calculations, we suggest new classes of topological crystalline insulators characterized by non-zero mirror Chern numbers (MCNs) hosted on the mirror-invariant plane at the boundary of the Brillouin zone (BZ). We demonstrate that the new TCI phases can be realized in layered materials, and the topological phase transitions associated with the proposed TCI phases occur under an external pressure. Our results shed light on the role of the MCNs hosted on the surface of the BZ, and open new possibilities for finding TCI materials.

12:03PM M7.00003 Strain engineering Dirac surface states in heteroepitaxial topological crystalline insulator thin films

ILJIA ZELJKOVIC, DANIEL WALKUP, BADIOH ASSAF, KANE SCIPIONI, Boston College, RAMAN SANKAR, FANGCHENG CHOU, National Taiwan University, Taipei, VIDYA MADHAVAN, University of Illinois Urbana-Champaign — In newly discovered topological crystalline insulators (TCIs), the unique crystalline protection of the surface state (SS) band structure has led to a series of intriguing predictions of strain generated phenomena, such as the momentum-space tunability of the Dirac nodes. In this work, we have designed an experiment to not only generate and measure strain locally, but to also directly measure the resulting effects on the Dirac SS. We grow heteroepitaxial thin films of TCI SnTe in-situ and measure them by using high-resolution scanning tunneling microscopy (STM). Large STM images were analyzed to determine picoscale changes in the atomic positions which reveal regions of both tensile and compressive strain. Simultaneous Fourier-transform STM was then used to determine the effects of strain on the Dirac electrons. We find that strain continuously tunes the momentum space position of the Dirac points, consistent with theoretical predictions. Our experiments demonstrate the fundamental mechanism necessary for using TCIs in strain-based applications.

12:15PM M7.00004 ABSTRACT WITHDRAWN
12:27PM M7.00005 Realization of topological phase transition in Pb$_{1−x}$Sn$_x$Te (111) films
CHENHUI YAN, Institute of Metal Research, Chinese Academy of Sciences, JUNWEI LIU, YUNYI ZANG, ZHENYU WANG, JIANFENG WANG, Department of Physics, Tsinghua University, ZHIDONG ZHANG, Institute of Metal Research, Chinese Academy of Sciences, LILI WANG, XUCUN MA, SHUAIHUA JI, KE HE, Department of Physics, Tsinghua University, LIANG FU, Department of Physics, Massachusetts Institute of Technology, WENHUI DUAN, QI-KUN XUE, XI CHEN, Department of Physics, Tsinghua University — Recently, it was confirmed that the single crystal SnTe is a Topological crystalline insulator (TCI) by theoretical calculations and experiments. It is well known that the (001) surfaces of SnTe are the natural cleavage planes and therefore all the previous experiments for the TCI phase were performed on the (001) surfaces. The (111) surface, which is a polar surface with unpaired electrons, is very difficult to obtain by traditional crystal growth method. Here we present the epitaxial growth of high quality Pb$_{1−x}$Sn$_x$Te (111) films and observation of TCI phase by in-situ angle-resolved photoemission spectroscopy. The Pb$_{1−x}$Sn$_x$Te (111) films undergo a topological phase transition from trivial insulator to TCI via increasing the Sn/Pb ratio, accompanied by a crossover from n-type to p-type doping in the films. In addition, a sizeable Rashba effect is clearly seen in the PbTe (111) film. Our work demonstrates the manipulation of topological properties of TCI, which is crucial for future fundamental research and applications. C. Yan et al., Phys. Rev. Lett., 112, 186801 (2014).

12:39PM M7.00006 Searching for ideal bulk insulating Pb-system topological crystalline insulator materials
GENDA GU, R.D. ZHONG, JOHN SCHNEELOCH, T.S. LIU, JHON TRANQUADA, X.G. HE, WEI KU, I. PLETIKOSIC, T. VALLA, Brookhaven Natl Lab, CONDENSED MATTER PHYSICS & MATERIALS SCIENCE, BROOKHAVEN NATIONAL LABORATORY TEAM — The discovery of topological crystalline insulator materials is a breakthrough in the search for new electronic materials available for experimental research so that we can explore the new field. In order to search for the ideal bulk insulating topological crystalline insulator materials, we have grown a large number of the single crystals of Pb-system (Pb-Sn-In-Te) topological crystalline insulator. We have measured the physical properties on these single crystals by various techniques. We have studied the effect of crystal growth condition, impurity and composition on the bulk electrical conductivity of these single crystals. We try to find out which composition and crystal growth condition is the best for the ideal bulk insulating topological crystalline insulator materials.

1:27PM M7.00010 ABSTRACT WITHDRAWN —

1:03PM M7.00008 Properties of thin film SnTe grown by molecular beam epitaxy
K. ZOU, Department of Applied Physics and CRISP, Yale University, New Haven CT 06652, STEPHEN D. ALBRIGHT, Department of Physics and CRISP, Yale University, New Haven CT 06620, G.H. SIMON, Department of Mechanical Engineering & Materials Science, Chemical & Environmental Engineering, and CRISP, Yale University, New Haven CT 06620, M.D. MORALES-ACOSTA, Department of Applied Physics and CRISP, Yale University, New Haven CT 06620, ERIC ALTMAN, Department of Chemical & Environmental Engineering and CRISP, Yale University, New Haven CT 06620, F.J. WALKER, Department of Applied Physics and CRISP, Yale University, New Haven CT 06620, C.H. AHN, Department of Applied Physics, Mechanical Engineering & Materials Science, and CRISP, Yale University, New Haven CT 06620 — The topological crystalline insulator SnTe exhibits multiple surface states protected by crystal symmetry. Thin films of SnTe have been grown by physical vapor deposition techniques on several substrates; these films tend to consist of a heterogeneous collection domain structures. In this talk, we report systematic studies of the structure and transport properties of SnTe films grown by molecular beam epitaxy (MBE). Combining atomic force microscopy and x-ray diffraction measurements, we find that the domains consist of crystallites with 100 and 111 surfaces. When the thickness of SnTe exceeds 400 Å, the 100 surface becomes dominant. Transport measurements show that conduction in the films can be attributed to both Sn vacancies in bulk SnTe and the surface topological states of SnTe.

1:15PM M7.00009 Electronic and spin structure of topological surface state in Sn-based ternary topological insulators
MAIA G. VERGIÑO, Donostia International Physics Center, 20018 Donostia-San Sebastian, Spain, TATIANA V. MENSCHIKOVA, Tomsk State University, pr. Lenina 36, Tomsk, 634050 Russia, IGOR V. SILKIN, Tomsk State University, Tomsk, 634050 Russia, YURY M. KOROTEEV, SERGEY V. EREMEEV, Institute of Strength Physics and Materials Science, Siberian Branch, Russian Academy of Sciences, Tomsk, 634021 Russia, EUGENIU C. CHULKOV, Donostia International Physics Center, 20018 Donostia-San Sebastian, Spain, CHULKOV GROUP TEAM — We report the bulk and surface electronic properties and spin polarization of a new rich family of Sn-based ternary complex topological insulators studied by means of first principles calculations. These compounds exist in different stoichiometries: Sn$_x$Sb$_y$Z$_z$ (A=Sb and B=Te and Se). The crystal structure of these compounds are characterized by alternating along hexagonal axis quintuple, septuple and nonuple layer van der Waals bonded building blocks. We reveal that the bulk band gap in these systems is about 200 meV and the spin polarization near the Dirac point is up to 85%, one of the highest predicted hitherto. At the same family, for some of these compounds which crystal structure has ionic-covalent bonded Bi$_2$Te$_3$ and crystalline topological insulator SnTe atomic layers within building block the complex SOI-induced bulk band inversion caused by competition of band inversions in Bi$_2$Te$_3$ and in SnTe layers occurs and results in inherently nonlinear dispersion of the topological surface state.

1:27PM M7.00010 ABSTRACT WITHDRAWN —

1:39PM M7.00011 Hidden topological surface states on SnTe (111) surface
JIANFENG WANG, JUNWEI LIU, WENHUI DUAN, Tsinghua University — Abundant and interesting properties of topological crystalline insulator SnTe (111) surface have been studied here. Using first-principles calculations, we show the stable structures and their related topological surface states (TSS) under different growth conditions. Surface reconstruction can induce the TSS type transition. More interestingly, the position of TSS can be hidden deeply below the surface, which depends on the interlayer relaxation. The underlying mechanism can be understood by the distortion-induced topological phase transition. Our work paves the way to control the TSS, especially to realize the physical protection in real environment.
shows little or no length-dependence of the current. The dephasing is also shown to lead to a substantial reduction of the current in that dephasing leads to an exponential decay of the current as a function of molecular length, even for resonant tunneling, where the fully coherent calculation.

I will present an approach for calculating the transport properties of SAM-MJs that inherently takes into account in-plane dephasing. The approach describes well the two hallmarks of transport through SAM-MJs, namely the exponential decay of current with molecular chain length and the reduction of the current per molecule as compared to single-molecule junctions. Specifically, I will show that in-plane dephasing is a departure from existing approaches to co-crystallization, as it could guide the discovery of potentially valuable molecular ferroelectrics, and enable the rational design of organic ferroelectric co-crystals and n-crystals, which quickly become prohibitively complex to investigate using heuristic-guided approaches.

11:51AM M8.00002 Surface Dipole Control of Liquid Crystal Alignment. JEFFREY SCHWARTZ, Department of Physics & Astronomy, University of California, Los Angeles, YUXI ZHAO, ALEXANDRA MENDOZA, NATCHA WATTANATORN, Department of Chemistry & Biochemistry, University of California, Los Angeles, PAUL WEISS, Departments of Chemistry & Biochemistry and Materials Science & Engineering, University of California, Los Angeles — We investigate the influence of surface dipoles on the alignment of liquid crystals (LCs). Carbonar ethiol self-assembled monolayers (SAMs) are shown to induce planar anchoring in 4-cyano-4′-pentylphenyl LCs at the SAM/nematic interface. We exploit the different dipole moments of carbonar ethiol structural isomers in order to deconvolute the influence of SAM-LC dipolar coupling from variations in molecular geometry, tilt, and order. The LC director orientation and anchoring energy are measured for devices employing varying carbonar ethiol isomer alignment layers. By using LC orientation as a probe of interaction strength, we demonstrate that dipolar coupling of SAMs to their environment plays a key role in determining molecular orientations. This understanding may advance the engineering of molecular interactions at the nanoscale.

12:03PM M8.00003 Self-assembly of functionalized indoles on surfaces. FABRIZIO DE MARCHI, DALING CUI, JOSH LIPTON-DUFFIN, Institut National de la Recherche Scientifique, Centre Energie, Matériaux, Télécommunications, 1650 Lionel Boulet Boulevard, J3X 1S2 Varennes, CLARA SANTATO, Département de Génie Physique, École Polytechnique de Montréal, C.P. 6079, Succ. Centre Ville, H3C 3A7, Canada, JENNIFER MACLEOD, FEDERICO ROSEI, Institut National de la Recherche Scientifique, Centre Energie, Matériaux, Télécommunications, 1650 Lionel Boulet Boulevard, J3X 1S2 Varennes — To predict how a molecule on a surface will interact with its neighbors or with the substrate itself is an intriguing challenge. If overcome, it would allow the design of a pattern by the proper selection of monomers. However, we are far from a complete understanding of self-assembly mechanisms on surfaces, and more insight can be gathered by studying small, simple systems. In nature, small molecules are the building blocks for more complex systems, such as enzymes and DNA; understanding their self-assembly could lead to the ability to encode this kind of complexity and information density into engineered self-assembled molecular architectures. We report here on the self-assembly of two simple molecules: indole-2-carboxylic acid (I2CA) and 5,6-dihydroxyindole-2-carboxylic acid (DHICA) over various substrates. DHICA is one of the monomers that forms eumelanin, and brings the possibility of different bonding architectures due to its combination of carboxyl and hydroxy groups. At surfaces, DHICA forms a number of structures depending on the conditions used to prepare the surface film. On the other hand, I2CA self-assembles into a simple ordered pattern that is relatively independent of the substrate and preparation conditions. DFT calculations corroborate these observations.

12:15PM M8.00004 Stereoelectronic Switching in Single-Molecule Junctions. HAIXING LI, Department of Applied Physics and Applied Math, Columbia University, TIMOTHY SU, MICHAEL STEIGERWALD, COLIN NUCKOLLS, Department of Chemistry, Columbia University, LATHA VENKATARAMAN, Department of Applied Physics and Applied Math, Columbia University — We demonstrate the first single-molecule switch that operates through a stereoelectronic effect in silicon-based molecular backbones terminated with methyl-sulfide linker groups. We utilize the subangstrom level of control in a scanning tunneling microscope-based break-junction (STM-BJ) technique to manipulate the conformation of these molecule switch that operates through a stereoelectronic effect in silicon-based molecular backbones terminated with methyl-sulfide linker groups. We utilize the subangstrom level of control in a scanning tunneling microscope-based break-junction (STM-BJ) technique to manipulate the conformation of these molecule switch that operates through a stereoelectronic effect in silicon-based molecular backbones terminated with methyl-sulfide linker groups. We utilize the subangstrom level of control in a scanning tunneling microscope-based break-junction (STM-BJ) technique to manipulate the conformation of these molecule switch that operates through a stereoelectronic effect in silicon-based molecular backbones terminated with methyl-sulfide linker groups. We utilize the subangstrom level of control in a scanning tunneling microscope-based break-junction (STM-BJ) technique to manipulate the conformation of these.

12:27PM M8.00005 Transport through Self-Assembled Monolayer Molecular Junctions: Role of In-Plane Dephasing. JONATAN DUBIN, Ben-Gurion University of the Negev — Self-assembled-monolayer (SAM) molecular junctions (MJ) constitute a promising building block candidate for future molecular electronic devices. Transport properties of SAM-MJs are usually calculated using either the phenomenological Simmons model, or a fully-coherent transport theory, employing the SAMs periodicity. As I will show, the standard theory seems to have some discrepancy with experimental observations. To overcome these discrepancies, I suggest that dephasing plays an important role in determining the transport properties of SAM-MJs. I will present an approach for calculating the transport properties of SAM-MJs that inherently takes into account in-plane dephasing in the electron motion as it traverses the SAM plane. The approach describes well the two hallmarks of transport through SAM-MJs, namely the exponential decay of current with molecular chain length and the reduction of the current per molecule as compared to single-molecule junctions. Specifically, I will show that dephasing leads to an exponential decay of the current as a function of molecular length, even for resonant tunneling, where the fully coherent calculation shows little or no length-dependence of the current. The dephasing is also shown to lead to a substantial reduction of the current in a...
12:39PM M8.00006 SERS detection of vibrational Stark effect using PCBM-based molecular junctions, YAJING LI, Department of Physics and Astronomy, Rice University, PETER DOAK, Department of Chemistry, University of California, Berkeley, PAVLO ZOLOTAVIN, Department of Physics and Astronomy, Rice University, JEFFREY BEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University — Understanding the interplay of local electric field and vibrational degrees of freedom of molecules are of interest. We fabricate gold bowtie structures with nanometer inter-electrode spacing using controllable electromigration. Those gold nanostructures support highly localized plasmons and have proven to be suitable SERS substrates with single-molecule sensitivity, which enable the study of molecular vibrational and electronic physics. By measuring the Raman emission from the electrically biased PCBM-containing junctions, we observed strong linear shifts on the vibrational energies of PCBM.

We will present the experiments as well as preliminary theoretical expectations obtained by DFT calculations. We compare the field driven change of vibrational energies of PCBM with those observed in C60 junctions, which have been reported to exhibit quadratic change of vibrational energies due to bias induced charge variation.

12:51PM M8.00007 Graphene Template for Epitaxial Growth of Pentacene and C60 Thin Film, KWANPYO KIM, Ulusan National Institute of Science and Technology, Korea, ELTON J.G. SANTOS, Department of Chemical Engineering, University of Maryland, TAE HOON LEE, YOSHIKO NISHI, Department of Electrical Engineering, Stanford University, ZHENAN BAO, Department of Chemical Engineering, Stanford University — The study and reliable control of molecular packing structures at the graphene-molecule interface are of great importance for various applications. We utilize suspended graphene as an assembly template to investigate thin-film epitaxial growth of various organic molecules. Thin-film packing structures of pentacene and C60 on graphene are investigated using transmission electron microscopy. For pentacene thin-film, we observe an unusual polymorph growth on graphene, which shows significant strain along the c-axis of pentacene crystals. Moreover, the strained film exhibits a specific molecular orientation and a strong azimuthal correlation with underlying graphene lattice. For C60 crystals, we observe large grain sizes and somewhat strong azimuthal correlation with respect to underlying graphene lattice direction. Utilizing ab initio electronic structure calculations with van der Waals interactions, we understand the observed molecular growth behavior mainly with graphene-molecule interaction.

1:03PM M8.00008 Study of the phase separation of organic molecules from solution on Si(111) substrates, MIRIAM CEZZA, COLIN QUALTERS, RAYMOND PHANEUF, Department of Materials Science and Engineering, University of Maryland, College Park, MD — Understanding the science behind assembly of small organic molecules into domains is important for numerous applications, among which organic solar cells are especially noteworthy. An important process on which organic solar cells depends is the phase separation of organic molecules. The formation of a morphology during phase separation from a solvent-based, bimolecular solution onto a substrate depends on several parameters: relative molecular concentrations, solubilities of each type of molecule in the solvent, solvent evaporation rate, and annealing conditions. We carry out studies on molecular mixtures consisting of tetratrito zinc-phthalocyanine (tn-ZnPc) and PCBM in chloroform, and native oxide-covered Si(111) substrates. We investigate the role that solvent evaporation rate during deposition, followed by solvent vapor annealing (SVA), plays on the formation of phase separated mixtures and their crystallization and phase transformation. We also investigated the relative concentration of individual molecules in mixtures. We found that PCBM molecules alone undergo several phase transformations as the solvent evaporation rate decreases, while tn-ZnPc is very stable. Moreover, the concentration of tn-ZnPc in mixtures highly affects the PCBM crystallization.

1:15PM M8.00009 Atmospheric Effects on dF TESADT Thin-Film Transistors, BRAD CONRAD, CORTNEY BOUGHER, SHAWN HUSTON, Appalachian State Univ, JEREMY WARD, Wake Forest University, ABDUL OBAID, MARSHA LOTH, JOHN ANTHONY, University of Kentucky, OANA JURCHESCU, Wake Forest University — Crystalline organic semiconductors often display carrier mobilities that vary with environmental conditions and fabrication parameters. Additionally, the electrical properties of organic thin-film devices are highly dependent on film structure, crystallinity, and molecular packing. In solution-deposited polycrystalline thin-films, the regions between crystals often affect the overall device performance, as molecular ordering and crystal structure may differ significantly from neighboring regions. Device characterization and Kelvin Probe Force Microscopy (KPFM) is used to analyze the electrical properties of grain boundaries, electrodes, and crystalline regions within 2,8-difluoro-5,11-triethysilylethynylanthradithiophene (dF TESADT) thin-film transistor surfaces. The influence of both atmospheric dopants and exposure time is examined and explained in the context of device characterization and interfacial effects.

1:27PM M8.00010 2d Assembly and solvation of supramolecular ionic polymers, JANICE REUTT-ROBEY, QIAN SHAO, LEVAN TSKIPURI, University of Maryland, DAISUKE TAKAJJO, Osaka University — Supramolecular polymers are important building blocks for functional nanomaterials. The structural fidelity of soft (non-covalent) species during transfer from the solution phase to a solid substrate is an important issue for many applications. We report on the 2D structures of supramolecular ionic polymer chain structures consisting of the ionic solutes C18H24N3O12 (-3) and IrN6C30H24 (-3). In solution, these ionic solutes assemble into supramolecular chain-like structures, with lengths averaging 20 nm. Deposition onto an Ag(111) substrate by a liquid microaerosol source yields 2D islands of the ionic polymers embedded in a thin film of the solvent, CH3Cl. Molecularly resolved UHV-STM images reveal in tact transfer of the supramolecules with size distributions comparable to the solution phase. Solute ion attachment/detachment from the supramolecular chain ends occurs, facilitated by the bounding solvent layer. Solvent-solute islands adopt striking geometric shapes and these structures are discussed in terms of 2-d solvation energies. This work was supported by the National Science Foundation under CHE-MSN Grant CHE1310380.

1:39PM M8.00011 High-resolution imaging of interfacial water: from water monomer to two-dimensional ice, YING JIANG, JING GUO, XIANGZHI MENG, JI CHEN, JINBO PENG, JIMING SHENG, LIMEI XU, XIANGZHE LI, ENGE WANG, International Center for Quantum Materials (ICQM) and School of Physics, Peking University, Beijing 100871, P. R.China — Water-solid interactions are of broad importance both in nature and technology. The hexagonal bilayer model based on the Bernal-Fowler-Pauling ice rules has been widely adopted to describe water structuring at interfaces. Recently, we made a breakthrough in achieving submolecular-resolution imaging of individual water molecules using a scanning tunneling microscope (STM) [1]. Such a technique opens up the possibility of determining the detailed topology of H-bonded networks at water/solid interfaces with atomic precision. Thanks to the high-resolution STM imaging, we discover a new type of two-dimensional (2D) ice-like bilayer structure built from cyclic water tetramers on an insulating NaCl(001) film, which is completely beyond the conventional bilayer picture [2]. A novel bridging mechanism allows the interconnection of water tetramers to form chains, flakes and eventually a 2D extended ice bilayer containing a regular array of Bjerrum D-type defects. Ab initio density functional theory calculations substantiate this bridging growth mode and reveal a striking proton-disordered ice structure. [1] J. Guo, X. Z. Meng, J. Chen, J. B. Peng, J. M. Sheng, L. M. Xu, J. R. Shi, E. G. Wang* and Y. Jiang*, Nature Materials 13, 184 (2014). [2] J. Chen, J. Guo, X. Z. Meng, J. B. Peng, J. M. Sheng, L. M. Xu, Y. Jiang*, X. Z. Li*, E. G. Wang, Nature Communications 5, 4056 (2014).

1Supported by the National Basic Research Programs of China and the National Science Foundation of China.
network on the reconstructed Au(100) surface are closer to that of Pt atoms in PtO, which is +2, than in Pt. This result agrees extremely well with experimental XPS data [1].

Results of our simulations show that the Pt-dipyridyltetrazine complexes form 1-dimensional chains aligned 45° with respect to the Au(100) reconstruction row with the molecule-molecule distance of 6.93 Å. More importantly, Bader analysis shows that Pt atoms are cationic with +0.75 charge. This amount of charge is in accord with the charge on Pt in PtO determined by the same analysis indicating that the oxidation states of the Pt atoms in the Pt-dipyridyltetrazine network on the reconstructed Au(100) surface are closer to that of Pt atoms in PtO, which is +2, than in Pt₂O₃ or PtO₂. This result agrees extremely well with experimental XPS data [1].

In the presence of copper, the amino acids open a channel to the surface as mediated by temperature and molecular coverage facilitated the growth of copper islands. The growth and size fluctuation of the islands offered an interesting snapshot of metal nanocluster diffusion that often occurs at time scales beyond the resolution of a given experimental technique. The presence of ~1 ML of molecules on the surface effectively trapped the metal atoms into localized islands. Elevated temperatures (≤350 K) were used to promote the further diffusion, coalescence, and extinction of the islands for a more detailed understanding of the coarsening and ripening mechanisms.

2:03PM M8.0013 Metal-Organic Chains with Single-Site Pt(II): Insights from first principles simulations1, DUY LE, TALAT S. RAHMAN, Department of Physics, University of Central Florida — Creation, stabilization, characterization and control of single atom transition metal sites on surfaces may lead to significant advancement of the next-generation catalyst. Motivated by the experimental results of Skomski et al. [1], we have performed density functional theory calculations of Pt-dipyridyltetrazine complexes on the reconstructed Au(100) surface.

The results of our simulations show that the Pt-dipyridyltetrazine complexes form 1-dimensional chains aligned 45° with respect to the Au(100) reconstruction row with the molecule-molecule distance of 6.93 Å. More importantly, Bader analysis shows that Pt atoms are cationic with +0.75 charge. This amount of charge is in accord with the charge on Pt in PtO determined by the same analysis indicating that the oxidation states of the Pt atoms in the Pt-dipyridyltetrazine network on the reconstructed Au(100) surface are closer to that of Pt atoms in PtO, which is +2, than in Pt₂O₃ or PtO₂. This result agrees extremely well with experimental XPS data [1].

11:15AM M9.00001 Self-heating in an AlGaN/GaN transistor studied by ultraviolet and visible micro-Raman scattering, MOHAMMAD NAZARI, LOGAN HANCOCK, EDWIN PINER, MARK HOLTZ, Texas State University — The two-dimensional electron gas (2DEG) at GaN/AlGaN interface is the basis for high electron mobility transistor. The 2DEG region forms spontaneously without any doping and is less than 10 nm in thickness. Current-induced self-heating results in large temperature rises in these devices and represents the principal limiting factor in these devices. We report direct measurements of self-heating in an AlGaN/GaN high electron mobility transistor using ultraviolet (UV) and visible micro-Raman spectroscopy. The phonon shift is used to evaluate the temperature rise in different layers of the material stack corresponding to different optical penetration depths, giving temperature rise in top 100 nm of GaN, i.e., close to the 2DEG. The visible measurements provide an average temperature rise through the 1 micron thick GaN layer and in the Si substrate close to the interface. A depth profile is developed based on the combined data sets obtained under experimentally identical conditions. Finite element thermal simulation developed based on the experimentally determined temperature-depth profile reveal thermal resistance barrier of 10⁻⁸ K·m²/W at the interface between AlN and Si substrate.

1A grant from the Korea Institute of Science and Technology (KIST) institutional program.

11:27AM M9.00002 Growth of high quality GaN layer on carbon nanotube-graphene network structure as intermediate layer1, TAEHO HOON SEO, Korea Institute of Science and Technology, AH HYUN PARK, Chonbuk National University, SUNGCHAN PARK, MYUNG JONG KIM, Korea Institute of Science and Technology, EUN-KYUNG SUH, Chonbuk National University — In general, high-quality GaN layers are synthesized on low-temperature (LT) GaN buffer layer on a single crystal sapphire substrate. However, large differences in fundamental properties such as lattice constants and thermal expansion coefficients between GaN layer and sapphire substrate generate high density of threading dislocation (TD) that leads to deterioration of optical and structural properties. Graphene has been attracting much attention due to its excellent physical properties however, direct epitaxial growth of GaN film onto graphene substrate is not easily accessible due to the lack of chemical reactivity on graphene which consisted of C-C bond of sp² hexagonally arranged carbon atoms with no dangling bonds. In this work, an intermediate layer for the GaN growth on substrate was constructed by inserting carbon nanotubes and graphene hybrid structure (CGH) Optical and structural properties of GaN layer grown on CGH were compared with those of GaN layer directly grown on sapphire CNTs as nucleation sites and play a crucial role in the growth of single crystal high-quality GaN on graphene layer. Also, graphene film acts as a mask for epitaxial lateral overgrowth of GaN layer, which can effectively reduce TD density.

Crystal growth and detector performance of large size high-purity Ge crystals, GUOJIAN WANG, Department of Physics, University of South Dakota, MARK AMMAN, Ernest Orlando Lawrence Berkeley National Laboratory, HAO MEI, DONGMING MEI, Department of Physics, University of South Dakota, THOMAS S. RITTER, Leibniz Institute for Crystal Growth, YUTONG GUAN, GANG YANG, Department of Physics, University of South Dakota — High-purity germanium crystals with 12 cm in diameter were grown in a hydrogen atmosphere using the Czochralski method. The dislocation density of the crystals was determined to be in the range of 2000 - 4000 cm⁻², which meets a requirement for use as a radiation detector. The axial and radial distributions of impurities in the crystals were measured by Hall effect and Photo-thermal ionization spectroscopy (PTIS). Two detectors were also fabricated from one of the crystals with different techniques and then evaluated for electrical and spectral performance. Measurements of gamma-ray spectra from ¹³⁷Cs, ²⁴¹Am and ¹⁰⁰Co sources demonstrate that the detectors have excellent energy resolution. Keywords: High-purity germanium crystal, Czochralski method This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.
11:51AM M9.00004 Characterization of dislocation and defects for large high purity Ge crystals\(^1\), HAO MEI, GOUO JIAN WANG, YUTONG GUAN, GANG YANG, DONGMING MEI, University of South Dakota, CUBED COLLABORATION — Large diameter (~ 10 cm) high purity Germanium (HP-Ge) crystals have been growing via Czochralski method at University of South Dakota. We investigate the impacts of growth rate, time-temperature profile, and thermal gradient on the dislocation and defects distribution in HP-Ge crystals along <100> orientation. The dislocation density across the entire cross-section of a grown crystal is measured using microscope. Utilizing X-Ray Diffraction method, we obtain the rocking curves from the same crystal samples. We analyze the correlation between the full width at half maximum (FWHM) of the rocking curves and the dislocation densities from the optical observations (etch pits distribution). A model that describes the correlation of dislocation density, along the HP-Ge crystal, with the FWHM of the rock curves for XRD is established. We report these analytic results.

12:03PM M9.00005 The Relationship Between Terminating Oxide Chemistry and InAs (100) Two-Dimensional Electron Gas (2DEG) Conductivity, KRISTEN COLLAR, Department of Physics, Duke University, Durham, NC, United States, WENYUAN JIAO, JINCHENG LI, WEI KONG, APRIL BROWN, Department of Electrical and Computer Engineering, Duke University, Durham, NC, United States — InAs grown in high-conductance defect density state, high electron mobility and quasi-two dimensional electron gas (2DEG) form at the surface of oxidized and atomically-clean InAs. Electrical characterization of the 2DEG, particularly its correlation to oxide-InAs interface states is key to understanding the factors controlling conductivity. This study perturbs the oxide formation by investigating the dominating chemical reactions yielding the heterogeneous In- and As-based native oxide. Herein, we study the relationships between the conductivity and oxide surface chemistry of 100nm InAs films terminated with In or As monolayers using Molecular Beam Epitaxy then oxidized upon exposure to air. We speculate that the observed trends in the 2DEG conductivity are due to differences in the nature of predominate defects associated with oxide chemistries and their formation. Angle-resolved X-ray photoelectron spectroscopy revealed that In oxide was dominate at all probing depths, with more As oxide at the surface. Furthermore, an increase in incorporated oxygen degraded the mobility. Thus, we show that the surface termination impacts the 2DEG mobility and carrier concentration through the extent and homogeneity of oxygen incorporation during the formation of the oxide layer.

12:15PM M9.00006 Purification of Germanium Crystals by Zone Refinement: Theoretical and Experimental Approaches, GANG YANG, YUTONG GUAN, GOUO JIAN WANG, HAO MEI, FANYI JIAN, DONGMING MEI, University of South Dakota, CRYSTAL GROWTH TEAM — The results of single germanium crystals grown from zone-refined germanium ingots, identified by photon thermal ionization spectroscopy (PTIS), show that there are four main impurities, aluminum (Al), phosphor (P), boron (B) and gallium (Ga) in the crystals. Based the PTIS results, we investigated the influences of zone speed, zone width and the number of passes on effective segregation coefficient of Al, P and Ga in the process of zone refinement, then the further calculation of distribution of Al, P and Ga along the zone refined ingots has been conducted. In terms of trend of impurity distribution, the calculated results have a very good agreement with the experimental results. We report both the theoretical calculations and the experimental results. This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

12:27PM M9.00007 Effects of Light Exposure on Dopant Incorporation and Migration in MBE-Grown GaAs(001), CHARLOTTE E. SANDERS, D.A. BEATON, K. ALBERI, National Renewable Energy Laboratory — Light-stimulated epitaxy of II-VI semiconducting materials is known to reduce crystalline defect density and enhance substitutional dopant incorporation relative to traditional “dark” epitaxial growth. These effects have been speculated to arise from photon-atom interactions at the growth front, and from involvement in bonding processes by photogenerated carriers; however, a conclusive explanation of the observed effects has yet to be found. We are revisiting this topic, attempting to clarify the mechanisms of light-stimulated epitaxy and to explore its effects on the class of III-V materials. Here we report an ongoing investigation into dopant incorporation and migration in MBE-grown GaAs(001) when the growth front is irradiated during deposition. On the basis of our preliminary findings, and by comparing our new results with results previously obtained for light-stimulated effects on doping of II-VI systems, we can begin to draw conclusions about the mechanisms underlying light-stimulated epitaxy and their potential utility to MBE growth of complex multilayer structures. This work was supported by the DOE Office of Science, Basic Energy Sciences, under contract DE-AC36-08GO28308.

12:39PM M9.00008 Progress in the growth and optical properties of dilute bismide III-V semiconductor alloys, DANIEL A. BEATON, T. CHRISTIAN, Nat’l Renewable Energy Lab, R.B. LEWIS, Paul-Drude-Institut für Festkörperphysik, K. ALBERI, A. MASCARENHAS, Nat’l Renewable Energy Lab — The dilute bismuth containing III-V semiconducting alloys of great potential for application in many areas of semiconductor technology, such as multijunction photovoltaics and solid-state lighting. There is a large reduction of the fundamental bandgap of GaAs with bismuth incorporation resultant from the raising of the valence band maximum. Dilute bismide alloys have long been compared to the dilute nitride alloy because bismuth introduces a state near the valence band edge of the host GaAs (in contrast to the conduction band edge in the nitride alloys) that affects its optical and electronic properties. Here I will discuss some recent advances in our understanding of the surface processes involved in dilute bismide alloy growth by molecular beam epitaxy which have lead to improved film quality and the potential utility to MBE growth of complex multilayer structures. The improved film quality has made it possible to further explore the properties of this material.

12:51PM M9.00009 Interplay of film thickness and laser fluence in laser-crystallized silicon films, MATTHEW R. SEMLER, JUSTIN M. HOEY, SRINIVASAN GURUVENKET, CODY R. GETTE, ORVEN F. SWENSON, ERIK K. HOBIE, NDSU — A detailed study of the laser crystallization of amorphous silicon thin films as a function of laser fluence and film thickness will be presented. Silicon films grown through plasma-enhanced chemical vapor deposition were crystallized with a pulsed, neodymium-doped vanadate laser, operating at 355 nm. The crystallinity, morphology, and optical and electronic properties of the films are characterized through transmission and reflectance spectroscopy, resistivity measurements, Raman spectroscopy, X-ray diffraction, atomic force microscopy, and optical and scanning-electron microscopy. The films reveal a unique surface morphology that strongly couples to the electronic characteristics of the films, with a minimum laser fluence at which the film properties are optimized.
1:03PM M9.00010 Investigation of Nanodiamond and Silicon Carbide Foils Product for H-Stripping to Support Spallation Neutron Source1, GARY HARRIS2, JAMES GRIFFIN, Howard Univ, RD VISPUTTE, Bluewave Semiconductor. CIQM COLLABORATION — Diamond and silicon carbide (SiC) is an ideal material as an H-stripper foil for spallation neutron source (SNS) applications due to their high thermal conductivity, low molecular weight, and strength. Cubic silicon carbide grown on silicon is a material tension stress and the foil does not curl. Polycrystalline diamond is characterized by a high degree of internal stress, which causes the foil to curl when not supported by the substrate. the sic is grown using a RF CVD system. Hot filament chemical vapor deposition (HFCVD) was used to grow diamond on a silicon substrate. In both cases a 1.2 cm diameter window was etched in the silicon using a 1.13 solution of hydrofluoric, nitric, and acetic acids so that the diamond of SiC foil would be suspended while being supported on all sides by the silicon. Wax and or photoresist were used as masks to protect the outer silicon from etching. Raman spectroscopy verified the quality of the grown material. Atomic force microscopy (AFM) revealed that the diamond foil originally against the substrate had an average roughness of <6.7 nm while the foil away from the substrate had an average roughness of 13.2 nm. The SiC foils had roughness less than 3 nm. Scanning electron microscopy (SEM) revealed no cracks in the suspended foil.

1:15PM M9.00011 Synthesis and structural characterization of Nb2O5, LEONILSON KIYOSHI HERVAL, DRIELE VON DREIFUS, ADRIANO C. RABELO, ARIANO D. RODRIGUES, YARA GALVÃO GOBATO, ADILSON J.A. DE OLIVEIRA, ERNESTO C. PEREIRA, MARCIO P.F. DE GODOY, Universidade Federal de Sao Carlos, LABORATÓRIO INTERDISCIPLINAR DE ELETROQUÍMICA & CERÂMICA - DEPARTAMENTO DE QUÍMICA, GROUP DE DOPTELETRÔNICA E MAGNETO-ÓPTICA - DEPARTAMENTO DE FÍSICA — Niobium and niobium alloys are used in a large number of industrial applications. Niobium Pentoxide (Niobic Anhydride, Nb2O5) is probably the commonest compound of niobium. It is a colourless, stable solid that is fairly unreactive and it is the main precursor to all materials with application in electronic components such as capacitor and optical glasses. In general Nb2O5 samples present many crystalline phases which are strongly dependent on the preparation parameters. We have studied two different phases (hexagonal and orthorhombic) of Nb2O5 synthesized by Pechini method and characterized them by X-Ray Diffraction (XRD), Raman spectroscopy and Magnetometry using a Superconducting Quantum Interference Device (SQUID). Our results show that the hexagonal phase dominates for samples prepared at 500°C while the orthorhombic phase is increased for samples prepared at 600°C. Correlation between Raman spectroscopy and XRD allowed the identification of these crystalline phases as well the study of annealing effects in-situ. Both phases are paramagnetic and the orthorhombic phase presents a significant increase of effective magnetic moments as compared to hexagonal phase.

1:27PM M9.00012 Kondo effect in a novel 5d quasi-skutterudite Yb3O5SiGe3, YUGUO SHI, CHONGJING YANG, XIA WANG, XU ZHANG, DESHENG WU, YIFENG YANG, JIANLIN LUO, Beijing National Laboratory for Condensed Matter Physics & Institute of Physics, Chinese Academy of Science — We report the crystal growth of a new compound, Yb3O5SiGe3, by using a Bi-flux method. It crystalizes in the quasi-skutterudite-type caged structure with a cubic space group of Pm-3n (No. 223). Magnetic measurements reveal almost fully localized Yb f-moments above 120 K. The resistivity exhibits a crossover from metallic to insulating behavior with a logarithmic increase below ~ 40 K. The specific heat coefficient shows a rapid upturn below ~ 5 K and exceeds 2 J mol^-1 K^-2 at 2 K. Our experimental analysis and electronic band structure calculations demonstrate that Yb3O5SiGe3 exhibits the Kondo effect due to strong hybridization of the localized Yb f-moments with the p-electrons of the surrounding Ge-cages.

1:39PM M9.00013 Formation of ST12 phase Ge nanoparticles in ZnO thin films, ABDULLAH CECILYAN, Department of Physics Engineering, Hacettepe University, 06800, Ankara, Turkey, EMRE GUMRUKCU, Department of Nanotechnology and Nanomedicine, Hacettepe University, 06800, Ankara, Turkey — In this work, we investigate the effects of reactive and nonreactive growth of ZnO on the rapid thermal annealing (RTA) induced formation of Ge nanoparticles (Ge-np) in ZnO: Ge nanocomposite thin films. The samples were deposited by sequential sputtering of ZnO and Ge thin film layers with a total thickness of about 600 nm on Si substrates followed by an ex-situ (RTA) at 600°C for 30, 60, 90, 120, 150, 180, and 210 s under forming gas atmosphere. In order for the reactive sputtering of Ge, 5 mTorr Oxygen was introduced to the growth chamber. XRD and Raman analyses were utilized to investigate the effect of RTA time on the structural evolution of the samples. It has been realized that crystal structure of Ge nanoparticles is significantly affected by the growth method of the embedding ZnO layer. While reactive deposition of ZnO layers results in a mixture of diamond cubic (DC) and simple tetragonal (ST12) Ge-np, nonreactive deposition of ZnO layers leads to the formation of pure DC Ge-np upon RTA process. Formation of these two phases has been discussed based on the existence of native point defects such as oxygen vacancies and Zn interstitials.

1:51PM M9.00014 Single Element Silicon Quasicrystal on Glass, ABDUL MIDDYA, Silicon Solar, Inc., PROF. KARTIK GHOSH, PHYSICS, MATERIAL'S SCIENCE AND ASTRONOMY, MISSOURI STATE UNIVERSITY, MO 65804 COLLABORATION — Quasicrystal is an exotic form of ordering of materials structure found in nature. In this work, we report on formation of single element silicon (Si) quasicrystal, instead of metallic alloys. We found small quantity of quasicrystalline silicon on glass substrate when silicon (Si) and atomic hydrogen (H) atoms in vacuum chamber are allowed to condense on glass substrate maintained at 250°C in hot wire chemical vapor deposition (hot-wire CVD) technique. We observed Penrose tiling at the surface of silicon thin-film as observed by atomic force microscopy (AFM). However, this texturing consists of six-fold symmetry and five-fold symmetry on the surface of spherical ball. We found experimental evidence of the quasi-unit cell, building blocks of quasicrystalline structure. The ordering of quasi-unit cell improves with increasing hydrogen dilution. The Raman transverse optical (TO) peak is observed at 517 cm-1, although the grain size is only 1 to 2 μm. We also found, for the first time, direct experimental evidence of real existence of crystallographic plane in crystal structure. The micrograph of SEM shows grains appear in a very symmetric position, like diffraction spots of ceramics (alloy), we found ceramics-like silicon thin-film.

2:03PM M9.00015 Increasing The Efficiency of Silicon Solar Cells via an Anti-reflecting Nanoporous Surface Layer, AHMET COSKUNER, AISHA GOKCE, OMER ALTUNAY, YANI SKARLATOS, OZHAN OZTAY, Bogazici Univ — Electrochemical etching of silicon in a controlled environment results in a porous surface that has many application areas from drug delivery to optoluminescent devices. There is vast interest in implementing porous silicon in silicon solar cells to increase light absorption and therefore the efficiency. Here we demonstrate successful formation of a nano-porous surface on monocrystalline Si wafers as well as doped Si solar cells. Our results show that pre-cleaning and post-drying is crucial to acquire a smooth, non-cracked topography. We also find that under similar conditions, smaller pores in a denser arrangement and with shorter depths form in p-n junction type Si wafers compared to n-type or p-type Si. In ITO coated porous Si solar cells with Al back contacts, the measured efficiency increase is almost 50% of those without a porous surface. This is a promising result to further enhance the performance of Si solar cell devices.

Wednesday, March 4, 2015 11:15AM - 2:15PM – Session M10 DCMP: Anomalous Quantum Hall Effect 007A - James Williams, University of Maryland

Magnetic resistance associated to spin spur is given by the following universal expression:

\[ R_{xx} = \frac{h}{e^2} \left| \frac{\nu_{xy}}{\nu_{yy}} \right| \]

\[ \sigma_{xx} \] is the electron charge, but perfect quantization has so far proved elusive. Here, we study the QAHE in the limit of zero applied magnetic field, and measure Hall resistance quantized to within one part per 10,000. Deviation from quantization is due primarily to thermally activated carriers, which can be nearly eliminated through adiabatic demagnetization cooling. This result demonstrates an important step toward dissipationless electron transport in technologically relevant conditions.

11:27AM M10.00002 Universal scaling of the quantum anomalous Hall plateau transition1. Jing Wang, Biao Lian, Shou-Cheng Zhang, Stanford Univ — We study the critical properties of the quantum anomalous Hall (QAH) plateau transition in magnetic topological insulators. We introduce a microscopic model for the plateau transition in the QAH effect at the coercive field and then map it to the network model of quantum percolation in the integer quantum Hall effect plateau transition. Generally, an intermediate plateau with zero Hall conductance could occur at a coercive field. \( \sigma_{yx} \) would have double peaks when the corresponding single peak has single peak. Remarkably, this theoretical prediction is already borne out in experiment. Universal scaling of the transport coefficients \( \rho_{xy} \) and \( \rho_{xx} \) are predicted.

\[ \frac{E}{T} = \frac{1}{\hbar} \left( \frac{1}{2\pi k_B T} \right)^{1/2} \left( \frac{N}{L} \right)^{1/2} \]

\[ \frac{1}{\lambda} = \frac{1}{L} \left( \frac{N}{L} \right)^{1/2} \]

11:39AM M10.00003 Tunable Anderson metal-insulator transition in quantum spin Hall insulators, Chui-Zhen Chen, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, Haiwen Liu, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China, Huai Jiang, College of Physics, Optoelectronics and Energy, Soochow University, Suzhou 215006, China, Qing-Feng Sun, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China, Ziqiang Wang, Department of Physics, Boston College, Chestnut Hill, Massachusetts 02167, USA, X.C. Xie, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — We study disorder effects in Bernevig-Hughes-Zhang (BHZ) model (unitary system), and find that Anderson transition of quantum spin Hall insulator (QSHI) is determined by model parameters. In contrast to the common belief that 2D unitary system scales to insulator except at certain critical points, we find that an exotic metallic phase emerges between QSHI and normal insulator phases in InAs/GaSb-type BHZ model. On the other hand, direct transition from QSHI to normal insulator is found in HgTe/CdTe-type BHZ model. Furthermore, we show that the metallic phase originates from the Berry phase and can survive both inside and outside the gap.

11:51AM M10.00004 Spin Texture and Mirror Chern number in Hg-Based Chalcogenides1. Qing-Ze Wang, The Pennsylvania State University, Shu-Chun Wu, Claudia Felser, Max Planck Institute for Chemical Physics of Solids, Binghai Yan, Max Planck Institute for Chemical Physics of Solids, & Max Planck Institute for Physics of Complex Systems, Chao-Xing Liu, The Pennsylvania State University — One special feature of surface state in topological insulators is the so-called spin-momentum locking, which means that electron spin is oriented along a fixed direction for a given momentum and forms a texture in the momentum space. In this work, we study spin textures of two typical topological insulators in Hg-Based Chalcogenides, namely HgTe and HgS, based on both the first principle calculation and the eight band Kane model. We find opposite helicities of spin textures between these two materials, originating from the opposite signs of spin-orbit couplings. Furthermore, we reveal that different mirror Chern numbers between HgTe and HgS characterize different topological natures of the systems with opposite spin textures and guarantee the existence of gapless interface states.

12:03PM M10.00005 Edge states in twisted bilayer graphene: quantum spin Hall and electron-hole bilayers. Javier D. Sanchez-Yamagishi, Jason Luo, Massachusetts Institute of Technology, Kenji Watanabe, Takashi Taniguchi, National Institute of Materials Science, Japan, Pablo Jarillo-Herrero, Massachusetts Institute of Technology — Twisted bilayer graphene offers a unique platform for studying 1d edge states in a bilayer 2-dimensional electron gas. Despite being spaced by only 0.34 nm, a large interlayer twist decouples the layers in the bulk, while opening the door for interesting interactions at the edges. To probe this physics, we study the electronic transport through quantum Hall edge modes twisted bilayer graphene devices. Using a large electrostatic gate, we independently control the filling factor of each layer to form different combinations of bilayer edge states while measuring their conductance. The most dramatic transport effects are observed when the layers are doped to have edge states of opposite chiralities, resulting in coexisting electron- and hole-like states. We will present evidence that, in this regime, the twisted bilayer graphene can form a quantum spin Hall state where edge states in each layer counter-propagate in opposite directions with opposite spin polarizations. This bilayer realization offers a flexible system to study quantum spin Hall edge transport as well as to build more complex 1d circuits. We will also discuss the possibility for fractional generalizations of this edge physics and our measurements of the fractional QHE in twisted bilayer graphene.

12:15PM M10.00006 ABSTRACT WITHDRAWN

12:27PM M10.00007 Interaction induced topological phases in partially flat band graphene-like systems. Jorn W.F. Venderbos, Liang Fu, Massachusetts Inst of Tech-MIT — In this work we show how periodically modulated strain fields lead to partially flat bands resembling Landau level quantization due to pseudo-magnetic fields. These partially flat pseudo-Landau levels occur in systems such as graphene or at the interface between a trivial and topological crystalline insulator, where in both cases strain fields couple as pseudo-gauge fields. With these examples in mind, we discuss several different physical implementations. Periodically modulated strain fields hold the promise of realizing Quantum Hall physics on a large scale, whereas constant pseudo-magnetic fields are generally limited to the nanoscale. The electronic properties of these systems being fundamentally altered by the formation of these flat bands, we investigate the effect of electron-electron interaction and find that they induce topological phases, notably the Quantum Anomalous Hall state.

11:15AM M10.00001 Precise quantization of anomalous Hall effect near zero magnetic field. Andrew Bestwick, Eli Fox, Stanford University, Xufeng Kou, Lei Pan, Kang Wang, University of California, Los Angeles, David Goldhaber-Gordon, Stanford University — The quantum anomalous Hall effect (QAHE) has recently been of great interest due to its recent experimental realization in thin films of Cr-doped (Bi, Sb)\(_2\)Te\(_3\), a ferromagnetic 3D topological insulator. The presence of ferromagnetic exchange breaks time-reversal symmetry, opening a gap in the surface states, but gives rise to dissipationless chiral conduction at the edge of a magnetized film. Ideally, this leads to vanishing longitudinal resistance and Hall resistance quantized to \( h/ e^2 \), where \( h \) is Planck’s constant and \( e \) is the electron charge, but perfect quantization has so far proved elusive. Here, we study the QAHE in the limit of zero applied magnetic field, and measure Hall resistance quantized to within one part per 10,000. Deviation from quantization is due primarily to thermally activated carriers, which can be nearly eliminated through adiabatic demagnetization cooling. This result demonstrates an important step toward dissipationless electron transport in technologically relevant conditions.
12:39PM M10.00008 Optimizing proximity induced anomalous Hall effect in (Bi$_{1-x}$Sb$_x$)$_2$Te$_3$/YIG heterostructures. ZILONG JIANG, CHI TANG, JING SHI, UC Riverside, CUIZU CHANG, PENG WEI, JAGADEESH S. MOODERA, MIT — The spontaneously broken time reversal symmetry leads to an energy gap in the Dirac spectrum of the surface states of a topological insulator (TI) which gives rise to the quantized anomalous Hall effect (QAHE). QAHE has been observed in TI doped with Cr. Here we explore an alternative route by coupling the surface states of TI with yttrium iron garnet (YIG) ferrimagnetic insulator (FI). Just as in Cr-doped TI, a major challenge is to reduce the bulk conduction which overwhelms the surface state contribution. We have successfully grown 5 quintuple layer thick ternary (Bi$_{1-x}$Sb$_x$)$_2$Te$_3$ on atomically flat YIG films, in which the Fermi level of TI can be controlled by the Bi:Sb ratio. We have observed the anomalous Hall effect (AHE) in TI/YIG heterostructure over a wide range of carrier density and in both electron and hole types induced by varying the Bi:Sb ratio from 0:1 to 1:0. Both $R_{xx}$ and $R_{XY}$ undergo systematic and dramatic changes as the Bi:Sb ratio is varied. The maximum $R_{XY}$ occurs near the p-n cross-over region at Bi:Sb ratio 0.2:0.8, which is nearly two orders of magnitude greater than the minimum value at Bi:Sb ratio 1:0. As the Bi:Sb ratio is varied, we find that $R_{AH}$ scales quadratically with $R_{xx}$ indicating the scattering rate independent AHE. The electric field effect study further demonstrates the existence of robust AHE while the Fermi level of TI is tuned. This research was supported by UC Lab fees program and a DOE/BES award at UCR, and by NSF/DMR at MIT.

1:03PM M10.00010 Honeycomb lattice with multiorbital structure: Topological and quantum anomalous Hall insulators with large gaps. GU-FENG ZHANG, Univ of California - San Diego, YI LI, Princeton University, CONJUIN WU, Univ of California - San Diego — We construct a minimal four-band model for the two-dimensional topological insulators and quantum anomalous Hall insulators based on the $p_z$- and $p_y$-orbital bands in the honeycomb lattice. The multiorbital structure allows the atomic spin-orbit coupling which lifts the degeneracy between two sets of on-site Kramers doublets $j_z = \pm \frac{3}{2}$ and $j_z = \pm \frac{1}{2}$. Because of the orbital angular momentum structure of Bloch-wave states at $\Gamma$ and $K(K')$ points, topological gaps are equal to the atomic spin-orbit coupling strengths, which are much larger than those based on the mechanism of the $s-\pi$ band inversion. The energy spectra and eigen wave functions are solved analytically based on Clifford algebra. The competition among spin-orbit coupling $\lambda$, sublattice asymmetry $m$, and the Néel exchange field $n$ results in band crossings at $\Gamma$ and $K(K')$ points, which leads to various topological band structure transitions. The quantum anomalous Hall state is reached under the condition that three gap parameters $\lambda$, $m$, and $n$ satisfy the triangle inequality. Flat bands also naturally arise which allow a local construction of eigenstates. The above mechanism is related to several classes of solid state semiconductor.

1:15PM M10.00011 Observation of topological surface state quantum Hall effect in an intrinsic three-dimensional topological insulator. YANG XU, IRENEUSZ MIOTKOWSKI, YONG CHEN, Department of Physics and Astronomy, Purdue University, West Lafayette, IN 47907, YONG P.CHEN'S GROUP IN PURDUE TEAM, CHIH-KANG SHIH'S GROUP IN UT-AUSTIN COLLABORATION, M. ZAHID HASAN'S GROUP IN PRINCETON COLLABORATION — A three-dimensional (3D) topological insulator (TI) is a novel quantum matter with a gapped insulating bulk yet a conducting surface hosting topologically-protected gapless surface states of Dirac fermions. One of the most distinct electronic transport signatures predicted for such topological surface states (TSS) is a half-integer quantum Hall effect (QHE) in a magnetic field. We have observed well-developed QHE arising from TSS in an intrinsic TI of Bi$_2$Se$_3$. Our samples can exhibit surface dominated conduction even close to room temperature, while the bulk conduction is negligible. At low temperatures and high perpendicular magnetic fields, the Hall conductance shows well quantized integer plateaux in exfoliated flake devices on SiO$_2$/Si substrates, where the top and bottom surface each contributing a half integer $e^2/h$ Hall conductance, accompanied by vanishing longitudinal resistance. We have also studied dual-gated devices where both the top and bottom surfaces can be independently gated. Such intrinsic 3D TI materials exhibiting no measurable bulk conduction and well-developed surface state QHE pave the way for further applications of topological quantum electronics.

1:27PM M10.00012 Giant Band Gap Quantum Spin Hall Phase with Weak Spin-Orbit Coupling. ZHIGANG WU, MARC DVORAK, Colorado Sch of Mines — The typical quantum spin hall (QSH) insulator relies on spin-orbit (SO) coupling to open a band gap in the bulk material. However, the intrinsic SO coupling is often rather weak, especially in graphene, and most researchers have focused on enhancing the SO interaction, e.g., by adsorbing heavy adatoms, to increase the bulk band gap. We have demonstrated that if patterned properly, periodic defects on graphene are able to induce intervalley scattering between Dirac points and then open a large ($\sim 1$ eV) bulk band gap. Using both tight-binding method and density functional theory, we explore the possibility of creating a QSH insulator in a graphene nanomesh. We find that an arbitrarily weak SO coupling is able to induce the spin-filtered edge states to traverse the bulk band gap. Here the SO coupling is not responsible for band gap opening, but only serves to connect the K and K' points, leading to a QSH phase with a giant band gap without the existence of strong SO coupling.

[3] This work was supported by a U.S. DOE Early Career Award (Grant No. DE-SC0006433).

— Recently, this long-sought quantum anomalous Hall effect was realized in the magnetic topological insulator. However, the requirement of an extremely low temperature (~30 mK) hinders realistic applications. Based on honeycomb lattices comprised of Sn and Ge, which are found to be 2D topological insulators, we propose a quantum anomalous Hall platform with low energy gap of 0.34 and 0.06 eV, respectively. The ferromagnetic order forms in one sublattice of the honeycomb structure by controlling the surface functionalization rather than dilute magnetic doping, which is expected to be visualized by spin polarized STM in experiment. Strong coupling between the inherent quantum spin Hall state and ferromagnetism results in considerable energy splitting and consequently an ferromagnetic insulator with large energy gap. The estimated mean-field Curie temperature is 243 and 599 K for Sn and Ge lattices, respectively. The large energy gap and high Curie temperature indicate the feasibility of the quantum anomalous Hall effect in the near-room-temperature and even room-temperature regions. Ref: S.-C.Wu, G. Shan, B. Yan, arXiv:1405.4731 (2014).

1:51PM M10.00014 Electronic Structure of Quantum Spin Hall Parent Compound CdTe, GUANG BIAN, Department of Physics, Princeton University — Cadmium telluride, a compound widely used in devices, is a key base material for the experimental realization of the quantum spin Hall phase. The electronic structure of CdTe has been studied by various theoretical and experimental methods. However, high-resolution band mapping has been lacking to this date. The detailed low-energy electronic structure of CdTe is thus unavailable, but it is of fundamental importance for understanding the topological properties and trends of this type of materials. We report herein, for the first time, a systematic study of the electronic structure of CdTe by angle-resolved photoemission spectroscopy from well-ordered (110) surfaces. The results are compared with first-principles calculations to illustrate the topological distinction between CdTe and a closely related compound HgTe. In addition, topological phase transition from CdTe to HgTe upon alloying and the massless Dirac-Kane semimetal phase at the critical composition are illustrated by computations based on a mixed-pseudopotential simulation.

2:03PM M10.00015 Unexpected edge conduction in HgTe quantum wells under broken time reversal symmetry, ERIC YUE MA, M. REYES CALVO, JING WANG, BIAO LIAN, Stanford University, MATTHIAS MUEHLBAUER, CHRISTOPH BRUNE, Universität Würzburg, YONGTAO CUI, Stanford University, KEJI LAI, UT Austin, WORASOM KUNDHIKANJANA, YONGJIANG YANG, MATTHIAS BAENNINGER, MARKUS KONIG, Stanford University, CHRISTOPHER AMES, HARTMUT BUEHMANN, PHILIPP LEUBNER, LAURENS MOLENKAMP, Universität Würzburg, SHOU-CHENG ZHANG, DAVID GOLDBERGER-GORDON, MICHAEL KELLY, ZHI-XUN SHEN, Stanford University — A key prediction of quantum spin Hall (QSH) theory that remains to be experimentally verified is the breakdown of the edge conduction under broken TRS by a magnetic field. Here we use a unique cryogenic microwave impedance microscopy (MIM) on two HgTe QW devices, corresponding to a trivial (5.5 nm) and an inverted (7.5 nm) band structure, to find unexpectedly robust edge conduction under broken TRS. At zero field and low carrier densities, clear edge conduction is observed only in the local conductivity profile of the 7.5 nm device, consistent with QSH theory. Surprisingly, the edge conduction persists up to 9 T with little effect from the magnetic field, as confirmed by both transport and real space MIM images. This indicates physics beyond current simple QSH models, possibly associated with material-specific properties, other symmetry protection and/or electron-electron interactions.

Wednesday, March 4, 2015 11:15AM - 2:15PM – Session M11 DCMP: Superconductivity: Mostly Meso-Nano Scale 007B - Timir Datta, University of South Carolina

11:15AM M11.00001 Size dependent suppression of superconductivity in granular mesoscopic Nb islands. MALCOLM DURKIN, University of Illinois at Urbana-Champaign, SARANG GOPALAKRISHNAN, Harvard University, RITA GARRIDO MENACHO, NADYA MASON, University of Illinois at Urbana-Champaign — While the suppression of superconductivity has been studied in bulk, 2D, and 1D systems, it remains largely unstudied in systems of mesoscopic granular islands. We investigate critical temperature ($T_c$) suppression in mesoscopic granular Nb islands as a function of island diameter. By performing transport measurements, we find that superconductivity is suppressed at diameters considerably larger than the coherence length of Nb. This behavior cannot be explained by competition between charging and Josephson energies. Instead, variations in island $T_c$ for fixed diameters suggest that the onset—and suppression—of superconductivity may be determined by rare region effects.

11:27AM M11.00002 Origin of superconductivity and ferromagnetism in Bi/Ni/Bi sandwich trilayers1, WEIWEI ZHAO, Center for Nanoscale Science and Physics Department, PSU, CUI-ZU CHANG, Francis Bitter Magnet Lab, MIT, DUK-Y KIM, Physics Department, PSU, JAGADEESH MOODERA, Francis Bitter Magnet Lab and Physics Department, MIT, MOSES CHAN, Center for Nanoscale Science and Physics Department, PSU — Coexistence of superconductivity and ferromagnetism was experimentally observed in Bi/Ni bilayers [PRL 94, 037006 (2005)]. To reveal the origin of the superconductivity in this system, we here systematically studied the superconductivity and the ferromagnetism in Bi/Ni/Bi trilayers, Bi/Ni bilayers and Ni/bilayers. We found the superconducting transition temperature to be independent of the thickness of Ni layers from 1nm to 45nm in Bi/Ni/Bi trilayers. The superconducting critical magnetic fields of trilayers were higher than those of bilayers. In addition, we observed conventional ferromagnetism in both trilayers and bilayers. These observations can be explained by a model that the superconductivity originates from the Bi/Ni interfaces with spin triplet pairing.

11:39AM M11.00003 Electron Pairing Without Superconductivity 1. JEREMY LEVY, G. CHENG, M. TOMCZYK, S. LU, University of Pittsburgh, J.P. VEAZEY, Grand Valley State University, M. HUANG, P. IRVIN, University of Pittsburgh, S. RYU, H. LEE, C.-B. EOM, University of Wisconsin-Madison, C.S. HELLBERG, Naval Research Laboratory — Strontium titanate (SrTiO$_3$) exhibits an extremely low carrier density threshold for superconductivity, and possesses a phases diagram similar to high-temperature superconductors. Two factors that suggest an unconventional pairing mechanism. We describe transport experiments with nanowire-based quantum dots localized at the interface between SrTiO$_3$ and LaAlO$_3$. Electrostatic gating of the quantum dot reveals a series of two-electron conductance resonances—paired electron states—that bifurcate above a critical magnetic field B$_c$, an order of magnitude larger than the superconducting critical magnetic field. For B$<$B$_c$, these resonances are insensitive to applied magnetic fields; for B$>$B$_c$, the resonances exhibit a linear Zeeman-like energy splitting. Electron pairing is stable at temperatures as high as an order of magnitude larger than the superconducting critical magnetic field. However, the requirement of an extremely low temperature (~30 mK) hinders realistic applications. Based on honeycomb lattices comprised of Sn and Ge, which are found to be 2D topological insulators, we propose a quantum anomalous Hall platform with low energy gap of 0.34 and 0.06 eV, respectively. The ferromagnetic order forms in one sublattice of the honeycomb structure by controlling the surface functionalization rather than dilute magnetic doping, which is expected to be visualized by spin polarized STM in experiment. Strong coupling between the inherent quantum spin Hall state and ferromagnetism results in considerable energy splitting and consequently an ferromagnetic insulator with large energy gap. The estimated mean-field Curie temperature is 243 and 599 K for Sn and Ge lattices, respectively. The large energy gap and high Curie temperature indicate the feasibility of the quantum anomalous Hall effect in the near-room-temperature and even room-temperature regions. Ref: S.-C.Wu, G. Shan, B. 11:51 AM M11.00004 Andreev Bound States in Confined Superconducting Semiconductor Nanowires1, GUANGLEI CHENG, MICHELLE TOMCZYK, SHICHEANG LIU, JOSH VEAZEY2, MENGCHEN HUANG, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh, HYUNGWOO LEE, SANWOON RYU, CHANG-BEOM EOM, University of Wisconsin-Madison — The hybridization of superconductors (SC) and semiconducting nanowires leads to a variety of interesting phenomena including nanoscale superconductivity and Majorana fermion physics. Andreev bound states (ABS), which are a discrete energy spectrum as a result of Andreev reflections of electrons and holes between two normal-SC interfaces, are predicted to support Majorana bound states under certain conditions. The LaAlO$_3$/SrTiO$_3$ interface possesses native superconductivity and strong spin-orbit coupling and is thus a promising platform for observing signatures of Majorana fermions. Here we investigate a superconducting nanowire quantum dot created by reversible “write” and “erase” processes using a conductive atomic force microscope tip. Transport studies show that electrons can travel in different regimes dominated by resonant pair tunneling and Andreev reflection in a single device.

2Present Address: Grand Valley State University

12:03PM M11.00005 Detection of vortex trapping in mesoscopic single-crystal loops of NbSe$_2$ by magnetoresistance oscillations1, SHAUN MULLS, The Pennsylvania State University, CHENYI SHEN, ZHAUN XU, Zhejiang University, YING LIU, The Pennsylvania State University, Shanghai Jiao Tong University — Vortex crossing of a doubly-connected mesoscopic loop of a type II superconductor will lead to magnetoresistance oscillations because the free energy of the loop is modulated by the enclosed flux. The amplitude and temperature dependence of the oscillations in these mesoscopic loops of type II superconductors differ from the conventional Little-Parks effect. In addition to Abrikosov vortex crossing, vortex trapping within the arms of a mesoscopic loop should be possible. London calculations predict a phase shift in the free energy modulation when a single vortex is trapped within the arm of a superconducting loop. We present magnetoresistance measurements on mesoscopic, single-crystal NbSe$_2$ loops exhibiting the anticipated free energy modulation phase shift at a critical vortex trapping field that can be tuned by sample geometry, temperature, and external current in agreement with theoretical expectations.

1Work supported in part by the NSF under Grant DMR 0908700 with nanofabrication done at the Penn State MRI Nanofabrication Lab under NSF Cooperative Agreement 0335765, NNIN with Cornell University. Work in China supported by MOST of China and NSFC.

12:15PM M11.00006 Andreev states in the spin-symmetric solution of a quantum dot attached to superconducting leads, VAACLAV JANIS, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, VLADISLAV POKORYN, Institute of Physics, ASCR, Prague, Czech Republic — A quantum dot with Coulomb repulsion attached to left and right superconducting leads is studied via the perturbation expansion in the interaction strength. We use the Nambu formalism and the standard many-body diagrammatic representation of the impurity Green functions. We formulate the perturbation expansion in the spectral representation so that to be able to separate contributions from the isolated gap states (Andreev bound states) and from the continuous band states. We resolve exactly the spin-symmetric state in the asymptotic limit with Andreev states approaching the Fermi energy. We demonstrate that a spin-symmetric state reaches saturation at zero temperature at a critical interaction at which the Andreev states merge and freeze at the Fermi energy. There is no solution above this critical interaction with Andreev states split from the Fermi energy unless external magnetic field breaking the spin symmetry is applied and degeneracy of the ground state lifted.

12:27PM M11.00007 Splitting individual Cooper pairs and single photon detection in superconducting aluminium, MEGAN EDWARDS, NICHOLAS LAMBERT, ADAM ESMAIL, ANDREW FERGUSON, University of Cambridge, BRENDON LOVETT, University of St. Andrews, FELIX POLLOCK, University of Oxford, UNIVERSITY OF CAMBRIDGE TEAM, UNIVERSITY OF OXFORD/UNIVERSITY OF ST. ANDREWS TEAM1 — Using superconducting aluminium quantum dots, we demonstrate the splitting of individual Cooper pairs using microwave light [1]. Within our nanoscale devices, the competition at low temperatures between the charging energy, superconducting gap and Josephson energy enables single Cooper pairs to be split and reformed. The delivery of constituent quasi-particles to separate quantum dots has facilitated measurements of both splitting and recombination. The devices are probed by radio-frequency reflectometry, a technique sensitive to the ‘quantum capacitance’ of the device band structure [2]. We intentionally induce splitting via the application of a microwave field, indicating a system able to detect individual photons of microwave light [1]. To controllably separate a Cooper pair into two quasi-particles may have important implications for quantum information processing; future experiments will investigate the coupling of a double quantum dot to a microwave resonator for single photon detection [3], with applications to circuit quantum electrodynamics.

1Valuable contributions to this work have been made by a joint team from the Universities of Oxford and St. Andrews.

12:39PM M11.00008 Stripe-like nanoscale structural phase separation and optimal inhomogeneity in superconducting BaPb$_{1-x}$Bi$_x$O$_3$, PAULA GIRALDO-GALLO, Stanford University, YING ZHANG, Chinese Academy of Sciences, CAROLINA PARRA, Universidad Tecnica Federico Santa Maria, HARI MANOHARAN, MALCOLM BEASLEY, THEODORE GEBALLE, Stanford University, MATTHEW KRAMER, Ames Lab - Iowa State University, IAN FISHER, Stanford University — Structural phase separation in the form of partially disordered stripes, with characteristic length scales in the nanometer range, is observed for superconducting BaPb$_{1-x}$Bi$_x$O$_3$. The evolution of the superconducting coherence length with composition relative to the size of these stripes suggests an important role of the nanostructure in determining the shape of the superconducting dome. It is proposed that the maximum $T_c$ is determined by a kind of “optimal inhomogeneity,” characterized by a crossover from an inhomogeneous macroscopic superconductor to a granular superconductor for which phase fluctuations suppress $T_c$.

12:51PM M11.00009 ABSTRACT WITHDRAWN —
tunnel barrier strength at the critical angle as a criterion for establishing the topological nature of the observed signal. Majorana zero modes. We investigate the effect of tilting the magnetic field relative to the spin-orbit coupling direction in a simple continuum model and in the confined region on Cd$_3$3 measurements on the 3D Dirac semi-metal Cd$_3$3.

Therefore, in principle, it should be possible to drive them into exotic new phases by breaking certain symmetries. We will discuss point-contact spectroscopic circuits.

1:15PM M11.00011 Strong effects of weak ac driving in short superconducting junctions

ROMAN-PASCAL RIFWAR, MANUEL HOUZET, JULIA S. MEYER, UNIV. GRENoble ALPES, INAC-SPSMS, F-38000 Grenoble, France; CEA, INAC-SPSMS, F-38000 Grenoble, France, YULI V. NAZAROV, Kavli Institute of NanoScience, TU Delft, Lorentzweg 1, NL-2628 CJ, Delft, The Netherlands — We study a short superconducting junction subject to a dc and ac phase bias. The ac modulation changes the occupation of the Andreev bound states formed at the constriction by transitions between bound states and the continuum. In a short junction, the non-equilibrium Andreev bound state population may relax through processes that conserve parity of the occupation number on the same bound state and processes that do not conserve it. We argue that the parity conserving processes occurs on a much faster time scale. In this case, even a weak driving may lead to a large deviation of the supercurrent from its equilibrium value. We show that this effect is accompanied by a quasiparticle current which may lead to a measurable charge imbalance in the vicinity of the junction. Furthermore, we study the time evolution of the supercurrent after switching off the ac drive. On a time scale where parity relaxation is negligible, the supercurrent relaxes to a stationary non-equilibrium state. Finally, we briefly outline the regime of ultraweak driving where the ac-induced processes occur on a time scale comparable to parity relaxation.

1:27PM M11.00012 Weber blockade in superconducting nanowires

TYLER MORGAN-WALL, BENJAMIN LEITH, NIKOLAUS HARTMAN, ATIKUR RAHMAN, NINA MARKOVIC, Johns Hopkins University — Vortices in superconductors are topological excitations that carry quantized magnetic flux and can be viewed as basic degrees of freedom that describe the low-energy states of the system. Here we show that a short superconducting nanowire can behave as a quantum dot for vortices. In the range of magnetic fields in which vortices can enter the nanowire in a single row, we find regular oscillations of the critical current as a function of magnetic field, with each oscillation corresponding to the addition of a single vortex to the nanowire. A charge-vortex dual of the Coulomb-blockaded quantum dot for electrons, the nanowire shows diamond-shaped regions of zero resistance as a function of current and magnetic field, in which the number of vortices is fixed. Besides demonstrating that macroscopic objects such as vortices can behave as fundamental particles, the fine control over critical currents and vortex configurations may prove useful for quantum devices that employ superconducting circuits.

1:39PM M11.00013 Generation of photon pairs at different frequencies: route toward quantum microwave source

DANIEL ESTEVE, OLIVIER PARLAVECCHIO, CARLES ALTIRMAS, PHILIPPE JOYEZ, DENIS VION, PATRICE ROCHE, FABIEN PORTIER, Service de Physique de l’Etat Condensé (CNRS URA 2464), IRAMIS, CEA Saclay, 91191 Gif-sur-Yvette, France, NANOELECTRONICS-QUANTRONICS GROUPS COLLABORATION — The dynamical Coulomb blockade (DCB) is a quantum phenomenon that隧tunneling of charge through a tunnel junction is modified by its electromagnetic environment. The sudden charge transfer generates photons in the electromagnetic modes. We coupled a Josephson junction to two resonators at frequencies $\nu_1 \neq \nu_2$ when voltage-biased at $2\nu_1 = h\nu_1 + h\nu_2$. Cooper pairs can tunnel only if two photons, one at each frequency, are simultaneously emitted. We measured the cross-correlations between the emission rates and showed that a Cauchy-Schwarz inequality is violated. This result, in agreement with theoretical prediction made by Leppakkangas and coworkers, reveals the amplitude two-mode squeezing. Our setup is a easy way to produce non-classical microwave radiation from a battery. We believe that this source is a good candidate for producing pairs of entangled photons with high rate (few hundreds of MHz).

1:51PM M11.00014 Point-contact spectroscopy on the 3-Dimensional Dirac Semi-metal Cd$_3$As$_2$

GOUTAM SHEET, ABHISHEK GAURAV, Indian Institute of Science Education and Research, Mohali, GOHIL SINGH THAKUR, ZEBA HAQUE, Department of Chemistry, Indian Institute of Technology, New Delhi, ASHOK KUMAR GANGULI, Institute of Nano Science & Technology, Mohali, LEENA AGGARWAL, Indian Institute of Science Education and Research, Mohali — The three dimensional (3D) Dirac semi-metals exist close to topological phase boundaries. Therefore, in principle, it should be possible to drive them into exotic new phases by breaking certain symmetries. We will discuss point-contact spectroscopic measurements on the 3D Dirac semi-metal Cd$_3$As$_2$ using several normal metallic tips. We have found that the mesoscopic point-contacts between elemental normal metals (like silver (Ag), platinum (Pt) and gold (Au)) and Cd$_3$As$_2$ exhibit signatures of certain exotic new phases. The possible origin of such phases in the confined region on Cd$_3$As$_2$ will also be discussed.

2:03PM M11.00015 Tilting of the magnetic field in Majorana nanowires

STEVEN REX, ASLE SUDBO, Department of Physics, Norwegian University of Science and Technology — Semiconductor nanowires with strong spin-orbit coupling and proximity-induced $s$-wave superconductivity in an external magnetic field have been the most promising settings for approaches towards experimental evidence of topological Majorana zero modes. We investigate the effect of tilting the magnetic field relative to the spin-orbit coupling direction in a simple continuum model and provide an analytical derivation of the critical angle, at which the topological states disappear. We also obtain the differential conductance characteristic of a junction with a normal wire for different tilting angles and propose a qualitative change of the dependence of the zero-energy differential conductance on the tunnel barrier strength at the critical angle as a criterion for establishing the topological nature of the observed signal.

1Supported by the Norwegian Research Council, Grant Nos. 205591/V20 and 216700/F20.

Wednesday, March 4, 2015 11:15AM - 2:15PM — Session M12 DCMP: Exotic Topological Superconductors II 007C - Dale Van Harlingen, University of Illinois
11:15AM M12.00001 Symbiosis of ferromagnetism and superconductivity in topological insulators1 Y. S. HOR, Y. QIU, K. N. SANDERS, J. E. MEDVEDEVA, T. VOJTA, Missouri University of Science and Technology, J. DAI, W. WU, Rutgers University, P. GHAEMI, City College of the City University New York — Three-dimensional topological insulators (TIs) have been found to depict topological distinct phases of matter and have attracted great interest due to helical spin texture on the surfaces. By Nb-doping in bismuth selenide, the TI turns into a type-II bulk superconductor while maintaining its helical metallic surface state in its normal state. However, at high magnetic field this doped TI behaves superparamagnetically. Niobium is usually considered a non-magnetic cation but it exhibits a unique magnetic behavior in this doped TI. Moreover, magnetic correlations appear in the system when the superconductivity emerges at below 3.2 K, presenting novel magnetic coupling of the Nb cations through modification of supercurrents mediated by Nb magnetic moments. As a consequence, ferromagnetism is induced in the superconducting regime below the upper critical field. Magnetic susceptibility of the TI shows paramagnetic behavior at high field due to destruction of the superconductivity which is the underlying bases for ferromagnetic coupling of Nb moments. The superconductivity and ferromagnetism, which are usually mutually destructive, can mutually benefit each other in the system giving rise to a zero-field magnetization which results in a symbiotic relationship between ferromagnetism and superconductivity.

11:27AM M12.00002 High field magnetization of Half-Heusler compound LuPdBi BENJAMIN LAWSON, GANG LI, COLIN TINSMAN, FAN YU, TOMOYA ASABA, Univ of Michigan - Ann Arbor, XIAOFENG WANG, JOHNPIERRE PAGLIONE, University of Maryland, LU LI, Univ of Michigan - Ann Arbor — Topological insulators and topological superconductors are a novel phases of matter that have been an area of rich new physics in recent years. Half-Heusler compound LuPdBi has been suggested to have a topologically nontrivial phase by theoretical calculations and has been shown to have superconductivity and weak antilocalization in magneto-transport measurements. Given the promise of this compound, we performed and report here preliminary results of magnetization measurements in LuPdBi at high magnetic fields up to 45T.

11:39AM M12.00003 Superconductivity induced by In substitution into the topological crystalline insulator Pb0.5Sn0.5Te RUIDAN ZHONG, JOHN SCHNEELOCH, TIANSHENG LIU, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, NY 11973, USA, FERNANDO CAMINO, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY 11973, USA, JOHN TRANQUADA, GENDA GU, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, NY 11973, USA — Indium substitution turns the topological crystalline insulator (TCI) Pb0.5Sn0.5Te into a possible topological superconductor. To investigate the effect of the indium concentration on the crystal structure and superconducting properties of (Pb0.5Sn0.5)xInxTe, we have grown high-quality single crystals using a modified floating-zone method and have performed systematic studies for indium content in the range 0 ≤ x ≤ 0.35. We find that the single crystals retain the rocksalt structure up to the solubility limit of indium (x ∼ 0.30). Experimental dependencies of the superconducting transition temperature (Tc) and the upper critical magnetic field (Hc2) on the indium content x have been measured. The maximum Tc is determined to be 4.7 K at x = 0.30, with μ0Hc2(T = 0) ≈ 5T.

11:51AM M12.00004 mk-STM study of Cu0.2Bi2Se3 with W and Nb Tips RAMI DANA, WAN-TING LIAO, University of Maryland, IRENEUSZ MIOTKOWSKI, YONG P. CHEN, Purdue University, MICHAEL DREYER, University of Maryland — The Cu intercalated Bi2Se3 is predicted to be a time-reversal invariant topological superconductor with Majorana bound state in the vortex core. The samples are characterized by intrinsic inhomogeneity and disorder. Using mk-STM, a variety of high resolution superconducting gaps and sub-gap structures were observed. Our data from SIN and SIS junctions, using W and Nb tips on Cu0.2Bi2Se3 and while applying of a magnetic field will be discussed in details.

12:03PM M12.00005 Quasiparticle Interference Patterns on the Surface of a Topological Insulator with Superconductivity AARON FARRELL, McGill University, MAXIME BEAUDRY, University of Montreal, TAMIR PEREG-BARNEA, McGill University, MARCEL FRANZ, University of British Columbia — When the electrons on the surface of a strong topological insulator are forced to undergo superconductive pairing (perhaps via proximity effect) a topological superconducting state is formed. Such a state is of interest as it plays host to Majorana modes on its boundaries and in vortex cores. For this reason it is currently of great interest to develop a theoretical understanding of any experimental probes of such systems. In this talk we will discuss the theory of one such probe. Namely, we present results for local density of states measurements in a Dirac system with superconductivity added. These results should be relevant to measurements in Scanning Tunnelling Spectroscopy (STS) on the surface of strong topological insulators with pairing either naturally arising or driven by proximity effect. By considering a variety of different impurity scatterers and tunings of the chemical potential in the system, we discuss different probes of the underlying Dirac physics present in these patterns.

12:15PM M12.00006 Topological superconductors with unconventional pairing symmetry characterized by monopole harmonics YI LI, Princeton University — We study the topological structure of Cooper pairing whose symmetry is characterized by the monopole harmonic functions instead of the usual spherical harmonic functions. This pairing symmetry can be either driven by the non-trivial topology of the Fermi surface or by interaction effects. The Bogoliubov quasi-particles are nodal which can either exhibit time-reversal invariant Dirac type spectrum or the time-reversal symmetry breaking Weyl spectra with the winding numbers determined the monopole harmonic functions. The non-trivial electromagnetic responses are also discussed. These exotic pairing symmetry can be realized in 3D Weyl metal and fermion systems with magnetic dipolar interactions.

12:27PM M12.00007 Low-energy phonons and superconductivity in Sn5In2Te3 GUANGYONG XU, Brookhaven National Laboratory, ZHIJUN XU, UC Berkeley, JOHN SCHNEELOCH, RUIDAN ZHONG, Brookhaven National Laboratory, J.A. RODRIGUEZ-RIVERA, L. HARRIGER, NIST Center for Neutron Research, ROBERT BIRGENEAU, UC Berkeley, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory — We present neutron scattering measurements on low-energy phonons from a superconducting (Tc = 2.7 K) Sn5In2Te3 single crystal sample. The longitudinal acoustic phonon mode and one transverse acoustic branch have been mapped out around the (002) Bragg peak for temperatures of 1.7 K and 4.2 K. We observe a substantial energy width of the transverse phonons at energies comparable to twice the superconducting gap; however, there is no change in this width between the superconducting and normal states. We also confirm that the compound is well ordered, with no indications of structural instability.

Discovery of superconductivity in Bi$_2$Te: evidence of universal behavior in an infinitely adaptive series under compression

We study a two-band model of fermions in a 1D chain with an antisymmetric hybridization that breaks inversion symmetry. We show that by imposing a reality constraint on the order parameter, the resulting zero energy junction bound state can be mapped onto a soliton solution of a Jackiw-Rebbi type Dirac equation similar to that in polyacetylene. Further, we consider $\pi$-junctions where the order parameter phase winds across the junction so that the aforementioned bound state generically acquires a gap. We relate these observations to the classification of the junctions according to their anti-unitary symmetries.

We wish to thank the Brazilian agencies, CAPES, FAPERJ, CNPq and FAPEMIG for financial support. We (DN and NT) would like to acknowledge funding from Grant No. NSF DMR-1309461.

2Princeton University
explore the consequences of bulk quantum fluctuations of the order parameter in Hamiltonians by Bogoliubov-de Gennes Hamiltonians. Band insulators and superfluids are, however, fundamentally different. In particular, unlike the static energy gap of a band insulator, the gap in a superfluid is due to a dynamical order parameter that is subject to both thermal and quantum fluctuations. We explore the consequences of bulk quantum fluctuations of the order parameter in $^3\text{He}-B$ on the topologically protected Majorana surface states. We find that one of the three spin-orbit Goldstone modes couples to the surface Majorana fermions, which induces an effective short-range two-body interaction between the Majorana fermions with coupling constant inversely proportional to the strength of the nuclear dipole-dipole interaction. A mean-field theory estimate of the value of this coupling suggests that the surface Majorana fermions in $^3\text{He}-B$ are in the vicinity of a quantum phase transition to a gapped time-reversal symmetry breaking phase.

2:03PM M12.0015 Conditions for Non-Abelian Braiding in Time-Reversal Invariant Topological Superconductors, PIN GAO, VIC KAM TUEN LAW, Hong Kong Univ of Sci & Tech, XIONG-JUN LIU, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — We study the validity of the non-Abelian braiding in 1D time-reversal invariant (DIII class) topological superconductors which host Majorana Kramer’s pairs in the ends. It has been shown that braiding two Majorana Kramer’s pairs can generically be reduced to two independent braiding processes of two different time-reversed copies, while the local noise or perturbations may lead to decoherence in the braiding operations. Here we examine in detail the braiding of Majorana Kramer’s pairs in the presence of disordered local couplings and noises, and show the generic conditions under which the decoherence effects are negligible and the non-Abelian braiding can be validated.

Session M13 DMP: Focus Session: Complex Oxide Interfaces - LaAlO$_3$/SrTiO$_3$ I

11:15AM M12.0001 Emergent Phenomena in Oxide Superlattices from DFT+DMFT, CHRIS MARIANETTI, Columbia Univ — Density functional theory plus dynamical mean-field theory (DFT+DMFT) has proven to be an instrumental tool in describing transition metal-oxides, and DFT+DMFT is well poised to search the rich phase space of oxide superlattices for emergent phenomena. In this talk, we focus on double-perovskite heterostructures of the form $AA’BB’O_6$. Our two separate goals are to design new ferroelectric Mott insulators and high temperature ferromagnetic Mott insulators. In the context of ferroelectric Mott insulators, we demonstrate the ability to design in-plane ferroelectrics based upon transition metal charge transfer and $A/A’$ cation size mismatch, harnessing displacements of both the A-site and B-site. In the context of ferromagnetic Mott insulators, we detail the different mechanisms for obtaining high temperature ferromagnetic Mott states, and we present new candidates for high temperature ferromagnetic insulators. Finally, we discuss the prospect of coupling magnetic and ferroelectric states in addition to potential applications.

The authors acknowledge support from FAME, one of six centers of STARnet, a Semiconductor Research Corporation program sponsored by MARCO and DARPA.

11:51AM M13.00002 Structural, chemical and electronic changes at LaAlO$_3$/SrTiO$_3$ interfaces near the critical thickness, ROHAN MISHRA, S.T. PANTELIDES, Vanderbilt University, Oak Ridge National Laboratory, JAUME GAZQUEZ, G. HERRANZ, M. STENGEL, M. SCIGAJ, N. DIX, F. SANCHEZ, J. FONTCUBERTA, Institut de Ciència de Materials de Barcelona, M. VARELA, Oak Ridge National Laboratory, Universidad Complutense de Madrid, A.Y. BORISEVICH, Oak Ridge National Laboratory — The formation of two-dimensional electron gas (2DEG) at the n-type LaAlO$_3$/SrTiO$_3$(LAO/STO) heterostructure is a paradigmatic example for emergent functionalities at oxide heterointerfaces. However, the origin of this 2DEG at the LAO/STO interface still remains unclear. In this work, we use scanning transmission electron microscopy and electron energy loss spectroscopy (STEM/EELS) to study a series of (LAO)$_n$(STO) films, both below (n=3) and above (n=5,7) the critical thickness for the formation of the 2DEG (n>$\approx$3). From STEM imaging, we observe dramatic changes in the polar distortion of the AIO$_3$ layers in response to the built-in electrostatic potential in the three films. We also observe changes in the octahedral tilts across the interface for different LAO thicknesses. We obtain information about cation intermixing across the heterointerface from EELS. We combine these results with density functional theory calculations to discuss the effect of each of these different structural and chemical changes on the electronic property of the interfaces. Overall, our results present a detailed understanding of the role of electronic and atomic reconsctructions and defects on the emergence of 2DEG at these interfaces.

12:03PM M13.00003 Surface charging in LaAlO$_3$/SrTiO$_3$ heterostructures, KARTHIK KRISHNASWAMY, CYRUS E. DREYER, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — The two-dimensional electron gas (2DEG) observed at the interface between LaAlO$_3$(LAO) and SrTiO$_3$(STO) is known to depend on its proximity to the LAO surface (thickness of LAO) and the conditions to which the surface is exposed. It has been proposed that electrons from the 2DEG can leak to surface states, resulting in a charged surface. Using first-principles calculations, we determine the electronic structure of the LAO surface and the coupling between the surface of LAO and the interface 2DEG. We develop a methodology for treating charged dielectric surfaces and apply it to LAO. This allows for the determination of the 2DEG density as well as the stable surface terminations and reconstructions of LAO on STO as a function of LAO thickness, under any given experimental conditions. Under oxygen-rich conditions, we find an increase in critical thickness required to form the 2DEG, and under hydrogen-rich environment the critical thickness decreases.

This work was supported by the LEAST Center (SRC/DARPA) and by ARO.

12:15PM M13.00004 Understanding enhanced UV photo-response of Pd nanoparticle-coated LaAlO$_3$/SrTiO$_3$ using ambient control Kelvin probe force microscopy, DONG-WOOK KIM, HAERI KIM, Department of Physics, Ewha Womans University, NGAI YUI CHAN, JIYAN DAI, Department of Applied Physics, The Hong Kong Polytechnic University — Significant enhancement in photoresponse of Pd nanoparticle-coated LaAlO$_3$/SrTiO$_3$(LAO/STO) heterostructure is observed under UV illumination compared with a bare LAO/STO sample. Clear ambient dependence suggests crucial roles of gas adsorption/desorption and resulting carrier transfer in the enhanced UV response. In this work, we have measured surface work function of the samples with and without UV light using Kelvin probe force microscopy (KPFM). We perform both transport and the surface potential measurements at the same time. Such simultaneous measurements can help us to improve our understanding regarding the light sensing and strong ambient dependence of the LAO/STO heterointerface.
12:27PM M13.00005 Increasing the capacitance beyond the classical limits in capacitors with free-electron like electrodes, JAVIER JUNQUERA, PABLO GARCIA-FERNANDEZ, PABLO DE CASTRO-MANZANO, CITIMAC, Universidad de Cantabria, Avda. de los Castros s/n, E-39005 Santander, Spain, MASSIMILIANO STENGEL, Institut de Ciència de Materials de Barcelona (ICMAB-CSIC) Campus UAB, E-08193 Bellaterra, Barcelona, Spain — Capacitors are ubiquitous in solid state devices like metal oxide semiconductors field effect transistors (MOSFET). For energy efficiency, the MOSFET should operate at small gate voltages. In this regime, to increase the channel conductivity and performance, the capacitance of the capacitor between the gate and the channel should be made as large as possible. Recently, an enhancement of the capacitance of up to 40 % with respect this classical limit has been reported in two-dimensional electron gases formed at the interface between two oxides, SrTiO$_3$ and LaAlO$_3$. A first theoretical analysis pointed to the quantum exchange-energy in the electron-electron interactions as the driving force to explain the anomalous behavior. The exchange-interaction would produce a lowering of the chemical potential of the electron system as the electronic density increases (the negative compressibility effect). Here we test the validity of the approach, carrying out self-consistent calculations on a capacitor where the metallic plates are simulated by a jellium. We study the effect of the thickness of the metallic electrode and the density of the free electron, on the spillage of the electronic clouds into the dielectric and the variation of the chemical potential.

12:39PM M13.00006 2D charge confinement in oxide heterostructures: fundamentals from First-Principles, ALESSIO FILIPPETTI, CNR-IOM UOS Cagliari, c/o Physics Dept. University of Cagliari, Italy — The accurate description of the fundamental properties of complex oxides by First-Principles (FP) is tantamount with the possibility of achieving reliable theoretical design. Here we use the variational pseudo-self-interaction corrected density functional theory (VPSIC) to investigate structural and electronic properties of several exceptionally interesting heterostructures (the STO/LAO interface, the Nb-doped STO superlattice, the SrTiO$_3$/SrZrO$_3$ superlattice, the SrTiO$_3$ surface). The key features which are at the fundament of the 2DEG formation (film polarity, band disalignment, doping, structural and electronic screening, chemistry of 3d orbitals) are described and discussed. Furthermore, we propose a combined VPSIC plus Bloch-Boltzmann approach as reliable and efficient method, applicable to generic doped oxides, to obtain thermolectric and transport properties in satisfying agreement with the available experimental data. Our theoretical analysis consents to relate the calculated transport properties to the specific features of the band structure at the interface, e.g. on-site and inter-site band splitting, which govern the confinement process. This is instrumental to achieve guidelines for the design of interfaces with enhanced transport and thermolectric functionalities.

12:51PM M13.00007 Role of Oxygen in the Resistance Upturn of LaAlO$_3$/SrTiO$_3$ Heterostructures1. H. ZHANG, University of Toronto, J.H. NGAI, University of Texas at Arlington, C. AHN, Yale University, C. MCMAHON, D.G. HAWTHORN, University of Waterloo, J.Y.T. WEI, University of Toronto and the Canadian Institute for Advanced Research — Among the phenomena exhibited by LaAlO$_3$/SrTiO$_3$ (LAO/STO) heterostructures, the appearance of a low-temperature resistance upturn has attracted much recent debate [1-4]. This phenomenon has been observed to co-occur with both nonlinear Hall effect and negative magnetoresistance, and attributed to either the Kondo effect, multiband conduction, or weak localization. More importantly, it is primarily seen in samples grown by pulsed laser deposition, and is sensitive to film layer thickness, growth condition and electrostatic gating, all of which could affect the oxygen content. In this work, we study the occurrence of resistance upturn in samples grown by molecular beam epitaxy, and how the sheet resistance and Hall conductance are affected by post-growth oxygenation. X-ray photoelectron spectroscopy is used to monitor the cation valences, and correlate them with the conduction and magnetic properties. Our results are analyzed in terms of oxygen vacancies in the presence of polar charge transfer, and the effect of these vacancies on the resistance upturn in LAO/STO heterostructures.

1:03PM M13.00008 The Role of Lattice Mismatch and Polar Fluctuation at the Conducting Oxide Interfaces, ZHEN HUANG, NUSNNI-NanoCore, National University of Singapore, KUN HAN, Department of Physics, National University of Singapore; NUSNNI-NanoCore, National University of Singapore, SHENGWEI ZENG, MALLIKARJUNA MOTAPOTHULA, WEIMING LÜ, YONGLIANG ZHAO, CHANGJIAN LI, NUSNNI-NanoCore, National University of Singapore, WENXIONG ZHOU, Department of Physics, National University of Singapore; NUSNNI-NanoCore, National University of Singapore, MICHAEL COEY, School of Physics and CRANN, Trinity College; NUSNNI-NanoCore, National University of Singapore, ARIANDO ARIANDO, Department of Physics, National University of Singapore; NUSNNI-NanoCore, National University of Singapore — Two key questions have been raised since the discovery of two-dimensional electron gas (2DEG) at the interface between insulating oxides LaAlO$_3$ and SrTiO$_3$. One is the origin for such 2DEG, and the other is how to improve carrier mobility. By replacing LaAlO$_3$ with the cubic polar perovskite insulator (La$_0.35$Sr$_0.7$)(Al$_0.65$Ta$_0.35$)O$_3$ (LSAT), carrier mobility can be increased by 30 times and reach 35,000 cm$^2$/V·s at 2 K, accompanied by reducing lattice mismatch from 2.98% to 0.96%. Moreover, two critical thicknesses for LSAT/SrTiO$_3$(001) interface are found: one is 5 unit cells for 2DEG appearance, and the other is around 12 unit cells for carrier mobility optimization. This phenomenon can be explained in terms of polar fluctuation in LSAT(001), while the conducting (110)- and (111)-orientated LSAT/STO interfaces without such polar fluctuation shows less thickness-dependent carrier mobility.

1:15PM M13.00009 Interface orientation dependent carrier distribution in LaAlO$_3$/SrTiO$_3$ heterostructures, TULA R. PAUDEL, EUGENY Y. TSYMBAL, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE 68588 — Carrier distribution in widely studied LaAlO$_3$/STO$_3$ heterostructures depends upon the directionality of the interface. From the first-principles calculations, we find that, for the (001) interface, most carriers are localized at the interface and have the $d_{xy}$ character, which decays away from the interface on the scale of 1 nm. The $d_{xy}$ and $d_{x^2-y^2}$ carrier concentration increases, peaks at about three unit cells (1.15 nm), and then decays very slowly away from the interface. For the (111) interface, we find that the total carrier distribution is similar to that of $d_{xy}$ and $d_{x^2-y^2}$ in the (001) heterostructure. It has a maximum that lies at about four-bilayers (0.89 nm) away from interface and then decays very slowly producing a long-ranged tail. This difference in the carrier distribution is controlled by the $d$-orbital splitting which depends on the interface orientation. For the (001) interface, the tetragonal distortion brings the in-plane $d_{xy}$ orbital to about 0.5 eV below the Fermi energy, creating a deep localized state, whereas the $d_{x^2-y^2}$ and $d_{z^2}$ orbitals are much shallower and hence less localized. For the (111) interface, the rhombohedral distortion splits the $d$-orbitals by about 0.1 eV so that they are all located in vicinity of the Fermi energy and therefore less localized at the interface.
1:27PM M13.00010 Scanning Tunneling Microscopy of 2DEG in Complex Oxide Interfaces and Heterostructures, IGOR ALTZFEDER, Air Force Research Laboratory, HYUNGWOO LEE, University of Wisconsin-Madison, ALP SEHIRLIOGLU, Case Western Reserve University, CHANG-BOOM EOM, University of Wisconsin-Madison, ANDREY VOEVODIN, Air Force Research Laboratory — New experimental data clarifying the origin of 2DEG at LaAlO3 (LAO) - SrTiO3 (STO) interfaces will be presented. The materials that have been studied include (a) 4 unit cells of LAO on STO and (b) symmetric n-type 2DEG bilayer heterostructures prepared by atomic layer engineering method [1]. All studied materials are grown by pulsed laser deposition (PLD). UHV STM results obtained on 4LAO/STO samples do not confirm the prediction of electronic reconstruction model [2]. On the other hand, UHV STM results obtained on symmetric n-type 2DEG bilayer heterostructures indicate that the formation of n-type 2DEG is caused by complex interplay of oxygen vacancy doping and interfacial band bending at LaO-TiO2 interfaces. The physical mechanisms of interface induced charge density multiplication effect will be discussed.

1:39PM M13.00011 The role of La displacement in Titanium $d_{xy}$ ferromagnetism at the LaAlO$_3$/SrTiO$_3$ — double-exchange like mediation$^1$, SUNG-HYON RHIM, Univ of Ulsan, DORJ ODKHUU, Inchen National University, DONGBIN SHIM, NOEJUNG PARK, Ulsan National Institute of Science and Technology — In this talk, we argue that La site polar distortion is the key for magnetism without oxygen vacancy, whereby coupling between La $d_{z^2}$ and O $2p_{x,y}$ offer a pathway for double-exchange like interaction to support Ti $d_{xy}$ ferromagnetism. While ferromagnetism found in the n-type LAO/STO has been mainly attributed to oxygen vacancy near the interface, the mechanism we propose a possibility of ferromagnetism without any defect. We show that there is a phase separation between charge-order and half-metallicity that can be characterized by La displacement - this can be tailored through adsorption on the outer AlO$_2$ surface or electrostatic bias.

1:51PM M13.00012 Importance of the surface in interfacial conductivity in LaAlO$_3$ thin films on SrTiO$_3$. C. STEPHEN HELLBERG, Naval Research Lab — Careful growth of LaAlO$_3$ thin films on SrTiO$_3$ by molecular beam epitaxy has shown that the La/Al ratio of the film is key to the formation of a two-dimensional electron liquid at the interface—metallic conductivity is only observed in Al-rich films. The interfacial electron liquid forms due to the polar catastrophe, the diverging potential caused by the atomic layer arrangement at the interface when polar LaAlO$_3$ is grown on TiO$_2$-terminated non-polar SrTiO$_3$. The system eventually reconstructs, moving negative charges to the interface to screen the diverging potential. I will present density functional calculations showing the defects that form in the film depend on the stoichiometry, and these defects lead to electronic reconstruction in Al-rich films and ionic reconstruction in La-rich films. The stoichiometry of the surface differs from that of the bulk of the film, and I will show that the LaAlO$_3$ surface is unstable to phase separation. The interaction between surface and bulk leads to a scenario where the insulating La-rich films have an Al-rich surface.

2:03PM M13.00013 Effects of structural phase transitions on the interface of perovskite oxides$^1$, NICHOLAS J. GOBLE, Department of Physics, Case Western Reserve University, RICHARD AKROBETU, ALP SEHIRLIOGLU, Department of Materials Science and Engineering, Case Western Reserve University, THONG Q. NGO, JOHN G. EKERD'T, Department of Chemical Engineering, University of Texas at Austin, KRISTY J. KORMONDY, ALEXANDER A. DEMKOV, Department of Physics, University of Texas at Austin, XXUAN P.A. GAO, Department of Physics, Case Western Reserve University — Conductivity at the interface of perovskite oxides such as LaAlO$_3$/SrTiO$_3$ is a wildly growing area of research. These interfaces are rich in phenomena including superconductivity, large negative in-plane magnetoresistance, giant persistent photoconductivity, and ferromagnetism. Although this field has seen rapid growth in the recent decade, there is yet to be a systematic study on what effect structural phase transitions in strontium titanate play on the interface. It is well understood that strontium titanate transitions from a cubic to tetragonal phase most notably at 105K, but how this effects oxide interface conductivity has yet to be reported on. Through transport measurements, we observe evidence of structural phase transitions in LaAlO$_3$/SrTiO$_3$ and Al2O3/SrTiO3 interfaces at 80K and 200K. These effects are enhanced when the scale of the devices is reduced to a few microns.

11:15AM M14.00001 Hydrodynamic Coulomb drag, magnetodrag and Hall drag of strongly correlated electron liquids$^1$, STANISLAV APOSTOLOV, ALEX LEVCHENKO, Michigan State University, ANTON ANDREEV, University of Washington — We develop a theory of Coulomb drag in ultraclean double layers with strongly correlated carriers. In the regime where the equilibration length of the electron liquid is shorter than the interlayer spacing the main contribution to the Coulomb drag arises from hydrodynamic density fluctuations. The latter consist of plasmons driven by fluctuating longitudinal stresses, and diffusive modes caused by temperature fluctuations and thermal expansion of the electron liquid. We express the drag resistivity in terms of the kinetic coefficients of the electron fluid. Our results are nonperturbative in interaction strength and do not assume Fermi-liquid behavior of the electron liquid.

$^1$This work was supported by NSF Grant No. DMR-1401908.

11:27AM M14.00002 Spin-charge scattering in generic Luttinger liquids$^1$, ALEX LEVCHENKO, Michigan State University — We discuss the violation of spin-charge separation in generic nonlinear Luttinger liquids and investigate its effect on the relaxation, electrical and thermal transport of genuine spin-1/2 electron liquids in ballistic quantum wires. We identify basic scattering processes compatible with the symmetry of the problem and conservation laws that lead to the decay of plasmons into the spin modes and Brownian backscattering of spin excitations. We derive a closed set of coupled kinetic equations for the spin-charge excitations and solve the problem of conductance of interacting electrons for an arbitrary relation between the quantum wire length and spin-charge relaxation length.

11:39 AM M14.00003 Determination of time-reversal symmetry breaking lengths in an InGaAs Sagnac interferometer array. SHAOLA REN, J.J. HEREMANS, Virginia Tech, C.K. GASPE, S. VIJAYARAGUNATHAN, T.D. MISHIMA, M.B. SANTOS, University of Oklahoma — Time-reversed trajectories in Aharonov-Bohm ring Sagnac interferometers yield AAS oscillations if time-reversal symmetry is preserved. The quantum interference oscillations can be used to quantify time-reversal symmetry breaking, more particularly the mesoscopic dephasing length associated with time-reversal symmetry breaking under applied magnetic field, an effective magnetic length. We measured AAS oscillations with periodicity 13 G, corresponding to h/2e flux in the 650 nm radius rings of a 5 × 5 Sagnac interferometer array fabricated on a 2D electron system in an InGaAs/InAlAs heterostructure at 0.4 K. The oscillation amplitudes were investigated over magnetic field spanning 2.2 T, with the amplitude estimated by Fourier transform of the oscillation. For a magnetic field, the oscillation amplitudes depend on the magnetic field, the magnetic field increases, the amplitude decreases due to time-reversal symmetry breaking by the magnetic field in the interferometer arms. A dephasing model for coherent networks allows extraction of the effective magnetic length. In wide diffusive system this length corresponds theoretically and experimentally to the usual magnetic length, whereas the data show that corrections enter for ballistic quasi-1D systems (DOE DE-FG02-08ER46532, NSF DMR-0520550).

11:51 AM M14.00004 Quantum interference and correlations in single dopants and exchange-coupled dopants in silicon1 JOE SALFI, Centre for Quantum Computation and Communication Technology, University of New South Wales — Quantum electronics exploiting the highly coherent states of single dopants in silicon invariably requires interactions between states and interfaces, and inter-dopant coupling by exchange interactions. We have developed a low temperature STM scheme for spatially resolved single-electron transport in a device-like environment, providing the first wave-function measurements of single donors and exchange-coupled acceptors in silicon. For single donors, we directly observed valley quantum interference due to linear superpositions of the valleys [1], and found that valley degrees of freedom are highly robust to the symmetry-breaking perturbation of nearby (3 nm) surfaces. For exchange-coupled acceptors, we measured the singlet-triplet splitting, and from the spatial tunneling probability, extracted enough information about the 2-body wavefunction amplitudes to determine the entanglement entropy [2], a measure of the quantum inseparability (quantum correlations) generated by the interactions between indistinguishable particles. Entanglement entropy of the J=3/2 holes was found to increase with increasing dopant distance, as Coulomb interactions overcome tunneling, coherently localizing spin towards a Heitler-London singlet, mimicking 5=1/2 particles [3]. In the future these capabilities will be exploited to peer into the inner workings of few-dopant quantum devices and shed new light on multi-dopant correlated states, engineered atom-by-atom.

12:27PM M14.00005 Spin Technologies in Silicon Carbide1, PAUL KLIMOV2, University of California, Santa Barbara and University of Chicago — Over the past several decades SiC has evolved from being a simple abrasive to a versatile material platform for high-power electronics, optoelectronics, and nanomechanical devices. These technologies have been driven by advanced growth, doping, and processing capabilities, and the ready availability of large-area, single-crystal SiC wafers. Recent advances have also established SiC as a promising host for a novel class of technologies based on the spin of intrinsic color centers. In particular, the divacancies and related defects [1,2] have ground-state electronic-spin triplets with ms-long coherence times that can be optically addressed near telecom wavelengths [3] and manipulated with magnetic, electric [4], and strain fields [5]. Recently, divacancy addressability has been extended to the single defect level [6], laying foundation for single spin technologies in SiC. This rapidly developing field has prompted research into the SiC material host to understand how defect-bound electron spins interact with their surrounding nuclear spin bath. Although nuclear spins are typically a major source of decoherence in color-center spin systems, they are also an important resource since they interact with magnetic fields orders of magnitude more weakly than electronic spins. This fact has motivated their use for quantum memories and ultra-sensitive sensors. In this talk I will review advances in this rapidly developing field and discuss our efforts towards this latter goal.

1:03PM M14.00006 Al Nanowire Arrays For Plasmonic Devices1 NATHAN T. NESBITT, AARON H. ROSE, YITZI M. CALM, JUAN M. MERLO, STEVE SHEPARD, GREG MCMAHON, CHIA-KUANG TSUNG, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, Boston College — Aluminum nanowires have been fabricated in ordered vertical arrays on bulk Al foil with controlled wire dimensions and spacing. Large aspect ratio wires were obtained, including sub-micron wire diameters and supra-10 µm height. The somewhat novel method of fabrication utilizes nanoimprint lithography and the economical electrochemical anodization process used to make anodized aluminum oxide (AAO) templates, suggesting potential facile production and scalability. To our knowledge, arrays of vertical metallic nanowires (i.e. differing from semiconductor nanowire or carbon nanofiber arrays) of the obtained dimensions have not been previously reported. These dimensions may be favorable for nanoscale photonic and plasmonic transmission, nanoax solar cells, and non-diffraction-limited optical microscopy.

1:15PM M14.00007 ABSTRACT WITHDRAWN

1:27PM M14.00008 Dielectric tuned surface plasmon resonances on metallic gratings1, ADAM HAUSER, BILL FLAHERTY, KA MING LAW, EVGENY MIKHEEV, ADAM KAUDOS, SUSANNE STEMMER, S. JAMES ALLEN, Univ of California - Santa Barbara — We explore the effect of substrate dielectric constant on the dispersion of infrared surface plasmons supported by micron scale metal gratings. Of particular interest are substrate dielectrics that can be tuned by electric fields and thereby make possible gated plasmonic devices. Angle resolved s and p polarized reflectivity is used to observe the plasmon dispersion for Pt gratings on various oxide dielectrics and heterostructures, LSAT, SrTiO3, Nb:SrTiO3 and LSAT/SrTiO3/GdTiO3. Most striking is the shift in the plasmon dispersion upon Nb doping of SrTiO3 caused by the free carrier contribution to the dielectric constant. We focus our attention on a metal-oxide-metal heterostructure, Pt/Ba0.3Sr0.7TiO3/Pt-grating that serves to confine the infrared field to the electric field modulated region enhancing the potential for a gated plasmonic structure.

V reasonable assumptions, the “localization product” $\kappa a V$. Low temperature resistance measurements show a characteristic dependence of $R$ on external parameters such as pH (T. Simon et al., Nature Mat. 13, 1013 (2014)).

2:03PM M14.00011 Interferometric Plasmonic Lensing with Nanohole Arrays, YU GONG, ALAN JOLY, PATRICK EL-KHOURY, WAYNE HESS, Pacific Northwest National Laboratory, CHEMICAL PHYSICS TEAM — Nonlinear photoemission electron microscopy (PEEM) is used to map propagating surface plasmons launched from lithographically patterned isolated nanoholes and nanohole arrays in gold films. A damped elongated ring-like photoemission beat pattern is observed from individual nanoholes. Strong near field photoemission patterns are observed in the PEEM images, recorded following low angle of incidence irradiation of the plasmonic nanohole arrays with sub-15 fs laser pulses centered at 780 nm. The recorded photoemission patterns are attributed to constructive and destructive interference between propagating surface plasmons launched from the individual nanoholes which comprise the array. By exploiting the wave nature of propagating surface plasmons, we demonstrate how varying the array geometry (hole diameter, pitch, and number of rows/columns) ultimately yields intense localized photoemission patterns. Through a combination of PEEM experiments and finite-difference time-domain simulations, we identify the optimal array geometry for efficient light coupling and interferometric plasmonic lensing. We also describe an exemplary practical application of the nanohole array-based plasmonic lenses, namely, enhanced photoemission from a vertex of a strategically positioned gold triangle.

11:15AM M15.00001 Photocatalytic Solar Fuel Generation on Semiconductor Nanocrystals1, JOCHEN FELDMANN, Photonics and Optoelectronics Group, Ludwig-Maximilians-Universitaet (LMU), Munich, Germany — I will review our scientific work on photocatalytic solar fuel generation utilizing colloidal semiconductor nanocrystals decorated with catalytic metal clusters. In particular, nanocrystals made of CdS, TiO$_2$ and organo-metal halide perovskites will be discussed. Key issues are the role of hole scavengers (M. Berr et al., Appl. Phys. Lett. 100, 223903 (2012)), the size and density of catalytic clusters (M. Berr et al.: Appl. Phys. Lett. 97, 093108 (2010) and Nano Letters 12, 5903 (2012) , and dependencies on external parameters such as pH (T. Simon et al., Nature Mat. 13, 1013 (2014)).

11:51AM M15.00002 Gate-Induced Carrier Delocalization in Quantum Dot Field Effect Transistors1, M.E. TURK, J.-H. CHOI, S.J. OH, A.T. FAFARMAN, B.T. DIROLL, C.B. MURRAY, C.R. KAGAN, J.M. KIKKAWA, University of Pennsylvania — We study the low temperature resistance and transport properties of high-mobility indium-doped CdSe quantum dot (QD) field effect transistors [1]. Low temperature resistance measurements show a characteristic dependence of $R(T) = R_0 \exp (T_0/T)^p$ with $p = 2/3$, consistent with a recent model based on Coulomb gap variable range hopping plus thermal broadening. We show that using the gate bias $V_G$ to accumulate electrons in the QD channel increases the “localization product” $a a$ (localization length $a$, dielectric constant $\kappa$), as expected for Fermi level changes near an Anderson mobility edge. Under any reasonable assumptions, $a$ increases significantly beyond the QD diameter as gate bias is applied. Magnetoresistance (MR) measurements display both positive and negative MR contributions that vary with $V_G$ and $T$. For each $V_G$, we observe a universal negative MR line shape for higher temperatures ($T > 20K$) that scales as $T^{-4/3}$, consistent with Zeeman MR for $p = 2/3$ with a gate bias-modulated mobility gap ($\Delta \varepsilon$).

12:03PM M15.00003 Charge trapping and de-trapping in isolated CdSe/ZnS nanocrystals under an external electric field: indirect evidence of a permanent dipole moment, HUIDONG ZANG, MINGZHAI LIU, FERNANDO CAMINO, MIRCEA COTLET, Brookhaven National Laboratory, CENTER FOR FUNCTIONAL NANOMATERIALS TEAM — The charge trapping and de-trapping processes in single CdSe/ZnS nanocrystals under external electric field were systematically studied. The results clearly demonstrated that the external electric field can reversibly modulate the exciton dynamics and photoluminescence blinking, which provide further evidence for the existence of a permanent ground state dipole moment in isolated nanocrystals. A model which assumes energetically deep charge traps is proposed to explain on/off blinking in isolated CdSe/ZnS nanocrystals with the presence of a permanent dipole moment.
12:15PM M15.00004 Probing Energy Levels of Large Array Quantum Dot Superlattice by Electronic Transport Measurement, S.Z. BISRI, RIKEN-CEMS, Japan, E. DEGOLI UNIMORE, Italy, N. SPALLANZANI, Univ.Rome II, Italy, G. KRISHNAN, B. KOOI, Univ.Groningen, Netherlands, C. GHICA, NIMB-Bucharest, Romania, M. YAREMA, Univ.Linz, Austria, L. PROTESCIU, ETHZurich, Switzerland, W. HEISS, Univ.Linz, Austria, M. KOVALENKO, ETHZurich, Switzerland, O. PULCI, Univ.Rome II, Italy, S. OSSICINI, UNIMORE, Italy, Y. IWASA, RIKEN-CEMS, Japan, M. LOI, Univ.Groningen, Netherlands — Colloidal quantum dot superlattice (CQDS) emerges as new type of hybrid solids allowing easy fabrication of devices that exploits the quantum confinement properties of individual QD. This materials displays peculiar characters, making investigation of their transport properties nontrivial. Besides the bandgap variations, 0D nature of QD lead to the formation of discrete energy subbands. These subbands are crucial for multiple exciton generation (for efficient solar cell), thermoelectric material and multistate transistor. Full understanding of the CQDS energy level structure is vital to use them in complex devices. Here we show a powerful method to determine the CQDS electronic energy levels from their intrinsic charge transport characteristics. Via the use of ambipolar transistors with CQDS as active materials and gated using highly capacitive ionic liquid gating, Fermi energy can be largely tuned. It can access energy levels beyond QD’s HOMO & LUMO. Ability to probe not only the bandgap, but also the discrete energy level from large assembly of QD at room temperature suggests the formation of energy minibands in this system.

12:27PM M15.00005 Singlet and Triplet Exciton Harvesting in the Thin Films of Colloidal Quantum Dots Interfacing Phosphorescent Small Organic Molecules, BURAK GUZELTURK, PEDRO LUDWIG HERNANDEZ-MARTINEZ, Nanyang Technological University, Bilkent University, DEWEI ZHAO, XIAO WEI SUN, Nanyang Technological University, HILMI VOLKAN DEMIR, Nanyang Technological University, Bilkent University — Efficient nonradiative energy transfer is reported in an inorganic/organic thin film consists of a CdSe/ZnS colloidal quantum dot (QD) layer interfaced with a phosphorescent small organic molecule (Frlpic) coated fluorphore host (TCTA). The nonradiative energy transfer in this films has a cascaded energy transfer behaviour: first from the fluorescent host TCTA to phosphorescent Frlpic and then to QDs. The nonradiative energy transfer in these films enables very efficient singlet and triplet state harvesting by the QDs with a fluorescence enhancement factor of 2.5-fold, while overall nonradiative energy transfer efficiency is over 90%. The experimental results are nicely supported by the theoretical model which includes exciton diffusion assisted Förster-type near-field dipole–dipole coupling within the films.

12:39PM M15.00006 Electron-Exciton and Electron-Phonon interactions effects on the tunnel electronic spectrum of PbS quantum dots, HONGYUE WANG, EMMANUEL LHUILLIER, QIAN YU, ALIREZA MOTTAGHAZI, Laboratoire de Physique et d’Etude des Matériaux, UMR 8213, ESPCI-ParisTech-CNRS-UPMC, 10 rue Vauquelin, 75231 Paris, France — We present a tunnel spectroscopy study of the electronic spectrum of single PbS Quantum Dots (QDs) trapped between nanometer-spaced electrodes, measured at low temperature T=5 K. The carrier filling of the QD can be controlled either by the drain voltage in the shell filling regime or by a gate voltage. In the empty QD, the tunnel spectrum presents the expected signature of the 8x degenerated excited levels. In the shell filled regime, the levels degeneracies are lifted by the global electrostatic Coulomb energy of the QD; in the gate controlled shell filling regime, the levels degeneracies are lifted by the intra-Coulomb interactions. In the charged quantum dot, electron-phonons interactions lead to the apparition of Franck-Condon side bands on the single excited levels and possibly Franck-Condon blockade at low energy. The sharpening of excited levels at higher gate voltage suggests that the magnitude of electron-phonon interactions is decreased upon increasing the electron filling in the quantum dot.

12:51PM M15.00007 Impact of particle interactions on the photoluminescent stability of silicon nanocrystal clusters, JOSEPH B. MILLER, Rice University, NAVEEN DANDU, NDSU, REBECCA J. ANTHONY, UWE R. KORTSHAGEN, UMN, DANIEL M. KROLL, SVETLANA KILINA, ERIK K. HOBBIE, NDSU — We combine experiments, Monte Carlo simulations and ab initio calculations to explore the influence of inter-particle interactions on the photoluminescent stability of silicon nanocrystal (SiNC) clusters. The time-dependent photoluminescence (PL) emitted by structures ranging in size from a single nanocrystal to collections of several thousand SiNCs is compared with Monte Carlo simulations of non-interacting nanocrystal ensembles. The discrepancy is modeled using calculations of the energy transfer rate between neighboring SiNCs as a function of material composition and shape, bringing the possibility to control the photoluminescent stability of silicon nanocrystal clusters.

1:03PM M15.00008 Plasmonic Cavity Transparency Induced by a Single Quantum Dot, THOMAS HARTSFIELD, Department of Physics, The University of Texas at Austin, WEI-SHUN CHANG, Department of Physics, Rice University, SUNG-CHEOL YANG, TZUHSUAN MA, Department of Physics, The University of Texas at Austin, JINWEI SHI, Department of Physics, Beijing Normal University, LIUYANG SUN, GENNADY SHVETS, Department of Physics, The University of Texas at Austin, STEPHAN LINK, Department of Physics, Rice University, XIAOQIN LI, Department of Physics, The University of Texas at Austin — There are a large number of studies devoted to designing and characterizing plasmonic cavities. However, few experiments investigate interaction of individual quantum absorbers and emitters with a plasmonic cavity, which is essential for exploring cavity quantum electrodynamic (QED) effects. The main experimental challenge lies in the difficulty of placing an absorber and emitter at the desired positions. The very virtue of the small mode volume of plasmonic cavities demands precise spatial placement of emitters. Here, we study the simplest plasmonic cavity: a spherical metallic nanoparticle (MNP). By placing a semiconductor quantum dot (QD) controllably in the close proximity of the MNP cavity, its scattering spectrum is modified drastically. A Fano resonance is observed due to interference between the plasmonic resonance of the MNP and the exciton resonance in the QD. The experiment demonstrates that transparency of the MNP cavity can be effectively induced by a single quantum dot, achieving an important step toward realizing plasmonic quantum devices.

1:15PM M15.00009 Ultrafast Excitonic and Plasmonic Processes at the Nanoscale: Understanding Energy Flow in Hybrid Nanostructures, GARY WIEDERRECHT, Center for Nanoscale Materials, Argonne National Laboratory — Nanoscale plasmonic and excitonic structures frequently possess ultrafast processes that can be initiated and monitored by light. Nanoscale structures lend themselves to strong light-matter interactions for a variety of reasons, including a tendency towards large optical extinction and polarizability. Many times these nanostructures have strong resonances due to collective excitations with coherence, a property that lends itself very well to optical control opportunities. These types of collective excitations can also couple strongly to excitations of other nanostructures with different composition and with disparate properties in order to realize hybrid excitations. Hybridization presents unique opportunities for inducing directional energy and charge flow initiated by light. Thus, using ultrafast pulses of appropriate photon energy, combined with considerations of material composition and shape, brings the possibility to control energy flow in excitonic and plasmonic hybrid nanostructures. In this talk, I discuss our recent efforts to create and characterize electronically coupled nanostuctures and the impact this has on ultrafast photoreponse. These processes have strong impact on applications such as light harvesting and nonlinear optical responses in nanoscale structures. Use of the Center for Nanoscale Materials was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-AC02-06CH11357.
1:27PM M15.00010 Directed synthesis of Mn\textsubscript{1-x}Ti\textsubscript{x}O\textsubscript{2} tunnel structured materials for energy applications, TIM DROUBAY, ANNE CHAKA, SEBASTIEN KERISIT, EUGENE MILTON, Pacific Northwest National Laboratory — Mn oxides with tunnel structures are crucial in technological applications such as Li batteries, catalysis, fuel cells, electrochemical capacitors, sensors, and groundwater remediation. However, the complexity and poor quality of natural Mn oxide has hindered efforts to understand their fundamental structure-property relationships. To address this issue, we used PLD to make high-quality Mn\textsubscript{1-x}Ti\textsubscript{x}O\textsubscript{2} single-crystal films. Attempts to synthesize pure $\beta$-MnO\textsubscript{2} thin films on TiO\textsubscript{2} substrates resulted in Mn\textsubscript{2}O\textsubscript{3} dominant films. Results of ab initio thermodynamics to explain film stability as a function of growth conditions and Mn/Ti composition suggest that “protecting” the Mn in a TiO\textsubscript{2} matrix by co-deposition would be beneficial. This approach has met with initial success even though the resultant films have oxygen vacancies. XPS indicates that (110) oriented films are Mn-rich near the surface while (001)-oriented films are Mn-rich near the interface. XRD shows that the films are coherently strained to the substrate which may influence the oxygen non-stoichiometry. Aberration corrected TEM results corroborate the XPS and XRD results and indicate a potential Mn-dependent defect. These films will be discussed along with multilayered (MnO\textsubscript{2})\textsubscript{m}–(TiO\textsubscript{2})\textsubscript{n} films. Atomic modeling shows that alternating cation rows that only contained Ti or Mn (m,n = 1) greatly lower the activation energy for Li diffusion relative to films where Mn and Ti were homogeneously mixed.

1:39PM M15.00011 Energy filtering in nanowires, MAARTEN THEWISSEN, BART SORÈE, WIM MAGNUS, Univ of Antwerp, IMEC COLLABORATION — Nanowires present a viable geometry to allow for future semiconductor device scaling. When the dimensions of these nanowires become comparable to the wavelength of the carriers, quantum effects may have a profound impact on the transport properties of the wire. An example of such effect, theoretically investigated here, is the introduction of a periodic potential profile along the transport direction. This could be achieved by repeatedly varying the diameter of the wire, by including a superlattice perpendicular to the wire, by applying a periodic electric field etc. The consequent resonances will effectively block electrons at some energies, while allowing others to pass, and hence function as an energy filter. Such property might be beneficial for its use in a transistor. The transmission of electrons through the wire is examined here, by solving Schrödinger’s equation in the effective mass approximation and Poisson’s equation self-consistently. As for the contacts, quantum transmitting boundary conditions are used as suggested by Lent. The result shows that energy filtering as described can indeed occur in realistic device structures.

1:51PM M15.00012 Influence of non-gaussian statistics and dynamic non-locality in temporal evolution of open quantum systems, CARLOS FLOREZ, LEONARDO PACHÓN, Univ de Antioquia — The study of quantum dissipation and non-local dynamics in phase space demands an extension of the Ullersma-Caldeira-Leggett framework to include non-linearities either in the system or the bath or even in the couplings between them. In this work, the special case of a linear open system interacting with a harmonic thermal bath by means of non-linear couplings is considered. This framework is constructed by extending the path integral formulation into phase space and applying the Feynman-Vernon influence functional theory to study the perturbative regime at different orders in the couplings. In doing so, the formal correspondence between the perturbative contributions and the Feynman diagrams that arise from the $n$-point correlation functions in the canonical variables are used. The effect of the non-local behavior induced by the non-linear contributions on the dissipative and decohering mechanisms are analyzed. The main features are the presence of non-Gaussian statistics and multiplicative, instead of additive, noises.

2:03PM M15.00013 First-Principles Approach to Transient Heat Flow in Quantum Systems\textsuperscript{1}, KAMIL WALCZAK, Department of Chemistry and Physical Sciences, Pace University, One Pace Plaza, New York City, NY 10038, KIRK YERKES, Aerospace Systems Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH 45433, NANOSCALE PHYSICS DIVISION TEAM, THERMAL MANAGEMENT CENTER COLLABORATION — We examine heat transfer via quantum advection modes (coherently correlated quantum states) between two thermal baths of different temperatures mediated by quantum system with discrete spectrum of accessible energy levels. Nanoscale transport is treated within the first-principles method by including the superposed wave functions into the quantum expression for heat flux. Our results show the specific modifications of heat transport characteristics due to the dynamics of quantum systems under consideration. Such dynamics is captured by non-steady-state solutions to time-dependent Schrödinger wave equation or by specific solutions of interrelated Pauli rate equations. Since the applicability of Fourier’s law is questionable at nanoscale and in the case of transient heat conduction, we pay particular attention to the new physics of post-Fourier heat transport and its further consequences. For instance, the non-equilibrium conditions may establish and maintain certain degree of coherence between correlated quantum states which are involved into the energy conduction process. Understanding and gaining control of coherent manipulations of qubits (two-level quantum systems) is crucial for further development of quantum informatics.

Wednesday, March 4, 2015 11:15AM - 1:51PM —
Session M16 DMP: Focus Session: Designed Function in Reduced Dimensional Materials and Clusters 101AB - Raghunathan Ramakrishnan, University of Basel, Switzerland

11:15AM M16.00001 Topologically nontrivial electronic bands and tunable Dirac cones in graphynes with spin-orbit coupling\textsuperscript{1}, VLADIMIR JURICIC, GUIDO VAN MIERT, CRISTIANE MORAIS SMITH, Univ of Utrecht — Graphynes represent an emerging family of carbon allotropes that differ from graphene by the presence of the triple bonds (-C≡C-) in their band structure. They have recently attracted much interest due to the tunability of the Dirac cones in the band structure. I will show that the spin-orbit coupling in $\beta$-graphyne could produce various effects related to the topological properties of its electronic bands. Intrinsic spin-orbit coupling yields high- and tunable Chern-number bands, which may host both topological and Chern insulators, in the presence and absence of time-reversal symmetry, respectively. Furthermore, Rashba spin-orbit coupling can be used to control the position and the number of Dirac cones in the Brillouin zone\textsuperscript{1}. Finally, I will also discuss the electronic properties of $\alpha$- and $\gamma$-graphyne in the presence of the spin-orbit coupling within recently developed general theory of spin-orbit couplings in graphynes\textsuperscript{2}.

11:27AM M16.00002 Chemical Trends for Transition Metal Compound Bonding to Graphene, JOERN LANGE, VOLKER BLUM, Department of Mechanical Engineering and Materials Science, Duke University, Durham, NC, USA — Transition metal compounds are of interest as catalysts for the hydrogen evolution reaction (HER). However, a perfect candidate to replace expensive platinum has not yet been identified. To tailor a specific compound, several properties come into play. One is the bonding to the underlying substrate, for which π-bonded carbon nanostructures are promising candidates. Here we analyze the bonding of small transition metal compound nano-clusters to a graphene layer for a range of chemical compositions: M₆A₈ (M = Mo, Ti; A = S, O, B, N, C). The clusters are generated by an unbiased random search algorithm. We perform total energy calculations based on density functional theory to identify lowest energy clusters. We calculate binding energies using the PBE and HSE functionals with explicit van der Waals treatment[1] and benchmark those against RPA cluster calculations. Our results indicate that molybdenum-carbides and -nitrides tend to bond tightly to graphene. Mo-oxides and -sulfides show small binding energies, indicating van der Waals bonding.

11:39AM M16.00003 Density-Functional Theory Study of Nucleation and Growth of Metallic Nanoparticles on MoS₂(001), WISSAM A. SAIDI, Mechanical Engineering and Materials Science, Univ of Pittsburgh — The dispersion of metallic Pt nanoparticles (NPs) on MoS₂ monolayers is systematically analysed using first-principles density functional theory calculations. The nucleation of the NPs is followed step-by-step where we find that n = 5 is the cluster size where the growth of the NPs transforms from 2-dimensional (2D) to 3D. Owing to the topography of MoS₂(001), the 2D NPs mostly attach to the support via a direct bonding with Mo atoms that sit in the troughs of the surface, while the 3D NPs are bonded to the sulfur atoms that are more extended in the vacuum region. Furthermore, we find that Pt is sufficiently mobile on the surface where the number of hopping events per second is ≈ 10⁹ s⁻¹. Moving from smaller width to a larger width, nanoribbons were showing more of a sheet like character. Other properties of these nanoribbons will also be discussed.

11:50AM M16.00004 Li Storage Properties of Disordered Single- and Bi-Layer Graphene, H. YILDIRIM, Purdue University School of Chemical Engineering, ALPER KINACI, Argonne National Laboratory, ZHI-JIAN ZHAO, Purdue University School of Chemical Engineering, MARIA CHAN, Argonne National Laboratory, JEFFREY P. GREELEY, Purdue University School of Chemical Engineering — Due to the limited capacity of the traditional intercalation-type graphite materials (373 mAh/g, LiC₆), much effort has been made to explore new anode materials to meet the increasing demand for batteries of high energy density. Among them, graphene has much attracted attention as an ideal platform for higher Li storage capacity, and for obtaining fundamental understanding of Li-C interaction. In this respect, we performed extensive first-principles calculations to model Li adsorption and intercalation in single- and bi-layer graphene, which are activated by defects for Li adsorption. For a wide range of Li coverages, the calculations predict that defect-free single layer graphene is not thermodynamically favorable compared to bulk metallic Li. However, graphene activated by defects are generally found to bind Li more strongly, and the interaction strength is sensitive to both the nature of defects and their densities. A rigorous thermodynamic analysis establishes the theoretical Li storage capacities of the defected graphene, and in some cases, these capacities are found to approach, although not exceed, those of bulk graphite. We will provide a performance comparison between defected single- and bi-layer graphene and bulk-graphite for Li storage capacities. A detailed analysis of the effect of the van der Walls (vdW) interactions will also be presented.

12:03PM M16.00005 Structure and electronic properties of alkali and alkaline-earth metals on graphene, JIAN ZHOU, Virginia Commonwealth University, SHUNHONG ZHANG, QIAN WANG, QIANG SUN, Peking University, PURUSOTTAM JENA, Virginia Commonwealth University — A thorough search of the monolayer structure of Li, Na, K, and Ca atoms on graphene, based on a synergistic combination of density functional theory and particle swarm optimization algorithm, yielded unusual deposition patterns. For Li atoms, we show that they prefer to cluster on graphene, irrespective of their concentration. We further show that an external electric field applied vertically to the graphene surface or doping with boron can prevent this clustering, leading to the homogeneous growth of Li. For larger atoms Na, K, and Ca, they distribute uniformly when their coverage ratio M:C is 1:6, but the Na and Ca atoms self-assemble to form parallel quasi-one-dimensional chains when their coverage is reduced to 1:8. Electron-phonon coupling calculations further show that the NaC₆ is a superconductor with critical temperature of 5.8 K. At low concentration (M:C = 1:8) and depending on metal species, well-aligned atomic metal chains interact with graphene with varying intensity, making it possible to achieve either rigid or non-rigid band doping in graphene.

12:15PM M16.00006 The effect of depolarization fields on the electronic properties of two-dimensional materials, YOUNG-HAN SHIN, HYE JUNG KIM, MOHAMMAD NOOR-A-ALAM, Department of Physics, University of Ulsan, Ulsan 680-749, Republic of Korea — Graphene is a two-dimensional semimetal with a zero band gap. By weakening the sp² covalent bonding of graphene with additional elements such as hydrogen or fluorine, however, it is possible to make it insulating. We can expect that the band gap converges to that of a three-dimensional analogue by repeating such two-dimensional layers along the normal to the layer. If we control the position of additional elements to make a dipole monolayer, the system will have an intrinsic internal field decreases as the number of layers increases. But, for two-dimensional bilayers, depolarization field is so strong that its electronic properties can be much different from its monolayer analogue. In this presentation, we show that the internal fields induced by dipole moments can change electronic properties of two-dimensional materials such as graphene-like structures and complex metal oxides.

12:27PM M16.00007 First-principles studies of hematite nanoribbons, PRABATH WANAGURU, JIAO AN, QIMING ZHANG, The University of Texas at Arlington — We study two types of hematite nanoribbons, based on density functional theory has been performed. Geometry and magnetic order of these nanoribbons were optimized using DFT+U method implemented in VASP suite of software. It is found that the band gaps decreases from the value of ~ 2.0eV to ~ 1.7eV as the widths increase from 6Å to more than 40Å. Despite the bulk hematite is indirect in band gap nature, one type of nanoribbons show direct band gap nature in several widths. Cleaving energies are positive with respect to the hematite sheet and as width increases it is decreasing. Moving from smaller width to a larger width, nanoribbons were showing more of a sheet like character. Other properties of these nanoribbons will also be discussed.

12:39PM M16.00008 Getting the Most from 2-D Materials: the Role of Device Dimensionality
HUAISHAN LI, DAVID STRUBBE, JEFFREY GROSSMAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology — While the control of material dimensionality has been widely used as an important design means, the device dimensionality, which relates to the regularity of the material ensemble rather than the material itself, has received far less attention. Recently, both vertical [1,2] and lateral [2] heterojunctions based on 2-D materials have been successfully synthesized, which provides an unprecedented opportunity to renew our understanding of the concept of “dimensionality.” In this study, we propose a design strategy of controlling device dimensionality by computationally investigating a “1.5-dimensional” solar cell device made of a 2-dimensional graphene based material. According to the predicted optical properties and charge dynamics, this prototype system has the potential to achieve desirable characteristics of robustness against defects, efficient polaron pair dissociation, broad tunability with surface functionalization and the possibility to form tandem cells. In addition, the optimization of correlated light harvesting procedures simultaneously becomes attainable in such 1.5-d solar cell due to the extra degree of freedom to manage the flux of mass and energy.

12:51PM M16.00009 Structure Matters More than Size: Tuning the Electronic Properties of (TiO$_2$)$_n$ Clusters, NOA MAROM, Tulane University, New Orleans, LA, USA, SASWATA BHATTACHARYA, LUCA GHIRINGHELLI, Fritz-Haber-Institut der MPG, Berlin, Germany — To design (TiO$_2$)$_n$ clusters with desired properties we implemented a suite of three genetic algorithms (GA) tailored to optimize for low total energy (EGA), high vertical electron affinity (VEA-GA), and low vertical ionization potential (VIP-GA). The property-based GAs are an extension of the cascade GA reported in [1]. Analysis of the structures found by the VEA-GA and the VIP-GA vs. the EGA reveals structure-property relations. A high VEA is correlated with the presence of several dangling-O atoms (typically 3-4), rather than the previously suggested tri-coordinated Ti atom [2]. A low VIP is correlated with low bond connectivity (typically 2) between two dangling-O atoms. We show that the electronic properties of (TiO$_2$)$_n$ clusters with n up to 20 correlate more strongly with the presence of these structural features than with size. We further propose that the presence of these structural features causes the observed large magnitude of the dipole moment of TiO$_2$ clusters.

1:03PM M16.00010 Electronic and optical properties of ultrathin silicon nanomembranes: A first-principles investigation, WOOSUN JANG, SU-HYUN YOO, ALOYSIUS SOON, Global E3 Institute and Department of Materials Science and Engineering, Yonsei University, Seoul 120-749, Korea — Owing to its unique and exotic physical and chemical properties, there has been a lot of effort undertaken to explore and study ultrathin low-dimensional nanomaterials (e.g. graphene and MoS$_2$). Of late, two-dimensional (2D) nanomembranes of silicon — a well-known prototypical bulk semiconductor - have attracted much attention, and has found its potential in niche nanodevice applications e.g. field effect transistors (FET) and secondary battery anodes. In this work, after considering various nanomembranes of Si with varying thicknesses, we study geometric and electronic structures using first-principles density-functional theory calculations (and beyond). Here, we consider both bulk-terminated pristine Si nanomembranes as well as surface-reconstructed ones, as motivated by available experimental and theoretical reports. To understand the influence of growth conditions on these Si nanomembranes, we have also studied the role of surface-passage (e.g. with O, H, and OH) on their electronic and optical properties. Namely, we carefully investigate their thickness-dependent electronic band structure (i.e. both their fundamental and optical band gap energies), so as to elucidate their intrinsic structure-property relations for designing future technologically important nanodevices.

1:15PM M16.00011 What is the work function of a small nanocrystal?, LINGYUAN GAO, JAIME SOUTO, ALEX DEMIKOV, JAMES CHELIKOWSKY, Univ of Texas, Austin — The work function is defined as the difference between the electrostatic potential energy (\(\phi\)) of an electron in the vacuum near the metal surface and the metal’s Fermi energy. For a single crystal metal, the measured work function typically depends on the orientation of the metal surface. This seems counterintuitive, as the Fermi energy is the same across the metal sample, and the vacuum energy is also expected not to depend on the direction. The problem becomes even more interesting for a metallic nanocrystal, where facets of different orientation meet. We undertake to explore and study ultrathin low-dimensional nanomaterials (e.g. graphene and MoS$_2$). Of late, two-dimensional (2D) nanomembranes of silicon — a well-known prototypical bulk semiconductor - have attracted much attention, and has found its potential in niche nanodevice applications e.g. field effect transistors (FET) and secondary battery anodes. In this work, after considering various nanomembranes of Si with varying thicknesses, we study geometric and electronic structures using first-principles density-functional theory calculations (and beyond). Here, we consider both bulk-terminated pristine Si nanomembranes as well as surface-reconstructed ones, as motivated by available experimental and theoretical reports. To understand the influence of growth conditions on these Si nanomembranes, we have also studied the role of surface-passage (e.g. with O, H, and OH) on their electronic and optical properties. Namely, we carefully investigate their thickness-dependent electronic band structure (i.e. both their fundamental and optical band gap energies), so as to elucidate their intrinsic structure-property relations for designing future technologically important nanodevices.

1:27PM M16.00012 Effects of Interaction Range and Strength on the Phase Behavior of Small Clusters of Colloidal Particles, RAY SEHAGL, DIMITRIOS MAROUDAS, Univ of Mass - Amherst — We report the findings of a computational study of the phase behavior of thermodynamically small assemblies (clusters) of colloidal particles interacting via a potential that includes electrostatic repulsion and depletion-based attractive interactions. We applied the data mining technique of diffusion mapping to determine the dimensionality of an appropriate coarse-grained description of the phase behavior and to assess the suitability of chosen order parameters. The results of this technique indicate that two coarse variables, which represent metrics of assembly density and crystallinity, are required to describe the phase behavior of these colloidal assemblies. We generate free-energy landscapes (FELs) in this well-justified coarse-variable space using Monte Carlo umbrella sampling. We constructed these FELs over a range of interaction strength changes and obtained a comprehensive picture regarding the possible stable configurations of such colloidal assemblies at equilibrium and the phase changes observed between them. In particular, we observe an order-to-disorder transition between crystalline and liquid-like phases as well as a polymorphic transition between relaxed face-centered cubic and hexagonal close-packed structures.

Wednesday, March 4, 2015 11:15AM - 2:15PM  
Session M17 DCMP: Graphene: Terahertz Physics and Plasmons 102AB - Junichiro Kono, Rice University

11:15AM M17.00001 Optimizing Broadband Terahertz Modulation with Hybrid Graphene/Metasurface Structures , SUFEI SHI, BO ZENG, HUI-LING HAN, XIAOPING HONG, HSIN-ZON TSAI, HAE SAE, ALEX ZETTL, MIKE CROMMIE, FENG WANG, UC Berkeley, UC BERKELEY TEAM — We demonstrate efficient terahertz (THz) modulation by coupling graphene strongly with a broadband THz metasurface device. This THz metasurface, made of periodic gold slit arrays, shows near unity bandwidth transmission that arises from coherent radiation of the enhanced local field in the slits. Utilizing graphene as an active load with tunable conductivity, we can significantly modify the local-field enhancement and strongly modulate the THz wave transmission. This hybrid device also provides a new platform for possible nonlinear THz spectroscopy study of graphene.

11:27AM M17.00002 Full-range Gate-controlled Terahertz Phase Modulation with Graphene Metasurfaces , QIONG WU, ZIQI MIAO, XIN LI, DING KUN, QIONG HE, ZHENHUA AN, YUANBO ZHANG, LEI ZHOU, Fudan Univ, LEI ZHOU’S GROUP COLLABORATION, YUANBO ZHANG’S GROUP, ZHENHUA AN’S GROUP TEAM — Local phase control of electromagnetic wave is the basis of a diverse set of applications such as hologram imaging, polarization manipulations and wave-front controls. Here, we demonstrate full-range THz phase modulation realized on a metasurface featuring magnetic resonators that are coupled with graphene as a tunable loss. A gate bias applied through liquid ion tunes graphene’s optical conductivity, turns the coupled system from an under-damped resonator to an over-damped one, and induces dramatic modulation in the phase of the reflected wave. Our one-port resonator (i.e. resonator with only reflection channel) model reveals the underlying mechanism of our extreme phase modulation, and points to general guidelines for achieving large, tunable phase modulation in THz regime. A gate-tunable polarizer will be presented as an early demonstration of the capability of our graphene metasurfaces.

11:39AM M17.00003 Coupling of strongly localized graphene plasmons to molecular vibrations , DAMON FARMER, IBM T. J. Watson Research Center, YILEI LI, Columbia Univ, HUGEN YAN, IBM T. J. Watson Research Center, XIANG MENG, Columbia Univ, WENJUN ZHU, IBM T. J. Watson Research Center, RICHARD OSGOOD, TONY HEINZ, Columbia Univ, PHAEDON AVOURIS, IBM T. J. Watson Research Center — In this work, we present a new mechanism to couple graphene plasmons to vibrations in the PMMA molecules. The enhanced interaction is manifested through induced transparency in the graphene plasmon optical response when the plasmon and the vibrational frequencies are matched. We also show that this coupling is of an electromagnetic nature by comparing the evolution of the line shape as a function of the detuning of the two frequencies to simulations using the finite-difference time-domain method.

11:51AM M17.00004 Effects of screening on the propagation of graphene surface plasmons , KEN-ICHI SASAKI, NORIO KUMADA, NTT Basic Research Laboratories — We investigated surface plasmons in epitaxial graphene, while paying particular attention to the effect of interface states and resistivity on the transport properties[1,2]. The propagation velocity of the surface plasmons is much slower than the electron Fermi velocity when the screening effect induced by interface states is taken into account. Furthermore, slow-moving surface plasmons undergo a strong diffusion when the Fermi energy is near the Dirac point. This is shown by a numerical simulation of an RLC circuit model and its continuum approximation known as the telegrapher’s equation. We could explain recent experimental results for the surface plasmons satisfactorily. [1] Kumada et al., New J. Phys. 16, 063055 (2014). [2] Sasaki and Kumada, Phys. Rev. B 90, 035449 (2014).

12:03PM M17.00005 Retardation effect in graphene plasmonics , HUGEN YAN, IBM T. J. Watson Research Center — Localized plasmons in graphene micro- and nano-structures have attracted lots of attention recently. Typically the size of the graphene structure is much smaller than the on-resistance light wavelength and the quasi-electrostatic treatment of the light-matter interaction is sufficient. However, with increasing graphene structure size and stacked layer thickness, the quasi-electrostatic treatment fails. Retardation effect and dynamic depolarization have to be taken into account. In the paper, we’ll focus on two major topics related to the retardation effect. First, ultralow damping of graphene plasmons can be achieved in ultra-large graphene disk and ribbon arrays. Second, the coupling of graphene structures in the same array is radiative in nature and the resonance associated with the periodic lattice of the graphene disk or ribbon arrays play an role in the plasmonic response.

12:15PM M17.00006 Plasmon-enhanced terahertz photodetection in graphene1 , XINGHAI CAI, ANDREI SUSHKOV, CNAM, University of Maryland, College Park, MOHAMMAD JADIDI, IREAP, University of Maryland, College Park, R.L. MYERS-WARD, A.K. BOYD, R.M. DANIELS, D. KURT GASKILL, U.S. Naval Research Laboratory, Washington, DC, THOMAS MURPHY, IREAP, University of Maryland, College Park, H. DENNIS DREW, CNAM, University of Maryland, College Park, MICHAEL FUHRER, School of Physics, Monash University, Victoria, Australia — Graphene is a promising material for high speed room-temperature terahertz photodetection. However, the limited absorption in monolayer graphene remains a key challenge. We present here a large area terahertz detector that utilizes a plasmonic resonance in sub-wavelength graphene micro-rubbons to increase the absorption efficiency, and exploits the hot-electron photothermoelectric effect for detection. Through Fourier transform infrared spectroscopy we show that by tailoring the orientation of the graphene ribbons with respect to an array of sub-wavelength bimetallic electrodes, the plasmonic resonance can be efficiently excited, with a gate-tunable resonance frequency across the terahertz range. Polarization-dependent photoresponse measurements show an enhanced photothermal voltage between the outermost electrodes due to the plasmonically enhanced absorption.

12:27PM M17.00007 Controlling Terahertz Waves using Graphene Supercapacitors , NURBEK KAKENOV, Osman Balcı, EMRE O. POLAT, Bilkent University, HAKAN ALTAN, Middle East Technical University, COSKUN KOÇABAS, Bilkent University — Ability to control density of high mobility charge carriers on graphene provides a unique platform to control electromagnetic waves in a broad spectrum. In this work, we demonstrate a terahertz intensity modulator using a graphene supercapacitor which consists of two large area graphene electrodes and electrolyte medium. This simple device structure enables us to modulate THz waves in a broad spectrum without any metallic gate electrodes. The mutual electrostatic gating between the graphene electrodes provides a very efficient electrostatic doping with Fermi energies of 1 eV. We show that, the graphene supercapacitor yield more than 50% modulation between 0.1 to 1.4 THz with operation voltages less than 3V. The low insertion losses, the simplicity of the device structure and polarization independent device performance are the key attributes of graphene supercapacitors for THz applications.
12:39PM M17.00008 THz pump-THz probe study of electrostatically gated graphene1, JINGDI ZHANG, MENGKUN LIU, MARTIN WAGNER, D. N. BÁSOV, RICHARD D. AVERITT, Univ of California - San Diego — We investigate ultrafast carrier dynamics in graphene using THz-pump THz-probe spectroscopy. In contrast to recent studies using optical excitation [1] [2], THz excitation exclusively initiates intra-band transitions, resulting in an increase in the carrier scattering rate. The corresponding transient peak of the transmitted probe signal scales linearly with the E-field of the incident THz pump pulse. Further, the decay time of the excited carriers is independent of the gating voltage. As the Fermi level is tuned toward the charge neutral point (CNP) by varying the electrostatic gate voltage, the induced increase in transmission is strongly suppressed. We believe that the low density of states near the CNP is responsible for this suppression. [1] Shi, S. F., Tang, et. al. Nano Lett., 14(3), 1978-1982 (2014). [2] A. J. Frenzel, et. al. Phys. Rev. Lett. 113, 056602 (2014).

12:51PM M17.00009 Top Gated Graphene PN junctions for THz detection1, ANTHONY BOYD, US Naval Research Laboratory, ANINDYA NATH, George Mason University, MEHDI JADIDI, RYAN SUESS, ANDREI SUSHKOV, GREGORY JENKINS, H. DENNIS DREW, THOMAS MURPHY, University of Maryland, RACHEL MYERS-WARD, KEVIN DANIELS, D. KURT GASKILL, US Naval Research Laboratory — The search for terahertz (THz) detectors based on graphene is encouraged by the fact that the ballistic regime in graphene occurs at room temperature over a distance of few dozens of nanometers. The naturally occurring 2-D carriers have extremely high intrinsic mobility at room temperature. Despite being only one atomic layer thick, graphene still absorbs several percent of incoming THz radiation well. THz detectors are fabricated on epitaxial graphene using an improved lithography process using lift off resist to achieve low contact resistance [1]. The devices are field effect transistors constructed with a thin asymmetric nichrome (NiCr) top gate that facilitates tuning the photovoltaic effect. The thin NiCr gate possesses a sheet resistance of 390 ohms which enables better matching of free space and does not block the incoming THz radiation.

1:03PM M17.00010 Strong exciton-plasmon coupling in graphene-semiconductor structures , TIGRAN V. SHAHBAZYAN, Jackson State Univ, KIRILL A. VELIZHANIN, Los Alamos National Lab — We study strong coupling between plasmons in monolayer doped graphene and excitons in narrow gap semiconductor quantum well separated from graphene by a potential barrier. We show that Coulomb interactions between excitons and plasmons result in mixed states described by Hamiltonian similar to one describing exciton-polaritons and derive the exciton-plasmon coupling parameter that depends on system geometry and material properties. We calculate numerically the Rabi splitting of exciton-plasmariton states and discuss the manifestation of these states in optical and electrical measurements. We also study how the contacts affect the coupling to and from free-space radiation. This provides insight to design and optimize plasmonic devices in the terahertz spectral range that can be tuned by application of a gate voltage. These features make graphene an attractive candidate for a variety of electrically tunable and broad bandwidth photodetectors of the THz regime.

1:15PM M17.00011 Plasmons in metal contacted graphene1, M.M. JADIDI, Institute for Research in Electronics and Applied Physics(IREEAP), Univ of Maryland, College Park, A.B. SUCHKOV, Center for Nanophysics and Advanced Materials(CNAM), Univ of Maryland, College Park, R.L. MYERS-WARD, A.K. BOYD, K.M. DANIELS, D.K. GASKILL, US Naval Research Laboratory, H.D. DREW, CNAM, Univ of Maryland, College Park, T.E. MURPHY, IREEAP, Univ of Maryland, College Park — Subwavelength graphene structures exhibit standing-wave plasmon resonances throughout the terahertz spectral range that can be tuned by application of a gate voltage. These features make graphene an attractive candidate for a variety of electrically tunable terahertz devices, including filters, sensors, sources, and modulators. Plasmonic modes have been observed and analyzed in finite-size graphene elements such as ribbons and disks. However, nearly all optoelectronic applications require electrical connection to the graphene element, which drastically alters the plasmonic boundary conditions and mode structure. We present a study of the effects of conductive electrical contacts on the plasmonic modes of a graphene channel, and examine how the contacts affect the coupling to and from free-space radiation. We show that radiation effects are essential in defining and understanding the properties and linewidths of these modes. We also study how the graphene plasmon mode interacts with the antenna modes of the contacts. These results provide valuable insight for designing antenna-coupled graphene plasmonic devices, including detectors and emitters.

1:27PM M17.00012 Electro-optic and Many-body Effects on Optical Absorption of Twisted Bilayer Graphene , KAN-HENG LEE, LUJIE HUANG, CHEOL-JOO KIM, JIWOOONG PARK, Cornell University — In twisted bilayer graphene (tBLG), the interlayer rotation angle between the two graphene layers induces additional angle-dependent van Hove singularities (vHSs) in its band structure where the two Dirac cones from each layer intersect. These vHSs introduce extra angle-dependent absorption peaks in the optical absorption spectra of tBLG. Here, we experimentally investigate the overall doping and the interlayer potential on these interlayer absorption features at various angles. We independently tune the doping concentration of each layer with a newly-developed, optically transparent, dual-gate transistor geometry to perform simultaneous optical and electrical measurements. Our data show strong electro-optic phenomena in the optical absorption of tBLG, the peak energy and width of the interlayer resonance feature sensitively depends on the overall doping and interlayer potential. We explain our observation using a simple band picture as well as many-body effects. Our study provides a powerful experimental platform for studying more complicated structures such as rotated tri- and multi-layer graphene systems in the future. Moreover, the understanding of electro-optic and many-body effects in these materials opens up a way for novel electrochromic devices.

1:39PM M17.00013 Doping and Field Dependent Electrical Conductivity of Angle-Resolved Twisted Bilayer Graphene , LUJIE HUANG, CHEOL-JOO KIM, Cornell, ADAM WEI TSEN, Columbia, LOLA BROWN, JIWOOONG PARK, Cornell — In twisted bilayer graphene (tBLG), the interlayer interaction induces additional van Hove singularities (VHS) and mini-gaps near the intersections between the Dirac cones of the two layers; this results in several electrical and optical phenomena at an energy level that monotonically increases with the twist angle θ. While there exist previous studies on the electrical properties of tBLG, the electrical conductivity of tBLG and its dependence on the overall doping and interlayer potential (field) have not been measured using tBLG samples with known θ. Here, we report the electrical conductivity of θ-resolved tBLG in a dual-gate field effect transistor geometry which allows an independent control of the doping and interlayer potential. In large θ tBLG, the total conductivity is approximately proportional to the total carrier density (the sum of the carrier number densities from the top and the bottom layers), indicating that large θ tBLG acts as two independent single layers carrying the electrical current in parallel. Among tBLG samples with a small θ, however, we observe an extra resistance peak besides the Dirac point, which may correspond to the minigap near the VHS. In order to perform further experiments for this small-θ tBLG samples, we use a doubletransfer of CVD grown graphene films with a uniform lattice orientation over a large scale. This allows a direct optical characterization in the relevant IR wavelengths, a critical capability for determining and the twist angle θ.

1:51PM M17.00014 Resonant Tunneling and Intrinsic Bistability in Twisted Graphene Structures, JOAQUIN RODRIGUEZ-NIEVA, MILDRED DRESSELHAUS, LEONID LEVITOV, MIT — Bistable systems exhibit several distinct macroscopic states and can switch between them upon variation of some control parameter. Nonvolatile electronic systems that exhibit intrinsic bistability and fast switching times are desirable for low-power memory and logic. Experimental realizations of such systems, however, are scarce. We propose a novel mechanism for intrinsic bistability in van der Waals heterostructures formed by twisted graphene monolayers. Bistability in these systems originates from resonant tunneling and charge coupling between different graphene layers. These characteristics, governed by Dirac-like spectrum and Moiré periodicity of the tunneling Hamiltonian, allow multiple stable states in the sequential tunneling regime. In the bistability region, an intermediate electrically decoupled graphene layer can, for the same external bias, be either in a resonant or non-resonant state with respect to the top/bottom layer. Features of interest, such as resonant tunneling, negative differential resistance and bistability, are controlled by parameters easily accessible in experiments, namely the twist angle and interlayer conductances. We estimate the power required to retain this state, switching times, and assess volatility of such intrinsically bistable systems.

2:03PM M17.00015 Discovery of bound excitons in twisted bilayer graphene, HIRAL PATEL, Department of Physics, Oregon State University, JIWOOG PARK, Department of Chemistry, Cornell University, MATT GRAHAM, Department of Physics, Oregon State University — Recent first principle Bethe-Salpeter simulations of twisted bilayer graphene (tBLG), predict that the unique geometry of tBLG’s overlapping interlayer 2p orbitals produce a strong destructive coherence effect that results in stable, strongly bound exciton states. We directly probe the electronic dynamics of twisted bilayer graphene for the first time by developing a unique ultrafast confocal microscopy approach that combines transient absorption, and transmission electron microscopy. We find resonantly excited twisted bilayer regions display distinct, long-lived dynamics that are not present in 0° stacked bilayers. We further map out the electronic structure using one and two-photon transient absorption microscopy to observe signatures of both unbound and strongly bound excitonic states predicted by the theory. The probable existence of the stable excitons opens up the possibility of efficient carrier extraction by exploiting the unusual hybrid metallic-excitonic nature in twisted bilayer graphene systems.

Wednesday, March 4, 2015 11:15AM - 2:15PM

11:15AM M18.00001 From ground-state densities to entangled wave functions: an exploration for the Hubbard model, KLAUS CAPELLE, Universidade Federal do ABC (UFABC), Sao Paulo — The fundamental Hohenberg-Kohn theorem of density-functional theory (DFT) guarantees that, in principle, all information about a many-body system is contained in its ground-state density. Most effort in DFT is thus directed at finding ways to reliably calculate this density and to extract useful information from it. Quantum-information theory (QIT), on the other hand, is little concerned with ground-state densities, focusing instead on wave functions and density matrices, with a view on exploiting entangled states in information processing. In spite of these different philosophies, many connections exist between both approaches. In this talk, I review how some of these connections have been discovered and quantified in the context of the Hubbard model: (i) DFT calculations for a model Hamiltonian serve to relate the entanglement entropy to phase transitions; (ii) a local-density-type approximation can be used to calculate the entanglement entropy of spatially inhomogeneous systems, such as cold atoms in optical traps and large superlattices, where traditional numerical methods encounter difficulties; (iii) a combination of DFT with a Bethe-ansatz ansatz allows one to calculate the values of system-specific parameters in expressions for the block-block entanglement that remain undetermined in scaling approaches; (iv) the construction of suitable metrics shines light on how the Hohenberg-Kohn theorem relates densities and wave functions for different systems.

11:51AM M18.00002 Time-Dependent Density Functional Theory for Universal Quantum Computation, DAVID TEMPEL, Harvard University — In this talk, I will discuss how the theorems of TDDFT can be applied to a class of qubit Hamiltonians that are universal for quantum computation. The theorems of TDDFT applied to universal Hamiltonians imply that single-qubit expectation values can be used as the basic variables in quantum computation and information theory, rather than wavefunctions. From a practical standpoint this opens the possibility of approximating observables of interest in quantum computations directly in terms of single-qubit quantities (i.e. as density functionals). Additionally, I will discuss how TDDFT provides an exact prescription for simulating universal Hamiltonians with other universal Hamiltonians that have different, and possibly easier-to-realize two-qubit interactions.

12:27PM M18.00003 The computational complexity of many-electron problems and Density Functional Theory, NORBERT SCHUCH, RWTH Aachen University — Quantum computation and complexity has helped us to sharpen our understanding of the common origin for the difficulty of a wide range of problems in quantum many-body physics. In my talk, I will discuss the implications of quantum complexity theory to understanding systems of interacting electrons, and show how it allows us to determine the fundamental limitations to any numerical method for the simulation of those systems, including our ability to approximate the universal functional in Density Functional Theory.

1:03PM M18.00004 What Density Functional Theory could do for Quantum Information, ANN MATTSSON, Sandia National Laboratories, Albuquerque NM — The Hohenberg-Kohn theorem of Density Functional Theory (DFT), and extensions thereof, tells us that all properties of a system of electrons can be determined through their density, which uniquely determines the many-body wave-function. Given access to the appropriate, universal, functionals of the density we would, in theory, be able to determine all observables of any electronic system, without explicit reference to the wave-function. On the other hand, the wave-function is at the core of Quantum Information (QI), with the wave-function of a set of qubits being the central computational resource in a quantum computer. While there is seemingly little overlap between DFT and QI, reliance upon observables form a key connection. Though the time-evolution of the wave-function and associated phase information is fundamental to quantum computation, the initial and final states of a quantum computer are characterized by observables of the system. While observables can be extracted directly from a system’s wave-function, DFT tells us that we may be able to intuit a method for extracting them from its density. In this talk, I will review the fundamentals of DFT and how these principles connect to the world of QI. This will range from DFT’s utility in the engineering of physical qubits, to the possibility of using it to efficiently (but approximately) simulate Hamiltonians at the logical level. The apparent paradox of describing algorithms based on the quantum mechanical many-body wave-function with a DFT-like theory based on observables will remain a focus throughout. The ultimate goal of this talk is to initiate a dialog about what DFT could do for QI, in theory and in practice. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

Wednesday, March 4, 2015 11:15AM - 1:39PM

11:15AM M19.00001 Advances in Additive Manufacturing, VLASTIMIL KUNC, ORNL — No abstract available.

11:51AM M19.00002 3D Printing of Human Tissue Mimics via Layer-by-Layer Assembly of Polymer/Hydrogel Biopapers, BRADLEY RINGEISEN, Naval Research Laboratory — The foundations of tissue engineering were built on two fundamental areas of research: cells and scaffolds. Multipotent cells and their derivatives are traditionally randomly seeded into sophisticated polymer or hydrogel scaffolds, ultimately with the goal of forming a tissue-like material through cell differentiation and cell-material interactions. One problem with this approach is that no matter how complex or biomimetic the scaffold is, the cells are still homogeneously distributed throughout this three dimensional (3D) material. Natural tissue is inherently heterogeneous on both a microscopic and macroscopic level. It also contains different types of cells in close proximity, extracellular matrix, and a complex vascularized network. Recently deposited 3D cell and organ printers may be able to enhance traditional tissue engineering experiments by building scaffolds layer-by-layer that are crafted to mimic the microscopic and macroscopic structure of natural tissue or organs. Over the past decade, my laboratory has developed a capillary-free, live cell printer termed biological laser printing, or BioLP. We find that printed cells do not express heat shock protein and retain >99% viability. Printed cells also incur no DNA strand fracture and preserve their ability to differentiate. Recent work has used a layer-by-layer approach, stacking sheets of hybrid polymer/hydrogel biopapers in conjunction with live cell printing to create 3D tissue structures. Our specific work is now focused on the blood-brain-barrier and air-liquid interface and will be described during the presentation.

12:27PM M19.00003 3-D Constructs—Molded vs. Printed: The differences from a cell based perspective, MARCIA SIMON, Professor and Director of Graduate Studies, School of Dental Medicine, Stony Brook — Additive manufacturing technologies are increasingly being used to replace standard subtractive molding methods in engineering polymeric biomedical implants and devices. The principal advantage of this new technology is the ability to print directly from a scan and hence produce parts which are an ideal fit for an individual, which eliminates much of the sizing and fitting associated with standard manufacturing methods. The question though arises whether devices which may be macroscopically similar, serve identical functions, and be produced from the same polymeric material, in fact interact in the same manner with living tissue. Here we will discuss the differences in the surface structures produced by these manufacturing methods and the interactions of dental pulp stem cells with structures of multiple length scales as they impact cell differentiation and tissue mineralization.

In collaboration with Kuan Che Feng, Mariah Geritano, Michael Cuiffo, and Gary Halada, Materials Science and Engineering, Stony Brook University; Adriana Pinkas-Sarafova, Oral Biology and Pathology and Materials Science and Engineering, Stony Brook University; Sihana Rugova, Oral Biology and Pathology, Stony Brook University; and Miriam Rafailovich, Materials Science and Engineering, Stony Brook University.

1:03PM M19.00004 Novel Patterning Approaches for Continued Device Scaling, FLORIAN Gstrein, Intel Corporation — Top-down patterning techniques based on optical lithography have made semiconductor products ever more powerful, ubiquitous and affordable. This is largely due to the ability of conventional lithographic techniques to transfer trillions of mask features to wafers at defect densities approaching virtually zero throughout high-volume manufacturing. As features continue to shrink, the ability to print and to correctly place tight-pitch patterns have quickly emerged as two of the greatest challenges to scaling. Given the fundamental physical limitations of conventional optical lithography, complimentary patterning techniques and bottom-up patterning approaches are needed to overcome shortcomings in resolution and pattern placement accuracy. This presentation will focus on the enabling role novel materials can play in achieving both critical dimension scaling and reduced pattern placement errors. The talk will first outline how extreme UV lithography (EUV) and directed self-assembly (DSA) can simplify patterning and improve multilayer pattern placement by reducing the number of masks and associated overlay steps required to achieve the desired resolution. Novel EUV resist materials require amplification mechanisms that overcome acid blur and new strategies to improve shot noise limitations and mechanical stability. For DSA, novel block co-polymers are needed with a higher chi parameter to yield tighter pitch and improved roughness. The second part of the talk will highlight opportunities for self-aligned patterning with a special emphasis on the emerging field of selective deposition. Atomic layer deposition (ALD) is derived from the chemical nature of precursors and co-reactants. The ability of these molecules to recognize chemical functionalities and surfaces, results in the deposition of thin films only where they are desired. Selective deposition is a powerful and so far unexploited patterning tool capable of further reducing or even eliminating pattern placement errors.

Wednesday, March 4, 2015 11:15AM - 1:45PM
Session M20 FEb: Invited Session: Reichert Award Session: Re-imagining the Advanced Lab Ballroom B - Randall Knight, California Polytechnic State University

11:15AM M20.00001 Reichert Award Talk: Preparing Physics Students in an Era of Virtual Reality, CARL Akerlof, RAMON TORRES-ISEA, University of Michigan — Like many other institutions with a large and active faculty, the University of Michigan Physics Department has a rich curriculum of undergraduate courses that focus on the use of 19th Century mathematics to understand the behavior of matter and energy. Most people who have pursued a career in this field appreciate that success usually depends on a much wider variety of skills. Addressing those needs has been the major emphasis of our undergraduate advanced lab program. This covers a broad range of topics. First of all, physics will continue to enlarge its encroachment into new areas. Thus, we have added experiments in radio astrophysics and non-linear dynamics. Computational and statistical methods are integrated into the experiments as appropriate and development of effective communication skills is heavily stressed. While there are efforts elsewhere to replace traditional hands-on experimentation with simulations, interactive video-based laboratory modules, and remotely controlled laboratory experiments, we consider these tools to be appropriate only for pre-lab and post-lab activities. None of these tools can provide the long-lasting experimental skills and knowledge-packed memories that a well-designed teaching experiment can. Hence, we choose to focus on providing a comprehensive list of experiments in a safe, well-equipped, teaching environment. The overall guiding principle is to provide a multi-faceted introduction to a rewarding career in science.

11:45AM M20.00002 A hands-on introduction to quantum mechanics, DAVID JACKSON, Dickinson College — At Dickinson College, we have designed a series of experiments that are designed to expose students to the strange and fascinating world of quantum mechanics. These experiments are employed in our sophomore-level course titled Introduction to Relativistic and Quantum Physics, our version of the traditional Modern Physics course. The experiments make use of a correlated light source produced via the process of Spontaneous Parametric Down Conversion (SPDC). Using such a light source, students can experimentally verify that when a single photon is incident on a beam splitter, the photon is either transmitted or reflected — it never goes both ways. If instead the photons are directed into a Mach-Zehnder interferometer, students then observe an interference pattern, suggesting that each photon must somehow take both paths in the interferometer (in apparent contradiction of the first experiment). Finally, the interference pattern is observed to disappear if the photons are “tagged” to distinguish which path they take, only to mysteriously reappear if that path information is “erased” after emerging from the interferometer. In this talk, I will provide an overview of these experiments and the accompanying theory that students learn in this course.

This work was supported, in part, by NSF grant 0737230.
12:15PM M20.00003 Preparing students for experimental research through instructional labs, HEATHER LEWANDOWSKI, University of Colorado — Preparing undergraduate physics majors for future careers in experimental science is one of the main goals of our current physics education system. At the University of Colorado, we have been working to transform our upper-division laboratory courses to better prepare students for future undergraduate, industrial, or graduate experimental work. Through this process, we have developed learning goals, curricular materials, and assessments for two upper-division lab courses. The transformation process and measured outcomes will be presented.

12:45PM M20.00004 Autonomy, D.A. VAN BAALK, TeachSpin, Inc. — Advanced-laboratory experiences have long been a formative part of the undergraduate curriculum, and this presentation reviews some of the purposes that they serve. One under-acknowledged purpose for these laboratories is the role they serve in cultivating students’ capacity for exercising autonomy as scientists. Overt recognition of this implicit purpose of laboratory courses has implications for the organization and execution of such courses.

1:15PM M20.00005 Investigating student learning in upper-division laboratory courses on analog electronics1, MACKENZIE STETZER, University of Maine — There are many important learning goals associated with upper-division laboratory instruction; however, until recently, relatively little work has focused on assessing the impact of these laboratory-based courses on students. As part of an ongoing, in-depth investigation of student learning in upper-division laboratory courses on analog electronics, we have been examining the extent to which students enrolled in these courses develop a robust and functional understanding of both canonical electronics topics (e.g., diode, transistor, and op-amp circuits) and foundational circuits concepts (e.g., Kirchhoff’s laws and voltage division). This focus on conceptual understanding is motivated in part by a large body of research revealing significant student difficulties with simple dc circuits at the introductory level and by expectations that students finish electronics courses with a level of understanding suitable for building common, practical circuits in a real-world environment. Recently, we have extended the scope of our investigation to include more laboratory-focused learning goals such as the development of (1) troubleshooting proficiency and (2) circuit chunking and design abilities. In this talk, I will highlight findings from written questions and interview tasks that have been designed to probe student understanding in sufficient depth to identify conceptual and reasoning difficulties. I will also use specific examples to illustrate the ways in which this research may inform instruction in upper-division laboratory courses on analog electronics.

11:15AM M21.00001 Measurement and Instrumentation Challenges at X-ray Free Electron Lasers1, YIPING FENG, SLAC National Accelerator Laboratory — X-ray Free Electron Laser sources based on the Self Amplified Spontaneous Emission process are intrinsically chaotic, giving rise to pulse-to-pulse fluctuations in all physical properties, including intensity, position and pointing, spatial and temporal profiles, spectral content, timing, and coherence. These fluctuations represents special challenges to users whose experiments are designed to reveal small changes in the underlying physical quantities, which would otherwise be completely washed out without using the proper diagnostics tools. Due to the X-ray FEL’s unique characteristics such as the unprecedented peak power and nearly full spatial coherence, there are many technical challenges in conceiving and implementing these devices that are highly transmissive, provide sufficient signal-to-noise ratio, and most importantly work in the single-shot mode.

1Portions of this research were carried out at the Linac Coherent Light Source (LCLS) at the SLAC National Accelerator Laboratory. LCLS is an Office of Science User Facility operated for the U.S. Department of Energy Office of Science by Stanford Univ.

12:27PM M21.00003 LCLS-II: Upgrade Plans for the Linac Coherent Light Source–Including New Scientific Opportunities1, WILLIAM SCHLOTTER, LCLS, SLAC National Accelerator Laboratory, LCLS-II TEAM — The Linac Coherent Light Source (LCLS) is planning a major upgrade that will provide revolutionary new scientific capabilities for exploring materials on the atomic and nano-scale with element specificity and ultrafast temporal resolution. The LCLS is an x-ray free electron laser with six experimental instruments accessible via a peer-reviewed proposal process. The upgraded LCLS-II facility will continuously deliver ultrafast x-ray pulses at repetition rates greater than 100kHz with photon energies tunable between 250 eV and 5 keV. The upgrade will also produce pulses with photon energies as high as 25 keV at a repetition rate of 120 Hz. These capabilities will enable new scientific methods that will revolutionize the study of highly correlated electron systems, magnitization dynamics and nanoscale fluctuations in soft matter to name a few. Expected capabilities and prospective experimental examples will be presented.

1The Linac Coherent Light Source (LCLS) at the SLAC National Accelerator Laboratory. LCLS is an Office of Science User Facility operated for the U.S. Department of Energy Office of Science by Stanford University.

12:39PM M21.00004 Fourier transform inelastic x-ray scattering from phonons using Free Electron Laser pulses, MARIANO TRIGO, SLAC/Stanford University, THOMAS HENIGHAN, Stanford University, DAVID REIS, SLAC/Stanford University — We demonstrate that ultrafast x-ray scattering at Free Electron Lasers (FELs) provides a new approach for measuring phonon dispersion relations spanning the entire Brillouin zone, without the need for complex monochromators and spectrometers. Our method uses an ultrafast optical laser as pump and the dynamics are probed using femtosecond x-ray pulses from an FEL. We obtain the entire transverse acoustic phonon dispersion in germanium with ~ 0.5 meV energy resolution by a simple Fourier transform of the oscillatory dynamics of the scattered x-ray intensity. Using coherent control with a pair of pump pulses, we show that the femtosecond laser couples to pairs of phonons, analogous to a second order Raman scattering mechanism, which also explains the excitation of large-wavevector phonons by the long wavelength (optical) pump pulse. This shows that the generation mechanism is quite general and thus this ultrafast approach could be applicable as a general spectroscopic tool of phonons near to and far from equilibrium.

12:51PM M21.00005 ABSTRACT WITHDRAWN –
The frequency of the AIDT excitation. Diffraction measurements of a Pt thin film grown on the LiNbO
the strain is identical to that measured using light reflectivity. From x-ray diffraction measurements, we obtained a quantitative measure of the strain amplitude,
the ring frequency of the Advanced Photon Source, where x-ray diffraction measurements were carried out with a focus of 7
µ3
follow the constant velocity curve of the piezoelectric surface to focus the strain wave over a small focal area. A detailed analysis of the strain around the focal
waves can be used to determine the charge and vibrational asymmetry in the bulk crystal. These effects are demonstrated with in situ synchrotron x-ray scattering measurements on S(111)7x7 surfaces with and without Ag films.

A MEMS-based device used for alignment and manipulation of MLL x-ray focusing optics, WEIHE XU, KENNETH LAUER, HUI YAN, Brookhaven Natl Lab, VELIKO MILLANOVIĆ, Mirrorce Technologies, Inc, EVGENY NAZARETSKI, Brookhaven Natl Lab, BROOKHAVEN NATL LAB TEAM, MIRRORCLE TECHNOLOGIES, INC. TEAM — Multilayer Laue lenses (MLLs) X-ray microscopy is a powerful tool used for materials research. To push the spatial resolution of x-ray microscopy studies below 10 nm the system needs to be compact and rigid. Applications of MEMS based tip-tilt stages used for alignment and manipulation of nanofocusing optics is a promising route to achieve high stability. In this work, we report characterization and stability testing of a MEMS device suitable for manipulation of nanofocusing optics. We developed two closed-loop circuits implemented in a MEMS tip-tilt device utilizing capacitive and laser interferometry techniques. Test results demonstrate better than 10 mille-degree resolution when using capacitive sensors and better than 0.8 mille-degree resolution when using interferometry sensing respectively.

Forbidden Reflections in X-ray Crystal Truncation Rods: Using Surface Reference Waves to Distinguish Charge and Vibrational Asymmetry in Bulk Silicon1, JESSE KREMEN-NAK, YIYAO CHEN, SHAWN HAYDEN, MICHAEL GRAMLICH, PAUL MICELI, University of Missouri — X-ray reflections from diamond crystal structures with Miller indices that satisfy h+k+l = 4n+2, where n is an integer, are considered to be forbidden by crystal symmetry. However, asymmetry from valence charge distribution as well as anharmonic vibrations break the symmetry and result in non-zero intensity “forbidden reflections.” Due to the absence of phase information, considerable effort, involving combined temperature-dependent x-ray and neutron scattering studies, was previously required to determine the contributions of charge and vibrations to these reflections. In the present work, we demonstrate that useful phase information can be gained in x-ray reflectivity and crystal truncation rod measurements where there is interference between waves scattered from the bulk and the surface. In this manner, surface reference waves can be used to determine the charge and vibrational asymmetry in the bulk crystal. The DOD-AFOSR Award FA9550-14-1-0363 and the LANSCE-ROSEN Professorship supported work at NMSU/LANL. Research at UCSD was supported by the NSF & NIH/NIGMS via NSF award DMR-1332208.

Phonon Mapping in Flowing Equilibrium1, J.P.C. RUFF, CHESS, Cornell University — When a material conducts heat, a modification of the phonon population occurs. The equilibrium Bose-Einstein distribution is perturbed towards flowing-equilibrium, for which the distribution function is not analytically known. Here I argue that the altered phonon population can be efficiently mapped over broad regions of reciprocal space, via diffuse x-ray scattering or time-of-flight neutron scattering, while a thermal gradient is applied across a single crystal sample. When compared to traditional transport measurements, this technique offers a superior, information-rich new perspective on lattice thermal conductivity, wherein the band and momentum dependences of the phonon thermal current are directly resolved. The proposed method is benchmarked using x-ray thermal diffuse scattering measurements of single crystal diamond under transport conditions.

CHESS is supported by the NSF & NIH/NIGMS via NSF award DMR-1332208.

Mapping of Strain Inhomogeneity within a Single Ni-NiO Core-Shell Nanoparticle using Bragg Coherent Diffraction Imaging1, ERANDI WIJERATHNA, NMSU, R. HARDER, APS, Argonne National Laboratory, J. CLARK, SLAC National Accelerator Laboratory, B. KIEFER, NMSU, E. FULLERTON, O. SHPYRKO, UCSD, E. FOHTUNG, NMSU — We report on recent progress in mapping strain inhomogeneity within a single core/shell ferromagnetic/antiferromagnetic Ni-NiO nanoparticle (NP) using Bragg Coherent X-ray Diffraction Imaging (CXDI). By collecting CXD maps from the NP in the vicinity of two different reciprocal lattice points we observe variations in the sign and magnitude displacement gradients within the core and shell regions indicative of anisotropy and inhomogeneity. We utilize computations with atomic resolution to model a guess of the deformations within the core structure. This serves as guide for apriori support. Finite difference analysis is used alongside CXDI to reconstruct the core-shell regions. This approach opens new avenues in studying buried structures and multifunctional properties using CXDI.

Work at UNL is supported by NSF Grant No. 1409622 and MRSEC DMR-0820521, and at Argonne by DE-AC02-06CH11357.

Measurement of fast dynamic strain generated by focusing of surface acoustic waves1, UDAY SINGH, Univ of Nebraska - Lincoln, Y. LI, D.A. WALKO, Argonne National Lab, S. ADENWALLA, Univ of Nebraska - Lincoln — We have measured the spatial and temporal dependence of high frequency (88 MHz) strain waves in a focused surface acoustic wave (FSAW). Increasing the strain generated by a SAW to levels that are comparable with epitaxial strains in thin films (~ 1%) necessitate annular inter-digital transducers (AIDT) that follow the constant velocity curve of the piezoelectric surface to focus the strain wave over a small focal area. A detailed analysis of the strain around the focal center of an AIDT patterned on 128 Y-cut LiNbO3 shows shifts in the (104) x-ray diffraction peak. The AIDT spacing was chosen to produce a resonance at the ring frequency of the Advanced Photon Source, where x-ray diffraction measurements were carried out with a focus of 7 µm. The spatial dependence of the strain is identical to that obtained measuring light reflectivity. From x-ray diffraction measurements, we obtained a quantitative measure of the strain amplitude, 0.5% at an AIDT excitation power of 24 dBm. The temporal dependence showed a sinusoidally varying strain that cycles between compressive and tensile at the frequency of the AIDT excitation. Diffraction measurements of a Pt thin film grown on the LiNbO3 show significant strain transfer. These data lay the groundwork for future experiments that involve tuning the physical properties of strain sensitive thin film materials at high frequencies.

Work at UNL is supported by NSF Grant No. 1409622 and MBSEC DMR-0820521, and at Argonne by DE-AC02-06CH11357.

Wednesday, March 4, 2015 11:15 AM - 2:03 PM –
Session M22 DCMP: Heavy Fermions: Ce-115 and Yb-based Compounds: Experiment 202A -
Steven Dissler, NIST
11:15AM M22.00001 An Angle Resolved Photoemission Survey of the Band Structure of the Heavy Fermion Superconductor, CeCoIn$_5$.

THEODORE REBER, JONATHON RAMEAU, RONGWEI HU, CEDOMIR PETROVIC. peter johnson, Brookhaven National Lab — With the highest $T_c$ of the non-radioactive heavy fermion materials, CeCoIn$_5$ has been extensively studied by a host of techniques. However direct measurements of the band structure via angle resolved photo-emission spectroscopy has been limited to just a few experiments. We will present our studies of the momentum, temperature, photon energy and polarization dependence of the band structure of CeCoIn$_5$. We will compare our results with theory and other experimental results.

1Present address: Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University

11:27AM M22.00002 Landau Renormalizations of Superfluid Density in the Heavy-Fermion Superconductor CeCoIn$_5$.

LEI SHU, Fudan University, D.E. MACLAUGHLIN, C.M. VARMA, UC Riverside, O.O. BERNAL, California State U. LA, P.-C. HO, R.H. FUKUDA, California State U. Fresno, X.P. SHEN, Fudan University, M.B. MAPLE, UC San Diego — The formation of heavy fermion (HF) bands can occur by means of the conversion of a periodic array of local moments into itinerant electrons via the Kondo effect and the huge consequent Fermi-liquid(FL) renormalizations. Leggett predicted for liquid $^3$He that FL renormalizations change in the superconducting state, leading to a temperature($T$) dependence of the London penetration depth $\lambda$ quite different from that in the BCS theory. Using Leggett’s theory, as modified for HF, it is possible to extract from the measured $T$ dependence of $\lambda$ in high quality samples both Landau parameters $F_0$ and $F_1$; this has never been accomplished before. A modification of the $T$ dependence of the specific heat $C_\lambda$, related to that of $\lambda$, is also expected. We have carefully determined the magnitude and $T$ dependence of $\lambda$ in CeCoIn$_5$ by muon spin relaxation rate measurements to obtain $F_0=36\pm1$ and $F_1=1.2\pm0.3$, and find a consistent change in the $T$ dependence of electronic specific heat $C_\lambda$. This, the first determination of $F_1$ with a value $< F_0$ in a HF compound, tests the basic assumption of the theory of HF, that the frequency dependence of the self-energy is much more important than its momentum dependence.

1This research is supported by the NSF of China (11204041), NSF of Shanghai (12ZR1401200), USDoE (DE-FG02-04ER46105), and U.S. NSF(DMR 0802478, 0801407, 1206298, 1104544, 1105380).

ELI LEVENSON-FALK, JOSHUA STRAUQUADINE, ELIZABETH SCHEMM, AHARON KAPITULNIK, Stanford University, PRISCILLA ROSA, ZACHARY FISK, Department of Physics, UC Irvine — The heavy-fermion superconductor CeCoIn$_5$ is of great interest, as it shares many features with high-$T_C$ d-wave superconductors, with unconventional pairing and competition between superconducting and magnetic phases. Understanding the mechanisms of superconductivity in this material can elucidate the physics of high-$T_C$ and of unconventional superconductivity in general. We present measurements of the polar Kerr effect in CeCoIn$_5$ using a zero-area Sagnac interferometer. We observe an onset of Kerr rotation near the superconducting transition temperature, indicating an order parameter which breaks time reversal symmetry. We discuss the relation of this symmetry breaking to the superconducting state, and place our measurement in context with other experiments on this material.

11:51AM M22.00004 Ultrafast dynamics in CeCoIn$_5$.

INNA VISHIK, FAHAD MAHMOOD, ZHANYBEK ALPICHSHEV, Massachusetts Institute of Technology, SHANTA SAHA, JOHNPIERRE PAGLIONE, University of Maryland, College Park, NUH GEDIK, Massachusetts Institute of Technology — We present ultrafast pump-probe and transient grating spectroscopy studies of the heavy Fermion superconductor CeCoIn$_5$. In pump-probe experiments, a 100-femtosecond 800nm-wavelength pulse creates transient electronic excitations whose decay is probed by studying transient changes in reflectivity as a function of time. We observe changes in pump-probe decay dynamics across the Kondo coherence temperature. In transient grating spectroscopy, two pump-pulses are interfered to produce a spatially periodic excitation, and the system’s response to this periodic perturbation is studied through a diffracted probe beam. The temporal evolution of this signal indicates a non-trivial motion of the excitation grating in the heavy electron regime.

12:03PM M22.00005 Field induced density wave in the heavy fermion compound CeRhIn$_5$.

PHILIP MOLL, Department of Physics, University of California, Berkeley, California 94720, USA, BIN ZENG, LUIIS BALICAS, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32310, USA., STANISLAW GALESKI, Solid State Physics Laboratory, ETH Zurich, Switzerland, FEDOR BALAKIREV, National High Magnetic Field Laboratory, LANL, E536, Los Alamos, NM 87545, USA, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory, Los Alamos, NM 87545, USA.187 — We will present evidence for a magnetic field induced phase-transition to a state akin to a density-wave (DW) in the heavy fermion superconductor CeRhIn$_5$. The DW state is signaled by a hysteretic anomaly in the in-plane resistivity accompanied by the appearance of non-linear electrical transport at high magnetic fields ($>27T$), which are distinctive characteristics of density-wave states. The differential resistance $dV/dI$ is strongly suppressed by currents in excess of an critical electric field $E_c$, 15mV/cm, which would be a typical value for depinning thresholds in incommensurate density waves such as NbSe$_2$ or TaS$_2$. Intriguingly, the out-of-plane resistivity as well as the magnetic torque remain unaffected by the transition.

12:15PM M22.00006 Observation of field-induced Fermi surface reconstruction in CeRhIn$_5$.

HUIQIU YUAN, LIN JIAO, ZONGFA WENG, YE CHEN, Zhejiang Univ, FRANK STEGLICH, Zhejiang Univ/Max-Planck Institute for Chemical Physics of Solids, DAVID GRAF, Florida State University, JOHN SINGLETON, MARCELO JAIME, ERIC BAUER, JOE THOMPSON, Los Alamos National Lab — CeRhIn$_5$ provides a prototype compound for studying quantum criticality and its interplay with superconductivity. Application of pressure suppresses the antiferromagnetic (AF) order and gives rise to superconductivity [1]. A sharp change of Fermi surface was observed just at the pressure-tuning AF quantum critical point (QCP) [2], which was argued to support the scenario of local quantum criticality [3]. By measuring the dHvA oscillations and specific heat in a pulsed magnetic field, we have demonstrated the existence of a field-induced AF QCP around $B_c$=50T in this compound [4]. In this presentation, we will report the measurements of dHvA effect and Hall resistivity of CeRhIn$_5$ performed by using the 45T hybrid magnet and the pulsed field magnet at NHMFL. Field-induced changes of the dHvA frequencies and Hall coefficient are observed around $B^*=31T$. Detailed analyses suggest that the Fermi surface reconstruction at $B^*$ corresponds to a localized-itinerant transition of Ce 4f-electrons attributed to the Kondo effect. Our results indicate that multiple quantum phase transitions may exist in CeRhIn$_5$ which can be classified by the measurements of Fermi surface topology. [1] T. Park et. al., Nature 440, 65 (2006). [2] H. Shishido et. al., J Phys Soc Jpn 74, 1103 (2005). [3] Q. Si, F. Steglich, Science 329,1161 (2010). [4] L. Jiao et al., arXiv:1308.0294.
12:27PM M22.00007 The magnitude of the magnetic exchange interaction in the heavy fermion antiferromagnet CeRhIn$_5$; P. DAS, Ames Laboratory, IA, USA; Los Alamos National Laboratory, NM, USA, S.-Z. LIN, N.I. GHIMIRE, F. RONNING, E.D. BAUER, J.D. THOMPSON, C.D. BATISTA, M. JANOSCHEK, Los Alamos National Laboratory, NM, USA, K. HUANG, University of California, San Diego, CA, USA, G. EHLERS, Oak Ridge National Laboratory, TN, USA — The family of heavy fermion compounds CeTIn$_5$ ($T=Co$, Rh, Ir) has been a fertile ground to explore and understand the interplay between magnetism, unconventional superconductivity, and quantum criticality due to their tunability by pressure, substitution and magnetic field. CeRhIn$_5$ is a heavy fermion antiferromagnet which can be tuned to quantum criticality under pressure. The strength of the magnetic exchange interaction, which is a key parameter to understand its complex properties, however remained unknown. We have used high-resolution neutron spectroscopy to determine the complete spin wave spectrum in CeRhIn$_5$. The spin wave dispersion can be quantitatively reproduced with a simple frustrated $J_1-J_2$ model that also naturally explains the magnetic spin-spiral ground state of CeRhIn$_5$ and yields a dominant in-plane nearest-neighbor magnetic exchange constant $J_0 = 0.74(3)$ meV. Our results pave the way to a quantitative understanding of the rich low-temperature phase diagram of the prominent CeTIn$_5$ class of heavy fermion materials.

1Work at LANL was performed under the auspices of the US DOE, OBES, MSE division and partly funded by LDRD.

12:39PM M22.00008 Fine tuning of the quantum criticality in the heavy fermion superlattices CeRhIn$_5$/YbRhIn$_5$; RYOTA ENDO, RINTARO TODA, YOUSUKE HANAOA, MASAaki SHIMOZAWA, TAKUYA YAMASHITA, YUSUKE SHIMOYAMA, SHIGERU KASAHARA, YOSHI TOWKI, YUITI KASAHARA, Kyoto University, TAKASADA SHIBAUCHI, The university of Tokyo, TAKAHITO TERASHIMA, YUJI MATSUDA, Kyoto University — Bulk CeRhIn$_5$ shows an antiferromagnetic order at $T_N=3.8$ K. Using molecular beam epitaxy, we fabricate artificial superlattices CeRhIn$_5$(m)/YbRhIn$_5$($n$) containing $m$ layers of CeRhIn$_5$, alternating with seven layers of the nonmagnetic metal YbRhIn$_5$. With decreasing $m$, $T_N$ is seriously reduced and nearly vanishes at the $m=3$, indicating the dimensional tuning of the quantum critical point. When the magnetic field is applied to $m=3$ superlattice perpendicular to the plane, $T$-linear resistivity, a hallmark of non-Fermi liquid, persists down to 50 mK, demonstrating the fine tuning of the quantum critical point.

12:51PM M22.00009 Pressure studies of the quantum critical alloy Ce$_{0.93}$Yb$_{0.07}$CoIn$_{13}$; Y.P. SINGH, D.J. HANEY, X.Y. HUANG, Kent State University, B.D. WHITE, M.B. MAPLE, University of California, San Diego, M. DZERO, C.C. ALMASAN, Kent State University — We performed experimental and theoretical studies of the effect of pressure on the heavy fermion quantum critical alloy Ce$_{0.93}$Yb$_{0.07}$CoIn$_{13}$. As observed in resistivity measurements, the Ce$_{1-x}$Yb$_x$CoIn$_{13}$ system exhibits non-Fermi liquid behavior with two distinct contributions to resistivity (linear-in-$T$ and square-root-in-$T$). Our measurements suggest that linear in $T$ resistivity is governed by heavy/large Fermi surface and is suppressed with pressure, together with the suppression of the quantum fluctuations with pressure in Ce$_{0.93}$Yb$_{0.07}$CoIn$_{13}$. The square-root-in-$T$ dependence originates from two different physics: (i) the $\sqrt{T}$ dependence just above $T_c$ is suppressed with the application of pressure, and is a result of superconducting fluctuations; (ii) the higher temperature $\sqrt{T}$ contribution to resistivity remains insensitive to pressure, indicating that the scattering processes in this $T$ range are governed by the scattering of light electrons from the small Fermi surface. We demonstrate that the growth of the coherence temperature with pressure, as well as the decrease of the residual resistivity, can be accurately described by employing the coherent potential approximation for a disordered Kondo lattice.

1:03PM M22.00010 Chemical substitution study on magnetism and superconductivity in Ce$_{1-x}$Sm$_x$CoIn$_{13}$; SOOYOUNG JANG, B.D. WHITE, D. YAZICI, A.S. WONG, M.B. MAPLE, Department of Physics, University of California, San Diego, La Jolla, CA 92039, USA — We have investigated the system Ce$_{1-x}$Sm$_x$CoIn$_{13}$ ($0 < x < 1$) by means of x-ray diffraction, electrical resistivity, specific heat, and magnetization measurements. We observe a crossover from a coherent Kondo lattice exhibiting superconductivity to a single-ion impurity Kondo effect coexisting with magnetic order on the Sm-rich side of the phase diagram. The superconducting transition temperature, $T_c$, and Kondo lattice coherence temperature, $T_K$, are suppressed near $x \sim 0.2$ and $x \sim 0.5$, respectively, which is consistent with the effect of substitution with other rare-earth (RE) ions on CeCoIn$_{13}$. After $T_{coh}$ is suppressed to 0 K, a single-ion impurity Kondo effect is observed for 0.5 $< x \leq 0.85$. The compound SmCoIn$_{13}$ exhibits three distinct magnetic phase transitions at roughly 8, 10, and 12 K, which are presumably associated with magnetic order; similar features are observed in the related compound SmIn$_3$. These transition temperatures are gradually suppressed by Ce substitution and completely vanish near $x \sim 0.2$. We establish the phase diagram of the system Ce$_{1-x}$Sm$_x$CoIn$_{13}$ and compare our results with those obtained from chemical substitution studies of CeCoIn$_{13}$ involving other RE ions.

1:15PM M22.00011 Tuning the Kondo effect in YbFe$_{1-x}$Co$_x$Zn$_{20}$; TAI KONG, VALENTIN TAUFOUR, SERGEY BUD’KO, PAUL CANFIELD, Ames Laboratory / Iowa State University — YbCo$_{20}$Zn$_{30}$ is a heavy fermion compound with a Sommerfeld coefficient, $\gamma$, value, of about 8000 mJ/mol-K$^2$ with an estimated single ion Kondo temperature, $T_K$, of about 1.5 K. One the other hand, YbFe$_2$Zn$_{20}$ is less heavy with an $\sim 500$ mJ/mol-K$^2$ and $T_K \sim 30$ K. From a generalized Kadowaki-Woods picture, degeneracies that relate to their Kondo phenomena are large while different: 8 for YbFe$_2$Zn$_{20}$ and 4 for YbCo$_{20}$Zn$_{30}$. In order to understand the effects of Fe-Co substitution on the Kondo effect, a family of YbFe$_{1-x}$Co$_x$Zn$_{20}$ were studied. We performed zero-field resistivity and specific heat measurements on single crystals of YbFe$_{1-x}$Co$_x$Zn$_{20}$ that were synthesized using a high-temperature solution growth technique [2]. The Kondo characteristic temperatures do not change monotonically in between pure YbFe$_2$Zn$_{20}$ and YbCo$_{20}$Zn$_{30}$. Data and a summarize phase diagram of characteristic temperatures as a function of Co doping will be presented and discussed.

1:27PM M22.00012 Thermal expansion and quantum criticality of the heavy fermion antiferromagnet YbBiP; RISHI BHANDIA, Occidental College, E.D. MUNN, Simon Fraser University, S.L. BUD’KO, P.C. CANFIELD, Ames Laboratory/Iowa State University, G.M. SCHMIEDESOff, Occidental College — YbBiP is a stoichiometric heavy fermion compound with an enormous Sommerfeld coefficient and an antiferromagnetic ground state that is suppressed by magnetic fields of about 0.4 T. Non-Fermi liquid behavior, and other signatures of field-induced quantum criticality have been observed. In this talk we will present measurements of the thermal expansion of YbBiP along the [111] axis from 30K to below 400 mK and in magnetic fields as high as 9 T. We will discuss the implications of our measurements on the quantum criticality of YbBiP and we will discuss an unusual feature in the data near 5K. Work at Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358. Work at Occidental College was supported by the National Science Foundation under DMR-1408598.
1:39PM M22.00013 Hybridization and coherence in the intermediate valence compound YbAl$_3$ via quasiparticle scattering spectroscopy (QPS). L.H. GREENE, S.M. NARASIWODEYAR, M. DWYER, W.K. PARK, University of Illinois at Urbana-Champaign, P.C. CANFIELD, Iowa State University — Band renormalization and hybridization in Anderson lattices has been a subject of continued interest [1]. The intermediate valence compound YbAl$_3$, which does not order magnetically nor superconducts, is a good model system for the study of the hybridization process. A microscopic understanding is still lacking although some characteristic temperature and energy scales have been identified. As shown by our previous works [1,2], QPS is a powerful tool to investigate the hybridization process via measurement of the hybridization gap. Here we report our recent QPS results on YbAl$_3$ [3]. Conductance spectra over a wide temperature range indicate that the hybridization process begins around 110 K, a new temperature scale found in this study, well before the full coherence is achieved (∼34 K). Our observations agree with the slow crossover scenario discussed recently in the literature [4]. The hybridization gap opens concomitantly with the emergence of a coherent Fermi liquid, suggesting that its measurement can be a more rigorous way to define the coherence temperature. *The work at UIUC is supported by the NSF DMR 12-06760 and the work done at Ames Lab. was supported under Contract No. DE-AC02-07CH11358.

1:51PM M22.00014 Visualizing Heavy Fermions in Thin Films by in situ ARPES. SHOUVIK CHATTERJEE, DARRELL SCHLOM, KYLE SHEN, Cornell University — Heavy Fermions are an important class of materials, which has attracted a lot of interest as they seemingly host a number of exotic ground states viz. unconventional superconductivity, Quantum Critical Fermi Liquid, FFLO states etc. Stabilizing these materials in a thin film form and extracting their spectral function via ARPES opens up new possibilities of dimensional and strain tunability and in understanding and designing materials with exotic emergent properties. I will present our recent efforts in stabilizing thin films of Yb based heavy fermion compound YbAl$_3$ and the conventional metal analog LuAl$_3$ on MgO substrates. With the aid of an Al buffer layer crystalline, phase pure and fully-oriented epitaxial thin films can be grown with sub-nm surface roughness. Using in situ angle resolved photoemission we, for the first time have been able to directly map out their electronic bandstructure and Fermi Surface. Measurements on LuAl$_3$ were found to be in good agreement with ab-initio calculations that provided us with an excellent reference to identify the signatures of heavy fermion formation in YbAl$_3$.

Wednesday, March 4, 2015 11:15AM - 1:51PM –
Session M23 DCOMP: Focus Session: Petascale Science and Beyond: Applications and Opportunities in Materials Science and Chemistry II
202B - Barry Schneider, National Institute for Standards and Technology

11:15AM M23.00001 DAG Software Architectures for Multi-Scale Multi-Physics Problems at Petascale and Beyond. MARTIN BERZINS, SCI INSTITUTE, UNIVERSITY OF UTAH — The challenge of computations at Petascale and beyond is to ensure how to make possible efficient calculations on possibly hundreds of thousands for cores or on large numbers of GPUs or Intel Xeon Phis. An important methodology for achieving this is present thought to be that of asynchronous task-based parallelism. The success of this approach will be demonstrated using the Uintah software framework for the solution of coupled fluid-structure interaction problems with chemical reactions. The layered approach of this software makes it possible for the user to specify the physical problems without parallel code, for that specification to be translated into a parallel set of tasks. These tasks are executed using a runtime system that executes tasks asynchronously and sometimes out-of-order. The scalability and portability of this approach will be demonstrated using examples from large scale combustion problems, industrial detonations and multi-scale, multi-physics models. The challenges of scaling such calculations to the next generations of leadership class computers (with more than a hundred petalapps) will be discussed.

*3Thanks to NSF, XSEDE, DOE NNSA, DOE NETL, DOE ALCC and DOE INCITE

11:51AM M23.00002 High performance electronic structure engineering. MARCO GOVONI, GIULIA GALLI, Institute for Molecular Engineering, The University of Chicago, Materials Science Division, Argonne National Laboratory — We discuss the efficiency of a recently proposed method for the calculation of energy levels in condensed and finite systems with density functional theory and many-body perturbation theory at the GW level. We present applications of this technique to the calculation of electronic properties of systems with thousands of electrons, including semiconductor nanoparticles, solid/liquid interfaces and defective materials. In addition we discuss the parallel performance and scalability on high performance architectures of a newly developed code [1], implementing the method.

12:03PM M23.00003 Excited calculations of large scale multiwalled nanotubes using real-space pseudopotential methods. CHARLES LENA, JAMES CHELIKOWSKY, University of Texas at Austin, JACK DESLIPPE, National Energy Research Scientific Computing Center, YOUSEF SAAD, University of Minnesota, CHAO YANG, Lawrence Berkeley National Laboratory, STEVEN G. LOUIE, University of California at Berkeley and Lawrence Berkeley National Laboratory — One method for calculating excited states is the GW method. The GW method has many computational requirements. One of the bottlenecks is the calculation of numerous empty states. Within density functional theory, we use a real-space pseudopotential method (PARSEC) to calculate these empty states for multiwalled nanotubes. We illustrate the use of these empty states for calculating excited states using the GW method (BerkeleyGW). We demonstrate why using real-space density functional theory is advantageous for calculating empty states.

12:15PM M23.00004 Scalable real space pseudopotential-density functional codes for materials applications

JAMES R. CHELIKOWSKY, CHARLES LENA, GRADY SCHOFIELD, University of Texas at Austin, YOUSEF SAAD, University of Minnesota, JACK DESLIPPE, National Energy Research Scientific Computing Center, CHAO YANG, Lawrence Berkeley National Laboratory — Real-space pseudopotential density functional theory has proven to be an efficient method for computing the properties of matter in many different states and geometries, including liquids, wires, slabs and clusters with and without spin polarization. Fully self-consistent solutions have been routinely obtained for systems with thousands of atoms. However, there are still systems where quantum mechanical accuracy is desired, but scalability proves to be a hindrance, such as large biological molecules or complex interfaces. We will present an overview of our work on new algorithms, which offer improved scalability by implementing another layer of parallelism, and by optimizing communication and memory management.

12:27PM M23.00005 Numerical solutions of the time-dependent Schroedinger equation for atoms and molecules in intense laser fields

XIAOXU GUAN, Louisiana State University — Recent progress in ab initio computational methods allows us to treat the laser-atom, laser-molecule interaction, and other collision processes with improved accuracy. Full-dimensional quantum calculations for even a few particles are extremely demanding because of the unfavorable scaling of the full quantum wave function, but they are of significant importance for understanding the entangled response of electrons and nuclei in a system strongly influenced by intense lasers and particle beams. In this talk I will concentrate on the applications of grid-based approaches to the time-dependent problems of atoms and molecules driven by intense ultrafast laser pulses. The spatial coordinates are discretized via the finite-element discrete-variable representation. Examples include ionization dynamics in complete breakup processes through few-phonon absorption in helium atoms and hydrogen molecules, and also time-delayed attosecond transient absorption spectra in helium.

1This work was supported by DOE DE-FG02-13ER16403, NSF PHY-0757755, NSF PHY-1068140, and XSEDE PHY-090031.

1:03PM M23.00006 Solving the Time Dependent Schroedinger Equation using the FEDVR/SIL Method

BARRY SCHNEIDER, NIST — In this talk we will explore how the finite element discrete variational representation coupled to the short iterative Lanczos method has enabled our group to make substantial progress in understanding the single and double ionization of atoms and simple diatomic molecules in short, intense electromagnetic fields. Particular attention will be paid to new time-dependent propagation techniques to shorten the computational times.

1:15PM M23.00007 Hybrid MPI/OpenMP First Principles Materials Science Codes for Intel Xeon Phi (MIC) based HPC: The Petascale and Beyond

ANDREW CANNING, Lawrence Berkeley National Laboratory and University of California, Davis, JACK DESLIPPE, Lawrence Berkeley National Laboratory, JAMES CHELIKOWSKY, University of Texas at Austin, STEVEN G. LOUIE, University of California, Berkeley and Lawrence Berkeley National Laboratory — Exploiting the full potential of present petascale and future exascale supercomputers based on many core chips requires a high level of threading on the node as well as reduced communications between the nodes to scale to large node counts. We will present results for a variety of first principles materials science codes (Berkeley-GW, PARATEC, PARSEC) on Intel Xeon Phi (MIC) based supercomputers for algorithms using hybrid OpenMP/MPI parallelism to obtain both efficiently threaded single chip performance and parallel scaling to large node counts.

1Support provided through the SciDAC program funded by U.S. Department of Energy, Office of Science, ASCR and BES under Contract No. DE-AC02-05CH11231 at LBNL and Award No. DESC0008877 at UT, Austin

1:27PM M23.00008 Time-Dependent Superfluids on Heterogeneous Computing Platforms

KENNETH ROCHE, Pacific Northwest National laboratory and University of Washington — The superfluid local density approximation (SLDA) and its time-dependent extension (TDSLDA) can be used to study strongly interacting fermion systems. SLDA and TDSLDA have been verified, and validated theoretically and experimentally for both homogeneous and inhomogeneous systems. Our numerical implementation enabled the first time-dependent simulations of fermionic superfluid systems within the DFT approach. Recently, we have developed novel algorithms for the efficient evaluation of the theory using hybrid CPU-GPU computer architectures. In this talk, I will focus on the challenges and implementation details of the hybrid CPU-GPU time-dependent code.

1:39PM M23.00009 Identification of metastable ultrasmall titanium oxide clusters using a hybrid optimization algorithm

ERIC INCLAN, Florida International University, Miami, FL 33174, DAVID GEOHEGAN, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Nanostructured TiO₂ materials have interesting properties that are highly relevant to energy and device applications. However, precise control of their morphologies and characterization are still a grand challenge in the field. Using a hybrid optimization algorithm we theoretically explored configuration spaces of energetically metastable TiO₂ nanostructures. Our approach is to minimize the total energy of TiO₂ clusters in order to identify the structural characteristics and energy landscape of plausible (TiO₂)n (n = 1-100). The hybrid algorithm includes a modified differential evolution algorithm, a permutation operator to perform global optimization on a set of randomly generated structures, and then structure refinement using a BFGS Quasi-Newton algorithm. The results were compared against known physical structures and numerical results in the literature as well as our experimentally synthesized structures. Although the global minimum became more computationally expensive to locate with increasing number of TiO₂ units, the optimizer successfully identified numerous plausible structures along a range of energies close to the global minimum energy structure for all clusters in the given range.

1This work is supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
The vacuum size. In contrast, the HGH and PAW PPs show fast and stable convergence with the same settings. The origin of these oscillations will be discussed.

for both TM and USPP PPs, the phonon energies at the Brillouin zone center exhibit oscillations and even large negative phonon modes with the increase of

11:15AM M24.00001 A Novel Gaussian-Sinc mixed Basis Set for Electronic Structure calculations1, JONATHAN JERKE, YOUNG LEE, C.J. TYMCZAK, Texas Southern University — A Gaussian-Sinc mixed basis set for the computation of the electronic structure of atoms and molecules is presented. Excellent bases functions are known for “core” and “valence” separately, such as Gaussians for the “core” wave functions and Plane-waves for “valence” wave functions, but as yet no method is known that can accurately deal with both regimes in a single basis. A Gaussian-Sinc mixed basis can do both. This method resolves several issues such as: i) the sincs basis spans the same space as the plane-waves basis, yet are semi-local enough to define all interaction elements including Exchange; ii) the Gaussians span the spherically symmetric core states and can be mixed with the sinc functions in a computationally efficient methodology; iii) together, this mixed basis set is a flexible, computationally efficient and a highly accurate method for solving atomic and molecular problems. This methodology has been implemented within the Hartree-Fock level of theory within ultra-strong magnetic fields. To demonstrate the utility of this new method, we calculated the ground state Hartree-Fock energies to five digits accuracy in ultra strong magnetic fields for Helium to Neon, Molecular Hydrogen, Water, Carbon dioxide and Benzene.

11:27AM M24.00002 Modeling the kinetic energy density of molecules – towards an orbital-free meta-GGA, ANTONIO CANCIO, DANE STEWART, JEREMY REDD, Ball State University — Driven by applications at high temperature and large system size, interest has recently turned to the construction of orbital-free density functionals, modeling the Kohn-Sham kinetic energy solely as a functional of the electron density and its derivatives. We report work on a metaGGA level orbital-free kinetic energy functional parametrized in terms of the local Laplacian and gradient of the density, and based on insights gained in the visualization of the kinetic energy density (KED) for atoms and the AE6 test set of molecules. Visualization of the KED, particularly in the region of localized electron pairs, such as atomic lone pairs and covalent bonds, pointed out significant flaws in an earlier metaGGA proposed by Perdew and Constantin. We find that these can be substantially fixed by revising an implicit constraint built into the prior model in the limit of strong electron localization – when the Kohn-Sham KED approaches the bosonic limit. A first attempt at an improved model dramatically improves atomization energies for the AE6 test set, but remains an order of magnitude worse than a conventional Kohn-Sham GGA. We are currently working to fix a notable over-correction of the PC meta-GGA for the electron localization limit that may lead to further improvement.

11:39AM M24.00003 Convergence of the phonon energy in two-dimensional atomic crystal of lead1, JIA-AN YAN, Department of Physics, Astronomy and Geosciences — Accurate phonon energies are important for the study of two-dimensional (2D) atomic crystals. Using the 2D honeycomb lattice of lead (Pb) as a model system, we studied the convergence of the phonon energies on several important parameters in supercell calculations based on the density-functional perturbation theory as implemented in Quantum Espresso code. These parameters include the planewave cut-off energy, the vacuum space size, the charge density cut-off, and FFT grid. The tested pseudopotentials (PPs) include the widely used Troullier-Martin (TM), Hartwigsen-Goedeker-Hutter (HGH), Projector Augmented-Wave (PAW), and ultrasoft pseudopotential (USPP), with the same PBE exchange-correlation functional. Surprisingly, the phonon energies calculated using these PPs exhibit quite distinct dependence on those parameters. Specifically, for both TM and USPP PPs, the phonon energies at the Brillouin zone center exhibit oscillations and even large negative phonon modes with the increase of the vacuum size. In contrast, the HGH and PAW PPs show fast and stable convergence with the same settings. The origin of these oscillations will be discussed.

11:51AM M24.00004 Implicit solvent models in VASP, KIRAN MATHEW, Cornell university, RICHARD HENNIG, University of Florida — Solid-liquid interfaces are at the heart of many modern-day technologies and presents challenges for materials simulation methods. A realistic first-principles computational study of such systems entails the inclusion of solvent effects. In our previous work, employing a linear implicit solvent model, we have demonstrated the importance of the inclusion of solvent effects on the calculation of reaction energy barriers and surface energies of semiconductor nanocrystals. In this work we propose to extend the implicit solvent model to incorporate the effects of the ions in the solvent and also to include the effects of dielectric saturation phenomenon. A solvation model that includes the effects of ionic solution at a first principle level, takes us one step closer to a more realistic simulation of an electrochemical interface. Incorporating the dielectric saturation effects further advance the capabilities of the state of the art DFT tools to study the Solid Electrolyte Interface(SEI) films formed on highly ionic surfaces such as Lithium halides.

12:03PM M24.00005 Compact wavefunctions from compressed imaginary time evolution, JAR- ROD MCCLEAN, ALAN ASPURU-GUZIK, Harvard University — Simulation of quantum systems promises to deliver physical and chemical predictions for the frontiers of technology. The success of approximation methods for quantum systems has hinged on the relative simplicity of physical systems with respect to the exponentially complex worst case. Exploiting this relative simplicity has required detailed knowledge of the physical system under study. In this talk, we will introduce a general and efficient black box method for many-body quantum systems that utilizes technology from compressed sensing to find the most compact wavefunction form possible without detailed knowledge of the system. It is a Multicomponent Adaptive Greedy Iterative Compression (MAGIC) scheme. No knowledge is assumed in the structure of the problem other than correct particle statistics. This method can be applied to many quantum systems such as spins, qubits, oscillators, or electronic systems. I will show the relation of this approach to matrix product states and discuss the implications. As a practical application, I use this technique to compute the ground state electronic wavefunction of hydrogen fluoride and recover 98

12:15PM M24.00006 First-Principles Studies of the Excited States of Chromophore Monomers and Dimers, SAMIA HAMED, University of California at Berkeley, SAHAR SHARIFZADEH, Boston University, JEFFREY NEATON, University of California at Berkeley — Elucidation of the energy transfer mechanism in natural photosynthetic systems remains an exciting challenge. Through the careful analysis of excited states on individual chromophores and dimers – and the predictive first-principles methods used to compute them – we are building towards an understanding of the nature of excitation transfer among arrays of chromophores embedded in protein environments. Excitation energies, transition dipoles, and natural transition orbitals for the important low-lying singlet and triplet states of experimentally-relevant chromophores are obtained from first-principles time-dependent density functional theory (TDDFT) and many body perturbation theory. The effects of the Tamm-Dancoff approximation and the performance of several exchange-correlation functionals, including an optimally-tuned range-separated hybrid, are evaluated with TDDFT, and compared to MBPT calculations and experiments. This work has been supported by the DOE; computational resources have been provided by NERSC.
12:27PM M24.00007 “Phantom” Modes in *Ab Initio* Tunneling Calculations: Implications for Theoretical Materials Optimization, Tunneling, and Transport. SERGEY V. BARABASH, DIPANKAR PRAMANIK, Intermolecular Inc. — Development of low-leakage dielectrics for semiconductor industry, together with many other areas of academic and industrial research, increasingly rely upon *ab initio* tunneling and transport calculations. Complex band structure (CBS) is a powerful formalism to establish the nature of tunneling modes, providing both a deeper understanding and a guided optimization of materials, with practical applications ranging from screening candidate dielectrics for lowest “ultimate leakage” to identifying charge-neutrality levels and Fermi level pinning. We demonstrate that CBS is prone to a particular type of spurious “phantom” solution, previously deemed true but irrelevant because of a very fast decay. We demonstrate that (i) in complex materials, phantom modes may exhibit very slow decay (appearing as leading tunneling terms implying qualitative and huge quantitative errors), (ii) the phantom modes are spurious, (iii) unlike the pseudopotential “ghost” states, phantoms are an apparently unavoidable artifact of large numerical basis sets, (iv) a presumed increase in computational accuracy increases the number of phantoms, effectively corrupting the CBS results despite the higher accuracy achieved in resolving the true CBS modes and the real band structure, and (v) the phantom modes cannot be easily separated from the true CBS modes. We discuss implications for direct transport calculations. The strategy for dealing with the phantom states is discussed in the context of optimizing high-quality high-κ dielectric materials for decreased tunneling leakage.

12:39PM M24.00008 Three- to two-dimensional crossover in time-dependent density-functional theory1, SHAHRZAD KARIMI, CARSTEN ULLRICH, University of Missouri — Quasi-2D systems, such as an electron gas confined in a quantum well, are important model systems for many-body theories. Earlier studies of the crossover from 3D to 2D in ground-state DFT showed that local and semilocal exchange-correlation functionals which are based on the 3D electron gas are appropriate for wide quantum wells, but eventually break down as the 2D limit is approached. We now consider the dynamical case and study the performance of various linear-response exchange kernels in TDDFT. We compare approximate local, semilocal and orbital-dependent exchange kernels, and analyze their performance for inter- and intrasubband plasmons as the quantum wells approach the 2D limit. 3D (semi)local exchange functionals are found to fail for quantum well widths comparable to the 2D Wigner-Seitz radius, which implies in practice that 3D local exchange remains valid in the quasi-2D dynamical regime for typical quantum well parameters, except for very low densities.

12:51PM M24.00009 ABSTRACT WITHDRAWN

1:03PM M24.00010 Ultrafast coupled plasmon-phonon mode dynamics in GaAs, a combined experimental and theoretical study. EVAN THATCHER, CHRISTOPHER STANTON, Univ of Florida - Gainesville, KUNIE ISHIOKA, National Institute for Materials Science, Tsukuba, Japan, AMLAN BASAK, HRVOJE PETEK, Univ of Pittsburgh — We present results from a joint experimental and theoretical study exploring the excitation of coupled plasmon-phonon modes in GaAs. In contrast to previous coherent phonon studies in GaAs where electrons were generated primarily in the Γ valley, we use a pump-probe technique with a 10 fs pulse width and a shorter 400 nm laser wavelength to photoexcite electrons predominantly in the L valley. As a result: i) damping of the electron-hole plasma is faster and ii) diffusion of the carriers from the surface becomes important compared to the shorter absorption length. The probe pulses measure the time-dependent changes to the reflectivity due to the coupled plasmon-phonon modes created by the ultrafast photoexcitation and the subsequent depletion field screening. To model this, we solve for the time and density dependent coupled-mode frequencies allowing for ambiplar diffusion. Simulation of the coupled plasmon-phonon dynamics allows for comparison with, and a better understanding of experiments.

1:15PM M24.00011 Surface Dangling Bonds Are a Cause of Type-II Blinking in Si Nanoparticles1, NICHOLAS BRAWAND, MARTON VOROS, GIULIA GALLI, Univ of Chicago — Exponential blinking statistics was reported in oxidized Si nanoparticles and the switching mechanism was attributed to the activation and deactivation of unidentified nonradiative recombination centers. Using *ab initio* calculations, we predicted that Si dangling bonds at the surface of oxidized nanoparticles introduce defect states which, depending on their charge and local stress conditions, may give rise to ON and OFF states responsible for exponential blinking statistics. Our results are based on first principles calculations of charge transition levels, single particle energies, and radiative and nonradiative lifetimes of dangling bond defects at the surface of oxidized silicon nanoparticles under stress.

1Supported by the Department of Energy/Basic Energy Sciences grant No. DE-FG02-06ER46262.

1:27PM M24.00012 Auxiliary density functionals: a new class of methods for efficient, stable density functional theory calculations1, PHIL HASNIP, MATT PROBERT, University of York — *Ab initio* materials modelling methods have become an essential tool for physical scientists in a wide variety of fields. The advent of more and more powerful computers has allowed larger, more complex systems to be simulated and the dramatic improvements in both experimental growth and characterisation methods have allowed the length scale of theoretical simulations and experimental studies to coincide at the nanoscale. Whilst there has been undisputed success in the modelling of nanomaterials, the approach is not without its problems. As the size of the simulation system is increased, the conventional algorithms used to find the electronic ground state often show poor convergence, and for large or complex systems they may fail to converge at all. We present a new class of methods for solving the Kohn-Sham equations based on constructing a mapping dynamically between the Kohn-Sham system and an auxiliary system. This auxiliary system is not required to be fermionic, and an exemplar bosonic scheme is presented which captures the key features of the Kohn-Sham behaviour. This auxiliary scheme is shown to provide good performance for a variety of bulk materials, and a substantial improvement in the scaling of calculations with system size for a range of materials.

1:39PM M24.00013 Speeding up DFT: A new approach to k-point integration. JEREMY J. JORGENSEN, Brigham Young University, DEREK C. THOMAS, University of Texas at Austin, MATTHEW M. BURIDGE, Brigham Young University, IAN H. SLOAN, The University of New South Wales, CONRAD W. ROSENBROCK, RODNEY W. FORCADE, BRET C. HESS, GUS L.W. HART, Brigham Young University — The bottleneck for high throughput material property calculation is computational speed. Increasing the convergence rate of the band energy integration will decrease computation time. Band energy, despite its small contribution to the total energy, plays a large role in the calculation of formation enthalpies, where energy differences and not magnitudes are of greater importance. Current DFT codes generally choose k-points using the Monkhorst-Pack scheme, and then integrate the energy bands using the rectangle method. Instead, we interpolate the energy bands with splines, create a spline representation of the Fermi surface, and analytically integrate the energy bands beneath the Fermi surface to find the band energy. Our conservative estimate is a tenfold increase in computational efficiency for the band energy calculation.

2:03PM M24.00015 Ab-initio atomic level stress and role of d-orbitals in CuZr, CuZn and CuY, MADHUSUDAN OJHA, Univ of Tennessee, Knoxville, DON M. NICHOLSON, University of North Carolina Asheville, TAKESHI EGAMI, Univ of Tennessee, Knoxville — Atomic level stress offers a new tool to characterize materials within the local approximation to density functional theory (DFT). Ab-initio atomic level stresses in B2 structures of CuZr, CuZn and CuY are calculated and results are explained on the basis of d-orbital contributions to Density of States (DOS). The overlap of d-orbital DOS plays an important role in the relative magnitude of atomic level stresses in these structures. The trends in atomic level stresses that we observed in these simple B2 structures are also seen in complex structures such as liquids, glasses and solid solutions. The stresses are however modified by the different coordination and relaxed separation distances in these complex structures. We used the Locally Self-Consistent Multiple Scattering (LSMS) code and Vienna Ab-initio Simulation Package (VASP) for ab-initio calculations.

11:15AM M25.00001 Ab initio molecular dynamics simulations of electron doped ZrNCl, ANTHIAS R. A. BOTANA, FRANCOIS GYGI, WARREN E. PICKETT, University of California Davis — When electron doped, the layered transition metal nitride ZrNCl becomes superconducting with an impressive critical temperature $T_c = 15K$. Its isovalent sisters become superconducting at 17K (TaNCl) and 26K (HNCl). This class has very strong 2D character, as cuprates, iron pnictides, and MgB$_2$, but the pairing interaction is not magnetic nor conventional electron-phonon in origin. To explore the dynamical behavior of electrons doped into a highly ionic insulator, ab initio molecular dynamics calculations have been carried out on doped ZrNCl. The simulations allow us to analyze the electronic response in real space, and to study the differences in behavior of the two experimental mechanisms of doping electronic carriers: alkali metal intercalation and Cl vacancies, both of which give nearly the same high critical temperature.

11:27AM M25.00002 Density Functional Theory for Superconductors: new functionals and applications, ANTONIO SANNA, E.K.U. GROSS, Max Planck Institute of Microstructure Physics — Density functional theory for superconductors (SCDFT) is a fully parameter-free approach that allows for accurate predictions of the critical temperature and other properties of superconductors. We report on the most recent extensions of this theoretical framework, in particular the development of new functionals to:
- incorporate in a correct fashion Migdal's theorem;
- compute the excitation spectrum;
- include spin-fluctuation mediated pairing

Applications and predictions are shown for a set of materials including conventional and unconventional superconductors.

11:39AM M25.00003 Unconventional superconductivity and charge fluctuations in Li$_{x}$Mo$_6$O$_{17}$, NATALIA LERA, JOSE ALVAREZ, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid — We study superconductivity in Li$_{x}$Mo$_6$O$_{17}$ considering charge and spin fluctuations as the pairing mechanism. We model the low-energy electronic properties of the material with a multiorbital extended Hubbard model and compute the superconducting vertex within the RPA. We found that charge collective modes induced by Coulomb repulsion favor the superconductivity both the singlet and triplet channels. Superconductivity is favored as the charge ordering transition of the model is approached by tuning the interaction. We compare with another quasi-one-dimensional approach where the superconductivity is an instability of a generalized Luttinger Liquid (LL) to higher dimensions, known as Quantum Smectic Metal or Sliding LL. We also discuss these results on the context of the dimensional crossover issue in the unconventional metallic phase of the material.

11:51AM M25.00004 Superconducting phase diagram of itinerant antiferromagnets, ASTRID ROEMER, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark, ILYA EREMIN, Institut für Theoretische Physik III, Ruhr-Universität Bochum, D-44801 Bochum, Germany, PETER J. HIRSCHFELD, Department of Physics, University of Florida, Gainesville, USA, BRIAN M. ANDERSEN, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark — We investigate the formation of Cooper pairs in systems with itinerant antiferromagnetic (AF) order. Our theory is a generalization of earlier studies of spin fluctuation mediated pairing on top of AF [1,2]. The AF order is manifested by gapless transverse spin waves as well as gaped longitudinal spin fluctuations. Both changes contribute to the Cooper pairing. We map out the superconducting gap as a function of electron doping and find a robust d-wave gap on the electron pockets in the anti-nodal regions with no nodes at the Fermi surface. Close to the critical doping of onset of AF order we observe a highly non-monotonic form of the superconducting gap due to enhancements at the "hot spots." In this doping regime we explore the presence of p- and f-wave triplet gaps competing with the d-wave solution [3].

12:03PM M25.00005 Dynamical Jahn-Teller instability in metallic fullerides, NAOYA IWAHARA, LIVIU CHIBOTARU, Theory of Nanomaterials Group, Katholieke Universiteit Leuven — Dynamical Jahn-Teller effect has escaped so far direct observation in metallic systems. It is particularly believed to be quenched also in correlated conductors with orbitally degenerate sites such as cubic fullerides. Here the Gutzwiller approach is extended to treat electron correlation over metals with Jahn-Teller active sites and applied to the investigation of the ground state of K$_3$C$_{60}$. It is shown that dynamical Jahn-Teller instability fully develops in this material when the interelectron repulsion $U'$ on C$_{60}$ sites exceeds some critical value. The latter is found to be lower than the current estimates of $U'$, meaning that dynamical Jahn-Teller effect takes place in all cubic fullerides. This leads to strong splitting of LUMO orbitals on C$_{60}$ sites and calls for reconsideration of the role of orbital degeneracy in the Mott-Hubbard transition in fullerides.

displays a characteristic Fano effect as an incipient charge density wave state forms. SLAC National Lab and Stanford University — I this talk I will present a theory for resonant photoexcitation of phonons using x-ray inelastic spectroscopy. I behavior as the dilution tends to the percolation threshold. The worm algorithm [PRL 87, 160601 (2001)]. We present results for the scalar susceptibility and O(N) conductivity in the critical region and follow the system's scaling in the vicinity of the quantum critical point [PRL 110, 140401 (2013)]. We report on the O(N) model with random site dilution, which we study using the worm algorithm [PRL 87, 160601 (2001)]. We present results for the scalar susceptibility and O(N) conductivity in the critical region and follow the system's behavior as the dilution tends to the percolation threshold.

12:39PM M25.00008 Amplitude mode in diluted O(N) models , YURY KISELEV, DANIEL AROVAS, Univ of California - San Diego — The relativistic O(N) model has recently been shown to exhibit a robust amplitude mode peak in its scalar susceptibility which exhibits scaling in the vicinity of the quantum critical point [PRL 110, 140401 (2013)]. We report on the O(N) model with random site dilution, which we study using the worm algorithm [PRL 87, 160601 (2001)]. We present results for the scalar susceptibility and O(N) conductivity in the critical region and follow the system's behavior as the dilution tends to the percolation threshold.

12:51PM M25.00009 Phonon Fano effect in RIXS across a CDW instability , THOMAS DEVEREAUX, SLAC National Lab and Stanford University — I this talk I will present a theory for resonant photoexcitation of phonons using x-ray inelastic spectroscopy. I will show how the strength of electron-phonon can be characterized in a momentum dependent way, and demonstrate how the phonon-continuum linehape displays a characteristic Fano effect as an incipient charge density wave state forms.

1:03PM M25.00010 Thermodynamics of superconducting quantum metamaterials , PIERRE-LUC DALLAIRE-DEMERS, FRANK WILHELM-MAUCH, Universite des Saarlandes — Left-hand matematerials are capacitively coupled layers of inductive pieces of conductors. These systems are well studied in the context of microwave metamaterials but their full quantum description or their embedding in highly correlated materials like superconductors are still an open problem. Notably, they are known to have a Van Hove singularity in the density of states at low energy and high pseudo-momentum that could effectively couple and condense Cooper pairs. The goal of this research is to analyze the thermodynamical properties of the order parameter of stacked layers of superconductors with a small repulsive Coulomb interaction. A 3D toy model of such a material is mapped to a Fermi-Hubbard lattice. The temperature independent anomalous correlation functions are computed variationally from a self-energy functional of a small cluster where inter-cluster tunneling is treated perturbatively. The effect of the repulsive interaction on the Cooper pairs binding can then be seen from the momentum distribution of the condensation amplitude. Such a material could potentially be realized with optical lattices or nanoscaled superconductors.

1:15PM M25.00011 Transport in thin insulating films close to the Boson-Fermion Crossover , J.C. JOY, X. ZHANG, S.M. HOLLEN, Department of Physics, Brown University, G. FERNANDES, J.M. XU, Division of Engineering, Brown University, J.M. VALLES, JR., Department of Physics, Brown University — In two-dimensional systems, sufficient levels of disorder are known to localize Cooper Pairs into a phase incoherent insulating state. While many theoretical and experimental works have shown this state's existence, its ubiquity close to the disorder tuned Superconductor to Insulator transition is still an open problem. Recent experiments on nanopatterned Pb0.5Sr1.5 films have suggested a crossover from Bosonic to Fermionic transport deep in the insulating phase, indicating that the Cooper Pair Insulator (CPI) only persists to a finite level of microscopic disorder. The normal state resistance at which this crossover occurs is governed by the extent coupling constant inhomogeneities on the scale of the coherence length, which allow the formation of locally phase coherent superconducting islands in the insulating state. By tuning the scale of these inhomogeneities and examining the extent of the CPI state, we argue that the disorder tuned Superconductor to Insulator transition proceeds via pair breaking and Anderson localization of fermions when the level spacing in the islands approaches the size of the mean field gap. This work was supported by the NSF through grants No. DMR-1307290 and DMR-0907357 and by the AFRL, the ONR, and the AFSOR.

1:39PM M25.00013 Probing the charge-vortex duality near the superfluid-to-insulator transition , SNIR GAZIT, DANIEL PODOLSKY, ASSA AUERBACH, Technion - Israel Institute of Technology — We study the charge vortex duality near the superfluid-to-insulator quantum phase transition in d=2–1 dimensions. We use a generalized reciprocity relation between charge and vortex conductivities at complex frequencies to identify the capacitance in the insulating phase as a measure of vortex condensate stiffness. We then compute the ratio of boson superfluid stiffness to vortex condensate stiffness at mirror points to be 0.21(1). This corroborates and provides a quantitative measure to the non self-dual nature of the charge-vortex duality. We further study deviations from self-duality at finite frequency by computing the product of Matsubara frequency conductivities at mirror points across the phase transition. Finally, we propose experimental realizations that test our predictions in THz spectroscopy of disordered superconductors and cold atomic systems trapped in an optical lattice. [1] S. Gazit, D. Podolsky, A. Auerbach, arXiv:1407.1055 (2014)
1:51PM M25.00014 Theory of phase-slip-center effects on superconducting kinetic inductance

MASAHIKO MACHIDA, YUKIHIRO OTA, Japan Atomic Energy Agency — Fluctuations significantly alter the conventional picture on transport phenomena in 1D superconductors. We study the current-dependence of the kinetic inductance in superconducting wires using the Ginzburg-Landau approach with fluctuations. We obtain a non-monotonic current-dependence of the kinetic inductance when the thermal fluctuations predominate the behaviors of the superconducting phase. This result is ascribed to the occurrence of phase-slip centers from thermally-activated processes. We also find that our approach qualitatively reproduces the experiment by Anzunziata et al. [Nanotechnology 21, 445202 (2010)]. Moreover, we discuss the effects of thermal fluctuations on the characteristics of superconducting detectors. We will also discuss the effects of quantum phase slips on superconducting detectors.

2:03PM M25.00015 Pairing in doped Hubbard model on a honeycomb lattice: A quantum Monte Carlo study

TIANXING MA, Department of Physics, Beijing Normal University — Inspired by the recent discovered graphene, we performed a systematic QMC study of the magnetic and pairing correlation in the t-U-V Hubbard model on a honeycomb lattice. Close to half filling, we find that pairing with d+id symmetry dominates over pairing with extended-s symmetry. As the doping increases, the next-nearest-neighbor t' tends to be important and when $t'/t < -0.65$, the single-particle spectrum is featured by the continuously distributed Van-Hove saddle points at the band bottom, where the density of states diverges in power-law. We investigate possible unconventional superconductivity in such system with Fermi level close to the band bottom, and our studies reveal a possible triplet p+ip superconductivity with appropriate interactions. By including the spin-orbit coupling, it is shown that the d+id pairing is enhanced while the p+ip pairing is decreased by increasing spin-orbit coupling. Our results might provide a possible route to look for triplet superconductivity with relatively-high transition temperature in a doped graphene and other similar systems.

Wednesday, March 4, 2015 11:15AM - 2:15PM –
Session M26 DCMP: Nanowires: Mechanical, Electronic, Optical, and Transport Properties

204A - Luis Balicas, Florida State University

11:15AM M26.00001 Synthesis and Photoresponse of Hydrothermally Grown ZnO Nanowires

AHMED AL-ASADI, LUKE HENLEY, SUJOY GHOSH, ABDIEL QUETZ, IGOR DUBENKO, Department of Physics, Southern Illinois University Carbondale, Carbondale-IL 62901, United States, NIHAR PRADHAN, LUIS BALICAS, National High Magnetic Field Laboratory, Florida State University, Tallahassee-FL 32310, United States, SAIKAT TALAPATRA, NAUSHAD ALI, Department of Physics, Southern Illinois University Carbondale, Carbondale-IL 62901, United States — We will present our results of hydrothermally grown ZnO nanowires (NWs) using ZnO nanoparticles as seeds. The seed layer was prepared simply by spraying commercially obtained ZnO nanoparticles with a diameter ~20 nm mixed with Isopropanol (IPA) onto Si/SiO2. A detailed structural characterization of the ZnO nanowires indicate that highly crystalline nanowires with an average diameter 45-55 nm and length 1 ~ 1.3 µm with an optical band gap of ~3.7 eV can be obtained using this method. We also show that a significant amount of photocurrent is generated in these nanowires when illuminated with UV radiation. The variation of photo response with light intensity as well as the nature of rise and decay of photocurrent will be presented and discussed in the light of available theoretical models.

11:27AM M26.00002 Controlling the electrical impedance of nanomechanical oscillators by electromigration

FENGPEI SUN, JIE ZOU, HO BUN CHAN, The Hong Kong University of Science and Technology — Detection of nanomechanical motion is of fundamental and practical interests. For doubly clamped nanobeams, a common method is the magnetomotive reflection technique. However, this technique usually suffers from large signal background due to the mismatch of the electrical resistance (R_e) of the oscillators to the impedance (50 ohm usually) of the cables for detection. The large signal background precludes the possibility of driving the device into self-sustaining oscillations using a phase-locked loop. We develop a reproducible method of minimizing the signal background in the magnetomotive reflection technique. A gold nanowire with a junction in the middle is fabricated on the top of a doubly-clamped SiNx nanobeam via e-beam lithography. By passing a large direct current through the nanowire, migration of the gold atoms around the junction is activated due to the heat dissipated. An analog feedback loop is designed to maintain a stable process of electromigration until the target R_e is reached. Initially, R_e is smaller than 500 ohm. The motional impedance of the nanowire shifts the total impedance closer to 500 ohm so that the resonance of the nanobeam appears as a dip on a large background in the amplitude spectrum. As R_e is increased to near 500ohm, the background reaches a minimum, and the resonance of the nanobeam turns into a peak. Self-sustaining oscillations of the nanobeam are successfully achieved via a phase-locked loop in this case. As R_e is further increased, the background becomes higher again. The dependence of the background signal on R_e agrees with calculations.

11:39AM M26.00003 In-situ electromechanical properties of suspended Poly-pyrrole (PPy) nanotube using metal coated AFM tip manipulations

SANG WOOK LEE, HAKSEONG KIM, SUNG HO JHANG, Konkuk University, NENM TEAM — Electromechanical properties of individual suspended poly-pyrrole (PPy) nanotube were investigated. PPy nanotubes were positioned and suspended using the ac electrophoresis and micro transfer method. The metal coated atomic force microscope tip was used as a pressure source of the suspended PPy tube and, at the same time, one of the contact electrodes for measuring in-situ current-voltage characteristics while the PPy tube is under stressed. The resistance of the PPy tube was decreased in electromechanical measurements with increasing pressure using a metal coated AFM tip. 1.36 GPa of maximum contact pressure on the tip-tube contact was estimated to reduce the contact resistance for making to 6.8 ohm cm in a lateral configuration.

This work was supported by NRF.

11:51AM M26.00004 GPU Accelerated Quantum Transport Modelling of Realistic Large Cross-Section Silicon Nanobeams

MOHAMMED HARBI, HONG GUO, McGill University — Understanding the quantum transport properties of silicon nano-beams or -wires is important for many practical applications. But for nanobeams with a cross section larger than 10 nm square or so, typical transport modelling techniques based on Green’s functions and atomistic DFT Hamiltonians become very computationally demanding. The computational burden becomes even greater when electron scattering with phonons is included. In this work we report hardware acceleration of the computational algorithm using a cluster of CPUs and GPUs working together in a heterogenous computing scheme. The GPU accelerated transport scheme is implemented for atomistic tight-binding Hamiltonian within the non-equilibrium Green’s function formalism. As examples, we calculate charge transport properties of realistic large cross-section Si nanobeams with several defect configurations, and report how local density of states can be significantly perturbed by the presence of the atomic impurity.
12:03PM M26.00005 Thermal properties of semiconductor nanowires using electromechanics . JOHN MATHEW, MANDAR DESHMUKH, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, Mumbai, India — We present low temperature measurements of thermal expansion and diffusivity of InAs nanowires using electromechanical response of the nanowire. To realize this, we fabricate InAs nanowire devices in doubly clamped, suspended field effect transistor geometry, and use direct radio frequency detection of the nanowire electromechanics. The resonant frequency of the nanowire is studied at different temperatures as a function of applied source-drain bias voltage. Due to Joule heating and the non-monotonic thermal expansion of InAs we observe positive and negative dispersion of the nanowire resonant frequency with applied bias. We also study dynamical response to heating to understand the thermal diffusivity in these sub-micron structures. We show that the resonant frequency of NEMS devices acts as a good indicator of thermal properties of semiconductor materials providing information on thermal conductivity, expansion and diffusivity.

12:15PM M26.00006 Optimizing electronic characteristics of SnO2 nanobelts for FET devices . TIMOTHY KEIPER, JORGE BARREDA, Department of Physics, Florida State University, JIM P. ZHENG, Electrical and Computer Engineering, FAMU/FSU College of Engineering, PENG XIONG, Department of Physics, Florida State University — Oxide semiconductors are attractive channel materials for nanoscale field effect transistors (FETs), especially for applications in chemical and biological sensing. Here we focus on optimizing the current-voltage relationship and gating response of SnO2 nanobelts (NB) FETs, a widely used sensor material. The NBs are grown by a physical vapor-liquid-solid process, with dimensions that are desirable for FET application, however the electrical characteristics of the as-grown materials are often not optimum for high-performance FETs. We have developed a multistep thermal annealing procedure in low vacuum ranging from 150 to 250 °C and oxygen environment at atmospheric pressure and 600 °C to increase the conductivity by more than 10^2. The multistep annealing process is necessary to consistently obtain FETs with low resistance, Ohmic contacts which differ by <5%. Utilizing a typical backgate geometry the device is transitioned from the on state to the off state over a gate voltage range of less than 30 V through a thick 250 nm SiO2 dielectric layer. The On/Off ratio is as large as 10^4. We surmise the oxygen annealing effectively activates the NBs while the vacuum annealing both helps clean the material and tune the carrier density at the surface, affecting metallization.

12:27PM M26.00007 Optoelectronic Properties of Hybrid Titania Nanotubes/Hematite Nanoparticles Structures . LILI WANG, EUGEN PANAITESCU, LATIKA MENON, Northeastern University — TiO2/Fe2O3 nanostructures are becoming promising alternatives for improving cost effectiveness (in $/W) of emerging photovoltaic devices such as dye sensitized or metal-insulator-semiconductor solar cells, combining the low cost, earth abundance and stability of the materials with the enhanced performance offered by the nanoscale architecture. We investigated novel, high quality titania/hematite composites, namely hematite nanoparticle decorated titania nanotube arrays, which were obtained by a simple, inexpensive and easily scalable two-step process, electrochemical anodization of titanium followed by forced hydrolysis. The titania nanotubular scaffold provides a large active surface area, while the iron oxide nanoparticles significantly broaden the light absorption range into the visible region. The morphological and structural characteristics of the samples were analyzed by scanning electron microscopy (SEM), X-ray diffraction (XRD) and transmission electron microscopy (TEM). The light absorption efficiency was measured by diffuse reflectance spectroscopy (DRS), and the optoelectronic behavior of the hybrid structures was analyzed by IV measurements under simulated solar illumination. The influence of the synthesis process and the structure design on the photovoltaic performance is currently investigated for optimal device prototyping.

12:39PM M26.00008 Structural and electronic properties of CdS/ZnS core/shell nanowires: A first-principles study . HYO SEOK KIM, YONG-HOON KIM1 , Korea Advanced Institute of Science and Technology — Carrying out density functional theory (DFT) calculation, we studied the relative effects of quantum confinement and strain on the electronic structures of II-IV semiconductor compounds with a large lattice-mismatch, CdS and ZnS, in the core/shell nanowire geometry. We considered different core radii and shell thickness of the CdS/ZnS core/shell nanowire, different surface facets, and various defects in the core/shell interface and surface regions. To properly describe the band level alignment at the core/shell boundary, we adopted the self-interaction correction (SIC)-DFT scheme. Implications of our findings in the context of device applications will be also discussed.

12:51PM M26.00009 Surface States and Transport in Bismuth Nanowires with Strong Magnetic Field . SHIANG FANG, BERTRAND HALPERIN, EFTHIMIOS KAXIRAS, Department of Physics, Harvard University — Bismuth nanowires have attracted attention due to the enhancement of thermoelectricity in the one-dimensional geometry. Because of the large surface-bulk ratio and gapped bulk-like states, the transport in Bismuth nanowires is dominated by surface states, which may be probed by measurement in magnetic field ~14T. However, due to the spiral motion of electrons between various nanowire facets, the electron would bounce between multiple wire surface with different crystal orientations. Shubnikov-de Haas oscillations in magneto-resistance in transport encode the convoluted information for different surface states. To study these effects and the mechanism for transport in strong magnetic field, we employ a density functional theory calculation for the band structure. Maximally-Localized Wannier Functions are used to construct an empirical tight-binding model, which provides numerically accurate results at reduced computational cost. In this way, the surface states in a semi-infinite geometry can be obtained from the efficient iteration of Greens functions. The formation of Landau levels can also be studied by Peierls substitution.

Center for Integrated Quantum Materials, National Science Foundation DMR-1231319

1:03PM M26.00010 Transport through double quantum dots in Ge/Si core/shell nanowires . AZARIN ZARASSI, ZHAOEN SU, DHARMRAJ K. PATIL, SERGEY M. FROLOV, University of Pittsburgh, MOIRA HOCEVAR, Institute Neel CNRS, MINH NGUYEN, JINKYOUNG YOO, Los Alamos National Lab, SHADI A. DAYEH, University of California San Diego — In the studies of spin qubits long dephasing times are crucial. Qubits made of materials with low abundance of nuclear spin, group IV semiconductors, have shown long spin coherence times. On top of this, the predicted strong spin-orbit interaction in the valence band of Ge/Si makes it a good platform to electrically manipulate spin states. We have formed stable and tunable double quantum dot by confining holes with the help of bottom gate electrodes in Ge/Si core/shell nanowires. Hole transport through the dots exhibits excited hole states from Zeeman splitting of which g-factors can be extracted. We are searching for spin blockade in the transport between double dots, which can be used to readout spin qubits and study spin-orbit interaction.
1:15PM M26.00011 Intrinsic and extrinsic effects on electron-phonon coupling strength in individual ZnTe nanowires: The effects of laser annealing and metallic Te. JASON MARMON, Nanoscale Science Program, UNC-Charlotte, TAO SHENG, HAITAO ZHANG, Mechanical Engineering & Engineering Science, UNC-Charlotte, YONG ZHANG, Electrical & Computer Engineering, UNC-Charlotte — Electron-phonon coupling is typically studied as an intrinsic property for a given bulk material, and modifying the coupling has been explored in a nanostructure. We point out that the coupling strength can be easily perturbed both significantly and unintentionally. Nanowires, with their large surface-to-volume ratio, are more susceptible to extrinsic perturbations that affect coupling strength, although literature assumes that coupling is intrinsic. This work uses vibrational spectroscopy under a near resonant condition to probe the coupling strength of individual ZnTe nanowires. Using the intensity ratio of the first and second order Raman peaks, \( R = I_{1LO}/I_{2LO} \), as a measure of the electron-phonon coupling strength (proportional to the Huang-Rhys factor), we find that the ratio can change greatly when varying either the sample or measurement condition, for instance, the presence of defects in the as-grown sample and their removal though laser illumination.

1:27PM M26.00012 Single Schottky junction FETs based on Si:P nanowires with axially graded doping. JORGE BARREDA, TIMOTHY KEIPER, MEI ZHANG, PENG XIONG, Florida State University — Si nanowires (NWs) with a systematic axial increase in phosphorus doping have been synthesized via a vapor-liquid-solid method. Silane and phosphine precursor gases are utilized for the growth and doping, respectively. The phosphorus doping profile is controlled by the flow ratio of the precursor gases. After the as-grown product is ultrasonically agitated into a solution, the Si NWs are dispersed on a SiO\(_2\) substrate with a highly doped Si back gate. Individual NWs are identified for the fabrication of field-effect transistors (FETs) with multiple Cr/Ag contacts along the NW. Two-probe and four-probe measurements are taken systematically under vacuum conditions at room temperature and the contribution from each contact and each NW section between adjacent contacts is determined. The graded doping level, produced by a systematic reduction in dopant density along the length of the NWs [1], is manifested in the regular increases in the channel and contact resistances. Our Si NWs facilitate the fabrication of asymmetric FETs with one ohmic and one Schottky contact. A significant increase in gate modulation is obtained due to the single Schottky-barrier contact. Characterization details and the applicability for sensing purposes will be discussed.

1:39PM M26.00013 Fabry Perot phenomena in nanowire cavities, SHICHENG LU, JOSHUA VEAZEY, MENGCHEN HUANG, PATRICK IRVIN, Univ of Pittsburgh, HYUNGWOO LEE, SANGWOONG RYU, CHANG-BEOM EOM, Univ of Wisconsin-Madison, JEREMY LEVY, Univ of Pittsburgh — A solid-state geometry analogous to an optical Fabry-Perot cavity gives evidence for coherent transport on the order of microns through nanowires at the LaAlO\(_3\)/SrTiO\(_3\) (LAO/STO) interface. Conductive AFM lithography is used to create both the nanowires and the two confining barriers which define the cavity. These two barriers act as the primary scattering centers so that as the chemical potential is tuned through the conducting state of the device, partial reflections from the barriers interfere in the cavity, resulting in quasi-periodic oscillations of the conductance at low temperatures. Full and extended single-mode periodicity is not observed in all devices; however, the conductance oscillations are only observed in cavity structures, suggesting that the effects of the two manufactured barriers dominate over any random scattering sites from disorder. The conductance oscillations from interference of coherently scattered electrons give evidence for ballistic transport on much longer length scales than implied by mobility measurements in two-dimensional LAO/STO.

1:51PM M26.00014 Quantized conductance through reconfigurable 1D channels, SHICHENG LU, ANIL ANNADI, GUANGLIE CHENG, MICHELLE TOMCZYK, MENGCHEN HUANG, University of Pittsburgh, HYUNGWOO LEE, SANGWOONG RYU, CHANG-BEOM EOM, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — In recent years, a high mobility two-dimensional electron gas LaAlO\(_3\)/SrTiO\(_3\) (LAO/STO) system has become a model system to investigate various exotic ground states of condensed matter physics. This system can co-host superconductivity, magnetism, and strong spin-orbit coupling at 2D interfaces which led to predictions of exotic phenomena such as unconventional superconductivity, helical/chiral modes, and Majorana phases in these interfaces. In order to explore these exotic phases high quality 1D devices are desirable. We demonstrate the realization of a gate tunable quantum point contact (QPC) structure embedded in a LAO/STO nanowire created using conductive AFM lithography. We observe integer quantized conductance in the units of \( e^2/h \) at high magnetic fields (\( B = 9 \text{ Tesla}, T = 50 \text{ mK} \)), a signature of the existence of 1D quantum channels. Significantly, we observe quantized conductance for nanowires as long as 1 \( \mu m \), implying that transport is ballistic along the magnetic-field induced chiral edge states in these devices.

2:03PM M26.00015 Magnetoeconductance signatures of subband structure in semiconductor nanowires, GREGORY HOLLOWAY, CHRIS HAAPAMAKI, University of Waterloo, RAY LAPIERRE, McMaster University, JONATHAN BAUGH, University of Waterloo — Understanding the subband structure due to radial confinement in semiconductor nanowires can benefit technologies ranging from optical sensors to quantum information processing. An axial magnetic field couples to the orbital angular momentum, giving rise to non-trivial features in electronic transport as a function of magnetic field. Previous reports focused on conduction electrons confined to a thin shell near the nanowire surface, which lead to flux-periodic energies and conductance oscillations. Here, we calculate the eigenstates for more general radial potentials with moderate to low surface band bending such that electrons are distributed more uniformly across the nanowire cross-section. It is found that the energy spectrum becomes aperiodic in both gate voltage and magnetic field as the radial potential becomes flatter. The behavior of an energy level is dictated by its angular momentum, and this allows, in principle, each state to be identified based on its dependence on magnetic field and the chemical potential. We experimentally investigate a short-channel InAs nanowire FET in search of conductance features that reveal this subband structure. A qualitative measure for assigning conductance features to specific transverse states is introduced and applied to this device.

2:03PM M27.00007 Probing Individual Atoms and Molecules on Pt(111) 1, ZHU LIANG, University of Illinois at Chicago, SURFACE AND INTERFACE SCIENCE LABORATORY, RIKEN, JAPAN COLLABORATION — A low-temperature scanning tunneling microscopy (LT-STM) is used to investigate the structure and reactivity of atomic nitrogen on Pt surfaces, which is important to a variety of catalytic processes. The adsorption of ammonia on an oxygen covered Pt surface leads to the formation of an NH1–O2 complex. Such a complex serves as a precursor to ammonia oxo-dehydrogenation, which produces an ordered atomic N layer on the surface when annealed to temperatures above 300 K. (√3 × √3)R30°-N and p(2 × 2)-N phases are found to coexist at temperatures between 360 and 400 K. After exposing the N-covered surface to hydrogen gas at 300 K, NH molecules are present as scattered molecules, as well as in dense islands. Mechanisms of dissociation of NH and lateral movement of H have been explored by examining the threshold energies and reaction rates. Measuring the response of the motion against applied bias voltages reveals the threshold energy, which is the energy of the vibrational mode that is responsible for activating a given motion. A theoretical model is used to fit the spectra, from which an estimate of reaction rate is obtained. ND dissociation and D hopping have also been investigated to role the role of hopping in these reactions.

Session M28 GMAG DMP: Focus Session: Spin Liquids II 205 - Shigeki Onoda, RIKEN

11:15AM M28.00001 Numerical evidence of quantum melting of spin ice: quantum-classical crossover, YASUYUKI KATO, RIKEN Center for Emergent Matter Science, SHIGEKI ONODA, Condensed Matter Theory Lab., RIKEN; RIKEN Center for Emergent Matter Science — Unbiased quantum Monte-Carlo simulations are performed on the simplest case of the quantum spin ice model, namely, the nearest-neighbor spin-1/2 XXZ model on the pyrochlore lattice with an antiferromagnetic longitudinal and a weak ferromagnetic transverse exchange couplings, J and J⊥. On cooling across Tcsti ≈ 0.2J, the specific heat shows a broad peak associated with a crossover to a classical Coulomb liquid regime characterized by a remnant of the pinch-point singularity in longitudinal spin correlations as well as the Pauling ice entropy for |J⊥| ≪ J, as in classical spin ice. On further cooling, the entropy restarts gradually decaying to zero for J⊥ > J⊥c ≈ −0.10J, as expected for bosonic quantum Coulomb liquids. With negatively increasing J⊥ across J⊥c, a first-order transition occurs at a nonzero temperature from the quantum Coulomb liquid to an XY ferromagnet. Relevance to rare-earth pyrochlore oxides is discussed.

11:27AM M28.00002 Possible algebraic spin liquid in half-filled Hubbard model at intermediate U/t, XIANG LI, Institute for Advanced Study, Tsinghua University, Beijing, 100084, China, ZI YANG MENG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, HONG YAO, Institute for Advanced Study, Tsinghua University, Beijing, 100084, China — Using large-scale fermion-sign-free projective Determinant Quantum Monte-Carlo (DQMC) method, we study the half-filled Hubbard model on the square lattice with staggered-flux. We calculate the single-particle gap, charge gap, as well as the improved dimensionless estimator of the antiferromagnetic (AF) order parameter, and map out the ground state phase diagram of this model spanned by U/t and staggered-flux. The lattice in our DQMC simulations has 2L×L sites with largest L=28. In the case of φ-flux, finite-size scaling analysis indicates a possible algebraic quantum spin liquid phase between the semi-metal phase at small U/t and the AF phase at large U/t. The algebraic spin liquid occurs in the arrange of 5.4 < U/t < 5.6. When the staggered-flux is smaller than the critical value of about \sqrt{φ}/10, the Fermi velocity in this system is largely anisotropic and it exhibits a direct transition from semi-metal phase to AF phase.

11:39AM M28.00003 Confinement–deconfinement transition in the algebraic RVB states, JI-QUAN PEI, SHAO-KAI JIAN, HONG YAO, Institute for Advanced Study, Tsinghua University — Deconfined algebraic spin liquids are usually expected when Gutzwiller projecting the non-interacting wave function of half-filled electrons on the square lattice with staggered flux φ. However, our large-scale variational Monte Carlo simulations show that there is the confinement-deconfinement transition at φ = φc, where φc ≈ 0.2 is the critical flux. When 0 < φ < φc, spinons are confined and the ground state develops an unexpected antiferromagnetic Neel ordering. From renormalization group analysis of anisotropic Dirac fermions coupled with U(1) compact gauge fields, we argue that the confinement of spinons in the Gutzwiller projected wave function might be due to the large anisotropy of Fermi velocity of Dirac fermions.

11:51AM M28.00004 ABSTRACT WITHDRAWN –

12:03PM M28.00005 Schwinger boson spin liquid states on square lattice: projective symmetry group study, XU YANG, FA WANG, Peking Univ — We will report our results on possible spin liquids on square lattice that respect all lattice symmetries and time-reversal symmetry within the framework of Schwinger boson (mean-field) theory. Such spin liquids have spin gap and emergent gauge field excitations. We classify them by the projective symmetry group method, and find six spin liquid states that are potentially relevant to the J1–J2 Heisenberg model. The properties of these states are studied under mean-field approximation and by projected wave functions on small lattices. Interestingly we find a spin liquid state that can go through continuous phase transitions to either Néel magnetic order or magnetic order of wavevector at Brillouin zone edge center. We propose that this state may be realized in J1–J2 Heisenberg model with ring exchange.

12:15PM M28.00006 Projective symmetry of partons in Kitaev’s honeycomb model1, PAULA MELLADO, Adolfo Ibañez University — Low-energy states of quantum spin liquids are thought to involve partons living in a gauge-field background. We study the spectrum of Majorana fermions of Kitaev’s honeycomb model on spherical clusters. The gauge field endows the partons with half-integer orbital angular momenta. As a consequence, the multiplicities reflect not the point-group symmetries of the cluster, but rather its projective symmetries, operations combining physical and gauge transformations. The projective symmetry group of the ground state is the double cover of the point group.

1We acknowledge Fondecyt under Grant No. 11121397, Conicyt under Grant No. 791112004, and the Simons Foundation (P.M.); the Max Planck Society and the Alexander von Humboldt Foundation (O.P.); and the US DOE Grant No. DE-FG02-08ER46544 (O.T.)
12:51PM M28.00007 Chiral spin liquid and emergent anyons in a Kagome lattice Mott insulator 
BELA BAUER, Microsoft Corp, LUKASZ CINCO, Perimeter Institute, BRENDAN P. KELLER, University of California, Santa Barbara, MICHELE DOLFI, ETH Zurich, GUIFRE VIDAL, Perimeter Institute, SIMON TREBST, University of Cologne, ANDREAS W. W. LUDWIC, University of California, Santa Barbara — One of the earliest proposals for a topological phase in a quantum spin system was the chiral spin liquid put forward by Kalmeyer and Laughlin in 1987 as the bosonic analogue of the fractional quantum Hall effect. Here, we examine a physically motivated model for a Mott insulator on the Kagome lattice with broken time-reversal (TR) symmetry that gives rise to a chiral spin liquid. We present unambiguous numerical identification and characterization of the universal topological properties of the phase, including ground state degeneracy, edge physics, and anyonic bulk excitations. To this end, we use a variety of powerful numerical probes, including the entanglement spectrum and modular transformations. We then discuss the phase diagram resulting from the competition of the TR symmetry breaking chiral term and a TR-symmetric Heisenberg term, which on the Kagome lattice has been argued to give rise to a TR-symmetric topological phase. In particular, we elucidate the dynamics of the chiral phase upon approaching the putative topological phase transition.

1:03PM M28.00008 Impact of non-Abelian anyons on criticality , MARC SCHULZ, FIONA BURNELL, Univ of Minn — Topological order provides an interesting playground to investigate criticality in phase transitions with no local order parameter where the condensing excitations interact statistically. We investigate the impact of these exchange statistics on critical properties by comparing two closely related models, which differ only by the presence or absence of such long-ranged statistical interactions for the condensed excitations:

1. The Ising string-net Hamiltonian, in which the transition is between a topologically ordered phase (with doubled Ising topological order) and a trivial phase. The excitations that condense across this transition are achiral non-Abelian anyons.

2. The Ashkin-Teller model on a triangular lattice, in which the transition is from a paramagnetic to a ferromagnetic phase.

We show that the non-Abelian excitations in the first model can be mapped onto the spin degrees of freedom of the second, and that the mapping captures all relevant features except the non-Abelian statistics. We derive the low-energy spectra of these models by means of high-order perturbation theory and exact diagonalization to study the resulting differences in their critical behavior.

1:15PM M28.00009 Variational Monte Carlo Study of a Non-Abelian Spin-1 Spin Liquid , JULIA WILDEBOER, N.E. BONESTEEL, NHMFL, Florida State University — Using variational Monte Carlo we analyze the properties of a non-Abelian spin-1 spin liquid state proposed in [1]. In this state the bosonic $\nu = 1$ Moore-Read Pfaffian wavefunction is interpreted as a wavefunction for a gas of bosons on a 2D square lattice with one flux quantum per plaquette. For this wavefunction the number of bosons on a given lattice site can be 0, 1 or 2, corresponding, respectively, to $S_z = -1$, 0 or 1 for a spin-1 degree of freedom on that site. Calculations are performed both in the planar geometry and on the torus. For the torus there are three distinct states corresponding to the three-fold degeneracy of the $\nu = 1$ bosonic Moore-Read state, and we show that the correlation functions in these states become identical in the limit of large system size. The Renyi entanglement entropy is also calculated for different system partitions in order to extract the topological entropy $\gamma = \ln D$ where $D$ is the total quantum dimension, predicted to be $D = 2$ for this state.

1:27PM M28.00010 Coherent Transmutation of Electrons into Fractionalized Anyons , MAISSAM BARKESHLI, Microsoft Station Q, EREZ BERG, Weizmann Institute, STEVEN KIVELSON, Stanford University — Electrons have three quantized properties — charge, spin, and Fermi statistics — that are directly responsible for a vast array of phenomena. Here we show how these properties can be coherently and dynamically stripped from the electron as it enters certain exotic states of matter known as a quantum spin liquid (QSL). In a QSL, electron spins collectively form a highly entangled quantum state that gives rise to emergent gauge forces and fractionalization of spin, charge, and statistics. We show that certain QSLs host distinct, topologically robust boundary types, some of which allow the electron to coherently enter the QSL as a fractionalized quasiparticle, leaving its spin, charge, or statistics behind. We use these ideas to propose a number of universal, conclusive experimental signatures that would establish fractionalization in QSLs.

1:39PM M28.00011 Chiral spin liquid in the frustrated XY model on the honeycomb lattice , TIGRAN SEDRAKYAN, Fine Theoretical Physics Institute, University of Minnesota and Physics Frontier Center, Joint Quantum Institute, University of Maryland — A honeycomb lattice allowing hops between nearest- and next-nearest neighbors hosts “moat” bands with degenerate energy minima attained along closed lines in Brillouin zone. If populated with hard-core bosons, a variety of unconventional ground states stabilizes. We argue that the degeneracy prevents Bose condensation, stabilizing novel spin liquid phases including composite fermion state and a chiral spin liquid. The latter stabilizes at half-filling, when the system is equivalent to $s = 1/2$ XY model at zero magnetic field. Absence of condensation means no spontaneous polarization in XY plane, however our consideration indicates formation of a state spontaneously breaking the time-reversal symmetry. This state has a bulk gap and chiral gapless edge excitations, and is similar to the one in Haldane’s “quantum Hall effect without Landau levels” in its topologically nontrivial sector with Chen number $C = \pm 1$. The applications of the developed analytical theory include an explanation of recent unexpected numerical findings and a suggestion of a chiral spin liquid realization in experiments with cold atoms in optical lattices.

Session M29 GMAG DMP FIAP: Focus Session: Spin-Torque Oscillators 206A - Igor Barsukov,
University of California, Irvine

11:15AM M28.00001 Time domain mapping of spin torque oscillators dynamics , JIEYI ZHANG, YUJIN CHEN, UC Irvine, GRAHAM ROWLANDS, Cornell University, ILYA KRIVOROTOV, UC Irvine, PATRICK BRAGANCA, JEFF CHILDRESS, BRUCE GURNEY, Hitachi Global Storage Technologies, UC IRVINE, HGST AND CORNELL UNIV COLLABORATION — Time domain measurements of spin torque oscillators (STOs) offer important insights into the magnetization dynamics under the action of spin torque. We use the time domain data to map statistical distributions of the STO free layer trajectories and analyze them in the framework of the Fokker-Planck effective energy approach. We make time-resolved measurements of the microwave voltage signal generated by an STO based on a 90 nm circular nanopillar patterned from IrMn/CoFe/CoFeGe/CoFe/Cu/CoFe/CoFeGe/CoFe multilayer. Based on our time domain data and the angular dependence of giant magneto-resistance of the device, we map out dynamic trajectories of the free layer. We then apply the Fokker-Planck approach to calculate spin torque dependent STO effective energy $E_{\text{eff}}$ from the experimentally measured statistical distributions of the free layer trajectories. We compare the measured $E_{\text{eff}}$ to that calculated in the macrospin approximation and discuss how such a comparison can be used for quantification of non-linear damping in the high-amplitude regime of STO operation.
11:27AM M29.00002 Tapered nanowire spin torque oscillator driven by spin orbit torques. LIU YANG, ANDREW SMITH, BRIAN YOUNGBLOOD, ZHENG DUAN, ILYA KRIVOROTOV, University of California, Irvine — We report microwave signal emission from a spin torque oscillator driven by spin orbit torques in a tapered Pt(7nm)/Py(5nm) ferromagnetic nanowire with 2 um long active region. The tapered nanowire oscillator exhibits lower spectral linewidth (<1 MHz) and higher integrated power (>1 nW) compared to a spin tube oscillator based on a nanowire with spatially uniform width. The tapered nanowire oscillator has two distinct regimes of the microwave signal emission: a low-current, low-amplitude regime with a soft onset of the microwave emission and a higher-current regime with a hard onset of large-amplitude oscillations. The existence of the two regimes arises from spatially non-uniform effective damping in the tapered nanowire geometry. The non-uniformity of the effective damping results in nucleation of magnetization self-oscillations at the narrow end of the nanowire and subsequent steady growth of the self-oscillatory region with increasing current throughout the low-power regime. The sudden turn on of the high-power regime takes place at a critical current, for which spatially averaged effective damping of the nanowire changes sign from positive to negative. Our work paves the way towards high-power spectrally pure spin torque oscillators driven by spin orbit torques.

11:39AM M29.00003 Spin Torque Oscillators with Highly Spin-Polarized Heusler Alloy. TAKESHI SEKI, TATSUYA YAMAMOTO, KOKI TAKANASHI, Institute for Materials Research, Tohoku University — An intriguing spin torque device is the spin torque oscillator (STO). An important issue for STOs from the viewpoint of practical use is to enhance the rf output power (Pout). Since Pout is roughly proportional to the square of the magnetoresistance (MR) ratio, a ferromagnetic material showing a large MR effect is a candidate for high-performance STO. In this study, we have developed high-power all-metal STOs with a full Heusler Co2Fe0.4Mn0.6Si (CFMS) showing a large MR effect. The present STOs consist of current-perpendicular-to-plane (CPP) giant magnetoresistance (GMR) stacks of CFMS | Ag | CFMS. A pillar-shaped STO showed clear auto-oscillation. The large Pout of 23.7 nW was obtained owing to its out-of-plane magnetization precession. Simultaneously, the oscillation linewidth showed the minimum value of 10 MHz. On the other hand, a point-contact-type STO showed auto-oscillation even at zero external magnetic field, and the oscillation mode was drastically changed as the bias current was increased. The large Pout for both STOs indicates the CPP-GMR devices with CFMS layers are promising for high performance STO.

11:51AM M29.00004 Linewidth reduction in spin–torque oscillators by delayed self-injection. JG thanks the European Research Council NanoBrain Grant 259068

12:03PM M29.00005 Spin wave beam mediated synchronization of nano-contact spin torque oscillators. AFSHIN HOUSHANG, EZIO IACOCCA, PHILIPP DURRENFELD, University of Gothenburg, SOHRAB SANI, New York University, JOHAN AKERMAN, RANDY DUMAS, University of Gothenburg — The synchronization of multiple nano-contact spin torque oscillators (NC-STOs) [1-3] is mediated by propagating spin waves (SWs). While it has been shown that the Oersted field generated in the vicinity of the NC can dramatically alter the emission pattern of SWs [4], its role in the synchronization behavior of multiple NCs has not been considered. We investigate the synchronization behavior in double NC-STOs oriented either vertically or horizontally, with respect to the in-plane component of the external field. Two NCs with nominal diameters of 100 nm and a center-to-center spacing of 300 nm are defined on top of an all metallic Co/Cu/NiFe pseudo spin valve. Synchronization is promoted (impeled) by the Oersted field strength when the NCs are oriented vertically (horizontally) due to the highly anisotropic SW propagation. The vertical positioning of the NCs gives rise to a unique magnetic field landscape that acts to localize SWs in a region just outside one of the NCs, as confirmed by micromagnetic simulations. [1] S. Kaka, et al., Nature 437, 389 (2005) [2] F.B. Mancoff, et al., Nature 437, 393 (2005). [3] S.R. Sani, et al., Nat. Comm. 4, 2731 (2013) [4] R.K. Dumas, et al., Phys. Rev. Lett. 110, 257202 (2013)

12:15PM M29.00006 Directional spin wave emission by the spin transfer torque oscillator into a nanomagnonic waveguide. VLADISLAV DEMIDOV, SERGEI DEMOKRITOV, Muenster University, SERGEI URAZHDIN, Emory University — Magnonics is based on signal transmission and processing by spin waves in a magnetic medium. Spin-torque nanooscillators (STNO) driven by dc electrical current can provide a local source of spin waves for nanomagnonics, but their spectral mismatch with the magnetic medium limits the spin wave emission efficiency. We have developed a nanomagnonic structure that combines a point-contact STNO with a dipolar field-induced nanowaveguide. We will describe our microfocus Brillouin light scattering microscopy measurements demonstrating efficient excitation of spin waves by the STNO and their directional propagation in the waveguide. Spectroscopic measurements and micromagnetic simulations indicate that efficient spectral matching between the waveguide and the STNO is achieved due the internal dipolar field of the nanopatterned waveguide. We show that the spin wave propagation length is increased compared to the extended films, due to their larger group velocity and the lack of wavefront spreading. Our results provide a simple and efficient route for the implementation of magnonic structures that integrate spin torque-based sources of spin waves and their processing via waveguiding structures.

12:27PM M29.00007 Coherent magnetization oscillation induced by nonlocal spin injection. SERGEI URAZHDIN, ANDREI ZHOLUD, Emory University, VLADISLAV DEMIDOV, SERGEI DEMOKRITOV, Muenster University — We experimentally demonstrate coherent magnetization oscillations induced by nonlocally injected pure spin current in a CoFe/Cu/Permальloy(Py) magnetic thin film heterostructure. The current injected into CoFe through a point contact is drained through the Cu spacer, while the spins diffusing from the CoFe/Cu interface to Py cause magnetic oscillations of the latter. Symmetry analysis and numeric calculations show that the current is negligible in the active region of the Py layer, and does not exceed 3 percent of the total current away from it. The oscillation frequency decreases with increasing current, and an additional spectral peak appears at large currents. Micro-focus Brillouin light scattering microscopy shows that the size of the oscillation region is larger than expected from the usual self-localization mechanism of auto-oscillation. Micromagnetic simulations suggest that the oscillation mode is localized by an effective potential well formed due to the local reduction of magnetization by the effects of spin current, providing a route for the development of spin-torque nano-oscillators with controllable spatial oscillation characteristics.

12:39PM M29.00008 Noise-enhanced synchronization of stochastic magnetic oscillators1. JULIE GROLLIER, ALICE MIZRAHI, CNRS/Thales, Palaiseau, France, NICOLAS LOCATELLI, Institut d’Electronique Fondamentale, Orsay, France, ARTUR ACCIOLY, Instituto de Fisica, Univ. Federal do Rio Grande do Sul, Porto Alegre, Brazil, RIE MATSUMOTO, AKIO FUKUSHIMA, HITOSHI KUBOTA, SHINJI YUASA, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan, VINCENT CROS, CNRS/Thales, Palaiseau, France, LUIGI GUSTAVO PEREIRA, Instituto de Fisica, Univ. Federal do Rio Grande do Sul, Porto Alegre, Brazil, DAMIEN QUERLOZ, JOO-VON KIM, Institut d’Electronique Fondamentale, Orsay, France — Due to their small magnetic volume the magnetization dynamics of spin-torque nano-oscillators is very sensitive to thermal fluctuations. The effect of thermal noise is large and can phase-lock the system to the thermal noise. Here we study how the thermal noise influences the phase-locking and the synchronization of a stochastic oscillator driven by spin-torque ferromagnetic resonance in YIG/Pt bilayers and the corresponding spatially-resolved spin-wave distribution are presented.

1We thank the European Research Council NanoBrain Stg Grant 250908.

12:51PM M29.00009 Terahertz Nano-oscillator using Antiferromagnet. RAN CHENG, DI XIAO, Carnegie Mellon University, ARNE BRATAAS, Norwegian University of Science and Technology — We present an analytical study on the current-induced dynamics of collinear antiferromagnets (AFs), and find that a sufficiently large current gives rise to terahertz auto-oscillation of the staggered order. For easy-plane AFs such as NIO, the acoustic and optical modes are well separated in frequency, and none of them exhibit chirality of precession. However, with increasing current-induced torque, the two modes become degenerate at a threshold, after which the chirality of precession is acquired. At a second threshold, the degenerate mode is driven into auto-oscillation with elliptical precession where the semi-major axis is 45 degree with respect to the easy-plane. The terahertz nano-oscillator is illustrated by X/AF/X heterostructures where X can either be a heavy metal or topological insulator.

1:03PM M29.00010 Nanoconstriction-based Spin Hall nanooscillator. ANDREI ZHOLUD, SERGEI URAZHODIN, Emory University, VLADISLAV DEMIDOV, SERGEJ DEMOKRITOV, University of Muenster — We experimentally demonstrate coherent magnetization oscillations induced in a bow tie-shaped Pt/Permalloy nanoconstrastion by pure spin current generated by the spin Hall effect. The devices generate microwave signals with a significant power and the spatial linewidth as low as 6.2 MHz at room temperature (RT). In contrast to the previously demonstrated spin Hall oscillators governed by the dynamical nonlinear self-localization mechanism, the localized oscillation mode is present in the thermal fluctuation spectrum even below the auto-oscillation onset and exhibits a significant redshift. These observations suggest that the localized auto-oscillation mode is formed due to the confinement in an effective potential well produced by a combination of the dipolar field of the magnetic nanoconstriction and the Oersted field of electrical current. The studied devices are characterized by a large oscillation area, minimizing the effects of thermal fluctuations and resulting in a narrow RT spectral linewidth without compromising the single-mode regime of autooscillation. Moreover, the simple structure of the proposed oscillators enables their cascading, which can be utilized to further improve the oscillation characteristics in mutually coupled devices.

1:39PM M29.00013 Spin-transfer torque induced spin waves in antiferromagnetic insulators1. MATTHEW DANIELS, Carnegie Mellon University, WEI GUO, Fudan University, G. MALCOLM STOCKS, Oak Ridge National Laboratory, DI XIAO, Carnegie Mellon University, JIANG XIAO, Fudan University — We explore the possibility of exciting spin waves in insulating antiferromagnetic films by injecting spin-transfer torque, the two modes become degenerate at a threshold, after which the chirality of precession is acquired. At a second threshold, the degenerate mode is driven into auto-oscillation with elliptical precession where the semi-major axis is 45 degree with respect to the easy-plane. The terahertz nano-oscillator is illustrated by X/AF/X heterostructures where X can either be a heavy metal or topological insulator.

1:51PM M29.00014 Spin dynamics in patterned nanometer-thick yttrium iron garnet films1. MATTHIAS BENJAMIN JUNGLEISCH, WEI ZHANG, WANGJUN JIANG, STEPHEN M. WU, JOHN E. PEARSON, ANAND BHATTACHARYA, AXEL HOFFMANN, Argonne National Laboratory, JOSEPH SKLEWAR, JOHN B. KEITZER, Northwestern University, HOUCHEN CHANG, MINGZHONG WU, Colorado State University — We present experimental investigations on the propagation of spin-wave modes in micro-structured yttrium iron garnet (YIG) stripes.1 The stripes were patterned by photo-lithography from high-quality 40-nm-thick YIG films grown by sputtering.2 Magnetization dynamics is driven by the rf field of a shorted coplanar waveguide patterned onto the YIG stripes. The propagation of spin waves are detected by means of spatially-resolved Brillouin light scattering microscopy. The propagation distance of spin waves is determined in the linear regime, where an exponential decay of 10 µm is observed. The estimated Gilbert damping parameter extracted from the spin-wave decay length is 3 times larger than that obtained through ferromagnetic resonance measurements in unstructured films, which is possibly due to enhanced two-magnon scattering in the patterned films. Furthermore, studies on the spin dynamics driven by spin-torque ferromagnetic resonance in YIG/Pt bilayers and the corresponding spatially-resolved spin-wave distribution are presented.

2:03PM M29.00015 Probing excitations in insulators by injecting spin currents. SHUBHAYU CHATTERJEE, SUBIR SACHDEV, Harvard University — Observation of fractional excitations in insulating spin-systems has been a long-sought goal in physics. In spite of promising evidence for observation of spin liquids, the exact nature of possible ground states, and in particular, the presence of a spin-gap is still unclear. Most experiments till this point have focused on thermodynamic measurements. We suggest a transport measurement as an alternate window into the nature of excitations of insulating spin systems. We couple a metal with a non-equilibrium spin-accumulation to an equilibrium insulating spin-system [1], and develop a general formalism to compute the spin current. We use this to calculate the current into ordered antiferromagnets as well as spin liquids, and note salient features in the spin conductance. [1] Takei et. al. Phys. Rev. B 90, 094408 (2014).
Preliminary electrical measurements on these devices show \( \sim \) transition from superparamagnetism to ferromagnetism-like, with ferromagnetism persisting at 300K. This transition is attributed to changes in both the amount of Ni \( \sim 10^{-25} \text{nm} \) and density \( \sim \) inside CNTs. Magnetometry results indicate that free-standing CS NPs and filled CNTs share a similar magnetic interaction mechanism. However, the overall magnetic moment in the graphene superlattice, helping to mediate the superexchange between the impurities. Depending on the choice of ion used, the interactions between the two ions can exhibit either a ferromagnetic or an antiferromagnetic behavior. These correlations indicate an RKKY-like behavior in the system. The effect of carrier doping, chemical modification at the edge, and finite temperature on the edge magnetism has been studied. The magnetic phase diagram with varied carrier doping, and on-site Coulomb interaction is found to be complex. Chemical modification of the edge atoms by hydrogen leads to partial quenching of local moments, giving rise to a richer phase diagram. We further report the influence of temperature on the long-range magnetic ordering at the edge using ab initio molecular dynamics. These findings will have important implications in controlling magnetism in graphene based low dimensional structures for technological purpose, and in understanding varied experimental reports.²

12:15PM M30.00006 Synthesis and properties of ferromagnetic nanostructures embedded within a high-quality crystalline silicon matrix
12:27PM M30.00007 Helical spin order in Fe nanoislands, SOO-HYON PHARK, Center for Activated Electron Systems, Institute for Basic Science, Seoul National University, Seoul, Korea. KOHJI NAKAMURA, Department of Physics Engineering, Me University, Japan. JASON FISCHER, MARCO CORBETTA, SAFIA OUZI, DIRK SANDER, JUERGEN KIRCHNER, Max-Planck-Institute of Microstructure Physics, Halle, Germany — We report a spin-polarized scanning tunneling microscopy and spectroscopy (SP-STM) using an atomic scale resolution, of individual nanostructures of biatomic-layer-high Fe on Cu[111]. SP-STM/S of the Fe nanoislands reveals a magnetic stripe phase with a period of 1.28 nm, which is identified as a one-dimensional helical spin order [1]. *Ab initio* calculations identify reduced-dimensionality-enhanced long range antiferromagnetic interactions as the driving spin-ordered phenomena [2,3]. In addition, electron-mapping provides a spatially-resolved and spin-dependent electronic structure of this helical spin order. The wave vector describing the spin order remains constant in the energy range -0.8 to +0.6 eV, whereas the spin contrast shows dissipation features around and sign change across the Fermi energy. We discuss the results in view of an energy gap opening associated with the non-collinear spin order. Our result identifies a novel aspect of SP-STM/S to characterize complex spin order with respect to the corresponding spin-dependent electronic band structure.

12:39PM M30.00008 Unconventional top down synthesis of FeNi core and C shell magnetic nanoparticles, RAKESH CHAUDHARY, ALI R. KOYMEN, Department of Physics, The University of Texas at Arlington — Carbon encapsulated FeNi nanoparticles were prepared by a top down approach using plasma in organic solvents. FeNi core-Carbon shell morphology of nanoparticles have been observed using transmission electron microscopy (TEM). FeNi nanoparticles prepared in toluene are of diameter 3-820 nm and encapsulated by a 3-60 nm shell. FeNi nanoparticles prepared in ethanol are of diameter 15-820 nm and encapsulated by a 4-34 nm shell. Using x-ray diffraction (XRD) the core crystal observed using transmission electron microscopy (TEM). FeNi nanoparticles prepared in toluene and ethanol showed a saturation magnetization of ∼1 emu/g and ∼3 emu/g and moderate coercivity ∼40 Oe and ∼10 Oe respectively at room temperature. We explore the uncommon and new, top down synthesis route of bimetallic nanoparticles of FeNi phase using plasma. These carbon-encapsulated FeNi nanoparticles could have potential applications in biomedicine, especially hyperthermia.

12:51PM M30.00009 Facile Synthesis of L10 FePt/Reduced-Graphene Oxide Nanocomposites, XIAOCAO HU, VASILIS TZITZIOS, University of Delaware, DAVID SELLMYER, University of Nebraska, GEORGE HADJIPANAYIS, University of Delaware — FePt nanoparticles (NPs) have attracted much attention recently for applications in high density recording media and catalysis. Usually the as-made FePt NPs are in the fcc phase and must be annealed at high temperatures to be converted to the L1(0) structure and because of this the particles agglomerate. In this paper, we used a novel fabrication method to directly prepare FePt NPs in fct phase on the surface of R-GO (Reduced Graphene oxide). A layered bimetallic precursor Fe(H2O)6[PtCl6] was mixed in water environment with exfoliated GO. The precipitates were annealed under a forming gas (5% H2 and 95% Ar)atmosphere at different temperatures varying from 500 °C to 950 °C. During the annealing process, the layered precursor [Fe(H2O)6][PtCl6] was reductively decompose directly to the L10 FePt crystal structure while the GO reduced by H2 atmosphere. Transmission electron microscopy (TEM) results showed that the FePt NPs have the L10 structure and a uniform size distribution with their average particle size in the range from 5 nm to 28 nm depending on the annealing temperature used. The fct particles had coercivity values in the range of 6 kOe-9 kOe. Furthermore, it is clear that the FePt nanoparticles are formed only on the surface of the graphene and no individual particles were observed off the graphene. The L10 FePt NPs are still isolated on the surface of the graphene and the particle size remains quite small (8 nm) even at annealing temperatures as high as 750 °C. Work supported by DOE-BES-DMSE (Grant No. DE-FG02-04ER4612).

1:03PM M30.00010 Ferromagnetic to antiferromagnetic transition in the Fe11/3(Ta1−x,Nbx)S2 layered dichalcogenides, CHIH-WEI CHEN, JESSE ADAMS, WILL HARDY, DOUGLAS NATELSON, EMILIA MOROSAN, Physics & Astronomy Department, Rice University — Fe11/3TaS2 is known to order ferromagnetically with Tc = 40 K, while the stoichiometric Nb compound orders antiferromagnetically below TN = 40 K. The Ta-Nb solid solution provides an opportunity to search for a quantum phase transition (QPT) as we tune the magnetic order in Fe11/3TaS2 by doping between T = Ta and T = Nb. We will analyze magnetization, specific heat, and resistivity data to search for signatures of a T = 0 transition. Additionally, we will compare the magnetoresistive effects in these Fe-intercalated TaS2 (T = Ta, Nb) and compare with our previous results on Fe11/3TaS2 (x = 0.25, 0.28). Small departures from the superstructure Fe compositions (x = 0.25, 0.33) in Fe11/3TaS2 resulted in two orders of magnitude increase in the magnetoresistance.

1:15PM M30.00011 Influence of interparticle interactions on the blocking temperature and high frequency permeability of Fe3O4 nanoparticle systems, M DHANSADAT, DAVID B. MAST, DONGLU SHI, University of Cincinnati, SERGEY L. BUD’KO, Ames Laboratory, Iowa State University — In Néel’s model of superparamagnetism, magnetization and relaxation dynamics depend on the magnetic anisotropy constant of the non-interacting, individual nanoparticle (NPs). However, NP interactions modify these dynamics in real systems. To investigate the influence of magnetic interactions on NP anisotropy, we compare the results from measurements of the blocking temperature of Fe3O4 NPs systems with very different average interparticle separations, one with uniformly dispersed NPs and the other with the NPs tightly confined in a polystyrene matrix. The blocking temperature for the confined NPs (263K) was substantially higher than for the uniformly dispersed NPs (131K), which we attribute to stronger dipolar interactions. The relaxation times are determined from peaks in the imaginary part of the complex permeability versus frequency from 10 MHz - 3 GHz. For uniformly dispersed Fe3O4 NP (in hydrocarbon carrier), the Néel relaxation and the gyromagnetic resonance were observed at 41 MHz and 1.2 GHz, respectively, which corresponds to an anisotropy constant of ~15 Kj/m3 compared to 12 Kj/m3 predicted by Néel’s relaxation model for 10 nm diameter Fe3O4 NPs. Details of this correlation between the blocking temperature and high frequency permeability will be discussed.

1:27PM M30.00012 Novel magnetic and electric properties of small pure gold clusters, LEI MA, RAMIRO MORO, BAIQIAN ZHANG, JOHN INDERGAARD, ILJA LARKIN, Georgia Institute of Technology, HANNU HÄKKINEN, Department of Physics Engineering, Me University, Japan. MAUSIT KINDBERG, Department of Physics, University of Jyväskylä, MATHEUS KINDBERG, Department of Physics, University of Jyväskylä, and the Center for Activated Electron Systems, Institute for Basic Science, Seoul National University, Seoul, Korea. — FePt nanoparticles (NPs) have attracted much attention recently for applications in high density recording media and catalysis. Usually the as-made FePt NPs are in the fcc phase and must be annealed at high temperatures to be converted to the L1(0) structure and because of this the particles agglomerate. In this paper, we used a novel fabrication method to directly prepare FePt NPs in fct phase on the surface of R-GO (Reduced Graphene oxide). A layered bimetallic precursor Fe(H2O)6[PtCl6] was mixed in water environment with exfoliated GO. Work supported by DOE-BES-DMSE (Grant No. DE-FG02-04ER4612).
1:39PM M30.00013 Effect of confinement on spin polarization and magnetism of Co$_2$Si nanoclusters$^1$, DAVID SELLMYER, BALAMURUGAN BALASUBRAMANIAN, PRIYANKA MANCHANDA, RALPH SKOMSKI, PINAKI MUKHERJEE, BHASKAR DAC, NCMN, University of Nebraska, Lincoln, NE 68588, GEORGE HADJIPANAYIS, University of Delaware, Newark, DE 19716 — Size-modified electronic structure and surface effects can lead to unusual magnetic ordering, modified ordering temperatures, and different spin structures in nanoclusters as compared to the corresponding bulk alloys. Thus nanoclusters can be used as building blocks to create new complex magnetic nanostructures for potential applications. We show room-temperature ferromagnetic ordering in Co$_2$Si nanoclusters with relatively large magnetic moments (0.49 $\mu_B$/Co at 300 K and 0.70 $\mu_B$/Co at 10 K) and magnetocrystalline anisotropy ($K_1 \approx 4$ Mergs/cm$^3$ at 10 K), as contrasted to very weak itinerant magnetism in bulk Co$_2$Si (0.001 $\mu_B$/Co at 300 K and 0.072 $\mu_B$/Co at 10 K). The DFT and analytical model calculations explain the size-dependence of the observed magnetic moments on the size of Co$_2$Si nanoclusters, which vary from 0.6 to 30 nm, by a surface-induced spin polarization of nanoclusters.

$^1$This research is supported by U.S. DOE-BES-DMSE (Grant No. DE-FG02-04ER46152) and NCMN.

1:51PM M30.00014 Magnetic properties of ternary and quaternary transition metal nanoclusters, JAIME SOUTO CASARES, JAMES CHELIKOWSKY, University of Austin at Texas — The magnetic properties of transition-metal nanostructures is a topic that has attracted much interest, mainly because of the dramatic difference that exists in comparison with the bulk. Without a proper knowledge of the fundamental mechanism behind the magnetic phenomena, it is hard to predict the properties of complex materials. We investigate the electronic and magnetic properties of nanoclusters made of ternary and quaternary compounds of transition metals (Fe, Co, and Ni) using PARSEC, a real-space implementation of pseudopotentials within density functional theory. Our code is well suited for the study of isolated structures because of its implementation of very efficient techniques for solving the Kohn-Sham equations. The real-space nature of PARSEC allows the use of proper boundary conditions, imposing the electronic wave functions to vanish outside a spherical domain. With these computational tools we can cover a wide spectrum of magnetic alloys and look for specific magnetic properties. This work is supported by NSF grant DMR 14-35219.

11:15AM M31.00001 Heat transport in the frustrated spin-ladder compound, BiCu$_2$PO$_6$$^1$, NARAYAN PRASAI, ALWYN REBELLO, JOSHUA L. COHN, University of Miami, SUELI H. MASUNAGA, JOHN J. NEUMEIER, Montana State University — We report measurements of thermal conductivity ($\kappa$) in the range 0.4 K $\leq T \leq$ 300 K for single-crystal BiCu$_2$PO$_6$, a recently discovered frustrated 2-leg spin-ladder compound. For heat flow both along and transverse to the spin ladders, $\kappa$ exhibits a broad maximum near 60 K, coinciding with a similar maximum reported in the magnetic susceptibility, and consistent with resonant phonon scattering from spin excitations with an energy scale 40-60 K. Anisotropy in $\kappa$, evidence for a spin contribution at low temperatures, and the influence of magnetic field will be discussed.

$^1$This material is based upon work supported by the U.S. Department of Energy Office of Basic Energy Sciences grant DE-FG02-12ER46888 (Univ. Miami) and the National Science Foundation under grant DMR-0907036 (Mont. St. Univ.).

11:27AM M31.00002 Evolution of magnetic excitations in BiCu$_2$PO$_6$ observed via magnetic suppression of phonon heat conduction, BYUNG-GU JEON, B., KOTESWARARAO, C.B. PARK, KEE HOON KIM, Seoul Natl. Univ., Korea, G.J. SHU, F.C. CHOU, Natl. Taiwan Univ., Taiwan, S.C. RIGGS, NHMFL, USA, S.B. CHUNG, IBS-CCES, Korea — We report the thermal conductivity of a frustrated spin ladder BiCu$_2$PO$_6$ under high magnetic field up to 30 T. At 0 T, strong suppression of the thermal conductivity is emerged around 15 K, leading a double-peak shape in the temperature-dependent thermal conductivity. Upon increasing the magnetic field, the suppression is further enhanced and shows a sharp dip in the magneto-thermal conductivity around the critical magnetic field. The anomalous, field-dependent thermal conductivity is interpreted as a resonance scattering of phononic heat carriers by magnetic excitations. From the analysis based on the transport theory, we successfully traced the magnetic field dependence of the magnetic excitation gaps up to 25 T.

11:39AM M31.00003 Stepwise orderings in anisotropically coupled spin ladders, SHUNSUKE FURUYA, THIERRY GIAMARCHI, Univ of Geneva — In low-dimensional quantum magnets, lowering the temperature, we can find phase transitions from lower to higher dimensional phases. The (unfrustrated) spin ladder is a good example to see such a change of the dimensionality because it occurs only under strong enough magnetic field. That is, the dimensionality in the coupled spin ladder system is controllable by means of the temperature and the magnetic field. In this presentation, we will discuss a cascade of the dimensionality from the 1D phase to the 3D ordered phase via a quasi-2D ordered phase and its interesting manifestation in stepwise temperature dependence of the order parameter. We presume two inequivalent interladder exchange interactions $J'_1$ and $J'_2$. The former connects spin ladders in a plane to form 2D layers and the latter connects those layers. For $0 < J'_2 \ll J'_1$, we would naively expect a very low critical temperature $T_c \rightarrow 0$ because quantum fluctuations prevents spontaneous breaking of continuous symmetries. However we would like to point out that it is not the case, that is, $T_c$ remains finite even for infinitesimal $J'_2$, leading to a sudden growth at a certain temperature $T_{cr}$ below $T_c$.
An extremely well-isolated 2D antiferromagnet

12:27PM M31.00005 An extremely well-isolated 2D antiferromagnet, CHRISTOPHER LAMDEE, NIZAR NAITLHO, Department of Physics, Clark University, M.M. TURNBULL, Carlson School of Chemistry, Clark University — We report on the synthesis, structure, and magnetic susceptibility of an extremely well-isolated rectangular Heisenberg, \( S = 1/2 \) antiferromagnet, \([\text{Cu}(pz)_2(4-\text{OHpy})_2](PF_6)_2\), where \( pz = \text{pyrazine} \) and \( 4-\text{OHpy} = 4\)-pyridine. The copper and pyrazine form nearly square layers of pyrazine-bridged copper(II) ions, with the pyridine molecules normal to the layers, coordinated to the copper sites by the oxygen. The distance between copper sites in adjacent layers is approximately 13 Å indicating a high degree of two-dimensionality. The magnetic susceptibility is best described by a model of an antiferromagnetic rectangle with the stronger and weaker interactions of 8.3 and 4.0 K, respectively. The compound is more symmetric than an analogous compound \([\text{Cu}(pz)_2(2\text{-OHpy})_2](\text{ClO}_4)_2\), reported previously [1].

12:27PM M31.00004 Temporal correlations in tunable Luttinger spin liquids, ANDREY ZHELudev, Laboratory for Solid State Physics, ETH Zurich, Switzerland — Landau’s theory of Fermi liquids, which is the cornerstone of our understanding of fermionic systems, breaks down in low dimensions. In one dimension, interacting fermions are in a quantum critical state with some fascinating universal thermodynamic properties and correlation functions. This particularly interesting case is quantitatively described by the so-called Luttinger liquid theory. The cleanest real-world realizations of this model are found in low-dimensional spin systems [1], such as in Heisenberg spin chain and ladder materials. The universal scaling relations in these Luttinger liquids have been studied both theoretically and experimentally. In this quest, neutron scattering has proven to be instrumental, as it provides direct access to spatial and temporal correlation functions. In classic previous studies [2,3], this technique has been employed to measuring finite-temperature scaling in the simplest spin chain models. The latter are described by Luttinger liquid theories with the so-called Luttinger parameter \( K=1/2 \), corresponding to a strong repulsion between particles. The new challenge is to investigate the scaling for other values of \( K \), particularly in systems with \( K>1 \) (attractive fermions). In experiments, \( K \) and other characteristics of Luttinger spin liquids can be, in principle, tuned continuously by the application of an external magnetic field. In practice, measurements under such conditions are extremely challenging due to several unexpected technical difficulties. Nevertheless, recent advances in neutron instrumentation, particularly at pulsed neutron sources, help overcome these obstacles. In my talk I shall review the most recent results of experimental studies of Luttinger liquid properties of low dimensional quantum magnets under high magnetic fields. I will cover spin chain materials where \( K \) is continuously tunable in the range \( 1/2< K <1 \), and the strong leg spin ladder compound DIMPY where \( K>1 \) was achieved for the first time [4-6]. I will also describe how residual 3-dimensional interactions, usually considered a nuisance for low-dimensional physics, can in certain cases be exploited to accurately measure the exact field-dependent values of all relevant one-dimensional Luttinger liquid parameters.

12:39PM M31.00006 Dynamics of a quasi-2D \( S = 1/2 \) spin-dimer Heisenberg antiferromagnet under hydrostatic pressure, GERARD PERREN, JOHANNES MOELLER, NSM group, ETH Zurich, Switzerland, DAN HUEVONEN, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, ANDREY ZHELudev, Oak Ridge National Laboratory, Oak Ridge, USA, ANDREY ZHELudev, NSM group, ETH Zurich, Switzerland — We present Inelastic Neutron Scattering measurements (INS) under hydrostatic pressure on a quasi-2D \( S = 1/2 \) spin-dimer Heisenberg antiferromagnet. At high pressure, the observed dynamic structure factor \( S(Q, \omega) \) features Goldstone modes, which is a key signature of long-range (magnetic) order. This is in good agreement with recent \( \mu\mathrm{SR} \) findings and the presence of a pressure-induced quantum critical point at a moderate pressure [1]. Furthermore, we suggest an explanation for an apparent contradiction with a previous INS study performed under similar conditions [2].

12:39PM M31.00004 Temporal correlations in tunable Luttinger spin liquids, ANDREY ZHELudev, Laboratory for Solid State Physics, ETH Zurich, Switzerland — Landau’s theory of Fermi liquids, which is the cornerstone of our understanding of fermionic systems, breaks down in low dimensions. In one dimension, interacting fermions are in a quantum critical state with some fascinating universal thermodynamic properties and correlation functions. This particularly interesting case is quantitatively described by the so-called Luttinger liquid theory. The cleanest real-world realizations of this model are found in low-dimensional spin systems [1], such as in Heisenberg spin chain and ladder materials. The universal scaling relations in these Luttinger liquids have been studied both theoretically and experimentally. In this quest, neutron scattering has proven to be instrumental, as it provides direct access to spatial and temporal correlation functions. In classic previous studies [2,3], this technique has been employed to measuring finite-temperature scaling in the simplest spin chain models. The latter are described by Luttinger liquid theories with the so-called Luttinger parameter \( K=1/2 \), corresponding to a strong repulsion between particles. The new challenge is to investigate the scaling for other values of \( K \), particularly in systems with \( K>1 \) (attractive fermions). In experiments, \( K \) and other characteristics of Luttinger spin liquids can be, in principle, tuned continuously by the application of an external magnetic field. In practice, measurements under such conditions are extremely challenging due to several unexpected technical difficulties. Nevertheless, recent advances in neutron instrumentation, particularly at pulsed neutron sources, help overcome these obstacles. In my talk I shall review the most recent results of experimental studies of Luttinger liquid properties of low dimensional quantum magnets under high magnetic fields. I will cover spin chain materials where \( K \) is continuously tunable in the range \( 1/2< K <1 \), and the strong leg spin ladder compound DIMPY where \( K>1 \) was achieved for the first time [4-6]. I will also describe how residual 3-dimensional interactions, usually considered a nuisance for low-dimensional physics, can in certain cases be exploited to accurately measure the exact field-dependent values of all relevant one-dimensional Luttinger liquid parameters.

12:51PM M31.00007 Magnetic phase diagram of the spatially anisotropic spin-1/2 zigzag ladder, MOHAMMAD SOLTANIEH-HA, ADRIAN FEIGUIN, Northeastern University — We study the magnetic phase diagram of a spatially anisotropic zigzag ladder with exchange interactions \( J_z \) and \( J_x^\prime \) along the legs. This system interpolates between the conventional \( J_1-J_2 \) chain, and the “sawtooth,” or “delta” chain, described by a linear arrangement of triangles. Both systems display dimerization in a region of the zero-field phase diagram, but the anisotropy leads to two excitations with different velocities. We study the magnetic phase diagram of the system as a function of \( J_z \) and \( J_x^\prime \) and find commensurate plateaus at \( m = 1/2 \) and \( m = 1/3 \), and study the competition between different orders, including incommensurate, chiral, polar, and two-component liquid phase.

1:03PM M31.00008 Symmetry protected topological states in antiferromagnets with magnetic field, SHINTARO TAKAYOSHI, National Institute for Materials Science, KEISUKE TOTSUKA, Yukawa Institute for Theoretical Physics, Kyoto University, AKIHIRO TANAKA, National Institute for Materials Science — A symmetry protected topological (SPT) phase is a short-range entangled state that cannot be adiabatically deformed into a direct product state under some symmetry. We show that magnetization plateau states of one-dimensional antiferromagnets in external magnetic field is in an SPT phase when \( S - m \) is odd, where \( S \) and \( m \) represent a spin quantum number and magnetization per site, respectively, if the system respects a bond-center inversion symmetry. We map the antiferromagnets into a field theory of a nonlinear sigma model with a Berry phase term which has a coefficient proportional to the quantity \( S - m \). This term appears in the functional form of the ground state wave function and dictates whether or not the system is in the SPT phase. We verify this prediction through numerical calculations of the entanglement spectra and an analysis using a matrix product state representation.

1:15PM M31.00009 Detailed analysis of critical points in coupled spin dimer systems, DOMINIK STRASSEL, Univ. of Kaiserslautern, PETER KOPIETZ, Univ. of Frankfurt, SEBASTIAN EGGERT, Univ. of Kaiserslautern — Spin dimer systems are a promising playground for the detailed study of quantum phase transitions. In many cases it is sufficient to use the magnetic field as the tuning parameter in order to reach interesting non-trivial critical points and observe a crossover from the characteristic scaling near the critical point to the behavior of a finite temperature phase transition. In order to quantitatively demonstrate those effects and inspired by recent experiments we have started large scale quantum Monte Carlo simulations in order to analyze several different physical quantities in spin dimer systems, namely the susceptibility, the magneto-caloric effect, and the spin stiffness. We discuss in detail how the phase transitions (quantum and finite temperature) are manifest in the characteristic scaling behavior near critical points by comparing them with interacting boson theories. For two dimensional systems the predicted logarithmic corrections cannot be observed, however.

1:27PM M31.00010 Magnetization Plateaux in a frustrated spin ladder, TAKANORI SUGIMOTO, Tokyo Univ of Science, MICHIMARU IGAMI, Japan Atomic Energy Agency, TAKAMI TOHYAMA, Tokyo Univ of Science, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — Recently, successive phase transitions induced by magnetic field have been observed in BiCu\(_{2}\)PO\(_4\), whose effective spin model, a frustrated two-leg spin ladder, bridges between the frustrated spin chain and the non-frustrated spin ladder with one-half spins. According to theoretical studies, the frustrated spin chain exhibits one third plateau, although no plateau emerges in non-frustrated spin ladders. Therefore, a simple question arises as to whether the plateaux do appear in the frustrated spin ladder, or not. To clarify this question, we calculate the magnetic-field dependence of magnetization by using density-matrix renormalization-group method. In this calculation, we find some plateaux, which appear in neither the frustrated spin chain nor the non-frustrated spin ladder. Our study is useful to analyze experimental data of BiCu\(_{2}\)PO\(_4\).

1:39PM M31.00011 Fractional excitations in the square-lattice quantum antiferromagnet, H.M. RÖNNOW, EPFL Lausanne, M. MOURILGA, Georgia Institute of Technology, B. DALLA PIAZZA, EPFL Lausanne, N.B. CHRISTENSEN, Technical University of Denmark, G.J. NILSEN, Institut Laue-Langevin, T.G. PERRING, Rutherford Appleton Laboratory, M. ENDERLE, Institut Laue-Langevin, D.F. MCMORROW, University College of London, D.A. IVANOV, ETH Zurich and University of Zurich — The quantum square-lattice Heisenberg antiferromagnet (QSLHAf) exhibits a strongly anomalous magnetic spin spectrum. This question manifests itself in excitations propagating with the specific wavevector (\(\pi/2\),\(\pi\)). We used polarized neutron spectroscopy to fully characterize the magnetic fluctuations in the metal-organic compound Cu\(_4\)(DCCO\(_2\))\(_2\)\(4\)D\(_2\)O (CFTD), a known realization of the QSLHAF model. Our experiments reveal an isotropic excitation continuum at the anomaly, which we analyse theoretically using Gutzwiller-projected trial wave functions [1]. The excitation continuum is accounted for by the existence of pairs of fractional S = 1/2 quasiparticles that deconfine over intermediate length-scales. Away from the anomalous wavevector, these fractional excitations are bound and form conventional magnons. Our results reveal the existence of fractional quasiparticles in the high-energy spectrum of a quasi-two-dimensional antiferromagnet, even in the absence of frustration. [1] B. Dalla Piazza et al., to appear in Nature Physics (December 2014)

1:51PM M31.00012 Generalization of Magnetic Dimer Excitations, G. HOUCHINS, J.T. HARALDSEN, Department of Physics and Astronomy, James Madison University — Magnetic dimers commonly appear in the study of molecular magnets and quantum dots. Here, we discuss analytical representations for the inelastic neutron scattering excitation cross sections and static structure factor for the general S\(_2\)\(4\)\(_2\) dimeric system. Employing generalized Pauli matrices and the Kronecker tensor product to construct the matrix representation of the spin Heisenberg spin-spin Hamiltonian. After using exact diagonalization to determine the eigenstates of the spin Hamiltonian, we formulated an analytical solution to find the structure factor coefficients used in determining the inelastic neutron scattering excitation cross section from both the ground state and first excited state. We also detail a method for finding the S\(_2\) polarization constant within an applied field that may represent the presence of an external magnetic field. Furthermore, we provide a sample set of data and intensity plot generated from our results to illustrate experimental representations for split energy levels.

Session M32 GMAG DMP: Focus Session: Multiferroics II and Other 3d Transition Metal Oxides

11:15AM M32.00001 Imaging and characterization of conducting ferroelectric domain walls by photoemission electron microscopy, JAKOB SCHAAAB, ETH Zurich, INGO KRUG, TU Berlin, ZEWU YAN, EDITH BOURRET, Lawrence Berkeley National Laboratory, CLAUS SCHNEIDER, FZ Juelich, RAMAMOORTHY RAMESH, UC Berkeley, DENNIS MEIER, ETH Zurich — Unusual electronic properties arise at ferroelectric domain walls due to the low local symmetry and hypersensitivity of these natural oxide interfaces to electrostatics and strain. A major challenge is to expand the experimentally accessible parameter space in order to better understand these interfacial phenomena and ultimately exploit them to design domain-wall-based next-generation devices. Here, we show that ferroelectric domain walls can be visualized based on photo-induced charging effects using high-resolution X-ray photoemission electron microscopy (X-PEEM). We probe local variations in the electronic conductance in the ferroelectric semiconductor ErMnO\(_3\) contact-free and with nanometer resolution by mapping the kinetic energy distribution of photoelectrons. We find a pronounced domain-wall contrast which we assign to the local conductivity by a direct comparison with scanning probe microscopy data. Our experiments reveal a new and non-destructive pathway for element-specific studies of electronic and chemical domain-wall structures in ferroelectric and multiferroic bulk systems.

11:27AM M32.00002 Magnetochiral dichroism resonant with electromagnons in a chiral-lattice magnet Cu\(_2\)OSeO\(_3\), YOSHIHIRO OKAMURA, Univ. of Tokyo, FUMITAKA KAGAWA, SHINICHIRO SEKI, MASASHI KAWASAKI, RIKEN Center for Emergent Matter Science (CEMS), YOSHINORI TOKURA, Univ. of Tokyo, UNIV. OF TOKYO TEAM, RIKEN CENTER FOR EMERGENT MATTER SCIENCE (CEMS) COLLABORATION, POWER ELECTRONICS R&D UNIT, ROHM CO., LTD. COLLABORATION — Multiferroics, in which magnetic and ferroelectric properties coexist and are entangled, is one of the most promising candidates for materials that are capable of the control of the magnetization (M) by an electric field and the electric polarization (P) by a magnetic field. One direct consequence of the strong magnetoelectric (ME) coupling in multiferroics is an intriguing spin excitation endowed with electric-dipole activity. This remarkable spin excitation, termed as electromagnon, is ubiquitously found in multiferroics. In this study, we performed broadband microwave spectroscopy under magnetic fields in Faraday geometry to study the ME resonant character of the electromagnon in a multiferroic chiral-lattice magnet Cu\(_2\)OSeO\(_3\). We successfully observed different transmittance for oppositely propagating microwaves upon the electromagnon—the behavior known as magnetochiral dichroism (MChD). By studying the MChD spectra for various configurations, we elucidate the relationship between the MChD spectra and the dynamics of M and P upon the electromagnon excitation. We also discuss the magnitude of the MChD within a quantum theory and find that the theory well reproduces the experiment.

11:39AM M32.00003 Giant thermal Hall effect in polar magnets (Zn,Fe)\(_2\)Mo\(_3\)O\(_8\), TOSHIYA IDEUE, TAKASHI KURUMAJI, HOSHO KATSURA, SHINTARO ISHIWATA, Univ. of Tokyo, NAOTO NAGAOSA, YOSHINORI TOKURA, Univ. of Tokyo, RIKEN CENTER for Emergent Matter Science (CEMS), DEPARTMENT OF APPLIED PHYSICS, UNIVERSITY OF TOKYO TEAM, DEPARTMENT OF PHYSICS, UNIVERSITY OF TOKYO COLLABORATION, RIKEN CENTER FOR EMERGENT MATTER SCIENCE (CEMS) COLLABORATION — Spin transport in magnetic insulators has been attracting much attention because of the fundamental and technological interest for future spintronics. Recently we have observed Hall effect of magnons in ferromagnetic insulators with pyrochlore and perovskite structures in terms of the thermal Hall effect. Observed thermal Hall conductivity can be well explained by the Berry curvature of magnons induced by the Dzyaloshinsky-Moriya spin-orbit interaction which reflects the lattice geometry, while the magnitude of the signal is small and Hall effects in other magnetic phases have been unknown. In this work, we have studied thermal Hall effect in magnetic insulators (Zn,Fe)\(_2\)Mo\(_3\)O\(_8\). (Zn,Fe)\(_2\)Mo\(_3\)O\(_8\) has the polar crystal structure and shows various magnetic phases by changing the composition ratio of Fe and Zn or by applying the magnetic field. We have observed giant thermal Hall effect in ferrimagnetic phase in which the thermal Hall conductivities are twenty times larger than those of the magnon Hall effect observed in the previous study. We discuss possible mechanism of the large thermal Hall effect in this systems.
12:39PM M32.00008 Carrier Mediated Ferromagnetism in Fe-doped SrTiO$_3$.

CHUN-LAN MA, School of Mathematics and Physics, Suzhou University of Science and Technology, Suzhou 215009, China, ROCIO CONTRERAS-GUERRERO, RAVI DROOPAD, Ingram School of Engineering, Texas State University, San Marcos, TX 78666, USA — The discovery of III-V dilute magnetic semiconductors (DMS) and the subsequent unsuccessful search for room temperature ferromagnetism in DMSs have motivated researches on alternate dilute magnetic systems. Recent progresses in thin film growth techniques of perovskite oxides suggest that dilute magnetic oxides (DMOs) can be viable candidates to improve the magnetic properties of DMSs. In this talk we present an ab initio study of Fe-doped SrTiO$_3$. We find that a ferromagnetic ordering among localized Fe $t_{2g}$ spins is mediated by itinerant Fe $e_g$ electrons. The exchange interaction between $t_{2g}$ and $e_g$ electrons depends on crystal field splitting, on-site electron-electron interaction, and the relative energy of Fe d-orbitals to oxygen p-orbitals. The exchange coupling and the majority-minority spin splitting decrease with decreasing carrier concentration, confirming that itinerant carriers mediate the ferromagnetism.

12:51PM M32.00009 Spin waves and phonons in a paraelectric antiferromagnet EuTiO$_3$.

HUIBO CAO, JIANGWANG HONG, OLIVIER DELAIRE, STEVEN HAHN, GEORG EHLERS, SONGXUE CHI, VASILE GARLEA, JAIME FERNANDEZ-BACA, BRYAN CHAKOUMAKOS, JIAQIANG YAN, BRIAN SALES, Oak Ridge National Laboratory — Perovskite titanates ATiO$_3$ (A=Ba, Pb, Sr, Ca, Cd, or Eu) are widely studied for their interesting instabilities and broad applications. A ferroelectric (FE) transition occurs in Ba, Pb, and Cd titanates, but not in SrTiO$_3$ (STO) or EuTiO$_3$ (ETO). In the case of STO, fluctuations yield a quantum paraelectric state, but whether ETO is quantum paraelectric remains an open question.

Despite a number of similarities with well-studied STO, ETO is also unique owing to the magnetic Eu ions. By applying a tuning parameter, such as bi-axial tension, ETO can be turned into a FE ferromagnet, the ideal multiferroic. [J. H. Lee, et al., Nature 466, 954 (2010)]

Spin-phonon and spin-lattice couplings in ETO are of great interest not only from a fundamental standpoint, but also for technological applications. We successfully grew a large, high-quality isotopically-enriched ETO crystal for neutron scattering. The crystal and magnetic structures were characterized with single crystal diffraction at HB-3A at HFIR at ORNL and with neutron diffraction at ORNL. In this presentation, we will discuss structural instabilities, spin-spin interactions, and spin-phonon couplings in ETO.

1:03PM M32.00010 Changes in magnetic properties of cobalt-iron-titanium oxide due to temperature variations1. CAJETAN NLEBEDIM2, Ames Laboratory, U.S. Department of Energy, DAVID JILES1, Department of Electrical and Computer Engineering, Iowa State University. — It has been found that the magnetic properties of cobalt ferrite such as magnetization, Curie temperature, including the electrical and structural properties can be tailored in a remarkably linear pattern by substituting titanium and controlling its concentration. The dependence of magnetocrystalline anisotropy and coercivity on temperature variations was found to be different compared to previous studies on cation substitution in cobalt ferrite. For example, we found a competition between magnetocrystalline anisotropy and microstructure in controlling coercivity; one dominating at higher concentration of substitution and the other dominating at lower concentration. It was also found that, while magnetocrystalline anisotropy controls the temperature dependence of coercivity, obstruction to domain wall processes by pinning sites in the microstructure controls the compositional dependence of coercivity. The physics of magnetism controlling the observed properties and how those depend on temperature variations will be presented. Such understanding is necessary for the application of the material in device development.

1:15PM M32.00011 The impact of small polaronics on the properties of rare-earth titanates1. CHRIS VAN DE WALL, LARS BJAALIE, BURAK HİMMETOĞLU, ANDERSON JANOTTI, Materials Department, Univ. of California - Santa Barbara. — Optical conductivity measurements are frequently applied to determine the band gaps of complex oxides, such as the rare-earth titanate (RTIO₃) Mott insulators. The onset of the measured spectra, in the range of 0.2-0.7 eV, is commonly interpreted as the Mott-Hubbard gap. However, first-principles calculations that take strong electron-electron interactions into account using either density functional theory (DFT) with a hybrid functional or DFT+U) produce band gaps close to 2 eV for GdTiO₃ and YTiO₃ [Hümmeroglu et al., Phys. Rev. B 90, 161102 (2014)]. This raises the question of the origin of the absorption below 2 eV observed in optical experiments. We attribute this signal to excitation of small hole polarons. The rare-earth titanates commonly exhibit unintentional p-type conductivity, and we show that hole localization in the form of small polarons is enabled by the combined electron-configuration-strains enable us not only to assess the peak in optical absorption, but also to model the lineshape. Good agreement with experiment indicates that the infrared absorption is indeed likely to be polaron-related in GdTiO₃. The results probably apply to other rare-earth titanates as well.

1:27PM M32.00012 Twofold spin reorientation and field induced incomplete phase transition in single crystal Dy₀.₅Pr₀.₅FeO₃. SHIXUN CAO, WEI REN, XIAOLING QIN, BAOJUAN KANG, JINCAIZHANG, Shanghai University. — Recently, rare earth orthoferrites show emerging magnetoelectric effect, ultrafast optomagnetic effect, promising applications in multiferroics and ultrafast optomagnetic recording. All these properties come from its intrinsic coupling between R-4f and Fe-3d electrons, and strongly correlated with the spin reorientation (SR) transition. We report an intriguing twofold SR transition for the Fe magnetic sublattice near room temperature TSRI=77 K and TSR2=45 K in Dy₀.₅Pr₀.₅FeO₃ single crystal. Magnetic field-induced incomplete spin configuration transition was observed by measurement of magnetization as a function of temperature. The SR temperature of Dy₀.₅Pr₀.₅FeO₃ single crystal can be controlled by changing the magnitude of the applied magnetic field. We also show that SR between TSR2 and TSR1 can be induced by an applied magnetic field along c-axis. The origin of the magnetic behavior is ascribed to the anisotropic effective field whose strength is determined by the interactions with rare-earth spins and can be modified by the external applied magnetic field. It provides deeper insights into the R-4f and Fe-3d magnetic interaction which dominate the sophisticated magnetic phase transitions in the rare earth orthoferrites.

1:39PM M32.00013 A-site magnetic ordering in quadruple perovskite oxides, MASAYUKI TOYODA, CREST, Japan Science and Technology Agency, KUNIHKO YAMAUCHI, ISIR, Osaka University, TAMIO OGUCHI, CREST, Japan Science and Technology Agency. — In the crystal structure of perovskites AA'ₓBₓO₃ is comprehensively investigated by using first-principles calculations. The ideal crystal structure (Im3) is characterized by the square-planer oxygen coordination around A' cations as well as the a²+a⁴ type tilting of BO₆ octahedra. Owing to these structural features, the compounds can include transition-metal ions both at the A' and B sites. Consequently, there are two magnetic sublattices with different oxygen coordination. Unlike the B-site magnetism that has been investigated for decades, detailed mechanisms for the A'-site magnetism and A'-B intersublattice magnetism are still unclear. In insulating compounds such as CaₓLaₓGeO₃ and YₓMnₓAl₂O₁₂, it is found that the nearest-neighbor superexchange interaction between the A' sites determines the ground-state magnetic ordering. Furthermore, in our simulation, it is shown that magnetic phase transition from antiferromagnetism to ferromagnetism will occur along with insulator-to-metal transition in YMnₓAl₂O₁₂ by modulating the tilting of AlO₆ octahedra. Possible strategies are suggested to realize such a modulation, for example, by imposing chemical or physical pressure.

1:51PM M32.00014 Looking for multiferroics through oxygen deficiency in Sr₄₋ₓ(FeₓCoₓ)O₃₋₄₋δ, JUAN MANUEL FLOREZ, Technical University Federico Santa Maria (Chile) and MIT, MEHMET CENGIZ ON-BASLI, DONG HUN KIM, MIT (USA), SHYUE PING ONG, University of California at San Diego, GERBRAND CEDER, MIT (USA), PATRICIO VARGAS, Technical University Federico Santa Maria (Chile), CAROLINE A. ROSS, MIT (USA) — We present a theoretical/experimental study of Sr₄₋ₓ(FeₓCoₓ)O₃₋₄₋δ magnetic perovskites obtained by solid solution of Fe and Co into SrTiO₃. We focus on the role of the oxygen deficiency as the factor triggering both a change of the saturation magnetization and the appearance of a macroscopic electric polarization. The magnetization is analyzed by calculating the t₂g⁵e₈ occupations of the magnetic levels as well as the same for the electric polarization. The electric polarization is calculated through the noncentrosymmetric resulting structures generated by the intrinsic strain related to the oxygen holes and changes of the ions radii. The optical properties are quantified by calculating the total and projected density of states while we take into account all the possible configurations of the O-vacancies respect to the noncentrosymmetric resulting structures generated by the intrinsic strain related to the oxygen holes and changes of the ions radii. The optical properties are quantified by calculating the total and projected density of states while we take into account all the possible configurations of the O-vacancies respect to the noncentrosymmetric resulting structures generated by the intrinsic strain related to the oxygen holes and changes of the ions radii. The optical properties are quantified by calculating the total and projected density of states while we take into account all the possible configurations of the O-vacancies respect to the noncentrosymmetric resulting structures generated by the intrinsic strain related to the oxygen holes and changes of the ions radii.

2:03PM M32.00015 Electronic structure of Fe₃O₄ revealed by RIXS, HSIAO-YU HUANG, Doctor Program of Science and Technology of Synchrotron Light Source, National Tsing Hua University, Hsinchu 30011, Taiwan, RU-PAN WANG, Department of Chemistry, Utrecht University, Utrecht, Netherlands, CHIEN-TE CHEN, National Synchrotron Radiation Research Center, Hsinchu 30076, Taiwan, JIANSHI ZHOU, Department of Mechanical Engineering, Texas Material Institute, The University of Texas at Austin, Texas 78712, USA, FRANK DE GROOT, Department of Chemistry, Utrecht University, Utrecht, Netherlands, CHUN-CHU LAI, Department of Chemistry, National Synchrotron Radiation Research Center, Hsinchu 30076, Taiwan — Magnetite (Fe₃O₄) is a prototypical example of a mixed valence compound. At 125 K, Fe₃O₄ undergoes the Verwey transition associated with charge ordering. The valence electrons order themselves over the octahedral sites (B sites) to form a Fe⁴⁺ and Fe³⁺ superstructure in the insulating phase below the transition temperature. Here we report measurements of resonant inelastic x-ray scattering (RIXS) to unravel the electronic structures of Fe₃O₄. By the advantage of high energy-resolution (∆E ≈ 80 meV) of the RIXS spectra, we found two distinctive features of magnetic excitations, coming from octahedral Fe²⁺ and Fe³⁺ separately. These magnetic excitations are described well by a local ionic model. The dd excitations of the different Fe sites are also revealed in the RIXS spectra.
11:15AM M33.00001 Chemical Physics and Properties of ThPt$_2$, ANDREAS LEITHE-JASPER, MPI-CPfS Dresden, ROMAN GUMENIUK, MPI-CPfS Dresden and TU Bergakademie Freiberg, WALTER SCHNELLE, MICHAEL NICKLAS, YURI GRIN, MPI-CPfS Dresden — ThPt$_2$ crystallizes with a unique type of structure (space group $I4/mmm$, $a = 4.1690(2)$ Å, $c = 14.3678(6)$ Å), which belongs to the group of the close-packed tetragonal structures (Pearson symbol $I12$). An analysis of the chemical bonding by the electron density/electron localization approach reveals formation of two-dimensional platinum anions separated by the Th cations. Measurements of magnetic susceptibility, electrical resistivity and specific heat show ThPt$_2$ to be diamagnetic with good metallic conductivity ($\rho$($300 \text{ K}$) ≈ 8.5 µΩ cm). The properties are in good agreement with the calculated electronic structure with a low DOS ($N(E_F) = 0.92$ states eV$^{-1}$ fm$^{-3}$). The stability of the compound with respect to other possible structural modifications was studied theoretically.

11:27AM M33.00002 Entanglement changes and caloric effects in $RAI_2$ single crystals, NILSON ANTUNES DE OLIVEIRA, JULIETH CARO PATIÑO, PEDRO J. VON RANKE, Universidade do Estado do Rio de Janeiro — In this work we theoretically discuss the entanglement changes and the caloric effects in $RAI_2$ single crystals, which crystallize in the cubic symmetry and have large magneto crystalline anisotropy due to the crystal electric field. For this purpose, we use a model of interacting magnetic moments including a term to account for the crystal electric field. We apply the model to calculate the entropy changes and the magnetocaloric quantities in TmAl$_2$ and NdAl$_2$ by applying magnetic field variations in different crystallographic directions. Our calculations for the entropy changes in these compounds are in a reasonable agreement with the available experimental data for $\Delta S$ at $T = 10$ K. Further experimental data are necessary to compare with our theoretical predictions for the adiabatic temperature change. We also calculate the caloric quantities by fixing the magnitude of the magnetic field and rotating its direction. In this case, our calculations predict an anomaly (i.e. a change of sign) in the caloric quantities of TmAl$_2$ when a magnetic field of 3 T rotates from $< 100 >$ to $< 110 >$ direction. A similar behavior is also observed in NdAl$_2$. This very interesting fact, which is basically due to the magneto crystalline anisotropy, needs experimental data to be confirmed.

11:39AM M33.00003 First-principles molecular dynamics simulations of high-concentration deuterium implantation in liquid lithium, MOHAN CHEN, Department of Mechanical and Aerospace Engineering, Princeton University, Princeton, NJ, 08544, USA, TYLER ABRAMS, MICHAEL JAWORSKI, Princeton Plasma Physics Laboratory, Princeton, NJ, 08543, USA, EMILY CARTER, Department of Mechanical and Aerospace Engineering, Program in Applied and Computational Mathematics, and the Andlinger Center for Energy and the Enviro — First-principles molecular dynamics (FPMD) is performed to study liquid lithium (Li) samples with high-concentration deuterium (D) implantation. First, we validate FPMD against experimental properties of solid and liquid Li and LiD. The calculated properties of both Li and LiD include relative stabilities and bulk moduli of several solid phases, melting temperatures, pair distribution functions, and bond angle distribution functions. Excellent agreement is obtained between FPMD and available experimental data. Next, we randomly implant D atoms at four different concentrations into liquid Li at different temperatures. Specifically, the ratios of D:Li atoms studied are 0.25, 0.50, 0.75 and 1.00, and the temperatures range from 400 to 1143 K. FPMD reveals several interesting properties of these liquid Li samples with implanted D atoms. For example, we observe fast nucleation of rock-salt structures of LiD for samples at temperatures lower than the melting point of LiD (960 K). We find that the pure Li component is quickly suppressed with increased concentration of D atoms, and that no D clusters form. Finally, because measured diffusivities of D in liquid Li vary by several orders of magnitude, we predict the diffusivities of both Li and D atoms in all samples.

11:51AM M33.00004 Spin-phonon interactions to control the thermal transport in uranium dioxide, K. GOFRYK, Idaho National Laboratory, S. DU, C.R. STANEK, J.C. LASHLEY, X.-Y. LIU, R.K. SCHULZE, J.L. SMITH, D.J. SAFAIRK, D.D. BYLER, K.J. MCCLELLAN, B.P UBERUAGA, B.L. SCOTT, D.A. ANDERSSON, Los Alamos National Laboratory — Despite more than sixty years of intense research of uranium dioxide, a thorough understanding is lacking for the microscopic processes that control its transport and thermodynamic properties. In particular, it is not clear how different degrees of freedom and quasiparticle excitations interact and what is the relationship to the thermal behavior. We report our new experimental and theoretical studies on oriented and well characterized single crystals of uranium dioxide. Our results indicate that strong spin-phonon coupling and resonant scattering are important for understanding the general thermal behavior, and also explains the observed anisotropy in thermal conductivity by coupling to the applied temperature gradient and breaking cubic symmetry. We will discuss implications of these results.

12:03PM M33.00005 Simulating Order Parameters for Phase Transitions in Alloys, RICHARD R. VANFLEET, CONRAD W. ROSENROCK, GUS L.W. HART, BRANTON J. CAMPBELL, Department of Physics and Astronomy, Brigham Young University Provo — When determining the structure of alloys using diffraction patterns, possible distortions that lower the symmetry of the parent phase can be limited by group-theoretical arguments as long as a group-subgroup relationship exists between the parent and distorted phases. Order parameters are vectors in representation space where each dimension corresponds to a specific superlattice vector in reciprocal space (e.g. $L = [0.5,0.5,0.5]$ or $X=[1,0,0]$); such order parameters determine the distortions that may arise during a phase transition. By measuring the Fourier transform of the structure at each relevant superlattice vector during a Monte Carlo simulation for CuPt$_2$, we were able to extract these thermodynamic order parameters and qualitatively confirm distortions in the L and X order parameters observed in experiment. The methodology presents a highly effective avenue for comparing simulated phase transitions with experimental results.

12:15PM M33.00006 Concentration Waves in High-Entropy Alloys - a new alloy design approach, PRASHANT SINGH, Ames Lab, DUANE D. JOHNSON, Ames Lab and Iowa State University — Chemical short-range order (SRO) in solid solutions can be interpreted as a “concentration wave” — a Fourier decomposition of nascent order — identified experimentally via Warren-Cowley SRO parameters. We present a rigorous thermodynamic theory to predict and uniquely interpret the SRO in N-component alloys. Based on KKR-CPA electronic structure, we implemented this method using thermodynamic linear-response to include all alloying effects, e.g., band-filling, hybridization, Fermi-surface nesting and van Hove instabilities. We apply this first-principles method to high-entropy alloys (HEAs), i.e., solid solutions with N > 4 that inhibit small-cell order due to large entropy competing against ordering enthalpy, as their properties are sensitive to SRO. We validated theory with comparison to experiments in A2 Nb-Al-Ti and A1 Cu-Ni-Zn. We then predict and analyze SRO and mechanical trends in Ni-Ti-Zr-Cu-Al and Co-Cr-Fe-Mn-Ni systems — showcasing this new first-principles-based alloy design method.
12:27PM M33.00007 Magnetic Landau free energy density for the bcc-hcp phase transformation , MAHDI SANATI, Texas Tech Univ, ROBERT C. ALBERS, TURAB LOOKMAN, AVADH SAXENA, Los Alamos National Lab. — We have studied the he bcc-hcp phase transformation in Fe and Co with the use of first-principles calculations. The complete energy surface as the system goes from the bcc to hcp structure is determined. The results are used to find an appropriate Landau free energy (LFE) density for describing this transformation. The Landau free energy consists of three order parameters: shear, shuffle, and magnetization. The coefficients of the Landau free energy density are obtained from first-principles energy fits. The stability of the bcc phase in both elements has been studied and the results are then extended to understand the stability of the bcc Fe-Co alloys with varying stoichiometry.

12:39PM M33.00008 Vibrational entropy changes the solid solubility of a random alloy at high temperatures1 , NINA SHULUMBA, Linköping University Sweden, OLLE HELLMAN, California Institute of Technology USA, ZAMANAAN RAZA, Linköping University Sweden, JENIFER BARRIRERO, FRANK MÜCKLICH, Saarland University Germany, IGOR A. ABRIKOSSOV, MAGNUS ODÉN, Linköping University Sweden — We have developed a method to accurately and efficiently determine vibrational entropy as a function of temperature and volume for substitutional alloys from first principles. Using Ti1−xAlxN metal alloy as a model system we calculate the isostructural phase diagram by minimization of the free energy, solving the original Gibbs problem of finding its global minimum corresponding to the true equilibrium state of the system. We demonstrate that the vibrational contribution to the free energy has a decisive impact on the calculated phase diagram of Ti1−xAlxN alloy, lowering the maximum temperature for the miscibility gap from 9000 K to 2400 K. The solubility limit of the predicted phase diagram is experimentally verified by local chemical composition measurements of thermally aged Ti50Al50N alloys.

1:03PM M33.00010 Excited-state electron-dynamics probed by Alg phonons in Bi, Sb, and Bi2Te3 , CRYSTAL BRAY, Stanford University, PULSE Institute, EAMONN MURRAY, Tyndall National Institute, Cork, Ireland, STEPHEN FAHY, Tyndall National Institute; University College Cork, Ireland, DAVID REIS, Stanford University, PULSE Institute — We report on dynamics of photo-excited electronic states in bismuth, antimony and bismuth telluride as a function of photon energy and carrier density using the coherent A1g phonon as a probe. Previous National Institute; University College Cork, Ireland, DAVID REIS, Stanford University, PULSE Institute — We report on dynamics of photo-excited electronic states in bismuth, antimony and bismuth telluride as a function of photon energy and carrier density using the coherent A1g phonon as a probe. Previous studies have shown that the coherent dynamics of these materials are strongly coupled to the A1g phonon modes. We have observed a variety of dynamical processes including interband transitions, intraband excited state interactions and phonon-assisted transitions. In this work we present a detailed analysis of the coherent phonon dynamics in Bi, Sb and Bi2Te3, focusing on the excited state electron dynamics probed by the coherent A1g phonon. The results are compared to theoretical calculations to understand the underlying physical mechanisms.

1:15PM M33.00011 Hydrodynamics of Dirac and Weyl materials , GUSTAVO MONTEIRO, ALEXANDER ABANOV, Stony Brook University, V. PARAMESWARAN NAIR, City College of New York — The study of transport in Weyl and Dirac metals should account for additional contributions to the electric current coming from the chiral anomaly, namely chiral magnetic and chiral vortical effects. These responses are non-dissipative and fully characterized by the chiral anomaly coefficient. In addition, they are believed to be robust even in a strongly interacting regime, due to the topological nature of the anomaly. The fundamental equations for the hydrodynamic limit of such transports were introduced in [1], in order to describe the quark-glue plasma in nuclear collision. Having these equations as starting point, we present a variational principle for them and discuss the canonical structure of the corresponding hydrodynamic modes [2].

1:27PM M33.00012 Electronic properties and electron-phonon interaction in complex, multi-component alloys in application to high-entropy alloys , GERMAN SAMOLYUK, Oak Ridge National Laboratory, MARKUS DAENE, Lawrence Livermore National Laboratory, GEORGE MALCOLM STOCKS, Oak Ridge National Laboratory, JOSE ALFREDO CARO, Los Alamos National Laboratory, JAGER STOLLER, Oak Ridge National Laboratory — High-entropy alloys (HEAs) have recently been developed as nontraditional alloy systems. They are composed of multiple elements at or near equiatomic ratios that form random solid solutions on simple underlying fcc or bcc lattices. In recent years HEAs have attracted significant attention due to their high strength, ductility and possible high radiation resistance. The complexity of the alloys results in very interesting electronic system behavior. Even in thermal equilibrium, disorder, especially extreme disorder, has important impacts on all electronic, atomic, and magnetic properties. In the current work we present results of first-principles investigation of the electronic and magnetic properties of Ni-based multicomponent concentrated alloys using the coherent potential approximation (CPA). The influence of electronic structure modifications on the electron mean free path and values of electron-phonon coupling are calculated, together with preliminary results on similar quantities obtained by Time Dependent DFT. We discuss possible effects of tuning the mean free path and energy dissipation mechanisms to defect production and recombination in HEAs under irradiation.

1 A work supported by the Semiconductor Research Corporation
In addition, the Casimir stiction considering both quantum and thermal fluctuations is found to be relieved compared with bulks.

is shown that the heat flux can be greatly enhanced and the accurate prediction may differ significantly from that of the geometry-based Derjaguin’s proximity nanostructures capable of supporting higher efficiency or greater heat flux than simple planar substances. In this work, efficient and delocalized radiative heat of near-field heat transfer in thermophotovoltaic devices, thermal imaging, thermal rectifiers, and local thermal management have motivated the search for.

XIANGLEI LIU, BO ZHAO, ZHUOMIN ZHANG, Georgia Institute of Technology — The promising applications inhomogenous boundary conditions is also discussed.

For a deformed strip and for two compact objects of arbitrary shape in terms of the free energy of a standard region (circular ring or flat strip) whose dimension forces between objects that couple to the underlying field. For two dimensional conformal field theories (CFT) we derive exact results for the Casimir interaction.

Technology, Physics Department, 77 Massachusetts Avenue Cambridge, MA 02139 — Thermal fluctuations of a critical system induce long-ranged Casimir Fisiche, Universita di Napoli Federico II, Complesso Universitario MSA, Via Cintia, I-80126 Napoli, Italy, MEHRAN KARDAR, Massachusetts Institute of

The repulsive Casimir effect in Weyl semimetals1. Justin Wilson, Andrew Allocca, Victor Galitski, Univ of Maryland-College Park — Weyl semimetals are a proposed topological material with broken time-reversal symmetry. Due to this, they experience a particular bulk Hall effect as well as a weak longitudinal conductance. In such a situation, one can see a repulsive Casimir effect between two Weyl semimetals (similar to what has been studied for topological insulators and quantum hall materials), and the effect can be tuned from attractive to repulsive with chemical potential or magnetic field. We consider, separately, a simplified bulk description and a thin film geometry taking into account the band structure.

1 This work was supported by JQI-PFC.

Weak localization as a definitive test of diffusive models in the Casimir effect1. Andrew Allocca, Justin Wilson, Victor Galitski, Univ of Maryland-College Park — Results from many measurements of the Casimir effect suggest that the metallic plates in these experiments should be modeled with the plasma model of free electrons as opposed to the naive diffusive Drude model, while other experiments seem to indicate the exact opposite, with results more in line with a diffusive model. We study the Casimir effect at low temperatures between a thick disordered plate and purely two-dimensional disordered system where the Drude conductivity decreases logarithmically at low temperatures due to weak localization. This effect can be tuned with either temperature or applied magnetic field leading to a measurable change in the Casimir force. On the other hand, a ballistic model cannot experience such an effect and is only weakly dependent on temperature and magnetic field. As a result, we propose that an experiment would unambiguously differentiate between diffusive and ballistic models by measuring the effect at low temperatures with an applied magnetic field. Additionally, we calculate the impact that fluctuations in the disorder distribution have on the Casimir effect. Assuming the validity of a diffusive model, we find that the Drude model is a good approximation of a more exact treatment of disorder.

1 This work was supported by the DOE-BES (Grant No. DESC0001911) (A.A. and V.G.), the QJ-I-PFC (J.W.), and the Simons Foundation.

Is it plasma or Drude? Experimental answer using rotating engineered samples. Ricardo Decca, Indiana Univ-Purdue Univ Indianapolis — Measurements done between a Ni covered sphere and a Au coated rotating sample made of sectors of Au and Ni are presented. This approach follows the proposal made by G. Bimonte1 Many samples with different thicknesses t of the top Au film (t ∈ [20, 84] nm) were prepared to measure the interaction. The Ni-coated sapphire sphere was mounted on a sensitive mechanical torsional oscillator. Measurements were done for separations between the sphere and the Au-coated engineered sample in the {200–1000} nm range. With integration times ~1000 s and after accounting for a systematic, once-per-revolution impulsive signal from the air-bearing spindle, the error in the measurement is ~0.3 fN. In all cases it was observed that a plasma-like model provides good agreement with the experiment, while the Drude model is off by factors as large as 1000. The experimental apparatus and the potential source of errors will be briefly discussed.

Casimir effect and radiative heat transfer between Chern Insulators. Pablo Rodriguez Lopez, LPTMS, CNRS et Univ de Paris - Sud, Adolfo Grushin, Max-Planck-Institut für Physik komplexer Systeme, Wang-Kong Tse, Diego Dalvit, Theoretical Division MS B213, Los Alamos National Laboratory — Chern Insulators are a class of two-dimensional topological materials. Their electronic properties are different from conventional materials, and lead to interesting new physics as quantum Hall effect in absence of an external magnetic field. Here we will review some of their special properties and, in particular, we will discuss the radiative heat transfer and the Casimir effect between two planar Chern insulators sheets. Finally, we will see how to control the intensity and sign of this Casimir force and the requirements to observe a repulsive Casimir force in the lab with those materials.

The research leading to these results has received funding from the People Programme (Marie Curie Actions) of the European Union’s Seventh Framework Programme (FP7/2007-2013) under REA grant agreement no. 302005.

Conformal field theory of critical Casimir forces. Thorsten Emig, Massachusetts Institute of Technology, UMI Multi-Scale Materials Science for Energy and Environment, Physics Department, Giuseppe Bimonte, Dipartimento di Scienze Fisiche, Universita di Napoli Federico II, Complesso Universitario MSA, Via Cintia, 180126 Napoli, Italy, Mehran Kardar, Massachusetts Institute of Technology, Physics Department, 77 Massachusetts Avenue Cambridge, MA 02139 — Thermal fluctuations of a critical system induce long-ranged Casimir forces between objects that couple to the underlying field. For two dimensional conformal field theories (CFT) we derive exact results for the Casimir interaction for a deformed strip and for two compact objects of arbitrary shape in terms of the free energy of a standard region (circular ring or flat strip) whose dimension is determined by the mutual capacitance of two conductors with the objects’ shape; and a purely geometric energy that is proportional to conformal charge of the CFT, but otherwise super-universal in that it depends only on the shapes and is independent of boundary conditions and other details. The effect of inhomogeneous boundary conditions is also discussed.

Efficient near-field energy transfer and relieved Casimir stiction between sub-wavelength gratings. Xianglei Liu, Bo Zhao, Zhijun Zhang, Georgia Institute of Technology — The promising applications of near-field heat transfer in thermophotovoltaic devices, thermal imaging, thermal rectifiers, and local thermal management have motivated the search for nanostructures capable of supporting higher efficiency or greater heat flux than simple planar substances. In this work, efficient and delocalized radiative heat transfer between two aligned 1D sub-wavelength gratings is demonstrated based on the scattering theory using the rigorous coupled-wave analysis (RCWA). It is shown that the heat flux can be greatly enhanced and the accurate prediction may differ significantly from that of the geometry-based Derjaguin’s proximity approximation (PA). The underlying mechanism is attributed to the excitation of hyperbolic modes that increase the energy transmission by supporting propagation of waves with large parallel wavevectors and. Besides efficient energy transport, the performance is robust, insensitive to the relative lateral shift. In addition, the Casimir stiction considering both quantum and thermal fluctuations is found to be relieved compared with bulks.
12:27PM M35.00007 Possibilities of Verifying Dynamical Casimir Effect with Nonlinear Materials in Microwave Cavities, VIKTOR DODONOV, Institute of Physics, University of Brasilia — I evaluate the number of “Casimir quanta” that could be created in high-quality electromagnetic cavities containing materials with big third-order nonlinear optical coefficients, due to the parametric amplification of the microwave vacuum field, if the effective refractive index of the material is modulated by periodic high-intensity short laser pulses. The main result is that the expected total number of created microwave photons depends neither on the laser beam shape, nor on the duration or power of individual pulses, but it is determined by the total energy of all pulses, provided the duration of each pulse is much shorter than the period of field oscillations in the selected resonant mode. The experiment can be feasible in small cavities with high resonance frequencies. Possible spurious effects will be discussed, too.

12:39PM M35.00008 Electrostatic patch potentials in Casimir force measurements, JOSEPH GARRETT, DAVID SOMERS, JEREMY MUNDAY, University of Maryland — Measurements of the Casimir force require the elimination of the electrostatic force between interacting surfaces. The force can be minimized by applying a potential to one of the two surfaces. However, electrostatic patch potentials remain and contribute an additional force which can obscure the Casimir force signal [1-2]. We will discuss recent measurements of patch potentials made with Heterodyne Amplitude-Modulated Kelvin Probe Force Microscopy that suggest patches could be responsible for >1% of the signal in some Casimir force measurements, and thus make the distinction between different theoretical models of the Casimir force (e.g. a Drude-model or a plasma-model for the dielectric response) difficult to discern [3].

12:51PM M35.00009 Tunable Casimir-Polder Forces and Spontaneous Emission Rates, FELIPE ROSA, WILTON KORT-KAMP, FELIPE PINHEIRO, TARIK CYSENE, DIEGO OLIVER, CARLOS FARINA, Universidade Federal do Rio de Janeiro — We investigate the dispersive Casimir-Polder interaction between a Rubidium atom and a graphene sheet subjected to an external magnetic field B. We demonstrate that this concrete physical system allows for a high degree of control of dispersive interactions at micro and nanoscales. Indeed, we show that the application of an external magnetic field can induce a 80% reduction of the Casimir-Polder energy relative to its value without the field. We also show that sharp discontinuities emerge in the Casimir-Polder interaction energy for certain values of the applied magnetic field at low temperatures. In addition, we also show that atomic spontaneous emission rates can be greatly modified by the action of the magnetic field, with an order of magnitude enhancement or suppression depending on the dipole’s moment orientation.

1:03PM M35.00010 Suppression of chaos assisted stiction in Casimir oscillators due to surface roughness, WUJAN BROER, GEORGE PALASANTZAS, JASPER KNOESTER, Zernike Institute for Advanced Materials, University of Groningen, HOLGER WAALKENS, Johann Bernoulli Institute of Mathematics and Computer Science, University of Groningen, VITALY B. SVETOVOY, MESA-Institute for Nanotechnology, University of Twente — At separations below 100 nm, the Casimir force strongly influences the vibration dynamics of MEMS (Micro mechanical systems) in dry vacuum conditions. This theoretical analysis includes the effects of both the material response and that of surface roughness in an experimentally relevant way. Moreover, energy gains and losses during actuation are considered via driving and damping, respectively. We show that the system can exhibit chaotic motion for certain actuation parameter values due to the nonlinearity of the Casimir force. Surface roughness of the interacting components turns out to make the MEMS actuation less susceptible to chaotic motion than that of flat surfaces.

1:15PM M35.00011 Influence of dissipation on two-atom dispersion interactions, PABLO BARCELONA, STEFAN YOSHI BUHMANN, Albert-Ludwigs-University of Freiburg, Institute of Physics — We consider the dispersion interaction between two neutral, ground-state atoms at zero and finite temperatures by means of a dynamical approach. Our result differs from the previous ones obtained with time-independent perturbation theory because it correctly accounts for the influence of dissipation via the atomic decay rates. Modern measurements of Casimir force seem to suggest a suppressed influence of dissipation. Our new result shows similar features and can hence help resolve the Drude-plasma debate. We also consider the interaction between a ground-state atom and an excited atom. There are discordant results in the literature for the retarded potential: one oscillating and one monotonic. Our dynamical result uniquely leads to the oscillating result when taking into account the decay rates.

1:27PM M35.00012 Giant vacuum forces via transmission lines, EPHRAIM SHAHMOON, Weizmann Institute of Science, IGOR MAZETS, Atominstitut, TU Wien, Vienna, Austria, GERSHON KURIZKI, Weizmann Institute of Science — Quantum electromagnetic fluctuations induce forces between neutral particles, namely, the van der Waals (vdW) and Casimir interactions. Here we show that these fundamental interactions can be enhanced by many orders of magnitude upon changing the character of the mediating vacuum photon-modes. We consider two dipoles in the vicinity of any standard electric transmission line and find analytically that the interaction scales non-trivially with the inter-dipolar distance, resulting in a strong and long-range interaction. This may have profound implications on the non-additivity of vdW and Casimir interactions in many-particle systems, and opens the door for Casimir Physics in 1d. We discuss the possibilities of realizing this effect, e.g. in a coplanar waveguide line.

In January 2015, my affiliation is supposed to change to “Department of Physics, Harvard University”

1:39PM M35.00013 ABSTRACT WITHDRAWN —

1:51PM M35.00014 Negative Casimir Entropies in Nanoparticle Interactions, KIMBALL MILTON, Univ of Oklahoma, ROMAIN GUEROUT, Laboratoire Kastler-Brossel, CNRS, ENS, UPMC, Case 74, F-75252 Paris, France, GERT-LUDWIG INGOLD, Institut fur Physik, Universitat Augsburg, Universitaetsstrasse 1, D-86135 Germany, ASTRID LAMCREHT, SERGE REYNAUD, Laboratoire Kastler-Brossel, CNRS, ENS, UPMC, Case 74, F-75252 Paris, France — Negative entropy has been known in Casimir systems for some time. For example, it can occur between two perfectly conducting spheres, between two electrically polarizable nanoparticles if there is sufficient anisotropy, between a perfectly conducting sphere and a conducting plate. The latter effect is most pronounced in the dipole approximation, which occurs when the size of the sphere is small compared to the separation between the sphere and the plate. Therefore, here we examine cases where negative entropy can occur between two electrically and magnetically polarizable nanoparticles or atoms, which need not be isotropic, and between such a small object and a conducting plate. Negative entropy can occur even between two perfectly conducting spheres, between two electrically polarizable nanoparticles if there is sufficient anisotropy, between a perfectly conducting sphere and a Drude sphere, and between a sufficiently anisotropic electrically polarizable nanoparticle and a transverse magnetic conducting plate.

2:03PM M35.00015 Probing the Casimir force with optical tweezers, PAULO MAIA NETO, DINEY ETHER, LUIS PIRES, YARENI AYALA, FELIPE ROSA, UFRJ, STEFAN UMRATH, GERT INGOLD, U. Augsburg, NATHAN VIANA, MOYSES NUSSENZVEIG, UFRJ — Optical tweezers (OT) are single-beam laser traps for neutral particles, usually applied to dielectric microspheres immersed in a fluid. The stiffness is proportional to the trapping beam power, and hence can be tuned to very small values, allowing one to measure femttonewton forces, once the device is carefully calibrated. We employ OT to measure the Casimir (or retarded van der Waals) force between polystyrene beads in ethanol, for distances between 50 nanometers and 1 micrometer. The spherical beads have diameters ranging from 3 to 7 micrometers. We find a rather large correction to the widely employed Proximity Force approximation (PFA), since the ratio between distances and sphere radii is much larger than the typical values probed in recent experiments. For the comparison with experimental data, we compute the Casimir force using the scattering approach applied to the spherical geometry, including the contribution of double-layer forces. We also present experimental results for the total force between a mercury microdroplet and a polystyrene bead immersed in ethanol, with similar distances and diameters. In short, we probe the Casimir force with different materials in a regime far from the validity of PFA, such that the spherical geometry plays a non-trivial role.

11:15AM M36.00001 Superfluidity in Strongly Interacting Spin-Polarized Fermi Gases, BEN A. OLSEN, MELISSA REVELLE, JACOB A. FRY, RANDALL G. HULET, Department of Physics & Astronomy and Rice Quantum Institute, Rice University, Houston, TX 77005, DANIEL E. SHEEHY, Department of Physics & Astronomy, Louisiana State University, Baton Rouge, LA 70803 — We report measurements of phase separation in a harmonically trapped, spin polarized two-component Fermi gas. The interactions in the gas are varied using a magnetically-tuned Feshbach resonance between the weakly-interacting BCS and strongly-interacting BEC regimes. Using spin-selective imaging, we measure the density profiles for the two lowest hyperfine levels of $^6$Li, with the superfluid phase being indicated by an unpolarized central core. We determine phase boundaries for the superfluid transition as a function of interactions and polarization, finding results that are consistent with earlier experimental results in the crossover regime. We also explore the BEC side of resonance, where we compare our measurements to Quantum Monte Carlo simulations and also the deep BCS regime, where few theoretical predictions are available.

11:27AM M36.00002 Equation of State of One-Dimensional Fermions in Harmonic Traps, CASEY BERGER, The Ohio State University, ERIC ANDERSON, JOAQUIN DRUT, The University of North Carolina at Chapel Hill — We test a novel numerical method for computing the ground state energy of fermions in a harmonic trapping potential. The new technique combines hybrid Monte Carlo and a Gauss-Hermite discretization instead of a uniform lattice. Use of the harmonic oscillator basis and Gauss-Hermite points avoids the problem of edge effects and spurious copies that arise from periodic boundary conditions. This study sets the stage for calculations in higher dimensions, relying on non-uniform Fast Fourier Transform algorithms for acceleration. Based on this method we determine the ground-state energy of unpolarized few-body systems constrained to one-dimensional motion.

11:39AM M36.00003 Strongly interacting fermions in 1D, LI YANG, Department of Physics and Astronomy, Rice University, Houston, Texas 77251, USA, TIMING GUAN, Institute for Advanced Study, Tsinghua University, Beijing 100084, People’s Republic of China, HAN PU, Department of Physics and Astronomy, Rice University, Houston, Texas 77251, USA, DEPARTMENT OF PHYSICS AND ASTRONOMY, RICE UNIVERSITY, HOUSTON, TEXAS 77251, USA, TEAM, INSTITUTE FOR ADVANCED STUDY, TSINGHUA UNIVERSITY, BEIJING 100084, PEOPLE’S REPUBLIC OF CHINA TEAM — Under second order degenerate perturbation theory, we show that the physics of N fermions with arbitrary spin in one dimension in Tonks-Girardeau (TG) and super-Tonks-Girardeau(sTG) regions can be described by super-exchange interaction. An effective spin chain Hamiltonian (none-translational-symmetric Sutherland model) can be obtained from this procedure. For spin-1/2 particles, this model is the none-translational-symmetric Heisenberg model, where a transition between Heisenberg anti-ferromagnetic (AFM) and ferromagnetic (FM) states is expected to occur when the interaction strength is increased from TG to sTG limit. We show that the FM and AFM states can be distinguished in two different methods: the first is based on their distinct response to a spin-dependent magnetic gradient, and the second is based on their distinct momentum distribution. We examine the validity of the spin-chain model by comparison with results obtained from unbiased techniques such as exact diagonalization and TEBD.

11:51AM M36.00004 1D-3D Crossover in a Spin-Imbalanced Fermi Gas, MELISSA REVELLE, BEN A. OLSEN, JACOB FRY, RANDALL G. HULET, Department of Physics and Astronomy and Rice Quantum Institute, Rice University, Houston, TX 77005 — We experimentally study the phases of an ultracold two-component gas of atomic fermions ($^6$Li) confined to 1D tubes formed by a 2D optical lattice. The atoms are prepared in the lowest two hyperfine sublevels where their interactions are tuned by a Feshbach resonance. We previously observed phase separation into a partially-polarized superfluid core and either fully-paired or fully-polarized wings depending on the spin polarization in 3D. In 1D, the phase separation is inverted, such that the cloud center is fully paired and the wings are partially-paired. We investigate the transition from 1D to 3D gas by varying the lattice depth and interaction strength which changes the ratio of the tunneling rate between the tubes to the pair binding energy. We are exploring a region of parameter space that is believed to be the most promising region for the exotic FFLO superfluid phase.

12:03PM M36.00005 Stability of Fulde-Ferrell-Larkin-Ovchinnikov states in ultracold atomic Fermi gases, JIBIAO WANG, QUIN CHEN, Zhejiang University — The elusive Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) states have attracted enormous attention in the condensed matter and AMO communities. They have not been observed experimentally in three-dimensional (3D) Fermi gases, largely due to their predicted small region in the phase space and very low temperature required. In this talk, we will discuss the stability of the FFLO states in 3D homogeneous Fermi gases, both in equal-mass and mass imbalanced systems, within a pairing fluctuation theory. We find that the effective mass of noncondensed pairs in the directions perpendicular to the FFLO wavevector is negative, leading to instability of the FFLO states previously predicted in the literature. Treatment beyond the T-matrix level and further symmetry breaking effects such as optical lattices and spin-orbit coupling may be necessary in order to find stable FFLO states.

12:15PM M36.00006 Strong-coupling ansatz for the one-dimensional Fermi gas in a harmonic potential, MEERA PARISH, London Centre for Nanotechnology, JESPER LEVINSEN, Aarhus University, PIETRO MASSIGNAN, ICFO, GEORG BRUUN, Aarhus University — The 1D Fermi gas with repulsive short-range interactions provides an important model of strong correlations and is often amenable to exact methods. However, in the presence of confinement, no exact solution is known for an arbitrary number of strongly interacting fermions. Here, we propose a novel ansatz for generating the lowest-energy wavefunctions of the repulsive 1D Fermi gas in a harmonic potential near the Tonks-Girardeau limit of infinite interactions. We specialize to the case of a single impurity interacting with N majority particles, where we may derive analytic forms of the approximate wavefunctions. Comparing with previous work, we show that our ansatz becomes exact for many-body wavefunctions of fermions and the exact ones for the ground-state wavefunction for N ≥ 8. Moreover, the overlap for the ground-state wavefunction extrapolates to 0.9999 as N → ∞. Thus our ansatz is essentially indistinguishable from numerically exact results in both the few- and many-body limits.

12:39PM M36.00008 Pseudogap phenomenon near the phase transition from $p_x$- to $p_x + ip_y$-wave Fermi superfluid, DAI SUKE INOTANI, YOJI OHASHI, Department of Physics, Keio University — We discuss an ultracold superfluid Fermi gas with a $p$-wave Feshbach resonance (FR). In this system, it has been predicted that the split of $p_x$- to $p_y$- and $p_z$-wave channels in the $p$-wave FR by a dipole-dipole interaction leads to multi-superfluid phases. While the $p_x$-wave state appears below $T_c$, the $p_x + ip_y$-wave state is expected to become more stable below a certain temperature ($\equiv T_{p_x+ip_y}^c < T_c$). In this talk, including the split of FR, as well as $p$-wave pairing fluctuations, within a $T$-matrix approximation, we find that, near $T_{p_x+ip_y}^c$, the $p_x$-phase, pairing fluctuations in the non-condensed $p_y$- and $p_z$-wave channels cause the pseudogap phenomenon in the nodal direction of the $p_x$-wave order parameter. This pseudogap is shown to continuously change into the $p_x + ip_y$-superfluid gap, as one goes away from the nodal direction. Since pairing fluctuations are soon suppressed below $T_c$ in the ordinary $s$-wave case, this pseudogap near $T_{p_x+ip_y}^c (< T_c)$ is a characteristic phenomenon of a $p$-wave Fermi superfluid with multi-superfluid phases. In this talk, we also discuss how this pseudogap develops, as one decreases the temperature from $T_c$ to $T_{p_x+ip_y}^c$.

12:51PM M36.00009 Quantum Monte Carlo Simulation of one dimensional SU(N) Fermion system, SHENGLONG XU, CONGJUN WU, University of California, San Diego — One dimensional interacting fermionic systems with SU(N) symmetry have been realized in ultracold atom systems. The interplay between the dimensionality and symmetry provides a platform to search for unconventional phenomena. Inspired by recent experiments, we use quantum Monte Carlo to explore the metallic phase, nature of the metal-insulator transition as well as possible exotic magnetic orders of such systems. The effects of trapping potential are also discussed.

1:03PM M36.00010 Stoner ferromagnetism of a strongly interacting Fermi gas in the quasipulsive regime, LIANYI HE, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, XIA-JI LIU, Centre for Quantum and Optical Science, Swinburne University of Technology, Melbourne 3122, Australia, XU-GUANG HUANG, Physics Department, Fudan University, Shanghai 200433, China, JOSEPH CARLS ON, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, HUI HU, Centre for Quantum and Optical Science, Swinburne University of Technology, Melbourne 3122, Australia — Recent advances in rapidly quenched ultracold atomic Fermi gases near a Feshbach resonance arise a number of interesting problems, in the context of observing the long-sought Stoner ferromagnetic phase transition. The possibility of experimentally obtaining a “quasipulsive” regime in the upper branch of the energy spectrum due to the rapid quench is currently debated and theoretically, the Stoner transition has mainly been investigated at zero temperature or high polarization, due to the limited theoretical approaches in the strongly repulsive regime. Here, we develop a nonperturbative large-N expansion theory for a quasipulsive Fermi gas near resonance and present a finite temperature phase diagram for its Stoner instability. Our results agree well with the known quantum Monte-Carlo simulations at zero temperature and recover the virial expansion prediction at high temperature for arbitrary interaction strengths. At resonance, we find that the unitary Fermi gas undergoes the Stoner transition at about 1.5TF, where TF is the Fermi degeneracy temperature.

1:15PM M36.00011 Three-Component Fermi Gases in Two Dimensions, THOMAS KIRK, MEERA PARISH, London Center Nanotechnology, CONDENSED MATTER AND MATERIALS PHYSICS TEAM — We study a three-component Fermi gas in two spatial dimensions using a two-channel model. We investigate both few- and many-body properties of the gas, and we construct the ground-state phase diagram as a function of the effective range and coupling strength. We discuss how such a system may be experimentally realisable in the context of cold-atomic gases.

1:27PM M36.00012 Spin susceptibility and effects of fluctuating Cooper pairs in the BCS-BEC crossover regime of a superfluid Fermi gas¹, HIROYUKI TAJIMA, RY O HANAI, YOJI OHASHI, Keio University — We theoretically discuss the spin susceptibility $\chi$ and effects of strong-coupling corrections in the BCS-BEC crossover regime of an ultracold Fermi gas. Using an extended $T$-matrix approximation, we calculate $\chi$ over the entire BCS-BEC crossover region, showing that this magnetic quantity is very sensitive to pairing fluctuations in both the normal and the superfluid phase. In the normal state, it is suppressed by preformed singlet Cooper pairs near $T_c$, being similar to the spin-gap phenomenon in high-$T_c$ cuprates. Below $T_c$, on the other hand, pairing fluctuations enhance $\chi$, in the sense that the suppression of this quantity by the superfluid order is weakened due to partial dissociation of Cooper pairs. From these, we determine the region where pairing fluctuations strongly affect spin excitations in the phase diagram of a Fermi gas with respect to the temperature and the strength of a pairing interaction. We also compare our results with the recent experiments on a $^{40}$K Fermi gas. Our results indicate that the spin susceptibility is a useful observable in understanding strong-coupling properties of an ultracold Fermi gas in the BCS-BEC crossover region.

1:39PM M36.00013 Exact Ground-state Properties of Atomic Fermi Gases in Two Dimensions

Hao Shi, Simone Chiesa, Shiwei Zhang, William & Mary Coll — Experimental realization of the interacting Fermi gas in three dimensions and the precise comparison it has allowed with theory and computation have lead to rapid advances in the study of strongly paired fermions. Two-dimensional systems are being realized and offer many new opportunities. We perform exact calculations on the two-dimensional strongly interacting, unpolarized Fermi gas with a zero-range attractive interaction. A new auxiliary-field approach is used which is exact and accelerates the sampling of imaginary-time paths by a force bias technique. The method allows calculations with long imaginary-time and large lattice sizes. We present the calculated equation of state, the contact parameter, the condensate fraction, and the pairing correlation function. The structure of the pairing wave function is determined as a function of $k_F a$, we will also discuss the effect of spin-orbit coupling.

1:51PM M36.00014 Absence of spin order in a two-dimensional orbital optical lattice

Zhenyu Zhou, George Mason University, University of Pittsburgh, Vincent Liu, University of Pittsburgh, Erhai Zhao, George Mason University — Mott insulators with both spin and orbital degeneracy are pertinent to a family of transition metal oxides. The intertwined spin and orbital fluctuations can lead to exotic phases such as quantum spin-orbital liquids. Here we consider two-component spin 1/2 fermionic atoms with strong repulsive interaction on the p-band of the square optical lattice. We derive the spin-orbital exchange for quarter filling of the p-band in the Mott limit, and show it frustrates the development of long range spin order. Exact diagonalization indicates a spin-disordered ground state with ferro-orbital order. The system dynamically decouples into individual Heisenberg spin chains, each realizing a Luttinger liquid accessible at higher temperatures compared to atoms confined to the s-band. Our model serves as an example of how orbital order enhances quantum fluctuations to prevent spin order and leads to dimension reduction in a quantum gas system.

2:03PM M36.00015 Intrinsic p-wave pair amplitude in a trapped ultracold s-wave superfluid Fermi gas

Yuki Endo, Daisuke Inotani, Ryo Hanai, Yoji Ohashi, Keio University — We theoretically discuss the possibility that an unconventional p-wave Cooper-pair amplitude is induced in the ordinary s-wave superfluid Fermi gas. Using a Hubbard model, we numerically show that such a phenomenon really occurs, when both the spatial and (pseudo) spin inversion symmetries of the system are broken. In an ultracold Fermi gas, this situation is shown to be realized, when two spin states (that describe two atomic hyperfine states contributing to s-wave Cooper pairs) feel different trap potentials. Thus, in this situation, when the s-wave pairing interaction is suddenly changed to a p-wave one by using the Feshbach resonance technique, at least just after this tuning, the p-wave superfluid Fermi gas is expected to be realized (which is characterized by the superfluid order parameter given by the product of the p-wave pair amplitude and the p-wave pairing interaction). In this talk, we also clarify the optimal condition to obtain the p-wave pair amplitude in the BCS-BEC crossover region, using the BCS-Leggett strong-coupling theory.

Wednesday, March 4, 2015 11:15AM - 2:03PM — Session M37 GQI: Focus Session: Quantum Optics and Photonic Architectures 212A - Alexey Gorshkov, Joint Quantum Institute

11:15AM M37.00001 Demonstration of Backward-wave Parametric Down-Conversion

Chih-Sung Chuu, Chun-Yao Yang, Jim Lin, Department of Physics and Frontier Research Center on Fundamental and Applied Sciences of Matters, National Tsing Hua University, Taiwan, Charlotte Liljestrand, Carola Canalias, KTH - Royal Institute of Technology, Sweden, Stephen Harris, Edward L. Ginzbrot Laboratory, Stanford University, USA — Ultrabright sources of temporally long and spectrally narrow photons are essential for efficient light-matter interaction at the single-atom level. To achieve high brightness, parametric single-down-conversion of the backward-wave type was proposed for single-mode generation of long biphonons [1]. In this talk I will describe the demonstration of backward-wave parametric down-conversion in a nonlinear crystal, of which the time-energy entanglement was characterized by the Franson interference. I will also discuss the possibility of realizing a miniature ultrabright biphonon source.

11:27AM M37.00002 Nanomechanical single-qubit gates and iSWAP gate of single-electron spins in a carbon nanotube

Heng Wang, Guido Burkard, University of Konstanz, Germany — A universal gate set for quantum computation can be built with one-qubit and iSWAP gates. We theoretically investigate mechanically-induced single-electron spin resonance in a quantum dot [1] and a phonon-mediated iSWAP gate of two separate single electron spins in two quantum dots on a suspended carbon nanotube which is driven by an external electric field. The intrinsic spin-phonon coupling between the spin and the mechanical mode is induced by the spin-orbit coupling. Arbitrary-angle rotations about arbitrary axes of the single electron spin can be achieved by varying the frequency and the strength of the external electric driving field. If two single-electron spins in two quantum dots couple to the same vibrational mode simultaneously, the two spins are indirectly coupled via phonon exchange. Both electron spin resonance and the iSWAP gate can be turned off by suppressing the spin-phonon coupling by electrostatically shifting the electron wave function on the nanotube. Combining iSWAP and single spin gates, maximally entangled states of two spins can be generated in a single step. [1] H. Wang and G. Burkard, Phys. Rev. B 90, 035415 (2014).

11:39AM M37.00003 Nanophotonic photon echo memory based on rare-earth-doped crystals

Tian Zhong, Jonathan Kindem, Evan Miyazono, Andrei Fararon, Caltech, Caltech Nano Quantum Optics Team — Rare earth ions (REIs) are promising candidates for implementing solid-state quantum memories and quantum repeater devices. Their high spectral stability and long coherence times make REIs a good choice for integration in an on-chip quantum nano-photonics platform. We report the coupling of the 883 nm transition of Neodymium (Nd) to a Yttrium Orthosilicate (YSO) photonic crystal nano-beam resonator, achieving Purcell enhanced spontaneous emission by 21 times and increased optical absorption. Photon echoes were observed in nano-beams of different doping concentrations, yielding optical coherence times $T_2 > 80$ μs that are comparable to unprocessed bulk samples. This indicates the remarkable coherence properties of Nd are preserved during nanofabrication, therefore opening the possibility of efficient on-chip optical quantum memories. The nano-resonator with mode volume of $1.6(λ/ n)^3$ was fabricated using focused ion beam, and a quality factor of 3200 was measured. Purcell enhanced absorption of 80% by an ensemble of $1 \times 10^9$ ions in the resonator was measured, which fulfills the cavity impedance matching condition that is necessary to achieve quantum storage of photons with unity efficiency.

11:51AM M37.00004 Photons in synthetic gauge fields

Mohammad Hafezi, Joint Quantum Institute — Electronic transport is localized in low-dimensional disordered media. The addition of gauge fields to disordered media leads to fundamental changes in the transport properties. We implement a synthetic gauge field for photons using silicon-on-insulator technology. By determining the distribution of transport properties, we confirm that waves are localized in the bulk and localization is suppressed in edge states. Furthermore, we measure corresponding topological invariants and investigate the chiral gauge anomaly in the context of Chern-Simons theory. Our system provides a new platform for investigating the transport properties of photons in the presence of synthetic gauge fields.
12:27PM M37.00005 Harnessing gauge fields for maximally entangled state generation. SEBASTIAN REYES, LUIS MORALES-MOLINA, MIGUEL ORSZAG, Pontificia Universidad Catolica de Chile, DOMINIQUE SPEHNHER, Univesite Grenoble Alpes — We study the generation of entanglement between two species of bosons living on a ring lattice, where each group of particles can be described by a d-dimensional Hilbert space (qudit). Gauge fields are exploited to create an entangled state between the pair of qudits. Maximally entangled eigenstates are found for well-defined values of the Aharonov-Bohm phase, which are zero-energy eigenstates of both the kinetic and interacting parts of the Bose-Hubbard Hamiltonian, making them quite exceptional. We propose a protocol to reach the maximally entangled state (MES) by starting from an initially prepared ground state. Also, an indirect method to detect the MES by measuring the current of the particles is proposed.

12:39PM M37.00006 ABSTRACT WITHDRAWN —

12:51PM M37.00007 What does it mean for half of an empty cavity to be full? . ERIC BROWN, University of Waterloo — It is well known that the vacuum state of a quantum field is spatially entangled. This is true both in free and confined spaces, for example in an optical cavity. The obvious consequence of this, however, is surprising and intuitively challenging. Namely, that in some sense half of an empty box is full. Formally this is clear, but what does this physically mean in terms of, say, measurements that can actually be made? In this contribution I will discuss a new and simple perspective that answers this question precisely and physically concretizes the phenomenon. In so doing I will also propose a simple experimental setup for the verification of, and indeed the efficient harvesting of, vacuum entanglement. Preprint: http://arxiv.org/abs/1409.4203

1:03PM M37.00008 Protocols for a quantum network based on single photons . SUSANNE BLUM, Theoretical Physics, Saarland University, Germany, CHRISTOPHER O’BRIEN, Department of Physics and Astronomy, Texas A&M University, DANIEL REICH, Theoretical Physics III, University of Kassel, Germany, NIKOLAI LAUK, Physics Department, University of Kaiserslautern, Germany, CHRISTIANE KOEL, Theoretical Physics III, University of Kassel, Germany, MICHAEL FLEISCHHAUER, Physics Department, University of Kaiserslautern, Germany, GIOVANNA MORIGI, Theoretical Physics, Saarland University, Germany — Two protocols for interfacing single optical photons with individual qubits are theoretically discussed. The first is a protocol which allows one to interface a single optical photon with a superconducting qubit. It makes use of a spin ensemble, where the individual emitters possess both an optical and a magnetic dipole transition. Reversible frequency conversion is realized by combining optical photon storage, for instance by means of EIT, with the controlled switching on and off the coupling of the magnetic dipole transition with a microwave cavity, which in turn couples to a superconducting qubit. We test various strategies and compare their efficiencies in terms of robustness and transfer time. The second protocol aims at achieving perfect absorption of a photon by a single trapped atom, or solid-state emitter, by means of optimal control theory. We make use of the Krotov algorithm for the purpose of identifying pulses driving the atom, that maximize the efficiency and fidelity of absorption in the setup of [Reiser et al., Nature 508, 237 (2014)]. These protocols contribute to the development of a toolbox for quantum networks using hybrid platforms.

1:15PM M37.00009 QNIX: A Linear Optical Architecture for Quantum Computing . MERCEDES GIMENO-SEGOVIA, PETER J. SHADBOLT, TERRY G. RUDOLPH, Department of Physics, Imperial College London, SW7 2AZ, UK, DAN E. BROWNE, Department of Physics and Astronomy, University of Oxford, OX1 3RH, UK, GABRIEL MENDOZA, NICHOLAS J. RUSSELL, JOSHUA W. SILVERSTONE, ALBERTO SANTAMATO, JACQUES CAROLAN, JEREMY O’BRIEN, Centre for Quantum Photonics, H.H. Wills Physics Laboratory & Department of Electronic and Electrical Engineering, University of Bristol, BS8 1UB, UK — There is currently a great deal of effort to develop a large-scale quantum computer, and one of the most promising platforms to do so is integrated linear optics. We present a proposal for a dynamical scheme for an integrated linear optics implementation of a one-way quantum computer. We go beyond the purely theoretical work and address practical issues in order to create a physically realistic design. We describe every step of cluster state construction and processing, showing the outstanding issues left to be addressed and our contributions to the different stages of the dynamical process. These include optimised interferometers for the generation of GHZ states, a universal and scalable architecture which requires entangled sources of no more than 3 photons with no active feed-forward, and loss-tolerant and fault-tolerant strategies specifically tailored to our proposed architecture. Our work demonstrates that building a linear optical quantum computer need be less challenging than previously thought, and brings large-scale switch-free linear optical architectures for quantum computing much closer to experimental realisation.

1:27PM M37.00010 ABSTRACT WITHDRAWN —

1:39PM M37.00011 Reshaping quantum wave packets through time-dependent absorption . ARSENI GOUSSEV, Northumbria University — The problem of control and reliable manipulation of quantum states finds importance in many areas of physics including quantum metrology and matter-wave interferometry. Here we propose a new approach to reshaping the spatial wave function of a quantum particle, e.g., an atom, by passing the latter through a time-dependent absorbing barrier. Experimentally, such a barrier can be realized by means of a sharply focused laser beam or a light sheet, with the radiation frequency chosen to make the passing atom undetectable, for instance, by ionizing the atom or changing its internal state. In particular, we show how the proposed method can be used to shift, squeeze, or split spatially-localized quantum wave packets.

1:51PM M37.00012 Correlated random walks induced by dynamical wavefunction collapse1 . DANIEL BEDINGHAM, University of Oxford — Wavefunction collapse models modify Schrödinger’s equation so that it describes the collapse of a superposition of macroscopically distinguishable states as a genuine physical process [PRA 42, 78 (1990)]. This provides a basis for the resolution of the quantum measurement problem. An additional generic consequence of the collapse mechanism is that it causes particles to exhibit a tiny random diffusive motion. Furthermore, the diffusions of two sufficiently nearby particles are positively correlated — it is more likely that the particles diffuse in the same direction than would happen if they behaved independently [PRA 89, 032713 (2014)]. The use of this effect is proposed as an experimental test of wave function collapse models in which pairs of nanoparticles are simultaneously released from nearby traps and allowed a brief period of free fall. The random displacements of the particles are then measured. The experiment must be carried out at sufficiently low temperature and pressure for the collapse effects to dominate over the ambient environmental noise. It is argued that these constraints can be satisfied by current technologies for a large class of viable wavefunction collapse models.

11:15AM M38.00001 Contextuality: a benchmark for “quantumness” in theory and experiment, MATTHEW PUSEY, Perimeter Institute for Theoretical Physics — An ontological model for a quantum experiment is a purported explanation for the probabilities we see. Non-contextual models are particularly compelling because they never offer two different explanations for the same observations. I will review these notions and argue that the impossibility of non-contextual models is a good way to rigorously define “genuine quantumness”. Two examples of phenomena whose “quantumness” have been debated are “anomalous weak values” and “logical pre- and post-selection paradoxes”. I will outline how their incompatibility with non-contextual models clarifies why both defy compelling classical explanation. A related idea is to use contextuality to certify that an experiment has achieved quantum coherence without requiring a full characterization. To this end I will present a simple yet robust non-contextuality inequality that can be violated with a single qubit. (The work on pre- and post-selection paradoxes was done in collaboration with Matt Leifer.)

11:51AM M38.00002 Ordering relations for quantum states1, IAN DURHAM, Saint Anselm College — It is often desirable to model physical states in an order-theoretic manner, e.g. as a partially ordered set. Classical states are known to possess a unique ordering relation corresponding to a neo-realist interpretation of these states. No such unique relation exists for quantum states. This lack of a unique ordering relation for quantum states turns out to be a manifestation of quantum contextuality vis-à-vis the Kochen-Specker theorem. It also turns out that this provides a link to certain large-scale thermodynamic processes. The suggestion that the ordering of quantum states leads to macroscopic thermodynamic processes is at least five decades old. The suggestion that the mechanism that drives the ordering is contextuality, is unique to this work. The argument is framed in the language of the theories of domains, categories, and topology.

12:03PM M38.00003 Advances in weak-values based metrology, ANDREW JORDAN, GERARDO VIZA, JUILLIÁN MARTÍNEZ-RINCÓN, University of Rochester, GABRIEL ALVES, Universidade Federal do Rio de Janeiro, JOHN HOWELL, University of Rochester, PAUL KWIAT, University of Illinois at Urbana-Champaign — We theoretically [1] and experimentally [2] describe the relative advantages of implementing weak-values-based metrology versus standard methods. To accomplish this, we measure small optical beam deflections both a weak-values-based technique, and a standard technique. By introducing controlled external modulations of the detector, and transverse beam-jitter, we quantify the mitigation of these sources in the weak values-based experiment versus the standard experiment. In all cases, the weak-values technique performs the same or better than the standard technique by up to two orders of magnitude in precision for our parameters. We further measure the statistical efficiency of the weak-values-based technique. By post-selecting on 1% of the photons, we obtain 99% of the available Fisher information of the beam deflection parameter. We also discuss ways to recycle the discarded events [3], obtaining much greater precision on a measured parameter.

12:15PM M38.00004 On the efficacy of weak measurements for tomography, JONATHAN A. GROSS, CHRISTOPHER FERRIE, NINNAT DANGNIAM, CARLTON M. CAVES, University of New Mexico, Center for Quantum Information and Control — Recently there has been a fascination with weak measurements in the field of tomography. We conduct a detailed analysis of two specific schemes: so-called “direct state tomography”, and another scheme marketed as outperforming “standard” tomography with respect to fidelity considerations. Through the application of generalized measurement theory we clearly identify what weak measurements contribute beyond “standard” projective measurements and what simple techniques the application of weak measurements obscures.

12:27PM M38.00005 Many Worlds, the Born Rule, and Self-Locating Uncertainty, SEAN CARROLL, Caltech — A longstanding issue in attempts to understand the Everett (Many-Worlds) approach to quantum mechanics is the origin of the Born Rule: why is the probability given by the square of the amplitude? Recently, Page has raised another puzzle: the Born Rule itself is insufficient in cases where the wave function includes multiple indistinguishable observers in the same branch. I will argue that both problems share a common solution, arising from a proper treatment of self-locating uncertainty (physical situations containing multiple copies of identical observers). This analysis gives a simple, physics-oriented derivation of the Born Rule, as well as a justification for the treatment of identical classical observers.

1:03PM M38.00006 Quantum phenomena modelled by interactions between many classical worlds, HOWARD WISEMAN, MICHAEL HALL, Centre for Quantum Dynamics, Griffith University, DIRK-ANDRE DECKERT, Ludwig-Maximilians-Universität München — [Ref. Phys. Rev. X 4 041013 (2014)] We investigate how quantum theory can be understood as the continuum limit of a mechanical theory, in which there is a huge, but countable, number of classical “worlds,” and quantum effects arise solely from a universal interaction between these worlds, without reference to any wave function. Here a “world” means an entire universe with well-defined properties, determined by the classical configuration of its particles and fields. In our approach each world evolves deterministically; probabilities arise due to ignorance as to which world a given observer occupies; and we argue that in the limit of infinitely many worlds the wave function can be recovered (as a secondary object) from the motion of these worlds. We introduce a simple model of such a “many interacting worlds” approach and show that it can reproduce some generic quantum phenomena—such as Ehrenfest’s theorem, wavepacket spreading, barrier tunneling and zero point energy—as a direct consequence of mutual repulsion between worlds. Finally, we perform numerical simulations using our approach. We demonstrate, first, that it can be used to calculate quantum ground states, and second, that it is capable of reproducing, at least qualitatively, the double-slit interference phenomenon.

1:15PM M38.00007 Does protective measurement imply the reality of the quantum state?, MATTHEW LEIFER, Perimeter Institute for Theoretical Physics, JOSHUA COMBES, University of Waterloo, CHRIS FERRIE, University of New Mexico, MATTHEW PUSEY, Perimeter Institute for Theoretical Physics — In 1993, Aharonov and Vaidman claimed that the quantum state of a single system could be measured in a scheme they called ‘protective measurement’ and hence that the quantum state must be a real property of a single system. Despite attracting considerable controversy, we do not think that the existing criticisms have put their finger on precisely what is wrong with this claim. We explain why we think that, in the protective measurement scheme, the vast majority of the information about the quantum state comes from the protection operation rather than from the state itself. We also give simple toy models of protective measurement which show that the protection operation effectively reprepares the system in an independent copy of the initial state. Thus determining the quantum state by protective measurement is conceptually no different from performing state tomography on an ensemble of independently prepared systems.
Finally, we give simple quantum circuits for the implementation of this protocol with qubits, including initialization, weak interaction and postselection. With this result, we further find the Fisher information of weak measurement can approximately reach the Heisenberg limit with the assistance of entanglement.

In this work, we study the optimization of weak measurement and propose an entanglement-assisted protocol for practical application of weak measurement. In this work, we present the microscopic derivation of the OQBM for a Brownian particle. Here, we present the microscopic derivation of the OQBM for a Brownian particle with two internal degrees of freedom. Examples of the dynamics for initial Gaussian and non-Gaussian distributions are presented.

1:27PM M38.00008 Most likely paths for quantum trajectories: multiple solutions and generalization to two-qubit case. AREEYA CHANTASRI, Rochester Theory Center, University of Rochester, New York, ANDREW JORDAN, Rochester Theory Center, University of Rochester, New York; Institute of Quantum Studies, Chapman University, Orange, California — We study trajectories of quantum states evolving under the quantum measurement. We further analyze and develop our recent approach for finding the most likely path for quantum trajectories between any two states at different times. Under certain conditions, we find that the most likely path can bifurcate and multiple solutions do exist. Two or more solutions can have comparably large probability weights associated with them, implying multiple likely paths for the state trajectories. In developing this approach, we go beyond a single qubit. In this work, we study the optimization of weak measurement and propose an entanglement-assisted protocol for it. We start from maximizing the postselection probability with a given weak value. The result shows the maximum postselection probability is proportional to the variance of the observable under the initial state of the system. As is known that the variance has different scaling under entangled or uncorrelated states, it inspired us to show using entanglement in the initial state of the system can increase the postselection efficiency beyond that with sequential use of systems. With this result, we further find the Fisher information of weak measurement can approximately reach the Heisenberg limit with the assistance of entanglement. Finally, we give simple quantum circuits for the implementation of this protocol with qubits, including initialization, weak interaction and postselection.

1:39PM M38.00009 Microscopic derivation of open quantum Brownian motion¹, FRANCESCO PETRUCCIONE, ILYA SINAYSKIY, University of KwaZulu-Natal and National Institute for Theoretical Physics (KZN), UKZN TEAM — Recently a model of open quantum Brownian motion (OQBM) [M. Bauer, D. Bernard, A. Tilloy, Phys. Rev. A 88 (2013) 062340] was introduced as a scaling limit of Open Quantum Walks (OQWs) [S. Attal, F. Petruccione, C. Sabot, I. Sinayskiy, J. Stat. Phys. 147 (2012) 832]. OQBM is a new type of quantum Brownian motion where the dynamics of the Brownian particle not only depends on the interactions with a thermal environment, but also depends on the state of the internal degrees of freedom of the Brownian particle. Here, we present the microscopic derivation of the OQBM for a Brownian particle with two internal degrees of freedom. Examples of the dynamics for initial Gaussian and non-Gaussian distributions are presented.

¹This work is based upon research supported by the South African Research Chair Initiative of the Department of Science and Technology and National Research Foundation.

2:03PM M38.00011 Pricing postselection: the cost of indecision in state discrimination, JOSHUA COMBES, Perimeter Institute for Theoretical Physics, CHRISTOPHER FERRIE, University of New Mexico — Postselection is the process of discarding outcomes from statistical trials that are not the event one desires. Postselection can be useful in many applications where the cost of getting the wrong event is implicitly high. However, unless this cost is specified exactly, one might formally conclude that discarding all data is optimal. Here we analyze the optimal decision rules and quantum measurements in a decision theoretic setting where a pre-specified cost is assigned to discarding data. Non-trivial solutions are found for even the simplest state discrimination problem of choosing between two nonorthogonal qubit states. Our solutions interpolate between the Helstrom measurement and the unambiguous state discrimination experiment.

Wednesday, March 4, 2015 11:15AM - 2:15PM — Session M39 GQI: Focus Session: Superconducting Qubits: Hybrid Systems 213AB -

11:15AM M39.00001 Towards hybrid quantum devices combining superconducting qubits to a spin-ensemble multi-qubit register. CECILE GREZES, CEA Saclay — Processing quantum information requires quantum-mechanical systems with long coherence times and that can be easily coupled together to perform logic operations. We report progress on hybrid quantum devices, in which an ensemble of spins provides a long-lived multi-qubit register for superconducting qubits. We design a memory protocol able to store and retrieve on demand the state of a large number of qubits in the spin ensemble [1]. Qubit states are written by resonant absorption of a microwave photon in the spin ensemble and read out of the memory by applying Hahn echo refocusing techniques to the spins. In a first experiment, we demonstrate the write step of the protocol by integrating on the same chip a superconducting qubit, a resonator with tunable frequency, and an ensemble of NV center spins in diamond [2]. In a second experiment, we demonstrate an important building block of the read step, which consists in retrieving multiple classical microwave pulses at the few photon level using Hahn echo refocusing techniques [3]. First experimental results will be presented in the direction of combining these two building blocks for retrieving a field in the quantum regime.

11:51AM M39.00002 Exploring the Physics of Semiconductor Quantum Dots using Circuit Quantum Electrodynamics, ANNA STOCKKLAUSER, VILLE MAISI, THOMAS IHN, KLAUS ENSSLIN, ANDREAS WALLRAFF, ETH Zurich — Semiconductor quantum dots and superconducting qubits both possess excitations in the microwave domain for which a wide range of novel approaches to create, store, manipulate and detect individual photons have been developed. A key ingredient are coplanar waveguide resonators in which the field energy of an excitation is distributed over a small mode volume. This feature creates sizable electromagnetic fields at the level of individual microwave photons mediating strong electromagnetic interactions with a variety of quantum systems. In an approach known as circuit quantum electrodynamics (QED) we both probe fundamental quantum optical effects and demonstrate basic features of quantum information processing. In this presentation, I will discuss experiments exploring the physics of semiconductor quantum dots in the context of circuit QED. We investigate the coherent dipole coupling of double dots to microwave photons [1,2] and detect radiation emitted from the dots in inelastic electron tunneling processes. This approach may allow us to explore quantum coherent interfaces between semiconducting and superconducting qubits.

12:03PM M39.00003 Improving the coherence time of a quantum system via a coupling with an unstable system, YUICHIRO MATSUZAKI, XIAOBO ZHU, KOSUKE KAKUYANAGI, HIRAKU TOIDA, NTT Basic Research Laboratories, TAKAAKI SHIMO-OKA, NORIKAZU MIZIOCHI, University of Osaka, KAE NEMOTO, National Institute of Informatics, KOJI SEMBA, National Institute of Information and Communications Technology, WILLIAM MUNRO, HIROSHI YAMAGUCHI, SHIRO SAITO, NTT Basic Research Laboratories — One of the promising candidates for the realization of quantum information processing is nitrogen-vacancy (NV) center. High controllability of NV centers has been achieved with the current technology, including reliable single qubit operations and quantum non-demolition measurements. However, NV center is affected by dephasing due to magnetic-field environmental noise, which limits the coherence time of the quantum states. In this talk, we propose a counter-intuitive way to improve the coherence time of an NV center where we use a coupling with an unstable system. If we couple a two-level system such as a superconducting qubit with a single NV center, then a dark state of the NV center naturally forms after the hybridization. We show that this dark state becomes robust against environmental fluctuations due to the coupling even when the coherence time of the two-level system is much shorter than that of the NV center.

12:15PM M39.00004 Spin-qubit inspired architectures for superconducting quantum computing, YUN-PIL SHIM, CHARLES TAHAN, Laboratory for Physical Sciences — In recent years, the superconducting qubit community has achieved single and two-qubit benchmarked gate fidelities approaching 99.9%, fast readout with novel superconducting amplifiers, distributed entanglement, and other milestones on the road to fault-tolerant quantum information processing. Obviously, this is a field that could use some help from the semiconductor qubit community! Here we present theoretical work on superconducting qubit systems inspired by our experience with semiconductor qubits. We discuss initialization, single- and two-qubit gate operations, and measurement schemes for an encoded qubit in a two-dimensional architecture. Our results motivate new ways of designing or operating superconducting quantum information processors.

12:27PM M39.00005 Superconducting qubits with semiconductor nanowire Josephson junctions, K.D. PETERSSON, T.W. LARSEN, F. KUEMMETH, T.S. JESPERSEN, P. KROGSTRUP, J. NYGÅRD, C.M. MARCUS, Center for Quantum Devices, Niels Bohr Institute, Denmark — Superconducting transmon qubits are a promising basis for a scalable quantum information processor. The recent development of semiconductor InAs nanowires with in situ molecular beam epitaxy-grown Al contacts presents new possibilities for building hybrid superconductor/semiconductor devices using precise bottom up fabrication techniques. Here, we take advantage of these high quality materials to develop superconducting qubits with superconductor-normal-superconductor Josephson junctions (JJs) where the normal element is an InAs semiconductor nanowire. We have fabricated transmon qubits in which the conventional Al-AlOx-Al JJs are replaced by a single gate-tunable nanowire JJ. Using spectroscopy to probe the qubit we observe fluctuations in its level splitting with gate voltage that are consistent with universal conductance fluctuations in the nanowire’s normal state conductance. Our gate-tunable nanowire transmons may enable new means of control for large scale qubit architectures and hybrid topological quantum computing schemes.

12:39PM M39.00006 Coherent control of a transmon qubit with a nanowire-based Josephson junction, T.W. LARSEN, K.D. PETERSSON, F. KUEMMETH, T.S. JESPERSEN, P. KROGSTRUP, J. NYGÅRD, C.M. MARCUS, Center for Quantum Devices, Niels Bohr Institute, Denmark — Transmon qubits[1] have taken great leaps towards realizing a quantum processor[2]. Here we present measurements on a novel, gateable transmon. By tuning the electron density in a semiconducting nanowire transmon, we can control the qubit frequency from ~3 GHz to ~8 GHz. The transmon was embedded in an aluminum coplanar waveguide cavity for readout and qubit control. In the resonant regime we observe strong cavity-qubit coupling. In the dispersive regime we demonstrate coherent control on the Bloch sphere. The life- and coherence times were measured to $T_1 \approx 2T_2 \sim \sim 1 \mu$s. The coherence time was measured to almost $1 \mu$s. Fast gate operations facilitate z-rotations as well as promising fast two-qubit operations in future multiple-qubit devices. These measurements open new possibilities for gateable superconducting qubits and promise a plausible system for Majorana hybrid devices.

12:51PM M39.00007 Fermion parity measurement and control in Majorana circuit quantum electrodynamics, ERAN GINOSSAR, Advanced Technology Institute and Department of Physics, University of Surrey, Guildford, United Kingdom GU2 7XH, CONSTANTIN YAVILBERG, EYTAN GROSFELD, Department of Physics, Ben-Gurion University of the Negev, Be’er-Sheva 84105, Israel — Combining superconducting qubits with mesoscopic devices that carry topological states of matter may lead to compact and improved qubit devices with properties useful for fault-tolerant quantum computation. Recently, a charge qubit device based on a topological superconductor circuit has been introduced where signatures of Majorana fermions could be detected. This device stores quantum information in coherent superpositions of fermion parity states originating from the Majorana fermions, generating a highly isolated qubit whose coherence time could be greatly enhanced. We extended the conventional semi-classical method and obtain analytical derivations in the strong coupling regime of the device to cavity photons. We study the effect of the Majorana fermions on the quantum electrodynamics of the device embedded within an optical cavity and develop protocols to initialise, control and measure the parity states. We show that, remarkably, the parity eigenvalue is revealed via dispersive shifts of the optical cavity in the strong coupling regime and its state can be coherently manipulated via a second order sideband transition.

12:57PM M39.00008 ABSTRACT WITHDRAWN —
1:15PM M39.00009 Photon-assisted tunnelling with nonclassical microwaves in hybrid circuit QED systems by JEAN-RENE SOUQUET, McGill Univ, MATTHEW WOOLLEY, University of New South Wales, JULIEN GABELLI, PASCAL SIMON, QED systems — Motivated by recent experiments where superconducting microwave circuits have been coupled to electrons in semiconductor nanostuctures [1-3], we study theoretically the interplay of non-classical light produced in a cavity with electron transport through a tunnel junction [4]. We demonstrate that this basic light-matter interaction is naturally characterized by non-positive definite quasi-probability distributions which are intimately connected to the Glauber-Sudarshan P-function. We further demonstrate that this negative quasi-probability has unequivocal signatures on the differential conductance that should be easily detectable in state of art experiments. This thus turns the tunnel junction into a non-trivial probe of the microwave state. We also present a rigorous extraction of the interaction current on the cavity.

1:27PM M39.00010 Novel quantum electro-optic transducer for quantum information processing using superconducting 3D qubits by H. PAIK, L. S. BISHOP, D. T. MCCLURE, S. FILIPIK, J. M. GAMBITTA, C. B. LIRAKIS, IBM T. J. Watson Research Center, C. A. RYAN, J. SCHLAFER, M. P. DA SILVA, M. SOLTANI, M. PATEL, Z. DUTTON, Raytheon BBN Technologies — We propose a novel electro-optic system, SQOT (Superconducting Qubit Optical Transducer) [1] which can directly exchange quantum information between optical photons at telecom frequencies and superconducting qubits. Our scheme is based on three-dimensional qubits directly on top of a ultra-high Q whispering gallery mode optical cavity. The optical cavity is itself made from an electro-optic material such that we obtain a direct microwave-optical interaction between the qubit and optical cavity. In this talk, we present recent progress in designing and building the SQOT device and some challenges such as fabricating Josephson junctions on the electro-optic material and cryogenic microwave losses and possible solutions. [1] H. Paik, U.S. Patent Submitted (2013)

1:39PM M39.00011 Manipulation of non-classical microwave states using parametric interactions by MANUEL CASTELLANOS-BELTRAN, NIST - Boulder, MICHAEL DEFEO, ADAM SIROIS, LEONARDO RANZANI, NIST - Boulder, University of Colorado - Boulder, RAYMOND SIMMONDS, JOHN TEUFEL, JOSE AUMENTADO, NIST - Boulder — A primary tool for research in quantum optics has been the generation of exotic quantum states – such as Fock states or superpositions of two coherent states. These states have served well in many basic tests of the foundations of quantum theory and the latter may eventually prove useful for quantum computing, communication, and metrology. One important requirement for the generation and use of these states is their precise control and manipulation. In this respect, c-QED is a very versatile tool. In the past decade there have been extensive improvements in the storage and retrieval of quantum states of light in this experimental platform and more recently in the manipulation of those states using parametric interactions. In this talk, I will discuss our progress toward the goal of efficiently generating a superposition of small-amplitude coherent states, as well as their detection. This follows from our attempt/goal to implement an “on-chip” optical table which utilizes parametric interactions for state preparation and measurement. I will also discuss how we use homodyne tomography to fully characterize the states prepared in our setup.

1:51PM M39.00012 Fast control and Floquet state dynamics of a strongly driven superconducting qubit by CHUNQING DENG, FEIRUO SHEN, JEAN-LUC ORGIAZZI, Univ of Waterloo, SAHEL ASHHAB, Qatar Environment and Energy Research Institute, ADRIAN LUPASCU, Univ of Waterloo — Floquet states are quasi-stationary solutions of the Schrödinger equation with a time-periodic Hamiltonian. They are the appropriate states for describing the dynamics of a qubit in the strong driving regime, where the rotating wave approximation is no longer valid. We performed experiments on strong driving of a superconducting flux qubit using pulses with sub-nanosecond duration. We explore driving strength up to 5.0 GHz, largely exceeding the qubit Larmor frequency of 2.2 GHz. Floquet state dynamics is visible in the appearance of fast oscillating components in the qubit evolution in the rotating frame. Using pulse shaping, we also demonstrate the control of adiabatic/nonadiabatic transitions between the Floquet states. The control of the Floquet states is relevant for high-fidelity single-qubit operations in the strong driving regime.

2:03PM M39.00013 Probing an ensemble of superconducting devices by ADAM SEARS, DAVID HOVER, THEODORE GUDMUNSDEN, JONILYN L. YODER, MIT Lincoln Laboratory, ARCHANNA KAMIL, FLEI YAN, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, ANDREW KERNER, WILLIAM OLIVER, MIT Lincoln Laboratory — We present experimental results on a system in which we use a flux qubit to probe an ensemble of weakly coupled superconducting devices. We employ standard qubit metrology techniques to reveal global device properties. In addition, we discuss the connection with engineered environmental decoherence. This work is sponsored by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract FA8721-05-0002. Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the United States Government.

11:15AM M41.00001 Driving with squeezed vacuum in strong dispersive circuit-QED by MATTHEW ELLIOTT, ERAN GINOSAR, Advanced Technology Institute and Department of Physics, University of Surrey, Guildford, Surrey GU2 7XH — Recent experiments have demonstrated that it is possible to achieve a significant interaction between a squeezed microwave state and a superconducting qubit. Motivated by the success of coherent driving in circuit-QED, we study the dynamics of a two-part system where the squeezed output of a degenerate Josephson parametric amplifier, is used to drive a cavity-qubit system. We develop a Gaussian mean field model to describe the cavity state in the strong-dispersive regime and use this to investigate its steady-state behaviour. We compare this to full numerical solutions of the master equation, allowing us to also consider transient dynamics. Despite the effect of the qubit non-linearity, we demonstrate that it is possible to generate a stable, highly squeezed intracavity field in a range of parameters where the qubit can be used to reconstruct the states of the cavity. These results are testable using current experimental set-ups. Additionally, we discuss possible applications in the characterisation of sources of itinerant squeezed vacuum.

11:27AM M41.00002 Measurement of an ac Stark shift in a superconducting qubit under strong Rabi drive by YOUNG CHONG, DONG-GWANG HA, JUNG HWAN PARK, WON SONG, Korea Research Institute of Standards and Science, GWAN YEOL PARK, SOON GUL LEE, Korea University — We present a measurement of an ac Stark shift in a superconducting 3D transmon qubit. The qubit is strongly coupled to a superconducting aluminum cavity in circuit QED architecture. We observed the ac Stark shift under strong Rabi drive and measured it from detuning behavior of the Rabi oscillations as a function of the Rabi frequency. We also confirmed the shift by the Butler-Townes splitting measurement as a function of the qubit drive power.
11:39AM M41.00003 Observation of Dark State in a Three-dimensional Transmon Superconducting Qutrit

YUHAO LIU, XINSHENG TAN, DONG LAN, PENG ZHAO, JIE ZHAO, MENGMENG LI, SHUDONG HUANG, HAIFENG YU, SHILIANG ZH, YANG YU, School of Physics, Nanjing University, China — Dark state refers to a particular state of a quantum system that cannot absorb or emit photons in driving fields. It has important applications in quantum information processing and quantum metrology. Here we report the observation of dark state in a three-dimensional transmon superconducting qutrit. The transmon qutrit, which has cascade three energy levels $|0\rangle$, $|1\rangle$ and $|2\rangle$, is embedded in the center of a rectangle waveguide cavity. When two tone microwaves are applied resonantly between $|0\rangle$, $|1\rangle$ and $|2\rangle$, the state of the system will evolve in time domain. However, if we initialize the qutrit in the coherent superposition state, it will not change with time for certain driving amplitudes. The observed relationship between the initial state and the amplitudes of the two tone microwaves agrees well with the results from numerical calculations.

11:51AM M41.00004 Resonance Fluorescence and Photon Correlations Produced by 1-10 Qubits in 1D Infinite or Semi-Infinite Waveguides

YAO-LUNG L. FANG, HARALD BARANGER, Duke University — We study multiple two-level systems (2LS) coupled to a 1D waveguide in which one end is open and the other is either open (infinite waveguide) or closed (semi-infinite). Resonance fluorescence and two-photon correlations are presented for weak coherent driving. We show that while for a single 2LS coupled to an infinite waveguide the reflected photons are initially anti-bunched, for a semi-infinite waveguide they become highly bunched. As the number of 2LS increases (up to 10), rapid oscillations build up in the correlations that persist for a long time. At the same time, incoherently reflected photons are mostly distributed within the photonic band gap when driven resonantly, accompanied by sharp side peaks. Our calculations can be explained using the poles of the Green function in the Markovian regime together with the notion of time delay. Finally, in the non-Markovian regime we demonstrate that a 2LS in a semi-infinite waveguide can no longer be decoupled by placing it at the node of the photonic field, in sharp contrast to a recent experimental finding in the Markovian regime using superconducting qubits.

12:03PM M41.00005 Electromagnetically induced transparency and coherent population trapping with a superconducting artificial atom

SERGEY NOVIKOV, University of Maryland, College Park, TIMOTHY M. SWEENEY, J.E. ROBINSON, Laboratory for Physical Sciences, BALADITYA SURI, University of Maryland, College Park, F.C. WELLSTOOD, QJI, CNAM, Dept. of Physics, University of Maryland, College Park, B.S. PALMER, Laboratory for Physical Sciences — We embed a superconducting Al/AlOx/Al transmon qubit that acts as an artificial atom in a three-dimensional copper microwave cavity at a temperature of 22 mK. By addressing the hybridized qubit-cavity levels with two microwave drives (probe and coupler), we are able to create a $\Lambda$-like system with highly asymmetric decay rates. We observe electromagnetically induced transparency, and use this feature to achieve coherent population trapping (CPT) by creating a superposition state with the two drives whose duration is much longer than any coherence times in the system. After the drives are turned off, the resultant CPT dark state is coherent for $T_{\mathrm{CPT}} \approx 7.4 \mu s$. We estimate the minimum fidelity of the dark state achievable in this system to be 60%. These results present a way of superposition and entanglement generation with CW tones in a superconducting system.

12:15PM M41.00006 Electromagnetically Induced Superluminal Light in a 3D Transmon Device

TIMOTHY M. SWEENEY, Lab. for Physical Sciences, BALADITYA SURI, University of Maryland, College Park, F.C. WELLSTOOD, QJI, CNAM, Dept. of Physics, University of Maryland, B.S. PALMER, Lab. for Physical Sciences — Quantum interference in a three level $\Lambda$-type system can result in non-linear optical effects such as electromagnetically induced transparency/absorption (EIT/EIA), slow, and fast light. We have created a $\Lambda$ system with an effectively metastable state by dispersively coupling an Al/AlOx/Al transmon qubit (T$_1$ = 4 us) to a 3D Cu microwave cavity (T$_1$ = 340 ns). By probing the transmission through the cavity while pumping a qubit-cavity sideband yields a large change in the dispersion. We observe group advances of up to 10 us for Gaussian pulses propagating through the system, corresponding to a group index of -176,000.

12:27PM M41.00007 A superconducting qubit coupled to propagating acoustic waves

MARTIN V. GUSTAFSSON, Columbia University (USA) and Chalmers University of Technology (Sweden), THOMAS AREF, ANTON FRISK KOCKUM, MARIA K. EKSTRÖM, GÖRAN JOHANSSON, PER DELSING, Chalmers University of Technology (Sweden) — Mechanical devices in the quantum regime have so far consisted mainly of suspended resonators, where standing modes can be populated with quanta of vibrational energy. We present a fundamentally different system, where the mechanical excitation is not restricted to a specific mode and location. Instead, we demonstrate strong non-classical coupling between propagating phonons and a superconducting qubit. The qubit is fabricated on a piezoelectric substrate, and is designed to interact with Surface Acoustic Waves (SAWs) in the gigahertz frequency range. A separate on-chip transducer allows us to launch SAWs toward the qubit from a distance and pick up SAW phonons that the qubit reflects and emits. In a series of experiments where the qubit is addressed both electrically and acoustically, we show that the qubit couples much more strongly to SAWs than to any electrical modes. The low speed of sound sets phonons apart from photons as a medium for transporting quantum information, and should enable real-time manipulation of propagating quanta. The short acoustic wavelength and strong piezoelectric coupling should also allow regimes of interaction to be explored which cannot be reached in photonic systems.

12:39PM M41.00008 Strong qubit-phonon interactions in a superconducting 1D open space

POL FORN-DIAZ, JEAN-LUC ORGIAZZI, MARTIN OTTO, ALI YURTALAN, Institute for Quantum Computing, University of Waterloo, Waterloo, Canada, BORJA PEROPADRE, Department of Chemistry and Chemical Biology, Harvard University, Cambridge MA, USA, JUAN-JOSE GARCIA-RIPOLL, Instituto de Física Fundamental IFF-CSIC, Madrid, Spain, CHRISTOPHER WILSON, ADRIAN LUPASCU, Institute for Quantum Computing, University of Waterloo, Waterloo, Canada — The field of superconducting quantum circuits has seen much progress using many ideas formerly developed for atomic systems, while at the same time exploring new avenues unattainable in other quantum systems. A novel, promising architecture for fundamental studies of quantum electrodynamics in one dimension can be built by coupling a single superconducting qubit to a transmission line [1]. The qubit interacts with the modes of the transmission line, behaving like a single scatterer that can interfere strongly with propagating photons. The interaction between the qubit and the propagating modes of the line can be made ultrastrong, thus enabling a new domain of physics and applications to be investigated. We will present preliminary results on an experiment consisting in a flux qubit-transmission line system at different coupling strengths and its connection to existing models of spin-boson physics [2].

A interacting with a one-dimensional waveguide through a realistic minimal-coupling interaction. We show that the diamagnetic term

two collective cooperativity parameters.

We present spectroscopic quantum operations in hybrid quantum systems. As an example of the application, we determine their coupling to transmon qubits with different frequencies and we present a bi-chromatic scheme for entanglement and gate operations. In this calculation, we obtain a maximally entangled state with a fidelity $F = 95\%$. Our proposal is competitive with the achievements of other entanglement-gates with superconducting devices and it may offer some advantages: (i) There is no need for additional control lines and dephasing associated with the conventional frequency tuning of qubits. (ii) When our qubits are idle, they are far detuned with respect to each other and to the resonator, and hence they are immune to cross talk and Purcell-enhanced decay.

12:51PM M41.00009 Flux qubit ultrastrongly coupled to two resonators. A. BAUST, E. HOFFMANN, M. HAEBERLEIN, M.J. SCHWARZ, P. EDER, J. GOETZ, F. WULSCHNER, E. XIE, L. ZHONG, K. FEDOROV, E.P. MENZEL, F. DEPPE, A. MARX, R. GROSS, TU Muenchen, Nanosystems Initiative Munich and Walther-Meissner-Institut, Germany — Circuit quantum electrodynamics has not only become a versatile toolbox for quantum information processing, but is also a powerful platform for the investigation of light-matter interaction. The coupling strength between microwave resonators and qubits acting as artificial atoms can be tuned over several orders of magnitude and can even reach the regime of ultrastrong coupling. We present a recently developed gapless two-qubit setup coupling two qubits with a long superconducting resonator. We report the first observation of a strong coupling regime between microwave resonators and qubits acting as artificial atoms.

By minimal, we mean that sending just one photon two photons are generated through the qubit. In our calculations, the parameters are taken from the chip reported in a recent Science paper by the Wallraff group [van Loo et al, Science 342, 1494 (2013)].

1:03PM M41.00010 ABSTRACT WITHDRAWN —

1:15PM M41.00011 Circuit QED Photonics, DAVID ZUECO, EDUARDO Sánchez-BURILLO, Universidad de Zaragoza-CSIC, JUANJO GARCIA-RIPOLL, CSIC, LUIS MARTÍN-MORENO, Universidad de Zaragoza-CSIC — In this talk we report our theoretical results for the scattering of few photons against few two level systems. The photons travel through an open superconducting coplanar waveguide transmission line and the two level systems can be flux qubits or transmons. Several phenomena will be discussed: the linear and nonlinear behavior as a function of the ratio between the number of photons and number of qubits. For the case of flux qubits we discuss the cases of strong and ultrastrong line-qubits coupling. Different phenomena are found and described: Fano profiles, Raman scattering, photon generation and novel and non-perturbative qubit-qubit interecations through the line. Finally, we consider the case of transmon qubits. We theoretically demonstrate that driven transmons can be used as a minimal setup for doing up and downconversion. By minimal, we mean that sending just one photon two photons are generated through the qubit. In our calculations, the parameters are taken from the chip reported in a recent Science paper by the Wallraff group [van Loo et al, Science 342, 1494 (2013)].

1:27PM M41.00012 Light-matter decoupling and $A^2$ term detection in superconducting circuits. JUAN JOSE GARCÍA-RIPOLL, Instituto de Física Fundamental, IFF-CSIC, Madrid, BORJA PEROPADRE, Department of Chemistry and Chemical Biology, Harvard University, SIMONE DE LIBERATO, School of Physics and Astronomy, University of Southampton — We study the spontaneous emission of a qubit interacting with a one-dimensional waveguide through a realistic minimal-coupling interaction. We show that the diamagnetic term $A^2$ leads to an effective decoupling of a single qubit from the electromagnetic field. This effect is observable at any range of qubit-photon couplings. For this we study a setup consisting of a transmon that is suspended over a transmission line. Assuming a standard model of qubit-line interaction, we prove that the relative strength of the $A^2$ term is controlled with the qubit-line separation and show that, as a consequence, the spontaneous emission rate of the suspended transmon onto the line can increase with such separation, instead of decreasing.

1:39PM M41.00013 Beyond strong coupling in a massively multimode cavity, NEEREJA SUNDARESAN, YANBING LIU, DARIUS SADRI, LASZLO SZOCS, DEVIN UNDERWOOD, MOEIN MALEKAKHLAGH, HAKAN TÜRECİ, ANDREW HOUCK, Princeton University — We present experiments in a new regime of cavity quantum electrodynamics (cQED), the multimode strong coupling regime, in which the qubit-cavity coupling is comparable to the free spectral range, thus requiring the collective treatment of all modes along with the qubit. Here we show that this regime is accessible in circuit QED by coupling a 90MHz microwave cavity with a transmon qubit, resonant with the 75th harmonic with a coupling strength exceeding 30MHz. When driving this system, we observe multimode fluorescence consistent with cavity-enhanced sideband emission, with unexpected multi-photon processes and the emergence of ultra-narrow linewidths. This multimode coupling opens the door for a wide range of potential experiments, including studying the manifestation of complex many-body phenomena, the breakdown of the rotating wave approximation, and the bridge between discrete and continuous Hilbert spaces.

1:51PM M41.00014 Multi-frequency modes in superconducting resonators: Bridging frequency gaps in off-resonant couplings, CHRISTIAN KRAGLUND ANDERSEN, KLAUS MØLMER, Univ of Aarhus — A SQUID inserted in a superconducting waveguide resonator imposes current and voltage boundary conditions that make it suitable as a tuning element for the resonator modes. If such a SQUID element is subject to a periodically varying magnetic flux, the resonator modes acquire frequency side bands. We calculate the multi-frequency eigenmodes and these can couple resonantly to physical systems with different transition frequencies and this makes the resonator an efficient quantum bus for weak and strong coupling schemes.

2:03PM M41.00015 Amplitude Bistability in the Multimode Regime of Circuit-QED, MOEIN MALEKAKHLAGH, NEEREJA SUNDARESAN, YANBING LIU, DARIUS SADRI, ANDREW HOUCK, HAKAN TÜRECİ, Princeton University, MESOSCOPIC QUANTUM OPTICS GROUP TEAM, QUANTUM COMPUTING AND CONDENSED MATTER PHYSICS WITH MICROWAVE PHOTONS TEAM — In theory of dynamical systems, bistability refers to a situation where the system has two possible stable equilibrium states. For certain optical devices, it is possible to have two resonant transmission states that only differ in amplitude and is referred as “optical amplitude bistability.” This phenomenon occurs due to nonlinear nature of light-matter interaction where the light absorption or blockade by the absorber strongly depends on the drive strength. The transition between these two bistable solutions happens when the absorber is saturated and no longer capable of blocking light. In this talk, we study the dynamics of a transmon qubit coupled to a large number of modes of a long superconducting resonator and driven by an external microwave drive. We introduce a generalized theory of multimode amplitude bistability first discussed by C.M. Savage and H.J. Carmichael [1] for a resonant single mode cavity. We will demonstrate that bistability is a characteristic of the entire system including the qubit and all modes of the resonator and can be characterized analytically by the knowledge of two collective cooperativity parameters.

Wednesday, March 4, 2015 11:15AM - 2:15PM –
Session M43 DPOLY FIAP: Focus Session: Industry Day: Applied Polymer Physics in Advanced Manufacturing 214C - Brent Neal, Milliken & Company
Elasticity and Extensibility Determine Printability and Spinnability of Polymer Solutions. Jelena Dinić, Leidy Nallely Jiménez, Vicky Mei Yiran Zhang, Vivek Sharma. Chemical Engineering, University of Illinois Chicago. Many advanced manufacturing technologies like inkjet printing, 3D printing, nano-fiber spinning, gravure printing and nano-imprint lithography involve complex free-surface flows, where both shear and extensional rheology affect processability. In applications that involve progressive thinning and break-up of a fluid column or sheet into drops, the dominant flow within the filament is extensional in nature. Polymer fluids exhibit a much larger resistance to flow in an elongational flow field than Newtonian fluids with same shear viscosity. Characterizing the filament thinning and break-up kinetics in jetting, dripping and stretching liquid bridge provides invaluable insight into the interplay of elastic, viscous, capillary and inertial stresses relevant for these applications. In this talk, we elucidate how polymer composition, flexibility, and molecular weight determine the kinematics of capillary-driven thinning and pinch-off in our experiments. Both effective relaxation time and transient extensional viscosity are found to be strongly concentration dependent even for dilute solutions. Further, we show how fragile extensibility of polymers dramatically changes the kinematics from elastocapillary to visco-capillary under strong extensional flow fields that can lead to coil-stretch transition.

Controlling Fiber Morphology in Simultaneous Centrifugal Spinning and Photopolymerization. Yichen Fang, Austin Dulaney, Christopher Ellison. University of Texas at Austin - McKetta Department of Chemical Engineering. Current synthetic fiber manufacturing technologies use either solvent or heat to transform a solid preformed polymer into a liquid before applying a force to draw the liquid into fiber. While the use of solvent poses concerns regarding process safety and environmental impact, the use of heat may also lead to polymer degradation and excessive energy consumption. To address these critical challenges, here we present an alternative fiber manufacturing method that encompasses extruding a monomer solution through an orifice, drawing it using centrifugal Forcespinning and polymerizing the monomer jet into solid fiber in flight using UV initiated thiol-ene chemistry. This method not only negates the use of both heat and solvent, but also produces fibers that are highly crosslinked, mechanically robust, and thermally stable. In this process, the balance between curing kinetics, fiber flight time, and solution viscoelasticity is essential. Studies were conducted to quantitatively investigate the effect of these factors on fiber formation and morphology. An operating diagram was developed to show how the intricate interplay of these factors led to the formation of smooth fibers and other undesirable fiber defects, such as beads-on-string, fused fibers, and droplets.

Engineering the Crystalline Morphology of Polymer Thin Films at a Molecular Level via Matrix Assisted Pulsed Laser Evaporation. Hyuncheol Jeong, Craig Arnold, Rodney Priestley. Princeton University. Controlling the crystalline morphology of polymeric thin films at a molecular level has been increasingly important due to their potential as the active layer in organic electronics. Typically, the crystalline morphology in films is achieved via thermal annealing or melt-crystallization of spin-cast polymers. This approach often leads to a spherulitic morphology where the crystalline lamellae grow in all directions. Here, we introduce an alternative approach to make crystalline polymer films via Matrix Assisted Pulsed Laser Evaporation (MAPLE). Using polyethylene oxide (PEO) as a model polymer, we show that the preferential orientation of polymer crystals can be controlled during the film growth. By laser-ablatting a frozen dilute solution of the desired polymer, MAPLE provides a non-destructive means for the deposition of polymer films. Due to the liquid nature of as-deposited polymers confined in nanodroplets, this technique can exploit the substrate effect on the crystal nucleation and growth of nano-confined polymers during the film growth. Mimicking the epitaxial growth of metallic films, this novel polymer deposition technique may enable the engineering of film properties in a way not achievable in bulk.

Coupling frontal photopolymerization and surface instabilities for a novel 3D patterning technology. Alessandra Vitale, Matthew Hennessy, Omar Matar, Imperial College London. Patterning of soft matter provides an exceptional route for the generation of micro/nanostructured and functional surfaces. We describe a new 3D fabrication process based on coupling frontal photopolymerization (FPP) with precisely controlled, yet spontaneous, interfacial wrinkling. FPP is a complex spatio-temporal process that can lead to well-defined propagating fronts of network formation, both stable and unstable. We investigate this process focusing on the interfacial monomer-to-polymer conversion profile and its wave propagation. A simple coarse-grained model is found to describe remarkably well the planar frontal logarithmic kinetics, capturing the effects of UV light exposure time (or dose) and temperature, as well as the front position. In defined conditions, surface instabilities are introduced and interfere with wave planarity, resulting in the formation of "minimal" surfaces with complex 3D geometries. Building on this understanding on the propagation of wavefronts of network formation during photopolymerization, we demonstrate the design and fabrication of 3D patterned polymer materials with tunable shapes with optical and surface functionality.

Improving information density in ferroelectric polymer films by using nanoimprinted gratings. Daniel E. Martínez-Tong, Département de Physique, Faculté des Sciences, Université libre de Bruxelles (ULB), Boulevard du Triomphe, 1050 Brussels, Belgium. The development of polymer non-volatile memories depends on the effective fabrication of devices with high information density. Well-defined low aspect ratio nanogratings on thin films of poly(vinylidene fluoride–trifluoroethylene) copolymers can be fabricated by using Nanoimprint Lithography (NIL). By using these nanogratings, an improved management of writing and reading information can be reached as revealed by Piezoresponse Force Microscopy (PFM). Structural investigation by means of Grazing Incidence X-ray (GX) scattering techniques indicates that the physical confinement generated by nanoimprint promotes the development of smaller and edge-on oriented crystals. Our results evidence that one-dimensional nanostructuring can be a straightforward approach to improve the control of the polarization in ferroelectric polymer thin films.
mobilities, \( P \) can be used to reveal additional structure in the MBL phase, and to make progress on otherwise intractable theory problems. I also show how this “spectral perspective” is far more robust than the conventional “eigenstate” perspective. Eigenstates thermalize upon functions of local operators, evaluated in arbitrary states. This perspective reformulates the standard theory in terms of (in principle) experimentally measurable quantities. Moreover, this “spectral” perspective on MBL is far more robust than the conventional “eigenstate” perspective. Eigenstates thermalize upon arbitrary weak coupling to an external environment, but the correlation functions (which are the physical observables) continue to show signatures of MBL as long as the coupling to the environment is weaker than the characteristic energy scales in the system Hamiltonian. I explain how MBL can be reformulated without invoking exact eigenstates or perfect isolation. I introduce a way to think about MBL in terms of correlation functions. I study a two-level system controlled in a discrete feedback loop, modeling both the system and the controller in terms of stochastic Markov processes. We find that the extracted work, which is known to be bounded from above by the mutual information acquired during measurement, has to be compensated by an additional energy supply during the measurement process itself, which is bounded by the mutual information from below. Our results confirm that the total cost to operate an information engine is in full agreement with the conventional second law of thermodynamics. We also consider the efficiency of the information engine in the finite-time case.

The standard theory of many body localization (MBL) is framed in terms of exact eigenstates of perfectly isolated quantum systems. Has shown that human pluripotent stem cells differentiated in 3D environments are mature and possess high degree of biological function necessary for them to function in vivo. 3D Printing of Personalized Organs and Tissues, KAIMING YE, SUNY Binghamton — A wide variety of systems exhibiting spatiotemporal chaos have been shown to be extensive, in that their fractal dimensions grow linearly with volume. Ruelle argued that this extensivity is evidence that these systems can be viewed as a gas. We have tested this hypothesis by performing large-scale computational studies of spatiotemporal chaos in the 1D complex Ginsburg-Landau equation, and we have found that aspects of the coarse-grained system are well-described not only as a gas, but as an equilibrium gas. This result not only supports Ruelle’s picture but also suggests that the coarse-grained behavior of this far-from-equilibrium system might be understood using equilibrium statistical mechanics.

How to detect many body localization in experiments, RAHUL NANDKISHORE. The standard theory of many body localization (MBL) is framed in terms of exact eigenstates of perfectly isolated quantum systems. However, exact eigenstates can neither be prepared nor measured in the laboratory, and perfectly isolated quantum systems are equally unrealizable. In this talk I explain how MBL can be reformulated without invoking exact eigenstates or perfect isolation. I introduce a way to think about MBL in terms of correlation functions of local operators, evaluated in arbitrary states. This perspective reformulates the standard theory in terms of (in principle) experimentally measurable quantities. Moreover, this “spectral” perspective on MBL is far more robust than the conventional “eigenstate” perspective. Eigenstates thermalize upon arbitrarily weak coupling to an external environment, but the correlation functions (which are the physical observables) continue to show signatures of MBL as long as the coupling to the environment is weaker than the characteristic energy scales in the system Hamiltonian. I also show how this “spectral perspective” can be used to reveal additional structure in the MBL phase, and to make progress on otherwise intractable theory problems.

Kinetics of Brownian Maxima, ELI BEN-NAIM, Los Alamos National Laboratory, PAUL KRAPIVSKY, Boston University — We study extreme-value statistics of Brownian trajectories in one dimension. We define the maximum as the largest position to date and compare maxima of two particles undergoing independent Brownian motion. We focus on the probability \( P(t) \) that the two maxima remain ordered up to time \( t \), and find the algebraic decay \( P \sim t^{-\beta} \) with exponent \( \beta = 1/4 \). When the two particles have diffusion constants \( D_1 \) and \( D_2 \), the exponent depends on the mobilities, \( \beta = \frac{1}{4} \arctan \sqrt{D_2/D_1} \). We also use numerical simulations to investigate maxima of multiple particles in one dimension and the largest extension of particles in higher dimensions.
12:27PM M44.00007 Attaining local temperatures close to absolute zero in a nonequilibrium quantum system. ABHAY SHASTRY, CHARLES STAFFORD, University of Arizona — We consider a question motivated by the third law of thermodynamics: Can there be a local temperature arbitrarily close to absolute zero in a nonequilibrium quantum system? We consider ballistic quantum conductors with the source reservoir held at finite temperature and the drain held at or near absolute zero, a problem outside the scope of linear response theory. We compute the local temperature by numerically solving a nonlinear system of equations describing equilibration of a scanning thermoelectric probe with the system, and obtain excellent agreement with analytic results derived using a method analogous to the Sommerfeld expansion.

12:39PM M44.00008 Local temperature of an interacting quantum system far from equilibrium. CHARLES STAFFORD, University of Arizona — A theory of local temperature measurement of an interacting quantum electron system far from equilibrium via a floating thermoelectric probe is developed [1]. A number of relations are derived relating the probe temperature (and chemical potential) to the local properties of the nonequilibrium system, including a fluctuation-dissipation relation [2]. It is shown that the measured local electron temperature of a steady-state system far from equilibrium is consistent with the zeroth, first, second, and third laws of thermodynamics, provided the probe-system coupling is weak and broad band (ideal temperature measurement). For general probe-system couplings, there are corrections to the zeroth and first laws that are higher-order in the Sommerfeld expansion. The corrections to the zeroth and first laws are related, and can be interpreted in terms of the error of a non-ideal temperature measurement. [1] C. A. Stafford, arXiv:1409.3179; [2] J. Meari, J. P. Bergfield, C. A. Stafford, Ph. Jacquod, Phys. Rev. B 90, 035407 (2014)

12:51PM M44.00009 Thermodynamics of Maximum Transition Entropy for Quantum Assemblies. DAVID ROGERS, University of South Florida — We present one possible unifying framework for the statistics of driven quantum systems in terms of a stochastic propagator for the density matrix. Its classical limit [Rogers, Beck and Rempe, J. Stat. Phys 145:385, 2011] takes the form of a Langevin equation with an associated large-deviation functional intimately related to the partition function of statistical mechanics. Surprising results of this quantum theory are that work is a measurable quantity, and that a precise form of the second law of thermodynamics can be stated for dynamical systems. Numerical results are presented for the time-course of work and heat production for trapped 1D particles. Properties of the large deviation functional are discussed in the context of the quantum measurement problem.

1:03PM M44.00010 Entropy Production in Isolated Quantum Many-Body Systems. EDGARDO SOLANO CARRILLO, ANDREW MILLIS, Columbia University — Beginning with the Liouville-von Neumann equation for the density matrix of an isolated quantum many-body system, and applying well-known projection-operator techniques, we derive an equation of motion for the rate of change of the thermodynamic entropy, valid to arbitrary order in the perturbation deviating the system from equilibrium. To lowest order, a balance equation is obtained which coincides with the one defining the entropy production in irreversible thermodynamics. A connection with fluctuation theorems is mentioned, as well as an application of the results to clarify the “thermalization problem” in the Jaynes-Cummings model.

1:15PM M44.00011 ABSTRACT WITHDRAWN —

1:27PM M44.00012 Spin Noise Spectroscopy Beyond Thermal Equilibrium and Linear Response. NIKOLAI SINITSYN, Theoretical Division, Los Alamos National Laboratory, PHILIPP GLASENAPP, Experimentelle Physik, Technische Universität Dortmund, D-44221 Dortmund, Germany, DIBYENDU ROY, Experimentelle Physik, Technische Universität Dortmund, D-44221 Dortmund, Germany, LUYI YANG, SCOTT CROOKER, National High Magnetic Field Lab, Los Alamos National Laboratory, D. G. RICKEL, National High Magnetic Field Lab, Los Alamos National Laboratory, ALEX GREILICH, M. BAYER, Experimentelle Physik, Technische Universität Dortmund, D-44221 Dortmund, Germany, LUYI YANG, SCOTT CROOKER, National High Magnetic Field Lab, Los Alamos National Laboratory — Per the fluctuation-dissipation theorem, the information obtained from spin fluctuation studies in thermal equilibrium is necessarily constrained by the systems linear response functions. However, by including weak radio frequency magnetic fields, we demonstrate that intrinsic and random spin fluctuations even in strictly unpolarized ensembles can reveal underlying patterns of correlation and coupling beyond linear response, and can be used to study nonequilibrium and even multiphoton coherent spin phenomena. We demonstrate this capability in a classical vapor of 41K alkali atoms, where spin fluctuations alone directly reveal Rabi splittings, the formation of Mollow triplets and Autler-Townes doublets, ac Zeeman shifts, and even nonlinear multiphoton coherences.

1:39PM M44.00013 Finite N corrections to Vlasov dynamics and the range of pair interactions. ANDREA GABRIELLI, Institute of Complex Systems (ISC) - CNR (Italy), MICHAEL JOYCE, JULES MORAND, LPNHE - Univ. Paris VI "Pierre et Marie Curie" (France) — We explore [1] the conditions on a pair interaction for the validity of the Vlasov equation to describe the dynamics of an interacting N particle system in the large N limit. Using a coarse-graining in phase space of the exact Klimontovich equation for such a system, we evaluate the scalings with N of the terms describing the corrections to the Vlasov equation for the coarse-grained one particle phase space density. Considering an interaction with radial pair force $F(r) \sim 1/r^d$, regulated to a bounded behavior below a "softening" scale l, we find that there is an essential qualitative difference between the cases $a<d$ (i.e. the spatial dimension) and $a>d$, i.e. depending on the the integrability at large distances of $F(r)$. For $a<d$ the corrections to the Vlasov dynamics for a given coarse-grained scale are essentially insensitive to the softening parameter l, while for $a>d$ the corrections are directly regulated by l, i.e. by the small scale properties of the interaction, in agreement with the Chandrasekhar approach [2]. This gives a simple physical criterion for a basic distinction between long-range $(a<d)$ and short range $(a>d)$ interactions, different from the thermodynamic one $(a<d-1)$ or $(a>d-1)$. This alternative classification, based purely on dynamical arguments, is relevant notably to understanding the conditions for the existence of so-called quasi-stationary states in long-range interacting systems.

1:51PM M44.00014 Molecular dynamics study on a nonequilibrium motion of a colloidal particle driven by an external torque, DONGHWAN YOO, Myongji University, YOUNGKyun JUNG, KISTI, CHULAN KWON, Myongji University — We investigate the motion of a colloidal particle driven out of equilibrium by an external torque. We use the molecular dynamics simulation that is alternative to the simulation based on the Langevin equation and is expected to mimic an experiment more realistically. We choose a heat bath composed of about a thousand particles interacting to each other through the Lenard-Jones potential and impose the Langevin thermostat to maintain it in equilibrium. We prepare a colloidal particle to interact with the particles of the heat bath also by the Lenard-Jones potential while any dissipative force and noise are not employed explicitly. We study the stochastic properties of the nonequilibrium fluctuation for work and heat produced incessantly in the steady state. We accurately confirm the fluctuation theorem for the work production. We also investigate the motion beyond the overdamped limit by varying the mass of the particle. We compare our result with a previous theoretical result in the overdamped limit based on the Langevin equation.

2:03PM M44.00015 Transient Orthogonality Catastrophe in a Time Dependent Nonequilibrium Environment, MARCO SCHIRO, CNRS and CEA-Saclay, ADITI MITRA, NYU, 0 TEAM — We study the response of a highly-excited time dependent quantum many-body state to a sudden local perturbation, a sort of orthogonality catastrophe problem in a transient non-equilibrium environment. To this extent we consider, as key quantity, the overlap between time dependent wave-functions, that we write in terms of a novel two-time correlator generalizing the standard Loschmidt Echo. We discuss its physical meaning, general properties, and its connection with experimentally measurable quantities probed through non-equilibrium Ramsey interferometry schemes. Then we present explicit calculations for a one dimensional interacting Fermi system brought out of equilibrium by a sudden change of the interaction, and perturbed by the switching on of a local static potential. We show that different scattering processes give rise to remarkably different behaviors at long times, quite opposite from the equilibrium situation. In particular, while the forward scattering contribution retains its power law structure even in the presence of a large non-equilibrium perturbation, with an exponent that is strongly affected by the transient nature of the bath, the backscattering term is a source of non-linearity which generates an exponential decay in time of the Loschmidt Echo, reminiscent of the standard Loschmidt Echo. The main points of our approach are: (i) The use of a generating function formalism, (ii) The derivation of simple equations for the moments of these clusters.

We discuss the intimate connection between network symmetry and cluster synchronization. We apply computational group theory to reveal the clusters and determine their stability. In complex networks the symmetries can number in the millions, billions, and more. The connection between symmetry and cluster synchronization is experimentally explored using an electro-optic polarization modulator to observe and explain a new dynamical state in which acluster of pendulums loses synchrony while leaving others connected to them synchronized. We show the isolated desynchronization is intimately related to the decomposition of the group of symmetries into subgraphs. The results could guide the design of new power grid systems or lead to new understanding of the dynamical behavior of networks ranging from neural to social.

Wednesday, March 4, 2015 11:15AM - 2:03PM - Session M45 Focus Session: Emerging Topics in Network Synchronization: Patterns, Stability, and Transitions 216AB - Takashi Nishikawa, Northwestern University

11:15AM M45.00001 Symmetries, Cluster Synchronization, and Isolated Desynchronization in Complex Networks, LOUIS PECORA, Naval Research Laboratory — Many networks are observed to produce patterns of synchronized clusters, but it has been difficult to predict these clusters in general or understand the conditions for their formation. We show the intimate connection between network symmetry and cluster synchronization. We apply computational group theory to reveal the clusters and determine their stability. In complex networks the symmetries can number in the millions, billions, and more. The connection between symmetry and cluster synchronization is experimentally explored using an electro-optic polarization modulator to observe and explain a new dynamical state in which a cluster of pendulums loses synchrony while leaving others connected to them synchronized. We show the isolated desynchronization is intimately related to the decomposition of the group of symmetries into subgraphs. The results could guide the design of new power grid systems or lead to new understanding of the dynamical behavior of networks ranging from neural to social.

11:51AM M45.00002 Chimera states: limits and open questions, DANIEL ABRAMS, Northwestern University, MARK PANAGGIO, Northwestern University and Rose Hulman Institute of Technology — ‘Chimera states’ are surprising patterns that can be found in systems of identical coupled oscillators, where synchrony and incoherence seem to stably coexist in a spatially asymmetrical state. The existence and stability of chimera states in a variety of settings relevant to real-world systems remains an active topic of research. Here I summarize what is known and present preliminary results for interesting limits including small and large-N, small and large coupling lag, as well as near-local and near-global coupling.

12:03PM M45.00003 Cluster dynamics of pulse coupled oscillators, KEVIN O’KEEFFE, STEVEN STROGATZ, Cornell University, PAUL KRAPIVSKY, Boston University — We study the dynamics of networks of pulse coupled oscillators. Much attention has been devoted to the ultimate fate of the system: which conditions lead to a steady state in which all the oscillators are firing synchronously. But little is known about how synchrony builds up from an initially incoherent state. The current work addresses this question. Oscillators start to synchronize by forming clusters of different sizes that fire in unison. First pairs of oscillators, then triplets and so on. These clusters progressively grow by coalescing with others, eventually resulting in the fully synchronized state. We study the mean field model in which the coupling between oscillators is all to all. We use probabilistic arguments to derive a recursive set of evolution equations for these clusters. Using a generating function formalism, we derive simple equations for the moments of these clusters. Our results in good agreement simulation. We then numerically explore the effects of non-trivial connectivity. Our results have potential application to ultra-low power “impulse radio” & sensor networks.

12:15PM M45.00004 Driven Synchronization in Random Networks of Oscillators, JASON HINDES, CHRISTOPHER R. MYERS, Cornell University — Synchronization is a universal phenomenon found in many non-equilibrium systems. Much recent interest in this area has overlapped with the study of complex networks, where a major focus is determining how a system’s connectivity patterns affect the types of emergent behavior that it can produce. Thus far, modeling efforts have focused on the tendency of networks of oscillators to mutually synchronize themselves, and largely neglected the effects of external driving, even though both effects are present, and often compete, in many naturally occurring systems. In this work we study the interplay between mutual and forced synchronization in networks of phase oscillators, and in particular resolve how the structure and emergence of these states depends on the underlying network topology for simple random networks with a given contact distribution. We provide a bifurcation analysis, centering on the unfolding of a Takens-Bogdanov-Cusp singularity, which naturally separates homogeneous and heterogeneous network behavior, and determines the number, stability, and appearance of entrained and mutually synchronized states as a function of a few system parameters.

12:27PM M45.00005 Mode-Locking Behavior of Ihizikevich Neuron Under Periodic External Forcing, AMIRALI FAROKHNIAEE, EDWARD LARGE, Department of Physics, University of Connecticut — In this study we obtained the regions of existence of various mode-locked states on the periodic-strength plane, which are called Arnold Tongues, for Izhikevich neurons. The study is based on the new model for neurons by Izhikevich (2003) which is the normal form of Hodgkin-Huxley neuron. This model is much simpler in terms of the dimension of the coupled non-linear differential equations compared to other existing models, but excellent for generating the complex spiking patterns observed in real neurons. Many researchers have studied both of these cases, but the brain must encode amplitude variations of a periodic signal. These neurons under periodic stimulation display rich dynamical states including mode-locking and chaotic responses. Periodic stimuli such as sinusoidal waves and amplitude modulated (AM) sounds can lead to various forms of n : m mode-locked states, similar to mode-locking phenomenon in a LASER resonance cavity. Obtaining Arnold tongues provides useful insight into the organization of mode-locking behavior of neurons under periodic forcing. Hence we can describe the construction of harmonic and sub-harmonic responses in the early processing stages of the auditory system, such as the auditory nerve and cochlear nucleus.
12:39PM M45.00006 Synchronization On Hanoi Networks, SHANSHAN LI, STEFAN BOETTCHER, Emory University — Synchronization of coupled oscillators has been intensively studied on a variety of structures. It is believed that the dynamics is deeply associated with its structure. To explore this relation, we study the synchronization of coupled oscillators on Hanoi networks. We analyze the evolution of coupled units over time, and characterized the convergence to the global synchronized state. For this state, the results show a close connection to the spectrum of connectivity matrix. Inspired by this connection, we try to show a dynamical pattern that describes the entire synchronization process from the onset to the final state. This may unveil the unique hierarchical structure of these self-similar Hanoi networks. Our goal is to map the dynamics to the spectrum of the connectivity matrix that encodes significant information about the structure of the underlying system. This exploration may have implications on designing networks that synchronizes coupled units efficiently.

1Supported through NSF grant DMR-1207431

12:51PM M45.00007 Synchronization in growing populations of coupled oscillators and excitable elements, WEN YU, Graduate Student Research Assistant, Univ of Michigan - Ann Arbor, KEVIN WOOD, Assistant Professor, Univ of Michigan - Ann Arbor — In biological systems, synchronized dynamics often exist in growing populations. We show here that population growth can have significant effects on collective synchronization in discrete phase models of coupled oscillators or excitable elements. Using numerical simulations, mean field theory, and linear stability analysis, we demonstrate that coupling between population growth and synchrony can lead to a wide range of dynamical behavior, including extinction of synchronized oscillations, the emergence of asynchronous states with unequal state (phase) distributions, bistability between oscillatory and asynchronous states or between two asynchronous states, and modulation of the frequency of bulk oscillations.

1:03PM M45.00008 A Simple Kuramoto-like Circuit, ZHUWEI ZENG, DAVID MERTENS, Dickinson College — The toy model for spontaneous collective synchronization is the Kuramoto model, a model of nonlinear coupled phase oscillators. Although it is a popular theoretical tool, the Kuramoto model is too simple to accurately characterize the dynamics of any experimental collection of oscillators. In this talk, we present a simple electronic oscillator design similar to the Wien bridge design of Temirbayev et al. Although the oscillator is not strictly modeled by the Kuramoto model, it can be quantitatively modeled by a more generic phase oscillator model. The coefficients governing the oscillator’s behavior can be directly extracted from the voltage time series of the oscillator. We find that, in practice, only a handful of coefficients are necessary to quantitatively describe the behavior of the oscillators, making precise theory tractable.

1Dickinson Woodside Student-Faculty Research Fund

1:15PM M45.00009 A rule for coarse graining phase oscillator models, DAVID MERTENS, Dickinson College — The Kuramoto model is often studied as a paradigm for synchronization. Among phase oscillator models, the Kuramoto model exhibits unique properties that simplify the analysis, and call into question whether or not results from the Kuramoto model are applicable to other phase oscillator models. Instead of focusing on the Kuramoto model, I show how a coarse graining procedure can be applied to generic phase oscillator models with global coupling, providing an alternative method for analyzing their critical behavior. In particular, I discuss a simple geometrically motivated rule that is crucial for the coarse graining approximations.

1:27PM M45.00010 Phase patterns in finite oscillator networks with insights from the piecewise linear approximation, DANIEL GOLDSTEIN, Brandeis Univ — Recent experiments on spatially extend arrays of droplets containing Belousov-Zhabotinsky reactants have shown a rich variety of spatio-temporal patterns. Motivated by this experimental set up, we study a simple model of chemical oscillators in the highly nonlinear excitable regime in order to gain insight into the mechanism giving rise to the observed multistable attractors. When coupled, Zhabotinsky reactants have shown a rich variety of spatio-temporal patterns. Motivated by this experimental set up, we study a simple model of chemical oscillators in the highly nonlinear excitable regime in order to gain insight into the mechanism giving rise to the observed multistable attractors. When coupled, these two attractors have different preferred phase synchronizations, leading to complex behavior. We study rings of coupled oscillators and observe a rich array of oscillating patterns. We combine Tuning analysis and a piecewise linear approximation to better understand the observed patterns.

1:39PM M45.00011 Improving the Network Structure can lead to Functional Failures, TIAGO PEREIRA, Imperial College London, PHILIPP PADE, Humboldt University — In many real-world networks the ability to synchronize is a key property for their performance. Examples include power-grid, sensor, and neuron networks as well as consensus formation. Recent work on undirected networks with diffusive interaction revealed that improvements in the network connectivity such as making the network more connected and homogeneous enhances synchronization. However, real-world networks have directed and weighted connections. In such directed networks, understanding the impact of structural changes on the network performance remains a major challenge. Here, we show that improving the structure of a directed network can lead to a failure in the network function. For instance, introducing new links to reduce the minimum distance between nodes can lead to instabilities in the synchronized motion. This counter-intuitive effect only occurs in directed networks. Our results allow to identify the dynamical importance of a link and thereby have a major impact on the design and control of directed networks.

1:51PM M45.00012 Observability and Controllability of Nonlinear Networks: The Role of Symmetry, STEVEN SCHIFF, ANDREW WHALEN, SEAN BRENNAN, Penn State University, TIMOTHY SAUER, George Mason University — Observability and controllability are essential concepts to the design of predictive observer models and feedback controllers of networked systems. For example, noncontrollable mathematical models of real systems may have subspaces that influence model behavior, but cannot be controlled by an input. Such subspaces are difficult to determine in complex nonlinear networks. Since most of the present theory was developed for linear networks without symmetries, here we present a numerical and group representation framework, to quantify the observability and controllability of nonlinear networks with explicit symmetries that shows the connection between symmetries and measures of observability and controllability. We numerically observe and theoretically predict that not all symmetries have the same effect on network observation and control. We find that the presence of symmetry in a network may decrease observability and controllability, although networks containing only rotational symmetries remain controllable and observable. These results alter our view of the nature of observability and controllability in complex networks, change our understanding of structural controllability, and affect the design of mathematical models to observe and control such networks.

11:15AM M46.00001 Soft Electronics for the Human Body, JOHN ROGERS, University of Illinois — Biology is soft, curvilinear and transient; modern silicon technology is rigid, planar and everlasting. Electronic systems that eliminate this profound mismatch in properties will lead to new types of devices, capable of integrating non-invasively with the body, providing function over some useful period of time, and then dissolving into surrounding bioloids. Recent work establishes a complete set of materials, mechanics designs and manufacturing approaches that enable these features in a class of electronics with performance comparable to that of conventional wafer-based technologies. This talk summarizes the key ideas through demonstrations in skin-mounted ‘epidermal’ monitors, advanced surgical tools and biodegradable electronic bactericides.

11:51AM M46.00002 The Physics of Food, DAVID WEITZ, Harvard University — This talk will describe some experiences gained from an introductory physics course at Harvard University, developed several years ago as part of the general education curriculum. The course is entitled “Science and Cooking: From Haute Cuisine to Soft Matter Science,” and has become a popular course for non-science majors. It has also been successful in outreach, to help develop interest in science for the general public. This talk will describe how the course uses cooking to teach concepts of soft matter science. It will include a description of course and the learnings about how to excite non-science majors in science through the use of a theme in which they are interested. It will also include some demos used in the course and in outreach lectures for the general public.

12:27PM M46.00003 Picasso at the Nanoscale: The Art of Using Cutting-Edge Science to Understand Cultural Heritage1, VOLKER ROSE, Argonne National Laboratory — Scientists are using high-energy X-ray instruments to solve mysteries behind art masterpieces, including artwork by Picasso. Learn how Argonne National Laboratory is working with major art institutions, such as The Art Institute of Chicago and Smithsonian Institution, to unlock groundbreaking information about art, the artist, and our cultural heritage. A deep connection to our past and shared cultural heritage must be preserved to foster a balanced society where all humanity can thrive. This talk will describe the analysis of paint materials used by Pablo Picasso at the nanoscale, as only possible at the brightest synchrotron sources. It will highlight how new imaging techniques can reveal the invisible, bringing to light underlying compositions of old master’s paintings. This in turn enables the writing of new art history and provides important material clues that can assist with attribution and authentication. We will explain how the use of new technology can lead to new discoveries, which, in turn, can change the public’s and the specialists’ perception of great works of art. In collaboration with scientists from The Art Institute of Chicago we have teamed up to study the chemical make up of zinc oxide pigments used in artworks by Pablo Picasso. We will show how highly focused X-ray beams with nanoscale spatial resolution and trace element sensitivity have helped to determine that Picasso has used conventional house paint in some of his paintings. Surprisingly, the study gives also new insights into the pigment material zinc oxide, which has also great potential in applications such as in spintronics or as transparent electrodes in solar panels.

1:03PM M46.00004 A molecular compass for bird navigation1, PETER HORE, University of Oxford — Migratory birds travel spectacular distances, navigating and orienting by a variety of means, most of which are poorly understood. Among them is a remarkable ability to perceive the intensity and direction of the Earth's magnetic field. Biologically credible mechanisms for the sensing of such weak fields (25-65 microtesla) are scarce and in recent years just two proposals have emerged as frontrunners. One involves biogenic iron-containing nanoparticles; the other relies on the magnetic sensitivity of short-lived photochemical intermediates known as radical pairs. The latter began to attract attention following the proposal 15 years ago that the necessary physics and chemistry could take place in the bird's retina in specialized phototactic proteins called cryptochromes. The coherent dynamics of the electron-nuclear spin systems of pairs of photo-induced radicals is conjectured to form the basis of the sensing mechanism even though the interaction of an electron spin with the geomagnetic field is six orders of magnitude smaller than the thermal energy. The possibility that slowing decohering, entangled electron spins could form the basis of an important sensory mechanism has qualified radical pair magnetoreception for a place under the umbrella of “Quantum Biology.” In this talk, I will introduce the radical pair mechanism, comment on the roles of entanglement and quantum coherence, outline some of the experimental evidence for the cryptochrome hypothesis, and summarize what still needs to be done to determine whether birds (and maybe other animals) really do use a chemical compass to find their way around.

1This work was supported by grants from DARPA, AFOSR, ERC and the EMF Biological Research Trust.

1:39PM M46.00005 The Physics of Data: Can your degree in condensed matter theory get you a job at Google? , JEFF M. BYERS, Materials and Sensors Branch, Naval Research Laboratory, Washington, DC — All around us data is being collected by governments, corporations and individuals in staggering amounts. Entire industries are emerging to collect and process this Big Data with the expectation that more is better. But is more better and what can actually be learned? Interestingly, physics confronted this problem more than 150 years ago and developed many important concepts and computational tools within statistical mechanics to address these issues. A great deal of this apparatus has been exported into statistics and computer science to form a heterogeneous conglomeration called machine learning that is leading the charge into the Big Data problem. A brief tour through this world shows how statistical mechanics has been abstracted from its physical origins and transformed into a collection of powerful data processing tools. However, machine learning has interesting things to tell physics as well and can amply re-pay its intellectual debts. The reason for this emerges from the different relationships of physics and machine learning to their respective data. In physics, data is collected by arguably the best experimentalists in the world that attempt to isolate the physical processes so that a direct theoretical analysis is possible. In machine learning, the data is usually an uncontrolled accretion of nearly random instances with limited knowledge of the underlying structure that generated it. Poor data quality forces the analysis tools to acquire powerful new capabilities not usually required in physics. These analysis strategies, in turn, can be valuable to physicists tackling complex phenomenon not amenable to traditional approaches. Examples from biology and astronomy will be used to illustrate the point.

11:15AM M47.00001 Computing the properties of ferroelectrics and magnetoelectrics in applied electric fields, DAVID VANDERBILT, Rutgers University — The technology for computing properties of insulators in a finite electric field \( \hat{E} \), based on the coupling of \( \hat{E} \) to the Berry-phase polarization \( P \), has been available for over a decade and is currently implemented into several standard code packages. I will give an overview of recent developments in the extension of these methods and their applications to studies of ferroelectrics and multiferroics. I will first discuss the extension to allow calculations at fixed electric displacement field \( D \), emphasizing its advantages for calculations on superlattice and ultrathin capacitor geometries. I will also discuss the qualitative differences, as evidenced by their distinct electric equations of state (\( P \) vs. \( \hat{E} \), \( P \) vs. \( D \), or \( D \) vs. \( \hat{E} \)), for ordinary ferroelectrics, improper ferroelectrics, and “hyperferroelectrics.” The latter constitute a new class of proper ferroelectrics that polarize even when the depolarization field is unscreened, i.e., even at fixed displacement field \( D \). I will then turn to magneto-electric effects, which can be computed by studying the change in magnetization as an electric field is applied. A particularly subtle component is the one that comes from the change of orbital magnetization. This is found to have an isotropic component, the so-called “axion coupling,” that takes the form of an integral of a Chern-Simons three-form over the three-dimensional BZ, as well as anisotropic components that can be expressed in a more conventional Kubo-Greenwood form. I will end with some comments on current and future challenges.
11:51AM M47.00002 The quantum nature of skyrmions and half-skyrmions in Cu2OSeO3.
JEROEN VAN DEN BRINK, IFW Dresden — The Skyrme-particle, the skyrmion, was introduced over half a century ago in the context of dense nuclear matter. But with skyrmions being mathematical objects—special types of topological solitons—they can emerge in much broader contexts. Recently skyrmions were observed in helimagnets, forming nanoscale spin-textures. Extending over length scales much larger than the interatomic spacing, they behave as large, classical objects, yet deep inside they are of quantum nature. Penetrating into their microscopic roots requires a multi-scale approach, spanning the full quantum to classical domain. We performed such an approach for the first time in the skyrmionic Mott insulator Cu2OSeO3. We show that its magnetic building blocks are strongly fluctuating Cu4 tetrahedra, spawning a continuum theory that culminates in 51 nm large skyrmions, in striking agreement with experiment [1]. Another consequence is the presence of two distinct types of modes: a low-energy manifold that includes a gapless Goldstone mode and a set of weakly dispersive high-energy magnons [2]. Using high-field electron spin resonance with a terahertz free-electron laser and pulsed magnetic fields up to 64 T we identified these modes [3], corroborating the presence of fluctuating Cu4 tetrahedra. We also show that the emerging electric polarization P is governed by quadrupolar spin contributions from symmetry inequivalent bonds and to calculate the induced P in different crystallographic directions as a function of the orientation of an applied magnetic field, which are confirmed by experiment [2]. One so far untested prediction that ensues is the temperature-dependent decay of skyrmions into half-skyrmions.

12:27PM M47.00003 Electric polarization of Sr0.5Ba0.5MnO3: a multiferroic Mott insulator. REZA NOURAFKAN, Département de Physique and RQMP, Université de Sherbrooke, Sherbrooke, Québec, Canada — Multiferroics, materials which display simultaneous magnetic and ferroelectric orders, are interesting both for their rich physics and for their promising practical applications. The search for multiferroic materials with strong-magnetoelectric coupling is challenging and requires an understanding of how the magnetic order, or more specifically the correlations, influence the electric polarization and vice versa. A calculations of the electric polarization in the paramagnetic (PM) insulating phase of multiferroics is essential to address this mutual influence. Ab initio calculations of the electric polarization are based on the modern theory of polarization, which is a single-electron theory. Thus, a correlation driven insulating state is beyond the scope of this approach. Here we show that combining correlated band structure calculations (DFT+DMFT) with a formula for the electric polarization of interacting insulators, expressed in terms of the full Green and vertex functions, allows for the first time to reliably calculate the polarization in the PM phase. We focus on the Mott insulator Sr0.5Ba0.5MnO3, in which both magnetic and ferroelectric instabilities are related to the Mn ions. We predict a ferroelectric polarization of \( \approx 16.5 \, \mu C/cm^2 \) in the high temperature paramagnetic phase and recover the measured value of \( \approx 13.3 \, \mu C/cm^2 \) in the low temperature antiferromagnetic phase. Our calculations reveal that the the driving force behind the ferroelectric distortion comes from the tendency of Mn \( g \) states to establish a stronger covalency with the surrounding oxygens. This covalency is reduced by correlations, in particular by Hund coupling. On the other hand, the half-filled Mn \( t_2g \) orbitals give rise to the magnetic ordering which decreases the ionic displacement, hence its contribution to the polarization. For fixed ionic displacement, the magnetic order also slightly decreases the electronic contribution to the electric polarization. For fixed ionic displacement, the magnetic order also slightly decreases the electronic contribution to the electric polarization.

1:03PM M47.00004 Mott Multiferroics and Ferroelectric Metals from Dynamical Mean-Field Theory combined with Density-Functional Theory. MASSIMO CAPONE, International School for Advanced Studies (SISSA) and CNR-IOM, Trieste — Multiferroic materials, in which ferroelectricity and long-range magnetic ordering coexist, are natural candidates for applications. In this perspective, the most promising compounds are those in which the two phenomena do not simply coexist, but they influence each other through a magnetoelastic coupling. We present different applications of Density Functional Theory combined with Dynamical Mean-Field Theory in which electron-electron correlation effects are crucial in the stabilization of multiferroic behavior and in the magnetoelectric coupling. Within this wide family we can distinguish different cases. In \( \text{Sr}_3\text{Ba}_2\text{Mn}_5\text{O}_{12} \), the ferroelectric behavior is associated with a Mott insulating state in which the Mn half-filled \( t_2g \) orbitals are responsible for the magnetic properties and the value of the polarization is strongly affected by the magnetic state [1]. \( \text{LiOsO}_3 \) shares the same electronic configuration with half-filled Os \( t_2g \) orbitals. Despite this configuration enhances the effect of electron-electron interactions, the material remains metallic and represents a peculiar ferroelectric metal [2]. We propose however how to turn this non-magnetic polar metal into a multiferroic through the design of a superlattice, which increases the degree of correlation, leading to Mott localization of the Os orbitals [3]. In completely different systems, such as organic crystals like \( (\text{TMTTF})_{2}\text{X} \), strong correlations can lead to multiferroicity in organic crystals such as \( (\text{TMTTF})_{2}\text{X} \), where charge ordering promotes a polarization which is favored by an antiferromagnetic spin ordering [4]. We finally discuss how strong correlations can play a major role away from half-filling when the Hund’s coupling is sizable in compounds with a nominal valence of, e.g., two electrons in the three \( t_{2g} \) orbitals. Such “Hund’s metals” are correlated despite being far from Mott localization.

This physical regime can be a fertile ground to obtain other ferroelectric materials.

1:39PM M47.00005 Electric field effects in transition metal oxides, their surfaces and heterostructures. KARSTEN HELD, Vienna University of Technology — Modern computational tools such as density functional theory and its merger with dynamical mean field theory are nowadays inevitable for the modeling and understanding of oxides, their heterostructures and surfaces. In this talk, I will concentrate on the impact of electric fields, how they affect the physical properties and how to make use of them. Substantial internal electric fields are created at polar surfaces, and even for an isolator-interface the electronic reconstruction can lead to a charge transfer and hence a dipole field [1]. Such internal fields can be employed to efficiently separate electrons and holes in a oxide solar cell [2]. Even if the polar dipole field is compensated by a surface reconstruction, a local surface potential remains, and makes SrTiO3 (110) the arguably simplest 2 dimensional electron gas (2DEG) [3]. External electric fields, on the other hand, can trigger "gigantic" responses, since correlated oxides are prone to small perturbations. For example, a field-effect Mott transistor can be realized in a few layers of \( \text{SrVO}_3 \), where ideal on-off (metal-insulator) switching properties [4], and interfacing a ferroelectric, \( \text{BaTiO}_3 \), plus a 2DEG with large spin-orbit coupling, BaO_{0.5}, allows for a giant switchable Rashba effect.

12:15PM M49.00006 Tension and Rupture Dynamics of Freely-Suspended Bent-Core Liquid Crystalline Fibers, OLIVER KRESS, SEYYED MUHAMMAD SALILI, Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State University, Kent, OH 44242 USA, TANYA OSTAPENKO, Institute of Experimental Physics, Otto-von-Guericke-Universit"at, Universitatsplatz 2 39106 Magdeburg, Germany, CHRISTOPHER BAILEY, Leidos, 3745 Pentagon Blvd., Beavercreek, OH 45431, ALEXEY EREMIN, RALF STANNARIUS, Institute of Experimental Physics, Otto-von-Guericke-Universit"at, Universitatsplatz 2 39106 Magdeburg, Germany, ANTAL JÁKLI, Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State University, Kent, OH 44242 USA, JÁKLI LAB TEAM, ABTEILUNG NICHTLINEARE PHÄNOMENE, DEPARTMENT OF NONLINEAR PHENOMENA, PROF. RALF STANNARIUS TEAM — Euler buckling, a physical mechanism which classically describes deformations in an elastic beam, has been expanded to describe the recoil of viscoelastic liquid crystalline filaments. Rupture of the freely suspended filaments resulted in a buckling instability that propagated through the filament. A characteristic wavelength and a time constant emerge as the filament recoils. Tensions of the suspended filaments were measured by induced mechanical deflection. The analysis of the results reveals a temperature dependent competition between surface and bulk effects that distinguishes these viscoelastic filaments from classical elastic beams.

12:27PM M49.00007 Dynamics of Stable and Metastable Structures of Liquid Crystal and Lipid Systems at Interfaces, LAWRENCE HONAKER, Liquid Crystal Institute, Kent State University, PIOTR POPOV, ELIZABETH MANN, Department of Physics, Kent State University, EDGAR KOOLMAN, Department of Biological Sciences, Kent State University, ANTAL JÁKLI, Liquid Crystal Institute, Kent State University — Due to the amphiphilic structure and character of liquid crystal molecules, they tend to align in a planar fashion at a boundary with water and homeotropically at a boundary with air. However, the introduction of heteromolecules with long aliphatic tails, such as phospholipids, into the system promotes alignment, a conformational change which is easily visually observable. It can be expected that the presence of these lipids induces a uniformly homeotropic texture in the liquid crystalline system, but experimental observations show otherwise. Studies of the textures and features that arise in such systems are presented here with an emphasis on the study of the metastable hybrid textures that develop, their stability, the characteristics of their alignment, and factors that influence their presence.

12:39PM M49.00008 Self-assembly of DNA origami particles in suspension of non-absorbing depleting polymers, MAHSA SIAVASHPOURI, MARK ZAKHARY, Brandeis University, CHRISTIAN WACHAUF, HENDRIK DIETZ, Technische Universität München, ZVONIMIR DOGIC, Brandeis University — The connection between the macroscopic properties of a liquid crystalline material and the microscopic features of the constituent molecules is the essential theme that permeates the field of liquid crystals. Previous studies have shown that monodisperse rod-like colloids such as filamentous bacteriophage self-assemble into 1D twisted ribbons in presence of attractive interactions mediated by non-absorbing polymers. The microscopic properties of the colloidal particles play an important role in determining the physical properties of these mesoscopic assemblies. Using structural DNA nanotechnology, we present the design and structure of DNA origami six-helix bundles with tunable microscopic properties, which can be used as a new building block for the self-assembly of rod-like colloidal particles. We demonstrate that formation of higher order structures from the assembly of colloidal rods is universal. By tuning the chirality, aspect ratio and flexibility of the DNA origami particles we can control the physical properties of the entire self-assembled structures.

12:51PM M49.00009 Dynamic Theory for Polydomain Structures in Liquid-Crystal Elastomers1, AYHAN DUZGUN, JONATHAN SELINGER, Kent State Univ - Kent — Liquid-crystal elastomers are remarkable materials that combine the elastic properties of cross-linked polymer networks with the anisotropy of liquid crystals. Any distortion of the polymer network affects the nematic order of the liquid crystal, and, likewise, any change in the magnitude or direction of the nematic order influences the shape of the elastomer. When elastomers are prepared without any alignment, they develop disordered polydomain structures as they are cooled into the nematic phase. To model these polydomain structures, we develop a dynamic theory for the isotropic-nematic transition in elastomers. In this theory, the local nematic order is coupled to the strain tensor, which satisfies the constraint of elastic compatibility. If the system is rapidly cooled into the nematic phase, a polydomain state with a characteristic length scale can emerge. This polydomain state may eventually become uniform, or it may be locked in by quenched impurities.

1:03PM M49.00010 Novel confinement of liquid crystals in Janus droplets1, WEI-SHAO WEI, JOONWOO JEONG, University of Pennsylvania, Department of Physics and Astronomy, PETER J. COLLINGS, Swarthmore College, Department of Physics and Astronomy, TOM C. LUBENSKY, A. G. YODH, University of Pennsylvania, Department of Physics and Astronomy — In this work we create and investigate Janus droplets composed of liquid crystal (LC) and polymer. The Janus droplets are formed when homogeneous droplets of LC-polymer-solvent phase separate into LC and polymer regions during solvent evaporation through aqueous continuous phase. This scheme enables us to realize unique confinement geometries for LCs such as spherical caps and bowls, which are difficult to be achieved via other systems. The morphologies and surface anchoring conditions can be controlled by changing the size of droplets, the volume ratio between LC and polymer, and the type/concentration of surfactants in aqueous background phase. We explore a variety of defects in these novel confined geometries including dislocations and focal conic defects of smectic LCs. Nematic and cholesteric LCs are also explored. Models that balance the energetics of bulk elasticity and surface anchoring determine the director configurations of confined liquid crystals (LCs).

1:15PM M49.00011 Microlenses of smectic flowers1, FRANCESC A SERRA, MOHAMED-AMINE GHARBII, Dept. Physics and Astronomy, CBE, LRS M, University of Pennsylvania, IRIS B. LIU, YIMIN LUO, NATHAN D. BADE, Chemical and Biomolecular Engineering, University of Pennsylvania, RANDALL D. KAMEN, Dept. Physics and Astronomy, University of Pennsylvania, SHU YANG, LRS M, University of Pennsylvania, KATHLEEN J. STEBE, Chemical and Biomolecular Engineering, University of Pennsylvania — The search for new and tunable optical components finds suitable candidates in liquid crystals, which have both reconfigurability and unique optical properties. Here we discuss smectic liquid crystals arranged in focal conic domains (FCDs), which can work as gradient-refractive index microlenses. We exploit this property to create an assembly of microlenses that resembles an insect compound eye. The system consists of a thin layer of smectics on a substrate patterned with microposts. The smectic film is pinned at the microposts, creating a curved interface that induces a hierarchical assembly of FCDs called the “flower pattern”: each FCD resembles the petal of a flower around the micropost. The arrangement of FCDs, with the largest eccentricity, only work as microlenses for one direction of light polarization.

1 We thank the MRSEC NSF grant DMR11-20901.
1:27PM M49.00012 Phototropic liquid crystal materials containing naphthopyran dopants. MARIACRISTINA RUMI, Seth CAZZELL, Air Force Rsch Lab - WPAFB, TAMAS KOSA, LUDMILA SUKHOMLINNOVA, BAHMAN TAHERI, Alpha Micron Inc., TIMOTHY BUNNING, TIMOTHY WHITE, Air Force Rsch Lab - WPAFB — Dopant molecules dispersed in a liquid crystalline material usually affects the order of the system and the transition temperature between various phases. If the dopants undergo photosomerization between conformers with different shapes, the interactions with the liquid crystal molecules can be different for the material in the dark and during exposure to light of appropriate wavelength. This can be used to achieve isothermal photoinduced phase transitions (phototropism). With proper selection of materials components, both order-to-disorder and disorder-to-order photoinduced transition have been demonstrated. Isothermal order-increasing transitions have been observed recently using naphthopyran derivatives as dopants. We are investigating the changes in order parameter and transition temperature of liquid crystal mixtures containing naphthopyrans and how they are related to exposure conditions and to the concentration and molecular structure of the dopants. We are also studying the nature of the photoinduced phase transitions, and comparing the behavior with that of azobenzene-doped mixtures, in which exposure to light leads to a decrease, instead of an increase, in the order of the system.

1:39PM M49.00013 A Simple Method For The Determination of High-Accuracy Refractive Indices of Liquid Crystals via High-Resolution Birefringence Data. SENAY USTUNEL, ERLIN KUTLU, MEHMET CAN CETINKAYA, HALUK OZBEK, Istanbul Tech Univ — We proposed a simple procedure to determine extraordinary (n_e) and ordinary refractive indices (n_o) of LCs both in the N and Sm A phases based on the high-accuracy birefringence measurements. We show that, apart from the birefringence data, the procedure needs only a single value for the refractive index which is the value of that in the isotropic (I) phase just above the N-I transition temperature. By checking the consistency of our approximation model using the criteria found in the literature, we then conclude that our proposal is self-consistent. Additionally, we show that the temperature variation of refractive indices is well portrayed by the fit expression presented here for the first time contrary to the Haller extrapolation method. Furthermore, we then show that, without addressing density measurements, the proposed method allows one to obtain the temperature dependence of normalized molecular polarizabilities for extraordinary and ordinary rays, and the effective geometry parameter.

1:51PM M49.00014 Liquid Crystal Based Sensor to Detect Beta-Sheet Formation of Peptides. MONIROSAUT SADATI, University of Chicago, ASLIN IZMITLI APIK, NICHOLAS L. ABBOTT, University of Wisconsin, Madison, JUAN J. DE PABLO, University of Chicago and Argonne National Laboratory — Protein aggregation into amyloid fibrils is involved in the progression of Alzheimer’s, typeII diabetes, MONIROSADAT SADATI, University of Chicago, ASLIN IZMITLI APIK, NICHOLAS L. ABBOTT, University of Wisconsin, Madison, JUAN J. DE PABLO, University of Chicago and Argonne National Laboratory — Protein aggregation into amyloid fibrils is involved in the progression of Alzheimer’s, typeII diabetes and Huntington’s diseases. Although larger aggregates remain important for clinical determination, small oligomers are of great interest due to their potentially toxic nature. It is therefore crucial to develop methods that probe the aggregation process at early stages and in the vicinity of biological membranes. Here, we present a simple method that relies on liquid crystalline materials and a Langmuir monolayer at the aqueous-liquid crystal (LC) interface. The approach is based on the LC’s specific response to β-sheet structures, which abound in amyloid fibrils. When the system is observed under polarized light, the fibrils formed by amyloidogenic peptides give rise to the formation of elongated and branched structures in the LCs. Moreover, the PolScope measurements prove that the LCs are predominantly aligned along the fibrils when exposed to a β-sheet forming peptide. In contrast, non-amyloidogenic peptides form ellipsoidal domains of irregularly tilted LCs. This method is capable of reporting aggregation at lipid-aqueous interfaces at nanomolar concentrations of the peptide, and much earlier than commonly used fluorescence-based techniques.

We thank Prof. Oleg D. Leventovich and Young-Ki Kim from the Liquid Crystal Institute of Kent State University for the use of their PolScope instrument. This work was primarily supported by the Swiss National Science Foundation (P300P2_151342).

2:03PM M49.00015 Liquid Crystalline Compositions as Gas Sensors. PETR SHIBAEV, JOHN MURRAY, ANTHONY TANTILLO, MADISON WENZLICK, Fordham University, JORDAN HOWARD-JENNINGS, Bronx Science High School — Droplets and films of nematic and cholesteric liquid crystalline materials were studied as promising detectors of volatile organic compounds (VOCs) in the air. Under increasing concentration of VOC in the air the detection may rely on each of the following effects sequentially observed one after the other due to the diffusion of VOC inside liquid crystalline matrix: i. slight changes in orientation and order parameter of liquid crystal, ii. formation of bubbles on the top of the liquid crystalline droplet due to the mass transfer between the areas with different order parameter, iii. complete isotropisation of the liquid crystal. All three stages can be easily monitored by optical microscopy and photo camera. Detection limits corresponding to the first stage are typically lower by a factor of 3-6 than detection limits corresponding to the beginning of mass transfer and isotropisation. The prototype of a compact sensor sensitive to the presence of organic solvents in the air is described in detail. The detection limits of the sensor is significantly lower than VOC exposure standards. The qualitative model is presented to account for the observed changes related to the diffusion, changes of order parameter and isotropisation.

Wednesday, March 4, 2015 11:15AM - 2:15PM — Session M51 DCMP: Invited Session: Topological Superconductivity in Ferromagnetic Metal Chains Grand Ballroom C1 - Allan MacDonald, University of Texas at Austin

11:15AM M51.00001 Topological Superconductivity with Magnetic Atoms. LEONID GLAZMAN, Departments of Physics and Applied Physics, Yale University, New Haven, CT 06511, USA — Chains of magnetic impurities embedded in a conventional s-wave superconductor may induce the formation of a topologically non-trivial superconducting phase. If such a phase is formed along a chain, then its ends carry Majorana fermions. We investigate this possibility theoretically by developing a tight-binding Bogoliubov-de Gennes description, starting from the Shiba bound states induced by the individual magnetic impurities. While the resulting Hamiltonian has similarities with the Kitaev model for one-dimensional spinless p-wave superconductors, there are also important differences, most notably the long-range (power-law) nature of hopping and pairing as well as the complex hopping amplitudes. We develop an analytical theory, complemented by numerical approaches, which accounts for the electron long-range pairing and hopping along the chain [1], inhomogeneous magnetic order in the chain of embedded impurities or spin-orbit coupling in the host superconductor, and the possibility of direct electron hopping between the impurity atoms. This allows us to elucidate the domain of parameters favoring the formation of a topological phase and to find the spatial structure [2] of Majorana states appearing in that phase.

This talk is based on joint work with F. von Oppen, Falko Pientka, and Yang Peng.

11:51AM M51.00002 Observation of Majorana fermions in ferromagnetic atomic chains on a superconductor

STEVAN NADJ-PERGE, Princeton University, USA — Majorana fermions are zero-energy excitations predicted to localize at the edge of a topological superconductor, a state of matter that can form when a ferromagnetic system is placed in proximity to a conventional superconductor with strong spin-orbit interaction. With the goal of realizing a one-dimensional topological superconductor, we have fabricated ferromagnetic iron atomic chains on the surface of superconducting lead [1]. Using high-resolution spectroscopic imaging techniques, we show that the onset of superconductivity, which gaps the electronic density of states in the bulk of the chains, is accompanied by the appearance of zero-energy end-states. This spatially resolved signature provides strong evidence, corroborated by other observations and theoretical modeling [2], for the formation of a topological phase and edge-bound Majorana states in this system. Our results demonstrate that atomic chains are viable platform for future experiments to manipulate Majorana bound states [3] and to realize other related 1D or 2D topological superconducting phases. [1] S. Nadj-Perge, I. K. Drozdov, J. Li, H. Chen, S. Jeon, J. Seo, A. H. MacDonald, B. A. Bernevig, and A. Yazdani, Science 346, 602 (2014). [2] Jian Li, Hua Chen, Ilya K. Drozdov, A. Yazdani, B. This work has done in collaboration with Ilya K. Drozdov, Jian Li, Hua Chen, Sangjun Jeon, Jungpil Seo, Allan H. MacDonald, B. Andrei Bernevig and Ali Yazdani. We acknowledge ONR, NSF-MRSEC, ARO-MURI, NSF-DMR and EU Marie Curie for support.

12:27PM M51.00003 Theory of Topological Superconductivity in Ferromagnetic Metal Chains on Superconducting Substrates

HUA CHEN, University of Texas at Austin — Recent experiments have provided evidence that one-dimensional (1D) topological superconductivity based on transition metal atom chains formed on a superconducting substrate can be realized experimentally when the chain behaves like a ferromagnetic macrospin [1]. In this talk I will address the structural and bonding considerations which determine whether or not a particular atom chain will have magnetic and electronic properties favorable for topological superconductivity. By using a Slater-Koster tight-binding model to account for important features of transition metal electronic structure, I conclude that topological states are common for ferromagnetic chains on superconductors and that they are nearly universal when ferromagnetic transition metal chains form straight lines on superconducting substrates. The proximity induced superconducting gap on the chain is ~ \Delta E_{so}/J where \Delta is the s-wave pair-potential on the chain, E_{so} is the spin-orbit splitting energy induced in the normal state chain bands by hybridization with the superconducting substrate, and J is the exchange-splitting of the ferromagnetic chain d-bands. Because of the topological character of the 1D superconducting state, Majorana end modes appear within the gaps of finite length chains. I will specifically discuss the spatial decay length of the Majorana end modes which can be much shorter than the coherence length from the induced \gamma-wave gap on the chain due to its strong coupling to the three-dimensional superconducting substrate, in agreement with experimental results [2]. Pb is a particularly favorable substrate material for ferromagnetic chain topological superconductivity because it provides both strong \gamma-wave pairing and strong Rashba spin-orbit coupling, but there seems to be considerable scope to optimize the 1D topological superconductivity by varying the atomic composition and structure of the chain. [1] S. Nadj-Perge, I. K. Drozdov, J. Li, H. Chen, S. Jeon, J. Seo, A. H. MacDonald, B. A. Bernevig, and A. Yazdani, Science 346, 602 (2014). [2] J. Li, H. Chen, I. K. Drozdov, A. Yazdani, B. A. Bernevig, and A. H. MacDonald, ArXiv:1410.3453.

The authors acknowledge support from the Office of Naval Research under grant ONR-N00014-14-1-0330.

1:03PM M51.00004 Experimental progress on Majoranas in semiconductors

LEO KOUVENHOVEN, Delft Univ of Tech — Majoranas in semiconductor nanowires can be probed via various electrical measurements. Tunnel spectroscopy reveals zero-bias peaks in the differential conductance. These zero-bias peaks have a particular dependence on magnetic field (amplitude and direction) and electron density. This dependence allows to falsify many alternative theories for the observations. New challenges include a direct demonstration of topological protection, which is provided by a parity protection: How stable is the system’s occupation in terms of an even or an odd number of quasi-particles? We demonstrate that the quasi-particle parity in a superconducting Cooperpair box can be stable over timescales of minutes. To demonstrate this protection for Majoranas it is crucial that the induced superconducting gap has negligible sub-gap states. To obtain such “hard gaps” under Majorana conditions currently forms the most important challenge. We report on progress in optimizing materials and measurement techniques.

1:39PM M51.00005 Fermionic and Majorana Bound States in Hybrid Nanowires With Rashba and Synthetic Spin-Orbit Interactions

We acknowledge support from the Harvard Quantum Optical Center, the Swiss NSF, and NCCR QIST.

11:15AM M52.00001 Entanglement Hamiltonians in Fermion Systems and the Riemann-Hilbert problem

ISRAEL Klich, University of Virginia — In this talk, I will discuss work on entanglement in fermion systems. I will describe recent results on effective entanglement hamiltonians in conformal quantum field theories, and how the free fermion entanglement Hamiltonian in 1d can be obtained by solving a Riemann-Hilbert problem. I will also show how finite size corrections to the Hamiltonian may be obtained by perturbing around the Riemann-Hilbert solutions, as well as explore subtle difference between the Neveu-Schwarz and Ramond sectors of free fermion fields.
11:51AM M52.00002 Entanglement Scaling Laws and Eigenstate Thermalization in Many-Particle Systems, KUN YANG, Florida State University — While entanglement entropy of ground states usually follows the area law, violations do exist, and it is important to understand their origin. In 1D they are found to be associated with quantum criticality. Until recently the only established examples of such violation in higher dimensions are free fermion ground states with Fermi surfaces, where it is found that the area law is enhanced by a logarithmic factor. In Ref. [1], we use multi-dimensional bosonization to provide a simple derivation of this result, and show that the logarithmic factor has a 1D origin. More importantly the bosonization technique allows us to take into account the Fermi liquid interactions, and obtain the leading scaling behavior of the entanglement entropy of Fermi liquids. The central result of our work is that Fermi liquid interactions do not alter the leading scaling behavior of the entanglement entropy, and the logarithmic enhancement of area law is a robust property of the Fermi liquid phase. In sharp contrast to the fermionic systems with Fermi surfaces, quantum critical (or gapless) bosonic systems do not violate the area law above 1D (except for the case discussed below). The fundamental difference lies in the fact that gapless excitations live near a single point (usually origin of momentum space) in such bosonic systems, while they live around an (extended) Fermi surface in Fermi liquids. In Ref. [2], we studied entanglement properties of some specific examples of the so called Bose metal states, in which bosons neither condense (and become a superfluid) nor localize (and insulate) at T=0. The system supports gapless excitations around “Bose surfaces,” instead of isolated points in momentum space. We showed that similar to free Fermi gas and Fermi liquids, these states violate the entanglement area law in a logarithmic fashion. Compared to ground states, much less is known concretely about entanglement in (highly) excited states. Going back to free fermion systems, in Ref. [3] we show that there exists a duality relation between ground and excited states, and the area law obeyed by ground state turns into a volume law for excited states, something widely expected but hard to prove. Most importantly, we find in appropriate limits the reduced density matrix of a subsystem takes the form of thermal density matrix, providing an explicit example of the eigenstate thermalization hypothesis. Our work [3] explicitly demonstrates how statistical physics emerges from entanglement in a single eigenstate.

12:27PM M52.00003 Entanglement and Stability of Quantum Matter: from Spin-liquids to Many Body Localization, TARUN GROVER, Kavli Institute for Theoretical Physics, Univ of California - Santa Barbara — Quantum entanglement often serves as a fruitful order parameter to characterize quantum phases and phase transitions. However, recent developments have lead to a completely new role for quantum entanglement: the nature of quantum entanglement also plays strong constraints on the structure of phase diagrams itself. Specifically, the universal part of entanglement provides a natural ordering for critical systems whereby a critical, scale-invariant phase can be unstable only if the instability reduces entanglement. In this talk, I will elucidate implications of the aforementioned general relation between entanglement and critical phases for a wide variety of challenging problems in condensed matter physics. I will first discuss general arguments on why a large class of gapless quantum spin-liquids, which possess exotic properties such as emergent fermions and photons, must be stable. In a similar vein, I will show that certain quantum transitions must lie beyond a simple Landau order parameter description. Finally, I will discuss a generalization of such arguments to disordered quantum systems in the context of many-body localization transition. Specifically, I will show that at a continuous many-body localization transition, the system is necessarily ergodic.

1:03PM M52.00004 Einstein’s Equations From Entanglement, BRIAN SWINGLE, Stanford — I will outline a path by which a semi-classical geometry obeying Einstein’s equations emerges holographically from entanglement in certain quantum many-body systems. Although some challenges remain, I will argue that the core concepts are in place. I will discuss in particular two crucial results, one establishing the existence of tensor networks for a wide class of quantum many-body systems, and one showing how the equivalence principle is encoded in the universality of entanglement. The first result establishing the existence of tensor networks has independent interest for the classical simulation of quantum many-body physics.

1:39PM M52.00005 Quantum Entanglement and the Topological Order of Fractional Hall States1, EDWARD REZAYI, Cal State Univ. Los Angeles — Fractional quantum Hall states or, more generally, topological phases of matter defy Landau classification based on order parameter and broken symmetry. Instead they have been characterized by their topological order. Quantum information concepts, such as quantum entanglement, appear to provide the most efficient method of detecting topological order solely from the knowledge of the ground state wave function. This talk will focus on real-space bi-partitioning of quantum Hall states and will present both exact diagonalization and quantum Monte Carlo studies of topological entanglement entropy in various geometries. Results on the torus for non-contractible cuts are quite rich and, through the use of minimum entropy methods, yield the modular S-matrix and hence uniquely determine the topological order, as shown in recent literature. Concrete examples of minimum entropy states from known quantum Hall wave functions and their corresponding quantum numbers, used in exact diagonalizations, will be given.

In collaboration with Clare Abreu and Raul Herrera. Supported by DOE grant DE-SC0002140

11:15AM M53.00001 Importance of anisotropic exchange interactions in honeycomb iridates. New phenomena due to Kitaev interactions.1, NATALIA PERKINS, Univ of Minnesota, Minneapolis — We investigate the microscopic nature of the magnetism in honeycomb iridium-based systems. We show that the minimal model describing the magnetism in A2IrO3 includes both isotropic and anisotropic Kitaev-type spin-exchange interactions between nearest and next-nearest neighbor Ir ions, and that the magnitude of the Kitaev interaction between next-nearest neighbor Ir magnetic moments is comparable with nearest neighbor interactions. We computed the low temperature phase diagram of the effective model with classical Monte Carlo simulations. Due to the presence of the anisotropic Kitaev interactions and the frustration introduced by the competition of the spin couplings between nearest and next-nearest neighbors, the resulting phase diagram is very rich. It contains both various commensurate states and incommensurate single-Q and multi-Q phases, whose regions of stability are controlled by the ratios between competing exchange constants. We showed that the second neighbor Kitaev term plays an important role in the stabilization of the commensurate antiferromagnetic zigzag phase which has been experimentally observed in Na2IrO3. In our simulations, we found this phase to be the ground state for parameters of the model of both the correct signs and magnitudes.

1 NSF grant DMR-1255544
11:51AM M53.00002 Magnetic and Orbital Excitations in α-A₂IrO₃ (A = Li, Na) Probed by Resonant Inelastic X-ray Scattering, JAMES CLANCY, University of Toronto — The honeycomb lattice iridates Na₂IrO₃ and Li₂IrO₃ are two of the most promising candidates for the experimental realization of Kitaev-like physics. Although the formation of long-range magnetic order (T_N ~ 15 K) excludes a pure Kitaev model, there are many extended Kitaev models (which include contributions such as isotropic Heisenberg exchange, further-neighbour interactions, symmetric off-diagonal exchange, and structural distortions) that may be relevant to these materials. We have performed high-resolution Ir L₃-edge resonant inelastic x-ray scattering (RIXS) measurements to investigate the excitation spectra of Na₂IrO₃ and Li₂IrO₃. In Na₂IrO₃, we observe a new branch of dispersive magnetic excitations, which reaches a maximum energy of ~35 meV at the Γ point [1]. This mode is distinct from the low energy (~6 meV) magnon mode observed in previous inelastic neutron scattering measurements [2], and implies the presence of a significant bond-dependent Kitaev interaction. The d-d excitations in Na₂IrO₃ and Li₂IrO₃ reveal important information about crystal electric field effects, and the potential impact of trigonal and monoclinic structural distortions [3]. New developments in high pressure RIXS allow us to study the evolution of these excitations up to 6 GPa, providing insight into future prospects for tuning Kitaev interactions via applied pressure.

Work performed in collaboration with H. Gretarsson, J.A. Sears, Y.-J. Kim (University of Toronto), M.H. Upton, J. Kim, Y. Ding, A.H. Said, D. Casa, T. Gog (Argonne National Laboratory), S. 1:03PM M53.00004 Generic spin model for the honeycomb iridates with trigonal distortion, JEFFREY G. RAU, University of Waterloo — Recently, realizations of Kitaev physics have been sought in the A₂IrO₃ family of honeycomb iridates, originating from oxygen-mediated exchange through edge-shared octahedra. However, for the j = 1/2 Mott insulator in these materials exchange from direct d-orbital overlap is relevant, and it was proposed that a Heisenberg term should be added to the Kitaev model. Here we provide the generic nearest-neighbour spin Hamiltonian when both oxygen-mediated and direct overlap are present, containing a bond dependent off-diagonal exchanges in addition to Heisenberg and overlap is relevant, and it was proposed that a Heisenberg term should be added to the Kitaev model. Near the Kitaev limit, we find new magnetic phases, 120 degree and incommensurate spiral order, as well as extended regions of zigzag and stripy order. By including a small amount of trigonal distortion, as found in Na₂IrO₃ and Li₂IrO₃ reveal important information about crystal electric field effects, and the potential impact of trigonal and monoclinic structural distortions. For the latter material, very recent magnetic resonant X-ray diffraction experiments allowed a complete solution of the magnetic structure. Incommensurate magnetic order with non-coplanar and counter-rotating Ir moments are found, similar as also realized in another polytype, the “stripy/honeycomb” γ-Li₂IrO₃. Theoretically, such structure is stabilized by dominant Kitaev interactions. The similarities between the two materials which share similar local connectivity between the Ir neighbors suggest dominating Kitaev magnetic exchange in both materials. Work in collaboration with F. Freund, S. Manni, Y. Singh, S. Choi and R. Coldea.

P1.00001 SOFT CONDENSED MATTER

P1.00002 Slow Relaxations of Supercooled Water Determined by Energy Landscape Sampling, NATHAN WALTER, YANG ZHANG, Univ of Illinois - Urbana — Molecular Dynamics simulations have been widely used to provide insight into atomistic scale materials behavior and to compare with neutron scattering experiments. However, such simulations are inhibited by temporal scale and spatial scale constraints. As a consequence, it is only possible to predict the dynamical behavior of materials at short times, while atomistic simulations beyond microsecond remain a challenge. The energy landscape sampling methods have been suggested to predict materials behavior at long times. Herein, we show that by efficiently sampling the activation barriers of the high-dimensional energy hypersurface we were able to study the slow dynamics of supercooled ST2 water down to deeply supercooled temperatures. Furthermore, the method allows us to quantify the statistics of the activation barriers, yielding insight into the slow and fast dynamics of ST2 water at low temperatures. The computed transport coefficients across a wide temporal range are useful to bridge the gap between neutron scattering experiments and other bulk measurements.

P1.00003 Single-stranded DNA induced chirality and helical twist in achiral liquid crystals, RAJRAJAT BASU, US Naval Academy — A small quantity of single-stranded DNA (Deoxyribonucleic acid—cellulose single-stranded from calf thymus DNA in lyophilized powder form) was doped in an achiral liquid crystal (LC), and the mixture was found to exhibit a weak degree of chirality. The induced chirality in the LC was probed by means of the electroclinic effect in the LC's smectic-A phase, which showed significant pretransitional behavior on approaching the smectic-A—smectic-C transition temperature from above. The same DNA was doped in an achiral nematic LC and the mixture was found to exhibit an average mechanical twist over macroscopic dimensions. The single-stranded DNA-induced chiral pitch length P was determined by measuring the radius of curvature of the LC mixture, the LC's benzene rings interact with the nucleobases of the DNA through π—π stacking, which induces a molecular conformational demerization in the LC.

P1.00004 Magnetic properties of hexagonal iridates, PHILIPP GEGENWART, Experimentalphysik VI, Augsburg University, Germany — Hexagonal iridates AᵢIrO₃ (A=Na, Li) are discussed in the context of realizing magnetic Kitaev exchange between j=½ moments. This talk reports experimental investigation of magnetic properties of Na₂IrO₃ and α-Li₂IrO₃, crystallizing in a layered honeycomb structure, as well as the related “hyper-honeycomb” β-Li₂IrO₃. For the latter material, very recent magnetic resonant X-ray diffraction experiments allowed a complete solution of the magnetic structure. Incommensurate magnetic order with non-coplanar and counter-rotating Ir moments are found, similar as also realized in another polytype, the “stripy/honeycomb” γ-Li₂IrO₃. Theoretically, such structure is stabilized by dominant Kitaev interactions. The similarities between the two materials which share similar local connectivity between the Ir neighbors suggest dominating Kitaev magnetic exchange in both materials. Work in collaboration with F. Freund, S. Manni, Y. Singh, S. Choi and R. Coldea.

P1.00004 Local environment of iron in garden soil Vs Plants

Sunil Dehipawala, Chaojung Dong, Stephen Smith, Patricia Schneider. Queensborough Community College of CUNY, Harry Gafney. Queens College of CUNY — Iron is an essential nutrient not only for humans, but also for all types of plants. Plants use iron for chlorophyll formation, RNA metabolism, and transpiration process regulation. Iron is one of the most abundant metals in the soil and occurs in a wide range of chemical forms. The correlation between the iron species presents in soil and in Petrostelium crispum (parsley) plants were investigated using the room temperature Mössbauer spectroscopy. Mössbauer spectrum of garden soil consists of two doublets. Based on the established isomer shift and quadrupole splitting values of iron, these doublets can be identified as due to octahedrally coordinated Fe$^{3+}$ and tetrahedrally coordinated Fe$^{2+}$. Most of the iron present in the parsley has the form Fe$^{3+}$ or electron density at the site of the iron nucleus similar to that of Fe$^{3+}$. These findings will help establish soil conditions necessary to increase Fe$^{3+}$ intake by plants similar to the form of iron present in most supplements.

P1.00005 Chemotaxing and haptotaxing random walkers having directional persistence

Tae Goo Kwon, Korea Univ, Kyoungjin Lee Team, TaeSeok Daniel Yang Team — Biological cell crawling is a rather complex process involving various bio-chemical and bio-mechanical processes, many of which are still not well understood. The difficulties in understanding the crawling are originating not just from cell-intrinsic factors but from their complex social interactions, cell-to-substrate interactions and nonlinear responses toward extrinsic factors. Here, in this report we investigate chemotactic behavior of mathematical model cells that naturally have directional persistence. A cell density is measured as a function of time and space, then the resulting steady state is compared with that of the well-known Keller-Segel model, which describes a population of chemotactic random walker. Then, we add a cell-to-cell interaction, mimicking a “haptotaxis” mediated interaction, to the model and access its role as for altering the steady-state cell density profile. This mathematical model system, which we have developed and considered in this work, can be quite relevant to the chemotactic responses of interacting immune cells, like microglia, moving toward and around a site of wound, as for an example. We conclude by discussing some relevant recent experimental findings.

P1.00006 Aqueous Foam Stabilized by Tricatonic Amphiphilic Surfactants

Seth Heerschap, John Marafino, Kristin Mckenna, Kevin Caran, Klebert Feitosa, James Madison University, Kevin Caran’s Research Group Collaboration — The unique surface properties of amphiphilic molecules have made them widely used in applications where foaming, emulsifying or coating processes are needed. The development of novel architectures with multi-cephalic/tailed molecules have enhanced their anti-bacterial activity in connection with tail length and the nature of the head group. Here we report on the foamability of two triple head double, tail cationic surfactants (M-1,14,14, M-P, 14, 14) and a triple head single tail cationic surfactant (M-1,14,14) and compare them with commercially available single headed, single tailed anionic and cationic surfactants (SDS, CTAB and DTAB). The results show that bubble rupture rate decrease with the length of the carbon chain irrespective of head structure. The growth rate of bubbles with short tailed surfactants (SDS) and longer, single tailed tricationic surfactants (M-1,14,14) was shown to be twice as high as those with longer tailed surfactants (CTAB, M-P,14,14, M-1,14,14). This fact was related to the size variation of bubbles, where the foams made with short surfactants exhibited higher polydispersivity than those with short tails. This suggests that foams with tricationic amphiphiles are closed linked to their tail length and generally insensitive to their head structure.

P1.00007 Reversible mechano-memory in sheared cross-linked actin networks

Sayantan Majumdar, Margaret L. GarDEL, MRSEC and the James Franck Institute, University of Chicago, IL 60637 — Is it possible to control the shear modulus of a material mechanically? We reconstitute a network of actin filaments cross-linked with Filamin A and show that the system has remarkable property to respond under shear in a deformation history dependent manner. When a large shear stress pulse is applied to the system, the system remembers the direction of deformation long after the stress pulse is removed. For the next loading cycle, shear response of the system becomes anisotropic; if the applied pulse direction is same as the previous one, the system behaves like a viscoelastic solid but a transient liquefaction is observed if the pulse direction is reversed. Imaging and normal force measurements under shear suggest that this anisotropic response comes from stretching and bending dominated deformation directions induced by the large shear deformation giving rise to a direction dependent mechano-memory. The long time scale over which the memory effect persists has relevance in various deformations in cellular and multicellular systems.

P1.00008 Understanding hydrodynamics in the cell at the molecular level

Xiaoyu Bai, Peter WolyneS, Rice Univ — Cellular collective motion is a result of complex coupling of nonequilibrium mechano-chemical events in the cytoskeleton, of which the underlying physics is far from completely understood. In an attempt to study the cytoskeletal dynamics, we develop analytical theories based on a coarse-grained model, Cat’s Cradle. Our current work highlights how the activated events due to energy-consuming molecular motors are coupled by hydrodynamic interaction and therefore reveals the modified cytoskeletal dynamics. Within our framework, we were able to find the stability limit of the uniformly flowing phase, which is consistent with the predictions from the well-studied continuum models. In the model we accounted for the effect of shear-stretching forces on the extended structure of molecular motors. The resulting influenced stochastic properties of motor power strokes provide us with further insights into the nonequilibrium aspects of cellular dynamics.

P1.00009 Behavior of Caulobacter Crescentus Diagnosed Using a 3-Channel Microfluidic Device

Jay Tang, Michael Morse, Brown University, Remy Colin, Max Planck Institute-Marburg, Laurence Wilson, University of York — Many motile microorganisms are able to detect chemical gradients in their surroundings in order to bias their motion towards more favorable conditions. We study the biased motility of Caulobacter crescentus, a singly flagellated bacteria, which alternate between forward and backward swimming, driven by its flagella motor, which switches in rotation direction. We observe the swimming patterns of C. crescentus in an oxygen gradient, which is established by flowing atmospheric air and pure nitrogen through a 3 parallel channel microfluidic device. In this setup, oxygen diffuses through the PDMS device and the bacterial medium, creating a linear gradient. Using low magnification, dark field microscopy, individual cells are tracked over a large field of view, with particular interest in the cells’ motion relative to the oxygen gradient. Utilizing observable differences between backward and forward swimming motion, motor switching events can be identified. By analyzing these run time intervals between motor switches as a function of a cell’s local oxygen level, we demonstrate that C. crescentus displays aerotactic behavior by extending forward swimming run times while moving up an oxygen gradient, resulting in directed motility towards oxygen sources. Additionally, motor switching response is sensitive to both the steepness of the gradient experienced and background oxygen levels with cells exhibiting a logarithmic response to oxygen levels.

P1.00010 Influence of Chirality in Ordered Block Copolymer Phases, ISHAN PRASAD, GREGORY GRASON, University of Massachusetts Amherst — Block copolymers are known to assemble into rich spectrum of ordered phases, with many complex phases driven by asymmetry in copolymer architecture. Despite decades of study, the influence of intrinsic chirality on equilibrium mesophase assembly of block copolymers is not well understood and largely unexplored. Self-consistent field theory has played a major role in prediction of physical properties of polymeric systems. Only recently, a polar orientational self-consistent field (oSCF) approach was adopted to model chiral BCP having a thermodynamic preference for cholesteric ordering in chiral segments. We implement oSCF theory for chiral nematoc polymers, where segment orientations are characterized by quadrupolar chiral interactions, and focus our study on the thermodynamic stability of bi-continuous network morphologies, and the transfer of molecular chirality to mesoscale chirality of networks. Unique photonic properties observed in butterfly wings have been attributed to presence of chiral single-gyroid networks, this has made it an attractive target for chiral metamaterial design.

P1.00011 Jamming, Self-Filtration and Cake Growth in Concentrated Particle Suspensions, YOUJING GUO, Chemical Engineering, Tongji University, Shanghai, SHOUBO LI, DONGLEI YANG, YONGLI MI, Department of Chemistry, Tongji University, Shanghai, XIAORONG WANG, Institute for Advanced Study, Tongji University, Shanghai, P. R. China — We study the flows of concentrated particle suspensions driven through a circular gap. Above a critical concentration, a jammed structure (i.e., quasi-solid sphere) often forms in the flow and at the entrance of the geometrical constriction. Once occurred this jammed structure grows fast as time t passes and produces a reduction in the solid concentration downstream. Our analysis shows that a combination of the particle jamming, the self-filtration, and the cake-formation with the flow passing through the pores of the jammed solid is responsible for the occurrence of such phenomena. Based on this mechanism, we establish a mathematical model to show how the jammed structure is propagated. Our results suggest that the size D of the jammed structure in this case is proportional to a 1/3 power of the time t. Experiments also support this conclusion.

P1.00012 Designing thermo-responsive nanocomposites with anti-fouling properties, YA LIU, GER-MALD MCFARLIN, University of Pittsburgh, XIN YONG, Binghamton University, OLGA KUKSENOK, ANNA BALAZS, University of Pittsburgh — Inspired by marine organisms that utilize active “defense” (such as active cilia) to prevent the biofouling of their surfaces, we use computational modeling to design synthetic gel-based composite films that provide dual “defense” for anti fouling applications. We design a nanocomposite gel film that can be harnessed to repel a variety of particles via either a temperature change or an imposed shear. Incorporation of stiff hydrophobic posts into a gel composed of cross-linked poly(N-isopropylacrylamide) chains allows us to drastically alter the film’s surface properties when gel undergoes temperature-induced volume phase transition. Depending on whether the system’s temperature is below or above the lower critical solution temperature (LCST) of the gel, the posts are hidden in the swollen gel or exposed to the external solution. We model our system using dissipative particle dynamics (DPD); we validate our model through comparisons with Flory-Rehner theory. We focus on the influence of shear and rotational motion on the position of the particles in the system and isolate the conditions under which adsorption of particles of different sizes to the substrate is effectively prevented.

P1.00013 Optically driven translational and rotational motions of micro-rod particles in a nematic liquid crystal, RALF STANNARIUS, ALEXEY EREMIN, HAJNALKA NADASI, HIDEO TAKEZOE, Otto von Guericke University, Magdeburg, PEMIKA HIRANKITTIWONG, NATTAPORN CHATTHAM, Kasetsart University, Bangkok, OSAMU HABA, KOICHIRO YONETAKE, Yamagata University, Yonexawa — Liquid crystals are self-organized mesomorphic materials with various symmetries and structures. Their unique features can be exploited for smart multi-functional materials. Cylindrical dispersions of micro- and nano-particles in LCs have been widely studied. We demonstrate controlled light-driven translational and rotational motions of micro-rods in a nematic liquid crystal. A small amount of azo-dendrimer molecules dissolved in a liquid crystal drives translation and rotation under non-polarized UV light irradiation. This is initiated by a light-induced trans-to-cis conformational change of the dendrimer adsorbed at the rod surface and the associated director reorientation. This system represents an optically driven molecular microactuator, which exploits molecular reorientation on a particle surface and transforms it into a mechanical torque.

P1.00014 Thermophoresis of micrometer-sized poly(N-isopropylacrylamide) microgel particles, KEVIN APTOWICZ, West Chester University, TIM STILL, ARJUN YODH, University of Pennsylvania — We investigate the diffusion and thermophoresis of micrometer sized poly(N-isopropylacrylamide) (PNIPAM) gel particles in a temperature gradient. Recently published results of the thermophoretic mobility of PNIPAM systems are puzzling. Cross-linked microgel particles show unusually large thermophoretic mobility whereas the mobility of micrometer-sized poly(N-isopropylacrylamide) chains allows us to drastically alter the film’s surface properties when gel undergoes temperature-induced volume phase transition. The adsorption behavior of CO2 under mesoporous confinement at room temperature is particularly relevant. Small Angle Scattering of X-ray (SAXS) and Neutron (SANS) were used to probe the adsorption process of CO2 under such mesoporous confinement MCM-41 and details of nucleation pathways were mapped out by fitting the scattering intensities with adsorption models. From both experiments, the nucleation of CO2 on the inner pore surface of MCM-41 is found to be a two-step process; high density liquid phase CO2 first forms uniform layers following the long range translational symmetry of the porous matrix, above one CO2 filling, determined by the pore size and capillary condensation initiates. The nucleation sites formed during capillary condensation start to separate the long range symmetry from the one at uniform layers. Finally, SAXS and SANS techniques are compared and they both showed their unique properties of probing the filling-dependent structures of adsorbed CO2 under such mesoporous system.

P1.00016 Divergence of the Long Wavelength Collective Diffusion Coefficient in Quasi-one and Quasi-two Dimensional Colloid Suspensions, BINHUA LIN, University of Chicago, BIANXIAO CUI, Stanford University, XINLIANG XU, MIT, RONEN ZANGI, Basque Foundation for Science, Spain, HAIM DIAMANT, Tel Aviv University, STEWART A. RICE, University of Chicago — We report the results of experimental study of the short-time long-wavelength collective diffusion behavior of particle displacements in q1D and q2D colloid suspensions. Our results are reported via the q>0 behavior of the hydrodynamic function H(q) that relates the effective collective diffusion coefficient, Dc(q), with the static structure factor S(q) and the self-diffusion coefficient of isolated particles Dc. H(q)Dc(q)S(q)/Dc. We find an apparent divergence of H(q) as q>0 with the form H(q)~(1−7q<1−9), for both q1D and q2D colloid suspensions. Given that S(q) does not diverge as we infer that Dc(q) does. This behavior is qualitatively different from that of the three-dimensional H(q) and Dc(q) as q>0, and the divergence is of a different functional form from that predicted for the diffusion coefficient in one component 1D and 2D fluids not subject to boundary conditions that define the dimensionality of the system.

The research was supported by the NSF MRSEC at the U of Chicago (NSF/DMR-MRSEC 0820054), NSF/CHE 0822838 (ChemMatCARS), and Israel Science Foundation (Grant No. 8/10).
Predicting and measuring the effects of colloid polydispersity during spinodal decomposition. JOHN WILLIAMSON, Georgetown University, R. MIKE L. EVANS, University of Leeds — Polydispersity pervades soft matter physics, but remains so poorly understood that its effects are often guessed at or ignored entirely. Significant progress has been made on the phase equilibria of polydisperse colloids, but practical understanding of the kinetics that govern real systems lags behind. We employ Kinetic Monte Carlo simulation to study the gas-liquid spinodal decomposition of a size-polydisperse colloid, particularly focusing on fractionation (demixing) between the phases, an effect which causes the properties of the “daughter” phases to depart significantly from the overall “parent” particle distribution. We find that intricate fractionation takes place from the earliest times, so can play a role even in arrested, far-from-equilibrium states (e.g. gels). Novel techniques (in principle applicable to experiment) are developed to detect fractionation: a parameter-free method of systematically coarse-graining local volume fraction; and several spatial correlation functions. The qualitative features of fractionation, including a striking dependence on inter-particle potential, are correctly predicted by a theory requiring only a monodisperse reference free energy.

Cooperative dynamics in ultrastiff 2D crystals. JORIS SPRAKEL, Wageningen University, BEREND VAN DER MEER, MARJOLEIN DIJKSTRA, JASPER VAN DER GUCHT, Utrecht University — The creation, annihilation, and diffusion of defects in crystal lattices play an important role during crystal melting and deformation. Although it is well understood how defects form and react when crystals are subjected to external stresses, it remains unclear how crystals cope with internal stresses. We report a study in which we create a highly localized internal stress, by means of optical tweezing, in a crystal formed from micrometer-sized colloidal spheres and directly observe how the solid reacts using microscopy. We find that, even though the excitation is highly localized, a collective dance of colloidal particles results: these collective modes take the form of closed rings or open-ended strings, depending on the sequence of events which nucleate the rearrangements. Surprisingly, we find from Brownian Dynamics simulations that these cooperative dynamics are thermally-activated modes inherent to the crystal, and can even occur through a single, sufficiently large thermal fluctuation, resulting in the irreversible displacement of 100s of particles from their lattice sites.

Fabrication of Uniform Janus Microparticles by Photopolymerization-Driven Phase Separation and their Asymmetric Hybridization with Metal Nanoparticles. JANGWOO CHO, JEONG WON KIM, JIN WONG KIM, Hanyang Univ — In the field of colloid science, there is growing interest in synthesis of anisotropic particles, since they are desirable for controlling light scattering. These anisotropic particles have been developed by using sophisticated techniques, including clusternization, stamping, microfluidics, and controlled nucleation and precipitation. This study introduces a facile approach for fabrication of uniform Janus microparticles with anisotropic phases as well as selected surface chemistry. The technique we employed to synthesize these microparticles was the seeded swelling and polymerization method, in which complete compartmentalization of the particles into two distinct phases occurred upon polymerizing the monomer-swollen droplets. Then, we patched nanoparticles, such as gold nanoparticles and magnetic nanoparticles, onto one of the compartmentalized phases of the Janus microparticles. Finally we demonstrate that these asymmetrically hybridized Janus microparticles are of great importance and play a role in the designated colloidal 2D array.

Fabrication of Uniform Hydrogel Microparticles with Alternate Polyelectrolyte/Silica Shell Layers for Applications of Controlled Loading and Releasing. EUN SOOK JEONG, JIN WONG KIM, Hanyang Univ — Hydrogel particles, also known as microgels, consist of cross-linked three-dimensional water-soluble polymer networks. They play an essential role in loading and delivering active ingredients in medicine, cosmetics, and foods. Despite their excellent biocompatibility as well as structural diversity, much wider applications are limited due mainly to their intrinsically loose network nature. This study introduces a practical and straightforward method that enables fabrication of hydrogel microparticles layered with a mechanically robust hybrid thin shell. Basically highly monodisperse hydrogel microparticles were produced in microcapillary devices. Then, their surface was coated with alternate polyelectrolyte layers through the layer-by-layer deposition. Finally a thin silica layer was again formed by reduction of silicate on the amino-functionalized polyelectrolyte layer. We have figured out that these hybrid hydrogel microparticles showed controlled loading and releasing behaviors for water-soluble probe molecules. Moreover, we have demonstrated that they can be applied for immobilization of biomacromolecules, such as bacteria and living cells, and even for targeted releasing.

2D Colloidal Wigner crystals in confined geometries. RUBEN HIGLER, JORIS SPRAKEL, Wageningen University — Crystalization of bulk systems has been widely studied using colloids as a model system. However, study into colloidal crystallization in confined geometries has been sparse and little is known about the effects of confinement on the dynamics of colloidal crystal. In our research we prepare 2D crystals from charged colloids in an apolar solvent to study crystal dynamics, formation, and structure in circular confinements. These confining geometries are made using soft lithography techniques from SU-8. In order to broaden the parameter space we can reach in experiments we employ Brownian dynamics simulations to supplement our experimental results. Using single-particle tracking we have subpixel resolution positional information of every particle in the system. We study the vibrational modes of our confined crystals and find well defined modes unique to confined systems, such as a radially symmetric compression (or breathing) mode, a collective rotation mode, and distinct resonance modes. Furthermore, due to the circular nature of our confinements, defectless crystals are impossible, we find, for sufficiently high area fractions, that the defects order at well defined points at the edge. The effect of this “defect-localization” has a clear influence on the vibrational modes.

Shear-induced demixing of glassy suspension. TIES VAN DE LAAR, JORIS SPRAKEL, KARIN SCHROEN, Wageningen University — The ground state of a binary suspension composed of particles of incommensurate size is that of two demixed crystal phases. However this has never been experimentally observed, due to the prohibitively long time scales associated with diffusion in a glass. Here we show that enhancing particle mobility in a glass, by means of flow, can lead to this type of solid-solid demixing. We study this phenomenon at the scale of single particles by means of high speed confocal imaging of suspensions flowing through microfluidic concentrators and deformation of glasses.
for both systems will be presented and discussed in light of available experimental data. The POL FF showed a much stronger sensitivity to the details of biphenyl conformational properties and was able to predict $T_{NI}$ which is very close to the experimental $T_{NI}$. We derive the equations that couple the electric potential to the orientation of the NLC’s director field and use asymptotic and computational methods to address the question: Under what conditions is the uniform field assumption justified, and when is it inappropriate?

The electric field is generated by the applied voltage across the NLC cell, which consists of two plates with a liquid crystal mixture between them. One of the plates is a photosensitive plate, while the other has a coating of azo dye molecules.

P1.00025 Hyperuniformity of self-assembled soft colloidal spheres, COLINE BRETZ, University of Pennsylvania, YU XU, Complex Assemblies of Soft Matter, CNRS-Rhodia-UPenn; University of Pennsylvania, TIM STILL, University of Pennsylvania, JEAN BAUDRY, ESPCI ParisTech/CNRS, LAWRENCE A. HOUGH, Complex Assemblies of Soft Matter, CNRS-Rhodia-UPenn, ARJUN G. YODH, University of Pennsylvania, SALVATORE TORQUATO, Princeton University, REMI DREYFUSS, Complex Assemblies of Soft Matter, CNRS-Rhodia-UPenn, COMPLEX ASSEMBLIES OF SOFT MATTER TEAM3, DEPARTMENT OF PHYSICS AND ASTRONOMY TEAM2, LABORATOIRE DE COLLOIDES ET MATIERES DIVISES TEAM3 — Hyperuniformity characterizes a state of matter for which density fluctuations vanish on large scales. Hyperuniform materials are of technological importance as they exhibit interesting photonic properties. We have shown that such materials can be obtained by assembling spheres into a disordered 2D-packed. To this end, we use a binary mixture of large and small Poly(NIPAM) particles confined between two cover slips. These soft spheres have been chosen for their temperature-sensitive properties. We can locally increase or decrease the volume fraction occupied by the spheres by finely tuning the temperature.

By applying various temperature patterns, we are studying the spatial arrangements of the microgels and characterizing their hyperuniform properties through reconstruction and detection algorithms.

P1.00028 Interfacial Behavior of Polymer Coated Nanoparticle, LUQING QI, HADI SHAMSIJAZEYI, JASON MANN, RAFAEL VERDUZCO, GEORGE HIRASAKI, Rice Univ, RICE UNIVERSITY TEAM — Oxidized carbon black (OCB) nanoparticle is functionalized with different coatings, i.e. alkyl group, polyvinyl alcohol (PVA) and partially sulfonated polyvinyl alcohol (spVA). In oil and water systems, the functionalized nanoparticle is found to have a versatile dispersion i.e. in lower aqueous phase, in upper oil phase, or in middle phase microemulsion. Oil substitute n-octane and commercial oil IOSPAR have been test as oil phase; series of commercially available surfactant, C12-4.5 orthoxylene sulfonate(OXS), i-C13-(PO)7 –SO4Na (S13B), surfactant blend of anionic Alfolterna with nonionic Tergitol have been test as additive to help with the OCB dispersion. It is found that the OCB with sulfonated polyvinyl alcohol attachment (spVA-OCB) stays in microemulsion; with the increase of salinity, it follows the microemulsion to go from lower phase, to middle phase, and to upper phase. The dispersion of spVA and alkyl functionalized OCB (Cn-OCB-spVA) is the balance of the length of alkyl and spVA and the degree of sulfonation of PVA, depending on which, it can either disperse into microemulsion or form a separate layer. The spVA-OCB also indicates a tolerance of high salinity; this is shown by the stable dispersion of it in blend surfactant solution of anionic Alfolterna and nonionic Tergitol at high salinity API brine (8% NaCl and 2% CaCl2). The study of different functionality on OCB dispersion can help design appropriate modified nanoparticle as additive for enhanced oil recovery either to reduce the interfacial tension between oil and water, or to stabilize microemulsion.

P1.00029 Nematic Liquid Crystal reorientation with a Photosensitive layer, ADRIAN REYES, LAURA PALOMARES, PATRICIA GUTIERREZ, Universidad Nacional Autonoma de Mexico — We assume a nematic cell in a planar configuration for which one of their confining plates, is submitted to a hard-anchoring boundary condition and the other plate has a coating monolayer of azo dye molecules, such that the change of the orientation of azo dye isomers, due to light, causes changes in the nematic director. We find an approximated expression for the density of isomers, written in terms of the director angle, which allows us to close the equation for the director’s angle on the boundary having a photosensitive plate. We have managed to decouple the director’s angle and the isomer densities by assuming extremely different temporal time scales between them. We show that switching times inversely depend on trans-cis transition rate of photo-excitation meanwhile relaxation times do not depend on it, for a given sample. On the other hand, switching and relaxation times linearly depend on surface viscosity values.

P1.00030 Electric field variation within a nematic liquid crystal layer1, LINDA CUMMINGS, ENSELA MEMA, CHENJING CAI, LOU KONDIC, New Jersey Institute of Technology — A thin layer of Nematic Liquid Crystal (NLC) across which an electric field is applied is a setup of great industrial importance in Liquid Crystal Display devices, and there is a wide associated literature. A common assumption is that an electric field generated by constant-potential electrodes at the two bounding surfaces of the layer will produce a field that is uniform: the presence of NLC does not affect the electric field. We derive the equations that couple the electric potential to the orientation of the NLC’s director field and use asymptotic and computational methods to address the question: Under what conditions is the uniform field assumption justified, and when is it inappropriate?

P1.00032 Polarized Raman Spectroscopic and Conoscopic study of twist-bend nematic liquid crystal CB7CB

JINXIN FU, KARTHIK NAYANI, JUNG OK PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology — The liquid crystal CB7CB, which exhibits a new twist bend nematic phase, has aroused lots of interests recently. We use polarized Raman Spectroscopy to measure the liquid crystal order parameters, which are crucial to know the molecular orientation distribution and to understand the phase transition. It is found that in the twist-bend phase, both $P<200$ and $P<400$ increase with temperature before the nematic transition takes place at 103°C, and then decrease in the nematic region until the LC becomes isotropic at 116°C. Conoscopy is a convenient tool to determine the structure and orientation of crystals. We develop a monochromatic conoscopy method to study the uniaxial and biaxial behavior of CB7CB in the different phases.

P1.00033 Ground states of lyotropic chromonic liquid crystals in cylindrical capillaries

RUI CHANG, School of Chemical and Biological Engineering, Georgia Institute of Technology, KARTHIK NAYANI, JINXIN FU, School of Material Science and Engineering, Georgia Institute of Technology, ELSA REICHMANIS, School of Chemical and Biological Engineering, Georgia Institute of Technology, JUNG OK PARK, MOHAN SRINIVASARAO, School of Material Science and Engineering, Georgia Institute of Technology — We investigate the ground states of nematic lyotropic chromonic liquid crystals (LCLCs) confined in cylindrical capillaries. Two line defects with double helical configuration is observed for Sunset Yellow FCF with the homeotropic anchoring being obtained by parylene-N coating. The striking features of nematic-isotropic phase transition is also studied, in which we find a coexistence of double helix configuration and escape radial configuration mediated with point defects in biphasic temperature range. However with Disodium Cromoglycate (DSCG) we observe that the anchoring is planar anchoring in both parylene-N coated and uncoated boro silicate capillaries.

P1.00035 Lipid Nanodiscs as potential carriers of enzymes: a light scattering study

KIRIL STRELETZKY, GAITH TAWALBEH, MEKKI BAYACHOU, Cleveland State University — The structure and dynamics of discoidal phospholipid protein complexes (nanodiscs) with and without endothelial nitric oxide synthase (eNOS) were studied with multilength polarized and depolarized light scattering. Nanodiscs present a mobile system that is similar to enzyme’s native microenvironment which allows to explore the potential effect of membrane phospholipids on the activity of eNOS. Light scattering revealed at least two different size distribution modes for empty nanodiscs, and nanodiscs loaded with eNOSs and eNOSs. In both cases, the first mode was diffusive (linear $Γ$ vs $q^2$ with a small intercept) with apparent Rh $= 4.5$ nm for empty nanodiscs and 4.9nm for loaded nanodiscs, sizes consistent with nanodisc dimensions. The second mode contributed only about 20% to the intensity and showed non-diffusive behavior which might correspond to coalesced nanodiscs present in solution. Studied concentration dependencies and depolarized scattering measurements on enzyme free and enzyme loaded nanodiscs corroborated these findings. Also, the specific activity of nanodiscs-bound eNOS was found to be significantly lower than the specific activity of free eNOS.

P1.00036 Active motion induced break-up of colloidal gels

MEGAN SZAKASITS, MICHAEL SOLOMON, University of Michigan — We found that fractal gel networks of polystyrene colloids can be broken up by active motion of Janus colloids that have been incorporated into them. Janus particles were synthesized by electron beam deposition of platinum onto one micron carboxylate modified polystyrene particles. Through addition of the divalent salt magnesium chloride, an initially stable suspension of Janus and polystyrene colloids, present in equal proportion, underwent aggregation to yield a fractal gel. The Janus colloids were activated by addition of 30% v/v hydrogen peroxide through a porous hydrogel membrane. Changes in structure and dynamics were visualized by two channel confocal laser scanning microscope (CLSM). By means of image analysis, we calculated the mean squared displacement (MSD) and radial distribution function (RDF) for gel samples before and after addition of hydrogen peroxide. The MSD confirmed the Janus particles we synthesized undergo active motion. The RDF and cluster size distribution of gel samples before and after addition of peroxide demonstrate how active motion broke apart the gel network into smaller clusters.

P1.00037 Direct visualization of photoinduced glassy dynamics on the amorphous silicon carbide surface by STM movies

DUC NGUYEN, LEA NIENHAUS, RICHARD T. HAASCH, JOSEPH LYDING, MARTIN GRUBELE, Univ of Illinois - Urbana — Glassy dynamics can be controlled by light irradiation. Sub- and above-bandgap irradiation cause numerous phenomena in glasses including photosynthesis, photodimerization, photoreduction and photoduced fluidity. We used scanning tunneling microscopy to study surface glassy dynamics of amorphous silicon carbide irradiated with above- bandgap 532 nm light. Surface clusters of $\sim 4$-5 glass forming unit in diameter hop mostly in a two-state fashion, both without and with irradiation. Upon irradiation, the average surface hopping activity increases by a factor of 3. A very long ($\sim 1$ day) movie of individual clusters with varying laser power density provides direct evidence for photoinduced enhanced hopping on the glass surfaces. We propose two mechanisms: heating and electronic for the photoenhanced surface dynamics.

P1.00038 A Simulation Study on Translation-Rotation Decoupling and its Dependence on Tracer Shape in Two Dimensional Colloids

JEONGMIN KIM, BONG JUNE SUNG, Department of Chemistry and Research Institute for Basic Science, Sogang University — Near the glass transition, translation is often faster than expected from the viscosity of liquids unlike rotation. We acknowledge the support from the U.S. Office of Basic Energy Sciences, Department of Energy: grant DE-SC 0001412.

P1.00039 Trimerization of Phenyl Cyanate Ester

MADHUSUDHAN REDDY PALLAKA, SINDEE L. SIMON, Texas Tech Univ — The kinetics of phenyl cyanate ester trimerization is studied in the bulk using differential scanning calorimetry. Dynamic experiments for different heating rates are analyzed for the activation energy using the model-free Kissinger-Akahira-Sunose(KAS) isocconversion method. The activation energy and other kinetic parameters are also obtained by fitting the dynamic data to a first order autocatalytic reaction model, which well describes the experimental data. The activation energy obtained from the KAS isocconversion method (70.1 kJ/mol) is in good agreement with that obtained from the kinetic model (73.2 kJ/mol) and is much lower than the more bulky cyanate esters studied in our laboratory, which have activation energies of approximately 95 kJ/mol. In addition, the rate constant for the phenyl cyanate ester is one to two orders higher than the bulkier cyanate esters in the temperature range of 200 to 300°C. Further elucidation of the dynamic experiments revealed a strong dependence of the reaction kinetics on the sample weight. Future work aims to understand this finding.
AT model is known to exhibit a fluctuation-driven first-order transition. An analytical renormalization group treatment by Cardy predicts that disorder rounds in the presence of quenched disorder. In this context, we numerically study the critical behavior of a three-color Ashkin Teller (AT) model in the presence of bond randomness. The clean phase transitions can be related to the eigenvalues of the transition matrix which governs the stochastic dynamics of the representative point in the FEL. We apply this formalism to various structures of the FEL which include the small world and the scale free network. We show that the TTT diagram is sensitive to the structure of the FEL, indicating the possibility of obtaining the structural information from the TTT diagram.

Critical adsorption and colloidal interaction in binary liquid mixtures. SHARMINE ALAM, RAMI OMARI, CHRISTOPHER GRABOWSKI, ASHIS MUKHOPADHYAY, Wayne State Univ — We studied critical adsorption on colloidal nanoparticles in binary liquid mixture of 2,6 lutidine + water by using fluorescence correlation spectroscopy (FCS). Our results indicated that the adsorbed film thickness is a decreasing function of temperature. The former behavior is believed to be controlled by the thermodynamics and the latter is governed by the slow dynamics. Exploiting the merit of the free energy landscape (FEL) approach which can handle both thermodynamic and dynamic processes in the same framework, we investigated the crystallization of super-cooled liquids as the first passage process of a representative point to the crystalline basin in the FEL. We first show that the crystallization time can be related to the eigenvalues of the transition matrix which governs the stochastic dynamics of the representative point in the FEL. We apply this formalism to various structures of the FEL which include the small world and the scale free network. We show that the TTT diagram is sensitive to the structure of the FEL, indicating the possibility of obtaining the structural information from the TTT diagram.

Control of nanoparticle formation using the constrained dewetting of polymer brushes. THOMAS LEE, School of Chemistry, The University of Sydney, Campdenown, NSW 2006, Australia, SHAUN C. HENDY, MacDiarmid Institute for Advanced Materials and Nanotechnology, Department of Physics, University of Auckland, Auckland 1142, New Zealand, CHIARA NETO, School of Chemistry, The University of Sydney, Campdenown, NSW 2006, Australia — We have used coarse-grained molecular dynamics simulations to investigate the use of pinned micelles formed by the constrained dewetting of polymer brushes to act as a template for nanoparticle formation. The evaporation of a thin film containing a dissolved solute from a polymer brush was modeled to study the effect of solubility, concentration, grafting density, and evaporation rate on the nucleation and growth of nanoparticles. Control over particle nucleation could be imposed when the solution was dilute enough such that particle nucleation occurred following the onset of constrained dewetting. We predict that nanoparticles with sizes on the order of 1 nm to 10 nm could be produced from a range of organic molecules under experimentally accessible conditions. This method could allow the functionality of organic materials to be imparted onto surfaces without the need for synthetic modification of the functional molecule, and with control over particle size and aggregation, allowing for the preparation of surfaces with useful optical, pharmaceutical, or electronic properties.

Critical behavior of the disordered three-color Ashkin-Teller Model – A Monte Carlo study. QIONG ZHU, XIN WAN, Zhejiang University, RAJESH NARAYANAN, Indian Institute of Technology, Madras, JOSÉ A. HOYOS. Instituto de Física de São Carlos, Universidade de São Paulo, THOMAS VOJTA, Missouri University of Science and Technology — The impact of quenched disorder on systems undergoing first-order phase transitions has received less attention than its effects on critical points. A notable exception is the seminal work by Aizenmann and Wehr. Building on earlier work by Imry, Ma and others, they rigorously proved the vanishing of latent heat in dimensions \( d \leq 2 \) in the presence of quenched disorder. In this context, we numerically study the critical behavior of a three-color Ashkin Teller (AT) model in the presence of bond randomness. The clean AT model is known to exhibit a fluctuation-driven first-order transition. An analytical renormalization group treatment by Cardy, predicted that disorder rounds this transition and leads to a critical point in the clean Ising universality class. However, recent numerical work has questioned the veracity of these results. We therefore use Monte-Carlo techniques to re-examine the role of quenched disorder on the three-color AT model. We determine the order of the phase transition, and we perform a systematic finite-size scaling analysis of various thermodynamic quantities to extract the critical behavior.
P1.00046 Discontinuous phase transitions via cooperative contagion . FAKHTEH GHANBARNEJAD, Max-Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany, WEIRAN CAI, TU Dresden, Germany, LI CHEN, Robert Koch-Institute, 13353 Berlin, Germany, PETER GRASSBERGER, Forschungszentrum Juelich, 52425 Juelich, Germany — We study the spreading of two diseases that interact cooperatively (the presence of one helps the other one to spread) on different network topologies, and with two microscopic realizations, both of which are stochastic versions of an SIR type studied by us recently in mean field approximation. We had shown that cooperativity can lead to discontinuous transitions (DT). However, due to the rapid mixing implied by the mean field assumption, DTs were seen only when there were finite (non-zero) densities of sick individuals in the initial state. In this paper we find that the results on the stochastic model depend strongly on the underlying network. In particular, DTs are found when there are few short but many long loops: (i) No DTs exist on trees, due to the absence of loops; (ii) On 2-d lattices with local contacts there are no DTs either, but because of too many short loops; (iii) We do find DTs on Erdos-Renyi (ER) networks, on d-dimensional lattices with $d \geq 4$, and on 2-d lattices with sufficiently long-ranged contacts; (iv) On 3-d lattices with local contacts the results depend on the microscopic details of the implementation. All found discontinuous transitions are of “hybrid” type, i.e. they display also scaling features usually associated with continuous transitions.

P1.00047 ABSTRACT WITHDRAWN –

P1.00048 Origin of the $1/f^\alpha$-Spectral-Noise in Chaotic and Regular Quantum Systems . LEONARDO A. PACHON, Instituto de Fisica, Universidad de Antioquia. Department of Chemistry and Chemical Biology, Harvard University., ARMANDO RELAÑO, Departamento de Fisica Aplicada I and GISC, Universidad Complutense de Madrid, Spain., BORJA PEROPÁDRE, ALAN ASPURÚ-GUZIK, Department of Chemistry and Chemical Biology, Harvard University. — Based on the recent connection between the spectral form factor and the probability to return [Phys. Rev. Lett. 102, 150401 (2009)], the origin of the $1/f^\alpha$-noise in fully chaotic and fully integrable systems is tracked to the quantum interference between invariant manifolds of the classical dynamics and the dimensionality of those manifolds. This connection and the order-to-chaos transition are analyzed in terms of the statistics of Floquet’s quasienergies of a classically chaotic driving non-linear system. The direct connection established here allows for predicting that in the presence of decoherence, the statistics of the spectral correlations of both, chaotic and integrable, coincide.

P1.00049 Enhanced rare-region effects in the contact process with long-range correlated disorder . AHMED K. IBRAHIM, HATEM BARGHATHI, THOMAS VOJTA, Missouri Univ of Sci & Tech — We investigate the nonequilibrium phase transition in the disordered contact process in the presence of long-range spatial disorder correlations. These correlations greatly increase the probability for finding rare regions that are locally in the active phase while the bulk system is still in the inactive phase. Specifically, if the correlations decay as a power of the distance, the rare-region probability is a stretched exponential of the rare-region size rather than a simple exponential as is the case for uncorrelated disorder. As a result, the Griffiths singularity transforms into a non-power-law form. The critical point itself is of infinite-randomness type but with critical exponent values that differ from the uncorrelated case. We report large-scale Monte Carlo simulations that verify and illustrate our theory. We also discuss generalizations to higher dimensions and applications to other systems such as the random transverse-field Ising model, itinerant magnets, and the superconductor-metal transition.

P1.00050 Critical Initial Slip Scaling for Driven-dissipative Bose-Einstein Condensation1 . WEIGANG LIU, UWE TAUBER, Department of Physics, Virginia Tech — We investigate the universal non-equilibrium critical behavior at the driven- dissipative Bose-Einstein condensation phase transition by means of the perturbative field-theoretic renormalization group method. Such criticality may be realized experimentally in driven open systems on the interface of quantum optics and many-body physics, ranging from exciton-polariton condensates in optically pumped semiconductor wells to cold atomic gases. We describe the critical dynamics through a noisy and dissipative Gross- Pitaevski or time-dependent Ginzburg-Landau equation with complex coefficients. We focus on the universal critical behavior of this system in the early stages of the relaxation process following a quench from an initially (Gaussian distributed) disordered state that is characterized by broken time translation invariance and governed by the “initial slip” exponent $\theta$. We compute $\theta$ to first order in the dimensional $z = 4 - d$ expansion with respect to the upper critical dimension $d=4$, and find that its one-loop value is identical to that of the classical relaxational model $A$ for a two-component non-conserved order parameter.

P1.00051 Energy flow between two hydrodynamically coupled particles kept at different effective temperatures1 . SERGIO CILIBERTO, ENSL-CNRS, ANTOINE BERUT, ENSL, ARTYOM PETROSYAN, ENSL-CNRS, EQ 2 TEAM — We measure the energy exchanged between two hydrodynamically coupled micron-sized Brownian particles trapped in water by two optical tweezers. The system is driven out of equilibrium by random forcing the position of one of the two particles. The forced particle behaves as it has an “effective temperature” higher than that of the other bead. This driving modifies the variance functions and cross-correlation functions of the bead positions: we measure an energy flow between the particles and an instantaneous cross-correlation, proportional to the effective temperature difference between the two particles. A model of the interaction which is based on classical hydrodynamic coupling tensors is proposed. The theoretical and experimental results are in excellent agreement.

P1.00052 Effect of Graphene in Quenching Fluorescence from Strained Conjugated Polymer Doped Polystyrene Composite Films1 , XUAN LONG HO, YAN-HAO CHEN, JONATHON DAVID WHITE, NEN-WEN PU, Yuan Ze University, Taiwan, ARNOLD CHANG-MOU YANG, National Tsing Hua University, Taiwan — Introduction of graphene into films and solutions of conjugated polymers has been observed to dramatically quench photoluminescence (PL) of MEH-PPV. In other work, the PL of MEH-PPV well dispersed in an optically inert matrix was seen to be dramatically increased when the individual molecular strands were fully stretched. Strong polarization effects indicated that stretching individual polymer chains was responsible for the observed enhancement. We examine the combined effect of stress and the addition of reduced graphene oxide (rGO) on PL. We found that the addition of a small amount of rGO (0.3%) into polystyrene films lightly doped with 1% MEH-PPV quenched 40% of the PL. Stretching resulted in the creation of local deformation zones (LDZ) of high stress and strain. Within these zones, while the PL efficiency increased dramatically (rGO) on PL. We found that the addition of a small amount of rGO (0.3%) into polystyrene films lightly doped with 1% MEH-PPV quenched 40% of the PL.

P1.00053 Mechanical Properties of Hydrogel Beads . KEELY CRIDDLE, THOMAS BENNS, DAN SHORTS, KLEBERT FEITOSA, James Madison University — Fragile solids made of dense disordered packing of bubbles, droplets and grains are able to withstand small stresses by virtue of system-wide force chains that lock the system into a jammed state. The nature of the jamming transition in such soft materials has been the subject of intense research, but despite much effort, a deep understanding remains elusive. In this experiment we study the mechanical properties of hydrogel beads to exploit them as force transducers in densely packed systems. The experiment consists of applying uniaxial planar compressions on the beads, and correlating the force to the bead’s strain and contact area. The results show that while the strain scales linearly with the diameter of the contact area, the force and strain are found to obey a power law relation with two distinct exponents at small and large strains. This result leads to a power law dependence of the force on the contact area diameter of the compressed bead.
P1.00054 The nature of long-ranged forces between pinned particles in a jammed system. JUAN-JOSE LIETOR-SANTOS, JUSTIN BURTON, Emory University — We explore the interaction between two fixed-position particles immersed in a binary, two-dimensional jammed system of disks at $T=0$. In our simulations, the two pinned particles develop an interaction along their alignment direction. At short distances, their interaction can be described by a mean-force potential derived from the particle-particle correlation function, $g(r)$, and thus have a repulsive and attractive nature which depends on separation. However, there is an additional repulsive force that dominates at large particle separation or when the ambient jammed disks are much smaller than the pinned particles. We will show that the nature of this repulsive force stems from fluctuations near the jamming transition, in analogy with other fluctuation-induced forces, such as the thermal Casimir effect. We expect these results will be relevant to other studies of pinned particles near the glass transition [1]. The dependence of the long-ranged force on packing fraction, particle separation, and the size ratio of pinned to free particles will be discussed.

P1.00055 “Anti-Equilibrium”: The limiting frozen state of kappa distributions. GEORGE LIVADIOTIS, Southwest Research Institute, USA — The kappa distribution of particle velocities provides an unambiguous replacement of the Maxwell distribution for systems out of thermal equilibrium. The kappa index is a measure of how far the system of particles is from thermal equilibrium. This “thermodynamic distance” is inversely proportional to the kappa index; it becomes zero at thermal equilibrium where the kappa index is infinite, while it obtains its maximum at the furthest state from thermal equilibrium, where the kappa index is zero, a state called “anti-equilibrium.” By keeping fixed the temperature and decreasing the kappa index, the particles approach this peculiar state of anti-equilibrium and are characterized by a power-law distribution density with spectral index $\sim 1.5$; this constitutes a universal behavior, independent of the system’s number of particles or degrees of freedom. As the kappa decreases and the system approaches the anti-equilibrium state, the particles lose their kinetic energy. This procedure of “kappa-freezing” by decreasing the kappa index at a fixed temperature is similar to the more familiar freezing procedure of decreasing temperature and approaching the “absolute zero” for a fixed kappa index.

P1.00056 The price of anarchy is maximized at the percolation threshold. BRIAN SKINNER, Argonne National Laboratory — When many independent users try to route traffic through a network, the flow can easily become suboptimal as a consequence of congestion, if the number of efficient paths is small. The degree of this suboptimality is quantified by the so-called “price of anarchy” (POA), but so far there are no general rules for when to expect a large POA in a random network. Here I address this question by introducing a simple model of flow through a network with randomly-placed “congestible” and “incongestible” links. I show that the POA is maximized precisely when the fraction of congestible links matches the percolation threshold of the lattice. Both the POA and the total cost demonstrate critical scaling near the percolation threshold.

P1.00057 Four Parameter Characterization of Network Reliability and Analysis of Critical Point Phenomenology. MADHURIMA NATH, STEPHEN EUBANK, MINA YOUSSEF, YASAMIN KHORRAMZADEH, SHAHIR MOWLAEI, Virginia Tech — A new characterization of network structure as represented by the reliability polynomial is introduced that requires only four parameters. Exact evaluation of the polynomial is not feasible for large graphs. Approximation to within a specified error is feasible, but a complete specification of the polynomial still requires many parameters. However, it turns out that a two-parameter family of functions fits the non-trivial part of the reliability polynomial to within approximation error. We demonstrate this by fitting the reliability polynomials of both random graphs with different sizes and synthetic social networks to the error function. The network reliability can be viewed as a partition function of a physical system, for example percolation on a network. This method produces a good analytical approximation to the partition function and suggests a way to explore critical point phenomenology.

P1.00058 Diffusion theory of Brownian particles moving at constant speed in $D$ dimensions. FRANCISCO J. SEVILLA, Instituto de Física, Universidad Nacional Autónoma de México — The propagation of Brownian-active particles that move at constant speed in the limit of short times, differs from wave-like propagation in that active particles propagate without leaving a wake trailing characteristic of wave propagation in even dimensions. In the long time regime, normal diffusion is expected due to random fluctuations that disperse the particle direction of motion. A phenomenological equation that describe the transition from the behavior free of effects of wake, to the normal diffusion of the particles is proposed. A comparison of the results predicted by such equation with those obtained from models using Langevin equations is presented in the spherically symmetric case.

P1.00059 ABSTRACT WITHDRAWN —

P1.00060 Nature of the Congested Traffic and Quasi-steady States of the General Motor Models. BO YANG, Institute of High Performance Computing, XIHUA XU, National University of Singapore, JOHN Z.F. PANG, CHRISTOPHER MONTEROLA, Institute of High Performance Computing — We look at the general motor (GM) class microscopic traffic models and analyze some of the universal features of the (multi-)cluster solutions, including the emergence of an intrinsic scale and the quasistationary dynamics in the real traffic dynamics, especially the phase transition from the free flow to the congested phase, from which the wide moving jams emerges (the F-S-J transition pioneered by B.S. Kerner). In particular, the congested phase can be associated with either the multi-cluster quasi-steady states, or their more homogeneous precursor states. In both cases the states can last for a long time, and the narrow clusters will eventually grow and merge, leading to the formation of the wide moving jams. We present a general method to fit the empirical parameters so that both quantitative and qualitative macroscopic features can be reproduced with a minimal GM model. We present numerical results for the traffic dynamics both with and without the bottleneck, including various types of spontaneous and induced “synchronized flow,” as well as the evolution of wide moving jams. We also discuss its implications to the nature of different phases in traffic dynamics.

P1.00061 New Analysis Techniques for Avalanches in a Conical Bead Pile with Cohesion. CATHERINE TIEMAN, SUSAN LEHMÁN, Department of Physics, College of Wooster, Wooster, OH — Avalanche statistics and pile geometry for 3 mm steel spheres dropped on a conical bead pile were studied at different drop heights and different cohesion strengths. The pile is initially built on a circular base and is subsequently slowly driven by adding one bead at a time to the apex of the pile. We investigate the dynamic response of the pile by recording avalanches off the pile over the course of tens of thousands of bead drops. The level of cohesion is tuned through use of an applied uniform magnetic field. Changes in the pile mass and geometry were investigated to determine the effect of cohesion and drop height on the angle of repose. The angle of repose increased with cohesion strength, and decreased somewhat for higher drop heights. The packing density of beads is expected to decrease as magnetic cohesion increases, but for our 20 000-bead pile, this effect has not been observed. The proportion of beads removed from the pile by different avalanche sizes was also calculated. Although larger avalanches are much rarer occurrences, they carry away a larger fraction of the total avalanching mass than small avalanches. As the pile cohesion increases, the number of small and medium avalanches decreases so that this mass loss distribution shifts more strongly to large sizes.
Use of a magnetic field to modify and detect avalanche behavior on a conical bead pile. NATHAN J. HAYNES, SUSAN LEHMAN. Department of Physics, College of Wooster, Wooster, OH — A conical bead pile subject to slow driving and an external magnetic field is used to test the effects of drop height and cohesion on avalanche statistics. Magnetically susceptible beads were dropped onto a pile from different heights and into different strengths of magnetic field. Avalanches were recorded by the change in mass as beads fall off the pile. For beads dropped from a low drop height with no cohesion, the avalanche size distribution follows a power law. As cohesion increases, we observe an increase in the probability of very large avalanches and decreases in the mid-size avalanches. The resulting bump in the avalanche distribution moves to larger avalanche size as the cohesion in the system is increased, matching the prediction by an analytic theory from a mean-field model of slip avalanches. The model also makes predictions for avalanche duration, which is not measurable with our current system. Since the steel beads are magnetized while in the applied magnetic field, their motion during an avalanche creates a change in magnetic field. To detect this motion, we have placed a large-diameter pick-up coil around the pile. Results of the testing and calibration of this coil to measure avalanche duration are presented.

Granular gas mediated attraction of intruders in a granular Casimir effect. GEORGE WILKES, BRIAN UTTER. James Madison University — When two objects are submerged in a granular gas, entropic effects due to inelastic collisions lead to attractions between the objects. This has been referred to as an analog to the Casimir effect, though arises via a different mechanism. In this experiment, we place two objects (such as vertical plates or spheres) in either a strongly driven granular gas or dense fluid. We find that when the plates are closely spaced, there is a net attractive force. By analyzing high-speed video, we track the distance between these plates and characterize the effective force versus distance with changes in the vibration parameters and initial separation. A 2D simulation is also used to further explore parameter space.

Fingerling in Confined Elastic Layers. JOHN BIGGINS, University of Cambridge, L. MAHADEVAN, Harvard, Z. WEI, Stanford, B. BAUDOUIN-SAINTEVES, Harvard, E. BOUCHAUD. Commissariat à l’énergie atomique et aux énergies alternatives — Fingerings has recently been observed in soft highly elastic layers that are confined between and bonded to two rigid bodies. In one case an injected fluid invades the layer in finger-like protrusions at the layer’s perimeter, a solid analogue of Saffman-Taylor viscous finger. In a second case, separation of the rigid bodies (with maintained adhesion to the layer) leads air to the formation of similar fingers at the layer’s perimeter. In both cases the finger formation is reversible: if the fluid is removed or the separation reduced, the fingers vanish. In this talk I will discuss a theoretical model for such elastic fingers that shows that the origin of the fingers is large-strain geometric non-linearity in the elasticity of soft solids. Our simplified elastic model unifies the two types of fingerling and accurately estimates the thresholds and wavelengths of the fingers.

Non-equilibrium relaxation between two quasi-stationary states in a stochastic lattice Lotka-Volterra model. SHENG CHEN, UWE C. TÄUBER. Department of Physics, Virginia Tech — Spatially extended stochastic models for predator-prey competition and coexistence display complex, correlated spatio-temporal structures and are governed by remarkably large fluctuations. Both populations are characterized by damped erratic oscillations whose properties are governed by the reaction rates. Here, we specifically study a stochastic lattice Lotka-Volterra model by means of Monte Carlo simulations that impose spatial restrictions on the number of occupants per site. The system tends to relax into a quasi-stationary state, independent of the imposed initial conditions. We investigate the non-equilibrium relaxation between two such quasi-stationary states, following an instantaneous change of the predation rate. The ensuing relaxation times are measured via the peak width of the population density Fourier transforms. As expected, we find that the initial state only influences the oscillations for the duration of this relaxation time, implying that the system quickly loses any memory of the initial configuration.

Implications of lack-of-ergodicity in 2D Potts model. SMITA OTA. None — Microcanonical Monte Carlo simulation is used to study two dimensional (2D) q state Potts model. We consider a 2D square lattice having N×N spins with periodic boundary condition and simulated the system with N=15 and q=10. The demon energy distribution is found to be exponential for high system energy and large system size. For smaller system size and above the first order transition the demon energy distribution is found to deviate from exp(-βE) and has the form exp(-βE + γD). Here β = 1/k_BT and k_B is the Boltzmann constant. It is found that γ is finite at higher temperatures. As the system energy is reduced γ becomes zero near the first order transition. It is found that during cooling γ changes sign from negative to positive and then to negative again near the 1st order transition. Therefore the demon energy distribution becomes exp(-βE^*P(x)) (or ergodic) at two properties of system energy near the 1st order transition. Further cooling or at still lower temperatures the system shows lack of ergodicity. However, difference in heating cooling curves are apparent in E vs γ. The system energies for which γ is zero during cooling can represent the ‘ergodic’ states. This can be related to the two-level systems observed in glasses at low temperatures.

Use of a magnetic field to modify and detect avalanche behavior on a conical bead pile. NATHAN J. HAYNES, SUSAN LEHMAN. Department of Physics, College of Wooster, Wooster, OH — A conical bead pile subject to slow driving and an external magnetic field is used to test the effects of drop height and cohesion on avalanche statistics. Magnetically susceptible beads were dropped onto a pile from different heights and into different strengths of magnetic field. Avalanches were recorded by the change in mass as beads fall off the pile. For beads dropped from a low drop height with no cohesion, the avalanche size distribution follows a power law. As cohesion increases, we observe an increase in the probability of very large avalanches and decreases in the mid-size avalanches. The resulting bump in the avalanche distribution moves to larger avalanche size as the cohesion in the system is increased, matching the prediction by an analytic theory from a mean-field model of slip avalanches. The model also makes predictions for avalanche duration, which is not measurable with our current system. Since the steel beads are magnetized while in the applied magnetic field, their motion during an avalanche creates a change in magnetic field. To detect this motion, we have placed a large-diameter pick-up coil around the pile. Results of the testing and calibration of this coil to measure avalanche duration are presented.

Granular gas mediated attraction of intruders in a granular Casimir effect. GEORGE WILKES, BRIAN UTTER. James Madison University — When two objects are submerged in a granular gas, entropic effects due to inelastic collisions lead to attractions between the objects. This has been referred to as an analog to the Casimir effect, though arises via a different mechanism. In this experiment, we place two objects (such as vertical plates or spheres) in either a strongly driven granular gas or dense fluid. We find that when the plates are closely spaced, there is a net attractive force. By analyzing high-speed video, we track the distance between these plates and characterize the effective force versus distance with changes in the vibration parameters and initial separation. A 2D simulation is also used to further explore parameter space.

Fingerling in Confined Elastic Layers. JOHN BIGGINS, University of Cambridge, L. MAHADEVAN, Harvard, Z. WEI, Stanford, B. BAUDOUIN-SAINTEVES, Harvard, E. BOUCHAUD. Commissariat à l’énergie atomique et aux énergies alternatives — Fingerings has recently been observed in soft highly elastic layers that are confined between and bonded to two rigid bodies. In one case an injected fluid invades the layer in finger-like protrusions at the layer’s perimeter, a solid analogue of Saffman-Taylor viscous finger. The system energies for which γ is zero during cooling can represent the ‘ergodic’ states. This can be related to the two-level systems observed in glasses at low temperatures.
**P1.00069 Signatures of the Berezinskii-Kosterlitz-Thouless transition on the zeros of the canonical partition function for the 2D XY-model.** JULIO ROCHA, LUCAS MOL, BISMARCK COSTA, Universidade Federal de Minas Gerais — In this work we show that the canonical partition function zeros, the Fisher zeros, can be used to uniquely characterize a transition as being in the Berezinskii-Kosterlitz-Thouless (BKT) class of universality. By studying the zeros map for the 2D XY model we found that its internal border coalesces into the real positive axis in a finite region corresponding to temperatures smaller than the BKT transition temperature. This behavior is consistent with the predicted existence of a line of critical points below the transition temperature, allowing one to distinguish the BKT class of universality from other ones.

This work was partially supported by CNPq and Fapemig, Brazilian Agencies.

**P1.00070 Nonlinear dynamics of three gravitating rods.** ZIYI SANG, JOHN LINDNER, The College of Wooster — As a generalization of Newton’s three body problem, we explore the dynamics of three massive line segments interacting gravitationally. The extension of each line segment or slash (/) provides extra degrees of freedom that enable the 1/2/3/4 rotating small third massive line segment to resist implosion or explosion. In two-dimensional Euclidean space, we find an equilibrium configuration of a rotating ring of massive dust whose inward gravity is the centripetal force that spins it. We find similar solutions in three-dimensional Euclidean and hyperbolic spaces, but only in the limit of vanishing mass. Finally, in three-dimensional Euclidean space, we generalize the two-dimensional result by finding an equilibrium configuration of a spherical shell of massive dust that supports itself against gravitational collapse by spinning isoclinically in four dimensions so its three-dimensional acceleration is everywhere inward. These Newtonian “atoms” illuminate classical physics and geometry.

**P1.00071 Balancing Newtonian gravity and spin to create localized structures.** MICHAEL BUSH, JOHN LINDNER, The College of Wooster — Using geometry and Newtonian physics, we design localized structures that do not require electromagnetic or other forces to resist implosion or explosion. In two-dimensional Euclidean space, we find an equilibrium configuration of a rotating ring of massive dust whose inward gravity is the centripetal force that spins it. We find similar solutions in three-dimensional Euclidean and hyperbolic spaces, but only in the limit of vanishing mass. Finally, in three-dimensional Euclidean space, we generalize the two-dimensional result by finding an equilibrium configuration of a spherical shell of massive dust that supports itself against gravitational collapse by spinning isoclinically in four dimensions so its three-dimensional acceleration is everywhere inward. These Newtonian “atoms” illuminate classical physics and geometry.

**P1.00072 BIOLOGICAL PHYSICS —**

**P1.00073 Single-molecule optical study of cholesterol-mediated dimerization process of EGFRs in different cell lines.** CHIEN YU LIN, JUNG Y. HUANG, Department of Photonics, Chiao Tung University, LEU-WEI LO, Institute of Biomedical Engineering and Nanomedicine, National Health Research Institutes — A growing body of data reveals that the membrane cholesterol molecules can alter the signaling pathways of living cells. However, the understanding about how membrane cholesterol modulates receptor proteins remains lacking. In this study we apply single-molecule optical tracking on ligand-induced dimerization process of EGFRs in the plasma membranes of several cancer and normal cell lines. We tracked individual EGFR and dual correlated receptors in the plasma membranes of live cells. We developed an energetic model based on the generalized Langevin equation and the Cahn-Hilliard equation to help extracting information from single-molecule trajectories. From the study, we discovered that ligand-bound EGFRs move from non-raft areas into lipid raft domains. This ligand-induced motion is a common behavior for all cell lines under study. By manipulating the total amount of cholesterol with methyl-Î²-cyclodextrin and the local concentration of cholesterol with nystatin, we found that the amount of cholesterol can affect the stability of EGFR dimers. The EGFR dimers in the plasma membrane of normal cells are more sensitive to the local concentration changes of cholesterol than EGFR dimers in the cancer cells.

**P1.00074 Conformational transitions of plasmid ds-DNA on ultrathin films of alkylamines on graphite.** CAROLINE FALK, HUA LIANG, NIKOLAI SEVERIN, WEI ZHUANG, Department of Physics & IRIS Adlershof, Humboldt-Universität zu Berlin, STEFAN ZAUSCHER, Mechanical Engineering and Materials Science, Duke University, JÜRGEN P. RABE, Department of Physics & IRIS Adlershof, Humboldt-Universität zu Berlin — DNA replication is an important process in the human body. Replication of double-stranded (ds)-DNA requires its local melting into two single strands [1]. DNA, when stretched in solution, overwinds and melts [2]. This was argued to give insight onto the replication mechanism. It is difficult, however, to access the direct conformational changes during stretching in solution. Recent work demonstrated that this transition can be imaged with scanning force microscopy on a graphite surface that is coated with an alkylamine layer [3]. ds-DNA can be controlled by an amphiphilic layer, since the DNA conformation depends on the amphiphile concentration. In particular we analyzed different DNA lengths on the same surface, and we found that at a specific concentration of octadecylamine the ds-DNA pUC19 plasmid ring splits into two single strands at one position. We will discuss methods to mark the DNA to determine the exact location at which the plasmid ring splits.  

**P1.00075 Modification of protein structure and function using photoactivated porphyrin ligands.** GABRIEL MORENO, University of Texas at San Antonio — The tremendous advances in genomic research have sparked an interest in investigating the possibility to “manipulate” the structure of proteins that modify existing functionality. This study makes use of small molecules (e.g., porphyrins) to photo-sensitize proteins and modify the higher order structure of the polypeptide with the goal of engineering novel functions, or affecting/eliminating native functions. The irradiation of non-covalently bound ligands prompts charge transfer events that have the potential to locally modify the structure of the host protein. The characterization of photoinduced conformational changes in the protein/porphyrin complex is carried out using a combination of electronic spectroscopy and kinetics (e.g., fluorescence spectroscopy, fluorescence decay, circular dichroism). This study is focused primarily on human serum albumin (HSA) as a model. The structure of HSA is well established, the binding sites for an array of ligands are well characterized (including one for protoporphyrins), and HSA provides a series of functions (including some allosteric activity) that can be tested.

**P1.00076 Bacterial Chemotaxis with a Moving Target.** COREY DOMINICK, Univ of Pittsburgh — Most chemotaxis studies so far have been conducted in a quiescent fluid with a well-defined chemical gradient. Such experiments may be appropriate for studying enteric bacteria, such as Escherichia coli, but the environment it provides is very different from that typically encountered by marine bacteria. Herein we describe an experiment in which marine bacterium Vibrio alginolyticus subject to stimulation by a small moving target. A micropipette of the tip size <1 ?m is used to slowly release a chemoattractant, serine, at different concentrations. The pipette is made to move with different patterns and speeds, ranging from 0 to 100 ?m/s; the latter is about twice the bacterial swimming speed. We found that if the pipette is moved slowly, with 1/4 of bacterial swimming speed, cells accumulate near the tip region but when it is moved with speed greater than 1/2 the bacterial swimming speed, cells trail behind the pipette over a large distance. The behaviors observed in V. alginolyticus are significantly different from E. coli, suggesting that the former is a better chemotaxer in a changing environment.
P1.00077 Bacterial Growth in Weak Magnetic Field
SAMINA MASOOD, University of Houston Clear Lake — We study the growth of bacteria in a weak magnetic field. Computational analysis of experimental data shows that the growth rate of bacteria is affected by the magnetic field. The effect of magnetic field depends on the strength and type of magnetic field. It also depends on the type of bacteria. We mainly study gram positive and gram negative bacteria of rod type as well as spherical bacteria. Preliminary results show that the weak magnetic field enhances the growth of rod shape gram negative bacteria. Gram positive bacteria can be even killed in the inhomogeneous magnetic field.

P1.00078 Phase Transitions in the Nucleus: the functional implications of concentration-dependent assembly of a Liquid-like RNA/Protein Body
LIAN ZHU, STEPHANIE WEBER, JOEL BERRY, NILESH VAIDYA, MIKKO HAATAJA, CLIFFORD BRANGWYNNIE, Princeton University — The nucleus is a liquid-like membrane-less nuclear body which plays an important role in cell growth and size control. By modulating nucleolar component concentration through RNAi conditions that change C. elegans cell size, we find that nucleoli only assemble above a threshold concentration; moreover, the ripening dynamics of nucleated droplets are consistent with the hypothesis that the assembly of the nucleolus represents an intracellular liquid-liquid phase transition. A key question is how this phase-transition is linked to the primary function of the nucleolus, in transcribing and processing ribosomal RNA. To address this, we characterize the localization of RNA Polymerase I, a key transcriptional enzyme, into nucleolar foci as a function of nucleolar component concentration. Our results suggest that there are a small number of key disordered phosphoproteins that may serve as a link between transcription and assembly. Finally, we present preliminary results using a reduced model system consisting of purified nucleolar proteins to assess the ability of nucleolar proteins to drive liquid-liquid phase separation in vitro. These results lay the foundation for a quantitative understanding of intracellular phase transitions and their impact on biomedically-critical RNA-processing steps.

P1.00079 Kinesin-1 Translocation along Human Breast Cancer Cell Microtubules in Vitro
MITRA SHOJANIA FEIZABADI, Physics Department, Seton Hall University, YONGGUN JUN, Developmental and Cell Biology, School of Biological Sciences, University of California, Irvine, CA — A principle approach to better understand intra-cellular microtubule based transport is to study such it in vitro. Such in vitro examinations have predominantly used microtubules polymerized from bovine brain tubulin, but motor function can also in principle be affected by the specific tubulin isotypes present in different cells. The human breast cancer cells carry different beta tubulin isotype distribution. However, it is entirely unknown whether transport along the microtubules is different in these cells. In this work we have characterized, for the first time, the translocation specifications of kinesin-1 along human breast cancer cell microtubules polymerized in vitro. We found that as compared with the translocation along bovine brain microtubules, kinesin-1 shows a fifty percent shorter protractive run length and slightly lower velocity under similar experimental conditions. These first time results support the regulatory role of tubulin isotypes in regards to motor protein translocations, and quantify the translocation specifications of kinesin-1 along microtubules of human breast cancer cells.

P1.00080 Dissipative Dynamics of Enzymes
AMILA ARIYARATNE, University of California Los Angeles, CHENHAO WU, University of California San Diego, CHIAO-YU TSENG, GIOVANNI ZOCCHI, University of California Los Angeles, ZOCCHI LAB FOR MOLECULAR BIO-PHYSICS TEAM — We explore enzyme conformational dynamics at sub - A resolution, specifically temperature effects. The ensemble averaged mechanical response of the folded enzyme is viscoelastic in the whole temperature range between the warm and cold denaturation transitions. The dissipation parameter γ of the viscoelastic description decreases by a factor 2 as the temperature is raised from 10 C to 45 C; the elastic parameter K shows a similar decrease. Thus when probed dynamically, the enzyme softens for increasing temperature. Equilibrium mechanical experiments with the DNA spring (and a different enzyme) also show, qualitatively, a small softening for increasing temperature.

P1.00081 Effects of solvent (effective medium versus explicit) on the structure of a protein (H3.1)
RAS PANDAY, University of Southern Mississippi, BARRY FARMER, Air Force Research Laboratory — Structure and dynamics of a histone (H3.1) are studied in the presence of effective medium and explicit solvent over a range of temperatures with coarse-grained Monte Carlo simulations. The protein is represented by a coarse-grained chain of residues whose interactions are described by knowledge-based residue-residue and hydrophathy-index-based residue-solvent interactions. Each empty lattice site acts as a solvent in effective medium while a fraction of sites are occupied by mobile solvent constituents in explicit solvent medium. The presence of fluctuations with explicit solvent may affect the structure and dynamics of protein differently than that in effective solvent medium. Large scale simulations are performed to analyze the structure of the protein for a range of residue-solvent interactions and temperature, and a number of local and global physical quantities are analyzed. Differences due to type of solvent on the response of some of these quantities as a function of temperature will be presented.

P1.00082 ABSTRACT WITHDRAWN

P1.00083 ABSTRACT WITHDRAWN

P1.00084 Effect of Nanodiamond Surfaces on tRNA Dynamics Studied by Neutron Scattering and MD Simulations
GURPREET DHINDSA, DEBSINDHU BHOWMIK, Wayne State University, PANCHAPAKESAN GANESH, MONOJOY GOSWAMI, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, VADYM N. MOCHALIN, Drexel University, HUGH O'NEILL, Biology and Soft Matter Division, Oak Ridge National Laboratory, USA, YURY GOGOTSI, Drexel University, EUGENE MAMONTOV, SNS OakRidge National Laboratory, USA, XIANG QIANG CHU, Wayne State University — Nanodiamond (ND) inherits most of the superior properties of bulk diamond and delivers them at the nanoscale. ND is non-toxic and possesses excellent mechanical and optical properties with large surface area and surface functionality. ND mixed with biomolecules can be a good platform for drug delivery. Here we demonstrate the adsorption of tRNA on the ND surface and investigate the change in the tRNA dynamics using neutron scattering technique and molecular dynamics (MD) Simulations. We compare the dynamics of hydrated tRNA on ND surfaces with that of freestanding hydrated tRNA molecules and dry tRNA on ND surfaces. Both experiments and simulations show that the relaxational dynamics of tRNA on ND surface is faster than that of the freestanding tRNA molecules and dry tRNA on ND surfaces. Our results suggest that the tRNA on the ND surfaces has fewer hydration water molecules on it due to the water adsorption on the ND hydrophilic surface. Therefore fewer hydrogen bonds formed on its surface results in the tRNA faster motion. The MD simulations also show a “caged” dynamics of the water molecules adsorbed on the ND surfaces.

P1.00085 Fast loop modeling for protein structures
JIONG ZHANG, SON NGUYEN, YI SHANG, DONG XU, IOAN KOSZTIN, University of Missouri — X-ray crystallography is the main method for determining 3D protein structures. In many cases, however, flexible loop regions of proteins cannot be resolved by this approach. This leads to incomplete structures in the protein data bank, preventing further computational study and analysis of these proteins. For instance, all-atom molecular dynamics (MD) simulation studies of structure-function relationship require complete protein structures. To address this shortcoming, we have developed and implemented an efficient computational method for building missing protein loops. The method is database driven and uses deep learning and multi-dimensional scaling algorithms. We have implemented the method as a simple stand-alone program, which can also be used as a plugin in existing molecular modeling software, e.g., VMD. The quality and stability of the generated structures are assessed and tested via energy scoring functions and by equilibrium MD simulations. The proposed method can also be used in template-based protein structure prediction.
P1.00086 Bio-inspired metal-coordination dynamics: A unique tool for engineering novel properties in soft matter systems. SCOTT GRINDY, QIAOCHU LI, ABIGAIL HALIM, ROBERT LEARSCH, NIELS HOLTE-N-ANDERSEN, Massachusetts Inst of Tech-MIT — In soft matter systems, materials properties are generally governed by transient, dynamic interactions of many types over many hierarchical length- and time-scales. However, explicit control over these dynamics is not always possible, leaving open questions into how transient interactions can be exploited to design soft materials with unique and exceptional properties. Inspired by the adhesive chemistry and tough character of mussel byssal threads, we present several studies on both the mechanical properties of soft materials and templated crystallization kinetics to show the diverse array of materials properties that can be generated using bio-inspired metal-coordination. By studying our model systems, we can determine the explicit effects of metal-coordination dynamics on various bulk properties, further adding to the set of tools we can use to design soft material systems.

P1.00087 Examining the role of finite reaction times in swarming models. KATHERINE COPENHAGEN, University of California Merced, DAVID QUINT, Stanford University, AJAY GOPINATHAN, University of California Merced — Modeling collective behavior in biological and artificial systems has had much success in recent years at predicting and mimicking real systems by utilizing techniques borrowed from modeling many particle systems interacting with physical forces. However, unlike inert particles interacting with instantaneous forces, living organisms have finite reaction times, and behaviors that vary from individual to individual. What constraints do these physiological effects place on the interactions between individuals in order to sustain a robust ordered state? We use a self-propelled agent based model in continuous space based on previous models by Vicsek and Couzin including alignment and separation maintaining interactions to examine the behavior of a single cohesive group of organisms. We found that for very short reaction times the system is able to form an ordered state even in the presence of heterogeneities. However for larger more physiological reaction times organisms need a buffer zone with no cohesive interactions in order to maintain an ordered state. Finally swarms with finite reaction times and behavioral heterogeneities are able to dynamically sort out individuals with impaired function and sustain order.

P1.00088 High Intensity Pressure Noise Transmission in Human Ear: A Three Dimensional Simulation Study1, TAKUMI HAWA, RONG GAN, KEGER LECKNESS, The University of Oklahoma — High intensity pressure noise generated by explosions and jet engines causes auditory damage and hearing loss of the military service personal, which are the most common disabilities in the veterans. Authors have investigated the high intensity pressure noise transmission from the ear canal to middle ear cavity. A fluid-structure interaction with a viscoelastic model for the tympanic membrane (TM) as well as the ossicular chain has been considered in the study. For the high intensity pressure simulation the geometry of the ear was based on a 3D finite element (FE) model of the human ear reported by Gan et al. (Ann Biomed Eng 2004). The model consists of the ear canal, TM, ossicular chain, and the middle ear cavity. The numerical approach includes two steps: 1) FE based finite-volume method simulation to compute pressure distributions in the ear canal and the middle ear cavity using CFX; and 2) FE modeling of TM and middle ear ossicles in response to high intensity sound using multi-physics analysis in ANSYS. The simulations provide the displacement of the TM/ossicular chain and the pressure fields in the ear canal and the middle ear cavity. These results are compared with human temporal bone experimental data obtained in our group.

P1.00089 Computational Characterization of Type I collagen-based Extra-cellular Matrix1, LONG LIANG, Department of Physics, Arizona State University, CHRISTOPHER ALLEN RUCKSACK JONES, DANIEL LIN, Department of Physics, Oregon State University, YANG JIAO, Department of Materials Science and Engineering, Arizona State University, BO SUN, Department of Physics, Oregon State University — A model of extracellular matrix (ECM) of collagen fibers has been built, in which cells could communicate with distant partners via fiber-mediated long-range-transmitted stress states. The ECM is modeled as a spring-like fiber network derived from skeletonized confocal microscopy data. Different local and global perturbations have been performed on the network, each followed by an optimized global Monte-Carlo (MC) energy minimization leading to the deformed network in response to the perturbations. In the optimization, a highly efficient local energy update procedure is employed and force-directed MC moves are used, which results in a convergence to the energy minimum state 20 times faster than the commonly used random displacement trial moves in MC. Further analysis and visualization of the distribution and correlation of the resulting force network reveal that local perturbations can give rise to global impacts: the force chains formed with a linear extent much further than the characteristic length scale associated with the perturbation sites and average fiber length. This behavior provides a strong evidence for our hypothesis of fiber-mediated long-range force transmission in ECM networks and the resulting long-range cell-cell mechanical signaling.

P1.00090 Hidden Markov models for the analysis of single particle trajectories containing multiple mobile states. DYLAN YOUNG, JAN SCRIMGEOUR, Clarkson Univ — Single particle tracking offers significant insight into the molecular mechanics that govern the behavior of living cells. The analysis of trajectories that transition between different motive states, such as diffusive, driven and tethered modes, is of considerable importance, with even single trajectories containing significant amounts of information about a molecule’s environment and its interactions with structures such as the cell cytoskeleton, membrane or extracellular matrix. Traditional analysis of particle trajectories has relied heavily on evaluation of the mean squared displacement, but often struggles to extract information reliably from small quantities of data or when multiple mobile states are present. Here, we present hidden Markov models for the analysis of complex multi-mobility tracks, focusing on transitions between states exhibiting free diffusion and either driven or tethered motion. The models were tested using simulated trajectories and practical limitations on the track length and state switching probabilities needed for accurate extraction of the physical parameters in the model are identified. These results provide critical information for the design of particle tracking experiments where trajectories containing multiple mobile states are expected.

P1.00091 A theoretical analysis of inferring molecular interactions from single particle trajectories1. ZIYA KALAY, Kyoto University — Single molecule/particle tracking has become a valuable tool in microscopy that allows for recording trajectories of probes such as individual biological molecules with high temporal and spatial resolution. With the trajectory of a particle, mesoscale transport properties such as diffusion coefficients and first-passage times can be calculated. With the trajectories of two particles that interact, we can investigate the kinetics of reactions by analyzing the statistics of overlap between trajectories. This approach is useful for single molecule biophysics in exploring the kinetics of reversible binding among molecules in biological membranes and on the DNA. Nevertheless, extracting information from noisy trajectories, where the noise stems from a combination of thermal fluctuations and uncertainty introduced by measuring apparatus, is a challenging task. In this work, we consider an exactly solvable model of diffusion and reversible binding in a 1-D structure, such as the DNA, and present a mathematical analysis of how much information about the binding kinetics can be reliably extracted from experimental data. With insight gained from this low-dimensional model, we discuss the analysis of trajectory pairs in two-dimensional systems such as biological membranes.

**P1.00092** Stochastic Movement of Multiple Motor Transported Cargo , DAVID ANDO, AJAY GOPINATHAN, JING XU, UC Merced — Experimental observations of cargo position during transport by multiple motors are determined by several coupled stochastic processes. During collective transport, each motor can transition between multiple kinetic states, with the state of each motor influencing the states of the others via mechanical coupling through a common cargo. We measured the motion of a micron sized bead as it is transported by two kinesins along a single microtubule track, focusing on cargo displacements which are both axial and transverse to the microtubule. We model the effects of inter-motor interference and the state of each motor throughout time, and back out motor properties using a systematic comparison of experimental observations with simulated model traces over a wide parameter space. Our model captures a surface-associated mode of kinesin, which is only accessible via inter-motor interference in groups, in which kinesin diffuses along the microtubule surface and rapidly “hops” between protofilaments without dissociating from the microtubule. This enhances local exploration of the microtubule surface, possibly enabling cellular cargos to overcome macromolecular crowding and to navigate obstacles along microtubule tracks without sacrificing overall travel distance.

**P1.00093** Light, Imaging, Vision: An interdisciplinary undergraduate course1, PHILIP NELSON, Univ Pennsylvania — The vertebrate eye is fantastically sensitive instrument, capable of registering the absorption of a single photon, and yet generating very low noise. Using eyes as a common thread helps motivate undergraduates to learn a lot of physics, both fundamental and applied to scientific imaging and neuroscience. I’ll describe an undergraduate course, for students in several science and engineering majors, that takes students from the rudiments of probability and statistical inference to the quantum character of light, including modern experimental methods like fluorescence imaging and Förster resonance energy transfer. After a digression into color vision, we then see how the Feynman principle explains the apparently wavelike phenomena associated to light, including applications like diffraction, subdiffraction imaging, total internal reflection and TIRF microscopy. Then we see how scientists documented the single-quantum sensitivity of the eye seven decades earlier than “ought” to have been possible, and finally close with the remarkable signaling cascade that delivers such outstanding performance. Parts of this story are now embodied in a new textbook (WH Freeman and Co, 1/2015); additional course materials are available upon request.

1Work supported by NSF grants EF–0928048 and DMR–0832802.

**P1.00094** A new course and textbook on Physical Models of Living Systems, for science and engineering undergraduates1, PHILIP NELSON, Univ Pennsylvania — I’ll describe an intermediate-level course on “Physical Models of Living Systems.” The only prerequisite is first-year university physics and calculus. The course is a response to rapidly growing interest among undergraduates in a broad range of science and engineering majors. Students acquire several research skills that are often not addressed in traditional courses:

- Basic modeling skills
- Probabilistic modeling skills
- Data analysis methods
- Computer programming using a general-purpose platform like MATLAB or Python
- Dynamical systems, particularly feedback control.

These basic skills, which are relevant to nearly any field of science or engineering, are presented in the context of case studies from living systems, including:

- Virus dynamics
- Bacterial genetics and evolution of drug resistance
- Statistical inference
- Superresolution microscopy
- Synthetic biology
- Naturally evolved cellular circuits.

**P1.00095** Analytical framework for modeling of long-range transport of fungal plant epidemics, OLEG KOGAN, KEVIN O’KEEFFE, DAVID SCHNEIDER, CHRISTOPHER MYERS, Cornell University, ANALYTICAL FRAMEWORKS FOR INFECTIOUS DISEASES DYNAMICS TEAM — A new framework for the study of long-range transport of fungal plant epidemics is proposed. The null nonlinear model includes advective transport through the free atmosphere, spore production on the ground, and transfer of spores between the ground and the advective atmospheric layer. The competition between the growth wave on the ground and the effect of the wind is most strongly reflected in upwind fronts, which can propagate into the wind for exponential initial conditions. If the rate of spore transfer into the advective layer is below critical, this happens for initial conditions with arbitrary steepness. Upwind fronts from localized initial conditions will propagate in the direction of the wind above this critical parameter, and will not propagate below it. On the other hand, the speed of the downwind front does not have a strong dependence on the rate of spore transfer between the advective layer and the ground. Thus, even vanishingly small, but finite transfer rates result in a substantial epidemic wave in the direction of the wind. We also consider the effect of an additional, random-walk like mechanism of transport through the near-ground atmospheric boundary layer, and attempt to understand which route dominates the transport over long distances.

**P1.00096** Interstitial flows promote an amoeboid cell phenotype and motility of breast cancer cells1, CHIH-KUAN TUNG, YU LING HUANG, ANGELA ZHENG, MINGMING WU, Department of Biological and Environmental Engineering, Cornell University — Lymph nodes, the drainage systems for interstitial flows, are clinically known to be the first metastatic sites of many cancer types including breast and prostate cancers. Here, we demonstrate that breast cancer cell morphology and motility is modulated by interstitial flows in a cell-ECM adhesion dependent manner. The average aspect ratios of the cells are significantly lower (or are more amoeboid like) in the presence of the flow in comparison to the case when the flow is absent. The addition of exogenous adhesion molecules within the extracellular matrix (type I collagen) enhances the overall aspect ratio (or are more mesenchymal like) of the cell population. Using measured cell trajectories, we find that the persistence of the amoeboid cells (aspect ratio less than 2.0) is shorter than that of mesenchymal cells. However, the maximum speed of the amoeboid cells is larger than that of mesenchymal cells. Together these findings provide the novel insight that interstitial flows promote amoeboid cell morphology and motility and highlight the plasticity of tumor cell motility in response to its biophysical environment.

P1.00097 Robust Nonlinear Neural Codes\textsuperscript{1}. QIAINU LIANG, Rice Univ, XAQ PITKOW, Rice Univ. Baylor College of Medicine — Most interesting natural sensory stimuli are encoded in the brain in a form that can only be decoded nonlinearly. But despite being a core function of the brain, nonlinear population codes are rarely studied and poorly understood. Interestingly, the few existing models of nonlinear codes are inconsistent with known architectural features of the brain. In particular, these codes have information content that scales with the size of the cortical population, even if that violates the data processing inequality by exceeding the amount of information entering the sensory system. Here we provide a valid theory of nonlinear population codes by generalizing recent work on information-limiting correlations in linear population codes. Although these generalized, nonlinear information-limiting correlations bound the performance of any decoder, they also make decoding more robust to suboptimal computation, allowing many suboptimal decoders to achieve nearly the same efficiency as an optimal decoder. Although these correlations are extremely difficult to measure directly, particularly for nonlinear codes, we provide a simple, practical test by which one can use choice-related activity in small populations of neurons to determine whether decoding is suboptimal or optimal and limited by correlated noise. We conclude by describing an example computation in the vestibular system where this theory applies.

P1.00098 Spatiotemporal discrimination in neural networks with short-term synaptic plasticity. BENJAMIN SHLAER, PAUL MILLER, Brandeis Univ. — Cells in recurrently connected neural networks exhibit bistability, which allows for stimulus information to persist in a circuit even after stimulus offset, i.e. short-term memory. However, such a system does not have enough hysteresis to encode temporal information about the stimuli. The biophysically described phenomenon of synaptic depression decreases synaptic transmission strengths due to increased presynaptic activity. This short-term reduction in synaptic strengths can destabilize attractor states in excitory recurrent neural networks, causing the network to move along stimulus dependent dynamical trajectories. Such a network can successfully separate amplitudes and durations of stimuli from the number of successive stimuli\textsuperscript{1} and so provides a strong candidate network for the encoding of spatiotemporal information. Here we explicitly demonstrate the capability of a recurrent neural network with short-term synaptic depression to discriminate between the temporal sequences in which spatial stimuli are presented.

P1.00099 The Brain Physics: Multi Laser Beam Interaction with the Brain Topions (the Brain Neurocenters)\textsuperscript{1}. V. ALEXANDER STEFAN, Institute for Advanced Physics Studies, Stefan University, La Jolla, California 92037 — A novel method for the treatment of the neurological diseases is proposed. The multi-energy laser photons\textsuperscript{2} (the blue scanning photons and ultraviolet focusing photons) interact with the specific DNA molecules within the topion (such as Parkinson’s and Alzheimer’s brain topion) via the matching of laser frequency with the oscillation eigen-frequency of a particular molecule\textsuperscript{3} within the DNA\textsuperscript{4} . In this way, the corrupt molecules (the structure of molecules) can be manipulated so as to treat (eliminate) the neurological disease.

P1.00100 Network oscillations of inferior olive neurons: entrainment and phase-locking of locally-coupled oscillators. THOMAS CHARTRAND, MARK S. GOLDMAN, TIMOTHY J. LEWIS, University of California, Davis — Although the inferior olive is known to contribute to the generation of timing and error signals for motor control, the specific role of its distinctive spatiotemporal activity patterns is still controversial. Olfactory neurons display regular, sometimes synchronized oscillations of subthreshold membrane potential, driven in part by the highest density of electrical coupling of any brain region. We show that a reduced model of coupled phase oscillators is sufficient to reproduce and study experimental observations previously only demonstrated in more complex models. These include stable phase differences, variability of entrainment frequency, wave propagation, and cluster formation. Using the phase-response curve (PRC) of a conductance-based model of olivary neurons, we derive our phase model according to the theory of weakly-coupled oscillators. We retain the heterogeneity of intrinsic frequencies and heterogeneous, spatially constrained coupling as weak perturbations to the limit-cycle dynamics. Generalizing this model to an ensemble of coupled oscillator lattices with frequency and coupling disorder, we study the onset of entrainment and phase-locking as coupling is strengthened, including the scaling of cluster sizes with coupling strength near each phase transition.

P1.00101 Temporal Evolution Of Information In Neural Networks With Feedback\textsuperscript{1}. ARAM GIAHI SARAVANI, Baylor College of Medicine, XAQ PITKOW, Baylor College of Medicine/Rice University — Recurrent neural networks are pivotal for information processing in the brain. Here we analyze how the information content of a neural network is altered by dynamic feedback of a stimulus estimated from the network activity. We find that the temporal evolution of the Fisher information in the model with feedback is bounded by the Fisher information in a network of pure integrators. The available information in the feedback model saturates with a time constant and to a final level both determined by the match between the estimator weights and the feedback weights. This network then encodes signals specifically from either the beginning or the end of the stimulus presentation, depending on this match. These results are relevant to recent experimental measurements of psychophysical kernels indicating that earlier stimuli have a stronger influence on perceptual discriminations than more recent stimuli. We discuss consequences of this description for choice correlations, a measure of how individual neuronal responses relate to perceptual estimates.

P1.00103 The Deterministic Information Bottleneck. D.J. STROUSE, Princeton University, DAVID SCHWAB, Northwestern University — A fundamental and ubiquitous task that all organisms face is prediction of the future based on past sensory experience. Since an individual’s memory resources are limited and costly, however, there is a tradeoff between memory cost and predictive payoff. The information bottleneck (IB) method (Tishby, Pereira, & Bialek 2000) formulates this tradeoff as a mathematical optimization problem using an information theoretic cost function. IB encourages storing as few bits of past sensory input as possible while selectively preserving the bits that are most predictive of the future. Here we introduce an alternative formulation of the IB method, which we call the deterministic information bottleneck (DIB). First, we argue for an alternative cost function, which better represents the biologically-motivated goal of minimizing required memory resources. Then, we show that this seemingly minor change has the dramatic effect of converting the optimal memory encoder from stochastic to deterministic. Next, we propose an iterative algorithm for solving the DIB problem. Additionally, we compare the IB and DIB methods on a variety of synthetic datasets, and examine the performance of retinal ganglion cell populations relative to the optimal encoding strategy for each problem.
