9:31AM H38.00008 A Theoretical Model of Flow in a Pleated Filter Membrane Cartridge¹, DANIEL FONG, US Merchant Marine Academy, PEJMAN SANAEI, New York Institute of Technology — A 3D model is developed for fluid flow in a cylindrical pleated membrane filter cartridge consisting of a central hollow region surrounded by annular pleated membrane within an external housing. In the region outside of the pleated filter and the hollow region, flow is described using Stokes equation, while in the pleated membrane region Darcy’s law is used to model flow through the porous pleated membrane. The governing equations are reduced by exploiting the small aspect ratios of both the membrane and housing. This yields a coupled simplified system of equations for the pressures and velocities in these three regions which is solved numerically. The model is used to investigate the effect of changing various pleated membrane cartridge geometrical parameters on the filter efficiency.

9:44AM H38.00009 Liquid flow through paper with the consideration of swelling and intra-fiber pores¹, WONJUNG KIM, SOOYOUNG CHANG, Sogang University — Paper is one of the most widely used porous media for absorbing liquid, and accurate control of water imbibition in paper is crucial in developing paper-based microfluidic devices. Washburn equation is usually used to describe the dynamics of the liquid flow through the cellulose matrix of paper. However, it is well known that this equation has limitations in predicting water flow in paper. We report that swelling and intra-fiber pores that have not been considered in developing Washburn equation are mainly responsible for the limited accuracy when predicting imbibition length of water. We demonstrate that cellulose fibers have significant internal voids that absorb water. In addition, we quantify water induced swelling that leads to the expansion of inter-fiber space. We develop a hydrodynamic model of water imbibition with the consideration of intra-fiber voids and cellulose fiber swelling that well explain experimental observations. Our study provides a new insight into not only porous media flow with intra-void structure and swelling effects, but also a theoretical background to design μPADs.

9:57AM H38.00010 Pressure-driven flow across a hyperelastic porous membrane,¹ RYUNGEUN SONG, Sungkyunkwan University, HOWARD STONE, Princeton University, KAARE JENSEN, Technical University of Denmark, JINKEE LEE, Sungkyunkwan University — We report an experimental investigation of pressure-driven flow of a viscous liquid across thin polydimethylsiloxane (PDMS) membranes. Our experiments revealed a nonlinear relation between the flow rate Q and the applied pressure drop ∆p, in apparent disagreement with Darcy’s law, which dictates a linear relationship between flow rate, or average velocity, and pressure drop. These observations suggest that the effective permeability of the membrane decreases with pressure due to deformation of the nanochannels in the PDMS polymeric network. We propose a model that incorporates the effects of pressure-induced deformation of the hyperelastic porous membrane at three distinct scales: the membrane surface area, which increases with pressure, the membrane thickness, which decreases with pressure, and the structure of the porous material, which is deformed at the nano-scale. With this model, we are able to rationalize the deviation between Darcy’s law and the data. Our result represents a novel case in which macroscopic deformations can impact the microstructure and transport properties of soft materials. ¹JL thanks to the support by NRF (2017R1A2B2006964) and KEITI (2019002790003). 10:01AM H38.00011 Nonlinear Fluid-Structure Coupling in Flow through a Deformable Porous Medium,¹ TYLER LUTZ, LARRY WILEN, JOHN WETTLAUFER, Yale University — Fluid flow through a deformable, porous matrix of solid particles is generally seen to exhibit non-Darcy behavior: viscous drag forces exerted on the solid constituents by the fluid may be communicated throughout the solid matrix, leading to a spatially inhomogeneous permeability and ultimately a nonlinear relationship between bulk pressure drop and volume flux. We present results of an experiment in three dimensions designed to provide a closure condition on the mathematical theory of large-deformation flow through a deformable porous medium. Our specific realization of uniaxial flow through a cylindrical foam is robust enough to capture the nonlinear coupling between the solid and fluid components, while the geometry is sufficiently simple to enable detailed comparisons to theoretical expectations. We focus in particular on precision measurements of the pore pressure gradient as a function of the driving pressure head; we use these measurements in combination with direct measurements of the foam deformation to determine the relationship between porosity and permeability, a crucial theoretical input parameter. This closure condition allows us to make explicit, quantitative comparisons to theoretical predictions.

10:23AM H38.00012 Random Resistor Networks and Porous Media, AHMAD ZAREEI, SHIMA PARS, ARIEL AMIR, Harvard University — Pore-level flow distribution in a disordered porous medium is determined through its heterogeneous micro-structure. Dissolution of solid matrix or solute retention during flow of a solution dynamically changes the micro-structure, affects the velocity distribution of pores in unpredictable ways, and further changes the bulk behavior. In order to understand the dynamics of local structural changes during polymer solution flow and its effects, we investigate random resistor networks as a model of disordered porous medium. The network of pores is modeled using connected network of pipes with a random distribution of diameters, and then the critical behavior and averaging behavior of such networks are developed. We further study the dynamics of structural changes during polymer retention process in the random resistor network, and show how this model is able to predict local process of polymer retention, micro-structural changes, flow velocity distribution of pores, and bulk properties consistent with experiments.
8:00AM H39.00001 Turbulent mixing in oceanic flows: challenges and insights for improved prediction. KARAN VENAYAGAMOORTHY, Colorado State University — The understanding and quantitative prediction of diapycnal (irreversible) mixing of density and momentum in the oceans remains an important ongoing challenge. From a practical perspective, there is a critical need to obtain accurate prediction of turbulent heat, mass and momentum fluxes using indirect measurements in the field. Indirect methods for estimating mixing rates typically rely on the inference of three key quantities namely: (i) the rate of dissipation of turbulent kinetic energy; (ii) the mixing efficiency, which is a measure of the amount of turbulent kinetic energy that is irreversibly converted into background potential energy; and (iii) the background density stratification, respectively. In this talk, an overview on how these quantities are typically inferred and/or parameterized will be presented. Some important challenges, ambiguities and new insights will also be presented with an eye toward improved prediction of ocean mixing.

8:13AM H39.00002 Predicting regions of ocean vertical transport via surface coherent structures. MICHAEL ALLSHOUSE, H M ARAVIND, Northeastern University — Vertical transport in the upper ocean impacts the surface mixing, advection of nutrients, and the ocean energy budget. Observing regions of significant vertical transport is difficult because vertical velocities in the ocean are often orders of magnitude smaller than horizontal velocities. Some tools for predicting where large vertical velocities will occur include HF radar, satellite altimetry, and modeled horizontal velocity fields, which all provide ocean surface velocities. While Eulerian analysis of these fields can yield some information, Lagrangian coherent structures are more robust to noisy observational data and model parameter uncertainty. We correlate surface coherent structures to vertical transport below the surface to evaluate their capacity to predict regions of strong vertical transport. In particular, we compute the finite-time Lyapunov exponent field from the surface velocity and compare this with the corresponding local vertical subduction. This correlation is tested on a high-fidelity simulation of a sheared subsmesoscale flow and an operational ocean forecast. The identification of coherent structures provides a target zone for anticipated vertical transport that could be observed via Lagrangian floats.

8:26AM H39.00003 Oceanic Sub-mesoscale Wave-Vortical Interactions and Their Effect on Scalar Transport. GERARDO HERNANDEZ-DUENAS, National Autonomous University of Mexico, PASCALE LEULONG, NorthWest Research Associates, LESLIE SMITH, Department of Mathematics, University of Wisconsin - Madison — The mechanisms driving lateral dispersion in the ocean on scales of 100 m − 10 km remain, by and large, not well identified. Dominant motions in this regime, known as the subsmesoscale, are internal waves and vortical motions. These two components have similar spatial scales but evolve on different temporal scales. Small-scale vortical mode are susceptible to instabilities and may not be as long-lived as their larger-scale geostrophic counterparts. While vortices are more efficient at dispersing a passive tracer than waves, the role of the latter remains less well understood. In this talk, we will present simulations using a set of intermediate models to identify the role of various non-linear interactions between vortical and wave motions. These intermediate models range from the quasi-geostrophic model which only includes PV/PV/PV nonlinearities and GGG model with only wave/wave/wave nonlinearities to the full Boussinesq model which retains all. Statistics such as energy transfer spectra and diffusivity will be shown to identify the effect of different non-linear interactions on scalar transport.

8:39AM H39.00004 The Energetics of Seamount Wakes. BRAD PERFECT, NIRNIMESH KUMAR, JAMES RILEY, University of Washington — This work revisits the longstanding hypothesis that seamounts are the "stirring rods" of the ocean. Specifically, it has been proposed that the eddy motions generated by the interaction of underwater mountains with ocean currents might play a significant role in the broader field of ocean mixing. We report on the results of a series of numerical simulations for an idealized seamount in rotating, stratified flow at a range of Froude and Rossby numbers (0.014 < Fr < 0.14 and 0.053 < Ro < 0.21). This parameter space is consistent with the strongly stratified, strongly rotating flow experienced by a large seamount. In each simulation, the seamount generates a distinctive wake and produces internal wave radiation. We explore the energetics of the wake and waves separately, and find that the wake is predominantly controlled by the Burger number, while the internal wave radiation has a more complex dependence that can be predicted by modifying pre-existing linear wave models. Ultimately, our results suggest that for low-Froude number flows, the wake of the seamount extracts more energy from the mean flow than the internal wave flux, supporting the stirring rod view of seamount energetics.

8:52AM H39.00005 Observations of nonlinear internal wave evolution and mixing from the shelf to the surf zone. KRISTEN DAVIS, GREGORY SINNETT, EMMA REID, University of California, Irvine, Civil & Env. Engineering — Internal waves strongly influence the physical and chemical environment of coastal ecosystems worldwide. We report novel observations from a distributed temperature sensing (DTS) system that tracked the transformation of internal waves from the shelf break to the surf zone over a shelf-slope region of a coral atoll in the South China Sea. The spatially-continuous view of the near-bottom temperature field provided by the DTS offers a perspective of physical processes previously available only in laboratory settings or numerical models. Additionally, we report observations of turbulent dissipation during the passage of a shoaling internal wave train and examine the implications for irreversible mixing of subthermocline water into the nearshore region and onto a shallow coral reef. We find that during summer, internal waves shoaling on the shallow atoll regularly transport cold, nutrient-rich water shoreward, altering near-surface water properties on the fore reef. This water is transported shoreward of the reef crest by tides, breaking surface waves and wind-driven waves, where it significantly alters the water temperature and nutrient concentrations on the reef.
Towards an accurate parameterization of mixed layer deepening during ocean convection. TAIMOOR SOHAIL, The Australian National University, BISHAKHDATTA GAYEN, The University of Melbourne, ANDREW HOGG, The Australian National University — We investigate the growth and equilibrium of the oceanic mixed layer during a deep convective event using a Direct Numerical Simulation (DNS) and a large-scale ocean model. The DNS resolves all scales of flow, providing the opportunity to quantify vertical buoyancy flux and mixing in a deep convective event. The inferred vertical diffusivity and mixed layer depth (MLD) are simulated over a range of background stratifications and surface buoyancy forcings in the DNS model. A scaling theory for convective mixing is proposed which robustly predicts the rate of MLD growth and vertical diffusivity during deep convection. We directly compare the MLD predicted from the scaling theory with existing vertical parameterizations in a large-scale ocean model. Specifically, we run analogous deep convection experiments with the Modular Ocean Model (MOM) 6 running three different vertical parameterizations for the ocean boundary layer: CVMix, KFP and ePBL. We quantify the difference between the MLD derived from these parameterization schemes and the predictions from the theoretical scaling, thereby quantifying the accuracy of existing parameterization schemes.

Impacts of inertial/symmetric instabilities on ocean fronts1. NICO-LAS GRISOUARD, University of Toronto — Oceanic submesoscale density fronts are structures in geostrophic and hydrostatic balance. They tend to be small (100 m to 10 km wide at mid-latitudes) and ubiquitous features of the near-surface of the oceans. They tend to be unstable, which may be key to understanding the kinetic energy budget of the ocean, as well as their effects on gas and nutrient exchanges between the surface and the abyss. In this presentation, we focus on the inertial or symmetric instability. We present a series of numerical experiments to investigate energetic impacts of these instabilities on fronts. Our set of experiments covers the submesoscale portion of a three-dimensional parameter space consisting of the Richardson and Rossby numbers, and a measure of stratification or latitude. We first argue that contrary to parameterization prototypes that are currently being developed, drainage of available potential energy from the geostrophic flow can be a leading-order source of their growth. We also argue that a front is relatively robust when experiencing this instability, and provide hints as to its contribution to the shape of fronts. We also caution modellers about a possibly large impact of the choices of the dissipation operator on the dynamics of the instability.

Equilibration of symmetric instability and inertial oscillations at an idealised submesoscale front. AARON WIENKERS, DAMTP, University of Cambridge, LEIF THOMAS, Stanford University, JOHN TAYLOR, DAMTP, University of Cambridge — Submesoscale fronts with large lateral buoyancy gradients and O(1) Rossby numbers are common in the upper ocean. These fronts are associated with large vertical transport and are hotspots for biological activity. Submesoscale fronts are susceptible to symmetric instability (SI) — a form of stratified inertial instability which can occur when the potential vorticity is of the opposite sign to the Coriolis parameter. Growing SI modes eventually break down through a secondary shear instability, leading to 3D turbulence and vertically mixing the geostrophic momentum. Once out of thermal wind balance, the front undergoes inertial oscillations which can drive further small-scale turbulence. Here, we consider the idealised problem of a balanced front with uniform horizontal buoyancy gradient and bounded by flat no-stress horizontal surfaces. We study the equilibration of this unstable front using a linear stability analysis and 3D numerical simulations. We find drastically different behavior emerging at late times. While weak fronts develop frontlets and excite subinertial oscillations, stronger fronts produce bore-like gravity currents. We describe the details of these energy pathways as the front evolves towards the final adjusted state in terms of the dimensionless front strength.

Global Distribution of the Oceanic Bottom Mixed Layer Thickness1, PENG-QI HUANG, XIAN-RONG CEN, YUAN-ZHENG LU, SHUHANG-XI GUO, SHENG-QI ZHOU, State Key Laboratory of Tropical Oceanography, South China Sea Institute of Oceanology, Chinese Academy of Sciences, Guangzhou, China — With the increasing number of available potential energy from the geostrophic flow can be a leading-order source of their growth. We also argue that a front is relatively robust when experiencing this instability, and provide hints as to its contribution to the shape of fronts. We also caution modellers about a possibly large impact of the choices of the dissipation operator on the dynamics of the instability.

Setting of randomly formed marine aggregates. EUNJI YOO, SHILPA KHATRI, FRANCOIS BLANCHETTE, Applied Mathematics, University of California, Merced — Setting marine aggregates plays an important role in transporting carbon from the surface ocean to the deep ocean. Investigation of settling rates is critical to understand the ecological importance of these particles. We study the setting of Diffusion-Limited-Agregates as a model of marine aggregates in the ocean. The aggregates are assembled as a collection of cubic particles formed by cluster-to-cluster aggregation, resulting in fractal objects. The stresses on the surface and flow around the aggregates are computed in the limit of zero Reynolds number using a single-layer potential boundary integral method and we handle the challenges of singularities analytically. We first validate and analyze the performance of our numerical method. We then present the statistical distribution of drag and torque on aggregates of various sizes. We determine that the gyration radius is the key project (201804020056), and the Research Programs of the Chinese Academy of Sciences (XDA11030302 and ISEE2018PY05).

A Brownian dynamics model for the formation of marine aggregates. FRANCOIS BLANCHETTE, CHANGHO KIM, UC Merced — Marine aggregates, the largest of which are called marine snow, play an important role in the oceanic carbon cycle. As microorganisms form, grow, and die near the ocean surface, they tend to cluster and form aggregates. We study numerically the formation of these aggregates using a Brownian dynamics model. The mobility tensor of each aggregate particle, which significantly depends on its shape and size, is computed by a boundary integral method to solve the corresponding Stokes equations. Thus, our model provides a more accurate description of the formation mechanism of aggregates. We investigate the fractal dimension and size distribution of aggregates and also characterize the settling speed as a function of a properly defined size of an aggregate.
8:00AM H40.00001 The Age of a Wake, DAVID LEWIS, TIMOUR RADKO, None — This study attempts to quantify decay rates of stratified wakes in active oceanic environments, characterized by the presence of intermittent turbulence and double-diffusive convection. The investigation is based on a series of direct numerical simulations of wakes produced by a sphere uniformly propagating in stratified two-component fluids. We examine and compare the evolution of wakes in fluid systems that are initially quiescent, double-diffusively unstable, or contain preexisting turbulence. Model diagnostics are focused primarily on dissipation of turbulent kinetic energy ($\epsilon$) and thermal variance ($\chi$). Analysis of decay patterns of $\epsilon$ and $\chi$ indicates that microstructure generated by an object of $D = 0.6$ m in diameter moving at the speed of $U = 0.02$ m/s could be detected, using modern high resolution profiling instruments, for 0.5–0.7 h. Convective overturns are shown to be particularly effective in terms of dispersion of microscale wake signatures. Extrapolation of model results to objects of $\sim 10$ m in diameter propagating with speeds of $\sim 10$ m/s suggests that this form of detection is feasible for at least 4 h after the object’s passage through the monitored areas.

8:13AM H40.00002 Characterization of the Far-Wake of an Inclined 6:1 Prolate Spheroid, JONATHAN PECK, ETHAN LUST, U.S. Naval Academy — The study of flow around prolate spheroids has informed our understanding of fundamental hydrodynamics. For example, they have been used to study boundary layer development, turbulent flow transition, and vortex shedding. Because of the simplicity of the model and the rich hydrodynamic result, prolate spheroid data are often used to validate computational fluid dynamics codes. There are many examples from the literature featuring spheroids in various configurations: aspect ratio (L:D), Reynolds number, and inclination angle. However, there is little consideration of the far-wake, at downstream diameters greater than 6D, particularly at Reynolds numbers in excess of $4 \times 10^6$. The focus of the present study was on this region. The experiment was conducted in the large towing tank at the U.S. Naval Academy. The 6:1 prolate spheroid, measuring 54 in. in length and 9 in. in diameter, was sting-mounted at a 20° angle of inclination. An underwater, stereo particle image velocimetry system was attached to a structure fixed at a point approximately half the length of the towing tank. The spheroid was towed through the field of view in a number of configurations. The field of view was oriented laterally, capturing the strength, size, and evolution of the trailing vortex.

8:26AM H40.00003 Spreading and decay of axisymmetric drag wakes: theory, SCOTT WUNSCH, Johns Hopkins University, THEODORE D. DRIVAS, Princeton University, D. CURTIS SAUNDERS, Johns Hopkins University — The spreading and decay of drag wakes is of interest to a wide variety of applications in geophysics and engineering, such as the wakes of mountains, sea-mounts, windfarms, and buildings. For axisymmetric bodies, the classical self-similar scaling law formulated by Swain (1929) has long been widely accepted (Tennekes and Lumley 72) and used to describe the wakes of spheres (Bevilaqua and Lykoudis 78) and slender bodies (Pao & Lin 73). However, recent experiments have cast doubt on the classical decay law (Bonnier and Eiff 02; Nedic, Vassilicos, and Ganapathisubramani 13), indicating more rapid wake spreading and decay than the classical result. Here, new laboratory data from a dimpled sphere (Re = 50,000) are compared with various theoretical explanations for non-classical self-similar wake decay.

8:39AM H40.00004 Spreading and decay of axisymmetric drag wakes: experiment, D. CURTIS SAUNDERS, SCOTT WUNSCH, Johns Hopkins University — The spreading and decay of drag wakes is of interest to a wide variety of applications in geophysics and engineering, such as the wakes of mountains, sea-mounts, windfarms, and buildings. For axisymmetric bodies, the classical self-similar scaling law formulated by Swain (1929) has long been widely accepted (Tennekes and Lumley 72) and used to describe the wakes of spheres (Bevilaqua and Lykoudis 78) and slender bodies (Pao & Lin 73). However, results from recent experiments have cast doubt on the classical decay law (Bonnier and Eiff 02; Nedic, Vassilicos, and Ganapathisubramani 13), indicating more rapid wake spreading and decay than the classical result. Here, new laboratory data from a dimpled sphere are presented. The Reynolds number (50,000) exceeds previous experiments, and the dimples alleviate issues with Strouhal vortex shedding. Particle Imaging Velocimetry (PIV) data in both along-track and cross-track configurations are used to illustrate various aspects of the wake decay. The observed wake decays at a greater rate than suggested by the classical result, and extends the self-similar decay to further downstream distances than previously reported.

8:52AM H40.00005 Investigation of Large-Scale Coherent Structures in Flow past a Sphere for Scale-Resolving Simulations (SRS), CHEHTA KAMBLE, FREDDIE WITHERDEN, SHARATH GIRIMAJI, Texas A&M University — Success of Scale-Resolving Simulations (SRS) depends on accurately reproducing the large-scale structures in complex turbulent flows. Yet, no clear procedure exists for a quantitative assessment of the fidelity of these flow structures. The objective of this work is to develop such an assessment framework in the context of wake flow past a sphere which is chosen due to its inherent complexity and three-dimensional features. Numerical computations at different degrees of physical resolution are performed using the Partially-averaged Navier-Stokes (PANS) bridging-SRS method. Proper Orthogonal Decomposition (POD) is employed for a quantitative analysis of the computed large-scale structures in the wake. Most energetic structures resolved at different physical resolution are extracted and compared. Furthermore, the dominant structures are also qualitatively examined using the iso-surfaces of Q-criterion, i.e., second invariant of velocity gradient tensor. These results are compared to Direct Numerical Simulations (DNS) studies to establish the efficacy of the PANS-SRS simulations in capturing the large-scale vortical structures.

9:05AM H40.00006 Direct measurements of the mode B instability in the wake of a two-dimensional blunt trailing edge, BRADLEY GIBEAU, SINA GHAEMI, University of Alberta — Recent work has revealed contradictory results regarding the secondary instabilities that appear in the wake of a two-dimensional body with a blunt trailing edge (BTE). A linear stability analysis at Reynolds numbers near transition predicted that the aspect ratio (AR) of the body, i.e. the ratio of chord length to body thickness, dictates the secondary instabilities that exist in the wake. These authors predicted that a mode B’ instability will appear in the wake for AR $> 7.5$, in contrast to the mode B that exists in the wakes of cylindrical bodies (AR = 1). There are experimental results in the literature to support the existence of mode B’. However, the indirect analysis techniques used to show its existence have recently been found to be inadequate. We match the AR of 12.5 used in the studies that reported mode B’ and also extend to a large AR of 46.5 and conduct particle image velocimetry measurements to unambiguously characterize the secondary instability in the wake. Mode B is found to be present in the wake for all Reynolds numbers investigated (Re(h) = 2600 to 26000 where h is the thickness of the BTE), suggesting that AR does not play an important role in the formation of the secondary instability. No evidence of mode B’ was found.
Stratified near wake of a slender body

Jose Luis Ortiz-Tarin, Sheel Nidhan, Sutantu Sarkar, University of California San Diego — Motivated by applications in submersible hydrodynamics, the effect of density stratification on the wake of a slender body is numerically investigated. Large-eddy simulations with an immersed boundary method are employed to simulate the flow past a 6:1 prolate spheroid at zero angle of attack. The Reynolds number based on the minor-axis diameter is fixed to \( Re_D = UD/\nu = 10^5 \), and different levels of stratification measured by \( Fr = U/ND \) are compared: \( Fr = 2 \) which is close the critical value of Froude number \( (Fr_c = 6/\pi ) \) where the turbulence suppression in the wake is maximal; a moderately stratified case \( (Fr = 4) \) and the unstratified case \( (Fr = \infty) \). A trip placed near the nose of the body is used to force laminar-turbulent transition and the wake is simulated to \( 25D \). Preliminary results that include the evolution of the boundary layer, mean velocity and turbulence statistics will be presented.

Office of Naval Research

High Reynolds Number Stratified Turbulent Sphere Wake Measurements

Kenneth Kalumuck, Alan Brandt, Johns Hopkins U. Applied Physics Lab — There are virtually no data on wake turbulence for Reynolds numbers \( (Re) \) of one million or larger, above the drag crisis, even though aircraft and ships operate at \( Re \sim 10^6 \). This study seeks to characterize the near-field of a stratified wake at large \( Re \sim 2 \times 10^5 - 1.4 \times 10^6 \), by towing a large diameter \( (\sim 0.5 \text{ m}) \) sphere through a thermally stratified lake and a thermally stratified large salt water tow tank. The stratification produced BV frequencies, \( N \), up to 0.07 s\(^{-1}\) with Froude numbers \( F = U/ND \geq 15 \). Three component turbulent velocity and temperature measurements were obtained using Acoustic Doppler Velocimeters (ADVs) and an array of fast response thermistors at various downstream distances. Wake turbulence characteristics including rms velocity and temperature fluctuation spectra, dissipation, integral scales, and Reynolds stresses are presented. Velocity and temperature power spectra exhibit clear -5/3 slopes while velocity co-spectra and transverse spectra exhibit -7/3 slopes over order-of-magnitude ranges in wavenumber, which are generally not clearly evident for lower \( Re \) laboratory experiments.

Office of Naval Research Subsurface Hydrodynamics Program

Spectral Proper Orthogonal Decomposition of Flow Around a Disk in Homogeneous and Stratified Fluids

Sheel Nidhan, University of California San Diego, Karu Chongsiripinyo, Chulalongkorn University, Sutantu Sarkar, Oliver Schmidt, University of California San Diego — The elucidation of coherent structures and quantification of their role is a cornerstone of research in turbulent flows. Proper orthogonal decomposition (POD) introduced by Lumley to turbulent flows is a technique which can be used to identify the coherent structures that optimally capture the fluctuation kinetic energy of the flow. In this study, a space-time variant of POD, namely spectral POD (SPOD) is used to study the dynamics of the wake behind a disk at \( Re = 50,000 \). Two cases, a stratified flow with \( Fr = U/ND = 2 \) that evolves into a regime of strongly stratified turbulence (SST) and an unstratified case with \( Fr = \infty \), are analyzed. Preliminary results for \( Fr = \infty \) show that the wake fluctuation energy is dominated by azimuthal modes, \( m = 0, 1, \text{and } 2 \). As the wake evolves downstream beyond \( x/D \approx 60 \), \( m = 2 \) (at Strouhal number, \( St = 0 \)) becomes dominant while the \( m = 1 \) mode (at \( St = 0.136 \)) dominates in the near wake. At \( Fr = 2 \), the energy captured in the most energetic POD mode increases downstream, indicating the increasing importance of coherent modes in the stratified wake as it evolves downstream. In further analysis of modal dynamics, the Reynolds stresses carried by the dominant modes and the intermodal energy transfer among these modes will be quantified.

Office of Naval Research

Direct Numerical Simulation of a Turbulent Wake behind a Body of Revolution at \( Re_D = 5000^3 \)

Fengrui Zhang, Yulia Peet, Ronald Adrian, School for Engineering of Matter, Transport and Energy, Arizona State University — This study is concerned with the numerical investigation of a three-dimensional wake behind a body of revolution via Direct Numerical Simulations. Direct Numerical Simulations with the Reynolds number \( Re_D = 5000 \) based on the bluff body diameter are performed using a high-order spectral-element solver Nek5000. The focus of the study is on characterizing the wake asymmetries and low-frequency behavior observed in previous experimental studies with similar bluff body models. Modal analysis will be presented to show the wake dynamics in both the near-wake and the far-wake region.

The current work is supported by NSF CBET grant 1707075.

Vertical Flux of Mean Flow Kinetic Energy in the Near-Wake of a Marine Propeller in the Presence of External Turbulence

Luksa Luznik, Bennitt Hermse, United States Naval Academy — This experimental study examines the spatial evolution of the three-bladed marine propeller model \((D=13\text{cm})\) near wake in the early stages from the immediate wake behind the propeller up to 7 propeller diameters downstream for two inflow conditions: one with imposed external turbulence with \( 7\% \) intensity and integral scale compared to propeller blade geometry, and the second one with clean inflow conditions as a reference. Resulting Reynolds number is \( Re_D \approx 4.7 \times 10^5 \). All components of the vertical fluxes of mean flow kinetic energy are calculated from available three-dimensional PIV data and compared for the two inflow conditions. Influence of external turbulence on the wake instability process of mutual induction is examined and it was found that external turbulence enhances tip-vortex roll up mechanism resulting in earlier breakdown of individual vortices into small scale turbulence. Conditional sampling is performed to analyze the mechanisms of mean flow kinetic energy transport and it was found that outward interactions and sweep events contribute the most to the vertical transfer of mean flow kinetic energy from the inner wake to the free stream.

10:23AM H40.00012 Do ribs help succulents to cope with aerodynamic loads in their natural environment?1
OLEKSANDR ZHDANOV, ANGELA BUSSE, University of Glasgow — Ribs on cacti stems play an important role for their survival not only in terms of water storage and evaporation control but also in attenuating high wind loads. Studies of flow past circular cylinders with many ribs inspired by the Saguaro cactus, which is native to the North American deserts, showed a reduction in drag and amplitude of unsteady force fluctuations compared to the smooth circular cylinder. In the Eastern Hemisphere some succulents have independently developed a similar plant structure as cacti but with a low number of ribs. If aerodynamics is one of the driving factors behind this convergent evolution, shapes with a low number of ribs should show similar benefits. In the present work, we experimentally investigated the aerodynamics of a cylinder with four ribs inspired by the succulent Euphorbia Abyssinica. As its outer shape is approximately square, i.e. non-circular, the aerodynamic coefficients show a strong dependence on its orientation with respect to the mean flow. The experimental results are compared to the square cylinder at the same angular orientations and to results obtained from large-eddy simulations. The optimal orientation of this shape where aerodynamic loads are minimised is also discussed.

8:00AM H41.00001 Uncertainty quantification in CFD simulations of natural ventilation to support designing experiments for model validation1  
CHEN CHEN, CATHERINE GORLE, Stanford University — Natural ventilation can significantly reduce building energy consumption, but the variability in the boundary and operating conditions makes the robust design of an HVAC system challenging. In previous studies, a computational framework using an integral model and a computational fluid dynamics (CFD) model with uncertainty quantification (UQ) was used to predict the volume-averaged indoor air temperature during night-time ventilation in Stanford’s Y2E2 building. Comparison to point-wise building sensor measurements indicated that spatial variability in the temperature field is non-negligible. Hence, the sensor measurements might not be representative of the volume-averaged temperature. The objective of the present study is to use CFD simulations with UQ to design an experiment that optimizes temperature sensor placement to (1) obtain measurements that are representative of the volume-averaged temperature, and (2) support further analysis of the spatial variability in the temperature field for validation of CFD results. The presentation will discuss the methodology used to account for the variability in the boundary and initial conditions, the design of experiments based on the results, and the use of the measurements for validation of the model results.

8:13AM H41.00002 Uncertainty quantification of the scale determination in steady RANS modeling for turbulence with large-scale structures1  
ZENGRONG HAO, CATHERINE GORLE, Stanford University, WIND ENGINEERING LAB TEAM — The scale determining variable (e.g. energy dissipation rate $\epsilon$, frequency scale $\omega$, or length scale $l$) is notoriously difficult to model and thus a major source of uncertainties in RANS simulations for turbulence. Particularly in the turbulence with large-scale structures that usually yield highly non-equilibrium energy spectra, a steady RANS simulation using a single modeled scale can result in considerable errors, especially for energy levels. In this report, we present a dual-scale, three-equation steady RANS approach to quantify the uncertainties originating in the scale determination in a model for the turbulence with large-scale structures (LS). The uncertainty quantification (UQ) approach is developed in three steps. First, we obtain the equations for the energies of LS and quasi-equilibrium small-scale turbulence (ST) from a triple decomposition, and employ a traditional model for the dissipation rate of ST energy. Second, under the limit condition where LS and ST have identical scales, we derive the form of the energy transfer rate (ETR) from LS to ST via a conceptual analysis with the 'return-to-isotropy' evolution of Reynolds' stresses. Last, a marker with a single uncertain parameter is designed to identify the regions potentially bearing LS (particularly for those in large separation regions), and is used to suppress the ETR. Applications of this UQ approach in several cases show its capability of encompassing the real energy levels in the separation regions.

8:26AM H41.00003 Estimating model-form uncertainty for multi-scale systems  
JIN-LONG WU, TAPIO SCHNEIDER, ANDREW STUART, California Institute of Technology — Global climate models (GCMs) are widely used to simulate climate change. However, their predictions have large uncertainties, arising primarily in subgrid-scale (SGS) parameterizations for globally unresolved small-scale processes. Work to quantify parametric uncertainties in these parameterizations is underway, using methods from data analysis and machine learning. Quantifying structural or model-form uncertainties is more challenging. Here we propose a non-parametric approach to model structural errors that uses Gaussian processes and ensemble Kalman sampling and that respects physical constraints (e.g., energy conservation). We illustrate how this approach can be used to quantify model-form uncertainties in low-dimensional multi-scale systems and with an idealized GCM. The results demonstrate that this approach allows us to go beyond merely calibrating model parameters toward quantifying model uncertainty more broadly.

8:39AM H41.00004 Uncertainty quantification for RANS simulations of variable density flows  
AAASHWIN MISHRA, ZHU HUANG, JAN HEYSE, GIANLUCA IACCARINO, Center for Turbulence Research, Stanford University, TIMOTHY CLARKE WALLSTROM, DAVID SHARP, Los Alamos National Laboratory — Variable density turbulent flows are widely encountered in a variety of natural phenomena and industrial applications, from the Jovian atmosphere and its Giant Red Spot to nuclear applications such as Inertial Confinement Fusion. RANS models and specifically eddy viscosity closures are widely used for investigations into variable density turbulence. However, RANS models have shortcomings in accounting for the effects of anisotropy, rotation, streamline curvature. This is further exacerbated by the forced alignment of the heat flux with the temperature gradient and the relationship between eddy diffusivity and viscosity. These assumptions lead to significant errors and uncertainties in turbulent model predictions for such flows. In this investigation, we outline the application and extension of tensor perturbations to estimate the uncertainties in variable density turbulent flows, deriving uncertainty estimates for the Besnard-Harlow-Raupenzahn (BHR) model. This is carried out for a variety of flows including tilted rocket rigs, variable density turbulent jets, etc. The selected cases show that extension of tensor perturbation can be utilized for uncertainty estimation for predictions of variable density turbulent flows.
Order Models for multifidelity uncertainty quantification, JIAN-XUN WANG, LUNING SUN, HAN GAO, University of Notre Dame, SHAOWU PAN, (W911NF-15-1-0562) and by ARO Young Investigator Program Award (W911NF-19-1-0444).

Flow fields, hence predictive simulations of flow instabilities. brake system input parameters in addition to the investigation of forward uncertainty propagation from the available data and model into the corresponding forward and backward uncertainty quantifications are also performed. This study leads to the Bayesian inference of the stochastic complex-geometry capturing, and cost-efficient direct numerical simulation of the fluid flow. Given available experimental (PIV) data, the rotating cylinder, fully filled with water, arrives at rest within a short time-period from a constant rotational speed. We employ spectral element method to perform highly-accurate, nature of vorticity dynamics, arising from the uncertain initial/ boundary/ topological conditions. The rotating cylinder, subject to an imperfect/ random rotational brake system is modeled and simulated to better understand the stochastic nonlinear behavior.

For modeling closure, we provide an inferred eddy viscosity using two different strategies. The main test case is the flow over an airfoil, with the QoI taken as the lift and/or drag. The parameter space is taken as the angle-of-attack and the Reynolds number. Here, the accuracy of the frozen eddy viscosity assumption for different parameters is assessed.

Model form uncertainty arises from physical assumptions made in constructing models either to reduce the physical complexity or to model physical processes that are not well understood. Understanding these uncertainties is important for both quantifying prediction uncertainty and understanding the source and nature of model errors. Data-based methods for model form uncertainty quantification (UQ) are limited by the availability of data, and, in turbulence, data is often limited by Reynolds number or geometry. In contrast, physics-based UQ seeks to analyze the model form uncertainty by leveraging the physical assumptions inherent in these models so that it can be extrapolated beyond available data. In this work, an "implied models" approach is developed and applied to Reynolds stress modeling. In the approach, a model error transport equation is derived from the fundamental governing equations by taking the difference between the exact Reynolds stress equation and the equation implied by a particular model form. Budgets of the model error transport are analyzed to better understand the sources of error in RANS models, focusing on the relative contributions from the Boussinesq hypothesis and the specific form of the eddy viscosity in canonical turbulent flows.

Many realistic science and engineering applications require complex high-fidelity (HF) simulations for the characterization of the system’s response, in combination with large numbers of random parameters that need to be propagated through these HF simulations. In these cases, a single fidelity approach for UQ becomes intractable due to the extreme cost of resolving both deterministic and stochastic errors. Multifidelity strategies have been introduced to alleviate this issue by fusing information from simulations with varying levels of fidelity, in order to obtain estimators that preserve HF statistics at much lower overall cost. This is typically accomplished through a priori definition of a sequence of model physics or discretizations of varying accuracy and expense. Less attention has been dedicated to the automatic generation of low-fidelity models using data from a small number of HF simulations. In this work, we focus on the case in which low-fidelity models are data-driven using HF samples/snapshots, with initial emphasis on projection-based reduced-order models.

We investigate how the accuracy and certainty of the quantities of interest (QoIs) of canonical wall-bounded turbulent flows are sensitive to various numerical parameters and time averaging. The scale-resolving simulations are performed by Nek5000, an open-source high-order spectral-element code. Different uncertainty quantification (UQ) techniques are utilized in the study. Using non-intrusive polynomial chaos expansion, portraits of error in the QoIs are constructed in the parameter space. The uncertain parameters are taken to be the grid spacing in different directions and the filtering parameters. As a complement to the UQ forward problems, global sensitivity analyses are performed with the results being quantified in the form of Sobol indices. Employing Bayesian optimization based on Gaussian Processes, the possibility of finding optimal combinations of parameters for obtaining QoIs with a given target accuracy is studied. To estimate the uncertainty due to time averaging, the use of different techniques such as classical, batch-based and autoregressive methods is discussed and suggestions are given on how to efficiently integrate such techniques in large-scale simulations. Comparisons of the certainty aspects between high-order and low-order codes (OpenFOAM) are given.

Numerical simulations on fluid dynamics problems can often be computationally prohibitive for most realistic and many-query applications, and developing a cost-effective surrogate model of great practical significance. Deep learning (DL) has shown new promises for surrogate modeling due to its capability of handling strong nonlinearity and high dimensionality. However, the off-the-shelf DL architectures fail to operate when the data becomes sparse, which is often the case in most parametric fluid dynamics problems since each data point in the parameter space requires an expensive numerical simulation. In this paper, we provide a physics-constrained DL approach for surrogate fluid modeling without relying on any simulation data. Specifically, a structured deep neural network (DNN) architecture is devised to enforce the boundary conditions, and the Navier-Stokes equations are used to drive the training. Numerical experiments are conducted on a number of vascular flows and forward propagation of uncertainties in fluid properties and domain geometry is studied as well. The results show excellent agreement on the flow field and propagated uncertainties between the DL surrogate approximations and the first-principle numerical simulations.

This work was supported by the AFOSR Young Investigator Program Award (FA9550-17-1-0150), and partially by MURI/ARO (W911NF-15-1-0562) and by ARO Young Investigator Program Award (W911NF-19-1-0444).

9:44AM H41.00009 Surrogate Modeling for Fluid Flows Using Physics-Constrained, Label-Free Deep Learning, JIAN-XUN WANG, LUNING SUN, HAN GAO, University of Notre Dame, SHAOWU PAN, University of Michigan, Ann Arbor — Numerical simulations on fluid dynamics problems can often be computationally prohibitive for most realistic and many-query applications, and developing a cost-effective surrogate model of great practical significance. Deep learning (DL) has shown new promises for surrogate modeling due to its capability of handling strong nonlinearity and high dimensionality. However, the off-the-shelf DL architectures fail to operate when the data becomes sparse, which is often the case in most parametric fluid dynamics problems since each data point in the parameter space requires an expensive numerical simulation. In this paper, we provide a physics-constrained DL approach for surrogate fluid modeling without relying on any simulation data. Specifically, a structured deep neural network (DNN) architecture is devised to enforce the boundary conditions, and the Navier-Stokes equations are used to drive the training. Numerical experiments are conducted on a number of vascular flows and forward propagation of uncertainties in fluid properties and domain geometry is studied as well. The results show excellent agreement on the flow field and propagated uncertainties between the DL surrogate approximations and the first-principle numerical simulations.

9:57AM H41.00010 Stochastic Simulation of Flow Instabilities in a Rotating Cylinder, S. HADI SEYEDI, ALI AKHAVAN-SAFAEI, JOHN FOSS, MOHSEN ZAYERNOURI, Michigan State University — A rotating cylinder subject to an imperfect/ random rotational brake system is modeled and simulated to better understand the stochastic nonlinear nature of vorticity dynamics, arising from the uncertain initial/ boundary/ topological conditions. The rotating cylinder, fully filled with water, arrives at rest within a short time-period from a constant rotational speed. We employ spectral element method to perform highly-accurate, complex-geometry capturing, and cost-efficient direct numerical simulation of the fluid flow. Given available experimental (PIV) data, the corresponding forward and backward uncertainty quantifications are also performed. This study leads to the Bayesian inference of the stochastic brake system input parameters in addition to the investigation of forward uncertainty propagation from the available data and model into the flow field, hence predictive simulations of flow instabilities.
Orthogonal (DO) method and Bi-Orthogonal (BO) method for highly ill-conditioned cases. In particular, we demonstrate that the presented real-time reduced-order modeling of transient stochastic systems for the purpose of uncertainty propagation. We present a closed-form evolution equation for a low-rank time-dependent basis that evolves with the dynamics. An on-the-fly reduction of the dynamical system is then obtained by projecting the full-dimensional system onto the low-rank basis. The presented method is compared against the state-of-the-art Dynamically Orthogonal (DO) method and Bi-Orthogonal (BO) method for highly ill-conditioned cases. In particular, we demonstrate that the presented method preserves the accuracy of the solution and the shape of the modes as the system passes through a low eigenvalue phase. The results for several demonstration cases are presented, including linear advection equation, stochastic Burgers’ equation and stochastic flow in a channel.

least-squares Petrov-Galerkin (LSPG) ROM (equipped with hyper-reduction) has demonstrated the ability to significantly reduce simulation costs while retaining high levels of accuracy on a range of problems including subsonic CFD applications. This work presents the first application of LSPG to hypersonic CFD problems including the Blottner sphere and HiFIRE experimental flight vehicle. This shows the ability of LSPG ROMs while retaining high levels of accuracy.

10:23AM H41.00002 Dynamically bi-orthonormal formulation for stochastic partial differential equations
1, PRERNA PATIL, HESSAM BABAE, University of Pittsburgh — A new method is presented for a real-time reduced-order modeling of transient stochastic systems for the purpose of uncertainty propagation. We present a closed-form evolution equation for a low-rank time-dependent basis that evolves with the dynamics. An on-the-fly reduction of the dynamical system is then obtained by projecting the full-dimensional system onto the low-rank basis. The presented method is compared against the state of the art Dynamically Orthogonal (DO) method and Bi-Orthogonal (BO) method for highly ill-conditioned cases. In particular, we demonstrate that the presented method preserves the accuracy of the solution and the shape of the modes as the system passes through a low eigenvalue phase. The results for several demonstration cases are presented, including linear advection equation, stochastic Burgers’ equation and stochastic flow in a channel.

Least-Squares Petrov–Galerkin Reduced-Order Models for Hypersonic Flight Vehicles
PETER BLOM, PATRICK BLONIGAN, Sandia National Laboratories, FRANCESCO RIZZI, NexGen Analytics, MICAH HOWARD, JEFF FIKE, KEVIN CARLBERG, Sandia National Laboratories — High-speed aerospace engineering applications rely heavily on computational fluid dynamics (CFD) models for design and analysis due to the expense and difficulty of flight tests and experiments. This reliance on CFD models necessitates performing accurate and reliable uncertainty quantification (UQ). However, it is very computationally expensive to run CFD for highly grid resolution cases. Additionally, UQ methods are many-query problems requiring many runs with a wide range of input parameters. One way to enable computationally expensive models to be used in such many-query problems is to employ projection-based reduced-order models (ROMs) in lieu of the (high-fidelity) full-order model. In particular, the least-squares Petrov-Galerkin (LSPG) ROM (equipped with hyper-reduction) has demonstrated the ability to significantly reduce simulation costs while retaining high levels of accuracy on a range of problems including subsonic CFD applications. This work presents the first application of LSPG to hypersonic CFD problems including the Blottner sphere and HiFIRE experimental flight vehicle. This shows the ability of LSPG ROMs to significantly reduce computational costs while maintaining high levels of accuracy in computed quantities of interest.

Session H42 Boundary Layers: Multi-scale Roughness and Secondary Flows

8:00AM H42.00001 Time-varying secondary flows in turbulent boundary layers over surfaces with spanwise heterogeneity
1, DEA WANGSAWIAYA, KEVIN KEVIN, DANIEL CHUNG, IVAN MARUSIC, NICHOLAS HUTCHINS, The University of Melbourne — Secondary flows form in turbulent flow over surfaces with spanwise heterogeneity. In this study, we use surfaces comprised of spanwise alternating smooth and rough (P-36 grit sandpaper) strips to investigate the behaviour of these secondary flows for various strip widths. PIV measurements are performed on the wall-parallel plane above surfaces with various strip widths $S$ ($0.3 \leq S/\delta \leq 3.6$), where $\delta$ is the spanwise-averaged boundary layer thickness. We find that, when $S/\delta \approx 1$, these secondary flows not only strengthen but also exhibit a pronounced unsteadiness. This unsteadiness is consistent with a fluctuating from side-to-side of large-scale streaks with a streamwise wavelength of 3-4f.

8:13AM H42.00002 Turbulent wall flows over spanwise-heterogeneous surfaces: non-periodic deviation from Reynolds-averaged flow patterns
WILLIAM ANDERSON, UT Dallas — Turbulent flows respond to bounding walls with a predominant spanwise heterogeneity – that is, a heterogeneity parallel to the prevailing transport direction – with formation of Reynolds-averaged turbulent secondary flows. These secondary flows constitute manifestation of Prandtl’s secondary flow of the second kind: driven and sustained by spatial heterogeneities in the Reynolds (turbulent) stresses. Results from large-eddy simulations and complementary experimental measurements of flow over spanwise-heterogeneous surfaces are shown: the resultant secondary cell location is clearly correlated with the surface characteristics, which ultimately dictates the Reynolds-averaged flow patterns. However, results also show the potential for instantaneous sign reversals in the rotational sense of the secondary cells. This is accomplished with probability density functions and conditional sampling. In order to further this, a base flow representing the spanwise rolls is introduced. Upon substitution of the base flow into the streamwise momentum and streamwise vorticity transport equations, and via use of a vortex forcing model, we assess phase-space evolution (orbit) of the resulting system of ordinary differential equations. The system resembles the Lorenz system, but the forcing conditions differ intrinsically. Nevertheless, the system reveals that chaotic, non-periodic trajectories are possible for sufficient inertial conditions.

8:26AM H42.00003 Extending the restricted nonlinear model to flow over rough surfaces with spanwise heterogeneities
1, XIAOWEI ZHU, BENJAMIN MINNICK, DENNICE GAYME, Johns Hopkins University — The restricted nonlinear (RNL) model has shown success in accurately predicting statistical features of smooth wall-turbulence. The RNL equations are obtained by decomposing the Navier-Stokes equations into a streamwise-averaged component and streamwise-varying perturbations, and then restricting the nonlinearity in the perturbations. The resulting dynamics are supported by a small number of streamwise varying modes ($k \times w$ wave numbers) interacting with the streamwise constant mean flow. In this work, we extend the RNL modeling paradigm to rough walls by first determining the streamwise wave number support that correctly predicts the log-law behavior associated with rough wall flows. We demonstrate that the parametrization can be obtained analogously to the smooth-wall case, where it was shown that the particular streamwise varying modes required to correctly reproduce low-order statistics and spectra at low and moderate Reynolds numbers are associated with the outer-layer peak of the surrogate dissipation spectra. Comparisons of DNS and RNL simulations over riblets at various spanwise spacing using an immersed boundary method indicate that the properly parameterized rough-walled RNL model reproduces low-order statistics and spanwise energy spectra reminiscent of the DNS data.

8:39AM H42.00004 Effect of roughness texture on transient, accelerating channel flows. SAI CHAITANYA MANGAVELLI, JUNLIN YUAN, GILES BRERETON, Michigan State University — The effect of surface roughness on non-equilibrium, accelerating wall turbulence is studied using direct numerical simulation of transient periodic channels. The smooth-wall base case is compared with two irregular rough surfaces: i) a small-wavelength sand-grain roughness and ii) a multiscale turbine-blade roughness. The flow is accelerated from a bulk Reynolds number of 3000 to 12000 in a short time interval, rendering the rough-wall flows transitionally-rough to fully-rough. The smooth wall undergoes reverse transition towards a laminar-like state with quasi-1D turbulence, being replaced by a new equilibrium state. In contrast, near a rough wall a more isotropic Reynolds stress tensor and a higher friction coefficient are observed. This is mainly due to the fast responses of the form-induced Reynolds-stress production and pressure work to the increased shear, both contributing significantly to higher Reynolds-stress isotropy. As the characteristics of the form-induced fluctuations are important for these mechanisms, the roughness texture determines the initial rate of turbulence response. Results show that the roughness geometry is important in a non-equilibrium turbulence over a rough wall.

8:52AM H42.00005 Secondary flow structure development in multi-scale rough wall turbulent boundary layer. NASEEM ALI, JULIANTA BOSSUYT, BIANCA VIGGIANO, Portland State University, BHARATHRAM GANAPATHISUBRAMANI, University of Southampton, JOHAN MEYERS, KU Leuven, RAUL CAL, Portland State University — Fluid motions in the narrow slits between the cubical roughness elements are resolved. We find pairs of relatively small-sized counter rotating rollers triggered by a Kelvin-Helmholtz type instability. Measurements are used to characterize changes in the mean profile and turbulence statistics, and to test for the emergence of spanwise-coherent disturbances. As Reynolds number increases, the turbulence statistics change, and the flow undergoes a large transition from the low-Reynolds stress state to a high-Reynolds stress state. The new transition mechanism is found to be a combination of large-scale ejections that carry energy from the boundary layer to the outer region. The results are relevant to the prediction of drag and boundary layer development over urban surfaces and roughness transition in the presence of secondary flows.

9:05AM H42.00006 Turbulent boundary layer development over a step change in multiscale roughness. JOHN LAWSON, BHARATHRAM GANAPATHISUBRAMANI, University of Southampton — We examine the development of the turbulent boundary layer across a step-change transition between four different three-dimensional, multiscale, cuboidal roughness surfaces. We collected wind-tunnel measurements of the flow above the canopy in spanwise stereo-PIV planes at 72 streamwise locations up- and downstream of the transition, as well as direct measurements of the skin-friction drag immediately downstream of the transition. This extensive dataset allows us to quantify the development of the resultant internal boundary layer in terms of its mean velocity profile, Reynolds and dispersive stresses, using true repeating-unit averaging. In addition, we compare measurements of surface drag to estimates from a recently-developed morphometric drag prediction model (Yang et al. 2016). Our findings are relevant to the prediction of drag and boundary layer development over urban surfaces and roughness transition in the presence of secondary flows.

1EPSRC EP/P021476/1

9:18AM H42.00007 On the interaction of streamwise vortices with surface textures. SAIKISHAN SURYANARAYANAN, DAVID GOLDSMITH, The University of Texas at Austin, GARRY BROWN, Princeton University, ALEXANDRE BERGER, EDWARD WHITE, Texas AM University — Recent studies (Suryanarayanan et al., AIAA 2017-4417, AIAA 2018-3077) have demonstrated the possibility of mitigating roughness induced transition using surface textures that can dissipate the streamwise vortices responsible for the lift-up effect. In order to identify the optimal surface texture geometry, a fundamental investigation into the effect of surface textures on the evolution of a streamwise vortex in a boundary layer is performed. This study involves a combination of scaling arguments (of the enstrophy flux transport equation) and direct numerical simulations of a single streamwise vortex in a laminar boundary layer with different (2D) surface textures. The results are analyzed from a vorticity dynamics point of view. The effects of local flow acceleration and enhanced dissipation are separately studied using appropriate synthetic simulations. Simple models are suggested and connections are made to previous work on the evolution of perturbations over wavy walls. Supporting wind tunnel experiments that study the development of streamwise vortices generated by micro vortex generators in the presence of surface textures will be presented. Applications to cross flow instability and other technologically relevant scenarios will be discussed.

9:31AM H42.00008 Measurements in turbulent boundary layers over designed anisotropic porous materials. CHRISTOPH Efstathiou, MITUL Luhar, University of Southern California — This talk describes the design and testing of anisotropic porous media with directional resistance as a means to control the development of the turbulent boundary layer. A high-resolution stereolithographic 3D printer is used to manufacture a substrate with higher streamwise than wall-normal permeability ($\phi_{xy} > k_{xx}$). Such streamwise-preferential materials have demonstrated potential for passive turbulence suppression and drag reduction. Measurements are made using a Particle Image Velocimetry system in a high-speed wind tunnel in a large-scale water channel facility. The friction Reynolds number is varied between $Re_f \approx 200$ to $Re_f \approx 2000$. Measurements are made using a time-resolved Particle Image Velocimetry system and a 2-component Laser Doppler Velocimeter mounted on a precision traverse. These velocity measurements are used to characterize changes in the mean profile and turbulence statistics, and to test for the emergence of spanwise-coherent rollers triggered by a Kelvin-Helmholtz type instability.

9:44AM H42.00009 Cube-roughened surfaces at high and extreme packing densities. HAOSEN XU, XIANG YANG, The Penn State University — We study turbulent channel flows with rough walls comprised of aligned arrays of cubic roughness elements at high surface coverage densities ($\lambda$). Specifically, we carry out direct numerical simulations (DNS) at $\lambda = 0.5 \sim 0.9$. Fluid motions in the narrow slits between the cubic roughness elements are resolved. We find pairs of relatively small-sized counter rotating vortices in between and above the cubes at moderately high packing densities, i.e., $\lambda = 0.5 \sim 0.7$. These vortices are replaced by large ones above each cube when surface coverage is high ($\lambda \leq 0.8$). Last, we will compare our DNS to wall-modeled LES, which is a more affordable tool than DNS at high Reynolds numbers. For the flows considered, WMLES compare reasonably well with the DNS, although noticeable differences in the roughness occupied layer is found.
10:10AM H42.00011 Three-dimensional measurements of flow structure and turbulence around a pair of cubic roughness elements embedded in the inner part of a turbulent channel. JIAN GAO, JOSEPH KATZ, Johns Hopkins University — The 3D flow and turbulence around a pair of roughness cubes embedded in the inner part of a turbulent channel flow (Re = 2500) are measured using microscopic tomographic holography accelerated using GPU-based algorithms. The cube height, a = 1 mm, is 90 wall units. The cubes decrease the near-wall velocity and generate secondary flows as far as 3a upstream. Horseshoe vortices form at the front surface, and propagate asymmetrically around the cubes, generating secondary vortices along the side surfaces. Each cube and its near wake are engulfed by a vortical canopy dominated by wall-normal vorticity along the sides and spanwise vorticity above the cube. Merging of the “tip vortices” developing along the cube upper edge, horseshoe and secondary vortices occurs downstream at locations that decrease with the spacing. They form a large streamwise vortex behind each cube, which rotates in the same direction as the inner leg of the horseshoe vortex. With decreasing spacing, the flow accelerates faster between cubes, but also decelerates faster in the near wake. Streamwise velocity fluctuations of 40% of the freestream velocity and negative Reynolds shear stress develop near the front upper corner of the cube. The turbulence remains high around the entire surface and near wake.

10:23AM H42.00012 Experimental flow characteristics over different area density roughness. Kwonho Park, HEECHANG LIM, Pusan National University — In this study, we aim to observe the flow and surface pressure characteristics over a variety of roughness pattern in a boundary layer wind tunnel. For each roughness element, the cuboid shape was chosen and size 50x50x50mm3. The atmospheric boundary layer (hereafter, ABL) has an important role of exchange and transfer in momentum flux at ground level. The roughness sub-layer (RS), the lower part of ABL, is usually 2 times thicker than the building height, and the urban canopy layer (UCL) was the same as the building height. Therefore, this study performed experimentally the generation of boundary layer in a wind tunnel and observed the flow characteristics of boundary layer and the surface pressure distribution around each roughness. Besides, to observe the effect of the roughness pattern, changes in area density of surface roughness were made by 11, 17, and 25%, of boundary layer in a wind tunnel and observed the flow characteristics of boundary layer and the surface pressure distribution around each roughness. In addition, the surface pressure at top face becomes higher as area density increases, whereas the pressure on the back remains almost constant regardless of area density. In addition, the surface pressure at top face becomes higher as area density increases.

Monday, November 25, 2019 11:00AM - 11:35AM — Session J01 Invited Talk: Impact of Wettability on Multiphase Flow and Granular Mechanics: Experiments, Modeling and Theory 6b - Gareth McKinley, MIT

11:00AM J01.00001 Impact of Wettability on Multiphase Flow and Granular Mechanics: Experiments, Modeling and Theory. RUBEN JUANES, Massachusetts Institute of Technology — Many natural subsurface processes involve the interaction between multiphase flow and deformation of porous media like rocks and soils. Examples include hydraulic fracturing, induced seismicity from fluid injection, and subsidence from groundwater extraction, just to name a few. In some cases, capillary effects can control surface tension force, and in some cases there is a fundamental role in the fluid-solid interaction. Here, we report some recent observations on how, in these cases, the flow and deformation are strongly modulated by wettability, which is the relative affinity of each fluid to the solid making up the porous medium. These observations are surprising and intriguing, but a mechanistic explanation has heretofore remained elusive. Here, we present a fully-coupled dynamic model of granular mechanics and multiphase flow at the pore scale, which explicitly incorporates the impact of wettability. This mechanistic model allows us to explore the rich emerging behavior as a function of different parameters, such as capillary number, contact angle, initial packing density, and grain rigidity. Beyond the suggestive predictions of pattern formation, the model also hints at the origin of the transitions between patterns. We reconcile the rich behavior we observe in terms of a jamming transition, which opens a promising way to understand novel aspects of wet granular systems.

Monday, November 25, 2019 11:00AM - 11:35AM — Session J02 Invited Talk: Unsteady aerodynamic response of rigid wings in gust encounters 6c - Beverly McKeon, Caltech

11:00AM J02.00001 Unsteady aerodynamic response of rigid wings in gust encounters. ANYA R. JONES1, University of Maryland, College Park — Controlled flight in unsteady environments presents a challenge that has gained interest in recent years. Unsteady flight conditions exist in many scenarios including urban areas, airwaves, and extreme weather. In cases such as these, large force transients on wings and other lifting surfaces occur due to rapid variations in effective angle of attack resulting in flow separation and the formation of large-scale vortices. The growth and motion of these vortices can have a large impact on the resulting force transient and recovery, and often requires advanced control either locally via flow control or more globally at the vehicle level. Current research efforts focus on the effect of large wind gusts that result in changes to the relative flow that are of the same order of magnitude as the freestream flow. In these large-amplitude gust encounters, flow separation is significant, so the classical linear solution for the flow does not apply. Separated shear layers emanating from the wing tend to roll up into leading and trailing edge vortices that are shed into the wake. The formation and motion of these vortices are characterized via a series of canonical experiments in an attempt to better understand their contribution to aerodynamic forcing.

1:58PM L01.00002 Transport of gas mixtures in a Knudsen pump with specular and diffuse walls, TOBIAS BAER, STEFFEN HARDT, Institute for Nano- and Microfluidics, TU Darmstadt, Germany — Gas flow in Knudsen pumps is induced by thermal gradients in channels or pores when the mean free path of the gas molecules is comparable to the geometric feature size. While thermal transpiration is often associated with flow along pores with a net axial temperature gradient, flow can also be induced by imposing a temperature difference across the channel, when suitably structured walls induce a periodic but non-mirror-symmetric temperature profile along the channel. One such arrangement, inspired by the Crookes radiometer, consists of placing an array of plates with different reflection properties on their opposing sides along a channel. By direct simulation Monte Carlo (DSMC) we investigate the transport of gas mixtures along such channels, focusing on the discrimination of individual species in the mixture by molecular size and mass during flow due to temperature, composition and pressure gradients. As Knudsen pumps do not possess any moving parts, they lend themselves for operation in low-maintenance situations such as for feeding gases to sensor surfaces. The observed discrimination of different gas species may thus adversely or favorably influence the overall detection characteristic of such a combined device.

2:11PM L01.00003 Soot chemical pathways under elevated pressures in co-flow ethylene flames, SUO YANG, DEZHI ZHOU, HONGYUAN ZHANG, University of Minnesota — Internal combustion engines and gas turbines are operating under high pressures. One of the major concerns in high pressure combustion is its high soot yield, which was found in many sooting flame experiments. Specifically, the maximum soot volume fraction increases with the increasing pressure, with the dependence of soot on pressure weaker as pressure is further increased. To explain the dependence of soot on pressure, most of the experiments attribute this phenomenon to higher temperature, steeper precursor concentration gradients, and increased gas density. However, an exact and comprehensive mechanism behind this phenomenon, from a chemical kinetics perspective, is still elusive. In this study, a series of pressurized (from 1 to 16 atm) co-flow ethylene diffusion flames are simulated with detailed finite rate chemistry. The soot evolution is described by the bivariate Hybrid Method of Moments (HMM). The experimental maximum soot volume fraction in the flames are reproduced by the simulations. Most importantly, the Global Pathway Analysis (GPA) is conducted to reveal the dominance and sensitivity of soot chemical pathways under elevated pressures.

2:24PM L01.00004 Influence of Temperature and Dilution on Final Soot Nanostucture, JUSTIN DAVIS, IGOR NOVOSSELOV, University of Washington — Morphological evolution of nascent to mature combustion-generated particles is of interest due to changes in particle optics, chemical composition, and their effect on human health. In this work, the nanostructure of primary soot particles is investigated using argon dilution in laminar ethylene, ethane, and methane flames. A co-flow reactor oriented downwards allows for precise control on combustion conditions due to increased flame stability brought on by competing buoyant and convective forces. The dilution is varied from 0% to 90% by volume to investigate particle formation in temperature ranges from 1500 to 1950 K. High-resolution TEM displays different levels of particle maturity, from young soot with minimal order to mature particles with a core-shell nanostructure. A novel image processing algorithm helps to quantify differences in soot nanostructure, indicating the molecular weight of PAHs is similar for young and mature soot. However, molecular curvature decreases, suggesting the driving factor of soot maturity is a reduction in steric hindrance due to carbonization kinetics at high flame temperatures. These results can be used for validation of soot modeling approaches and to improve the understanding of structural changes as soot particles traverse the flame front.

2:37PM L01.00005 ABSTRACT WITHDRAWN — 

2:50PM L01.00006 Experimental investigation of solid fuel smoldering using 3D X-ray computed tomography with gas-phase temperature measurements, EMERIC BOIGNE, MATTHIAS IHME, Stanford University — Smoldering is a regime of combustion that is characterized by low temperatures, slow rates of fuel consumption, and the absence of a flame. Recent research investigations on smoldering have focused on applications within confined environments such as peat fires, subsurface wildfires, and remediation of soil contamination. The present work reports on the use of 3D X-ray computed tomography to experimentally investigate smoldering in confined configurations. By temporally resolving the surface recession of solid fuel materials, the local consumption rates are extracted at the submillimeter scale. By diluting the ambient flow with Krypton, an inert X-ray tracer, the X-ray measurements enable simultaneous estimations of the 3D gas-phase temperature field. First, a configuration within an over-ventilated environment is considered for validation. Then, more complex fuel-configurations are examined, exhibiting spatial fuel heterogeneities and different fuel materials. Effects of the spatial heterogeneities on the smoldering process are discussed using the temporally-resolved 3D measurements. The simultaneous measurements of local consumption rate and gas-phase temperature allow further investigations of state-of-the-art models of smoldering.

3:03PM L01.00007 Experimental Investigation of Combustion in Porous Media Burners with Tailored Matrix-Structure Using Additive Manufacturing, PRIYANKA MUNHUNTHAN, SADAF SOBHANI, EMERIC BOIGNE, DANYAL MOHADDES, MATTHIAS IHME, Stanford University — Porous Media Burners (PMBs) have been shown to enable enhanced burning velocities, extend flammability limits, and lower emissions. In this study, the viability of 3D printing complex ceramic structures is examined, and the performance of a novel functionally graded PMB design is investigated. Three different alumina matrix foams were designed and printed using lithography-based ceramic manufacturing. The flame stability, temperature profiles, and pressure drop for each burner are examined. X-ray computed tomography is used to characterize the printed matrix structure and to obtain important geometric information about pore diameter and porosity profiles. This work builds upon previous experimental investigations into graded PMBs, and the results demonstrate the feasibility of using additive manufacturing for tailoring PMB topologies to achieve specific system requirements.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L02 Multiphase Flows: Modeling and Theory II 2B - Duan Zhang, Los Alamos National Laboratory
1:45PM L02.00001 High-Fidelity Simulation of a Rotary Bell Atomizer with Electrohydrodynamic Effects, VENKATA KRISSHNA, MARK OWKES, Montana State University — Rotary Bell Atomizers (RBA) are extensively used as paint applicators in the bell competitive industry. Atomization of paint is achieved by a bell cup rotating at high speeds (40k-60k RPM) and in the presence of a background electric field. Current estimates report a maximum paint transfer efficiency of only 60%. The atomization process in an RBA affects the droplet size and velocity distribution which subsequently control the transfer efficiency and surface finish quality. Moreover, optimal spray parameters used in industry are often obtained from expensive trial-and-error methods. In this work, a computational approach is used to simulate three-dimensional near-cup flows (mainly primary and secondary breakup) using a high-fidelity volume-of-fluid transport scheme that includes the effects of Electrohydrodynamics (EHD). This work involves the use of two meshes, one to solve the Navier-Stokes equations in the atomization region and a second on a larger region to solve for the electric field with realistic boundary conditions. This research aims to develop a cost-effective method to investigate the influence of various flow characteristics on the atomization and breakup processes of the liquid.

1:58PM L02.00002 An Eulerian-Eulerian CFD Study of Surface Wetting at Different Richardson Numbers in Dispersed Oil-Water Pipe Flow, JAKOB ROAR BENTZON, JENS HONORE WALther, Technical University of Denmark — An Eulerian-Eulerian two-phase CFD model has been employed to investigate the variation of dispersion and liquid holdup in the horizontal section of wells used for oil production under operating conditions with water-cut ranging from 25-75%. The employed model uses a 5-gamma droplet distribution model to estimate droplet sizes based on statistical moments with breakup and coalescence models. The model has been validated against experimental measurements with good accuracy on phase distribution but challenges obtaining correct droplet sizes. Consequently, the model is used to study different flow conditions, namely at varied Richardson numbers through changing the Froude number and the Atwood number separately. From the results, it is observed that similarly to what is seen in the Kelvin-Helmholtz instability, a higher Richardson number reduces mixing of the interface and thus decreases the rate of dispersion. Eight differences in the results from varying the Atwood number and the Froude number to same Richardson numbers are observed on both dispersion and liquid holdup.

2:11PM L02.00003 Thermal and Fluid Dynamics of Snow vs. Rain at the Air-Water Interface, MEHDI VAHAB, Kourosh ShoELE, Florida State University, DAVID MURPHY, University of South Florida — The effects of precipitation in the forms of rain, snow, and hail are studied using computational methods for multimaterial/multiphase systems. The comparison of single droplet impacts shows the phase-dependency (a liquid or solid droplet) of the momentum and energy transfer to the surface and body of water. The depth of penetration and the resultant vertical flow are found highly dependent on the phase-change rate of the droplet. Multiple models of snow particles with systematic geometrical complexities are tested for the role of shape in air pocket entrapment at the impact. The sensitivity of the single droplet impact dynamics is also studied by varying droplets size and temperature, and are used for investigation of the precipitation events with the average ensemble effects of multiple droplet impacts. The size and velocity of the droplets are set based on the observed size/velocity distribution of frequent rain, hail, or snow events. A predictive model is developed to predict the changes in the water surface and body energy content following each precipitation event.

2:24PM L02.00004 Assessment of surfactant models with applications to crude oil-water coalescence or aggregation modeling, SHAOLIN MAO, Engineering Department, University of Jamestown, ND — We study surfactant models with focus on crude oil — sea water aggregation/coalescence analysis and modeling. Undesired crude oil-water emulsion exists in most crude oil production and recovery process; therefore, costly process such as destabilizing of oil-water emulsion in petroleum engineering is required from reservoirs, wellbores, to wellheads and transport of crude oil. This research is limited to physics of coalescence or aggregation of water in oil mixing (crude oil is the dominant phase). Parameter studies will be conducted in this work to assess surfactant models, elucidate the factors which influence the aggregation/coalescence of crude oil-sea water mixing process. Numerical simulation is based on commercial CFD tool such as ANSYS FLUENT by using population balance model (PBM) coupling with CFD solvers. Experimental observation and comparison will also be given.

2:37PM L02.00005 Manipulating gas-assisted atomization by inlet gas turbulence, DELIN JIANG, YUE LING, Baylor University, DANIEL FUSTER, STEPHANE ZALESKI, Sorbonne Universites, GRETAIR TRYGGVASON, Johns Hopkins University — In an airlift atomization process, the destabilization and breakup of a liquid jet is assisted by a co-flowing high speed gas stream. Recent experiments and simulations show that the inlet gas turbulence has a strong impact on the interfacial instability development near the nozzle exit and also the liquid breakup downstream. In this study we will systematically investigate the effect of inlet gas turbulence on the interfacial instability and spray formation through high-fidelity simulation. The gas-liquid interface is resolved by a momentum-conserving volume-of-fluid method. A digital filter approach is used to generate temporally and spatially correlated velocity fluctuations at the gas inlet. The dominant frequency and spatial growth rate of the mixing layer are observed to increase significantly with the inlet gas turbulence intensity. The dominant frequency predicted by simulations are in a good agreement with the experimental data. Spatial-temporal viscous linear instability analysis is also conducted using the eddy-viscosity model. The simulation results also reveal the change of dominant breakup mechanism when gas inlet turbulence is present.

2:50PM L02.00006 Sloshing and its effects on thermal mixing in aircraft fuel tanks, CONNOR ROHMANN-SHAW, DUNCAN BORMAN, MARK WILSON, University of Leeds — Modern aircraft designs are becoming ever more complex, with higher demands on their performance capabilities. As the thermal loads from the airframe, engine, electrical systems etc. increase, one of the key challenges is thermal management. A solution is to use the fuel as a coolant; fuel is used as a heat sink for components around the aircraft and then recirculated back into the fuel tanks. To fully optimise this method however we must expand upon existing thermal management models by better understanding the thermal mixing process internal to the fuel tanks, with particular attention given to the role of fuel sloshing. The multi-phase Volume of Fluid method of free-surface tracking is used to predict fluid motion, which we couple to the thermal flow field using the Boussinesq approximation. Using these numerical simulations, we investigate the effect that sloshing has on thermal mixing, allowing us to inform future design considerations. Experiments undertaken using thermocouples to measure the evolution of the temperature field in a turbulent free-surface flow will also be presented.

Effect of inertial forces on constitutive behaviors of the RVE granular model

We are grateful to the financial support from Los Alamos Machine Learning Program.
2:37PM L03.00005 A proprioceptive robotic swimmer. — MEDERIC ARGENTINA, JESUS SANCHEZ RORIDGUEZ, CHRISTOPHE RAUFASTÉ, Université Cote d’Azur, Nice France — In the context of fish locomotion, Lighthill proposed in 1971 his elongated body theory to predict the swimming gait [1]. Since his seminal article, the swimming velocity has been related to the fin kinematics (tail-beat amplitude and frequency) through the Strouhal number [2], which is found to be constant over 6 decades of Reynolds number for natural swimmers [3]. This result can be accounted for by a simple force balance, but the selection mechanism of the fin kinematics is still poorly understood. Here, we propose that the swimming locomotion might be driven by a proprioceptive feedback, which determines the tail-beat amplitude and frequency. A robotic fish has been built to test this mechanism and we will present our last results.

2:50PM L03.00006 Empirical generalizations for swim speed and endurance of sturgeon species — CHRISTOS KATOPODIS, Retired, LU CAI, Institute of Hydroecology, Ministry of Water Resources and Chinese Academy of Sciences, Wuhan 430079, China, RICHARD GERVAIS, Freshwater Institute, Fisheries and Oceans Canada, Winnipeg R3T 2N6, Canada — Swim performance data of various fish species ranging from prolonged (low) to burst (high) speeds are useful for both theoretical hydrodynamics and ecophysical applications, such as fish passage. Commonly such data are collected with experimental tests, are limited to fish speed and endurance for a small percentage of species, and are insufficient for variables such as tailbeat frequency. Limited data are available for the Sturgeon species, especially for burst speeds, and dimensionless variables use them more effectively. Robust regressions for several groups of species, as well as sturgeon, are obtained with a dimensionless fish speed, expressed in the form of a fish Froude number which does account for fish length. Regressions improve with dimensionless variables, including fish speed expressed as a fish Reynolds number, compared to traditional measures such as body lengths/s. Such regressions demonstrate swim performance similarity in sturgeon and other fish groups, offer empirical data generalizations, data collection strategies, and help validate biomimetic simulations.

3:03PM L03.00007 Impact of hydrodynamics of porous and non-porous structures on upstream fish passage performance1 — STEPHANIE MUELLER, ELIZABETH FOLLETT, CATHERINE WILSON, PABLO OURO, JO CABLE, Cardiff University — Flow visualization and velocity measurements using ADV were used to assess upstream and wake flow characteristics of non-porous and porous structures made of wooden dowels. Upstream of the structure, flow becomes diverted towards the bed with higher downwards vertical velocities for the non-porous case. A turbulent wall jet formed beneath, showing higher flow acceleration with decreasing porosity, leading to stronger turbulent momentum exchange through the shear layers in the wake. Behind the non-porous structure a larger recirculation area formed. At the downstream edge of the structure, turbulent kinetic energy (TKE) was larger for the non-porous case, with highest levels found approximately at mid-structure height. In the porous cases, two peaks in TKE occurred at the trailing edge of the lowest dowel, due to inter-dowel wake effects. Swimming behavior observations of rainbow trout (Oncorhynchus mykiss) revealed fish spent time beneath the structure, likely to avoid the high momentum jet. With increasing structure porosity, fish preferred to swim in the structure’s wake due to reduced mean velocities and turbulent fluctuations near the bed. These observations indicate that porous and non-porous structures create heterogeneous habitats, influencing fish behavior.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L04 Focus Session: Probing Multi-scale Flows by Coarse-graining 203 - Nicholas T. Ouellette, Stanford

1:45PM L04.00001 Gaining “insight” by blurring one’s “sight”. — HUSSEIN ALUIE, University of Rochester — Coarse-graining (CG), which is equivalent to observing flows through eyeglasses of varying strength, provides a powerful yet intuitive approach to analyze and understand multiscale flows. This is because it allows for resolving the dynamics simultaneously in scale and in space, at every instant in time, and without requiring assumptions of homogeneity or isotropy, making it ideal to probe complex non-canonical flows that are unsteady, inhomogeneous, anisotropic, and multi-phase. With examples from plasma, oceanic, and variable-density flows, I will illustrate some of the advantages CG has over traditional tools such as Reynolds averaging, structure functions, and Fourier analysis. I will discuss a new method based on CG to extract the spectrum, including that of non-quadratic quantities such as kinetic energy in variable density flows, self-consistently, which the Fourier spectrum and the wavelet spectrum cannot. I will also discuss the emergence of new invariants in MHD and in compressible turbulence which can be unraveled by the proper scale-decomposition based on CG. Finally, I will present a generalization of CG to spherical domains, allowing for the analysis of scale-processes in oceanic flows from satellites.

1:58PM L04.00002 Enhanced Spectral Transfer in Weakly Mixing Regions of a Turbulent Flow1 — LEI FANG, NICHOLAS OUELLETTE, Stanford University, SANJEEVA BALASURIYA, University of Adelaide — Scale-to-scale spectral energy flux is a hallmark of turbulent flows. The geometric alignment of small-scale turbulent stress and large scale rate of strain leads to the net flux of energy from small scales to large scales in 2D turbulence. We have found, however, that the instantaneous alignment between these two tensors is surprisingly weak, and thus that the spectral transport of energy is inefficient. In our experimental work, we have shown that the strain rate is much better aligned with the stress at times in the past, suggesting that the differential advection of the two is responsible for the inefficient spectral transfer. Based on this understanding, we developed a tool to specifically look for weakly mixing regions in the flow based on the linearity this implies, which we term Linear Neighborhoods (LN). We demonstrate that these LN’s are computable in real data using experimental measurements from a 2D turbulent flow. Consistent with our previous results, we find that that the spectral energy flux behaves differently inside the LN’s, where the spectral energy flux is more efficient. Our results add additional support to the conjecture that turbulent flows locally tend to transport energy and momentum in space or between scales but not both simultaneously.

2:11PM L04.00003 Baroclinic Energy Transfer in the Ocean

The role of baroclinicity, which arises from the misalignment of pressure and density gradients, is well-known in the vorticity equation, yet its role in the kinetic energy budget has never been obvious. Ref. [1] has recently shown that baroclinicity appears naturally in the kinetic energy budget after carrying out the appropriate scale decomposition. Here, we extend the coarse-graining decomposition to study this process within the shallow water model and apply it to numerical simulations as well as satellite data. [1] A. Lees and H. Aluie, Fluids 4, 92 (2019).

2:24PM L04.00004 Eigenframe alignment dominates scale-to-scale energy fluxes in turbulence

In large-eddy simulation, the cascade is cut off at a certain scale and the transfer term to smaller scales is modeled. This transfer term depends on the eigenvalues of the turbulent stress and resolved strain-rate tensors and the Euler angles between their eigenframes. In a typical Smagorinsky closure, two assumptions are made: these angles are set to zero and the stress eigenvalues are modeled as scaled version of the stress. We show that it is the Euler angles that have a much larger effect on the transfer in terms of the directionality of the cascade and its efficiency.

2:37PM L04.00005 Filter-width and Atwood number effects in filtered homogeneous variable density turbulence

We investigate Atwood number (A) and filter width (w) dependence in filtered DNS of buoyancy-driven homogeneous variable density turbulence, where density differences affect mixing and turbulence, and we discuss implications for modeling. We show that statistics and budgets of filtered fields transition smoothly between DNS and RANS fields and budgets, and we discuss these transitions in the context of flow length scales. At small w, filtered fields tend to DNS fields and the large-scale flow kinetic energy (k1) budget tends to the total kinetic energy (k2) budget, at large w, filtered fields approach RANS fields and k1 approaches the mean kinetic energy (k0) budget. At intermediate w, the k1 budget has dissipation and pressure-dilatation work terms from the k1 budget, a mean pressure gradient term from the k0 budget, a production term from both the k1 and k0 budgets, and work by residual stresses against the filtered shear $\varepsilon_k$, which tends to zero at both limits. Work by mean pressure gradients and by $\varepsilon_k$ exhibit density dependent back-scatter: at high A, $\varepsilon_k$ back-scatter occurs mainly in liquid. Statistics of filtered fields, normalized by their RANS counterparts, smoothly and monotonically vary between 0 and 1 as w varies from dx to domain size, and the dependence on w is different for different quantities.

2:50PM L04.00006 Data-driven coarse-grained modeling for polymers

Iao Pan, University of Wisconsin-Madison — We present a data-driven coarse-graining method to establish coarse-grained (CG) modeling for polymers, which conserves both static and dynamic properties of the fine-grained (FG) system. The dynamics of the CG system is governed by the generalized Langevin equation (GLE) derived via the Mori-Zwanzig formalism, by which the CG variables can be directly linked to the statistics of FG data. The effect of unresolved degrees of freedom on the kinetics of polymers can be captured by the non-Markovian stochastic dynamics in GLE, where the memory kernel is determined from the FG data. To circumvent the difficulty of directly solving the GLE with memory term and colored noise, we exploit the equivalence between the non-Markovian dynamics and Markovian dynamics in an extended space. To this end, the CG system is supplemented with auxiliary variables that are coupled linearly to the momentum and among themselves, subject to uncorrelated Gaussian white noise. For several different polymer systems in melts or in solution, we demonstrate that the established CG modeling can reproduce both static and dynamic properties of the reference FG system.

1NSF grant CMMI-1761068

3:03PM L04.00007 Is vortex stretching the main cause of the turbulent energy cascade?

Andrew Bragg, Duke University, Maurizio Carbone, Polytechnic University of Turin — While the dominant idea is that in 3D turbulence, the energy cascade occurs through the process of vortex stretching, evidence for this is debated. In the framework of the Karman-Howarth equation, we derive a new result for the average flux of kinetic energy between two points in the flow. The result shows that vortex stretching is in fact not the main contributor to the average energy cascade; the main contributor is the self-amplification of the strain-rate field. We emphasize the need to correctly distinguish and not conflate the roles of vortex stretching and strain-self amplification in order to correctly understand the physics of the cascade, and also resolve a paradox regarding the differing role of vortex stretching on the mechanisms of the energy cascade and energy dissipation rate. Direct numerical simulations are used to confirm the results, as well as provide further results and insights on vortex stretching and strain-self amplification at different scales in the flow. Interestingly, the results imply that while vortex stretching plays a sub-leading role in the average cascade, it may play a leading order role during large fluctuations of the energy cascade about its average behavior.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L05 Shock-Boundary Layer Interactions

1:45PM L05.00011 Low-frequency unsteadiness in a shock wave boundary layer interaction

Roi Baidya, Sven Scharnowski, Matthew Bross, Christian J. Kähler, Bundeswehr University Munich — Large field-of-view (FoV) particle image velocimetry experiments are conducted in the vicinity of a shock wave boundary layer interaction (SWBLI) at Mach 2. The current FoV covers up to 30 boundary layer thicknesses, comprising of upstream and downstream regions relative to the SWBLI, thereby allowing the turbulent boundary layer and shock to be simultaneously captured. The relationship between the boundary layer features and the instantaneous shock location is directly quantified, with the aim of better understanding the mechanisms responsible for oscillation of the reflected shock. Simultaneous wall-pressure measurements indicate that the low-frequency fluctuation arising from the oscillating shock foot is not necessarily an independent phenomenon from the turbulent features entering the SWBLI region and interact with the shock. Instead, a large scale separation between their dominant time-scales is due to dampening of high-frequency content beyond the critical frequency of the globally unstable mode occurring at frequencies that are orders of magnitudes slower than the dominant frequency of the very-large-scale velocity features.

1:58PM L05.00002 Shock-wave boundary layer interactions in an engine intake with a spectral/hp element method.\textsuperscript{1} , GIACOMO CASTIGLIONI, FRANCESCO MONTOMOLI, SPENCER J. SHERWIN, Imperial College London — During take off and climbing, i.e. at high angle of attack and high mass flow rate through the engine, the flow on the upper surface of a nacelle bottom lip can develop a region of supersonic flow. The supersonic pocket terminates with a near normal shock-wave which interacts with the incoming boundary layer leading to a shock-wave boundary layer interaction (SWBLI). The aim is to assess the capability of discontinuous Galerkin spectral element methods in conjunction with an artificial viscosity shock capturing method to predict the onset of SWBLI unsteadiness in complex geometries relevant to industrial applications. Here it is simulated an experimental rig recently investigated by Coschignano et al. The rig is designed around a section of the bottom dead center of a real 3D intake lip, the geometry downstream of the lip is arbitrary and resembles that of an airfoil. Under resolved direct numerical simulations are performed at design conditions which are characterized by an angle of incidence of 23\textdegree and a free stream Mach number $Ma = 0.435$ resulting in a closed, shock-induced, boundary layer separation; the Reynolds number based on lip thickness overlaps the lowest one available experimentally ($Re_x = 4 \times 10^5$).

\textsuperscript{1}The authors would like to thank EPSRC for the computational time made available on the UK supercomputing facility ARCHER via the UK Turbulence Consortium EP/R029326/1 and by the High Performance Computing facilities at Imperial College London.

2:11PM L05.00003 Shockwave Boundary Layer Interaction Control Using External Forcing from Nanosecond Repetitively Pulsed Dielectric Barrier Discharge , RAVICHANDRA JAGANNATH, LALIT RAJENDRAN, GEORGE SCHMIDT, TANBO ZHOU, SALLY BANE, Purdue University — The interaction between shock waves and turbulent boundary layers is an interesting phenomenon in high speed aerodynamics. The presence of a shock wave creates an adverse pressure gradient leading to boundary layer separation. This interaction causes unsteadiness in the flow where the separation bubble oscillates at low frequency and the shock oscillates at broadband frequency. The cause of this unsteadiness still remains unanswered. Some results show an upstream influence, while others have shown the downstream separation bubble causing the unsteadiness. This uncertainty in the unsteadiness mechanism makes it difficult to find an ideal location for an active flow control actuator. In the past, plasma jets, localized arc filaments and quasi-DC discharges have been used to control the shock unsteadiness. In this study, a nanosecond repetitively pulsed surface dielectric barrier discharge is used on a 25\textdegree compression corner in Mach 2.5 flow to create an external perturbation in the upstream turbulent boundary layer ahead of the shock wave. The goal is for the external perturbation to be convected downstream and influence the shock oscillation. A combination of schlieren visualization and wall pressure measurements is used to investigate the effect of plasma actuator on shock unsteadiness. The actuator is placed at different locations upstream of the shock to identify the optimal location. The plasma frequency is also varied to identify the optimal frequency for controlling the shock unsteadiness.

2:24PM L05.00004 Analysis of the effect of elasticity on Shock Turbulent Boundary Layer Interaction\textsuperscript{1} , JONATHAN HOY, IVAN BERMEJO-MORENO, University of Southern California — The effect of elasticity on the unsteady behavior of a shock-turbulent boundary layer interaction (STBLI) is investigated through the use of a coupled fluid structure interaction (FSI) solver which incorporates a wall-modeled large eddy simulation (WMLES) finite-volume flow solver, an undamped finite-element solid mechanics solver, and a mesh deformation solver based on a fictitious spring-system which calculates the change in flow domain mesh geometry as it is deformed by the solid domain. The FSI solver is validated through comparison to the experimental work of Willems et al (2016) and to the LES simulations of Pasquariello et al (2015). In these cases, a supersonic flow at Mach 3 is deflected downward by 20 degrees to create an oblique shock wave that impinges on the turbulent boundary layer developed over a flexible elastic panel (with a Reynolds number of 205,000 based on the boundary layer thickness upstream of the interaction). Parametric studies are then performed to investigate the impact of panel vibration on the STBLI and separation bubble dynamics, varying the panel natural frequencies and shock strength.

2:37PM L05.00005 Mean and Unsteady Characteristics of Swept SBLIs\textsuperscript{1} , SATHYAN PADMANABHAN, JORGE CASTRO MALDONADO, JAMES THREADGILL, JESSE LITTLE, University of Arizona — An experimental study has been conducted on swept impinging oblique shock turbulent boundary layer interactions (SBLIs) generated by 12.5\textdegree shock generators at various sweep angles in Mach 2.3 flow. Mean and unsteady features are examined using oil flow visualization, mean pressure measurements, and high bandwidth pressure transducers. Mean results show the flow is fully separated, and for higher sweep angles, exhibits a spanwise growth of the interaction, displaying a conical behavior away from the inception region. Unsteady pressure measurements reveal low-frequency unsteadiness along the separation shock foot, with reduced amplitude in comparison to similar strength unsept interactions. Separation shock motion is coherent along the span in lower frequencies while spanwise traveling ripples present in the shock foot accelerate from the root towards the tip over the range of 15-25\% of $U_{\infty}$. Minor correlation is observed between shock motion and pressure disturbances directly upstream in the incoming boundary layer, but this becomes negligible when offset in the spanwise direction. This suggests that shock rippling is not driven by upstream disturbances, but instead associated with a time scale inherent to the interaction.

\textsuperscript{1}Air Force Office of Scientific Research (FA9550-15-1-0430)

2:50PM L05.00006 Structure and Unsteadiness of Shock-foot and Separation in a Swept SBLI at Mach 2\textsuperscript{1} , LEON VANSTONE, MUSTAFA MUSTA, NOEL CLEMENS, The University of Texas at Austin — This study examined the structure and unsteadiness of a 3D shock wave / boundary layer interaction (SBLI) generated by a swept compression ramp in a Mach 2 flow. Fast response PSP was used to examine the behavior of the separation shock foot unsteadiness and high frequency PIV data was used to examine the separation line unsteadiness. Shock-foot unsteadiness was broadband, having significant low- ($St_{0.01}$), mid- ($0.01; St_{0.10}$), and high-frequency ($St_{0.10}$) content. Generally, the shock foot contained lower frequency content in comparison to the separation line. In a low-frequency band the behavior of the shock foot was similar to that of the separation line. The mid- and high-frequency band shock-foot unsteadiness was not characteristically similar to the separation location. Many studies examine SBLI unsteadiness using only a single characterising feature (shock foot, separation line, etc.). Our results showed that the shock and separation lines have different characteristic lines. Hence, different features within the SBLI give different characteristic impressions of unsteadiness.

Session L06 Reactive Mixing 205 - Douglas Kelley, University of Rochester

1:45PM L06.00001 Comparing laminar flows for efficient reactive mixing, DANIEL TROYET-SKY, THOMAS D. NEVINS, DOUGLAS H. KELLEY, University of Rochester — As a chemical reaction occurs, a front is formed at the boundary between reacted and non-reacted regions. We wish to quantify the efficiency of reactive mixing by a variety of shear flows by understanding how fronts evolve over time. A more efficient flow causes the reacted region to grow more quickly. To do this we have performed numerical simulations of chemical reactions in the presence of two-dimensional, laminar shear flow using both the one-dimensional Eikonal approximation, which assumes fronts are thin curves with an inherent burning speed, as well as the two-dimensional advection-reaction-diffusion equation, which captures the dynamics of reactant concentration through both space and time. We find that the key factor in improving mixing efficiency is to maximize the absolute velocity difference in the flow. We have also developed an analytical solution to model these front dynamics and have successfully predicted the final front shape and growth rate for six unique flow profiles.

1:58PM L06.00002 Reactive mixing in a shear flow, EMILIE GUILBERT, CHRISTOPHE ALMARCHA, Aix Marseille University, HENRI LHUSSIERS, BLOEN METZGER, CNRS, EMMANUEL VILLERMAUX, Aix Marseille University — We investigate the interaction between chemical reaction and diffusion on a moving substrate and by means of an original chemical reaction between two transparent reactants (fluorescin and potassium ferricyanide) which produce a fluorescent product in water (fluorescein) with tunable kinetics. A blob of fluorescin in a cell filled with potassium ferricyanide is advected in a simple shear flow. The blob deforms into an elongated strip diffusing from its borders at a shear-dependent rate. Depending on the ratio of the mixing time to the reaction time (Damköhler number $Da$), several regimes are identified: When $Da > 1$, the product concentration increases linearly in time at a rate controlled by the reaction only. The mixing-controlled decay rate of the final product concentration after the reaction is completed is described as well.

2:11PM L06.00003 Flow Characteristics of Mixing in Continuous Flow Supercritical Carbon Dioxide Material Synthesis Reactor, COURTNEY OTANI, ELIZABETH RASMUSSEN, JOHN KRAM-LICH, IGOR NOVOSSELOV, University of Washington — Supercritical carbon dioxide ($scO2$) is being increasingly employed for advanced clean energy research including turbomachinery, electronics cooling, and more recently material synthesis. Understanding the fluid mechanics that dictate optimum operation is key to wide-spread application. The research presented here focuses on the mixing section of a continuous flow $scO2$ material synthesis reactor. Modeling the transient and multiphase mixing between $scO2$ and precursor materials gives insight into optimizing reactor conditions for uniform and controllable crystallization growth. Therefore, the commonly used counter-current design as well as three others are analyzed using computational fluid dynamics (CFD) to determine the flow characteristics of various geometries. Velocity and temperature contour plots and profiles are presented to identify regions with high vorticity, large temperature gradients, areas of stagnation, and boundary layer effects. Comparison of these results highlight the attributes and inefficiencies of different mixing section geometries.

2:24PM L06.00004 In-line spectroscopic diagnostics to investigate mixing-limited consecutive-competitive reaction systems, GOKUL PATHIKONDA, MICHAEL AHMAD, MUSTAFA USTA, Georgia Institute of Technology, IRFAN KHAN, Dow Company, CYRUS AIDUN, DEVESH RANJAN, Georgia Institute of Technology — Many complex industrial processes involve mixing-limited reaction chemistry in highly turbulent and complex environments. The proportions of reaction products (‘reaction yield’) involving consecutive-competitive reactions have long been known to depend on characteristics of turbulent mixing, necessitating the need for better injector designs for turbulent control. The relevant experimental studies frequently require the ability to measure the chemical reaction products in complex turbulent environments. We present a novel in-line spectroscopic measurement to study the reaction between 1-Napthol and Diazotized Sulfanilic acid. The concentrations of mono- (primary) and di-azo (secondary) reaction products averaged diametrically are measured using visible-light absorption spectroscopy at various distances from the injector. The diagnostic is characterized using bench-top measurements of known concentrations, and implemented on a co-flowing jet injector facility. Preliminary results demonstrating the effect of viscosity gradients on reaction yield is presented. It was noticed that an increase in the viscosity gradients in the reaction environments (owing to disparity in viscosity of inlet liquids) significantly alters the selectivity of the overall reaction.

2:37PM L06.00005 Experimental investigation of disparate viscosity turbulent mixing in a coaxial jet mixer\textsuperscript{1}, MICHAEL AHMAD, GOKUL PATHIKONDA, MUSTAFA USTA, Georgia Institute of Technology, IRFAN KHAN, Dow Company, CYRUS AIDUN, DEVESH RANJAN, Georgia Institute of Technology — Industrial chemical processes often involve continuous mixing of streams of reactants at different viscosities. In contrast to streams of constant viscosity, the variable viscosity streams provoke different mechanisms for turbulence and mixing, which are known to affect chemical yield. These mechanisms need thorough study to enable predictive modeling of such phenomena. Thus, simultaneous PIV and PLIF are employed to measure the turbulent and mixing dynamics in a confined, co-axial jet flow with viscosity ratios up to 40. This data reveal the effects of the imposed viscosity gradients on the nature in which the jet spreads into the co-flow. Evidently, the viscosity disparity largely confines the vortical structures to the lower viscosity fluid resulting in larger and more intermittent scalar structures in the higher viscosity fluid. This overarching phenomena reflects itself within realizations of the mean velocity and scalar fields, but also the Reynolds stresses and turbulent and scalar dissipation. These observations allude to differences in expected chemical yield. This study is performed concurrently with a computational effort to develop insight for SGS models of turbulent mixing within mediums with viscosity gradients.

1We gratefully acknowledge support from The Dow Chemical Company under the University Project Initiative.

2:50PM L06.00006 Competitive-consecutive reaction of liquids with disparate viscosity\textsuperscript{1}, MUSTAFA USTA, GOKUL PATHIKONDA, MICHAEL AHMAD, Georgia Institute of Technology, IRFAN KHAN, Dow Company, DEVESH RANJAN, CYRUS AIDUN, Georgia Institute of Technology — Competitive-consecutive reactions between liquids with disparate viscosity come along with several challenges due to high Schmidt (Sc) number and high reaction rates. The relevant scales at high Sc for a scalar become much smaller than turbulent dissipative scales. Higher reaction rates turn the problem into mixing limited reactions. In this study, we employ large-eddy simulation (LES) to investigate the effect of viscosity ratio on the reaction yields. The focus is on the co-axial jet and jet in crossflow mixing. In addition to the computations, the experimental setup features PIV and PLIF measurements to resolve the velocity and the mixture fraction. The investigations not only the mixing and reaction characteristics are considerably affected by the viscosity ratios of the liquids. The results for the mixing will be presented with comparison to experiments for the viscosity ratio of up to 40. The chemical reaction results; and the challenges in the subgrid scale modeling of variable viscosity, high Schmidt number, and high reaction rates will be presented for various viscosity ratios.

1We gratefully acknowledge support from The Dow Chemical Company under the University Project Initiative

3:03PM L06.00007 Experimental Study of a Turbulent Liquid Flame. , MICHAEL LE BARS, CNRS, IRPHE UMR 7342, Marseille (France), BAPTISTE ISNARD, Ecole Normale Supérieure de Lyon et IRPHE UMR 7342, Marseille (France), CHRISTOPHE ALMARCHA, Aix-Marseille Univ, IRPHE UMR 7342, Marseille (France) — Turbulent deflagrations are of fundamental importance for industrial applications and security issues. When the environment is congested by numerous obstacles, the turbulence generated by the blast upstream of the front strongly influences the flame speed and its acceleration. Our objective is to characterize experimentally turbulent premixed combustion so as to improve its modeling and predictability. In particular, we aim at collecting experimental data for a critical analysis of flame velocity models, based on detailed non-intrusive measurements of local turbulence and front parameters. We investigate the coupling between turbulence and the premixed flame thanks to a so-called liquid flame, using an autocatalytic chemical reaction \[1\]: this chemical reaction generates an intermediate product that increases the reaction rate, leading to the building-up of a front with the final products in close similarity with premixed combustion. In our system, the turbulence is generated by 2 oscillating grids. PIV-PLIF measurements allow simultaneously quantifying the turbulence rate and the front evolution. The experimental results are used to challenge the predictions from classical theoretical and numerical models. [1] Shy et al. Combust. Flame 1999. Pocheau & Hariambet PFE 2006.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L07 Non-Linear Dynamics and Chaos I

1:45PM L07.00001 A 3D View on Elastic Instabilities of Polymeric Solutions in Cross-Channel Flow, PAULO ARRATIA, BOYANG QIN, RANJINGSHANG RAN, University of Pennsylvania, PAUL SALIPANTE, STEVEN HUDSON, NIST — Over a decade ago Jerry Gollub along with two talented Haverford College undergraduate students and one of the authors (PEA) investigated the flow of viscoelastic fluids near hyperbolic points using a cross-slot channel. We found two novel flow instabilities of a planar extensional flow under steady forcing: (i) a symmetry breaking and steady instability and (ii) a time-dependent flow as strain-rate is increased. Here, new experiments using 3D particle tracking velocimetry are presented. We find a new symmetry-breaking instability normal to the extension plane, marked by a bi-stable flow switching in that direction and “buckling” of the separatrix between the impinging inflow streams. A strong connection exists therefore between temporal fluctuations and 3D flow. We explore this connection in some detail comparing the distribution of 3D modes with fluctuations of local pressure in inlet channels.

1:58PM L07.00002 Controlling thermal convection with sidewall heating, JUN ZHANG, MAC JINZI HUANG, New York University — Thermal convection of fluids takes place ubiquitously in nature and in our lives. It powers the motion of the earth’s mantle, drives winds in the atmosphere and currents in the oceans, and determines how fast we cook food and cool computers. Once a temperature difference is applied across a fluid, a thermal energy passes through the fluid from the heated bottom to the cooled top. This heat flow is known to depend on the applied temperature difference. Here we study a simple way to control or modify this heat flow by injecting an additional heat flow from the side of the fluid. Our thermal system is reminiscent of an electronic transistor where an electrical current controls another electrical current.

2:11PM L07.00003 Active matter and fluid dynamics from the cell, MICHAEL SHELLEY, Flatiron Institute (Simons Foundation) & Courant Institute (NYU) — Inside of cells, the nature of the forces that underlie important transport and developmental processes therein are often obscure. These forces are exerted through the activity of the cellular cytoskeleton, a collection of transitory biopolymers and their associated molecular motors. Fluid dynamics and fluid-structure interactions have a role to play in understanding the internal dynamics of cells; the fluidic cytoplasm both modulates and transmits forces generated by motion of the active cytoskeleton, while the induced flows can reveal how and where those forces are being produced. These same cytoskeletal components, when studied in vitro, outside of the cell, evince self-organizing dynamics reminiscent of the self-organization seen in mitotic spindles – the organelle that orchestrates the division of chromosomes – in early development.
2:24PM L07.00004 The Role of Disorder in Gravity-Driven Granular Flow . KERSTIN NORSTROM, GRACE CAI, ANNA BELLE HARADA, Mount Holyoke College — The gravity-driven flow of a granular material in a silo has been studied for many years due to its obvious practical importance. It has been shown that placing a fixed intruder near the exit aperture can suppress clogging and enhance flow, but the dominant mechanisms have been debated. We present results on the flow of monodisperse grains in a quasi-2D silo in the presence of a fixed intruder using high speed video to track the individual grain motions. We find the intruder dramatically affects not only the structural order of the packing, but also the spatiotemporal dynamics of the flow, creating flow that alternates but lacks a characteristic frequency or frequencies. We find a combination of geometrical effects and enhanced granular temperature are responsible for suppression of clogs in the presence of the intruder; the dominant effect depends on where the intruder is placed.

2:37PM L07.00005 Measurements of capillary-gravity wave reflection from surface intersecting structures. LIKUN ZHANG, XINYUE GONG, ROBERT LIRETTE, ZHEGUANG ZOU, The University of Mississippi — A full understanding of the fluid surface wave interactions with solid boundaries in micro-gravity environments is essential for the containment and control of liquids during manned space missions. When containing fluids using minimal support structures, capillary oscillations occur and capillary wave energy is dissipated at contact lines. We present results of experimental measurements on the reflection and transmission of capillary-gravity waves encountering a surface pieceing barrier. Dissipation near the contact lines for capillary waves is deduced from the transmission and reflection measurements. The surface perturbation is measured by the ultrasonic Doppler-shift method. We determine the dependence of the interactions with the wave frequency. The frequency is varied from the gravity wave limit to the short-wavelength regime where surface tension effects are dominant over gravity effects.

2:50PM L07.00006 Stretching Fields in Chaotic and Turbulent Fluid Flows . GREG VOTH, Wesleyan University — The stretching that fluid elements experience along their trajectories is responsible for many of the dominant features of passive scalar fields (such as an advected dye), passive director fields (such as advected fibers) and the vorticity field. Recent work on passive director fields has shown that fibers are usually aligned with their neighbors by fluid stretching. However, there are also thin walls across which the fiber orientation changes rapidly which we call alignment inversion walls. Experiments in a turbulent flow between oscillating grids and numerical simulations of homogeneous isotropic turbulence are used to explore the mechanism that produces alignment inversion walls in a fractal pattern in chaotic and turbulent flows. The orientation field of fibers provides not only fascinating mathematical structure but also a new way to study the dynamics of the turbulence.

3:03PM L07.00007 Dynamics of Carbon Nanotube Porins in Supported Lipid Bilayers . MARY LOWE, KYLIE SULLIVAN, JOSEPH LOPEZ, Loyola University Maryland, YULIANG ZHANG, ALEKSANDR NOY, Lawrence Livermore National Laboratory — Cell membranes in bacteria and eukaryotes possess transmembrane proteins called “porins,” which provide channels for ions and small molecules to enter or exit the cell. The cell membrane is composed of a phospholipid bilayer that behaves like a two-dimensional fluid in which lipids and membrane proteins laterally diffuse within the plane. Recently techniques have been developed to insert carbon nanotubes with a 1.5 nm diameter into a lipid bilayer to form “carbon nanotube porins” (CNTPs). Using high-speed atomic force microscopy, we recorded the movement of CNTPs in real time in a lipid bilayer supported on a mica surface. The diffusion coefficient was measured for varying concentrations of phospholipids DOPC and DMPC. The data reveal that the CNTP diffuses more quickly at lower concentrations of DMPC, exhibits fluctuations in tilt with respect to the membrane normal, and changes its azimuthal orientation within the membrane over time. Molecular dynamics simulations of a CNTP in DOPC:DMPC bilayers support our experimental findings and reveal additional information on molecular structures and movements of the CNTP and lipids. CNTPs can be a biomimetic platform for studying biological channels, or a means of developing stochastic sensors for measuring ionic transport through pores.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L08 Non Newtonian Fluid: Rheology 212 - Dana Grecov, University of British Columbia

1:45PM L08.00001 New methodology for rheological properties calculation of disotic nematic Liquid Crystals . DANA GRECOV, ARASH NIKZAD, University of British Columbia, ABOZAR AKBARI, Monash University — In this study, the main objective is to propose a methodology to calculate various rheological properties and viscosity coefficients for a disotic nematic LiquidCrystal (DNLC). Liquid Crystals (LCs) are anisotropic viscoelastic materials with fluid-like and crystal-like properties. The anisotropy of the viscosity coefficients, with respect to different flow directions, is a unique property of the liquid crystalline phase. Using the presented method, the required viscosity coefficients for different concentrations of Graphene Oxide (GO) dispersion, as a DNLC, were obtained. GO, the most processable derivative of graphene, is oxygen-functionalized graphene and has attracted enormous attention due to the unique liquid crystal and rheological properties. Shear-thinning rheological behavior of the nematic GO dispersion has opened an easy way to fabricate graphene-based devices in micro and macro scales. Our results showed that the alignment viscosity from the analytical method was consistent with the experimental one. Using the calculated viscosity coefficients, the numerical simulation results of the nematic GO under flow were consistent with the experimental results.

1:58PM L08.00002 Lubrication theory applied to the Landau deGennes theory . SOMESH BHATIA, DANA GRECOV, University of British Columbia — Liquid crystals (LCs) are anisotropic, viscoelastic materials with properties intermediate of solids and liquids. They are useful structural and functional materials; due to their ability to form ordered layers close to the bounding surfaces they are used as lubricants. The material properties and the behavior of LCs are dependent on the microstructure of the LCs which is affected by the strength of the hydrodynamic field and elastic effects of the bounding surfaces. Working towards the goal of studying thin films of LCs, the tensorial Landau de-Gennes theory is simplified using the Reynolds scaling approach. The solution of the fully coupled system of Navier-Stokes equations with a modified stress tensor which accounts for the viscoelastic contribution and the equations of Landau de-Gennes (LdG) theory was obtained using COMSOL Multiphysics™. The simplified equations derived from the lubrication theory were solved on MATLAB and the results were validated using a Couette flow by comparison with the simulations of the fully coupled system. As the LdG theory is a multiscale theory, the solution of the coupled system requires important computational resources. The advantage of the simplified equations of lubrication theory is that it allows the reduction of study time.

1The financial support of the Natural Sciences and Engineering Research Council (NSERC) of Canada is gratefully acknowledged.
2:11PM L08.00003 Electrostatics and Rheology in Semidilute Polyelectrolyte Solutions, GUANG CHEN, ANTONIO PERAZZO, HOWARD STONE, Princeton University — Polyelectrolyte (PE) solutions, which are charged polymers in aqueous solvents, have been studied from many perspectives in the past century. However, the effect of added salt on semidilute PE solutions remains unclear. To understand the electrostatic interactions among the polymers and electrolyte ions, we use a mean-field approach to determine the electrostatic energy of a PE solution at various polymer concentration $n_p$ and salt concentration $n_s$. We derive asymptotic approximations for the potential and ion distributions in nano-confined charged systems by probing the Poisson-Boltzmann equation within and beyond the Debye-Hückel linearization, and obtain distinct scaling laws for the electrostatic energy and viscosity for PE solutions at different regimes of $n_p/n_s$. One of our predictions coincides with the empirical Fuoss law for viscosity $\eta \propto n_p^{1.5}$ under the same assumption $n_s \ll n_p$, as in de Gennes scaling theory. Our theory also captures an unexplained empirical observation $\eta \propto n_p^{0.68}$ for salt-free PE solutions [1], and provides more physical insights on the effects of salt and charge fraction on the properties of PE solutions. [1] C. G. Lopez, R. H. Colby, P. Graham and J. T. Cabral, Macromolecules, 50, 332 (2017)

2:24PM L08.00004 Influence of pH value on gel reaction for fluid flow pattern in a circular flow pipe, MASAKI YAMAGUCHI, Graduate school of science and technology, Keio University, TAKESHI YOKOMORI, TOSHIHISA UEDA, Department of mechanical engineering, Keio University — Influence of pH value for flow pattern and pressure variation with PVA–borax gel reaction in a circular flow pipe are experimentally investigated. The working fluids are 10 mass% polyvinyl alcohol (PVA) solution and 3 mass% borax solution. The pH value of borax solution is varied from 6.9 to 11.7 using sodium hydroxide (NaOH) or hydrogen chloride (HCl) solution. Three distinct flow patterns with gel reaction in a flow pipe are described at each pH value as, 1. Parallel flow, 2. Capsule flow and 3. Clogging. In the parallel flow, the injected borax is stretched by main flow velocity and it smoothly flows to downstream direction. The pressure is not varied since the gel reaction does not effect for flow pattern. In the capsule flow, the injected borax forms capsule shape and it flows to downstream region. The capsule is produced by gel sheet which is generated the interface between the injected borax and PVA solution. As a result, the injected borax is separated from PVA region. In clogging, injected borax forms fine finger shape product. Finally, injected material stays on the main flow pipe. The pressure cannot recover to the initial pressure because formed gel is adhered to the wall of main flow pipe. Thus, the pressure monotonically increases with time.

2:37PM L08.00005 Macromolecular Architecture and Complex Viscosity, ALAN JEFFREY GIACOMIN, MONA KANSO, CHAIMONGKOL SAENGOW, JOURDAIN PIETTE, Queen’s University — General rigid bead-rod theory [Hassager, J Chem Phys, 60, 4001 (1974)] explains polymer viscoelasticity from macromolecular orientation. By means of general rigid bead-rod theory, we relate the complex viscosity of polymeric liquids to the architecture of axisymmetric macromolecules. In this work, we explore the zero-shear and complex viscosities of 24 different axisymmetric polymer configurations. When non-dimensionalized with the zero-shear viscosity, the complex viscosity depends on the dimensionless frequency and the sole dimensionless architectural parameter, the macromolecular lopsidedness. In this work, in this way, we compare and contrast the elastic and viscous components of the complex viscosities of macromolecular chains that are straight, branched, ringed, or star-branched. We explore the effects of branch position along a straight chain, branched-chain backbone length, branched-chain branch-functionality, branch spacing along a straight chain (including pom-poms), the number of branches along a straight chain, ringed polymer perimeter, branch-functionality in planar stars, and branch dimensionality.

2:50PM L08.00006 Rheology of Pluronics: morphological transitions induced by temperature and concentration, ROSSANA PASQUINO, ALFONSO DI SARNO, MARINA D’APUZZO, SALVATORE COSTANZO, DImPai, Universit degli Studi di Napoli Federico II — Pluronics are a class of water-soluble triblock copolymers made by a sequence polyethylene oxide (PEO)-polypropylene oxide (PPO)-polyethylene oxide (PEO) segments. Due to the presence of hydrophilic and hydrophobic parts on the same molecule, they have the ability to self-assemble in water. By varying the molecular weights of EO and PO sections, it is possible to obtain different types of Pluronics, recognized by a different code. In this work, we study the structures detected in aqueous solutions of Pluronic F68 at different temperatures by means of Small Angle X-ray Scattering (SAXS) and Small Angle Neutron Scattering. Various concentrations ranging between 10% and 80% by weight of Pluronic in water were tested. We performed dynamic temperature ramp tests in linear regime at different ramp rates and we were able to evaluate, via a rheological extraction, the temperatures at which transitions occur. The temperature at which the transitions appear were measured as a function of the triblock-copolymer concentration. Molecular structures were analyzed via SAXS measurements, which showed a liquid to body-centered cubic phase transition. The results allowed for the determination of a complete rheological phase diagram water/F68.

3:03PM L08.00007 Dynamics of DNA-bridged particle dimers in well-entangled polymer solutions under large amplitude oscillatory shear (LAOS), SEUNGHWAN SHIN, KEVIN DORFMAN, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455 — Although evidence for shear-banding flows in highly entangled polymer solutions has accumulated over the last two decades, the shear-induced microscopic conformational changes of individual chains that trigger shear banding remains unknown. Here, using a custom-built high-resolution rheo-confocal shear cell, we experimentally study the dynamics of DNA-bridged particle dimers in the shear-banding flow of well-entangled double-stranded DNA (dsDNA) solutions under LAOS to reveal the microscopic dynamics of entangled DNA chains in shear-banding flows. In our experiments, we first confirm that the velocity profiles of the entangled DNA solutions are inhomogeneous at high Weissenberg number (Wi) and develop into strong shear-banding flows with two distinct shear bands. Second, we investigate the dynamics of the particle dimers linked by long linear dsDNA chains and measure the distribution of dimer orientations in the high and low shear-rate bands. Quantitative analyses of the spatially distinct dynamics of such DNA-bridged dimers in the two co-existing bands provide important insights into the microscopic origin of the shear-banding flows in entangled polymer solutions.

1:45PM L09.00001 Control of the Aerodynamic Loads on a 3-D Wing using Distributed Active Bleed. M.E. DESALVO, D. HEATHCOTE, M. SMITH, A. GLEZER, Georgia Institute of Technology — The aerodynamic loads on a 3-D wing with a trailing-edge flap are controlled in wind tunnel experiments using active distributed bleed of ambient air that is driven through arrays of surface openings by the inherent pressure differences between the pressure and suction surfaces and regulated by integrated lateral louvers. Interaction between the bleed and the local cross flow over the surface induces large-scale changes in the global flow field which lead to direct modification of the aerodynamic loads and thereby can augment conventional electromechanical control surfaces without changing angle of attack or flap deflection. The leading edge actuator (LEA) is designed to take advantage of the inherent temporal modulation of the bleed through different spanwise segments of the wing over a range of angles of attack and flap deflections. Stereo PIV measurements of the wake acquired phase-locked to the actuation in a streamwise-normal plane downstream of the model show the temporal effects of bleed on distributions of streamwise vorticity (including the tip vortex) and on the spanwise loading of the wing.

1Supported by ONR.

1:58PM L09.00002 A numerical study on the delay of airfoil stall by traveling wave surface morphing. AMIR AKBARZADEH, IMAN BORAZJANI, J. Mike Walker ’66 Department of Mechanical engineering, Texas A&M University, College Station, TX, 77840 — Surface morphing is found to be an energy efficient active flow control technique. While these morphings are typically, in the form of a simple vibration or a standing wave, a traveling wave morphing might to be more effective because traveling wave oscillations are thought to reattach the flow over aquatic swimmers and bluff bodies. Large eddy simulations (LES) of flow over a low Reynolds number (Re=50,000) airfoil at stall angle, which has a oscillatory suction side, are performed to investigate the effect of the morphing function, i.e., backward traveling waves, standing waves, and forward traveling waves, on reducing flow separation. In addition, the effects of frequency and amplitude of the wave are investigated. It has been observed that backward traveling waves can be more effective than other types of oscillations, including forward traveling waves and standing waves.

1This work was partly supported by the National Science Foundation (NSF) CAREER Grant CBET 1453982, and the High Performance and Research Center (HPRC) of Texas A&M University.

2:11PM L09.00003 Characterizing Prescribed Surface Morphing for Aerodynamic Flows: Mechanistic Insights for Control. KEVIN TRINER, ANDRES GOZA, University of Illinois at Urbana-Champaign — Robust and efficient flow control is key to improving the maneuverability and disturbance rejection of micro- and unmanned aerial vehicles. Previous and current actuation strategies to achieve this aim include zero-net mass flux (synthetic), plasma, and combustion actuators. We investigate an alternative actuation framework in which prescribed deformations are imposed along the suction surface of the airfoil. This prescribed surface morphing, which is a variant of the actuation methodology suggested by Jones et al. (2016), is designed to take the form of a traveling wave. This actuation strategy is promising because it has the ability to affect flow over the entire suction surface of the airfoil, and is not limited to specific streamwise locations. We use high-fidelity nonlinear simulations to quantify the effect of the surface morphing function, i.e., backward traveling waves, standing waves, and forward traveling waves, on reducing flow separation. In addition, the effect of frequencies and amplitude of the wave are investigated. It has been observed that backward traveling waves can be more effective than other types of oscillations, including forward traveling waves and standing waves.

2:24PM L09.00004 Transitory, Bi-Directional Control of the Aerodynamic Loads on an Airfoil in an Attached Flow. YUEHAN TAN, A. GLEZER, Georgia Institute of Technology, R. PATTERSON, P. FRIEDMANN, University of Michigan — The aerodynamic loads on a VR-12 airfoil are regulated bi-directionally to enable mitigation of structural vibrations when the base flow is fully-attached by using pulsed fluidic control upstream of the trailing edge. Actuation is effected using independently controlled high aspect ratio bi-stable, fluidically-switched actuation jets on the pressure and suction surfaces at nominally 0.88c. The transitory actuation temporally manipulates the circulation around the airfoil and its Kutta condition yielding changes in the aerodynamic loads. For example, it is shown that time-invariant actuation on the pressure and suction surfaces can lead to respective lift increments CL of up to +0.73 and -0.65 with relatively low drag penalty. The transitory characteristics of the aerodynamic loads to pulsed actuation are investigated with specific emphasis on the initial response following the onset of the actuation along with corresponding unsteady vortex shedding near the trailing edge using phase-locked particle image velocimetry. Supported by Vertical Lift Research Center of Excellence (VLRCOE).

2:37PM L09.00005 ABSTRACT WITHDRAWN —

2:50PM L09.00006 Manipulation of Streamwise Vortices by Air Injection on Trapezoidal Vane-Type Vortex Generators. GIOVANNI NINO, University of Washington, LUCAS WEBER, Technical University of Berlin, ROBERT BREIDENTHAL, University of Washington — This work investigated the feasibility of manipulating a streamwise vortex position by injecting pressurized air through the leading edge of a trapezoidal vortex generator (VG). The VGs were tested on a miniature wind tunnel. A pressure sensor was mounted on a two-dimensional traverse to gather dynamic pressure cross sections downstream of the vortex generator. From these pressure profiles, the vortex position was measured to determine the influence of the air injection. Supplied air pressure was varied as well as the location of the injection at three different positions along the leading edge. In addition, vortex generators with small round holes as injection ports as well as rectangular slots were investigated. Experimental results showed that injection at different VG leading-edge positions were able to displace the vortex in a controllable way.

3:03PM L09.00007 Passive drag reduction on a sphere using polyhedral designs. NIKOLAOS BERALTIS, KYLE SQUIRES, School for Engineering of Matter, Transport and Energy, Arizona State University, ELIAS BALARAS, Department of Mechanical and Aerospace Eng., George Washington University — It is established today that dimples are efficient in accelerating the drag crisis on a sphere reducing the drag coefficient at much lower Reynolds numbers when compared to a smooth sphere. Recently we reported Direct Numerical Simulations (DNS) demonstrating that the large difference in the minimum drag coefficient between a dimpled and smooth sphere in the post-critical regime comes from the dimples themselves as the flow separates and reattaches inside them. In this talk we propose a new class of geometries based on polyhedral designs resembling a faceted sphere. Wind tunnel testing and DNS demonstrate drag reduction by as much as 15% compared to a typical dimpled sphere, without affecting the critical Reynolds number marking transition to the post-critical regime. We utilize the experiments to establish the behavior of the drag coefficient as a function of the Reynolds number for different geometries and then use DNS for selected cases to obtain a detailed understanding of the flow physics. We will show important differences in the evolution of the boundary layers between a polyhedral and dimpled sphere as well as their wakes that reveal the underlying mechanism for the reduction in the drag coefficient.
Research under Award Number DE-SC0019290.

interface between any two consecutive partitions. We test our framework using different convection-dominated, unsteady-flow problems.

we introduce a long short-term memory (LSTM) neural network architecture along with a principal interval decomposition (PID) framework as

global nature often causes a deformation of the generated bases, especially in convective flows. Based on dimensionality reduction using POD,

framework. Proper orthogonal decomposition (POD) is well-known for its optimality in representing complex systems. However, its intrinsic

mathematical form of the driving physics. Conventional projection-based reduced order modeling (ROM) techniques can satisfy the first two

stationary conditions for the time-continuous minimization problems are obtained by deriving the associated Euler-Lagrange equations. Both
direct (discretize then minimize) and indirect (minimize and then discretize) solution techniques are explored. The proposed approach displays

commonalities with optimal control problems and can be viewed as a generalization of the popular Least-Squares Petrov-Galerkin (LSPG)
method. By formulating the residual minimization problem from the time-continuous level, the TC-LSRM approach overcomes the time-step
sensitivity and time-scheme dependence that LSPG is subject to. Numerical experiments demonstrate that the proposed approach can lead to
more accurate and physically relevant solutions than existing model reduction approaches.

This approach significantly outperforms linear methods, such as POD, for drastic dimensionality reduction. Furthermore, evolving the nonlinear
spatiotemporal dynamics in translation-symmetric systems via deep learning

is presented. The proposed approach, referred to as Time-Continuous Least-Squares Residual Minimization (TC-LSRM), sequentially minimizes the time-continuous full-order model residual within a low-dimensional trial space over a series of time slabs. The stationary conditions for the time-continuous minimization problems are obtained by deriving the associated Euler-Lagrange equations. Both
direct (discretize then minimize) and indirect (minimize and then discretize) solution techniques are explored. The proposed approach displays

commonalities with optimal control problems and can be viewed as a generalization of the popular Least-Squares Petrov-Galerkin (LSPG)
method. By formulating the residual minimization problem from the time-continuous level, the TC-LSRM approach overcomes the time-step
sensitivity and time-scheme dependence that LSPG is subject to. Numerical experiments demonstrate that the proposed approach can lead to
more accurate and physically relevant solutions than existing model reduction approaches.

1:45PM L10.00001 A Bayesian Reinterpretation of Dynamical System Identification by Sparse Regression Methods

1:45PM L10.00001 A Bayesian Reinterpretation of Dynamical System Identification by Sparse Regression Methods1, ROBERT K NIVEN, The University of New South Wales, Australia, LAURENT CORDIER, Institut Pprime, Poitiers, France, MARKUS ABEL, MARKUS QUADE, Ambrosys GmbH, Potsdam, Germany, ALI MOHAMMAD-DJAFARI, CentraleSupélec, Gif-sur-Yvette, France. — Recently, many researchers have developed sparse regression methods for the identification of a
dynamical system from its time-series data. We demonstrate that these methods fall within the framework of Bayesian inverse methods. Indeed,
the Bayesian maximum a posteriori method, using Gaussian likelihood and prior functions, is equivalent to Tikhonov regularization based on
Euclidean norms. This insight provides a Bayesian rationale for the choice of residual and regularisation terms for any problem, respectively
from the Bayesian likelihood and prior distributions. It also provides access to the full Bayesian inversion apparatus, including estimation of
uncertainties in the inferred parameters and the model, explicit calculation of the optimal regularisation parameter, and the ranking of competing
models using Bayes factors. In addition, advanced Bayesian methods are available to explore the inferred probability distribution of the model,
should this be desired. We demonstrate these points by analysis of several dynamical systems using standard and Bayesian sparse regression
methods. We also discuss the estimation of intermediate parameters and their handling within a Bayesian framework.

2:50PM L10.00006 A Koopman-based framework for forecasting the spatiotemporal evolution of chaotic dynamics. MOHAMMAD AMIN KHODKAR, PEDRAM HASSANZADEH, ATHANASIOS ANTOULAS, Rice University — We show the remarkable skills of a data-driven method in spatiotemporal prediction of high-dimensional and chaotic dynamics. The method is based on a finite-dimensional approximation of Koopman operator where the observables are vector-valued and delay-embedded, and the nonlinearities are treated as external forcings. The predictive capabilities of the method are demonstrated for well-known prototypes of chaos such as the Kuramoto-Sivashinsky equation and Lorenz-96 system, for which the data-driven predictions are accurate for several Lyapunov timescales. Similar performance is seen for two-dimensional lid-driven cavity flows at high Reynolds numbers.

3:03PM L10.00007 Predicting long-term dynamics of chaotic systems with hybrid machine learning1, SREE TEJ LAKKAM, BALAMURALI B T, Singapore University of Technology and Design, JURRIAAN J J GILLISSEN, Department of Mathematics, University College London., ROLAND BOUFFANAI S, Singapore University of Technology and Design — Forecasting of chaotic systems relies on estimating long-term dynamics of the system to make reasonable predictions. Our work aims to use an efficient hybrid machine learning technique to improve the estimation of long-term statistics while being resilient to short-term anomalies in determining future states of the system. Our hybrid machine learning technique combines a Long Short Term Memory (LSTM) architecture and ensemble modeling. LSTM is used to extract the long-term dependencies in the chaotic system data, while ensembling perturbs and combines multiple LSTMs to obtain better predictive performance compared to any of the constituent LSTM alone. We demonstrate the forecasting capability of this framework using time-series data from a Lorenz system and subsequently apply it to planar homogeneous turbulence flow field. Using visual verification and power spectra analysis, we conclude that our model can learn and predict the long-term dynamics even when short-term forecasting fails owing to the inherent unpredictability of chaotic systems. These results have far-reaching implications for the use of machine learning in fluid mechanics. Moreover, this approach is completely data-driven and relies on the LSTM capability to capture the long-term statistics of a chaotic system. 1 MOE-SUTD PhD fellowship and SUTD grants (IDC: IDG31800101 and AI Sector: PIE-SGP-AI-2018-01)

Monday, November 25, 2019 1:45PM - 3:16PM — Session L11 Experimental Techniques: Microscale 3B - Ralph Budwig, U. Idaho

1:45PM L11.00001 Microfluidic Study of Temperature Dependent Phase Changes in Aqueous Aerosol Systems1, PRIYATANU ROY, CARI DUTCHER, University of Minnesota — Atmospheric aerosols are suspensions of small liquid or solid particles suspended in air which play a major role in climate change, either directly by absorption and scattering of solar irradiation or indirectly by cloud formation. They are complex multiphase fluid systems and experience a broad range of relative humidities and subzero temperatures in the atmosphere affecting their phase state i.e. well-mixed liquid, phase separated or crystallized solid. In situ observation of relative humidity and temperature of aerosol droplets are difficult and expensive. In this work, low cost microfluidic devices are used to generate and study phase states of aqueous droplets of real aerosols and chemical mimics in static and flow-through devices at subzero temperatures. The static device dehydrates trapped droplets in quasi-equilibrium to study the effect of relative humidity and water loss on phase state at different temperatures. The high-throughput flow-through microfluidic device measures ice nucleation temperature of aerosols. The results will be used to predict the cloud and ice formation activity of atmospheric aerosols. 1 NSF CAICE and UMN MNC

1:58PM L11.00002 Droplet Nucleation and Condensation on a Hydrophilic Surface. SHAHAB BAYANI AHANGAR, JEFFREY ALLEN, Michigan Technological University, SEONG HYUK LEE, Chung-Ang University, CHANG KYOUNG CHOI, Michigan Technological University — Dropwise condensation is a ubiquitous phenomenon in nature. Dropwise condensation has the potential to improve the efficiency of condensing surfaces and reduce the maintenance costs of systems. However, efforts to design and fabricate surfaces that can sustain long-term dropwise condensation have not been successful. The main reason is that the nucleation physics, which are key to understanding degradation, behind dropwise condensation are not fully understood; thus, researchers have mostly relied on a trial and error approach for developing new surfaces. In this work, a series of fundamental experiments were done to identify the governing mechanism of dropwise condensation on smooth hydrophilic surfaces by probing the solid-vapor interface during phase-change. The results evaluate the existence and structure of the thin film and initial nuclei that develop during condensation. The adsorption kinetics theory is used to improve understanding of the dropwise condensation mechanism during droplet formation at the onset of condensation.

2:11PM L11.00003 Measurement of biofilm stresses in laminar flows by a digital holography interferometry (DHI) and an embedded wrinkle free thin-film polymer mirror. MARYAM JALALI, JIAN SHENG, Texas A&M — Bacteria are unicellular microorganisms that commonly exist in either planktonic and biofilm lifestyles. Biofilms have viscoelastic nature and are subject to deformation under external disturbances (e.g. fluid shear stress). Here, we developed a technique to perform in-situ measurement of viscous stresses exerted biofilm under different flow velocities. The experiments are performed in a uniquely developed microfluidic platform composed of a flexible thin-film mirror embedded in Polydimethylsiloxane (PDMS), that performs as a stress sensitive substrate. This 30nm aluminum thin film is sandwiched between two PDMS layers, and is free of wrinkles and cracks in addition to being specular reflective. The microfluidics is attached to a chemostat and two peristaltic pumps that continuously flow bacterial suspensions in close-loop to facilitate biofilm growth and generate flow shear. DHI measures nano-strain of the thin-film and consequently stresses via finite element modeling of thin film.
2:24PM L11.00004 Off-axis digital holographic microscopy (DHM) as a method of high temporal and spatial resolution flow visualization¹. MANUEL BEDROSSIAN, Department of Medical Engineering, California Institute of Technology, 1200 E. California Blvd. Pasadena CA 91125, KURT LIEWER, CHRIS LINDENSMITH, Jet Propulsion Laboratory, California Institute of Technology. 4800 Oak Grove Dr. Pasadena CA. 91011, JPL-NEXT TEAM — Off-axis digital holographic microscopy is a developing optical modality that is capable of achieving diffraction limited resolution on the sub-micron spatial scale at high temporal resolution and across a large depth of field. By using two coherent beams of light that become recombined at the optical detector, off-axis of each other, the 3D optical information of the sample becomes encoded in the resulting interference pattern (hologram). Numerical processing of the hologram allows the volumetric reconstruction of the sample. The temporal resolution is limited by the frame rate of the camera used to record the holograms and thus dynamic processes such as fluid flows can be imaged and visualized by seeding the flow with appropriately sized particles. Our current implementation of an off-axis DHM is capable of diffraction limited resolution of 780 nm across an interrogation volume of 365x365x900 cubic microns. Hardware and software developments in off-axis DHM show this optical modality to be a promising method of high throughput flow visualization on the microscale.

²Funding for this project was provided by the JPL-NEXT program.

2:37PM L11.00005 Structured-illumination microscopy to improve the spatial resolution of microscale particle velocimetry². MICHAEL SPADARO, MINAMI YODA, Georgia Institute of Technology — The spatial resolution of optical methods in microchannel flows such as microscale particle image velocimetry (μPIV) is often limited because the entire flow volume is illuminated, and signal from tracers beyond the focal plane affects the measurement. Structured-illumination microscopy (SIM), originally developed for optical sectioning of stationary objects (e.g. cells) in fluorescence microscopy, is a promising way to acquire planar slices of the flow with a thickness comparable to the depth of field of the imaging system. SIM reconstructs the signal from the focal plane using multiple “raw” images of the flow illuminated by a sinusoidally varying (i.e., structured) intensity distribution at different phases using (spatial) frequency mixing. Initial results are presented here for microscale particle velocimetry using SIM images reconstructed from two raw images of laminar Poiseuille flow seeded with fluorescent polystyrene microparticles through a microchannel. The velocities obtained using SIM-based particle velocimetry are compared with results obtained from “standard” μPIV obtained with volume illumination in the same flow, and used to estimate the spatial resolution of this new technique.

²Supported by US Army Research Office

2:50PM L11.00006 A Novel Transparent Sediment Simulant for Unveiling the Bed Topography and Interstitial Processes, BRANDON HILLIARD, RALPH BUDWIG, DANIELE TONINA, JEFF REEDER, University of Idaho, RICHARD SKIFTON, Idaho National Laboratory — Particle Image Velocimetry (PIV) and Planar Laser-Induced Fluorescence (PLIF) are two commonly used and powerful laboratory experimental methods for whole-field velocity measurements and flow visualization. When they are coupled with refractive index matching (RIM), they can map both velocity fields and porous media architecture. We present a study that utilizes RIM coupled-PIV and RIM coupled-PLIF methods to not only quantify the flow within a packed bed of irregular shaped grains but also to map the internal structure of the porous media. We use a fluoro-carbon polymer with a specific gravity of 1.97 and optical properties similar to that of water as a simulate for sediment grains within a flow cell. These irregular grains, varying in shape and size, provide a structure that may simulate stream bed sediment and other porous media of granular materials. Here, we present the first experiments and discuss the image processing of both PIV and PLIF experiments, the image quality necessary for mapping the grain bed, and its errors and limitations. Our results pave the way for a novel application where both biological (microbial growth) and physical processes can be studied simultaneously.

3:03PM L11.00007 Added mass of porous solids oscillating in dense gas³. XIAOLONG YIN, SIRADON PRATEEPSWANGWONG, KEERTHANA KRISHNAN, Colorado School of Mines — Oscillation frequency of an object submerged in fluid is usually detectably retarded by the mass of co-accelerated fluid. In this study, this added-mass effect is explored for porous solids oscillating in dense gas, using an enclosed spring-mass system at high pressures. Compared with a non-porous solid of the same shape, the added mass of a porous solid is always higher because of pore-residing gas. When the period of oscillation is much greater than the time of viscous relaxation inside the pores, pore-residing gas follows the motion of the porous solid, and its mass can be estimated using the difference in the added mass between porous and non-porous solids. Experiments conducted using Berea sandstone show that masses of pore-residing gas obtained from oscillations were in good agreement with those calculated using pore volume of the sandstone and gas densities. Added mass of porous solids observed from oscillations can therefore serve to give pore volume when gas density is known, or gas density when pore volume is known. Additional added mass was noticed, however, when mesoporous solids (nanoporous silica and rocks) were used with a condensable gas.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L12 Vortex Dynamics and Vortex Flow: Instability 303 - Eckart Meiburg, UCSB

1:45PM L12.00001 Turbulence generation through an iterative cascade of the elliptical instability¹. RYAN MCKEOWN, Harvard University, RODOLFO OSTILLA-MONICO, Houston University, ALAIN PUMIR, ENS Lyon, MICHAEL BRENNER, SHMUEL RUBINSTEIN, Harvard University — We demonstrate the existence of a novel mechanism in which two counter-rotating vortices violently collide and break down, leading to the rapid development of a turbulent energy cascade mediated by iterations of the elliptical instability. We probe the full 3D dynamics of this breakdown by conducting both experimental visualizations of colliding vortex rings and numerical simulations of colliding vortex rings and vortex tubes. We observe how the onset of the elliptical instability causes the vortex cores to develop antisymmetric perturbations, which give rise to an ordered array of secondary vortex filaments, perpendicular to the original cores. Adjacent secondary filaments counter-rotate and interact with each other in the same manner as the original configuration. In the high-Reynolds number limit, we observe after a few iterations of this instability, whereby a new generation of tertiary filaments forms perpendicular to the interacting secondary filaments. The energy spectrum of this turbulent breakdown exhibits ~ k⁻⁵/³ scaling, a hallmark of homogeneous isotropic turbulence. We find that the elliptical instability must play a major role in the formation and sustenance of turbulent flows by providing a means through which energy is conveyed down to dissipative scales.

1:58PM L12.00002 Vortical structures of an axisymmetrically oscillating self-excited jet subjected to transverse acoustic forcing. ABHIJIT KUMAR KUSHWAHA, The Hong Kong University of Science and Technology, NICHOLAS WORTH, JAMES R. DAVISON, Norwegian University of Science and Technology, MAE-HKUST/EPT-NTNU COLLABORATION COLLABORATION — We experimentally examine the vortical structures in the near-field region of an axisymmetrically oscillating self-excited low-density jet subjected to axial and transverse acoustic forcing. We apply the forcing at frequencies around the global frequency of the jet and measure its response via time-resolved stereoscopic particle image velocimetry. We find that, when forced at amplitudes sufficient for synchronization, the jet exhibits two distinct roll-up of shear layers when the forcing is axi and (ii) an inverse roll-up of shear layers when the forcing is transverse. We find that the latter type coincides with a suppression of the self-excited global mode via asynchronous quenching. Using proper orthogonal decomposition, we extract the dominant modes of the jet, resolving the flow structures associated with acoustic and vortical disturbances. As well as providing new insight into the way external acoustic oscillations interact with self-excited hydrodynamic oscillations, this study clarifies the role of symmetry breaking in suppressing global instability in axisymmetrically oscillating self-excited jets.

2:11PM L12.00003 Topology and dissipation during vortex reconnection. ROBERT M. KERR, University of Warwick — The evolution of the vortical, topological and geometric properties of several configurations of vortices are compared. Trefoil vortex knots, coiled rings, anti-parallel perturbed vortices and colliding rings and one goal is to identify what the influence twist, writhe, linking numbers and helicities have upon the generation, or suppression, of energy dissipation. The focus will be upon the latest anti-parallel vortices reconnection calculations for which the growth of the enstrophy $Z$, the volume-integrated vorticity squared, is consistent with $\nu$-independent energy dissipation $\Delta \epsilon = \int_0^t \epsilon \ dt$, $\epsilon = \nu \Delta Z$ when the Reynolds number is high enough and the domain is large enough. This is consistent with the $\nu$-independent growth of $\epsilon$ for trefoil vortices (JFM 839, R2, 2018) and the type of reconnection structures observed when vortex rings collide (McKeown et al. PR Fluids 3, 124702, 2018). However, the $Z \sim (T/\nu)(r-v)^{-2}$ (or linear $B_0(t) = (\nu T/2)^{-1/2}$) regime seen for trefoils and nested coiled rings (JFM 854, R2, 2018) is not observed. Could the geometric numbers and helicity be why? The helicity of anti-parallel vortices is identically zero, while the others' topological helicity = twist + writhe is large.

2:24PM L12.00004 Flow-Induced Flapping Foil Instability. JIAQI MAI, PAUL F. FISCHER, ARNE J. PEARLSTEIN, Department of Mechanical Science and Engineering, University of Illinois at Urbana-Champaign — We have conducted a computational investigation of two-dimensional self-excited flapping-foil instability in the channel formed by two parallel plates, up to Reynolds numbers (based on average velocity and plate separation) of 400, and the effects on heat transfer. Our approach, for a massless foil, spatially discretizes the incompressible Navier-Stokes equations by a spectral-element method, while the dynamical equation describing foil deformation is discretized by a p-type finite element method. The spectral-element mesh for fluid temporally moves, based on an arbitrary Lagrangian-Eulerian (ALE) formulation, so that zero-thickness foil is always attached to the mesh and the no-slip condition is satisfied. Nonlinear terms in the incompressible Navier-Stokes equations are advanced explicitly in time, while linear terms are advanced implicitly. The structural equations are advanced in a weakly coupled sense, consistent with semi-implicit temporal discretization of Navier-Stokes, and the ALE moving-mesh strategy. We update the flow from Navier-Stokes, with a prescribed zero relative velocity on the foil, by superposing a series of Stokes solutions, each representing unit acceleration for one discretized degree of freedom of the foil, and weighted to satisfy the structural equation. This approach efficiently avoids the numerical instability of traditional partitioned fluid-structure interaction algorithms in the zero-mass case.

2:37PM L12.00005 Coupling of vortex breakdown and stability in a vortex T-mixer flow. SAN TO CHAN, Okinawa Institute of Science and Technology Graduate University, JESSE AULT, Biomedical Sciences, Engineering, and Computing Group, Oak Ridge National Laboratory, SIMON HAWARD, Okinawa Institute of Science and Technology Graduate University, ECKARTE MEIBURG, Department of Mechanical Engineering, University of California, Santa Barbara, AMY SHEN, Okinawa Institute of Science and Technology Graduate University — We use microfluidic experiments and numerical simulations to study the flow in a vortex T-mixer: a T-shaped channel with staggered, offset inlets. The vortex T-mixer flow is characterized by a single dominant vortex, the stability of which is restabilized by the vortex. Finally, a third vortex breakdown region appears at $Re \sim 90$, a first vortex breakdown regime seen for trefoils and nested coiled rings (JFM 839, R2, 2018) is not observed. Could the geometric numbers and helicity be why? The helicity of anti-parallel vortices is identically zero, while the others' topological helicity = twist + writhe is large.

2:50PM L12.00006 Influence of bottom topography on vortex stability. BOWEN ZHAO, Yale University, EMMA CHIEUSSE-GERARD, ENSTA ParisTech, GLENN FLIERL, MIT — The effects of topography on the linear stability of both barotropic vortices and two-layer, baroclinic vortices are examined by considering cylindrical topography and vortices with stepwise relative vorticity profiles in the quasi-geostrophic approximation. Four vortex configurations are considered, classified by the number of relative vorticity steps in the horizontal and the number of layers in the vertical. In the barotropic calculation, the vortex is destabilized by topography having an oppositely signed potential vorticity jump while stabilized by topography steps in the horizontal and number of layers in the vertical. This is consistent with the barotropic calculation except that the growth rate weakens and, for a two-step vortex, becomes less sensitive to topography (sign and magnitude) as baroclinicity increases. The smaller growth rate for a baroclinic vortex is consistent with previous findings that vortices with sufficient baroclinic structure could cross the topography relatively easily.

3:03PM L12.00007 Analysis of the transition between Kelvin’s equilibria using proper orthogonal decomposition. MIRA KIM, Concordia University, HAMID AIT ABDELLAHMAINE, Khalifa University, HOI DICK NG, GEORGIOS VATISTAS, Concordia University — The stirring flow driven by a rotating disk of a shallow water layer confined in a cylindrical bucket is revisited. The formation of a system of two and three satellite vortices, nested within slightly elliptical and triangular paraboloid free surface, orbiting around the center of the disk, is observed. At critical disk speeds transitions between these two systems of satellite vortices occur. These transitions were imaged and the velocity fields at the free surface of the shallow water were obtained via particle image velocimetry (PIV) measurement. The nucleation or theihilation of the satellite vortex during the two transitions is discussed in relation with the eigenmodes of the vortex-patterns.
1:45PM L13.00001 The Shedding of Jupiters Red Flakes Does Not Mean It Is Dying
PHILIP MARCUS, UC Berkeley, PEDRAM HASSANZADEH, Rice University, MICHAEL WONG, IMKE DE PATER, AIDI ZHANG, UC Berkeley, JOSEPH BARRANCO, UCSF, DAVID LEE, Rice University — During 2019 the Great Red Spot (GRS) of Jupiter repeatedly shed large (100,000 km$^2$) chunks of itself as red flakes. Rather than the GRS “dying” as report in the popular press, we have a more benign hypothesis tested with 3D numerical simulations. There are 2 distinct boundaries of the GRS (n.b., neither of which is coincident with the boundary of its cloud cover): (1) the boundary of its potential vorticity (PV) anomaly, and (2) its last “closed streamline”. An isolated vortex has nested closed streamlines, both interior to it and exterior it. The latter circumscribe the vortex. However, an anti-cyclone embedded in an anti-cyclonic zonal shear only has exterior closed streamlines near the PV boundary. Farther from its PV boundary, it has “open streamlines” that circumscribe the planet, not the vortex. The last close streamline contains at least one stagnation point. We show that when there is large area between the last closed streamline and the PV boundary, vortices “fed” to the GRS merge with it. However, when that area is small, vortices fed to the GRS will be expelled at or near a stagnation point. Thus, our explanation of the of recent Red Flakes is that area between the PV boundary of the GRS and its last closed streamline has shrunk.

1:58PM L13.00002 Nonlinear Magnetosonic Periodic and Solitary Waves in a Magnetized Dusty Plasma
NIMARDEEP KAUR, NARESHPAL SINGH SAINI, Guru Nanak Dev University, Amritsar — An investigation of magnetosonic nonlinear periodic (cnoidal) waves is presented in a magnetized electron-ion-dust plasma having cold dust fluid with inertialess warm ions and electrons. The reductive perturbation method is employed to derive the Korteweg-de Vries equation. The magnetosonic cnoidal wave solution is derived using the Sagdeev pseudopotential approach under the specific boundary conditions. There is the formation of only positive potential magnetosonic cnoidal waves and solitary structures in the high plasma-b limit. The findings of the present investigation may be helpful in describing the characteristics of various nonlinear excitations in Earth’s magnetosphere, solar wind, Saturn’s magnetosphere, and space/astrophysical environments, where many space observations by various satellites confirm the existence of dust grains, highly energetic electrons, and high plasma-$\beta$.

2:11PM L13.00003 Quantitative Flow Field Measurements of Astrophysical Relevance on the Blast-Driven Instability (RMI & RTI)$^1$ . SAMUEL PETTER, BENJAMIN MUSCI, GOKUL PATHIKONDA, DEVESH RANJAN, Georgia Institute of Technology — The presented work focuses on the implementation of Particle Image Velocimetry (PIV) to study the Blast-Driven Instability (BDI) in cylindrical geometry at the Georgia Tech Shock Tube and Advanced Mixing Laboratory. The facility uses detonators to generate a blast wave that accelerates the flow through a diverging test-chamber. The blast wave then interacts with a gaseous, membrane-less, interface of differing density, causing the occurrence of the combined Richtmyer-Meshkov (RMI) and Rayleigh-Taylor Instabilities (RTI); the two instabilities comprising the BDI. Previous validation of the facility was completed using high speed Mie Scattering and demonstrated faithful reproduction of the BDI phenomena. This validation garnered information about the qualitative development of the instability and identified aspects of improvement within the facility, both of which will be covered in this presentation. Preliminary PIV results are shown to corroborate the earlier Mie Scattering findings as well as predictions made by Taylor-Sedov theory derived from experimental pressure data.

$^1$DOE Early-Career Award, and DOE NNSA SSGF

2:24PM L13.00004 Horizontal shear instabilities in stellar radiative zones$^1$ . JUNHO PARK, VINCENT PRAT, STPHANE MATHIS, CEA Paris-Saclay (DRF/IRFU/DAP) — Shear flows in stratified-rotating fluids have been a popular research topic in astrophysics due to their applications for stellar evolution modeling. In stellar radiative zones, the thermal diffusivity is high with small Prandtl number of order $10^{-5}$. Also, the horizontal rotation component in latitudinal direction has not been generally considered with the traditional f-plane approximation, but recent research has revealed that it modifies significantly dynamics of inertia-gravity waves in the radiative zones. In this presentation, we revisit the horizontal shear instability problem by considering two components: the thermal diffusivity and the complete Coriolis acceleration rotation (i.e. the non-traditional f-plane approximation). And we study their impacts on hydrodynamic instabilities: inflection-point and inertial instabilities. With numerical and asymptotic stability analyses, we will present new results with mathematical formulations how the thermal diffusivity and horizontal modify these instabilities. For instance, a fast thermal diffusion destabilizes the inertial instability due to the suppression of the stratification effect while the horizontal rotation promotes instabilities and broadens the unstable regime.

2:37PM L13.00005 Dynamics in the Ball: Models for Fully Convective, Rotating M-Dwarf Stars . BENJAMIN BROWN, University of Colorado, JEFFREY OISHI, Bates College, DANIEL LECOANET, Princeton University, KEATON BURNS, Massachusetts Institute of Technology, GEOFFREY VASIL, University of Sydney — M-dwarf stars are smaller and less luminous than our Sun. In their interiors, convection dominates energy transport from the center of the star to their surface. This ball-like geometry is unique among all the stars on the main-sequence; in our Sun, solar convection is bounded from below by regions of stable stratification, creating a shell-like geometry instead. Within stellar convection zones, the turbulent plasma motions act as a dynamo, stretching and amplifying magnetic fields. M-dwarf stars have abundant and strong magnetic fields at their surfaces, but at a fundamental level we do not know whether these ball-like stars are similar to or different from our shell-like Sun. Here, using the novel spherical Dedalus pseudospectral framework, we consider the properties of convection and magnetic dynamo action in rotating, stratified simulations within global ball domains that capture the coordinate singularity at the center ($r = 0$), as well as the north and south pole. We find that global shearing flows are built by the convection, and these amplify global magnetic fields. Many ingredients in the fully convective M-dwarf simulations are similar to those found in simulations of the solar dynamo; this implies that these dissimilar stars may have similar internal processes.
2:50PM L13.00006 Radiative damping of convectively-driven gravity waves in the atmospheres of hot Jupiters1, JHETT BORDWELL, BENJAMIN BROWN, University of Colorado Boulder, JEFFREY OISHI, Bates College, WHITNEY POWERS, University of Colorado Boulder — Jovian atmospheres consist of a substantial, deep convection zone underlying a stably stratified region populated by convectively driven waves at many scales. These waves are significant to the pumping of large scale atmospheric jets, upper atmosphere heating, and chemical transport. To understand the role that radiation plays in the propagation of these waves, we perform numerical experiments with Dedalus at small scales studying wave driving and chemical transport in an atmosphere with radiative diffusion (appropriate for a hot Jupiter). We find that assuming an opacity structure appropriate for a Jovian atmosphere, all but the smallest of these waves are damped by radiative diffusion. We further compare our results with those of a Reynolds’ stress forcing model of wave driving, and explore the transport of reactive passive tracers through a simple Newtonian relaxation model.

3:03PM L13.00007 Nonlinear dynamics of forced baroclinic critical layers1, CHEN WANG, NEIL BALMFORTH, University of British Columbia — Baroclinic critical levels are singularities of waves propagating in inviscid stratified shear flow, and they play a crucial role in the self-replication of ’zombie vortices’. Our previous work has shown that for baroclinic critical layers under continuous forcing, the linear evolution features secular growth of density and decreasing thickness, and the following nonlinear evolution is characterized by a jet-like mean flow, which is focused exponentially at later times. In the present work, we show that thermal diffusion can arrest the focussing. A coherent structure of density is formed instead, which drifts in the cross-stream direction and leaves behind a growing defect in the mean-flow velocity. We explore detailed properties of the drifting coherent structure, and conjecture that it could be responsible for the expansion of critical layers as observed in the zombie vortices.

1C.W. thanks the University of British Columbia for a four-year doctoral fellowship.

Monday, November 25, 2019 1:45PM - 3:16PM
Session L14 Energy: Hydropower and General

1:45PM L14.00001 Influence of sea bed slope on the performance of a shore-fixed oscillating water column wave energy converter1, PIYUSH MOHAPATRA, TRILOECHAN SAHOO, ANIRBAN BHATTACHARYYA, Indian Institute of Technology Kharagpur — The oscillating water column (OWC) devices have been quite effective in harnessing energy from the ocean waves at prototype scales. A numerical study was carried out to analyze the influence of sea bed slope on the hydrodynamic efficiency of such a device. A computational fluid dynamics (CFD) based numerical wave tank (NWT) was developed using ANSYS-Fluent which uses a multiphase volume of fluid (VOF) method to simulate the ocean waves. The power take-off (PTO) unit of the device is modeled as a porous jump in the flow field to impose the pressure jump versus flow characteristics of the turbine. The sea bed beneath the OWC chamber is varied in accordance with slope height and slope length. The fluid flow parameters inside the chamber and the hydrodynamic efficiency of the chamber are calculated for various sloping bed conditions. The efficiency is plotted against the incident wave frequency and it was observed that the efficiency curve reaches a maximum for a certain incoming wave frequency. It was observed that depending on the sea bed slope not only the value of the peak efficiency varies but also there is a phase shift in the efficiency plot. It was verified that for a few of the slopes there is an improvement in hydrodynamic capture efficiency.

1:58PM L14.00002 Characterization of a Mangrove-Like System for Tidal Energy Harvesting: Effect of root and path diameter.1, DANIEL O. GOMEZ VAZQUEZ, Undergraduate Student, Universidad Ana G. Mendez, EDUARDO E. CASTILLO CHARRIS, Assistant Professor, Universidad Ana G. Mendez, AMIRKHOSRO KAZEMI, Post Doctoral Research Associate, Florida Atlantic University, OSCAR CURET, Assistant Professor, Florida Atlantic University — Tidal energy is a potential source of renewable energy for many coastal locations in the US. However, many of the conventional devices to convert hydrokinetic energy to electrical energy are not necessarily apt in these locations. Inspired by mangrove roots - a tree that is abundant along the tidal stream in tropical and sub-tropical areas, we designed a novel device to harvest hydrokinetic energy from tidal currents. This device consists of one or multiple oscillating cylinders, partially submerged in the water and an electric generator composed of fixed magnets and a winding. A steel plate provides a restoring spring force for the system. The device was tested in a recirculating water tunnel for different cylinder diameters, array sizes and flow speeds. The kinematics and the voltage output were measured for the different conditions. The flow downstream the model was measured using Particle Image Velocimetry. In general, the device starts to oscillate at a critical flow speed and reach a maximum velocity until the motion decreases. The maximum amplitude oscillation and voltage output tend to increase with larger cylindrical diameters and when the cylinders were closer to each other. The power performance and wake structure are also compared.

1 National Science Foundations Research Experience for Undergraduates program (EEC-1659468)

2:11PM L14.00003 Energy Harvesting from Mangrove-like Structure in Tandem and Staggered Arrangements.1, EDUARDO E. CASTILLO, Assistant Professor, Universidad Ana G. Mendez, DANIEL O. GOMEZ VAZQUEZ, Undergraduate Student, Universidad Ana G.Mendez, AMIRKHOSRO KAZEMI, Post Doctoral Research Associate, Florida Atlantic University, OSCAR CURET, Assistant Professor, Florida Atlantic University — This work investigates the performance of a mangrove-inspired structure that uses vortex induced-vibration to harvest hydrokinetic energy. The device consists of a coil and magnets attached to a vertical wood cylinder submerged in water and connected to a thin steel plate. This cantilever configuration allows only oscillations perpendicular to the flow. Three independent devices were placed in tandem and staggered arrangement in a water tunnel to measure the power generation and the kinematics of the three devices. Reynolds numbers ranged from 200 to 1500, based on cylinder diameter. It was found that the energy generated was proportional to the oscillation’s amplitude. The results show that in both arrangements as the velocity of the flow increases, the amplitude of oscillation increases from zero to a region with high values to then decrease to zero for high velocities. The up-stream device shows a delay in that behavior, compare to the other devices, but reach higher frequency of the oscillations. Additionally, we measured the flow structure to explore the hydrodynamic interaction within the devices. These renewable energy devices could have applications to power small actuators or sensors to monitor coastal infrastructure.

2:24PM L14.00004 Numerical simulation of a horizontal axis tidal turbine with a passive load-control system, WEIDONG DAI, IGNAZIO MARIA VIOLA, University of Edinburgh, RICCARDO BROGLIA, CNR.Institute of Italian Ship Model Basin Insein — Load fluctuations on Horizontal Axis Tidal Turbines (HATT) may result in fatigue failures, and this is one of the main factors that affect the reliability and durability of tidal turbines. While passive load-control systems for horizontal axis wind turbine have been well studied, there are few studies about such systems for tidal turbines. We propose a passive pitching mechanism to mitigate the change of angle of attack and, in this way, to lower the fatigue loading. We studied the fluid mechanics of a HATT with and without the passive pitching mechanism in open channel flow conditions. The flow field around the blades and forces on the blades were computed numerically both with a commercial and an in-house finite-volume CFD code, and validated with experimental data. We found that the use of passive pitching mechanism can reduce the amplitudes of thrust fluctuations by around 80% without affecting the mean power generated. We also observed that this mechanism can mitigate the fluctuation of power output by around 20%.

2:37PM L14.00005 A total-flow design of geothermal power generator using Turgo turbines1, TZU-YUAN LIN, HSIEH-CHEN TSAI, National Taiwan University — We combine Turgo turbines and two-phase supersonic nozzles to design a total-flow geothermal power generator. The high-pressure subcooled liquid from the well forms supersonic flashing jets through the nozzles and the high-speed two-phase jets impinge turbine blades obliquely to drive the Turgo turbine. This new generator converts geothermal power directly from the two-phase fluid without implementing any phase separator or heat exchanger, which results in a simple and easy-to-maintain system. Compared with traditional Organic Rankine Cycle (ORC) generators, results from theoretical analysis and field tests in Yilan, Taiwan show that the new design of geothermal power generator has a competitive geothermal efficiency operating at moderate reservoir enthalpy.

2:50PM L14.00006 ABSTRACT WITHDRAWN —

3:03PM L14.00007 CFD Simulations of Floating Offshore Wind Turbine Platform1, MOSTAFA ELASKALANY, MAYSAM MOUSAVIRAAD, University of Wyoming — Computational modeling of offshore wind turbines imposes significant challenges due to the multiphysics nature of the system that involves both the turbine and the support structure. To provide reliable experimental data for validation of simulation tools, the OC5 DeepWind floating semi-submersible wind system was designed and tested through DOE support. The purpose of this work is to develop and validate a high-fidelity computational solver for floating offshore platforms that is capable of modeling incident waves, sea current, hydrodynamics, mooring dynamics, and foundation dynamics. The high-performance fluid solver is based on URANS CFD methods, capable of modeling incoming waves, including stochastic/random ocean waves based on specified spectrum, and resolves the nonlinear wave dynamics. Validation studies are presented for free decay as well as wave-only excitation in regular waves free to surge, heave, and pitch motions. Further computational studies are carried out in unidirectional irregular stochastic waves, including uncertainty quantification (UQ) for random input wave parameters. Future studies will include coupling with fully resolved turbine blades modeling, as well as stochastic optimization studies for improved hydrodynamics and aerodynamics.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L15 Turbulent Boundary Layers: Curvature and Pressure Gradients II

1:45PM L15.00001 Non-Equilibrium Boundary Layer Development in Response to Changing Pressure Gradients1, RALPH VOLINO, U.S. Naval Academy — Experiments were conducted in non-equilibrium turbulent boundary layers on a smooth flat wall. The test section included a zero pressure gradient (ZPG) development region, followed by a favorable pressure gradient (FPG) region with constant acceleration parameter $K = (\nu/U_{\infty}^2)(dU_{\infty}/dx)$, a ZPG recovery, and a constant $K$ adverse pressure gradient (APG) region. Eight cases were included with three different inlet velocities and $K$ in the FPG ranging from $0.125 \times 10^{-6}$ to $2 \times 10^{-6}$. The $K$ magnitude of the APG in each case was half that of the FPG. Velocity profiles were acquired at 12 streamwise stations using a two component LDV, and PIV was used to document velocity fields at the same stations. The mean velocity and turbulence profiles and correlations were observed to change in response to the changing pressure gradients, and changes in various quantities (e.g. wake strength or $u''$ at representative $y^+$) were quantified as functions of streamwise location. Normalizations of streamwise distance were found for the FPG, ZPG, and APG regions that caused the data to collapse, quantifying the non-equilibrium response to the changing pressure gradients.

1:58PM L15.00002 Spatio-temporal dynamics of pressure-induced turbulent separation bubbles1, WEN WU, CHARLES MENEVEAU, RAJAT MITTAL, Johns Hopkins University — The spatio-temporal dynamics of separation bubbles (SBs) induced to form in a fully-developed turbulent boundary layer over a flat plate are studied via direct numerical simulations. Two different SBs are examined: one induced by a suction-blowing velocity profile on the top boundary and the other, by a suction-only velocity profile. The latter condition allows reattachment to occur without an externally imposed favourable pressure gradient and leads to a SB more representative of those occurring over airfoils and in diffusers. The suction-only SB exhibits a range of clearly distinguishable modes. The high-frequency modes are well characterized by classical frequency scalings for a plane mixing layer and are associated with the formation and shedding of spanwise oriented vortex rollers. The topology associated with the low-frequency motion is revealed by the application of dynamic mode decomposition (DMD) and is shown to be dominated by highly elongated structures in the streamwise direction. The possibility of Görtler instability as the underlying mechanism for these structures is explored.

1The authors acknowledge support from AFOSR Grant FA9550-17-1-0084
2:11PM L15.00003 Effects of Adverse Pressure Gradient and Convex Curvature on the Evolution of Turbulence Statistics and Coherent Structures. SIMERET GENET, LIUYANG DING, ALEXANDER SMITS, MARCUS HULTMARK, Princeton University — Here we are interested in developing models and scaling relationships that better characterize non-equilibrium, turbulent, wall-bounded flows. In this study, an axisymmetric body is used to introduce streamwise pressure gradients and streamline curvature to a fully developed turbulent flow in a pipe. This body consists of three sections which are the bow, recovery region and the stern. The flow first sees the bow that creates a favorable pressure gradient. It then passes over the recovery region before meeting the stern that introduces an adverse pressure gradient (APG). Particle Image Velocimetry (PIV) is used to measure the flow field. The evolution of turbulent statistics as well as deformations of coherent structures are quantified in the stern region of the body of revolution. Different sized bodies are used to vary the strengths of the APG. Lastly, results from PIV are compared with data obtained from hot wire measurements at high Reynolds numbers in the Superpipe.

2:24PM L15.00004 Mean Momentum Balance in Adverse Pressure Gradient Boundary Layers. SYLVIA ROMERO, SPENCER ZIMMERMAN, JIMMY PHILLIP, JOSEPH KLEWICKI, University of Melbourne — Utilizing Large Eddy Simulation (LES) data from Bobke et al. (2017) the mean momentum equation for a two-dimensional adverse pressure gradient boundary layer (APG BL) will be analyzed in comparison to the channel flow case. The properties of the mean momentum balance (MMB) for a channel flow are well characterized (e.g. see Wei et al. (2005)). Like the channel flow case, the MMB for the two-dimensional zero pressure gradient boundary layer (ZPG BL) is a balance of three terms. Morrill-Winter et al. (2017) transformed the MMB terms of the ZPG BL into a form like the channel flow case. Using the data of Bobke et al. (2017), the present analysis examines whether a similar transformation is applicable to APG flows. The MMB for APG flows is a balance of four terms, unlike the three for the ZPG BL and channel flow. The four terms have physical interpretations that are tied to the flow physics. The change in dominance of the MMB terms will be discussed, as well as the dependence of the balance on the pressure gradient and distance from the wall. Various aspects such as the history effects of the developing pressure gradient and the location where the viscous force loss dominance will also be discussed.

2:37PM L15.00005 Direct Numerical Simulations of Separated Flow over a Bump. RICCARDO BALIN, University of Colorado Boulder, PHILIPPE SPALART, The Boeing Company, KENNETH JANSEN, University of Colorado Boulder — A turbulent boundary layer over a Gaussian bump is computed by direct numerical simulation (DNS) of the incompressible Navier-Stokes equations. The two-dimensional bump causes a rapid succession of favorable-to-adverse pressure gradients that can lead to shallow separation on the downstream side, both of which are characteristic of the flow over the flap of an aircraft wing in high-lift configurations. At the inflow, the momentum thickness Reynolds number is approximately 1,000, and the boundary layer thickness is 1/8 of the bump height. Results from DNS are discussed, describing the complex flow physics observed and the effects of variations to the inflow mean profile. Data from this study will be used for the development of lower fidelity turbulence models through data driven approaches.

1 This work is supported by the National Science Foundation (NSF), award number CBET-1710670, and by the National Aeronautics and Space Administration (NASA), award number 80NSSC18M0147. Resources of the Argonne Leadership Computing Facility, a DOE Office of Science User Facility, and of the NASA HECC facilities were used.

2:50PM L15.00006 Validation Experiments for Turbulent Separated Flows over Axysymmetric Afterbodies. SAMANTHA GILDERSLEEVE, CHRISTOPHER L. RUMSEY, NASA Langley Research Center — Historically, the flow physics involved with most turbulent separated flows have presented fundamental challenges in validation between experimental and numerical approaches. As recognized by the CFD Vision 2030 study commissioned by NASA, validation of RANS models and scale-resolving methods for turbulent flows requires the support of advanced, high-fidelity experiments designated specifically for CFD implementation. In accordance with this effort, a new test platform, referred to as the NASA Axysymmetric Afterbody, was designed to obtain detailed information in a flow with a smooth, adverse-pressure gradient induced separation. The parametric body offers a range of flow behaviors from fully attached, incipient separation, to fully separated flow at subsonic conditions. In an initial effort to validate CFD capabilities, surface pressure measurements and flow visualizations at Re=180,000 are compared against several RANS turbulence models to understand the separation behaviors and identify critical variability between the models. Results indicate potential discrepancies due to the effect of Reynolds number and physical tunnel blockage. Ongoing work will continue the experimental campaign to obtain off-body flow measurements using SPIV and LDV techniques to yield further insight.

3:03PM L15.00007 The law of incipient separation for turbulent flows as inferred by RANS. DAWEI LU, ABHIRAM AITHAL, ANTONINO FERRANTE, University of Washington, Seattle — We have performed Reynolds-averaged Navier-Stokes (RANS) computations of incompressible turbulent boundary layer with adverse pressure gradient over two-dimensional smooth curved ramps of length L for 982 ≤ Re₉ ≤ 3698. First, we have validated the RANS by comparing the results with the experiments of Song & Eaton (Expts. Fluids, 2004) for the separated flow over an arc at Re₉ = 1100. Then, we have investigated the effects of the ramp slope and curvature on the skin-friction and pressure coefficients. Our results show a numerical criterion of incipient flow separation determined only by the geometrical parameters of maximum slope, |z'|max, length, L, and height, h, of the ramp, and by Re₉. Specifically, incipient separation occurs when |z'|max normalized by h/L (|z'|max = |z'|max/hL) reaches a critical value that is determined according to the following law: |z'|crit = αRe₉⁻¹/θ + β, where α < 0 and β > 0 are constants. Accordingly, the flow separates over a curved smooth ramp for which |z'|max > |z'|crit. The uncertainty of the law is also reported.

Session L16 Focus Session: Exascale Computations of Complex Turbulent Flows II
4c3 - Fady Najjar
Applications, and report progress testing its implementation for relevant canonical problems. Test cases include the Taylor-Green vortex closures. We propose a dynamic blended hybrid RANS/ILES bridging strategy for applications involving variable-density turbulent mixing promoted by energy deposited at the material interfacial layers during the shock interface interactions. Transition involves unsteady large-scale multiscale resolution issues of shocks and variable density turbulence, we must address the difficult problem of predicting flow transitions implicit LES (ILES), where the small-scale flow dynamics is presumed enslaved to the dynamics of the largest scales. Beyond the complex Confinement Fusion (ICF) capsule implosions. Such complex flow physics is capturable with coarse grained simulation (CGS) – classical and from perturbations at shocked material interfaces, as vorticity is introduced by the impulsive loading of shock waves – e.g., as in Inertial GERMANO, Duke U. — We focus on simulating the consequences of material interpenetration, hydrodynamical instabilities, and mixing arising of the thermal scales within the flow.

were able to identify the destruction of turbulent convection caused by radiative damping of thermal fluctuations and relate it to the dimension level Regent programming language, which is itself a high level counterpart to the Legion programming system. We will give an overview of the whole description of TRI in a direct numerical simulation framework. We applied the algorithm to a thermally developing turbulent channel and the radiative transfer equation is solved on GPUs using an optimized Monte Carlo method. With our method it is possible to access the solution of the radiative transfer problem on fine grids is notoriously challenging, especially for optically intermediate systems; we implemented so called turbulence-radiation interactions (TRI) greatly modify the well-known patterns of heat transfer and variable property turbulence. The Delft University of Technology — When dealing with high temperature applications, thermal radiation plays an important role in the heat transfer process. In particular, due to its non-locality, radiation causes counter-intuitive interactions with the turbulent temperature field. These so called turbulence-radiation interactions (TRI) greatly modify the well-known patterns of heat transfer and variable property turbulence. The solution of the radiative transfer problem on fine grids is notoriously challenging, especially for optically intermediate systems; we implemented an innovative approach which exploits heterogeneous high performance computing facilities. The Navier-Stokes equations are solved on CPUs, and the radiative transfer equation is solved on GPUs using an optimized Monte Carlo method. With our method it is possible to access the whole description of TRI in a direct numerical simulation framework. We applied the algorithm to a thermally developing turbulent channel flow of high temperature water vapor to study the interaction between the different heat transfer mechanisms. With the obtained results we were able to identify the destruction of turbulent convection caused by radiative damping of thermal fluctuations and relate it to the dimension of the thermal scales within the flow.

Direct Numerical Simulation of Coupled Convection and Radiation on Heterogeneous Computing Architectures. SIMONE SILVESTRI, RENE PECNIK, DIRK ROEKAERTS, Delft University of Technology — When dealing with high temperature applications, thermal radiation plays an important role in the heat transfer process. In particular, due to its non-locality, radiation causes counter-intuitive interactions with the turbulent temperature field. These so called turbulence-radiation interactions (TRI) greatly modify the well-known patterns of heat transfer and variable property turbulence. The solution of the radiative transfer problem on fine grids is notoriously challenging, especially for optically intermediate systems; we implemented an innovative approach which exploits heterogeneous high performance computing facilities. The Navier-Stokes equations are solved on CPUs, and the radiative transfer equation is solved on GPUs using an optimized Monte Carlo method. With our method it is possible to access the whole description of TRI in a direct numerical simulation framework. We applied the algorithm to a thermally developing turbulent channel flow of high temperature water vapor to study the interaction between the different heat transfer mechanisms. With the obtained results we were able to identify the destruction of turbulent convection caused by radiative damping of thermal fluctuations and relate it to the dimension of the thermal scales within the flow.

Dynamic Bridging Modeling for Coarse Grained Simulations of Shock Driven Turbulent Mixing. FERNANDO GRINSTEIN, JUAN SAENZ, RICK RAUENZAHN, LANL, MASSIMO GERMANO, Duke U. — We focus on simulating the consequences of material interpenetration, hydrodynamical instabilities, and mixing arising from perturbations at shocked material interfaces, as vorticity is introduced by the impulsive loading of shock waves — e.g., as in Inertial Confinement Fusion (ICF) capsule implosions. Such complex flow physics is capturable with coarse grained simulation (CGS) – classical and implicit LES (ILES), where the small-scale flow dynamics is presumed enslaved to the dynamics of the largest scales. Beyond the complex multiscale resolution issues of shocks and variable density turbulence, we must address the difficult problem of predicting flow transitions promoted by energy deposited at the material interfacial layers during the shock interface interactions. Transition involves unsteady large-scale coherent-structure dynamics resolvable by CGS but not by RANS modeling based on equilibrium turbulence assumptions and single-point-closures. We propose a dynamic blended hybrid RANS/ILES bridging strategy for applications involving variable-density turbulent mixing applications, and report progress testing its implementation for relevant canonical problems. Test cases include the Taylor-Green vortex – prototyping transition to turbulence, and a shock tube experiment – prototyping shock-driven turbulent mixing.

Large-eddy simulation of Rayleigh-Taylor mixing on the Sierra supercomputer. BRANDON MORGAN, JASON BURMARK, MICHAEL COLLETTE, CYRUS HARRISON, MATTHEW LARSEN, BRIAN PUBLINER, BRIAN RYUJIN, Lawrence Livermore National Laboratory — The Sierra system is Lawrence Livermore National Laboratory’s first production supercomputer accelerated by graphics processing units (GPUs). As part of the system’s initial acceptance testing in October 2018, large-eddy simulation was conducted of Rayleigh-Taylor mixing in a spherical geometry using 97.8 billion computational volumes across 16,384 GPUs on Sierra. This talk will discuss how the Sierra system enabled such a massive calculation and how the results have been used to inform development of the k-L-a-Y1 Reynolds-averaged Navier-Stokes (RANS) model for reacting turbulence [Morgan, B. E., Olson, B. J., Black, W. J., and McFarland, J. A., “Large-eddy simulation and Reynolds-averaged Navier-Stokes modeling of a reacting Rayleigh-Taylor mixing layer in a spherical geometry.” Phys. Rev. E 98, 033111 (2018)].

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
2:50PM L16.00006 Towards Exascale Direct Numerical Simulations of Multi-Stage Ignition and Turbulent Mixing in Diesel Jets. JACQUELINE CHEN, MARTIN RIETH, MYOUNGKE LEE, Sandia National Laboratories, ELLIOTT SLAUGHTER, SESHU YAMAJALA, SLAC Accelerator National Laboratory, ALEX AIKEN, Stanford University — Direct numerical simulations of multi-stage ignition in low-temperature surrogate diesel jets is used to study ‘turbulence-chemistry’ interactions governing cool flame propagation and turbulent diffusion and their role in accelerating low- and high-temperature ignition. The effects of varying the ambient temperature and oxygen concentration on mixture formation and combustion processes is quantified. Conditional statistics are presented showing the significance of turbulent diffusion relative to laminar flame propagation. These simulations are enabled by an asynchronous task-based programming model and runtime, Legion, which is used to obtain scalable performance of the Legion-S3D DNS code on Summit at the Oakridge Leadership Computing Facility. The Legion runtime is able to hide the memory latency by overlapping communication and computation and to optimize data movement. Refactoring Legion-S3D in Regent, a companion compiled language that maps directly onto the Legion runtime, simplifies and enforces the rules of the Legion programming model enabling domain scientists to write extensible code with sequential semantics.

3:03PM L16.00007 Parallel and dynamic mesh adaptation of tetrahedral-based meshes for propagating fronts and interfaces: application to premixed combustion and primary atomization. VINCENT MOUREAU, PIERRE BENARD, GHISLAIN LARTIGUE, CORIA, CNRS UMR6614, Normandie University, INSA et Université de Rouen, France — Thanks to the steady growth of computational resources and a large effort on solver optimization, Large-Eddy Simulation (LES) of realistic systems has become attainable. In these systems, turbulent multi-physics flows involve a large range of scales that need to be resolved by the mesh to capture the proper flow dynamics. Adaptive or dynamic mesh adaptation (AMR) is an appealing technique to reduce the modeling errors in LES. AMR of tetrahedral-based meshes for LES is difficult as it requires numerous mesh topology changes and high-quality grids to resolve the turbulent scales that are close to the cut-off frequency of the mesh. A parallel AMR strategy has been developed recently [Bnard et al., IJNMF 2015] in the YALES2 flow solver [www.coria-cfd.fr]. It combines adaptation and repartitioning steps to enable the AMR of massive grids counting billion cells exploiting up to tens of thousand cores. Mesh adaptation relies on the work of Dapogny et al. [JCP 2014] available in the MMG library [www.mmgtools.org]. The presentation will focus on the parallel adaptation strategy for both volume and surface meshes, its optimization on modern super-computers and on various academic and industrial applications related to premixed turbulent combustion and primary atomization.

Monday, November 25, 2019 1:45PM - 3:16PM –
Session L17 Focus Session: Recent Advances in Data-driven and Machine Learning Methods for Turbulent Flows III

1:45PM L17.00001 Machine learning meets mechanism: Mechanism of roll reversal in Rayleigh-Bénard Convection, XI CHEN, XIAOJUE ZHU, MICHAEL BRENNER, Harvard University — Understanding the precise physical events that underlie the reversal of circulation direction in Rayleigh-Bénard (RB) convection has long been a mystery. We aim to solve this problem by using a machine learning model to classify the events related to a reversal in convection. We found a unique time scale indicating the transition between two circulation directions of RB-Flow, which is much shorter than the periodicity of reversals. We then try to invert the neural network, to discover the precise flow events that cause the physics on this timescale. This allows us to identify local patterns of the flow field that are critical to the reversal phenomena. We use these as the basis for building a phenomenological theory of reversal. We believe using interpretable machine learning in this way can be applied for the study of other fluid dynamics problems and even a lot of science problems.

1:58PM L17.00002 Physics-Informed Echo State Networks for the Prediction of Extreme Events in Turbulent Shear Flows. NGUYEN ANH KHOA DOAN, WOLFGANG POLIFKE, Technical University of Munich, LUCA MAGRI, University of Cambridge — A large number of turbulent flows exhibit extreme events. Extreme events are here defined as large-amplitude deterministic events, which suddenly occur aperiodically in the chaotic attractor. The time-accurate prediction of extreme events is challenging because of (i) the butterfly effect, which is the main property of the chaotic dynamics of turbulent flows, and (ii) the unpredictable nature of extreme events. We develop a physics-informed data-driven framework, the Physics-Informed Echo State Network (PI-ESN), to predict extreme events in turbulent flows. The PI-ESN consists of a reservoir of dynamical neurons, which learn the systems dynamics from time-series of its evolution. We apply this method to a turbulent shear flow between two free-slip walls subject to a sinusoidal force. This flow displays abrupt transition between quasi-laminar and fully-turbulent states. We are able to time-accurately predict the flow evolution during these extreme events by imposing the physical principles as constraints in the learning algorithm. This physics-informed data-driven approach outperforms purely data-driven approaches, which opens up new horizons for the time-accurate prediction of turbulent flows by leveraging on data and physical principles.

2:11PM L17.00003 Data-driven prediction of vortical structures in turbulent flows employing deep learning techniques, BABAK KASHIR, MARCO RAGONE, VITALIY YURKIV, FARZAD MASHAYEK, University of Illinois at Chicago — The vortical structures are inherent characteristics of turbulent flows. Significant research has been conducted to understand, characterize and locate the vortical structures in turbulent flows in complex configurations. However, the identification of the size and location of the vortices in practical flows is often challenging due to the interplay of various parameters. To overcome these challenges, we have developed a deep learning model to identify and locate the vortical structures. The deep learning model is trained and tested in lid-driven cavity flow fields to predict the vortical structures in different conditions. The architecture of the model is characterized by multiple layers with random initialization and linear regularization, whereas the final prediction is performed through a binary classification. The second invariant of the velocity gradient tensor (known as the Q-criterion) is used to locate the vortical structures in fluid dynamics. This criterion describes a vortex as a continuous fluid region with the positive second invariant. The neural-network predictions are compared with the results from the previously validated numerical simulations. The present study allows for advance accelerated analysis of complex turbulent flows.

A priori translational invariance and different inputs are tested aiming to provide a Galilean invariant model. A convolution operation ensures of the local three-dimensional (3D) strip which provides a two-dimensional formulation with additional statistical terms accounting for the 3D.

We propose a new flow decomposition based on the spanwise average fluctuations and sound level spectrum of pressure fluctuations are successfully obtained to assess flow and noise characteristics of side mirror models.

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (MSIT) (No. 2011-0030013, No. 2018R1A1B2007117).

2:37PM L17.00005 Deep learning the spanwise-averaged turbulent wake of a circular cylinder1, BERNAT FONT GARCIA, Univ. of Southampton and Inst of High Performance Computing (A*STAR), GABRIEL WEYMOUTH, University of Southampton, VINH-TAN NGUYEN, Institute of High Performance Computing (A*STAR), OWEN TUTTY, University of Southampton — Numerical simulations of long and flexible cylindrical structures become prohibitive at high Reynolds regimes because of the wide range of spatial and temporal scales that need to be resolved. We propose a new flow decomposition based on the spanwise average of the local three-dimensional (3D) strip which provides a two-dimensional formulation with additional statistical terms accounting for the 3D.

Numerical simulations of long and flexible cylindrical structures become prohibitive at high Reynolds regimes because of the wide range of spatial and temporal scales that need to be resolved. We propose a new flow decomposition based on the spanwise average of the local three-dimensional (3D) strip which provides a two-dimensional formulation with additional statistical terms accounting for the 3D.

The equations highlight a symmetry of the pressure Hessian. Indeed, the component of the non-local pressure Hessian, reducing it to a tensor of rank two. This simplifies the geometric interpretation of the pressure Hessian effect on the dynamics of the velocity gradient invariants and allows to compare two- and three-dimensional flows. We characterize the geometry of the effective pressure Hessian by means of DNS results, focusing on the statistics of its independent eigenvalue and the alignment between the effective pressure Hessian and Navier-Stokes equations.

This work was supported by Samsung Research Funding Center of Samsung Electronics under Project Number SRFC-TB1703-01 and National Research Foundation of Korea (NRF) under Project Number NRF-2017R1E1A1A03070514.

2:50PM L17.00006 Mechanisms of convolutional neural networks for learning three-dimensional unsteady wake flow1, SANGSEUNG LEE, DONGHYUN YOU, Pohang University of Science and Technology — Recently, convolutional neural networks (CNNs) have been applied to predict or model flow dynamics. However, mechanisms of CNNs for learning flow dynamics are still not well understood, while such understanding is highly necessary to reduce trial-and-errors in designing networks. In the present study, we investigate the mechanisms of a CNN for prediction of three-dimensional unsteady wake flow behind a circular cylinder. Feature maps in the CNN are visualized to compare flow structures that the CNN extracts from flow at different flow regimes. A Fourier analysis is conducted to reveal the mechanisms, which enable the CNN to predict flow dynamics at different flow regimes, of a convolution layer to integrate and transport wave number information from flow. The integration and transportation characteristics of information of flow variables and histories in the CNN are discussed.

1This work was supported by Samsung Research Funding Center of Samsung Electronics under Project Number SRFC-TB1703-01 and National Research Foundation of Korea (NRF) under Project Number NRF-2017R1E1A1A03070514.

3:03PM L17.00007 Learning effective viscosity for moderate Reynolds number Navier-Stokes equations, XIAOJUE ZHU, MICHAEL BRENNER, Harvard University — We propose that with an appropriately chosen effective viscosity $\nu(Re)$, a linearization of the Navier-Stokes equations perfectly captures the drag-determining features of flows around unsteady translating bodies, in the Reynolds number of order hundreds. Two ways are implemented to find the effective viscosity. First, $\nu(Re)$ is determined so that the time-averaged shapes of separatrix, a fluid surface that delimits the compact region of fluid that is entrained by the moving point force, match as closely as possible between the linearization equation and the Navier-Stokes equation. Second, $\nu(Re)$ is learned from a data-driven method, i.e. a deep neural network, by minimizing the mean squared error loss. We compare the results for the two methods, and we find that the data-driven method dramatically outperforms the former traditional method. We apply the linearization to the classical problem of predicting vortex shedding around a cylinder.

1This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (MSIT) (No. 2011-0030013, No. 2018R1A1B2007117).
1:58PM L18.00002 Velocity gradient (VG) decomposition into normal-strain, pure shear, solid-body-rotation tensors: new insights into turbulence VG dynamics, RISHTA DAS, SHARATH GIRIMAJI, Texas A&M University — Velocity gradient tensor (VGT, \(A_{ij}\)) decomposition into symmetric (\(S_{ij}\)) and anti-symmetric (\(W_{ij}\)) tensors is unable to segregate the effect of shear present in both the strain-rate and rotation-rate tensors. In this study, an additive decomposition of VGT into normal strain-rate (\(N_{ij}\)), solid body rotation (\(R_{ij}\)) and pure shear (\(H_{ij}\)) tensors, is employed. In this decomposition, shear is clearly demarcated from pure rotation and pure normal strain effects. Then, we use direct numerical simulation data of incompressible forced isotropic turbulence in Taylor Reynolds number range \(Re_{\lambda} \in (200 - 600)\), to examine statistical and dynamical aspects of velocity gradient dynamics. We investigate (i) the probability distribution of the magnitude (Frobenius-norm) of these pure strain, pure shear and solid-body rotation tensors; (ii) the preferential alignment of the axis of solid-body rotation with the normal strain-rate eigenvectors; (iii) the conditional statistics of different VG processes as a function of these tensors; and (iv) intermittency phenomenon. The study develops unique and novel insights into turbulence processes which are not evident from previous VGT decompositions.

2:11PM L18.00003 Area Rule for velocity circulation\(^1\), KARTIK IYER, KATEPALLI SREENIVASAN, New York University, P.K. YEUNG, Georgia Institute of Technology — The statistical theory of velocity circulation at high Reynolds numbers has witnessed renewed interest following recent studies, both empirical (Iyer et al., arXiv:1902.07326, 2019) and theoretical (Migdal, arXiv:1903.08613, 2019). A central tenet in the scaling theory of circulation is the Area Rule which states that the probability distribution of the circulation around closed contours, whose characteristic dimensions reside in the inertial range, depends solely on the minimal spanning surface of the contour. We examine the Area Rule for both low and high order circulation moments, for different contour shapes and sizes, using the DNS of the three-dimensional Navier-Stokes equations within a cube with periodic boundary conditions, with the integral-scale Reynolds number spanning over two decades. Useful comparisons with other fields such as the Gaussian random fields will be discussed to highlight the simplicity afforded by circulation in the statistical description of small-scale turbulence.

\(^1\)This work is supported by NSF grant 1640771. The computations were performed using supercomputing resources provided through the XSEDE consortium at the Texas Advanced Computing Center at the University of Texas (Austin) and the Blue Waters Project at the National Center for Supercomputing Applications at the University of Illinois (Urbana-Champaign).

2:24PM L18.00004 Intermittency of Incompressible Passive Vector Convected by Homogeneous Turbulence\(^2\), TOSHIYUKI GOTOH, JINGYUAN YANG, Nagoya Institute of Technology, HIDEAKI MIURA, National Institute for Fusion Science, TAKEHISI WATANABE, Nagoya Institute of Technology — It is known that the fluctuation of passive scalar convected by turbulence is stronger than that of the turbulent velocity. In order to understand the physical mechanism yielding this difference we have studied the fluctuations of an incompressible passive vector \(u\) convected by the isotropic turbulence by comparing them with the passive scalar. It is found that the passive vector spectrum obeys the Obukhov-Corssin spectrum \(k^{-5/3}\) with constant \(C = 0.09\) and the low order statistics is close to the velocity spectrum at large scales and resembles the passive scalar at small scales. Strength of the intermittency of the passive scalar is intermediate between the velocity and the passive scalar. The domain size of intense \(\nabla \times u^2\) is found to be sheet like and similar to the scalar gradient. It is argued that the linearity of the equation is the key to generate the stronger intermittency of the passive fields.

2:37PM L18.00005 Toward investigation of local vortex line topology in turbulence, BAJIRANG SHARMA, RISHTA DAS, SHARATH GIRIMAJI, Texas A&M University — Current vortex identification methods employ \(Q\) or \(\lambda_2\) criterion to investigate vortical structures in turbulent flows. We propose an alternate method to examine the local vortex structure. Specifically, we construct the vorticity vector field (\(\zeta\)) and compute the vorticity gradient tensor \(J_{ik} \equiv \partial \omega_i / \partial x_k\). The tensor \(J_{ik}\), similar to the velocity gradient tensor \(A_{ij} \equiv \partial u_i / \partial x_j\), is trace free. In a manner similar to streamline topology analysis using the second and third invariants of \(A_{ij}\), the second (\(Q_2\)) and third (\(R_3\)) invariants of \(J_{ik}\) are used to develop the topological description of local vortex line structure. Such a representation is not only useful for investigating the local vortex-line structure but is also useful in identifying key turbulence phenomena such as vortex line reconnection. Direct numerical simulation (DNS) data of incompressible forced isotropic turbulence and perturbation-evolution in plane-Poiseuille flow are analysed in this study. We investigate the following: (i) distribution in these two key canonical turbulent flows; and (ii) the formation of hair-pin vortices in transitioning plane Poiseuille flow using the aforementioned method.

2:50PM L18.00006 Origin and implications of odd-spin contributions in rapidly distorted turbulence, SUSAN KURIEN, Los Alamos National Laboratory, TIMOTHY CLARK, University of New Mexico, ROBERT RUBINSTEIN, Retired — We present mathematical calculations and supporting data from numerical simulations to demonstrate the emergence of reflection-symmetry breaking along the polar axis in flows, in the rapid distortion limit. The mathematical decomposition of second-rank tensors (eg: velocity correlations in wavenumber space) is done in the SO3 basis. We show the appearance of symmetry breaking for various reflection-symmetric initial conditions including isotropic and axisymmetric turbulence. The strain-rate tensor used to achieve rapid distortion also remains symmetric in all our test cases. These results help to elucidate the mechanism by which the so-called odd-spin (reflection-symmetry breaking) terms arise in the SO3; they also clarify the separate role of this type of symmetry breaking from other explicitly reflection-symmetric forcings such as helical or rotational strains.

3:03PM L18.00007 How the ramp-cliff structures in scalar turbulence vary with the Schmidt number and how to model that variation\(^3\), DHAWAL BUARI, New York University, M.P. CLAY, Georgia Institute of Technology, K.R. SREENIVASAN, New York University, P.K. YEUNG, Georgia Institute of Technology — In turbulent mixing of passive scalars, the ramp-cliff structures observed in one-dimensional cuts of the scalar field are responsible for a few important consequences, such as, departure from local isotropy, saturation of scaling exponents with respect to the moment-order. These results are established under the case of unity Schmidt number (\(Sc\)) given by the ratio of the kinematic viscosity of the fluid to the scalar diffusivity. In this talk, our first goal is to show how the above results vary with increasing \(Sc\). We utilize a massive DNS database with the Taylor-scale Reynolds number in the range \(140 - 650\), and \(Sc\) in the range \(1 - 512\), for the case of passive scalar with a uniform mean scalar gradient, mixed by forced isotropic turbulence. In particular, we investigate how the odd moments of the scalar derivatives (which are the symptoms of the ramp-cliff structures) vary with \(Sc\). A model based on the changing ramp-cliff structures is presented to describe the observed scaling of the scalar derivative statistics. We also address the scaling of scalar increments for varying \(Sc\) and particularly explore the saturation of exponents with respect to the order of their moments.

1:45PM L19.00001 Numerical multiscale methods and effective boundary conditions
SEAN CARNEY, BJORN ENGQUIST, ROBERT MOSER, University of Texas at Austin — Numerical homogenization refers to the numerical extraction of the effective, “macroscopic”, or large scale behavior of a complex dynamical system at a reduced cost to resolving the full dynamics at all levels of detail. The no-slip boundary condition (BC) for viscous fluid flow over a solid surface can introduce asymptotically small scales that pose severe challenges for simulation; in this case it can be preferable to replace the no-slip condition with a homogenized BC. This talk discusses numerical techniques for generating slip BC, or wall laws, for laminar flows over rough boundaries, as well as turbulent boundary layer flows for constant favorable, zero, or adverse \( \nabla \cdot \mathbf{v} \). Guided by rigorous mathematics in the former case and recent empirical advances in the latter, numerical strategies are presented to overcome the high computational cost of resolving the full near wall dynamics. In both settings, the main idea consists of running high resolution simulations in a relatively small domain localized to the boundary. Numerical examples presented throughout validate the modeling approach.

1:58PM L19.00002 Extending Partially-Averaged Navier-Stokes equations to Variable-Density Turbulent Flow
FILOPE PEREIRA, FERNANDO GRINSTEIN, DANIEL ISRAEL, RICK RAUENZAHN, Los Alamos National Laboratory, SHARATH GIRIMAJI, Texas A&M University — The mixing of distinct fluids is of importance to various areas of engineering. This class of problems is featured by its variable-density (VD) that leads to buoyancy effects, hydro-dynamical instabilities, transition and turbulent flow. All these phenomena turn the modeling of VD flows difficult. Whereas DNS and LES models are excessively demanding for practical problems, RANS tends to poorly predict such flows. Bridging methods, on the other hand, have the potential to surpass many of the limitations of the former models. By resolving only the phenomena that are not amenable to be modeled, these models can achieve a good compromise between accuracy and cost. Yet, their development for VD flows is rife with challenges. The aim of this work is to develop a Partially-Averaged Navier-Stokes (PANS) framework for VD flow. To this end, the PANS framework proposed by Girimaji (2005) is extended to VD flow in order to derive a PANS-BHR2 closure. Particular attention is paid to the selection of the physical resolution (range of resolved scales) of the model. Thus, apriori testing is conducted to propose guidelines toward the efficient selection of the parameters determining the physical resolution of PANS-BHR2. The proposed model is then evaluated on two archetypal flow problem.

2:11PM L19.00003 Identifying benefits of PANS-modeling over LES for engine flows
BRANISLAV BASARA, ZORAN PAVLovic, AVL List GmbH — Large-Eddy Simulation (LES) has been frequently used for engine flows providing reliable and accurate results. On the other hand, the limitations of Reynolds-Averaged Navier-Stokes (RANS) models are very well known and some of them are possible to compensate with e.g. modelling in combustion (knock), or they are just ignored like cycle-to-cycle variability etc. Most of limitations are solved by applying LES but leading to much higher computational costs. Up to now, it has not been clear if some of hybrid RANS-LES models could improve engine calculations with a moderate increase of computational costs. The Partially-Averaged Navier-Stokes (PANS) approach (Girimaji, 2006) is designed to resolve a part of the turbulence spectrum adjusting seamlessly from RANS to DNS. In order to optimize the basic PANS method for moving geometries, Basara, Pavlovic and Girimaji (2018) introduced an additional equation for the scale supplying variable. In this approach, the main resolution parameter, the unresolved to total kinetic energy ratio, can be calculated in-situ enabling simple and cost-effective calculations of engines. Cycle-to-cycle variations have been achieved with amplitudes of cycle relevant variables that are depending on the ratio between unresolved and total kinetic energy. Nevertheless, benefits in PANS calculations are also expected to come from the proper modelling of the wall including the heat transfer even for larger \( g+ \) values as RANS models are applied there. This should have a positive impact on the emission predictions. The work presented here will try to provide answers on all these questions.

2:24PM L19.00004 Enhancement of PANS with Non-Linear Eddy Viscosity Closure
SAGAR SAROHA, KRISHNENDU CHAKRABORTY, SAWAN SUMAN SINHA, IIT Delhi, SUNIL LAKSHMIPATHY, Gecon AS, Norway — In recent years partially-averaged Navier-Stokes (PANS) method has emerged as a promising bridging method for simulating turbulent flows. However, most PANS simulations reported in the literature have been performed employing linear constitutive equation for unclosed stresses. While PANS inherently addresses the limitations of Reynolds-averaged Navier-Stokes (RANS) by reducing the overly diffusive effects by choosing appropriate sub-unity values of its filter parameters, the limitations of a linear eddy viscosity model inherited from a parent RANS model still bottleneck its performance. Indeed experimental evidence suggest that in flow past bluff bodies, there are regions where the Reynolds stress tensor is substantially misaligned with the local resolved strain rate, and a simple linear eddy viscosity assumption is not realistic. We present an enhanced version of the PANS methodology which employs a non-linear eddy viscosity model. We show that this enhancement substantially improves the prediction of various hydrodynamic as well as heat transfer statistics in flows past two representative bluff bodies: a square cylinder and a sphere. This enhanced nonlinear PANS methodology is presented as a more potent bridging method than its linear counterpart.

2:37PM L19.00005 Sensitized RANS modeling of turbulence: a scale-resolving ERM-based eddy-viscosity model
SUAD JAKIRLIC, BENJAMIN KRUMBEIN, Technische Universitaet Darmstadt, Germany, ROBERT MADUTHA, OutoTec GmbH, Oberursel, Germany, CAMERON TROPEA, Technische Universitzaet Darmstadt, Germany, 1 TEAM — A near-wall URANS (Unsteady Reynolds-Averaged Navier-Stokes) eddy-viscosity model based on elliptic-relaxation methodology (ERM) is sensitized to resolve fluctuating turbulence by introducing an appropriately formulated source term in the scale-supplying equation governing the turbulent inverse time scale. The latter term, inspired by the scaleadaptive simulation concept (Menter and Egorov, FTAc 85, 2010), enables an adequate suppression of the modeled turbulence intensity toward the respective sub-scale level. It implies the model’s self-balancing between the resolved and modeled (unresolved) contributions to the turbulence kinetic energy. The feasibility of this grid-spacing-free model formulation is checked by computing a series of internal heat and fluid flow configurations featuring boundary layer separation, flow impingement, thermal mixing of flow-crossing streams as well as flows over rough and porous walls. Comparison to under-resolved Large-Eddy Simulations (LES) applying the dynamic Smagorinsky model and to a hybrid RANS/LES model based on the same eddy-viscosity scheme, denoted by VLES (Very LES, Chang et al., IJHFF 49, 2014) indicates an advantage in terms of the predictive capabilities of the presently proposed model, especially on relatively coarser meshes.

1TRR150 project granted by the German Research Foundation
simulations of turbulent channel flow. IMU based controllers. Controllers make use of inertial measurement units (IMUs) located in the main body and require motion to occur before attempting to counter with a 1KHz sampling rate and its roll was recorded. Long short-term memory (LSTM) neural networks processed the information gathered by the acquired data. The approach for from planar experimental measurements can be fed into a turbulent channel flow DNS to reduce the required computational time and domain for a given friction Reynolds number. The effect of inlet resolution and required spanwise extent are examined by generating synthetic experimental fields from streamwise periodic channel flow DNS at Re = 180 and 550 and using this data as the inlet to a channel flow DNS with inlet-outlet boundary conditions. When fully resolved inlet data is used the streamwise domain of the inlet-outlet DNS can be reduced to 1/16 of the periodic domain with minimal influence on the flow statistics and can even withstand a halving of the spanwise domain.

Monday, November 25, 2019 1:45PM - 3:16PM
Session L20 Low-Order Modeling and Machine Learning

2:11PM L20.00003 Bringing Computational Fluid Dynamics at the heart of industrial processes: can Machine Learning help? . CHRISTOS VARSAKELIS, SANDRINE DESSOY, GlaxoSmithKline Biologicals — Advances in both physical understanding and computational power have rendered several industrial problems amenable to a Computational Fluid Dynamics (CFD) analysis. However, even though in silico prototyping is gradually becoming the norm, utilizing the predictive power of CFD for real-time tasks, e.g. controlling a process, remains prohibitive. Recent literature has suggested that Machine Learning (ML) algorithms may be trained by CFD simulations and, subsequently, replace CFD codes due to their speed advantage. In this talk, we systematically evaluate this proposal through a series of industrial test cases of varying complexity. Both laminar and turbulent test cases are examined for various spatio-temporal scales. The talk concludes with the ranking of the performance of ML algorithms in terms of accuracy, speed to completion are often limiting factors for the problems that can be studied numerically. At the same time, problem-specific extensions to the simulation code are often necessary. The Julia programming language promises to enable quick, iterative development in a friendly, high-level language while achieving a performance comparable to Fortran and C. We present a new code for direct numerical simulation of turbulent channel flows written in Julia, scaling to thousands of CPU cores. We compare its performance to a Fortran code with the same numerical approach and discuss advantages and drawbacks of the new code.

2:24PM L20.00004 Prediction of aerodynamic loads in turbulent flow conditions . ANDREAS NATSIS, Portland State University, RAL BAYON CAL TEAM, ALEXANDER J. HUNT TEAM — In the direct numerical simulation (DNS) of turbulence it is the large scales that require large computational domains and long simulation times to attain the correct statistically stationary state. In contrast experimental measurements struggle to resolve down to the dissipative flow scales, but have far less trouble capturing the large scales. In this work we demonstrate how large scale information from planar experimental measurements can be fed into a turbulent channel flow DNS to reduce the required computational time and domain for a given friction Reynolds number. The effect of inlet resolution and required spanwise extent are examined by generating synthetic experimental fields from streamwise periodic channel flow DNS at Re = 180 and 550 and using this data as the inlet to a channel flow DNS with inlet-outlet boundary conditions. When fully resolved inlet data is used the streamwise domain of the inlet-outlet DNS can be reduced to 1/16 of the periodic domain with minimal influence on the flow statistics and can even withstand a halving of the spanwise domain.

2:37PM L20.00005 Airfoil control with Proximal Policy Optimization, DENIS DUMOULIN, PHILIPPE CHATELAIN, UCLouvain — Airfoil control generally relies on techniques based on a dynamical model of the actual system one wants to control. Such methods are in some cases limited by the expressiveness of the model and its linearization around equilibrium points. This is the case in aerodynamics where non-linearities (e.g., turbulent structures or dynamic stall) strongly affect the flight conditions and more specifically aerodynamic loads undergone by the flying body. To avoid such limitations, we propose the use of a model-free control method based on Reinforcement Learning (RL) algorithms. This study relies on a low-order inviscid planar solver which accounts for separation; this model controls its computational cost through lumping of the shed vortices in the wake. The complexity of the model is critical for RL methods which require large amounts of data. We then use Proximal Policy Optimization (PPO) to control the dynamics of a NACA0012 airfoil. This planar body goes through a random train of vortical dipoles while trying to keep its aerodynamic coefficients constant. Within a few thousands of episodes of training, the controller is able to stabilize the airfoil regardless of the incoming vortices using pressure measurements distributed on the body and its kinematics.

2:50PM L20.00006 A reduced order model for store separation in high speed flow, NICHOLAS PETERS, JOHN EKATERINARIS, Embry-Riddle Aeronautical University — Store separation from aircraft and spacecraft has historically been a critical issue for the aerospace industry. Given the severity of the problem much effort has been spent on the topic. Yet, the process for identifying potential failures is a resource intensive and iterative process. A potential remedy for reducing iterations in this process is the implementation of an active controller for use during separation. The objective of this study is to design such a controller, using a reduced ordered model (ROM) for the flow around an external store undergoing separation. A combination of computational fluid dynamic (CFD) solvers, fun3D and Ansys Fluent, is employed to obtain flow fields around the vehicle and the store. Preliminary validation of the numerical results is initially carried out. Representative cases of store separation are obtained next. Proper Orthogonal Decomposition (POD) and Dynamic Mode Decomposition (DMD) are used to obtain leading modes that will be used to reconstruct a ROM of the flow field. These models will be compared with the objective of seeing which method better represents the numerical solution to the problem at different flow speeds with and without the presence of shock waves. The ROM will then be used to construct the controller.

3:03PM L20.00007 Fast potential flow computations for low-order aerodynamic modelling, DIEDERIK BECKERS, JEFF D. ELDREDGE, University of California, Los Angeles — Lightweight aircraft are vulnerable to flow separation induced by gusts. For purposes of regulating flight in the presence of such gusts, it is important to estimate the flow behavior and the instantaneous aerodynamic forces. In previous work, it was shown (D. Darakananda et al., Phys. Rev. Fluids 3, 124701, 2018) that low-order vortex models can be assimilated with sensor measurements to achieve this estimation. However, traditional vortex element models using Biot-Savart interactions can be computationally inefficient, particularly for 3D models. This work addresses grid-based computations for potential flows in 2D and 3D with the goal of implementing a low-order vortex model for fast modeling of separated aerodynamic flows and gust interactions. The immersed boundary projection method is used to solve for the vector potential field subject to the constraints introduced by the presence of a body. The equations are discretized on a staggered Cartesian grid and solved using the lattice Green’s function. The accuracy of these computations is demonstrated for singular vortex elements in 2D and the extension to 3D flows will be discussed.

Monday, November 25, 2019 1:45PM - 3:16PM – Session L21 Drops: Impacts with Solids II 603 - Jeffrey Marshall, Univ Vermont

1:45PM L21.00001 Rebound and Sticking Dynamics of Droplets Impinging on Wettable Surfaces, ANUPAM MISHRA, YANBAO MA, Department of Mechanical Engineering, University of California, Merced, ARVIND GOPINATH, Department of Bioengineering, University of California, Merced — We investigate the rebound and sticking dynamics of liquid droplets impinging on wettable surfaces under zero gravity conditions using Multi-body Dissipative Particle Dynamics. A soft potential with an attractive and a repulsive component is used to model surface tension for liquid. The surface-droplet interactions are modeled by a similar potential with independently tunable attractive and repulsive components to obtain a wide range of wettability. The viscosity of the ambient medium is set to zero and the droplet density is held constant. Varying the attractive liquid-solid potential, the droplet velocity and size independently, we classify the impact dynamics into one of two categories - rebound or stick. Collapsing the results in two dimensionless parameters - the Weber number \(W_e\) based on drop properties, and an attraction parameter \(A_e\) based on the surface-drop potential - we obtain the critical curve separating the rebound from stick responses. Upon impact, both rebounding and sticking droplets form a pancake-shaped disk on the substrate. We calculate the evolution of the radius of the disk, track the center of mass distance from the substrate, calculate the rebound time and compare with analytical scalings in the literature.

1:58PM L21.00002 Bouncing Dynamics of Liquid Marbles, NIKOLAY IONKIN, DANIEL HARRIS, Brown University — Liquid marbles are millimetric droplets of fluid coated in a hydrophobic powder, which behave like soft solids that can readily roll and bounce. In this talk, we demonstrate that a liquid marble bouncing on a vertically vibrated surface demonstrates a period-doubling cascade to chaos as the vibration amplitude is increased. The resulting sequence of bifurcations is highly reminiscent to that of the extensively studied 1D model of a bouncing ball on a vibrating platform. Unlike the classical model however, our bouncer is relatively soft, and thus the time evolution of both the center of mass and the contact point is significantly affected by the vibration period. The experimental results are directly compared to predictions of a simple bouncing spring model. Our findings may help further elucidate the subtle mechanical behavior of these complex fluid objects.

2:11PM L21.00003 Deformation and bursting of elastic capsules impacting rigid walls, ETIENNE JAMON-PUILLET, TREVOR JONES, PIERRE-THOMAS BRÜN, Princeton University — From water balloons to cells, eggs and various organs, thin elastic shells enclosing a liquid core, or capsules, are ubiquitous. Yet, despite their prominence, an understanding of how capsules deform and burst under impact is lacking. Here, combining controlled experiments with formal models, we study the deformation of elastic capsules impacting rigid walls. We unravel a strong analogy with liquid drop impact; the shell surface modulus taking the place of the surface tension, albeit the details of the scalings are different. By computing the shell elastic energy during impact and performing a detailed energy balance, we rationalize this analogy and quantitatively predict the capsule maximal deformation for liquids with viscosities up to 1000 cP (Re > 100). Unlike drops however, capsules can burst and be pre-stretched. Experiments show a significant shift in the critical burst velocity induced by the pre-stretch, a feature also captured by our model once pre-stretch is included.
2:24PM L21.00004 Modeling of Volcanic Ash Impingement in Gas Turbine Engines 1
, DRUE SEKSINSKY, JEFFREY MARSHALL, University of Vermont — Impact of volcanic ash particles on heated surfaces of gas turbine engines (GTEs) are a significant concern for the aviation community. Deposition of molten volcanic ash particles within GTEs has led to aircraft engine damage and shut-down, as well as airspace closure within a wide region surrounding volcanically active areas. Unlike most studies of droplet-surface impact, in this problem the molten liquid viscosity is sufficiently large that the droplet Reynolds number (Re) is significantly less than unity. The research describes numerical simulations of low Re droplet impact using the combined level-set-volume-of-fluid (CLSVOF) method, as well as a simplified theory for the low Re impact process. Two distinct phases of the low Re droplet impact process are observed. In the first phase, the droplet kinetic energy decreases rapidly, which is roughly balanced by the energy dissipation. In the second phase, the droplet motion is controlled by potential energy balance with viscous dissipation. The second phase occurs over a time period that is much larger than that of the first phase. Since there is little experimental data for droplet collisions in this regime, we are using our numerical results to guide and validate the theory development.

2:37PM L21.00005 Impact of a compound drop produces fine radial jetting 1, SIGURDUR THORODDSEN, King Abdullah University of Science and Technology (KAUST), Thuwal, Saudi Arabia. JIAMING ZHANG, Physics of Fluids Group, University of Twente, The Netherlands, ERQIANG LI, University of Science and Technology of China, Hefei, China — We study the impact of a compound drop on a solid surface and the fine radial jets, which emerge at high speed near the solid substrate. The drop is made in a flow-focusing micro-fluidic device feeding smaller droplets into the pendent drop at a nozzle. The outer continuous phase consists of water-glycerin mixtures of various viscosities, while the disperse-phase inner droplets are of a much heavier perfluorohexane liquid. The inner droplets therefore sink to the bottom of the pendent drop before its release from the nozzle. We use a handful of inner droplets which can arrange into regular patterns around the axis of symmetry. The early impulsive stage of the impact forms a radial jet under each of the inner droplets, which emerge at about 8 times faster than the drop-impact velocity, but are only 40 microns thick. We use a million fps bottom imaging, through a glass substrate, to show that the jets are formed by flow-focusing under the inner droplets. We systematically change the droplets, which emerge at about 8 times faster than the drop-impact velocity, but are only 40 microns thick. We use a million fps bottom imaging, through a glass substrate, to show that the jets are formed by flow-focusing under the inner droplets. We systematically change the number of inner droplets and the viscosity of the continuous phase to identify the splashing threshold for this configuration. The inner droplets are greatly deformed and break up into smaller satellites by viscous stretching, involving capillary pinch-off or tip streaming.

2:50PM L21.00006 Impact of Highly Concentrated Milk Droplets with Clean and Fouled Surfaces, MIGUEL BALZAN, F. STEVEN WELLS, GEOFF WILLMOTT, The Department of Physics, The University of Auckland — Wall deposition in milk spray dryers occurs due to the repeated impact of milk droplets against solid surfaces. Milk can be characterized as a solution of water with solids. Since there is limited information on the literature about single milk droplet collisions against solid surfaces, our study focuses on exploring this phenomenon by characterizing the effect that the surface properties and solids concentration have on the spreading dynamics. Substrates of varied nature; either clean, chemically treated with acid, and milk-product fouled surfaces, were used, resulting in mean roughness values that ranged from 0.023 to 6.270 μm. Our results indicate that the droplet dynamics are weakly dependent on the surface roughness during the kinematic and spreading stages after drop impact. The effect of solids concentration does play a significant role in the spreading and recession dynamics. The fluid behavior is Newtonian up to solids concentrations approximately equal to 20%. Afterward, the fluid is shear-thinning. We quantified the effect that increasing the solid concentration had on the maximum spreading dynamics, finding that increasing the concentration from 10% up to 40% reduced the maximum spreading diameter after impact by approximately 40%.

3:03PM L21.00007 ABSTRACT WITHDRAWN

Monday, November 25, 2019 1:45PM - 3:16PM
Session L22 Drops: Heat Transfer and Evaporation II
604 - Paul Steen, Cornell University

1:45PM L22.00001 Evaporation of sessile drops on soft membranes with capillary origami 1, YUHONG CHEN, DANIEL OREJON, PRASHANT VALLURI, VASILEIOS KOUTSOS, KHELLIL SEFIANE, the University of Edinburgh — Drops evaporating on soft substrates are common in nature, such as raindrops on tree leaves. If the substrate is thin enough, it can get deformed by the action of surface tension of a drying drop. This folding is known as ‘capillary origami’, which provides a simple and cheap method for fabricating predetermined 3D structures at the micro/nano-scale. Here, we explore the influence of capillary origami on drop evaporation. Our experiments concern with evaporation of sessile microliter water drops on soft PDMS membranes. We consider the effect of substrate thickness noting that bending stiffness is a cubic function of thickness. Thus, drying sessile droplets of the same size can lead to either absent, partial or complete folding of the substrate. The evolution of evaporation fluxes is obtained through a microbalance with a resolution of 0.1 mg/s, and is simultaneously imaged by a side-view CCD camera and a top-view optical camera, respectively. These videos are processed using ImageJ to extract the data and quantify the folding extent of the membranes. Our results show that foldable membranes reduce evaporation rates of sessile droplets thereby lengthening the drop lifetimes.

1:58PM L22.00002 Inclination effect on evaporation of colloidal droplets 1, JIN YOUNG KIM, Research Center for Advanced Materials Technology, SSKU Advanced Institute of Nanotechnology, Sungkyunkwan University, MARTA GONCALVES, SSKU Advanced Institute of Nanotechnology, Sungkyunkwan University, HYOUNGOO KIM, Department of Mechanical Engineering, Korea Advanced Institute of Science and Technology, BYJUNG MOOK WOON, School of Advanced Materials Science and Engineering, SKKU Advanced Institute of Nanotechnology, Sungkyunkwan University — When colloidal droplets including micro- and nanoparticles evaporate on flat solid substrates, commonly ring-like depositions are generated by continuous outward capillary flows. When the substrate is inclined, droplets become asymmetric and non-spherical by gravity and it affects evaporation dynamics and particle deposition. However, inclination effects on evaporation and deposition are not clear yet. Here we observe evaporation and deposition of colloidal droplets by changing particle sizes and tilting angles. We find that there is competition between downward sedimentation flows by gravity and upward capillary flows by evaporation, inducing that uniformity of coffee-rings depends on particle sizes and tilting angles. For small particles, evaporation-driven upward flows are more dominant than gravity-driven downward flows.

A non-equilibrium multi-component evaporation model for blended diesel/alcohol droplets. HONGYUAN ZHANG, PING YI, SUO YANG, University of Minnesota — A non-equilibrium Langmuir-Knudsen model for multi-component pure diesel and blended diesel/alcohol droplets and sprays is developed. This model takes into account most of the key processes during the droplet lifetime, including the finite heat conduction and limited mass diffusion inside the droplet, the differential diffusion in gas phase, and the non-equilibrium Langmuir-Knudsen evaporation law for multi-component droplets. The present model shows good agreements with experimental measurements for pure ethanol, diesel, and blended diesel/ethanol droplets. The non-equilibrium effects become significant when the initial droplet diameter is smaller than 20 μm, and these effects are enhanced with increasing ambient temperature and forced convection intensity. The non-equilibrium effects are more significant for the blended diesel/alcohol droplets than pure diesel, especially during the evaporation period of ethanol. The present evaporation model has also been applied to calculate the evaporation processes of single- and multi-component fuel sprays under various ambient conditions. The non-equilibrium effects for the blended diesel/alcohol sprays are significant in terms of the fuel vapor component concentrations.

Channel Flow with Evaporation of Spatially Resolved Droplets GIANDOMENICO LUPO, KTH, ANDREA GRUBER, SINTEF, CHRISTOPHE DUWIG, KTH — We perform direct numerical simulations (DNS) of more than 14000 cold spherical droplets evaporating in hot turbulent channel flow ($Re_\tau = 180$, 5% initial liquid volume fraction), at conditions representative of industrial applications. Four-way coupling of the droplet motion with the turbulent carrier phase and interface-resolved evaporation dynamics allow us to fully describe the intra- and inter-phase exchange of heat, species and momentum transfer, at all relevant scales of motion. We analyze the modulation of turbulence by the dispersed phase, and the associated migration of the droplets towards the channel centreline. The redistribution of the droplets has a strong impact on the evaporation dynamics, which we characterize by the joint probability density function of the evaporation rate and the droplet distance from the wall. This leads to an inquiry of the feasibility of film theory for modelling the present evaporation regime, and the definition of an appropriate nondimensional parameter for the scaling of the evaporation rate (correlation of Sherwood number). Finally, we investigate the influence of the energy boundary condition (adiabatic vs. isothermal walls) on the evaporation dynamics.

Experimental and numerical study of the flow instabilities during sessile droplet evaporation in microgravity. SANJEEV KUMAR, MARC MEDALE, DAVID BRUTIN, Aix-Marseille University, JUSTI TEAM — Our current research is focused on thermal Marangoni instabilities in sessile ethanol and Hydronfluoroether (HFE7100) droplets, which develop spontaneously during forced evaporation. We will present the numerical modelling in 3D unsteady with moving interface of a sessile droplet under forced evaporation and showing internal flow instabilities. We assumed a pinned contact line and a spherical-cap shape of the liquid-gas interface. Our computations contribute to figure out the internal 3D flow structure in the droplet and also to determine the driving mechanism and energy sources of the observed thermo-convective instability and thus clarifies its nature. We will compare the numerical results with experimental results obtained with ARLES experiment in microgravity during the ESA SSC MASER-14 rocket campaign for the HFE7100 droplets and the parabolic flight campaign CNES VP139 and ESA VP140 for the ethanol, methanol and pentane droplets.

The role of substrate geometry on droplet evaporation. JOHN MCCARTHY, Department of Engineering Science, University of Oxford, DOMINIC VELLA, Mathematical Institute, University of Oxford, ALFONSO A. CASTREJON-PITA, Department of Engineering Science, University of Oxford — The coffee ring effect is the name given to the phenomenon where particles suspended in an evaporating droplet migrate towards the contact line, producing characteristic dense rings of particles. It is observed in many everyday and technological settings, from stains after coffee spills to imperfections in inkjet printed objects. Methods to control and even suppress this - often undesired - effect include the use of tailored mixtures of solvents to control evaporation, the use of elongated particles, the use of electrowetting and surface acoustic waves to induce internal flows, etc. All these methods have the objective of reducing, eliminating or overcoming the capillary flows leading to the deposition of suspended particles along the contact line during (differential) evaporation. Each method limits to some extent the type of droplets for which it can be used. We explore the role played by substrate geometry in controlling the evaporation of droplets and its role on the formation, or otherwise, of a coffee ring.

Effects of contact lines on evaporative heat transfer of liquid films JUNGTAEK KIM, HANSEUL Choi, YUN SEOG LEE, HO-YOUNG KIM, Seoul National University — Falling film evaporators cool liquids that flow through a bundle of tubes, over which refrigerants are sprayed and evaporated. A key parameter to determine the heat transfer coefficient is the film Reynolds number ($Re_f$) that depends on the spraying amount of refrigerant. Because dry-out of tube walls occurs when $Re$ is too low while the liquid film becomes too thick for too high $Re$, an optimal $Re$ exists that maximizes the heat transfer coefficient. Here we show that the optimal $Re$ for evaporative heat transfer over geometrically patterned tube walls is also critically affected by the enhanced mass transfer rate at the solid-liquid-gas three phase contact lines. It is experimentally found that the heat transfer of partially filled grooves with contact lines is more efficient than completed wet grooves, despite the decreased heat transfer area. We experimentally measure the heat transfer coefficient from various surface patterns under contact line effects. Then we provide a mathematical model to optimize enhanced surface features maximizing evaporative heat transfer coefficient.

1:58PM L23.00002 An extension to the extended Beltrami solution method and solutions to the 3D Navier-Stokes equations1. NOLAN DYCK, ANTHONY STRAATMAN, The University of Western Ontario — Recirculating flows, such as those seen in vortex separators, swirl combustion chambers, and Ranque-Hilsch vortex tubes can seldom be modelled analytically, and where exact solutions may be found, viscous effects are neglected. In this work we attempt to describe swirling motions, by extending the extended Beltrami solution method for the Navier-Stokes equations to describe 3D flows where the flow variables may be written as a function of two spatial co-ordinates. The new formulation emerges when auxiliary functions are added to the general Bragg-Hawthorne equations and reinserted into the governing equations. As is the case with the extended Beltrami approach, solutions are sought by guessing forms of the auxiliary functions, and attempting to solve the system of equations. Using this technique, we find many new solutions. Well known planar flows including Kovasznay flow and Wang’s flow have been generalized to three-dimensions. A unique solution in plane polar co-ordinates has been found. A new 3D swirling flow solution which can be calculated the angular analogue to Kovasznay flow is found which exhibits many realistic features observed in swirling flow applications.

The authors gratefully acknowledge the financial support from the Natural Sciences and Engineering Research Council of Canada (NSERC).

2:11PM L23.00003 Exact Solutions for Flows in Periodic Domains. PETER BADDOO, DARREN CROWDY, Imperial College London — In this work it is shown that recent advances in conformal geometry can be leveraged to obtain analytic solutions for flows in periodic domains. The solutions are constructed in a parametric circular domain and then conformally mapped to the periodic physical domain. By expressing the problem in terms of the transcendental Schottky–Klein prime function, the ensuing solutions are valid for domains of arbitrary connectivity, i.e. any number of objects per period window. Moreover, the conformal mapping to the desired physical domain may be constructed using a new periodic Schwarz–Christoffel formula. The mathematical analysis is valid for conformally invariant equations and is therefore applicable to a range of scenarios in fluid mechanics including potential flows, advection-diffusion problems and interfacial dynamics. Accordingly, the solutions find relevance in areas such as vortex dynamics, transport phenomena, turbomachinery flows, mesh generation and fractal growth.

2:24PM L23.00004 Comparison of Deep Learning strategies for flow field reconstruction from wall measurements. SAMIR BENEDDINE, ONERA, 8 rue des Vertugadins, FR-92190 Meudon, FRANCE — This work explores deep learning reconstruction techniques to estimate the pressure field in the laminar wake of a bluff body from a few wall measurements. It aims at comparing two main strategies: a classical approach, where a neural network maps the input (the point-wise pressure measurements) to the target (the full pressure field) by minimizing the $L_2$-norm of the error between the output of the network and ground truth, a so-called decoupled approach, based on Generative Adversarial Networks. For the latter, a network is first trained to generate fields that are not distinguishable from actual pressure field obtained from a simulation. Then, given input measurements, it searches for the best match among all the possible field that it can generate. This generative strategy is a state-of-the-art approach for image inpainting, and it presents several strong advantages over the first method. For instance, it is totally flexible with respect to the input measurements: the same network can carry out the reconstruction no matter the location or the number of input sensors. Other interesting advantages will be detailed during the presentation, such as the ability of generative approaches to be used for temporal super-resolution.

2:37PM L23.00005 Deep Learning Time-Dependent Hagen-Poiseuille Flow. NINA PRAKASH, WEI HU, AMIR BARATI FARIMANI, Carnegie Mellon University — Deep learning has emerged as a valuable tool for data-driven modeling of fluid flow. Rather than a traditional physics-based computational approach based on solving equations, deep learning can be used to derive models of flow systems directly from experimental or simulation data. In this work, we use Long Short Term Memory (LSTM) to learn the velocity profile development of Hagen-Poiseuille Flow in its time-dependent entry region. Given arbitrary boundary conditions including the pipe diameter, fluid properties, and axial pressure gradient, the network is able to predict the entry region velocity profiles as flow develops from rest with a mean squared error of less than 1%. The model is trained solely on simulation data and thus is able to learn the behavior of the system with no knowledge of the physical mathematical model. This work contributes to a growing body of work on the application of machine learning to fluid modeling by proving the success of LSTM to model a time-dependent fluid flow system. The deep learning framework presented in this work has the potential to be successful for systems that involve complex geometries or turbulence that can make traditional approaches computationally inefficient and cumbersome, or for systems for which the underlying mathematical model is unknown.

2:50PM L23.00006 On the Advection-Diffusive Mass Transport of Gas Mixtures. ALEX JARAUTA, VALENTIN ZINGAN, PETER MINEV, MARC SECANELL, University of Alberta, DEPARTMENT OF MATHEMATICAL AND STATISTICAL SCIENCES, UNIVERSITY OF ALBERTA TEAM, ENERGY SYSTEMS DESIGN LABORATORY, DEPARTMENT OF MECHANICAL ENGINEERING, UNIVERSITY OF ALBERTA TEAM — Mass transport of gas mixtures often occurs in a variety of engineering applications such as fuel cells and coal fired power plants. Classical convection-diffusion equations are limited to binary mixtures and dilute species in a mixture. Also, these theories have been shown to be unable to reproduce several phenomena occurring in capillaries or small pores [1], such as osmotic diffusion (i.e., diffusion without a concentration gradient), reverse diffusion (i.e., diffusion in the direction of a positive concentration gradient), and diffusion barrier (i.e., no diffusion with a concentration gradient). The limitations of these classic models stem from the fact that only a mass-averaged velocity field is considered. In this work, a new multiphase mass transport model was developed based on the work of Kerkhof and Geboers [1]. This model considered the velocity of each individual species, as well as an individual momentum equation. The Stefan tube diffusion experiment was used to compare our model to the advection-diffusion equation. Partial viscosities and gradients of species velocities were identified as key parameters to overcome the limitations of the advection-diffusion equation. References: [1] P.J.A.M. Kerkhof and M.A.M. Geboers, AIChE J., 51(1):79-12.
3:03PM L23.00007 On the structure of distribution function in kinetic methods and its implications, LIAN-PING WANG, Southern U of Sci and Tech and U of Delaware — This theoretical talk will provide a derivation of the structure of the distribution functions in kinetic schemes such as the lattice Boltzmann method and the discrete unified gas kinetic scheme. Starting from the continuous Boltzmann equation with the BGK collision model and an external force field, the structure of the distribution functions, in terms of the macroscopic variables, is derived by using only the Chapman-Enskog expansion for continuum flows. The result then is used to understand why a source term in the kinetic equation can be designed to adjust fluid viscosity and thermal conductivity, etc. The structure of the discrete distribution functions used in the kinetic methods is then derived by proper transformation and the use of Gauss-Hermite quadrature. The result then provides a basic framework to discuss proper implementation of boundary condition in the kinetic methods. Previous boundary implementation methods will be examined under this framework and alternative boundary implementation methods will be explored. Possibility of using this approach to explore truncation errors in kinetic methods will also be discussed.

Session L24 Bubbles: Growth, Heat Transfer and Boiling II

1:45PM L24.00001 ABSTRACT WITHDRAWN

1:58PM L24.00002 Light-guided surface plasmonic bubble movement via contact line de-pinning by in-situ deposited plasmonic nanoparticle heating.1. QIUSHI ZHANG, EUNGYU LEE, YUNSONG PANG, Department of Aerospace and Mechanical Engineering, University of Notre Dame, 365 Fitzpatrick Hall, Notre Dame, IN 46556, JARROD SCHIFFBAUER, Department of Physics, Colorado Mesa University, Grand Junction, CO, USA, ALEKSANDAR JEMCOV, HSUEH-CHIA CHANG, TENGFEI LUO, Department of Aerospace and Mechanical Engineering, University of Notre Dame, 365 Fitzpatrick Hall, Notre Dame, IN 46556 — Precise spatio-temporal control of surface bubble movement can benefit a wide range of applications like high-throughput drug screening, combinatorial material development, microfluidic logic, colloidal and molecular assembly, etc. In this work, we demonstrate that surface bubbles on a solid surface are directed by a laser to move at high speeds (>1.8 mm/s), and we elucidate the mechanism to be the de-pinning of the three-phase contact line (TPCL) by rapid plasmonic heating of nanoparticles (NPs) deposited in-situ during bubble movement. Based on our observations, we deduce a stick-slip mechanism based on asymmetric fore-aft plasmonic heating: local evaporation at the front TPCL due to plasmonic heating de-pins and extends the front TPCL, followed by the advancement of the trailing TPCL to resume a spherical bubble shape to minimize surface energy. The continuous TPCL drying during bubble movement also enables well-defined contact line deposition of NP clusters along the moving path. Our finding is beneficial to various microfluidics and pattern writing applications.

2:11PM L24.00003 The physics of plasmonic vapor-gas bubbles in a gassy liquid, YUHANG ZHANG, Johns Hopkins University, ANDREA PROSPERETTI, University of Houston — When illuminated by resonant irradiation of a continuous-wave laser, gold nanoparticles deposited on a surface immersed in a liquid generate huge amount of heat in a very short period of time, leading to the nucleation of vapor bubbles referred to as plasmonic bubbles. In this work, a spherically symmetric mathematical model is proposed to describe the various physical processes that affect the dynamics of these bubbles: growth, condensation, the diffusion of dissolved gas into and out of the bubble and the attendant mass and heat transfer. The model is solved by transforming the partial differential equations into a system of ordinary differential equations using a collocation method. The different phases of the bubble behavior on short (microseconds) and longer (milliseconds to seconds) time scales found in experiments are reproduced by the numerical simulations. The effects of the degree of dissolved gas saturation in the liquid are discussed.

2:24PM L24.00004 Direct Numerical Simulations of Surfactant Effects on Heat and/or Mass Transfer Around a Bubble1. THOMAS ABADIE, OMAR MATAR, Imperial College London — Contaminants or surfactants are involved in a wide range of environmental and industrial applications and their presence can affect significantly both the dynamics and transfer phenomena around bubbles and droplets. In this study, a front-tracking method is presented and assessed in order to model accurately surface tension forces for capillary driven flows and heat and mass transfer around a bubble rising in a continuous liquid phase. The effects of Marangoni stresses on the bubble dynamics on the one hand and on the Sherwood or Nusselt number on the other are investigated as a first step towards improve the understanding of heat and/or mass transfer in contaminated bubble swarms.

2:37PM L24.00005 Bubble Dynamics on Nanostructured Microwires1. LAUREN COERTZE, DANIEL OREJON MANTECON, MARILIZE EVERTS, PRASHANT VALLURI, JOSUA MEYER, KHELLIL SEFIANE — Boiling on microwires is investigated aiming to provide a better understanding of the bubble dynamics and heat transfer as these are of great importance to many industrial and everyday processes. It is proposed that nanoparticle surface coatings may be a simple and scalable method of modifying the surface wettability and structure with the associated differences in bubble-surface interactions and the consequent variations in bubble dynamics, critical heat flux (CHF) and heat transfer coefficient. This work aims to develop an improved understanding of bubble dynamics such as bubble velocity, growth rate, bubble density distribution and detachment frequency on coated microwires at various heat fluxes. Experimental investigations will consider nanoparticle coated and bare platinum microwires with diameters of 100 and 250 micrometres, in pool boiling with water as working fluid. High speed, high resolution videography will be used to observe bubbles from nucleation to departure. The analysis will focus on the bubble dynamics occurring on nanoparticle coated and bare microwires. Bubble dynamics and CHF for the coated surfaces are expected to change compared to the bare wire depending on the nature of the surface coating applied.

2:50PM L24.00006 Heat transport by bubbles in vertical natural convection\textsuperscript{1}, CHONG SHEN NG, University of Twente, ROBERTO VERZICCO, University of Rome Tor Vergata, DETLEF LOHSE, University of Twente — We consider a basic configuration of bubbles in vertical natural convection. The datasets are obtained from direct numerical simulations for one decade of Rayleigh numbers, a Prandtl number of 7 and the bubbles are simulated with immersed boundaries using the interaction potential approach. By separately enabling the thermal and mechanical coupling, we show evidence that the heat transport is enhanced when the bubbles are both thermally and mechanically coupled to the flow. When only pure mechanical coupling is considered, we instead find a lower heat flux in the system. The enhanced heat flux from the addition of thermal transport highlights the importance of thermal transport by bubbles in this setup. To shed light on the details of the mechanism, we discuss the contributions to the heat flux with reference to local statistics of the thermal boundary layers.

3:03PM L24.00007 Direct numerical simulation of heat transfer in turbulent bubbly pipe flow\textsuperscript{1}, IN-KOO LEE, JAEHEE CHANG, HAECHEON CHOI, Seoul National University — In pipe flows occurred in a reactor of a nuclear power plant and a radiator in a car, forced convection with bubbles occasionally occurs in an undesirable manner. These bubbles significantly change the flow structures and heat transfer in a pipe. We perform direct numerical simulation of fully developed turbulent bubbly flow with heat transfer in a vertical pipe to examine the variations of flow structure and heat transfer due to bubbles. The phase interface is tracked by level-set method in the Cartesian coordinates. The simulation results show that heat transfer is enhanced by the motion induced by counter-rotating vortices existing in the rear of the bubble. As the bubble volume fraction increases, the radial distribution of bubbles becomes flat due to the interaction among bubbles. This flat bubble distribution results in flattened temperature profile in the radial direction. Therefore, the rate of increase in the heat transfer coefficient decreases with increasing bubble volume fraction.

Monday, November 25, 2019 1:45PM - 3:16PM – Session L25 Vortex Dynamics and Vortex Flow: Theory

1:45PM L25.00001 The motion of buoyant point vortices\textsuperscript{1}, ANIRBAN GUHA, School of Science and Engineering, University of Dundee, JEFF CARPENTER, Institute of Coastal Research, Helmholtz Zentrum Geesthacht — A general formulation is presented for studying the motion of buoyant vortices. It extends the well-known Hamiltonian framework for interacting homogeneous point vortices to include buoyancy effects acting on the vortices. This is then used to systematically examine the buoyant 1-, 2-, and 3-vortex problems. In doing so we find that 2 buoyant vortices may either evolve as a pair in bounded circular orbits, or as two independent unbounded vortices that drift apart, and a criteria is found to distinguish these cases. Special attention is given to the buoyant vortex couple, consisting of two vortices of equal and opposite circulation, and equal buoyancy anomaly. We show that a theoretical maximum height is generally possible for the rise (or fall) of such couples against buoyancy forces. Finally, the possibility and onset of chaotic motions in the buoyant 3-vortex problem is addressed. In contrast to the homogeneous 3-vortex problem, the buoyant vortex system shows evidence that chaos is present. We also demonstrate the chaotic advection of tracer parcels arising from the flow field induced by just 2 buoyant vortices.

1:58PM L25.00002 Performance of Overset Mesh in Modeling Generic Wakes for Underwater Swimming: SUYASH VERMA, ARMAN HEMMATI, University of Alberta — The wakes of generic stationary, and oscillating square panels are examined using Overset Grid Assembly (OGA), implemented in OpenFOAM. Using Direct Numerical Simulation (DNS), this study focused on the accuracy and effectiveness of OGA in simulating wake, through combination of multiple meshes for domain and bodies respectively. First, the wake of a stationary square panel is considered at angles of attack between 0° and 60°. The results are compared with the numerical study of Taïra et al. (2009) based on Immersed Boundary Method. Then, the wake of a pitching panel is examined at Re=2000 and St=0.2. Comparing the results with previous numerical (Senturk et al. 2018), and experimental (Buchholz, et.al. 2006) studies, show that the mean drag coefficient are in good agreement, and wake features were captured accurately. This provides sufficient evidence for the high capabilities of overset methodology in analyzing wake physics of sharp-edge bodies in oscillatory, and mixed motion. Future studies on complex shaped bodies are examined by combining fluid structure interaction with OGA, which also enables studying the effect of flexibility on hydrodynamic performance of propulsors.

2:11PM L25.00003 Evolution of Vortex Dipole Disturbances in Channel Flow, ANTHONY LEONARD, Graduate Aerospace Laboratories, Caltech — The initial-value problem for the linearized Navier-Stokes equations for channel flow with mean velocity and mean vorticity given by $U = (U(y), 0, 0)$ and $\Omega = (0, 0, -\partial U(y)/\partial y)$ is investigated for initial disturbances consisting of vortex dipoles. Approximate analytical solutions to the resulting Orr-Sommerfeld (OS)/Squire equations are found in terms of special functions, thus avoiding the need of large-scale computation. Under the assumption of linearity, the initial vortex dipole merely travels downstream with the local mean velocity $U(y)$ as a diffusive scalar. However, additional disturbances are produced continually because the quantity $U''(y)\partial y/\partial z$ appears in the OS equation as a source for transported quantity $\nabla^2 v$. In turn, $-U''(y)\partial y/\partial z$ is the source term in the Squire equation for the transported quantity $\omega_y$. We find it particularly effective to represent this additional $v$ field as an expansion in terms of eigenfunctions of the OS equation with complex values of $k_\perp$ ($k_\perp^2 = k_x^2 + k_z^2$). For the inviscid case, e.g., these solutions satisfy

$$\frac{d^2 v_j}{dy^2} - \frac{U''(y)v_j}{U(y)} = c k_{\perp j} v_j$$

2:24PM L25.00004 Tomo-PIV measurements of tethered sphere VIV onset while crossing the Hopf bifurcation\(^1\) . RENE VAN HOUT, LIOR ESHBAL, DANIEL KOVALEV, DAVID GREENBLATT, Technion—Israel Institute of Technology — Here, for the first time we examine the transient evolution of the vortical structures in the wake of a tethered sphere as the uniform upstream velocity is slowly increased and the tethered sphere (diameter \(D\)) dynamics passes through the Hopf bifurcation. Tomo-PIV experiments (at 15Hz) were performed in a closed-loop water tunnel. The volume of interest (4.5 \(\times\) 6.5 \(\times\) 2.5\(D^3\)) was located immediately downstream of the sphere. The reduced velocity, \(U^* = U/(f_N D)\), was stepwise raised from 2.2 to 4.5 in 100s \((dU/dt = 4.36 \times 10^{-4}\text{m/s})\), where \(U\) is the free-stream velocity, and \(f_N\) is the natural frequency of the tethered sphere. Large coherent structures resembling two streamwise oriented, longitudinal “legs” were observed at \(U^* = 2.5\) while the sphere was stationary. Approaching \(U^* = 3\), hairpin vortices, having a vertical plane of symmetry, were shed, alongside weaker induced hairpins that strengthened with increasing \(U^*\). While vertical symmetry was sporadically disturbed, the onset of VIV occurred around \(U^* = 3.7\), peaking at \(U^* = 4.4\), as the plane of symmetry was shifted to the horizontal.

2:37PM L25.00005 Compressible swirling flow states in diverging or contracting pipes . YUXIN ZHANG, Washington State Univ., NOAH CYR, ZVI RUSAK, Rensselaer Polytechnic Institute, SHIXIAO WANG, Auckland Univ., New Zealand — The dynamics of inviscid, compressible and axisymmetric swirling flow of a perfect gas in diverging or contracting circular pipes is studied by global analysis techniques and numerical simulations. Inlet flow is described by profiles of circumferential and axial velocities and temperature with a fixed azimuthal vorticity. Outlet flow is a non-reflective zero radial-velocity state. We first solve the column flow ODE problem developed by Rusak et al. (2015) for the outlet state as a function of inlet swirl ratio, Mach number and pipe geometry. Several steady states are possible including centerline decelerated velocity states, centerline accelerated velocity, vortex breakdown states and wall-separation states. Numerical simulations using the unsteady and axisymmetric Euler equations are also conducted. They are based on Steger & Warming (1979) flux-splitting, finite-difference method. Simulations shed light on the stability of the various steady states and their domain of attraction in terms of initial conditions. Results show that increasing inlet Mach number with a fixed geometry delays the appearance of vortex breakdown and wall-separation to higher swirl levels. Pipe divergence at a fixed Mach number promotes breakdown while pipe contraction induces wall-separation.

2:50PM L25.00006 New exact solutions of the Euler equation: hybrid equilibria of Stuart vortices and point vortices . VIKAS KRISHNAMURTHY, MILES WHEELER, University of Vienna, DARREN CROWDY, Imperial College London, ADRIAN CONSTANTIN, University of Vienna — We present a large class of exact solutions to the planar, steady, incompressible Euler equation. These solutions combine the celebrated Stuart vortices with point vortices to form stationary ‘hybrid’ equilibria. These equilibria consist of a set of point vortices otherwise surrounded by a sea of everywhere smooth Stuart vorticity. The solutions can be deformed continuously and non-trivially by varying a parameter which appears as a simple integration constant in the theory. Various limits of these solutions result in purely point vortex equilibria in otherwise irrotational flow. It is also possible to construct an infinite sequence of such solutions, with increasing numbers of point vortices. In this talk, we will present several examples as well as a brief outline of the general theory.

3:03PM L25.00007 The three-dimensional stability of Lamb-Oseen vortex flows in a finite-length pipe . WEIMIN YUAN, SHIXIAO WANG, Auckland University, ZVI RUSAK, Rensselaer Polytechnic Institute — The 3D viscous flow instability modes that appear on a Lamb-Oseen vortex flow in a finite-length straight, circular pipe are analyzed. This study extends the previous stability analysis of a solid-body rotation flow. Neutral stability lines of the axisymmetric \((m = 0)\) and spiral \((m = 1)\) modes are presented in a Reynolds number \((Re)\) versus inlet swirl ratio \((\omega)\) operational diagrams for various vortex core sizes of Lamb-Oseen vortex flow. The analysis reveals the significant role of the vortex core size on the onset of the dominant flow instability. The vortex is dominated by \(m = 1\) (spiral) modes for a relatively large vortex core size. This behavior shifts to dominant \(m = 0\) (axisymmetric) modes for smaller vortex core sizes. The Reynolds-Orr equation is then used to analyze the various production terms of the perturbation’s kinetic energy in the vortex core as well as on the pipe boundaries. It is found that for a medium or small core size of the vortex the base flow in the core is actively involved with the shedding of the shed vortices. These mechanisms are mitigated when the after body is removed, such as for the flat plate.

Monday, November 25, 2019 1:45PM - 3:16PM – Session L26 Flow Control: Jets 608 - Robert Martinuzzi, University of Calgary

1:45PM L26.00001 Influence of the obstacle after-body on actuation effectiveness for wake control\(^1\) . ROBERT MARTINUZZI, ALEX LI, University of Calgary — The dynamic response of the turbulent wake to leading-edge synthetic jet actuation was investigated experimentally for a two-dimensional normal flat plate and square cylinder. The obstacles are immersed in a uniform stream of turbulent intensity less than 0.5%. The actuators are placed directly behind one of the obstacle leading edges. The leeward surface pressure and wake velocity (PIV) measurements are synchronized. For actuation frequencies approaching those of the Kelvin—Helmholtz shear layer instability, mean drag and wake velocity fluctuation levels can be reduced for both geometries. The flat plate wake is generally insensitive to lower frequency actuation. In sharp contrast, for the square cylinder the vortex shedding frequency can lock-on to subharmonics of the actuation frequency. Most striking is that the wake can be manipulated to increase or decrease drag. It will be shown that two different mechanisms underlie the low-frequency response. First, actuation results in a pulsed vortex pair which can interfere with the shear layer to trigger shedding. Second, the after-body can act to alter the vorticity flux along the shear layers and thus modify the strength of the shed vortices. These mechanisms are mitigated when the after body is removed, such as for the flat plate.

1:58PM L26.00002 The effects of geometrical modifications on flow characteristics of a sweeping jet actuator.\textsuperscript{1} ABDUL RAOOF TAJIK, BARTOSZ SLUPSKI, VLADIMIR PAREZANOVIC, Khalifa University, UAE — This work studies the effects of modifications of the internal geometry of a sweeping jet (SWJ) actuator, such as the feedback channel diameter ($D_1$) and the size of its exit nozzle ($D_2$). The effects on the jet frequency and the overall pressure drop in the actuator are investigated using time-resolved flow fields from 2D-URANS simulations and local pressure data from experimental measurements. Similarly to \textsuperscript{1}, it is observed that the variation of the feedback channel diameter $D_1$ has little impact on the sweeping jet frequency magnitude. However, the spectrum of the sweeping jet yields a much better definition of the frequency peaks for larger $D_1$ diameters of the feedback channel. This is a surprising result, considering that the enlarged diameter could be expected to diffuse the feedback flow momentum and thus reduce the quality of the peak definition. On the other hand, the reduction of diameter $D_2$ of the feedback channel exit yields up to 50% increase in the SWJ oscillation frequency for the same pressure drop along the actuator axis. This could be a significant optimization of the SWJ geometry, given that reduced energy investment is required to produce the same oscillation frequency.

\textsuperscript{1}[1], J.H. Seo, et al, AIAA Journal 56(6) 2208-2210 (2018). This work has been supported by the Khalifa University of Science and Technology under Award No(s), FSU-2018-21 and CIRA-2019-025.

2:11PM L26.00003 Computational Analysis of Turbulence and Interactions in an Array of Fluidic Oscillators for Flow Control\textsuperscript{1} N. KOUKPAIZAN, D. HEATHCOTE, C.J. PETERSON, B. VUKASINOVIC, A. GLEZER, M. SMITH, Georgia Institute of Technology — The interactions between a spanwise array of fluidic oscillating jets and a separation bubble that is formed over a 2-D curved surface modeling the suction surface of a VR-12 airfoil are investigated numerically to capture the suppression of the separation with increasing actuation momentum. The high-fidelity simulations first examine the fully-resolved spatio-temporal evolution of the oscillating jets within the actuator cavity in a quiescent ambient. These findings are used to develop a boundary condition model for the actuator array in the cross flow. It is shown that the boundary condition model developed including turbulent variables provides good agreement with the experimental measurements of the flow control effects at a significantly reduced computational cost, and thereby enables additional insight into the flow physics in the vicinity of the actuators exit planes where the measurement techniques are limited by adequate access or resolution. The effect of turbulence on the interactions of the oscillating jets with the separated outer flow are also assessed.

\textsuperscript{1}Supported by the Vertical Lift Research Center of Excellence (VLRCOE).

2:24PM L26.00004 Active control of large-scale structures in turbulent boundary layers using wall-normal jets ZHUOSHUN RUAN, Department of Mechanical Engineering, The University of Melbourne, Melbourne, Australia, CHARITHA DE SILVA, School of Mechanical and Manufacturing Engineering, University of New South Wales, Sydney, Australia, IVAN MARUSIC, NICHOLAS HUTCHINS, Department of Mechanical Engineering, The University of Melbourne, Melbourne, Australia — This experimental study uses a spanwise array of nine wall-normal jets to actively perturb large-scale structures in a high Reynolds number turbulent boundary layer. The footprints of passing large-scale structures are sensed by an upstream spanwise array of hot-film sensors, which provides the input to the real-time controller. Various real-time large-scale control strategies can be tested with this facility. Downstream of the jet array, a further sensing array probes the efficacy of the control strategy. A large field of view streamwise / wall-normal plane PIV experiment also provides additional opportunities to investigate the interaction between the jet actuators and the large-scale structures. Results demonstrate that the degree of drag reduction attained is strongly correlated to how effectively large-scale positive fluctuations have been targeted by the control scheme. In addition, there is a strong correlation between the reduction of large-scale energy and the observed drag reduction. Such control effects persist to 23 (approximately 28000 wall units) downstream of the control input. Further analysis of the near-wall small scale turbulence reveals that the near-wall cycle has been modified due to the altered footprint from the controlled large-scale events.

2:37PM L26.00005 Vortex ring bifurcation in a moderate aspect ratio, rectangular orifice synthetic jet\textsuperscript{1} JOSEPH STRACCIA, JOHN FARNSWORTH, University of Colorado, Boulder — Vortex ring dynamics play an important role in setting the shape, entrainment rate, and near field unsteadiness in synthetic jets. In this study multi-planar stereo particle image velocimetry (SPIV) data obtained for an AR=13 rectangular orifice synthetic jet is used to volumetrically reconstruct the coherent structures of the jet. Analysis of this data reveals the axis switching dynamics of the primary vortex ring in addition to identifying several types of related secondary structures. Most significant however is the confirmation that the vortex rings undergo a viscous interaction called vorticity reconnection which causes the vortex rings, and the momentum of the jet, to bifurcate. The structure of the vortex ring during and after the vorticity reconnection event is reported at different phases of the jet and compared with studies of isolated vortex rings. To understand how this phenomenon is affected by the unique environment inside of the synthetic jet the Reynolds and Strouhal numbers of the jet were varied independently and centerline SPIV data was examined. From these results conclusions are drawn regarding which conditions allow for more complete vortex ring bifurcation.

\textsuperscript{1}This material is based upon work supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. (DGE 1144083).

2:50PM L26.00006 Synthetic jet-based control of wing tip vortices CARLO SALVATORE GRECO, ANDREA PICCOLO, MIRKO ZACCARA, GÉRARD PAOLILLO, TOMMASO ASTARITA, GENNARO CARDONE, Università degli Studi di Napoli “Federico II” — Wing tip vortices are coherent structures generated by the roll-up process developing in the wake of a finite lifting wing. Currently, winglets are the unique passive control device employed in the general aviation to weaken these undesired vortices, reducing their related problems, although active control devices (ACD) are studied in the literature. ACD try to weaken the wing tip vortices by triggering their inherent instabilities. Although these instabilities are caused by the mutual induction of the vortices, all the experimental works in this field employ only half-wing models and report only time-averaged results. The purpose of the present experiment is testing the effects of rectangular synthetic jets, placed at the wing tips and actuated at the wing-tip vortex instability frequencies, on the wing tip vortices generated by a finite-span airfoil placed at the exit of an open jet wind tunnel. Phase-locked Stereo-PIV measurements of the flow field in the wing extended near-wake are carried out. The main observed effects of the control are the reduction of the wing tip vortex vorticity and induced rotational velocity.
3:03PM L26.00007 Constraints of scaling synthetic jet trajectories in crossflow , GIRISH JANKEE, BHARATHRAM GANAPATHISUBRAMANI, University of Southampton — Synthetic jet actuators remain coveted components in flow control applications as the convection of vortex rings allows distribution of momentum in a boundary layer although the net mass flux remains zero. The ability to predict the trajectory of these vortex rings is critical for efficient and targeted usage of such actuators. In this investigation, a synthetic jet is issued into a crossflow from rectangular orifices with aspect ratios 3, 6 and 12 over a range of operating frequencies and blowing ratios, with the flowfield being captured through PIV measurements. An assessment of the trajectories culminates in scaling characteristics which encapsulate the aspect ratio, momentum ratio and the Strouhal number. We observe synthetic jets to follow identical trajectories provided the total momentum ratio between the jet and the crossflow remain the same, irrespective of the actuation frequency. However, the universality of such scaling is subject to certain constraints with a lower bound defined by the jet formation criterion and an upper bound related to successive vortex pair interactions.

Monday, November 25, 2019 1:45PM - 3:03PM — Session L27 Biological Fluid Dynamics: Insect Flight III - Small Insects

1:45PM L27.00001 Fluid-Structure Interactions in Bristled Insect Wings , MATTEO PEZZULLA, FRANCOIS GALLAIRE, PEDRO REIS,cole polytechnique fédrale de Lausanne — The wings of some small insects, such as the Mymaridae (fairyfly), comprise an unconventional porous structure with bristles emanating from an inner core. Despite the relatively large porosity of this structural layout, the wing can generate sufficient lift to enable a rich flight dynamics. The presence of the bristles seems to be a key element in the clap and fling flight dynamics at low-to-moderate Reynolds numbers, due to a non-trivial coupling between the deformation of the bristles, and the low-to-moderate Reynolds number flow, which can make a largely porous wing behave as an impervious one. Here, we study the morphology of bristled wings to rationalize the influence of their geometrical and mechanical properties on the interactions with the surrounding fluid. Specifically, we make use of micro-fabrication techniques to manufacture deformable hairy strips, which are the simplest synthetic counterpart of bristled wings. Then, we perform a systematic exploration of the geometry of the bristle-arrangements to understand how a specific combination of porosity and permeability is optimized in insect flight. We hope that our findings can provide a better understanding of the morphology of insect wings, together with their interplay with the surrounding fluid.

1:58PM L27.00002 Bristled wings in fling: effects of varying wing kinematics , VISHWA KASOJU, ARVIND SANTHANAKRISHNAN, Oklahoma State University — Flight capable tiny insects of body lengths <2 mm, such as thrips and fairyflies use wing-wing interaction (‘clap and fling’) to augment lift generation at chord-based Reynolds number (Re) on the orders of 1-10. In addition, these insects possess wings with closely-packed long bristles at the fringes. Previous studies have shown that bristles can reduce drag needed to fling by leaking flow through the gaps. These studies used combinations of rotational and translational motion to prescribe wing kinematics, due to lack of high-magnification video recordings of freely flying tiny insects. We experimentally investigated the effects of varying wing kinematics (pure rotation, pure translation, and overlapping rotation and translation) on force generation and leakiness during fling of a bristled wing at Re = 10. The results show that (i) drag decreased during pure rotation of the wing, (ii) peak drag increased with increasing overlap, and (iii) decreasing initial inter-wing spacing at the start of fling reduced the strength of the trailing edge vortex, resulting in asymmetric leading and trailing edge vortices.

2:11PM L27.00003 Optimal aerodynamic design of a wing with bristles , SEUNG HUN LEE, MINHYEONG LEE, DAEGYOUm KIM, KAIST — The smallest flying insects such as a fairyfly or a thrips living in a low Reynolds-number environment have evolved a bristled wing, a wing with several bristles on a thin main frame. Previous studies on the aerodynamic characteristics of a bristled wing have revealed that the gap width and the Reynolds number based on the chord length or the bristle diameter are important parameters that determine the aerodynamic performance of a bristled wing. However, these two important parameters have been treated independently thus far although they are strongly coupled aerodynamically. To examine the combined effects of the gap width and the Reynolds number, we numerically investigate a two-dimensional bristled wing with wide ranges of the gap width and the Reynolds number for a given number of bristles. With some interesting characteristics of viscosity-dominant flow, we introduce a new dimensionless parameter and propose analytic methods to estimate the aerodynamic force generation of a bristled wing for arbitrary Reynolds number and configuration.

2:24PM L27.00004 Stability of a falling bio-inspired bristled disk , MINHYEONG LEE, SEUNG HUN LEE, DAEGYOUm KIM, KAIST — Unlike most flying insects whose wings are covered by membranes, some of the smallest flying insects, Thysanoptera and Mymaridae, have wings that consist of bristles attached to a central frame. Due to their microscopic size, the smallest flying insects live in a very low-Reynolds-number regime of the order of 10 or less. Previous researches on the bristled wing have focused on finding the effects of the gaps on aerodynamic performance under various kinematics of the wing. Interestingly, tiny insects possessing the bristled wings have been reported to perform parachuting, one of passive flight modes. However, the dynamics of the bristled wing during parachuting and their effects on stability have not been studied yet. In this study, we examine the stability of a freely falling bristled disk experimentally in the low-Reynolds-number regime by changing the number of bristles and an initial falling orientation and compare with those of a full circular disk without bristles. Our experiments show that a full disk undergoes large disturbance in its orientation and displacement at the initial transient phase of free fall while a bristled disk shows more stable motion explicitly.

2:37PM L27.00005 A Novel Cylindrical Clap-and-Fling Maneuver by Swimming Marine Snails , FHERHAT KARAKAS, ALI AL DASOUQI, University of South Florida, AMY MAAS, The Bermuda Institute of Ocean Sciences, DAVID MURPHY, University of South Florida — Many insects use the Weis-Fogh clap-and-fling maneuver once per wingbeat to generate lift. Lighthill (1973) hypothesized that using this mechanism twice per stroke would create two circular vortex rings, thereby maximizing downward momentum per unit kinetic energy. We show via high speed stereophotogrammetry and micro-PIV that several pteropod species, both shelled and shell-less, do indeed use a variation of this maneuver twice per wingbeat. These pteropods flap their highly flexible wings 180° in both posterior and anterior directions so that their wingtips overlap at the end of both half-strokes to create a cylinder. The animal forces water downwards in a jet as this cylinder forms (the ‘clap’). As the wings then begin the next half-stroke, the cylinder transforms into a cone with the narrow end along the wings’ trailing edges. This cylindrical clap-and-fling maneuver induces downward flow into the cone and forms a lift-enhancing vortex ring around the wings’ leading edges (the ‘fling’). We discuss implications of performing the clap-and-fling maneuver with this cylindrical geometry versus the classic version used by insects. Further, we present preliminary results from a soft robot pteropod wing being developed to study the fluid dynamics of cylindrical clap and fling.
2:50PM L27.00006 High speed Schlieren photography on small insects , DAVID GALARZA, YUN LIU, Purdue University Northwest — The high-speed Schlieren photography has been successfully implemented in studying large flying insects like Hawkmoth Manduca, showing some promising capabilities of capturing complex three-dimensional flow structures on flying insects. To further extend our study to a wider range of insect species, like fruit fly particularly, new approach of introducing density gradient is introduced in this work for studying the flow on small insects. A preset temperature gradient is achieved inside a clear acrylic container from using a constant high temperature iron plate at the top to elevate the air temperature evenly from the top to bottom. Then an electric magnetic tethered fruit fly is carefully introduced into the container using a pole. The fruit fly is de-tethered to set for free fly afterward and flying fruit fly disturbs the evenly distributed temperature/density/gradient ambient that later can be visualized by a two-mirror parallel light high-speed Schlieren photography system.

Monday, November 25, 2019 1:45PM - 3:03PM -
Session L28 Particle Laden Flows: Deformable Particles 610 - Alfredo Soldati, TU Wien

1:45PM L28.00001 A minimal stochastic model capturing intermittency effects on coagulation in turbulence , ALAN KERSTEIN, Consultant, STEVEN KRUEGER, University of Utah — A recent theory, confirmed by direct numerical simulation, established that intermittency dominates the early transient period of zero-inertia particle coagulation in inertial-range turbulence [1]. Namely, starting from a monodisperse system, the i-mer population increases as a power of time, where the i-dependent exponent involves the third-order scalar structure-function exponent due to the connection between particle number density and an inertial-range passive-scalar field. In effect, scalar intermittency boosts the likelihood that a pairwise coalescence event is promptly followed by another due to 3-particle (hence third-order) correlations. The following minimal model reproduces the exponent values and related properties. The system state is a list of particle locations. The triplet, a measure-preserving map often used in 1D simulations and newly extended to 3D by applying it to planar slabs instead of line intervals [2], displaces particles within a given slab along the (x, y, or z) coordinate normal to the slab faces. Sampling of map occurrence times and slab orientations, locations, and widths incorporates inertial-range phenomenology. [1] J. Bec et al., Phys. Rev. E 93, 031102(R) (2016). [2] S. K. Krueger, A. R. Kerstein, J. Adv. Model. Earth Sys. 10, 1858-1881 (2018).

1:58PM L28.00002 Dynamics of chains of deformable particles in strongly confined Poiseuille and Couette flows1, SAGNIK SINGHA, Texas Tech University, ABHILASH REDDY MALIPEDDI, George Washington University, MAURICIO ZURITA-GOTOR, Universidad Loyola Andalucia, KAUSIK SARKAR, George Washington University, JERZY BLAWZDZIEWICZ, Texas Tech University — In a strong confinement system of deformable drops shear flow triggers their rearrangement into highly ordered linear arrays oriented in the flow direction. In our recent investigation [Soft Matter, 2019, 15, 4873-4889] we have found that the drop arrays behave like strongly overdamped bead-spring chains, with springs representing effective inter-drop hydrodynamic interactions. As a result, the relaxation of perturbed chains is diffusive. This behavior is in contrast to the drop-chain dynamics in a confined Poiseuille flow, which is described by the first-order wave equation. To elucidate this difference, we analyze how elementary contributions of inter-particle interactions, i.e., (i) dipolar, (ii) quadrupolar, and (iii) swapping-trajectory effects influence the collective drop dynamics. Due to antisymmetry with respect to the flow reflection, the Hele–Shaw dipoles contribute to wave propagation in a particle array. The symmetric Hele–Shaw quadrupoles together with the swapping trajectory effect produce diffusive relaxation in Couette flow and either wave decay or growth in Poiseuille flow.

1NSF Grant CBET 1603027

2:11PM L28.00003 Breakup of bubbles driven by vortex ring collision , YINGHE QI, CARL URBANIK, NOAH CORBITT, ASHWANTH SALIBINDLA, RUI NI, Department of Mechanical Engineering, Johns Hopkins University — We present an experimental investigation of bubble breakup at the moment when two vortex rings collide with each other head on at high Reynolds number, characterized by the vortex cores break into finer scales, bubbles will experience strong fluctuations of local shear and pressure at multiple length scales, reproducing a flow environment that bubbles tend to experience in fully-developed turbulence. In this study, we use the piston-cylinder arrangement to produce and control the vortex ring collision, and the timing of bubble injection is adjusted to vary the distance between bubbles and the location where two vortex cores touch each other. Four high-speed cameras are used to simultaneously measure both the bubble breakup process as well as the surrounding flow. This study will help us to explore the idea of bubble-eddy collision that has been widely used in describing bubble deformation and breakup in fully-developed turbulence.

2:24PM L28.00004 Dynamics of large and deformable bubbles in turbulence , LABANCA GABRIELE, TU Wien, GIOVANNI SOLIGO, ALESSIO ROCCON, ALFREDO SOLDATI, TU Wien; University of Udine — The dynamics of large, deformable bubbles in a turbulent channel flow is investigated coupling direct numerical simulations of turbulence with the phase-field method (PFM). In the framework of the PFM a marker function (phase field) defines the local concentration of each phase; the phase field is uniform in the bulk of the phases and undergoes a smooth transition across the interface. All fluid properties are defined as proportional to the phase field. An interfacial term (based on the Korteweg tensor) in the Navier-Stokes equation accounts for the effects of a deformable interface on the flow field. We will present the effects of density and viscosity contrasts between the dispersed and the carrier phase at a constant shear Reynolds number, Reτ = 300 (ratio between inertial and viscous terms, defined on the channel half-height), and at a constant Weber number, We = 1.5 (ratio between inertial and surface tension forces). In particular, the effects of density and viscosity contrast between the two phase on the dispersed phase morphology (drop, Sauter mean diameter, interfacial area) and the local flow field will be investigated and detailed.

2:37PM L28.00005 ABSTRACT WITHDRAWN

2:50PM L28.00006 Measurements of Deformations of Fibers and Multi-armed Particles in Fluid Flows1, BARDIA HEJAZI, LEE WALSH, GREG VOTH, Wesleyan University — We measure the deformation of fibers and particles made of 3 and 4 slender arms. The multi-armed particles are triads (3 symmetric arms in a plane) and tetrads (4 symmetric arms separated by the tetrahedral angle) with rigid arms connected near the center of the particle by a weak rubber joint. For fiber-like particles we used two arms joined at the center by a weak joint. The particles are 2cm in diameter and are 3D printed using a soft rubber-like polymer. We show that multi-armed particles deform at lower order of the aspect ratio of the arm in uniform velocity gradients compared to buckling and bending of fibers. We first examine triads in the turbulent flow of a vertical water tunnel and use 4 high-speed cameras to achieve high precision in measuring particle orientations and arm deformations with an uncertainty of roughly 10° rad. Multi-arm particles deform more readily than fibers, but the measured deformations in the water tunnel are still small and only slightly larger than our measurement uncertainty. We continue our study by measuring the deformation of fibers and tetrads in a Taylor-Couette apparatus. In these experiments we have higher velocity gradients and use a more viscous fluid than water which allows us to measure larger deformations.

1:58PM L29.00002 A multiphysics computational model for design and optimization of drug transport in an endovascular Chemofilter device\(^1\), NAZANIN MAANI\(^2\), TYLER C. DIORIO, Biomedical Engineering, Purdue University, West Lafayette, IN, STEPHEN W. HETTS, Radiology and Biomedical Imaging, University of California, San Francisco, CA, VITALIY L. RAYZ, Biomedical Engineering, Purdue University, West Lafayette, IN — The effectiveness of Intra-arterial chemotherapy (IAC) is limited by the majority of drugs, e.g. Doxorubicin (Dox), that pass into systemic circulation and cause cardiac toxicity. These excessive drugs can be captured by the Chemofilter (CF) — a 3D-printable, catheter based device deployed in a vein downstream of the liver during IAC. The CF chemically adsorbs Dox via ion-exchange with a surface-coated resin. In this study, the CF hemodynamic performance and drug transport were evaluated with multiphysics computational modeling. Device design was optimized using a sensitivity analysis of flow and geometry parameters. The electrochemical binding was modeled based on concentrated solution theory, where diffusion and ion migration were incorporated into an effective diffusivity term. The Navier-Stokes and Advection-Diffusion-Reaction equations were coupled in ANSYS Fluent. The optimized CF consists of an array of hexagonal channels that are twisted, perforated, and aligned with the flow direction to enhance mixing and drug binding. The optimized CF results in a 66.8% drug reduction and pressure drop of 3mmHg, with model validation by in-vivo porcine studies. These results demonstrate the utility of the CF in improving IAC performance while preventing flow stagnation regions.

2:24PM L29.00004 Computational modeling of bacterial dynamics under shear flow\(^1\), KARTIK JAIN, CHRISTOPH LOHRMANN, CHRISTIAN HOLM, Institute for Computational Physics, University of Stuttgart, Germany — Bacteria can propel, proliferate and accumulate in a number of media and their dynamics are affected by shear flow. In addition to self-propulsion, bacteria can stick to each other and to surfaces where they can create fast growing colonies, called biofilm. Studies have shown that bacteria more commonly accumulate at surfaces and around obstacles. In the present work we modeled dynamics of E.Coli in a water like fluid. In the model the bacteria are represented by molecular dynamics (MD) particles while the fluid is represented by a lattice Boltzmann method (LBM). The MD particles are coupled to the LB fluid using a frictional point coupling that ensures momentum conservation of the total system. We present collective transient dynamics of up to 4000 bacteria in porous configurations. Our results show that the bacteria tend to a state of momentary stasis in regions where the underlying fluid recirculates, and thus result in a sticking behavior near the obstacles of the porous media. Our findings indicate that such a behavior is manifested mainly due to hydrodynamics interactions between a bacterium and the surfaces. Our model of bacterial replication agrees well with experimental data and ongoing work includes coupling of time scales in bacterial life cycle to model biofilms.

2:37PM L29.00005 Efflux Pumping Mechanism of AcrB in Multidrug Resistance Bacteria. QUYNH DINH, JIN LIU, PRASHANTA DUTTA, Washington State University — The AcrB is a multidrug pump in gram-negative bacteria responsible for ejecting antibiotics and other metabolic waste for its survival. Thus, understanding the expelling mechanisms of AcrB is essential in designing successful drugs. Though crystal structure of AcrB can be captured by the X-ray diffraction, the molecular details of AcrB-drug interaction are difficult to be identified by experiment. We have developed a hybrid coarse-grained molecular dynamics (MD) model to capture conformational changes of AcrB in presence of drug candidates at the distal binding pocket to understand the efflux mechanism. Binding energy of drugs with AcrB and potential of mean force (PMF) on drugs along the expelling pathway are also calculated. Our MD simulations show that AcrB monomer changes from binding state to extrusion state in the presence of drug or other substrate, if transmembrane residues Asp407 and/or 408 are being protonated by an antiport mechanism. Moreover, computed binding energy and PMF reveals that inhibitor-like drugs bind with AcrB much stronger than metabolic waste or conventional antibiotics. Our study suggests that inhibitor-like multifunctional drugs could effectively block AcrB pumping.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L30 Biological Fluid Dynamics : Cardiac Flows I 612 - Niema Pahelevan, USC

1:45PM L30.00001 Designing a Low Reynolds Number Ejector Pump for Infants with a Single Ventricle. DONGJIE JIA, MAHDI ESMAILY, MATTHEW PERONI, Sibley School of Mechanical and Aerospace Engineering, Cornell University, TIGRAN KHALAYAN, Dept of Cardiothoracic Surgery, Stanford University School of Medicine — Simulations have shown modifying stage-1 operation on single ventricles to incorporate an ejector pump presents several advantages, including improved oxygen delivery and low heart load. However, the efficient operation of an ejector pump relies on sufficient mixing to transfer energy and pump low-pressure fluid. Thus, the standard design of an ejector pump cannot operate effectively in infants where the blood flow Reynolds number is low. To address this issue, we present a novel design of an ejector pump that can effectively operate at a low Reynolds number environment. The performance of this ejector pump will then be demonstrated through implementation in the assisted bidirectional Glenn procedure that treats Hypoplastic heart syndrome. The further potential use of the device will be discussed.

1:58PM L30.00002 Artificial Right Atrium Design for Univentricular Heart Patients. HENG WEI, University of Southern California, CYNTHIA HERRINGTON, JOHN CLEVELAND, Children’s Hospital Los Angeles, VAUGHN STARNES, NIEMA PAHELEVAN, University of Southern California — Infants born with single ventricle pose a large challenge. The Fontan operation for univentricular heart patients creates a unique circulation whereby systemic veins get connected to the pulmonary arteries without passing through the cardiac chambers. As getting older, individuals with single ventricle tend to develop long-term complications like heart failure and require heart transplant. Previous studies have attempted to mechanically support these patients with standard left ventricular assist devices (LVAD). The primarily difficulty in establishing mechanical support for Fontan is that there is no blood reservoir in the closed Fontan circulation. An artificial right atrium is one of the treatments that could be implanted into the Fontan graft and provide a reservoir for blood and allow for full circulatory support. We investigated the optimum geometrical design of artificial right atrium by minimizing the particle residence time to reduce the chance of blood stagnation and clotting. Non-Newtonian Fluid-Structure Interaction (FSI) simulations employing Lattice-Boltzmann and immersed boundary method were utilized to evaluate Fontan hemodynamics. Our results indicate that the artificial atrium optimum shape is similar to the real human atrium.

2:11PM L30.00003 Is 3D Measurement Necessary for Quantifying Fluid Mechanics in a Left Ventricle? ZHENGJUN WEI, KESHAV KOHLI, YINGNAN ZHANG, VAHID SADRI, IKECHUKWU OKAFOR, AJIT YOGANATHAN, Georgia Institute of Technology — Left ventricle (LV) fluid mechanics has been broadly investigated in vitro, in vivo, and in silico over the past few decades. Previous studies have successfully demonstrated clinical relevance for hemodynamic metrics of the LV, e.g., energy dissipation, washout time, and vortex formation time, etc. A majority of these studies extracted conclusions based on 2D measurements. Additionally, 2D phase-contrast magnetic resonance imaging (PC-MRI) and echocardiography are the most common measurement tools in clinical practice. The current 3D tools do not meet the clinical demand. Unfortunately, previous literatures marginally discussed the validity of reducing the order of LV hemodynamic metrics (from 3D to 2D). In this study, an in silico LV model is developed and firstly validated against 4D PC-MRI in an in vitro, patient-specific, 3D LV phantom. Then, the settings of the in silico model are adjusted to mimic diseased states. The center-plane of the 3D phantom is extracted to represent a 2D measurement plane. The necessity of 3D measurement is elucidated based on the comparison between the LV hemodynamic metrics obtained from 3D and 2D measurements.

2:24PM L30.00004 Theoretical and Experimental Evidence for the Role of Viscosity in Ventricular Flow. ALEJANDRO ROLDN-ALZATE, RYAN PEWOWARUK, University of Wisconsin - Madison — In the ventricular flow literature, viscosity is a frequently reported parameter that is credited for being a key marker of blood flow dynamics and particularly flow efficiency. However, the exact role of viscosity in ventricular flow efficiency has yet to be explained. We apply the concept of enstrophy from turbulence and geophysical fluid dynamics to ventricular flow to explain the relationship between vorticity and viscous energy dissipation. Theoretically, enstrophy predicts a quadratic relationship between vorticity and viscous energy dissipation. Magnetic resonance velocimetry is performed in pigs using a high spatial resolution, radial acquisition (PC-VIPR). Velocity derived vorticity and viscous energy dissipation in both the left and right ventricle of pigs show strong agreement with the theoretical quadratic relationship ($R^2 = 0.94$). This work is the first rigorous explanation of the importance of vorticity in ventricular flow and we hope the concept of enstrophy is further applied in cardiovascular research. Additionally, experimental evidence shows strong agreement with theory, highlighting the ability of magnetic resonance velocimetry to quantify key aspects of cardiovascular fluid dynamics in living subjects.
2:37PM L30.00005 Cardiac Triangle Mapping: A Novel Systems Approach for Non-invasive Evaluation of Left Ventricular End Diastolic Pressure. NIEMA PAHLEVAN, MELISSA RAMOS, RAY MATTHEWS, University of Southern California — Left ventricular end diastolic pressure (LVEDP) is an important measure of global left ventricle (LV) function. Elevated LVEDP is indicative of poor LV function in both heart failure with preserved ejection fraction and in heart failure with reduced ejection fraction. This highlights LVEDP’s importance as quantitative biomarker for diagnosis, chronic monitoring, and evaluating response to therapy. Here, we introduce a new systems approach, called Cardiac Triangle Mapping (CTM), for non-invasive and instantaneous measurement of LVEDP. CTM uses arterial pressure waves and ECG to map the global ventricular function; hence, allowing computation of LVEDP. The accuracy and validity of CTM have been shown using prospective clinical data. Here, we present the validity and accuracy of CTM method using data from a prospective clinical study at the Keck Medical Center of USC.

2:50PM L30.00006 Patient-Specific Computational Fluid-Structure Interaction (FSI) Modeling of Full Cardiac Cycle1, MOHAMMAD MEHRI, MATTHEW FIG, MAYSAM MOUSAVIRAAD, University of Wyoming — A patient-specific computational fluid-structure interaction (FSI) model of full-cycle cardiac dynamics is presented. One-way and two-way coupling simulations are carried out for 2D and 3D geometries. The patient-specific 3D left ventricle (LV) geometry is constructed from 2D echocardiography images based on biplane ellipsoid model. One-way coupling studies use the wall motions and the pressure-volume (PV) loop data to specify the solid and fluid boundary conditions. The two-way coupled simulations model the myocardium passive dynamics with anisotropic Mooney-Rivlin method. Active contractions are modeled by stiffening and softening the myocardial material properties calculated as part of the one-way studies. The compressibility of blood is included in the model to produce the entire curve of the PV loop. The wall motions and PV loop data are used to validate the two-way results. Next steps will include invariant-based orthotropic models for passive behavior of myocardium and electrophysiology models for active contractions. The valvular dynamics will also need to be included for improved vorticity dynamics modeling.

3:03PM L30.00007 Elastohydrodynamics of the heart, VAMS SPANDAN, EMMANUELI VIROT, LAUREN NIU, Harvard University, WIM VAN REES, MIT, L MAHADEVAN, Harvard University — Animal hearts are deformable shells pumping large volumes of blood which guarantees oxygen for cells. Here we present a scaling for the heart rate based on a simple idea: Elastohydr

Monday, November 25, 2019 1:45PM - 3:16PM — Session L31 Biological Fluid Dynamics: Micro-swimmer Experimental

1:45PM L31.00001 Bacterial ridesharing: swimming and rolling of a sessile-motile aggregate, BIN LIU, YU ZENG, Department of Physics, University of California, Merced — While motile microorganisms disperse actively in aqueous environments by exploiting locomotory organelles, sessile cells are deficient in locomotory organelles and disperse passively through flow entrainment. Beyond these two discrete classes of motility, we explore an assembly containing both motile and sessile cells, a sessile aggregate of Caulobacter crescentus. Despite its predominantly sessile cells, the C. crescentus rosette exhibits surprisingly active motility, powered by as little as a single flagellar motor. In addition, proximity to a solid surface promotes rolling movements along the solid-liquid interface. This rolling mechanism emerges from a division of labor between sessile and motile compartments that respectively function as structural and powering modules, which can be extended to a wide range of natural and engineered microbial systems.

1:58PM L31.00002 Navigating through complex networks by sniffing gradients: diffusiophoresis vs. chemotaxis, JINZI MAC HUANG, TANVI GANDHI, ANTOINE AUBRET, DESMOND LI, SOPHIE RAMANANARIVO, MASSIMO VERGASSOLA, JEREMIE PALACCI, University of California San Diego — At the beginning of life, searching for food and evading hazards are two essential activities for microorganisms to survive, and the way they navigate is through chemotaxis. The optimal chemotaxis in complicated terrains determines the fate of living creatures, and natural selection ensures the existence of such an optimization. In our study, we investigate the navigation of inert particles in a network that has multiple junctions. In micro-networks manufactured through photolithography, a background gradient of salt is established as the signal of chemotractant by placing a source and a sink of salt. Colloidal particles then follow this signal through diffusiophoresis and move towards the source. Through stochastic modeling, we show that particles prefer to exit each junction at the end with higher concentration gradient. This preference is further enhanced when the particle size is larger, which leads to a way to magnify small signals in a network so that the colloidal particles larger than a critical size can always move towards the source of salt through the shortest path. Ultimately, we compare the navigation schemes of inert particles and living organisms, aiming to understand biological chemotaxis and shed light on future manufacturing of navigable microswimmers.

2:11PM L31.00003 Alleviation of hypoxia by biologically generated mixing from aggregations of centimeter-scale swimmers1, ISABEL HOUGHTON, University of San Francisco, JOHN DABIRI, Stanford University — Daily vertical migrations of zooplankton have been shown to affect nutrient distributions and dissolved gas concentrations in ocean and lake environments. Additionally, laboratory experiments have demonstrated the potential for mixing generated by these migrations to alter the physical structure of a water column by mixing different density water. In this work, we investigate the importance of biologically generated mixing relative to other processes in determining the biogeochemical structure of a water column inhabited by migrating zooplankton. Specifically, we consider oxygen, a highly ecologically relevant scalar, and the competition between metabolic consumption and biogenic mixing in a stably stratified water column with a hypoxic layer. We illustrate the potential for migrating animals to alleviate hypoxia, introducing complex feedbacks between the presence of animals and the biogeochemical state of their surroundings. Furthermore, we demonstrate the feasibility of oxygen as a potential indicator of biogenic mixing for future in situ investigation given its low diffusivity and higher signal-to-noise.

2:24PM L31.00004 Surfing the Wave: How Bacteria Migrate through Porous Media  
TAPOMOY BHATTACHARJEE, Andlinger Center for Energy and the Environment, Princeton University, DANIEL AMCHIN, FELIX KRATZ, SUJIT DATTAR, Department of Chemical and Biological Engineering, Princeton University — While bacterial motility is well-studied for motion on flat surfaces or in unconfined liquid media, most bacteria are found in heterogeneous porous media, such as biological gels and tissues, soils, and sediments. However, it is unknown how pore-scale confinement alters bacterial motility, because the opacity of typical 3D media precludes direct visualization. Here, we reveal that the paradigm of run-and-tumble motility is dramatically altered in a porous medium. By directly visualizing individual E. coli, we find a new form of motility in which cells are intermittently and transiently trapped as they navigate the pore space; analysis of these dynamics enables prediction of single-cell transport over large length and time scales. Moreover, we show that concentrated populations can collectively migrate through a porous medium despite being strongly confined by chemotactically surfing a self-generated nutrient gradient. This behavior depends sensitively on pore-scale confinement, initial colony density, and nutrient consumption, providing a means to control collective migration in bacterial populations. Our work provides a revised picture of active matter transport in complex media, with implications for healthcare, agriculture, and bioremediation.

2:37PM L31.00005 Controlling topological defects in Living Liquid Crystals  
NURIS FIGUEROA-MORALES, The Pennsylvania State University, ANDREY SOKOLOV, Argonne National Laboratory, MIKHAIL M. GENKIN, Cold Spring Harbor Laboratory, IGOR S. ARANSON, The Pennsylvania State University — A realization of active nematics has been conceived by combining swimming bacteria and a lyotropic liquid crystal. The complex dynamics of such active material arises from the non-trivial interplay between hydrodynamic flows and elastic forces: while bacteria are guided by the local director field, the local alignment of the liquid crystal is disturbed by the swimming bacteria. At high bacterial concentration, the domination of bacterial activity leads to creation of motile topological defects, which alter bacterial distribution. Here, we experimentally explore the possibility of controlling and pinning of emerged topological defects by artificially created microstructures. The microstructures were printed using a state-of-art multiphoton 3D lithography system and mimicked the shape of defects cores. While 1/2 defects may be easily pinned to the created pattern, -1/2 defects remain mobile. Due to an attraction between opposite defects, positive defects remain in the vicinity of pinned negative defects, significantly diminishing their diffusivity.

2:50PM L31.00006 Experimental investigation of hydrodynamic interactions between motile green algae  
JUNAID MEHMOOD, ABEL-JOHN BUCHNER, KOEN MULLER, DANIEL TAM, Delft University of Technology — The motility of micro-organisms plays a crucial role in many biological processes, such as reproduction and biofilm formation. Mechanical interactions between swimming cells can lead to collective phenomena, e.g., bio-convention or pattern formation. Hydrodynamic interactions between swimming cells have been the focus of several numerical studies, but experimental evidence of intercellular hydrodynamic interaction remains scarce. Here, we use a unique multi-camera microscopy set-up to track a dilute suspension of the model green alga Chlamydomonas reinhardtii. The cells are free to swim within a flow cell, which does not constrain their dynamics. The resulting three-dimensional trajectories provide data by which to examine pair-wise interactions between the motile cells. Hydrodynamic interactions can lead to a change in direction or velocity magnitude. This information is used to find out the length and time scale for which interaction is occurring between the pair of swimmers. We also study the velocity correlations between all the swimmers to find out the extent of length and time scale associated with these interactions.

3:03PM L31.00007 Self-organization of active spinners in liquid metamaterials  
JEAN-BAPTISTE GORCE, HUA XIA, NICOLAS FRANCOIS, HORST PUNZMANN, MICHAEL SHATS, Australian Natl Univ — The new concept of liquid metamaterials opened new ways of engineering fluids with adjustable properties at microscales. The liquid-interface metamaterials are generated by the superposition of two orthogonal standing surface waves. Fluid particles exhibit different type of trajectories depending on the phase shift between the two orthogonal waves. Circular orbits can be created when the two orthogonal waves are phase shifted by 90 degrees. The liquid metamaterials are periodic arrays of unit cells, somewhat analogous to optical lattices. The similarity with optics triggered recent investigation into the trapping of surface magnetic spinners within the liquid metamaterials. A single spinner exhibits stable orbits in a unit cell and can be guided by changing the spinning frequency and the spin direction. The spinner’s motion arises from the coupling between the spinner angular momentum and the wave angular momentum. Multiple spinners self-organize into stable configurations around the centre of the unit cells. The results offer novel methods of manipulation and confinement of actively moving surface particles at the fluid interfaces using waves and suggest new analogies between surface wave physics and confinement of nano- and micro-particles and atoms by optical fields.

1:45PM L32.00001 Effects of Extracellular Transforming Growth Factor-mediated Fibroblast Activation in Tumor Microenvironment  
ROBERT DILLON, ADNAN MORSHEID, PRASHANTA DUTTA, Washington State University — The transforming growth factor (TGF) is known to prevent differentiation of benign tumor cells to malignancy. Paradoxically, cancer cells exploit the immune regulation and microenvironment modulatory functions of TGF to their advantage. This makes TGF response highly sensitive to tumor progression. In vitro experimental data for several intercellular and cell surface reactions involving the fibroblasts indicate a switch-like behavior based on extracellular TGF conditions. We modeled a single tumor cell with surrounding fibroblasts to create a specific tumor microenvironment. The extracellular transport through advection, reaction and diffusion as well as cell surface reactions are captured through an immersed interface approach. Flow of extracellular nutrients and fluid-structure interactions are modeled with an immersed boundary description. The unknown reaction parameters were estimated using Bayesian inference with experimental data on the PE25 cell line. Variation in spatial distance and arrangement of tumor cells and fibroblasts showed significant change in reaction dynamics and intracellular TGF production. Microfluidic results also highlight the clinical relevance and therapeutic potential of TGF/Smad pathway.

1:58PM L32.00002 Molecular Simulations of Synaptotagmin-like Protein-4-a during the Vesicle Docking and Fusion with Endothelial Cells upon Ca\(^{2+}\) Binding \(^1\), JIN LIU, QUYEN DINH, PRASHANTA DUTTA, School of Mechanical and Materials Engineering, Washington State University, Pullman WA USA — Synaptotagmin-like protein-4-a (Slp4-a) is a calcium sensor protein which plays critical roles in triggering the vesicle docking and fusion with blood-brain barrier endothelial cells during the exocytosis process. Upon binding Ca\(^{2+}\), Slp4-a undergoes a series of global translational/rotational movements and conformational changes, actively interacts with the SNARE complex, penetrates into the membrane bilayer, and triggers the pore opening. The exact molecular mechanism of how Ca\(^{2+}\) binding to Slp4-a leads to vesicle-cell fusion is not fully understood. In this work, we implement a hybrid coarse-grained force field that couples the united-atom protein models with the coarse-grained MARTINI water/lipid, to investigate the responses of Slp4-a upon Ca\(^{2+}\) binding. The hybrid coarse-grained molecular simulations enable us to explore large scale protein changes while retaining detailed molecular interactions. Our simulation results show that the binding of calcium ions causes dramatic reorientation and structural reorganization of Slp4-a. These changes induce local re-arrangement of membrane lipids at the Slp4-a-membrane contact areas leading to stronger attractive force between vesicle and endothelial cell membranes, which clearly indicate the initial docking and fusion process.

2:11PM L32.00003 Investigation of the Key Parameters Impacting the Receptor Dependent Clathrin-mediated Endocytosis through Stochastic Modeling and Simulations \(^1\), MD MUHTASIM BILLAH, HUA DENG, PRASHANTA DUTTA, JIN LIU, School of Mechanical and Materials Engineering, Washington State University, Pullman WA USA — Receptor dependent clathrin-mediated endocytosis (CME) is one of the most important endocytic pathways taken by bioparticles, such as viruses and drug carriers, to enter the cells. During CME, the ligand-receptor interactions, assembly/disassembly of clathrin-coated pit ( CCP) and membrane deformation all act together to drive the internalization of bioparticles. Study of CME through experiments is significantly challenging because of the number of parameters impacting this complex biological process. In this work, we develop a stochastic computational model for the CME based on the Metropolis Monte Carlo simulations. After validation, we implement the model to systematically investigate effects of a wide range of biochemical and geometrical parameters on the overall internalization efficiency of particles. Specifically, results from our simulations demonstrate that the particle size and shape play critical roles during internalization. In addition, the ligand-receptor parameters, such as the receptor flexural rigidity/size and ligand-receptor reaction cutoff/energy, also significantly impact the internalization efficiency. Our model and simulations yield critical insights into CME and may provide guidelines for intra/transcellular drug delivery design.

2:24PM L32.00004 Filter Flows at Low Reynolds Number \(^1\), ANDERS ANDERSEN, Department of Physics and Centre for Ocean Life, Technical University of Denmark — Filter feeders that create flows through fibrous structures to capture prey particles are common among the plankton. Often the filter is external to the organism, and depending on the filter permeability and the overall motion of fluid and filter, the flow may or may not circumvent the filter. To capture small prey particles it may be advantageous to have small spacing between the filter elements, but at the same time, small filter spacing corresponds to low permeability and may result in filter circumvention and low flow rate through the filter. To explore this trade-off, we focus on low Reynolds number flow perpendicular to a thin, circular filter (permeable disk), and we determine an analytical solution for the flow through and around the filter. We compare the solution with the well-known solution for the flow past an impermeable disk, and we determine the dependence of the flow rate through the filter on its permeability and size. Finally, we discuss the possible biological implications of the results for planktonic organisms.

\(^1\)The project is supported by The Independent Research Fund Denmark (grant no. 7014-00033B), and the Centre for Ocean Life, a VKR Centre of Excellence supported by the Villum Foundation.

2:37PM L32.00005 Pinning and hydrodynamic coupling determine the motility pattern of interfacially trapped bacteria \(^1\), JIAYI DENG, MEHDI MOLAEI, NICHOLAS CHISHOLM, KATHLEEN STEBE, University of Pennsylvania — Fluid interfaces are unique environments for swimming bacteria, which display complex motility patterns influenced by concomitant capillary forces and hydrodynamic interactions. In 3-d suspension, P. aeruginosa swims along symmetric straight paths in run and reverse motions by altering the rotation direction of its flagellum to switch between pusher and puller modes. Near solid walls, the straight trajectories become circular paths due to the well understood hydrodynamic interactions. Trajectories of P. aeruginosa trapped at an oil-water interface, however, display a diverse set of trajectory types: fast and straight visitors, Brownian diffusive cells, stable curvy paths, and pirouettes. Which of these patterns occurs depends on the trapping state of the cell and its orientation with respect to the interface. An analysis of the curvy paths reveals that highly asymmetric trajectories occur with higher angular velocity and curvature for pullers and higher linear velocity and lower curvature for pushers. Our hydrodynamic analysis suggests that this motion is regulated by the re-orientation of the bacterial flagellum, which pivots normal to the interface in the puller mode and parallel to the interface in the pusher mode.

2:50PM L32.00006 The colloidal hydrodynamics of intracellular transport \(^1\), ROSEANNA ZIA, AKSHAY MAHESHWARI, ALP SUNOL, EMMA GONZALEZ, DRÉW ENDY, Stanford University — Many representations of intra-cellular behavior rely on abstractions that do not account for how macromolecules are organized and move inside the cell. For many questions in biology and medicine these simpler models have been sufficient. However, fundamental gaps in understanding of many cell functions persist; physics may provide a bridge to close such gaps. I will discuss our computational and theoretical models of spherically confined colloidal suspensions, as a simple model cell, where biomolecules and their interactions can be physically represented individually and explicitly. A primary challenge in models of confined colloidal suspensions is the accurate and efficient representation of many-body hydrodynamic interactions, Brownian motion, and the enclosure. To this end, we developed the Cellular Stokesian dynamics framework. Utilizing this model, we studied diffusion, cooperative motion, and self-organization with confinement and crowding levels representative of a cell interior. I will discuss the qualitative influence of hydrodynamics, confinement and crowding on transport behavior, as well as the consequences of neglecting such influences. Connections to underlying structure are made, and implications for cellular function are discussed.

3:03PM L32.00007 Fluid forces and flows in muscle’s contractile lattice\textsuperscript{1} SAGE MALINGEN, University of Washington, KAITLYN HOOD, ANETTE HOSOI, Massachusetts Institute of Technology, THOMAS DANIEL, University of Washington — Muscle cells are specialized for large, rapid shape change. Their contraction is powered by the collective action of molecular motors anchored to long protein filaments (thick filaments) that form a densely packed, fluid filled lattice. Molecular motors bind to thin filaments and pull them past the thick filaments. These motors are estimated to produce 5 pN forces. As filaments slide they shear with the surrounding fluid. Additionally, the lattice volume can change during contraction, causing flows that create axial and radial shear forces. With an inter-filament gap distance of only 30 nm surface-to-surface, viscous drag forces could be non-trivial and have not been measured. Using a finite element model (COMSOL) of the contractile machinery we estimate that viscous drag forces on single filaments are on the order of 10 fN. We estimate that the energy dissipated by viscous drag over all filaments is less that 1% of the energy used by the system. However additional proteins occupying the gaps between filaments, variable inter-filament spacing and viscosity values greater than that of water may influence this result.

Monday, November 25, 2019 1:45PM - 3:16PM — Session L33 Flow Instability: Geophysical

1:45PM L33.00001 The Weakly Nonlinear Evolution of Superharmonics Generated by Model Oceanic Internal Tides\textsuperscript{1} BRUCE SUTHERLAND, University of Alberta, LOIS BAKER, Imperial College London — It is now well-established that a vertically confined, horizontally periodic internal mode in non-uniformly stratified fluid self-interacts through the advection terms resulting in the forcing of superharmonics with double the horizontal wavenumber and frequency of the parent mode. The work presented here examines the linear and weakly nonlinear response to this forcing resulting from mode-1 “parent” waves in stratification typical of the ocean. It is shown that the forcing results in the excitation of a near-pure mode-1 (“sibling”) internal wave with double the horizontal wavenumber of the parent, though the natural frequency of this mode differs slightly from double the frequency of the parent. As a result, the sibling wave first grows and decays, doing so periodically at the beat frequency set by the difference of the natural frequency of the mode and double the parent-mode frequency. A weakly nonlinear analysis is necessary to predict the maximum amplitude of the superharmonic. This considers how the interaction between the parent-mode and its superharmonic sibling put energy into or take energy out of the parent-mode.

\textsuperscript{1}This research was made possible due to the National Science Foundation (Grant OCE-1332750) for their support of the WHOI Geophysical Fluid Dynamics Summer Program. Additional funds were provided to Sutherland by the Natural Sciences and Engineering Research Council (NSERC) of Canada through its Discovery Grant program.

1:58PM L33.00002 Dynamic stability of a jet near a transition in static stability JOHN MCHUGH, The University of New Hampshire — The vertical profile of the Earth’s atmosphere contains a sharp transition region at the tropopause between two roughly constant stability layers, and also jet streams at nearly the same altitude, with the jet stream core possible above or below the tropopause, depending on location. This proximity of the jet to the tropopause would be expected to greatly affect the dynamic stability of the jet, treated here with the jet modeled with the Bickley \textit{sech}\textsuperscript{2} profile and the tropopause modeled as a smooth transition region with a tanh profile. Stability results are obtained numerically using a Chebyshev collocation spectral method. The results show that the jet becomes more unstable as it is moved further beneath the tropopause. Corresponding two-dimensional direct numerical simulations of the flow confirm the initial growth rate, but then show that the most unstable mode achieves more kinetic energy when the jet is just above the tropopause. Overall, the results indicate that when a jet is above the tropopause, the configuration is more stable and more likely to produce a strong single unstable mode. Conversely, when a jet is below the tropopause, the jet is more likely to form a broad spectrum of motion.

2:11PM L33.00003 Four wave interactions for internal waves JEAN-MARC CHOMAZ, LadHyX, CNRS-Ecole polytechnique, SABINE ORTIZ, Unit de Mcanique, Ecole Nationale Suprieure de Techniques Avances, Paris, LADHYX, CNRS-ECOLE POLYTECHNIQUE TEAM, UNIT DE MCAINIQUE, ECOLE NATIONALE SUPRIEURE DE TECHNIQUES AVANCES, PARIS TEAM — Triadic instability is a very generic mechanism by which a primary wave of finite amplitude is destabilized by two secondary waves (daughter waves) forming a resonant triad. For gravity waves in the ocean, as shown by Philips, O.M. (UPC, 1967), resonant triads form several continuous branches, which can be represented in two dimensions as resonant lines in the plane of the wave vector of one of the secondary waves. We show here that the crossing of two of these branches radically modifies the nature of triadic instability by coupling, no longer two daughter waves, but three that form two triads sharing one same wave. Instability is then reduced for the triad unstable in classical theory while the second triad, stable according to classical theory, is strongly destabilized. Building on McEwan, A.D. & Plumb, R.A. (Dyn. Atm. & Oceans, 1977), we show that this modification of triadic instability affects a finite region around the crossing point of resonant branches in the plane of wave vectors, region whose extent increases very rapidly as the amplitude of the primary wave increases. The direct calculation of instability modes by a Floquet method shows that, even for a very small amplitude of the primary wave (Froude number of about 0.01), the deviation from the classical theory.

2:24PM L33.00004 Linear instability of the Prandtl model for stratified slope flows\textsuperscript{1} INANC SENOCAK, CHENG-MIAN XIAO, University of Pittsburgh — Ludwig Prandtl dedicated the last three pages in the authorized translation of his famous book “Essentials of Fluid Dynamics” to describe mountain and valley winds in stratified air. The exact solution assumes the presence of a constant linear background stratification above a sloped surface of infinite extent in all directions with a constant heating or cooling applied to it. Over the years, the Prandtl model has been found to describe the flow profile of kataibatic winds observed in nature. Despite the usefulness of the Prandtl model, its stability characteristics have gone unexplored for many decades since its publication. In the present work, we use linear modal analysis and direct numerical simulations to uncover two types of flow instabilities in the Prandtl model for anabatic and kataibatic slope flows. These instabilities manifest themselves as a function of the slope angle, the Prandtl number and a newly introduced stratification perturbation parameter, which is a measure of the relative importance of the surface heat flux with respect to the background stratification. We investigate the characteristics of these instabilities as a function of the aforementioned dimensionless parameters and highlight their differences under kataibatic and anabatic scenarios.

2:50PM L33.00006 Shear instabilities in laboratory arrested salt-wedge flows

ADAM JIANKANG YANG, EDMUND TEDFORD, JASON OLSTHOORN, GREGORY LAWRENCE, University of British Columbia — The spatial variation in the properties of an arrested salt wedge and its resulting Holmboe instabilities have been investigated, both analytically and in the laboratory. In the laboratory particle image velocimetry and laser induced fluorescence are used to obtain flow velocities and the height of the density interface. The positive and negative Holmboe wave modes are separated by the 2D Fourier transform. An analytical solution for the profile of interface height, in the absence of interfacial flow instabilities, has been developed from two-layer internal hydraulic theory. The evolution of the velocity profile is predicted using a momentum diffusion equation following a Lagrangian frame of reference along the interface of the salt wedge. The centre of the shear layer is predicted to lie above the density interface, with this offset decreasing in the downstream direction. Due to the offset and lower boundary, the growth rate of the negative instability is smaller than that of the positive instability. Our theoretical predictions are in good agreement with the laboratory measurements.

3:03PM L33.00007 Halite precipitation from double-diffusive salt fingers in the Dead Sea: Numerical simulations

RAPHAEL QUILLON, University of California, Santa Barbara, NADAV LENSKY, VLADIMIR LYAKHOVSKY, ALI ARNON, Geological Survey of Israel, ECKART MEIBURG, University of California, Santa Barbara — Thick, extensive salt layers are commonly found in the Earths geological record and formed as a result of a negative water balance in hypersaline lakes saturated in salt. Today, the Dead Sea is considered to be the only modern analog to these deep hypersaline lakes. Recent field work conducted by the Geological Survey of Israel showed that during the dry summer season, the top layer of the Dead Sea is warmer, saltier and undersaturated in salt, and that double-diffusive convection is responsible for delivering dissolved salt from the top layer to the bottom layer, resulting in continuously supersaturated bottom layer and seasonally undersaturated top layer. We present numerical simulations of this double-diffusive process directly based on measurements from the field work. The simulations account for the phase change from dissolved to crystalline salt, and for the settling of the salt crystals. We show that no other physical mechanism than double-diffusion is required in order to generate sufficient transport of salt and obtain the salinity and temperature profiles measured in the summer in the Dead Sea. The combined field measurements and numerical simulations paint a novel and promising picture for the mechanisms of salt deposition in the historical record.

Monday, November 25, 2019 1:45PM - 3:16PM —
Session L34 Flow Instability: Rayleigh-Taylor II

1:45PM L34.00001 Effect of Magnetic Fields on the Nonlinear Rayleigh-Taylor Instability

XIN BIAN, RICCARDO BETTI, HUSSEIN ALUIE, University of Rochester — The magneto-Rayleigh-Taylor instability (mRTI) plays an important role in inertial fusion schemes, including ICF and magLIF. It is also hypothesized that mRTI is pervasive in the interstellar medium, where it tends to concentrate the plasma into discrete clouds. We investigate numerically the effects of external magnetic fields on RTI during its nonlinear stages in 2D and 3D. We consider magnetic fields oriented in both parallel and perpendicular directions relative to the initial interface. Both magnetic orientations tend to suppress bubble development in 2D but can enhance it in 3D, where we find a non-monotonic dependence on field strength. For example, we observe that a perpendicular magnetic field stronger than a threshold enhances the RTI growth by enhancing the anisotropy of mixing and suppressing horizontal motions, especially at the smallest scales. Moreover, magnetic fields in either direction tend to accentuate the asymmetry between bubbles and spikes

1:58PM L34.00002 Direct Numerical Simulations of Magnetic Rayleigh-Taylor Instability in ICF Coasting Stage

ZHAORUI LI, Texas A&M University, DANIEL LIVESCU, Los Alamos National Laboratory — The development of hydrodynamic instabilities is generally believed to be one of the main obstacles to achieving economically controlled inertial confinement fusion (ICF). In this study, accurate simulations of 2D magnetic Rayleigh-Taylor instability (RTI) under ICF coasting stage conditions have been conducted with a newly developed high-order two-fluid plasma solver (Li and Livescu, 2019), in which full transport terms, including temperature and magnetic field dependent ion and electron heat fluxes and viscous stresses, are implemented. The numerical results show that, for the initial configuration with small Atwood number (0.33) and high hot-spot temperature (10 keV), the extremely large heat conduction and viscous stresses completely suppress the RTI development. Instead, the late-time RTI and magnetic field can grow to structures close to those seen in previous studies, which relied on numerical transport to regularize the equations, only when unrealistically small transport coefficients are used for calculating heat conductivity and viscosity. Further simulations with realistic transport phenomena are being conducted with more relevant ICF coasting stage conditions (e.g. Weber et al. 2014) in which Atwood number is 0.875 and hot-spot temperature is 2.25 keV.
The presented work focuses on the preliminary implementation of Planar Laser Induced Fluorescence (PLIF) to study the Blast-Driven Instability (BDI) in cylindrical geometry at the Georgia Tech Shock Tube and Advanced Mixing Laboratory. By using detonators to generate blast waves, a gaseous interface is subject to the combined Richtmyer-Meshkov (RMI) and Rayleigh-Taylor Instabilities (RTI); the two instabilities comprising the BDI. Previous validation of the facility was completed using high speed Mie Scattering and demonstrated faithful reproduction of the phenomena of the BDI. Previously completed Mie Scattering measurements will be used in conjunction with PLIF to measure the degree of interfacial stretching for bubble-spike pairs in this facility. These efforts will be put toward the implementation of simultaneous PLIF and PIV for full flow field measurements.

1 Authors acknowledge support from DOE/NNSA Grant DE-NA0003195 and the NSF-CAREER Award 1453056.
We observe that for k study the dynamics of arbitrary-shaped particles in a second-order fluid, subject to a general quadratic flow field. For the two model constants \( v_1 \) and \( v_2 \) (first and second normal stress coefficients) we assume the relationship \( v_1=2v_2/3 \). The assumption allows us apply a multipole expansion to derive analytical expressions for the polymeric force and torque of the particle. We apply the analytical solutions to track the translational and rotational trajectories of spherical, spheroids, and general ellipsoids in shear and pressure driven flows. In shear flows, we observe that prolate-like particles undergo a transition from tumbling to log-rolling motion (i.e., alignment along the vorticity direction) as the shear rate increases. At very large shear rates, the particles can reorient along the flow direction, but this state is metastable. In pressure driven flows, we find that particles migrate to the center of the flow, with the tumbling period increasing in time until the particle eventually aligns along the flow direction.

We vary the drop-to-medium viscosity ratio (k) by varying the PVP concentration and demonstrate center-ward droplet migration for k \( \leq 3.72 \) respectively, while droplets stay near the wall for 3.72 \( \leq k \leq 18.52 \), contrary to Chan and Leal’s prediction with second-order fluids. We observe that for k = 12, Newtonian castor oil (viscosity 650 mPa-s, relaxation time = 0) droplets migrate to center while PDMS (average viscosity 666 mPa-s, relaxation time = 0.001) droplets stay near the wall. Finally, we demonstrate viscoelasticity based sorting of castor and PDMS droplets.

1.45PM L35.00001 Cross-stream migration of non-spherical particles in a second-order fluid. SHIYAN WANG, CHENG-WEI TAI, VIVEK NARSMIHAN, Purdue University — Particle migration in viscoelastic suspensions is vital in many applications in the biomedical community and the chemical/oil industries. Despite previous studies on the motion of spherical particles in simple viscoelastic linear flows, the combined effect of more complex flow profiles and particle shapes is underexplored. Here, we study the dynamics of arbitrary-shaped particles in a second-order fluid, subject to a general quadratic flow field. For the two model constants \( v_1 \) and \( v_2 \) (first and second normal stress coefficients) we assume the relationship \( v_1=2v_2/3 \). The assumption allows us apply a multipole expansion to derive analytical expressions for the polymeric force and torque of the particle. We apply the analytical solutions to track the translational and rotational trajectories of spherical, spheroids, and general ellipsoids in shear and pressure driven flows. In shear flows, we observe that prolate-like particles undergo a transition from tumbling to log-rolling motion (i.e., alignment along the vorticity direction) as the shear rate increases. At very large shear rates, the particles can reorient along the flow direction, but this state is metastable. In pressure driven flows, we find that particles migrate to the center of the flow, with the tumbling period increasing in time until the particle eventually aligns along the flow direction.

1.58PM L35.00002 Viscoelasticity based droplet migration and sorting. SHAHMIK HAZRA, Indian Institute of Technology, Madras, SUSHANTAA MITRA, Waterloos Institute for Nanotechnology, University of Waterloo, ASHISH KUMAR SEN, Indian Institute of Technology, Madras — We experimentally elucidate the cross-stream migration behavior of viscoelastic Polydimethylsiloxane (PDMS) droplets in the non-inertial Poiseuille flow of constant viscosity aqueous viscoelastic solution of Polyvinylpyrrolidone (PVP) in straight rectangular microchannels. We investigate the complex interaction among deformability induced non-inertial lift force, viscoelastic lift force due to matrix viscoelasticity, and viscoelastic lift force due to droplet viscoelasticity and propose a new droplet migration regime. We vary the drop-to-medium viscosity ratio (k) by varying the PVP concentration and demonstrate center-ward droplet migration for k \( \leq 3.72 \) respectively, while droplets stay near the wall for 3.72 \( \leq k \leq 18.52 \), contrary to Chan and Leal’s prediction with second-order fluids. We observe that for k = 12, Newtonian castor oil (viscosity 650 mPa-s, relaxation time = 0) droplets migrate to center while PDMS (average viscosity 666 mPa-s, relaxation time = 0.001) droplets stay near the wall. Finally, we demonstrate viscoelasticity based sorting of castor and PDMS droplets.

2:11PM L35.00003 Oscillations of a cantilevered micro beam driven by a viscoelastic flow instability1, ANITA DEY, YAYHA MODARRES-SADEGHI, University of Massachusetts Amherst, ANKE LINDNER, ESPCI, CNRS, University Paris Diderot, JONATHAN ROTHSTEIN, University of Massachusetts Amherst — We will present the results of our study of the flow of a viscoelastic polymer solution past a cantilevered beam in a confined geometry. The flow of viscoelastic fluids, unlike Newtonian fluids, become unstable even at infinitesimal Reynolds numbers due to purely elastic flow instabilities that occur at large Weissenberg numbers. With increasing Weissenberg number, we will show that elastic instabilities occur in the vicinity of a flexible beam and begin to interact with the beam. We will report these interactions for cantilevered beams with varying elastic modulus, beam length and rigidity. Over a range of Weissenberg numbers, we will show that the flow field transitions from a stable detached vortex upstream of the beam to a time-dependent unstable vortex shedding. The shedding of the unstable vortex upstream of the beam will be shown to couple with the flow-induced beam deformation triggering oscillations of the beam. The critical onset of the flow transitions, mechanism of vortex shedding, and dynamics of the cantilevered beam oscillations will be presented for beams with varying flexibility. The oscillations of the flexible beam will be shown to have distinct regimes: a clear single vortex shedding regime and another regime characterized by a 3D chaotic flow instability.

2:24PM L35.00004 Two ball interaction while settling in an Oldroyd-B fluid: one atop the other initially, TSORNG-WHAY PAN, Dept. of Mathematics, University of Houston, SHANG-HUAN CHIU, Dept. of Scientific Computing, Florida State University, ROLAND GLOWINSKI, Dept. of Mathematics, University of Houston — In this talk we present a numerical study of two ball interaction while settling in a vertical channel with a square cross-section filled with an Oldroyd-B fluid. Two balls are released one atop the other initially and the effects of particle inertia and fluid inertia are not ignored. We have obtained that either the trailing ball catches up the leading one to form a chain or two balls separate with a stable final distance at the end. For the cases of the ball density slightly heavier than that of the fluid, they can form a vertical chain or tilted chain. But when increasing the ball density, the two balls can form a chain for smaller initial gaps; but they move away from each other and the distance between two balls reaches a constant for a larger initial gap. When the density of the balls is up to, at least, 3.3 times of the fluid density, the two ball settling velocity (i.e., the ball density), initial gap between two balls and elasticity number. Also the fluid polymer extension limit has its effect on the formation of two ball chain when they settle in a FENE type of viscoelastic fluid.

2:37PM L35.00005 Filament thinning dynamics of Boger fluids in extensional flow under microfluidic environment. TANOY KAHALI, SUMAN CHAKRABORTY, Department of Mechanical Engineering, Indian Institute of Technology Kharagpur, Kharagpur - 721302, India — Polymer addition to Newtonian-fluid drastically alters the neck thinning dynamics especially in reduced length scale system due to enhanced elasticity. This motivates to study the neck thinning of two-phase polymeric–Newtonian system in micro-scale. Previous studies are mostly focused on gravity assisted filament thinning in macro-scale. Here, we intend to study the effect of elasticity on filament thickness for a series of Boger fluids(dispersed phase)stretched in a medium of silicon oil under micro-environment. Qualitatively, we observed that the filament thinning rate is much slower compared to Newtonian fluid. At an earlier stage, both fluids undergo a shearing thinning process where the filament thickness decays exponentially with time. In later stage, for Newtonian fluid a capillary driven regime dictates further thinning and rupture of the filament. In contrast, a second exponential thinning regime (causing the delay) is observed for polymer filaments along with capillary-driven thinning before pinch off. We envisage that this analysis may elucidate the role of different types of polymer addition and its concentration on the universal trend of filament thinning process in micro-scale.

2:50PM L35.00006 Viscoelastic fluid-structure interactions in microfluidics1, SIMON HANGARD, CAMERON HOPKINS, AMY SHEN, Okinawa Institute of Science and Technology — Flow of a viscoelastic wormlike micellar solution around a slender, but rigid, microfluidic post at negligible Reynolds number (Re<1) undergoes a supercritical bifurcation to a steady asymmetric state when a critical Weissenberg number (Wi) is exceeded. A second transition above a higher critical Wi results in time-dependence of the asymmetric flow with a characteristic frequency \( 1/\lambda_M \), where \( \lambda_M \) is the Maxwellian relaxation time. We examine the effect of this time dependence on the behavior of flexible cantilevered micro-posts, showing post oscillations at the same characteristic frequency \( 1/\lambda_M \), thus demonstrating a “purely-elastic” fluid-structure interaction. A second flexible post positioned downstream, shows a remarkable degree of synchronization with the first. The time lag between their correlated motions is much shorter than any expected flow time between the two posts. Our experiments show that the posts are effectively linked by an elastic strand of highly stressed fluid originating in the wake of the upstream post. Our results indicate that the time lag between their motion is dictated by the speed of the elastic wave traveling along this strand.

3:03PM L35.00007 Motion of nanoparticle-covered droplet in a square microchannel

ZHENGYUAN LUO, BOFENG BAI, State Key Laboratory of Multiphase Flow in Power Engineering, Xin Jiaotong University — The flow of complex droplets with contaminated surfaces (e.g., nanoparticle-covered interface) in microchannels with non-circular cross-sections is ubiquitous in nature and various engineering applications. For example, deformable droplets through porous media in underground oil reservoir and droplet transport and manipulation in microfluidic devices. It is also an important fundamental question in the discipline of fluid mechanics. Extensive studies have been dedicated to the study of the motion, deformation and breakup of an individual droplet in cylindrical capillaries or non-circular channels, most of which have been focused on clean droplets. However, little is known about the effects of contaminated surfaces, e.g., nanoparticle-covered interface. In this study, we will show our new numerical results on flow dynamics of complex droplets with nanoparticle-covered interface in a square microchannel. We find the adsorption of nanoparticles tends to assemble at the drop rear and immobilize the drop surface, and thus enlarges the droplet-induced extra pressure loss.

Session L36 Microscale Flows: Emulsions

1:45PM L36.00001 Effect of adding dispersant on the structures of water-in-oil emulsions.

DIEGO F. MURIEL, JOSEPH KATZ, Johns Hopkins University — It is believed that dispersant application to break up marine oil slicks is effective only before stable water-in-oil emulsions develop. Both breaking waves and gentle mixing produce stable emulsions, and surfactants present in crude oil stabilize entrained sea water even in calm seas. Once formed, the interaction of these emulsions with chemical dispersant is poorly understood, partially because field observation at microscopic scales is challenging. This study examines the effect of adding dispersant (Corexit 9500) on the structure of emulsions with or without external mechanical energy. Microscopic imaging examines the size, spatial distribution, and time evolution of water droplets in the emulsion prior to and after introducing dispersant. Initially, these droplets form a multi-scale lattice with small droplets aggregating around larger ones. Adding dispersant without mixing generates secondary flows as the water droplets coalesce. In time, part of the water separates, a fraction forms a cloud of submicron droplets, and the rest remains unchanged. Agitating the dispersant-emulsion mixture enhances the phase separation, removing about 66% of the entrained water, and leaving an emulsion with finer droplets with different rheological properties (higher viscosity).

1:58PM L36.00002 Droplet coalescence using a microfluidic hydrodynamic trap.

SHWETA NARAYAN, University of Minnesota - Twin Cities, DAVIS MORAVEC, BRAD HAUSER, ANDREW DALLAS, Donaldson Company, Inc., CARI DUTCHER, University of Minnesota - Twin Cities — Coalescence of micrometer-sized droplets to form larger drops is a fundamental process leading to separation of complex emulsions. Single droplet coalescence experiments are challenging, particularly with micrometer-sized droplets, compared to bulk studies. We have shown using microfluidics that the dynamic interfacial tension equilibration timescale is orders of magnitude shorter in micrometer-scale droplets compared to large millimeter-sized drops. Here we employ a microfluidic hydrodynamic trap to trap and coalesce single micrometer-sized droplets formed on-chip using feedback pressure control. Similar to the macro-scale four-roll mill, single droplet coalescence experiments are conducted using a microfluidic trap, with precise control over droplet size and speed. The systems studied are light and heavy mineral oils with varying concentrations of SPAN 80 in the continuous phase, with water as the dispersed phase. Film drainage times are measured as a function of Capillary number, surfactant concentration and viscosity ratio.

1This work was funded by Donaldson Company and performed at the University of Minnesota. Portions of this work were conducted in the Minnesota Nano Center, which is supported by the National Science Foundation through the National Nano Coordinated Infrastructure Network (NCCI) under Award Number ECCS-1542202.

2:11PM L36.00003 Study on the lateral migration of a ferrofluid droplet in a plane Poiseuille flow under uniform magnetic fields.

MD. RIFAT HASSAN, CHENG WANG, Department of Mechanical and Aerospace Engineering, Missouri University of Science and Technology — Droplet dispersion in another immiscible fluid is important in a variety of technological processes that involve liquid-liquid extraction where phase separation is crucial to the purification of the product. In this study, we investigate the lateral migration of a ferrofluid droplet in a plane Poiseuille flow under uniform magnetic fields by means of a numerical simulation, which uses a level set method to track the droplet interface between the two phases. Focusing on low droplet Reynolds number (i.e., $Re_d \leq 0.05$), the results indicate that the magnetic field plays a pivotal role in the motion trajectory of the droplet and the final equilibrium position in the channel. When the magnetic field acts in a direction parallel to the flow direction (i.e., $\alpha = 0^\circ$), the droplet settles closer to the bottom wall with increasing magnetic field strength, while at $\alpha = 45^\circ$ the droplet settles closer to the center. Also, variation of initial droplet sizes results in different equilibrium positions along the channel. Furthermore, at $\alpha = 90^\circ$ the droplet finds its equilibrium position at the channel center irrespective of different magnetic field strengths and droplet sizes.

2:24PM L36.00004 Bubble Nucleation and Streaming in Degasosed Water.

KYOKO NAMURA, SHUNSUKE OKAI, SAMIR KUMAR, MOTOFUMI SUZUKI, Kyoto University, MICRO PROCESS ENGINEERING LABORATORY TEAM — Marangoni flow around a microbubble has been extensively studied to apply it for microfluidic control. However, precise control of the Marangoni flow is not straightforward because of the difficulty in controlling temperature distribution around the tiny bubble. Especially, the bubble growth under heating affects the temperature gradient on the bubble surface, which is generally induced by the diffusion of the dissolved air gases into the bubble. Here we study the bubble nucleation and subsequent flow generation in well-degassed water. The ultrapure water was sonicated under vacuum (5 kPa) to remove dissolved gases. In order to realize the localized heating of the prepared degassed water, we used the photothermal effect of the gold nanosand film. By irradiating CW laser on the film immersed in the degassed water, a water vapor bubble was generated. The bubble oscillated at sub-MHz, where its maximum size was 10 μm. The bubble involved significantly rapid flow of the order of 1 m/s under continuous photothermal heating, which is expected to be useful for microfluidic mixing and pumping. The rapid flow generation is attributed to the Marangoni force and bubble oscillation, which are induced under the steep temperature gradient.

2:11PM L37.00003 Physics of liquid break-up in a two-fluid coaxial atomizer forced by an external acoustic field. PETER DEARBORN HUCK, RODRIGO OSUNA-OROZCO, NATHANIEL MACHICOANE, ALBERTO ALISEDA, University of Washington — We investigate acoustic forcing as a means of actuation in the formation of liquid drops and ligaments at the interface between a low momentum liquid cylinder and a high momentum coaxial gas jet. A canonical two-fluid co-axial atomizer is experimentally investigated, at a wide range of gas to liquid momentum ratios, but within the high Weber number break-up limit. The liquid cylinder placed at the velocity of an acoustic waveguide where the second traverse mode of the cavity is excited. Anemometry measurements show disturbances in the boundary layer at the nozzle orifice, but the self-similar nature of the gas-phase jet is retained in the mid-field. Phase Doppler Interferometry measurements of the droplet size, velocity and number density confirm that acoustic forcing in the near field is effective at enhancing atomization (the Sauter Mean Diameter decreases by 25%).

2:24PM L37.00004 Swirl Optimization to Maximize Spray Angle from a Coaxial Airblast Atomizer. SCOTT A. ZMUDA, TIMOTHY B. MORGAN, JULIE K. BOTHELL, THEODORE J. HEINDELM, Iowa State University, EXPERIMENTAL MULTIPHASE FLOW LAB TEAM — Liquid sprays play a key role in many engineering processes (e.g., food processing, coating and painting, 3D printing, fire suppression, combustion systems, etc.). One method of forming a spray is through a coaxial airblast atomizer in which a liquid stream is surrounded by a gas jet. Adding swirl to the gas jet can modify the resulting spray angle. This study completes a parametric study over a range of gas and liquid flow rates, momentum ratios, and swirl percentages, to identify those conditions that maximize spray angle. The spray angle is determined by back-illuminating the spray with an LED light panel to form a shadow of the resulting spray. A high-speed camera is then used to capture a series of successive images. Image analysis is then used to determine an average spray angle. It is shown that the swirl percentage for the maximum spray angle is a function of the flow conditions.

2:37PM L37.00005 Particle-droplet interaction in turbulent channel flow. ARASH HAJSHARIFI, CRISTIAN MARCHIOLI, University of Udine, ALFREDO SOLDATI, TU Wien — We examine the interaction between small (sub-Kolmogorov) inertial particles and large deformable droplets in turbulent channel flow. To simulate such solid-liquid-liquid flow, we exploit a Eulerian-Lagrangian methodology based on direct numerical simulation of turbulence, coupled with a Cauchy-Hillard Phase Field Model to capture the interface dynamics and Lagrangian tracking to compute particle trajectories. We model the particle-interface interaction via a capillary force based on the liquid-liquid surface tension and on the local interface curvature. This force gives a potential well that drives particle accumulation on the droplet interface, which acts as particle adsorber. We quantify particle-interface interaction in a simplified situation where the droplets have the same density and viscosity of the carrier liquid (mimicking a water-oil emulsion), and particles are one-way coupled with the fluids. Particle-induced deformation of the interface and the effect of gravity are neglected. Preliminary simulations indicate that particles tend to aggregate in regions of the interface characterized by high curvature, and that this tendency is modulated by particle inertia. The higher the inertia of the particles, the stronger the tendency to escape from the interface.

2:50PM L37.00006 Multi-Scale Investigation of Spray Droplets Issued in a Turbulent Background. DOUGLAS CARTER, ROUMAISSA HASSAINI, FILIPPO COLETTI, University of Minnesota — We present time-resolved planar measurements of an upward-facing hollow cone spray with simultaneous large and small scale fields of view. The measured mean droplet diameter of 50um for the spray issued into both quiescent and turbulent backgrounds is found to correspond to Stokes numbers approaching order one, indicating that the droplets act as non-ideal flow tracers. The dynamics of the drops are investigated by particle tracking velocimetry (PTV) to deduce the instantaneous droplet motion and particle image velocimetry (PIV) to extract the correlated droplet motion in the far field of the spray. It is found that the droplets issued into quiescent air exhibit greater random uncorrelated motion (RUM) compared to the droplets in a turbulent background, implying that the turbulent eddies prevent the droplets from moving ballistically. This is also reflected by the lesser drop in the Eulerian autocorrelations at small separations for droplets issued into a turbulent background as well as the general increase in the magnitude of the Lagrangian autocorrelations. These results provide novel insight into the motion of inertial droplets in a turbulent gas, and have implications for the numerical modeling and control of liquid sprays.

3:03PM L37.00007 Experimental Analysis of Spray Atomization for Targeted Deposition of Nanoparticles. SHADI SHARIATNIA, Texas A&M University, FARZAD POURSADEGH, Georgia Institute of Technology, AMIR ASADI, DORRIN JARRAHBASHI, Texas A&M University, A&M-GT COLLABORATION, A&M-GT COLLABORATION — Targeted delivery of nanoparticles has a wide range of applications in electronics, pharmaceuticals, and advanced manufacturing. A novel process that deposits cellulose nanocrystals (CNC) on a silicon wafer has been introduced. CNC-containing droplets were generated by injecting aqueous suspension of CNC through an air-atomized nozzle, where a high-pressure liquid jet undergoes severe instabilities due to the large pressure drop between the injector and ambient atmospheric conditions. High-speed diffuse back illumination (DBI), laser diffraction techniques and scanning electron microscopy (SEM) are employed to visualize and quantify the effects of spray parameters on nanoparticles distribution. The liquid jet breaks up into ligaments that later form large number of micron-size droplets at a small distance downstream of the nozzle that further evaporate and release nanoparticles on the targeted surface. Controlling process parameters such as pressure and temperature of the jet, and ambient medium, characteristics of the nozzle and rheology of the aqueous nanoparticle suspension directly impacts the droplet size distribution and hence dispersion of nanoparticles.

Monday, November 25, 2019 1:45PM - 3:16PM – Session L38 Porous Media Flow General II 620 - Prabir Daripa, Texas AM University
1:45PM L38.00001 Microscale heterogeneous pore occupancy with variable background pressure gradient. OLIVER MCRAE, Boston University, T.S. RAMAKRISHNAN, Schlumberger-Doll Research, JAMES BIRD, Boston University — Fluid flow through small length scale networks—porous rock, or tumor vasculature—is typically governed by a pressure driven flow dominated by viscous resistance. In the displacement of an immiscible nonwetting fluid, in addition to an external pressure, an internal capillary pressure at the interface of the fluids causes spontaneous movement of the fluid interface. This creates two characteristic regimes: one dominated by capillarity (imbibition), and one dominated by viscosity (drainage). However, the role of the background pressure gradient and heterogeneity on microscale displacement dynamics, and subsequent pore occupancy is unclear. Here we show that the interaction between two parallel pores and a common node with a background resistance is the simplest system to exhibit two distinct imbibition regimes. With this pore doublet model and numerical simulations, we uncover a crossover in pore occupancy as a function of channel size ratio and outlet resistance, and remarkably obtain the same relationship between capillary number and the global residual fluid saturation previously observed in sandstone cores.

1:58PM L38.00002 Study of Flow Over and Through the Porous Bed: Experimental and Numerical Study, NARENDRA KUMAR PATEL, JUNKIE GUO, DAVID ADMIRAAL, University of Nebraska Lincoln — Guo et al. (2016) suggested velocity profile in vegetated flows. Objectives of this research are to extend the velocity profile suggested by Guo et al. (2016) to generate velocity profile over and through the porous gravel bed, and suggest values for the fitting parameters in equations. Numerical-Stokes-Forchheimer equation for flow within the bed and Navier-Stokes equation for flow above the bed are solved simultaneously to generate unified velocity profile. Experimentally, dye was injected in the gravel bed at different depths and its peak concentration was observed at multiple locations at downstream side. A fiber optics based sensor was developed and time for peak concentration at different locations was identified by LabVIEW to generate velocity profile in bed. An ADV is used to measure flow velocity above the bed. V-notch is used to measure total flow at the end of flume. Numerically, Fluent software is used to simulate combine flow field in and above the porous bed. Our preliminary experimental data well matched with numerical results and help us to find values of fitting parameters in theoretical equations. Reference: Junkie, Guo; Jianmin Zhang (2016) Velocity distributions in laminar and turbulent vegetated flows. J. of hydraulic research, volume 54, issue 2, pp 117-130.

2:11PM L38.00003 Gravity-driven sliding motion on soft porous layer.1, RUNGUN NATHAN, Penn State Berks, ZENGHAO ZHU, QIANHONG WU, Villanova University — Soft porous lubrication is a new concept in porous media flow. In this paper, we report a novel experimental study to investigate the gravity-driven sliding motion of a planar board over a tilted soft porous layer. A laser displacement sensor was used to measure the motion of the board, while a high-speed camera was adopted to capture the detailed compression of the porous layer when the board glided over it. The pore pressure generation, as a result of the compression, was recorded by pressure sensors mounted on the bottom surface of the porous layer. One finds that, the pressure distribution agrees well with theory developed by Wu & Sun (Wu Q. & Sun Q., Med. Sci. Sport. Exerc. 2011, 43:1955-63). Extensive parametric study was performed by varying the center of gravity of the planar board, the tilted angle and the porous material. Consistent agreement between the theory and experimental results was obtained. It shows that, the effect of soft porous lubrication is enhanced when the center of gravity moves toward to the trailing edge of the planar board, or the slope of the porous layer is increased, or smoother fibrous surface is used.

2:24PM L38.00004 Experimental study on the phase behavior of fluids confined in nanoporous media.1, XINGDONG QIU, Department of Petroleum Engineering, University of Wyoming, 1000 E. University Avenue, Laramie, WY 82071-2000, USA, SUGATA P. TAN, Planetary Science Institute, Tucson, Arizona 85719-2395, USA, MORTEZA DEJAM, HERTANTO ADIHARMA, Department of Petroleum Engineering, University of Wyoming, 1000 E. University Avenue, Laramie, WY 82071-2000, USA — Phase behavior of fluids in nanoporous media is of great significance in science and engineering applications and has direct and crucial implications in disciplines like drug delivery, CO2 sequestration, and hydrocarbon production and recovery enhancement from unconventional reservoirs, e.g., tight shale formations. It has been well-known that confinement can play an essential role on the abnormal physical behavior of nano-scaled fluids, compared to their counterparts in bulk space. Recently, we developed a new isochoric method using a high-pressure Differential Scanning Calorimeter (DSC) to measure the phase transition of both pure substances and mixtures confined in nanoporous media (SBA-15 matrices with different pore diameters), which turns out to be quite straightforward and reliable. Particularly, this method allows us to achieve detailed insights with regard to the criticality of confined fluids as well as the heat involved during capillary condensation, both of which have hardly or even never been experimentally explored, especially with confined mixtures. The results demonstrate that confinement can shift the critical point of fluid and have an appreciable effect on the heat released during phase transition.

2:37PM L38.00005 A study of the effect of shear thinning in EOR by surfactant-polymer Flooding1, PRABIR DARIPA, Department of Mathematics, Texas AM University, ROHIT MISHRA, Department of Mechanical Engineering, Texas AM University — We have developed an in-house robust hybrid method for multi-component multi-phase flow in porous media arising in the context of enhanced oil recovery. This hybrid method is based on modified method of characteristics and discontinuous finite element methods. We use this method to study the effects of a mixing model and effect of shear thinning on the fingering in enhanced oil recovery by surfactant-polymer flooding. This is an ongoing project and results of our study will be presented.

2:50PM L38.00006 Optimization study of porous wind fence on reducing and stabilizing fluctuating pressure in the wake region. XINGZHOU ZHOU, HEECHANG LIM, Pusan National University — The sheltering effect of the porous wind fence on wind flow has been highlighted last several decades, which provides a tremendous reduction and stability of wind speed in vegetation area by changing the porosity. This study aims to examine a variety of the wind fence, which varies the porosity (i.e., 0.1, 0.2, 0.3, 0.35, 0.4, 0.45, 0.5, 0.7) and the location of a porous fence placed in a simulated turbulent boundary layer. The sheltering effect was observed by the mean and fluctuating quantities such as velocity and pressure variation in the wake of porous fences. The study performed a numerical simulation by using a 2-equation RANS model such as k- turbulence closure models, k- SST, and LES models. The study analyzes wind and pressure characteristics behind wind fences under flat smooth surface as well as rough. In a preliminary result, the wind speed behind the wind fence decreased more than 50% in the porosity 0.1-0.6, which is considered as the wind-protect (i.e., stable) area. In addition, the numerical predictions show good agreements with the existing experiments. Regarding optimum porosity, around 0.3-0.5 seems to be most effective in terms of reduction in wind speed and fluctuating pressure in the wake of wind fence.
which fluid is entrained is found to be dependent on the drop Froude number. Significant retention only occurred for \( Fr < \) of the trailing column of entrained fluid. These dynamics are independent of the far-field nature of the droplets wake. This timescale over a droplet is significantly slowed by its interaction with the ambient stratification over a characteristic timescale, which coincides with the decay of gradients. The present work aims to quantify and explain retention of an oil droplet rising through a transition between two homogeneous-density fluids. Our estimated approximately 40 percent of that oil was trapped beneath the ocean surface, primarily in regions with strong oceanic density gradients. The authors gratefully acknowledge funding from the Hellman Faculty Fellows Fund.

Monday, November 25, 2019 1:45PM - 3:03PM –
Session L39 Geophysical Fluid Dynamics Stratified Flow II

1:45PM L39.00001 Nonlinear dynamics of destabilized array of vortices in stratified fluid1, MATTHIEU MERCIER, CNRS-IMFT, UMR5502, FRANCE — The settling dynamics of small objects in stratified fluids is important to understand the fate of the biomass in lakes or oceanic environments, for industrial applications such as waste-water disposal. More specifically, the settling of a suspension of solid particles is a fundamental problem, well-studied for a homogeneous fluid and barely investigated numerically for stratified fluids. We present experimental results on the settling dynamics at low Reynolds number of an initially homogeneous suspension of non-Brownian particles immersed in a linearly stratified viscous fluid, due to a linear variation with depth of salt. We characterize the mean and fluctuations of these quantities for various stratification intensities, in order to quantify the influence of the stratification on settling. We compare these results with similar experiments realized in a homogeneous viscous fluid.

1JSPS Kakenhi 17K05561

1:58PM L39.00002 Low-Reynolds dynamics of a suspension of spheres in a stratified fluid1, MESKO WALEN, J. Fluid Mech. 310, (1996). The authors gratefully acknowledge funding from the Hellman Faculty Fellows Fund.

2:24PM L39.00004 Retention of oil droplets rising in a stratified fluid: Part 2. Dynamics1, MAXIME THEILLARD, DUSTIN KLECKNER, SHILPA KHATRI, University of California, Merced — During the Deepwater Horizon oil spill in 2010, about 5 million barrels of petroleum were discharged from the Macondo Well into the Gulf of Mexico. Oceanographic studies (McNutt, 2012) estimated approximately 40 percent of that oil was trapped beneath the ocean surface, primarily in regions with strong oceanic density gradients. The present work aims to quantify and explain retention of an oil droplet rising through a transition between two homogeneous-density fluids. Using laboratory experiments, we examined droplet behavior for a range of droplet densities, drop sizes, and ambient stratification profiles. We observed that droplets experienced significant slow down as it passed through the stratification. We characterized the droplet slowdown by delineating two droplet motion timescales: entrainment time, the span of time droplet velocity was less than the upper layer terminal velocity, and retention time, the span of time the droplet was retained in the transition layer. We observed a strong relationship between the two metrics, where retention time is a function of the length of time that dense fluid is entrained and the magnitude of the droplet’s slowdown.

2:37PM L39.00005 Cluster formation and self-assembly in stratified fluids: a novel mechanism for particulate aggregation1, RICHARD MCLAUGHLIN, ROBERTO CAMASSA, University of North Carolina at Chapel Hill, DANIEL HARRIS, Brown, ROBERT HUNT, University of North Carolina at Chapel Hill, ZELIHA KILIC, Arizona State University — We observe experimentally and mathematically model a new fundamental attractive mechanism we have found in our laboratory by which particles suspended within stratification may self-assemble and form large aggregates without need for short range binding effects (adhesion). This phenomenon arises through a complex interplay involving solute diffusion, impermeable boundaries, and the geometry of the aggregate, which produces toroidal flows. We show that these flows yield attractive horizontal forces between particles. The collective motion we observed experimentally appears to solve jigsaw-like puzzles on its way to organizing into a large scale disc-like shape, with the effective force increasing as the collective disc radius grows. Control experiments with two objects (spheres and oblate spheroids) isolate the individual dynamics, which are quantitatively predicted through numerical integration of the underlying equations of motion. With this two-body information, we present simulations with hundreds of spheres which reproduce many of the features of our self-assembly experiments.

1DMS-1910824, DMS-1909521, ONR N00014-18-1-2490.

2:50PM L39.00006 Cluster formation and self-assembly in stratified fluids: Particle imaging velocimetry and modified Stokesian dynamics® ROBERT HUNT, ROBERTO CAMASSA, University of North Carolina at Chapel Hill, DANIEL HARRIS, Brown, ZELIHA KILIC, Arizona State University, RICHARD MCLAUGHLIN, University of North Carolina at Chapel Hill — We report on a new fundamental attractive mechanism we have found at the UNC Joint Fluids laboratory by which particles suspended within stratification may self-assemble and form large aggregates without need for short range binding effects (adhesion). This phenomenon arises through a complex interplay involving solute diffusion, impermeable boundaries, and the geometry of the aggregate, which produces nontrivial fluid flows. Numerical simulations are directly compared with particle imaging velocimetry for a single oblate spheroid and are shown to agree both qualitatively and quantitatively with PIV data. Numerical simulations with two spheres at an observation distance dictated by the calculations of an effective force between pairs of particles. With this two-body information, we extend to multiple bodies by modifying a Stokesian dynamics solver to include these forces. Simulations with hundreds of spheres reproduce many of the features of our self-assembly experiment.

Monday, November 25, 2019 1:45PM - 3:16PM
Session L40 Jets: Control 6b - Peter Schmid, Imperial College of London

1:45PM L40.00001 Determining spray axial velocity from focused-beam X-ray radiography. JULIE BOTHELL, TIMOTHY MORGAN, Iowa State University, ALAN KASTENGREN, Argonne National Laboratory, THEODORE HEINDEL, Iowa State University, ENERGY SYSTEMS DIVISION, X-RAY SCIENCE DIVISION TEAM, EXPERIMENTAL MULTIPHASE FLOW LAB TEAM — Coaxial atomizing sprays are used across a variety of industries from gas turbines to food processing. Far-field spray dynamics depend on the primary breakup region, but this region is challenging to study as it contains thick liquid that is opaque to visible light. However, X-rays are capable of penetrating the dense liquid region, providing insight that is unavailable from visible light testing methods. This study modifies a method used in previous studies for determining the mass-average axial velocity from a diesel injector spray, and applies it to investigate the mass-average axial velocity from a coaxial atomizing spray. The original method was developed for a narrow-angle, time-varying spray, but was modified in this study for a wide-angle, steady-state spray. Experiments at the Advanced Photon Source at Argonne National Laboratory provided focused-beam X-ray radiographs along the spray. The mass-average axial velocity along the spray increased linearly with axial distance from the nozzle for varying momentum ratios. The slope of the velocity-distance relation also increased linearly when plotted as a function of gas flow rate.

Portions of this work was performed at the 7-BM beamline of the Advanced Photon Source, a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory under Contract No. DE-AC02-06CH11357.

1:58PM L40.00002 The azimuthal and wavy deformation of vortex rings and the formation of separated flows in a round jet using synthetic jets. AKINORI MURA MATSU, College of Science and Technology, Nihon University, KOHEI TANAKA, Graduate School of Science and Technology, Nihon University — Vortex rings are periodically formed in the initial region of a round jet and change to a wavy shape in the azimuthal direction. As a result, the vortex rings collapse three-dimensionally. It is suggested that the azimuthal deformation of vortex rings is affected by streamwise vortices. In order to investigate the relation between the azimuthal deformation of the vortex ring and the streamwise vortices, we attempted to artificially deform the vortex ring in the azimuthal direction using synthetic jets. The synthetic jets are formed utilizing a sound wave with a natural frequency for the vortex-ring formation. The vortex rings azimuthally and wavy deform by introducing disturbances through small holes at a nozzle exit, so that the streamwise vortices are generated at certain locations in the round jet. At the same time, the jet branches off slanting upward at the initial region in relation to azimuthal deformation of the vortex ring. The streamwise vortices are formed inside the vortex ring and move to the outside of the vortex ring, when the vortex ring is moving the downstream. At this time, the streamwise vortices are separated from the vortex ring. The branched flows, as similar to side jets, are formed by moving the streamwise vortices.

2:11PM L40.00003 Adjoint-based analysis of controllability of turbulent jet noise. SEUNG WHAN CHUNG, JONATHAN FREUND, University of Illinois at Urbana-Champaign — Past efforts have used optimal control theory, based on the numerical solution of the adjoint flow equations, to perturb turbulent jets to reduce radiated sound. These have been successful in that sound is reduced, with consequent changes to large-scale turbulence structures in the flow. However, control remains challenged by the chaotic dynamics of the turbulence, which degrades smoothness of cost functional in control parameter space, thus limiting control effects to a relatively short time horizon. Wave packets can be a useful and relatively deterministic model for the large-scale noise mechanisms in jets. Using discrete-exact, dual-consistent adjoint gradients in conjunction with high-fidelity simulations, we assess the growth of sensitivity in time and general controllability. The most effective immediate control of a $M = 1.3$ jet is achieved with a control-time horizon of $32 AD/a_{\infty}$; longer or shorter time horizons prove less effective, which thus marks a balance between increasing authority through sensitivity and the disruptive influence of chaotic effect in the turbulence for this objective. After the control period, the rate at which the jet returns to its baseline louder state also presents a potentially important time scale for the flow and chaotic dynamics.
2:24PM L40.00004 Dynamics of Axisymmetrically Excited Transverse Jets\textsuperscript{1}, ELIJAH HARRIS, DAVID D. W. REN, ANDREÁ BESNARD\textsuperscript{2}, STEPHEN SCHEIN, ROBERT M’CLOSKLEY, ANN KARAGOZIAN, University of California, Los Angeles, LUCA CORTELEZZI, Politecnico di Milano — The present experimental study investigates axisymmetric excitation of a gaseous jet issuing into a uniform crossflow as pertains to jet dynamics as well as structural and mixing characteristics. A naturally absolutely unstable (AU) transverse jet, with a jet-to-crossflow momentum flux ratio of $J=6$, is forced with a variety of different periodic waveforms including sinusoidal, square wave, and multi-pulse square waves. For specific perturbation amplitudes and within specific forcing frequency regimes, the jet locks-in to the forcing frequency, prior to which there is evidence of quasi-periodicity. The critical conditions to achieve lock-in differ amongst the various excitation waveforms, where the sinusus forcing cases have the greatest challenges in achieving lock-in for this AU jet. As one increases the forcing amplitude beyond lock-in, the jet displays complex synchronization dynamics and mode shapes, en route to more chaotic behavior, as quantified through snapshot proper orthogonal decomposition (POD) analysis of the velocity field extracted via stereo particle image velocimetry (PIV), and time delay embedding of velocity fluctuations along the jet shear layer.

2:37PM L40.00005 Open-loop control of a weakly non-linear swirling jet instability by harmonic forcing, CALUM SKENE, Imperial College London, UBAID QADRI, University of Cambridge, PETER SCHMID, Imperial College London — Highly swirling flows are often prone to a global instability with an azimuthal wavenumber of $m=1$, where the sign is chosen so that the instability precesses against the mean-flow swirl. This instability is linked to the recirculation region typical of a vortex breakdown induced by high swirl, and can affect many types of flow. In particular, in lean premixed combustors swirling flows are often utilised to stabilise a flame onto a burner, as the recirculation region caused by vortex breakdown acts as a natural ‘flame holder’. We investigate the manipulation of the global instability by harmonic forcing through a weakly non-linear analysis of an incompressible swirling jet. The flow is expanded about the critical Reynolds number where instability first occurs. Linear effects are obtained at first order, including both the unstable mode and the response to harmonic forcing. At second order, harmonics and base-flow modifications caused by non-linear interactions of the mode and forced response are obtained. An equation for the mode amplitude is obtained at third order, allowing for the effect of harmonic forcing to be quantified. In this manner, the effectiveness of control across a variety of forcing frequencies and azimuthal wavenumbers is assessed.

2:50PM L40.00006 Internal Flow Dynamics and Spray Characteristics in Liquid Swirl Injectors, JACOB GAMERTSFELDER, PRASHANT KHARE, University of Cincinnati — The focus of this research effort is to investigate the internal flow dynamics and subsequent spray characteristics in swirling liquid fuel injectors. While significant progress has been made in the past to enhance the understanding of the internal dynamics of the vortex generator and resulting liquid sprays, limited studies exist that capture both the detailed mechanistic processes leading to swirling liquid and the resulting spray formation. This effort will fill this gap in the literature. The theoretical formulation is based on three-dimensional incompressible Navier-Stokes equations with surface tension. A volume of fluid (VOF) method is used for interface capturing. The swirl injector geometry consists of three equally spaced (at 120 degrees) tangential inlets of 1 mm diameter, a 6 mm vortex generator and a 2 mm diameter spray nozzle with a $L/D$ ratio of 12. The operating conditions consists of a Weber number of 1556, corresponding to a flow rate of 25.51 g/s at an injector pressure of 0.579 MPa. The ambient chamber pressure and temperature are 4 MPa and 300 K, respectively. Preliminary results show that the swirl generated in the injector leads to the formation of a hollow cone spray that breaks up to form ligaments and droplets. A systematic analysis will be conducted to quantitatively identify the processes leading to the formation of liquid swirl near the injector walls, air core in the center and subsequent spray formation including droplet size distributions, breakup length and spray angles.

3:03PM L40.00007 Helical Vortex Characterization in Swirling Jets from Planar Measurements\textsuperscript{1}, BENJAMIN EMERSON, TIM LIEUWEN, Georgia Institute of Technology — The fluid mechanics of swirling jets are highly three-dimensional, but most state of the art measurement capabilities are only planar. This work demonstrates an experimental data analysis methodology for swirling jets. The methodology is implemented on planar velocity field data to interpret the dynamical, three-dimensional topology of the velocity field. The methodology blends physical understanding of reacting swirling jets with clues that are present in stereoscopic particle image velocimetry data to infer a helical vortex tube inclination angle. With this inclination angle, the planar measurement data can be revolved to re-construct the three-dimensional velocity field.

Monday, November 25, 2019 1:45PM - 3:03PM — Session L41 CFD: Discontinuous Galerkin Methods

1:45PM L41.00001 High-order extended discontinuous Galerkin methods for sharp shock-capturing\textsuperscript{2}, MARTIN OBERLACK, MARKUS GEISENHOFER, FLORIAN KUMMER, BJÖRN MUELLER, TU Darmstadt, FLUID DYNAMICS TEAM — We study unsteady high Mach number flows using a Discontinuous Galerkin (DG) solver (Mueller 2016) that was extended to immersed boundary methods (IBM) using level sets. Cell-agglomeration was applied for small and ill-shaped cut cells. To cope with shocks, we used an artificial viscosity shock-capturing approach (Persson 2006) that was coupled to IBM (Geisenhofer 2019). There a shock sensor is used to identify critical cells and artificial viscosity smoothens the solution. The severe time stepping restrictions due to an explicit time step together with the additional diffusive term are dealt by an adaptive local time stepping (LTS) approach (Winters 2014) that dynamically (re-)partitions the grid according to their local time step. Presently we extend the shock-fitting techniques using an eXtended DG (XDG) method (Kummer 2016) to regain the desirable DG convergence rates and a sharp jump representation. For this, we first investigate shock tracking in 1D, where we prescribe the flow properties across shocks using the Rankine-Hugoniot conditions in combination with the level set propagation speed. Second, we consider the formation of stationary shocks in 2D, where the artificial viscosity IBM, LTS method will be the initial solution to be morphed to a XDG shock-fitting approach.

1:58PM L41.00002 Reacting flow simulations using high-order discontinuous Galerkin methods1, KIHIRO BANDO, MATTHIAS IHME, Stanford University, MICHAEL SEKACHEV, Total — High-order discontinuous Galerkin (DG) methods have been an increasingly popular topic of research for enabling high-fidelity simulations on complex geometries. They present several attractive features such as high-order accuracy on arbitrary mesh topologies, compact implementation and support of advanced hp-refinement strategies which can be leveraged to increase computational efficiency. However, the application of such methods to flows presenting complex thermodynamics and chemical reactions is still sparse. In particular, the accurate prediction of such flows requires the consideration of complex transport and the treatment of stiff reaction chemistry. This talk will discuss challenges associated with reacting flow simulations in the context of a DG discretization. Simple one-dimensional cases will first be investigated to gain insight at the fundamental properties of the scheme when applied to such flows. Subsequently, more challenging cases in multiple dimensions will be examined to highlight the performance as well as the need for further developments to enable reacting flow simulations using DG methods.

2:11PM L41.00003 Development of a Four-Way-Coupled Lagrangian Particle Method for Discontinuous Galerkin Schemes1, ERIC CHING, MATTHIAS IHME, Stanford University — In this talk, we present an Euler-Lagrange methodology within the framework of discontinuous Galerkin methods. We discuss strategies to track particle trajectories through curved elements near walls while taking into account finite particle sizes. The back-coupling of particles to the carrier gas is treated in an efficient manner. In addition, we introduce a particle-particle collision algorithm that utilizes information provided by the geometric mapping from physical space to reference space. In doing so, the proposed algorithm reduces the number of particle pair inspections compared to standard methods. The algorithm is verified by drawing comparisons to kinetic theory. To demonstrate the capability of the multiphase flow solver, we consider a variety of test cases that include hypersonic dusty flows over blunt bodies and erosive action of sand blasting.

2:24PM L41.00004 An Enriched-Basis Discontinuous Galerkin Method for Wall-Modeled Large-Eddy Simulations1, STEVEN R. BRILL, MATTHIAS IHME, Stanford University — We developed an enriched-basis discontinuous Galerkin (DG) method for wall-modeled large-eddy simulations (WMLES) of turbulent flows. Ordinarily, higher-order methods, such as DG-schemes, require significant mesh refinement near the wall in order to resolve the turbulent boundary layer without spurious oscillations due to large gradients in the boundary layer. To avoid this issue, we enrich the traditional polynomial basis with a problem-specific non-polynomial basis function in the near-wall elements in order to capture the inner boundary-layer structure while still using a coarse mesh. In this method, the enrichment function is not required to be active, but is chosen by the Galerkin procedure when it is optimal, such as near the wall. As a result, the enrichment basis functions capture the mean behavior near the wall, the polynomial basis functions resolve the large eddies, and a subgrid scale model represents the small scale behavior. We discuss the procedure for choosing the proper enrichment functions for a problem and integrating non-polynomial basis functions into the DG framework. The method is demonstrated in application to turbulent channel flows and other canonical wall-bounded turbulent flows.

2:37PM L41.00005 A High-Order Lagrangian Discontinuous Galerkin Method on Hybrid Curved Meshes1, XIAODONG LIU, NATHANIEL MORGAN, DONALD BURTON, Los Alamos National Lab, HIGHORDER LAGRANGIAN AT LANL TEAM — We present a high-order (up to fourth order) Lagrangian DG hydrodynamic method using subcell mesh stabilization (SMS) for compressible flows on hybrid curved meshes (up to cubic meshes) in 2D Cartesian coordinates. The physical evolution equations for the specific volume, velocity, and specific total energy are discretized using a modal DG method. The challenge for Lagrangian hydrodynamics is to guarantee the stable mesh motion for the edge vertex, that can easily deform in unphysical ways. With SMS, each cell is decomposed into several subcells, that move in a Lagrangian manner. The edge vertex is surrounded by several subcells so that enough information can be obtained, that is similar to the corner vertex. As such, the same multidirectional approximate Riemann problem can be solved for these both types of vertices. This SMS scheme enables stable mesh motion and accurate solutions in a context of the Lagrangian high-order DG method. We also present effective limiting strategies that ensure monotonicity of the primitive variables with the high-order DG method. A suite of test problems are calculated to demonstrate the designed order of accuracy of this method and the robustness for the strong shock problems.

2:50PM L41.00006 A Recovery-Assisted Discontinuous Galerkin Method for the Compressible Navier-Stokes Equations1, ERIC JOHNSON, PHILIP E. JOHNSON, University of Michigan — The Discontinuous Galerkin (DG) method is a promising approach for high-fidelity simulations of turbulent flows in complex geometries, given the method’s capability for arbitrarily high orders of accuracy on unstructured meshes. We propose a DG approach for advection-diffusion equations (such as the Navier-Stokes equations) based on the principle of Recovery, whereby the underlying solution between two adjacent computational elements is “recovered” into a smooth, more accurate polynomial representation. By combining a biased approach to Recovery for advection with a compact gradient recovery for diffusion, we achieve $2p + 2$ order of accuracy in the cell-average error on a nearest-neighbors stencil, where $p$ is the degree of the polynomial basis, and demonstrate higher efficiency than other state-of-the-art DG approaches. Several test cases, including compressible turbulence, are presented to support our method.

in the streamwise direction while it becomes a U-shaped curve when the flow is super-critical. Time-dependency effects are also investigated.

Interestingly, when the flow is sub-critical the optimal wind turbine thrust set-point assumes a sinusoidal behavior of the wind turbines. We implement an optimization model in order to derive the turbine thrust coefficient distribution that maximizes the atmosphere in three layers; the wind-farm drag force is applied over the whole wind-farm area and is directly proportional to the thrust set-point and in the free atmosphere. These waves impose significant pressure gradients in the boundary layer causing detrimental consequences in terms of high-gradient surface slope on the energy entrainment and the vertical transport of momentum and kinetic energy over the model wind farm.

In order to better understand the effect of the complex terrains, wind tunnel experiments were performed on a 1:290 scale model wind farm. To explore the advantages of complex topographic regions, scaled-down turbine in the model of Ollantaytambo region of Peru was used to analyze the wake effects through power output and particle image velocimetry (PIV). The results from the model wind farm over the complex terrain are indicative of greater efficiency in wind farms in terms of power output. Additionally, we will discuss the role of high-gradient surface slope on the energy entrainment and the vertical transport of momentum and kinetic energy over the model wind farm.

2:24PM L42.00004 Effect of nocturnal low-level jet on wind farm performance. SRINIDHI NAGARADA GADDE, RICHARD STEVENS, University of Twente — Large-eddy simulations of wind farms in a quasi-stationary, nocturnal, stable boundary layer are performed to understand the effects of the low-level jets (LLJ) on the farm performance. The effect of the LLJ is studied by systematically varying the cooling rate at the surface. The height of the boundary layer decreases with the increasing cooling rate and forms a LLJ due to the frictional decoupling at the inversion layer. We find that the power production of the wind farm increases with the cooling due to the high shear in the LLJ. For strong cooling, the destruction of turbulence by buoyancy causes a drop in the vertical entrainment; consequently, the turbines in the rear of the wind farm produce less power compared to the turbines operating in a low or moderately stable boundary layers. In addition to the power production, we analyse the flow structures to better understand the wind farm-boundary layer interaction in the highly stratified atmosphere.

2:37PM L42.00005 Positive effect of a synthetic low-level jet on the mean power and momentum transport of a wind-turbine array. ALI DOOSTTALAB, DIEGO SIGUENZA, JOSSY O’DONNELL, Purdue University, WALTER GUTIERREZ, Texas Tech University, VENKATESH PULLETIKURTHI, Purdue University, YAOQING JIN, University of Texas at Dallas, LEONARDO P. CHAMORRO, University of Illinois at Urbana-Champaign, LUICANO CASTILLO, Purdue University — Nocturnal low-level jet (LLJ) is a distinctive phenomenon at the top of stable boundary layers. A low-level velocity peak results in attractive power resource for wind turbines. However, a maximum in the mean wind speed profile implies the co-existence of positive and negative mean shear in the vicinity of the peak. To gain better understanding of the impact of LLJ (e.g., positive & negative shear) on the performance of a scaled-down power plant, with similar LLJ profile in the atmosphere were performed using particle imaging velocimetry (PIV). The results from single turbine and 3 x 2 turbines array in the positive and negative shear regions of the synthetic LLJ were compared to canonical turbulent boundary layer. For both positive and negative shear cases a 12% increase in power generation in the 2nd row were observed in comparison to the unstable boundary layer condition. In addition, the role of energy entrainment induced by the positive and negative shear of the LLJ and the contribution to the vertical transport of momentum and kinetic energy across the turbine array are explored in depth.

2:50PM L42.00006 The low-level jet role on the mean power and momentum transport of vertical axis wind turbines. DIEGO SIGUENZA, ALI DOOSTTALAB, HUMBERTO BOCANEGRA-EVANS, Purdue University, LEONARDO P. CHAMORRO, University of Illinois at Urbana-Champaign, LUICANO CASTILLO, Purdue University — The stable temperature stratification at the lower part of the atmosphere causes a particular phenomenon known as low-level jet (LLJ) where its velocity peak results in attractive power resource for wind turbines. The positive and negative shear layers of the LLJ influences the wake recovery by encouraging the energy entrainment into the horizontal-axis wind farm canopy. To extend the knowledge of LLJ impact on wind farms, we aim to explore the effect of the LLJ on vertical-axis wind turbines (VAVT) in terms of its wake energy entrainment. The LLJ was synthetically generated in a wind tunnel to test different arrays of scaled-down VAWT where we measured the velocity fields downstream particle image velocimetry (PIV), and the power output of the turbines. We will discuss the role of the wake energy entrainment induced by the positive and negative shear in comparison with a regular unstable boundary layer scenario.

Monday, November 25, 2019 3:20PM - 4:13PM –
Session M01 Flash Oral Presentations: Turbulence 6a - Mark Glauser, Syracuse University
Subspaces be compared to a reduced-order model constructed using static (i.e. time invariant) POD modes. Reduced-order modeling of: (1) transient instabilities in Kuramoto-Sivashinsky equation, and (2) transient flow over a bump. The results will be validated using deterministic/stochastic systems constructed by projection of the full-dimensional dynamics onto a time-dependent basis. To this end, we explore the possibility of a deep learning model to mimic the remap function. Our deep neural network is trained on the nodal velocities of a structured mesh before and after the remap step in our Eulerian hydrocode. We show that our deep learning model can accurately reproduce the remap function to acceptable accuracy, and we compare speeds between our DNN and the existing remap function. This work continues to demonstrate that deep learning models can enhance numerical predictive capabilities. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-NA0003525.

This study was provided funding via research grants by the Air Force Office of Scientific Research (AFOSR) grant number FA9550-19-1-0081 (Program Manager: Dr. Greg Abate) and Spectral Energies LLC.

Towards a machine learning method for simulating turbulence-shockwave interactions. In recent years, machine learning has been used to create data-driven solutions to problems for which an algorithmic solution is intractable, as well as fine tuning existing algorithms. This research applies machine learning to the development of an improved finite-volume method for turbulence-shockwave interactions. Shock capturing methods make use of complicated nonlinear functions that are not guaranteed to be optimal. Because data can be used to learn complicated nonlinear relationships, we train a neural network to improve the results of WENO5. We also post-process the outputs of the neural network to guarantee that the method is consistent. The training data is generated using integrable functions that represent the waveforms we would expect to see while simulating a PDE, which gives us an exact mapping between cell averages and interpolated values. We demonstrate our method on linear advection of a discontinuous function, the inviscid Burgers equation, and the 1D Euler equations. Specifically, we examine the Shu-Osher problem, a toy problem for turbulence-shockwave interactions. We also show preliminary results for dynamically trained models.

This research was funded by the National Natural Science Foundation of China (Grant No. 51776011).

Reinforcement learning enabled control of chaotic dynamics. A deep RL policy network, based on proximal policy optimization, is employed to stabilize the unstable fixed points and periodic orbits embedded in the chaotic-attractor of the Lorenz system. Previous attempts to control the underlying chaotic trajectories have relied on linearization of the dynamics around the targeted solutions, or on time-delayed feedback based on the output variables. However, there are certain caveats associated with these control approaches such as, requiring an a priori understanding of the chaotic system to be controlled, and difficulty in stabilizing certain classes of periodic orbits. These issues are overcome in the RL enabled control, especially when long term correlations are accounted for using layers of Long Short Term Memory (LSTM) cells in the policy network.

This work continues to demonstrate that deep learning models can enhance numerical predictive capabilities. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-NA0003525.

Real-Time Reduced Order Modeling Using Time Dependent Subspaces. We present real-time reduced-order models for deterministic/stochastic systems constructed by projection of the full-dimensional dynamics onto a time-dependent basis. To this end, we leverage a scalable algorithm to extract time dependent modes from highly transient data sets. We will present two case studies for the reduced-order modeling of: (1) transient instabilities in Kuramoto-Sivashinsky equation, and (2) transient flow over a bump. The results will be compared to a reduced-order model constructed using static (i.e. time invariant) POD modes.

NASA Grant 80NSSC18M0150

POD analysis of the unsteady behavior of the wake under the influence of laminar to turbulent transition in a compressor cascade. For low incidence angle and Reynolds number, the transition region is usually located closer to the trailing edge, which leads to a strong interaction of the vortex shedding of the laminar separation bubble and the wake flow. In this paper, particle image velocimetry (PIV) measurements have been performed in order to analyze the unsteady flow field in a compressor cascade. The instantaneous snapshots have been post-processed by means of proper orthogonal decomposition (POD). The first mode pair allows the instantaneous snapshot to be correctly sorted in the wake field. For all the time steps, according to the extent of the deviation between the time-averaged flow field and the phase-averaged counterpart, the flow field can be divided into three regions associated with the LSB vortex shedding, the wake flow and the interaction between the former two dynamics. The triple decomposition of the velocity fluctuations enables the quantification of the contribution associated with the three coherent motions as well as the stochastic motions to the overall velocity fluctuations.

3:27PM M01.00008 Sparse Identification of Nonlinear Dynamics in 2D Chaotic Electrohydrodynamic Convection, IGOR NOVOSSELOV, YIFEI GUAN, STEVEN BRUNTON, University of Washington — This study focuses on developing a reduced-order model for the chaotic electro-hydrodynamic (EHD) convection flow between two parallel electrodes with unipolar charge injection. A Lattice Boltzmann Method with two-relaxation times solver [1] is used to obtain a numerical data set for electroconvective instabilities. Under strong charge injection and high electrical Rayleigh number, the system transitions from structured electroconvective vortices to chaotic motion. The chaos in this system is related to the standard Lorenz model obtained from Rayleigh-Benard convection, although this model system exhibits a more complex three-way coupling between the fluid, the charge density, and the electric field. Fluid coherent structures are extracted from the temporally and spatially resolved chaotic system via proper orthogonal decomposition (POD). A nonlinear model is developed for the chaotic time series of these POD coefficients with the sparse identification of nonlinear dynamics (SINDy) algorithm [2]. The resulting sparse nonlinear model captures a similar phase portrait and the dominant chaotic dynamics of the original system. References: [1] Y. Guan and I. 3:28PM M01.00009 Wavelet-based Data Compression for Three-dimensional Fluid Flow Simulations on Regular Grids, DMITRY KOLOMENSKYI, RYO ONISHI, HITOSHI UEHARA, Japan Agency for Marine-Earth Science and Technology — High-performance computational fluid dynamics can produce large volumes of output data. Even though data reduction may be performed during the course of computation to store only the quantities of interest such as statistical moments, it is often necessary to store full three-dimensional fields for purposes including simulation restart, time-resolved visualization and exploratory analyses. In this talk, I will present a wavelet-based method for compression of numerical simulation data on regular structured grids. It is inspired by image compression, and it consists of discrete wavelet transform, quantization adapted for floating-point data, and entropy coding. I will discuss different aspects of these numerical techniques, present an open-source software WaveRange, and show example numerical tests, ranging from idealized configurations to realistic global weather simulation data.

3:29PM M01.00010 Data Compression for Turbulence Databases Using Spatio-Temporal Sub-Sampling and Local Re-simulation, CHARLES MENEVEAU, TAMER ZAKI, ZHAO WU, Johns Hopkins University — The size of datasets from numerical simulations of turbulent flows has been growing roughly at the rate expected from Moore’s law. However, storing the rapidly growing amounts of numerical simulation data is very challenging. Motivated by specific data and accuracy requirements for building numerical databases of turbulent flows, data compression using spatio-temporal sub-sampling and local re-simulation is proposed. The DNS data are aggressively subsampled in space and time during the simulation, and a local re-simulation is performed later when the data are needed. Numerical re-simulation experiments for decaying isotropic turbulence based on sub-sampled data are undertaken. The results and error analyses are used to establish parameter choices for sufficiently accurate sub-sampling and sub-domain re-simulation. It is found that the numerical algorithms of the re-simulation have to match the original simulation exactly to reproduce error-free results: any mismatch between the two is found to lead to surprisingly large errors. By carefully controlling the re-simulation parameters, re-simulation errors close to single-precision machine accuracy can be achieved under stringent conditions.

3:30PM M01.00011 Temporal evolution and statistical characteristics of uniform momentum zones using data-informed resolvent hierarchies, ANGELIKI LASKARI, BEVERLEY MCKEON, California Institute of Technology — Experimental data from time-resolved planar particle image velocimetry in streamwise-wall-normal planes of a turbulent boundary layer are used for the determination of temporal evolution and statistical characteristics of uniform momentum zones. Specifically, the temporal variation of both the probability density function (pdf) of the streamwise velocity and the instantaneous number of zones is assessed. Statistically important patterns observed in the experimental data are then used to guide the selection of modes on a self-similar resolvent hierarchy. Although the full range observed for the instantaneous number of zones is not recovered with the use of this restricted number of modes, it is shown that the largest variation observed is due to the modes located in the middle of the logarithmic region. Additionally, results indicate that a single resolvent hierarchy can reproduce a prominent semi-periodic behaviour observed in the experimentally constructed temporal pdf of the streamwise velocity. It is further shown that this behaviour is directly related to the wavenumber of the modes closest to the edge of the logarithmic region.

3:31PM M01.00012 Resolvent analysis-based models of nonlinear Taylor vortex flow, BENEDIKT BARTHEL, California Institute of Technology, XIAOJUE ZHU, Center of Mathematical Sciences and Applications, and School of Engineering and Applied Sciences, Harvard University, BEVERLEY MCKEON, California Institute of Technology — Taylor vortices have recently garnered renewed attention as an analogue for the self-sustaining process (SSP) in wall bounded shear flows. An instability of the mean flow leads to streamwise rolls which form streaks, which in turn become unstable and feedback to the rolls. We seek to shed light on the SSP by first understanding the dominant nonlinear interactions which sustain Taylor vortices. Here we use the resolvent formulation of McKeon and Sharma to treat the nonlinearity not as an inherent part of the governing equations but rather as a triadic constraint which must be satisfied by the model solution. We exploit the low rank linear dynamics of the system to calculate an efficient basis for our solution, the coefficients of which are then calculated through an optimization problem where the cost function to be minimized is the triadic consistency of the solution with itself as well as with the input mean flow. We compare our results to DNS of Taylor Couette flow for a range of Reynolds numbers (Zhu et al., Comp. Phys. Comm., 2018). Our model solution replicates both the flow structures as well as the turbulent statistics observed in the simulations.

1ONR grant number: N0014171-3022
3:32PM M01.00013 A Time-Spectral Analysis for Summed Linear and Product Signals with Applications to Fluid Mechanics and Chaotic Systems1, CHIEN C. CHANG, Guangxi University and National Taiwan University, SHENG-SHENG LIU, YEN-LIANG LEE, Guangxi University, JEN-JEN LIN, Ming-Chuan University — There are time signals of general interest put in the form: Time signal = trend with time + periodic components + residual or randomness. It is of great importance to identify the periodic components whose frequencies and amplitudes may be varying with time. In the past, we have seen excellent works on time-frequency analysis of a signal such as short-time Fourier, wavelet, Hilbert-Huang transforms among others. Yet there are still critical and fundamental issues to be addressed. Notably all the previous analysis (tacitly) assumes that the signal concerned is a linear superposition of its decomposed components no matter whether a base set of functions or no base is employed. Moreover, a common query is that the signal may often be over-decomposed that the analysis with respect to individual modes does not catch the essential features of the signals spectral content. In this study, we propose to develop a principal frequency analysis suitable for general summed linear signals and product signals (beats/wave-packets). As an illustration, this approach of analysis is first applied to several basic examples and then to time-dependent drag in fluid mechanics and signals of a chaotic Rossler system.

3:33PM M01.00014 Bio-inspired flows in unsteady environments. Part I: highly unsteady ambient flows, MEILIN YU, NARESH POUDEL, University of Maryland, Baltimore County, JOHN HRYNUK, U.S. Army Research Laboratory — Autonomous underwater vehicles (AUVs) and unmanned aerial vehicles (UAVs) usually need to carry out tasks in unstructured and dynamic flow environments. This poses a number of challenges that cannot easily be addressed by approaches developed for highly controlled environments, such as unstructured flows frequently used in experiments and numerical simulation. This work studies the impact of highly unsteady ambient flows on the performance of flapping wings/ fins at relatively high Reynolds numbers (i.e., 12,000 based on the foil chord length). The unsteady flow environment is generated by an array of incline small cylinders or three arrays of staggered ones placed upstream of the flapping wing/fin. A high-order accurate flux reconstruction flow solver with moving/deforming body-fitted unstructured meshes is used to perform the numerical simulation. We find that highly unsteady flow environments dominated by small eddies can always enhance time-averaged thrust generation, no matter how the foil location is changed within the ambient chaotic flows; the effect of environmental unsteadiness on lift production seems to be random. The effects of wing/fin kinematics and the size of cylinders are also studied.

3:34PM M01.00015 Turbulent flow structure associated with interacting 3D bedforms, NATHANIEL BRISTOW, GIANLUCA BLOIS, University of Notre Dame, JAMES BEST, University of Illinois at Urbana-Champaign, KENNETH CHRISTENSEN, University of Notre Dame — Barchan dunes are three-dimensional, crescent-shaped bedforms, and while most commonly associated with aeolian environments, recent observations have shown them to form in subaerial and extraterrestrial environments as well. As barchans migrate in the direction of the flow, they interact with their neighbors, typically by way of a collision. The morphodynamics of such collision processes are complex, where the role of the turbulent flow structure is strongly coupled to that of the sediment transport and morphological change. Here we study the flow structure in a decoupled manner through measurements of the turbulent flow over fixed-bed models of barchan dunes in various configurations involved in a barchan collision process. Particle image velocimetry is used to measure the flow in a refractive-index matched flume environment that enables access to the whole flow field around these geometrically complex bedforms. Presented herein are results from planar PIV measurements in several measurement planes, including the cross-plane, showing the dynamics of turbulent flow structures associated with barchan dunes which are hypothesized to drive the morphodynamics of the dune interaction.

3:35PM M01.00016 Application of the One-Way Navier-Stokes (OWNS) equations to hypersonic boundary layers, OMAR KAMAL, GEORGIOS RIGAS, California Institute of Technology, MATTHEW T. LAKEBRINK, The Boeing Company, TIM COLONIUS, California Institute of Technology — Prediction of linear instability and amplification of disturbances in hypersonic boundary layers is challenging due to the presence and interactions of Tollmien-Schlichting, Mack, and entropic modes. While DNS and global analysis can be used, the large grids required make the computation of optimal transient and forced responses very expensive, particularly when a large parameter space is required. At the same time, parabolized stability equations (PSE) are unreliable for multi-modal interactions. In this work, we instead apply a newly developed technique, the One-Way Navier-Stokes (OWNS) equations, which are based on a rigorous parabolization of the full equations of motion. OWNS removes disturbances with upstream group velocity using a high-order recursive filter. We extend the original algorithm by considering body-fitted curvilinear coordinates incorporating full compressibility and real gas effects. We validate the results by comparison with DNS. We present preliminary results for the optimal growth of disturbances in flat-plate and conical boundary layers. This work has been supported by the Boeing Company through a Strategic Research and Development Relationship Agreement CT-BA-GTA-1.

3:36PM M01.00017 Turbulence drag modulation by combined effect of solid particles injection and synthetic roughness1, CARLOS DUQUE-DAZA, Universidad Nacional de Colombia, JESUS RAMIREZ-PASTRAN, Universidad Santo Tomas — The combined effect of geometric perturbations at one of the walls and injecting spherical solid particles on the behaviour of an incompressible turbulent channel flow at low friction Reynolds number ($Re_f = 180$) was investigated through numerical simulations. The effect of the presence of spherical solid particles was explored from the perspective of the particles-mass-fraction (PMF), whereas spanwise ribs-like and cavity-like geometrical alterations were prescribed as synthetic large scale roughness elements in one of the walls. Values of particle-volume fraction (PVF) or $\phi_v$ and particle to fluid density ratio of $\phi_c = 10^{-3}$ and $C^+ = 2700$, respectively, were employed to allow the use of a two-way coupling approach between the particles and the carrier phase. It is shown that, regardless of the type of geometric perturbation prescribed, the injection of solid particles exhibited a strong attenuating effect of the turbulent intensity of the flow, as well as a turbulent skin friction drag reduction. These findings reinforce the concept of a selective stabilising effect induced by the solid particles. In this case, the PMF played an important role on the seemingly selective modulation of the turbulent activity.

Analysis of Varying-Phase Opposition Control with Spatial Scale Restriction 1. SIMON TOEDTLI, BEVERLEY MCKEON, Caltech — This study considers a generalized version of the opposition control scheme (Choi et al, J Fluid Mech, 1994) from a Fourier domain perspective. Recent work (Toedtli et al, PRF, 2019) has shown that the effectiveness of the controller strongly depends on the relative phase between sensor measurement and actuator response, but an understanding of the underlying physics proves difficult so long as the controller simultaneously acts on a large number of spatial scales. We therefore consider here controllers with spatial scale restrictions and show that such controllers are capable of substantially altering the flow structure and drag. We first focus on the adverse scenario, where control leads to a pronounced drag increase, and use a combination of numerical simulation and modal analysis to shed light on the mechanisms underlying the change in drag. Insights obtained from the drag-increasing scenarios may help guiding the search for scale-restricted controller parameters that lead to drag reduction, which would be an important step towards a practical implementation of the control scheme.

Control of a Turbulent Boundary Layer Separation Bubble by Shortfin Mako Shark Skin 1. AMY LANG, LEONARDO SANTOS, ANDREW BONACCI, JACOB PARSONS, University of Alabama — It has been demonstrated that real shortfin mako shark skin can control turbulent boundary layer separation due to the passive actuation of the scales in the presence of reversing flow. Unlike vortex generators, this passive flow-actuated mechanism functions locally at the point where there flow needs to be controlled and this study demonstrates that shark skin is capable of controlling the flow even downstream of the point where separation is already occurring. As in previous studies, shark skin specimens were mounted to a flat plate and placed in a tripped turbulent boundary subjected to an adverse pressure gradient induced by a rotating cylinder. DPIV experiments were conducted in a water tunnel facility for three different Reynolds numbers (on the order of 10^5) with different strengths of adverse pressure gradient to measure the control the presence of the shark skin had on the flow separation when the skin was placed on the downstream half of a quasi-steady turbulent separation bubble. Results confirm that the shark skin is able to control the flow by impeding the reversing flow near the surface. Furthermore, wall skin friction was calculated showing that the presence of the skin lowered the skin friction to the near zero vicinity but prevented it from going significantly negative as on the smooth wall cases.

Effect of mass transfer on aeroheating in hypersonic chemically reacting boundary layers 1. MONA KARIMI, STC, NASA Ames Research Center, JOSEPH SCHULZ, AMA, NASA Ames Research Center, NAGI MANSOUR, NASA Ames Research Center — At atmospheric entry hypersonic speeds, ablation as well as surface catalycity will impact boundary layer aeroheating. Outgassing occurring from an ablative surface in planetary entry environment introduces a rich set of problems incorporating thermodynamic, fluid dynamic, and material pyrolysis. Although it is established that mass injection diminishes the wall heat transfer via convective blockage, understanding the underlying physical mechanism of the mass injection-induced boundary layer turbulence is still unresolved. To properly characterize the aerothermal environment and the required protection system, it is important to investigate gas-surface interaction models that inherently couple material response and boundary layer physics. The present study examines the aeroheating budget in hypersonic boundary layer with mass transfer produced material pyrolysis that reacts with the boundary layer environment. A coupled simulation of a chemically reacting viscous Navier-Stokes solver of the boundary layer over a pyrolyzing material is analyzed.

Comparison of turbulent/non-turbulent interfaces in an adverse and zero pressure gradient turbulent boundary layer 1. JONGMIN YANG, JINYUL HWANG, MIN YOON, HYUNG JIN SUNG, KAIST, HYUNG JIN SUNG TEAM — The turbulent/non-turbulent interfaces of the zero pressure gradient (ZPG) and adverse pressure gradient (APG, \( \beta = 1.45 \)) turbulent boundary layers (TBLs) are explored using the direct numerical simulation data (Re76 = 830), where \( \beta \) is the Clauser pressure gradient parameter. The interfaces are extracted by the method based on the entrophy magnitude. Depending on the entrophy, the outer boundary layer flow can be classified into free stream, boundary layer wake, and intermittent flow regimes. In addition, we analyze the behavior of the intermittent flow regime by changing the threshold. The fractal dimension is obtained by using the box-counting algorithm. The fractal dimensions in the APG and ZPG TBLs are constant over the long range of the box size. The interfaces of the APG and ZPG TBLs show the monofractal behaviors. The geometric complexity of the interfaces in the APG and ZPG TBLs can be represented by the genus, which is defined by the number of handles in the geometric object. The genus in the APG TBL is larger than that in the ZPG TBL. The geometric complexity of the intermittent flow regime is increased in the APG TBL. In addition, we examine the projection area and the volume of the genus and the pockets to analyze the entrainment process in the APG and ZPG TBLs.

3:44PM M01.00025 Influence of Splitter Plate Geometry on a Multi-Stream Jet Nozzle

EMMA GIST, Syracuse University, CORY STACK, The Ohio State University, DOMINIC DIDOMINIC, TYLER VARTABEDIAN, SETH KELLY, Syracuse University, DATTA GAITONDE, The Ohio State University, MARK GLAUSER, Syracuse University — Current and future aircraft designs are focusing on the integration of propulsion systems into the airframe to maximize efficiency and provide a stealth profile. This integration has led to different nozzle configurations such as the Multi-Aperture Rectangular Single Expansion Ramp Nozzle (MARS) where the nozzle has a primary and secondary bypass. This examination focuses on the reintroduction of the secondary subsonic bypass with the supersonic core flow and their merging behind a splitter plate. The two streams differ from each other in all aspects, including the velocity, pressure and density. Large-Eddy simulations (LES) have shown that splitter plate thickness affects the formation and evolution of large-scale structures in the presence of the shock and expansion wave system. This also impacts the acoustics as well as the mechanical loading due to the unsteady fluctuations in the flow. This study focuses on using thinner splitter plates and the introduction of passive control by a geometric change on the end of the splitter plate where the streams coalesce. This study aims to provide insight into the physics associated with the complex merging flows and how a splitter plate can be used to manipulate the flow to reduce noise without compromising performance.

3:45PM M01.00026 Computational Study of Film Cooling Performance of a Gas Turbine: An application of the Transverse Jets

GERMAN SIERRA-VARGAS, CARLOS DUQUE-DAZA, Dept. of Mechanical and Mechatronics Engineering, Universidad Nacional de Colombia — Film cooling technology based on transverse jets is employed to provide and control a protective film that remains attached to the surface and therefore to reduce the heat transfer from a high temperature main flow to the surface to be protected. Aiming to assess the impact of the jet-to-crossflow velocity ratio on the film cooling effectiveness, a number of numerical experiments were performed using four jet-to-crossflow velocity ratios over a NACA 4412 cascade vane. A computational model based on finite volume discretization, employing a WALE turbulence model, was prescribed to solve an incompressible flow on a 3D structured mesh. A passive scalar was included in the model to simulate temperature and transport of energy. Y+ values and Courant number were limited, in order to ensure convergence. Comparisons were made between the jet trajectory and the friction coefficient, evidencing how the mid-line of the cooling jet yields regions of boundary-layer separation and re-attachment. Analysis of the boundary-layer behavior indicates a relation with the local convective coefficient increments. Moreover, the results showed how the film cooling decreased the heat transfer at the region near the injection, but increased detrimentally the heat flux at the end of the vane.

3:46PM M01.00027 Multi-Jet Impingement Array Performance

ESCALLE THIBAUD, St. Cyr Military Academy, DAVID HELMER, MICHAEL BENSON, U.S. Military Academy — Impinging jets are frequently used in applications requiring cooling, and the design of such arrays requires understanding of both fluid dynamics and convective heat transfer. While impinging jet arrays have been extensively studied historically, there remain relatively few combined velocity and heat transfer datasets. This report presents such coupled measurements for an impinging jet array, including three-dimensional, three-component velocity measurements acquired using Magnetic Resonance Velocimetry, as well as full-field heat transfer measurements acquired with steady-state IR thermography with a joule-heating boundary condition. The goal of this measurement is to provide a benchmark dataset against which future experiments and especially simulations can be validated in detail.

3:47PM M01.00028 Viscous elastic fluid jets induced by sudden acceleration

YOSHIYUKI TAGAWA, ANDRES FRANCO-GOMEZ, HAJIME ONUKI, YUICHIRO NAGATSU, Tokyo University of Agriculture and Technology — Modern interest for 3D-manufacturing applications requires controlled ejection of liquids with viscous non-Newtonian properties, such as polymer solution and molten resin. In this study, we compare jet evolutions of two viscous polymer solutions with different elasticity but similar shear-thinning properties (i.e. elastic and inelastic). Both jets are ejected by using our novel jet generation system employing an impulsive force (Onuki & Tagawa, Phys. Rev. Applied, 2018). The inelastic solution eventually pinch-off into droplets. In contrast, remarkably, jets of the elastic solution completely retract after ejection, even though the initial velocity of the jet is high (>10 m/s). We rationalize these behaviors by considering high elongational rate of liquids, which is beyond an explored range of existing studies. This contribution may open a new door for developing new additive-printing systems.

3:48PM M01.00029 Eddy viscosity for resolvent analysis of turbulent jets

ETHAN PICKERING, GEORGIOS RIGAS, Caltech, OLIVER SCHMIDT, University of California, San Diego, DENIS SIPP, ONERA — The French Aerospace Lab. TIM COLONIUS, Caltech — Resolvent modes of turbulent jets have shown striking qualitative agreement with data-deduced modes, found via spectral proper orthogonal decomposition (SPOD), of high-fidelity, large-eddy simulations (LES), however, quantitative comparisons are still lacking. The discrepancy is linked to the presence of spatially colored noise inherently contained within SPOD modes, found via spectral proper orthogonal decomposition (SPOD), of high-fidelity, large-eddy simulations (LES), however, quantitative comparisons are still lacking. The discrepancy is linked to the presence of spatially colored noise inherently contained within SPOD modes. The optimization is applied to Mach 0.4, 0.9, and 1.5 round, isothermal, turbulent jets, using five eddy-viscosity models: linear damping, a relation with the local convective coefficient increments. Moreover, the results showed how the film cooling decreased the heat transfer at the region near the injection, but increased detrimentally the heat flux at the end of the vane.

Between Quasi-Steady and Unsteady Dynamics

1 time-averaged flow fields are analyzed to understand the evolution of tip vortex under confinement. These contributions are measured in a water tunnel, at Reynolds numbers on the order of $10^4$, for regions spanning the suction surface of a delta wing with leading-edge sweep angle of 50 degrees. It is found that the balance depends on the chordwise position along the wing, with the shear layer contributing to LEV growth primarily near the apex of the wing, and transport further downstream dominated by flow three-dimensionality and interaction with the surface. Understanding these interactions provides a foundation for the design of flow control strategies and the prediction of aerodynamic loads and their fluctuations due to exogenous inputs.

3:50PM M01.00031 Fluid forces and flow transitions for a NACA0012 hydrofoil at low Reynolds numbers 1, Siddharth Gupta, Jisheng Zhao, Mark Thompson, Monash University, Australia, Atul Sharma, Amit Agrawal, IIT Bombay, India, Kerry Hourigan, Monash University, Australia — A study has been conducted to investigate the effect of angle of attack ($\alpha$) on the hydrodynamic performance and wake structure of a static NACA0012 hydrofoil in a free-stream flow at low Reynolds number ($Re$). The investigation employed water-channel experiments and in-house numerical simulations (based on an immersed interface method) over the angle of attack range of $0^\circ \leq \alpha \leq 90^\circ$ and the Reynolds number range of $2000 \leq Re \leq 10,000$. The angle of attack of a foil is an important parameter affecting the fluid dynamics and fluid-structure interaction; however, this problem has been poorly understood at low Reynolds numbers and particularly at large angles of attack, despite its importance in numerous applications, such as fish-like locomotion, autonomous underwater vehicles, bird-insect flights, micro-air vehicles, and wind turbines. The present findings showed that there exist different flow regimes and transitions over the $\alpha$ and $Re$ ranges investigated: e.g., a laminar flow regime is observed for $0^\circ \leq \alpha \leq 5^\circ$, followed by a transition regime prior to three distinctly different vortex shedding modes I, II and III for higher angles of attack. More details will be presented at the Division of Fluid Dynamics Meeting.

3:50PM M01.00032 Jacobi polynomial solution technique for the unsteady aerodynamics of porous airfoils 1, Rozhin Hajian, Harvard University, Peter J. Badoo, Imperial College London, Justin W. Jaworski, Lehigh University — Recent research has uncovered analytic solution forms for the flow field past a thin airfoil with an arbitrary porosity distribution. However, efforts to extend this work to unsteady flows or airfoil motions fail due to the presence of extra terms in the singular integral equation that are not readily treated analytically. To circumvent this issue, the bound vorticity along the chord is expanded as a series of weighted Jacobi polynomials. Analytic expressions for the parameters of the Jacobi polynomials are derived via asymptotic analysis. This approach is shown to be valid for static airfoils in steady flows with either continuous or discontinuous porosity distributions. A numerical validation is presented that demonstrates the spectral convergence of the scheme. The mathematical method is then extended to consider the unsteady motions of porous airfoils where the classical singular integral approach breaks down.

3:52PM M01.00033 Confinement effects on the development of the tip vortex of an elliptical hydrofoil 1, Praveen Kumar, Krishnan Mahesh, University of Minnesota — Tip vortices are widely studied due to their relevance to many engineering applications. In many cases, e.g. ducted propulsors, tip vortices evolve under confinement. The effects of confinement on the development of tip vortex is the subject of the present work. Large eddy simulations are performed for flow over a confined elliptical hydrofoil at an incidence angle of 12 degrees and a Reynolds number of 0.9 million based on root chord length and freestream velocity. Two different cases of tip gap, i.e. the perpendicular distance between the hydrofoil tip and the bottom wall, are simulated and compared to the experiments of Boulon et al. (J. Fluid Mech. 1998, 390: 1-23), who studied confined effects on tip vortex cavitation. Instantaneous and time-averaged flow fields are analyzed to understand the evolution of tip vortex under confinement.

3:55PM M01.00036 Analysis of the Streamwise-Oscillating Cylinder Wake: Interplay Between Quasi-Steady and Unsteady Dynamics 1, Maysam Shamai, Caltech, Scott Dawson, Illinois Institute of Technology, Igor Mežić, University of California, Santa Barbara, Beverley Mckeeon, Caltech — The flow around a cylinder oscillating (surging) in the streamwise direction with a frequency, $f_s$, much lower than the shedding frequency, $f_s$, has been relatively less studied than the case when these frequencies have the same order of magnitude. We combine particle image velocimetry and Koopman Mode Decomposition to investigate the cylinder wake for nominal parameters $f_s/f_s \approx 0.04 - 0.2$ and mean Reynolds number, $Re \approx 900$. The amplitude of oscillation is such that the instantaneous Reynolds number is far from the critical value. Characterization of the wake reveals a range of phenomena associated with nonlinear interaction of the two frequencies, including amplitude and frequency modulation. We perform analyses in multiple frames of reference to motivate use of the cylinder-fixed frame. Utilizing this frame, we present a scaling parameter and associated transformation in order to relate the unsteady, or forced, dynamics to that of a quasi-steady, or unforced, system. Implications for Koopman analysis of the flow around a moving body will be discussed. This work is supported under ARO grant W911NF-17-1-0306.

1AMIR CHIZFAHM, RAJEEV JAIMAN, University of British Columbia — Fluid-structure interaction of an elastically-mounted sphere exhibits a wide range of complex flow-induced vibration (FIV) regimes. Unlike a vast amount of literature available on the vortex-induced vibration of an elastically-mounted circular cylinder, such studies on a sphere are limited. We aim to understand the fundamentals of new vortex-shedding modes and coupled dynamics pertaining to the FIV response of a freely vibrating sphere in all three spatial directions, using a body-fitted finite-element based fluid-structure interaction framework. To predict and analyze the vortex synchronization regimes and the wake patterns, the FIV response of the sphere at a low mass ratio is investigated over a broad range of reduced velocity and Reynolds number. We find that the sphere begins to move along a linear trajectory with hairpin vortex-shedding mode, finally transforming into a circular trajectory with spiral mode in its stationary state. We systematically examine these mode transitions and motion trajectories in the three degrees-of-freedom for the Reynolds number up to 30,000 which has not been studied in detail in the literature.

3:57PM M01.00039 What is a “Length Scale” in Variable Density Turbulence?1. DONGXIAO ZHAO, HUSSEIN ALUIE, University of Rochester — A “length scale” in a fluid flow does not exist as an independent entity but is associated with the specific flow variable being analyzed. While this might seem obvious, we often discuss the “inertial range” or the “viscous range” of length scales in turbulence as if they exist independently of a flow variable, which in incompressible turbulence is the velocity field. How should we analyze “length scales” in flows with significant density variations, such as across a shock or in multiphase flows? A choice can be made according to the so-called inviscid criterion. It is a kinematic requirement that a scale decomposition yield negligible viscous effects at sufficiently large “length scales.” Recently, we proved that a Hesselberg-Favre decomposition satisfies the inviscid criterion, which is necessary to unravel inertial-range dynamics and the cascade. We present numerical demonstrations of those results, where we also show that other commonly used decompositions can violate the inviscid criterion and, therefore, are not suitable to study inertial-range dynamics in variable-density turbulence.

1Supported by DOE grant DE-SC0014318

3:59PM M01.00040 Homogeneous variable-density turbulence with asymmetric initial density distributions1. DENIS ASLANGIL, Lehigh University, DANIEL LIVESCU, Los Alamos National Laboratory, ARINDAM BANERJEE, Lehigh University — In most natural and engineering applications, turbulent mixing occurs between unbalanced amounts of two or more miscible fluids of different densities. For example, during Rayleigh-Taylor and Richtmyer-Meshkov instabilities, the mole fraction percentages of the pure fluids change from zero to unity from edge to edge within the mixing layer. In this study, we investigate the effects of differential amounts of mixing fluids on the evolution of HVDT by using high-resolution direct numerical simulations (up to 20483) for two different density ratios- 1.1 and 7.1. Three cases with different initial compositions characterized by an initial composition ratio ($\chi$ = mole fraction of the heavy fluid/ mole fraction of heavy fluid) was chosen for each density ratio; a heavy fluid dominated case (HF) with $\chi$ = 3, a light fluid dominated case (LF) with $\chi$ = 1/3 and the classical HVDT case where $\chi$ = 1. It is found that at large density ratios, upon increasing the initial amount of the pure light fluid, the turbulence kinetic energy generation is enhanced, whereas upon increasing the initial amount of the pure heavy fluid, the turbulence generation is suppressed. In addition, it takes longer for turbulence to disperse into the regions of heavy fluid compared to regions of light fluid.

4:00PM M01.00041 A variational level set method without reinitialization for predicting equilibrium interfaces over arbitrary textured surfaces1. KARIM ALAME, SREEVATSA ANANTHARAMU, KRISHNAN MAHESH, University of Minnesota — A robust numerical methodology to predict equilibrium interfaces over arbitrary solid surfaces is developed. The kernel of the proposed method is the distance regularized level set equations (DRLSE) with techniques to incorporate the no-penetration and mass-conservation constraints. In this framework, we avoid reinitialization typically used in traditional level set evolution algorithms. The method is second-order accurate and requires only central difference schemes. The application of the method, in the context of Gibbs free energy minimization, to obtain liquid-air interfaces is validated against existing analytical solutions. The capability of our current methodology to predict equilibrium shapes over both structured and realistic rough surfaces is demonstrated.

Investigation of Mixing Law Efficacy for Hydrodynamic Simulations and Associated Compressibility Implications. CALEB WHITE, HUMBERTO SILVA III, Sandia National Laboratories, PETER VOROBIEFF, Department of Mechanical Engineering, University of New Mexico — A computational simulation of various mixing laws for gaseous equations of state (EOS) using planar traveling shocks for multiple mixtures in three dimensions (3D) is analyzed against nominal experimental data. Numerical simulations utilize the Sandia National Laboratories (SNL) shock hydrodynamic code CTH and other codes including the SNL thermochemical equilibrium code TIGER and the uncertainty qualification (UQ) and sensitivity analysis code DAKOTA. The mixtures are: a 1:1 and a 1:4 molar mixture of helium (He) and sulfur hexafluoride (SF\textsubscript{6}). The mixing laws to be analyzed are the ideal gas law, Amagat's Law, and Dalton's Law. Examination of the experimental data with TIGER revealed that the shock strength should not be considered when the mixture is non-ideal as the compressibility factor, \( \zeta \), was essentially unity (\( \zeta \approx 1.02 \)). Strikingly however, experimental results show that neither Dalton's nor Amagat's Law are able to accurately predict the properties of the shocked mixture. A methodology is being developed to possibly optimize the various mixing laws with computational results for the data set investigated. Lastly, a framework for future sensitivity and uncertainty quantification analysis will be established.

Effect of counter-gradient subgrid-scale transport on turbulent mixing. SIDHARTH GS, RAYMOND RISTORCELLI, Los Alamos National Laboratory — The present work explores the effect of subgrid-scale models on the statistics of turbulent mixing of passive and active scalars. We compare the commonly employed gradient diffusion model against the non-linear gradient model (related to Clark model/Finite-scale equations). The aim is to investigate the consequence of isotropic eddy viscosity/scalar diffusivity versus a tensorial viscosity and diffusivity that permits counter-gradient transport of resolved-scale variables. For an isotropic turbulent flow, an gradient diffusion model, the non-linear gradient model can be shown to preserve the combined supergrid and subgrid scalar variance to the leading order in filter width. Therefore, the effect of the two classes of models on the evolution of the scalar variance (passive and active) is contrasted. Furthermore, in the active scalar case (variable-density mixing), we compare the turbulence and mixing statistics in the Reynolds- versus Favre-filtered representation of large-scale velocity and scalar variables (Sidharth GS and Candler JFM (2018)). The role of variable-density subgrid acceleration on the dynamics of subgrid velocity variance is of particular interest and compared with the well-studied specific-stress based production term.

Topological classification of recurrences in turbulent flows. NAZMI BURAK BUDANUR, GÖKHAN YALNIZ, BJÖRN HOF, IST Austria — In recent years, numerical discoveries of unstable time-periodic solutions in various shear flow simulations have sparked hopes of developing a chaos theoretic understanding of turbulence. For many cases of interest, however, the standard tools of chaos theory, such as Poincaré sections, were insufficient for uncovering a complete picture of turbulent dynamics due to its high dimensionality. As a result, the discoveries of periodic orbits in turbulent flows have remained at an illustrative level with no obvious paths toward their utilization in turbulence modeling and control. One simple question one might ask is whether the turbulent dynamics transiently approximate periodic solutions, and if so, how frequently? We argue that a systematic study of this problem requires a method for unsupervised identification of geometric similarities between periodic orbits and turbulent trajectory segments in the system's state space. We will demonstrate with examples that topological data analysis methods can be employed for this purpose.

Probe into the gas leakage dynamics from the bubbly wake of a ventilated supercavity. SIYAO SHAO, JIARONG HONG, University of Minnesota — Understanding the liquid-gas interface instability and associated gas leakage mechanisms is critical for developing new strategies for sustainable ventilated supercavitation in practical applications. However, despite recent effort from Wu et al [JFM, 2019, 862, 1135-1165], to directly characterize the gas leakage through the cavity internal flow measurement is challenging, particularly across a broad range of cavity regimes. Here we probe into the gas leakage mechanism by investigating bubbly wake generated from a ventilated supercavity with various closure modes including re-entrant jet, twin and quad vortex closures. The size and shape of bubbles and their 3D distribution in the wake are captured using a high speed digital inline holography (DIH). The instantaneous gas leakage rate, estimated from the size and velocity of bubbles at each time instant, shows a strong intermittent behavior while the average gas leakage from DIH agrees well with the ventilation input under all experimental conditions. In addition, the detailed spatial and temporal characteristics of bubble distribution in the wake are found to vary under different closure conditions, connecting strongly with the interface instability and bubble breakup mechanism at the closure of the supercavity.

Kelvin wave generation on vortices in Bose-Einstein condensates. SCOTT STRONG, Applied Mathematics and Statistics, Colorado School of Mines, LINCOLN CARR, Department of Physics, Colorado School of Mines — A single line of concentrated vorticity is an open and fundamental problem in the study of superfluid turbulence. The local induction approximation, or LIA, is a straightforward integrable model of curvature induced flow. Here, the curvature and torsion evolve under a cubic focusing nonlinear Schrödinger equation whose wealth of conservation laws are thought to artificially constrain interactions between helical modes. Our work describes LIA as the lowest-order approximation in a fully nonlinear expansion of curvature induced motion honoring archlength conservation present in the Hamiltonian formulation of inviscid fluid dynamics. These higher-order corrections are accurate at scales where LIA is not, and accounts for locally induced flows and contributions due to the vortex core. Our fully nonlinear model predicts that traveling waves of localized curvature seek to transport bending along the vortex. Simulations show dynamics similar to those seen post-reconnection in vortices generated by obstacles and cavitation in classical flows. In ultratqumon turbulent tangles, energy transfer between helical Kelvin modes of vortex lines permits free decay and our relaxation of bending via Kelvin wave generation may be its most primitive manifestation.
4:08PM M01.00049 A formation time scale for vortex rings generated by pulsed planar jets. BEN STEINFURTH, TIM GEFFKE, JULIEN WEISS, Technische Universität Berlin — The flow field of a pulsed planar jet emitted from an outlet of high aspect ratio is studied experimentally. Considering that the effectiveness of various flow control applications is determined by large-scale coherent vortex structures, the objective of this study is to shed some light upon the generation mechanisms of these vortices. First, flow visualizations are conducted with pulsed jets issued into a steady water tank, verifying that the concept of an optimal generation time scale ensuring the exclusive generation of a leading vortex ring exists. Then, quantitative measurements are performed employing particle image velocimetry. Based on the derivation of flow diagnostics and additional extensive hotwire measurements, the following main conclusion can be drawn: increasing the pulse width, i.e., the amount of ejected fluid of a pulsed planar jet results in saturation of the leading vortex ring in terms of its dimensions and entrainment characteristics. Beyond a certain pulse width, a trailing structure with properties similar to a steady planar jet occurs. The shear rates of this trailing jet are well below those observed inside the vortex ring. Thus, jet modulation with the identified optimal pulse width may be beneficial from a flow control perspective.

4:09PM M01.00050 Semi-Lagrangian Lattice Boltzmann Method for Compressible Flows. DOMINIK WILDE, University of Siegen, ANDREAS KRAEMER, National Heart, Blood and Lung Institute, National Institutes of Health, HOLGER FOYSI, University of Siegen — The lattice Boltzmann method (LBM) is an established tool for the simulation of weakly compressible flows. However, in the field of compressible flows the LBM is still lacking a widely accepted framework, which is why it is an active field of research. On the one hand, traditional LBM solvers with an exact propagation of the distribution function values usually require large velocity sets. On the other hand, Eulerian solvers like finite volume or finite difference LBMs suffer from high computation costs. We propose a semi-Lagrangian streaming step allowing for unstructured grids and on non-integer-based velocity sets. This procedure effects small numerical dissipation, while the spatial order of convergence can be increased by the use of high-order interpolation polynomials in combination with an appropriate choice of support points. The semi-Lagrangian LBM circumvents the costly application of explicit time integration in Eulerian schemes. Instead, from an algorithmic point of view, the semi-Lagrangian LBM is still close to the original LBM formulation. Simulations of a Sod shock tube, a 2D Riemann problem, a shock-vortex interaction, and a 2D airfoil confirm the newly introduced semi-Lagrangian LBM to be appropriate for the calculation of compressible flows.

4:10PM M01.00051 ABSTRACT WITHDRAWN —

4:11PM M01.00052 Princeton High Reynolds Number Supertank facility. Konstantinos Steiros, Marcus Hultmark, Princeton University, Mechanical and Aerospace Engineering — Characterizing the aerodynamic behavior of large structures presents a major challenge in many engineering fields, including modern wind engineering, architecture, and urban planning research. The combination of enormous Reynolds numbers, relatively small Mach numbers, and unsteady or periodic events, render such flow measurements practically impossible in a conventional test facility. To address this issue, we present a novel recirculating wind tunnel facility, the Supertank, where the gauge pressure will be varied from 0 to 80 bar, enabling the testing of a large range of Reynolds numbers. The novelty of this facility lies in its large size, allowing a test section of 0.88 X 0.88 m^2 cross section and 7.5 m length, and in its easily accessible design. In that manner, series of wind turbines and even small wind farms will be able to be characterized at high Reynolds numbers, and it will serve as an ideal facility to evaluate numerical models and simulations. Several technical details of the facility will be discussed, along with the potential that this facility will unlock for applied and fundamental research.

4:12PM M01.00053 Leverage the Capability of Princeton Superpipe. LiuYang Ding, Alexander Pique, Simere Genet, Daniel Hoffman, Marcus Hultmark, Alexander Smits, Princeton University, Princeton University TEAM — The Superpipe facility at Princeton utilizes compressed air as the working fluid to obtain high-Reynolds-number turbulence. It comprises a recirculating pressure vessel that can hold up to 220 atm, and a test pipe of 200 diameter long inside the pressure vessel. The range of bulk Reynolds number achievable is 8x10^7 to 6x10^9. Previous measurements in the Superpipe have only employed hot wires and only investigated equilibrium flows. We now report our progress in maximizing the capability of Superpipe towards optical measurement of non-equilibrium turbulence at high Reynolds numbers. We designed a new traversing system with a miniature rail mounted inside the test pipe, which allows test models to travel over a large axial distance. The blockage ratio of the rail is 0.6% of the pipe cross section. A linear driving stage is placed in the diffuser section and is 16 diameters downstream of where the flow is sampled. We will present preliminary hot-wire data of turbulence past a streamlined body of revolution, and compare it with PIV measurement of the same flow in a water pipe. In addition, the design of a new PIV system for the Superpipe will be presented. Details regarding imaging and illumination with optical fibers, calibration procedure, and seeding method will be discussed.

Monday, November 25, 2019 3:20PM - 4:16PM — Session M02 Flash Oral Presentations: Geophysical Flows

3:20PM M02.00001 Passive vortical flows enhance mass transfer in a coral colony. MD MONIR HOSSAIN, ANNE STAPLES, Virginia Tech — Corals are sessile and rely on the surrounding ocean flow to obtain nutrients and carry out their other physiological functions. Recent studies have shown that corals in low flow conditions can stir the water column, creating vortical flows that enhance mass transfer rates by up to 400% (Shapiro et al., PNAS, 2014). Here, we perform three-dimensional immersed-boundary simulations of the flow through a single Pocillopora meandrina colony under high flow conditions. We demonstrate that the passive geometric features of the branching colony produce highly vortical internal flows. This enhances mass transfer at the interior of the colony and compensates almost exactly for flow speed reductions there of up to 64%, resulting in the advection time scale remaining roughly constant throughout the colony. We further compute the transport of a passive scalar from the surface of the colony under idealized sinusoidal oncoming flow conditions and find a double-peak concentration profile in the interior of the colony.

4:10PM M01.00051 ABSTRACT WITHDRAWN —

We further compute the transport of a passive scalar from the surface of the colony under idealized sinusoidal oncoming flow conditions and find a double-peak concentration profile in the interior of the colony.
at an angle of $\pm \sqrt{\frac{1}{2}} \approx \pm 35.35^\circ$ to the direction of travel of the carrier wave. Moreover, we analyse in detail the single crossed-wave component and find that group dispersion decreases to a minimum at the nondispersive crossing angle of approximately $\pm 35.26^\circ$. Our results may motivate investigations in other physical media, governed by weakly nonlinear evolution equations and improve understanding of extreme event lifetime.

3:25PM M02.00006 The Cooling Box Problem: A Freezing Lake in the Lab$^1$ JASON OLSTHOORN, KYLE GERRARD, EDMUND W. TEDFORD, GREGORY A. LAWRENCE, University of British Columbia — Recent field measurements have demonstrated that inland waters are warming rapidly and that seasonally ice-covered lakes are warming faster than those that do not. With limited field studies of lakes in harsh winter conditions, the impact of this changing environment is not clear, particularly from an ecological perspective. Similarly, the physical processes responsible for the warming within these cold-water bodies have not yet been identified. Our research focuses on the surface cooling processes occurring prior-to and immediately after ice formation, with a particular interest in the transport of heat. We model a cooling box problem, similar to the Rayleigh-Bernard problem. However, the nonlinear equation of state of freshwater complicates the traditional Rayleigh-Bernard analysis. We demonstrate that the nonlinear equation of state fundamentally alters the classical results of the Rayleigh-Bernard problem. Using a combination of linear stability analysis, numerical simulation and laboratory experiments, we quantify the mixing within the water column and the resultant surface heat transfer. Modified scaling laws for heat transport and energetics agree well with our data.

3:26PM M02.00007 ABSTRACT WITHDRAWN
3:27PM M02.00008 Local flow and turbulence at a tidal energy conversion installation near a pier of an estuarine bridge¹, MARTIN WOSNIK, KAELIN CHANCEY, University of New Hampshire — Estuarine bridges could serve as ideal locations to deploy marine hydrokinetic (MHK) energy conversion systems. The hydrokinetic resource is typically strong at these narrow locations, the bridge piers can serve as supporting structure for both the bridge and turbines, and synergies exist in the permitting processes. The Living Bridge Project installed a hydrokinetic turbine on a floating platform at Memorial Bridge in Portsmouth, NH. The location is well-suit-ed as a tidal energy test site, reaching tidal current speeds greater than 2.5 m/s during spring ebb tides. In tidal estuaries the currents can vary significantly in space and time. Measurements were conducted with two acoustic Doppler current profilers (ADCP), mounted on the bow and stern of the platform, and with two acoustic Doppler velocimeters, mounted in various locations. The ADCPs indicated higher maximum current velocities and mean kinetic power density than prior nearby resource assessments. The ADV measurements yielded turbulence time and length scales consistent with estuary scales, e.g., width of the river and distances between the bridge piers. The tidal flow turbulence characteristics, such as the size and occurrence of coherent structures, affects the loading on the tidal turbine.

3:28PM M02.00009 Duffing equation describes sloshing experiments, KERSTIN AVILA, BASTIAN BAUERLEIN, Center of Applied Space Technology and Microgravity (ZARM), University of Bremen, 28359 Bremen, Germany — In nature and in engineering, periodic forcing leads often to nonlinear resonances which are challenging to model and predict. The Duffing equation \( (\ddot{x} + \beta \dot{x} + \alpha x + \omega^2 x = F \cos \omega t) \) is the simplest and most widely studied model describing such phenomena and is thus used in introductory courses to nonlinear dynamics. Despite numerous analytical and numerical studies across disciplines investigating its properties and dynamics, laboratory experiments exhibiting its dynamics are very scarce and, to our knowledge, all of them have been constructed to behave as a Duffing oscillator. We show that sloshing of water in a rectangular container driven by harmonic horizontal excitation is accurately described by the Duffing equation. The choice of the setup combined with automated flow visualizations and PIV-measurements allow it to reproduce key features of the Duffing oscillator experimentally. Besides the characteristic resonance curve we observe a hysteresis which increases with the driving amplitude and features transitions at exactly 90°-phase-lag, as well as period-three-motion. The experiments reach from linear and nonlinear dynamics fully described by the Duffing oscillator, up to highly nonlinear effects with e.g. breaking surface waves.

3:29PM M02.00010 Effect of spring non-linearity on vortex-induced vibration of a circular cylinder¹, RAHUL MISHRA, Monash University, Australia, RAJNEESH BHARADWAJ, IIT Bombay, India, MARK THOMPSON, Monash University, Australia — The vortex-induced vibration (VIV) of a circular cylinder subject to nonlinear structural support has been studied computationally for fixed mass ratio \((m^* = 2.546)\) in the two-dimensional Reynolds number regime. Unlike for the classic case for which the structure support consists of a spring and damper in parallel, this study considers a system composed of two springs and one damper, where the two springs are in parallel and the damper is in series with one of the springs. The arrangement of the springs and damper is similar to the Standard Linear Solid (SLS) model used for modelling the behavior of a viscoelastic material. The spring in series with the damper is linear and that parallel to the damper provides a non-linear force. The non-linear structural system is governed by the following three parameters: (a) the ratio of the spring constant \((R)\), (b) damping ratio \((\zeta)\), and (c) non-linearity strength \((\lambda)\). The focus of the present study is to examine the response of the cylinder to VIV subject to changing \(\zeta\) and \(\lambda\). The main feature of this non-linear system is its ability to sustain vibration for a greater range of flow velocity; potentially useful for vibratory energy extraction.

3:30PM M02.00011 The flow surrounding fire whirls¹, ADAM D WEISS, PRABAKARAN RAJAMANICKAM, WILFRIED COENEN, ANTONIO L SANCHEZ, FORMAN A WILLIAMS, University of California San Diego — Despite significant research efforts, our current understanding of the flow structure and dynamics of fire whirls, including the reasons for their dramatic flame-lengthening effect and increased burning rate, is far from complete. The present study contributes to the needed understanding by investigating the steady axisymmetric structure of the cold outer flow surrounding fire whirls developing over localized fuel sources lying on a horizontal surface. Consideration is given to the three distinct flow regions arising from the disparity of length scales present in the problem, namely, an outer rotational inviscid region driven by the buoyant turbulent plume of hot combustion products that develops above the fire, a near-wall boundary layer, and a near-origin non-slender region where the radial inflow of the boundary layer collides. The resulting description, and in particular the terminal boundary-layer structure as the axis is approached, may be useful in future numerical computations of fire whirls.

3:31PM M02.00012 Potential Fluid Mechanisms for Low Frequency Sound from Tornadoes¹, BRIAN ELBING, CHRISTOPHER PETRIN, Oklahoma State University, MATTHEW VAN DEN BROEKE, University of Nebraska-Lincoln — Tornado-producing storms have been observed to emit infrasound (sound at frequencies below human hearing) up to 2 hours before tornadoogenesis. Weak atmospheric attenuation at these frequencies allows for long-range detection. Hence, passive infrasonic monitoring could be a method for long-range studying of tornadoogenesis as well as tornado characterization. Identifying the fluid mechanism(s) that produce the infrasound is critical to enable such capabilities. Besides the characteristic resonance curve we observe a hysteresis which increases with the driving amplitude and features transitions at exactly 90°-phase-lag, as well as period-three-motion. The experiments reach from linear and nonlinear dynamics fully described by the Duffing oscillator, up to highly nonlinear effects with e.g. breaking surface waves.

3:32PM M02.00013 Uncertainty Quantification of Models for Ocean Surface Boundary Layer Turbulence, GREGORY WAGNER, RAFFAELLE FERRARI, ANDRE SOUZA, Massachusetts Institute of Technology — The atmosphere and ocean communicate through the ocean’s turbulent surface boundary layer (OSBL), and accurate models of OSBL turbulence are necessary for accurate climate prediction. In this talk we use a suite of Large Eddy Simulations of OSBL turbulence in a range of physical scenarios to optimize and estimate the uncertainty of free parameters in models for OSBL turbulent mixing designed to be embedded in ocean general circulation models. We evaluate deficiencies in the structure of several different OSBL turbulence models by comparing the dependence of optimal parameters on the targeted physical scenario. Our ultimate goal is to choose a best OSBL turbulence closure for implementation in a new Earth System Model being developed as part of the Climate Machine (CiMa) project.
3:33PM M02.00014 Coupled-mode flutter in wind turbine blades – numerical prediction and experimental evidence.1 YAHYA MODARRES-SADEGHI, TODD CURRIER, PIETER BOERSMA, BRIDGET BENNER, University of Massachusetts Amherst, XAVIER AMANDOLESE, Ecole Polytechnique, France — We present a model to predict the onset of couple-coupled flutter in wind turbine blades as well as the post-instability behavior of the blade. While linear models to predict the onset of wind turbine blade instabilities have been around for a while, nonlinear models are lacking. Besides, experimental results to show these instabilities and to validate the models for wind turbine blades do not exist. We discuss a nonlinear model to predict these instabilities and present experimental results to validate the model for blades of around 200 cm in length. These results and other tests with blades of around 200 cm in length. In both series of experiments dynamic instabilities are observed. The larger-scale tests enable us to observe the coupling of two blade modes in a coupled-mode response, as well as oscillations purely in the torsional direction at higher wind speeds. The coupled-mode flutter is also predicted in the nonlinear numerical model.

3:35PM M02.00015 Effects of Land Cover on Wind Profiles: Case Study at Kirkwood Iowa. ROBERT AHLMAN, WEI ZHANG, Cleveland State University, COREY D. MARKFORT, University of Iowa — The atmospheric boundary layer serves as the incoming flow and kinetic energy source for wind turbines and remains a particularly challenging flow to study in fluid dynamics research. The difficulty lies in not only the wide range of spatial and temporal turbulent scales that need to be resolved but also the effects of the underlying surface. In particular, it is not well understood how wind velocity profiles respond to complex terrain and variations in atmospheric thermal stability. This research aims to characterize wind profiles in the surface layer and assess the accuracy of commonly used metrics for various terrain and thermal stability conditions. Data sets were recorded by various instruments mounted on a 106-meter tall meteorological tower at the Kirkwood Community College in Cedar Rapids, Iowa. Vertical profiles of wind speed and temperature, filtered by the direction of the incoming wind, for an entire year have been analyzed. Standard metrics and well-established formulations were assessed for their ability to accurately describe the wind profiles for a variety of different conditions. This work helps to provide insights into the effects of complex terrain and the atmospheric thermal stability on wind profiles, crucial to onshore wind resource assessment.

3:35PM M02.00016 Effect of the Instabilities in the Overlying Atmospheric Boundary Layer on the Street Canyon Ventilation TADEU MENDONCA FAGUNDES, NEDA YAGHOOBIAN, JUAN ORDONÉZ, Florida State University — Human health and air quality in urban areas are important problems that are linked to the pollution dispersion and ventilation capacity of urban streets. The ventilation mechanism and transfer process within urban streets is in strong connection with the instabilities in the overlying atmospheric boundary layer. In this study, we aim to use computational modelling to investigate the coupling between the flow within the street canyons and the turbulent structures in the above canopy flow. The state of the atmospheric boundary layer over an idealized urban area is controlled by the condition of the upstream topography. The transport phenomena in urban canyons is examined under different upstream conditions to reveal the ventilation mechanism in urban areas.

3:36PM M02.00017 Wake recovery in collocated wind plants RAL BAYON CAL, HAWWA KADUM, Portland State University, MIKE QUIGLEY, GERARD CÓRTINA, MARC CALAF, University of Utah — Large eddy simulations approach is used to investigate the power production enhancement mechanisms in collocated wind plants in which twelve clusters of vertical axis wind turbines are collocated with a 3x4 horizontal axis wind turbine array. Three cases are studied: 1.) a standard wind plant (SWP), 2.) an aligned collocated wind plant (CW1|P1), and 3.) a staggered collocated wind plant (CW1|P2). A control volume analysis is employed to examine the energy balance and relevant terms for the various characteristic compounded wakes. The results show that collocated configurations have an averaged 48.5% higher power than the standard wind plant due to the faster wake recovery and improved vertical transport of mean kinetic energy. The collocated plants spatial heterogeneity is found to play a significant role in mean kinetic energy vertical transport advancement by increasing the dispersive stress with an average of 37.5% increase in the vertical kinematic shear stress from the standard wind plant, consequently reinforcing the mean kinetic energy flux which is the lead term in mean kinetic energy budget. This arrangement resulted in 4% higher power production for the aligned configuration than the staggered even though the latter has faster wake recovery.

3:37PM M02.00018 ABSTRACT WITHDRAWN

3:38PM M02.00019 On the near-wake characteristics of a tidal current model in a sheared turbulent inflow1 ASHWIN VINOD, ARINDAM BANERJEE, Lehigh University — Tidal current turbines deployed in tidal flows can be anticipated to encounter sheared and turbulent flow environments. Therefore, a thorough understanding of the implications of such operating conditions would be valuable in optimizing the performance and operational life of the installed turbines. The ongoing experimental work at Lehigh University aims to improve the understanding of tidal turbine performance, and the mechanism of momentum transfer in its near-wake in a controlled, sheared, turbulent inflow. A 1:20 laboratory-scale tidal turbine model with a rotor diameter of 0.28m is used in the experiments. An active grid type turbulence generator consisting of a series of five stepper motor-controlled horizontal winglet shafts is employed to generate a vertically sheared, turbulent inflow. To better control the shear profile, winglets with different sizes/solidities are utilized in the active grid. All flow measurements were carried out using an acoustic doppler velocimeter. In addition to performance metrics, and mean, turbulent wake characteristics, contributions of the different terms in mean momentum and kinetic energy equations are also examined to better capture the process of wake re-energization.

3:39PM M02.00020 Low-order modelling of wake meandering behind turbines1 VIKKRANT GUPTA, MINPING WAN, Southern University of Science and Technology, Shenzhen — Far-wake regions behind tidal or wind turbines usually have low-frequency oscillations, referred as wake meandering, that cause an increase in turbulence level and thus adversely affect the performance of downstream turbines in an energy farm. We propose a Ginzburg–Landau equation based low-order model for the far-wake region. The model reproduces the main qualitative features of wake meandering: (i) its origin via amplification of upstream structures, (ii) dependence of oscillation frequency on the upstream disturbance amplitude (higher amplitudes lead to lower frequencies), and (iii) shift towards lower frequencies as the wake flow evolves in the streamwise direction. Additionally, the model also predicts the increase in the meandering amplitude and an advancement in its onset with increasing thrust coefficient. To our knowledge, this is the first low-order dynamical system in the literature that models wake meandering. The model coefficients are obtained from the mean flow local stability results that we show correctly account for the changing operating conditions and thus pave way for the prediction of wake meandering features. Its low-order makes it suitable to use inside an energy farm design model, where it can help to mitigate the adverse effects of wake meandering.

Gravitational Effects in Turbulent Two-Phase Heat Transfer in Horizontal Channels

Ilyas Yilgor, Pramod Bhuvanakar, Saedeh Dabiri, Purdue University, DABIRI RESEARCH TEAM — Present work explores heat transfer in horizontal turbulent bubbly flows. High fidelity direct numerical simulations (DNS) are conducted using finite volume and front-tracking methods to analyze the turbulent two-phase heat transfer between two parallel walls with Dirichlet boundary conditions at different temperatures for Eotvos and Archimedes numbers ranging from 0.03-0.6 and 500-10000, respectively. Non-condensable bubbles are present in the flow with a void fraction of 3% and Reynolds numbers ranging from 3000 to 5000. Two-phase simulations are compared to the corresponding single phase simulations with the same flow rate. The improvement in Nusselt number relative to single phase flow is quantified. A critical region where the improvement in heat transfer due to the presence of bubbles equals the convection heat transfer due to a reduced flow rate for a constant pressure gradient is documented. Change of void fraction distributions with gravity, flow rates, average Nusselt numbers and shear stresses are also presented. A range of parameters yielding optimum heat transfer are given.

Temporal dynamics and mode transition in a turbulent Rayleigh-Bnard Convection in a cylindrical domain with a moderate aspect ratio

Yulja Peet, Arizona State University, Philip Sakievich, Sandia National Laboratory, Ronald Adrain, Arizona State University — The current study focuses on dynamics and evolution of large-scale motions in a turbulent Rayleigh-Bnard convection in a cylindrical domain with a moderate aspect ratio of 6.3. We perform Direct Numerical Simulations of the problem with a spectral-element code, and analyze the temporal dynamics of the azimuthal Fourier modes associated with the large-scale motions. Focusing on the first several modes, we document the processes that govern their evolution and interactions, including the in-mode processes, such as fast and slow rotations, as well as inter-mode interactions associated with the mode cessations and transitions. Time scales associated with these processes are analyzed.

Curvature of magnetic field in plasma turbulence

Yan Yang, Minping Wan, Southern University of Science and Technology, Riddhi Bandypadhyay, William Mattheus, University of Delaware, Yipeng Shi, Peking University, Tulasi Parashar, University of Delaware, Quanming Lu, University of Science and Technology of China, Shiyi Chen, Southern University of Science and Technology — Magnetic field lines undergo stretch-twist-fold processes in the presence of turbulence. The curvature field, measuring the tangling of the magnetic field lines, is studied in detail here, using both simulations and observations. The probability distribution function (PDF) of the curvature has distinct power-law tails for both high and low limit values. A central finding is that high curvature co-locates with low magnetic field, which gives rise to the power-law tail of PDF at high curvature. The curvature drift term that converts magnetic energy into flow and thermal energy, largely depends on the curvature field behavior, a relationship that helps to explain particle acceleration due to curvature drift. This adds as well to evidence that turbulent effects most likely play an essential role in particle energization since turbulence drives stronger tangled field configurations, and therefore curvature.

Shear and buoyancy effects in the spatial organization of Stratocumulus clouds

Monica Zamora Zapata, Jan Kleissl, University of California, San Diego — The convective nature of Stratocumulus (Sc) clouds involves the motion of updrafts and downdrafts, driven by cloud-top radiative cooling and surface heat fluxes. Spatially, updrafts reach thicker cloud regions, while downdrafts are found at the thinner or cloud free regions. The balance of surface shear and buoyancy changes the coherent structures (Moeng and Sullivan, 1997). Surface rolls appear with stronger shear, and cells appear when buoyancy dominates. While stronger surface shear increases the cloud fraction of Cumulus clouds (Park et al., 2016), the shear effect on Sc clouds is unknown. Moreover, shear can also occur at the cloud top, where it erodes the Sc cloud from the top (Wang et al., 2012), but the effect on the horizontal spatial properties (aspect and cloud fraction) is unclear. In this work, we study the spatial organization of Sc clouds as a function of shear and buoyancy. We vary the heat flux and wind speed in Large Eddy Simulations (UCLA-LES) of the DYCOMS II RF01 reference case. Cells and rolls are observed at the surface depending on the heat flux and wind speed conditions, with clouds aligning in the direction of the wind for strong surface rolls. On average, the cloud base is more flat and cloud fraction is larger for stronger surface buoyancy.

Short-Wave Instability for Low Reynolds Number Flow over an Inclined Spinning Circular Disk at High Tip-Speed Ratios

Marcus Lee, Tim Colonius, Beverley McKeon, California Institute of Technology — Spin stabilization motivates the study of spinning circular disks for potential application to micro air vehicle design for increased flight robustness. We use a three-dimensional immersed boundary lattice Green’s function method (IBLGF) to simulate flow over a spinning circular disk at angle of attack for Reynolds numbers of $O(10^5)$ and tip-speed ratios up to 3. A short-wave instability emerges in the advancing tip vortex for tip-speed ratios greater than about 1.9. This instability is not present in the non-spinning case and can exhibit frequency lock-in behavior either with the rotation of the disk or with the vortex-shedding instability. Spectral proper orthogonal decomposition (SPOD) of the flow field isolates high-energy modes that help to characterize these instabilities and their coupling.

The simulations presented here used the Extreme Science and Engineering Discovery Environment (XSEDE), which is supported by National Science Foundation grant number CTS120005.
3:49PM M02.00030 Layering, transport and jet formation in rotating, stratified flows with a thermal wind. 1. STEVEN TOBIAS, ADRIAN BARKER, CHRIS JONES, University of Leeds — The Goldreich-Schubert-Fricke (GSF) instability may provide an important contribution to angular momentum transport in planets and stars. We investigate the nonlinear development of the instability, in particular noting the tendency for the transport to be affected by the formation of layers. This is perhaps not surprising as the linear and nonlinear evolution of the equatorial axisymmetric instability is formally equivalent to the salt fingering instability. This is no longer the case in 3D, but we find that the 3D equatorial instability behaves nonlinearly in a similar way to salt fingering. We propose and validate numerically a simple theory for nonlinear saturation of the GSF instability and its resulting angular momentum transport. Away from the equator the nonlinear development is more complicated with layers formed, though these are not perpendicular to the direction of gravity. We conclude by discussing the implications for transport of heat and angular momentum in planets and stars.

3:50PM M02.00031 Evaporation driven Rayleigh-Taylor instabilities in aqueous polymer solutions. ENDRE MOSSIGE, VINNY SUJA, SAM WHEELER, Stanford University, MEIRBEK ISLAMOV, Columbia University, GERALD FULLER, Stanford University — Understanding the mechanics of detrimental convective instabilities in drying polymer solutions is crucial in many applications such as the production of film coatings. It is well known that solvent evaporation in polymer solutions can lead to Rayleigh-Benard or Marangoni-type instabilities. Here we demonstrate another mechanism, namely that evaporation can cause the interface to display Rayleigh-Taylor instabilities due to the build-up of a dense layer at the air-liquid interface. We study experimentally the onset time \( (t_\text{p}) \) of the instability as a function of the initial polymer concentration \( (c_0) \) and molecular weight. In dilute solutions, \( t_\text{p} \) shows two limiting behaviors. For high diffusivity polymers (low molecular weight), the pluming time scales as \( c_0^{-2/3} \), while in the absence of diffusion, the pluming time scales as \( c_0^{-1} \). Above a critical concentration, \( c_\text{c} \), viscosity delays the growth of the instability, resulting in \( t_\text{p} \) scaling as \( (c_\text{c}/c_0)^{2/3} \). These scaling results are not restricted to polymer solutions or evaporation driven instabilities, but are transferable to other binary systems undergoing gravity driven instabilities.

3:51PM M02.00032 ABSTRACT WITHDRAWN

3:52PM M02.00033 Chaotic and steady regimes of elasto inertial turbulence in 2D channel flows 1. FUQIAN YIN, University of Vermon, USA, JACOB PAGE, RICH KERSWELL, Cambridge University, UK, VINCENT TERRAPON, University of Liege, VICTOR STEINBERG, Weizmann Institute, Israel — Elasto inertial turbulence (EIT) is a non-laminar state of flow occurring in polymer solutions in subcritical and supercritical flows. In 2D subcritical channel flows, the drag increases owing organized polymer dynamics which create flow structures through a backward energy transfer between polymer and the flow. Using viscoelastic direct numerical simulation based on the FENE-P model, we find two main regimes of flow: Chaotic and steady regimes with various variations in between these two bounds. Chaotic flows consist of elongated thin sheets of first normal stress with no particularly defined spacing between the sheets. In steady flow, a peculiar structure, dubbed the super core structure (SCS), emerges. Its existence is controlled by the polymer length and its shape varies with the Weissenberg number. The SCS has exceptional persistence and is speculated to be an exact solution of the flow, as well as a possible connection between EIT and elastic turbulence occurring in inertial-less flows.

3:53PM M02.00034 Sources of flexible wall excitation and wall-pressure fluctuation in turbulent channel flow 1. SREEVATSA ANANTHARAMU, KRISHNAN MAHESH, University of Minnesota - Twin Cities — Structural excitation by turbulent flows result in vibration. We present one-way coupled fluid structure interaction simulations of linear elastic and viscoelastic plates for different material and geometric properties excited by wall-pressure fluctuations generated from Direct Numerical Simulation (DNS) of incompressible turbulent channel flow at \( Re \text{v} \) of 180 and 400. Fluid DNS simulation is carried out in a moving frame of reference using the discrete kinetic energy conserving finite volume method of Mahesh et al. (2004) and the solid simulation is performed in stationary frame of reference using the finite element method. The one-way coupled results are analyzed by a novel framework that represents the plate averaged response spectral density as a double integral of the net source wall-normal cross-spectral density computed for both \( Re \text{v} \) using DNS data. The relative magnitude and phase of the cumulative sources for different frequencies is obtained using spectral proper orthogonal decomposition. Similar technique is applied to analyze the wall-pressure fluctuation spectra. The distribution and the properties of the net sources that contribute to the plate averaged response and wall-pressure fluctuation spectra is discussed for both \( Re \text{v} \).

3:54PM M02.00035 Experimental study of a forced plume in a linearly stratified environment using simultaneous measurements of velocity and density fields. HARISH MIRAJKAR, PARTHO MUKHERJEE, SRIDHAR BALASUBRAMANIAN, Indian Institute of Technology, Bombay India — We present the results of local small-scale measurements of a vertical forced plume ejecting into a linear stably stratified environment, with a stratification strength of \( N = 0.4 s^{-1} \). High-resolution measurements of velocity and density fields were acquired using simultaneous Particle Image Velocimetry (PIV) and Planar Laser Induced Fluorescence (PLIF). The refractive indices of the ambient and the plume fluids were matched to avoid optical aberrations. The energetics of an evolving forced plume were studied by measuring the terms in kinetic energy budget terms, such as mechanical production \( (P) \), buoyancy flux \( (B) \), and dissipation \( (\epsilon) \). The \( P \) and \( \epsilon \) magnitude decreases with increase in the height, while the magnitude of buoyancy flux \( B \), decreases with height and becomes zero at the neutral buoyant layer \( (Z_n) \). Below the neutral buoyant layer, the buoyancy flux, \( B \), shows presence of unstable motions and its sign changes as the plume intrudes into the neutral buoyant layer, indicating stability. The Kolmogorov -5/3 spectral slope is evident in the one-dimensional spatial spectra, indicating the existence of the inertial subrange.
3:55PM M02.00036 Effect of control parameters of traveling-wave blowing and suction on relaminarization phenomenon in fully developed turbulent Taylor-Couette flow

HIROYA MAMORI, The University of Electro-Communications, KOHEI OGINO, KOJI FUKUDOME, Tokyo University of Science, NAOYA FUKUSHIMA, Tokai University, MAKOTO YAMAMOTO, Tokyo University of Science — Direct numerical simulations of turbulent Taylor-Couette flows are performed to investigate the effect of control parameters of a traveling wave control. A traveling wave-like blowing and suction is imposed on inner or outer cylinder walls. The control is aiming the torque reduction effect. A parametric study is conducted to clarify the range of the control effect. A result shows a range of not only torque reduction but also relaminarization phenomenon of turbulent flow. In the inner wall control case, for example, the relaminarization phenomenon occurs, when the wave travels in corotating direction, the wavelength is long, and a wavspeed is faster than the wall velocity of the inner cylinder. We will also discuss the influence of the traveling wave on the Taylor vortex.

3:56PM M02.00037 An affine reconstructed discontinuous Galerkin algorithm for diffusion

YANG SONG, BHUVANA SRINIVASAN, Virginia Tech — In recent years, the discontinuous Galerkin (DG) method has been successfully applied to solving hyperbolic conservation laws. Due to its compactness, high order accuracy, and versatility, the DG method has been extensively applied to extension-convection-diffusion problems. Reliable DG algorithms for hyperbolic terms are well studied. However, an accurate and efficient diffusion solver still constitutes ongoing research, especially for a nodal representation of the discontinuous Galerkin (NDG) method. An affine reconstructed discontinuous Galerkin (aRDG) algorithm is developed in this work to solve the diffusion operator using unstructured NDG method. The proposed numerical approach is computationally efficient, uses minimal storage, and achieves the same order of accuracy as the conventional DG hyperbolic solver. Convergence studies will be presented along with numerical simulations of Rayleigh-Taylor instability growth in the presence of various diffusive mechanisms.

3:57PM M02.00038 Analysis of the Flow Over a Sphere Using Direct Simulation Monte Carlo Method in OpenFOAM

TADD YEAGER, DOUGLAS FONTES, MICHAEL KINZEL, University of Central Florida — Continuum assumptions are not valid for some flows such as those found in cases involving atmospheric reentry. For these kinds of problems, the flow field cannot be solved considering the average physical properties (usually used to describe the effects of molecular interactions) as the basic physical processes. The flow field is often characterized by the Knudsen number, which is related to the ratio of the flow’s Mach and Reynolds numbers. Aiming to study of the effects of these relevant dimensionless parameters as they pertain to flow over a blunt body, this paper presents an analysis of rarefied flow over a stationary sphere modeled using the Direct Simulation Monte Carlo (DSMC) method. In these simulations, high subsonic and supersonic flows of air are to be considered and discussed. These cases are simulated using the dsmcFoam solver from OpenFOAM. The preliminary average results of the surface force density and pressure distribution around the sphere surface are consistent with known physics, as are the velocity and momentum fields. Different particle velocities and particle number density should be evaluated to provide a better understanding of interactions between rarefied free stream flow and blunt solid bodies.

3:58PM M02.00039 Stability analysis without numerics: analytic approximations to the pseudospectra of linear operators in fluid mechanics

SCOTT DAWSON, Illinois Institute of Technology — The pseudospectra of a linear dynamical system determine the extent to which, and nature by which, disturbances to the system at a given frequency can be amplified. In practice, pseudospectral analysis (or equivalently, input-output or resolvent analysis) proceeds by computing leading singular values and vectors of the associated discretized operator. This talk will describe a methodology by which the pseudospectra of linear differential operators can instead be closely approximated by prescribed analytic functions. The methodology utilizes results and intuition from wavepacket pseudospectral theory to assume a general form of optimal pseudospectral modes, from which specific mode shapes and growth factors may be obtained by solving a low-dimensional optimization problem for a small number of unknown parameters. This method gives substantial computational savings over standard numerical approaches, and produces accurate results across regimes relevant to real flows. In particular, in such regimes the difference between numerically computed solutions and analytic approximations are typically much smaller than \( \epsilon \) for the \( \epsilon \)-pseudospectrum. We will further discuss connections to other nonmodal stability tools, such as optimal transient energy growth analysis.

3:59PM M02.00040 Scale dependence of entrainment bubble size distribution in free-surface turbulence

XIANGMING YU, KELLI HENDRICKSON, DICK YUE, Massachusetts Institute of Technology — Air entrainment by free-surface turbulence plays important roles in both natural processes and engineering applications. We consider the size spectrum of surface entrained bubbles under strong free-surface turbulence (SFST) and develop a physical/mechanistic model for the entrainment bubble-size spectrum per unit interface area \( \mathcal{N}_e(r) \). The model defines the spectrum dependence on gravity \( g \), surface tension \( \sigma / \rho \), and turbulence dissipation \( \epsilon \), and obtains two distinct entrainment regimes separated by bubble-size scale \( r_0 \). From the model we show that \( r_0 = r_c = \frac{1}{2} \sqrt{g \sigma / \rho g} \), the capillary length scale, and not the Hinze scale \( r_H \) as is generally assumed. For an air-water interface and earth gravity, \( r_c \approx 1.5 \text{mm} \). We confirm the theoretical model by high-fidelity, two-phase, volume-conserving direct numerical simulations (DNS) of a canonical SFST flow. We will present: (1) the respective power-laws of the two regimes; (2) the value \( r_0 = r_c \neq r_H \); (3) the scaling of \( \mathcal{N}_e \) with \( g \sigma / \rho \) and \( \epsilon \); and (4) confirmation of the \( \epsilon \)-- \( r \) entrainment regime map predicted by the model.

4:00PM M02.00041 Investigation of the effect of evaporating ocean spray on the air-sea heat fluxes in high-wind conditions

YEVENII RASTIGEJEV, North Carolina Agricultural and Technical State University, SERGEY A. SUSLOV, Swinburne University of Technology, Australia — We have studied the effect of evaporating ocean spray droplets of typical sizes on air-sea heat fluxes in a marine atmospheric boundary layer (MABL) with various vertical profiles of air temperature and moisture and values of turbulence intensity in high-wind conditions. We have found that the vertical latent and total heat fluxes are strongly enhanced by large spray droplets with radii 0.5mm because their presence results in steep vertical gradients of moisture and temperature in a MABL. The effect of small droplets on the total heat flux is not as profound: fine spray primarily redistributes thermal energy between its latent and sensible components. We have shown that spray affects the turbulent kinetic energy (and thus the intensity of the vertical turbulent transport) mostly mechanically (by altering the vertical distribution of mass density of the air-spray mixture) rather than thermodynamically (by changing vertical distributions of the air temperature and moisture). We have compared the dependence of the total vertical heat flux on the wind speed produced by the current model with the observation data that show seemingly anomalous growth of the vertical heat flux with the wind speed. We showed that this may be explained by the presence of ocean spray in a MABL.

This research was made possible by a grant from the Gulf of Mexico Research Initiative.
4:08PM M02.00049 Oil Droplet and Sediment Suspension in Laboratory-Scale Stommel Retention Zones, CARLOWEN SMITH, ZONGZE LI, University of South Florida Department of Mechanical Engineering, ANDRES TEJADA-MARTINEZ, University of South Florida Department of Civil and Environmental Engineering, DAVID MURPHY, University of South Florida Department of Mechanical Engineering — Langmuir supercells are helical wind- and wave-driven circulations in the ocean with alternating regions of upwelling and downwelling that extend to the full depth of the water column. These flows can trap suspended materials in sub-surface regions of turbulent vertical motion known as Stommel Retention Zones (SRZs), an effect that can specifically impact oil-particle aggregation following an oil spill. We present a laboratory facility recreating some aspects of SRZs and its characterization using PIV. The experimental facility consists of a 10.20.5 m tank in which a shear stress is applied on the side walls using conveyor belts, resulting in a counterrotating vortex pair with either a central downwelling or upwelling region of variable strength and turbulent kinetic energy. Mean up/downwelling flow speeds range from 0.05-0.2 m/s, where turbulent kinetic energy ranges over two orders of magnitude. The facility is used to study oil and particle dynamics within these zones of turbulent retention. Positively buoyant oil droplet and negatively buoyant sediment particle trajectories and spatial concentration fields are quantified, and droplet retention is then compared with sediment suspension, yielding information about the expected efficiency of oil-particle aggregation.

4:09PM M02.00050 3D PTV in a spray cloud from wave impact with wind interaction, REYNA RAMIREZ DE LA TORRE, ATLE JENSEN, UiO — Marine icing is a phenomenon of growing importance due to the increase of marine traffic in the Arctic sea. An interesting example is the ocean spray freezing on top of vessels. However, its dynamics is still to be understood. These type of studies are important for the safety of people, ships and installations that operate in the Arctic environment. It has been reported that sea spray formation is caused mainly by wave impact and wind. Therefore, an experimental model of this phenomenon was created to describe the trajectories of droplets in the spray cloud generated by wave impact and wind. The experiments were developed in the wave plume of the Hydrodynamics Laboratory in the University of Oslo. Breaking waves were generated, while a fan was used to produce wind on top of the waves. Droplet trajectories were reconstructed by 3D Particle Tracking Velocimetry. Using this setup we studied the dynamics of spray clouds with different wind conditions and compared the experiments with simulations. The overall goal is to develop solutions to reduce the icing of Arctic structures.

4:11PM M02.00052 Digital Aerodynamics, FLAVIO NOCA, HEPIA / HES-SO University of Applied Sciences, GUILLAUME CATRY, WindShape — Conventional wind tunnels have a limited number of fans. They are generally programmed to all turn at the same speed, thus generating a uniform and permanent flow. We have developed a technology to shape the morphology of wind in space and time. It is based on a large number of fans (wind pixels), which are distributed arbitrarily in space and can be modulated individually in time. We will provide preliminary experimental measurements on the correlation between a given fan-speed distribution and the resulting flow pattern in the test section using PIV and multihole pressure probes.

4:12PM M02.00053 ABSTRACT WITHDRAWN —

4:13PM M02.00054 ABSTRACT WITHDRAWN —

4:14PM M02.00055 Two-dimensional partially-ionized magnetohydrodynamic turbulence, SANTIAGO BENAVIDES, GLENN FLIERL, Massachusetts Institute of Technology — Ionization occurs in the upper atmospheres of Hot Jupiters and in the interiors of Gas Giant Planets, leading to Magnetohydrodynamic (MHD) effects which couple the momentum and the magnetic field, thereby significantly altering the dynamics. In regions of moderate temperatures the gas is only partially ionized, which leads to interactions with neutral molecules. To explore the turbulent dynamics of these regions we utilize Partially-Ionized MHD (PIMHD), a two-fluid model — one neutral and one ionized — coupled by a collision term proportional to the difference in velocities. Motivated by planetary settings where rotation constrains the large-scale motions to be mostly two-dimensional, we perform a suite of simulations to examine the parameter space of 2D PIMHD turbulence and pay particular attention to collisions and their role in the dynamics, dissipation, and energy exchange between the two species. We arrive at, and numerically confirm, an expression for the energy loss due to collisional heating in both the weakly and strongly collisional limits, and show that, in the latter limit, the neutral fluid couples to the ions and behaves as an MHD fluid.

4:15PM M02.00056 Multi-lens stereo reconstruction of the free surface waves in wave basin

1, HUA LIU, QIAN WANG, Shanghai Jiao Tong University, KEY LABORATORY OF HYDRODYNAMICS (MINISTRY OF EDUCATION OF CHINA) TEAM — A Multi-lens stereo reconstruction approach is developed to measure the free surface deformation of water waves in a wave basin. A massive of tiny granule served as the thin film floating on the free surface ensures the function of the common multi-lens stereo imaging technique in reconstructing the wave surface. The granule film and the highbrightness projector produces distinct pattern features on the free surface. The effect of the granule film on the wave propagation is checked which turns out that there is little influence on the wave propagation. Comparing the surface elevation computed from the reconstructed wave surfaces with the wave gauge data, a good agreement is found. The developed multi-lens stereo reconstruction approach is applied in investigating the propagation of a solitary wave over a submerged plate in a wave basin. The 3D deformation of the free surface with the high precision and efficiency for the considerable measuring area will be presented.

1This study is supported by the National Natural Science Foundation of China (Grant Nos. 11632012 and 14861144024).
3:20PM M03.00001 Long-term low shear of a waxy potato starch paste produces a highly viscous gel by formation of intermolecular double-helices.  FANG FANG, Whistler Center for Carbohydrate Research and Department of Food Science, Purdue University, XIAO ZHU, Information Technology at Purdue (ITaP), Purdue University, MARIO MARTINEZ, Whistler Center for Carbohydrate Research and Department of Food Science, Purdue University, OSVALDO CAMPANELLA, Whistler Center for Carbohydrate Research, Purdue University, Department of Food Science and Technology, The Ohio State University, BRUCE HAMAKER, Whistler Center for Carbohydrate Research and Department of Food Science, Purdue University — Our group recently reported that waxy potato and corn pure starch amylopectin pastes undergo a shear-thickening behavior at a low shear rate range of 5 to 25 s⁻¹, and that the effect did not occur in waxy rice starch. Here, we show that gelatinized potato amylopectin subjected to prolonged shear at 20 s⁻¹ for 24 h at 5°C produced a highly viscous gel with 5x more double-helices than without shear. Shear-induced aggregates formed within 20 min. Double-helices melted between 40 to 75°C leading to a total loss of gel elasticity and a steep decrease in G’, indicating that the retrogradation process occurred in part among amylopectin molecules (i.e. intermolecularly). Thus, a new phenomenon is reported whereby waxy potato amylopectin with long linear chains forms double-helical aggregated structures in the presence of long-term low shear that dramatically affects material properties.

3:21PM M03.00002 Numerical and experimental investigation of fluid flow in tapered orifices for needle-free injectors.² YATISH RANE, JEREMY MARSTON, Texas Tech University — Transdermal drug delivery using spring-powered jet injection has been studied for several decades, and is an attractive option for delivery of highly viscous and non-Newtonian fluids. In particular, third-generation vaccines such as DNA-vaccines have shear-thinning behaviour, which dictates the need to study the influence of fluid rheology in jet injection. Here, numerical simulations are performed with steady state flow and turbulence modelling based on the system Reynolds number at the orifice to generate characteristic curves of dimensionless pressure drop (Euler number) versus generalized Reynolds number. The results are experimentally validated for a given geometry over a wide range of Reynolds numbers (10¹ - 10⁴), and we find shear-thinning (Carreau) fluids with high zero-shear viscosities can be injected due to the presence of high shear (10⁶) regions near the orifice. In addition to fluid rheology, the orifice geometry (e.g. conical, multi-tier tapers and sigmoid contraction) is varied to study boundary layer thickness, which also affects jet collimation. Ultimately, our results indicate there may be optimal geometries for creating jets to target specific tissue depths.

3:23PM M03.00004 Acoustic Streaming in Confined Liquid Subject to High Intensity Focused Ultrasound (HIFU) Exposure³ GHADEM OWEIS, HUSSEIN DAOUD, RASHA SEBLANY, Mechanical Engineering, American University of Beirut — HIFU is an ex-corporeal therapeutic modality for the non-invasive treatment of tumors. A HIFU transducer emits spherically focused ultrasonic energy unto the target tissue deep under the skin, which is consequently absorbed and turned into heat, causing thermal ablation. Non-thermal effects can be present too, including cavitation bubble formation, radiation force, and acoustic streaming. The liquid streaming patterns were elucidated in previous HIFU investigations in an infinite medium. The aim of this study is to probe the effect of fluid confinement size on acoustic streaming. Two cubic water cuvettes of 5 mm, and 20 mm confinements were placed in an acoustic-coupling water bath at the geometric focus of the HIFU transducer (1.6 MHz, f ≠ 1, 60 mm). A single 30 ms HIFU pulse exposure was used. PIV was implemented to measure the centerline streaming field (radial and axial components) at the end of the acoustic emission (avg. of 100 repeats). Significant differences were found in the flow patterns between the small (5 mm) and large (20 mm) confinements. The streaming velocity levels were also dramatically different. In conclusion, fluid confinement has a very important effect on the streaming flow from HIFU.

³The data for this study were acquired for the course project (MECH 609, Exp. Fluid Dynamics, AUB, 2017)

3:24PM M03.00005 Could an implantable sensor both monitor lung flow and generate power?⁴ LUCY FITZGERALD, LUIS LOPEZ RUIS, JIANZHONG ZHU, JOHN LACH, DANIEL QUINN, University of Virginia — The rise of Smart Health has led to implantable healthcare devices that can diagnose and monitor diseases in real-time. Some diagnoses are based on fluids in the body, like asthma. A key challenge of current implantables is that they are difficult to power and require surgeries to replace batteries. We show that a piezoelectric flow sensor could monitor a fluid flow and simultaneously power itself from that flow. The effectiveness of this sensor/harvester depends on flow properties. It therefore demands advanced models that capture tradeoffs between sensing fidelity and harvesting potential. To develop these models, we built a platform for testing the sensing/harvesting capability of piezocantilevers in airflows modeled after human breathing. We found that oscillating voltage on the piezocantilever can both charge a capacitor and map to the amplitude and frequency of the breath. We explored how well models can predict harvesting and sensing potential based on breath type. These models open up a broad range of applications that we are exploring, including a smart stent that alerts patients to obstructions or dislodging. How these models scale with flow speed/direction, turbulence intensity, and cantilever size offer design ideas for sensing/harvesting in other bodily channels.

3:25PM M03.00006 Physics-Informed Deep Neural Nets for Super-Resolution, Denoising, and Velocity-Aliasing Correction of 4D-Flow MRI ROSHAN D’SOUZA, University of Wisconsin-Milwaukee, MOJTABA FATHI, ISAAC PEREZ-RAYA, University of Wisconsin - Milwaukee — 4D-Flow MRI is a non-invasive method for measuring blood velocities in the human vascular system. It suffers from issues such as low spatio-temporal resolution, acquisition noise, and velocity-aliasing artifacts. Here, we present a novel method based on physics-informed Deep Neural Nets (DNNs) for super-resolution, denoising, and velocity-aliasing correction of 4D-Flow MRI. The inputs are the sparsely-sampled 4D-Flow MRI images and a rough geometry mask. The loss function used to train the physics-informed DNN contains terms for volume-averaged data fidelity and point-wise flow physics. Noise is reduced by using an averaging filter on the input data as well as the DNN predictor. Velocity aliasing is handled by computing data fidelity in the velocity encoding space. The trained DNN can be sampled at any desired resolution to generate noise-free flow images without velocity aliasing. Preliminary tests on CFD-derived 2D synthetic data shows that the method is able to automatically address all the aforementioned issues with normalized-root-mean-squared-error in velocity less than 4.8 percent and direction error less than 0.096 when compared to the reference CFD.
3:26PM M03.00007 MRI-based modeling of CSF flow in the spinal canal1. JENNA J LAWRENCE, WILFRED COENEN, University of California San Diego, CANDIDO GUTIERREZ-MONTES, Universidad de Jaen, ANTONIO L SANCHEZ, University of California San Diego, CARLOS MARTINEZ-BAZAN, Universidad de Jaen, KEVIN KING, Huntington Medical Research Institutes, VICTOR HAUGHTON, University of Wisconsin Madison, JUAN C LASHERAS, University of California San Diego — The oscillatory flow of cerebrospinal fluid (CSF) in the subarachnoid space of the spinal canal is driven by the intracranial pressure fluctuations associated with cerebral blood flow and by the thoracic pressure fluctuations associated with the respiratory cycle. We have previously derived simplified flow models by exploiting the slenderness of the subarachnoid space and the limited deformation of the dura membrane. Application of these models to a specific human subject requires knowledge of their spinal-canal anatomy and of both their spinal-canal and cranial-cavity compliance. We show how this specific information can be extracted from high-resolution magnetic resonance (MR) imaging of the anatomy, along with MR phase-contrast flow measurements of venous and arterial blood flow at the C2 level and of CSF flow at several transverse sections along the spinal canal. We then show how the resulting subject-specific model can be used to predict steady bulk motion and drug-dispersion rates.

1National Science Foundation, Award Number 1853954

3:27PM M03.00008 In Vitro Assessment of Cycle to Cycle Flow Variability in Intracranial Aneurysms using Radial 4D Flow MRI and Tomographic PIV., RAFAEL MEDERO, KATRINA RUEDINGER, DAVID RUTKOWSKI, KEVIN JOHNSON, ALEJANDO ROLDN-ALZATE, University of Wisconsin-Madison — Intracranial aneurysm rupture has been related with aneurysm geometry, and high flow activity. 4D Flow MRI has been shown to be a feasible imaging technique for assessing hemodynamics in different vascular territories. However, one of its limitations is the need to average several cardiac cycles to obtain a complete data set, causing a smoothing of the velocity profiles and errors in areas with non-laminar flow. Additionally, it requires prospective determination of the velocity encoding setting, restricting the range of velocities acquired. Furthermore, the need for reasonable scan times can lead to limits in spatial resolution, which motivates the development of improved MRI sequences such as radial acquisitions. In this study, velocities acquired with radial 4D Flow MRI where compared to tomographic PIV using a patient-specific intracranial aneurysm in-vitro model under pulsatile flow. Velocity data from multiple time points within a group of 10 cardiac cycles acquired with tomo-PIV were compared pixel-to-pixel, and averaged velocity data was compared between methods. Statistically differences were found between velocities measured with tomo-PIV at peak systole and end diastole. However, good agreement was seen when comparing 4D Flow MRI with the average time points.

3:28PM M03.00009 An experimental study of pulsatile flow over rectangular sidewall cavities, RUIJANG ZHANG, BENJAMIN EICHHOLZ, YAN ZHANG, North Dakota State University — Open cavity flow is a classic benchmark fluid dynamic model that has been extensively studied over the past decades. The existence of the free shear layer causes variations of vortex structures and flow stagnations inside the cavity in different flow regimes. However, how the flow pulsatility affects the vortex dynamics of the cavity flow is still not fully understood. Such question is of critical importance to many biological flow phenomena, such as blood past the brain aneurysms and left atrial appendage blood flows. The goal of this study is to reveal the flow characteristics of two simple rectangular sidewall cavity models under physiologically-relevant pulsatile flow. Cavities with two depth-to-width ratios were studied. Flow waveforms were generated using a programmable pulsatile pump to mimic the heart functions. Phase-locked PIV were conducted to study the cyclic variation of vortex flow structures inside and across the cavity. The velocity and vorticity fields were analyzed and found to significantly vary at different peak Reynolds numbers, Womersley numbers, and pulsatility indices. This study represents a systematic experimental effort towards pulsatile flow over a standard cavity model, which could serve as a benchmark for future computational simulations.

3:29PM M03.00010 Elucidating Left Ventricular Hemodynamics and Aggregation Zones Using Platelet-focused Lagrangian analysis1, VENKAT KESHAV CHIVUKULA, FANETTE CHAS-SAGNE, JENNIFER BECKMAN, CLAUDIUS MAHR, ALBERTO ALISEDA, University of Washington — Left Ventricular Assist Devices (LVAD) have improved significantly over the last three decades and its use has expanded beyond the original Bridge-to-transplant indication. Thromboembolic complications, however, have not decreased in frequency or severity despite the advances in pump design. We investigate unfavorable hemodynamics in the left ventricle (LV) of a HF patient implanted with an LVAD. High-fidelity computational fluid dynamics are used to quantify thrombogenicity in the LV for several implantation configurations. Platelet Lagrangian tracking characterize the mechanical stimuli along individual trajectories, including residence time and shear stress history. Rigorous statistical analysis reveals recirculation zones inside the LV where platelet aggregation and thrombus formation can occur. PIV in a flow phantom implanted with a real-world LVAD provides validation. Clinically relevant parameters and patient management strategies are considered. A mathematical valve opening that encourage the patient’s ventricular contraction are assessed to optimize intraventricular flow patterns. Risk stratification is demonstrated to develop strategies that minimize stroke risk and have the potential to improve patient outcomes.

1This work was partially supported by an AHA postdoctoral fellowship 16POST30520004 and the Locke Trust Foundation of the University of Washington

3:30PM M03.00011 Hemodynamics of the left heart with physiologic and pathologic mitral valve: the chordae tendinae effect, ROBERTO VERZICCO, Uniroma2, UTwente, GSSI, VALENTINA MESCHINI, Uniroma2, FRANCESCO VIOLA, UTwente — One of the advantages of computational engineering is the possibility to vary one factor of a system, while leaving the others unchanged, and to assess its effect. In cardiovascular flows this strategy allows to selectively investigate modifications of the intraventricular hemodynamics produced by myocardial tissue remodeling or pathologies. In this study, we rely on our in-house multi-physics numerical model that dynamically couples electrophysiology, tissue mechanics and hemodynamics in physiological and pathological conditions to carry out direct numerical simulations of the left heart dynamics. Here, we present the effect of loose or broken chordae tendinae of the mitral valve on the ventricular pumping efficiency in terms of cardiac output, valve regurgitation and large scale flow structures. The results are seen to agree with the available clinical data, thus suggesting that this computational tool could be used to predict the effects of a valve sparing procedure and to improve the outcome of a surgical interventions.
3:31PM M03.00012 Computational Hemodynamics of Prosthetic Aortic Valves with Application to Continuous Monitoring of Valve Function1. SHANTANU BAILLOOR, JUNG-HEE SEO, Johns Hopkins University, HODA HATOUM, LAKSHMI PRASAD DASI, Ohio State University, RAJAT MITTAL, Johns Hopkins University, JOHNS HOPKINS UNIVERSITY TEAM, OHIO STATE UNIVERSITY TEAM — Transcatheter heart valves suffer from complications such as leaks, thrombosis, endocarditis etc. Of these, sub-clinical or clinical thrombosis, even if resolved by anti-coagulation therapy, impacts the long-term durability of the valve. Technology to help avoid these complications and detect them very early is key towards advancing heart valve therapy. A small number of wireless pressure micro-sensors mounted at strategic locations on the valve frame could enable continuous monitoring and alerting to very early stages of thrombosis or other complications, as well as to guide anti-coagulation therapy or other clinical management. We employ hemodynamics simulations of transvalvular flow in a canonical model of the aorta with a transcatheter valve and determine optimal sensor configurations for discriminating between healthy leaflets and those exhibiting reduced mobility. By applying machine-learning based techniques to a large cohort of in-silico aorta models, we demonstrate that a small number of in-situ sensors can effectively predict early-stage leaflet abnormalities.

3:32PM M03.00013 A novel 1D flow model for transient FSI simulation of aortic valve , HAOXING LUO, YE CHEN, Vanderbilt University, LUO LAB TEAM — In contrast with costly 3D flow simulations, simple aortic flow models are much more efficient and have applications in non-invasive clinical flow measurement as well as design optimization of prosthetic valves. Existing simple flow models are typically based on the old Bernoulli principle. In this work, we have developed a novel one-dimensional (1D) unsteady flow model based on the momentum and mass conservation equations, which takes into consideration of both valve movement and pressure loss through the valve. We couple this simplified flow model with a 3D FEM model of the thin-leaflet aortic valve as a 1D/3D hybrid model and perform FSI simulations for the valve of different bending rigidity. The nonuniform pressure distribution on the leaflets is included in the simulation. The full 3D FSI model that simulates the 3D pulsatile flow fully coupled with the same valve is used to assess the performance of the simplified flow model. The results show that the hybrid model is able to capture reasonably well the 3D deformation sequence of the leaflets, the valve opening area, and the flow rate, especially in the cases of low bending rigidity.

3:33PM M03.00014 Venous valve dynamic behavior and function: a computational investigation. MATTHEW BALLARD, PARKER ELLIOTT, Saint Martin’s University — To fulfill their role of returning blood from the body back to the heart, veins often need pumping beyond that provided by the heart. This is especially true where blood must be raised vertically a significant distance against gravity, such as from the deep veins of the legs. Thus, many veins contain a series of “venous valves” which open and close with pressure fluctuations to allow flow only in the direction back toward the heart. These valves enable veins to act as a series of “miniature hearts” that provide the requisite pumping effect. Under certain conditions including flow stasis associated with sitting still, long airplane flights and surgery, venous valves can become blocked through thrombus formation (deep vein thrombosis, or DVT), causing insufficient blood flow. Thrombi can even break free and become lodged in the lungs as a deadly pulmonary embolism (PE). We use a three-dimensional, fully coupled fluid-solid model based on the lattice-Boltzmann and lattice spring models to investigate the behavior of a viscous fluid and venous valves in a section of vein. We study the dynamics of venous valves and assess the effect of valve morphology on fluid transport. Further, we study flow in the valve region with a focus on understanding its effect on development of disease. This work increases our understanding of venous valve behavior and the resulting flow conditions, with possible applications in evaluating patient risk for DVT and in designing prosthetic venous valves.

3:34PM M03.00015 Can you hear better if you’re lopsided? Tympanic asymmetry may enhance hearing in a parasitoid fly1. MAX MIKEL-STITES, PAUL MAREK, ANNE STAPLES, Virginia Tech — *Ormia ochracea* is a parasitoid fly endemic to the Americas. Gravid females respond phonotactically to calls of their male *Gryllidae* cricket hosts. Astonishingly, *Ormia* can locate the source of sound equal to that much proucerates, in spite of their small size, which should prohibit this level of precision because of fundamental constraints imposed by the physics of sound propagation (Mason et al., Nature, 2001). Miles et al. demonstrated that *Ormia* is capable of resolving nanosecond time differences due to a direct mechanical coupling of the flies tympanic membranes (Miles et al., J Acoust Soc Am, 1995). This mechanical coupling increases the interaural time delay (ITD) between the tympana, thus enhancing the flies sound localization precision. Here, we introduce an asymmetry in tympanic area into the mathematical model provided by Miles et al. and demonstrate that an asymmetry of less than 10% between the left and right tympanal areas can more than double the ITD. We further present initial measurements of 44 *Ormia* tympana that demonstrate an average asymmetry in tympanal area of approximately 5%.

1Thank you to undergraduate Maddie Hellier for all her work measuring the O. ochracea tympanal membranes!

3:35PM M03.00016 Thumbs up! Bird’s thumb induces leading-edge vortex during slow gliding flight1. THOMAS LINEHAN, KAMRAN MOHSENI, University of Florida — The alula, or bird’s thumb, consists of a small set of feathers stationed near the bird’s wrist that protract from the wing during slow flight to enhance lift. The recent discovery of leading-edge vortices (LEVs) on the thin hand-wings of some birds suggest that the alula may play a role in LEV formation. Using stereoscopic-digital particle image velocimetry we measured the flow over a model wing with and without protracted alulae in a wind tunnel and made volumetric reconstructions of the three-dimensional vortex flow. We found that the alula induces and stabilizes a robust conical leading-edge vortex (LEV) that sweeps across the outer wing and smoothly merges with the tip vortex. LEV formation is the result of the alula scraping spanwise vorticity from the leading-edge shear layer and inducing its roll-up. The subsequent stabilization of the LEV is the result of root-to-tip spanwise flow in the LEV core of magnitude greater than 80% of the freestream value. In essence, the protracted alula, mimicking a canted flap, is a clever way of inducing and stabilizing a LEV on a steadily translating wing inclined to the flow at high angles. These results grant new insights into the intelligent design of the modern bird wing and have important implications for aircraft flight control.

3:36PM M03.00017 Wake Dynamics of Bat Flapping , VAIBHAV JOSHI1, RAJEEV JAIMAN, The University of British Columbia — Natural selection has evolved the geometry as well as mechanical properties of wings of a bat to achieve better flight performance, maneuverability and agility. The highly anisotropic and deformable membranes of the flapping wing and complex kinematics make their study more imperative for bio-inspired aerodynamic applications such as micro-air vehicles (MAVs). The current study is a first step towards understanding such complex flapping dynamics using a flexible multibody fluid-structure interaction framework. We aim to study the effect of the flexibility or compliance of the wing on the vortex dynamics and flight performance during hovering of the bat. We find that for the same power input to the flapping wing, the flexible compliant wing has better flight performance compared to its rigid counterpart. Moreover, the vortex structures generated supply more vorticity to the vortex ring patterns in the flexible wing leading to its large amplitude of deformation and unsteady lift coefficient.

3:37PM M03.00018 Hydrodynamic thrust generation by honeybee (Apis mellifera)1 , CHRIS ROH, MORTEZA GHARIB, California Institute of Technology — In our previous studies, we reported honeybee’s locomotion at the air-water interface. Their ventrally wetted wings beat at high frequency (30-220 Hz), which propel them forward. Honeybee’s locomotion on a water surface uses added mass as the dominant hydrodynamic force. Disregarding other forces, an added mass force associated with idealized sinusoidal wing kinematics is modeled. The resulting body movement shows good agreement with the experimentally measured body motion. Furthermore, body kinematics predicted based on the experimentally measured flow field under the mechanical model wing also shows similar locomotive pattern.

3:38PM M03.00019 ABSTRACT WITHDRAWN –

3:39PM M03.00020 Bioinspired Passively Actuated Microflap Surface for Improving Airfoil Performance1 , SEAN DEVEY, CHRIS JARMON, AMY LANG, PAUL HUBNER, The University of Alabama — Flow separation acts to limit the efficiency of aerodynamic systems. A novel dynamic surface is proposed as a mechanism to limit flow separation. This surface is derived from the flank skin of the shortfin mako shark, which has been proven effective at limiting flow separation in adverse pressure gradient flows. An array of passively actuable “microflaps” mimics the geometry and flexibility of mako flank denticles. It is hypothesized that these microflaps will respond to local reversing flows to passively enforce a selective flow direction and increase mixing within the boundary layer to limit flow separation. This surface has been produced with additive manufacturing and incorporated into the upper surface of a NACA 0012 airfoil. Low speed wind tunnel testing (Re ~2e5) of this airfoil is in progress. An increase in maximum lift and delay of stall is expected due to limiting of flow separation by the microflap array.

3:40PM M03.00021 Fluid dynamics of nutrient exchange through the branched arrays of sea fans and jellyfish oral arms , LAURA MILLER, University of North Carolina at Chapel Hill — Numerous small organisms that swim, fly, smell, or feed in flows at the mesoscale, where inertial and viscous forces are balanced, rely on branched, bristled and hairy structures. Such mesoscale structures can augment particle capture and nutrient exchange by moving in a manner to transition from acting as solid surfaces to leaky/porous rakes at Reynolds numbers close to one. Although mesoscale flows have been studied in many organisms, the fluid dynamic mechanisms underlying the leaky rake to solid plate transition remain unclear. A detailed understanding of how this leaky-to-solid transition affects chemical exchange and particle capture in mesoscale filtering, where advective and diffusive transport rates are nearly balanced, also remains unavailable. In this presentation, flow visualization and computational fluid dynamics will be used to quantify the fundamental fluid dynamics of biological filtering arrays in this regime. Two types of marine invertebrates will be examined for understanding mesoscale biological filters: 1) upside-down jellyfish that use bell pulsations to filter particles within 3D bristled oral arms, and 2) sea fans that are branched into approximately 2D sheets.

3:41PM M03.00022 CFD Time Machine: Using CFD to Understand the History of Long Extinct Swimmers , NICHOLAS HEBDON, KATHLEEN RITTERBUSH, University of Utah Geology and Geophysics, YUNJII CHOI, Jacobs Engineering Group — Ammonoids are a group of cephalopods that were found in oceans worldwide for nearly 300 million years. These organisms once swam freely in the ocean and were as abundant as fish are today but went extinct 65 million years ago in the same extinction that killed the dinosaurs. In this study, we use Computational Fluid Dynamics model (Ansys V18.0) to study the locomotion of these now extinct animals. The fossil record shows that ammonoids underwent numerous periods of evolutionary boom and bust. During these cycles, ammonoids with a planispiral shell type often show clear shifts in their shell morphology, strongly emphasizing traits such as lowered cross-sectional area or increased coiling exposure. However, because there are no modern members of the group and there is no soft tissue preservation, it has been difficult for researchers to understand the implications of these shifts on their swimming pattern. We used CFD to study the hydrodynamic impacts of their morphological transformation, in terms of drag and lift. Incremental changes in shell shape across three common shape characters were studied: Shell inflation (total shell width), Whorl Expansion (the rate at which coil diameter increases, and Umbilical Exposure (the ratio of exposed coiling to total diameter). Our results show that drag and lift are sensitive not only to the particular parameter being changed but also that they are non-uniformly sensitive to the direction (increasing or decreasing) and magnitude of how that parameter is being changed.
3:42PM M03.00023 Effect of viscosity on Lingulodinium Polyedrum micro swimmer motility and properties¹, LOURDES MNICA BRAVO ANAYA, Laboratoire Interdisciplinaire de Physique (LiPhy), HUGUES BODIGUEL, FRDRIC PIGNON, Laboratoire Rhologie et Procds, MARVIN BRUN-COSME-BRUNY, PHILIPPE PLEYLA, SALIMA RAFAI, Laboratoire Interdisciplinaire de Physique (LiPhy), LABORATOIRE INTERDISCIPLINAIRE DE PHYSIQUE (LIPHY) COLLABORATION, LABORATOIRE RHLOGIE ET PROCDS COLLABORATION — Lingulodinium Polyedrum (LP) microalgae is a marine protist, belonging to the dynoflagellata gender that emits bright blue light flashes once submitted to a shear stress. It carries an equatorial flagellum and a longitudinal one, allowing the swimming. In this work, we studied the effect of viscosity on LP microswimmer motility and bioluminescence properties through rheological measurements and a bright field microscopy imaging. The microalgae velocity dependency on the viscosity of the medium was measured in the presence of different concentrations of selected polymers. Xanthan was selected due to its shear-thinning behavior and a hydrolyzed polyacrylamide was also chosen due to its Newtonian behavior at concentrations lower than C*. These polymers were found to be biocompatible and stable in seawater and in presence of LP. The swimming velocity of LP microswimmer was found to be inversely proportional to the suspension viscosity for both polymers, suggesting that the force needed to stop the swimming LP cell remains constant. Finally, it was observed that the applied shear rate necessary for LP microalgae to emit bioluminescence decreases while increasing the suspension viscosity.

3:43PM M03.00024 Reversal of Flagellar Wave Propagation Is Controlled by Proximal to Distal Asymmetry in Molecular Motor Dynamics¹, FENG LING, YI MAN, EVA KANSO, University of Southern California — The '9+2' axoneme of the motile cilium/flagellum is an important cellular structure that is highly-conserved among eukaryotic cells. Asymmetries of dynein motors along the flagellum have been identified in a number of organisms, and they have been specifically linked to the reversal in the direction of flagellar wave propagation in certain trypanosomes. Trypanosomes are a class of single-celled parasites that are known to switch their flagellar beating between tip-to-base and base-to-tip waveforms. In this talk, we analyze cilia oscillations and direction of wave propagation in the context of a known geometric feedback model. We introduce proximal to distal asymmetry in the molecular motor dynamics, consistent with recent experiments on trypanosomes. We show that the experimentally-observed reversal of wave propagation is only achievable when sliding-control feedback is dominant. We conclude by commenting on the implications of these results to flagellar waveforms in other organisms, and the feasibility of a universal geometric feedback mechanism for explaining the diverse waveforms in cilia oscillations.

3:44PM M03.00025 Cilia-driven mixing and transport in complex geometries, HANLIANG GUO, HAI ZHU, SHRAVAN VEERAPANENI, University of Michigan, Ann Arbor — Cilia and flagella are self-actuated microtubule-based structures that are present on many cell surfaces, ranging from the outer surface of single-cell organisms to the internal epithelial surfaces in larger animals. A novel and exciting research direction is in vitro cell cultures is the development of engineered tissues in microfluidic chips, so called 'organs-on-chips'. A fast and reliable numerical method that simulates the coupled hydrodynamics of cilia and the constituent particles in the fluid such as rigid particles, drops or cells would be useful to not only understand several disease and developmental pathologies due to ciliary dysfunction but also to design microfluidic chips with ciliated cultures for some targeted functionality, e.g., maximizing fluid transport or particle mixing. Here we propose a hybrid numerical scheme that employs the boundary integral method for handling the channel and particle boundaries and the method of regularized Stokeslets for handling the cilia. The algorithm is efficient, easy to implement and scales linearly with the problem size. We provide several examples demonstrating the effects of complex geometries on cilia-generated fluid mixing as well as the cilia-particle hydrodynamics.

3:45PM M03.00026 Cryptographic analysis of chaotic fluid flows¹, WILLIAM GILPIN, Harvard Quantitative Biology Initiative — In computer science, hash functions are elementary operators that convert arbitrary-length inputs into finite-length outputs. We describe a direct analogy between these functions and the motion of particles advected by fluid flows, and we show that, when the governing flow is chaotic, hydrodynamic hash functions exhibit statistical properties typically associated with hash functions used for digital cryptography. These include non-invertibility, sensitivity to initial input, and avoidance of collisions, in which two similar inputs produce the same output. We show that this analogy originates from the tendency of certain chaotic flows to braid together particle trajectories across space in time in an irreducible manner, and we describe how techniques used to probe the properties of digital hash functions may be used to characterize the properties of flows when only limited observational data is available. Our findings have potential applications as microfluidic proof-of-work systems, as well as for characterizing large-scale transport by ocean flows and biological microswimmers.

3:46PM M03.00027 Development of a Microfluidic Device to Sort Sperm based on Rheotaxis Effect, AFROUZ ATAEI, ANDY W.C. LAU, WASEEM ASGHAR, Florida Atlantic University — The first step of in-vitro fertilization is to sort out the motile sperm from the non-motile ones. Currently, centrifugation based sperm swim-up and density gradient separation are commonly used methods. However, these methods reduce sperm quality during the repetitive centrifugation steps and isolate sperm with high DNA fragmentation. In this work, we construct a microfluidic device based on the observation that motile sperm can swim against the flow within a specific range of flow rates. This sperm sorting device consists of two chambers, separated by a filter. After 45 minutes the sorted motile sperm are collected from the top retrieval chamber and is placed on a glass slide for visual inspection and data collection. We find that 1) the most motile and functional sperm pass selectively through the micropores against the flow, 2) the optimum flow rate gives the highest concentration of motile sperm, the lowest DNA fragmentation and higher percentage of morphologically normal sperm compared to stock sample. Taken together, our device provide an efficient way to sort sperm without centrifugation.

3:47PM M03.00028 Bending of charged bilayer membranes¹, HAMMAD FAIZI, CODY REEVES, PETIA VLAHOVSKA, Northwestern University — Cells and internal cellular organelles are enveloped by membranes composed primarily of lipid bilayers. The bilayer bending rigidity (resistance to changes in curvature) plays a crucial role in cell deformations. We explore the effect of transmembrane potential on the bending rigidity. We experimentally analyze the dependence of bending rigidity on bilayer charge out of equilibrium due to charge accumulated near the membrane surfaces by an applied electric field. We measure the membrane bending modulus with three different techniques using the same giant unilamellar vesicle: equilibrium shape fluctuations, electrodeformation based on a frequency sweep, and shape fluctuations in the presence of uniform AC field.

3:48PM M03.00029 ABSTRACT WITHDRAWN —
Yasuda, Nonlinearity — Pattern formation of chemotactic bacteria is investigated numerically and theoretically based on a Boltzmann-like kinetic transport equation for chemotactic bacteria, say a kinetic model. The MC results illustrate the pattern formation mechanism of chemotactic bacteria induced by the stiff chemotactic response. Furthermore, the unstable modes are always bounded as is observed in Turing instability, so that instabilities are never growing. Our study reveals that slipper shape is the preferred equilibrium shape in low confinement (n = 0) while a transition to parachute shape takes place as n increases. Outward migration tendency due to higher viscosity contrast causes the shape transitions to occur at higher C_0 when λ = 0 compared to the case when λ = 1, resulting in a phase diagram shifted towards higher C_0.

3:51PM M03.00032 ABSTRACT WITHDRAWN —

3:52PM M03.00033 Numerical analysis of the pattern formation of chemotactic bacteria based on a kinetic transport model — SHUGO YASUDA, University of Hyogo — Pattern formation of chemotactic bacteria is investigated numerically and theoretically based on a Boltzmann-like kinetic transport equation for chemotactic bacteria, say a kinetic chemotaxis model. In the theoretical part, we discover a novel instability mechanism, i.e., stiff-response-induced instability [B. Perthame& S. Yasuda, Nonlinearity 31 (2018) 4065], where the uniform state of the bacterial population becomes unstable when the stiffness of the chemotactic response of bacteria is sufficiently large. Furthermore, the unstable modes are always bounded as is observed in Turing instability, so that the pattern formation occurs. A Monte Carlo method is also developed based on the kinetic chemotaxis model [S. Yasuda, J. Comput. Phys. 330 (2017) 1022] and the MC method is applied to the pattern formation problems of chemotactic bacteria in one- and two-dimensional spaces. The MC results illustrate the pattern formation mechanism of chemotactic bacteria induced by the stiff chemotactic response.

3:53PM M03.00034 3D vesicle microcirculation — DHVANIT AGARWAL, GEORGE BIROS, Oden Institute for Computational Engineering and Sciences, University of Texas at Austin — We study numerically the problem of equilibrium shapes of three-dimensional vesicles in confined axisymmetric Poiseuille flow. We explore a range of the following relevant dimensionless parameters: 1) reduced volume (a), defined as the ratio of volume of vesicle to the sphere of same area as vesicle, 2) viscosity contrast, λ, defined as the ratio of viscosities of internal and external fluids, 3) confinement ratio (C_n), defined as the ratio of vesicle diameter over channel width, 4) capillary number (C_0), measuring flow strength over membrane bending rigidity. We present a phase diagram of equilibrium shapes of vesicles, both with and without viscosity contrast. Our study reveals that the preferred equilibrium shape in low confinement (C_n < 0.5) while a transition to parachute shape takes place as C_n is increased. For high confinement (C_n >> 0.5), the force exerted by the confining walls dominates, causing the vesicle to mostly take axisymmetric shapes. Outward migration tendency due to higher viscosity contrast causes the shape transitions to occur at higher C_0 when λ = 0 compared to the case when λ = 1, resulting in a phase diagram shifted towards higher C_0.

3:54PM M03.00035 Design and validation of a microfluidic pillar device to study hemostasis under flow — HARI HARA SUDHAN LAKSHMANAN, Oregon Health and Science University, ADITYA PORE, Texas Tech University, RACHEL THOMPSON, Oregon Health & Science University, University of Connecticut, JEEVAN MADDALE, West Virginia University, PATRICK JURYNE, JOSEPH SHATZEL, Oregon Health & Science University, SIVA VANAPALLI, Texas Tech University, OWEN MCCARTY, Oregon Health & Science University — Hemostasis is an active process between plasma and blood cells, resulting in thrombin generation, platelet activation and fibrin formation to generate a hemostatic plug that staunches blood loss following vessel injury. The events that support hemostasis (outside the blood vessel) versus thrombosis (inside the blood vessel) are distinct in part due to the rheology of blood flow that differentially distributes blood constituents inside and outside blood vessels. We created an in vitro ‘bleeding chip’ to study the spatial dynamics and cell biology of hemostasis under shear flow. The bleeding chip consists of two orthogonal channels, with series of 3 pillars spaced 10 microns apart at the intersection of the channels acts as a model of endothelial cell barrier function between the intravascular and extravascular space. The bleeding channel is coated with extracellular matrix proteins. We found that platelets aggregate at or behind the pillars as a function of shear rate. Activation of the coagulation cascade staunches blood flow in the bleeding channel while blocking platelet function or coagulation prevented formation of a hemostatic plug. Based on the percolation theory of fluid dynamics, we will discuss the impact of platelet interactions during hemostasis.
to each of the phases and the aspect ratio of the particles are varied. Layers arresting coalescence with reduction of tumbling effects in the arrested state. The effects are changed when the affinity of the particles transition and droplet coalescence process is drastically reduced in presence of ellipsoids of varied hydrophobicity leading to formation of particle is observed with droplet deformation, coalescence and eventual collapse with the emulsion start breaking at the top of the cell. However, this effect govern the key features of elliptical particle-laden flows. As the denser liquid phase drains out, the dense to sparse emulsion transition with the orientation of the particles need to be accounted for because the mutual competition between these phenomena coupled with tumbling Model with long-range repulsive and frustrated short range attractive interactions. Both fluid-particle and particle-particle interactions along elliptical particles at droplet interfaces in a gravity-driven draining emulsion system consisting of a Newtonian fluid using 2D Lattice Boltzmann requires 60.6% less pressure drop than the reference. The results indicate the high potential of using charged nanoporous in reverse osmosis water desalination performance.

For the negatively charged membranes, optimum rejection efficiencies of 94% and 93% are obtained for Na\(^+\), \(\text{Cl}^-\) ions respectively, with 35% lower pressure drop than the reference. Simulations are performed for hydraulic pore diameter membrane as large as 14.40 Å with four different electric charges distributed on the pore surfaces. Pressure-driven flows are induced by moving specular reflection boundaries with a constant speed. Molecular dynamics (MD) simulations. Pressure-driven flows are induced by moving specular reflection boundaries with a constant speed. Dissipative relaxation of the order parameter at the boundary. This relaxation towards contact angle equilibrium involves a contact line friction \(\mu_f\). We thus compare interface shapes obtained from a phase-field diffusive-interface model with the results of molecular dynamics (MD) simulation using the GROMACS code. The setup is a simple Couette flow between two plates, with a vapor droplet sheared in the middle of the domain. Another comparison is performed between MD and the sharp interface model with a slip length and a Generalized Navier Boundary condition. The sharp interface model is implemented using a VOF method. The role of diffusion across the interface, which is possible in the diffuse interface model, is of particular interest.

Positively and negatively charged single-layer nanoporous graphene membranes are investigated for applications in water desalination using molecular dynamics (MD) simulations. Pressure-driven flows are induced by moving specular reflection boundaries with a constant speed. Simulations are performed for hydraulic pore diameter membrane as large as 14.40 Å with four different electric charges distributed on the pore edges. Salt rejection efficiencies and the resulting pressure drops are compared with the obtained free-living case of 9.9 Å diameter uncharged nanoporous graphene membrane, which exhibits 100% salt rejection with 35.02 MPa pressure drop at the same flow rate. For the positively charged membranes, \(q = 9e\) shows 100% and 98% rejection for Na\(^+\) and Cl\(^-\) ions respectively, with 35% lower pressure drop than the reference. For the negatively charged membranes, optimum rejection efficiencies of 94% and 93% are obtained for Na\(^+\) and Cl\(^-\) ions with \(q = -6e\), which requires 60.6% less pressure drop than the reference. The results indicate the high potential of using charged nanoporous in reverse osmosis (RO) desalination systems with significantly enhanced performance.

We study the dynamics of randomly placed two-dimensional elliptical particles at droplet interfaces in a gravity-driven draining emulsion system consisting of a Newtonian fluid using 2D Lattice Boltzmann Model with long-range repulsive and frustrated short range attractive interactions. Both fluid-particle and particle-particle interactions along with the orientation of the particles need to be accounted for because the mutual competition between these phenomena coupled with tumbling effect govern the key features of elliptical particle-laden flows. As the denser liquid phase drains out, the dense to sparse emulsion transition is observed with droplet deformation, coalescence and eventual collapse with the emulsion start breaking at the top of the cell. However, this transition and droplet coalescence process is drastically reduced in presence of ellipsoids of varied hydrophobicity leading to formation of particle layers arresting coalescence with reduction of tumbling effects in the arrested state. The effects are changed when the affinity of the particles to each of the phases and the aspect ratio of the particles are varied.

4:00PM M03.00041 Confinement effects on natural gas within carbon nanotubes. ALEXANDRO KIRCH, TERESA LANNNA, NAIYER RAZMARHA, JULIO MENEGHINI, CAETANO MIRANDA, Universidade de So Paulo — The current membrane technology for gas separation displays a low flow rate and/or low selectivity. Improvements in the separation technologies are desirable for natural gas usage as a fuel supply under carbon restraints. Advances in the membrane functionality may be favored by the development of nanotechnology. Notably with the emergence of the nanostructured carbon-based materials could lead to significant phase separation devices due to their fast mass flow and regular pore size. However, the separation process depends on fine-tuned properties of the pore structure which nowadays could be benefited by atomistic level research studies using molecular dynamics simulations (MD). In particular, the understanding of the fluids basic properties in confined geometries and interfaces plays a central role in the separation process optimization. In this work, we investigated the structure and transport of natural gas within carbon nanotubes in the light of fully atomistic MD simulations. Firstly, molecular models of natural gas are explored and confinement and interface effects on gas selectivity were analyzed with decreasing nanotube diameter. Finally, we could evaluate the underlying molecular mechanisms which could lead to the phase separation and influencing nanoflows.

4:01PM M03.00042 ABSTRACT WITHDRAWN —

4:02PM M03.00043 Effect of Volume Fraction on Droplet Break-up in an Emulsion flowing through a Microfluidic Constriction. ALISON BICK, SINDY K. Y. TANG, Stanford University — We report the effect of droplet volume fraction on the break-up of droplets within an emulsion flowing as a two-dimensional monolayer through a tapered microchannel into a constriction. A concentrated emulsion was injected into the channel, and an additional continuous phase was injected on-chip to dilute the emulsion to achieve different effective volume fractions. At a fixed flow rate, the break-up fraction decreases significantly when the droplet volume fraction \( \phi \) decreases below \( 0.50 \). This result is consistent with our previous report that droplet break-up arises primarily from droplet-droplet interactions. Furthermore, an optimal location for the introduction of the additional continuous phase to dilute the emulsion was identified as approximately equal to one to two droplet diameters upstream of the constriction. Away from this optimal location, the dilution of the emulsion is ineffective. Assuming a tolerance of a maximum break-up fraction of \( 0.1 \), diluting the emulsion 2.1 times from \( \phi = 0.85 \) to \( \phi = 0.40 \) increases the throughput by \( \sim 1.3 \) times. Consequently, although a higher emulsion volume fraction packs more drops per unit volume, the propensity of the drops to undergo break-up limits the throughput of the process if droplet integrity and assay accuracy are to be maintained.

4:03PM M03.00044 Fine-scale dynamics of bubble induced turbulence with and without breakup and coalescence. IMMANUVEL PAUL, Stanford University, BRUNO FRAGA, University of Birmingham, MICHAEL DODD, Stanford University, CHRIS LAI, Las Alamos National Laboratory — We study bubble induced turbulence (BIT) through a swarm of air bubbles rising in a vertical column. We consider two types of bubbles: one without and another with breakup and coalescence. The immersed boundary method is used to model the bubbles without breakup and coalescence while the volume of fluid is utilized for the other case. The void fraction of air bubbles is 0.5% at the start in both the simulations. We focus on the quasi-steady stage of the temporal evolution of the BIT. For this stage, we also note the -3 slope in the energy spectrum as reported in the experiments. We further explore the fine-scale turbulence dynamics by studying the evolution equation of the velocity gradient tensor (VGT) in Q-R space. We observe an entirely different conditional mean trajectories (CMT) of R and Q in both the BIT simulations. Here, the trajectories no longer spiral towards the origin as in the case of the homogeneous isotropic turbulence. Rather, the CMTs evolve to a particular line on the right branch of D=0 line leading to divergence in finite time. This is accompanied with the larger magnitude of the pressure Hessian term compared with all other terms in the VGT evolution equation.

4:04PM M03.00045 Secondary flows and bubbly drag reduction on heterogeneously rough surfaces in Taylor–Couette turbulence. PIM BULLEE, DENNIS BAKHUIS, RODRIGO EZETA, SANDER HUISMAN, Twente University, CHAO SUN, Tsinghua University, ROB LAMMERTINK, DETLEF LOHSE, Twente University — We investigate turbulent flow at Reynolds numbers (Re) ranging from \( 0.5 \times 10^5 \) till \( 1.8 \times 10^6 \) over surfaces that are composed of rough and smooth patches. Our main interest is in how the structure of the flow is influenced by this alternating rough and smooth surface, and how this changes the position of air bubbles in the flow. For this we use the Taylor–Couette geometry, which allows for accurate drag and flow measurements, as well as flow visualisations through its transparent outer cylinder. The inner cylinder wall is covered with sandpaper, leaving room between bands to form a constant pattern in axial direction. This results in a strong secondary flow pattern of radially outward flow on the rough patches and radially inward flow on the smooth patches. Surprisingly, air bubbles do not follow this secondary flow, but rather accumulate on top of the rough wall sections in the flow. Here, locally, the drag is largest and so the drag reducing effect of the bubbles is felt strongest. Therefore, a larger maximum value of bubbly drag reduction is found for the alternating rough and smooth inner cylinder walls compared to the completely rough and completely smooth inner cylinder walls.

4:05PM M03.00046 Investigation of Cavitation Regimes Using Large Eddy Simulations. MRUGANK BHATT, KRISHNAN MAHESH, University of Minnesota — Cavitation occurs over different regimes, ranging from inception to massive regions of vapor. We use LES to examine the different regimes of cavitation for i) partial cavitation over a wedge and ii) cavitation over a marine propeller. Cavitation over a wedge is simulated at \( Re = 200,000 \) and \( b=2.47, 1.89 \) and 1.78 demonstrating respectively the incipient, the transitory and the periodic regimes. Cavitation over five bladed marine propeller (P4381) is studied at \( Re = 894,000 \) and \( = 0.40 \) increases the throughput by \( \sim 1.3 \) times. Consequently, although a higher emulsion volume fraction packs more drops per unit volume, the propensity of the drops to undergo break-up limits the throughput of the process if droplet integrity and assay accuracy are to be maintained. This result is consistent with our previous report that droplet break-up arises primarily from droplet-droplet interactions. Furthermore, an optimal location for the introduction of the additional continuous phase to dilute the emulsion was identified as approximately equal to one to two droplet diameters upstream of the constriction. Away from this optimal location, the dilution of the emulsion is ineffective. Assuming a tolerance of a maximum break-up fraction of \( 0.1 \), diluting the emulsion 2.1 times from \( \phi = 0.85 \) to \( \phi = 0.40 \) increases the throughput by \( \sim 1.3 \) times. Consequently, although a higher emulsion volume fraction packs more drops per unit volume, the propensity of the drops to undergo break-up limits the throughput of the process if droplet integrity and assay accuracy are to be maintained.

4:06PM M03.00047 Dynamics of gas bubbles and slugs in 2-dimensional porous media, PETR DENISSENKO, University of Warwick, RUFAT ABIEV, St. Petersburg State Institute of Technology, SAM TUCKER HARVEY, EVGENY REBROV, University of Warwick — A 3d-printed 2-dimensional channel is used to study 2-phase flow in a bench-scale trickle-bed reactor. As the maximum size of a spherical bubble is limited by the pore size, slugs with complex shapes form when bubbles merge. The slugs do not move constantly but perform intermittent manoeuvres. Break-up, coalescence, and propagation dynamics of the slugs are studied in relation to their length. The balance between pressure, viscosity, and surface tension terms is considered to predict slug propagation dynamics. Interaction between slugs is considered. Results are interpreted in the context of the gas hold-up and the flow quality in relation to mass transfer between gas phase and liquid phase.

4:07PM M03.00048 Application-Specific Microfluidic Networks, FAIZ K. MOHAMMAD, VEDULA MURALI, RAGHUNATHAN RENGASWAMY, None, SENAI TEAM — Microfluidic devices have applications in various fields. This paper reports a simple approach for designing application-specific microfluidic networks with low effort and time. Here, we also demonstrate how this approach can be utilized to find networks that can perform logic computations based on droplets motion inside the network. We applied our approach to find networks that can control the motion of drops for logical computations, i.e., AND (·) gate where a drop will emerge from an arm only if drops enter the network simultaneously, and OR (+) gate when a drop will emerge from an arm whenever drops enter the network. Finding a device which can do AND (·), OR (+) logic computations might be easy (has been demonstrated) and can be achieved by trial and error. However, for more complex logical operations, trial and error approaches will be time consuming and unreliable. However, the proposed approach can handle these problems quite easily. This approach can also work with multiple drops entering from different source positions into the network to be used in more complex logical operations. We will describe computationally identified device designs for such logic computations in this work.

4:08PM M03.00049 Acoustic droplet vaporization on hydrophobic and hydrophilic solid surfaces, SEHO KWON, GIHUN SON, Sogang University — Acoustic-driven vaporization of volatile droplets, such as dodecafluoropentane (DDFP) droplets with a lower boiling temperature of 29°C, receives attention as a promising means for medical diagnostic and therapeutic applications. The acoustic droplet vaporization (ADV) process on hydrophobic and hydrophilic surfaces is experimentally investigated using a microscope and high-speed camera system with temporal and spatial resolutions of 150,000 frames/s and 5 pixels/um, respectively. A water-repellent agent is coated on a slide glass for a hydrophobic surface whereas an anti-fogging agent for a hydrophilic surface. The DDFP droplet has a contact angle of 105 degree on the hydrophobic surface and 45 degree on the hydrophilic surface. Ultrasound with a center frequency of 5 MHz was applied to DDFP droplets immersed in liquid water. The present ADV experiments show that the droplet vaporization rate is higher on the hydrophilic surface than on the hydrophobic surface. The droplet-bubble compound is always attached on the hydrophobic surface during the ADV process, but the compound grown on the hydrophilic surface slides off while leaving a small droplet portion. The effect of ambient water temperature on the droplet and bubble motion was quantified.

4:09PM M03.00050 Closed loop control of the acoustic energy shielding by cavitation bubble clouds1, KAZUKI MAEDA, Stanford University, ADAM MAXWELL, University of Washington — A closed loop control system is developed to regulate the transmission of ultrasound burst into a solid obstacle that is shielded by a layer of cavitation bubble clouds. The study is motivated by interest in improving the efficacy of kidney stone comminution during a recently proposed ultrasound-based lithotripsy. In the system, pulses of ultrasound with a frequency of $O(100)$ kHz and an amplitude of $O(1)$ MPa are focused on a stone model from a multi-element array transducer with a pulse-repetition-frequency (PRF) of $O(10)$ Hz. The far-field, bubble-scattered acoustic waves are concurrently measured at the transducer arrays. With a high PRF, the layer of bubbles is excited on the proximal side of the stone and scatters a large portion of the incoming acoustic energy. A data-driven, reduced-order model is used to estimate the portion of the energy transmitted into the stone from the acoustic measurement in real-time. Based on the offset of the estimation from a set point, a proportional-integral controller modulates the PRF to control cavitation. The controller showed favorable performance during $O(100)$ s of continuous insonification. Lastly, the system is used to identify the optimal set point that maximizes the effective rate of energy transmission into the stone.

4:10PM M03.00051 Ensemble-based Data Assimilation Methods for Viscoelastic Material Rheometry during Bubble Collapse1, J. JEAN-SEBASTIEN SPRATT, MAURO RODRIGUEZ, KEVIN SCHMID-MAYER, TIM COLONIUS, California Institute of Technology — We examine ensemble-based data assimilation methods for viscoelastic material rheometry, where observation of the radius versus time of a collapsing spherical cavitation bubble is used, together with a physical model for the bubble dynamics, to infer the surrounding material’s mechanical properties. Such ensemble-based stochastic methods are attractive for this type of problem, as they fully capture the nonlinear dynamics while keeping computational costs low given the large number of state variables. The ensemble Kalman filter (EnKF), iterative ensemble Kalman smoother (IEnKS), and a hybrid ensemble-based 4D-Var (En4D-Var) method are compared. These are first validated against simulated data with known parameters, and then applied to experimental measurements in water and Polyacrylamide gel [Estrada et. al. 2018, J Mech Phys Solids 112]. We show that the IEnKS and En4D-Var improve on the results of the EnKF as expected for this problem, and outperform existing viscoelastic material characterization methods by achieving comparable or better estimation with reduced computational cost. Each method demonstrates particular advantages, the IEnKS being less expensive and better suited for higher frequency data, and the En4D-Var more robust for sparse data sets spanning longer time.

4:11PM M03.00052 Selective Viscous Withdrawal: Entrainment of Micro-jets and Micro-drops, ZEHAO PAN, JANINE NUNES, NIKI ABBASI, HOWARD STONE, Princeton University, STONE GROUP TEAM — The study of microscale drop or jet generation has catalyzed the invention of numerous biomedical and industrial technologies. Existing shear-based technologies require active control of both the continuous and the dispersed phases, therefore limiting their capacity for large scale parallelization. A selective viscous withdrawal system is comprised of a nozzle immersed in one fluid near a fluid-fluid interface, where the application of a withdrawal flow can cause the entrainment of the second fluid into the nozzle forming jets or droplets. Since no active or independent flow rate control of the two fluids is needed, this system promises greater capacity for scale up of droplet or jet production. Here, we experimentally study the formation of jets and droplets in a selective viscous withdrawal system, and perform a scaling analysis of the jet and drop sizes with respect to key operation parameters including the flow rate, nozzle-interface distance, nozzle diameter, viscosity, and interfacial tension. Our work lays the groundwork for further application-driven explorations.
4:12PM M03.00055 Touch Down of a Sphere in Viscoelastic Media
THEODORE BRZINSKI, Haverford College, PAULO ARRATIA, University of Pennsylvania — Many fluids of practical interest contain polymers and show non-Newtonian behavior such as shear-thinning viscosity and elasticity. Lubrication forces in such fluids depend on conformation changes of polymer molecules and at sufficiently high strain-rates can become nonlinear. Here, we experimentally investigate the (lubrication) forces that arise as a sphere approaches the solid surface as a function of fluid elasticity. We use an Instron with a sphere-and-rod attachment to directly measure the forces experienced by a sphere that approaches a smooth surface in fluids with different levels of elasticity.

4:13PM M03.00054 Prediction of Rheological Behaviour of Unentangled Polymer Solutions in Steady Shear Flows Using a Blob-theory Based Constitutive Model
PRABHAKAR RANGANATHAN, Monash University — Understanding the effects of polymer concentration and flow-induced stretching on hydrodynamic interaction between segments of polymer molecules is the key to accurately predicting the dynamical behavior of unentangled polymer solutions. Conventional wisdom avers that a polymer solution is dilute when its concentration \( c \) is less the concentration \( c^* \) at which isotropic polymer coils begin to overlap and interpenetrate. This picture is simplistic. Inter-chain interaction becomes increasingly important as chains stretch in flow. In semi-dilute unentangled solutions, on the other hand, concentration-dependence is strong at equilibrium, but inter-chain interactions weaken as chains stretch during flow. Thus, dilute solutions self-concentrate, while semi-dilute solutions self-dilute. A constitutive model based on blob concepts is used to examine the concentration dependence of shear-thinning-thickening-thinning in steady shear flows. It is shown that qualitative nonlinear rheological behaviour in strong flows is surprisingly sensitive to the friction coefficient of the Kuhn segment.

4:14PM M03.00055 Rheological properties of encaustic painting
JORGE ARROYAVE, SANDRA ZETINA, Universidad Nacional Autonoma de Mexico, ROBERTO ZENIT, Brown University — Encaustic is a painting technique characterized by the use of wax as the main binding media. In addition to wax and pigments, some resins and solvents are used to create the painting media. Since the material is semi-solid at ambient conditions, the painting is often conducted with the aid of heated pallets and torches. As a result, mastering this technique is extremely challenging. In this work we investigate how the composition of the encaustic affects its rheological properties focusing on the effect of pigment color and concentration. We prepare encaustic paints following Diego Rivera’s, used for his first large-scale mural which was painted with this technique. In addition to determining the viscosity, using a rheometer, we also conducted controlled painting experiments: a device was designed and built to apply a drop of paint to heated surface at different shear rates. We found that all the paints were shear-thinning with small viscoelastic effects; surprisingly, the viscosity of the paints was significantly affected by the pigment color despite the fact that its proportion in the paints was always small (less than 10%). The size of the traces was found to scale with the shear Reynolds number. A discussion on the implications of these results for artists is presented.

4:15PM M03.00056 A Mesh Refinement framework for the Lattice Green’s Function method
KE YU, BENEDIKT DORSCHNER, MARCUS LEE, TIM COLONIUS, California Institute of Technology — We report on progress in developing the lattice Greens function (LGF) technique for solving viscous, incompressible flows on unbounded domains. This method exploits the regularity of the finite-volume scheme on a formally unbounded Cartesian mesh to yield robust (conservative, stable) and computationally efficient solutions. It is spatially adaptive, but of fixed resolution. Here we develop an adaptive mesh refinement strategy compatible with the LGF algorithm. The solution to the pressure Poisson equation is approximated using the LGF technique on a composite mesh where different regions can have different resolutions. This is further combined with an integrating factor technique for the viscous term and an appropriate Runge-Kutta scheme for the resulting differential-algebraic equations. The algorithm is verified and validated with numerical simulations of vortex rings.

3:20PM M04.00001 Local analysis of the clustering, velocities and accelerations of particles settling in turbulence
MOHAMMADREZA MOMENIFAR1, ANDREW D. BRAGG2, Duke University — We use Direct Numerical Simulations (DNS) and 3D Voronoi tessellation to analyze the local dynamics of small inertial particles in isotropic turbulence, considering the effect of Taylor Reynolds number (\( R_e \)), Froude number (\( Fr \)), and Stokes number (\( St \)). In line with previous results using global measures of particle clustering, we find that for small Voronoi volumes, the behavior is strongly dependent upon \( St \) and \( Fr \), but only weakly dependent upon \( R_e \), unless \( St > 1 \). However, larger Voronoi volumes (void regions) exhibit a much stronger dependence on \( R_e \), even when \( St < 1 \). This, rather than the behavior at small volumes, is the cause of the sensitivity of the standard deviation of Voronoi volumes \( \lambda \) that has been previously reported. Particle acceleration results indicate a non-trivial effect of gravity, while results for the fluid acceleration at the particle position call into question the sweep-stick mechanism for clustering. Comparing the local dynamics of particles in clusters to all particles in the flow reveals that while their kinetic energies are nearly the same, the clustered particles settle much faster on average, and this difference grows significantly with increasing \( R_e \).

3:21PM M04.00002 ABSTRACT WITHDRAWN —

3:22PM M04.00003 Feedback control of a combined two-fluid/electro-spray coaxial injector via real-time measurements and Principal Component Analysis
RODRIGO OSUNA-OROZCO, NATHANIEL MACHICOANE, PETER HUCK, ALBERTO ALISEDA, University of Washington — We present an experimental study of the physics of gas-assisted atomization combined with electro-spray. We leverage a low dimensional representation of the spray, from light attenuation measurements, to implement feedback control in real-time. The laminar liquid stream is injected through a long straight metallic needle at the center of the turbulent gas jet. The liquid is electrically charged by a very strong electric field at the nozzle exit. We apply an external electric field along the spray development region, characterizing the ability of an external sideways force on the individual droplets to modify the structure of the spray in the midfield. We characterize the break-up dynamics using high-speed visualizations in the near field and the droplet sizes and velocities in the midfield using light interferometry. In the implementation of real-time control, we use optical attenuation of light traversing the spray downstream of the nozzle in the mid-field. Low dimensional representations of the radial liquid volume fraction profiles allow for real-time control of the spray based on actuation on the gas total and angular momentum as well as on the external electric field.
3:24PM M04.00005 On The Relationship Between Internal Flow and Jet Dynamics in a Charge Injection Atomizer, WILLIAM DOAK, PAUL CHIAROT, State University of New York at Binghamton, MICROFLUIDICS AND MULTIPHASE FLOW LABORATORY TEAM — Atomization of a dielectric micro-jet is achieved using an electrohydrodynamic (EHD) charge injection process. The atomizer is comprised of a grounded nozzle plate and an internal high voltage probe, with electric potentials up to 20 kV, concentric with the emitting orifice. Dielectric liquid flows through the cavity between the electrodes, impeding electron transport from the probe to ground and imparting charge to the fluid. When the jet is uncharged, it breaks up via an axisymmetric (Rayleigh-Plateau) instability. Once charged, a non-axisymmetric (bending) instability, in addition to the axisymmetric instability, is observed in the jet. Both instabilities grow with increasing jet charge density: the abrupt jet length shortens and the bending amplitude increases. We have found that changes in the jet instability modes are related to the EHD flow induced inside the nozzle. A transparent nozzle was built and the flow was seeded with micro-spheres to study this phenomenon. High-speed microscopy and digital image correlation was used to measure the EHD flow at different jet stability conditions. We found that transitions in the internal flow are associated with changes in the jet stability regimes.

3:26PM M04.00007 Hindered coalescence and break-up with insoluble surfactants, CAROLINA VANNOZZI1. None — For Capillary numbers (Ca) greater than 0.05, the thin film between two drops undergoing a flow-induced head-on collision, in the creeping flow regime, thins to a steady state thickness hss, as shown in [1]. Here, we analyze numerically this phenomenon in the presence of surfactants. For trace amount of surfactants, hss diminishes with decreasing surfactant interfacial diffusivity (Ds) and , unlike Nemer et al.’s analysis for non-diffusing surfactants[1], surfactants are still present in the dome region. For higher surfactant concentration, hss is present only for very high Ds, while, as Ds decreases, the film drains continuously. As Ca increases the two drops break-up into 4 distinct drops. Interestingly, for low surfactant concentrations, the dome region will thin, becoming a neck. This will continuously thin and stretch as the two extremities depart from each other following the streamlines, while keeping hss constant. This process will proceed until instabilities arise in the neck. Whereas, for high surfactant concentrations, the dome region will thin only at the center and the extremities will keep draining in place. [1] Nemer et al. 2004 Phys. Rev. Lett. 92.

This work was undertaken while I was affiliated with UCSB.

3:28PM M04.00009 Particle aggregates via droplet evaporation on superhydrophobic fractal-like substrates, CAROLA SEYFERT, EVA KROLIS, Physics of Fluids, University of Twente, ERWIN J.W. BERENSCHOT, ARTURO SUSARREY-ARCE, NIELS TAS, Mesoscale Chemical Systems, University of Twente, ALVARO MARIN, Physics of Fluids, University of Twente — Sessile droplets on superhydrophobic substrates are common in nature and technology. In the case of droplets containing solid particles, the evaporation of the solvent turns into an effective tool to aggregate any non-volatile content. The high contact angles and unpinned contact lines of the droplets, induced by hydrophobicity, can lead to a complete recovery of the solid solute in form of aggregates. Under the right conditions, the solid remainder takes the form of highly compact and spherically shaped aggregates, featuring a minimal contact area with the supporting substrate. We investigate the evaporation of colloidal droplets on a new kind of superhydrophobic, micro-structured substrate, featuring fractal-like glass pillars. Such substrates present an intricate geometry with non-flat top surfaces of the pillars. Different sizes and concentrations of monodisperse polystyrene particles lead to various shapes of particle aggregates after the evaporation of the solvent.

We would like to acknowledge the financial support of the ERC-StG 678573 Nanopacks.

3:29PM M04.00010 Colloidal crystallization in cylindrical geometry: Effect of particle wettability on banding, TEJASWII SOORI, YING SUN, Drexel University — A colloidal drop constrained within a capillary tube subjected to evaporation results in crystallization and particle banding. Past studies have shown the width and spacing of bands to increase with concentration for cylindrical geometries. The radius of curvature \( R \) and capillary length \( \ell_c \), for drops over planar substrates are usually of the same order of magnitude, while for capillary tubes the radius of curvature \( R \) is equal to the capillary radius \( r \) which can be much smaller than the capillary length \( \ell_c \). Taking advantage of this fact, we use colloidal drops containing particles with different wetting properties in capillary tubes of radii \( r = 400 \) and \( 750 \) \( \mu \)m at initial concentrations \( \phi = 0.1 \) and \( 0.5 \) % wt. We perform all evaporation experiments at isothermal, controlled humidity conditions and use an in-house MATLAB code to analyze the images captured via a CCD camera to measure the transient quantities like contact angle and contact line position. In this talk, we report the results quantifying the effect of particle wettability on deposition dynamics, contact line motion, and banding.
3:30PM M04.00011 Determining time scales for directed assembly of particles by shear flow and electric field1. MINAMI YODA, ANDREW YEE, Georgia Institute of Technology, HAJIME ONUKI, YOSHIYUKI TAGAWA, Tokyo University of Agriculture and Technology — Suspended colloidal polystyrene particles assemble into structures called “bands” when subject to shear flow and a dc electric field. These bands exist only within a few μm of the wall, and have been observed over a wide range of conditions in combined Poiseuille and electroosmotic “counterflow” through microchannels, even at particle volume fractions as low as 0.33 ppm. There appear to be three stages in this process: 1) Accumulation, where particles are concentrated near the channel wall; 2) Band formation, with a relatively large number of unstable bands; and 3) Stable bands. The time scales for these stages were determined from evanescent-wave visualization images acquired at different streamwise channel locations. The standard deviation in the image grayscales was used to estimate the time required to reach the band formation stage, and compared with a similar time scale based instead on the time when the first band is observed. The mean grayscale, which was used instead to estimate the time to reach the stable bands stage, appears to have an exponential growth during the accumulation stage, and reaches its maximum value during the band formation stage, before decreasing to a relatively constant value in the stable bands stage.

3:31PM M04.00012 Defining dimensionless parameters for electrohydrodynamic field-directed nanowire assembly.1, RUSTOM BHILADVALA, University of Victoria, MAHSID SAM, QuirkLogic Inc. — We present an approach for defining dimensionless parameters based on competing forces on nanoparticles in an electrohydrodynamic assembly process. These forces can either direct or disrupt the assembly process in different assembly situations. We define dimensionless parameters to maximize the ratio of directive to disruptive forces. This work is motivated by promising scientific capabilities that have been demonstrated using nanostructured devices at laboratory scale. Their translation to useful devices over centimeter to meter squared area at reasonable cost, can be facilitated by methods of field-directed assembly of nanostructures. Capillary and viscous forces, dielectrophoresis and dipole-dipole interaction, electrode polarization and electroosmosis, are involved during assembly. These depend on values of physical properties of the nanoparticles and the suspension fluid, design of the electrode pattern and the potential and frequency chosen for the electric field. The value of some of these physical parameters can each simultaneously affect forces that direct and disrupt nanostructure assembly. The tedious trial and error involved in parameter selection is an impediment to nanomanufacturing. A systematic approach to eliminate it is the motivation for this work.

3:32PM M04.00013 ABSTRACT WITHDRAWN —

3:33PM M04.00014 Electrorotational instabilities of a drop in a uniform DC electric field1, PETIA VLAHOVSKA, JEREMY KOCH, MICHAEL MIKSIS, Northwestern University — In a uniform electric field, a weakly conducting drop bearing zero net charge initially adopts a prolate or olate spheroidal shape, with both the shape and flow axisymmetrically aligned with the applied field - a classical result from G.I. Taylor. At higher field strengths we find two symmetry-breaking instabilities: a high viscosity drop undergoes Quincke rotation (the global flow acquires a rotational component), while low viscosity drops only develop a secondary flow – a series of surface vortices – in a belt along the drop equator. We explore these phenomena experimentally in a silicone oil/caster oil system to map the region of the vortices-belt instability as a function of fluid viscosity and electric field strength.

3:34PM M04.00015 Chaotic dynamics of a Quincke rotor in 3D1. GERARDO PRADILLO, HAMID KARANI, PETIA VLAHOVSKA, Northwestern University — The Quincke effect is an electrohydrodynamic instability which gives rise to a torque on a dielectric particle in a uniform DC electric field. The equations which describe the resulting rotation are known to map onto the Lorenz equations (Peters et al, Chaos (2005)), predicting the existence of a second bifurcation upon which rotation is no longer steady. In this presentation we discuss the dynamics of the Quincke rotor in 3D, using the recently discovered hovering state (Pradillo et al, Soft Matter (2019)) at high field strengths. We experimentally confirm the existence of chaotic motion and demonstrate the presence of periodic regimes in this previously unexplored 3D system. Our experimental results are compared to the solutions of the fully three-dimensional model.

1supported by NSF awards CBET- 1704996 and CMMI- 1740011

3:35PM M04.00016 Electrohydrodynamic instability of a suspended liquid film, MO-HAMMADHOSSEIN FIROUZJIA, DAVID SAINTILLAN, University of California San Diego — Electrohydrodynamic instabilities at liquid-liquid interfaces are of high importance due to their relevance in various microfluidic applications. In this work, we analyze the stability of a system of three superposed layers of two immiscible liquids subject to a normal electric field. Following the leaky-dielectric model, the interfaces admit conduction, advection by the flow, and finite charge relaxation. We use this model to perform a linear stability analysis and uncover regimes of instability in terms of the relevant dimensionless groups of the problem.

3:36PM M04.00017 Modulation of the streaming potential and slip characteristics in electrolyte flow over liquid filled surfaces1. BEI FAN, PRABHAKAR BANDARU, University of California San Diego — A significant enhancement in the streaming potential (Vs) was obtained in experiments considering the flow of electrolyte over liquid-filled surfaces (LFSs), where the grooves in patterned substrates are filled with electrolyte immiscible oils. Such LFSs yield larger Vs (by a factor of 1.5) compared to superhydrophobic surfaces, with air-filled grooves, and offer tunability of electrokinetic flow. Through changing the filling oils, it is shown that the density, viscosity, conductivity, surface tension as well as the dielectric constant of the filling oil in the LFS, determine Vs. Considering the concentration polarization phenomenon for nonhomogeneous charged LFS, the hydrodynamic slip length is inversely proportional to the dielectric constant of the filled oil. Relating the hydrodynamic slip length to the obtained Vs offers insight into flow characteristics, as modulated by the liquid-liquid interfaces in the LFS.

3:37PM M04.00018 Low-voltage onset of electokinetic mixing at heterogeneous charge selective interfaces. ANNE BENNEKER, University of Calgary, BURCU GUMUSCU, ERNEST DERCKX, ROB LAMBERTINK, JEFFERY WOOD, University of Twente — Electokinetic mixing of the concentration boundary layer adjacent to charge selective interfaces can enhance the performance of electrodialysis systems and fuel cells by increasing the transport of ions towards the interface. Traditionally, electokinetic instabilities occur at relatively high potentials, significantly reducing the system efficiency. In this work, we experimentally show that altering the topology of the charge selective interface can induce electokinetic mixing at low potentials using patterned charge selective hydrogels. Fluorescence microscopy for mapping local ion concentration is combined with electrical characterization to unravel the development of ion depletion zones and the onset of electokinetic mixing. For different geometries, we find that the development of these depletion zones is distinctly different as a result of the distribution of the field lines through the different geometries. Enhancement in the total transport is observed with increasing system heterogeneity as a result of electrosomotic contributions to the charge transport, starting a low applied potentials. This indicates that inducing non-uniform electric fields using membrane topology variations and spacers is a promising route for increasing charge transport to the interface.

3:38PM M04.00019 ABSTRACT WITHDRAWN —

3:39PM M04.00020 Contact angle effect on the drop impact onto a solid substrate. ZHEN JIAN1, International Center for Applied Mechanics, School of Aerospace, Xi’an Jiaotong University, Xi’an 710049, P.R.China, CHRISTOPHE JOSSERAND, STEPHANE ZALESKI, PASCAL RAY, Sorbonne Universite, CNRS, UMR 7190, Institut Jean Le Rond d’Alembert, F-75005 Paris, France — As drop impacts onto a solid substrate, abundant outcomes such as splashing, bouncing can be observed under different conditions including liquid, gas and solid properties. We study the contact angle effect on the splashing of drop impact by direct numerical simulation with open source codes Gerris and Basilisk. For a typical partial wetting substrate with a contact angle of 90°, we obtain a phase diagram of splashing or not by varying the density and viscosity ratio between gas and liquid. Splashing can be either created by changing the contact angle to smaller than 90°, or eliminated with a contact angle larger than 90° with all the other properties constant. The wettability plays a role in the formation of splashing during drop impact on solid.

3:40PM M04.00021 An Evaluation of Droplet Breakup Characteristics for Low- and High-Speed Vehicle Impacts. MICHAEL KINZEL, University of Central Florida, JASON TURNER, University of Illinois Urbana Champagne, BRENDON CAVAINOLO, CAROLINE ANDERSON, University of Central Florida, UIUC TEAM, CFAL TEAM — In this work, computational fluid dynamics (CFD) predictions are used to simulate and study the evolution of a droplet in its approach of aerodynamic surfaces. The CFD effort is based on the volume-of-fluid (VOF) method in a formulation that contains the compressibility of both the liquid and gas. Using this formulation, the calculations of the breakdown of the droplet on impingement are directly simulated. These studies include evaporation and interaction with aerodynamic interference. The droplet travel speed depending on the threshold in oscillation acceleration, the water droplet started to travel to the down direction gradually increasing the travel speed. The opposite substrates propelled water droplets of few microliters preferentially in the down-hill direction relative to the sawtooth geometries. Above a threshold in oscillation acceleration, the droplet may either coalesce within less than one droplet diameter distance from the turning point or travel many droplet diameters. We find a clear bi-modal distribution in droplet travel distance at this transition point and present a physical model to explain this interaction.

3:41PM M04.00022 Contact line friction driven droplet transport over asymmetric sawtooth surface microstructures. YAERIM LEE, The University of Tokyo, GUSTAV AMBERG, KTH Royal Institute of Technology, JUNICHIRO SHIOMI, The University of Tokyo, CAROLINE ANDERSON, University of Central Florida, UIUC TEAM, CFAL TEAM — In this work, computational fluid dynamics (CFD) predictions are used to simulate and study the evolution of a droplet in its approach of aerodynamic surfaces. We find a clear bi-modal distribution in droplet travel distance at this transition point and present a physical model to explain this interaction.

3:42PM M04.00023 Flow field near Contact Lines : Role of Inertia1, ANJISHNU CHOUDHURY, CHARUL GUPTA, HARISH N. DIXIT, Indian Institute of Technology Hyderabad — The dynamics of contact line involves the movement of two immiscible fluids in contact with a solid surface. An analytical solution for Stokes flow near a moving contact line was solved by Huh & Scriven (JCIS, 1971) which suggests a simple classification of the flow field based on viscosity ratio, $R$ and contact angle, $\theta$. But experiments by Savelski et al. (JCIS, 1995) and Ito et al. (Trans. Vis. Soc. Japan, 2009) find flow fields which differ from predictions of Huh & Scriven theory. Our work is an attempt to resolve this contradiction by exploring the kinematics near the contact line through accurate simulations and scaling exponent on our attention focus our attention on fields in the region of $O(l_c)$, the capillary length. Excellent agreement between simulations and theory is found in the viscous limit. A careful examination of the parameters used in the reported experiments suggests that $Re$ based on $l_c$ is not small, hence inertial effects may not be negligible. We observe a stagnation point on the interface at length $l_i$ for moderate $Re$ and at $O(1)$ We. The obtained flow field potentially resolves the contradiction between theory and experiments. Experiments are underway to validate these flow field and will be discussed during the meeting.

3:43PM M04.00024 Droplet baseball: skirting droplets rebounding from a rigid wall1, JACOB HALE, ALYSSA FISHER, MOMOKA GOTO, ANH LE, MASON LEE, DePauw University — Droplets of 1 cm silicone oil, with an initial velocity component tangent to the surface of a bath of the same fluid, will roll along the surface for hundreds of milliseconds, slowing exponentially until eventual coalescence. A rigid vertical wall, placed in the bath perpendicular to the path of the droplet, forces early coalescence either on the meniscus formed on the wall or after rebounding from the wall. By moving the wall along the line of motion of the droplet, a transition point is found in the droplet’s trajectory in which, at a fixed wall position, the droplet may either coalesce within less than one droplet diameters distance from the turning point or travel many droplet diameters. We find a clear bi-modal distribution in droplet travel distance at this transition point and present a physical model to explain this interaction.

3:45PM M04.00026 Surface Chemistry Dramatically Influence Cassie-to-Wenzel Transitions in Doubly Reentrant CAVITIES 1, SANKARA NARAYANA MOORTHI ARUNACHALAM, ZAIN AHMAD, RATUL DAS, JAMILYA NAURUZBAYEVA, HIMANSHU MISHRA 2, King Abdullah University of Science and Technology — Surfaces and membranes that can robustly entrap air on immersion in liquids have proven valuable for drag reduction and desalination. Typically, the ability to entrap air is engendered by coating rough surfaces/membranes with water-repellent chemicals. Recently, it has been demonstrated that if microstructures comprising doubly reentrant cavities (DRCs), i.e., cavities that broaden below the inlets and whose walls have T-shaped cross-section, are carved on a surface, can entrap air despite the hydrophilicity of the material. Here, we studied wetting transitions in DRCs with a variety of surface chemistries and compared them with simple cylindrical cavities (SCCs). We realized arrays of DRCs and SCCs on SiO2/Si wafers using photolithography and dry etching processes, and modified surface chemistries of silica to realize water (intrinsically) contact angles, , 0, 40, 112. We found that life-times of Cassie-states could vary from s. The mechanisms underlying the wetting transitions including, the diffusion of the trapped air, the capillary condensation, liquid imbibition, and the release of the trapped air as a bubble will be explained.

3:48PM M04.00029 Dynamics of spontaneous emulsification at particle-laden interfaces: a coupling between interfacial microstructures and interfacial flows. , PARISA BAZAZI, HOSSEIN HEJAZI, university of Calgary — Interfaces between two immiscible liquids are omnipresent in nature and industrial processes including enhanced oil production, CO2 sequestration, and drug delivery. A thermodynamically stable dispersion of liquids, i.e. microemulsions, may develop at the fluid interfaces under specific circumstances such as having close to zero interfacial tension. In this work, we investigate the possibility of spontaneous emulsification at the particle-laden oil-water interfaces and examine the extent to which the phenomena are analogous to those of surface active molecules. It is shown that the nanoparticle-micelle complexes are formed at the interface of an aqueous drop submerged in an oleic phase promoting spontaneous emulsifications and double emulsion formation. Thus, the interface is covered with less than one-micron droplets of emulsified phase. The microemulsion detachment from the interface and their non-uniform distributions trigger fluid circulations inside the aqueous drop. The induced interfacial flow alters the drop shape, contribute in fluid mixing and consequently enhance the emulsification process. We quantify the emulsification rate and the fluid motions at the interfaces and provide plausible physical mechanisms describing the fluid dynamics of the process. We ultimately demonstrate the possibility of generating interfaces with specific microstructures and interfacial properties only by tuning the particle-surfactant concentrations.

3:49PM M04.00030 Particle monolayer growth in evaporating salty colloidal droplets 1, MYRTHE BRUNING, LAURA LOEFFEN, ALVARO MARIN. University of Twente — When pinned colloidal sessile droplets evaporate, the well-known coffee stain effect will occur: particles accumulate along the contact line and form a ring. However, when small amounts of salt are added to the droplet, interesting phenomena occur that alter the particle agglomeration process drastically. As a consequence of the inhomogeneous evaporation along the droplet interface, salt accumulates at the contact line. Since salt increases the surface tension, an interfacial Marangoni flow is generated. This surface flow is directed from the apex of the droplet towards the contact line. It overcomes the bulk capillary flow, resulting in a reversed flow direction as compared to the classical coffee-stain case. Interestingly, despite the flow reversal, particles still accumulate at the contact line. However, in this case particles arrive at the contact line along the liquid-gas interface of the droplet and form a monolayer there. The structure of this particle layer is studied in detail using laser scanning confocal microscopy, which allows us to access the full 3D-position of all particles at the interface and gain insight into their distribution. In this work we will study the dramatic effect that the salt concentration has on the particle layer structure.

3:50PM M04.00031 Effect of a second component in organic droplet evaporation: initially present versus absorbed during the process, SAHAR ANDALIB, ALI ALSHEHRI, PIROUZ KAVEHPOUR, University of California-Los Angeles — Evaporation of organic liquid has numerous applications ranging from bio-diagnostic to coating technology. Multi-component droplets are often encountered in industrial applications. Even, evaporation of a pure liquid droplet into an environment containing a second substance can result in a multi-component droplet. Despite their omnipresent nature, mechanisms underlying multi-component droplets are not yet fully understood. Present work studies the similarities and differences of the effect of a second component during evaporation of a droplet of an organic solvent. In the first case the second component was present in the droplet from the beginning of evaporation process, while in the second case the second component gets absorbed or adsorbed during the process of evaporation. Analysis of experimental data provides valuable insight into wetting and spreading phenomena of multi-component systems.

3:51PM M04.00032 Using Electrospray to Probe the Interfacial Flow of Evaporating Fluid Masses 1, PAUL CHIAROT, AREF GAFOURI, TIMOTHY SINGER, XIN YONG, SUNY at Binghamton — The ability to measure flow along the surface of an evaporating fluid mass remains a challenge. Tracers are typically dispersed throughout the bulk of the fluid, which means the interfacial transport cannot be easily isolated using particle imaging techniques. In this research, nanoparticles, acting as Lagrangian tracers, are delivered to the interface of sessile drops and rivulets using electrospray atomization. The microdroplets produced by electrospray evaporate in-flight, which leaves behind dry particles that adsorb at the target interface and do not desorb into the bulk. Using this technique, we captured the flow induced on the surface of the fluid masses during evaporation. The flow structure changed dramatically when surfactant was present or if the bulk solvent was a binary (water / alcohol) solution. For these cases, solutal Marangoni flow was induced along the fluid interface, producing flow patterns that were significantly altered from the pure (aqueous) solvent case.

3:55PM M04.00036 Effect of vapor pressure on the performance of a Leidenfrost engine. PRASHANT AGRAWAL, GARY WELLS, RODRIGO LEDESMA-AGUILAR, GLEN MCHALE, Northumbria University, ANTHONY BUCHOUX, KHELLIL SEFIANE, ADAM STOKES, ANTHONY WALTON, JONATHAN TERRY. The University of Edinburgh — Friction is a hindrance to effective mechanical energy conversion, especially at microscales where significant wear occurs due to a high surface-area to volume ratio. Recently, we have developed the concept of a virtually frictionless heat engine, employing levitating liquids (or solids) on turbine-inspired substrates to convert thermal energy to mechanical motion. The levitation is achieved via the Leidenfrost effect, where a liquid drop levitates on its own vapor when it contacts a substrate heated to temperatures significantly above the liquid’s boiling point. The vapor layer virtually eliminates friction and allows evaporating drops to self-propel on asymmetrically textured substrates. In this work, we operate this Leidenfrost heat engine continuously and control its output power by mechanically altering the vapor layer thickness. This is done by replenishing the liquid and supporting the rotor using a bearing assembly. We observe an increase in the power output despite the added bearing friction. The design principles described here can be extrapolated to develop mm and sub-mm scale engines for applications in extreme environments with naturally occurring low pressures and high temperature differences. We acknowledge funding from UK EPSRC (EP/P005896/1 and EP/P005705/1).

3:57PM M04.00038 PIV measurements of a dilute suspension flow over and through various porous media models1, THERESA WILKIE, EILEEN HAFFNER, PARISA MIRBOD, University of Illinois at Chicago — Porous media have become more prevalent in various engineering applications. This study’s aim is to provide insight on how different properties of porous media would affect a dilute suspension flow. Specifically, a suspension fluid containing neutrally buoyant, non-collodial, non-Brownian, rigid, spherical particles with a volume fraction of 3% was examined as it passed over and through various porous media models with porosities of 0.7, 0.8, and 0.9 and thicknesses of 5mm and 3mm. All Reynolds numbers were kept very low to neglect inertial effects. Particle image velocimetry (PIV) technique was used to obtain two-dimensional velocity vectors for planes on top and within the porous media models. To quantify the effect of different porosities and the porous media thickness on a dilute suspension the slip velocity and shear rate analyzed at the suspension-porous interface. We also compared our experimental results with the predicted model, and found a good agreement.

3:58PM M04.00039 Porous walls impact on suspension flows1, SEYEDMEHDI ABTAHI, University of Illinois at Chicago, MARCO ROSTI, KTH Royal Institute of Technology, PARISA MIRBOD, University of Illinois at Chicago, LUCA BRANDT, KTH Royal Institute of Technology — Suspension flows are encountered in various industrial applications including blood flow, transport of slurries, and pharmaceutical industries. We study suspensions of rigid particles in a plane Couette flow with porous walls. To tackle the problem at hand, we perform three-dimensional Direct Numerical Simulations of a plane Couette flow with a suspension of neutrally buoyant rigid particles simulated with an Immersed Boundary Method, while the flow inside the porous walls is simulated using the volume-averaged Navier-Stokes equations. We show that the porous walls produce a shear-thinning effect in the suspensions and this behavior originates from the interactions between the rigid particles, the porous walls and the carrier fluid: non-zero velocity fluctuations at the interface between the porous layers and the clear fluid regions are triggered by the presence of the particles, which in return migrates towards the bulk of the channel. We found that the effect grows with the particle volume fractions and with the permeability of the porous material. At the end for comparison, we also present how the interaction between porous walls and a particle suspension affects a fully developed plane turbulent channel flow.

4:00PM M04.00041 Versatile particle delivery into dead-end pores enabled by reactive solutes1. XIAOUY TANG, NAN SHI, ANIRUDHA BANERJEE, TODD SQUIRES, UC Santa Barbara — Particle delivery/extraction in dead-end pores is critical in many applications such as drug delivery and oil recovery. However, convective flow is suppressed due to geometrical confinement, while particle diffusion is prohibitively slow. Diffusiophoresis, in which solute concentration gradient drives particle migration, provides a promising strategy. The solute gradient is commonly imposed by introducing a solution of higher or lower concentration and relying on solute diffusion. However, single solute offers very little control over the particle delivery speed. Here, we present a new and versatile strategy to create solute gradient for diffusiophoretic particle migration: chemical reaction. Different model systems are demonstrated including acid-base and precipitation reactions. We will demonstrate that the speed and concentration of the particles can be controlled by varying reactant concentration ratio and reactant diffusivity ratio. Different particle delivery pattern can be achieved: non-focusing or focusing, where particles are delivered in a concentrated band. A theoretical model for the particle delivery dynamics agree well with the experiment. Diffusiophoresis under reactive solute gradient opens up new possibilities to manipulate particle migration in many configurations and applications.

4:01PM M04.00042 Transport phenomena in porous structures in interaction with the atmospheric boundary layer , SAURABH SAXENA, NEDA YAGHOOBIAN, Florida State University — This study lays emphases on the underlying physics of mass and heat transfer within porous structures found in the atmospheric boundary layer. The transport process in the porous media happens due to the variation in the structure surface temperature (induced by the variable solar fluxes) and instabilities in the atmospheric boundary layer turbulent flow. The study is inspired by the longstanding problem of the aeration function of soil-based animal-built structures in nature. Direct numerical simulation (DNS) is used to simulate the flow past and through porous media. The Navier–Stokes equations are modified using the Darcy-Brinkman-Forchheimer model to represent the porosity effect. To examine the effect of the natural and forced convection on the transport phenomena within the porous body, the system is further exposed to the diurnal surface temperature variation that is computationally simulated using detailed surface energy balance analyses.

4:02PM M04.00043 ABSTRACT WITHDRAWN —

4:03PM M04.00044 Stress and velocity fluctuations in photoelastic granular avalanches1 , NATHALIE VRIEND, AMALIA THOMAS, University of Cambridge — We study granular avalanches using a custom-built narrow chute where we release 2D photoelastic disks down an incline. Using high-speed imagery, we are able to obtain position and velocity data from particle tracking, and the full stress tensor, including normal and shear stress components, from the photoelastic response of interacting particles. Even though the avalanche is steady-state in time and space, minute fluctuations in velocity and forces away from the mean directly influence the rheology and fluidity. In this study, we analyze the correlation between velocity fluctuations and stress fluctuations in both the quasi-steady layer (close to the rough base) and the flowing layer (near the free surface). We correlate the fluctuations with direct measurements of the measured non-local properties within this photoelastic avalanche.

4:04PM M04.00045 Shear banding and shear jamming in homogeneously sheared granular material1 , YIQIU ZHAO, Department of Physics, Duke University, Durham, NC, 27708, USA, JONATHAN BARÉS, Laboratoire de Mécanique et Génie Civil, Université de Montpellier, CNRS, Montpellier, 34090, France, HU ZHENG, Department of Geotechnical Engineering, College of Civil Engineering, Tongji University, Shanghai, 200092, China, JOSHUA E. S. SOCOLAR, Department of Physics, Duke University, Durham, NC, 27708, USA — We experimentally study the generation and evolution of a shear band during quasistatic shearing of a 2D granular material using a novel split-bottom Couette apparatus in which a layer of photo-elastic disks rests on a base consisting of 21 independently controllable concentric rings. The rings rotate at different rates to generate a uniform basal shear profile. Previous experiments using this setup [arXiv:1904.10051] showed that a steady localized shear band is generated at sufficiently large strains when the packing fraction is higher than a critical value \( \phi_c \approx 0.78 \), which lies between the minimum shear jamming density and the isotropic jamming density. In the present work, we focus on the evolution and structure of the shear band. We find that for the width of the shear band is independent of the global packing fraction above \( \phi_c \), and we analyze the spatial variations in the local packing fraction, the force network structure, and the particle flow field throughout the shearing process.

4:05PM M04.00046 A Simple Photo-resistor sensor for detection and characterization of droplets , MOHAMMAD SHAHAB, ANSHUL VERMA, RAGHUNATHAN PENGASWAMY, Indian Institute of Technology Madras, SYSTEMS ENGINEERING OF THE NATURAL AND THE ARTIFICIAL AT IIT MADRAS TEAM — This work describes a method which utilizes the difference in optical properties (i.e. transmittance) of continuous and dispersed phase to detect droplets in a milli-channel made of PDMS using a sensor i.e. Light Dependent Resistor (LDR) and a light source i.e. Light Emitting Diode (LED). Due to low cost and footprint, LDR is a viable option. LDR also covers the entire spectrum in visible range and gives satisfactory response as opposed to planar diffused photo-diodes which respond only to a limited wavelength-band. Any change in the transmittance of the fluid flowing in the channel changes the intensity of light falling from the LED on LDR resulting in a resistance change in LDR. Droplet detection corresponding to the peaks in the sensor signal due to change in the resistance of LDR is established by comparing the sensor data with the video-processed data. After sensor validation, peak features such as peak height, width and saturation voltage are studied to measure droplet size, velocity and spacing. As an application of this multiphase flow detection, it has been shown that droplets can be classified on the basis of their chemical properties using Beer-Lambert law.

4:06PM M04.00047 Binary Aerosol Composition Measurements using Ultra Small Angle X-ray Scattering1 , DANIEL DUKE, HARRY SCOTT, ANESU KUSANGAYA, DAMON HONNERY, Monash University, BRANDON SFORZO, KATARZYNA MATUSIK, ALAN KASTENGREN, MATTHEW FRITH, JAN ILAVSKY, Argonne National Laboratory, DAVID LEWIS, Chiesi Limited — Nearly all consumer aerosols are binary mixtures of a product in a liquefied propellant. In the pressurised metered dose medical inhaler (PMDI) for example, drugs may be dissolved in ethanol if their solubility in the propellant is poor. The rate of change of liquid composition as the propellant flash-evaporates strongly affects precipitation of the inhaled particles. However, aerosol composition is difficult to measure in an optically dense flash evaporating spray. A novel approach to this problem is demonstrated using Ultra-Small Angle X-ray Scattering (USAXS) on a PMDI solution of 3.36 \( \mu \)g/\( \mu \)L ipratropium bromide, 85% \( \% \)/ R-134a propellant and 15% ethanol. The experiments were conducted at the 9-ID & 7-BM beamlines of the Advanced Photon Source at Argonne National Laboratory. USAXS exploits the high electron density of R-134a relative to ethanol, which leads to a measurable change in X-ray scattering cross-section at the droplet surface. By combining USAXS with X-ray radiography and laser diffraction, the change in cross-section can be measured using Porod’s Law. From this, an ensemble average composition is determined. This new approach enables quantitative validation of binary droplet evaporation models and may lead to improvements in nozzle design.

4:07PM M04.00048 Holographic astigmatic particle tracking velocimetry (HAPTV)¹
ZHOU ZHOU, College of Ocean and Atmospheric Sciences, Ocean University of China, SANTOSH KUMAR SANKAR, KEVIN MALLERY, Dept. of Mech. Engineering, UMN, CHENG LI, SAFL, UMN, WENSHENG JIANG, College of Env. Sci. & Engineering, JIARONG HONG, Dept. of Mech. Engineering, UMN — The formation of twin images in digital inline holography (DIH) is the main issue that constrains the placement of the focal plane in the center of the sample volume for DIH-based particle tracking velocimetry (DIH-PTV) with a single camera. As a result, it is challenging to apply DIH-PTV for flow measurements in large-scale laboratory facilities and many field applications despite its low cost and compact setup. Here we introduce holographic astigmatic PTV (HAPTV) by inserting a cylindrical lens in the optical setup of DIH-PTV which generates distorted holograms. Such distortion is subsequently utilized in a customized reconstruction algorithm to distinguish tracers positioned on different sides of the focal plane located in the center of a sample volume. Our HAPTV approach is calibrated under different magnifications, and is implemented to measure a vertical jet flow and the channel flow in a large-scale water tunnel. The results are compared with measurements from conventional particle image velocimetry and show a good agreement. The work has demonstrated that HAPTV can achieve improved spatial resolution compared to the conventional astigmatic PTV, and also enable the implementation of DIH-based PTV to flows in field applications.

¹Chinese Scholarship Council & Ocean University of China

4:08PM M04.00049 Machine learning based holography for flow diagnostics¹, KEVIN MALLERY, SIYAO SHAO, JIARONG HONG, University of Minnesota, Twin Cities — Digital inline holographic particle tracking velocimetry (DIH-PTV) is a promising single camera technique for 3D flow diagnostics due to its low cost, compact setup, versatility, and improved performance as demonstrated in the recent work by Mallery & Hong (Optics Express 27(13), 18069-18084). However, both measurement precision and processing speed remain challenges limiting the broad adoption of DIH-PTV. We present approaches utilizing machine learning to accomplish the particle localization task with both high accuracy and speeds comparable to commercial PIV software. Our approach avoids the need for experimental ground truth measurement by utilizing existing hologram simulation and processing methods to construct a training data set to train multiple convolutional neural networks (CNNs). Our algorithm addresses issues particular to holographic imaging through a novel unification of network elements (including UNET, SWISH activation, and TV loss). We demonstrate that this network can match the results of the best conventional DIH-PTV processing on experimental data and improve speed by a factor of 100. We further demonstrate that this method increases the tracer concentration limits of holography, improving the spatial resolution of measurements.

4:09PM M04.00050 Measuring the dispersion relation of stabilized Faraday waves using Bragg scattering, PAUL W. FONTANA, MASON BROWN, EILEEN FLESHLER, Seattle University — Parametrically excited surface waves, or Faraday waves, are produced on the free surface of a liquid that is vibrated vertically above a critical amplitude. Unlike standing waves, Faraday waves are composed of collections of oscillating solitons, or “oscillons.” These oscillons are generally subject to random motion, but they can be stabilized into a robust square crystalline lattice by dissolving a small amount of a protein, bovine serum albumin (BSA), in the liquid medium. In the experiments presented here, we demonstrate the use of grazing incidence Bragg scattering to measure the lattice spacing of the Faraday wave crystal, and hence the dominant wave number of the Faraday wave. Visible laser light (543.5 nm) is reflected off stabilized Faraday wave crystals at grazing incidence, producing an interference pattern in the far field. Analysis of the interference pattern yields the wave number to high precision and also brackets the wave height. The wave number was measured for driving frequencies from 200 Hz to 900 Hz. The resulting dispersion relation is compared with that of gravity-capillary waves in the same medium. Applications of the Faraday wave crystal as a liquid-based, tunable 2D diffraction grating are being explored.

4:11PM M04.00052 Drag forces of rectangular cylinders with different aspect ratios in a vertical soap film¹, SONG PAN, XINLIANG TIAN, State Key Laboratory of Ocean Engineering, Shanghai Jiao Tong University — The soap film provides a convenient way to study the drag force coefficient of a rectangular cylinder in the quasi-2D flow while it has been already investigated with numerical (2D) and experimental (3D) methods. We measured tiny drag forces of different rigid-wire rectangular cylinders by varying their aspect ratios in a vertical flowing soap film. We placed the pre-impregnated rectangular cylinders on a hook inserted into the soap film. The aspect ratios are defined as ratios of the length of cross-stream directions to height in the streamwise. We find that the measured drag forces do not match with published 2D numerical results, indicating the soap film shows 3D features when the aspect ratio is small.

4:12PM M04.00053 Gas Jet Blowing on a Falling Soap Film: Three Regimes of Interaction, MAKSIM MEZHERICHER, Princeton University, CEDRIC GERBELOT, Ecole Normale Superieure, ERIC QIU¹, ANTONIO PERAZZO, YIGUANG JU, HOWARD A. STONE, Princeton University — Recently, several studies reported on the generation of soap bubbles by a gas jet blowing perpendicular to a falling soap film. However, an extensive investigation of the regimes of interaction between the air jet and the falling soap film has not been performed yet. In this work, we used hypodermic blunt needles with inner diameters between 110-260 microns as small cylindrical nozzles to create air jets blowing perpendicular to falling soap films with thickness in the range of 2-10 microns, surface tension 25-32 mN/m and viscosity 1-7 mPa*s. While gradually increasing the jet velocity, three regimes of interaction between the blowing jet and the soap film were observed: formation of a dipole in the film for jet velocities smaller than the threshold for bubbling; a bubbling regime over and above a threshold velocity; and a regime of immediate film rupture when a critical jet velocity was achieved. In the bubbling regime, tuning some parameters enabled production of monodisperse bubble aerosols. The onset of the regime of immediate film rupture was found to strongly depend on the nozzle diameter and weakly depend on the film thickness and its physicochemical properties.

4:14PM M04.00055 A linear behavior between squeezing pressure and advancing length: when squeezing a viscous droplet into circular narrow confinement at capillary number $= \frac{3}{4}$, CHRISTOPHER LANDRY$^1$, XIAOLIN CHEN$^2$, Washington State University Vancouver, ZHIFENG ZHANG$^3$, Delaware Innovation Campus, American Air Liquide — Particle squeezing through narrow constricted channels occurs in many processes throughout biomedical and chemical engineering fields. Applications range from lab-on-chip devices and pipette aspiration to transport through single pore as well as porous media. Recently, particle behaviors are compared based on particle properties and operation parameters. In the present research, an approximately linear relation between squeezing pressure and advancing length, in which the squeezing of a viscous droplet behaves like a linear solid particle, is found at $\text{Ca}= \frac{3}{4}$. Within the range of theoretical assumption, numerical modeling is conducted to validate the linear relation between the squeezing pressure and advancing length. This finding may have potential implications in cell/particle filtration, aspiration device design, enhanced oil recovery, etc.

NP05.00002 Configurations and dynamics of membrane-bound elastic filaments$^1$, WILSON LOUGH, University of Wisconsin-Madison — Changes in the curvature and topology of cell membranes are responsible for numerous biological processes. Many of these changes seem to be driven by interactions with thin filament-like protein structures which form on the surface of membranes. While there are a number of proposed mechanisms, how exactly the filament-membrane interactions produce changes in curvature remains an open question. The feasibility of proposed mechanisms can be be investigated by modeling the filament as a thin elastic rod which is confined to the membrane surface. The interplay between the geometries of the the surface and the filament give rise to complex distributions of force and torque which are believed to play a crucial role in reshaping the membrane. We discuss the mechanics of surface-bound filaments and present a collection of analytical and numerical results.

$^1$NSF: DMS-1661900
NP05.00003 Dynamics of pulsing soft corals\footnote{Funding: NSF PHY grant #1505061}. GABRIELLE HOBSON, LAURA MILLER, University of North Carolina at Chapel Hill, SHILPA KHATRI, University of California, Merced — Soft corals of the family Xenidiidae have a pulsating motion that generates flow in their surrounding fluid. This flow brings new samples of fluid towards the coral, allows sufficiently slow mixing for removal of photosynthetic waste to occur, and then transports the fluid away from the polyp to reduce resampling (Samson et al. 2019). Generating this flow allows the pulsating corals to perform photosynthesis at much higher rates than non-pulsating soft corals (Kremien et al. 2013). Numerical simulations of the pulsations of the coral were conducted using the immersed boundary method. By quantifying flow characteristics such as velocity, vorticity, and Lagrangian coherent structures, we investigated how the flow changes as we varied the frequency-based Reynolds number and the length of the resting period between pulses. Further investigations into the efficiency of fluid transport by the polyps will also be presented. Key words: Immersed boundary method, pulsing soft corals, computational fluid dynamics, biomechanics

NP05.00004 Improving the Foundations for Large Eddy Simulation of Katabatic Flow\footnote{NP05.00007 Energy spectra for turbulent Rayleigh-Bénard convection}. KELSEY EVERARD, University of British Columbia, HOLLY OLDROYD, University of California at Davis, MARCO GIOMETTO, Columbia University, MARC PARLANGE, Monash University, GREG LAWRENCE, University of British Columbia — Large Eddy Simulations (LES) can pose an advantage over Reynolds Averaged Navier-Stokes in that only turbulence at and below the sub-grid scale (SGS) is dictated by a closure model. At the same time, LES can pose an advantage over Direct Numerical Simulations (DNS) in that it can be used to simulate flows at large Reynolds numbers. However, LES results can be sensitive to the choice of SGS turbulence model, especially in the near-surface region of stably stratified flows, making simulation accuracy highly dependent on the near-wall treatment and on grid resolution. For katabatic flow, it is surmised, based on the observed anisotropy and surface-normal flux divergence, that results are sensitive both to the choice of SGS model and to the wall-layer model. However, a mathematically consistent and physically grounded choice does not yet exist in either case, posing a bottleneck for the applicability of LES for katabatic flow simulation. Here, we propose improved models that explicitly account for the physics important to a statically stable fluid flowing under the influence of gravity over a sloped rough boundary. In this way, we contribute to increasing the utility of LES for studies on katabatic flows.

NP05.00005 Three-dimensional bubble mechanics in a corner subject to an acoustic wave. EOIN O’BRIEN, MEHDI MAHMUD, QIANXI WANG, University of Birmingham — The development of cavitation bubbles in a corner subject to an acoustic wave has important applications in ultrasonic cleaning, and cavitation damage. Previous developments have been made on the effects of an acoustic wave on a microbubble near a rigid wall, (K. Manmi 2014), highlighting the effects of the high intensity ultrasound on the bubble’s timespan, jet direction and overall shape of the bubble surface, regarding the initial radius of the bubble and the amplitude of the acoustic wave. Furthermore, numerical simulations have been made to accurately simulate the evolution of a cavitation bubble in a corner created by the intersection of two rigid walls for differing angles. In this presentation, I introduce the mathematical model used for a bubble in a corner subject to an acoustic wave along with the boundary integral method used to numerically model the development of the bubble surface with time. From this, numerical results are presented to highlight the effects of the corner and the acoustic wave for a range of angles, acoustic wave amplitude, and initial bubble radius. In doing so, the jet direction upon collapse can be found, along with the bubble migration towards the corner over time.

NP05.00006 Reliability of general purpose finite-volume solvers for wall-modeled large-eddy simulation of open channel flow at a moderate Reynolds number. WEIYI LI, MARCO GIOMETTO, Columbia University — Wall-modeled large-eddy simulation is increasingly being used in both industry and academia for the characterization of wall-bounded high Reynolds number flows. Numerical simulations are often carried out using general-purpose finite volume solvers, whose solution is known to be particularly sensitive to the nature of the discretization scheme. Such a sensitivity introduces a degree of uncertainty in model results that is yet to be fully quantified. Here we assess the quality and reliability of a general-purpose finite volume solver in wall-modeled large-eddy simulation of a pressure-driven, open-channel flow at frictional Reynolds number 2000. Simulations are performed using an algebraic, equilibrium, wall-layer model. Results are contrasted against corresponding DNS data and predictions from a single-domain pseudo-spectral solver. Model predictions will be discussed with a lens on the impact of the grid aspect-ratio, grid resolution, discretization schemes for the velocity and pressure, time stepping procedure, and velocity-pressure coupling scheme.

NP05.00007 Energy spectra for turbulent Rayleigh-Bénard convection. MICHAEL KWAN, JANET SCHEEL, Occidental College — We investigated the scaling behaviors for numerically simulated, turbulent Rayleigh-Bénard convection by determining the kinetic and thermal energy spectra. The systems have aspect ratio 1, Prandtl numbers 0.7, 0.021 and 0.005, and various Rayleigh numbers ranging from $10^5$ to $10^{10}$. Whereas in previous studies the frequency spectra from a time series were considered, we calculated the energy spectra from spatial fields. In particular, we performed Fourier analysis on two-dimensional cross sections of the temperature and velocity fields. We also computed the conditional velocity and temperature structure functions on the same cross sections to verify our findings. Lastly, we tested whether Kolmogorov’s 1941 (K41) scaling law or the Bolgiano-Obukhov (BO) scaling law applied to both the kinetic and thermal energy spectra for the various systems.

NP05.00008 Using reservoir computing to predict temperature fluctuations in turbulent Rayleigh-Bénard convection\footnote{We thank NSF Awards PHY-1756179 and EAR-1909055.}. SARAH CHANG, Swarthmore College, DANIEL LATHROP, University of Maryland, College Park — Turbulent flows are ubiquitous in the fundamental processes of nature—from the Earth’s mantle to its atmosphere. Among their many complexities, turbulent flows are chaotic, which makes them computationally expensive to simulate and difficult to study analytically. Thus, prediction of turbulent systems is an ongoing challenge. Machine learning methods, specifically reservoir computing, have recently shown promise in predicting turbulent flows. Reservoir computing is a recurrent neural network model that uses a reservoir of randomly connected nodes to process the input data and predict the output for the next time step. As a proof-of-concept, here we test the effectiveness of reservoir computing on the prediction of temperature fluctuations in turbulent Rayleigh-Bénard convection (RBC) because it has a relatively simple experimental setup and relevant applications, like weather prediction. We built a water-filled cylindrical convection apparatus, heated from below and cooled from above, and achieved Rayleigh numbers up to $4.5 \times 10^3$. We train the reservoir computer on our experiments temperature time-series data, collected with thermistors inserted at multiple heights in the flow, aiming to predict temperature fluctuations in turbulent RBC flow.
**NP05.00009 The Hydrodynamic Analysis of Fluid Flow over a Hydrofoil beneath a Free Surface in Subcritical Froude Number.** ZEDA YIN, Graduate student at Marshall University, MEHDI ESMAELPILAR, Assistant Professor at Marshall University — In this work, a numerical simulation of two-dimensional unsteady incompressible viscous flow generated by a shallowly submerged hydrofoil under the free surface is presented. The computation is based on finite volume discretization incorporating the interface capturing volume of fluid method to solve the fluid equation in the motion. The SST k-ω turbulence model is used to capture the turbulent flow for the wave around the hydrofoil. Submerged depths and different angles of attack will be presented in the numerical results. A comparison of the present numerical results with available experiments is performed with the focus on the free surface and flow field for varying AoA and submerged depths.

**NP05.00010 Traveling-Wave Solutions of Two BiDirectional Whitham Equations.** SALVATORE CALATOLA-YOUNG, JOHN CARTER, Seattle University — Following the work of Carter & Rozman (2019), we study traveling wave solutions of two versions of the bidirectional Whitham equation. These equations are extensions of Boussinesq-type models that enable the phase velocities to match those of the Euler equations. We study the systems introduced by Hur & Pandey (HP) (2018) and Aceves-Sanchez et al (2013). We compute families of periodic traveling wave solutions to the HP equation. Our goal is to compare the traveling-wave solutions of both equations to gain further understanding of the differences between them.

**NP05.00011 A Control strategy for Radial Miscible Viscous Fingering: Non Linear Simulations.** VANDITA SHARMA, Department of Mathematics, Indian Institute of Technology Ropar, Punjab India, CHING-YAO CHEN, National Chiao Tung University, Taiwan, MANORANJAN MISHRA, Department of Mathematics, Indian Institute of Technology Ropar, Punjab India — The displacement of a more viscous fluid by a less viscous one in a porous medium results in a hydrodynamic instability called viscous fingering (VF). Chui et al., Phys. Rev. E 92, 041003(R) (2015), experimentally reported the existence of a competition between advective and diffusive forces during the later stages of miscible radial VF. We numerically capture the competition between the aforementioned opposing forces from start to end of the instability. Many attempts have been reported in literature to control VF by utilizing time-dependent strategies, modifying the geometry and altering the fluid properties. However, we utilize the competition to control the instability. Stable displacement is observed despite a less viscous fluid displacing a more viscous one. The M-Pe parameter space is divided into stable and unstable zones by critical parameters following the relation $M_e = Pe_e^{1/2}$. The results are validated by diligently designed experiments.

**NP05.00012 Investigating Nontrivial Time-Periodic Solutions to the Whitham Equation.** CHERIOTHEPHER ROSS, JOHN CARTER, Seattle University — We are interested in waves on shallow water and are studying the existence and evolution of nontrivial time-periodic solutions to the Whitham equation. These solutions can be described as a small-amplitude traveling-wave interacting with a carrier wave. Ambrose and Wilkening (2009) introduced a numerical method for computing such solutions to the existence and evolution of nontrivial time-periodic solutions to the Whitham equation. We study the systems introduced by Hur & Pandey (HP) (2018) and Aceves-Sanchez et al (2013). We compute families of periodic traveling wave solutions to the HP equation. Our goal is to compare the traveling-wave solutions of both equations to gain further understanding of the differences between them.

**NP05.00013 Large Eddy Simulation of Turbulent Coherent Structures in a Storm-forced Surface Ocean Mixed Layer.** CLIFFORD WATKINS, National Center for Atmospheric Research — Submesoscale roll vortices in the ocean mixed layer (OML) are important to understanding and constraining the flux of momentum from the atmosphere into the ocean. In this study, we use large eddy simulations (LES) to investigate the impact of the superposition of Ekman inflection-point (EIP) instabilities on the entrainment and deepening of a shallow coastal ocean pycnocline under the wind forcing of Hurricane Irene (2011). We used reanalysis of the hurricane winds to force LES domains 100m to 4km in the horizontal dimension to observe the development and influence of EIP rolls. The EIP instability has a domain-scale independent wavelength on the order of 500m to a kilometer and transfers momentum to the shear instabilities at the pycnocline, leading to a more rapid deepening and cooling of the OML during the hurricane. By understanding the physical processes driving the changes in the OML both before and during the event, we will be able to predict the development of tropical cyclone intensity over stratified coastal oceans.

**NP05.00014 Three-dimensional visualization of stratified turbulent wakes at varying Reynolds number.** BASEM HALAWA, SHADEE MERHI, CYNTHIA TANG, QI ZHOU, University of Calgary — We present a series of three-dimensional visualizations of numerically simulated turbulent wakes in a stably stratified fluid, with a focus on the effects of the wake Reynolds number, $Re_e$, on the wake flow. The visualization of stratified wakes is complicated by the coexistence of regions of distinct dynamics in the flow, including the large-scale ‘pancake vortices’, small-scale shear instabilities within layers of concentrated vertical shear, and internal waves emitted by the wake to the ambient fluid. We apply various techniques to separate the dynamically distinct regions within a given wake and visualize them respectively. The volume fractions occupied by each of these regions are also quantified. Through the visualizations, we observe several significant effects on the wake’s evolution associated with increasing wake Reynolds number, which will be presented in the poster.

**NP05.00015 Providing biomimetic passive pumping on an implantable biosensor.** ALEC DRYDEN, MATTHEW BALLARD, Saint Martin’s University — Microfluidic technologies have opened doors to rapid, inexpensive and compact medical diagnostic testing, with one important example being the glucose meter. Technology continues to evolve to continuous compact medical diagnostic testing, with one important example being the glucose meter. Technology continues to evolve to continuous monitoring through mounting microfluidic devices onto the patient. A major hurdle in the development of on-body sensors is that they typically require flow of bodily fluids such as interstitial fluid or blood through the device. As a result, on-body sensors are typically bulky, requiring a pump and power source. We propose a solution for passive pumping on an implantable biosensor by mimicking nature’s elegant solution to the problem – lymphatic vessels. The lymphatic system pumps fluid using unidirectional flexible valves which open and close with fluctuations in fluid pressure, driven by contraction and expansion of surrounding muscle and of the lymphatic vessels. The ability of easily manufacturable bioinspired polydimethylsiloxane (PDMS) bioinspired valves, anchored to the microchannel floor, to mimic lymphatic valves, opening and closing to allow forward flow and prevent backflow, respectively. The design’s size scale, biocompatible materials, and reliance on biologically driven pressure gradients allow implantability and defeat the need for active pumping from an external source.

NP05.00016 Multiplicity in Stable Orbits for Prolate Capsules in Simple Shear Flow 1, XIAO ZHANG, MICHAEL D. GRAHAM, University of Wisconsin-Madison — Artificial capsules have been applied in numerous fields such as bioengineering, pharmaceutics, and food industry. This work investigates the motion of a deformable prolate capsule in unbounded simple shear flow at zero Reynolds number using direct simulations. The deformability, bending stiffness, initial orientation, aspect ratio of the capsule and the viscosity ratio between the inner and outer fluids are varied over a wide parameter space. At a low viscosity ratio, a capsule with large bending stiffness always tends towards an in-plane stable orbit, either tumbling or swinging, depending on the deformability, i.e., capillary number (Ca). At a high viscosity ratio, however, a tumbling-to-rolling transition is observed for a capsule with large bending stiffness at increasing Ca. In the transition regime, the capsule is found to adopt multiple stable orbital modes including tumbling, precessing and rolling, depending on the initial orientation. This multiplicity regime becomes broader as the aspect ratio of the capsule increases, while showing an opposite dependency on the viscosity ratio. The multiplicity in stable orbits leads to a multiplicity in the rheological behavior for a dilute suspension of such capsules.

NP05.00017 ABSTRACT WITHDRAWN —

NP05.00018 Water Desalination with Two-dimensional Metal Organic Framework Membranes, ZHONGLIN CAO, VINCENT LIU, AMIR FARIMANI, Carnegie Mellon University — Providing fresh and drinkable water is a grand challenge the world is facing today. Development in nano-materials can create possibilities of using energy-efficient nanoporous materials for water desalination. In this work, we demonstrated that ultrathin Metal Organic Framework (MOF) is capable of efficiently rejecting ions while giving access to high water flux. Through molecular dynamic simulation, we discovered perfect ion rejection rate by two-dimensional multi-layer MOF. The naturally porous structure of 2D MOF enables significantly 3 to 6 orders of magnitude higher water permeation compared to that of traditional membranes. Few layers MOF membranes show one order of magnitude higher water flux compared to single layer nanoporous graphene or molybdenum disulfide without the requirement of drilling pores. The excellent performance of 2D MOF membranes is supported by water permeation calculations, water density/velocity profiles at the pore and the water interfacial diffusion near the pore. Water desalination performance of MOF offers a potential solution for energy-efficient water desalination.

NP05.00019 Effects of Implant Separator Structure on Drug Delivery to the Posterior Eye,1, SEYEDALIREZA ABOOTORABI, Indiana University-Purdue University Indianapolis, ABHI TRIPATHI, LILIAN DAVILA, University of California, Merced, HUIDAN YU, Indiana University-Purdue University, Indianapolis — The prevalence of visual impairment and blindness attracts attentions to develop new types of implant for drug delivery that can reduce drug administration doses and regulate drug release rates. We use Comsol Multiphysics to simulate drug transport from a hydrogel implant behind the sclera layer to the posterior eye. The focus is on the time evolutions of the drug concentration in the sclera, choroid, and retina layers respectively. The computational domain and dimensions are from a prior study (Kavousanakis et al. 2014). The governing equations are coupled between incompressible Darcy’s law for flow and diffusion-advection for concentration. Drug delivery from the hydrogel implant directly agrees with open data. A new polymeric implant, containing several compartments defined by porous separators, is then introduced between the hydrogel and sclera to regulate the drug delivery rate. It is found that the peak concentration appears at approximately the same time but with much larger magnitude with no separator vs. with zero blockage separator. When the blockage widths in the separator is increased, the peak concentration appears in later time and smaller value. Such a new implant seems to be a plausible alternative to the drug delivery implants available to date in the market.

NP05.00020 Suspension flows in a pipe covered with permeable surfaces1, MARYAM BAGHERI, CHANGWOO KANG, PARISA MIRBOD, University of Illinois at Chicago — The flow of particulate suspensions driven by a constant pressure gradient is examined in a pipe where its walls are replaced with a permeable surface. We explore non-colloidal suspensions of rigid and spherical particles in a Newtonian fluid over a wide range of bulk particle volume fraction (0.1 ≤ φb ≤ 0.5) and the permeability of the porous medium. Direct numerical simulations (DNS) are performed to solve conservation equations of the flow coupled with the constitutive equation of suspensions (Diffusive Flux Model) and Darcy’s law in a porous medium. We aim to elucidate the effect of the permeable surface on the suspension flows. The velocity and concentration profiles are presented for various control parameters and show that the velocity of suspensions enhances by the slip effect at the suspension-porous interface. We evaluate the rate of suspension flows and slip velocity at the suspension-porous interface induced by the permeable surface. It reveals that the rate of suspension flow decreases as the bulk volume fraction φb increases and it builds up as the permeability of the porous media increases. We also show that there are two different regimes characterizing the slip velocity normalized by both shear rate and penetration depth, at the suspension-porous interface, namely the strong permeability regime and the weak permeability regime.

NP05.00021 Developing Notebook-based Flow Visualization and Analysis Modules for Computational Fluid Dynamics1, GERMAN SALTAR, University of Puerto Rico - Mayaguez, ADITYA AIYER, CHARLES MENEVEAU, Johns Hopkins University — Visualization techniques are essential in identifying complex features and patterns in fluid flows. Three dimensional visualization has long been confined to high-end software. Recently, packages for Python have been developed to overcome this limitation. We seek to implement them in the realm of fluid mechanics using Jupyter notebooks. To this end, we make use of Python’s J3D-Jupyter package to generate 3D volume rendering from Large Eddy Simulation (LES) datasets. Using volume rendering, we were able to visualize velocity and concentration fields of oil droplets of varying sizes injected at the centerline of a turbulent jet influenced by a uniform crossflow. Alternately, uniformly random spheres modulated by the LES computed concentration field were generated to represent the Eulerian concentration field. Interactive features allowed the 3D structure of the jet to be probed and the turbulent structure’s role in the oil’s spatial distribution to be inferred. Additionally, we were able to implement the modules to visualize Direct Numerical Simulation (DNS) data obtained from the Johns Hopkins Turbulence Data Base (JHTDB). The capability of exporting the interactive plots as html files, which can be embedded into a website or online research article, facilitates distribution.

1National Science Foundation (grant # OCE-1633124), Gulf of Mexico Research Initiative, JHU’s Whiting School of Engineering
NP05.00022 Inferring an effective eddy viscosity from High Fidelity Data. NIKHIL OBEROI, WALTER ARIAS RAMIREZ, JOHAN LARSSON, University of Maryland, College Park — Different ways to compute an inferred eddy viscosity from resolved turbulence data (from LES, DNS, experiments) based on optimization methods are investigated and assessed based on how well they reproduce the mean fields. The method is tested on wall bounded flows including a channel and a boundary layer. We further investigate the sensitivity of these methods to averaging error in the given Reynolds stress fields.

NP05.00023 Clustering of Vortex Wakes for Heaving-Pitching Foils Using Machine Learning, MUKUL DAVE, ALEJANDRO GONZALEZ CALVET, JENNIFER FRANCK, University of Wisconsin-Madison — A heaving-pitching foil produces different vortex patterns that are associated with propulsive regimes of high efficiency or high thrust, however there are many intermediate modes not readily classified due to a chaotic wake structure. Hence, machine learning techniques can be applied to help cluster wake patterns and associated performance. To evaluate the achievement of machine learning, a database of Reynolds-averaged Navier-Stokes simulations at Reynolds number of 10^6 and high heave amplitudes is utilized. The data includes sweeps in flapping frequency and pitch amplitude to produce a wide range of kinematics and propulsive modes. A convolutional autoencoder with lasso regularization was used to extract a latent space of important features from vorticity images of the wakes. Applying different clustering algorithms to the latent space groups the data into distinct flow regimes, such as a low vorticity regime with minimal flow separation and a high vorticity regime with a reverse von Kármán wake. The results are validated against a pre-labeled subset of samples to explore ways of improving the clustering. To correlate wake clustering with performance, support vector regression was used to predict the values of efficiency, power and thrust based on the kinematics.

NP05.00024 Simulation of nonlinear ocean waves using volume-of-fluid method, ZHOU ZHANG, KEVIN MAKI, YULIN PAN, Department of Naval Architecture and Marine Engineering, University of Michigan — The volume-of-fluid (VOF) method is widely used in the numerical simulation of multi-phase flows. In this work, we investigate the capability of VOF method to model nonlinear ocean waves, using several algebraic and geometric interface-capturing approaches. By considering a low viscosity and an initially irrotational flow field, the VOF solution can be validated against a fully nonlinear potential flow solution. We perform this study for both regular and irregular nonlinear waves, which benchmarks the capability of VOF to simulate the evolution of ocean waves. Furthermore, we develop a nonlinear wave inlet boundary based on the relaxation zone technique, enabling the simulation of prescribed incoming nonlinear waves into the computational domain. These developed capabilities are expected to be beneficial for different scenarios in ocean engineering.

NP05.00025 Numerical modeling of prostatic artery embolization: patient-specific blood flow and emboli transport, CHADRICK JENNINGS, MOSTAFA MAHMOUDI, Northern Arizona University, ANDREW HALL, Saint Louis University, AMIRHOSSEIN ARZANI, Northern Arizona University — Benign prostatic hyperplasia (BPH) is the most common non-cancerous tumor found in men. Symptoms caused by BPH can be treated by a recently proposed minimally invasive procedure known as prostatic artery embolization (PAE), where particles are injected through a catheter to limit blood supply to the enlarged prostate. The goal of this study is to characterize the complex blood flow patterns in common iliac and prostatic arteries and to model PAE with particle tracking in a patient-specific model. A computer model of common iliac arteries and the downstream vasculature was created from CT-angiography images using SimVascular. Image-based computational fluid dynamics (CFD) simulation using Oasis (a minimally dissipative open-source solver) was performed to obtain velocity data. Finally, the Maxey Riley equation was solved to model the PAE procedure and guide embolus injection. Our patient-specific computer model can provide valuable information for the PAE procedure.

NP05.00026 Wall shear stress manifolds and surface temperature patterns in heat transfer enhancement applications, CONNOR MORENO, AMIRHOSSEIN ARZANI, Northern Arizona University — Heat transfer enhancement has applications in many of the devices used by the public, directly or indirectly, on a daily basis. However, high-resolution heat transfer simulations are computationally costly, representing significant downtime in engineering industry and research. Meanwhile, wall shear stress (WSS) topology has been recently demonstrated as an effective estimator of surface concentration patterns in convective mass transport settings. Particularly, stable and unstable manifolds in WSS have been shown to control near-wall transport patterns in cardiovascular flows. Estimating surface concentration/temperature via WSS is desirable because of the significant reduction in computational time and the physical explanation of the results. In this study, it is investigated whether WSS topology proves an effective estimator of surface temperature patterns in heat transfer settings. The configuration used is the classical impinging jet, a widely used heat transfer enhancement application. WSS is obtained by computational fluid dynamics simulations and surface temperature is obtained by solving the advection-diffusion equation, both using the finite element method. Our results demonstrate a close connection between WSS manifolds and surface temperature patterns.

NP05.00027 2D CFD Analysis of NASA X-57 Maxwell High Lift Propeller Airfoil, SUSAN SANTIAGO, City College of New York, JINWEI SHEN, KYLE NELSON, The University of Alabama — The X-57 Maxwell is an experimental aircraft developed by NASA. This aircraft is designed to be quieter, lighter, and more efficient compared to the aircraft it is based on, the Tecnam P2006T. The aircraft has two large, outer propellers and 12 small, high lift, collapsible inner propellers. The high lift propellers are only active during low-speed flight which includes take-off and landing. During high-speed flights, the high lift propellers collapse into the wing of the aircraft and are no longer active. The goal of this aircraft is to demonstrate the benefits of distributed electric propulsion (DEP). Our research aims to calculate aerodynamic coefficients including lift, drag, and pitching moment on the airfoil of the high lift propellers. The coefficient tables generated will be used to obtain the aerodynamics for multi-body dynamics simulation testing of whirl flutter stability on the aircraft. To perform the computational fluid dynamics (CFD) calculations, we first conducted a validation study on a NACA 0012 airfoil. Using the same methodology, a CFD analysis was conducted on the high lift airfoil. The analysis on both the NACA 0012 and high lift airfoil were done using both Fluent and Genesis in order to validate the results obtained.

1NSF Grant: 1659710
NP05.00028 Molecular Dynamics Analysis on the Dynamic Contact Angle Based on the Extraction of the Stress Distribution in Steady-State Non-Equilibrium Systems of a Single Lennard-Jones Fluid between Solid Walls under Shear, HIROKI KUSUDO, TAKESHI OMORI, YASUTAKA YAMAGUCHI, Department of Mechanical Engineering, Osaka University — The Method of Plane (MoP) is a technique to calculate the stress distributions for systems in equilibrium molecular dynamics (EMD) simulations. In this study, we propose a method to extend the MoP to steady-state nonequilibrium molecular dynamics (NEMD) systems based on the velocity distribution function. Moreover, we examined the momentum balance exerted on a control volume set around the contact line for a single fluid between parallel walls under steady shear. By extending Bakkers equation, which connects the stress distribution and solid-related interfaces, we showed that the force balance among the dynamic interfacial tensions around the contact line can be rewritten by a model equation equivalent to Young's equation for equilibrium systems. We applied the model equation for steady state NEMD systems of single Lennard-Jones fluid by calculating the stress distribution, and showed that for the present system, the dynamic solid-liquid interfacial tension was constant sufficiently away from the contact line, and the constant value was almost equal to the static value irrespective of the shear rate tested. This result indicated that the dynamic apparent contact angle was not significantly different from the equilibrium apparent contact angle for the present system.

NP05.00029 Heat Transfer Analysis and Heat Sink Design for MELD Additive Manufacturing, JACOB STAFFORD, University of Evansville, DAVID MACPHEE, PAUL ALLISON, University of Alabama — MELD manufacturing is a solid-state additive manufacturing process that provides an alternate path to fusion-based additive manufacturing. Understanding the thermal cycle and hardness of the weld zone for components made using the MELD manufacturing process are essential in the quality of the manufactured components. To facilitate better understanding of the process, a simulation of the conjugate heat transfer problem was modeled in ANSYS Fluent. The model was then used to design a heat sink to better disperse thermal energy during material deposition. As a baseline for the heat sink design, a cold plate used in HVAC applications was modeled and tested experimentally. The computational solver was refined using grid size and time-step independence tests, and validated with experimental data. This computational solver was then used to design a new heat sink. By controlling the flow of the deposited material, better predictions for the thermal cycle and hardness are possible. This allows for improved prediction of the quality of solid-state additive manufacturing components.

NP05.00030 Understanding the dynamics of reservoir computing in chaotic dynamical systems, ADAM SUBEL, ASHESH CHATTOPADHYAY, PEDRAM HASSANZADEH, Rice University — Data-driven prediction of chaotic and multiscale dynamical systems is a daunting task. Recently there has been a lot of interest in predicting chaotic and turbulent flow using deep learning methods which have shown mixed results. However, reservoir computing algorithms such as echo state networks (ESN) have shown promise in capturing this behavior both in short term direct prediction as well as the long-term statistics of chaotic systems better than the state-of-the-art in recurrent neural networks. ESNs are an appealing choice for data driven prediction since unlike deep learning algorithms that train the weights through an expensive backpropagation algorithm, the ESN only trains a layer of output weights with linear regression making it orders of magnitude cheaper to train. The memory of the network comes from updating a state vector in the reservoir, using the previous state and the input to the system. In this work we present a theoretical understanding of reservoir dynamics and how it learns the behavior of chaotic signals and how the signals split up as the “echoes” of the system, an analytical expression and bound for the “dynamical memory” in the reservoir and seek to understand the mechanism which brings about the effectiveness of ESNs in capturing chaotic dynamics.

NP05.00031 Non-negligible Flow Scale for the Vortex Generation in an Isotropic Homogeneous Turbulence, SHO SAEKI, Division of Mechanical Engineering, Graduate School of Engineering, Aichi Institute of Technology — The present study investigates vortical structures in an isotropic homogeneous decaying turbulence in the Direct Numerical Simulation. Subjected nodes of the vortex generation are extracted by monitoring the swirlity that specifies the unidirectionality and intensity of the azimuthal flow. In the transition, middle and small flow scales, e.g., the flows composed of wavenumbers 20-40 and 60-120 in the total wavenumber less than 120, are indispensable for the creation of the key flow. Therefore, although much smaller flow scales have less kinetic energy and may be assumed not to affect greatly to turbulent flows in terms of flow dynamics, these may play non-negligible role for the vortex generation. This feature seems to be inherent in low Reynolds number of this turbulence.

NP05.00032 Analysis of Vortical Structure in Terms of Local Flow Topology in an Isotropic Homogeneous Turbulence, DAIKI AOYAMA, Graduate School of Engineering, Aichi Institute of Technology — The present study investigates vortical structures in an isotropic homogeneous decaying turbulence in the Direct Numerical Simulation. We apply the swirl plane and physical quantities, the swirlity, soriuity and vortical flow symmetry quantity, associated with the invariant local topology (Nakayama, FDR 2014). The swirlity and soriuity specify the unidirectionality and intensity of the azimuthal flow and radial flow, respectively in an arbitrary plane, and the symmetry quantity specifies the direction and the degree of skewness of the vortical flow. The vortical structure is statistically analysed in terms of the distribution of azimuthal velocity and radial velocity which are extracted from the flow in the swirl plane around points where the swirlity has maximum value after respecting the direction of skewness of the vortical flow in that plane because vortical flow generally swirls with respective skewness. The swirling radius is estimated from the distribution of both azimuthal velocity and swirlity. The distributions of azimuthal velocity and radial velocity that are non-axisymmetrically and non-linearly, respectively, indicates that none of vortex models is similar to this vortical structure.

NP05.00033 Relationships between the eigen-vortical-axis line and the vortex stretching in an isotropic homogeneous turbulence, HAYATO HORI, Graduate School of Engineering, Aichi Institute of Technology, KATSUYUKI NAKAYAMA, Department of Mechanical Engineering, Aichi Institute of Technology — The present study investigates the relationships between the eigen-vortical-axis line and the vortex stretching in an isotropic homogeneous decaying turbulence in a low Taylor Reynolds number. This axis line has been proposed as a vortical axis based on the invariant local flow topology and shown that it has stronger characteristics to pierce intense vortical regions than the vorticity line. The vortex stretching can be classified into (1) ineffective stretching that increases vorticity parallel to the swirl plane and (2) effective stretching that increases the orthogonality of the vortical axis and develops a vorticity component associated with swirling. The characteristics of the vortex stretching in a vortical axis are analysed focusing on the effective stretching and an angle between the directions of the vortical stretching and the local axis. Furthermore, it is analysed that the influence of the vortex stretching to the local axis geometry that is defined by the eigenvalues in terms of the gradient of the local axis direction and shows the behavior of the axis line, e.g., twist and convergence. These analyses show that the eigen-vortical-axis line has higher correlation with respect to the effective stretching than the vorticity line.
NP05.00034 ABSTRACT WITHDRAWN

NP05.00035 Qualitative Approaches to Understanding Coherent Structures in Turbulence
IHSAN T. SHAIFI, Department of Nuclear Engineering, Texas AM University, PAUL J. KRISTO, Department of Mechanical Engineering, Texas AM University, ABDULLAH G. WEISS, Department of Nuclear Engineering, Texas AM University, MARK L. KIMBER, Department of Mechanical Engineering, Department of Nuclear Engineering, Texas AM University — A review of several techniques is presented, with emphasis on recent developments in the mathematical treatment of the proper orthogonal decomposition (POD) as applied to experimental particle image velocimetry data. The experiment in question is the classical flow past a cylinder with three distinct shapes: round, square, and hexagonal at a Reynolds number of 16000. The purpose of the study is to analyze the identification of basic structures and estimation of energy content via filtering methods. Reynolds decomposition is the method of separating the flow field into its mean and fluctuating components. Galerkin decomposition uses the bulk velocity to identify small-scale vortices within the flow field. LES decomposition is analogous to a low pass filter that reveals small length scales. POD is an advanced method that takes high dimensional nonlinear coherent structures and converts them into a finite dimensional linearized projection. Vorticity is used to describe the local spinning motion near an eddy and to recover a velocity field from a vorticity field. The accuracy of each method is compared and differences in structures produced by each geometry are discussed. Practical concerns include computational time, data compression, and spatial resolution are addressed.

NP05.00036 Modeling Drop Carrier Particles Through Energy Minimization
BERNANDO HERNANDEZ ADAME, Massachusetts Institute of Technology, RYAN SHIJIE DU, University of California-Los Angeles, LILY LIU, University of Chicago, SIMON NG, University of California, Los Angeles, HANSSELL PEREZ, University of California, Merced, SNEHA SAMBANDAM, KYUNG HA, CLAUDIA FALCON, DINO DI CARLO, ANDREA BERTOZZI, University of California, Los Angeles — Drop Carrier Particles (DCPs) are solid microparticles designed to capture uniform microplet drops of a target solution without using costly microfluidic equipment and techniques. DCPs are useful for automated and high-throughput biological assays and reactions, as well as single cell analysis. However, little work has been done to understand the behavior of these particles in large scale systems, and researchers have had difficulty achieving uniform volume across the particles. Here we present a method for modeling a diverse range of geometric particle shapes using energy minimization techniques. Furthermore, interactions between two particles are modeled as a pairwise process of minimal energy splitting of the target fluid. We examined the effects of particle geometries on the expected number of interactions needed to achieve the desired uniform volume distribution. We then performed macro-scale experiments of two-particle interactions and compared the observed splitting behavior with our simulations. These comparisons indicate that the model accurately predicts particle splitting behavior and multi-particle volume distributions, thus providing engineers with insight regarding optimal particle geometries.

NP05.00037 Effects of Asymmetries on the Evolution of an Indirectly Driven ICF Capsule Outer Shell
CALVIN YOUNG, Los Alamos National Lab, UNIV. OF MICHIGAN COLUMBIA, ERIC LOOMIS, PAUL KEITER, Los Alamos National Lab, P-24, TANA CARDENAS, Los Alamos National Lab, MST-7, CASEY KONG, General Atomics, JACOB MCFARLAND, Univ. of Missouri Columbia — Nuclear fusion offers clean power production in a compact form, and as such is a focus of many avenues of research. Inertial Confinement Fusion (ICF) is particularly promising, though many hurdles remain in the attainment of fusion experimentally. ICF methods involve imploding a spherical capsule composed of hydrogen fuel sheathed in layer(s) of specially selected materials. The implosion is driven indirectly by bathing the capsule in laser driven x-rays. The ionized outer shell is forced inwards by ablative force, compressing the inner layers as a piston, until the fuel reaches an energy state at which robust burn and fusion reactions occur. Fabrication of the shell is difficult, and the form is an imperfect spheroid. Imperfections lead to asymmetrical evolution as the outer shell implodes, introducing instabilities which reduce compressive efficiency. It is necessary to be able to characterize the shape of the outer shell, to predict with simulations the effect of surface features on evolution during implosion. In this presentation I discuss the development of a tool which reads manufacturer profile data of the capsule surface and returns orientation and spherical harmonics. This data was then used to determine the evolution of features during initial implosion stages using an ablative rocket model. Results from these calculations can be used to calculate growth factors for instabilities such as the ablative Rayleigh-Taylor.

NP05.00038 Frequency Downshift in the Ocean
CAMILLE R. ZAUG, JOHN D. CARTER, Seattle University — Frequency downshift (FD) occurs when a measure of a waves frequency (typically its spectral peak or spectral mean) decreases monotonically. Carter et al. (2018) compared the efficacy of generalizations of the nonlinear Schrödinger equation (NLS) at modeling waves with and without FD in wave tank experiments. Narrow-banded swell traveling across the Pacific Ocean can also undergo FD, as evidenced in the classic experiments of Snodgrass et al. (1966). In this work, we compare (i) NLS, (ii) dissipative NLS, (iii) the Dysthe equation, (iv) the viscous Dysthe equation, (v) the dissipative Gramstad-Trulsen equation, and (vi) the Islas-Schober equation to see which model best describes the ocean data reported in Snodgrass et al., regardless of observed FD. We do so by comparing the Fourier amplitudes, spectral peak, spectral mean, and quantities representing mass and momentum between the ocean measurements and numerical simulations.

NP05.00039 Accuracy of Equations Modeling Higher Harmonics in Surface Water Waves
HANNAH POTGIETER, JOHN CARTER, Seattle University — We study the evolution of the higher harmonics in surface water wave experiments. We compare numerical predictions from asymptotic reductions of the Euler equations and its dissipative generalizations with measurements from water wave experiments conducted at Penn State University. Our models include the (i) nonlinear Schrödinger equation (NLS), (ii) dissipative NLS equation, (iii) Dysthe equation, (iv) viscous Dysthe equation, and (v) the dissipative Gramstad-Trulsen equation. We find the predictions from these models are not always consistent with the experimental data.

NP05.00040 Modeling Passive Drag-Based Fish Interactions and their Relation to Formation Behaviors
ABDRAHMAN MANSY, IMRAAN FARUQUE, Oklahoma State University — Recent work coupled high speed imagery-based fish schooling measurements with computational fluid dynamics to provide estimates of the fish’s thrust and drag forces. Reconfigurations indicating reductions in body drag during periods with minimal changes in kinematic inputs suggest that passive drag-based mechanisms could play a role in school reconfiguration and reduce the on-board sensory feedback demands. We use simplified interaction models to study the effects of passive drag-based interaction mechanisms in biological formations. Incompressible hydrodynamic forces were modeled as 1-D incompressible functions of egomotion, position, and velocity. We find conditions for relative position stability within the formation and compare two cases: (a) egomotion and relative position sensitivity only, and (b) egomotion, relative position, and relative velocity. Model (a) shows the agents’ relative positions are dynamically unstable theoretically and in simulation, while (b) is dynamically stable. This finding suggests that mechanisms to reconfigure individuals to lower drag states require relative velocity sensitivity, either through fluid interaction functions or active sensory feedback.
NP05.00041 Analysis of the flow of grains through a screw conveyor

AASHISH GUPTA, PRABHU NOTT, Indian Institute of Science — Screw conveyors are widely employed in industry for the bulk transport of particulate materials. Several studies have attempted to correlate the discharge rate with the angular velocity of the screw and the pitch to diameter ratio via experiments and particle dynamics simulations. However, a detailed mechanical model that would assist in optimal design of screw conveyors, hasn’t been attempted. In this study, we first construct a simple model that assumes the entire granular medium to move as a rigid body sliding along the surfaces of the screw and casing. By enforcing the balances of linear and angular momentum to a suitably chosen continuum element, we show that under certain limiting conditions, the discharge rate for a given angular velocity and screw geometry can be obtained. Further, the discharge can be maximized by setting the pitch to casing radius ratio to a particular value. We then study the detailed flow within the conveyor using the discrete element method and show that a significant fraction of the material exhibits solid body motion, in agreement with the simple model. We assess the effect of relaxing the limiting conditions employed in the model, thereby determining the connection between the friction at the walls and the discharge rate.

NP05.00042 A Yang-Mills Approach for Conformal Invariance in Turbulence

ANTONINO TRAVIA, RAZVAN TEODORESCU, University of South Florida — The relationship between conformal symmetry and stochastic processes has been a rapidly growing field over the last twenty years. Among other applications, this pairing was used to suggest the presence of conformal invariance in two-dimensional turbulence via numerical methods. We present a theoretical approach to realize this correlation for an incompressible fluid of the same dimension using techniques from Yang-Mills theory with a non-Abelian gauge group. In doing so, we also provide a new explanation for behavior near zero-vorticity lines.

NP05.00043 STUDENT POSTER COMPETITION: EXPERIMENTAL –

NP05.00044 Asymmetric forcing of two coupled thermoacoustic oscillators

YU GUAN, LARRY K.B. LI, The Hong Kong University of Science and Technology — In many combustion systems, such as gas turbines and domestic boilers, the presence of self-excited thermoacoustic oscillations can reduce reliability and efficiency. Recent studies have shown that such oscillations can be eliminated by carefully tuning the dissipative and time-delayed coupling between adjacent combustors, exploiting a nonlinear phenomenon known as amplitude death (AD). However, although the coupling conditions required for AD are well known, they may still be beyond the reach of practical systems because of the inherent space and operational limitations that such systems face. To address this issue, we examine whether external forcing can be used to enlarge the AD boundaries of a coupled thermoacoustic system. The system consists of two self-excited thermoacoustic oscillators interacting with each other via tunable acoustic dissipative and time-delayed coupling. By varying the strength of the forcing acting on each oscillator and the phase difference and detuning between the two forcing signals, we map out the forcing conditions required for AD under different initial coupling conditions, paving the way for an alternative method of suppressing harmful thermoacoustic oscillations in combustion systems.

NP05.00045 Closed-loop control of thermoacoustic oscillations using genetic programming

ANIMESH KUMAR JHA, BO YIN, LARRY K.B. LI, Hong Kong University of Science and Technology — The use of genetic programming (GP) to discover model-free control laws for nonlinear flow systems has gained considerable traction recently, having been applied for the closed-loop control of recirculation zones behind backward-facing steps, flow separation over sharp edges and turbulent mixing layers. This unsupervised data-driven control strategy has been shown to outperform conventional open-loop forcing, by enabling successful individual control laws to spread their genetic traits from one generation to the next. In this experimental study, we use GP to discover model-free control laws for the suppression of self-excited thermoacoustic oscillations, which are detrimental to combustion systems. We evaluate every individual control law in a given generation on a real-time closed-loop control system equipped with a single sensor (a pressure transducer) and a single actuator (a loudspeaker). We rank the effectiveness of the control laws with a cost function and use a tournament process to breed subsequent generations of control laws. We then benchmark the performance of the final generation against that of open-loop forcing, providing improved control laws for the suppression of self-excited thermoacoustic oscillations.

NP05.00046 Aerodynamic characteristics and flight behavior of the turbo-jav in the javelic throw

HARUKI NAKAYAMA, Graduate School of Kansai University, TOMOYA NAKAJIMA, Osaka Prefecture University, TOMOAKI ITANO, Kansai University, SUGIHARA-SEKI MASAKO, Kansai University, Osaka University — In order to improve the record of the javelin throw in the junior Olympic games, it is important to elucidate the flight characteristics of the “turbo-jav” used in this throwing event. The turbo-jav has many geometrical features different from a spear for the javelin throw, including the presence of tail fins. In the present study, we performed wind tunnel tests in a low speed wind tunnel to measure the drag force, lift force and pitching moment exerted on the turbo-jav for various angles of attack. Using the aerodynamic coefficients obtained, we numerically calculated the flight orbit of the turbo-jav for various angles of attack. Using the aerodynamic coefficients obtained, we numerically calculated the flight orbit of the turbo-jav for various angles of attack. This work was funded by the Research Grants Council of Hong Kong (Projects 16210418, 16235716 and 26202815).

NP05.00047 Using quadrotor IMU data to estimate wind velocity

MEGAN MAZZATENTA, DARIUS CARTER, DANIEL QUINN, University of Virginia — Due to their hovering ability and light frame, Micro Aerial Vehicles (MAVs) have the potential to conduct cheaper wind measurements with greater spatial resolution than weather balloons. However, wind sensors increase MAV payload and therefore increase cost and decrease endurance. To avoid a mounted sensor, wind velocity estimation models have been constructed using on-board Inertial Measurement Unit (IMU) data collected during flight. Existing models are able to relate IMU data to wind velocity, but they rely on calibrations and physical assumptions that limit measurement accuracy. To improve the accuracy of velocity measurements, we used a quadrotor to collect IMU data while surveying the surrounding flow using Particle Image Velocimetry (PIV). We compared IMU and PIV data for a quadrotor in still air, in the wake of another quadrotor, and in a vortex. We then evaluated how well existing models could determine velocity and turbulence intensity based on IMU data alone. Using IMU data in place of a mounted anemometer could reduce payload and allow low-cost tracking of gas plumes, pollution, and weather patterns.
NP05.00048 Improving the Descent Performance of Small-Scale Rotorcraft through Added Geometries1. DANIEL YOS, MORTEZA GHARIB, MARCEL VEISMANN, Caltech — The descent stage of all rotor vehicles—from helicopters to drones—results in a significant loss of thrust and increased fluctuations with respect to the system in hover condition. These losses are believed to derive from the reijestion of the rotor flow that causes an accumulation of tip vortices at the rotor plane: often referred to as the vortex ring state (VRS). An approach of utilizing additional geometries within the proximity of the rotor plane was investigated by using enclosed shrouds and various props (with enhanced blade tip designs), in order to improve the stability and performance of rotorcraft in descent. These geometries were aimed to prevent the interaction between the blade tip vortices and the rotor disk. Results from single rotor thrust tests indicate that it is possible to reduce the thrust losses within the VRS by adding geometries in distinct locations relative to the rotor disk, while additional PIV analysis potentially outlines the underlying flow mechanism that causes these performance improvements.

1The presented material is based upon work supported by the Center for Autonomous Systems and Technologies (CAST) at the California Institute of Technology

NP05.00049 2D Particle Image Velocimetry and Computational Fluid Dynamics Study on Sidewall Brain aneurysm1. JACOB BARRERA, HAN HUNG YEH, DANA GRECOV, The University of British Columbia — Cerebral aneurysms are cerebrovascular abnormalities characterized by the weakening and dilatation of a localized cerebral arterial wall. They are a prevalent vascular disorder affecting 2–5% of the worldwide population. Aneurysm rupture can be fatal. To prevent aneurysm rupture, endovascular stents can be deployed to redirect blood flow away from the aneurysm, reducing blood flow velocity in the aneurysm sac and encouraging blood vessel remodeling. Since hemodynamics plays a key role in aneurysm progression, an in vitro experimental setup was developed to mimic the cerebral circulation with particle image velocimetry (PIV) testing different internal carotid artery sidewall aneurysm models. The Newtonian and the non-Newtonian working fluids with matching density and viscosity of human blood were used. In addition, a computational fluid dynamics (CFD) analysis was conducted in parallel. Computational model was first verified and validated against PIV measurements and showed good agreements. The study showed that the Newtonian model overestimated hemodynamic parameters, such as the blood velocity and wall shear stress in the cerebral aneurysm sac, comparing to the non-Newtonian model, suggesting the shear thinning effects might be more prominent in this region.

NP05.00050 Towards a better understanding of the flow mechanisms involved in blunt traumatic aortic rupture. GHASSAN MARAOUCH, CURTIS H. HORTON, EDUARDO MALORNI, JOSEPH FANABERIA, GIAN-CARLO MIGNACCA, LORENZO MERCURI-BASTIEN, LYES KADEM, Concordia University, MARK COHEN, PMG Technologies — Blunt traumatic aortic rupture is a heart injury that can occur in falls, automobile accidents, and sporting injuries involving impact to the thorax. Despite its severity and high morbidity rate, the research still does not provide a consistent description of the mechanism of rupture. In this study, a crash testing dummy with an in-vitro pumping heart, 3D printed ribcage, and ballistic gel damping layer was developed to reproduce a realistic response to thoracic impact. Testing was performed using a standardized pendulum used for calibration of crash test dummies, with the location of impact being the middle of the sternum. Different impact severities were tested by adjusting the kinetic energy at impact with the initial height of the pendulum. Measurements on the dummy include instantaneous aortic pressure waveforms during impact and accelerations at the spine and sternum. The results of this experiment show that aortic pressure experiences significant changes in magnitude during simulated impact. This work could help contribute towards a better understanding of the mechanisms leading to blunt traumatic aortic rupture and the development of preventative measures.

NP05.00051 ABSTRACT WITHDRAWN –

NP05.00052 ABSTRACT WITHDRAWN –

NP05.00053 Modelling flow driven by travelling wave motion in the glymphatic system. LOGAN BASHFORD, NOAH ANDERSON, AMY BURKE, JEFFREY TITHOF, DOUGLAS H. KELLEY, University of Rochester — The glymphatic system is a waste removal mechanism of the brain. The glymphatic pathway includes perivascular spaces (PVS), which are annular channels surrounding blood vessels in the brain. These channels are filled with cerebrospinal fluid (CSF). There is substantial experimental evidence that the pulsation of these blood vessels drives CSF flow through the PVS. Irregular or weak arterial pulsations may cause suboptimal flow and poor waste removal. A build-up of these wastes (e.g., amyloid-beta) is linked to the development of neurodegenerative disorders such as Alzheimer’s disease. This research introduces a laboratory model of an artery and surrounding PVS. A viscous fluid fills the annular space between a small flexible tube and a rigid transparent cylinder. A travelling wave is generated by moving spherical beads through the flexible tube. The speed of the travelling wave is varied, and flow between the cylinders is quantified with a Lagrangian particle tracking algorithm. It was observed that increasing the speed of the travelling wave increased flow speed in a linear manner. This work provides an experimental foundation to investigate the effect of other parameters, such as frequency, amplitude, and wave shape.

NP05.00054 Hydrodynamics of Lemon shark’s (Negaprion brevirostris) dorsal fins. VIVIAN TURNER, ROI GURKA, ERIN E. HACKETT, Coastal Carolina University — To improve understanding of the hydrodynamic functionality of dorsal fins of sharks, we focus on the Lemon shark (Negaprion brevirostris), which features a second dorsal fin that is almost as large as its first dorsal fin; an uncommon feature of migratory shark species that is not well understood from both a physical and biological perspective. Laboratory experiments are performed in a flume using PIV to measure the near wake flow behind the first and second dorsal fins, and behind the tail of a deceased Lemon shark as well as a 1:1 ratio 3D printed flexible shark model. Vortex shedding in the wake is characterized through POD applied to vorticity fields estimated from the PIV data. Hydrodynamic forces are estimated using the velocity deficit in the wake to estimate drag, and a thrust model based on the characteristics of the vortex street in the wake. Drag and thrust coefficient results behind the first dorsal, second dorsal, and caudal fin are compared.

NP05.00055 Thrust generation of fish-fin geometries in continuous rotation. EMMA JAMIN, CECILIA FUERTAS-CERDEIRA, MORTEZA GHARIB, California Institute of Technology — Fish are known to use flapping motions of their caudal fins to propel, while man-made propellers commonly use continuous motion to achieve thrust. It is not known if fish use the flapping due to its limited range of motion or if it is the most effective way to maneuver in the water. The objective of this work is to analyze the propulsive performance of propeller geometries similar to those of fish fins when performing continuous rotary motions. Because caudal fins possess distinctive morphologies and stiffness adapted to the fish specific modes of life, varying geometries and compliances have been considered. In order to evaluate the thrust generation properties of these fins, an underwater vehicle capable of generating continuous rotation and equipped with exchangeable propellers has been built and tested in a water tunnel. The thrust forces generated by the different fins are presented and compared.
NP05.00056 Vapor bubble condensation in Hele-Shaw cell submerged in subcooled pool, MASASHIRO OKADA, Division of Mechanical Engineering, School of Science and Technology, Tokyo University of Science, Japan, TAKUMA HORI, Department of Mechanical Systems Engineering, Tokyo University of Agriculture and Technology, Japan, ICHIRO UENO, Research Institute for Science and Technology, Tokyo University of Science, Japan — Cooling technologies based on boiling heat transfer have attracted attentions as the heat-generation density of electronic devices increases. It is known that the microbubble emission boiling (MEB) can overcome critical heat flux under the specific subcooled condition; thus, MEB regime is expected to be applied to next-generation cooling devices. However, the occurrence condition of MEB has not been yet understood. Since MEB has the remarkable feature that vapor bubbles abruptly condense and collapse, it is important to understand the condensation process of the vapor bubble. In order to focus on the condensation process of the vapor bubble, we inject vapor into a narrow gap region between two glass plates (Hele-Shaw cell) submerged in subcooled pool of water. The Hele-Shaw cell allows us to access clear visualization inside the vapor bubble. Special attention has been paid on the correlation between the condensation process of vapor bubble and energy exchange through the bubble surface.

NP05.00057 Development of a nanoscale hot-wire probe for supersonic flow applications¹, KATHERINE KOKMANIAN, Princeton University, SVEN SCHARNOWSKI, MATTHEW BROSS, CHRISTIAN J. KAÆHLER, Bundeswehr University Munich, MARCUS HULTMARK, Princeton University — A new sensor based on the nanoscale thermal anemometry probe (NSTAP) was designed and fabricated in Princeton University’s clean room to obtain well-resolved mass flux measurements in supersonic flows. In order to withstand high forces, the sensing element was redesigned to be 400 nm thick, 2 µm wide and 30 µm long. The sensor was tested in the Trisonic Wind Tunnel Munich (TWM) at Bundeswehr University. The TWM is a two-throat blowdown tunnel with a unique capability of altering both the Mach number and the Reynolds number independently and in real-time. Freestream measurements were taken at M=2 to investigate the convective heat transfer characteristics of the sensor. A linear calibration between the Nusselt number and the Reynolds number appeared to best fit the data. This linear Nu-Re dependence has previously been observed when operating hot-wires in free-stream flows. The sensor exhibits effective heat transfer (Nu-Re dependence on both width and thickness of sensing element), the sensor is believed to operate in slip flow conditions, exhibiting unique heat transfer characteristics. The importance of both the thickness and the width of the sensing element was also investigated theoretically for various Mach numbers.

NP05.00058 Three distinct liquid drop detachment dynamics on vibrating 1D rod structure, SSNG JUN LEE, KYEONGMIN KIM, WONJOON CHOI, Korea University — Along with physical impact of liquid drops, condensations can induce undesirable drop formations on solid surfaces. This outcome can possibly downgrade the heat transfer efficiency and can even contaminate sophisticated structures that may cause costs during microfabrication processes. This problem can be alleviated by vaporizing unwanted drops through controlling temperature or humidity. However, this method is cumbersome and cannot be applied in the case of viscous fluids. Thus here, we explore precise dynamics of overall fluid drop detachment on solid surfaces through damped harmonic oscillations. To model the complexity of the surfaces, we utilized 1D cantilever rods having high curvatures. The vibration of cantilever beams with small deflections (below 1 cm) were tested to see three different types of drop detachment behaviors depending on surface energy, fluid viscosities and volumes. Three dimensionless numbers (Weber, Capillary, and Bond numbers) were used to identify at which conditions the drops detach from the beam sides. Thus, not affecting neighboring structures or other parts of the same body. We concluded that high gravitational and inertial forces (Wₑ>10 and Ca/Bo<0.1) are favorable for clean drop detachment leaving no residue on solid surfaces.

NP05.00059 Generating Unsteady Pressure Gradients Using Rapidly Deforming Surface, AADHY PARTHASARATHY, THERESA SAXTON-FOX, University of Illinois at Urbana-Champaign — This study demonstrates the capability of generating unsteady pressure gradients by an experimental flow. Given the relatable nature of complex multi-stream supersonic nozzle, a high-speed camera was used to observe the dynamic pressure gradient, a car's rapidly deforming ceiling causes a dynamically strengthening favourable and adverse pressure gradient in sequence. Curvature of the ceiling is characterised in an instantaneous manner by using a high-speed camera, along with the corresponding spatial variation of the strength of FPG and APG imposed. The maximum speed of deformation of the ceiling is 1 m/s, and the acceleration parameter, k, at the section at the point of maximum deformation ranges between 2.5 x 10⁻⁸ and 8.5 x 10⁻⁹. Time-resolved planar Particle Image Velocimetry is used to investigate the behaviour of the flow over and around the deforming ceiling. The different geometric and dynamic conditions tested will allow investigation of the effect of dynamic pressure gradients on the behaviour of turbulent boundary layers.

NP05.00060 Comparison of Complex Multi-Stream Supersonic Nozzle Geometry¹, TYLER VARTABEDIAN, SETH KELLY, EMMA GIST, DOMINIC DIDOMINIC, MARK GLAUSER, Syracuse University — Noise continues to be a concern with further developments of high-speed flow and the structural geometries surrounding it. A rectangular multi-stream supersonic nozzle with an aft deck is resolved utilizing stereo PIV along with near and far-field pressure and acoustic measurements. A focus is placed on optimizing for noise reduction while altering aft deck geometry through the development of a previously trained neural network. This is accompanied by incorporating a varied splitter plate which decomposes the flow field into two canonical flows, a core supersonic flow interacting with a subsonic wall-jet. The synergy of these two flows creates complex turbulent structures which feed into amplifying noise. Through the combined data from stereo PIV, near and far-field pressure and acoustic measurements, the goal is to design a low noise aft deck plate while furthering an understanding of how the splitter plate geometry affects the multi-stream flow interaction and relevant acoustic measurements.

¹This study was provided funding via research grants by the Air Force Office of Scientific Research (AFOSR) grant number FA9550-19-1-0081 (Program Manager: Dr. Greg Abate) and Spectral Energies LLC.

NP05.00061 Analysis of an acoustic levitator flow field using Particle Shadow Velocimetry, AMY LEBANOFF, Karlsruhe Institute of Technology, German Academic Exchange Service Research Internships in Science and Engineering, University of Central Florida, KAI SCHOENEWOLF, STEPHAN AUTENRIETH, CHRISTIAN LIEBER, RAINER KOCH, HANS-JOERG BAUER, Karlsruhe Institute of Technology — High concentrations of Nitrogen Oxide (NOx) emissions from diesel engines pose a threat to the environment. However, selective catalytic reduction (SCR) offers a means to reduce these NOx emissions. Optimization of SCR technology requires study of urea-water-solution (UWS) evaporation behavior to tune droplet evaporation models. Validation data for this purpose may be obtained via observation of acoustically levitated droplets under controlled pressure, temperature, humidity, and flow field conditions. Establishing well-defined conditions prior to actual evaporation experiments is vital for model development. One driving factor behind the heat and mass transfer associated with droplet evaporation is the relative velocity imposed by the flow field of the gas phase near the droplet. To characterize the levitator flow field, Particle Shadow Velocimetry was employed. The optical setup features a double-frame camera equipped with a long-distance microscope that is maneuverable along three axes, allowing for targeted assessment of locations in the acoustic levitator without adjusting the illumination. This measurement technique facilitated incremental improvements which resulted in a symmetric flow field deemed suitable for investigation of UWS droplet evaporation.
NP05.00062 Drive an Object Using Photothermal Convection Around a Water Vapor Microbubble. RYUTA MATSUMURA, SOUKI IMAFUKU, KYOKO NAMURA, MOTOFUMI SUZUKI, Kyoto University, MICRO PROCESS ENGINEERING LABORATORY TEAM — By using the photothermal heating of the thin film under laser irradiation, a water vapor microbubble is formed in degassed water. The bubble involves rapid flow, which results from the Marangoni force and bubble oscillation caused by a steep temperature gradient. It is assumed that the flow direction is changed by giving an asymmetric temperature gradient. Therefore, we changed temperature distribution by laser irradiation with multiple spots. By focusing a laser spot on the thin film immersed in degassed water, a water vapor bubble with a diameter of approximately 10 µm was created. Simultaneously, a sub laser spot was focused next to the bubble to yield a temperature gradient in the direction parallel to the film surface. Consequently, the rapid flow was generated around the bubble, whose direction was dependent on the power and position of the sub. Then, we formed on a thin mica chip as a lighter substrate the bubble which can generate flow parallel to the film surface. Finally, we succeeded in moving the mica chip by using the reaction force of the photothermal convection. It is expected to be utilized as the technique for a driving force in microfluidics.

1This project has received funding from JSPS KAKENHI Grant Nos 17H04904 and 17H01050.

NP05.00063 Double-diffusive and Rayleigh-Taylor instabilities in particle-laden water stratified over salt water in a Hele-Shaw cell. GRAHAM CHAMBERS-WALL, CATHERINE DEMA, ECKART MEIBURG, Department of Mechanical Engineering, University of California at Santa Barbara, Santa Barbara, CA 93106 U.S.A., PATRICK BUNTON, Department of Physics and Mathematics, William Jewell College, Liberty, MO 64068 U.S.A. — An experimental and computational investigation is performed for double-diffusive (DD) and Rayleigh-Taylor (RT) instabilities in particle-laden fresh water initially stably-stratified over salt water in a Hele-Shaw cell. Computationally, Darcy’s Law coupled with an advection-diffusion equation for salt and an advection-diffusion equation for particle concentration that includes a settling velocity is solved for two-dimensional stratified fluids in the presence of particle-loading. The flows are parametrized in terms of a stability ratio, a gravity parameter, and a dimensionless settling velocity. Results are analyzed in terms of relative dimensions of concentration profiles of sediment and salt. Experimentally, Schlieren imaging is used to image fresh water containing 3-6 µm glass microparticles layered above salt water both containing glycerol to slow dynamics. Dimensionless wavelength and time and distance until onset of instability are measured. Results are interpreted in terms of a “nose” region of increased density at the interface.

1This research was supported by NSF grant CBET-1914797.

NP05.00064 Experimental analysis of dilute particle-laden liquids over and through patterned structures. EILEEN HAFFNER, University of Illinois at Chicago, JONATHAN HIGHAM, University of Liverpool, PARISA MIRBOD, University of Illinois at Chicago — Particle-laden liquids are encountered in various applications both in laminar and turbulent flows. However, the concentration and velocity profiles of dilute suspensions when they are flowing over and inside a patterned surface are not yet known. This experimental study is conducted to examine the interaction of the particles in various dilute suspensions over and through a patterned structure. The patterned surface consists of cylindrical rods arranged in a square array. Particle Tracking Velocimetry data provides velocity and shear rate at the interface between the free flow region and the surface for dilute suspension flows. We examined the velocity and concentration profiles through and above the structure for various dilute suspensions. We find that the shear rate and velocity profiles are strongly dependent on the suspension properties and geometry of the structure.

NP05.00065 Accumulation structure of low-Stokes-number particles in high-aspect ratio half-zone liquid bridge of high Prandtl number fluid. TOMOKI SAKATA, HIROKI SAITO, Division of Mechanical Engineering, School of Science and Technology, Tokyo University of Science, Japan, TAKUMA HORI, Department of Mechanical Systems Engineering, Tokyo University of Agriculture and Technology, Japan, ICHIRO UENO, Research Institute for Science and Technology, Tokyo University of Science, Japan — Various space experiments on the International Space Station (ISS) have been conducted to elucidate the Marangoni convection in liquid bridge formed under the microgravity environment. Since the cost of space experiments is apparently expensive, it is necessary to accumulate knowledge of the phenomena on ground as much as possible in term of preliminary experiments. In addition, ground experiments can allow us to clarify the effects of gravity. We focus on the particle accumulation structure (PAS) produced by the thermocapillary effect in a half-zone liquid bridge on the ground. To compare with the PAS realized in Japanese Experimental Module Kibo in the ISS, the PAS in high-aspect ratio half-zone liquid bridge of high Prandtl number fluid is studied. The role of gravity is discussed through the comparison of these experimental results also together with linear stability analysis.

NP05.00066 Water entry of hydrophilic spheres through fabric-fluid interfaces. DAREN WATSON, CHRIS SOUCHIK, JOSHUA BOM, ANDREW DICKERSON, University of Central Florida — The vertical impacts of solid projectiles with the free surface of a deep aqueous pool are traditionally investigated with respect to impactor shape, entry speed, and surface roughness. Free surface alteration in some cases, may be more readily achieved for the modulation of splashes. In this combined experimental and theoretical study, smooth, free-falling, hydrophilic spheres impinge on penetrable and non-penetrable fabric substrates resting atop the fluid surface for Weber numbers in the range of 430-2700. Penetrated fabrics remain near the free surface, suppressing the splash crown, but allowing passage of a Worthington jet whose height increases with the depth of the trailing cavity. Non-penetrable fabrics create deep seal cavities by veiling the descending impactor, generating higher Worthington jets, and pronounced splash crowns. Some fabrics, both penetrable and non-penetrable reduce drag with respect to clean surface impacts by providing the drag-reducing benefits of flow separation while not offering a high inertial penalty. Such observations augur well for military and industrial applications where splashless warrant control to mitigate damage to life and property.

NP05.00067 Plume studies to characterize Turbulent Buoyant Plumes using multiple sensors. DANIEL BRUN, SUDHEER REDDY BHIMIREDDY, KIRAN BHAGANAGAR, University of Texas at San Antonio - Turbulent axisymmetric buoyant plumes released into calm air are studied experimentally using multiple sensing techniques by a hot-wire anemometer, Schlieren imaging and a FLIR VUE pro thermal camera. Heated Carbon Dioxide is released into a plume chamber under controlled conditions at a nozzle exit Reynolds number ranging from 1300 to 2000. The buoyancy flux and momentum flux at the nozzle exit are determined from the flow behavior as a function of initial conditions. Time-averaged statistics such as centerline velocity, temperature and plume half-width are calculated using hot-wire readings and image-processing of thermal camera and Schlieren recordings. To better understand the effect of buoyancy on turbulence and mean velocity, a reference case with no buoyancy flux at nozzle exit is studied.
NP05.00068 Interactions between bathtub vortices in a rotating experiment¹, DANIEL VAN BEVEREN, Haverford College. DANIEL LATHROP, University of Maryland — The bathtub vortex is a flow pattern uniquely suited for laboratory study, as the flow through a drain hole provides a radial inflow and vortex stretching in a controlled location, thus stabilizing the vortex. While these radial flow patterns provide stability, the attraction they cause between any number of such vortices makes it difficult to achieve a stable state of multiple bathtub vortices, thus limiting their utility as models for experimental study of vortex interactions. Here we test the effect of global rotation on such vortices by spinning a cylindrical container with two drain holes in the bottom, which we find allows the formation of multiple bathtub vortices in a co-rotating stable state. The orbit period of these vortices is observed to change with the global rotation rate, and apparently spontaneous switching between states with different numbers of vortices is observed, with larger numbers of vortices possible at higher global rotation rates.

NP05.00069 Flow induced vibrations from two circular cylinders in close proximity, CHRISTOPHER O’NEILL, APRIL JANG, BRANDON MCNEELY, ROBERT MARTINUZZI, CHRIS MORTON, University of Calgary — The present study is focused on investigating flow induced vibrations (FIV) of two circular cylinders (of diameter D and D/8) in proximity. The smaller diameter cylinder (referred to as the ‘control’ cylinder) is controlled via a two degree of freedom (x,y) traverse system. The system uses a genetic algorithm in an effort to maximize the amplitude response of the FIV of the larger diameter cylinder (referred to as the ‘main’ cylinder). Due to the difference in cylinder diameters and corresponding natural frequencies, at flow velocities where FIV begins to occur for the main cylinder, the control cylinder vibrates with a significant amplitude. To combat this issue, passive flow control methods are employed (i.e., helical strokes). The amplitude response of the main cylinder is investigated in detail in the present study using a combination of time-resolved planar FIV measurements and displacement measurements. The results show that the amplitude response and corresponding wake dynamics of the main cylinder are impacted significantly by the control rod and its positioning relative to the main cylinder.

NP05.00070 Noise Characterization of a Two Circular Cylinder Flow Induced Vibration Energy Harvester System, APRIL JANG, CHRISTOPHER O’NEILL, BRANDON MCNEELY, ROBERT MARTINUZZI, CHRIS MORTON, University of Calgary — The development of flow induced vibration (FIV) energy harvesters is an active area of interest as an alternative to traditional hydropower systems. We have developed a mechatronic system to investigate FIV of two circular cylinders (of diameter D and D/8) in proximity. The smaller diameter cylinder (referred to as the ‘control’ cylinder) is controlled via a two degree of freedom (x,y) traverse system. The system uses a genetic algorithm to find the optimal parameters describing a sinusoidal motion of the control cylinder, in order to maximize the amplitude response of the FIV of the larger diameter cylinder. In testing this system, various sources of noise have been identified that disrupt the genetic algorithm’s ability to find the optimal control cylinder parameters. To minimize the impact of noise on the system, a secondary genetic algorithm will be used to characterize the noise properties of the system as a function of the control cylinder parameters. Insights from this analysis will allow for modifications to both the mechanical system and the software to improve the overall performance of the system.

NP05.00071 Controlling chaos by the domain size, MAHDI GHADIRI MOTLAGH, ROUSLAN KRECHET-NIKOV, University of Alberta — As part of the recent effort to understand dynamics and evolution on time-dependent spatial domains, we present an experimental investigation on how domain deformation may serve as a mechanism regularizing chaotic motion. Faraday waves – standing waves formed on the free surface of a liquid layer due to its vertical vibration – are chosen here as a paradigm owing to their historical use in testing new theories and ideas. In our experimental setup of a vibrating water container with controlled positions of lateral walls, the Faraday patterns are visualized using the Fourier transform profilometry and the wave amplitude is measured using a high accuracy laser displacement sensor: these techniques allow us to reconstruct a time history of the pattern three-dimensional landscape. Data analysis reveals that domain deformation is not only able to transform the chaotic state of two competing modes into a regular (periodic) one, but also to isolate one of the competing modes in the regime, which on a time-fixed domain of the same size would otherwise correspond to a regular or chaotic pattern competition. These experimental findings are interpreted with appropriate theoretical arguments and insights.

NP05.00072 Measurements of Reacting Fuel Sprays Using High-Speed Imaging¹, JACKLYN HIGGS, JOSHUA BITTLE, The University of Alabama — Engineers are currently looking for solutions to reduce waste and the effects transportation needs have on the environment. One method is to transition to biofuels in diesel engines. Computational Fluid Dynamics (CFD) simulations can be useful provided enough experimental data is available for validation. Hence, we need real experiments to determine the relationship between simple properties of fuels that we can measure and the results of actual combustion experiments. An optically accessible constant pressure flow rig (CPFR) is the primary experimental apparatus and it can be used to set control parameters to study the fuel-air mixing in conditions similar to diesel engines. A schlieren camera measures initial fuel-air mixing, a chemiluminescence camera measures initial combustion, and a two color pyrometry camera measures soot production. Extensive test campaigns at various injection conditions, ambient conditions, and fuel type will enable a new level of understanding of the diesel combustion process. Before significant testing can be completed, the primary focus of the work presented here is on efforts to optimize the experimental set-up by addressing some key experimental challenges that had previously limited the quality of data obtained. Significant effort was also dedicated to developing code to aid in processing a limited initial data set. This code serves as a proof of concept that can be leveraged for larger data sets to be acquired in the future. As a result, the lab is an efficient and effective work space that allows for ease with acquiring data.

NP05.00073 Predicting Plasma Plumes Induced by High-Powered Lasers on a Copper Plate under Different Conditions¹, REECE FREDERICK, None — Industries that require material removal on a micro level, e.g., microelectronic industry, utilize high powered lasers that essentially vaporize the material away. When such high-power lasers strike materials, however, they often create plasma. The plasma plume absorbs the laser radiation before it reaches the target, reducing the rate of material removal. In the present work, plasma plumes induced by irradiation of a copper plate with a short-pulse laser under various background gas pressures are studied experimentally. The plasma is recorded using Schlieren imaging and a highspeed camera. This project is aimed to recreate the plasma environment in order to better predict its behavior. With better understanding of the plasma, we can more efficiently use these lasers to remove material by minimizing plasma absorption effects.

NP05.00074 Preliminary Characterization of an Iodine Plasma Source for use in Material Analysis

GEORGIA SHARP, JAMES ROGERS, RICHARD BRANAM, University of Alabama — Electric propulsion devices using xenon as a propellant are a high efficiency solution for large conventional satellites. The high storage density of iodine would enable these devices to require less mass for use in space technologies, if used as a propellant as an alternative to xenon. The ability to reduce the mass required for electric propulsion devices would not only reduce costs of space travel but also open up new opportunities for these devices to be used in smaller, more volume constrained missions. Iodine is a strong oxidizing agent. To determine if it is a viable alternative, the erosive properties must be quantified. The object of this research project was to characterize an iodine plasma source before using it for material exposure and analysis. A double Langmuir probe was used as the method of data acquisition for the plasma conditions. The plasma characterization identified the conditions in the plasma source that will be used to properly quantify the erosive properties in iodine plasma. Preliminary results indicate a maximum electron temperature of four electron volts, and a maximum plasma density of eight inverse cubic centimeters.

1This work is supported by the NSF Grant #1650710, the NSF EPSCoR RI-Track-I Cooperative Agreement OIA-1655280, and the Air Force Office of Scientific Research grant FA9550-17-1-0204.

NP05.00075 Measuring Pressure and Strain with Luminescent Coatings

KIMBERLY LOWNDES, Berry College, KYLE CHISM, AMRUTHKIRAN HEGDE, JAMES HUBNER, The University of Alabama — Often, researchers employ probes such as pressure taps and strain gauges to measure the pressure and strain on aerodynamic objects. However, these tools lack high-resolution and full-field capabilities that may be necessary for high-speed aerodynamic testing. A combination of photoelastic coatings (PEC) and pressure sensitive paint (PSP) has the potential to provide researchers with correlated, full-field surface measurements of maximum shear strain and pressure, respectively. Photoelastic coatings use circular polarized light along with birefringent material properties to provide information about the surface strain of objects, while pressure sensitive paint utilizes oxygen-quenched luminophores to measure pressure. Benchtop test results will be presented of a dual-layer PEC/PSP coating applied to cantilever specimens subjected to static and dynamic loading and imaged with a micro-polarizer digital camera.

NP05.00076 Can we measure the three-dimensional orientation of Vorticella from two-dimensional videos?

LUKAS KAROLY, RACHEL PEPPER, University of Puget Sound — Vorticella are aquatic suspension feeding microorganisms that live attached to surfaces and generate a feeding flow to draw in their food. They are crucial players in aquatic ecosystems, eating bacteria and debris as well as supporting larger aquatic organisms. To evaluate the impact of Vorticella feeding microorganisms that live attached to surfaces and generate a feeding flow to draw in their food. They are crucial players in aquatic ecosystems, eating bacteria and debris as well as supporting larger aquatic organisms. To evaluate the impact of Vorticella in their environments, as well as in practical applications like waste water treatment, it is important to understand Vorticella feeding rates. Previous work has shown that the orientation of Vorticella relative to the surface of attachment affects feeding flow and feeding rates. Vorticella cell body orientation is defined by the polar angle, which is measured from the vertical axis, and the azimuthal angle. Previous experiments have observed Vorticella using a horizontal microscope from which the polar angle was directly measured. The azimuthal angle was inferred as a function of the projected cell body length compared to a maximum measured cell body length. However, it is unknown how accurately this technique determines the azimuthal angle. We recorded time-lapse videos of Vorticella simultaneously from the side and the top. We then compared the calculated azimuthal angle from the side view to a direct measurement from the top view. We report the error in the calculated azimuthal angle as a function of the organism orientation.

NP05.00077 Influence of characteristic components of blood on blood splashing onto a solid wall

YUTO YOKOYAMA, MASANORI TAKEDA, HAJIME ONUKI, YOSHIYUKI TAGAWA, Tokyo University of Agriculture and Technology — Understanding of blood splashing on a solid wall is of great importance in forensic science since blood splashing determines the blood pattern remained on the wall. Blood is known as a complex liquid, containing platelets and blood cells such as red blood cells and white blood cells, as well as coagulant factors and liquid components such as water and proteins. In this study we investigate influence of characteristic components of blood on its splashing onto a solid wall by separating main components of the bloods. In our experiment, whole blood, containing all of the components, can be separated into three types of liquids: (i) Serum containing only liquid components of blood, (ii) PRP containing serum with coagulant factors, (iii) Plasma containing PRP with platelets. The droplets of these liquids and blood simulants are dropped from a needle at various heights and recorded by a high-speed camera. It is found that the droplet of whole blood shows a quite different behavior from droplets of the other types of liquids. We also compare the experimental results with the theories proposed recently and discuss the effect of the blood components on splashing.

NP05.00078 Wind tunnel testing of a NACA 0012 airfoil with passive biomimetic flow control devices

CHRIS JARMON, AMY LANG, PAUL HUBNER, SEAN DEVEY, The University of Alabama — Increased demand for eco-friendly and energy-efficient transportation has led researchers to explore methods of drag reduction for decades. Previous studies have shown some success by both passive and active flow control techniques. Recent studies have shown that shark skin has the ability to passively alter the flow by inhibiting flow reversal and controlling flow separation. This study examines various 3D printed biomimetic flaps and scales inspired by sharks and birds to begin to determine optimum design parameters such as the presence of surface riblets and characteristic length. The biomimetic surfaces are placed on the upper surface of a NACA 0012 wing. Force data is acquired for baseline and biomimetic surface models (Re = 200,000) at fixed angles of attack (steady case), gradual pitching rate (quasi-steady case), and high frequency pitching rate (dynamic case). Results will be presented as to the correlation between the biomimetic flaps and the alteration of airfoil lift and drag.

NP05.00079 Particle alignment under unsteady shear in non-Newtonian fluids causing modulations of effective viscoelasticity1, TAIKI YOSHIDA, Graduate School of Engineering, Hokkaido University, YUJI TASAKA, YUICHI MURAI, Faculty of Engineering, Hokkaido University — The effective viscoelasticity modulated by particle alignment in unsteady shear in non-Newtonian fluids was revealed by means of ultrasonic spinning rheometry (USR) [Yoshida et al., J. Rheol.(2019)]. The dispersed particles make alignments in the sheared direction in unsteady shear flows when the fluid media have sufficiently long relaxation time. USR evaluated the effective rheological properties modulated by the particle alignments; (1) the effective viscosity does not reach the value estimated by Einstein’s law; (2) the effective elasticity increases significantly with the increasing volume fraction of particles in the bulk of the measurement volume. To clarify factors causing the particle alignment in unsteady shear flows/deformations, numerical tests using a simple toy model with considering spring forces connecting between the particles with specific yield stresses were examined. The numerical tests explained the importance of the relaxation process on the orientation of the particles. To conclude the experimental findings supplemented with the results of the numerical tests, we suggest that local and macro rheological characteristics are strongly modulated by the particle alignment when the test fluid media have long relaxation times.

NP05.00080 Direct and indirect influence of crystallization on double-diffusive convection in ammonium-chloride solutions, DAISUKE NOTO, Hokkaido University, STEN ANDERS, SVEN ECKERT, Helmholtz-Zentrum Dresden-Rossendorf, YUJI TASAKA, Hokkaido University — Crystalization inside fluid flow is a complicated, but highly fascinating phenomenon in the field of geo- or astrophysics. For instance, a magnetic field of Jupiter’s moon Ganymede is thought to be sustained by crystalizing flow termed iron-snow, but little is known up to date. Thus, experimental tests to seek likely conditions for a presence of a dynamo are required. We have approached these phenomena via a model experiment using a test fluid of aqueous ammonium-chloride solution, which changes phase from liquid to solid under room temperature. To quantify velocity and temperature fields simultaneously, thermochromic liquid crystals (TLC) were suspended into the test fluid. We have established a masking technique to obtain velocity fields of the continuous and the solid phase. In addition, a neural network based thermometry utilizing TLC coloration has been established. With these methods, we found a direct and indirect influence of the crystals on the flow. At the beginning of the cooling process, intense precipitation of equiaxed crystals can directly modify the flow structure. Meanwhile, columnar crystals start to grow, and impede the cooling from the wall. Indirectly, crystal growth creates a stable density stratification, but an unstable temperature stratification.

NP05.00081 Experimental study on flow-induced vibration of tandem flexible cylinders at varying angles of inclination, GIANCARLOS CASTRO CASTRO, Miami University, BANAFSHEH SEYED-AGHAZADEH, University of Massachusetts, Dartmouth — Flow-induced vibration (FIV) response of a highly flexible inclined circular cylinder placed in the wake of a stationary cylinder is studied experimentally. The flexible cylinder is tension-dominated with an aspect ratio of 47 and a high mass ratio of 120. The cylinder was held fixed at both ends and placed in the test-section of a subsonic wind tunnel. The angles of inclination were varied from 0 to 45° with increments of 15. The inclined flexible cylinder lied in the wake of an upstream stationary cylinder of equal diameter and inclination. The dynamic response of the downstream flexible cylinder is studied for center-to-center spacing range from 3 to 7 times the cylinder diameter, in the reduced velocity range of $Re=260-3750$. Influence of inclination and cylinder spacing is investigated through studying the dynamic response of the cylinder in terms of the excited structural modes, amplitudes and frequencies of oscillations and transition between modes. Different values observed for the onset of oscillations and modal weight contributions explains that the FIV response of the system is different from that of a completely vertical cylinder for all angles of inclination larger than 15°. Dynamic response of the flexible cylinder was found to be always under the influence of the upstream one, even for large cylinder spacing of 7d.

NP05.00082 ABSTRACT WITHDRAWN

NP05.00083 ABSTRACT WITHDRAWN

NP05.00084 Effect of Seed Density on Dispersal of Seeds from Wet Splash Cup Plants, KELSY BRYSON, EMILY SAWICKY, RACHEL PEPPER, University of Puget Sound — Splash cup plants use raindrops to disperse their seeds. Plants are approximately 4-30cm tall with ~5mm-diameter fruit bodies. When raindrops fall into their conical fruit bodies, the splash ejects the seeds up to 1 m away from the parent plant. Understanding how the seeds are projected may enable a deeper understanding of dispersal after drop impact in other contexts and of splash cup plant evolution. Previous work using 3D printed cones as fruit body mimics found that maximum dispersal occurs with a 40° cone angle, defined as the angle between the side of the cone and the horizontal. Later work found that seeds, which were not accounted for in the original study, decrease dispersal distance. Seed density has also been found to correlate inversely with the average dispersal distance of seeds projected from a dry cup. In this study, we investigate the effect of seed density on dispersal from a cup that contains both seeds and water since this situation is commonly found in nature after one splash has occurred. We use 3D printed cones, a low-density polyethylene seed mimic, a high-density glass seed mimic, and high-speed video to analyze the splash. Our results show that lighter seeds travel further than heavier seeds, and the optimal cone angle remains 40° for both densities.

NP05.00085 Inertial, Aerodynamic and Elastic scaling of a passively pitching insect wing1, KIT SUM WU, JEROME NOWAK, KENNETH BREUER, Brown University — Evidence suggests that prominent features of insect wing pitching behavior are affected by inertial and aerodynamic forces with largely passive contributions from the wing hinge joint, which acts like a torsional spring. Motivated by the robotic applications of insect-inspired passive-pitching flapping wings, we study the scaling relationship between aerodynamics, inertia, and elasticity in the regulation of wing pitch and in the generation of lift forces in hovering flight. We measure forces and wing kinematics using an under-actuated robotic model with a prescribed wing stroke and an elastic wing hinge. Our data show that the fundamental dimensionless parameters for wings of varying geometrical, physical, and operational parameters. We also observe a dependency of pitching kinematics on these dimensionless parameters, providing a connection between lift coefficient and pitch angle characteristics. Our results illustrate the trade-off between contributions to lift by quasi-steady and rotational dynamics associated with wing translation and wing rotation at stroke reversal. These results will be of value both in understanding the mechanics of insect flight as well as in the future design of under-actuated flapping aerial robots.

NP05.00086 Waterbowls: Reducing Impacting Droplet Interactions by Momentum Redirection. HENRI-LOUIS GIRARD, DAN SOTO, KRIPA VARANASI, MIT. — Droplets impacting a solid surface can transfer mass and energy to that substrate. While superhydrophobic surfaces can restrict this transport by making drops bounce off, the liquid-solid contact is still extensive. Recent studies aiming to limit this transport further have focused on reducing the contact time. Here, we remark that flux-based transport phenomena scale with the contact area as well as time leading us to define an Interaction Parameter as the integral of the contact area as a function of time to describe the drop-substrate interaction. We design superhydrophobic surfaces with a macroscopic structure that redirects the momentum of the spreading lamella upwards, thereby restricting the liquid-solid contact. We show that, with optimally designed, such surfaces can reduce the interaction parameter by an order of magnitude compared to a regular superhydrophobic surface and provide design guidelines for the macroscopic structure. Finally, we demonstrate that a well-designed surface can reduce heat transfer between a simulated rain and a solid surface by a factor of two.

NP05.00088 Analysis of Shear Layer Structures from Time Resolved Schlieren Images of Supersonic Multi-Stream Rectangular Nozzle Flow. CHRISTOPHER HAUCK, JACQUES LEWALLE, MARK GLAUSER, Department of Mechanical and Aerospace Engineering, Syracuse University, Syracuse, New York. — Operational guidelines for new jet engines result in extreme flow physics. Using a Single-Expansion-Ramp-Nozzle (SERN), Syracuse University and The Ohio State University study the effects of variable operating conditions, nozzle configurations, and deck plate geometries on jet development and far-field acoustics. Identifying noise sources will allow the implementation of control systems to reduce the overall sound pressure levels. Building on previous APS presentations, Ruscher 2015 and Tenney 2018, this project uses time resolved (100 and 400 kHz) Schlieren imaging. Through filtering, these Schlieren images show dark “blobs” convecting along the top shear layer, and seemingly synchronized “bands” propagating off the exit shock wave. Upon analysis, these flow structures occur at a frequency of 34kHz. The frequency of the phenomena are due to von-Karman streets from the third-stream splitter plate, triggering Kelvin-Helmholtz Instabilities [KHI] in the shear layers. Analysis is occurring on the relationship between the KHI occurrences and resulting aeroacoustics. Ongoing work includes processing alternate image orientations and new data acquisition for variable splitter and deck plates.

1This study was provided funding via research grants by the Air Force Office of Scientific Research (AFOSR) grant number FA9550-19-1-0081 (Program Manager: Dr. Greg Abate), Spectral Energies LLC, and the Undergraduate Research Program at Syracuse University.

NP05.00089 Using Traveling Water Beads for Particle or Vapor Capturing. ABOLFAZL SADEGHPOUR, Mechanical and Aerospace Engineering Department, University of California, Los Angeles, HANGJIE LI, Department of Mathematics, University of California, Los Angeles. Y. SUNGTEAK JU, Mechanical and Aerospace Engineering Department, University of California, Los Angeles, ANDREA L. BERTOZZI, Department of Mathematics and Mechanical and Aerospace Engineering Department, University of California, Los Angeles. — Here, we report a new dehumidifier design with 200% higher water condensation rate per volume of the device compared to the traditional dehumidifiers while decreasing air-side pressure drop due to providing straight gas flow channels for the gas stream. This structure consists of cold fresh water beads traveling down along an array of vertically aligned strings, on which the counterflowing hot humidified air stream is condensed. The water beads are generated using the intrinsic instability of liquid films flowing down a vertical thread. Offering direct contact between the water and air stream, very high interface-to-volume ratios and long resistance times for heat/mass transfer, our unique dehumidifier is capable of achieving superior heat and mass transfer rates. Additionally, using our bead generating method, we developed an efficient particle capturing unit, in which an array of traveling beads is used as the collection section to capture charged ultra-fine particles (UFP) in the countercflowing air stream. Studies show that UFPs can enter the blood and penetrate the cell membranes. Our experimental results show that this design can remove more UFPs with significantly lower water consumption rate compared to the traditional particle capturing systems.

1U.S. NSF grant CBET-1358034 and Simons Foundation Math+X Investigator Award 510776.

NP05.00090 Plasma Assisted LCF Perovskite Ion Transport Membrane Processing of Methane. JULIO OCANA ORTIZ, CHIGOZIE CHINAKWE, REECE FREDERICK, RAJAGOPALAN RANGANATHAN, MRUTHUNJAYA UDDI, None — Ion Transport Membranes (ITM) are ceramic based materials that allow the permeation of ions, commonly oxygen, through the structure at high temperatures. ITMs can be utilized in oxy-combustion, molecular separation of hydrogen reactors, and is effective in Carbon Capture and Sequestration (CCS) methods. Nevertheless, such high operating temperatures are not completely ideal, mainly due to its environmental impact and high energy input. In this project, it is aimed to reduce the temperature required to enhance oxy combustion reactions by applying a low-temperature plasma-catalysis to a LaCaFeO3 (LCF) perovskite ITM. The experimental reactor is placed inside a ceramic casted furnace where the reaction takes place on each side of the membrane, monitoring the products on the sweep side using a Quad-Pole Mass Spectrometer (QPM). Future works aim to use solar energy to power the reactor.

1NSF EPSCOR Research Infrastructure Improvement (RII) Track-1 Cooperative Agreement OIA-1655280 grant and administered through the CPU2AL: Alabama Plasma Internship Program at the University of Alabama.
NP05.00091 Plasma Assisted LCF Perovskite Ion Transport Membrane Processing of Methane.\textsuperscript{1} CHIGOZE CHINAKWE, JULIO OCANA-ORTIZ, None, REECE FREDERICK, R. RANGANATHAN, DR. MRUTHUN-JAYA UDDI TEAM — Ion transport membranes (ITMs) have played a key role in the study of processing and converting natural gases. The membranes are composed of ceramic-based materials and allow the permeation of ions at temperatures ranging from 700° to 950°. Due to low energy conversion efficiency, the high temperatures related to the membrane separation system are inefficient for industry use. The experiment at hand focuses on treating LaCaFeO\textsubscript{3} (LCF) perovskite ITM with low-temperature plasma in order to lower the activation energy and heighten the performance of the ITM. The reactor was controlled in a two-inch diameter quartz tube placed inside an alumina ceramic furnace. Metal inlets sealed the opening ends of the quartz tube and allowed the insertion of the LCF perovskite ITM, feedstock gas (air), sweep gas or reactive gas (CH\textsubscript{4}), and plasma electrode (kanthal wire). To generate the plasma, the electrodes were connected to a 110 V PVM/DDR plasma drive. The study was inconclusive due to the damaging of the LaCaFeO\textsubscript{3} perovskite ITM. The bulk of the ITM, as well as the adhesive used to attach the membrane, assisted in the ITM rupturing. Moving forward we hope to find a solution to these problems in order to run the reactor and receive data.

NP05.00092 Particle enrichment and instability on a fluid interface\textsuperscript{1} BENJAMIN DRUECKE, ALIREZA HOOSHANGINEJAD, University of Minnesota, JENNA BROWN, Fort Lewis College, SUNGYON LEE, University of Minnesota — We investigate the displacement of a suspension of non-colloidal particles by an immiscible fluid inside a vertical Hele-Shaw cell with a gap less than twice the nominal particle size. We find that the particles move slower than the invading fluid and accumulate on the interface. The particle enrichment can cause an interfacial instability reminiscent of the classic Saffman-Taylor instability. However, unlike the classic viscous fingering patterns, the invading fluid penetrates into regions surrounding clusters of high particle concentration. In this way, the high-concentration clusters deform the otherwise flat interface. Although this effect is enhanced by the presence of many particles in a cluster, we show that the instability can also occur in the case of a single particle for a narrower range of parameters. In this poster, we present experimental results and discuss the competition between viscous drag and interfacial energy giving rise to this instability.

\textsuperscript{1} Funded by the National Science Foundation through the University of Minnesota MRSEC under Award Number DMR-1420013

NP05.00093 Flexible Airfoils and Their Effect on Flow Separation\textsuperscript{1} DAVID FARIYIKE, The University of Alabama, KELLIS KINCAID TEAM, LALIT ROY TEAM, DR. DAVID MACPHEE TEAM, ROOIHANY MAHMOOD TEAM — In the US alone there are 5,000 planes in flight at any given moment and 52,000 wind turbines in operation. Any object that is subject to high wind speeds or varying attack angles has the potential to have flow separation. Flow separation increases drag which results in a less efficient aerodynamic system. Previous research has shown that active shape changing airfoils can reduce flow separation. However, since the shape change is active it introduces parasitic cost to the system, detracting overall energy capture. In this project, a passive method of reducing flow separation with flexible airfoils is investigated. The flexible airfoils have shown to increase airfoil performance as compared to a rigid design. While the flexible airfoils can increase airfoil performance, it cannot withstand the same wind speeds as its rigid counterpart. The performance improvement is speculated to be a result of boundary layer reattachment post the point of stall, reducing the flow separation and increasing lift when compared to the rigid design.

NP05.00097 Numerical Study of the Hydroacoustic Characteristics of a Marine Propeller, VIJAYAKUMAR RAJAGOPALAN, VIJIT MISRA, DANIO JOE, Indian Institute of Technology Madras — Propulsion of surface and under water ships with low noise characteristics depends on a number of factors in terms of their safety and operational performances, and it is crucial to predict and control their underwater noise characteristics. In this respect, the main scope of this study is to calculate numerically the propeller noise, which is one of the main sources of underwater noise. Therefore, propeller noise is studied numerically for non-cavitating conditions. Flow around the propeller is solved with a commercial CFD software, while hydro-acoustic analysis is performed using a model based on Flowcs Williams-Hawking equation. Flow around a propeller is solved using a RANS solver with the SST k-\omega turbulence model. Then, transient solution is performed with second order implicit pressure-based solver. Velocity and pressure coupled via SIMPLE algorithm Numerical Methods and Flow Solver. Time dependent pressure data is used as the input for the FWH equation to predict far-field acoustics.

NP05.00098 Analysis of Unsteady Wall Jet Created by a Coaxial-Rotor in Ground Effect, VRISHANK RAGHAV, LOKESH SILWAL, Department of Aerospace Engineering, Auburn University — The study of unsteady characteristics of the outwash of a coaxial-rotor configuration droning at a fixed axial separation distance operating at a tip Reynolds number around 150,000. The effect of axial separation distance on the instantaneous interactions between the tip vortex structures in the outwash region and its influence on the dynamics generated in the outwash is investigated. The variation of the outwash characteristics with varying ground heights for the drone is also discussed.

NP05.00099 Circular towing: a restricted case, JAMES HANNA, University of Nevada, Reno — Dynamic equilibria of strings in fluids are relevant to a variety of situations including fiber sedimentation and cable towing. Here I consider a highly restricted special case of steadily rotating planar configurations experiencing purely normal linear drag forces, for which analytical results may be obtained. The resulting shapes approach Fermat spirals at sufficiently large radius.
NP05.00100 Analysis of the self-starting capability of a new hybrid vertical axis wind turbine with a fluid-structure interaction approach¹, MEILIN YU, KAN LIU, WEIDONG ZHU, University of Maryland, Baltimore County — Vertical axis wind turbines (VAWTs) provide promising solutions for distributed wind energy harvesting in both urban and rural areas. However, it is challenging to guarantee satisfactory self-starting capability and high power efficiency simultaneously in a VAWT design. We have recently designed a new hybrid Darrieus-Modified-Savonius (HDMs) VAWT to address this challenge. The aerodynamics of the new hybrid design is analyzed using a fluid-structure interaction approach based on high fidelity computational fluid dynamics. We find that compared to the Darrieus VAWT, the HDMs design has better self-starting capability due to the torque provided by the inner MS rotor at small tip speed ratios (TSRs); the HDMs design can maintain high power efficiency at large TSRS with an appropriately sized MS rotor. The key flow physics is that the HDMs design can keep accelerating at small TSRS due to the inner MS rotor, and can suppress dynamic stall on the Darrieus blades at large TSRS. The effects of the turbine configuration, inertia and loading on the self-starting capability and power efficiency are further studied.

NP05.00101 Dynamics of overshooting convection in a rotating spherical shell, LYDIA KORRE, Laboratory for Atmospheric and Space Physics, University of Colorado Boulder, NICHOLAS A. FEATHERSTONE, Department of Applied Mathematics, University of Colorado Boulder — Overshooting convection is a physical process by which turbulent convective motions generated in a convectively unstable region can propagate into a stably stratified zone that lies either on top or on bottom of the convective one. This process can lead to mixing of chemical species, thermal mixing, as well as contribute to the transport of magnetic fields and angular momentum. Thus, convective overshooting has direct and significant implications in stellar dynamics. Motivated by the Sun, we investigate these dynamics via numerical simulations in a spherical shell containing a convective zone with an underlying stable region. We present results of our runs which span a range of parameters and illustrate the dependence of convective overshooting on the intensity of the turbulence and degree of stratification of the convective region, the relative stability of the stable zone, the transition width between the two regions, as well as the rotation rate. These results can be particularly useful for gaining a better understanding of convective overshooting processes in stars and for improving existing models prescribed in 1D stellar evolution calculations.

NP05.00102 Modelling nutrient delivery to cells grown in a multiscale perfusable system, MOHIT DALWADI, University of Oxford — Growing cells in vitro expedites the process of testing viable drugs and reduces the need for animal testing. However, current methods to grow 3D structures eventually result in the formation of a necrotic core due to lack of nutrient access. One way to circumvent this is to use 3D bioprinting and photopatterning techniques to engineer multiscale perfusable systems that enhance nutrient delivery to cells. While these techniques offer a high degree of control over the configuration of the perfusable channels, it is not clear how the channels or cells should be distributed in order to maximize nutrient transport and avoid necrotic zones. To tackle these problems, it is imperative to have knowledge of the fluid flow within the perfusable hydrogel system; advection is the dominant nutrient transport mechanism. Thus, understanding and being able to control the flow within the biotube is paramount. In this talk, we use mathematical modelling to investigate how the nutrient transport to the growing cells is affected by experimentally controlled parameters, such as channel distribution, cell density, and the flow rate of nutrient fluid through the perfusable hydrogel structure.

NP05.00103 Transition to collective motion in two-dimensional microswimmer suspensions, VIKTOR SKULTETY, ALEXANDER MOROZOV, School of Physics & Astronomy, University of Edinburgh — A collection of microswimmers immersed in an incompressible fluid is characterised by strong orientational interactions due to the long-range nature of the hydrodynamic fields generated by individual organisms. As a result, suspensions of ‘pusher’ swimmers exhibit a state often referred to as collective motion or ‘bacterial turbulence’, which is dominated by jets and vortices compromising many microswimmers. The onset of collective motion can be understood within a mean-field kinetic theory for dipolar swimmers. In 3D, the theory predicts that the instability sets in at the largest scale available to the suspension. Here, we present a mean-field kinetic theory for a suspension of dipolar swimmers confined to a 2D plane embedded in a 3D fluid. We analyse the stability of the homogeneous and isotropic state, and find two types of instability: one is the analogous of the orientational instability in 3D systems, while the other is associated with strong density variations absent in 3D. In contrast to 3D suspensions, both instabilities occur at the smallest possible scale, and we discuss their implications for the ensuing collective motion.

NP05.00104 ABSTRACT WITHDRAWN

NP05.00105 Coupled fluid-structure interaction and mass transport in aortic valves, MOHAMMADREZA SOLTANY SADRABADI, Northern Arizona University, IMAN BORAZJANI, Texas A&M University, AMIRHOSSEIN ARZANI, Northern Arizona University — Near-leaflet biotransport processes play an important in calcific aortic valve disease initiation and complications are studied. First, constant biochemical concentration is imposed at the aortic root. Next, constant biochemical flux is imposed model of an aortic valve is coupled to continuum advection-diffusion transport equations. Two classes of problems representing aortic valve bioprosthetic aortic valve thrombosis. The solution to these transport processes involves coupled blood flow, nonlinear structural mechanics, and convective mass transport problems. Herein, 2D simulations are carried out where a two-way coupled fluid-structure interaction (FSI) model of an aortic valve is coupled to continuum advection-diffusion transport equations. Two classes of problems representing aortic valve complications are studied. First, constant biochemical concentration is imposed at the aortic root. Next, constant biochemical mass flux is imposed at the moving leaflet. Subsequently, biochemical transport near the leaflet is studied. The results show a close connection between vortex structures and biochemical concentration patterns. Distinctions in concentration patterns on the aortic and ventricular side of the leaflet are shown and implications for calcification and thrombosis discussed.

NP05.00106 Force exerted by a Stokeslet on confining boundaries, ALEXANDER MOROZOV, VIKTOR SKULTETY, School of Physics & Astronomy, University of Edinburgh, UK — Solutions to the Stokes equation can be constructed by combining suitably placed Stokeslets and other singular solutions, that simultaneously satisfy the equation of motion and the boundary conditions. This approach has proven especially fruitful in describing the motion of small solid bodies and self-propelled particles. Recent debate on the pressure exerted by microswimmers on the walls of the enclosing container, together with the observations of the apparent viscosity of microswimmer suspensions being strongly affected by their presence, stresses the need to evaluate the forces exerted by microswimmers on solid boundaries. Here, we study two archetypal problems: a Stokeslet next to a single flat boundary, and a Stokeslet confined in-between to parallel walls. This allows us to calculate forces exerted on the walls by microswimmers, and we find that while in the case of a single wall microswimmers exerts no total force on the wall, the force becomes nonzero in the latter. We estimate the pressure exerted on the wall by the typical dilute bacterial suspension used in experiments.
NP05.00107 An implicit adaptive high-order flux reconstruction framework for scale-resolving simulation of unsteady flows over moving complex geometries1, MEILIN YU, LAI WANG, University of Maryland, Baltimore County — We present a recent development of an implicit adaptive high-order flux reconstruction framework for moving domain simulation at intermediate and high Reynolds numbers. In this framework, the high-order flux reconstruction method is used for spatial discretization; the explicit first stage, singly diagonal implicit Runge-Kutta (ESDIRK) method is used to perform time integration; a dual-time stepping approach is used to assist convergence while maintaining temporal accuracy; a matrix-free implementation of the restarted generalized minimal residual (GMRES) method is employed to solve the large linear system; and a flow-resolution-based p-adaptation algorithm is adopted to apportion the computational resources to critical flow regions. The arbitrary Lagrangian and Eulerian (ALE) approach is used to enable moving domain simulation with body-fitted unstructured meshes, and the radial basis function (RBF) interpolation is employed to handle mesh movement and deformation. Several challenging 2D and 3D unsteady flow cases in the moderate to high Reynolds number range are used to demonstrate the capability of the new numerical framework.

1The authors gratefully acknowledge the support of the Office of Naval Research through the award N00014-16-1-2735.

NP05.00108 Bio-inspired flows in unsteady environments. Part II: crosswind gusts. MEILIN YU, NAKEIN POUD, University of Maryland, Baltimore County, JOHN HRYNUK, U.S. Army Research Laboratory — Autonomous underwater vehicles (AUVs) and unmanned aerial vehicles (UAVs) usually need to carry out tasks in unstructured and dynamic flow environments. This poses a number of challenges that cannot easily be addressed by approaches developed for highly controlled environments, such as uniform flows frequently used in experiments and numerical simulation This work studies the impact of crosswind gusts on the performance of flapping wings/fins at moderate to high Reynolds numbers (i.e., in the range from 10e+4 to 10e+6). A high-order accurate flux reconstruction flow solver with moving/deforming body-fitted unstructured meshes is used to perform the numerical simulation. We find that dynamic stall in a crosswind gust is very different from the stalled flow at a large geometric angle of attack (AoA) due to the different transient dynamics of the leading and trailing edge vortices. Reynolds numbers can significantly affect the vortex structures over the suction surface of the foil The effects of relative position between the gust and foil and gust strength are also discussed in this study.

NP05.00109 Bio-inspired flows in unsteady environments. Part III: mean flow shear. MEILIN YU, University of Maryland, Baltimore County, Z.J. WANG, SAEED FAROKHI, University of Kansas — Autonomous underwater vehicles (AUVs) and unmanned aerial vehicles (UAVs) usually need to carry out tasks in unstructured and dynamic flow environments. This poses a number of challenges that cannot easily be addressed by approaches developed for highly controlled environments, such as uniform flows frequently used in experiments and numerical simulation This work studies the impact of mean flow shear on the performance of flapping wings/fins. A hyperbolic tangent mean flow shear profile is superposed onto the uniform freestream to generate a shear flow A high-order accurate spectral difference flow solver with moving/deforming body-fitted unstructured meshes is used to perform the numerical simulation, and dynamic mode decomposition is applied to analyze coherent flow structures. We find that flapping motion can significantly promote unsteady lift generation in mean flow shear; the stronger the shear is, the larger the lift is. At the same time, the lift coefficient is much larger than that predicted by the Kutta-Joukowski theory under the same flow conditions. Thrust generation is almost not affected by the mean flow shear.

NP05.00110 Non-Newtonian effects on the slip and mobility of a self-propelling active particle, AKASH CHOUDHARY, PUSHPAVANAM S, IIT Madras — Self-propelling Janus particles generate concentration gradients along their surface by exploiting the asymmetry in surface activity. This gives rise to a ‘slip’ at the particle surface, which propels the particle without the requirement of external concentration gradients. In this work, the influence of viscoelasticity (second-order-fluid model) and shear-thinning/thickening (Carreau model) on the slip and mobility of an axisymmetric active particle. Using matched asymptotic expansions, we provide an analytical expression for the modification of slip. Using reciprocal theorem, we demonstrate the influence of fluid rheology on particle mobility for low Peclet numbers. The current study also provides insights into the transport of complex fluids through phoretic pumps.

NP05.00111 Computational simulation of guidewire motion in a blood vessel1, WANHO LEE, National Institute for Mathematical Sciences — The guidewire is made of a thin stainless-steel wire, inserted into the human body and moved through the blood vessel, and is an essential tool for the treatment and diagnosis of vascular diseases. In this study, Kirchhoff rod theory is applied to develop a guidewire model as an elastic rod, and to simulate moving within a given blood vessel. Particularly, the inherent characteristics (shape, strength, torque, and elasticity) of the guidewire are applied to the model, and the reaction of the guidewire to the axial movement and rotation of the operation portion is simulated. The blood vessel is presented with single branch, and the movement of guidewire along the shape of the vessel is examined. It will be also discussed the tip shape of the guidewire that must be selected to navigate to the desired path. The development of guidewire simulations can provide a safe environment for practitioners to practice as often as necessary while avoiding bioethics issues. In addition, it is possible to find an optimal pathways and controls for moving the guidewire to the clinical target with minimal stress on the environments within the vessel.

NP05.00112 A Mechanism by Which Nose Bluntness Suppresses Second-mode Instability. JOSEPH KUEHL, ARMANI BATISTA, ARHAM AMIN KHAN, University of Delaware — A physical mechanism by which nose bluntness suppresses second-mode instability is proposed. Considered are 7 degree half-angle straight cones of various nose bluntness radii at tunnel conditions relevant to the AFOSR-Notre Dame Large Mach 6 Quiet Tunnel (Lakebrink et al. 2018). It is shown that second-mode suppression is achieved via entropy layer modulation of the basic state density gradient. A weakening of the density gradient disrupts the acoustic resonance necessary to sustain second-mode growth. These results are consistent with the thermoacoustic interpretation (Kuehl 2018) which posits that second-mode instability can be modeled as thermoacoustic resonance of acoustic energy trapped within an acoustic impedance well. Furthermore, the generalized inflection point criteria of Lees and Lin (1946) is applied to develop a criteria for the existence of second-mode instability based on the strength of the basic state density gradient. Lakebrink, M., T., K. G. Bowcutt, T. Winfree, C. C. Huffman and T. J. Julian, 2018. Journal of Spacecraft and Rockets. 55 (2): 315-321. Kuehl, J. 2018. AIAA Journal, 1-8, 10.2514/1.J057015. Lees, L., and Lin, C.-C., 1946. NACA TR 1115.
NP05.00113 Observations of Thermodynamic and Kinematic Properties During the Morning Transition in a Wind Turbine Array Boundary Layer Using an Instrumented Unmanned Aerial Vehicle . KEVIN ADKINS, Embry-Riddle Aeronautical University, ADRIAN SESCUC, Mississippi State University, CHRISTOPHER SWINFORD, NIKOLAUS RENTZKE, Embry-Riddle Aeronautical University — Observation, simulation and modeling have shown that wind farms alter downstream atmospheric properties as turbulent wakes generated by turbines enhance vertical mixing. With a large portion of wind farms hosted within an agricultural setting, changes to the wind turbine array boundary layer (WTABL) are important as they can potentially impact crop productivity, along with inflow to downstream turbines. The authors, and others, have demonstrated changes to thermodynamic properties within the WTABL during daylight observations made by small unmanned aerial systems (sUAS). The attainment of permission to fly at night and at higher altitudes, along with the enhancement of the sUAS instrumentation suite with fast-response three-dimensional sonic anemometers, enabled observations during predawn hours and through the morning transition. This work details observed changes to thermodynamic and kinematic properties during a series of overnight field campaigns undertaken during the summer of 2019 around a utility-scale wind turbine.

NP05.00114 Experimental study on resonance heat generation due to shock wave compression1 . SEONGHYEON SEO, Hanbat National University — The presentation addresses an experimental study of heat generation phenomenon associated with the conversion of flow kinematic energy to thermal energy through acoustic resonance. The phenomenon has been examined using a set of a sonic nozzle and a resonance tube. An underexpanded jet from the nozzle enters the tube and its shock waves compress the gas in the tube and reflect from the end. The repetition of the compression in a resonant manner results in an abrupt increase of gas temperature inside. The results indicate that various geometrical and flow parameters including a nozzle diameter, a tube inlet diameter, a distance between the nozzle and the tube, a nozzle stagnation pressure, a mass flow rate and a working fluid, affect heat generation characteristics. High-speed Schlieren imaging of supersonic flow in the vicinity of the nozzle exit and the tube inlet successfully identifies and retraces the space adjacent to the nozzle edge to allow the reflecting flow to expand and escape the tube for the occurrence of the resonance. The application of helium as working gas compared with nitrogen shows that the temperature increase becomes two times greater and it reaches beyond 1000 K in less than two seconds.

NP05.00115 Stability of Semi-Extrapolated Finite Difference Schemes . NARSHINI GUNPUTH, MIKAYLA FELDBAUER, SHEILA WHITMAN, ANDREW BRANDON, Lycoming College — When numerically solving partial differential equations, finite difference methods are a popular choice. Several factors come into play when choosing a finite difference method, such as stability, accuracy, and computational cost. In response to the small stability regions of explicit methods and the computational cost of implicit methods, we've developed a novel discretization technique called semi-extrapolation. Semi-extrapolation generates explicit schemes from implicit schemes by applying extrapolation in an unconventional fashion. Extrapolation can severely curtail stability, however, we've found that semi-extrapolation can improve stability, as compared to analogous explicit methods. In our presentation, we'll introduce our semi-extrapolation technique and discretize the Advection-Diffusion Equation according to semi-extrapolated and mainstream methods. Then, we'll discuss the stability regions of the schemes and analyze how the stabilities of the semi-extrapolated schemes compare to the stabilities of analogous schemes.

NP05.00116 Accuracy and Computational Cost of Semi-Extrapolated Finite Difference Schemes . SHEILA WHITMAN, MIKAYLA FELDBAUER, NARSHINI GUNPUTH, ANDREW BRANDON, Lycoming College — When numerically solving partial differential equations, finite difference methods are a popular choice. Several factors come into play when choosing a finite difference method, such as stability, accuracy, and computational cost. In response to the small stability regions of explicit methods and the computational cost of implicit methods, we've developed a novel discretization technique called semi-extrapolation. Semi-extrapolation generates explicit schemes from implicit schemes by applying extrapolation in an unconventional fashion. Semi-extrapolation can improve stability, however, we've also found that semi-extrapolation can have unexpected and interesting effects on accuracy. In our presentation, we'll introduce our semi-extrapolation technique and discretize the Advection-Diffusion Equation and the Advection-Diffusion Equation according to semi-extrapolated and mainstream finite difference methods. Then, we'll examine the computational costs and accuracies of semi-extrapolated methods. Included in this examination will be a comparison against the costs and accuracies of mainstream methods and a discussion regarding how stability influences the accuracy of semi-extrapolated schemes.

NP05.00117 State-free Front Tracking for Compressible Multi-material Problems . DANAIL VASSILEV, JAMES PECOVER, NICHOLAS HAWKER, NATHAN JOINER, ARTURAS VENSKUS, NICHOLAS NIASSE, THOMAS EDWARDS, JON HERRING, DAVID CHAPMAN, MARTIN READ, NIKITA CHATURVEDI, ADAM FRASER, First Light Fusion Ltd. — High energy density physics (HEDP) is a rapidly growing field studying interaction of matter and energy under conditions of extreme temperature, pressure and density. Numerical models capturing hydrodynamic instabilities and shocks are of crucial importance for understanding HEDP and designing different experimental components. Interface tracking methods, and specifically the front-tracking method with a fixed Eulerian mesh and a moving Lagrangian interface, have been applied to these types of problems with a best-in-class success Glimm2002.

NP05.00118 A Modified Cut-cell Approach for Inclined Boundary Conditions on Computational Fluid Dynamics . SAYURI TANAKA, NAOKI SHIMADA, YOSIHIIDE MATOBA, Sumitomo Chemical Co., Ltd. — A simulation method of fluid dynamics based on cut-cell approach was modified to deal with distorted boundary conditions. Most conventional cut-cell methods focus on a flux control across computational grids. On the other hand, we combined interpolation of fluid velocity and re-defined wall shear stress by using normal distance and projected fluid velocity. This combination was implemented in the structured computational grid. In addition, Detached Eddy Simulation approach with non-slip wall and logarithmic wall function model were used for calculation on turbulent flow in this study. Two-dimensional laminar flow with an inclined channel and air flows around a cylinder in three-dimensional fields were calculated to demonstrate applicability of our approach. As a result, we were able to obtain fair flow fields without any numerical instability, and its calculation efficiency was much higher than that based on unstructured approach from the viewpoint of accessibility of computational memory.
NP05.00119 Hytrac: A Hydrodynamic Front-Tracking Code for the Study of High Energy Density Multi-Material Flows, NATHAN JOINER, DAVE CHAPMAN, NIKITA CHATURVEDI, THOMAS EDWARDS, ADAM FRASER, NICHOLAS HAWKER, ION HERRING, NICOLAS NIASSE, JAMES PECOVER, MARTIN READ, DAN VASILEV, ARTURAS VENSKUS, First Light Fusion Ltd. — Inertially Confined nuclear Fusion (ICF) is an established research field pursued in laboratories worldwide; most notably in the US National Ignition Facility. First Light Fusion (FLF) is exploring alternative ICF directions, with the prime focus being sustainable power generation. Hydrodynamics and mixing of materials are critical to the design of an ICF target, where high-energy densities bring additional complexities to CFD models. Interface-tracking is a challenging numerical problem in terms of accuracy and robustness. Hytrac, an AMR front-tracking code, was developed with the aim of overcoming these challenges, to enable reliable and robust iteration of complex target geometries and optimisation. It has been verified in detail, with standard compressible fluid tests and methods, and validated against in-house experimental capability. Hytrac is parallelised using HPX, for efficient load balancing. It includes state-free tracking methods, and the more established Glimm approach. It also supports fluid nodes of arbitrary order, includes thermal conduction, thermal nonequilibrium, advanced physics, exact and approximate Riemann solvers, and several algorithms for space reconstruction and explicit time solution.

NP05.00120 A parallel pore-scale multiphase flow tool using the lattice Boltzmann method, SAHAR BAKHSHIAN, SEYYED ABOLFAZL HOSSEINI, University of Texas at Austin — The main focus of our study is to mimic multiphase flow in realistic three-dimensional rock models that enables us to gain a better insight into the effect of pore-scale phenomena on real reservoir problems. We developed a fluid flow simulator using a D3Q19 multiphase multi-relation-time (MRT) lattice Boltzmann (LB) model. The present LB model is an extended Color-Gradient approach with improved numerical stability and can handle multiphase flow simulations with low capillary number and high viscosity ratio. To improve the computational efficiency of the LB simulations to a reasonable level for industrial applications, the model has been applied to a parallel scheme written in C++ using the Message Passing Interface (MPI). We herein introduce the capability of our tool for multiphase flow simulation in porous media and present its application to CO2 sequestration in geological formations. The model has been applied to the simulation of CO2 and brine in sandstone rocks, by employing three-dimensional micro-CT images of rock samples. Injection of supercritical CO2 into the brine-saturated rock sample is simulated and complex displacement patterns under various reservoir conditions are identified.

NP05.00121 A comparison between functional derivative-based global sensitivity analysis and mixed Karhunen-Loève active subspace analysis of flows through porous media with uncertain material properties, MEILIN YU, University of Maryland, Baltimore County, ALEN ALEXANDERIAN, HELEN CLEAVES, HAYLEY GUY, RALPH SMITH, North Carolina State University — Flows through porous media, such as aquifer and biological tissues, are usually affected by the uncertain material properties. Quantifying the flow uncertainty due to the material uncertainty, and identifying the flow sensitivity to material properties are important practices to understand the underlying flow physics. Recently we have developed a functional derivative-based global sensitivity analysis (GSA) method and a mixed Karhunen-Loève active subspace analysis method for surrogate modeling of models with high-dimensional inputs and functional outputs. We have applied these two approaches to analyze the pressure field from biotransport in porous tumors. We find that the functional derivative-based GSA method is effective in finding input parameters that are important to the parameterization of the pressure field from biotransport in porous tumors. We also propose a new scaling for tmax with respect to the impact velocity which is in agreement with the experimental observations. We then present a new way to collapse in a master curve the evolution of the micro to nanometer drop contact diameter during impact for different wettabilities and different impact velocities.

NP05.00122 Stable long-wavelength convection with Dirichlet thermal boundary conditions through a Batchelor-Nitsche instability, ALARIC ROHL, LAYACHI HADJI, The University of Alabama — It is a well known fact that the onset of Rayleigh-Bénard convection occurs via a long-wavelength instability when the horizontal wavelengths of the fluid motion are greater than a critical value. The present study considers the case of Rayleigh-Bénard convection in a cell of infinite extent in the horizontal direction and having vertical walls of arbitrary shape. We consider two cases, one with thermal boundary conditions and the other with no-slip conditions. The equation for the Rayleigh-Bénard convection is solved numerically using a finite difference method. We find that the critical wavelength for the onset of convection is independent of the shape of the vertical walls. We also find that the critical wavelength is sensitive to the Prandtl number and the Rayleigh number. We use lubrication theory to derive an equation for the critical wavelength, which agrees well with the numerical results.

NP05.00123 Insights into droplet impact shape dynamics, DURBAR ROY, SOPHIA M, Indian Institute of Science, RABIRRATA MUKHERJEE, Indian Institute of Technology, Kharagpur, SAPTARSHI BASU, Indian Institute of Science — The underlying mechanics related to the initial shape transition is being studied experimentally using high speed imaging techniques for a droplet impacting on various substrates. Two traditional (Glass and PDMS) and two bio-inspired surfaces were used. A very distinct change in the shape of the deforming droplet during the early phase of the droplet spreading was observed when the impact Weber number of the droplet was varied from 1 to 50. The number of the capillary waves (wavelength) on the droplet surface changes quite significantly. This shows the existence of a critical Weber number beyond which the shape of the droplet during the initial transient of the spreading phase changes. The wavelength of the capillary waves was found to be a function of the impacting Weber number. This work provides some basic insights related to this transitional behavior using basic dimensional analysis and scaling theories.

NP05.00124 Dynamics of droplet spreading on Non-Newtonian liquid films, GRIGORIOS-ATHANASIOS IOANNIDIS, GEORGE KARAPETSA, Aristotle University of Thessaloniki — We investigate the dynamics of a liquid drop as it spreads along the interface of a liquid film. We consider the case of a liquid layer which exhibits non-Newtonian characteristics and is described by the Ostwald de Waele constitutive law. In the limit of both a thin droplet and a thin subphase, we use lubrication theory to derive equations for the positions of the interfaces. We use a finite-element formulation to obtain numerical solutions of the evolution equations. The effects of the physical parameters and rheological characteristics on the interface shapes are studied.

NP05.00125 How wettability controls nanoprinting, JOEL DE CONINCK, University of Mons — Using large scale molecular dynamics, we study in detail the impact of nanometer droplets of low viscosity on substrates and the effect of the wettability between the liquid and the plate. We show the maximal contact diameter during the nanodroplet impact (Dmax) as well as the time required to reach it (tmax) agrees with experimental data at the macroscale showing similarities between droplet impacts at the nano and the macro scales. The comparison between the MD simulations and different models reveals that most of these models do not consider all the effects we observe at the nanoscale. Moreover, most of their predictions for the impact at the nanoscale do not correspond to the simulation results. We have developed a new model for Dmax which agrees not only with the simulation data but also the experimental observations and it also considers the effects of the liquid-solid wettability. We also propose a new scaling for tmax with respect to the impact velocity which is also in agreement with the experimental observations. We then present a new way to collapse in a master curve the evolution of the micro to nanometer drop contact diameter during impact for different wettabilities and different impact velocities.

1This project has received funding from the Hellenic Foundation for Research and Innovation (HFRI) and the General Secretariat for Research and Technology (GSRT), under grant agreement No 792
Controlling the pinning of a receding contact line in a flow coating process. JOEL DE CONINCK, University of Mons — Capillary flow coating is a simple and effective technique to print and assemble ordered nanoparticle-based structures over patterned surfaces. The technique makes use of a nanoparticle suspension confined between two plates. Solvent evaporation and sliding movement of the top plate induce an internal flow that leads to the accumulation of nanoparticles at the bottom receding contact line and to their deposition on the bottom plate. Nevertheless, a comprehensive understanding of the process remains elusive, and in this respect the dynamics of wetting at the receding contact line is known to play a critical role. With the help of large-scale molecular dynamics simulations, we investigate the dynamic contact angle at the receding contact line as well as contact-line pinning on substrate heterogeneities. We develop a model to predict the pinning time of a receding contact line as a function of the displacement speed of the top plate on both chemical and topographical heterogeneities. Confirmation of the dynamic nature of contact-line pinning and justification of the contact line settling time allow us to better describe the time evolution of the receding angle in presence of heterogeneities.

Hydrodynamics-Dominated Wetting Phenomena on Hybrid Superhydrophobic Surfaces. ARASH AZIMI, CHAE ROHRS, PING HE, Department of Mechanical Engineering, Lamar University, Beaumont, TX 77710 — On chemically heterogeneous rough surfaces, determining the true apparent contact angle is a challenging task, because the global minimum surface energy is hardly attainable. The equilibrium contact angle is associated with the global minimum surface energy of the droplet-air-substrate system. However, in practice, the most stable contact angle is the measurable contact angle of the system. We present a series of 3D simulations using various initial conditions to reach possible meta-stable states for a water droplet on four micro-patterned hybrid substrates. The surface energy and energy barriers are computed. The apparent contact angles compared with experiments, global contour of the droplets, and liquid-solid area fractions are presented. Our results reveal a hydrodynamics-dominated wetting behavior on these hybrid surfaces, and capture several meta-stable Cassie-Baxter states, which cause a large contact angle hysteresis. For a given micro-patterned hybrid substrate, a critical impact speed can be found, above which the impact method cannot overcome more energy barriers to reach a lower energy state. Furthermore, a smaller variation of the measured contact angles is observed on the substrate with a lower heterogeneity of topology and chemistry.

Spreading on viscoelastic solids: Are contact angles selected by Neumann’s law? STEFAN KARPITSCHKA, Max Planck Institute for Dynamics and Self-Organization (MPIDS), Göttingen, Germany, MATHIJS VAN GORCUM, Physics of Fluids Group, University of Twente, Enschede, The Netherlands, BRUNO ANDREOTTI, Laboratoire de Physique Statistique, Univ. Paris-Diderot, France, JACCO H. SNOELIJER, Physics of Fluids Group, University of Twente, Enschede, The Netherlands — The spreading of liquid drops on soft substrates is extremely slow, owing to strong viscoelastic dissipation inside the solid. A detailed understanding of the spreading dynamics has remained elusive, partly owing to the difficulty in quantifying the strong viscoelastic deformations below the contact line that determine the shape of wetting ridges. Here we present direct experimental visualizations of the dynamic wetting ridge, complemented with measurements of the liquid contact angle. It is observed that the wetting ridge exhibits a rotation that follows exactly the dynamic liquid contact angle, as was previously hypothesized [Karpitschka et al., Nature Commun. (2015)]. This experimentally proves that, despite the contact line motion, the wetting ridge is still governed by Neumann’s law. Furthermore, our experiments suggest that moving contact lines lead to a variable surface tension of the substrate. We therefore set up a new theory that incorporates the influence of surface strain, for the first time including the so-called Shuttleworth effect into the dynamical theory for soft wetting. It includes a detailed analysis of the boundary conditions at the contact line, complemented by a dissipation analysis, which shows, again, the validity of Neumann’s balance.

Droplet dynamics during condensation on tailoring nanostructured surfaces. HUA-YI HSU, CHUN-CHI LI, SHIH-YAO HUANG, Department of Mechanical Engineering, National Taipei University of Technology — Liquid condensation from the atmosphere on a solid surface is commonly found in nature. To enhance energy conversion, nanostructured surfaces are with high potential to utilize the water generating applications. In this work, the droplet condensation on the tailored surface has been investigated by a 2D phase field model which is favorable to study the interfacial dynamics under microscopic scale. To model the liquid extracted from the air, both liquid and vapor are initially coexisted in random distribution. Spinodal decomposition process is then used here in which the fluid starts from an unstable thermodynamic state, and the homogeneous phase separates into coexisting phases spontaneously. Initially the small liquid droplet generated along the nanostructured surface and gradually merged into a coalescence droplet. By analyzing the droplet formation, the phase change dynamics can be studied and its relation with the spatially distributed structures on surface. The overall performance enhancement created by surface nanostructured was examined in comparison to a flat surface. Our understanding of this work provides more insights into the nanostructured surface topography on mass and heat transfer to improve the energy efficiency.

Three-dimensional front-tracking model for evaporation of drops SAUL PIEDRA, CONACYT-CIDESI Centro Nacional de Tecnologías Aeronáuticas, ALFONSO CASTREJON-PITA, University of Oxford, EDUARDO RAMOS, UNAM, GRETAR TRYGGVASON, Johns Hopkins University — We present the development of a full three-dimensional model to simulate the evaporation of falling drops. The evaporation model is based on the simultaneous solution of the mass, momentum, energy and vapor mass fraction conservation equations for incompressible fluids, properly adapted to incorporate the possibility of mass transfer at the boundary between the phases. The mass reduction of the drop is influenced by local thermodynamic conditions which in turn are modified by the dynamics of the drop motion. The vapor mass fraction at the interface is computed through the Clausius-Claperyon relation. The set of equations is defined in the whole domain, including the interface, and are solved using the finite volume/front-tracking method. The solution of the resulting linear equations systems are solved using the CUSP library implemented in a GPU in order to reduce the computational time. The validation for the evaporative flux calculation was done by comparison with a one-dimensional analytical solution for the evaporation of a planar surface. The simulation results for a static drop showed very good agreement with the $d^2$ law. Simulations for a single and multiple falling drops are also presented.

NP05.00131 Proper Orthogonal Decomposition Analysis of Turbulent Cryogenic Liquid Jet Injection Under Transcritical Conditions

DORRIN JARRAHBASHI, SALAR TAGHIZADEH, Texas A&M University, TEXAS A&M UNIVERSITY TEAM — Liquid-rocket and high-pressure diesel engines operate at pressures and temperatures that exceed the critical pressure and temperature of the liquid fuels during injection. The turbulent flow features and turbulent fluctuations are impacted by the transition from subcritical to supercritical conditions that in turn affect the turbulent mixing between the fuel and oxidizer in the combustor. LES and the proper orthogonal decomposition (POD) algorithm are employed to study the turbulent flow and dominant unstable flow modes at transcritical and supercritical conditions for cryogenic nitrogen jet injected into a warm nitrogen environment. The effects of the transition from transcritical to supercritical conditions on mixing layer behavior are investigated. Real-gas thermodynamic properties at supercritical conditions are considered via implementing the cubic Peng–Robinson equation of state and Chung’s method for obtaining fluid transport properties. The results show that the presence of large density gradients in the mixing layer at transcritical conditions smear out the turbulent coherent structures in the radial direction and turbulence shows anisotropic behavior near the mixing layer that retards the overall mixing process.

NP05.00132 Slip flow-enhanced streaming current in graphene oxide nanochannels

CHIH-CHANG CHANG, Department of Industrial Technology Education, National Kaohsiung Normal University, HUNG-WEI CHANG, RUEY-JEN YANG, Department of Engineering Science, National Cheng Kung University — In recent year, fast transport of water in carbon-based nanochannels due to the slip effect has attracted much attention. In this work, the pressure-driven streaming currents through sub-1nm nanochannels reconstructed by the layered material of graphene oxide (GO) was investigated experimentally and theoretically. The results show that the measured values of streaming current are 2–3 orders of higher than the predicted values calculated from electrokinetic model under no-slip assumption. It is inferred that the streaming current is greatly enhanced due to the presence of water slippage in sub-1nm partial wetting GO nanochannels. In addition, it is found that the slip length is strongly dependent on the KCl concentration, i.e., surface charge density. The estimated slip length is from 1 to 22nm. The lower surface charge density (KCl concentration) reveals the larger slip length. It is believed that our finding is beneficial to develop a higher efficiency of electro-kinetic power generator and electro-osmotic pump.

NP05.00133 Investigation of Corner Flows in Complex Supersonic Rectangular Jet Nozzles

SETH KELLY, TYLER VARTABEDIAN, EMMA GIST, DOMINIC DIDOMINIC, MARK GLAUSER, Syracuse University — The understanding of complex turbulent flows is of utmost importance when designing propulsive systems for next-generation-plus aircraft. Due to the highly unsteady nature of these flows, innovative techniques are required to extract the key physics insights that effect the overall performance of jet nozzles. The experiments in this study investigate the flow from a rectangular jet nozzle, specifically a Single Expansion Ramp Nozzle (SERN) over a proximal surface. The primary area of investigation is the flow in the corner regions and their influence on the downstream shear layers. The experiments conducted utilized a variety of measurement techniques including; Particle Image Velocimetry (PIV) to obtain high-resolution velocity measurements, high frequency response pressure transducers to measure the unsteady deck surface pressure, and acoustic measurements to detect the acoustic field acoustic measurements. These measurements help determine the effects of the jet corner regions on both the wall (deck plate side) and free (SERN side) shear layers. Additionally, this study aims to determine the influence of the corner flows on the downstream separation region as well as their role in near wall turbulence dynamics and unsteady deck loading.

NP05.00134 Development of multiple-color fluorescence image velocimetry

YUSUKE OTSU, JUN SAKAKIBARA, Meiji University, VIVEK MUNGUNDHAN, SIGURDUR THORODDEN, King Abdullah University of Science and Technology — Scalar image velocimetry (SIV) is the technique to extract velocity vectors from scalar field measurements. The usual SIV involves minimizing a cost function, that penalizes the deviation from the one scalar transport equation. This method can lead to multiple solutions and additional condition must be applied to select the best one if the full scalar gradient is zero over the volume. In addition, this technique is not applied for images with large displacement between two instances. Here we propose to minimize these problem with the reconstruction of the velocity field by using two different dyes and image deformation. Conceptually, we argue that having a double set of convergence criteria will result in a much more accurate velocity field. This improved SIV scheme is applied to the coaxial round free jet in liquid phase. The spatial velocity fields thus obtained demonstrated the good agreement of the velocity field solution with the continuity condition. The PDF of velocity fields also represent Gaussian distribution.

NP05.00135 Visualization of flow structure and its changes on flap with vortex generators

YOSHIYUKI ICHIKAWA, SHUNSUKE KOIKE, YASUSHI ITO, MITSUHIRO MURAYAMA, KAZUYUKI NAKAKITA, KAZUOMI YAMAMOTO, KAZUHIRO KUSUNOSE, Japan Aerospace Exploration Agency (JAXA) — For the aircraft design, the high-lift systems have an important role because of satisfying the demand for improving the lift for the take-off and landing configurations and increasing the payload. Vane-type vortex generators (VGs) are sometimes installed on the flap as a passive flow control device to improve the high-lift performances. However, the effect of VGs on the flow physics of the flap is still in discussion. In this study, the performance of VGs installed on the flap of a half-span model with a three-element high-lift wing was investigated by low-speed wind tunnel tests. In the tests, VGs were installed where chordwise velocity became nearly maximum on the flap and flow visualization was conducted with VGs in different size. The test results revealed that the interaction between longitudinal vortices generated by the VGs and cross flow on the flap influenced flow separation patterns behind the VGs, which depended on the size and installation spacing of the VGs. We also evaluated the lift coefficient of the wind tunnel model to investigate the relationship between the flow structures and aerodynamic performance of the flap with VGs.

NP05.00136 Control of flow and sound around leading-edge slat of 30P30N airfoil using plasma actuator

YUSUKE ONISHI, JUN SAKAKIBARA, Meiji university — We studied active control of flow and noise around a multi-element airfoil (30P30N) using time-resolved particle image velocimetry (TR-PIV), microphone and dielectric barrier discharge plasma actuator (DBD-PA). The angle of attack of the wing model fixed in the hard wall test section was 6° to 10°, and the Reynolds number based on the stowed chord length was 1.1 x 10^5 to 1.5 x 10^5. As a result of acoustic measurement, characteristic peaks were confirmed in the range of Strouhal number St = 1.0 to 4.0, which is based on the slat chord length. Periodic disturbance (St = 0.3 – 3.9) was applied to a shear layer formed from the slat cup using a DBD-PA placed at the lower of the slat. The noise peak frequencies were modified in synchronization with the disturbance frequencies of St = 1.0 ~ 2.8. These Strouhal number is close to the vortex shedding frequency in the case where the DBD-PA was deactivated. It was confirmed by TR-PIV and dynamic mode decomposition that the flow structures at the characteristic peak frequencies modified by the disturbance frequencies. The results show that the noise and the flow field around the leading edge slat could be controlled by the periodic disturbance.
NP05.00137 Reduction of drag acting on the Ahmed body using plasma actuators

FUKA MATSUMURA, RYOSUKE ODA, JUN SAKAKIBARA, Meiji University — Ahmed body is a scientific model of automobile, and it is known that the rear end of this model has an important role in aerodynamic characteristics such as drag and the wake structure. In this study, we used a dielectric barrier discharge plasma actuator array (DBD-PA) at the rear end of the Ahmed body with a slant angle of $\phi = 25^\circ$ and $35^\circ$ to control the drag acting on the model. The experiment was conducted in the wind tunnel at $Re = 3.95 \times 10^4$. The DBD-PA were uniformly installed in the spanwise direction at the edge between the slant surface at the rear end and the roof, and burst control was applied by changing the excitation frequency (burst frequency $f^+$) and the ratio (burst ratio, $BR$). As a result, at $f^+ = 100$ Hz, the drag coefficient tends to decrease as $BR$ increases. However, when $f^+ = 100$ Hz, where the burst frequency was large, drag was most reduced at $BR = 30\%$. The drag coefficient hardly decreased at $\phi = 35^\circ$. We hope to present a results of the one-dimensional array of the DBD-PA, which introduce disturbance distributed in the spanwise direction with the temporal phase difference allowing to create lambda type vortices into the shear layer.

NP05.00138 Transient Evolution of Flow Profiles in Shear Banding Wormlike Micellar Fluids

HADI MOHAMMADIGOUSHKI, PETER RASSOLOV, Florida State University, FLORIDA STATE UNIVERSITY TEAM — We report experiments on spatiotemporal evolution of flow field in model shear-banding viscoelastic micellar solutions in a Taylor-Couette cell. Our goal is to systematically study the effects of fluid elasticity on transient evolution of flow fields. By varying surfactant concentration, salt concentration, and temperature, we vary the fluid elasticity in the range $4.21 \times 10^{-4}$ to $8.57 \times 10^{-4}$ while keeping entanglement density fixed at $5.1 \pm 0.7$, viscosity ratio fixed at $40.3 \pm 2.9$ Po$\.s$, and curvature fixed at $0.085$. Our experiments show as shear strain increases, shear stress shows an overshoot followed by a decay towards steady state. Simultaneously with shear stress decay, fluid moves in the opposite direction to that of the imposed motion in a subset of the gap (i.e., back flow). Consistently with theory, the back flow strengthens as elasticity number increases. However, at very high elasticity numbers, the transient backflow disappears, contrary to the same theoretical predictions. In addition to the back flow, multiple shear band structures are observed in the transient flow at high elasticity numbers. These transient multiple bands persist to steady state. We surmise that the lack of back flows at high elasticity numbers is linked to the formation of transient multiple bands.

NP05.00139 Ultra-fine roughness effect on a flat plate boundary layer transition

AKIO YAKENO, HIROKI TAMEIKE, SHIGERU OYABASHI, Tohoku University — To reduce the viscous drag around an airfoil, delaying turbulence transition is one of the effective ways. In this study, we analyzed the influence of very small wavy roughness on the two-dimensional boundary layer transition with Direct Numerical Simulation, by resolving each small roughness. First, we found that the transition considerably delayed by $BR = 30\%$. Different excitation ratio (burst ratio, $BR$) as $f^+ = 0.1$ and $f^+ = 400$ Hz, the drag coefficient tends to decrease as $BR$ increases. However, at $f^+ = 100$ Hz, the drag coefficient hardly decreased at $\phi = 35^\circ$. We hope to present a results of the one-dimensional array of the DBD-PA, which introduce disturbance distributed in the spanwise direction with the temporal phase difference allowing to create lambda type vortices into the shear layer.

NP05.00140 Instability analysis of Poiseuille flow between two parallel walls partially obstructed by porous surfaces

NAMRATA ACHARYA, Naperville Central High School, SAMAN HOOSHYAR, PARISA MIRBOD, University of Illinois at Chicago — Plane Poiseuille flow is widely encountered in studies of diverse fields such as filtration, biomechanics, and geological problems. This work explores the effect of porous geometrical parameters, namely depth ratio and porous resistivity on the stability of Poiseuille flow over various porous surfaces. The most unstable mode is determined by numerically solving the eigenvalue problem derived from coupling between Navier-Stokes and Brinkman equations. Comparison of critical Reynolds number versus porous resistivity graphs for different depth ratios shows that there is an instability mode shift from the porous to the fluid with increasing the depth ratio. Also, the most stable mode occurs at smaller porous resistivity as the depth ratio becomes larger. To validate the theoretical analysis, we performed a set of experiments in which a Water-Glycerin solution flows through a channel partially obstructed by porous medium. The porous medium is modeled as square arrays of cylinders and is installed on the bottom wall of the channel. We found a good agreement between the steady-state and perturbed velocity profiles obtained analytically and experimentally.

NP05.00141 Radial distribution function of Lennard-Jones fluids in shear flows from intermediate asymptotics

LUCA BANETTA, University of Cambridge, ALESSIO ZACCONI, University of Milan, STATISTICAL PHYSICS GROUP TEAM — The microstructure of a suspension of particles is ruled by the probability of finding a reference particle in a position with respect to a target one, the pair correlation function. Its description under shear flow has been a challenge for theoretical methods due to the singularly-perturbed boundary-layer nature of the problem. Previous approaches have been limited to hard-spheres (HS) and suffer from various limitations in their applicability. Here, we present an analytic scheme based on intermediate asymptotics which solves the Smoluchowski equation with shear in spherical coordinates including both intermolecular and hydrodynamic interactions with the intent of describing the pair correlation function for realistically interacting particles in shear flows. First, the method has been validated through a comparison with the rdf of a HS fluid under strongly sheared conditions. Finally, we have been capable of studying the microstructure of a complex shear-thinning fluid such as the Lennard-Jones at varying values of the attraction strength: a new depletion effect is predicted in the microstructure of the LJ fluid under shear, a feature to our knowledge never discovered before.

NP05.00142 Development of lubricant impregnated organogel surface for sustainable high drag reduction

JAEHYEON LEE, GUN YOUNG YOON, SANG JOON LEE, Pohang Institute of Science and Technology — Lubricant-infused surfaces (LIS) where micro/nanostructured surfaces are infused with lubricating liquids have attracted much attention due to their slippery properties for drag reduction. However, most state-of-the-art LIS technologies require complex fabrication processes and suffer from depletion problem of the infused lubricant, which limit their scalability and sustainability of high performance. Thus, a new strategy is proposed to overcome these problems by utilizing lubricant-impregnated organogel surfaces (LIOS) for efficient and sustainable drag reduction. In this LIOS, a lubricating liquid is dispersed in a solid 3D cross-linked network assimilated through physical or chemical interactions. Owing to its distinctive liquid absorption and retention capacity, the proposed LIOS might work out the lubricant depletion problem. The LIOS exhibited an extremely low sliding contact angle of 1.2 $\pm$ 0.2, indicating a highly slippery surface. Due to the high slipperiness feature, the organogel had a large slip length of 209.4 $\mu$m, which gives rise to high drag reduction. The present results demonstrate a new strategy for LIS system of low cost and sustainable high drag reduction.

NP05.00143 Enhancement for long term integration results of one-way nested regional ocean model by employing boundary small eddy additions technique

JIN HWAN HWANG, PHAM VAN SY, Seoul National University — Generating small-scales structures during dynamical downscaling using the nested regional oceanographic models have been studied by the numerous studies. Those studies generated fine-scales feature in the nested regional circulation model with the large scale information at the lateral boundary incorporating with the local forcing. Recent studies however, found that the small-scales motions are under-developed seriously by downscaling work and such errors in the small scales can be transferred to the larger scales by inverse cascading and this could lead degrading the whole scale motions. This mainly limits the jump ratio of resolutions to small requesting the higher cost for downscaling. From that point of view, this work proposed an efficient technique, named boundary small eddy additions (BSEA) to enhance the quality of simulation and allow the higher jump ratio of the down scaling. The BSEA adds artificially the small-scale motions to the boundaries of a nested model based the spectral information of large-scale and can greatly improve the quality of the reproduction, even at much higher spatial resolution difference between the driving and the nested models.

NP05.00144 1.5-layer flow along a slope and western boundary

JOSEPH KUEHL, CHARLES MCMHAON, University of Delaware, VITALII SHEREMET, NOAA — Analytic and semi-analytic solutions are derived for two important classes of layered geophysical flows: a topographically controlled flow along a slope and a western boundary current. Specifically, a similarity solution approach is used to solve the 1.5-layer shallow water equations. Case A: An analytic solution taking the form of an inverse tangent function is found to describe the flow of a bottom intensified (lower-layer), weak current moving along a broad shelf/slope. Case B: An ordinary differential equation is derived to describe the flow of a 1.5-layer (upper-layer) viscous western boundary current. This equation is solved numerically to study the effect of a deformable layer interface on the structure of the western boundary current and the results are compared with rotating tank laboratory experiments. Both cases are formulated as idealized, two-layer, rotating fluid basins with sloping bottom topography. Kuehl, J. J. 2014. Geophysical Research Letters, 41, Ibanez, R., J. Kuehl, K. Shrestha and W. Anderson 2018. Nonlinear Processes in Geophysics, 25, 201-205. Kuehl, J. J. and V. A. Sheremet 2014. Journal of Fluid Mechanics, 740 97-113. Zavala Sanson, L. and G. J. van Heijst 2002. Journal of Fluid Mechanics, 471, 239-255.

NP05.00145 Measuring Energy Flux using PIV Data

JIA, CHARLOTTE MABBS, BRUCE RODENBORN, Centre College — Determining the energy flux of an internal wave from the experimentally measured velocity field was made possible by the work of Lee et al. (Lee et al., Phys. Fluids, 26, 2014). This method is used in our work to measure the amount of energy dissipated when internal waves reflect from sloping boundaries by comparing the incoming energy flux to the outgoing energy flux through a surface near to the reflection region. We also use numerical simulations of the Navier-Stokes equations in the Boussinesq limit where the energy flux is known from the pressure and velocity fields. There is good agreement between our experimental and numerical simulation data, and we find that there are high rates of energy dissipation during reflection process at the critical angle when the boundary flows are strong. The results are consistent with Dettner et al. (Phys., Fluids, 25, 2013) who showed that strong boundary flows are excited by tidal motion over model topography, but the conversion of tidal energy into internal waves is weak.

NP05.00146 Cross-stream migration of a particle in a non-isothermal flow in a microchannel using inertial focusing

T. KRISHNAVENI, T. RENGANATHAN, S. PUS, Indian Institute of Technology, Madras — Cross-stream migration of particles is observed in an axial flow in the presence of finite inertia in inertial focusing. It is a passive separation method where particles migrate to equilibrium positions. These positions mainly depend on the two counteracting forces namely the wall lift force and the shear gradient force. The equilibrium positions can be altered by changing the velocity profile of the fluid. In this work, the migration characteristics of a particle in a parallel plate microchannel is studied numerically in a pressure driven flow under the influence of constant temperature gradient in the transverse direction. The viscosity variation in the lateral direction is considered since the fluid viscosity is dependent on the temperature. An immersed boundary method is used to study the particle migration. The particle equilibrium positions depend on the applied temperature gradient. The equilibrium positions are not symmetric since the velocity profile is not symmetric. The effect of temperature gradient, Reynolds number and particle size on the particle migration are analyzed.

NP05.00147 Van Hove Singularities due to hydrodynamic interactions among the spheres in two dimensional flow system

HYUK KYU PAK, IMRAN SAEED, TSVI TLUSTY, IBS Center for Soft and Living Matter/UNIST — Dispersion relation for the phonon-like collective vibration modes due to the hydrodynamic interactions among the spherical particles with periodic separation a in quasi two dimensional flow shows peaks at the wavelength of 4.759a. In analogy to Van Hove singularities in solids, the density of states for hydrodynamically interacting systems becomes infinite at this wavelength with vanishing group velocities. Existence of these singularities is verified by computer simulation of hydrodynamic phonons in two cases: for periodic boundary conditions and for the system with broken symmetries. However, in unbounded systems the collective vibration decays before reaching the singularity.

NP05.00148 The rising velocity of a slowly pulsating bubble in a shear-thinning fluid

MARCO DE CORATO, Institute for Bioengineering of Catalonia (IBEC), The Barcelona Institute of Science and Technology (BIST), YANNIS DIMAKOPOULOS, JOHN TSAMOPOULOS, Fluid Mechanics and Rheology Laboratory, Department of Chemical Engineering, University of Patras — We study the rising motion of small bubbles that undergo contraction, expansion or oscillation in a shear-thinning fluid. We model the non-Newtonian response of the fluid using the Carreau-Yasuda constitutive equation, under the assumptions that the inertia of the fluid and of the bubble are negligible, and that the bubble remains spherical. These assumptions imply that the rising velocity of the bubble is instantaneously proportional to the buoyancy force, with the proportionality constant given by the inverse of the friction coefficient. We evaluate the friction coefficient as a function of the rheological parameters and of the instantaneous expansion/contraction rate of the bubble. Our results show that the radial motion of the bubble reduces the viscosity of the surrounding fluid, and markedly decreases the friction coefficient of the bubble. We find that the average rise velocity of a bubble undergoes radical pulsations is increased. We compare our predictions with the experiments performed by [S. Iwata, Y. Yamada, T. Takashima, and H. Mori. J. nonNewton. Fluid Mech., 151(1-3):30–37, 2008], who found that the rise velocity of bubbles that undergo radial pulsations is increased by orders of magnitude compared to the case of bubbles that do not pulsate.
NP05.00149 Strategic placement of an obstacle eliminates droplet break-up in the flow of a microfluidic concentrated emulsion. ALISON BICK, JIAN WEI KHOR, YA GAI, SINDY K. Y. TANG, Stanford University — Droplet microfluidics has enabled a wide range of high throughput applications, such as digital polymerase chain reaction (dPCR) and antibiotic screening. However, few studies have attempted to increase the throughput of the droplet interrogation process. Previously, strategic placement of a circular post near a narrow exit reduced conflict between interactions among living organisms or particles. Inspired by such work, we placed a circular post close to the constriction entrance of a tapered microchannel. The results of our experiment demonstrate that the effects of this placement on droplet break up are noteworthy. If the obstacle position and size is properly selected, the probability that the droplet will break decreases by up to 99%, thereby enabling a 3-fold increase in droplet interrogation rate. Droplet break-up depends on drop-drop interaction and drop deformation. Optimal obstacle placement immediately before? the constriction reduces drop deformation, which in turn reduces drop break-up. Strategic obstacle placement is therefore an attractive strategy for increasing droplet throughput.

NP05.00150 Parametric Study of the Wetting Transition of a Moving Meniscus.1 JIHOON KIM, Korea Institute of Ocean Science and Technology, JIN HWAN KO, Jeju National University, HEUNGCHAN KIM, HWAJUN LEE, Korea Institute of Ocean Science and Technology — In this study, we investigated the wetting transition of a moving meniscus in a grooved microchannel through a detailed parametric study based on measurement by an optical tool and micro-particle image velocimetry to avoid the transition in designing the microchannel. The parameters investigated were pitch, flow rate, and height of a microchannel. The contact angle, contact speed, and interfacial pressure difference were analyzed according to the parameters. We found that the pitch is most effective, the flow rate is moderately effective, and the height is least effective on that. The height even does not affect the contact angle because the solid-fluid interaction at the groove edge is stronger than the fluid-air interaction. As the critical correlation, the contact angle, which is dependent on the pitch and the flow rate, and the height affect the air pressure between the grooves, which governs the air penetration flux and mainly determines the wetting transition. Therefore, a powerful way to delay the wetting transition is to reduce the degree of air pressure variation, specifically with a low pitch and a tall height with a low flow rate. Eventually, understanding dominant input parameters in relation to the wetting transition will be very useful in the design stage of microfluidic applications.

NP05.00151 Natural gas supercritical properties: a multiscale molecular simulations study1 ALEXANDRO KIRCH, NAIYER RAZMARA, JULIO MENEGHINI, CAETANO MIRANDA, Universidade de São Paulo — A typical deficiency of continuum approach relies on the models describing averaged fluid properties. In particular, those models usually do not consider important molecular features occurring at the atomic level, which influences the macroscopic regime. A suitable strategy to describe these phenomena occurring over temporal and spatial scales is to combine the continuum mechanics with higher resolution methodologies within a multiscale scheme. In this context, molecular dynamics (MD) simulations provide reliable values to describe fluid basic properties. The obtained quantities could serve as input parameters to address multiscale issues observed in numerous scientific and industrial applications, including the Oil & Gas challenges. In present study, we take advantage of the predictive role handled by MD simulations to determine natural gas properties in the supercritical region, since there exist a lack of experimental data describing the mixture properties. In light of the multiscale approach, we discuss how the gas density, viscosity, and diffusion could feed lower resolution methodologies to address Oil & Gas interest systems, including nanoflows in porous media and membranes technology for gas separation.

1This research was a part of the project titled Infrastructure project for underwater construction robot test(2nd), funded by the Pohang City in Korea.

NP05.00152 Single Pixel Resolution Optical Flow for Low-rank Flow Fields1 TAKU NONOMURA, Tohoku University, Presto, JST, SHUNSUKE ONO, Tokyo Institute of Technology, Presto, JST — Single pixel resolution optical flow for quasi-steady fluid motion is proposed, while the conventional methods have been smoothed temporally or spatially. The proposed method does not use any spatial or temporal smoothing but utilizes the prior information that the fluid fields can be expressed by low-rank dataset. The new objective function with the restriction of low-rank approximation is formulated and solved by fast iterative shrinkage thresholding algorithm (FISTA) and randomized singular value decomposition (rSVD). The use of both FISTA and rSVD help us to speed up to solve the optimization problems. This algorithm gives us the single-pixel resolution flow fields form the pair images of flows, such as particle images. In the presentation, the details of objective functions and the results of numerical experiments will be reported.

1This research is partially supported by Presto, JST (JPMJPR1678).

NP05.00153 Characterization of drag coefficients of a sphere in non-Newtonian fluids by energy dissipation rate1 HAE JIN JO, WOOK RYOL HWANG, Gyeongsang National University, YOUNG JU KIM, Korea Institute of Geoscience and Mineral Resources — Accurate prediction of the drag coefficient of a single particle in non-Newtonian fluid is often required for analysis of fluid particle systems: for examples, prediction of behavior of rock fragments in drilling system, design and operation of slurry pipelines and solid-liquid separation processes. In this study, we introduce an effective viscosity in terms of energy dissipation rate to define the viscosity of the non-Newtonian fluid, and estimate the settling velocity and drag coefficient using effective viscosity. This method is established on the balance of the energy dissipation rate such that the external power is dissipated within the system as viscous dissipation in a laminar regime. The effective viscosity is a function of the effective shear rate, and the effective shear rate is determined by the apparent shear rate, which is the ratio of flow velocity to characteristic length, and the two flow numbers which depend geometrical characteristics of flow field only, almost independent of rheological property of a fluid. 1This work is supported by Korea Agency for Infrastructure Technology Advancement grant funded by Ministry of Land, Infrastructure and Transport (17IFIP-B133614-01, The Industrial Strategic Technology Development Program) and by the National Research Foundation of Korea (NRF-2019R1A2C1003974).

NP05.00154 ABSTRACT WITHDRAWN

NP05.00155 ABSTRACT WITHDRAWN
NP05.00156 Transition to turbulence in randomly packed porous media: energy and mixing characteristics. REZA M. ZIAZI, JAMES LIBURDY. Oregon State University — Transition to turbulence in randomly arranged porous media is observed in nature in applications such as cardiovascular, respiratory, and biological systems. The mechanisms driving the transition to turbulence through these flows are not very well identified. This work describes the parameters influencing on overall mixing during the transition process from the perspective of energy and dispersion characteristics by addressing the following questions: (a) what are the dominant mechanisms for energy growth emanating from swirl as opposed to turbulent kinetic energy budget, and (b) how does the inertial effects of vortical structures enhance the flow transport properties such as tortuosity and dispersion. Using time-resolved PIV, flow structures are investigated in the range of macro-scale Reynolds numbers from 100 to 1000 to show the pore- versus macro-scale effects on the energy of flow and swirl structures, turbulence production and dissipation, as well as dispersion, and their contribution in interpreting the overall flow mixing. We also show Lagrangian mixing characteristics based on Eulerian local pore velocity variances and relate these to macro-scale bed characteristics for uncovering the transitional processes in randomly distributed porous media flows.

NP05.00157 Gravity-Induced Ripening Undermines Capillary Trapping Stability. KE XU, Massachusetts Institute of Technology, YASHAR MEHMANI, Stanford University, LUORAN SHANG, Fudan University, QINGRONG XIONG, University of Manchester — Capillary (residual) trapping has long been considered as one of the safest CO2 sequestration mechanisms due of its hydrodynamic stability. Here we show, for the first time, that the long-term thermodynamic stability of capillary trapping could be compromised because of gravity, which has thus far been neglected in studies of bubble ripening. The interaction of gravity with molecular diffusion causes the vertical redistribution of trapped bubbles in a geologic porous medium, where bubbles at the top grow at the expense of bubbles at the bottom. The result is the formation of a gas cap at the top of the reservoir poised subsequent leakage risks. Accurate predictions of CO2 storage stability must therefore account for gravity-induced ripening. Here, we analyze the evolution of a population of trapped bubbles over time and develop simplified pore-scale and continuum models capturing its salient physics. The models reveal that the upward migration of CO2 may be hindered through the judicious selection of CO2 storage sites.

NP05.00158 ABSTRACT WITHDRAWN —

NP05.00159 Prediction of scattering properties for gas molecules on solid surfaces1. HIROKI KUSUNOSE, HIDEKI TAKEUCHI, National Institute of Technology, Kochi College — In high Knudsen number flows, thermal and flow properties of gas are strongly influenced by the characteristics of reflected gas molecules at solid surfaces. The investigation of scattering properties of gas molecules on solid surfaces is therefore important to analyze the flow fields for micro/nano scale flows or rarefied gas flows. However, the scattering properties of gas molecules depend on many factors such as atomic species, pressure and temperature in a flow field, and solid surface states. It is difficult to completely consider these factors for the investigation of the gas-surface interaction. The purpose of this study is to construct an effective model for predicting the scattering behavior of gas molecules on solid surfaces with adsorbate using machine learning approaches. The molecular velocity distribution functions of the reflected gas molecules were obtained by molecular dynamics simulations for the gas-surface interaction. The parameters of a Gaussian function model which expresses these velocity distribution functions for various adsorbed surfaces were predicted using machine learning. The velocity distribution functions based on the constructed model properly reproduce the results of molecular dynamics analysis.

NP05.00160 Fundamental Differences between Large-Eddy Simulation of Incompressible Turbulence vs. Premixed Turbulent Combustion. JAMES BRASSEUR, Univ of Colorado, YASH SHAH, Penn State Univ, PAULO PAES, Gamma Technologies, YUAN XIJAN, Penn State Univ — In contrast with RANS where the modeled terms are of leading order, the LES framework requires that the modeled subfilter-scale (SFS) contributions be of lower order than the leading-order terms. This will be the case if the resolved-scale (RS) contributions to the triadic sum of advective nonlinearities in spectral space dominate the SFS triads, requiring an effective grid that resolves well Reynolds stress motions. Turbulent combustion deviates from the LES framework is several key ways, primarily in the existence of the chemical source terms that lead to the release of thermal energy at scales generally unresolved. In this study we quantify the dominant SFS contributions to the key nonlinearities that underlie RS evolution in LES of premixed turbulent combustion to isolate fundamental deviations from the LES framework. With a new method to remove spurious spectral content in inhomogeneous directions, we apply a concurrent physical-Fourier space methodology to compressible DNS of flame-turbulence interactions to isolate the triadic structure of advective nonlinearities and the quadratic structure of chemical nonlinearities in the Fourier representation from which the dynamically dominant contributions are determined. We find that when the RS fluctuations in momentum and energy are well resolved, the relative SFS contributions are very different depending on the type of nonlinearity and the evolving RS vs. SFS content of individual species. Supported by AFOSR.

NP05.00161 Numerical Study of Detonations in Multiphase Flows. BENJAMIN J MUSICK, JACOB A MCFARLAND, Univ of Missouri - Columbia, PRASHANT TAREY, PRAVEEN K RAMAPRABHU, Univ of North Carolina Charlotte, DOUGLAS A SCHWER, Naval Research Laboratory Washington DC — The detonation phenomenon is of great interest in the engineering and scientific community. Much work has been done for gaseous detonations and their processes are relatively well understood. However, multidimensional, multiphase detonations develop characteristics that are more complicated to predict and understand. Many practical engineering applications aim to utilize liquid fuels due to their convenient nature, thus, a need arises for a greater understanding of liquid spray detonations. This poster focuses on the effects of varied initial conditions and physical models in two-dimensional liquid droplet JP-10 detonations. The effects of equivalence ratios, droplet size, droplet distribution, and particle breakup will be discussed. Different methods for particle tracking and generation will be discussed as well. Data was generated using the FLASH code developed by the Flash Center for Computational Science and modified for this work to include reactions and active particles using the particle-in-cell method. The multiphase results will be compared to data from gas phase simulations and other multiphase simulation codes.

NP05.00162 Space charge in pneumatically assisted electrospray. JULIA ZAKS, Agilent Technologies, TRYGVE RISTROPH — The importance of coulombic repulsion due to space charge on the trajectories of ions and droplets in pneumatically assisted electrospray depends on numerous physical properties of the spray. The influence of space charge has practical implications for systems that use electrospray, including ion sources for mass spectrometers. We develop a simplified theoretical model system representing an electrospray plume with high-pressure nebulizing gas. We solve Poissons equation and the continuity equation for this model system to find the radius of the plume, and use this result to quantify the effect of space charge on the trajectories of charged liquid droplets in the spray. These results are applied to ion sources for liquid chromatography-mass spectrometry by considering the effects of space charge on the trajectories of various mobile phases. The mechanisms driving space charge can be ignored in the case of modest electrospray currents, which correspond to low liquid flow rates. At higher currents and flow rates, the magnitude of the electric field from the space charge of the spray itself is comparable to that of electric fields from externally applied sources, suggesting that the role of space charge influences ion source behavior at high flow rates.
NP05.00163 Turbulent wall flows large-scale roughness heterogeneity: flow response to oblique alignment, WILLIAM ANDERSON, YIRAN ZHENG, UT Dallas — The physics of wall turbulence – ducts, boundary layers, and pipes – affects the aero-/hydro-dynamic signature of an array of flows. Such flows often occur under the “fully rough”, inertial-dominated limits for which viscous effects can be readily neglected and skin friction is driven by form drag (i.e., turbulent mixing). Rough surfaces composed of a complex height distribution are common in engineering and geophysical flows. Prognostic flow description is confounded by the presence of large-scale heterogeneity in surface geometry: that is, “patches” of differing roughness type, with spatial extent at least equal to the depth of the flow (i.e., duct half height, pipe radius, or boundary layer depth). When the prevailing transport direction is aligned orthogonal and parallel to such a heterogeneity, the flow responds with formation of an internal boundary layer or with counter-rotating rolls, respectively. These surface-driven secondary flows can completely disrupt outer layer dynamics, and thus have direct implications for wall modeled large-eddy simulation predicated upon outer-layer content. Moreover, realizations of precise orthogonal/parallel alignment are expected to be rare, and oblique alignment is likely the norm (for example, during vehicle maneuver). Results of wall turbulence response to such oblique arrangements are shown.

NP05.00164 Autonomous RANS/LES hybrid models with data-driven subclosures, GAVIN PORTWOOD, JUAN SAENZ, DANIEL LIVESCU, Los Alamos National Laboratory — We investigate the use of artificial neural networks (ANNS) to adapt classical Reynolds averaged Navier-Stokes (RANS) turbulence models for use in subgrid large-eddy simulation (LES) closures with the framework suggested by Perot & Gadebusch Phys. Fluids 19, 115105 (2007). In this study, we consider the application of a slightly-modified k − ε model to simulate stationary and decaying homogeneous isotropic turbulence (HIT) at a range of grid resolutions. These modifications dynamically account for (I) grid resolution relative to resolved motions and (II) backscatter from unresolved to resolved scales. In this framework, a modified turbulent viscosity accounts for the former, and the latter is determined empirically as a multiplicative factor in the modeled turbulent stress tensor. We leverage artificial neural networks to establish a universal form of this backscattering factor as a function of filter size and resolved flow statistics via a-priori analysis of direct numerical simulations. We perform simulations of stationary and decaying HIT at multiple grid resolution with the model and show via a-posteriori analysis that the use of an ANN to model complex physical phenomena, such as local upscale transfer, is both attractive and practical.

High-performance computing resources were provided via the ASC program at Los Alamos National Laboratory. Approved for unlimited release as LA-UR-19-27064.

NP05.00165 Magnus effect near flat ground, CHIN-CHOU CHU, HSIN-HUA LEE, Institute of Applied Mechanics, National Taiwan University, CHIEN C. CHANG, Institute of Applied Mechanics and Center for Advanced Research in Theoretical Sciences, National Taiwan University — This research is aimed to conduct experimental and numerical analysis of the Magnus effect when a circular cylinder is approaching a flat ground. The Reynolds number is fixed at 2000. Normalized parameters include the translation-rotation speed ratio α, declining velocity ratio β (translation-downward), and the gap ratio, denoted by SG =gap/D, where D=2cm is the diameter of the cylinder. The range of interest for α is from 0 to 0.2, and SG from 5 to 0.5. Three types of flow behaviors are identified according to the rotation of the cylinder: (I) non-rotating (α = 0), (ii) rotating counterclockwise (α > 0) and (iii) rotating clockwise (α < 0). In the first case (α = 0), the ground effect mitigates eddies behind the cylinder and leads to a higher lift and drag. In the second case (α > 0), as SG is decreasing, the lift and drag drops while the vortex shedding frequency increases. The vortex around the cylinder is alleviated by the ground effect, and the separation occurs at a lower portion behind the cylinder. In the last case (α < 0), as SG is decreasing, the drag increases while the vortex shedding frequency decreases. The vortex is strengthened by the ground effect, and the separation occurs at a higher location with the same reasoning. Further, stability analysis is applied to the three distinguished types of motion to examine their stability. In comparison, the phenomena of the flow patterns are consistent in both static and dynamic cases, yet the forces exerted on the cylinder are smaller in the dynamic cases.

NP05.00166 Project micro-meddy: doubly-diffusive experiments with heated vortices, MICHAEL BURIN, ANDREW GONZALES, MARGARITA SANZ, CSU San Marcos, JOEL SOMMERIA, SAMUEL VIBOUD. Univ. Grenoble Alpes, CNRS, Grenoble INP, LEGI — We report on experiments that feature anticyclonic vortices embedded in linearly stratified, rotating tanks. When heated with respect to their surroundings there are two conspicuous instability features. First, prominent early, is that the circumferential edge appears serrated with cusp-like features from lateral intrusions, which are surmised to be due to thermal convection. Second, prominent later, a stepped layer develops above the vortex due to theromhaline diffusive convection. Observations are described from both the Coriolis platform (13m diameter tank, “1.5m diameter vortices”) and a prototype smaller vessel (0.3m diameter tank, “0.1m diameter vortices”). Our observations are considered with respect to previous laboratory work as well as to geophysical vortices that are thermally distinct from their enviorn, such as Atlantic Meddies.

NP05.00167 The trajectory of a leading-edge vortex following separation from an oscillating hydrofoil, YUNXING SU, QUENTIN GUILLAUMIN, KENNETH BREUER. Brown University — Oscillating hydrofoils operating at high angles of attack shed leading edge vortices (LEV) into the wake during their flapping cycle. Predicting the path that these vortices follow is critical when attempting to optimize the interactions between multiple foils operating in close proximity. Here, we report on Particle image velocimetry (PIV) measurements of the flow field generated by an oscillating hydrofoil at various pitch amplitude and reduced frequency. Using the Q-criterion (Haller 2005), the LEV location was identified and tracked both on the hydrofoil and in the wake. We find that a larger pitch amplitude generally resulted in an earlier LEV shedding from the foil together with the generation of a wider wake behind the foil; higher reduced frequency usually delayed the LEV shedding from the foil leading to a narrower wake. The effects of endplates were also explored. Here we find that that with endplates on the foil the LEV appeared more coherent and stayed closer to the foil. Once shed into the wake, the LEV shed with endplates generally travelled at the same cross-stream (Y) position, while the LEV shed without endplates continued to travel away from the centerline, resulting in a wider wake.
NP05.00168 Controlling the forces on tandem stationary cylinders using oscillatory rotational motion, RAVI CHAITANYA MYSA, Singapore University of Technology and Design, DOMINIC DENVER JOHN CHIDNDAR, Queen’s University Belfast, VINH-TAN NGUYEN INSTITUTE HIGH PERFORMANCE COMPUTING, ASTAR, PABLO VALDIVIA Y ALVARADO. Singapore University of Technology and Design — In a typical tandem circular cylinder set-up where the cylinders are held fixed, the forces acting on the downstream cylinder are primarily due to its own vortex shedding as well as the vortex interaction from the upstream cylinder. The upstream vortex upon interacting with the downstream cylinder displaces the boundary layer on it, which then leads to larger forces on the downstream cylinder compared to the upstream cylinder. The point of any stagnation point can however be controlled in a smart way by rotating the downstream cylinder in an appropriate manner. An oscillatory rotational motion with a frequency corresponding to the Strouhal frequency of the upstream cylinder is specified. However, the amplitude and phase of this rotational motion is actively monitored so that the forces on the downstream cylinder are controlled. A detailed analysis using the flow contours is conducted to explain the effect of oscillatory rotation motion on the forces of the downstream cylinder. Numerical simulations are performed at Reynolds number of 100 as well as at 0,000. This study will help in developing active feedback control for determining the forces acting on the downstream cylinder.

NP05.00169 Experimental Observation of Modulational Instability in Crossing Surface Gravity Wavetrains, JAMES N. STEER, The University of Edinburgh, MARK L. MCALLISTER, University of Oxford, ALISTAIR C. L. BORTHWICK, The University of Edinburgh, TON S. VAN DEN BREMER, University of Oxford — The coupled nonlinear Schrödinger equation (CNLSE) is a wave envelope evolution equation applicable to two crossing, narrow-banded wave systems. Modulational instability (MI), a feature of the nonlinear Schrödinger wave equation, is characterized (to first order) by an exponential growth of sideband components and the formation of distinct wave pulses, often containing extreme waves. Linear stability analysis of the CNLSE shows the effect of crossing angle, θ, on MI, and reveals instabilities between 0° < θ < 35°, 40° < θ < 143°, and 145° < θ < 180°. Herein, the modulational stability of crossing wavetrains seeded with symmetrical sidebands is determined experimentally from tests in a circular wave basin. Experiments were carried out at 12 crossing angles between 0° ≤ θ ≤ 88°, and strong unidirectional sideband growth was observed. This growth reduced significantly at angles beyond θ ≈ 20°, reaching complete stability at θ = 30°–40°. We find satisfactory agreement between numerical predictions (using a time-marching CNLSE solver) and experimental measurements for all crossing angles.

NP05.00170 Science for the People: The dual nature of Science, RODOLFO OSTILLA MONICO, Science for the People, SCIENCE FOR THE PEOPLE COLLABORATION — Science for the People is an organization dedicated to building a social movement around progressive and radical perspectives on science and society. We are STEM workers, educators, and activists who believe that science can be a positive force for humanity and the planet. Science is not an abstraction removed from society. Science is produced by our labor. But the conditions of this production and the use of science are not controlled by the general public. Science has been used historically against marginalized communities for example to justify racism. Today, we see anti-scientific movements such as anti-vaccines arising out of the mistrust between the scientific community and the people. We must ensure that science serves all people, including the most marginalized. Until this is addressed, the STEM field will lack diversity and any solutions to this are patchy. While knowledge is won with our labor and can be used to advance common goals, we recognize that technical knowledge alone never delivers justice. Because of this, our members are committed to educating scientists and university students about the role that science and technology play in shaping the world, and using our knowledge to work with specific grassroots campaigns.

NP05.00171 Creation and research at the arts & sciences chair in Paris, JEAN-MARC CHOMAZ, LADHYX, CNRS-Ecole Polytechnique — The “Arts & Sciences” Chair at the cole polytechnique, the cole nationale supérieure des Arts Dcoratifs-PSL and the Daniel and Nina Carasso Foundation was created in September 2017 with the ambition of bringing together the arts & sciences to imagine tomorrow, by promoting collaborative practices and a citizen approach. In a context of climate emergency and constant technological and digital developments, artists and scientists have in common that they can play a “scouting” role. The Arts & Sciences Chair offers a research and creation program to question our interdependence with the environment, human and non-human, whether it is to explore our relationship to plants and climate or human-machine interactions. Several examples of art installations involving rain, fog, oxygen, waves, instability and time will be presented.

NP05.00172 Data-driven design and predict heat exchanger performance: configuration complexity and difficulty of prediction, ZHIFENG ZHANG, Process Engineering and Combustion, Delaware Innovation Campus, American Air Liquide, Newark, DE 19702, YILUN CHEN, Computational and Data Science, Delaware Innovation Campus, American Air Liquide, Newark, DE 19702, JIEFU MA, Process Engineering and Combustion, Delaware Innovation Campus, American Air Liquide, Newark, DE 19702, COMPUTATIONAL AND DATA SCIENCE COLLABORATION, PROCESS ENGINEERING AND COMBUSTION COLLABORATION — Data-driven methods have shown potential capabilities in accelerating future designs, optimizations, and evaluations. However, due to the complexity of fluid flow and geometry configurations of industrial devices, it is challenging to train effective data-based models. In the present research, we explore the relationship between device configuration complexities and reliable prediction algorithms. Taking a 2D plate heat exchanger as an example, we first use computational fluid dynamics solver to generate fluid flow/heat transfer data and then we train machine learning models to predict device performance. By increasing the complexity of the geometry configurations, we repeat the process and study the relationship between geometry configurations and machine learning models. Through the study, we can conclude the suitable algorithm for the specific plate heat exchanger application.

NP05.00173 Effects of foil shape on fish-like swimming, COOPER KOVAR, MARGARET BYRON, AZAR ESLAM-PANAH, Penn State University — Aquatic animals have evolved a diversity of propulsive mechanisms to locomote effectively through water. Fishes produce hydrodynamic thrust by acceleration of water through movement of their body and tails, while simultaneously reducing the resistance to their motion through morphological design, phased kinematics, and behaviors. In this study, the effect of the shape of a fish-like caudal fin as well as changes in the frequency of the linear motion of the fin is investigated. Many numerical tests have been done due to optical limitations, and it’s time for experimental test to confirm the numerical data. Experiments were conducted on a square fin, triangle fin, and forked triangle fin in order to compare and observe the changes in efficiency and thrust produced. Furthermore, the amplitude and frequency of linear oscillations were varied to see the data at different speeds within the optimal Strouhal number range at which fish are more efficient. The results of this research can be used to confirm the data collected from numerical experiments and further be applied to future biomimicry.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P01 Waves and Free Surface Flows: Turbulence 2A - James H. Duncan, University of Maryland
We consider the long-term dynamics of nonlinear dispersive waves in a finite domain. This configuration arises both naturally (e.g., surface waves in a finite tank) and computationally (e.g., when periodic boundary conditions are used to approximate an infinite system). While the finite domain effect on the formation of power-law wave spectra has been studied in the framework of discrete wave turbulence, the effect of the aspect ratio of the domain has remained unexplored. In this work, we study the long-term evolution of the two-dimensional MMT (Majda, Mclaughlin, Tabak) equation on both rational and irrational tori (mapped from two-dimensional planes with rational and irrational aspect ratios). It is shown that the dynamics (e.g., power-law spectra) of the two systems are remarkably different, especially at lower nonlinearity levels. The results are explained in the context of discrete nonlinear resonances, in particular by the survival of exact resonances on rational/irrational tori. We conclude by outlining the implications of these findings for other physical wave contexts.

6:21PM P01.00006 Surface Waves Enhance Particle Dispersion. MOHAMMAD FARAZMAND, THEMIS SAPSIS, MIT — How quickly does a point source of pollution spread in a fluid flow? Taylor’s single-particle dispersion theory predicts that, in homogeneous isotropic turbulence, the tracer variance $\langle |X(t)|^2 \rangle$ grows quadratically for short times $\langle |X(t)|^2 \rangle \sim t^2$ and linearly for large times $\langle |X(t)|^2 \rangle \sim t$. We show that these predictions break down for tracers dispersed on the free surface of a gravity wave. Using an exact nonlinear model to advect the tracer particles, we show that the nonlinear effects significantly enhance the dispersion. In particular, the tracer variance grows as $\langle |X(t)|^2 \rangle \sim t^4$ for times $t$ less than one wave period. In the asymptotic limit, as $t$ increases beyond one wave period, the variance grows quadratically with time, i.e., $\langle |X(t)|^2 \rangle \sim t^2$. We show that this super-diffusive behavior is a result of the long-term correlation of the Lagrangian velocities of fluid parcels on the free surface.

6:34PM P01.00007 Large-eddy simulation of oil droplet aerosol transport in wind over waves. DI YANG, MENG LI, University of Houston, YAJAT PANDYA, GIACOMO VALERIO IUNGO, University of Texas at Dallas — In this study, large-eddy simulations (LES) are performed to study the transport of aerosolized small oil droplets in wind over surface waves. The LES model consists of a wind turbulence solver and an Eulerian scalar transport solver. The wind LES solver uses a boundary fitted computational grid system that follows the instantaneous sea-surface waves to capture the turbulent flow structures and transport phenomena near the sea surface, and a hybrid pseudo-spectral and finite-difference method for spatial discretization. The aerosol transport is modeled using an Eulerian approach, in which an advection-diffusion equation for the oil droplet concentration field is solved using the finite-volume method with a combination of upwinding scheme and central difference scheme. Using this LES model, a set of simulations with various oil droplet sizes and sea-surface conditions are performed to investigate their effects on the vertical and lateral transports of oil aerosols in the marine atmospheric boundary layer.

6:47PM P01.00008 Froude number effects on free surface turbulence in open channel flow. YUJIA DI, University of Minnesota, Twin Cities; Shanghai Jiao Tong University, BINGQING DENG, ANQING XUAN, University of Minnesota, Twin Cities, YE LI, Shanghai Jiao Tong University, LIAN SHEN, University of Minnesota, Twin Cities — Direct numerical simulations of free surface turbulent flows in open channel at different Froude numbers have been conducted to study the surface deformation and the turbulence below. The deformation of the free surface is captured using a boundary-fitted grid and fully nonlinear free-surface boundary conditions. By studying the frequency-wavenumber spectrum of surface elevation, we find that the advection of the mean current alone contributes to the surface deformation at low Fr, while the contribution of the surface wave becomes more important as Fr increases. It is also found that in the bulk flow region, more energy of the streamwise velocity component is distributed at large length scales as Fr increases, indicating that the Fr number effect can also reach into the bulk region. The underlying mechanism of the modified bulk flows at high Fr numbers is further analyzed using the TKE budget spectrum.

7:00PM P01.00009 Scale effects for air entrainment in quasi-steady breaking waves. KELLI HENDRICKSON, DICK YUE, Massachusetts Institute of Technology — Quasi-steady breaking waves are prominent and highly observable features in civil, environmental, ocean and naval engineering applications with direct impact on turbulent dissipation and air-sea interaction. We use high-resolution 3D direct numerical simulation of quasi-steady breaking waves to study the air entrainment characteristics as a function of resolvable features within the wave. The numerical method utilizes conservative Volume of Fluid (cVOF) to capture the interface on a Cartesian grid. A submerged body generates the quasi-steady breaking wave. Our particular interest lies in developing parameterizations and models that relate the entrainment due to quasi-steady wave breaking to underlying flow characteristics. For different Froude numbers $Fr$, we observe two flow regimes: a periodic-wave-breaking and a metastable regime. For the periodic-wave-breaking regime we show that the bubble-size correlation of the Lagrangian velocities of fluid parcels on the free surface.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P02 Multiphase Flows: Modeling and Theory III 2B - Andrea Prosperetti, University of Houston

5:16PM P02.00001 Interface Retaining Coarsening for Multiphase Flows. XIANYANG CHEN, JIACAI LU, GRETRAN TRYGGVASON, Johns Hopkins University Department of Mechanical Engineering — Multiphase flows are characterized by sharp moving phase boundaries, separating different fluids or phases. In many cases the dynamics of the interfaces determines the behavior of the flow. In a coarse, or reduced order model, either an averaged two-fluid model or a large-eddy-simulation like one, it is therefore critical to retain a sharp interface for the resolved scales. The point particle model for disperse flows is a widely used limiting case. Different strategies to retain sharp interfaces are possible. In the simplest case the indicator function identifying the different fluids is filtered and the sharp interface restored by nonlinear post-processing, consisting either of identifying the interface location from the filtered field, or letting the interface "flow to its new location. Another approach is to work directly with Lagrangian markers points identifying the interface and average their coordinates, or evolve the interface based on curvature or other measures. The different approaches are discussed and compared, the relationship with image processing in computer graphics pointed out, and implications for the flow field are studied. Modeling approaches for the unresolved scales are briefly reviewed.

5:29PM P02.00002 ABSTRACT WITHDRAWN —
both steady and transient flows. This study focuses on high fidelity simulations useful for the determination of both current study to develop a Drift-Flux model appropriate for mixing regions in pipe flows for a range of gas-liquid flow parameters that addresses, IVAN NEPOMNYASHCHIKH, JAMES LIBURDY, Oregon State University — The Drift-Flux model (DFM) is a powerful reduce order model that can be applied to gas-liquid flows. As applied to a one dimensional internal flow will be demonstrated and compared with experiments. Hydrodynamic, electrostatic and ultrasonic controlling strategies will also be modelled round-jet flow simulation according to experimental and theoretical statistics. Finally, Euler-Lagrange simulations incorporating these models will be demonstrated and compared with experiments. Hydrodynamic, electrostatic and ultrasonic controlling strategies will also be modelled to test their performance in changing the dispersion of spray droplets.

6:08PM P02.00005 Exploration of Gas-liquid Flow Mixing Region for the Purpose of Drift-flux Model Enhancement, IVAN NEPOMNYASHCHIKH, JAMES LIBURDY, Oregon State University — The Drift-Flux model (DFM) is a powerful reduce order model that can be applied to gas-liquid flows. As applied to a one dimensional internal flow the model requires specification of two parameters: \(C_0\) (distribution parameter) and \(v_s\) (weighted mean drift velocity). It is the goal of the current study to develop a Drift-Flux model appropriate for mixing regions in pipe flows for a range of gas-liquid flow parameters that addresses both steady and transient flows. This study focuses on high fidelity simulations useful for the determination of both \(C_0\) and \(v_s\). A wide range of both transient and steady flow conditions is used (inlet parameters and fluid properties). The result is a range of two phase flow conditions, or flow maps, within the mixing region. For each set of conditions results are used to identify values of \(C_0\) and \(v_s\). Functional relationships are then found to map these parameters to the flow map regimes. The extent and range of the functional relationships allows for a robust set of conditions that can be utilized in the Drift-Flux model. Using these results comparisons are made with existing functional forms of \(C_0\) and \(v_s\) to help identify the transient conditions of mixing.

6:21PM P02.00006 Nearest Particle Statistics and Particle-fluid-particle Stress of Multiphase Flows, DUAN ZHANG, Los Alamos National Laboratory — This presentation starts with showing an important relation between the ensemble average and the average based on the nearest particle. Using this relation one can study long-range particle-fluid-particle (PFP) interactions by defining an effective short-range correlation accounting for effects of other surrounding particles. Physical meanings of this correlation will be presented, and the mathematical derivations will be outlined. This nearest particle average is compared with the average conditional on a pair of particles. For short-range forces, the ensemble averages calculated from the both methods are the same. For long-range forces the nearest particle average has an advantage. Using the effective short-range correlation force for hydrodynamic interactions among particles, a PFP stress is defined. The physical meanings of this stress will be examined. Using dilute potential and Stokes flows as examples, the PFP stresses are calculated. For cases of finite particle volume fractions, a numerical method is proposed to calculate this stress using the results of particle forces. This study of nearest particle statistics leads to many interesting and unanswered questions of particle interactions in disperse multiphase flows.

6:34PM P02.00007 A Physics/Data-Driven Comprehensive Multiphase Force Coupling Model That Systematically Accounts For Clustering & Shear Effects, GEORGES AKIKI, Notre Dame University-Louaize, DUAN ZHANG, Los Alamos National Lab, S BALACHANDAR, University of Florida — Traditional approach to modeling the phase interaction has been through drag and lift force models that depend on Re and volume fraction \(\theta\). However, it has been recognized that it is important to take into account local volume fraction gradients in particle distribution. Recently, it has been shown that the Particle-Fluid-Particle (PFP) stress can be rigorously defined, whose divergence accounts for the effect of inhomogeneous particle distribution. A series of fully-resolved DNS of flow around a uniform random distribution of particles are performed from which the PFP stress was evaluated. We then show how the DNS results can be accurately recovered with the pairwise interaction extended point-particle (PIEP) model. This allows the evaluation of the PFP stress for a wide range of Re and \(\theta\) at a negligible computational cost. We then tested the PFP force in inhomogeneous distributions of particles by comparing the model prediction against results obtained from DNS. We also performed DNS of shear flow through a uniform random distribution of particles to establish the shear-induced lift force model at finite \(\theta\). The significance of these new forces are then analyzed and compared to the mean streetwise force in uniform flows and to the mean streetwise and lateral forces in shear flows.

6:47PM P02.00008 Resolved Simulations of Particulate Shear Flow – GEDI ZHOU, Johns Hopkins University, ANDREA PROSPERETTI, University of Houston — This work describes the results of a numerical study of a suspension of thousands of resolved spheres in shear flow carried out by means of the Physalis method. The particle/fluid density ratio is varied between 2 and 5, the volume fraction between 5% and 30% and the particle Reynolds number between 25 and 50. Gravity is disregarded. The results shown include the particle mean free path, the pair distribution function, the particle diffusivity, collision frequency, the mixture stress and others. The mean free path decreases as the particle density is increased. The significant particle lagging near the solid surface with increasing volume fraction, with a strong effect on the velocity distribution of the suspension and the wall shear stress. The collisional contribution to the stress becomes dominant as the particle density ratio and volume fraction increase.

7:00PM P02.00009 Comprehensive Analysis of Two Fluid Models for Turbulent Gas-Solid and Liquid-Solid Flow – OMAR RENZO PIMINCHUMO MARINOS, DONALD J. BERGSTROM, University of Saskatchewan — In the Eulerian Two Fluid Model (TFM) formulation, the transport equation for the disperse phase consisting of solid particles is obtained from the Kinetic Theory of Granular Flow (KTGF). The transport equation for the carrier fluid, either gas or liquid, closely resembles the single-phase Reynolds Averaged Navier-Stokes equation. Although successful predictions have been obtained for gas-solid flow, simulations of liquid-solid flow typically show less agreement with the experimental data. The present work compares a TFM developed for gas-solid flow with a recent TFM developed for liquid-solid flow: both describe the stresses of the solid phase using the KTGF. The main focus of the study is the difference in the predictions for the mean velocity, fluctuating velocity and volume fraction profiles, compared to experimental data for dilute liquid-solid flow in a vertical pipe. An outcome of the present research is a modification to the TFM which improves the predictions of the previous formulations. The modification considers changes to the model relations for the solid viscosity, granular temperature conductive coefficient and the source term intended to incorporate interstitial fluid effects.

Monday, November 25, 2019 5:16PM - 6:34PM – Session P03 Fluid Mechanics General 201 -

5:16PM P03.00001 Zermelo's problem: Optimal point-to-point navigation in 2D turbulent flows using Reinforcement Learning – MICHELE BUZZICOTTI, LUCA BIFERALE, University of Rome Tor Vergata and INFN, FABIO BONACCORSO, Center for Life Nano Science@La Sapienza, Istituto Italiano di Tecnologia, PATRICIO CLARK DI LEONI, Dept. of Mechanical Engineering, Johns Hopkins University, KRISTIAN GUSTAVSSON, Dept. of Physics, University of Gothenburg — To find the path that minimizes the time to navigate between two given points in a fluid flow is known as the Zermelo’s problem. Here, we investigate it by using a Reinforcement Learning (RL) approach for the case of a vessel which has a slip velocity with fixed intensity, \( \frac{V_s}{V_c} \), but variable direction and navigating in a 2D turbulent sea. We use an Actor-Critic RL algorithm, and compare the results with strategies obtained analytically from continuous Optimal Navigation (ON) protocols. We show that for our application, ON solutions are unstable for the typical duration of the navigation process, and are therefore not useful in practice. On the other hand, RL solutions are much more robust with respect to small changes in the initial conditions and to external noise, and are able to find optimal trajectories even when \( \frac{V_s}{V_c} \) is much smaller than the maximum flow velocity. Furthermore, we show how the RL approach is able to take advantage of the flow properties in order to reach the target, especially when the steering speed is small.

5:29PM P03.00002 Thermo-mechanics modeling and physics – DAVID KASSOY, Kassoy Innovative Science Solutions LLC, ADAM NORRIS, University of Colorado, Boulder — Thermal energy deposition into a finite volume of gas is the immediate source of thermodynamic and velocity disturbances. The thermo-mechanical response in a given geometry and system depends on a variety of physical parameters including the time scale and quantity of heat deposition into the volume, and on the time scale that characterizes acoustic disturbances in the volume. Thermo-mechanical modeling is based on the non-dimensional reactive Navier-Stokes equations. The relevant non-dimensional parameters include: \( \text{parda} \), the ratio of the characteristic time scale for heat release to the acoustic time scale of the volume, \( \text{parda} = \frac{\text{characteristic time scale for heat release}}{\text{characteristic time scale of the volume}} \). The traditional definitions of high activation parameter \( \text{parda} \) are based on the reactive Euler equations, are described for a wide range of non-dimensional parameters defined above. They are compared with asymptotic analytical results, obtained for a variety of limiting parameter values, that including non-intuitive nearly constant volume, nearly isobaric and fully compressible responses to energy deposition.

5:42PM P03.00003 Great operation – HAN YONGQUAN, 15611860790 — The even general formula is: \( 2n, \) where \( n \) is an integer greater than 1, and \( 2n \) can decompose the prime factor, that is, \( 2n=\text{prime numbers} \), when \( n \) is a prime number (specially pointed out: when \( n=2 \), \( 2n=2 \)), the proposition is proved. When \( m \) is a composite number, it is proved as follows: When \( m \) is an even number, \( m \) adds an odd number or subtracts an odd number to exhaust all odd numbers, and since more than 2 prime numbers must exist in the odd number, it is sure to find the sum of the two prime numbers to represent any even number (2n). That is, \( 2n=|(\text{N1N2N3...2a})+(\text{N1N2N3...2a})| \), whether \( a \) is an odd number when \( m \) is an even number, or \( a \) is an odd number when \( m \) is an odd number, 1 It can always be established the Goldbach conjecture can be proved.

5:55PM P03.00004 Reserves Classification and Well Pattern Infilling Adjustment in Tight Sandstone Gas Field – ZHI GUO1, AILIN JIA, Petrochina Research Institute of Petroleum Exploration and Development, TIGHT GAS DEVELOPMENT TEAM — Sulige is typical of tight sandstone gas field in China, with poor reservoir property and strong heterogeneity. The recovery factor is only about 30% under the current developing well pattern of 600m800m. Thus it is necessary to evaluate various types of reserves comprehensively and implement well pattern infilling adjustment respectively. Through fine reservoir description in dense well pattern and interference well test analysis, the reservoir distribution frequency was studied and reserves were classified into five types. Compared actual production data with modeling & simulation result, the relation of well pattern density, interference degree and recovery factor was researched for each type of reserves. Then, it can be concluded the appropriate well pattern density in various type of reserves area is 2~4 wells per square kilometers, and the ultimate recovery factor is about 50%. This research, makes reserves configuration clear in the tight sandstone gas field, provides geological basis for well pattern infilling adjustment in later development stage, lays a solid foundation for long-term stable production of gas field, and is also of certain reference significance to other gas field development under similar geological conditions.

1 No.1 research institute of petroleum in China
6:08PM P03.00005 Technologies advancement and prospect of natural gas development in China. AILIN JIA1, ZHI GUO, Petrochina Research Institute of Petroleum Exploration and Development, COMPLEX GAS RESERVOIR DEVELOPMENT TEAM — In recent years, international oil prices have stayed low and China strives to develop green energy. Under these backgrounds, natural gas has gradually become the key business of petroleum industry in China. After years of hardworking, several developmental technological breakthroughs are achieved for deep gas, tight gas, shale gas, coal-bed methane, development adjustment strategies, engineering technologies and decision-making system. With the depth of development, influenced by policy, environment and geological conditions, continuous efficient development of domestic natural gas faces many challenges: lower ratio of good quality reserves, more development expense, larger difficulties of remaining development benefit for unconventional gas reservoir, further upstream benefit compression, poorer stable production ability and fiercer competition in the energy market. In the future, natural gas development in China will enter into a new stage of emphasizing on both the unconventional gas and the conventional gas, gas imports will rise year by year, resulting in the increased external dependency, and natural gas will become the main growth engine in the process of energy structure adjustment.

6:21PM P03.00006 Plume-Chimney in Natural Convection from Large Sources. CHRISTOPHER CHU1, Universiti Malaysia Sabah — A natural draft chimney is defined by the existence of buoyancy and a solid wall barrier between two regions of fluids that differ in density. By preventing the mixing of two fluids at different densities in a fluid environment, there is effectively a wall-like characteristic, a chimney system without the solid walls. An “effective plume height” was pioneered by heat transfer engineers to close the solution loop of the natural convection performance of forced draft air-cooled heat exchangers, by modifying an atmospheric plume rise model. An improved prediction method was later developed and satisfactorily validated by both experiments and computational fluid dynamics (CFD) simulation of the natural convection performance of an industrial-scale air-cooled heat exchanger. The flow development region that has been identified in the field of jets is known as the zone of flow establishment (ZFE), but in lazy plumes of low Froude number it has stack effect. Two reasons for justifying the concept of plume-chimney are: 1) it affects the draft of a natural convection system of large source area by extending the solid-walled chimney height and 2) its existence anticipates a potential blockage to cross current such as wind in real natural convection systems, modifying the flow pattern.

The authors would like to offer their sincere thanks to the Ministry of Higher Education, Malaysia, for the kind assistance provided through fundamental grant No. FRG0022-TK-1/2006.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P04 Focus Session: Leidenfrost Drops and the Physics of the Vapor Layer 203 - Justin Burton, Emory University

5:16PM P04.00001 The vibrating life of Leidenfrost drops, AMBRE BOUILLANT1, LadHyX (Ecole polytechnique & CNRS) - PMMH (ESPCI Paris) — A volatile liquid is deposited on a hot solid can survive for minutes, which is known since Leidenfrost to rely on the presence of an insulating vapor layer beneath the liquid. In this levitating state, vapor prevents liquid adhesion leading to thriving dynamics, either spontaneous or forced. Among those spectacular features is the liquid ability to undergo a shape transition from axisymmetric to self-organized oscillations. Such liquid stars are not only encountered with Leidenfrost drops, but with weakly adhering liquids subjected to external periodic forcing. Brunet et al. reported stars are observed provided excitation exceeds a threshold. For Leidenfrost drops, however, the mechanism remains a mystery since there is no prescribed forcing - stars spontaneously appear and sustain. Various mechanisms were proposed invoking thermal convection. Yet, drops supported by steady air flow perform such oscillations. Our plan is to discuss the origin of Leidenfrost stars. We report that vapor self-vibrates, and explain the ensuing coupling that leads to those spectacular oscillations.

5:29PM P04.00002 Characterizing the final moments of the Leidenfrost vapor layer, DANA HARVEY, JOSHUA MENDEZ, JUSTIN BURTON, Emory University — The vapor layer generated between a very hot surface and an evaporating liquid thins as the surface cools down. Eventually, hydrodynamic fluctuations of the liquid will cause the vapor layer to fail, leading to liquid/solid contact and explosive boiling. Using a new electrical technique we can characterize the failure of the vapor layer on sub-microsecond time scales. The vapor layer is treated as a complex circuit component with measurable impedance. A heated titanium electrode is lowered into a bath of salt water. A 10 MHz carrier signal passes through the vapor layer and the liquid so that the capacitive reactance of the system is low. The amplitude of the carrier wave is monitored in time. Using a model circuit for the vapor layer, physical properties of the layer can be determined. Within the first millisecond, a touchdown event occurs where the liquid rapidly wets the solid surface, characterized by a precipitous drop in the resistive part of the impedance. Then, the heat transfer to the liquid causes vaporization and boiling spreads from the point of contact. We expect this technique will also shed light on the sensitive role that salt plays in the Leidenfrost effect, as well as surface properties such as roughness.

5:42PM P04.00003 The nanoscale instability driving Leidenfrost film collapse, TOM Y. ZHAO, NEELESH A. PATANKAR, Northwestern University — Above a critical temperature known as the Leidenfrost point (LFP), a heated surface can suspend a liquid droplet above its own film of vapor. Here, we identify the vapor film instability for small length scales that ultimately sets the collapse condition at the LFP. From a linear stability analysis, it is shown that the main film stabilizing mechanisms are the liquid-vapor surface tension, viscous transport of vapor mass, and evaporation at the liquid-vapor interface. Meanwhile, van der Waals interaction between the bulk liquid and the solid substrate across the vapor phase drives film collapse. This physical insight into vapor film dynamics allows us to derive an ab-initio, mathematical expression for the Leidenfrost point of a fluid. The expression captures the experimental data on the LFP for different fluids under various surface wettabilities and ambient pressures. For fluids that wet the surface (small intrinsic contact angle), the expression can be simplified to a single, dimensionless number that encapsulates the nanoscale instability governing the LFP.
ANÁIS GAUTHIER, ESPCI Paris, France, GUILLAUME LAJOINIE, CHRISTIAN DIDDENS, DETLEF LOHSE, JACCO DROPLETS.

A miniature celestial system. The attraction between identical menisci impacts the motion of approaching droplets which spontaneously orbit around each other – mirroring what happens on a droplet-laden cryogenic bath. In such freezing conditions, the droplets (which do not evaporate) can levitate for a dozen of minutes. We show here how the deformability of the liquid substrate dramatically impacts the Leidenfrost dynamics. First, we show that a micrometer-sized instability grows within the film sustaining the drop, which causes a partial redirection of the vapor flow and generates spontaneous self-propulsion. The drops then behave as active particles, which hover in straight lines above the bath and form a remarkably regular pattern. In addition, the bath surface is deformed at the millimeter scale by the droplets' weight. Due to this non-wetting meniscus, the particles are repelled at large distance by objects dipped into the bath: this can be used as a contactless method to finely control the particles trajectories. Conversely, we show that the attraction between identical menisci impacts the motion of approaching droplets which spontaneously orbit around each other – mirroring a miniature celestial system.

Leidenfrost droplets. ANÁIS GAUTHIER, ESPCI Paris, France, GUILLAUME LAJOINIE, CHRISTIAN DIDDENS, DETLEF LOHSE, JACCO SNOEIJER, DEVARAJ VAN DER MEER, PoF - University of Twente. The Netherlands — Ambient temperature drops deposited on a liquid nitrogen bath can be maintained in the inverse Leidenfrost state, a levitating state that is enabled by a continuous vapor flow produced by the cryogenic bath. In such freezing conditions, the droplets (which do not evaporate) can levitate for a dozen of minutes. We show here how the deformability of the liquid substrate dramatically impacts the Leidenfrost dynamics. First, we show that a micrometer-sized instability grows within the film sustaining the drop, which causes a partial redirection of the vapor flow and generates spontaneous self-propulsion. The drops then behave as active particles, which hover in straight lines above the bath and form a remarkably regular pattern. Leidenfrost droplets on superheated substrates. TAMAL ROY, Postdoctoral Research Associate, UDDALOK SEN, Postdoctoral Researcher, RANJAN GANGULY, Professor, LOUIS A. ANGELONI, Graduate Assistant, W. ANDREAS SCHROEDER, CONSTANTINE M. MEGARIDIS, Professor, DEPARTMENT OF MECHANICAL AND INDUSTRIAL ENGINEERING, UNIVERSITY OF ILLINOIS AT CHICAGO, USA TEAM, DEPARTMENT OF POWER ENGINEERING, JADAVPUR UNIVERSITY, KOLKATA, INDIA TEAM, DEPARTMENT OF PHYSICS, UNIVERSITY OF ILLINOIS AT CHICAGO, USA TEAM — Droplet impact on superheated smooth solids has attracted enormous attention since Leidenfrost reported the eponymous phenomenon more than 250 years ago. The related literature is almost exclusively focused on single component liquids, which maintain their identity even under disruptive boiling conditions. In this work, we provide evidence for the existence of a new regime - termed explosive boiling - for the impact of bicomponent (ethanol and water) droplets on superheated substrates at temperatures between the respective Leidenfrost temperatures of the two liquid constituents. This regime is characterized by a violent shattering of the main droplet upon impact, and is observed only for a certain range of alcohol concentrations of the binary mixture. We explore this behavior experimentally through high-speed imaging at different substrate temperatures, droplet concentrations, and impact velocities. Furthermore, we provide interferometric evidence for the cause of occurrence of this unprecedented regime.

6:08PM P04.00005 ABSTRACT WITHDRAWN

6:21PM P04.00006 Self-propulsion and capillary orbits of inverse Leidenfrost droplets. ANÁIS GAUTHIER, ESPCI Paris, France, GUILLAUME LAJOINIE, CHRISTIAN DIDDENS, DETLEF LOHSE, JACCO SNOEIJER, DEVARAJ VAN DER MEER, PoF - University of Twente. The Netherlands — Ambient temperature drops deposited on a liquid nitrogen bath can be maintained in the inverse Leidenfrost state, a levitating state that is enabled by a continuous vapor flow produced by the cryogenic bath. In such freezing conditions, the droplets (which do not evaporate) can levitate for a dozen of minutes. We show here how the deformability of the liquid substrate dramatically impacts the Leidenfrost dynamics. 6:34PM P04.00007 Explosive behavior of binary drops upon impact on a hot solid. PIERRE CHANTELOT, PALLAV KANT, JULIETTE COLIN, Physics of Fluids group, University of Twente, ANDREA PROSPERETTI, Physics of Fluids group, University of Twente and Department of Mechanical Engineering, University of Houston, DETLEF LOHSE, Physics of Fluids group, University of Twente and Max Planck Institute for Dynamics and Self-Organization — The vapor layer generated during the impact of a drop on a hot plate can prevent contact between the liquid and solid. The minimum temperature, $T_\text{min}$, needed to observe this dynamic Leidenfrost effect depends on the impact speed, and the thermal properties of the solid and liquid. Here, we perform impacts of binary drops of miscible liquids with different boiling points while monitoring the existence of contact using Total Internal Reflection (TIR) imaging. We report the occurrence of explosions, associated with a sudden failure of the vapor film, at the transition from levitation to contact. We study the destabilization of the vapor layer by measuring its dynamics for different liquid combinations and mixing ratios.

6:47PM P04.00008 Low-g Demonstrations of Leidenfrost Droplet Impacts with Applications to Non-Contact Fluidics Processing in Space. RAWAND RASHEED, MARK WEISLOGEL, Portland State University — Leidenfrost phenomenon has been studied extensively for its role in applications ranging from nuclear reactor cooling, to metals manufacturing, combustion, and other fields. Herein, Leidenfrost phenomenon is exploited as a potential solution to spacecraft water processing challenges by providing a method for non-contact fluid distillation. Leidenfrost investigations have been almost exclusively conducted in terrestrial environments and are in turn largely defined by the ever-presence of gravity. In this work we demonstrate a variety of dynamic Leidenfrost effects for large liquid droplets in the microgravity environment of a 2.1 second drop tower. A scaling model for the impact reveals the ease with which ‘non-contact’ impacts are achieved at low Weber numbers and low gravity levels. We find the vapor film thicknesses at impact are sub-millimetric as estimated analytically and confirmed qualitatively via experiments. Dynamic drop impact experiments are extended to a variety of heated substrates including macro-pillar arrays, confined passageways, and others. Leidenfrost droplet evaporation rates are measured analytically and confirmed qualitatively for binary drops of miscible liquids with different boiling points while monitoring the existence of contact using Total Internal Reflection (TIR) imaging. We report the occurrence of explosions, associated with a sudden failure of the vapor film, at the transition from levitation to contact. We study the destabilization of the vapor layer by measuring its dynamics for different liquid combinations and mixing ratios.

7:00PM P04.00009 Unexpected Suppression of Leidenfrost Phenomenon on Superhydrophobic Surfaces. MENG SHI, RATUL DAS, SANKARA ARUNACHALAM, HIMANSHU MISHRA, King Abdullah University of Science and Technology — The Leidenfrost phenomenon ascribes to a non-equilibrium situation, wherein a liquid droplet levitates above a superheated surface. Superhydrophobic surfaces are believed to dramatically reduce water’s Leidenfrost point (LFP - the temperature when the Leidenfrost phenomenon occurs), even approaching its boiling point in some cases. The causation is that superhydrophobic surfaces robustly entrap air when brought in contact with water, which reduce the contact area and adhesion between the droplet and the surface, and thus promote the formation of the vapor layer on heating. Here, we report on a curious exception. Using high-speed imaging, we investigated water droplets placed on hot superhydrophobic SiO2/Si surfaces adorned with arrays of doubly reentrant pillars (DRPs). We found the LFP for water droplets on SiO2/Si DRPs could be significantly higher than that smooth SiO2/Si surfaces, even though the former exhibits superhydrophobicity and the latter is hydrophilic. Thus, we advance the notion that superhydrophobic surfaces may not always lower the LFP of water. We will present deeper insights into our observations based on complementary experiments and theory.

Monday, November 25, 2019 5:16PM - 7:13PM – Session P05 Turbulent Combustion Modeling and Methods 204 - James Brasseur, University of Colorado, Boulder
5:16PM P05.00001 LES/PDF of Sandia flame D using a coupled adaptive chemistry and tabulation approach1, ASHISH NEWALE, YOUWEN LIANG, STEPHEN POPE, PERRINE PEPIOT, Cornell University — LES/PDF methods are known to provide accurate results for challenging turbulent combustion configurations. This higher level of fidelity, however, comes at the cost of added computational expense compared to other state-of-the-art methods. To reduce the magnitude of this cost differential, the majority of LES/PDF computations performed to date have used reduced mechanisms. We have recently proposed a coupled adaptive chemistry and tabulation approach to enable the use of the detailed mechanisms in LES/PDF computations. Specifically, we proposed a coupled pre-partitioned adaptive chemistry (PPAC) and in-situ adaptive tabulation (ISAT) method (Newale et al., CTM 2019). The proposed coupled method showed encouraging results in a partially stirred reactor configuration. In this work, we examine the performance of the coupled PPAC-ISAT method in a LES/PDF computation of Sandia flame D. We demonstrate that the coupled technique enables the use of detailed mechanisms at a significantly reduced computational cost, while retaining the level of fidelity attained by using the detailed mechanism without approximations.

5:29PM P05.00002 In-Situ Adaptive Manifolds: Enabling simulations of complex turbulent reacting flows, CRISTIAN E. LACEY, ALEX G. NOVOSELOV, MICHAEL E. MUELLER, Princeton University — Reduced-order manifold approaches to turbulent combustion modeling traditionally involve precomputation of manifold solutions and tabulation of the thermochemical database versus a small number of manifold variables. However, additional manifold variables are required as the complexity of turbulent combustion processes increases, for example, multi-modal combustion or combustion featuring multiple and/or inhomogeneous inlets. This increase in the number of manifold variables comes with an increase in the computational cost of precomputing a greater number of manifold solutions, most of which are never actually utilized in a CFD calculation. The memory required to store the pretabulated high-dimensional thermochemical database also increases, limiting the complexity of reduced-order manifold combustion models. In this work, a new In-Situ Adaptive Manifolds (ISAM) approach is developed that overcomes this limitation by combining ‘on-the-fly’ calculation of manifold solutions with In-Situ Adaptive Tabulation (ISAT), enabling the use of more complex manifold-based turbulent combustion models. The performance of ISAM is evaluated via LES calculations of canonical turbulent flames.

5:42PM P05.00003 Fundamental Differences between Large-Eddy Simulation of Incompressible Turbulence vs Premixed Turbulent Combustion, JAMES BRASSEUR, Univ of Colorado, YASH SHAW, Penn State University, PAULO PAES, Gamma Technologies, YUAN XUAN, Penn State University — In contrast with RANS where the modeled terms are of leading order, the LES framework requires that the modeled subfilter-scale (SFS) contributions be of lower order than the leading-order terms. This will be the case if the resolved-scale (RS) contributions to the triadic sum of advective nonlinearities in spectral space dominate the SFS triads, requiring an effective grid that resolves well Reynolds stress motions. Turbulent combustion deviates from the LES framework is several key ways, primarily in the existence of the chemical source terms that lead to the release of thermal energy at scales generally unresolved. In this study we quantify the dominant SFS contributions to the key nonlinearities that underlie RS evolution in LES of premixed turbulent combustion to isolate fundamental deviations from the LES framework. With a new method to remove spurious spectral content in inhomogeneous directions, we apply a concurrent physical-Fourier space methodology to compressible DNS of flame-turbulence interactions to isolate the triadic structure of advective nonlinearities and the quadratic structure of chemical nonlinearities in the Fourier representation from which the dynamically dominant contributions are determined. We find that when the RS fluctuations in momentum and scalar dissipation rate. This methodology allows for a clear assessment of the errors that arise from the three aspects of a model for combustion: turbulence-closure, modeling the turbulence-chemistry interaction, and chemical kinetics closures. As there is no conflation of errors arising via the chemical kinetics, the data can be used to directly assess the performance of RANS closures in representing the turbulence and the turbulence-chemistry interaction. Conversely, by comparing our DNS with one closed with a higher fidelity chemistry model from Attili and co-authors, any discrepancies can be attributed to the different chemical kinetics closures. Results are shown for the k−ε model with presumed-PDF approach for a non-premixed n-heptane flame.

5:55PM P05.00004 Direct Numerical Simulation of the Temporally-Evolving Reacting Jet for Model Error Assessment of RANS-based Closures for Non-Premixed Turbulent Combustion, BRYAN REUTER, TODD OLIVER, ROBERT MOSER, Oden Institute for Computational Engineering and Sciences, UT-Austin — High-fidelity DNS data of the temporal reacting jet is generated using a laminar flamelet closure, the same chemistry model as is typically employed in RANS-based approaches. The simulations solve the low-Mach Navier-Stokes equations with a pseudospectral Fourier-Galerkin/B-Spline collocation approach and a novel second-order, explicit time marching scheme. The turbulence is fully resolved, but the chemistry is modeled by obtaining the density from a flamelet library which is a function of the local mixture fraction and scalar dissipation rate. This methodology allows for a clear assessment of the errors that arise from the three aspects of a model for combustion: turbulence closures, modeling the turbulence-chemistry interaction, and chemical kinetics closures. As there is no conflation of errors arising via the chemical kinetics, the data can be used to directly assess the performance of RANS closures in representing the turbulence and the turbulence-chemistry interaction. Conversely, by comparing our DNS with one closed with a higher fidelity chemistry model from Attili and co-authors, any discrepancies can be attributed to the different chemical kinetics closures. Results are shown for the k−ε model with presumed-PDF approach for a non-premixed n-heptane flame.

6:08PM P05.00005 Timescale Analysis Procedure Applied to Premixed and Non-Premixed Turbulent Combustion1, SALVADOR BADILLO-RIOS, University of California, Los Angeles, MATTHEW HARRISON, VENKATESWARAN SANKARAN, AFRL Research Laboratory, Rocket Propulsion Division, ANN KARAGOZIAN, University of California, Los Angeles — Full detailed kinetics in turbulent combustion simulations can be computationally prohibitive for propulsion systems. While reduced kinetic models are often selected to reduce cost, there needs to be a clear understanding of their impact on the phenomena being modeled. The present study examines the effects of alternative kinetic models and flow parameters on turbulent combustion processes associated with non-premixed combustion in a shear-coaxial rocket injection configuration, as a means of determining the conditions under which turbulent reaction phenomena may be altered via the kinetics. A combination of 2D axisymmetric parametric studies and selected 3D simulations for a single element shear coaxial rocket injector are performed, incorporating GRI-Mech 3.0 and several alternative reduced kinetic models representing the combustion of gaseous methane and oxygen. Systematic timescale analysis procedures, e.g., the Chemical Explosive Mode Analysis (CEMA) procedure based on the Jacobian matrix of the chemical source term, are applied to explain differences in observed flame behaviors. This approach can serve as a quantitative method for the systematic detection of critical flame features, species, and reactions.

6:21PM P05.00006 Large Eddy Simulations of turbulent flames using two-dimensional reduced-order manifold models

ALEX G. NOVOSELOV, CRISTIAN E. LACEY, MICHAEL E. MUELLER, Princeton University — Recently, we have developed a set of two-dimensional manifold equations describing multi-modal combustion using the mixture fraction and a generalized progress variable. Information about the underlying mode of combustion is encoded in three scalar dissipation rates that appear as parameters in the two-dimensional equations. In this work, Large Eddy Simulations (LES) of turbulent hydrogen flames in both the asymptotic limits of combustion (i.e. nonpremixed and premixed) and multi-modal flames are performed using this new turbulent combustion model. These simulations are compared to LES performed using traditional one-dimensional manifold-based turbulent combustion models as well as experimental measurements. The new model is shown to describe the flames in the asymptotic limits just as well as the one-dimensional models but without any a priori knowledge of the flame necessary to select the model. Additionally, the new model is shown to be able to describe the behavior of multi-modal turbulent flames where traditional one-dimensional models fail.

6:34PM P05.00007 A Dispersion Model for Turbulent, Multi-Component Reacting Flows

OMKAR SHENDE, ALI MANI, Stanford University — It is theoretically and computationally challenging to build reduced-order models for turbulent reacting flows as the underlying chemical and transport processes are individually complex. Furthermore, an understanding of the coupled effects of these phenomena remains elusive. However, deeper insight into turbulent transport effects on reaction dynamics is essential for the future design of efficient energy systems. Using theory developed for non-reactive dispersion of scalars and linear reactions, an algebraic Reynolds-averaged Navier-Stokes model for capturing unresolved interactions between multi-component scalar reactions in turbulent flows is developed. This work extends the modified gradient diffusion model by Corrsin (JFM, vol. 11, p.407-416) beyond single-component transport phenomena with linear reactions. Using two- and three-dimensional direct numerical simulations, it is shown that this model improves prediction of mean quantities compared to traditional results.

6:47PM P05.00008 Conditional Reynolds stress modeling in turbulent premixed jet flames

JINYOUNG LEE, MICHAEL MUELLER, Princeton University — Conventional turbulence modeling approaches based on traditional unconditional averaging implicitly assume that combustion heat release does not affect turbulence. However, in turbulent premixed flames at low Karlovitz number, combustion-induced dilatation and flame motion significantly modify turbulence. Instead of relying on unconditional averaging, simultaneously solving momentum and scalar transport equations conditionally averaged on a flame structure variable could provide a superior framework for modeling combustion-affected turbulence since the flame dynamics are embedded into the flame-conditioning. The primary challenge in this approach is developing closure models for conditional terms, which evolve in both physical and conditional spaces. In this work, a new model for conditional Reynolds stresses, which appear in the conditionally averaged momentum equations, has been developed. The new model consists of a conditional Boussinesq-like term and a new term representing turbulent momentum transport in conditional space. A theoretical scaling of the new model has been investigated, and the model performance has been evaluated in a priori analyses using DNS databases of turbulent premixed jet flames at low and high Karlovitz numbers.

7:00PM P05.00009 DNS analysis of flame propagation for systematic variations in turbulence scales and intensity

SHREY TRIVEDI, R. STEWART CANT, University of Cambridge — Direct Numerical Simulation (DNS) of premixed hydrocarbon flames is performed using the DNS code Senga2 to investigate the role of varying integral length scale $l_0$ as well as the turbulence intensity $u'$ in the thin reaction zone regime. Different cases are studied by either systematically varying $l_0$ at constant $u'$ or by systematically varying $u'$ at constant $l_0$. Several aspects of these flames are compared. The turbulent flame speed $s_T$ is found to decrease as $l_0$ decreases or when $u'$ increases. The ratio of $s_T/l_0$ is generally accounted for by the area change $A_f/A_b$, but a significant deviation is observed between these values at high $u'$ cases. The size of the smallest scales of turbulence also decreases with $l_0$ and the interaction of these small scales with the flame produces an increase in the mean curvature of the flame which eventually reaches a saturation point. There is also an increase in the number of flame-flame interactions with decreasing $l_0$. Individual flame-flame interaction topologies are identified and analysed. All these findings serve to further our understanding of turbulent combustion and the role that the turbulence length scales play in flame propagation.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P06 Thermoacoustic Instability

5:16PM P06.00001 Three-dimensional Scanning Laser Induced Fluorescence for the investigation of flame dynamics on annular combustor instabilities

DIRREN GOVENDER, SAMUEL WISEMAN, JAMES R DAWSON, NICHOLAS WORTH, Department of Energy and Process Engineering, Norwegian University of Science and Technology, N-7491 Trondheim, Norway — The need for three dimensional techniques is of importance when investigating turbulent asymmetrical flame structures. In combustion systems, self-excited thermo-acoustic instabilities are a prevalent problem and many studies are aimed at better understanding the phenomena. In this study, a Scanning OH* Laser Induced Fluorescence method is introduced to spatially resolve three dimensional flame structures during forced azimuthal oscillations in an annular combustor. The scanning setup consisted of a galvanometer mirror that sweeps a laser sheet through the flame while imaging at 10kHz. The obtained images were phase averaged based on the forcing cycle and the results were used to reconstruct the three dimensional flame structure. A variety of forced standing and spinning modes were investigated. Phase-averaged Flame Surface density (FSD) was used to characterize the three-dimensional flames. A series of calibrations were performed and evaluated for the transformation of image space to object space. This consisted of an additional camera to characterize the laser sheet positions and track any movements of the calibration plate while calibrating the in-plane camera. The results shows the scanning method’s ability to resolve three-dimensional flame structures and dynamics.

5:29PM P06.00002 Exploration of Unstable Spray Flames Using Reduced-Order Models

ABDULLA GHANI, THOMAS STEINBACHER, ALP ALBAYRAK, WOLFGANG POLIFKE, TU Munich — We investigate low-frequency thermoacoustic instabilities of a swirling spray flame. This study is based on an aeronautical lab-scale experiment, for which a reduced-order model (ROM) has been generated. A parametric study of the ROM suggests that the instability mechanism is caused by an intrinsic thermoacoustic (ITA) feedback loop. Further analysis such as separation of acoustic and ITA modes or the scaling of the ITA frequency with the bulk velocity confirm the ITA feedback loop as the instability driver. Results of the ROM agree well with experimental observations and demonstrate the effectiveness of ROMs.
5:42PM P06.00003 Effect of Global Acceleration on the Stability of a Thermocoustically Coupled Shear Layer in a Backward-Facing Step Combustor, JOEL VASANTH, SATYANARAYANAN CHAKRAVARTHY, Department of Aerospace Engineering, IIT Madras — The impact of the acoustic field on variable density flow in a step combustor is explored via a linear stability analysis of the low Mach number Navier-Stokes equations. In the equi-time scales limit, the acoustic feedback to the flow reduces to a global acceleration (GA) as a momentum source. The velocity profiles are parametrized by shear layer thickness δ and reverse flow ratio β. To close the equation set, the n−r flame model is used. A local spatio-temporal perturbation analysis shows a shift in the absolutely/convectively unstable (AU/CU) transition boundaries towards the AU zone in the β-δ space as the flame response gain is increased. Further, the AU modes are less responsive to the acoustic feedback than the CU modes, affirming the semi-open/fully-closed loop mechanisms of acoustic feedback advanced in recent literature. Competing contributions of the vorticity equation source terms to the overall vorticity generation show that the GA is always destabilizing unlike the density gradient, which could be stabilizing under some conditions. The GA and the resultant of vorticity production and baroclinic vorticity are in phase under all conditions, which implies the forcing nature of the GA that unconditionally promotes combustion instability.

5:55PM P06.00004 Intrinsic thermoacoustic modes in systems with two axially separated heat sources, PHILIP BUSCHMANN, JONAS MOECK, NTNU — Modern gas turbines for power generation are required to provide high operational flexibility while complying with emission limits. Axially staged flames or sequential combustors are advantageous for this purpose. However, the distributed heat release rate in these systems gives rise to new thermoacoustic interaction phenomena. Recently, it has been shown that the forcing nature of the GA that unconditionally promotes combustion instability.

6:08PM P06.00005 Large-eddy simulations of a heated and combusting Rijke tube configuration, WEI XIAN LIM, WAI LEE CHAN, Nanyang Technological University, Singapore — Due to its potential to cause catastrophic damages to combustion engines, thermoacoustic instability is an active area of research that demands further understanding. The process to experimentally identify or eliminate thermoacoustic instability effects can be costly, so the ability to employ numerical simulation techniques will be advantageous. In this work, a canonical thermoacoustic configuration, known as the Rijke tube, was chosen to study the coupling effects between the heat-addition and acoustic pressure fluctuations. To this end, two large-eddy simulation cases were studied, one with heating wire and the other with combustion represented by the flamelet/progress-variable model. In all simulations, proper boundary coupling effects between the heat-addition and acoustic pressure fluctuations. To this end, two large-eddy simulation cases were studied, one with heating wire and the other with combustion represented by the flamelet/progress-variable model. In all simulations, proper boundary conditions and buoyancy force were accounted for to represent the actual conditions of Rijke tube in a laboratory space. Good results were obtained for the heating-wire case when comparing the theoretical and numerical resonant frequency. Meanwhile, additional flame-acoustics interactions were also observed in the flamelet/progress-variable case.

6:21PM P06.00006 Receptivity of a transversely forced jet\textsuperscript{1}, JOSE G. AGUILAR, EIRIK ASOY, JAMES DAWSON, NICHOLAS WORTH, Institute for Energy and Process Engineering, Norwegian University of Science and Technology (NTNU) — Annular combustion chambers are often used in gas turbines. These configurations are prone to thermoacoustic instabilities which emerge as standing or spinning azimuthal modes among others. During the instability the flow conditions of typical flames resemble swirling annular jets which are transversely forced by an acoustic wave. Previous studies suggest that in acoustically compact configurations the flame response to transverse flow excitation is strong if it is seen locally (within sections of the flame), but it is weak if it is seen globally given that there is negligible contribution to the total fluctuations of the heat release. By means of experimental analysis and numerical simulation the present study aims to quantify the receptivity of a more simplistic flow configuration, an isothermal jet subject to transverse forcing and elucidate the mechanism for its strong receptivity with a steady jet at different Mach numbers. The experiments show that the response of the jet depends on the position of the acoustic wave and is described by a mixture of the symmetric and antisymmetric modes. Receptivity analysis is carried out using numerical simulation in order to quantify the strength of each mode at the different forcing positions.

6:34PM P06.00007 Structure of thermoacoustic modes in can-annular combustion systems, JONAS MOECK, NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, GIULIO GHIRARDO, MIRKO BOTHEN, Ansaldo Energia Switzerland — Large gas turbines for power generation employ a can-annular combustor architecture. In contrast to annular combustors, in a can-annular system, the flames are isolated and burn in individual cans; however, there is acoustic communication between adjacent cans at the turbine inlet through a small gap. The thermoacoustic modal structure of a can-annular combustor significantly differs from that of the extensively studied annular combustor. We consider a can-annular configuration as a system composed of weakly coupled, nominally identical subcomponents. This provides a consistent framework for studying the spectral properties and explaining prevalent phenomena in these systems, such as eigenvalue clustering, and mode localization when the symmetry is perturbed. Based on a generic can-annular model system, we illustrate the general modal structure and derive the equivalent downstream boundary condition that links the multi-can resonances to a single-can model.

6:47PM P06.00008 Time-Accurate Calibration of a Thermoacoustic Model on Experimental Images of a Forced Premixed Flame, HANS YU, USHnish SENGUPTA, MATTHEW JUNIPER, Department of Engineering, University of Cambridge, LUCA MAGRI, Department of Engineering, University of Cambridge; Institute for Advanced Study, Technical University of Munich — Thermoacoustic instabilities are a persistent challenge in the design of jet and rocket engines. The time-accurate calculation of thermoacoustic instabilities is challenging due to the presence of both aleatoric and epistemic uncertainties, as well as the extreme sensitivity to small changes in certain parameters. We extend our previous work (Yu et al., CTR summer program 2018; Yu et al., J. Eng. Gas Turbines Power 2019) by applying our recently published level-set data assimilation framework (Yu et al., J. Comput. Phys. 2019) to experimental images of a forced premixed flame. We force a Bunsen flame with a loudspeaker and record videos at different frequencies and amplitudes. Data assimilation provides an optimal estimate of the true state of a system, and improves the predicted shape and location of the flame. Parameter estimation uses the data to find a maximum-likelihood set of parameters for the model while simultaneously quantifying their uncertainty and identifying deficiencies in the model. We demonstrate our level-set data assimilation framework using both the ensemble Kalman filter and smoother. More generally, we take a physics-informed, reduced-order model and use statistical learning techniques to make it quantitatively accurate.
7:00PM P06.00009 Forced and mutual synchronization of periodic and aperiodic oscillations in a self-excited thermoacoustic system\textsuperscript{1}, YU GUAN, The Hong Kong University of Science and Technology, VIKRANT GUPTA, Southern University of Science and Technology, LARRY K.B. LI, The Hong Kong University of Science and Technology — Recent studies have shown that external forcing is effective in controlling both periodic and aperiodic thermoacoustic oscillations. We examine the mutual synchronization of pressure ($p'$) and heat-release-rate ($q'$) fluctuations in a prototypical thermoacoustic system undergoing forced synchronization by periodic acoustic forcing. When unforced, the system can oscillate periodically, quasiperiodically or chaotically. For all three types of oscillations, we find several common features, including (i) the presence of a $T^2$ quasiperiodic state before lock-in in which asynchronous quenching occurs without mutual synchronization between $p'$ and $q'$, (ii) the emergence of synchronization between $p'$ and $q'$ and the forcing signal at lock-in, and (iii) the destruction of synchronization beyond lock-in. As well as providing new insight into the way external forcing affects the mutual synchronization of $p'$ and $q'$, this study shows that, regardless of its initial unforced state, a thermoacoustic system synchronized to external forcing does not necessarily remain synchronized if the forcing becomes too strong. For effective control, this implies that the forcing amplitude should be limited to a value just sufficient to cause the onset of lock-in.

Monday, November 25, 2019 5:16PM - 7:00PM — Session P07 Non-Linear Dynamics and Chaos II

5:16PM P07.00001 Passive and active mixing in vortex chain flows\textsuperscript{1}, TOM SOLOMON, Bucknell University — In 1988\textsuperscript{2} Jerry Gollub and I published an article that first identified chaotic mixing in an oscillating chain of alternating vortices, a model developed to describe transport in time-dependent Rayleigh- Bénard convection. In the thirty years since, the vortex chain flow (and the similar double-gyre flow) have become paradigm flows for studying fluid mixing in closed flows. In this talk, I’ll review studies that have demonstrated both enhanced diffusion and suppression of vortex stretching in this system, as well as extensions to vortex arrays and three-dimensional, time-independent flows, which also show chaotic mixing. We will also discuss recent studies of active mixing – both of propagating reaction fronts and of swimming microbes – in vortex chain flows.

5:29PM P07.00002 Particle-scale fluctuations and hindered settling of a granular dispersion at low-Re\textsuperscript{1}, TED BRZINSKI, JAMES STADLER, IVAN TSEYTLIN, CHARLES WALKER, Haverford College — Dense dispersions of grains sedimenting in a fluid at low-Re are characterized by mean settling velocities which are hindered relative to Stokes settling. Hindered settling data can be collapsed to a master curve which is well-described by the Richardson-Zaki function $H(\phi) \equiv v/v_s = (1-\phi)^{\alpha}$, where $\phi$ is the particle volume fraction, but with different exponents: $\alpha \approx 5.5$ for systems with a small Peclet number, and $\alpha \approx 4.5$ for systems with large Peclet number. This branching occurs at a surprisingly large value of Peclet number. We report the results of our latest experimental investigations into this unexpected behavior. Using diffusing-wave spectroscopy, we characterize the spatio-temporal particle velocity fluctuations on scales as small as the expected Brownian motion for our experimental systems, and systematically vary Peclet number around the branching-point to quantify differences in the grain-scale dynamics between systems on either branch of the hindered settling function. We also present a model for the self-diffusion of the particles below the transition and increases linearly with strain amplitude above. For a 40% volume fraction suspension, we see low-q long-wavelength fluctuations suppressed near the critical strain of $\gamma \approx 0.9$ with $S(q) \propto \gamma^{1/2}$.

5:42PM P07.00003 Random Organization: A Gift that Keeps on Giving\textsuperscript{1}, DAVID PINE, SANUEL WILKIN, PAUL CHAIKIN, NYU — Non-Brownian suspensions of spheres periodically sheared at low Reynolds number explore new configurations through collisions in an otherwise reversible flow. Below a critical strain, the particles remain active until they find a configuration with no collisions and fall into an absorbing state. Simulations by Hexner & Levine show that the system becomes hyperuniform near the critical configurations through collisions in an otherwise reversible flow. Below a critical strain, the particles remain active until they find a configuration with no collisions and fall into an absorbing state. This study shows that, regardless of its initial unforced state, a thermoacoustic system synchronized to external forcing does not necessarily remain synchronized if the forcing becomes too strong. For effective control, this implies that the forcing amplitude should be limited to a value just sufficient to cause the onset of lock-in.

5:55PM P07.00004 Nonlinear Dynamics in Sports, ANETTE HOSOI, Massachusetts Institute of Technology — In celebration of Jerry Gollub’s remarkable contributions to nonlinear dynamics, I would like to discuss a few examples of complex dynamical behavior in sports. In free-flowing team sports such as soccer, basketball, and hockey, the relationships between individual athletes can give rise to collective behavior that can enhance (or diminish) the effectiveness of the team. New high-quality tracking data of professional basketball and soccer players, i.e. center of mass coordinates at 25Hz with centimeter-scale resolution, reveals signatures of player fatigue, decision-making aptitude, and other athlete traits that have historically been unquantifiable. Here we borrow concepts from the analysis of the collective motion of birds and fish, e.g. schooling and flocking, to begin to draw insights from tracking data and construct a low dimensional portrait of athlete characteristics.

6:08PM P07.00005 Elastic Alfven waves in elastic turbulence, VICTOR STEINBERG, Weizmann Institute of Science, ATUL VARSHNEY, Institute of Science and Technology Austria, Am Campus 1, 3400 Klosterneuburg, Austria — Speed of sound waves in gases and liquids are governed by the compressibility of the medium. There exists another type of non-dispersive wave where that has speed depends on stress instead of elasticity of the medium. A well-known example is the Alfven wave, which propagates through plasma permeated by a magnetic field with the speed determined by magnetic tension. An elastic analogue of Alfven waves has been predicted in a flow of dilute polymer solution where the elastic stress of the stretching polymers determines the elastic wave speed. Here we present quantitative evidence of elastic Alfven waves in elastic turbulence of a viscoelastic creeping flow between two obstacles in channel flow. The key finding in the experimental proof is a nonlinear dependence of the elastic wave speed $c_{el}$ on the Weissenberg number $W_i$, which deviates from predictions based on a model of linear polymer elasticity.
6:21PM P07.00006 Mixing in Turbulent Fluids: From Quasi Two-Dimensional Systems to Stably-Stratified Shear Flows, ROBERT ECKE, Los Alamos National Laboratory — Mixing in fluids represents one of the most important roles of chaotic or turbulent flows, being responsible for, among many things, the dispersion of pollutants, the efficient mixing of fuel/gas in internal combustion engines, and the distribution of heat and salinity in the ocean. I will discuss Lagrangian and Eulerian measurements of a thin layer driven by electromagnetic forcing which is an experimental realization of two-dimensional turbulence. I will also present experimental results of fully three-dimensional stably-stratified shear flows that represent geophysical problems arising from, for example, oceanic overflows and river estuaries. The simultaneous planar velocity and density fields are determined using particle image velocimetry and planar laser-induced fluorescence. Different analysis methods for characterizing the interplay between mixing and turbulence are explored including Lagrangian methods obtained from high-resolution particle tracking, filtering (coarse-graining) applied to both systems, and comparison with traditional turbulence analysis approaches. These different analysis techniques give physical insight into the mechanisms of mixing and transport in scalar advection, both the passive and active cases.

6:34PM P07.00007 Geometric phase and dimensionality reduction in locomoting living systems, JENNIFER RIESER, Georgia Institute of Technology, CHAOHUI GONG, Bito Robotics, HENRY ASTLEY, University of Akron, PERRIN SCHIEBEL, Georgia Institute of Technology, ROSS HATTON, Oregon State University, HOWIE CHOSE, Carnegie Mellon University, DANIEL GOLDMAN, Georgia Institute of Technology — The apparent ease with which animals move requires the coordination of their many degrees of freedom to manage and properly utilize environmental interactions. Identifying effective strategies for locomotion has proven challenging, often requiring detailed models that generalize poorly across modes of locomotion, body morphologies, and environments. We present the first biological application of a gauge-theory-based geometric framework for movement, originally proposed by Wilczek and Shapere nearly 40 years ago, to describe self-deformation-driven movements through dissipative environments. Using granular resistive force theory to model environmental forces and principal components analysis to identify a low-dimensional space of animal postures and dynamics, we show that our approach captures key features of how a variety of animals, from undulatory swimmers and slitherers to sidewinding rattlesnakes, coordinate body movements and leverage environmental interactions to generate locomotion. Our results demonstrate that this geometric approach is a powerful and general framework that enables the discovery of effective control strategies, which could be further augmented by physiologically-relevant parameters and constraints to provide a deeper understanding of locomotion in a wide variety of biological systems and environments.

6:47PM P07.00008 Hysteresis Behavior of Large Scale Structure in Turbulent Rotating Plane Couette Flow1, YUHAN HUANG, State Key Laboratory for Turbulence and Complex Systems, College of Engineering, Peking University, Beijing 100871, China, ZHENHUA XIA, Department of Engineering Mechanics, Zhejiang University, Hangzhou 310027, China, MINPING WAN, SHIYI CHEN, Department of Mechanics and Aerospace Engineering, Southern University of Science and Technology, Shenzhen 518055, China — The existence of counter rotating vortex pairs is important in rotating plane Couette flow (RPCF). Two groups of numerical simulation were conducted with rotation number, \( Ro (Ro = 2\Omega b/U_w) \), with \( \Omega \) being the constant angular velocity in the spanwise direction, \( b \) being half channel height and \( U_w \) being half wall velocity difference, varying between 0.01 and 0.6. We found that the number of vortex pairs in a finite computation domain exhibits a hysteric behavior as \( Ro \) increases and decreases. When \( Ro \) decreases from 0.03 to 0.3, the number of vortex pairs is 2. When \( Ro \) decreases from 0.3 to 0.03, the number of vortex pairs is 3. This phenomenon is related to multiple states in RPCF or state bifurcation. Turbulent statistics such as friction, turbulent kinetic energy also form hysteresis loops. A linear stability analysis is performed on this problem to explain the formation of the hysteresis behavior.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P08 Non-Newtonian Flows II

5:16PM P08.00001 Entrance effects and high shear rate rheology of shear banding wormlike micelle fluids in microcapillary flow1 — PAUL SALIPANTE, VISHNU DHARMARAJ, STEVEN HUDSON, National Institute of Standards and Technology — The viscosity of a shear-banding wormlike micelle solution at high shear rates is investigated using capillary rheology and particle streak velocimetry. Measurements of the flow profile and pressure gradient show an extended entrance region, which exceeds a length to diameter ratio of 100, to reach a fully developed flow. We characterized this entrance region for capillaries with different cross-sections and used the results to select a downstream portion of the capillary where viscosity measurements can be made on fully developed flow. Measurements from this portion of the channel show a shear-thinning power-law behavior for all channel geometries from shear rates of 1,000 1/s to 120,000 1/s. Varying the surfactant concentration shows two distinct power-law behaviors that depend on both shear rate and concentration and are an indication of change in micelle length.

1NIST on a Chip

5:29PM P08.00002 Gels formed by worm-like micelles: Yielding and fluidization characteristics, RONAK GUPTA, RODRIGO MITISHITA, GWYNN ELFRING, Dept. of Mechanical Engineering, University of British Columbia, IAN FRIGAARD, Departments of Mathematics and Mechanical Engineering, University of British Columbia — A rarely studied system of long chain surfactant molecules has been shown to display ‘gel-like’ rheology at room temperature despite the absence of cross-linking. Using a similar model system, we investigate the yielding characteristics of micellar gels using creep and amplitude sweeps and elucidate dependencies on temperature and surfactant concentration. Further, we study the phenomenon of shear driven fluidization to better quantify the solid-liquid and yielding transitions in worm-like micellar gels.

5:42PM P08.00003 Linear and non-linear rheological study of long-chained surfactant solutions for gravel packing operations, RODRIGO MITISHITA, RONAK GUPTA, GWYN ELFRING, Department of Mechanical Engineering, University of British Columbia, IAN FRIGAARD, Departments of Mechanical Engineering and Mathematics, University of British Columbia — Long chained zwitterionic surfactants are extensively used in the oil industry, such as fracturing and gravel packing operations. Specifically in the context of gravel packing, the surfactant solutions need high viscosities over a wide range of shear rates and temperatures to successfully carry the gravel particles. The surfactant fluids are also drag-reducing due to their viscoelasticity, which aids in the transport over long distances at high pumping rates. In this study, we characterize a commercial surfactant for gravel packing by carrying out linear and non-linear rheology experiments. We show that the surfactant-water system exhibits a gel-sol transition with temperature. The results also quantify how the relaxation time of the solution and elastic modulus of the gel state depend on surfactant concentration and temperature. Finally, we discuss implications of rheology on gravel packing and turbulent drag reduction.

5:55PM P08.00004 Experimental method to measure liquid extensional properties during atomization, MARIE-CHARLOTTE RENOULT, CORIA-UMR 6614 INS A Rouen Normandy, CHRISTOPHE TIREL, CORIA-UMR 6614 Rouen University, CHRISTOPHE DEMOUCHET, CORIA-UMR 6614 CNRS — An experimental method has been developed to measure the extensional properties of a viscoelastic polymer solution experiencing atomization. It is based on the statistical and 3D multiscale analysis of the capillary thinning of liquid ligaments controlled either by elasticity or viscosity. The method principle will be first presented and validated using an ensemble of emulated ligaments. Then, the method procedure will be described from a free jet imaging setup to the extraction of the liquid extensional properties, i.e. the relaxation time and the terminal elongational viscosity. This procedure will be applied to a series of experiments conducted with several viscoelastic solutions, flow rates and quasi-cylindrical nozzles. Finally, the influence of the polymer concentration, of the jet velocity and of the nozzle dimensions on viscoelastic properties will be discussed.

6:08PM P08.00005 Taylor-Couette flow of shear-thinning and viscoelastic polymer solutions, NEIL CAGNEY, School of Engineering and Materials Science, Queen Mary University of London, Mile End Road, London, E1 4NS, UK, TOM LACASSAGNE, STAVROULA BALABANI, Department of Mechanical Engineering, University College London, Torrington Place, London, WC1E 6BT, UK — We study Taylor-Couette (TC) flow of a glycercol-water mixture containing xanthan gum (0 to 2000 ppm concentration). Both shear-thinning and viscoelasticity are induced, to assess the effect of the changes in rheology on various flow instabilities. The Reynolds number is slowly increased, and the flow is monitored continuously using flow visualisation [Cagney and Balaban, Phys. Fluids, 2019]. Shear-thinning is found to suppress many phenomena observed in previous studies of viscoelastic TC flow (e.g. diwhirls, disordered oscillations [Groisman and Steinberg, Phys. Rev, 1997]). The addition of polymers reduces the critical Reynolds number for the formation of Taylor vortices, but delays the onset of wavy flow. In the viscoelastic regime, the flow becomes unsteady soon after the formation of Taylor vortices, waviness changing with Reynolds number. Vortices are found to merge as Reynolds number increases, with the number of mergers increasing with polymer concentration. These changes in wavelength are hysteretic and occur in both steady and wavy regimes. Vortices in moderate and dense polymer solutions undergo a gradual drift in both their size and position, which appears to be closely linked to the splitting and merger of vortices.

6:21PM P08.00006 Co- and Counter-rotating Taylor-Couette Flows with Polyelectrolyte Solutions, VISHAL PANWAR, ATHENA METAXAS, CARI DUTCHER, University of Minnesota — Taylor-Couette flow, which is flow between two concentric, rotating cylinders, is ideal for studying flow behavior of complex solutions due to the wide variation of hydrodynamic flow states available. The addition of non-Newtonian polymer solutions increases the solution’s elasticity, which in turn can modify flow states that are typically dominated by inertial forces. In this study, a cationic polyacrylamide was used to modify the elasticity of the solution, and with varying concentrations of NaCl to alter the ionic strength of the solution. The coil conformation and relaxation times of charged polymers change depending on the ionic strength, from a more rigid conformation at low ionic strengths to a more flexible conformation at high ionic strengths, different in non-Newtonian responses to shear. The effect of polymer conformation as a result of varying solution ionic strength on TC flows with co- and counter-rotation of the cylinders will be discussed. In general, increasing ionic strength decreases elasticity, resulting in a shift towards a more Newtonian-like flow behavior. As the polymer conformation becomes more flexible, an overall trend of delayed transitions of flow states was observed.

6:34PM P08.00007 Viscosity measurement method of non-Newtonian fluids in pressure-driven flows based on energy dissipation rate, WOOK RYOL HWANG, HYE KYEONG JANG, Gyeongsang National University, SUN OK HONG, Ajou University, SANG BOK LEE, Korea Institute of Materials Science, JU MIN KIM, Ajou University — A novel viscosity measurement method is presented, which is established on the balance of the energy dissipation rate such that the external power is dissipated within the system as viscous dissipation in a laminar. The effective viscosity can be expressed algebraically in terms of the pressure drop and flow rate and the corresponding effective shear rate is readily determined by flow rate; the relationship between effective viscosity and effective shear rate is found identical to the true material viscosity behavior. The two flow numbers, which depend on flow geometry only and are almost independent of fluid rheology, are involved: the coefficient of energy dissipation rate that associates the total energy dissipation rate to the Reynolds number; and the coefficient of effective shear rate, which relates flow rate to effective shear rate. Three different flows with complicated geometries were tested: numerical validation for axisymmetric expansion-constriction flows and flows in a Kenics mixer, and experimental validation for flows in a complex microfluidic array with Xanthan gum solutions.

6:47PM P08.00008 Impacts of geometric parameters on bulge structure appearance in a cavity swept by a visco-elastic fluid, HIROSHI SUZUKI, MASAKI KAWATA, RURI HIDEMA, Department of Chemical Science and Engineering, Kobe University, FLUIDS AND PARTICLE ENGINEERING LABORATORY TEAM — We previously reported a bulge like flow structure is formed in a cavity swept by a visco-elastic fluid. In this study, effects of geometric parameters of the cavity on the bulge structure appearance have been investigated by flow visualization. As visco-elastic fluids, cationic surfactant aqueous solutions were treated with counter-ion suppliers of sodium salicylate. The molar ratios of sodium salicylate to cationic surfactants, oleylbishydroxyethylmethyammonium chloride, were changed from 1.5 to 10. The geometric parameters were also changed. The cavity depth, the wide flow path and the cavity length raged from 5 to 30 mm, from 25 to 40 mm and from 50 to 100 mm, respectively. From the results, three kinds of flow regimes were observed: 1. simple separation and reattachment occurrence, 2. bulge structure appearance and 3. recirculation region covering the cavity. In the cases when the molar ratio is high, bulge structure was not found to appear. When the aspect ratio of the narrow flow path was high, the flow also transited directly from 1 to 3 of the above flow regime. This flow regime was concluded to relate to the Deborah number of fluids.
resources from Consortium des Equipements de Calcul Intensif (CECI).

The position of the leader's wake is estimated and used as the target of the autopilot to maintain the follower in the optimal position. The efficiency is studied through the analysis of the related aerodynamic forces and the resulting wake. Finally, based on an Ensemble Kalman Filter, the robustness of the autopilot is verified with the LES of a single aircraft in turbulent flow. Then the influence of a leader's wake on a follower's dynamics is studied through the simulation of the aircraft dynamics and the LES of the wakes by means of a Vortex Particle-Mesh method. In a 2-ship formation, the distances between the vortex cores get altered in a random fashion. At $kh = 5$, the onset of jet switching in the trailing wake gets advanced $kh = 1$. The flow reattachment onsets inboard while the flow remains separated from the leading edge further outboard. Under certain axial acceleration magnitudes, a long whip-like nFTLE ridge lifting off the wing surface can be observed. The root of the whip-like structure moves toward the trailing edge and it closely follows a local chordwise pressure peak. It can be inferred that the nFTLE ridges’ roots across the span form a line that moves along with the high pressure zone in response to the axial gust. Following this region downstream along the chord is a region of low pressure, consistent with lift being re-established on the wing as the flow reattaches. Vertical accelerations will be studied and combined with axial acceleration cases to obtain further insight of flow structure evolution in highly unsteady environments for non-slender swept wings.

5:42PM P09.00003 Large Eddy Simulations of controlled aircraft in formation relying on wake sensing,¹, IGNACE RANSQUIN, DENIS-GABRIEL CAPRACE, PHILIPPE CHATELAIN, Universite Catholique de Louvain, UCLouvain, JEFFREY ELDREDGE, UCLA — Aircraft formation flight leads to substantial improvements in energetic efficiency even for large separations. Maintaining an energy-saving formation requires the estimation of the preceding aircraft’s wake position, and implies a sensing strategy. We propose to leverage the measurements of the six degrees-of-freedom dynamics of the follower aircraft. This study combines the simulation of the aircraft dynamics and the LES of the wakes by means of a Vortex Particle-Mesh method. In a 2-ship formation, the aerodynamics and vorticity sources are modeled using an immersed lifting line approach. The follower aircraft operates an autopilot in the form of a hierarchy of controllers that govern the ailerons, rudder, elevator and thrust in order to achieve wake sensing and tracking. The robustness of the autopilot is verified with the LES of a single aircraft in turbulent flow. Then the influence of a leader’s wake on a follower’s dynamics is studied through the analysis of the related aerodynamic forces and the resulting wake. Finally, based on an Ensemble Kalman Filter, the position of the leader’s wake is estimated and used as the target of the autopilot to maintain the follower in the optimal position. The efficiency of the tracking procedure is analyzed and shows promising results.

Timing compared to the starting and gust motions is shown to be important for the lift performance. Direct lift measurements are made via a transducer. The influence of varying the main-wing aspect ratio is also examined. The panel actuation promotes main-wing leading-edge vortex shedding, which should decrease the lift as desired. To test the effect of the modified flow on the force, towing-tank experiments to study the unsteady lift force produced by a high-angle-of-attack translating wing with a tip panel that rotates inward in the wing plane. The goal is to examine whether combined outboard sweep and rotation can influence the lift for two types of configurations such as different VG's angle of attack with respect to the air flow and different slot topologies were compared and discussed.

Interaction of the Leading Edge Vortex and Shear Layer Vortices for an Airfoil Undergoing Dynamic Stall

The flow field around a NACA0012 airfoil undergoing large amplitude sinusoidal pitching is investigated using Particle Image Velocimetry (PIV). The airfoil is pitched symmetrically about the quarter chord point with a pitch angle of 40, 30, and 20 at a reduced frequencies of =0.2-0.6 and Re =12000. In all cases a strong leading edge vortex (LEV) is formed with 2-3 weaker shear layer vortices (SLV) also forming along the airfoil surface. In some cases the LEV and the nearest SLV combine. In other cases SLV's combine. And finally in some cases the vortices remain independent of each other. The data suggest the formation a topological saddle forms between the two vortices that correlates with events in which the two vortices combine. The saddle appears below the center of the weaker vortex and moves relative to the vortices as they interact. The vortices are found to combine when the saddle moves above the center of the weaker vortex. The vortices remain distinct when no saddle appears. The data show that the interaction of the LEV and its nearest SLV occurs only for a limited range of the parameter space investigated.

6:34PM P09.00007 Wake transitions of flexible foils in a viscous uniform flow

We perform numerical simulations for two types of rigid and flexible thin foils in a viscous uniform flow to explore the effect of flexibility on wake structures. The thin foils are prescribed by the heaving oscillation motions and the relevant non-dimensional parameters are the chord length based Strouhal number and flapping amplitude. When the dynamical features of the flow wakes are varied with respect to the two parameters, it is possible to make a direct comparison between a rigid and flexible thin foils. The wake transition boundaries of the rigid thin foil are predicted by constant amplitude based Strouhal number lines, consistent with previous studies. However, contrary to the observation from the rigid thin foil, the wake transition boundaries of the flexible thin foil are not predictable by constant amplitude based Strouhal number lines. We find that the sum of the leading and trailing edge circulations plays an important role to determine a wake pattern behind a rigid and flexible foil, and wake transitions are observed beyond critical circumulations. 

6:47PM P09.00008 The Lift of a Translating Plate with Tip Sweep and Rotation

The lift of a translating plate with tip sweep and rotation are examined. This work could provide a method for drones to temporarily boost lift or outward in the wing plane. The goal is to examine whether combined outboard sweep and rotation can influence the lift for two types of motions: a starting flow and positive/negative 1/2-sine streamwise gusts. This work could provide a method for drones to temporarily boost lift during high-angle-of-attack maneuvers and reduce lift perturbations from streamwise gusts. For the starting flow, our prior flow visualization indicates that early outward panel motion produces a new swept-edge vortex (SEV) and stretches the tip vortex (TV) and trailing-edge vortex outboard, which should enhance lift. For a gust-like forward surge, inward panel motion prior to the gust sheds the panel SEV and TV, and promotes main-wing leading-edge vortex shedding, which should decrease the lift as desired. To test the effect of the modified flow on the force, direct lift measurements are made via a transducer. The influence of varying the main-wing aspect ratio is also examined. The panel actuation timing compared to the starting and gust motions is shown to be important for the lift performance.

5:16PM P10.00001 Time-frequency analysis of intermittent coherent structures in turbulent flows, AARON TOWNE, PEIJING LIU, University of Michigan, FLOW MODELING AND CONTROL TEAM — Time-frequency analysis is a popular and powerful tool for identifying and analyzing intermittent events in fluid systems. Typically, these analyses are carried out by computing spectrograms or scalograms from the time history of a single flow variable at a single location in space, e.g., one component of velocity at some location of interest. A disadvantage of this approach is that the relationship between spectrograms or scalograms computed at different points in the flow or for different flow quantities is ambiguous, and, in particular, the role of coherent structures in producing the observed intermittency is obscure. In this presentation, we introduce an approach for generating global spectrograms and scalograms that describe the time-frequency behavior of coherent structures defined over all flow variables and spatial locations. The method is based on two extensions of spectral proper orthogonal decomposition, which defines flow structures that evolve coherently in space and time (Towne et al., J. Fluid Mech. Vol. 847, 2018). We demonstrate the method using the example of coherent wavepacket structures in a turbulent jet.

5:29PM P10.00002 A modal decomposition for discovery of nonlinear triadic interactions from flow data, OLIVER SCHMIDT, University of California San Diego — We seek a decomposition of a flow field into spatial modes that reveal the footprint of triadic interactions. This goal is accomplished by extending bispectral signal analysis to multidimensional datasets with at least one inhomogeneous spatial direction. As we are interested in finding the dominant large-scale coherent structures associated with quadratic nonlinearities, we require the modal decomposition to optimally represent the data in terms of its phase coherence, as characterized by the third-order cumulant. In the frequency domain, this higher-order statistic is readily computed from a product of Fourier transforms at different frequencies. An algorithm for the computation of the proposed bispectral mode analysis is presented and applied to three data sets obtained from direct numerical simulation of cylinder flow at Re=300, large-eddy simulation of transitional jet flow, and particle image velocimetry measurements of a massively separated flat plate at a high angle of attack. The results are visualized in terms of frequency-frequency plots similar to the bispectrum that indicate the presence of the quadratic phase coupling, and spatial modes that can reveal the nature of the nonlinear interaction.

5:42PM P10.00003 Real-Time Reduced Order Modeling Of Deterministic and Stochastic Systems Using Time-Dependent Low-Rank Basis, HESSAM BABAE, MICHAEL DONELLO, University of Pittsburgh — We present a scalable method for the extraction of a time-dependent basis from observations of deterministic/stochastic systems. This method is based on a variational principle whose optimality condition leads to a closed-form evolution equation of the basis. The method is scalable with respect to the size of the data and the reduction order. We will also present real-time reduced order model, which are constructed from projections of the full-dimensional dynamics onto the time-dependent basis. We will present two case studies for the reduced-order modeling of: (1) transient instabilities in Kuramoto-Sivashinsky equation, and (2) transient flow over a bump.

5:55PM P10.00004 Data-driven modeling of chaotic flows with non-Gaussian statistics, HASSAN ARBABI, THEMISTOKLIS SAPSIS, Massachusetts Institute of Technology — We present a data-driven framework for modeling chaotic flows in the form of linear stochastic differential equations (SDEs) observed under a nonlinear map. We discover the nonlinear map using the theory of optimal transport for measures, and identify the system of SDEs by matching the spectral density of the optimally transported data. The inclusion of the nonlinear observation map allows us to build models of chaotic systems with moderate dimensions (e.g. 10 and more) that capture non-Gaussian features of the invariant measure including skewness and heavy tails. We demonstrate the application of our framework through a few examples including a high-Reynolds cavity flow and observational climate data.

6:08PM P10.00005 Reduced order flow control using input-output hidden Markov model, PALASH SASHITTAL, DANIEL BODONY, University Of Illinois at Urbana-Champaign — In this work we extend the cluster based reduced order modeling framework to partially observed fluid systems with a control oriented perspective. We employ a data-driven model learning approach coupled with a closed-loop control strategy. Model parameters are learned using expectation maximization in the presence of scarce and noisy data. Two feedback controller design methods are proposed to control the long term behavior of the system. We demonstrate the performance of the controllers by controlling the transitions of the Lorenz system and to suppress the nonlinear vortex shedding past an inclined flat plate. The application of hidden Markov model based control to primary atomization of a liquid jet in a high-speed gas co-flow will be discussed.

6:21PM P10.00006 Autoencoders for discovering coordinates and dynamics from data, KATHLEEN CHAMPION, University of Washington, BETHANY LUSCH, Argonne National Laboratory, NATHAN KUTZ, STEVEN BRUNTON, University of Washington — Understanding and efficiently modeling high-dimensional scientific data such as fluid flows require methods for identifying interpretable reduced models from the data. Deep learning methods are extremely flexible, showing a remarkable ability to behave as universal function approximators and demonstrating impressive performance at modeling and predictive tasks; however the resulting models have many parameters and are not constrained. A new family of linear model discovery (SINDy) provide parsimonious interpretable models, but require knowledge of the proper coordinates for representing dynamics. In this work, we present a method that combines an autoencoder network with SINDy for the simultaneous discovery of reduced coordinates and parsimonious dynamical models from high-dimensional data. The resulting models are interpretable, containing a small number of active terms that describe the dynamics in the reduced space. We demonstrate the success of this approach on data from a number of example systems.

6:34PM P10.00007 Identifying coarse-grained PDE models from data with the sparse identification of nonlinear dynamics, KADIERDAN KAHEMAN, EURIKA KAISER, ADITYA NAIR, NATHAN KUTZ, STEVEN BRUNTON, University of Washington — Identifying reduced order models of complex systems, such as are found in fluid mechanics, is a challenging, yet vital topic. In addition to Galerkin projection, which has been a mainstay of the fluid mechanics' community for decades, techniques from machine learning are emerging to identify accurate and efficient models from data. The sparse identification of nonlinear dynamics (SINDy) algorithm has recently been shown to provide data-driven reduced-order models for fluids that are both interpretable and generalizable. However, it is difficult to identify models with rational function nonlinearities using the SINDy approach, although these dynamics appear in many systems of interest, especially those systems with a separation of timescales. A recent extension to SINDy has enabled the identification of rational function nonlinearities, but this approach is numerically fragile and highly sensitive to noise. In this work, we develop a robust extension of SINDy to identify rational function nonlinearities, using an iterative approach to improve the conditioning of the algorithm. We demonstrate this implicit SINDy approach on several ODE and PDE systems, including the unsteady BZ chemical flow reaction.
6:47PM P10.00008 A study of state-of-the-art model reduction techniques applied to flow simulations with moving immersed boundaries. SERENA COSTANZO, TARANEH SAYADI, Sorbonne Université, PASCAL FREY, Sorbonne Université — Reducing a detailed system into smaller sized models, capable of reproducing the main features and dynamics of the original configuration is a common practice in optimisation and control community, which could also serve as a way to make function evaluations less expensive. Since control is one of the future applications of this study it is necessary to identify the most suitable methodology applicable to detailed Navier-Stokes simulations for prediction purposes. To this end various strategies such as the GNAT method (Gauss-Newton with approximate tensors), POD with Galerkin regression method, implemented with the machine learning algorithm SINDY (Sparse Identification of Nonlinear Dynamics), and conventional POD-DEIM methods are compared in the context of an incompressible Navier-Stokes solver with moving immersed boundaries capabilities. The capability of these methods to interpolate between various operating conditions and to extrapolate the solution is investigated. The ability of each reduction strategy in dealing with existing nonlinearities and moving immersed boundaries is also identified.

7:00PM P10.00009 Learning interpretable stochastic models with sparse regression1. JARED CALLAHAM, University of Washington, JEAN-CHRISTOPHE LOISEAU, Arts et Metiers ParisTech, J. NATHAN KÜTZ, STEVEN BINTUM, University of Washington — Learning interpretable stochastic models from high-dimensional data is a relevant task in many fields such as climate science, genomics, or turbulence. Recent advances in machine learning such as approximate inference from stochastic differential equations (SDEs) have demonstrated the effectiveness of neural networks to model complex systems. However, the over-parametrization of these models renders them uninterpretable from a physical point of view. In this work, we develop a methodology that allows to automatically discover interpretable stochastic models by learning reduced and interpretable SDEs directly from data. We describe an approach to learning interpretable stochastic models, devoting particular attention to practical considerations such as low sampling rates and time-correlated forcing. We apply our approach to prototypical nonlinear dynamics and demonstrate more accurate recovery than existing stochastic model discovery methods.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P11 Experimental Techniques: Quantitative Flow Visualization I 3B - Sam Grauer, Georgia Tech

5:16PM P11.00001 Three dimensional velocity and pressure measurements in a turbulent shear layer behind a backward-facing step.2. KARUNA AGARWAL, OMRI RAM, JIN WANG, YUHUI LU, JOSEPH KATZ, Johns Hopkins University — This study characterizes the unsteady pressure field generated by quasi-streamwise vortices that develop between the main spanwise vortices in the near field of a shear layer behind a backward facing step. Our objective is to understand the preferential location of pressure minima moves from the spanwise vortices at low Re to the core of quasi-streamwise vortices located between 45% and 75% of the reattachment length forming 1-2 mm wide and 5-7 mm long cavities. Tomographic imaging followed by 3D particle tracking using the Shake-the-Box method is used for calculating the instantaneous velocity and acceleration fields. These results are interpolated using singular value decomposition, and then refined using Constrained Cost Minimization to generate divergence free velocity and curl-free material acceleration at a spatial resolution of 250 m. The pressure is obtained by spatially integrating the material acceleration. The measurements are performed at Reynolds numbers based on separating boundary layer height Re=7100 and 17700. Analysis examines the effects of Re on the frequency, time evolution, size, strength and the pressure in the quasi streamwise vortices. The preferential location of pressure minima moves from the spanwise vortices at low Re to the quasi-streamwise structures at the higher Re.

5:29PM P11.00002 3D Particle Reconstruction of Volumetric Particle Image Velocimetry with Convolutional Neural Network3. SHAOWU PAN, Department of Aerospace Engineering, University of Michigan, Ann Arbor, USA, QI GAO, School of Aeronautics and Astronautics, Zhejiang University, China, QIJIE LI, HONGPING WANG, Key Laboratory of Fluid Mechanics, Beihang University, China — 3D particle reconstruction of volumetric Particle Image Velocimetry (PIV) is an under-determined inverse problem of which exact solution is difficult to obtain. Traditionally, approximated solutions can be obtained via optimization, e.g., multiplicative algebraic reconstruction technique (MART). Despite its popularity in recent years, the performance of MART-like algorithms deteriorates when the particle concentration becomes high, e.g., particle per pixel (ppp) ≈ 0.3. In this work, a particle reconstruction method based on convolutional neural network (CNN) is proposed. The method consists of two steps: first, an initial particle field is generated from a plurality of two-dimensional particle images get by camera using multiplied line-of-sight (MLOS) method; second, we use CNN to take the aforementioned initial particle field as input and output the 3D reconstructed particle fields. The data is artificially generated by randomly placing particle in 3D space then projected to four cameras to obtain 2D particle images. Compared to the traditional MART algorithm, the proposed method is not only significantly improving the accuracy of 3D particle reconstruction especially at high particle concentration but also eight times faster than the traditional MART algorithm.

A High-Spatial-Resolution Three-Dimensional Three-Component Velocimetry Method Based on Divergence-Free Polynomials

Present a physics-constrained method of inferring three-dimensional three-component (3D3C) velocity fields in constant-density flows from reconstructed 3D Mie-scattering fields of tracer particles. The proposed method is based on the representation of the estimated velocity field as a linear combination of divergence-free polynomial basis functions; the piecewise constant representation of the estimated velocity field that is inherent to tomographic particle image velocimetry (T-PIV) is replaced by a smooth representation that automatically satisfies conservation of mass. The appropriate linear combination is determined using a non-regularized motion estimation framework that is influenced by optical flow estimation. We provide a detailed evaluation of the proposed method in terms of accuracy and spatial resolution, treating 3D constant-density DNS data as the ground truth. We show that the proposed method (a) yields significant improvements in accuracy and spatial resolution compared to an idealized implementation of T-PIV and (b) achieves comparable accuracy and spatial resolution to an idealized estimate that corresponds to the theoretical one-vector-per-particle limit.

Direct background-oriented schlieren tomography

We present a novel approach to background-oriented schlieren (BOS) tomography that combines the deflection sensing and reconstruction algorithms. BOS imaging is a refraction-based flow visualization technique. Simultaneous BOS measurements from multiple cameras can be reconstructed by computed tomography to estimate the fluid’s 3D refractive index field, which is post-processed to obtain local densities. Each camera is focused on a textured background pattern that is positioned behind the fluid. Density gradients cause distortions in the image; the deflected light trajectories are typically determined using an optical flow algorithm. These deflections constitute the projection data for reconstruction. Deflection sensing is itself a complex inverse problem and a primary source of error in BOS tomography. We propose an alternative measurement model for BOS tomography that incorporates the optical flow equation. The deflection model is extended to calculate image gradients, directly, such that the refractive index field is reconstructed from the distorted images. As a result, reconstructions must satisfy observed gradients instead of inferred deflections, which are prone to error. The talk describes our measurement model and presents a numerical assessment of direct BOS tomography.

Volumetric Velocimetry in the Rotating Frame of Reference using a Plenoptic Camera

A single plenoptic camera mounted coaxially above a hub mounted mirror that rotates with the rotor enables instantaneous and three-dimensional flow field measurements over a wide range of azimuth angles. The design and implementation of this concept as an experimental test facility to conduct flow field and force measurements over a rotating wing is discussed. In the presentation, an overview of the methodology along with the challenges, details of the test facilities and some preliminary flow field and force measurement results will be discussed.

Application of Plenoptic Camera 3D PIV in a Rotating Frame of Reference

A major limitation to the thorough understanding of a rotating flow’s aerodynamic characteristics is the difficulty in measuring data within the rotating frame of reference. Rotating 3D Velocimetry (R3DV) is a concept designed to acquire volumetric flow field measurements over a rotor, within the rotating frame of reference, using a single camera. A submerged wing rotates in conjunction with a mirror that reflects light traveling through flow over the wing to a stationary plenoptic camera. The plenoptic camera’s added array of microlenses between the aperture and image sensor gives it the ability to capture the incident angle of light rays, allowing for 3D reconstruction of volumes. Traditionally, plenoptic camera calibration has been explored for a stationary field of view. In current development is a method to incorporate rotation into the calibration such that images from all azimuth angles can be calibrated by interpolation, thereby eliminating the need to calibrate each distinct angle. Other challenges include achieving sufficient depth resolution and obtaining an adequate depth of field at a distant focal plane. Preliminary results demonstrating the efficacy of the R3DV method will be presented along with explanations of how the aforementioned problems will be overcome.

Technique for Characterization of 3D Unsteady Fluid-Structure Interactions via a Single Plenoptic Camera

Auburn University — Due to flexible boundaries, many flows are unsteady, three-dimensional and subjected to fluid-structure interactions (FSI). Conventional studies of FSI nominally treat the flow and boundary surface measurements separately, resulting in a loss of true FSI physics, especially for aperiodic flows. More recently, simultaneous multi-camera approaches using tomographic-PIV/3D-PTV and Digital Image Correlation (DIC) have been implemented. This approach in this paper is to use a single plenoptic camera equipped with a microlens array, plenoptic cameras capture a volume’s light-field in 4D, which enables single-camera 3D measurements. In this study, a newly developed kHz-rate plenoptic camera is applied to characterize the FSI of a flexible 50x 30 x 30mm$^3$ tube model. Macroscopic painted dots were used to track surface motion, while micron-sized particles were used as the flow tracer. A pulsatile flow was applied to intermittently collapse the tube, during which the dots and seeds were simultaneously imaged. In post-processing, dots and seeds are separated by diameters and/or shape, after which their 3D trajectories are tracked separately via a plenoptic-PTV algorithm. Preliminary proof-of-concept results are presented, along with further analyses to optimize particles/dots sizes and densities.

The authors would like to acknowledge support from the Army Research Office under the Grant Number W911NF-19-1-0052.

6:47PM P11.00008 Technique for Characterization of 3D Unsteady Fluid-Structure Interactions via a Single Plenoptic Camera, BRIAN THUROW, ZU TAN, BIPIN TIWARI, VRISHANK RAGHAV, Department of Aerospace Engineering, Auburn University — Due to flexible boundaries, many flows are unsteady, three-dimensional and subjected to fluid-structure interactions (FSI). orifice-generated vortex rings

Trailing vortices merge with the primary ring to grow into a well-formed ring at an optimal formation time. Energy consideration based on the total circulation compared to a nozzle. In the case of orifice-generated vortex rings, the formation number has been found to range between 1.0 to 2.0. Furthermore, the radial component of velocity drastically destabilises the flow which results in an earlier pinch-off of the primary ring.

With the experimental data.

gases after bullet ejection is overlaid with the predicted flow field which reveals satisfactory agreement. Gunshot residue is an important factor and can either propel blood drops further from the target, or even turn them backwards toward the target. An image of the propagating muzzle backward blood spatter resulting from a gunshot.

Turbulent vortex rings of propellant gases skew the distribution of blood stains on the ground are an important phenomenon to consider in crime scene reconstruction. It is shown that this has a significant repercussion on the outcome of passive admixture by turbulent vortex rings. Turbulent vortex rings of propellant gases originating from the muzzle of a gun after a gunshot are a moment/torque on the vortex and the corresponding conservation is ensured by the appropriate vorticity flux into the core and throughout the sheet. The effect of this constraint on the total circulation in the sheet and the location of the vortex are presented for the roll-up of self-similar vortex sheets.

5:29PM P12.00002 Three-dimensional Vortical Structures in a Curved Pipe under Fully Developed Pulsatile Inflow

We numerically investigate spatial and temporal evolution of multiple three-dimensional vortices under a fully developed cardiac physiological (pulsatile) inflow of a Newtonian fluid in a 180 degree rigid pipe with circular cross-section, without taper or torsion. We identify vortical structures using vortex identification methods and characterize their evolution throughout the deceleration phase, capturing both Dean- and Lyne-type vortices for which the planes of rotation are different. We track trajectories of Dean-type vortices and find agreement with experimental results. We also show the connection along the axial direction between regions of organized vorticity observed at various cross-sections, which previous 2-D analysis could not provide, and demonstrate that the combined effect of geometry curvature and deceleration produces a strong helical flow that is conducive to the formation of a single pair of Dean-type counter-rotating vortices that is connected to the classical Dean vortex pair near the entrance to the curve. Understanding the formation of these vortical structures is necessary to draw any correlation between the flow and wall shear stress distributions produced under physiological conditions.

Alexander Yarin, University of Illinois Chicago — Self-similar turbulent vortex rings are investigated theoretically in the framework of the semi-empirical turbulence theory for the modified Helmholtz equation. The velocity and vorticity fields are established, as well as the transport of passive admixture by turbulent vortex rings. Turbulent vortex rings of propellant gases originating from the muzzle of a gun after a gunshot are an important phenomenon to consider in crime scene reconstruction. It is shown that this has a significant repercussion on the outcome of backward blood spatter resulting from a gunshot. Turbulent vortex rings of propellant gases skew the distribution of blood stains on the ground and can either propel blood drops further from the target, or even turn them backwards toward the target. An image of the propagating muzzle gases after bullet ejection is overlaid with the predicted flow field which reveals satisfactory agreement. Gunshot residue is an important factor in determining the events of a violent crime due to a gunshot and are considered to be entrained and transported by the propellant gases. The self-similar solutions for the flow, vorticity, and concentration of gunpowder particles are predicted and the results are shown to be consistent with the experimental data.

5:55PM P12.00004 Formation number, pinch-off time and optimal formation time of orifice-generated vortex rings

Raphael Limbour, Jovan Nedic, McGill University — Vortex rings are generated experimentally by impulsively discharging fluid through a sharp-edge nozzle or orifice. As the actuator pushes the flow through the tube, the shear layer at the outlet rolls-up, detaches and propagates downstream in one or several vortices from which we can define the pinch-off time, the formation number and an optimal formation time. The radial component of velocity at the exhaust of an orifice results in a significant increase in the final circulation, the kinetic energy and the hydrodynamic impulse (Krieg & Mohseni, 2013). Measurements show a 140% increase in the total circulation compared to a nozzle. In the case of orifice-generated vortex rings, the formation number has been found to range between 1.0 to 2.0. Furthermore, the radial component of velocity drastically destabilises the flow which results in an earlier pinch-off of the primary ring. Trailing vortices merge with the primary ring to grow into a well-formed ring at an optimal formation time. Energy consideration based on the Frenkel-Norbury family of vortex rings accurately predicts the formation number for orifice-generated vortex rings.
6:08PM P12.00005 Accurate and efficient coupling of a near-wall Eulerian solver with a Vortex Particle-Mesh method for aerodynamics and wakes\textsuperscript{1}, PHILIPPE BILLUARD, PHILIPPE CHATELAIN, GREGOIRE WINCKELMANS, Universite catholique de Louvain — We present and illustrate a new hybrid Eulerian-Lagrangian approach for aerodynamics: the near-wall region is resolved using an Eulerian solver (here finite differences) while the vortex-particle-mesh (VPM) method, supplemented by an immersed interface method (IIM), is used for capturing the wake region. Indeed, the isotropic elements of the VPM-IIM do not permit to resolve accurately and efficiently the boundary layer but perform very well in the wake region thanks to their negligible dispersion and diffusion. The grid-based solver is well suited for resolving the boundary layers. With such coupling, the advantages of both solvers are kept whereas their respective drawbacks are eliminated, permitting to simulate efficiently high Reynolds number flows. The key feature of the approach also lies in the way both methods are coupled: accurately and without Schwarz iteration. The approach is tested and analysed/validated on the flow past a cylinder. It is then applied to the flow past a regularized Joukowski airfoil.

\textsuperscript{1}The development work benefited from the computational resources provided by the supercomputing facilities of the Universite catholique de Louvain (CISM/UCL) and the Consortium des Equipements de Calcul Intensif en Federation Wallonie Bruxelles (CECI) funded by the Fond de la Recherche Scientifique de Belgique (F.R.S.-FNRS) under Convention No. 2.5020.11.

6:21PM P12.00006 Investigating the Van der Pol analogy in vortex shedding using Pade approximants and compact finite differences, DANIEL JOHNSTON, MOHAMMED AFSAAR, ADRIAN SESCU, IOANNIS KOKKINAKIS, University of Strathclyde — The Van der Pol (VDP) oscillator serves as an analogy for vortex shedding in the near-wake region of doubly infinite (i.e. spanwise homogeneous) slender bluff bodies. In this work, approximate solutions to the VDP equation are investigated using Pade approximants and compact finite difference schemes. The Pade approximant formulae are found using expansions of the well-known asymptotic solution. We compare this to the corresponding Taylor series and the classical 4th order Runge-Kutta solution. The Pade approximant solutions consistently show closer agreement to the numerical solution over their corresponding Taylor series, especially at $O(1)$ values of the small parameter in the VDP equation, for a longer interval in time. We then assess the accuracy of the numerical solution using compact difference schemes. We find that the spectral-like schemes introduced by Lele (J. Comp. Phys. 103, p.16, 1992) show closer agreement with the VDP analogy, when compared with conventional schemes, as the initial rate of growth of the oscillations in the near-wake is increased. Finally, we consider this analogy as a model of the Von-Karman vortex street in the wake behind a cylinder, validate the results using CFD simulations, and discuss conditions for which its applicability may break down.

6:34PM P12.00007 Numerical investigation of the model on vortex reconnection, YOSHIHUMI KIMURA, Nagoya University, KEITH MOFFATT, University of Cambridge — Recently we have developed an analytical model for the finite singularity problem for the Naiver-Stokes equations \cite{930967,2}. In this model, two circular vortex rings of circulation $\pm \Gamma$ and radius $R = 1/\kappa$ are symmetrically placed on two planes inclined to the plane $x = 0$ at angles $\pm \alpha$. Under an assumption that the vortex Reynolds number, $R_{\kappa} = \Gamma/\nu$, is very large, we have derived a nonlinear dynamical system for the local behavior near the points of closest approach of the vortices. Careful numerical investigation of the dynamical system reveals that the magnitude of vorticity could take any large value for small viscosity but remains finite since the minimum core radius never becomes zero. The assumptions for this analysis are far beyond the ones that the current DNS could attain, but we are curious whether and how much DNS can verify the tendency of the analysis. We are going to show some preliminary results of DNS. \cite{930967} Towards a finite-time singularity of the Naiver-Stokes equations Part 1. Derivation and analysis of dynamical system, H.K.M. & Y.K. JFM (2019) 861, 930967. \cite{2} Towards a finite-time singularity of the Naiver-Stokes equations Part 2. Vortex reconnection and singularity evasion, H.K.M. & Y.K. JFM (2019) 870, R1.

6:47PM P12.00008 Interaction of Tubular Vortices as a Function of Contact Angle, OSCAR VELASCO FUENTES, Departamento de Oceanografia Fisica, CICESE, Mexico — We study the evolution of two equal tubular vortices, which initially touch each other, as a function of the angle formed by their centerlines at the point of contact. To this end we solve the vorticity equation in a triple-periodic domain with a vortex-in-cell method, using as initial conditions two helical vortices of equal circulation $\Gamma$, pitch $L$, radius $R$ and core radius $a$. The axes of the helices are parallel lines separated by a distance $2R + 2a$, so that the vortices touch each other at a single point within the numerical domain. At this point the vortices centerlines make an angle $\alpha = 180^\circ - 2 \tan^{-1}(L/2\pi R)$. We analyzed the flow evolution by monitoring the position and topology of iso-surfaces of vorticity magnitude as well as the distribution of fluid particles initially located within the vortices. Both methods yield the same results in the identification of the following regimes: for small angles ($\alpha \to 0^\circ$) the vortices merge in a time that increases with the angle, for large angles ($\alpha \to 90^\circ$) the vortices reconnect in a time that decreases with the angle, for intermediate angles the vortices exchange mass but keep their identity during the whole simulation.

7:00PM P12.00009 Point vortices with dynamic circulation\textsuperscript{1}, PHILIP J. MORRISON, The University of Texas at Austin — The intimate connection between scalar vorticity dynamics and point vortex dynamics is well known. Because of Kirchhoff, Kida, and many others, Hamiltonian point vortex dynamics has been widely studied in a variety of contexts. In this talk I will discuss a generalization: a new conservative system of point vortex dynamics that allows for dynamic circulations.

Monday, November 25, 2019 5:16PM - 7:00PM – Session P13 Convection and Buoyancy-driven Flows: Simulation 304 - Roberto Verzicco, Twente
5:16PM P13.00001 Application of new unstructured geometry capability within FDS to simulation of outdoor smoke transport and deposition, MARCOS VANELLA, Fire Research Division, National Institute of Standards and Technology, Gaithersburg, MD, USA, ORIOL RIUS, HSE Department, CERN, 1211 Geneva 23, Switzerland, GLENN FORNEY, Fire Research Division, National Institute of Standards and Technology, Gaithersburg, MD, USA, EMANUELE GISSI, Corpo Nazionale dei Vigili del Fuoco, Italy, JASON FLOYD, Jensen Hughes, Rockville, MD, USA, SAVERIO LA MENDOLA, HSE Department, CERN, 1211 Geneva 23, Switzerland, RANDALL MCDERMOTT, Fire Research Division, National Institute of Standards and Technology, Gaithersburg, MD, USA — Over the years, the Fire Dynamics Simulator (FDS) has become one of the industry preferred tools for simulation of fire scenarios in design of indoor fire protection systems, forensic studies and wildland fires, among others. The flow solver of FDS evolves the Low Mach approximation equations for thermally driven buoyant flows by means of Large Eddy Simulation (LES), and standard discretization on block structured meshes. Recently, we have been developing the capability of FDS to simulate such flows over complex unstructured geometries via a cut-cell scheme and immersed boundary method. In this talk we will focus on the numerical scheme, and ongoing work on simulation of an outdoor smoke dispersion problem considering agglomeration and deposition in the kilometer scale CERN Meyrin campus. Details of the software implementation, simulation setup, and species transport and deposition results for a specific contaminant release scenario will be discussed.

5:29PM P13.00002 Effects of Equations of State Selection in Numerical Simulations of Supercritical Carbon Dioxide1, ELIZABETH RASMUSSEN, Mechanical Engineering Department, University of Washington, MICHAEL MARTIN, SHASHANK YELLAPANTULA, National Renewable Energy Laboratory, JOHN KRAMLICH, Mechanical Engineering Department, University of Washington — Supercritical carbon dioxide (scCO₂) is employed in a growing range of applications including novel material synthesis and advanced energy systems. However, a lack of understanding of how the complex behavior of scCO₂ near the critical point 304.25 K and 7.39 MPa affects the flow field, accompanied by numeric challenges of simulating under these conditions, limits the use of simulation as a predictive tool in these systems. Initial simulations using the high-fidelity Span-Wagner equation of state at a pressure of 8 MPa, fluid and wall temperatures ranging from 305 K to 390 K, and Reynolds numbers ranging from 0.1 to 35, show complex changes in flow and heat transfer. When simulations are repeated using the ideal gas law, Soave-Redlich-Kwong, and Peng-Robinson equations of state to the system, many of these effects are not captured. We compare the drastically different flow characteristics between non-ideal and ideal models as well as present on the computational cost of the varying degrees of accuracy.

1This work was facilitated through the use of advanced computational, storage, and networking infrastructure provided by the Hyak supercomputer system at the University of Washington. Funding also provided by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of two U.S. Department of Energy (DOE) organizations, the Office of Science and the National Nuclear Security Administration. The research was performed using computational resources sponsored by the Department of Energy’s Office of Energy Efficiency and Renewable Energy and located at the National Renewable Energy Laboratory.

5:42PM P13.00003 Boussinesq approximation in rapidly rotating flows1, JAGMOHAN SINGH, H. M. BLACKBURN, Monash University, Australia, J. M. LOPEZ, Arizona State University, USA, A. J. SMITS, Princeton University, USA — Rotating thermal convection (RTC) comprises of a thermal buoyant plume surrounded by a swirling flow. RTC is fundamental to many geophysical and engineering flows including tornados, firewhirls, dust devils and gas turbine combustors. Over the decades, RTC has been studied experimentally and numerically and it is shown that the axial buoyancy due to gravity in the presence of swirling creates a large updraft and aids to the formation of these columnar flows. In numerical simulations, the gravitational buoyancy is commonly modelled via the Boussinesq approximation which ignores the density variations in the momentum equation except in the terms multiplied by the gravity. However, a similar approach leads to additional buoyancy terms due to centrifugal forces, Coriolis forces and the inertia. The buoyancy due to centrifugal forces has recently started gaining attention but the other buoyancy terms are still overlooked and ignored. In this study, we systematically investigate the effect of different buoyancy terms in the Navier–Stokes equations via direct numerical simulations for flow inside the rotating container with an axial temperature gradient. Our results demonstrate that the buoyancy due to Coriolis forces and the inertia can change the flow behaviour significantly.

5:55PM P13.00004 Boundary treatment for the compressible natural convection with discrete-unified gas-kinetic scheme, XIN WEN, U. of Delaware, LIAN-PING WANG, U. of Delaware and Southern U of Sci and Tech, ZHAOLI GUO, Huazhong U of Sci and Tech — The buoyancy-driven natural convection in an enclosure has been studied by researchers for several decades, it plays an important role in both flow physics study and practical applications. When the temperature difference is large, the flow is beyond the Boussinesq limit and governed by full compressible Navier-Stokes equations. An aspect that has not been well studied in the kinetic method is the boundary treatment for compressible thermal flow when the temperature field and velocity field are strongly coupled. How to implement the no-slip condition, the isothermal wall temperature and the adiabatic boundary condition can be a challenge for the kinetic method. In this talk, we propose a systematic approach of deriving the bounce-back boundary treatment for the straight boundary using the Chapman-Enskog expansion. The bounce-back expression allows the boundary nodes to satisfy the compressible Navier-Stokes equations. For a curved boundary, we implement the immersed boundary method into the discrete-unified gas-kinetic scheme (DUGKS). By design, the IB forces only contribute the leading order of momentum and energy equation, the no-slip condition and isothermal wall can then be implemented for the curved boundary.

6:08PM P13.00005 AFiD-MF: an efficient solver for three-dimensional multiphase flows, HAORAN LIU, QI WANG, KAI LEONG CHONG, Univ of Twente, ROBERTO VERZICCO, Univ of Rome, DETLEF LOHSE, Univ of Twente — We propose an extension of our code AFiD (www.afid.eu) to simulate efficiently three-dimensional multiphase flows. In this approach, we implement the phase field model into AFiD in order to retain the massive solver for the incompressible Navier-Stokes equations. The performance of AFiD has been confirmed in many previous studies. To simulate the dynamics of multiphase flows, we rely on the phase field model to capture the fluid-fluid interface and deal with large density/viscosity ratios of the phases. The coupling of the phase field model with the AFiD solver is obtained by the volume fraction distribution of each phase and the surface tension force on the fluid-fluid interface. Our new approach, AFiD-MF, is validated by comparisons with data in the literature and verified through several numerical experiments, such as an oscillating droplet, the deformation of a drop in shear flow, the breakup of a rising bubble and the Rayleigh-Bénard flow with two immiscible phases.
6:21PM P13.00006 Variational multiscale large eddy simulation with diffusive flux reconstruction for Rayleigh-Bénard convection. DAVID SONDAK, Institute for Applied Computational Science, Harvard University, JOHN SHADID, Department of Computational Mathematics, Sandia National Laboratories, TOM SMITH, Department of Computational Science, Sandia National Laboratories, SIDAFA CONDE, Department of Computational Mathematics, Sandia National Laboratories, ROGER PAWLOWSKI, Department of Computational Science, Sandia National Laboratories — Large eddy simulation (LES) models for Rayleigh-Bénard convection are developed using the variational multiscale formulation (VMS). In the VMS formulation, a sum decomposition is used to split the fields into resolved and unresolved components. The unresolved components are modeled to be proportional to the residual of the governing equations. In this way, if the numerical solution exactly captures all scales of motion, the residual will be zero and the unresolved portion of the field vanishes. The result is a consistent numerical method and a dynamic LES model. When discretizing the resolved scales with linear finite elements, the diffusive terms in the residuals are zero and the true residual is not satisfied. In Rayleigh-Bénard convection, this unbalanced residual may negatively impact results due to the importance of boundary layer effects. In the current work, the diffusive terms are reconstituted and included in the stabilized residual. This reconstruction is shown to provide better numerical convergence to the correct solution. Moreover, coarse near-wall resolution can be partially offset by correctly reconstructing the residual. All of these effects have a bearing on the scaling of the heat transport with Rayleigh number.

6:34PM P13.00007 A cross Criticality in the convection of Yield Stress fluids. FRANCESCA PELUSI, MAURO SBRAGAILLA, Department of Physics & INFN, University of Rome Tor Vergata, ANDREA SCAGLIERINI, MASSIMO BERNASCHI, Istituto per le Applicazioni del Calcolo CNR — We study numerically the Rayleigh-Bénard instability of a two-dimensional multi-component system confined between two horizontal walls heated from below and cooled from above. We first carefully validate the numerical model in the mixed regime, by studying the transition from conduction to convection in a homogeneous Newtonian system. As a further upgrade of complexity, the system is prepared in the de-mixed regime, with many liquid droplets closely packed together and separated by thin interfaces. In such conditions, the system is a yield stress fluid, i.e. it exhibits reference stress (the yield stress) below which it reacts to external perturbations as a solid, and above which it flows with non-Newtonian rheology. The transition to convection is characterized as a function of the packing and the intensity of the initial perturbation. When the system exhibits convection, a crucial additional feature with respect to the Newtonian homogeneous system is the presence of plasticity at the droplets scale, which is expected to alter the heat transfer from the hot to cold walls.

6:47PM P13.00008 Using machine learning to predict 1D steady-state temperature profiles from compressible mantle convection simulations. SIDDHANT AGARWAL, HEIBRiDS, German Aerospace Center (DLR), Technical University Berlin (TUB), NICOLA TOSI, DLR, TUB, DORIS BREUER, DLR, PAN KESSEL, GREGOIRE MONTAVON, TUB — Thermal evolution simulations of planetary mantles in 2D and 3D are computationally intensive. A low-fidelity alternative is to use scaling laws based on boundary-layer theory to express Nusselt Number (Nu) as a function of Rayleigh Number (Ra). Such a Ra-Nu relation can be used to run ‘0D’ parametrized evolution models by solving a simple energy balance equation. Yet scaling relations are available only for simple flows that cannot capture the full complexity of mantle dynamics. We propose leveraging Machine Learning to find a higher-dimensional mapping from five different parameters to the entire 1D temperature profile. The parameters are Ra, internal heating rate, dissipation number and the maximum viscosity contrast between top and bottom due to temperature and pressure. We train a Neural Network (NN) to take these inputs and predict the resulting steady-state temperature profile. The training data comes from a subset of 20,000 compressible simulations on a 2D cylindrical grid. This results in predictions with an average error of 1.6% on the test set. The NN can potentially be used to build a 1D evolution model by stacking several steady-state temperature profiles together, with each prediction serving as an input at the next time step.

Monday, November 25, 2019 5:16PM - 7:00PM — Session P14 Vortex Induced Vibration 307/308 - David Olson, Michigan State University

5:16PM P14.00001 A passive amplification of VIV through a semi-hollow cylinder for Reynolds number 200. SUNGMIN RYU, Incheon National University, SEUNGMIN KANG, Hanyang University. VIV CONTROL TEAM — Since the demonstration that the kinetic energy generated by vortex-induced vibrations (VIVs) can be converted into electricity, the amplification of VIV has been of significant interest. For this practical relevance, we present a passive method to amplify VIVs of a circular cylinder for Reynolds number 200. We employ an empty space inside a solid circular cylinder and place an orifice on the stagnation point to embody a concept of passive control, considering a potential combination with existing passive devices. We quantified the performance of the semi-hollow model via two-dimensional simulations for a range of reduced velocity

5:29PM P14.00002 Transverse vortex-induced vibrations of a prolate spheroid. ALVARO SANCHEZ RUIZ, Flying Whales / IMFT, REMI BOURGUET, IMFT / CNRS, GUILLAUME MARTINAT, Flying Whales — A prolate spheroid of aspect ratio 6:1 can be regarded as a simplified model of the hull of an aeronautical or underwater vehicle. From a fundamental perspective, it represents an intermediate geometry between a sphere and an infinite circular cylinder, which have often served as paradigms to study bluff body wakes and flow-induced vibrations. When a rigidly mounted, prolate spheroid is placed in a cross-current, i.e. a flow normal to its long axis, previous studies have shown that its unsteady wake is characterized by the formation of large-scale hairpin vortices, which result in fluctuations of fluid forces. The case where the spheroid is elastically mounted and the possible occurrence of flow-induced responses of the body remain to be explored. This is the object of the present work where the spheroid is free to vibrate in the transverse direction. On the basis of direct numerical simulations, the behavior of the coupled flow-structure system is examined, at Reynolds number 100, over a wide range of values of the oscillator natural frequency. Focus is placed on the emergence of vortex-induced vibrations and on the associated alteration of the flow dynamics, compared to the stationary body wake.
Combined vortex-induced vibration of a rigid cylinder and a detached flexible splitter-plate

Ehsan and Scanlan (1990) with the stationary (or steady) flow assumption. We thus propose a slight variant of sparse identification of nonlinear dynamics (Ehsan and Scanlan, 1990) with the stationary (or steady) flow assumption. The interaction of the plate and the cylinder vortices leads to plate tip-displacement enhancement at smaller S* and intermediate U*. The overall cylinder-plate response indicates maximum energy harvesting potential at high U* and low S*. The present work is the first study on the combined VIV and presents a promising system for energy harvesting.

A moving time window is introduced to apply a typical SINDy regression at each time instant during the VIV event. A library of candidate nonlinear functions is constructed based on the laboratory model. A rig allows the cylinder to vibrate with one degree-of-freedom giving rise to wake interactions. They are arranged in an equilateral triangle. The tests have been conducted on a section model elastically suspended for different angles-of-attack and spacing ratios. All results are based on self-excited structural responses for test cases of undamped and damped structures in the subcritical Reynolds no. range. Cross-flow Vortex/Wake-Induced Vibrations (VIV/WIV) in pure heave motion were identified. These were typically double responses resulting in a wide Strouhal no. range. Oscillation hysteresis contributed to the lowest onset. A special case related to torsion was also identified. The stability of the structure depends on the mass-damping parameter, the Scruton no. The Galloping-Induced Vibrations (GIV) are special cases identified because VIV and GIV couple when the Scruton no. is relatively low. When this coupling occurs, large vibrations develop. Thus, structural design, to include dampers, should assure that the Scruton no. is above a certain minimum value which has been identified to be substantially higher than the ones related to pure VIV/WIV cases.

 detachment of the cylinder is maintained using a computer-controlled air bearing rig. The cylinder is designed to have one degree-of-freedom mass-damping systems. The aero-elastic instability may lead to self-sustained oscillation due to the unsteadiness in the aerodynamic forces, induced by variation in the instantaneous angle of attack as the cable oscillates normal to the mean flow direction. In order to have better insight into the underlying flow physics, one-component molecular tagging velocimetry has been employed in this study to measure the boundary layer development on the cylinder with canonical geometry representing the suction line cross-section. Specifically, those cylinders have rectangular cross-section with thickness d, side ratio and corner radius of c/d = 2.5 and r/d = 0.5, respectively, and surface topology. Results will be presented for Reynolds numbers of ReD = 1100 and 2500, with focus on cross-stream profiles of the mean and the fluctuating streamwise velocity component for a range of angles-of-attack. Data will also be presented for baseline smooth-surface cylinders in order to investigate the effect of surface topology.

The present work is the first study on the combined VIV and presents a promising system for energy harvesting.

A special case relates to torsion was also identified. The stability of the structure depends on the mass-damping parameter, the Scruton no. The Galloping-Induced Vibrations (GIV) are special cases identified because VIV and GIV couple when the Scruton no. is relatively low. When this coupling occurs, large vibrations develop. Thus, structural design, to include dampers, should assure that the Scruton no. is above a certain minimum value which has been identified to be substantially higher than the ones related to pure VIV/WIV cases.

The Galloping-Induced Vibrations (GIV) are special cases identified because VIV and GIV couple when the Scruton no. is relatively low. When this coupling occurs, large vibrations develop. Thus, structural design, to include dampers, should assure that the Scruton no. is above a certain minimum value which has been identified to be substantially higher than the ones related to pure VIV/WIV cases.
5:16PM P15.00001 Reynolds stress spectra in pipes and boundary layers up to $Re_\tau \approx 10^4$\textsuperscript{1}. SPENCER ZIMMERMAN, JIMMY PHILIP, JOSEPH KLEWICKI, University of Melbourne — Turbulent pipe flows and zero-pressure-gradient boundary layers (BLs) are frequently compared with the goal of elucidating the role of boundary conditions on turbulent wall flows. Since at least the early study by Schubauer (J. Appl. Phys., 25 (2), 1954, pp. 188–196), differences in the Reynolds stress (RS) profiles of the two flows have been described as resulting primarily from the turbulent/non-turbulent intermittency of the boundary layer. More recently, however, a number of researchers have shown differences in the streamwise velocity variance contributions per scale between the two flows even below the intermittent range. Despite these differences, Monty et al. (J. Fluid Mech., 632, 2009, pp. 431–442) showed that the streamwise variance profiles of the two flows match over most of the domain at matched friction Reynolds number. Extending this work, Zimmerman et al. (J. Fluid Mech., 869, 2019, pp. 182–213) showed experimental evidence that differences in the wall-normal and spanwise RS profiles can extend to within the log-layer. Here, we use the same experimental dataset to discuss features of the spectra common to both flows as well as the scales and wall-positions at which systematic differences are observed.

5:29PM P15.00002 Spectral analysis of Reynolds shear stress in high Re turbulent channel flows\textsuperscript{1}. ROBERT MOSER, University of Texas at Austin, MYOUNGKYU LEE, Sandia National Laboratory — We perform spectral analysis of the terms in the transport equation Reynolds shear stress, $\langle u'v' \rangle$ in high $Re$ wall-bounded turbulent channel flows, using the analysis technique from Lee & Moser (J. Fluid Mech., vol 860, 886-938). Specifically, a log-polar representation of two-dimensional spectra are used to study the interactions of turbulence at different length-scales and wall-normal distances. The analysis results show that $\langle u'v' \rangle$ production occurs primarily in the streamwise-elongated modes. Inter-scale transfer at fixed wall-normal distances transfers shear-stress to modes that are elongated in the spanwise direction, especially away from the wall. Wall-normal transport then moves this streamwise-elongated stress to the other side of the channel. This exchange of stress between the two sides of the channel is the primary balance of the production, since the dissipation is relatively weak. Wall-normal transport of streamwise-elongated modes is more complex, with $\langle u'v' \rangle$ exchange driven by the increasing spanwise scale of the dominant stress carrying modes. Finally, away from the wall, the characteristic length scales of production and wall-normal transport mechanisms grow linearly with wall-normal distance.

5:42PM P15.00003 Identification of nonlinear interaction of the self-sustaining process in wall-bounded turbulence using resolvent analysis\textsuperscript{1}. H. JANE BAE, BEVERLEY MCKEON, California Institute of Technology — The nonlinear interaction in the self-sustaining process of wall-bounded shear flows is investigated using resolvent analysis. Resolvent analysis (McKeon & Sharma 2010) is used to identify the principal forcing mode which produces the maximum amplification in the minimal channel (Jiménez & Moin 1991). The identified mode is then removed from the nonlinear term of the Navier-Stokes equations at each time step from a direct numerical simulation of a minimal channel. The results show that the removal of the principal forcing mode is able to laminarize the flow, while the removal of subsequent modes only marginally affects the flow. Using conditional averaging, the flow structures that are responsible for generating the principal forcing mode, and thus the nonlinear interaction to self-sustain turbulence, are identified to be spanwise rolls interacting with meandering streaks.

\textsuperscript{1}This work was funded in part by the Coturb program of the European Research Council.

5:55PM P15.00004 Two-Scale Interaction in Near-Wall Turbulence. PATRICK DOOHAN, Imperial College London, ASHLEY P. WILLIS, University of Sheffield, YONGYUN HWANG, Imperial College London — It has been shown that the dynamics of individual energy-containing eddies in the hierarchy of wall-bounded turbulence (Townsend,1980) are governed by the self-sustaining process (SSP) (Hwang & Bengana,2016). However, multiscale flows also exhibit interaction between structures of different scales, notably the energy cascade, but the temporal dynamics of multiscale turbulence are not well understood. In this study, the temporal dynamics of a two-scale near-wall flow are investigated using a shear stress-driven model (Doohan et al.,2019). In addition to the SSP at each scale, the energy cascade and feeding from small- to large-scales are identified as the primary scale interaction processes. The energy cascade is most active during the streak-breakdown stage of the large-scale SSP and the timescale of the resulting small-scale dissipation matches that of the large-scale motion i.e. non-equilibrium cascade. The wall-normal cascade can also fuel small-scale production, driving the small-scale SSP. The feeding of large-scale structures is correlated with the streak-breakdown stage of the small-scale SSP and results in increased large-scale pressure transport and dissipation. In the presentation, the dynamics of the two-scale interaction system will be discussed in detail.

6:08PM P15.00005 Linear mechanisms sustaining wall turbulence\textsuperscript{1}. ADRIAN LOZANO-DURAN, Stanford University, MARIOS-A. NIKOLAIDIS, National and Kapodistrian University of Athens, MICHAEL KARP, Stanford University, NAVID C. CONSTANTINOU, Australian National University — Turbulence is the primary example of a highly nonlinear phenomenon. Nevertheless, there is evidence that the energy-injection mechanisms sustaining wall turbulence can be ascribed to linear processes. The different scenarios stem from linear stability theory and comprise modal instabilities from mean-flow inflection points, transient growth from non-normal operators, and parametric instabilities from temporal mean-flow variations, among others. These mechanisms, each potentially capable of leading to the observed turbulence structure, are rooted in simplified theories. Whether the flow follows any or a combination of them remains unclear. In the present study, we devise a novel collection of numerical experiments in which the Navier-Stokes equations are sensibly modified to quantify the role of the different linear mechanisms. This is achieved by direct numerical simulation of turbulent channel flows with constrained energy extraction from the streamwise-averaged mean-flow. We demonstrate that (i) transient growth alone is not sufficient to sustain wall turbulence and (ii) the flow remains turbulent when the modal instabilities are suppressed. On the other hand, we show that the parametric instability due to the time-varying mean-flow is essential to maintain turbulence alive.

6:21PM P15.00006 Statistical characterization of inter-component energy exchange in turbulent channel flows1. YONGSEOK KWON, JAVIER JIMENEZ, Universidad Politécnica de Madrid — In turbulent channel flows, it is well understood that the fluctuating velocity extracts energy from the mean flow via the lift-up mechanism (as represented by the production term in the energy budget equations). In this process, the streamwise velocity perturbation receives energy from the mean flow by the linear advection of the streamwise momentum along the cross-shear direction. However, what is still unclear is the precise mechanism by which the strong cross-shear velocity is triggered. In this presentation, this process is investigated from the perspective of the mean turbulent kinetic energy exchange and the inter-component energy exchange processes are statistically characterized. In particular, the primary focus is put on the non-linear interactions leading to the inter-component energy exchange, to shed light on their roles in the sustenance of turbulence in channel flows.

6:34PM P15.00007 Large field of view volumetric measurement of a turbulent boundary layer1. FELIX EICH, MATTHEW BROSS, Universität der Bundeswehr München, DANIEL SCHANZ, MATTEO NOVARA, ANDREAS SCHRÖDER, DLR Göttingen, CHRISTIAN J. KÄHLER, Universität der Bundeswehr München — In order to understand the complex dynamics and interaction processes between flow motions within turbulent boundary layers, time resolved 3D data is necessary. Therefore, a unique time resolved 3D measurement was performed at $Re_x = 42000$ under zero and adverse pressure gradient conditions. Using 13 high speed PIV cameras, helium filled soap bubbles as tracer particles in combination with LED illumination, it was possible to measure a turbulent boundary layer flow over $2.9 \times 0.6 \times 0.25 \text{m}^3$ at a recording frequency of 1 kHz. The acquired data was analysed with Lagrangian particle tracking techniques to generate velocity fields. The turbulent superstructures and their dynamics could be directly resolved. The interaction between the superstructures gives insight into the exchange of mass and momentum between the coherent flow motions. Furthermore the interaction between the superstructures with the flow separation line is studied. The results show that the superstructures have a significant effect on the dynamics of the line of separation.

6:47PM P15.00008 Streamwise development of targeted coherent structures in turbulent pipe flow. TYLER VAN BUREN, University of Delaware, LEO HELLSTROM, Princeton University, IVAN MARUSIC, University of Melbourne, ALEXANDER SMITS, Princeton University — Our aim is to perturb specific naturally occurring energetic modes in turbulent pipe flow ($Re_{\tau} = 3486$) using sections of pipe with a periodic non-circular cross-section. We track the downstream development of these perturbations with stereoscopic particle image velocimetry. Cross-sections with an azimuthally varying radius (sinusoidal) delicately agitate the flow through excitation of the Reynolds stresses. These sections significantly alter the mean flow, and add energy in the targeted structures while simultaneously reducing the energy in the non-excited structures. Supported under ONR Grant N00014-15-1-2402, Program Manager/Director Thomas and the Australian Research Council.

7:00PM P15.00009 Application of the attached eddy hypothesis for turbulence characterization in marine boundary layer flows1. DACHUAN FENG, The Hong Kong University of Science and Technology, VIKRANT GUPTA, MINPING WAN, Southern University of Science and Technology, LARRY K.B. LI, The Hong Kong University of Science and Technology — Tidal current turbines usually operate in moderate to high current marine boundary layer (MBL) flows. Whereas the mean flow speed largely determines the average power extraction, it is the higher-order turbulence statistics that determine the structural load on turbines (required for device design) and the wake length behind them (required for array design). We propose to use Townsend’s attached eddy hypothesis to characterize the turbulence in MBL flows. To this end, we perform large-eddy simulations of high-Reynolds-number MBL flows with seabed roughness varying from the transitional to the fully rough regime. We find that, within the log-layer, the horizontally-averaged spanwise turbulence intensity follows a log-linear law while the wall-normal component remains nearly constant. These findings are consistent with the attached eddy model (Townsend 1976, The Structure of Turbulent Shear Flow, CUP), with the constants being dependent on the seabed roughness. The present work provides a reduced-order framework for studying the effect of boundary layer turbulence on turbines.

Session P16 Focus Session: Exascale Computations of Complex Turbulent Flows III

5:16PM P16.00001 A massively parallel unstructured overset method for large-scale simulation of moving bodies in turbulent flows1. WYATT HORNE, KRISHNAN MAHESH, University of Minnesota — We present an unstructured overset method capable of performing direct numerical simulation (DNS) and large eddy simulation (LES) of many ($O(10^5)$) moving bodies, utilizing many computational cores ($O(10^5)$) as shown in Horne & Mahesh [J. Comput. Phys.(2019) In Press]. A dynamic overset assembly is conducted to connect mesh solutions. To establish communication patterns a parallel master/slave algorithm is used. A parallel flood-fill algorithm is used for cutting. For searches, k-d tree data structures are used. Often the connectivity between overset meshes remains the same between time steps. The temporal coherence of objects is directly used to only update necessary information with time, resulting in substantial cost savings. A non-dissipative finite volume method is used for the fluid flow. An interpolant is used which has superior kinetic energy properties compared to local reconstructions. To solve pressure, a penalty constraint formulation is used, resulting in a symmetric, positive definite system. Strong scaling is demonstrated for 100,000 particles in a turbulent channel flow up to 492,000 cores. Detailed flow results illustrating the method are presented.

Objective of this work, therefore, is to explore the performance of multifidelity ensemble-based strategies in large-scale multiphysics applications. In this regard, multifidelity methods have become increasingly popular in the last years as acceleration strategies. Exascale computing resources promise to facilitate the use of these approaches on larger scale problems by providing 1-10k times augmented floating-point capacity. Significant fatigue load reduction is observed for all the simulated cases. The process is tested on a variety of test cases, including wall-resolved and wall-modeled LES of both canonical flows (channels and boundary layers) and complex memory hierarchies.

5:42PM P16.00003 High fidelity turbulence simulations with adaptive mesh refinement in Nek5000\(^1\), NICOLAS OFFERMANS, ADAM PEPLINSKI, PHILIPP SCHLATTER, Department of Mechanics, KTH Royal Institute of Technology, Sweden — The design of an adequate mesh is a complex and time-consuming task for users of computational fluid dynamics codes, which typically requires some a priori knowledge of the developing physics. We use adaptive mesh refinement, which combines error estimators and grid adaptation, as a tool for automatic mesh optimization. This strategy allows for better error control and easier mesh generation. Our framework is Nek5000, a highly-scalable code based on the spectral element method. The h-refinement technique is chosen for mesh adaptation, where selected elements are split via an octree structure, and two types of error estimators are considered. The first estimate relies on the local spectral properties of the solution. The second one is goal-oriented and based on the dual-weighted residual method, which requires the computation of an adjoint problem. Applications include direct numerical simulations of 3D turbulent cases such as the flow in a periodically constricted channel, also called periodic hill, and the flow around a NACA4412 wing profile at Re\(_c\) = 850,000. We ensure that the adaptive simulations are reliable and stable, and we compare the choice of error estimators on the refinement patterns and other relevant flow quantities.

5:55PM P16.00004 Algorithmic grid selection in LES\(^1\), SIVASH TOOSI, JOHAN LARSSON, University of Maryland, IVAN BERMEJO-MORENO, University of Southern California — Given the recent progress in LES modeling and numerical schemes, the computational grid has now become the single most important factor determining the quality of an LES; and yet the current state-of-the-art is to rely fully on user expertise to build the grid. While this is a workable process for academic problems in relatively simple geometries, it becomes untenable going forward towards more complex flows in complex geometries with multi-physics effects at increasing computational scales. The present work is aimed at developing an algorithmic process for how to select a nearly optimal grid (maximal accuracy at minimal cost) for LES. Two error indicators are used to drive an iterative grid selection process, where the solution from a previous LES run is used to select a more optimal grid for a subsequent run. The resulting method is highly systematic, with minimal dependence on user input, and can be operated both in a free mode that results in unstructured grids and in a constrained mode that results in structured grids. The process is tested on a variety of test cases, including wall-resolved and wall-modeled LES of both canonical flows (channels and boundary layers) and more complex flows (backward-facing step and smooth-body separation) with excellent results in all cases.

1This work has been supported by NASA.

6:08PM P16.00005 Multifidelity ensemble-based prediction of turbulent flows at the Exascale\(^1\), LLUIS JOFRE, MANOLIS PAPADAKIS, ALEX AIKEN, GIANLUCA IACCARINO, Stanford University — The study of complex multiphysics turbulent flows is commonly based on intensive computational high-fidelity simulations. To build confidence and improve their prediction accuracy, very large computational budgets are typically required to characterize the impact of uncertainties on the quantities of interest. In this regard, multifidelity methods have become increasingly popular in recent years as acceleration strategies. Exascale computing resources promise to facilitate the use of these approaches on larger scale problems by providing 1-10k times augmented floating-point capacity, but at expenses of requiring more complex data management as memory is expected to become more heterogeneous and distributed. The objective of this work, therefore, is to explore the performance of multifidelity ensemble-based strategies in large-scale multiphysics applications using an Exascale-ready computational framework.

6:21PM P16.00006 High-fidelity simulations for wind farm control co-design: evaluation of individual blade pitch control for turbine arrays and utility-scale wind farms\(^1\), FOTIS SOTIROPOULOS, XIAOLEI YANG, Stony Brook University, PETER SEILER, University of Minnesota — With the exponential growth of computer power, high-fidelity simulations are playing an increasingly important role enabling for the first time control co-design of wind farms, which can dramatically increase the annual energy production (AEP) and reduce the levelized cost of energy (LCOE). Individual blade pitch control (IBPC), which can effectively reduce the load fluctuations caused by the non-uniform incoming wind speed, has the potential to significantly reduce the LCOE of wind farms. IBPC, however, has been mostly evaluated for stand-alone individual wind turbines and its promise has yet to be demonstrated for turbine arrays especially at utility scale. We employ herein the VFS-Wind code to carry out large-eddy simulation (LES) with actuator-based parametrizations of turbine blades to explore the potential of IBPC in large wind farms. Two types of cases are investigated computationally: 1) a canonical turbine array with three different spanwise turbine spacings with the downwind turbine spacing fixed at seven rotor diameters; and 2) the XCEL Energy utility-scale wind farm in Pleasant Valley, Minnesota, United States, which consists of 100 wind turbines with generation capacity up to 200MW. Significant fatigue load reduction is observed for all the simulated cases.

1This work was supported by Xcel Energy through the Renewable Development Fund (RD4-13).
6:34PM P16.00007 Blade Resolved Wind Turbine Simulation with the Hybrid Time-Averaged Model Split Turbulence Model, JEREMY MELVIN, The Oden Institute, University of Texas at Austin, MARC HENRY DE FRAHAN, SHREYAS ANANTHAN, GANESH VIJAYAKUMAR, National Renewable Energy Lab (NREL), ROBERT MOSER, The Oden Institute, University of Texas at Austin — Blade resolved numerical simulations of wind turbines are an essential tool to help guide turbine design and placement in wind farms. Due to the high Reynolds number of these flows and the complex geometry of the turbine, a computational approach utilizing Reynolds Averaged Navier Stokes (RANS) or hybrid RANS/Large Eddy Simulation (LES) turbulence models are needed for computational feasibility. However, typical turbulence modeling approaches struggle with the complex flow characteristics present in flow fields around wind turbines. The newly developed Time-Averaged Model Split (TAMS) hybrid RANS/LES approach described by Haering et al. (AIAA Scitech 2019 Forum, AIAA 2019-0087, 2019) has shown the potential to resolve many of the issues with existing hybrid approaches for these complex flows. In this talk, we discuss efforts to conduct a blade resolved wind turbine simulation with the TAMS model. We integrate TAMS with a base SST RANS model, and conduct both airfoil and turbine simulations to compare performance and efficiency with standard DES hybrid approaches. We highlight the advantages of TAMS and discuss a path forward for additional improvements.

6:47PM P16.00008 Nek5000 LES of realistic urban geometries initialized from weather models, ALEKSANDR OABIKO, GKHAN SEVER, RAJEEV JAIN, YU-HSIANG LAN, Argonne National Laboratory, PAUL FISCHER, University of Illinois at Urbana-Champaign, HAOMIN YUAN, ROBERT JACOB, CHARLIE CATLETT, MUSIN MIN, Argonne National Laboratory — In the atmospheric modelling community, urban boundary layers have been generally treated using mesoscale models where a presence of obstacles are taken into account by parameterizations of the urban (or vegetation) canopy. There are not enough CFD-quality observations to validate the momentum and heat transfer in these models for all cases of interest. We seek to improve parametrization and complement observations with CFD reference solutions using an open-source CFD solver Nek5000. High scalability combined with high-order discretization and low count of degrees of freedom per processor allows an efficient exploitation of high-fidelity approaches like large-eddy simulation (LES) in complex geometries. With initial and boundary conditions derived from a High-Resolution Rapid Refresh (HRRR) initialized WRF-urban model, we have performed wall-resolved Nek5000 LES of realistic urban geometries including Lake Point Tower and Goose Island regions of Chicago. These preliminary simulations suggest we have the capability to start modelling the flow in any city geometry assuming a proper mesh can be built. Extending these reference simulations to larger domains will be possible with upcoming exascale supercomputers while longer simulation times may still remain a challenge.

7:00PM P16.00009 BCM-LES application to wind gust disaster under extreme meteorological events, TETSURO TAMURA, MASAHARU KAWAGUCHI, Tokyo Institute of Technology — Recently in Japan, people tend to realize so frequent occurrences of tornado and many attacks of typhoon to Japanese islands. In 2011, Tsukuba tornado arose in the Kanto plain based on a supercell. It causes the wind gust disaster on houses built on city area. In 2018, the typhoon Jebi attacked at Osaka area on September 4. High wind collapsed the wooden houses and the claddings of buildings and structures. This study applies LES based on BCM (Building Cube Method) to flow field for several km square area of disaster occurrence. This numerical model is formulated on the very fine Cartesian mesh system utilizing the IBM which can solve unsteady wind flows around actual complicated building shapes. Also, this research presents LES method for generating broad-banded turbulence flow that is able to regenerate high frequency components for existing meteorological model output. We performed the hybrid analysis of the meteorological model and engineering LES, in order to investigate near-ground turbulent wind under extreme meteorological events. This study numerically estimates the maximum wind velocity and the peak pressures on the building. Mechanism for process to failure of buildings will be discussed for establishment of safety at city.

Monday, November 25, 2019 5:16PM - 7:00PM — Session P17 Focus Session: Recent Advances in Data-Driven and Machine Learning Methods for Turbulent Flows IV

5:16PM P17.00001 Overview on sparsity in fluids, ZHE BAI, Lawrence Berkeley National Laboratory, STEVEN BRUNTON, University of Washington — Fluid flows are typically represented in high-dimension, although they often exhibit low-dimensional patterns. Understanding these patterns and their evolving dynamics is crucial for control. Thus, discovering these patterns from experimental and numerical data is a central challenge in fluid dynamics. The existence of these low-dimensional flow patterns also enable efficient sensing strategies, sparsity-promoting optimization, and randomized methods in fluids. In this talk, we will discuss integrated sparsification and modal decomposition for fluids, which involve compressed sensing, proper orthogonal decomposition, and dynamic mode decomposition, providing a foundation for pattern recognition and low-rank structure discovery of high-dimensional systems. These data-driven models save tremendous online experimental and computational resources by leveraging the existence of patterns. We will illustrate these ideas on a variety of engineering applications.

5:29PM P17.00002 Deep Neural Networks for Reduced Order Models for Fluid Flows, WILLIAM WOLF, HUGO LUI, University of Campinas — We present two numerical methodologies for construction of reduced order models, ROMs, of fluid flows through deep neural networks, DNNs. Here, the neural networks are used for regression and the frameworks are implemented in two contexts: one employs deep feedforward neural networks using a procedure similar to the sparse identification of non-linear dynamics algorithm, SINDy, and another is implemented using convolutional neural networks directly to the flow snapshots. The methods are tested on the reconstruction of a turbulent flow computed by a large eddy simulation of a plunging airfoil under dynamic stall. The reduced order models are able to capture the most energetic dynamics of dynamic stall including the leading edge stall vortex and the subsequent trailing edge vortex. The numerical framework allows the prediction of the flowfield beyond the training window and we demonstrate the robustness of the current ROMs constructed via deep neural networks through a comparison with sparse regression. The DNN approaches are able to learn transient features of the flow and present more accurate and stable long-term predictions compared to sparse regression.

2 Mr. Hugo Lui may become the presenter in case he attends the meeting.
5:42PM P17.00003 Modeling particle-induced turbulence using sparse regression with embedded invariance¹. SARAH BEETHAM, JESSE CAPECELATRO, University of Michigan — Turbulence is ubiquitous in science and industry and is nearly always multiphase. Given current computational capabilities and the wide range of time- and length-scales of industrial systems, direct numerical simulation (DNS) is prohibitively costly. Thus, some degree of modeling must be employed. Current state-of-the-art modeling for turbulent multiphase flows is predominantly based on extensions to single-phase models, making it largely unsuccessful beyond the dilute limit. This eliminates the augmentation of existing models as an option for solving the multiphase closure problem. Our goal is to propose compact, tractable multiphase turbulence closures. Thus, we first derive the exact Reynolds Stress equations for multiphase flows, which identifies the specific terms requiring modeling. To arrive at these closures, we use sparse regression with embedded invariance. In this talk, we demonstrate the promise of this technique for three classes of flow with increasing difficulty: (1) single-phase free shear turbulence, (2) turbulent flow over periodic hills and (3) gas-solid sedimenting flow.

5:55PM P17.00004 Leveraging Dynamics for Near-Optimal, Ultra-Sparse Sensor Placement¹. SAMUEL OTTO, CLARENCE ROWLEY, Princeton University — Optimal sensor placement in high-dimensional nonlinear dynamical systems like fluid flows remains a challenging problem. Most current methods identify an overly large number of sensors because they do not make use of the time histories at each sensor location. Our work begins by constructing a POD subspace capturing the finite-time state trajectories of interest. The sensors must be able to robustly reconstruct trajectories in this subspace, leading to an objective function that has “nice” mathematical properties (namely, it is normalized, monotone, and submodular). These properties guarantee that an accelerated greedy algorithm for sensor placement has performance within a constant factor of the optimal performance. In addition to reconstructing trajectories in POD subspaces, our method can be extended to identify even fewer sensors that enable nonlinear reconstruction of trajectories on curved manifolds (which we call “ultra-sparse” sensor placement). We illustrate these methods with examples including a cylinder wake flow and Burgers equation.

6:08PM P17.00005 Space-time recovery of high-resolution turbulent flow fields with machine learning based super resolution. KAI FUKAMI, KOJI FUKAGATA, Keio University, KUNIHIKO TAIRA, University of California, Los Angeles — In recent years, the use of machine learning based super-resolution analysis has enabled accurate reconstruction of high-resolution image from its low-resolution counterpart. Moreover, machine learning techniques referred to as inbetweening have also been developed to estimate data in between temporal snapshots. Here, we combine two of these approaches to reconstruct complex multi-scale turbulent flows both in space and time. A convolutional neural network-based architecture called hybrid Downsampled Skip-Connection and Multi-Scale (DSC/MS) model is developed for the recovery of complex flow fields. The proposed model is applied to two-dimensional isotropic turbulence and three-dimensional turbulent channel flow at $Re_x = 180$ so as to demonstrate its capability in reconstructing spatio-temporal high-resolution turbulent flow fields from their coarse flow field data. We find that the present approach is able to accurately recover the high-resolution flow fields with only a modest amount of training data, despite the turbulent flow being complex and multi-scale in nature. The first two authors acknowledge the support by JSPS (18H03758). The last author thanks the support from ARO (W911NF-17-0118), and AFOSR (FA9550-16-1-0650).

6:21PM P17.00006 Reinforcement learning versus linear control of Rayleigh-Bénard convection, ALESSANDRO CORBETTA, GERBEN BEINTEMA, Eindhoven University Of Technology, LUCA BIFERALE, University of Rome, Tor Vergata, PINAKI KUMAR, FEDERICO TOSCHI, Eindhoven University Of Technology — Thermally driven turbulent flows are common in nature and in industrial applications. The presence of a (turbulent) flow can greatly enhance the heat transfer with respect to its conductive value. It is therefore extremely important -in fundamental and applied perspective- to understand if and how it is possible to control the heat transfer in thermally driven flows.

In this work, we aim at maintaining a Rayleigh-Bénard convection (RBC) cell in its conductive state beyond the critical Rayleigh number for the onset of convection. We specifically consider controls based on local modifications of the boundary temperature (fluctuations). We take advantage of recent developments in Artificial Intelligence and Reinforcement Learning (RL) to find automatically efficient non-linear control strategies. We train RL agents via parallel, GPU-based, 2D lattice Boltzmann simulations. Trained RL agents are capable of increasing the critical Rayleigh number of a factor 3 in comparison with state-of-the-art linear control approaches. Moreover, we observe that control agents are able to significantly reduce the convective flow also when the conductive state is unobtainable. This is achieved by finding and inducing complex flow fields.

6:34PM P17.00007 Active feedback control of flow over a circular cylinder with wall pressure sensor using machine learning¹. JINHYEOK YUN, JUNGIL LEE, Ajou University — In the present study, we conduct active feedback control of laminar and turbulent flows over a circular cylinder with wall pressure sensor for suppression of vortex shedding in the wake. The blowing and suction actuations are imposed at the wall before the flow separation, and their magnitudes are proportional to the transverse velocity in the the wake. To avoid direct measurement of velocity in the wake, we build an artificial neural network (ANN) between the pressures on the cylinder surface and the transverse velocities. For the learning process to build ANN, instantaneous flow data sets are obtained from numerical simulations of flow over a cylinder at $Re = 60$ and 3900. The performance of ANN is assessed with the locations of wall pressures, structures of neural network, and etc. It is found that the wall pressures on the cylinder surface can accurately predict velocities in the wake with the neural network built. Active feedback control combined with this neural network successfully suppresses the vortex shedding behind the cylinder, leading to reductions of the drag and lift fluctuations of cylinder.

6:47PM P17.00008 Deep Learning for In-situ Compression of Large CFD Simulations

, RYAN KING, ANDREW GLAWS, MICHAEL SPRAGUE, National Renewable Energy Laboratory — The ExaWind project seeks to develop blade-resolved LES simulations of wind turbines for next-generation exascale computing architectures. Such simulations are expected to generate data with over a billion degrees of freedom and upwards of a million time steps, requiring significant computational resources to be dedicated to data storage, visualization, and analysis. In many cases, performing these tasks on the full dataset is intractable, prompting the need for in-situ data compression. The simplicity of deep learning lends itself to this problem, with the promise of a nonlinear turbulent flow data. In this work, we explore deep learning methods for in-situ data compression, specifically a deep convolution autoencoder network that that maps 3D turbulent fields to a low-dimensional latent space. We compare the autoencoder against single-pass randomized SVD approaches in lossy restart studies where simulations are check-pointed and restarted. Our results show that an autoencoder trained on canonical turbulent flows can be applied to unseen configurations and is competitive with a single-pass SVD in terms of compression ratio, error, and computational cost.

On the stochastic modeling of Lagrangian velocity and acceleration in turbulent flows

, LAURENT CHEVILLARD, Laboratoire De Physique De l’ENS De Lyon, BIANCA VIGGIANO, Department of Mechanical and Materials Engineering, Portland State University, Portland, Oregon, USA, JAN FRIEDRICH, ROMAIN VOLK, MICHAEL BOURGOIN, Laboratoire De Physique De l’ENS De Lyon, RAUL BAYOAN CAL, Department of Mechanical and Materials Engineering, Portland State University, Portland, Oregon, USA — We propose to answer the following question: can we build up an infinitely differentiable stochastic process, such that asymptotically, when the Reynolds number goes to infinity, it becomes irregular (in a Holder sense) and intermittent (in a way we will clarify)? This has importance while modeling velocity and acceleration of particles following their trajectories in a turbulent flow. We propose such a process as a solution of a stochastic differential equation, making it causal. We proceed with analytical and numerical solutions, and compare against experimental and numerical data. Come, it will be fun.

Linear Response Theory of Single Particle Diffusion in Turbulence

, YUKIO KANEDA, Graduate School of Informatics, Nagoya University — A theory is proposed for the statistics of single particle diffusion in stationary homogeneous isotropic turbulence of incompressible fluid. The theory is based on a generalization of the idea of linear response theory that is known in the statistical mechanics for systems at or near the thermal equilibrium state. The theory gives \( \langle |\Delta v(t)|^2 \rangle / \langle v(t) \rangle = C_0 + B_1 + \ldots \), for the inertial time interval \( t \) such that \( T \gg t \gg \tau \), where \( \Delta v(t) \) is the velocity increment of a particle during the time interval \( t \), \( \tau \) is the kinetic-energy dissipation rate per unit mass, \( T \) is the integral time scale, \( \tau \) is the Kolmogorov micro-time-scale, \( B_1 \) is a non-dimensional universal constant. \( C_0 \), and \( C_1, C_T, C_\tau \) are non-dimensional universal constants.

The origin of turbulence in thermal convection.

, KATEPALLI SREENIVASAN, New York University, JOERG SCHUMACHER, AMBRISH PANDEY, Technical University, Ilmenau, Germany, VICTOR YAKHOT, Boston University — If a fluid flow is driven by a weak Gaussian random force, the nonlinearity in the Navier-Stokes equations is negligibly small and the resulting velocity field obeys Gaussian statistics. Nonlinear effects become important as the driving becomes stronger and a transition occurs to turbulence with anomalous scaling of small scales. This process is reasonably well understood for homogeneous and isotropic turbulence. In this paper, we discuss the Reynolds-number dependence of moments of the kinetic energy dissipation rate in the bulk of thermal convection in the Rayleigh-Benard system. The data for different Reynolds numbers are obtained from direct numerical simulations using the dimensionless spectral element method in a convection cell with square cross section and aspect ratio 25. The normalized moments of the kinetic energy dissipation rate show a non-monotonic dependence for small Reynolds numbers before obeying the algebraic scaling for the turbulent state. This feature is explained via the transition akin to “soft-to-hard turbulence” in convection where, depending on the Rayleigh number, turbulence is produced by either the instabilities of the bulk and the wall boundary layers.

Fluctuation-induced forces in homogeneous isotropic turbulence

, RODOLFO OSTILLA MONICO, DANIEL PUTT, University of Houston, VAMSI ARZA SPANDAN, Harvard University, ALPHA ALBERT LEE, University of Cambridge — Understanding force generation in non-equilibrium systems is a significant challenge in statistical physics. We uncover a surprising fluctuation-induced force between two plates immersed in homogeneous isotropic turbulence using Direct Numerical Simulation. The force is a non-monotonic function of plate separation. The mechanism of force generation reveals an intriguing analogy with fluctuation-induced forces: energy in the fluid is localised in regions of high vorticity, or “worms”, which have a characteristic length scale.

Large-scale structure of a passive scalar field in homogeneous turbulence

, KATSUNORI YOSHIMATSU, YUKIO KANEDA, Nagoya University — We study the large-scale structure of a passive scalar field without any scalar source in incompressible homogeneous turbulence. We assume that the initial scalar spectrum at time \( t = 0 \) takes the form \( Ck^2 + o(k^2) \) at the wavenumber \( k \to 0 \), where \( C \) is independent of \( k \). Theoretical analysis [Yoshimatsu and Kaneda, Phys. Rev. Fluids 3, 104601 (2019)] shows that the spectrum keeps the form at \( k \to 0 \) and \( C \) is time independent for \( t \geq 0 \). On the basis of the independence and a constant assumption of a certain self-similar evolution of the scalar field at the large scales including the scales comparable to the scalar integral length scales, it is shown that a certain measure of the anisotropy of the scalar field remains time-independent at the large scales in a self-similar state, irrespective of the velocity field. In addition, we performed direct numerical simulation (DNS) of the passive scalar field in a periodic box. It is found that the DNS results are consistent with the theory.
6:34PM P18.00007 Three-point statistics of passive scalars at high Schmidt numbers\textsuperscript{1}, M. P. CLAY, Georgia Institute of Technology, K. P. IYER, D. BUARIA, New York University, P. K. YEUNG, Georgia Institute of Technology, K. R. SREENIVASAN, New York University — The turbulent mixing of passive scalars is a fundamental problem relevant to many natural and engineering flows. While traditionally analyzed via one- or two-point statistics, three-point statistics have also been used to gain insight into the structure of the scalar field [Warhaft, Annu. Rev. Fluid Mech 32, 203–240 (2000)]. Experimental data are scarce, and for the important case of scalar fluctuations generated under the presence of a mean gradient in isotropic turbulence, measurements are limited to Schmidt numbers (Sc) near unity [Mydlarski and Warhaft, Phys. Fluids 10, 2885–2894 (1998)]. Here we analyze three-point statistics from direct numerical simulations of scalars under a uniform mean gradient in $R_{\lambda}$ ≈ 140 forced isotropic turbulence. By using grids with up to 8192\textsuperscript{3} points and passive scalars with Sc up to 512, three-point statistics are gathered in the emerging viscous-convective range to study the approach to local isotropy exhibited by high-Sc scalars.

\textsuperscript{1}Supported through supercomputer resources at OLCF (DOE INCITE 2017) and TACC (XSEDE).

6:47PM P18.00008 Triad interactions in a four-dimensional fluctuating velocity field, PREBEN BUCHHAVE, Intarsia Optics, CLARA VELE, Technical University of Denmark — High intensity turbulence should be considered a stochastic function of four independent parameters, three spatial coordinates and time. The interaction between the different velocity structures is caused by the nonlinear term in Navier-Stokes equation and is conventionally analyzed by a three-dimensional spatial Fourier transform in a homogeneous velocity field resulting in the so-called triad interactions caused by the second order convection term. We present some conclusions resulting from an analysis of a four-dimensional Fourier transform of the fluctuating velocity. Moreover, we consider a case corresponding to a realistic experiment, where the velocity is digitally sampled with a finite sample rate and the flow is limited to a finite spatial and temporal range. Our results explain features observed in experiments such as the time development of the power spectrum, deviations from the conventional Richardson cascade and perseverance of initial large-scale spectral features.

7:00PM P18.00009 Triple-Correlations in Decaying Isotropic Turbulence\textsuperscript{1}, CLAYTON BYERS, Trinity College, JONATHAN MACART, University of Illinois at Urbana-Champaign, MICHAEL MUELLER, MARCUS HULTMARK, Princeton University — The self-similar scaling approach for decaying isotropic turbulence is utilized to extract constraints on the temporally dependent scaling parameters. The resulting similarity solution and constraints show that the temporal evolution of the length scale, which is shown to be the Taylor microscale, sets the exponent of decay. This exponent is found to retain a dependence on the initial conditions of the flow. Additionally, a new triple-correlation scaling parameter, $u'\lambda/Re_{\lambda}$, is found. The validity of this new scaling is checked in three different ways, each resulting in a collapse of the triple correlation data. The usefulness of this scale becomes apparent when compared to the results of Stewart & Townsend (1951), which utilized the classic $u'^{3}$ scaling and did not show collapse in their data. Three Direct Numerical Simulations at differing initial Reynolds numbers were performed to test the theoretical results.

Session P19 Advanced Turbulence Models II 401 - Guillaume Blanquart, Caltech

5:16PM P19.00001 Colouring turbulence with the nonlinear terms\textsuperscript{1}, SEAN SYMON, SIMON ILLINGWORTH, IVAN MARUSIC, University of Melbourne — We study the behaviour of the nonlinear terms in turbulent channel flow from direct numerical simulations (DNS) at low and moderate Reynolds numbers. These terms correspond to the nonlinear forcing of the (linear) resolvent-based models of McKeon & Sharma 2010. Spectral proper orthogonal decomposition (SPOD) is used to extract the most energetic structures and identify the power spectrum of the most energetic modes. We also compare the nonlinear terms to the equivalent nonlinear forcing supplied by eddy viscosity-enhanced resolvent models. At spatial wavenumbers where there is energetic activity, the nonlinear terms share many similarities with their velocity fluctuation counterparts. The nonlinear terms are also a good match with predictions from eddy viscosity at wavenumber pairs where the resolvent operator including eddy viscosity is low-rank. The implications for estimation techniques such as spectral linear stochastic estimation and the Kalman filter will be discussed.

5:29PM P19.00002 3D diffuser flow predictions using lag models, RAJARSHI BISWAS, Iowa State University, PAUL DURBING, Professor, Iowa State University — Lag RANS models employ the usage of a scalar parameter designed to represent the stress-strain misalignment in turbulent flows. The parameter is used to scale the eddy viscosity particularly in the near-wall region. This proves effective for improved prediction of 2D flows with separation. Two novel models, Lag k-epsilon and Lag k-omega are tested for a 3D diffuser configuration. The geometry is parameterized by the inlet aspect ratio(AR). LES predictions show the separation bubble switches position from one wall to the other as AR is increased. Typical RANS formulations such as k-omega SST predict the flow field inaccurately. The lag models are tested for six different ARs and compared against commonly used RANS models.

5:42PM P19.00003 Linear Navier-Stokes based model for turbulent channels with unstable stratification, ANAGHA MADHUSUDANAN, SIMON ILLINGWORTH, IVAN MARUSIC, University of Melbourne — Studies have shown that the linearized Navier-Stokes equations model the coherent large-scale structures in turbulent wall-bounded flows reasonably well. In the present work we aim to understand if this linear model can be extended to study the coherent large-scale structures that have been experimentally and numerically observed in turbulent Rayleigh–Bénard–Poiseuille flows [e.g., Chauhan et al., 2013, Pirozzoli et al., 2017]. In particular, we concentrate on two features of these structures. First, we look at the wall-normal coherence of the streamwise constant modes. And second, we study the inclination angle of the large-scale structures in these flows. These features are then compared to the available results from numerical and experimental studies.

5:55PM P19.00004 Restricting integral length scale growth in triply periodic turbulence simulations, LIMBERT PALOMINO, CHANDRU DHANDAPANI, JEFF RAH, GUILLAUME BLANQUART, California Institute of Technology — The 3D periodic box is an essential tool for studying turbulence. It is both an appropriate canonical configuration for homogeneous isotropic turbulence and a computationally efficient configuration to simulate. Unfortunately, without an active mean of generating turbulence, the turbulent kinetic energy decays over time due to viscous dissipation. Through the years, various methods of forcing the Navier-Stokes have been proposed to maintain this statistically stationary turbulence, including spectral and linear forcing. Although linear forcing schemes fully capture the physics of turbulence, as the simulation evolves in time, the largest eddies in the simulation grow to the order of the computational domain size. The current study characterizes this growth in terms of both the integral length scale and the corresponding energy spectra. Furthermore, we propose a modified linear forcing technique that is analogous to a re-scaling of the computational domain at each time step. This provides more active control over the integral length scale and eddy growth in the simulations.

6:08PM P19.00005 The Macroscopic Forcing Method and incorporating non-locality into macroscopic models1, JESSIE LIU, ALI MANI, Stanford University — The Macroscopic Forcing Method (MFM) (Mani and Park (2019), arXiv:1905.08342) is a newly-developed technique that can be used to determine differential operators associated with turbulence closure. The results of MFM can then be used to improve macroscopic models, i.e. models that describe averaged quantities such as Reynolds-averaged Navier-Stokes (RANS) models. One issue is that often the found differential operators are non-local and may be difficult to incorporate into existing models. We present application of MFM to an example problem involving scalar transport and temporal non-locality. We then present a method for easily incorporating the effects of temporal non-locality into the macroscopic model for the averaged-scalar transport.

6:21PM P19.00006 On new symmetry-generated RANS models1, DARIO KLINGENBERG, Graduate School of Excellence Computational Engineering, TU Darmstadt, MARTIN OBERLACK, DOMINIK PLUEMACHER, Chair of Fluid Dynamics, TU Darmstadt — We apply new insights into turbulent statistics obtained through Lie-symmetry analysis to the problem of RANS modeling. Symmetries mirror key physical principles from governing equations. The symmetries of the infinite hierarchy of multi-point correlation equations fall into two categories. Symmetries of classical mechanics, which have direct counterparts in the unaveraged Navier-Stokes equations, and statistical ones, which only arise when adopting a statistical view on turbulence. It was shown that some of the latter type encode crucial phenomena, in particular intermittency and non-Gaussianity (Waclawczyk 2014). In a modeling context, symmetries provide constraints on the model equations, because unless the model equations contain precisely the same symmetries as the exact equations, the model is prone to exhibiting nonphysical behavior. We therefore present a new modeling framework that allows algebraically generating turbulence models based on symmetries. We apply this method to obtain a prototype RANS model that is agreement with not only the classical, but also the statistical symmetries, which existing models fail to accomplish. It turns out to be necessary to introduce as a new model variable an additional velocity field with specific advantageous symmetry properties.

6:47PM P19.00008 Multi-level stochastic refinement for turbulent time series and fields, MICHAEL SINHUBER, Max Planck Institute for Dynamics and Self-Organization, Gottingen, JAN FRIEDRICH, ENS Lyon, RAINER GRAUER, Ruhr-Universitaet Bochum, GREGORY P. BEWLEY, Cornell University, MICHAEL WILCZEK, Max Planck Institute for Dynamics and Self-Organization, Gottingen — Many high-dimensional systems exhibit complex spatio-temporal dynamics. Typically, this complexity comes along with strong multi-scale correlations and scale-dependent deviations from Gaussianity, which requires multi-time-multi-point statistics for a full characterization. In many practical cases, obtaining sufficiently resolved data is prohibitively expensive or even impossible. While a statistical characterization of such systems is often sufficient, many applications where turbulence plays a key role require a complete spatio-temporal realization of the system. Examples range from modeling particle propagation in fusion plasmas to wind field modeling for wind energy applications. To address this challenge, we develop a stochastic refinement method that generates finely resolved data sets from readily available, coarsely sampled turbulence data as well as synthetic datasets within the scope of classical turbulence models. This is done by utilizing scale-Markovian properties of turbulence and scale-dependent three-point probability statistics. We test our approach both for wind tunnel data from the VDTT at the Max-Planck-Institute for Dynamics and Self-Organization in Gottingen as well as for simulated turbulent fields based on classical turbulence models.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P20 Experimental Techniques: Data Analysis, Bias and Uncertainty 602 - Barton Smith, Utah State University
compared to the change in voxel size. The bias error estimate is proportional to the square of the noise's standard deviation. Respectively, the estimates were compared to the true bias error calculated using the true velocity profile. Results show that the bias error is for measurement error, but neglects bias error. This study estimates bias error by integrating an approximated intravoxel velocity profile within providing time-resolved, volumetric, 3-directional velocity information of a patient's cardiovascular flow in vivo. This technique suffers from of high importance in space flight. However, the combustion process in hybrid rocket engines is still a matter of ongoing research and not fully understood yet. Recently, combustion tests with different paraffin-based fuels have been performed at the German Aerospace Center (DLR). For a better understanding of the experiments, the combustion process has been captured with a high-speed video camera, which leads to a huge amount of images for each test. In order to catch the essential flow structures, the combustion dataset has been analyzed with unsupervised machine learning techniques. In this talk, we present the outcome of the clustering. Using the machine learning techniques, valuable insights into the different combustion phases were obtained and a comparison of the quality of the combustion flame in the different tests could be made. In particular, depending on the fuel formulation and oxidizer mass flow, differences in the transients and flame brightness were found.

This work highlights the fact that the naive application of ML/AI will generally be insufficient to extract universal physical laws without further modification.

5:29PM P20.00002 Data Analysis of Hybrid Rocket Fuels Combustion Tests ALEXANDER RUETTGERS, German Aerospace Center (DLR), Simulation and Software Technology, ANNA PETRAROLO, MARIO KOBALD, German Aerospace Center (DLR), Institute of Space Propulsion — Clustering techniques were applied to hybrid rocket combustion tests to better understand the complex flow phenomena. Novel techniques such as hybrid rockets that allow for cost reductions of space transport vehicles are of high importance in space flight. However, the combustion process in hybrid rocket engines is still a matter of ongoing research and not fully understood yet. Recently, combustion tests with different paraffin-based fuels have been performed at the German Aerospace Center (DLR). For a better understanding of the experiments, the combustion process has been captured with a high-speed video camera, which leads to a huge amount of images for each test. In order to catch the essential flow structures, the combustion dataset has been analyzed with unsupervised machine learning techniques. In this talk, we present the outcome of the clustering. Using the machine learning techniques, valuable insights into the different combustion phases were obtained and a comparison of the quality of the combustion flame in the different tests could be made. In particular, depending on the fuel formulation and oxidizer mass flow, differences in the transients and flame brightness were found.

5:42PM P20.00003 Data assimilation method to de-noise and de-filter particle image velocimetry data. ROLAND BOUFFANAIS, Singapore University of Technology and Design, JURRIAAN J. J. GILLESSEN, University College London, DICK K. P. YUE, Massachusetts Institute of Technology — We present a variational data assimilation method in order to improve the accuracy of velocity fields \( \tilde{v} \), that are measured using particle image velocimetry (PIV). The method minimizes the space-time integral of the difference between the reconstruction \( u \) and \( \tilde{v} \), under the constraint, that \( u \) satisfies conservation of mass and momentum. We apply the method to synthetic velocimetry data, in a two-dimensional turbulent flow, where realistic PIV noise is generated by computationally mimicking the PIV measurement process. The method performs optimally when the assimilation integration time is of the order of the flow correlation time. We interpret these results by comparing them to one-dimensional diffusion and advection problems, for which we derive analytical expressions for the reconstruction error.

5:55PM P20.00004 State-space Optimized Dynamic Mode Decomposition for Noisy Data. TAKU NONOMURA, Tohoku University, Presto, JST, KAZUYUKI NAKAMURA, Meiji University, Presto, JST, NAOTO NAKANO, Kyoto University, STEVEN L. BRUNTUN, J. NATHAN KUTZ, University of Washington — This presentation proposes several new formulations of dynamic mode decomposition (DMD) for full-state measurements of a linear dynamical system with process and measurement noise. First, we develop two methods to denoise and reconstruct the true state of the approximated linear system from noisy experimental data: the DMD-based state variable reconstruction (DMDsrv) and the DMD-based state space reconstruction (DMDssr). DMDsrv estimates the state variable as a solution of a least square problem, when the system coefficients and the noise variances are known. DMDssr simultaneously estimates the noise variance and the state variables by the expectation-maximization (EM) algorithm in a Bayesian framework. The final method, state-space optimized DMD (soDMD), simultaneously estimates the DMD coefficients together with the noise variances and the state variable. The proposed soDMD can estimate the system coefficients, noise variance and true state variables from noisy data. Estimation of system coefficients and noise variances can be used for data-assimilation using Kalman filter. Numerical tests show an improvement of the proposed methods over conventional DMD for linear systems with process noise.

6:08PM P20.00005 4D Flow MRI Bias Error Estimation. SEAN ROTHENBERGER, Weldon School of Biomedical Engineering, Purdue University, JIACHENG ZHANG, MELISSA BRINDISE, School of Mechanical Engineering, Purdue University, SUSANNE SCHNELL, Feinberg School of Medicine, Northwestern University, PAVLOS VLACHOS, School of Mechanical Engineering, Purdue University, VITALIY RAYZ, Weldon School of Biomedical Engineering, Purdue University — 4D flow MRI is a non-invasive imaging technique providing time-resolved, volumetric, 3-directional velocity information of a patient’s cardiovascular flow in vivo. This technique suffers from low VNR and resolution. ‘Enhanced’ 4D flow MRI measurements can be produced by informing the measurements with high-resolution flow modeling methods, e.g. CFD, PIV. However, the error of the 4D flow MRI measurements must first be defined. Past literature defines a model for measurement error, but neglects bias error. This study estimates bias error by integrating an approximated intravoxel velocity profile within the limits of the voxel dimensions. The model of bias error was tested in synthetic flow with a velocity range of 2m/s. The effect of the voxel size and noise was determined by investigating a range of voxel sizes and noise standard deviations of 1 to 0.147mm³ and 0 to 6cm/s, respectively. The estimates were compared to the true bias error calculated using the true velocity profile. Results show that the bias error is proportional to the square of the noise’s standard deviation.

6:21PM P20.00006 Unscented Kalman filter (UKF) based nonlinear parameter estimation for a turbulent boundary layer: a data assimilation framework. ZHAO PAN, University of Waterloo, YANG ZHANG, JONAS GUSTAVSSON, Florida State University, JEAN-PIERRE HICKEY, University of Waterloo, LOUIS CATTAFASTA, Florida State University, UWATERLOO COLLABORATION, FSU COLLABORATION. - There is a vast amount of data available for the turbulent boundary layer and its potential use for predictive purposes has been established recently. However, accurate measurements of turbulent boundary layer parameters (e.g., friction velocity $u_*$ and wall shear $\tau_w$), are challenging, especially for high speed flows. Many direct and/or indirect diagnostic techniques have been developed to measure wall shear stress. However, based on different principles, these techniques usually give different results with different uncertainties. The current study introduces a nonlinear data assimilation framework based on the Unscented Kalman Filter that can fuse information from 1) noisy and gappy measurements from Stereo Particle Image Velocimetry, a Preston tube, and a MEMS shear stress sensor, as well as ii) the uncertainties of the measurements to estimate the parameters of a turbulent boundary layer. A direct numerical simulation of a fully developed turbulent boundary layer flow at Mach 0.3 is used first to validate the data assimilation algorithm. The algorithm is then applied to experimental data of a flow at Mach 0.3, which are obtained in a blowdown wind tunnel facility. The UKF-based data assimilation algorithm is robust to uncertain and gappy experimental data and is abl

6:34PM P20.00007 Power Law Decay Estimation for Turbulent Spectral Densities. CARL R. HART, U.S. Army Engineering Research and Development Center, Cold Regions Research and Engineering Laboratory, GREGORY W. LYONS, U.S. Army Engineer Research and Development Center, Construction Engineering Research Laboratory, NATHAN E. MURRAY, The University of Mississippi, National Center for Physical Acoustics — Turbulent flows commonly feature power law decay in one or more field quantities, such as the $-5/3$ inertial subrange power law for velocity spectra. Assuming sufficient time series data are collected, the problem of estimating the power law decay rate of a turbulent spectral density relies on two factors: the correct choice of data window in statistical signal processing, and an objective procedure to estimate the power law decay rate. In this context the single most important factor for a data window is the side-lobe decay rate. Ensuring the side-lobe decay rate exceeds that of measured data avoids the subtle error of spectral leakage. An objective procedure to estimate the power law decay rate is based on a maximum likelihood estimator. Under the assumption that the Fourier transform of turbulence time series is a circularly-symmetric complex normal random variable a likelihood function for the power spectral density is based on a Gamma distribution. Maximizing the log-likelihood, with a spectral model that parameterizes the Gamma distributions, leads to a robust estimator for the power law decay rate. These concepts are illustrated through synthetic realizations of colored noise, acoustic measurements of a supersonic turbulent jet, and atmospheric surface-layer turbulence.

6:47PM P20.00008 Identification of Dynamic Atmospheric Conditions via Total Variation. NICHOLAS HAMILTON, National Renewable Energy Laboratory — Selection of atmospheric events that conform to particular conditions of interest within multivariate data is necessary to validate emerging high-fidelity simulations of wind plant flows. Conditions of interest are frequently determined simply as those that occur most often, given the need for well-converged statistics from observations. Aggregation of observations without regard to covariance between time series discounts the dynamical nature of the atmosphere and is not sufficiently representative of wind plant operating conditions. Identification and characterization of continuous time periods representative of atmospheric conditions that have a high value for analysis or simulation sets the stage for validation of more advanced physical mechanisms. The total variation of the atmosphere is a metric that takes into account variability within each channel as well as covariance between channels and identifies periods of interest that conform to desired objective functions, such as quiescent conditions, wind speed ramps or waves, or sudden changes in wind direction. Direct identification and classification of events of interest within atmospheric data sets is vital to developing our understanding of wind plant response and to the formulation of forecasting and control models.

7:00PM P20.00009 Using Machine Learning to Determine the Velocity Information Content in OH-PLIF Images. SHIVAM BARWEY, MALIK HASSANALY, VENKAT RAMAN, University of Michigan, ADAM STEINBERG, Georgia Institute of Technology. — This study determines the velocity field information contained purely in OH-PLIF images in the closed domain of a premixed swirl combustor. A fully convolutional neural network (CNN) is used with a dataset containing simultaneous OH-PLIF and PIV measurements in both attached and detached flame regimes. To facilitate the study, the CNN represents a direct projection from OH-PLIF to PIV field. Two types of models are trained: 1) a global CNN which is trained using images from the entire domain, and 2) a set of local CNNs which are trained only on individual sections of the domain. Local models show improvement in creating PIV fields in both attached and detached regimes over the global models in most settings. A comparison between model performance in attached and detached regimes shows that the CNNs are much more accurate across the board in creating velocity fields for attached flames. Further, time history inclusion in the OH fields is also studied, as is the ability of the model to extrapolate to unexplored regions of the domain. Ultimately, this work shows that there is redundant information in the OH-PLIF images, and can open the door for the development of diagnostic tools that decrease the overlapping content between simultaneously measured fields.

5:16PM P21.00001 Pressure and Shear Stress Distribution of Drop Impacts. TING-PHI SUN, XIANG CHENG, University of Minnesota, Twin Cities — Drop impacts are ubiquitous and relevant to many important natural and industrial processes. Although the kinematics of drop impact such as the morphology of impactor drops have been extensively studied experimentally due to the fast advance of high-speed photography techniques, the dynamic aspects of drop impacts remains largely unexplored. Here, we investigate the pressure and shear stress distributions of drop impacts via a newly-developed experimental tool, high-speed 3D stress microscopy. By combining laser-sheet illumination with high-speed photography, we track the fast movements of fluorescent particles embedded in elastic gels under the impact of liquid drops. The measurements enable us to obtain a strain of the elastic gels induced by the impact. The temporal evolution of impact pressures and shear stresses of liquid drops can then be extracted based on the strain-stress relation of continuum mechanics. Our study on the pressure distribution confirms the key prediction of the self-similar theory and numerical simulations, where the maximum impact pressure occurs near the contact line, rather than the center of impacting drops. In addition, we also quantify the fast temporal evolution of impact-induced shear stresses, information crucial for mitigating impact-induced damages on solid substrates. This research is support by NSF CAREER DMR-1452180.
reduce the degree of non-monotonicity of the transitional boundaries between bouncing and merging states.

Shock wave-induced drop fragmentation upon raindrop impact

on biological surfaces , SEUNGHO KIM, BRIAN WU, JASON J. DOMBROWSKIE, SUNGHWAN JUNG, Cornell University — Rainfall on biological superhydrophobic surface (e.g. bird feathers, insect wings, plant leaves, etc) is ubiquitous in nature. Previous studies in the laboratory have focused on low-speed impacting drops (less than 1 m/s) only, which is far from the speed of real raindrops (more than 5 m/s). In this present work, we explore raindrop impact at high speeds, which exhibits unexpected drop dynamics: numerous shock-like waves are generated on a spreading drop in the presence of microscopic textures on biological surfaces. Then, the spreading drop with shock-like waves is fragmented soon after it approaches a maximal spreading extent, thereby reducing the residence/contact time more than twofold. Since it is known that the heat and momentum transfer of an impacting drop onto the substrate can be reduced by decreasing the contact time of impacting drop, our findings may help to understand how endothermic animals lower hypothermia risks, and how insects stabilize their flight position during rainfalls. Here, we visualize such salient high-speed drop dynamics using a high-speed shadowgraphy and validate the distinctive features through experiments and theoretical models.

Droplet Impact on dry solid surfaces: Traditional vs Bio-mimetic , SAPTARSHI BASIL, DURBAR ROY, Department of Mechanical Engineering, Indian Institute of Science, KHUSHBOO PANDEY, Interdisciplinary Center for Energy Research (ICER), Indian Institute of Science, RABIRRATA MUKHERJEE, Department of Chemical Engineering, Indian Institute of Technology, Kharagpur — An experimental study of droplet impact has been conducted on four different substrates (2 traditional and 2 bio-mimetic) in the impact Weber number range of 6 to 130. The droplet shape dynamics have been visualized using high-speed shadowgraphy (at 10 kHz). Glass and PDMS are the traditional substrates, whereas the other two surfaces are inspired by rose-petal and lotus-leaf micro-structures. Various regimes are demarcated for all the substrates depending on the impact Weber number. The receding rebound, and breakup mechanisms of bio-mimetic surfaces are found to be strikingly different from that of the traditional substrates. Dimensional analysis, scaling arguments and energetics have been utilized to unearth the underlying dynamics of the impact.

Drop Impact on Liquid Film: Bouncing to Merging Transition for Two-Liquid System , ABHISHEK SAHA, XIAN WU, University of California San Diego — Impact of a drop on liquid film is critical in several industrial applications, including inkjet printing and thermal sprays. Previous studies using single liquid for both drop and film showed that the impact could result in two outcomes, namely bouncing and merging, and the transition between these two states is a function of impact Weber number and film thickness. It was also reported that for a range of Weber number, the impact outcome changes from merging to bouncing, back to merging and then to bouncing again, as we increase the film thickness. Since many of the advanced printing technologies such as 3D inkjet printers can print multiple materials, very often the drop and the impacted the liquid film are required to be of different liquids with varying properties. Recognizing its importance, in this talk, we will present a study on the dynamics of drop impact on liquid film using two liquids with similar surface tension, but different viscosities. The results with two-liquid systems show a shift in the transitional boundaries with respect to that of the single-liquid system. In addition to the two types of merging, early merging and late merging, reported for single-liquid systems, a third kind of merging was also observed for two-liquid systems. This third kind of merging was found to reduce the degree of non-monotonicity of the transitional boundaries between bouncing and merging states.
We have constructed a 26-meter-tall vacuum tube to study drop impacts at very high velocities, in a controlled manner. Under reduced ambient pressure we can attain impact velocities up to 23 m/s and Reynolds numbers as large as $10^5$. We focus on the ejecta sheets produced when the drop impacts on a thin layer of liquid. The ejecta dynamics are captured with two simultaneous high-speed video cameras, one focused on the ejecta details and the other on the overall crown evolution. Experiments are performed over a wide range of drop and liquid viscosity combinations. The ejecta breakup and splashing are greatly affected by the ambient air pressure, where air-drag and Bernoulli suction pressure can bend the sheets into intricate shapes. The tip of the sheet can bend up or down depending on the viscosity ratio between the two liquids. Under some impact conditions the sheet entraps a toroidal bubble as the crown rises away from the substrate. The sheets finally rupture to produce a spray with a myriad of micro-droplets. We construct a simplified model to describe the shape evolution.

**Session P22 Drops: Multiple Drop Interactions**

604 - Alexander Wray, University of Strathclyde, Glasgow

**5:16PM P22.00001 Hydrodynamic Spin Lattices**

PEDRO SAENZ, UNC Chapel Hill, GIUSEPPE PUCCI, Institute of Physics of Rennes, SAM TURTON, ALEXIS GOUJON, RUBEN ROSALES, JORN DUNKEL, JOHN BUSH, MIT — In this talk, we will introduce a hydrodynamic analog system that allows us to investigate simultaneously the wave-mediated self-propulsion and interactions of effective spin degrees of freedom in inertial and rotating frames. Millimetric liquid droplets can walk across the surface of a vibrating fluid bath, self-propelled through a resonant interaction with their own guiding wave fields. A walking droplet, or ‘walker’, may be trapped by a submerged circular well at the bottom of the fluid bath, leading to a clockwise or counter-clockwise angular motion centered at the well. When a collection of such wells is arranged in a 1D or 2D lattice geometry, a thin fluid layer between wells enables wave-mediated interactions between neighboring walkers. Through experiments and mathematical modeling, we demonstrate the spontaneous emergence of coherent droplet rotation dynamics for different types of lattices. For sufficiently strong pair-coupling, wave interactions between neighboring droplets may induce local spin flips leading to ferromagnetic or antiferromagnetic order. Transitions between these two forms of order can be controlled by tuning the lattice parameters or by imposing a Coriolis force mimicking an external magnetic field.

**5:29PM P22.00002 The dipole approximation for droplets in Hele-Shaw flows**

YOAV GREEN, Ben-Gurion University of the Negev — For the past decade, the interaction between two droplets flowing in a Hele-Shaw cell has been modelled as a dipolar force. On one hand, the correspondence between experiments and the dipole model is remarkable. On the other hand, the dipole model doesn’t satisfy the required no-flux boundary condition at the droplet interfaces. Despite of this contradiction, the dipole model remained popular. In an attempt to bridge this gap, Sarig et al. [1] derived an exact analytical solution, for a two-droplet system satisfying zero-flux at both droplet interfaces, that showed remarkable correspondence to experiments. However, their solution was given in terms of an infinite Fourier series, which didn’t allow for the desired resolution of the contradiction. By deriving approximations for their Fourier series, for the cases of small and large droplet spacing, we resolved the contradiction [2]. We showed that the large spacing approximation reduces to the expected dipole-like solution. We extended our solution to arbitrary droplet numbers. Our infinite lattice solution includes a corrections term relative to the dipole model. Finally, our small spacing solution also provides a novel lower limit.

**5:42PM P22.00003 The Stability and Dynamics of Bouncing Droplet Rings**

MILES COUCHMAN, JOHN BUSH, Massachusetts Institute of Technology — Millimeter droplets bouncing on the surface of a vibrating fluid bath may interact through their shared wavefield to form bound states. In this talk, we present the results of a combined experimental and theoretical investigation of the stability of droplet rings. As the bath’s vibrational acceleration is increased progressively, droplet rings are observed to destabilize into a variety of dynamical states including steady rotational motion, radial oscillations, azimuthal oscillations, and azimuthally traveling waves. The instability observed is dependent on the ring’s initial radius and drop number, and whether the drop’s are bouncing in-or out-of-phase relative to their neighbors. As the vibrational acceleration is further increased, more exotic forms emerge including pentagonal and square structures. A linear stability analysis based on the trajectory equation of Couchman et al. (JFM, 2019) rationalizes the observed instabilities and provides insight into the dynamics of droplet lattices and other aggregates. Connections with vortex arrays in superfluid helium and Bose Einstein condensates are discussed.

6:08PM P22.00005 Competitive evaporation of multiple sessile droplets, STEPHEN WILSON, ALEXANDER WRAY, BRIAN DUFFY, University of Strathclyde — An asymptotic model is derived for the competitive diffusion-limited evaporation of multiple thin sessile droplets under the assumption that the droplets are well separated. Comparisons are made with numerical solutions of the full governing equations in order to verify the accuracy of the model; in particular, the model is found to perform well even outside its anticipated range of applicability, up to and including the limit of touching droplets. The shielding effect of other droplets is demonstrated, and the model is used to investigate the role of this effect on shielding droplet evolutions and lifetimes, as well as on the coffee-ring effect.

6:21PM P22.00006 On Splashing Dynamics of Diesel Drop Trains Under Engine-Relevant Impingement Conditions: a Computational Study1, DAVID MARKT JR., ASHISH PATHAK, MEHDI RAESSI, University of Massachusetts Dartmouth, ROBERTO TORELLI, Argonne National Laboratory, SEONG-YOUNG LEE, Michigan Technological University — In this study, advanced 3D simulations of micron-sized diesel drop trains impinging on a solid substrate are presented. The droplet size and impact velocity are representative of the impingement conditions during fuel injection in internal combustion engines. Generally, diesel fuel injection is studied using Lagrangian-Eulerian solvers which rely on spray-wall interaction sub-models to predict the drop impingement outcomes. We have found such sub-models may predict inaccurate splashing outcomes under such extreme impingement conditions. Therefore, using drop trains as an idealized spray, highly-resolved simulations are presented and quantities such as the splashed mass ratio and secondary droplet distribution are compared to common spray-wall interaction sub-models. The effects of liquid film thickness, contact angle and ambient gas pressure on the splashing dynamics are also quantified. By varying the impingement conditions, a robust analysis is presented highlighting the dominant parameters which affect splashing.

6:47PM P22.00008 Manipulation of drop-drop interactions in millifluidic device using inlet spacing design, E. M. ARUN SANKAR, RAGHUNATHAN RENGASWAMY, Indian Institute of Technology Madras — Colloidal particles of different shapes and anisotropy are required for various applications. Researchers have reported synthesis of simple structures of colloidal particles in 1D microfluidic devices. Synthesis of more complicated 2D structures by contacting drops in a 2D device demands knowledge of their movement. When there are many drops in the system, each drop disturbs the flow field and interact with other drops. By appropriately manipulating these hydrodynamic interactions, one can arrange the drops in a desired shape. A simple model which captures the dominant interactions in 2D millichannel Hele-Shaw geometry, and can be used in an optimization framework, was proposed from our group. We noticed that, the hydrodynamic interactions between the drops and therefore the resulting droplet pattern formation are affected by the initial inter-droplet spacing. The spacing between the drops can be changed by injecting (withdrawing) the continuous phase fluid into the system. Here, we present manipulation of hydrodynamic interactions to arrange the drops in a desired shape in a millifluidic device by sending them into the channel at optimum spacing.

7:00PM P22.00009 Measurement of hydrodynamic forces on near-contact droplets1, REECE KEARNIE, GREGORY P BEWLEY, LINDA BU, Cornell University — Collisions between particles in turbulent flows are important in many natural and industrial processes, including rainfall and combustion. Though three-dimensional particle tracking is used routinely to measure the motions of fluid, detection of collisions between particles has been limited to non-automated methods due to the difficulty of differentiating between particles as they come close together. Near contact, particle pairs may experience forces that arise from interactions between the background flow and the motion of the two particles, and these forces may tend to promote or prevent collision. In our experiment, we observe water droplets ranging from 10 microns to 100s of microns in radius. We present measurements of the hydrodynamic interactions between droplets at separations of less than one diameter using an in-house particle tracking algorithm that resolves trajectories approaching and including contact.

Session P23 Biological Fluid Dynamics : Cardiac Flows II

605 - Amir Arzani, Northern Arizona University
5:16PM P23.00001 In-vitro investigation of the effect of variable pulsatile flow and Left Ventricular Assist Device speed on the intraventricular hemodynamics. MARISSA MIRAMONTES, FANETTE CHASSAGNE, VENKAT KESHAV CHIVUKULA, JENNIFER BECKMAN, CLAUDIUS MAHR, ALBERTO ALISEDA, University of Washington, MECHANICAL AND CARDIOLOGY COLLABORATION — Left Ventricular Assist Devices (LVAD) are used to treat end-stage heart failure but induce unfavorable hemodynamics in the left ventricle (LV) that can result in thromboembolic and hemorrhagic events such as stroke. This study aims to quantify the impact of native contractility and LVAD speed on fluid mechanics inside the LV, and the associated thrombogenicity. Stereo Particle Image Velocimetry (PIV) measurements of the flow in a patient-specific LV flow phantom implanted with a real LVAD are analyzed under a wide range of clinically relevant parameters: pulsatility, preload and afterload. The combination of reduced pulsatility and LVAD speed results in highly heterogeneous flow patterns, with co-existing jet-like flow and high-residence time recirculating regions. Increased pulsatile flow and higher LVAD speeds improve velocity field variability, associated with less stagnation. Pulsatility plays a greater role in reducing stagnant regions compared to increasing LVAD speed. Unfavorable hemodynamics caused by decreased contractility combined with low LVAD speed may explain the persistent incidence of thrombosis even in new generation LVADs.

5:29PM P23.00002 Numerical Modeling of Thrombus Transport to the Cerebral Vasculature in the Presence of a Left Ventricular Assist Device. ANGELA STRACCIA, VENKAT KESHAV CHIVUKULA, FANETTE CHASSAGNE, JENNIFER BECKMAN, CLAUDIUS MAHR, ALBERTO ALISEDA, University of Washington — Left ventricular assist devices (LVAD) represent an increasingly available treatment for end-stage heart failure. Despite improvements in LVAD design that have greatly reduced the incidence of in-pump thrombosis, thromboembolic events, such as stroke, remain the main cause of mortality and morbidity. This study aims to identify the relationship between the source of thrombi – LVAD outflow graft or aortic valve – and their destination in the cerebral vasculature. The hemodynamics, from the aortic arch and LVAD outflow graft to the Circle of Willis, are investigated using 3D time-resolved computational fluid dynamics (CFD) in patient-specific models obtained from segmented medical imaging. Thrombi of different sizes are seeded in the blood flow and followed throughout their trajectories via Lagrangian particle tracking, accounting for inertial effects. We achieve a statistical description of the likelihood of thrombi being transported towards different regions of the cerebral vasculature by studying a wide distribution of thrombi properties and seeding locations. Patient-specific stroke risk, and its origins, is quantified, along with the altered hemodynamics in the cerebral vasculature in the presence of stroke.

5:42PM P23.00003 Further classification of the cardiac vortex: On the scaling of core vorticity with heart rate. GIUSEPPE DI LABBIO, LYES KADEM, Concordia University Montreal — The generation and persistence of a diastolic vortex ring within the healthy left ventricle has gained significant interest over the past two decades. This cardiac vortex has been shown to ease the transport of blood from inflow to outflow, preserving inflowing kinetic energy in a near-optimal manner while also promoting low blood residence time. Nonetheless, despite its practical interest and the multitude of associated diagnostic indices developed over the years, there has been no attempt at modeling the behavior of the cardiac vortex core. In this work, the flow in a healthy left ventricle was simulated in vitro in a double-activation left heart duplicator. The ensuing flow was captured using two-dimensional time-resolved particle image velocimetry in a clinically-relevant plane. Three heart rates were examined (50, 70 and 90 bpm). By comparison to the Lamb-Oseen-Hamel vortex, a one-parameter physics-based empirical fit is developed for the temporal evolution of the vorticity of the cardiac vortex core. The fitting constant is shown to be related to the circulation of the core by the end of the E wave of filling. With a suitable choice of scaling (dependent on the heart rate and ventricle width), the core vorticity at different heart rates appear to collapse onto a single curve.

5:55PM P23.00004 Computational study of blood flow patterns in a wall-deforming model of the left ventricle under healthy and LVAD-assisted conditions. TINGTING YANG, VENKAT KESHAV CHIVUKULA, ALBERTO ALISEDA, University of Washington, Seattle, WA, MULTIPHASE AND CARDIOVASCULAR FLOW LAB TEAM — Left ventricular assist device (LVAD) induce non-physiological flow patterns that are associated with thrombus formation. Numerical modeling of the hemodynamic environment inside simplified geometries of the human left ventricle incorporate wall deformation to simulate healthy and LVAD-assisted conditions. Input boundary conditions and wall deformation are derived from patient-specific measurements. Q-criterion, lambda-2 and streamline visualizations are used to compare the healthy and LVAD cases, better characterizing the impact of LVAD implantation on intraventricular flow patterns. Two vortex rings are formed during mitral filling that break down as they flow towards the ventricular apex, with the remaining filaments washed out through the aortic valve or inflow cannula. Small scale vortices, unreported in previous research with rigid ventricle walls, are found between the apex and the outer cannula wall. A methodology to investigate the physics underlying ventricular filling and emptying with different levels of ventricular contractility (ejection fraction) is demonstrated. LVAD surgical configurations, such as the inflow cannula and outflow graft angles, are studied to provide insights on risk assessment of these surgical techniques.

6:08PM P23.00005 Simulating Cardiac Fluid-Structure Interaction by an Immersed Finite Element Method. BOYCE GRIFFITH, MARSHALL DAVEY, University of North Carolina at Chapel Hill, CHARLES PUELZ, New York University, SIMONE ROSSI, MARGARET ANNE SMITH, DAVID WELLS, University of North Carolina at Chapel Hill — Cardiovascular diseases remain the leading causes of death worldwide, and tools for improving diagnosis, treatment planning, or medical device design promise to have a major impact on patient health. Simulating cardiac fluid dynamics across the cardiac cycle motivates the development of models that account for interactions between the blood, the muscular walls of the heart, and the thin cardiac valves. The immersed boundary method is a numerical approach to such problems of fluid-structure interaction (FSI). This talk will describe ongoing work to develop medical image-based models of cardiac FSI for modeling cardiac fluid dynamics. Our model of the heart includes image-based descriptions of the major anatomical features of the heart, including the atria and ventricles, and the nearby great vessels along with idealized anatomical models of the cardiac valves and experimentally constrained biomechanical models. To simulate cardiac FSI, we use an immersed boundary method that employs a finite element description of the immersed structure that enables the use of large-deformation nonlinear elasticity. The talk will outline the numerical approach and model formulation, and will investigate the role of pericardial tethering on establishing realistic intracardiac fluid flows.

6:21PM P23.00006 Implantation orientation effects of a bileaflet mechanical heart valve in an anatomic left ventricle-aorta configuration1, HOSEIN ASADI, MOHAMMADALI HEDAYAT, IMAN BORAZJANI, Texas A&M University — Three-dimensional high-resolution simulations of a bileaflet mechanical heart valve (BMHV) have been carried out for an anatomic left ventricle-aorta configuration. The geometry of the anatomic left ventricle (LV) is reconstructed from MRI scanned images of a healthy subject and its motion is prescribed based on a lumped parameter model. The highly validated multi-block sharp interface curvilinear immersed boundary method (CURVIB) fluid-structure interaction (FSI) solver is used in which anatomic aorta and LV are discretized with a boundary-conforming and non-conforming curvilinear meshes, respectively. The motion of BMHV is calculated using the strong coupled FSI accelerated with Aitken convergence technique. The simulations are performed for three valve orientations, differing 45° from each other for two cardiac cycles. The kinematics of heart valves and instantaneous hemodynamics of each case, as well as, shear stress and platelet activation are analyzed to investigate the performance of each orientation.

1This work was partially supported by National Science Foundation award CBET 1453982 and the American Heart Association Grant 13SDG17220022. The computational resources were provided by the High-Performance Research Computing (HPRC) center at Texas A&M University.

6:34PM P23.00007 An Immersed Interface Method for Biomedical Fluid Structure Interaction, EBRAHIM KOLAHDOUZ, University of North Carolina at Chapel Hill; BRENT CRAVEN, United States Food and Drug Administration, BOYCE GRIFFITH, University of North Carolina at Chapel Hill — The mechanical interaction of incompressible viscous flows with immersed bodies is ubiquitously found in medicine and biology. A fluid structure interaction (FSI) coupling strategy is presented within the framework of the immersed interface method that allows fluid and solid subproblems to be solved in a partitioned manner and coupled through interface conditions. The present FSI approach allows for general complex geometries with discrete surfaces while retaining sharp resolution of stresses at the fluid-solid interface. In the coupling of the fluid to the solid, the interfacial fluid stresses drive the solid motion, and a penalty method is used to ensure that the fluid satisfies the no-slip condition along the fluid-solid interface. This approach enables the use of unstructured finite element discretizations of the solid domain while making use of structured-grid solvers for the incompressible Navier-Stokes equations. The algorithm is systematically verified and validated through comparisons with numerical and experimental benchmarks of increasing complexity. Applications of this method to biomedical applications, including the dynamics of bileaflet mechanical heart valves and dynamics of deformable blood clots inside IVC filter will be presented.

6:47PM P23.00008 Optimal bending rigidity of the aortic valve leaflets, YE CHEN, HAOXIAO CHEN, IANG LUO, Vanderbilt University — Proper bending stiffness and the ability to quickly respond to the dynamic pressure load on their surfaces are critical for the heart valves to carry out their physiological functions. Studies on how the flexibility of the leaflets affects the fluid-structure interaction (FSI) of heart valves are still very limited. In this talk, three-dimensional FSI simulations of a bioprosthetic aortic valve are performed using a parallelized immersed-boundary method. The pressure distribution over the leaflets and transient force on the valve are calculated. The thickness of the leaflets is varied from 0.1 mm to 0.8 mm, which results in a wide range of non-dimensional bending rigidity $EB^*$, normalized by the transvalvar pressure gradient. For valves with low bending rigidity ($EB^* \approx 1.0 \times 10^{-2}$), the valve functions normally and produces physiological characteristics of healthy valves. However, exceedingly low rigidity (for example, $EB^* \approx 1.2 \times 10^{-3}$) leads to flapping motion of the leaflets and impairs the valve’s performance. Stiffer valves ($EB^* > 0.2$) are more difficult to open and slower to close, which leads to higher resistance and a reduced flow rate during systole. The results reveal the existence of an optimal range of bending rigidity for the valve, where $EB^*$ is roughly between 0.003 and 0.04. Effects of bending rigidity on valve deformation and flow characteristics will also be discussed.

7:00PM P23.00009 Aortic Wall Shear Analysis from Asymmetric Prosthetic Heart Valve Design, ALEXANDROS ROSAKIS, MORTEZA GHARIB, California Institute of Technology — Asymmetrically stiffened aortic trileaflet valve leaflets can divert the systolic flow away from the stiffened leaflets and into the wall of the aortic root. Asymmetrical stiffening of the aortic valve can be caused by aortic valve stenosis. We show the different flow profiles caused by different combinations of stiffened and unstiffened leaflets. Furthermore, we describe how this asymmetric stiffening alters the wall shear stress on a model aorta. This investigation can be used to better understand disease states in patients with aortic valve stenosis. Moreover, understanding the effects of asymmetric leaflet stiffening on the aortic flow may allow us to design patient specific prosthetic polymer heart valves. These valves would have carefully tuned leaflet thicknesses that would direct the systolic flow in a way that minimizes damage to the patient’s aortic wall and better resembles natural healthy heart valves.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P24 Bubbly Flow II 606 - Jack Keeler, University of Manchester

5:16PM P24.00001 Experimental and numerical study of bubble transport within multiphase cross flow over a cylinder, ERIC THACHER, SIMO MAKIHARJU, University of California, Berkeley — Vortex-induced vibration from cross flow over a cylinder is an important design consideration in numerous applications. For single phase flow, this phenomenon has been studied extensively; however, while past researchers have shown that increasing phase fraction decreases vibration amplitude while increasing shedding frequency, the mechanisms causing these changes are not fully understood. Studying individual bubble transport may provide insight, as indicated by Voutsinas et al. (2009) who demonstrated that the frequency shift depends on bubble size. In this work we begin by studying the flow of individual bubbles over a cylinder in cross-flow, to assess the time needed for bubbles to be captured in the shed vortices. Following the method of Oweis et al. (2005), the capture time is predicted using a point-particle tracking model, as a function of bubble size, release position, and flow rate. The numerical results are then verified experimentally using high speed camera visualization of a cylinder in cross flow within a vertical flow loop. The time-resolved transport of a single stream of monodisperse bubbles from a needle and co-flow apparatus is used to assess the impact of capture time on cylinder pressure fluctuations, before expanding the study to higher void fraction flows. -/abstract- Authors: Eric W. Thacher and Simo A. M
5:29 PM P24.00002 Modeling and validation of bubble-induced fluctuation in bubbly flows.\(^1\) JUBEOM LEE, HYUNGMIN PARK, Seoul National University — The nature of two-phase turbulence is of a great interest academically and practically. In general, it is decomposed into two contributions: one from the shear-induced turbulence in the absence of bubbles and the other from the bubble-induced turbulence (agitation or fluctuation). Regarding the latter, it is further broken down into non-turbulent (a potential drift) and turbulent (perturbations due to bubble wake) parts. In the present work, we are interested in this bubble-induced fluctuation and suggest a model, which is derived based on a mixing length model (analogous to the single-phase flow turbulence) but considering the effect of neighboring bubble and bubble-induced liquid flow. As a result, we suggest models for turbulent and streamwise normal stress that includes the contributions from gradients of liquid velocity, void distribution, and bubble velocity. The novelty of this work is, we try to combine the non-turbulent and turbulent parts together. Finally, we validate our models with available data in the literature, including our own, obtained from various flow configurations such as a bubble-swarm, laminar pipe, and bubbly wake flows. We discuss the advantages and limitations of our models.

\(^1\)Supported by grants (2017R1A4A1015523, 2017M2A8A4018482, KCG-01-2017-02) funded by Korea government and Korea Coast Guard.

5:42 PM P24.00003 Some notes on eddy viscosity in wall-bounded turbulent bubbly flows.\(^1\) TIAN MA, Duke University, Department of Civil & Environmental Engineering, YIXIANG LIAO, DIRK LUCAS, Helmholtz-Zentrum Dresden-Rossendorf, Institute of Fluid Dynamics, ANDREW BRAGG, Duke University, Department of Civil & Environmental Engineering, HELMHOLZ-ZENTRUM DRESDEN-ROSSENDORF, INSTITUTE OF FLUID DYNAMICS TEAM, DUKE UNIVERSITY, DEPARTMENT OF CIVIL & ENVIRONMENTAL ENGINEERING TEAM — Recently, based on data from DNS, Ma et al. (Phys. Rev. Fluids 2, 034301, 2017) proposed a model for closing the bubble-induced turbulence (BIT) in a typical Euler-Euler two-equation model, which appears to yield improved performance for predicting $k$ and $\epsilon$ over the previous models. The present study departs from this BIT model and purpose to use the same DNS data to investigate the behavior of the $C_\mu$ constant and standard eddy viscosity definition. It can be shown that $C_\mu$ constant computed using the DNS database has a very different behavior than that in single-phase flow. Checking closely, the deficiency originates from the description of the standard eddy viscosity that is intrinsic to this general hierarchy of Euler-Euler $k-\epsilon$ type model, hence, cannot be overcome by a more complex correction function for $C_\mu$. Departing from this point, a modification to the definition of the eddy viscosity in bubbly flows is derived for the Euler-Euler two-equation models. We focus on the intermediate region—a region extended from the core region, where bubble-induced production and dissipation are nearly in balance, and find that the modified model can lead to significantly improved predictions for the mean liquid, when compared with DNS data.

5:55 PM P24.00004 ABSTRACT WITHDRAWN —

6:08 PM P24.00005 Numerical two-phase flows study in channels with variable cross-section.\(^1\) GUSTAVO R. ANJOS, COPPE/Federal University of Rio de Janeiro — Bubbles and drops dynamics through capillaries of variable cross-section still remains of considerable importance in two-phase flows. The aim of this work is to investigate two-phase flows found in the cooling of new generation of computer processor units in the scope of the ThermoSMART - Marie-Curie/RISE Consortium. We seek to study numerically the effects of domain boundaries to the bubble dynamics, including change in the film thickness, bubble shape and vortex shedding in channels with variable cross-section using a moving mesh/boundary domain scheme, which dramatically shortens the domain length. Such a scheme moves the computational boundary nodes according to the bubble’s center of mass relative to the variable cross-section of a given problem. The new methodology proposed to simulate two-phase flows in variable cross-sectioned channels shows good accuracy to describe interface forces and bubble dynamics in different complex geometries with moving boundaries.

\(^1\)ThermoSMART (EU FP7-PEOPLE-2011-IRSES 294905), FAPERJ - Brazil

6:21 PM P24.00006 Bubbly flow in upward 90-degree elbow pipe: bubble dispersion and liquid flow structure\(^1\) HONGSEOK Choi, HYUNGMIN PARK, Seoul National University — In gas-liquid 2-phase flows, interfacial structure plays an important role in determining the transport characteristics, which changes with geometry and inlet condition. We experimentally investigate change in bubble dynamics and flow structures for gas-liquid bubbly flow in 90-degree bent square pipe, varying mean void fraction up to 3.0%. Continuous phase flows are chosen as laminar (Re = 550) and turbulent flows (Re = 7,000). We acquire the liquid-phase velocity using two-phase PIV technique, while gas-phase velocity and size distribution are measured with high-speed shadowgraphy. In laminar flow, bubbles move much faster than the liquid phase, resulting in a backflow and large recirculation region at the inner wall of the pipe. The size of this region increases with mean void fraction, inducing strong turbulence at the boundary. For turbulent flow, flow structure doesn’t show significant change with considered void fraction, but bubble trajectories move from the inner wall to the outer wall as mean void fraction increases. As a result, location of the maximum liquid-phase turbulence changes accordingly. Analysis of the interfacial force balance and mechanism for flow structure change will be discussed further.

\(^1\)Supported by grants (2017R1A4A1015523, 2017M2A8A4018482, KCG-01-2017-02) funded by Korea government and Korea Coast Guard.

6:34 PM P24.00007 Transient bubble dynamics in a constricted Hele-Shaw channel.\(^1\) ANTOINE GAILLARD, JACK KEELER, MCND (University of Manchester), GREGOIRE LE LAY, Ecole normale superieure de Paris , GREGOIRE LEMOULT, ANNE JUEL, ALICE THOMPSON, ANDREW HAZEL, MCND (University of Manchester) — We explore the applicability of dynamical systems concepts recently used to study the transition to turbulence in shear flows to other subcritical transitions in fluid mechanics. We are ultimately interested in the subcritical instability of the linearly stable Saffman-Taylor finger in a Hele-Shaw channel, where finite perturbations can initiate complex dynamics for sufficiently large values of the driving parameter. Here, we concentrate on a geometrically- perturbed Hele-Shaw channel which supports multiple stable modes. We experimentally investigate and classify the different time-evolution scenarios of an air bubble of given volume when varying both the flow rate and the initial bubble shape. As the flow rate increases, the bubble exhibits increasingly complex behaviors, including oscillatory deformations and transient explorations of multiple-tipped unstable modes which often lead to bubble breakup, followed by multiple bubble interactions. Besides, we show that long and disordered transients can be observed at large flow rates depending on the level of noise in the system.

\(^1\)Supported by grants (2017R1A4A1015523, 2017M2A8A4018482, KCG-01-2017-02) funded by Korea government and Korea Coast Guard.
In this talk, we attempt to understand the transition to disorder in this system for a bubble in Hele-Shaw channel by finding invariant solutions, in the form of steady states and periodic orbits, of the governing equations. Inspired by recent developments in the transition to turbulence in shear flow, and using dynamical systems theory, we discuss the idea, that when the flow-rate is large enough the bubble will transiently explore the stable manifolds of weakly unstable edge states of the system.

**Monday, November 25, 2019 5:16PM - 7:13PM – Session P25 Bubbles: Acoustics**

**5:16PM P25.00001 Model for lipid-encapsulated microbubbles using transient network theory**, BASHIR M. ALNAJAR, University of Colorado Colorado Springs, SHANKAR L. SRIDHAR, MARK A. BORDEN, FRANCK J. VERNEREY, University of Colorado Boulder, MICHAEL L. CALVISI, University of Colorado Colorado Springs — Encapsulated microbubbles (EMBs) are widely used to enhance contrast in ultrasound sonography and are finding increasing use in biomedical therapies such as drug/gene delivery and tissue ablation. EMBs consist of a gas core surrounded by a stabilizing shell made of various materials, including polymers, lipids, and proteins. Lipid-coated EMBs present a unique challenge for modeling due to their relatively large oscillations and nonlinear, viscoelastic properties. We propose a novel model for a lipid-coated, spherical EMB that utilizes a statistically-based continuum theory based on transient networks to simulate the encapsulating material. The use of transient network theory permits the viscoelastic properties of the encapsulation — such as stress, elastic energy and entropy — to be calculated locally based on the configuration of lipid molecules. The model requires a minimum number of parameters that include the lipid concentration, and the rates of attachment and detachment of lipids to and from the network. The model closely reproducibly the experimentally-measured radial response of an ultrasonically-driven, lipid-coated microbubble. The model also reproduces experimentally-observed nonlinear behavior, such as compression and expansion-dominated oscillations.

**5:29PM P25.00002 Direct Numerical Simulation of weakly nonlinear bubble oscillations**, YUZHE FAN, HAISEN LI, Acoustic Science and Technology Laboratory, Harbin Engineering University, Harbin 150001, China, DANIEL FUSTER, Sorbonne Université, Centre National de la Recherche Scientifique, UMR 7190, Institut Jean Le Rond D’Alembert, F-75005 Paris, France — Bubble dynamics have been studied extensively during the last century. Because of the highly nonlinear nature, the oscillations of gas bubbles in a liquid are of great practical interest and relevant in diverse technologies. Traditionally, to study stably oscillating micro-bubbles subjected to ultrasound or megasonic waves, Rayleigh-Plesset (R-P) type equations assuming spherical symmetry are frequently chosen. However, although the bubble can oscillate without breaking in such weakly nonlinear oscillation regimes, non-spherical effects neglected in R-P models will become increasingly important with the increasing of the amplitude of pressure pulse and the frequency of the incident wave. To investigate such non-spherical mechanisms, we present simulations of the interaction between a traveling acoustic wave and a single bubble using Direct Numerical Simulations (DNS) [Fuster and Popinet. (2018). J. Comput. Phys. 374, 752-768]. Depending on the pressure waves emitted by the moving non-spherical bubble, we characterize different weakly nonlinear oscillation regimes as a function of the Reynolds, Weber and the amplitude of incident pressure. The comparison between DNS and R-P type equations is also done to quantitatively estimate the range of applicability of simplified models.

**5:42PM P25.00003 Multiscale modeling of bubble acoustics**, SUHAS JAIN, JAVIER URZAY, ALI MANI, PARVIZ MOIN, Center for Turbulence Research — The detection of bubbles and the accurate determination of their sizes is important for several naval applications, including the characterization of ships and submarine wakes. One practical way of accomplishing this task is by using acoustic methods, in which the bubbles are sized using the dependence of their resonance frequency on their equilibrium radius. This work presents an algorithm that accurately captures the interface, maintains favorable characteristics such as boundedness and total-variation diminishing properties for the volume fraction, and is fully non-dissipative and numerically stable. In practical oceanic flows, there is a large separation of scales between the sizes of the bubbles and the correlation wavelengths of the free surface, and therefore their acoustic scattering behaviors are also different. Taking advantage of this disparity of scales and the resulting scattering behavior, a modeling technique for bubble-size detection is explored where the bubbles are modeled as point scatterers, whereas the free surface is resolved by the diffuse-interface method.

First author acknowledges the support from the Franklin P. and Caroline M. Johnson Fellowship.
The acoustically-driven expansion and collapse of a near wall bubble. A high-order accurate, fully compressible, multiphase model is used to simulate the acoustically-driven expansion and collapse of a gas bubble in water. The Rayleigh collapse has been the standard model of collapse: it uses initially static distributions of pressures for which the pressures in the two domains are unequal and uniform. The model presented here initiates the bubble dynamics and the surrounding fluid dynamics by an oscillating moving boundary condition. The results of the acoustically induced collapse are compared to those of the Rayleigh growth and collapse. A small standoff distance greatly restricts the sphericity during the bubble's expansion stage. For similar maximum bubble volumes, the acoustical-driven collapse predicts much higher wall pressures than the Rayleigh model.

Single Bubble Collapse at Audible Frequencies and High Amplitudes

While the characteristics of bubbles' radial motion have been widely studied for driving frequencies higher than 20 kHz, lower frequency ranges remain unexplored. In this work, dynamics of an acoustically forced gas/vapor single micro-bubble in water have been studied for driving frequencies below 20 kHz by means of a reduced-order model accounting for all the critical thermo-mechanical contributions. Our investigations in a large parameter space (frequency x amplitude = [1-100 kHz] x [1-7.5 atm]) suggest that at low frequencies and/or high amplitudes, water phase changes play a major role in determining the bubble dynamics, yielding a remarkably different behavior where the first bubble collapse is not necessarily the strongest one (which is the case for higher frequencies). However, at moderate amplitudes (1-1.1 atm), low frequency forcing yields bubble dynamics comparable to the high-frequency/high-amplitude cases.

This work was supported by the Netherlands Center for Multiscale Catalytic Energy Conversion (MCEC), an NWO Gravitation programme funded by the Ministry of Education, Culture and Science of the government of the Netherlands.

Ultrasound contrast agents are micron-sized bubbles used to increase contrast in ultrasound imaging. These microbubbles can be steered in the systemic circulation by the ultrasound-induced Bjerknes force, presenting a potential for highly-directed thrombolysis or cancer chemotherapy. While the dynamics of a single microbubble under ultrasound excitation are well understood, the dynamics of a suspension of microbubbles in physiologically-realistic flows are understudied: a greater understanding of the competition between hydrodynamic and ultrasound-induced forces in this flow regime would enable clinical applications. Experiments conducted in a cylindrical tube at physiologically relevant Reynolds numbers and under various pressure amplitudes and pulse repetition frequencies (PRF) will be presented. In-house high-speed tracking characterized the forces acting on the microbubbles by calculating microbubble velocities and accelerations. When the Bjerknes force is small, the microbubbles are only affected by the shear-induced lift force in the flow. At higher pressures and PRFs, the Bjerknes force overcomes the shear-induced lift force and displaces the microbubbles in the direction of ultrasound propagation, potentially putting them in contact with the arterial wall for drug delivery.

Ultrasound-enhanced mass transfer during single bubble diffusive growth

This project is co-funded by ThermaSMART under the European Unions Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie grant agreement No. 778104.

In-house high-speed tracking characterized the forces acting on the microbubbles by calculating microbubble velocities and accelerations. When the Bjerknes force is small, the microbubbles are only affected by the shear-induced lift force in the flow. At higher pressures and PRFs, the Bjerknes force overcomes the shear-induced lift force and displaces the microbubbles in the direction of ultrasound propagation, potentially putting them in contact with the arterial wall for drug delivery.

Ultrasound contrast agents are micron-sized bubbles used to increase contrast in ultrasound imaging. These microbubbles can be steered in the systemic circulation by the ultrasound-induced Bjerknes force, presenting a potential for highly-directed thrombolysis or cancer chemotherapy. While the dynamics of a single microbubble under ultrasound excitation are well understood, the dynamics of a suspension of microbubbles in physiologically-realistic flows are understudied: a greater understanding of the competition between hydrodynamic and ultrasound-induced forces in this flow regime would enable clinical applications. Experiments conducted in a cylindrical tube at physiologically relevant Reynolds numbers and under various pressure amplitudes and pulse repetition frequencies (PRF) will be presented. In-house high-speed tracking characterized the forces acting on the microbubbles by calculating microbubble velocities and accelerations. When the Bjerknes force is small, the microbubbles are only affected by the shear-induced lift force in the flow. At higher pressures and PRFs, the Bjerknes force overcomes the shear-induced lift force and displaces the microbubbles in the direction of ultrasound propagation, potentially putting them in contact with the arterial wall for drug delivery.

5:16PM P26.00001 The Unsteady Suction Actuator1, NIMROD SHAY, BAR MIZRAHI, OFEK DRORI, ARIEL YANIV, AVRAHAM SEIFERT, Tel Aviv University — Steady suction is known to be significantly more effective than steady blowing for boundary layer separation control. Pulsed blowing is known to be significantly more effective than steady blowing, owing to the instability and favorable timescales imposed by unsteady 3D vorticity components created by a suitable device. Recently it was shown that unsteady suction can be more effective even when compared to steady suction. This paper describes the development and characterization of a new fluidic device, capable of creating unsteady suction with no moving parts. The device uses at least one fluidic oscillator and at least one ejector to create unsteady suction. Detailed numerical and experimental rapid prototyping techniques were used and the results of the device characterization in still fluid are described. It is shown that the new device can create the required output signals for external flow separation control using relatively low input mass flux and low power. Further to its development, it was already tested interacting with a turbulent boundary layer and compared directly to other flow control devices in keeping an airfoil boundary layer attached. [1] Seifert, A. and Pack, L.G. “Active flow separation control on wall-mounted hump at high Reynolds numbers,” AIAA J., vol. 40, pp. 1363–1372, 2012. 5:29PM P26.00002 On the Interaction of Unsteady Suction and Turbulent Flat Plate Boundary Layer, BAR MIZRAHI, AVRAHAM SEIFERT, Tel Aviv University — This paper describes the interaction of unsteady suction created by the new oscillatory suction (OSUB) actuator with a turbulent, flat plate boundary layer. Unsteady suction is imposed on the boundary layer from four discrete holes in the plate in the transitional region of the boundary layer. The boundary layer is first characterized without excitation then two magnitudes and two frequencies for each magnitude are imposed. The resulting flow is very effectively modified by the imposed suction. Hot-wire scans of planes parallel to the wall at two different heights and full boundary layer velocity profiles along selected rays from the origin of the disturbances reveal a fascinating 3D complex yet quite coherent patterns. Phase-locked analysis decomposes the controlled flow field and reveals the unsteady flow created by the unsteady suction. The disturbances are compared to those created by discrete steady suction through the same array of four spanwise holes and reveal the parameter range in which unsteady suction has significant benefits as compared to steady suction.

5:42PM P26.00003 A Comparison Between Oscillatory and Steady Suction for Airfoil Separation Control1, AVRAHAM SEIFERT, BAR MIZRAHI, Tel Aviv University — This paper presents a direct comparison between two classes of flow control actuators. The first actuator uses steady suction while the other actuator uses unsteady suction. Both use also pulsed blowing (PB) downstream of the suction locations. Both actuators were installed on a custom-designed and 3D printed airfoil, specifically designed to have two distinct separation locations. At the upstream location, four suction holes each are placed symmetrically to the chord and are connected either to steady or unsteady suction devices. Further downstream, where the boundary layer tends to separate again, a pair of PB slots are placed, connected each pair to each device, again symmetrically to the chord line. The airfoil is mounted on a load cell and aerodynamic forces are measured at low speeds. The actuators were previously calibrated on a benchtop setup. Tests are conducted first in the absence of actuation, at low Reynolds numbers (up to 200K), then the two actuation concepts are directly compared. The range of parameters in which unsteady suction has benefits over steady suction for separation control are identified. Actuation energy expenditure is shown to be significantly lower when using unsteady suction.

5:55PM P26.00004 Preventing boundary layer separation by non-uniform suction control1, JAMES RAMSAW, MATHIEU SELLIER, University of Canterbury, WEI HUA HO, University of South Africa — Suction of the boundary layer has been studied as a method of flow control for over a hundred years. However, its use has failed to migrate to mainstream engineering applications. There are two main reasons for this: one, the relative complexity and broad parameter space for the control makes it difficult and costly to design; two, the energy required to generate the suction can often outweigh the savings from reduced drag or improved performance. To address these issues, an investigation of suction control on laminar flow around the circular cylinder and within an axisymmetric diverging pipe has been performed. Numerical simulations were performed with optimisation to determine the most effective and efficient applications of suction to achieve a variety of objectives. The models without suction were validated against experimental data from the literature. With the aim of making the design of suction control more accessible in real applications, the focus of the results was on the relationships between the uncontrolled flow and the optimised control parameters. Particular attention was paid to the objective of controlling the separation of the boundary layer and its potential use as an objective, or as an important feature, in determining the best control.

6:08PM P26.00005 Control of Shock-Induced Separation and Vorticity Concentrations in a Serpentine Diffuser1, TRAVIS BURROWS2, BOJAN VUKASINOVIC3, ARI GLEZER4, Georgia Institute of Technology — Advanced propulsion inlet systems utilize complex serpentine diffusers, whose geometry engenders large-scale streamwise vortices and boundary-layer separation coupled to shock formation at high flow rates that limit engine efficiency operating range due to severe losses and distortion. The present experimental investigation demonstrates active control of the diffuser transonic shock by utilization of surface-mounted fluidic oscillating jets, thereby indirectly control streamwise vorticity concentrations by exploiting the coupling to the shock. It is demonstrated that flow control modifies the shock topology and footprint, confining it towards the diffuser’s sidewalls. Consequently, the streamwise vortices are displaced, ultimately mitigating their advection of low-momentum fluid into core diffuser flow. This active flow control leads to a 35% reduction in average diffuser circumferential distortion and a concomitant increase in pressure recovery, indicating the capability of this flow control approach to extend the engine operation range beyond its nominal operating condition.

6:21PM P26.00006 Flow Physics and Scaling for Discrete Jet Forcing on a Wall-Mounted Hump. CHRISTOPHER OTTO, BENJAMIN CHAMPION, JESSE LITTLE, The University of Arizona, RENE WOSZIDLO, The Boeing Company — An experimental study is conducted to explore flow physics and scaling parameters (e.g., aspect ratio, exit area, spacing) for various types of fluidic oscillators in support of the development of active flow control technology. Various actuation modules are designed, built and tested on an existing model of the NASA hump geometry. Experiments are carried out at a Reynolds numbers of 1.0 x 10^6 (Ma = 0.09). Time-averaged pressure measurements are conducted along both the chord and span of the model. Stereoscopic PIV is performed downstream of the actuation location to investigate the underlying control mechanisms in detail. Flow control using various spatially distributed fluidic oscillators was applied for spacings of Δz/c = 4.55% & 9.09%. Performance curves were compared based on a momentum, mass flow, and particle image velocimetry. Of specific interest are the roles of independently-interchangeable variations between the inlet flow (M = 0.8) and crosswind speed (up 35 knots) on the on-set and evolution of topology of separation. It is shown that for a given inlet flow the presence of sufficiently high cross winds lead to the formation of a three-dimensional separation domain that has an azimuthal, horseshoe-like boundary with its tip near the windward edge. As the cross wind speed increases, separation spreads by the formation of secondary interacting azimuthal separation cells whose topology resembles the main separation domain. Fluidic control of the separation leads to significant reduction in losses that are manifested by reduction in cross stream total pressure deficit and a concomitant increase in the inlets mass flow rate.

6:34PM P26.00007 Fluidic Control of Round Inlet Flow in Cross Wind1. D.A. NICHOLS, B. VUKASINOVIC, A. GLEZER, Georgia Institute of Technology, M. DEFORE, B. RAFFERTY, The Boeing Company — The suction flow within a round inlet in the presence of cross wind is investigated experimentally with specific emphasis on characterization and control of separation over the surface of windward lip using arrays of surface static pressure ports and radial total pressure rakes, surface oil-flow visualization, and particle image velocimetry. The nominally 2-D curved surface is designed to promote separation representative of that seen in rotorcraft applications. A spanwise array of fluidic oscillating jets located upstream of the separation provides dissipative, high-frequency actuation, which in turn controls the characteristic scale of the separation domain. The effect of the actuation and its progression from the upstream to the downstream edges of the separated bubble are assessed using stereoscopic particle image velocimetry. Emphasis is placed on local entrainment and flow features near the actuators and their ensuing downstream progression throughout the separated region. Additionally, the relationship between the local flow features at separation and characteristics of the ensuing separated flow will be assessed with respect to the global flow control effectiveness.

7:00PM P26.00009 Controlled Aerodynamic Forces on Slender Axisymmetric Bodies at High Incidence1. E. LEE, Y. HUANG, B. VUKASINOVIC, A. GLEZER, Georgia Institute of Technology — The flow and aerodynamic loads over slender axisymmetric bodies at high incidence are dominated by interactions of a hierarchy of vortical structures resulting from streamwise- successive, wake instabilities of the cylinders forebody, main, and aft segments. These vortical interactions are driven by the onset of a counter-rotating vortex pair that form over the forebody and are extremely receptive to small perturbations and can rapidly evolve asymmetrically resulting in significant side force and yawing moment. The present wind tunnel investigations utilize an axisymmetric model (L/D = 10, incidence up to 65 o , Re D = 810 4 ) to exploit the receptivity of the forebody flow to small perturbations for controlling the evolution of the forebody vortices and thereby the aerodynamic loads (side forces and roll and yaw moments). Upwind actuation is effected using synthetic jet actuators at the juncture of several forebodies of different aspect ratios. It is shown that the flow is extremely receptive to actuation at high incidence angles yielding side force changes of up to C S = 5 (corresponding C L about 6.5). The effected side forces are used to control the models lateral stability.

5:16PM P27.00001 Combined Heaving and Pitching Propulsors of Non-Uniform Flexibility1. AMIN MIVECHI, TIANJUN HAN, Lehigh University, MEHDI SAADAT, GEORGE V. LAUDER, Harvard University, KEITH W. MOORED, Lehigh University — Many swimming animals propel themselves efficiently through water by oscillating their fins with combined heaving and pitching motions. Contrary to most research on flexible propulsors, these fins are not homogenously flexible, but rather their flexibility varies along their chord and span. Here, using a simple flexibility model we experimentally examine the effect of the distribution of flexibility on the performance of a three-dimensional propulsor using combined heaving and pitching motions. We manufacture propulsors with a combination of rigid and flexible materials where their proportion compared to the chord length is determined by the flexion ratio. The experiments are conducted in a recirculating water channel by varying the frequency of motion at Re = 10^4, with the pitching motion lagging the heaving motion by 90 degrees. Both the effective flexibility and the flexion ratio of the propulsors are varied independently and force, power and amplitude data are recorded for each experiment. We find peak efficiencies greater than 60% and we detail the dependency of the performance on the variation in the structural properties of the propulsor.

5:29PM P27.00002 Tailoring the Bending Pattern of Non-Uniformly Flexible Pitching Propulsors Enhances Propulsive Efficiency1, JIANJUN HAN, MELEKE KURT, AMIN MIVEHCHI, KEITH W. MOORED, Lehigh University — Aquatic animals swim rapidly and efficiently by using flexible propulsors. It has been observed that bio-propulsors typically have non-uniform flexibility with increasing flexibility towards the trailing edge. However, most previous research has examined the effect of uniform flexibility on bio-propulsion. Here, we conduct experiments on three-dimensional propulsors with non-uniform chordwise flexibility. We used a simple step function distribution where there is a rigid leading-edge section and a finite flexibility trailing-edge section. This piecewise distribution is defined by the flexion ratio, that is, the ratio of the rigid section length to the chord length. The forces and moments are measured for purely pitching propulsors with various flexion ratios and effective flexibilities. Peak efficiencies for these purely pitching propulsors reach as high as 56% and occur above the first resonant frequency of the system. Additionally, a scaling relation for the resonant frequency of non-uniformly flexible propulsors is determined. This work highlights the result that not only is the resonant condition important for high efficiency performance, but also the bending pattern of a propulsor.

5:42PM P27.00003 Efficient optimization of swimming gaits1, DANIEL FLORYAN, XUANHONG AN, CLARENCE W. ROWLEY, Princeton University — We study a simplified model of fish swimming—namely a rigid foil undergoing periodic motion—seeking motions that are optimal in regards to a particular objective (e.g. maximal thrust production). We use an immersed boundary method, and develop an adjoint formulation that allows us to efficiently calculate the gradient of the objective function that is used with gradient-based optimization. Moreover, the adjoint field provides sensitivity information which can be used to elucidate the physics responsible for optimality.

5:55PM P27.00004 Hydrodynamic performance of a self-propelled ray with oscillatory locomotion1, YOUNG DAL JEONG, JAE HWA LEE, UNIST — Mylobatoid rays have dorsoventrally flattened diamond-shaped bodies with expanded pectoral fins, and they swim by oscillating their large pectoral fins. This oscillatory locomotion utilizes the lift-based propulsion, which is specialized for efficient propulsion. Inspired by the high efficient rays, we perform numerical simulations of a self-propelled oscillating ray in a viscous quiescent flow. To consider the fluid-structure interaction between the oscillating ray and surrounding fluid, the penalty immersed boundary method is adopted. From references for the biological ray kinematics, the oscillatory locomotion in the vertical and spanwise directions is actively given at the leading edge, although the chordwise moving motion is freely movable by the fluid-flexible body interaction. Moreover, three-dimensional motion of the rest part is passively determined, and the propulsion performance is influenced by the elastic properties. The effects of the elastic properties on the cruising speed and the input power are investigated systematically.

1This research was supported by the National Research Foundation of Korea (NRF) funded by the Ministry of Education (NRF-2017R1D1A1A09000537) and the Ministry of Science, ICT & Future Planning (NRF-2017R1A5A1015311).

6:08PM P27.00005 Intermittent locomotion of a self-propelled plate.1, JAEHA RYU, HYUNG JIN SUNG, Department of Mechanical Engineering, KAIST — Many fish and marina animals swim by using a combination of the active bursting phase and the passive coasting phase, which is known as the burst-and-coast swimming. The immersed boundary method is applied to explore the intermittent locomotion of a three-dimensional self-propelled flexible plate. The degree of the intermittent locomotion is captured in a duty cycle (DC = \( T_b/T_f \), which is the ratio of the interval of the burst phase \( T_b \) to the total flapping period \( T_f \)) of the active flapping motion. The averaged cruising speed \( (U_c) \), the input power \( (P) \), and the swimming efficiency \( (\eta) \) are analyzed as a function of the duty cycle \( (DC) \). The maximum \( U_c \) is obtained at \( DC = 0.9 \), while the maximum \( \eta \) is at \( DC = 0.3 \). The hydrodynamics by the intermittent locomotion is scrutinized by using the superimposed flag and the phase map. The characteristics of the flapping motion are demonstrated at the bursting and coasting phases, respectively. The modal analysis is performed to examine how the flapping motion plays a role in the propulsion mechanism. The velocity map and the vortical structures are visualized to show the influence of the intermittent locomotion qualitatively and quantitatively.

6:21PM P27.00006 CFD-Based Multi-Objective Controller Optimization for Soft Robotic Fish with Muscle-like Actuation, ANDREW HESS, XIAOBO TAN, TONG GAO, Michigan State University — Soft robots take advantage of rich nonlinear dynamics and large degrees of freedom to perform actions by novel means beyond the capability of conventional rigid robots. Nevertheless, there have been considerable challenges in analysis, design, and optimization of soft robots due to their complex behaviors. This is especially true for underwater soft robotic swimmers whose dynamics are determined by highly nonlinear fluid-structure interactions. We present a holistic computation framework that employs a multi-objective evolutionary method to optimize feedback-based controllers of a soft robotic fish prototype subject to artificial muscle actuation. The resultant nonlinear fluid-structure interactions are fully solved by using novel fictitious domain active strain method which specify the entire-body curvature variation, we demonstrate that imposing contractile active strains locally can produce various swimming gaits using far fewer control parameters. It also facilitates feedback controller design for muscle actuation schemes using high-fidelity CFD simulation data. We optimize the controller coefficients via several “thought” experiments where we seek optimal swimming performances of the robotic fish tracking moving targets.

6:34PM P27.00007 Scaling Laws for Three-Dimensional Combined Heaving and Pitching Propulsors1, FATMA AYANCIK, KEITH MOORED, Lehigh University — The underlying physics of oscillatory swimming can be captured with simple models based on the scaling of the added mass and circulatory forces. Here, by considering both of these forces, we present new scaling relations for three-dimensional combined heaving and pitching propulsors with varying aspect ratios. Classic linear theory is augmented by additional nonlinearities and modified for three-dimensional effects by considering the added mass of a finite-span propulsor, the downwash/upwash effects from the trailing vortex system and the elliptical topology of shedding trailing-edge vortices. We verified the scaling relations by using experiments and self-propelled inviscid numerical simulations over a wide range of variables including the dimensionless amplitude, dimensionless heave-to-pitch ratio, Strouhal number, and aspect ratio. The developed relations are found to be in excellent agreement with the numerical and experimental data. These scaling laws are used to identify physical mechanisms that influence thrust and efficiency, and as a guide for improving performance.

6:47PM P27.00008 Geometric Influence on Force and Frequency Response of a Bioinspired Undulated Cylinder \quad KATHLEEN M. LYONS, University of Wisconsin - Madison, WI \quad CHRISTIN T. MURPHY, ANDREW GIARENDI, Naval Undersea Warfare Center - Newport, RI \quad JENNIFER A. FRANCK, University of Wisconsin - Madison, WI — The unique three-dimensional geometry of seal whiskers has been shown to significantly change the turbulent structures directly downstream, resulting in reduced forces and dampened vibrations when compared with circular cylinders. Biomimicry gives an opportunity to apply the unique whisker geometry to other areas of engineering that require vibration suppression, frequency tuning, or force reduction. This computational investigation isolates the complex geometric parameters of the seal whisker via an undulated cylinder model prescribed by seven non-dimensional parameters including undulation wavelength, thickness, slenderness, amplitudes in the streamwise and transverse flow directions, as well as a peak-shift and a symmetry parameter that induce a non-sinusoidal periodic undulation. Using a two-factor fractional factorial design of experiments, these simulations demonstrate the geometric parameters and two-parameter interactions that are most influential for reducing drag, root-mean-square lift force, and shifting the frequency spectra. It is shown that both transverse and streamwise undulation amplitudes have a notable impact on the downstream vortex structures, thus impacting the frequency spectra and recirculation region via different mechanisms.

5:16PM P28.00001 A simple hydride model for cerium ejecta particles\textsuperscript{1} \quad JONATHAN D. REGELE, JOHN D. SCHWARZKOPF, WILLIAM T. BÜTTLER, ALAN K. HARRISON, Los Alamos National Laboratory — Cerium ejecta particles created by shock driven Richtmyer-Meshkov instabilities are known to hydrde inside of deuterium gas and release exothermic energy in the form of heat and increased particle temperature. Cerium dihydride, which is the reaction product specie, is solid under the experimental conditions considered. A model is developed to describe the hydriding process by combining the lumped-capacitance thermal conduction model, Ranz-Marshall heat transfer correlation, and a diffusion-controlled reaction. Comparisons with experimental data are used to determine model accuracy and to discover what additional physics should be considered in the model.

5:29PM P28.00002 Modeling pseudo-turbulence in compressible particle-laden flows\textsuperscript{1} \quad GREGORY SHALLCROSS, University of Michigan, RODNEY FOX, Iowa State University, JESSE CAPECELATRO, University of Michigan — When a shock passes through a dense suspension of solid particles, velocity fluctuations are generated in particle interstitial sites. While this is captured in fully resolved simulations of shock-particle interactions, it remains a challenge to reproduce using coarse-grained models, such as Eulerian-Eulerian and Eulerian-Lagrangian methods. Recent work has revealed that pseudo-turbulent kinetic energy (PTKE) can contribute significantly to the overall kinetic energy during shock-particle interactions. We demonstrate this term acts to systematically increase the local Mach number, and needs to be accounted for to properly capture particle dispersion. A transport equation for PTKE is presented, and closure for the dissipation rate is proposed. The equations are implementing in a high-order Eulerian-Lagrangian framework and compared against direct numerical simulations of shock-particle interactions. We demonstrate the model is capable of predicting the pseudo-turbulent Reynolds stresses with correct levels of anisotropy, independent of the drag law employed. Finally, a stochastic model informed by the PTKE is proposed to improve the prediction of particle dispersion.

5:42PM P28.00003 Examination of Particle Force Model and its Uncertainty in a Detonation-Driven Multiphase Flow\textsuperscript{1} \quad JOSHUA GARNO, FREDERICK OUELLET, RAHUL KONERU, THOMAS JACKSON, S. BALACHANDAR, University of Florida, BERTRAND ROLLIN, Embry-Riddle Aeronautical University — Recent work in the compressible, multiphase flow community has shown that the compressible Maxey-Riley-Gatignol (MRG) force model captures the transient forces exerted on a particle by a passing air shock and compressed flow. In this work, the model’s predictive capability in the post-detonation flow regime is considered following a rigorous study of the explosive products as the carrier phase. The model parameters of the JWL equation of state are varied to observe their individual sensitivities on the post-detonation flow. Uncertainty quantification with experimental data provides the most influential and likely JWL parameters. With the gas phase in agreement with experiments, the validity of the compressible MRG model under extreme condition is reviewed. Experimental X-ray data provides the trajectory of a few Tungsten particles ejected from an initial explosion. Particle trajectory data from experiments is compared with finite-volume, Euler-Lagrange, point-particle simulations results employing the MRG model.

\textsuperscript{1}This work was supported (in part) by the U.S. Department of Energy, National Nuclear Security Administration, Advanced Simulation and Computing Program, as a Cooperative Agreement under the Predictive Science Academic Alliance Program, under Contract No. DE-NA0002378.

5:55PM P28.00004 Analyzing particle curtains with advection-corrected correlation image velocimetry and particle image velocimetry\textsuperscript{1} \quad JANGHAN PARK, DANIEL FREELONG, PATRICK WAYNE, PETER VOROBIEFF, University of New Mexico — We conduct an experimental study of an interaction between a planar shock in air and a nominally planar curtain of particles embedded in air. We investigate shocks at Mach numbers 1.2, 1.4, 1.7, and 2.0. Particle curtains of different nominal thickness (2, 4, and 6 mm) are subjected to shock acceleration. The particles are soda lime microspheres with a density of 1.4 g/cc and diameters ranging from 30 to 50 microns. The curtain formation prior to shock arrival is recorded by a high-speed camera during 2 seconds at 960 frames per second. The curtain mass flow rate is also acquired. Each frame of the particle curtain video is analyzed with advection-corrected correlation image velocimetry (ACCIV) and particle image velocimetry (PIV). We investigate whether ACCIV offers any advantages over PIV for this flow. Measurements of velocity combined with mass flow rate data can then be used to provide an estimate of the particle volume fraction and insights into the air entrainment by the curtain. The subsequent study must relate the local volume fraction in the curtain and its thickness with the post-shock features we observe.

\textsuperscript{1}This research is partially supported by NSF grant 1603915.
6:08PM P28.00005 Shock interaction with particle curtains of varying thickness. DANIEL FREELONG, PATRICK WAYNE, JANGHAN PARK, GREGORY VIGIL, CAROLINA SHAHEEN, Student Member, PETER VOROBL-EFF, Professional Member — The interaction of a curtain of particles with a shock wave is investigated experimentally. Soda lime particles form a gravity-driven curtain. The geometry of the curtain-forming nozzle can be adjusted, producing curtains with a nominal thickness of 2 mm, 4 mm, and 6 mm in the direction of the shock. Particle volume fractions for all three curtains range between 1% and 9%, with variations primarily due to particle acceleration along the vertical extent of the curtain. Prior to shock impact, we measure the instantaneous and average velocities of the particles to show that the particles are nearly in a free-falling state, with their average velocity increasing linearly with vertical distance. Experimental data reveal that the shock wave is both transmitted through and partially reflected by the curtain. Time-resolved images show the underlying flow structure of the interaction. This research is supported by the US Defense Threat Reduction Agency (DTRA) grant HDTRA1-18-1-002.

6:21PM P28.00006 Mach number and particle size effects on the unsteady drag of shocked micro-droplets. KYLE HUGHES, ADAM MARTINEZ, JOHN CHARONKO, Los Alamos National Laboratory — Experiments of shock-accelerated micro-droplets show high drag coefficients when the particles are tracked from initial acceleration through the relaxation times. An eight-pulse particle tracking diagnostic measures individual particle positions, and a shadowgraph system measures shock location, with pressure transducers providing shock speed at the test section. These diagnostics give us detailed measurements of particle positions versus time for Mach 1.2, 1.3 and 1.4 experiments, allowing us to calculate accelerations and drag. Comparison is made to previous experiments conducted on solid Nylon particles in similar flow regimes.

6:34PM P28.00007 Evaluation of Point-Particle Models in Shock-Particle Bed Interactions. RAHUL BABU KONERU, University of Florida, BERTRAND ROLLIN, Embry-Riddle Aeronautical University, FREDER-ICK OUELLET, S. BALACHANDAR, University of Florida — In this work, 3D Euler-Lagrange (EL) point-particle simulations of shock-particle cloud interaction are presented for two cases (i) shock interacting with a stationary bed of particles and (ii) a multiphase shock tube. In an effort to improve the point-particle models, results from these EL simulations are compared against particle-resolved (PR) Euler simulations in case of the stationary bed and experiments from the Multiphase Shock Tube facility at Sandia National Laboratories (SNL). In the stationary bed simulations, it is observed that at low incident shock Mach numbers and particle volume fractions (10%-15%), the point-particle models predict the average gas properties reasonably well. As the effects of compressibility become more prominent (presence of bow shocks), the models predict a higher drag than that is observed in the PR simulations. A sensitivity analysis is performed to identify the force components responsible for this additional drag. In the case of the multiphase shock tube, the effects of particle collisions and the initial curtain profile on the curtain expansion rate are explored. The particle collisions in this case are modeled using a soft-sphere type DEM model in CMT-Nek.

6:47PM P28.00008 Implementation of Key Capabilities to Study Unsteady Drag of Shock-Accelerated Particles with an Arbitrary Lagrangian-Eulerian Code. TANNER NIELSEN, Los Alamos National Laboratory, W. CURTIS MAXON, University of Missouri, NICK DENISSEN, Los Alamos National Laboratory — The dynamic drag coefficient on particles due to shock-acceleration has been observed, experimentally and computationally, to significantly increase during the passage of the shock over the particle. The later times, after the passage of the shock during which the particle is accelerated to the post-shock conditions, have not been as thoroughly studied nor are there models that accurately capture drag effects in this unsteady regime. This work details key capabilities that have recently been added to FLAG, an arbitrary Lagrangian-Eulerian (ALE) code developed at Los Alamos National Laboratory, to enable the study of shock-accelerated particles. This unique simulation tool allows high-resolution studies of a single particle from rest to post-shock acceleration. The ALE framework permits the particle to move freely within the computational domain based on the pressure and viscous forces. Details will be given regarding the implementation of the viscous terms in FLAG to enable the solution of the Navier-Stokes equations for the air surrounding the particle. The drag calculation is done in a way that allows the integration of the forces on the particle as it moves freely through the domain.

7:00PM P28.00009 High Resolution Simulations of Particle Acceleration in Shock-Driven Multiphase Flows. WILLIAM MAXON, Self, TANNER NIELSEN, Collaborator, NICHOLAS DENISSEN, JONATHAN REGELE, Mentor, JACOB MCFARLAND, Advisor, UNIVERSITY OF MISSOURI-COLUMBIA TEAM, LOS ALAMOS NATIONAL LABORA-TORY TEAM — Particle drag models, which capture macro viscous and pressure effects, have been developed over the years for various flow regimes to enable cost effective simulations of particle-laden flows. The relatively recent derivation by Maxey and Riley has provided an exact equation of motion for spherical particles in a flow field based on the continuum assumption. Many models that have been simplified from these equations have provided reasonable approximations; however, the sensitivity of the shock-driven multiphase instability to particle drag requires a very accurate model to simulate. To develop such a model, 2D axisymmetric and 3D Cartesian Navier-Stokes DNS of a single particle in a transient, shock-driven flow field were conducted in the hydrocode FLAG. FLAG’s capability to run arbitrary Lagrangian-Eulerian (ALE) hydrodynamics coupled with solid mechanic models in solids makes it an ideal code to capture the physics of the flow field around the particle as it is shock-accelerated — a challenging regime to study. Preliminary results have shown higher drag than the current models predict. Simulation results will be used to create a new drag model for multiphase particle-in-cell methods.

Monday, November 25, 2019 5:16PM - 7:00PM – Session P29 Biological Fluid Dynamics : Red Blood Cells and Hemodynamics
5:16PM P29.00001 Dynamics of RBCs under shear flow in sickle cell disease. A tool for monitoring the clinical state of patients.1 EMANUELLE HELFER, MAXIME SAHUN, SCOTT ATWELL, ALEXANDER HORNUNG, ANNE CHARRIER, ANNIE VIALLAT, Aix Marseille Univ, CNRS CINaM, CATHERINE BADENS, Aix Marseille Univ, INSERM, MMG — The regimes of motion of red blood cells (RBCs) under shear flow have been extensively studied because they directly relate to the cell mechanical properties. In addition to tumbling and tanktreading motions, other regimes were recently discovered, such as swinging, flip-flopping, and rolling. Computational studies provide complex phase diagrams of motion that depend on the ratio of RBC cytoplasm to external fluid viscosities and on the capillary number. Surprisingly, no experiments have been performed on RBCs from patients with sickle cell disease (SCD) which have altered mechanical properties. Here, we show that the dynamics of SCD-RBCs is modified and correlates with change in RBC density and state of hydration. Though the tumbling - flip-flopping - rolling path observed by increasing shear rate is not changed for SCD, the rolling to tanktreading threshold occurs at higher shear stress. We use this feature to propose a mechanical marker, namely the fraction of tanktreading RBCs in a large cell population, to follow the clinical state of SCD patients and to predict the very handicapping vaso-occlusive crises. We show that this marker is patient-dependent and is stable over time in the “out of crisis” period while it strongly varies during the course of a crisis.

1This work has been carried out thanks to the support of A*MIDEX.

5:29PM P29.00002 Flow-induced Segregation and Dynamics of Red Blood Cells in Sickle Cell Disease1 XIAO ZHANG, University of Wisconsin-Madison, CHRISTINA CARUSO, WILBUR A. LAM, Emory University, MICHAEL D. GRAHAM, University of Wisconsin-Madison — Blood flow in sickle cell disease (SCD) can substantially differ from the normal due to significant alterations in the physical properties of sickle red blood cells (RBCs). Chronic complications, such as endothelial dysfunction, are associated with SCD, for reasons that are unclear. Direct numerical simulations are performed to investigate the dynamics of a binary suspension of flexible biconcave discoids and stiff curved prolate spheroids that represent healthy and sickle RBCs, respectively, in plane Poiseuille flow. The key observation is that the sickles exhibit a strong margination towards the walls. The marginated sickle RBCs roll like rigid bodies and may poke and damage the walls due to their stiffness and “spikiness”. A simplified drift-diffusion model, which incorporates hydrodynamic migration and pair collisions, predicts a greater margination in a binary suspension containing a small fraction of stiff cells than in a pure suspension of stiff cells, which may explain the experimental observation that a heterogeneous blood sample containing healthy (flexible) RBCs with a small fraction of stiffened RBCs causes more severe endothelial inflammation and dysfunction than a homogeneous sample of stiffened RBCs.

1This work is supported by NIH grant 1R21MD011590-01A1.

5:42PM P29.00003 3 D Classification of Red Blood Cells in microchannels. CHRISTIAN WAGNER, Saarland University — Red blood cells (RBCs) are very soft objects that can pass capillaries smaller than the cell's diameter. Due to their high deformability, they couple strongly with the flow and can adopt many different shapes. For their quantitative characterization we developed a new confocal 3D imaging technique for fluorescent stained RBCs. We found two equilibrium cell shapes under certain flow condition: the so called ‘slipper’ and the ‘croissant’ shape. Numerical simulations are in good agreement with experimental observations. In addition, high throughput data of classical 2-D microscopy combined with an adaptive neural network allow us to obtain the full phase diagram of RBC shape as a function of the flow rate. In larger channels, we use the confocal technique to characterize the margination of single rigidified RBCs in a suspension of healthy RBCs. Margination of e.g. white blood cells or platelets at the vessel walls is a haemodynamic key mechanism of our immune system. Our confocal observation technique allows us to characterize the distribution of hard vs. soft cells in full time and space resolution for the first time. Again numerical simulations are in good agreement although some quantitative differences remain that need further investigations.

5:55PM P29.00004 Reduced-order Models for Migration and Shear-induced Diffusion of Red Blood Cells in Simple Geometries1. HARRY WANG, JOSEPH SHERWOOD, OMAR MATAR, Imperial College London — From a fluid dynamics perspective, blood can be treated as a suspension of highly-deformable red blood cells (RBCs). The RBCs migrate away from the walls of the confining vessel primarily due to their deformability, resulting in inhomogeneous distributions, distinctive in the microvasculature. Migration away from the walls is countered by shear-induced diffusion effects due to hydrodynamic particle-particle interactions. While mesoscale simulations can capture RBC dynamics well, there is a need for more efficient continuum models that can accurately model RBCs distributions in larger networks that describe the microvasculature. Here, we study the behaviour of RBC suspensions in simple flow configurations using reduced-order models. We use a drift-diffusion equation to describe the evolution of the RBC concentration, coupled to balance equations for the bulk mixture. Different forms for migration and shear-induced diffusion terms in the drift-diffusion equation are compared in rectangular and cylindrical geometries. The problem is reduced to two-dimensions using appropriate scaling, which exploits geometrical length-scale disparity, and asymptotic reduction. Velocity and concentration profiles predicted by our simulations are compared to experimental data in the literature.

1PhD funding from EPSRC CDT Fluid Dynamics across Scales for HW is acknowledged.

6:08PM P29.00005 Red cell-resolved blood flow modeling in in vivo-like microvascular networks: predicting hemodynamic changes due to loss of red cell deformability1. SAMIAN EBRAHIMI, PROSENJIT BAGCHI, Rutgers University — Microvascular networks in human body are made of the smallest blood vessels, and responsible for gas and nutrient transport to tissues, and regulation of blood flow in individual organs. The architecture of a microvascular network is complex and characterized by bifurcating, merging and tortuous vessels. Blood in such small vessels behaves as a concentrated suspension primarily made of red blood cells (RBC) which are extremely deformable. We developed a 3D simulation technique to model flow of deformable RBCs in physiologically realistic microvascular networks that are comprised of multiple bifurcating and merging vessels. The model is versatile, and can consider networks irrespective of topological/geometrical complexities. It provides fully 3D and detailed information of hemodynamic quantities, such as RBC partitioning at bifurcations, cell-free layer, and wall shear stress. Many diseases, such as sickle cell disease, malaria and diabetes mellitus, are associated with a loss of RBC deformability. A detailed quantification of changes in microvascular hemodynamics under such conditions is lacking. Using the model, we provide the first-ever simulation results on the changes in network-scale blood flow under varying RBC deformability. The specific focus is on retinal microcirculation which is known to be adversely affected due to loss of RBC deformability.

Monday, November 25, 2019 5:16PM - 7:13PM –
Session P30 Biological Fluid Dynamics : Medical Devices 612 - Wesley Harris, MIT

5:16PM P30.00001 The impact of cervical geometry and suture material on cerclage integrity . ALEXIA BAUMER, The George Washington University, ALEXIS GIMOVSKY, The George Washington University Medical Faculty Associates, MEGAN C LEFTWICH, The George Washington University — Cervical insufficiency is a medical condition during pregnancy in which the uterine cervix softens, shortens and dilates before reaching full term, usually between 18 and 22 weeks gestation, such that a preterm birth occurs. It is a common cause of second trimester pregnancy loss. Part of the clinical treatment of this condition is the cervical cerclage, a procedure to close the cervix with a purse-string stitch. There are conflicting findings on the efficacy of the cerclage, with most studies relying on statistical evidence. The purpose of this investigation is to examine the mechanical limitations of the cerclage. Working with physicians from The George Washington University Hospital, we create generalized, synthetic models of the cervix and fabricate them with silicone to mimic physiological, softening cervical tissue. Aspects of the cervical geometry (length of cervix, shape and width of dilatation) and suture material used in the cerclage are varied. The synthetic cervices are stitched by physicians according to clinical techniques. The maximum force required for the synthetic tissue to rupture through the cerclage stitch is recorded. The results of this study provide insight into the most effective clinical interventions and the mechanism of their success.

5:29PM P30.00002 A Magnetorheological Hemostatic Agent . YONATAN TEKLEAB, Massachusetts Institute of Technology, NIKOLAOS KOKOROSKOS, GEORGE VELMAHOS, Massachusetts General Hospital, GARETH MCKINLEY, WESLEY HARRIS, Massachusetts Institute of Technology — Magnetorheological (MR) suspensions are used in systems requiring responsive fluids with fast-acting, tunable properties. MR valves, have been effective in rapidly and locally arresting pressure-driven flows in mechanical systems. Motivated by these applications, we developed a magnetorheologically-actuated valve for use in the human body, to reduce or halt hemorrhage. 80% of trauma related deaths in the first hour of hospital admission are due to hemorrhagic shock. Such a hemostat would provide a prehospital intervention opportunity to stem bleeding, giving physicians more time to resuscitate patients upon trauma facility admission. The valve comprises an injectable, biocompatible MR suspension with externally-placed permanent magnets. To trigger the MR effect near the injury site in bleeding patients, the fluid was designed for biocompatibility, rapid injectability, and local actuation within blood vessels. We have synthesized, characterized, and demonstrated efficacy, through benchtop and in vivo rat tests, a novel, minimally invasive, MR hemostatic agent. Using magnets in 3D printed holders that can be worn by field surgeons, we demonstrate arrest of a major hemorrhagic event, dramatically reduced lost blood volume, sustained blood pressure, and significantly increased survival time.

5:42PM P30.00003 Influence on the fluid mechanics of blood flow of heterogeneity and anisotropy of the coil mass deployed inside intracranial aneurysms . JULIA ROMERO BHATHAL, Univ. Grenoble Alpes, CNRS, Grenoble INP, 3SR, Grenoble, France, FANETTE CHASSAGNE, LAUREL MARSH, Dpt. of Mechanical Engineering, Univ. of Washington, Seattle, WA, MIKE LEVITT, Dpt. of Neurological Surgery, Univ. of Washington, Seattle, WA, USA, CHRISTIAN GEINDREAU, Univ. Grenoble Alpes, CNRS, Grenoble INP, 3SR, Grenoble, France, ALBERTO ALISEDA, Dpt. of Mechanical Engineering, Univ. of Washington, Seattle, WA — Cerebral aneurysms are often treated with coils to induce thrombosis. Flow in coiled aneurysms has been studied extensively through CFD simulations to predict the flow after endovascular treatment. Representing coil mass as a homogeneous porous medium represents a limitation to the understanding of flow in coiled aneurysms and inhibits clinically accurate predictions. We present the characterization of the spatial heterogeneity and anisotropy of the coil mass deployed inside the aneurysmal sac based on synchrotron X-ray tomography of aneurysm phantoms treated with real coils and describe the resulting flow based on a parametrization of coil’s permeability that combines a theoretical model with the experimental results. The segmented images are used to compute the mean porosity, the porosity gradient along the inertial axis of the coil, the porosity map and the corresponding permeability map for different types of spatial discretization. The results show that the porosity varies between 0.6 to 0.95, leading to a factor 100 in permeability variations. CFD simulations results compare our results with standard homogeneous isotropic modeling.
5:55PM P30.00004 Effect of varying inhalation durations in normal breathing and HFOV conditions. MANIKANTAM GADDAM, YU FENG, ARVIND SANTHANAKRISHNAN, Oklahoma State University — Experimental and computational studies in idealized and subject-specific airways at normal breathing conditions (Womersley number, $Wo=2-4$) and in high-frequency oscillatory ventilation (HFOV, $Wo=4-25$) have shown flow separation at bifurcations, secondary flows, and steady streaming at the end of inhalation. However, the effects of varying inhalation duration (relative to breathing time period) on the flow field remain unclear. We conducted 2D simulations on a Weibel airway model representing mouth to trachea with G2 to investigate the influence of inhalation time (IT) to breathing time (BT) in normal breathing and HFOV conditions. Oscillatory breathing patterns, with peak inhalation at Reynolds number ($Re$) of 1070 and peak exhalation at $Re$ of 1100, were prescribed as inflow conditions for different $Wo$ values. With increasing $Wo$ for a given IT/BT ratio, residual flow region increased at the end of exhalation, affecting flow during inhalation in the next breathing cycle. With increasing IT/BT, residual flow region increased at the end of exhalation for Wo ranging from 2.4 to 7.5 in the oral region.

This work was supported by a Carroll M. Leonard Faculty Fellowship to Santhanakrishnan.

6:08PM P30.00005 Steady streaming and conditional turbulence in high-frequency ventilation. JUSTIN LEONTINI, CHINTHAKA JACOB, Swinburne University of Technology, DAVID TINGAY, Murdoch Children’s Research Institute — High-frequency ventilation (HFV) is a technique used to ventilate neonates and patients with critical respiratory distress syndrome. It uses very fast yet shallow inflations, resulting in small peak pressures, thereby protecting lungs from over-distension. There are several mechanisms proposed for the gas transport during HFV, and here we investigate two of the primary ones; turbulent mixing and mean streaming. We have conducted direct numerical simulations of these high-frequency reciprocating flows in 1:2 bifurcations with geometric proportions relevant to the first five generations of the neonatal airway. Conditional turbulence is observed in the first three generations of the airway, the turbulence occurring when the flow rate is near its maximum. The results suggest this turbulence is generated via an instability of the Dean vortices generated via the curvature of the bifurcation. This mechanism differs from that which leads to conditional turbulence in the reciprocating flow in a straight pipe. We also quantify the recirculating flow rate due to mean streaming and find it to be around 5% of the maximum flow rate in the upper airway - this is enough to provide adequate gas exchange during HFV.

6:21PM P30.00006 Effect of fluid properties and impact speed for ophthalmic drug delivery via droplet impact. IDERA LAVAL, Texas Tech University, PEDRO MALLET, Universidade Federal Fluminense, JEREMY MARSTON, Texas Tech University — Front-of-the-eye (FOTE) delivery is the most popular route for administering drugs to the eye (i.e. ophthalmic delivery), with dropper bottles constituting a vast majority of the current market. These are notoriously inefficient and dictate the need for innovative devices to deliver discrete volumes to the eyeball. In addition, to promote adhesion many novel formulations incorporate polymers, leading to complex fluid properties. However, the fluid dynamics of this process and the specific role of fluid rheology combined with the pre-existing tear film are not well understood. Here, we will present preliminary results on delivery of polymeric solution using droplets, and discuss the effect of rheology, impact speed, substrate curvature, and evaluate universal scaling laws to capture the dynamics.

6:34PM P30.00007 Effect of applied load and jet dispersion on efficiency of needle-free injections. PANKAJ ROHILLA, JEREMY MARSTON, Texas Tech University — Intradermal delivery of vaccines with the jet injections is one of the leading alternatives to the needle injections for needle free drug delivery. However, effect of various parameters related to nozzle geometry, fluid properties and skin properties are still not well understood. In addition to design parameter such as the orifice diameter, jet speed, ampoule volume, and standoff distances, we must also consider applied load of the device on the skin, skin tension, and jet collimation. These three parameters are studied herein using an ex-vivo model (guinea pig and human skin). We investigate the effect of the skin support, viscosity of the liquid injected, ampoule volume, standoff distance and loading mechanism on the dispersion of the vaccine and the drug delivery efficiency into the skin.

6:47PM P30.00008 Patient-specific analysis of esophageal transport using barium swallow fluoroscopy. SOURAV HALDER, Theoretical and Applied Mechanics, Northwestern University, SHASHANK ACHARYA, Mechanical Engineering, Northwestern University, WENJUN KOU, JOHN ERIK PANDOLFINO, PETER J. KAHRILAS, Feinberg School of Medicine, Northwestern University, NEELESH ASHOK PATANKAR, Mechanical Engineering, Northwestern University, Theoretical and Applied Mechanics, Northwestern University — Barium swallow is an X-ray test for diagnosis of esophageal disorders such as achalasia, diverticula, dysphasia, gastroesophageal reflux disease (GERD) etc. This test gives a qualitative idea of how efficiently a bolus is transported through the esophagus. We have developed a technique by which we can analyze a barium swallow fluoroscopy and calculate the velocity and pressure distribution inside the esophagus. In this technique, we use a Convolutional Neural Network to perform segmentation of image sequences generated from a fluoroscopy, and use these segmented images as input to a reduced-order model to calculate the velocity and pressure in the fluid inside the esophagus. We have also used this method along with High Resolution Manometry (HRM) to identify and estimate biomarkers such as wall-relaxation that occurs ahead of the peristalsis wave in the esophagus wall. This reduced-order model can run very fast, and hence can be used in clinical applications to add more quantitative information to the barium swallow test, thus resulting in better diagnosis of esophageal disorders.

7:00PM P30.00009 Flow in a cavity: fluid mechanics of kidney stone removal, JESSICA G. WILLIAMS, SARAH L. WATERS, DEREK E. MOULTON, BEN W. TURNERY, ALFONSO A. CASTRÉJÓN-PITA, University of Oxford — Flexible uretero-renoscopy provides a minimally invasive treatment for kidney stone removal. The ureteroscope is passed to the kidney through a hollow cylinder (access sheath) and has a central lumen (working channel) for surgical tools, such as laser fibres which pulverise stones. Resulting stone dust can impede the view from a miniscule camera at the scope tip; this necessitates irrigation – debris clearance by saline solution, which flows into the kidney through the working channel, and returns via the access sheath. Fast debris clearance allows for efficient ureteroscopy. We represent the renal pelvis of the kidney as a 2D rectangular cavity and investigate the effects of flow rate and cavity size on flow structure and subsequent clearance time. We model fluid flow with the steady Navier-Stokes equations, imposing a Poiseuille profile at the inlet boundary for the jet of saline, and zero-stress on the outlets, allowing for a parallel return flow. Resulting flow patterns in the cavity contain competing vortical structures. We demonstrate the existence of multiple solutions dependent on the Reynolds number of the flow and the aspect ratio of the cavity. We complement numerical predictions with PIV experiments. We model the clearance of an initial debris cloud via an advection-diffusion equation. We determine how the initial position of the debris cloud within the flow, and the Peclet number, affect clearance time, which is prolonged by entrapment of debris within closed streamlines. We discuss flow manipulation strategies to extract debris from vortices and decrease washout time.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P31 Biological Fluid Dynamics: Vesicle and Micelles I

5:16PM P31.0001 Patchy Vesicles Tremble Before a Flow, PRERNA GERA, University of Wisconsin-Madison, DAVID SALAC, University at Buffalo, The State University of New York, SAVERIO SPAGNOLIE, University of Wisconsin-Madison — Biological membranes, and recently engineered synthetic vesicles, may be host to numerous components which provide spatially varying material properties such as spontaneous curvature and bending rigidity. We will discuss the dynamics of a two-dimensional vesicle with such spatially varying material properties in a shear flow. Using small amplitude asymptotics and full numerical simulations, we pay special attention to the role of variable bending stiffness. Reduced-order models are derived and used to accurately predict phenomena ranging from low wavenumber breathing modes to highly oscillatory trembling modes.

5:29PM P31.0002 Non-contact Mechanical Characterization of Extracellular Vesicles with Raman Spectra Interpretations, JOANNA DAHL, University of Massachusetts Boston — Cells exchange information by secreting micro and nanosized extracellular vesicles (EVs) ranging in size from 30nm to 5um. While it was once thought these cell-derived membranous vesicles were simply cell debris, recent efforts have determined that EVs have profound biological significance and therefore potential for clinical therapies and disease diagnostics. There is still much to understand about fundamental EV biological, physical, and chemical properties before clinical applications can be developed. The mechanical behavior of EVs—the physical implications of the lipid, protein, and nucleic acid constituents and their arrangements, all of which are linked to EV biological signature, cell of origin, and mode of biogenesis—has hardly been explored. To date, EV mechanical properties have been measured with atomic force microscopy with its problematic adhesion and hard substrate effects for small, soft EVs. We present mechanical property measurements of single microscale EVs derived from human blood plasma using a non-contact microfluidic technique. Raman spectra are used to interpret the mechanical property measurements through analysis of protein and lipid composition and structures.

5:42PM P31.0003 Non-equilibrium Dynamics of Initially Spherical Vesicles in Shear Flows, AFSOUN RAHNAMA FALAVARIJANI, DAVID SALAC, University at Buffalo — Many vesicles have a spherical resting shape and exposure to shear flows induces an exchange between the suboptical/thermal fluctuations and system deformation, with the total area being conserved. Here, the dynamics of such vesicles is numerically explored. Unlike other models, we do not begin with a deflated vesicle. By taking into account the membrane fluctuations, our model allows for an increase in the apparent area of the vesicle which introduces an isotropic tension force on the membrane which grows exponentially with the change in the area in low tension regime. Our results, such as the viscosity-dependence of the tank-treading, breathing/trembling, and tumbling regimes, are in good quantitative agreement with experimental observations.

5:55PM P31.0004 Light-induced Non-pulsatile Bursting of Lipid Vesicles, VINIT KUMAR, University of Illinois at Urbana-Champaign, SANGWOO SHIN, University of Hawaii at Manoa, JIE FEŃG, University of Illinois at Urbana-Champaign — Lipid vesicles are topologically closed compartments bounded by semi-permeable lipid shells. Upon exposure to a hypertonic bath, vesicles respond with remarkable swell-burst events, showing oscillations in vesicle size and pore formation. Such lysis has been extensively harnessed to study dynamics of biological membranes, as well as releasing encapsulated actives for targeted drug delivery. Recently, some studies show osmotic shock by light-induced reactions achieves fast release of vesicle contents via an explosion process, e.g., irreversible bursting, yet the rationale for this is missing. Here we present a fundamental and quantitative understanding of bursting dynamics through a comprehensive theoretical model. Our model accounts for the kinetics of light-triggered reactions inside vesicles while considering the stochastic nature of pore nucleation by incorporating activation energy based on the vesicle expansion rate. The model quantitatively captures features of irreversible bursting dynamics, with good agreement between experimental observations and model predictions. Our work furthers a fundamental framework for nonequilibrium vesicle dynamics under osmotic stress induced by chemical reactions, offering design guidelines for vesicle-encapsulated substance release.
6:08PM P31.00005 Hydrodynamic stability of moderately-deflated, giant unilamellar vesicles in general linear flows. VIVEK NARSIMHAN, CHARLIE LIN, Purdue University — In this talk, we perform boundary element simulations to describe the shape and stability of osmotically deflated vesicles in a wide range of flows. The first half of this talk recaps vesicle dynamics in purely extensional flows, which are commonly found in contractions/expansions and/or suction flows. Above a critical flowrate, we find that moderately deflated vesicles undergo an asymmetric shape instability that looks fundamentally different than droplet breakup. The physical origins of such vesicle shapes are discussed in detail and compared with microfluidic experiments. In the second half of the talk, we discuss vesicle stability in a general linear flow that contains both vorticity and extension. We find that the critical capillary number for vesicle instability diverges as one moves from pure extension to pure shear, which suggests that vesicles are incredibly hard to break in pure shear flow. We also find that the vesicle’s interior viscosity plays little role in its stability, which is quite different than what is observed for droplets. We provide physical explanations for these observations by examining membrane tension profiles and using geometric scaling arguments. We will conclude by showing preliminary data of vesicle shapes in oscillatory flows.

6:21PM P31.00006 Break-up of synthetic capsule in shear flow. SEYEONG JEONG, DEEGYOUM KIM, KAIST — A capsule, a thin elastic membrane enclosing inner material such as colloid, has been used in diverse fields including drug delivery, cell encapsulation and cosmetics. The structural robustness of the capsule comes to an important issue for drug delivery because hydrodynamic shear stress acting on the membrane surface of the capsule in microcirculation environment may cause severe deformation and burst of the capsule. Previously, many studies have focused on the rheological behavior of the capsule immersed in simple flows such as shear flow, extensional flow or Poiseuille flow in small and moderate ranges of shear rate. However, little is known for the deformation of a capsule in high shear rate and furthermore its break-up phenomenon. For the break-up of a capsule in simple shear flow, experiment is performed with a flow rheoscope, and a capsule based on Human Serum Albumin is prepared. The capsule is modelled as a 2D thin shell by adopting the concept of hyperelasticity. The deformation and fracture of a capsule and the resultant stress distribution on the capsule surface are investigated by changing the mechanical properties of the capsule and the shear rate of the flow.

6:34PM P31.00007 ABSTRACT WITHDRAWN –

6:47PM P31.00008 Dynamics of highly deformed non-spherical vesicles in steady and time-dependent flow. DINESH KUMAR, CHANNING M. RICHTER, CHARLES M. SCHROEDER, Department of Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign — In this work, we study the non-equilibrium dynamics of vesicles in precisely-defined steady and time-dependent extensional flow. Using Stokes trap, we directly observe non-equilibrium vesicle shapes as a function of reduced volume \( \nu \), viscosity contrast \( \lambda \), and Capillary number \( \text{Ca} \) using fluorescence microscopy. Vesicles are found to deform through a wide-range of interesting shapes in flow, including asymmetric and symmetric dumbbells, in addition to pearling, wrinkling, and buckling instabilities depending on membrane properties. Using this approach, we determine the flow phase diagram for vesicles in \( \nu-\text{Ca} \) space. Our results show that the steady-state deformation of vesicles exhibits power-law behavior as a function of reduced Capillary number. We identify two distinct relaxation processes for vesicles stretched to high deformation, revealing two characteristic time scales: a short time scale corresponding to bending relaxation and a long-time scale dictated by the relaxation of membrane tension. We further discuss the dynamics of single vesicles in sinusoidal oscillatory extensional flow as a function of \( \text{Ca} \) and Deborah number.

7:00PM P31.00009 Collision of two deformable torque swimmers. HITOMU MATSUI, TOSHIHIRO OMORI, TAKUII ISHIKAWA, Dept. Finemechanics, Tohoku University — Understanding the property of a micro-organism suspension is important in bio-engineering. When the suspension is non-dilute, micro-organism interacts with each other and these interactions are governed by the hydrodynamical and biological features. Former studies focusing on cell-cell interaction have unveiled the hydrodynamical effect, however, contribution of cell’s deforming during the interaction is still unknown. Moreover, biological reaction, for example avoiding and escape reactions of a random effect, can react the suspension to affect the suspension to be initiated by mechanical stimuli imposing over cell membrane. Thus, analyzing membrane tension should help to understand the mechanism of ciliate biological responses. In this study, to investigate the contribution of deformation and membrane condition while two swimmers interact, we numerically simulate cell-cell interaction by applying a deformable ciliate model. We modeled a ciliate body as a deformable capsule and thrust forces generated by the ciliary beat as torque distribution. Owing to the tiny cell size of ciliate, fluid is regarded as Stokes flow. We computed a variety of collisions with different geometry and cell’s deformability, and then analyzed the trajectory and membrane tension. We found deformability affects the trajectory and clarified membrane tensions differ among the geometries. These results allow us to discuss the sensing ability of ciliate in the suspension.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P32 Biological Fluid Dynamics: General III

5:16PM P32.00001 Hydrodynamics of interphase chromatin. ACHAL MAHAJAN, University of California San Diego, WEN YAN. Center for Computational Biology, Flatiron Institute, New York, ALEXANDRA ZIDOVSKA, Center for Soft Matter Research, Department of Physics, New York University, MICHAEL J. SHELLEY, Center for Computational Biology, Flatiron Institute, New York and Courant Institute of Mathematical Sciences, New York University. DAVID SAINTILLAN, University of California San Diego. — Recent spectroscopy experiments on interphase chromatin have uncovered the existence of long-ranged coherent sub-diffusive motions on the scale of microns and persisting for seconds. These motions were found to be ATP-dependent suggesting the involvement of molecular motors. Motivated by these observations, we use Brownian dynamics simulations to elucidate the effects of microscale activity on the behavior and spatiotemporal dynamics of long flexible polymer chains in viscous solvents. We develop a coarse-grained model where active events are modeled as stochastic force dipoles, which drive long-ranged fluid flows inside an ellipsoidal nucleus. Numerical simulations based on a boundary integral formulation along with a kernel-independent fast multipole method demonstrate the key role played by hydrodynamic interactions and topological constraints in driving large-scale motions and chromatin reconfigurations.

5:29PM P32.00002 Application of a High-Speed Plenoptic Camera for 3D Measurements in Small-Scale Biological Flows  
ZU PUAYEN TAN, RICHARD ALARCON, JOHANNES ALLEN, BRIAN S. THUROW, ANTHONY MOSS, Auburn University, ADVANCED FLOW DIAGNOSTICS LAB TEAM, MOSS BIOLOGICAL SCIENCES LAB TEAM — The application of conventional multi-camera tomographic-PIV and related 3D techniques to study biological flows remains limited due to their expense, complexity and bulk. This is particularly true for small experiments (e.g., heart-valve and micro-swimmer) or portable setups (e.g., carried by divers in open-water measurements) where equipment footprint is a critical constraint. In this presentation, we propose single-camera plenoptic-PIV as an attractive alternative to the standard multi-camera techniques. Specifically, a modular kHz-rate plenoptic camera newly developed at Auburn University will be introduced. The system, composed of a single main-lens, a microlens adaptor and an off-the-shelf high-speed camera, was used to characterize unsteady 3D flows around a 2cm ctenophore Mnemiopsis in a 71x40x34mm volume. Various 3D flow features such as the creature’s downwash and intermittent vortex-ejections were successfully captured. These will be presented to showcase the plenoptic system’s capabilities for measuring small-scale biological flows.

5:42PM P32.00003 Visualizing flow inside a bone porous medium using an MRI machine 1, 2, 3, 4  
SUUYE HAN, TODD CURRIER, University of Massachusetts Amherst, MAHDIAR EDRAKI, Northeastern University, BOUYAN LIU, University of Massachusetts Amherst, MAUREEN LYNCH, University of Colorado Boulder, YAHYA MODARRES-SADEGHI, University of Massachusetts Amherst — We have used Phase-Contrast Magnetic Resonance Imaging (PC-MRI) flow measurement to quantify flow inside a 3D-printed artificial scaffold model to understand the flow behavior inside the 3D model of bone metastasis due to an applied perfusion. In order to perform the test using an MRI machine, a nonmagnetic water tunnel was designed and built. A 3D surface model created from a micro-CT scan of an artificial scaffold model was used to make the 3D-printed scaffold model. The 3D-printed scaffold was placed in the test section of the water tunnel inside the MRI machine. The flow velocity was varied over a range and images were captured using the MRI machine. The phase and magnitude data from the MRI experiment were then processed using an in-house code to quantify the flow inside the scaffold.

5:55PM P32.00004 A mathematical framework for developing freezing protocols in cryopreservation  
MOHIT DALWADI, SARAH WATERS, HELEN BYRNE, IAN HEWITT, University of Oxford — Cryopreservation is the process of preserving biological constructs by cooling to temperatures low enough to halt biochemical processes, such as metabolism. This allows biomaterials to be kept in 'suspended animation', with important applications in tissue engineering, fertility, and food security. However, many freezing protocols have low recovery rates. In general, cooling too quickly results in the formation of lethal intracellular ice, while cooling too slowly amplifies the toxic effects of the cryoprotective agents (CPA) added to limit ice formation. In this talk, we present a mathematical model for cryopreservation to understand and quantify these observations. We consider a system consisting of three different regions: ice, extracellular liquid, and intracellular liquid. The two interfacial boundaries separating the three phases can move and must be determined as part of the solution. The presence of CPA lowers the freezing point of the system, and the cell membrane moves due to the osmotic pressure difference across the membrane. We introduce two metrics to characterize the cell damage caused by freezing, accounting for supercooling and CPA toxicity. Given cell properties, we show how these damage metrics can be used to predict an optimal cooling rate.

6:08PM P32.00005 Characterization of mucus macro-rheology from the silver carp, Hypophthalmichthys molitrix 1, 2  
KARTIK V BULUSU, SAMANTHA RACAN, L PATRICIA HERNANDEZ, MICHAEL W PLEŚNIAK, The George Washington University — The silver carp, Hypophthalmichthys molitrix is a planktovorous filter feeder fish introduced to control algal blooms in natural waterways of the US. Since the early 1970s this invasive species has infested the Mississippi River basin. Its extraordinary feeding-efficiency is attributed to two unique organs viz., (i) the gill rakers (GR) and (ii) the palatal folds that enable capturing of food particles through the porous GR membranes. The GR mucus has the potential to enhance the filter feeding process by functioning as an adhesive and a transport vehicle for food particles. It is a gel-like, complex biological fluid that responds to external force and comprises a macromolecular network of glycoproteins (or mucins). Viscoelasticity and steady-state viscosity of the GR mucus of silver carps obtained from Hart Creek, Missouri River were investigated using a rheometer (DHR-2, TA Instruments) with cone geometry (1-deg., 40 mm dia.) and a Peltier plate. A digital camera attachment (546800.902, TA Instruments) was used to monitor microstructure changes. These experiments are aimed at understanding the role of mucus-laden fluid flow through porous GR channels and ultimately, the tremendous success of the silver carp in outcompeting native fish species.

6:21PM P32.00006 Self-organization of microtubules in cell-sized droplets 1  
YA GAI, Mechanical and Aerospace Engineering, Princeton University, SAGAR SEtru, Lewis-Sigler Institute for Integrative Genomics, Princeton University, BERNARDO GOUVEIA, HOWARD STONE, Mechanical and Aerospace Engineering, Princeton University, SABINe PETRY, Molecular Biology, Princeton University — We combine droplet microfluidics and cell-free biological systems to examine the effect of confinement and nucleation on the assembly of microtubule (MT) networks. Central to the spindle assembly is the spatial organization of MTs, a long tubular structure formed through the polymerization of tubulin dimmers. Such organization is regulated by RanGTP, a GTPase associated with chromosomal activities and acting as part of a major nucleation pathway for MTs. RanGTP has been explored using Xenopus egg extracts, a model cell-free system for probing spindle assembly. Most extract-based assays were performed in a test tube where cell-sized confinement was missing. Therefore, we asked whether confinement can affect the MT networks. We used droplet microfluidics for encapsulating extract-based assays by generating monodisperse, extract-in-oil droplets. By varying droplet diameters and encapsulated Ran concentrations, we demonstrate that these two physical factors regulate the assembly of MT networks. Together, the two factors yield MT networks with various steady-state architectures. Our results highlight the prominent role of MT nucleation in the self-organization of MTs in cell confinement and might have direct implications in nucleation-controlled soft matter processing.

6:34PM P32.00007 Stokes’ law in complex liquids and inside cell cytoplasm 1  
KAROL MAKUCH, California Institute of Technology, ROBERT HOLYST, TOMASZ KALWARCZYK, PIOTR GARSTECKI, Institute of Physical Chemistry, Polish Academy of Sciences, JOHN F. BRADY, California Institute of Technology — The ‘viscosity’ experienced by a small tracer particle in complex liquids depends both on its size and on the structure of the liquid, which itself may contain different length scales. Thus, in a microenvironment the complex liquid may best be described by wave-vector-dependent viscosity $\eta(k)$. Here we derive Stokes’ law in complex liquids and formulate a method to determine the wave-vector-dependent viscosity from microrheological experimental data. We initiate our approach by determining the wave-vector-dependent viscosities $\eta(k)$ of HeLa and Escherichia Coli cell cytoplasm from the experimental data on diffusion of macromolecules in these systems. Determination of this quantity opens an avenue for computer simulations of motion and biochemical reactions inside living cells.

6:47PM P32.00008 Freshwater Copepod Behavior in Turbulent Eddies. M. RUSZCZYK, D.R. WEBSTER, J. YEN, Georgia Tech — Previous studies have shown that marine copepod behavior is modulated by turbulence. We seek to expand on this observation by investigating a freshwater species, *Hesperodiaptomus shoshone*, and how it responds to small-scale turbulent vortices. The calanoid copepod *H. shoshone* is a dominant predator in high-altitude alpine lakes, ranging from 2-4 mm in length. The Burgers vortex model was used to simulate dissipative eddies with four levels of turbulent dissipation rates ranging from 0.002-0.25 cm$^2$/s$^3$, mimicking turbulent conditions found in natural habitats. Tomographic PIV was used to quantify the vortex circulation and axial strain rate of the vortices. *H. shoshone* males and females were separately exposed to the four Burgers vortex treatments in a horizontal axis orientation plus a stagnant fluid control treatment. In comparison to the morphologically-similar marine copepod *Calanus finmarchicus*, *H. shoshone* appears minimally responsive to the Burgers vortex. *H. shoshone* swimming speeds remained similar under different turbulence conditions, showed no circular trajectories, and made minimal attempts to escape the vortex. These results were consistent between males and females and suggest *H. shoshone* are not responsive to hydrodynamic cues of the vortex structure. The contrasting behavior will be discussed in the context of the ecology and environmental conditions of the different habitats.

7:00PM P32.00009 Computational Investigations on Flow-mediated Transport Processes at the Blood-thrombus Interface. DEBANJAN MUKHERJEE, University of Colorado Boulder — Pathological clotting of blood, referred to as thrombosis, is the primary cause of diseases like stroke and heart-attack which are associated with significant morbidity and mortality. Thrombus (blood clot) formation, and its behavior, is governed by multiple underlying physiological processes which are intimately related to flow and transport. Of specific importance is the role of transport processes near the blood-thrombus interface, and permeation of biochemical species (drug or coagulation factors) into the thrombus. Here we present the latest developments in our investigations into creating a computational multi-physics modeling framework for thrombus biomechanics and bio-transport. Our framework is based on a combination of Galerkin stabilized finite element method, and Lagrangian particle based approach. We have employed our framework to conduct a range of computational experiments to illustrate flow mediated near thrombus transport using thrombus models reconstructed from microscopy image data. We will present results from our computational investigations into: (a) the role of blood-thrombus interface properties on transport; (b) biochemical species permeation across the thrombus interface; and (c) subsequent influence on intra-thrombus transport.

Monday, November 25, 2019 5:16PM - 7:00PM — Session P33 Flow Instability: Boundary Layers 615 - Philipp Hack, Stanford University

5:16PM P33.00001 High-speed linear analysis of a blunt cone. TIM FLINT, PARVIZ MOIN, M. J. PHILIPP HACK, Center for Turbulence Research, Stanford University — Transition to turbulence critically affects heat transfer towards the walls in the flow over high-speed vehicles. We seek to identify the mechanisms which govern the receptivity and amplification of disturbances in the boundary layer on a blunt cone at Mach 6 by means of global linear analysis. The approach directly captures the influence of the bow shock wave as well as the geometry of the blunt nose of the cone. Two families of modes are computed, and their spatial structure is characterized. One group of modes extend beyond the boundary layer and interacts with the vortical post-shock flow near the cone tip. The other describes acoustic emissions and decays in the free-stream. The receptivity of the modes is directly captured in their corresponding adjoint eigensolutions. receptivity is highest upstream of the bow shock near the cone axis. The computations are performed using a curvilinear framework with shock capturing and continuous, discretely consistent formulations of the linearized and adjoint linearized governing equations.

5:29PM P33.00002 Study for Wall-shear Stress of Pulsatile Flows in 3-D Ducts. XIAOYU ZHANG, SYEEDALIREZ ABOOTORABI, Mechanical and Energy Engineering, Indiana University-Purdue University, Indianapolis, HIROKI YOKOTA, Biomedical Engineering, Indiana University-Purdue University, Indianapolis, INDIANPOLIS, HUIDAN YU, Mechanical and Energy Engineering, Indiana University-Purdue University, Indianapolis — Understanding wall shear-stress (WSS) in human tissues and organs such as blood vessels and synovial bursa is critically important in the prevention, pathogenesis, and treatment of varying diseases. Numerical simulation provides a unique tool for a fast and non-invasive quantification of WSS in realistic flows. We use a GPU-accelerated volumetric lattice Boltzmann method (VLBM) to assess WSS of pulsatile flows in 3D ducts with circular and rectangular cross sections. The computational results are validated through the comparisons with analytical solutions of Womersley flows in the two ducts. From the analytical solutions of Womersley flow, driven by pressure gradient $\partial p/\partial r=P_0+P_0 e^{i\omega}$, we observed that the WSS is linear to the magnitude of the unsteadiness ($P_0/P_0$). Preliminary analysis indicates that the WSS is promoted/suppressed with small/large Womersley number. The effects of pulsation in more realistic pulsatile pipe flows with and without turbulence will be further examined and presented.

5:42PM P33.00003 Hypersonic boundary layer transition over curved-walls: A mechanism based on Gorlter vortices. ANUBHAV DWIVEDI, University of Minnesota, GS SIDHARTH, Los Alamos National Lab, GRAHAM V CANDLER, University of Minnesota, MIHAILO R JOVANOVIC, University of Southern California — We investigate amplification of small disturbances in compressible boundary layers on a flat plate with a concave flare. To understand mechanisms that trigger the transition in the boundary layer flow over a curved wall, we utilize input-output analysis to quantify the receptivity of flow fluctuations to exogenous disturbances. Our analysis identifies Gorlter vortices as the most amplified flow structures and provides insights into mechanisms that select the dominant spanwise wavelength. The effect of wall heat transfer on the growth of boundary layer perturbations is also explored. Furthermore, we complement the input-output analysis with direct numerical simulations to investigate the non-linear stages of the disturbance evolution. Since Gorlter vortices are often responsible for boundary layer transition on curved walls, methods to attenuate early stages of their amplification are also analyzed and their effectiveness is discussed.

Interfacial instability in an azimuthally oscillatory two-layer fluid of oil and water1. LINFENG PIAO, HYUNGMIN PARK, Seoul National University — There are interfacial instabilities occurring in multi-layer flows, which are of practical importance in many industrial processes, such as coating, solvent extraction and oil recovery. Especially, these instabilities could be significantly influenced by the external perturbation, e.g., oscillating forcing. In this study, we present experimental results concerning the stability of oscillatory two-layer fluid in a vertical cylinder vessel, using a high-speed imaging. Two immiscible fluids (oil and water) with a relatively low viscosity contrast (~100), are superposed in the vessel and the oscillating frequency and angular amplitude are varied by 0.1-7.0 Hz and 45-180 degrees, respectively. We measure the evolution of the oil-water interface during the oscillation and identify the wavenumber of the disturbances is much smaller than both wall-normal and spanwise wavenumbers. The base flow is excited either by freestream disturbances imposed at the upstream boundary or by disturbances from the wall in the form of wall transpiration. An extensive parametric study is performed in different flow conditions to assess the development of these streaky structures.

Nonlinear spatial marching of high-amplitude perturbations1. SHAUN R. HARRIS, M. J. PHILIPP HACK, Center for Turbulence Research, Stanford University — The physics of bypass transition are closely related to the formation of highly energetic streaks within the boundary layer. Owing to the high amplitudes of the streaks, nonlinear interactions and the generation of harmonics play an important role in their development, as well as in triggering their secondary instability. The high amplitudes attained by the streaks also pose unique challenges for their computational modeling. While the nonlinear parabolized stability equations have been shown to accurately describe the exponential amplification of disturbances in classical transition scenarios, they inadequately capture the formation of streaks and the associated generation of perturbation harmonics. In this talk, we present a novel framework for the nonlinear spatial marching of high-amplitude perturbations. In comparisons with direct numerical simulations, we demonstrate the accuracy of the approach in predicting the growth of high-amplitude streaks. The computational cost of the method is comparable to that of the established nonlinear parabolized stability equations.

Session P34 Flow Instability: Interfacial and Thin Film Fingering 616 - Dominique Legendre, IMFT

5:16PM P34.00001 Linear Stability Analysis of Radial Miscible Viscous Fingering . MANORANJAN MISHRA, VANDITA SHARMA, Indian Institute of Technology Ropar, INDIA, SATYAJIT PRAMANIK, University of Oxford, CHING-YAO CHEN, National Chiao Tung University, Taiwan — Viscous fingering (VF) is a hydrodynamic instability ubiquitous during the displacement of a more viscous fluid by a less viscous one in a porous medium or Hele-Shaw flow. We perform a state-of-the-art linear stability analysis (LSA) of miscible VF with a radial flow. The LSA provides an alternate approach to study time dependent linear system arising in miscible VF. The time dependent base state is calculated numerically using the method of lines. The evolution of the disturbances is studied relative to the time dependent base state using momentary stability. Growth rate is adequately defined to take into account the radial source flow. The LSA captures the competition between advective and diffusive forces during the initial stages of radial VF and gives an insight into the effect of the competition on the onset of instability. The results are verified by performing the experiments and non-linear simulations.
5:29PM P34.00002 Immiscible Fingering Instability via Alternating Injection: Experiments and Simulations
CHI-CHIAN CHOU, WEI-CHENG HUANG, CHING-YAO CHEN, Department of Mechanical Engineering, National Chiao Tung University, Taiwan, R.O.C. — Viscous fingering instability on an immiscible interface via alternating injection is investigated by both experiments and numerical simulations. Multiple fluid annuluses associated with unstable and stable interfaces are resulted by injecting the less and more viscous fluid alternatively. We focus on the influences of two control parameters, e.g., the alternating injection interval and viscosity contrast, to the development of fingering instability. It is interesting to observe less prominent instability, determined by the injection interval and the viscosity contrast, as the interface grows. The results are inconsistent with the conventional continuous injection. This inconsistent behavior is mainly due to rupture of the fluid annuluses of the less viscous fluid. Because of surface tension, the ruptured less viscous fluids tend to form separated drops, so that the total interfacial length decreases. On the other hand, the fluid annuluses appear more stable in the cases of lower viscosity contrast, so that the annuluses are stretched to prolong the overall interfacial length.

5:42PM P34.00003 Pattern Formation from Instabilities in Chromonic Liquid Crystals
IRMGARD BISCHOFFBERGER, QING ZHANG, MIT, SHUANG ZHOU, UMass Amherst — The displacement of a more viscous fluid by a less viscous one in a quasi-two-dimensional geometry leads to the formation of complex fingering patterns. In isotropic systems, disordered dense-branching morphologies arise from repeated tip-splitting of the evolving finger. In anisotropic systems, by contrast, the growth morphology changes to a highly ordered dendritic growth characterized by stable needle-like protrusions decorated with regular side-branches. We investigate such morphology transitions between dendritic growth and dense-branching growth in an intrinsically anisotropic liquid; a lyotropic chromonic liquid crystal in the nematic phase. We show that the transition is remarkably sensitive to the interface velocity and the viscosity ratio between the less-viscous inner fluid and the more-viscous outer liquid crystal. We discuss the importance of a stable shear alignment of the liquid crystal in governing the morphology transition to dendritic growth.

5:55PM P34.00004 Rivulet formation in falling liquid films
GIANLUCA LAVALLE, JULIEN SEBILLEAU, DOMINIQUE LEGENDRE, Institut de Mécanique des Fluides de Toulouse (IMFT), Toulouse, France — When a thin liquid film falls down an inclined or vertical plane, a capillary ridge develops behind the advancing contact line. For sufficiently thick ridges, rivulets appear as a result of the contact-line instability. The formation of such complex liquid structures might degrade the performances of several industrial applications, such as coating, aerodynamic efficiency and chemical processes. We investigate the dynamics of liquid films of partially wetting fluids falling down a vertical plane. We are particularly interested in the fingering instability and the distribution of rivulets. Based on direct numerical simulations, we study the influence of initial contact-line perturbations and pre-existing surface contaminations upon the fingering topology. Interestingly, varying the wave-number of the initial sinusoidal contact-line perturbation leads to different rivulet topologies and root velocities. Meanwhile, the presence of a pre-existing sufficiently large drop forces the formation of a rivulet where the drop and the contact line interact, thus destroying the symmetry of the flow. Finally, we discuss the wetted area for several drop arrangements.

5:55PM P34.00005 Stability and fingering of radial flows
JOHN LISTER, FREDERIK DAUCK, University of Cambridge — A pool of honey spreading on a horizontal surface becomes axisymmetric, but radial flow in a Hele-Shaw cell is unstable to fingering if the injected fluid is sufficiently less viscous than the ambient. Why the difference? Radial geometries offer a distinct advantage for the analysis of fingering instabilities of spreading flows in that the azimuthal wavenumber remains constant and thus self-similarity methods can be employed. Several problems of this sort are described. For example, it is shown analytically that viscous gravity currents, with power-law injection and power-law flux relationship $q = -h^n \nabla h$, are stable. And it is shown by analysis of a self-similar kinematic wave that Hele-Shaw flows of miscible fluids at infinite Peclet number are unstable if and only if the viscosity ratio exceeds 3/2.

6:21PM P34.00006 Fingering Instabilities in Oxidizing Eutectic Gallium-Indium
KEITH HILLAIRE, North Carolina State University, WILLIAM LLANOS, Chicago State University, MICHAEL DICKEY, KAREN DANIELS, North Carolina State University — Eutectic gallium-indium (eGaIn), a room-temperature liquid metal alloy, has the largest tension of any liquid at room temperature, and yet can nonetheless undergo fingering instabilities. This effect arises because, under an applied voltage, an oxide builds up on the surface of the metal. The oxide acts like a surfactant, lowering the surface tension and allowing spreading under gravity. In the experiments described here, we examine the hypothesis that fingering instabilities, including tip-splitting, arise due to Marangoni instabilities. Our experiments are performed with eGaIn droplets placed in an electrolyte bath of sodium hydroxide; by placing the eGaIn on copper electrodes, which eGaIn readily wets, we are able to impose a fingering wavelength on the spreading. Two transitions are observed as a function of current: (1) a minimum current at which eGaIn spreads out from the copper electrode; (2) the current at which the fingers become unstable to shorter wavelengths and spread inhomogeneously. We present a phase diagram as a function of current and initial wavelength, and identify a minimum wavelength below which single tip-splitting does not occur.

6:34PM P34.00007 Delayed onset in viscous fingering
THOMAS VIDEBAEK, SIDNEY NAGEL, Department of Physics, University of Chicago — The viscous fingering instability occurs at the evolving interface between two viscous fluids confined to a thin gap. We investigate the onset of the instability in both radial and rectangular geometries for both miscible and immiscible pairs of fluids. In all four cases we observe a region of stable growth, $L_{\text{stable}}$, before fingers start to develop. While the initial stability in the radial cell has been ascribed to the velocity profile associated with point-source injection, this explanation is much too small to explain our observations. The region of stable growth before onset that we observe in the linear cell is unexpected. For miscible fluids, $L_{\text{stable}}$ can be tied to the distance it takes to form steady-state, interfacial structures in the gap. For immiscible fluids, where no internal structure is apparent, there is no obvious explanation for $L_{\text{stable}}$, which we find also depends on the capillary number. These results are not accounted for by current analyses of fingering dynamics. We suggest that this is because the experiments are by nature always quasi-two dimensional with an important length set by the gap size.

6:47PM P34.00008 Stabilization of viscous fingering in a partially miscible system
RYUTA SUZUKI, SHOJI SEYA, Tokyo University of Agriculture and Technology, TAKAHIKO BAN, Osaka University, MANORANJAN MISHRA, Indian Institute of Technology, Ropar, YUCHIRO NAGATSU, Tokyo University of Agriculture and Technology — Viscous fingering (VF) or Saffman-Taylor instability occurs when a less viscous fluid displaces a more viscous one in porous media or in Hele-Shaw cells. The classical VF can be divided into two; miscible and immiscible systems depending on whether two fluids are miscible or immiscible. In addition, it has been recently reported that a partially miscible VF has experimentally shown to change to multiple droplets pattern. However, in the present study, we have experimentally shown a partially miscible VF can have the potential to stabilize the interface more effectively, namely, leading to circular-like pattern in a radial geometry. This is considered to be caused by the two factors; a convection induced by spinodal decomposition directed from the more viscous fluid to the less viscous one and a high rate of the spinodal decomposition.
fingering formed by the injection of Newtonian surfactant solution can be used to contribute to the establishment of well-controlled processes for surfactant flooding and the recovery of residual NAPL in aquifers.

However, in the present study, phenomena contrary to these rules were observed: wider fingers occurred in the surfactant solution system compared to those in the water system, in the nonlinear stage of VF evolution, despite the fact that the capillary number had the same value for both systems. In addition, even though the surfactant system had a higher capillary number than the water system, wider surfactant fingers were observed. A possible mechanism explaining this is discussed by comparing with previous studies regarding VF with surfactants. The present study indicates that the capillary number does not control the nonlinear VF width in the surfactant system. Our results and discussion can be used to contribute to the establishment of well-controlled processes for surfactant flooding and the recovery of residual NAPL in aquifers.

Monday, November 25, 2019 5:16PM - 7:13PM
Session P35 Microscale Flows: Active Particles 617 - John Buchner, TU Delft

5:16PM P35.00001 MicroPIV measurements of flows induced by achiral microswimmers
JAMEL ALI, FAMU-FSU College of Engineering, LIYUAN TAN, XIANGCHENG SHI, Southern University of Science and Technology, DALHYUNG KIM, Southern Illinois University Carbondale, MIN JUN KIM, Southern Methodist University, U KEI CHEANG, Southern University of Science and Technology — We report on the low Reynolds number hydrodynamics induced by achiral microswimmers and analysis of their flow fields using particle image velocimetry. The flows produced by two types of rigid swimmers are examined. The first swimmer consists of three self-assembled magnetic beads bonded together with avidin-biotin complexes. The second swimmer consists of thin geometries in the shape of the letter ‘L’ produced through photolithography and thin-film deposition. Both swimmers were wirelessly actuated in precessing magnetic fields using electromagnetic coils positioned in an approximate Helmholtz configuration. A high speed camera was used to capture the motion of fluorescent seeding particles as well as track the rotation of the microswimmers. Analysis of microPIV data revealed microvortices produced during swimming, while the magnitude of the local flows scaled linearly with increasing rotation rate. The attractive and repulsive flows observed may be useful for applications such as non-contact micro manipulation and assembly/disassembly of modular swimmers.

1This work was funded by the National Natural Science Foundation of China (NSFC; 1850410516), Department of Education of Guangdong Province (2017KTSCX167), and Shenzhen municipal government (Peacock Plan, 20181119590C).

5:29PM P35.00002 Templated self-assembly of colloidal microswimmers
ANTOINE AUBRET, JEREMIE PALACCI, University of California San Diego — Biological living systems are prototypical examples of Active Matter. Cells, for instance, exist far from equilibrium behavior such as autonomous regulation or organization. Here, we show how we can carve non-equilibrium pathways for the controlled self-assembly of colloidal microswimmers using light as a tool. We use photocatalytic colloidal microparticles as primary building blocks for self-assembly. We specifically designed the particles to self-propel, and sense light gradients. Following sequential light-patterns, the particles autonomously assemble into robust self-spinning structures, or microgears. The gears interact with contactless ‘teeth’, synchronizing their motion. We characterize the interaction potential, and show that the synchronization originates from the coupling between the chemical clouds generated by the catalytic activity of the gears and the hydrodynamic interactions between their constituents. Following, the gears constitute the fundamental components of synchronized micro-machineries that auto-regulate and whose dynamics is tuned by the spins of their internal components. Our study demonstrates the potential of non-equilibrium interactions to program self-assembly of dynamical colloidal architectures.

5:42PM P35.00003 Steady streaming in a simple reciprocal swimmer
NICHOLAS DERR, CHRISTOPHER RYCROFT, Harvard University, DAPHNE KLOTSZA, University of North Carolina at Chapel Hill — While biolocomotion at high and low Re has been well-studied, swimming at intermediate Re ∼ 1–1000 — where both viscous and inertial forces are important — is less understood. Most previous investigations at intermediate Re have centered on individual species, implicitly focusing on a single example of the many ways such organisms self-propel. As a result, few underlying generic mechanisms that unify the many disparate intermediate-Re swimming methods have been identified. One possible such mechanism is steady streaming — the generation, due to inertial effects, of lower-order steady flow by periodic large-scale motion. In this talk, we examine the role of steady streaming in the locomotion of a simple reciprocal swimmer at intermediate Re. After asymptotically expanding the Navier–Stokes equations, we solve for time-periodic solutions to the resulting set of unsteady Stokes equations. We present the swimming speed and efficiency over a range of intermediate Re and comment on similarities to motility mechanisms at low Re.

5:55PM P35.00004 Life in the fast layer
ERNEST B. VAN DER WEE, Department of Physics & Astronomy, Northwestern University, BRENNAN SPRINKLE, Courant Institute of Mathematical Sciences, New York University, ISAIAH KATZ, Department of Physics & Astronomy, Northwestern University, MENA YOUSSEF, STEFANO SACANNA, Department of Chemistry, New York University, ALEKSANDAR DONEV, Courant Institute of Mathematical Sciences, New York University, MICHELLE M. DRISCOLL, Department of Physics & Astronomy, Northwestern University — Microrollers are rotating particles that become active close to a wall due to an asymmetric flow of the fluid around the particles. They can be experimentally realized by driving magnetic colloidal particles hovering above a wall with a rotating magnetic field. Introducing a small fraction of fluorescently labeled microrollers, we can measure their velocities using microscopy and particle tracking. We compare our results to high resolution Brownian dynamics simulations which include lubrication effects. The velocity of a microroller is much slower than the velocity of the fluid pumped around it. Therefore, a particle put in the flow field around a microroller will have a velocity much higher than the microroller itself. As a consequence, the average velocity of a suspension of microrollers increases as a function of their density. In addition, at higher densities the particles form two layers: a slow one close to the wall and a much faster one above it. We find that the microrollers switching between the slow and the fast layer, and characterize the lifetime of the particles in the two layers.

6:08PM P35.00005 Field flow on the interface induced by swimming and driven colloids1, MEHDI MOLAEI, JIA DIYI DENG, TIANYI YAO, NICHOLAS CHISHOLM, JOHN CROCKER, KATHLEEN STEBE, University of Pennsylvania — An active colloidal trapped on or near a fluid interface generates a complex flow field that differs from the bulk flow. The flow field depends on the modes of motion, the mechanics of the interface, and hydrodynamic coupling with the bulk fluids. To characterize the flow field, we introduce a method based on the correlated motion of active colloids and passive tracer particles. The challenge is to extract weak biased motions of probes via interaction with the active colloids given the noisy environment and significant Brownian displacement. We examine a gallery of active motions and their flow fields; we simultaneously measure the rheology of the interface. We first investigate a 2D bacterial suspension on an oil-water interface as a model active colloidal system. We analyze the flow field induced by pusher and puller bacteria (models of force dipoles) and “piroetting” bacteria (stationary rotlet dipoles) and driven magnetic microbeads (Stokeslets). The measurements are performed for the interfaces with different viscoelasticity. Tracer particle displacement fields at various lag times are compared to calculated displacement fields for hydrodynamic modes permitted in interfacial layers as a function of rheology and compressibility.

6:21PM P35.00006 Relating microswimmer synthesis to hydrodynamic actuation and rheotactic tunability1, ENKELEIDA LUSI, Department of Mathematics, New Jersey Institute of Technology, QUENTIN BROSSEAU, Courant Institute, New York University, FLORENCIO BALBOA USABIAGA, Flatiron Institute, YANG WU, New York University, LEIF RISTROPH, Courant Institute, New York University, JUN ZHANG, MICHAEL WARD, MICHAEL J. SHELLEY, New York University — We explore the behavior of micron-scale autophoretic Janus (Au/ Pt) rods, having various Au/Pt length ratios, swimming near a wall in an imposed background flow. We find that their ability to robustly orient and move upstream, i.e. to rheotax, depends strongly on the Au/Pt ratio, which is easily tunable in synthesis. Numerical simulations of swimming rods actuated by a surface slip show a similar rheotactic tunability when varying the location of the surface slip versus surface drag. Slip location determines whether swimmers are Pushers (rear-actuated), Pullers (front-actuated), or in between. Our simulations and modeling show that Pullers rheotax most robustly due to their larger tilt angle to the wall, which makes them responsive to flow gradients. Thus, rheotactic response infers the nature of difficult to measure flow-fields of an active particle, establishes its dependence on swimmer type, and shows how Janus rods can be tuned for flow responsiveness. We demonstrate the effectiveness of a simple geometric sieve for rheotactic ability.

6:34PM P35.00007 Mobility mechanisms condition the instabilities in active microdroplets1, MATVEY MOROZOV, SEBASTIEN MICHELIN, Ecole Polytechnique — Chemically active droplets submerged in the bulk of surfactant solution self-propel with straight, helical, or random trajectories. Here we employ numerical simulations to establish the link between the behavior of an active drop and its interfacial properties. To this end, we consider a drop that converts the gradients of surfactant concentration into flow via two different mobility mechanisms: diffusiophoresis and the Marangoni effect. The resulting surfactant advection is the only nonlinear effect and, thus, the only source of dynamical complexity in the model. Our numerical simulations indicate that strong advection may destabilize the regime of straight and steady self-propulsion. For axisymmetric flow, this instability results in a regime of symmetric extensile flow around a stationary droplet. If advection is strengthened further, chaotic oscillations may develop. In 3D, a drop driven by diffusiophoresis alone does not exhibit extensile flow and the random behavior emerges right after the steady self-propulsion becomes unstable. Our results reveal that the thresholds of these instabilities depend heavily on the balance between diffusiophoresis and the Marangoni effect.

6:47PM P35.00008 Direct Numerical Simulations of Electric Field Driven Hierarchical Self-assembly in Mixtures of Particles1, S. B. PILLAPAKKAM, Associate Professor, SUCHANDRA DAS, Student, EDISON AMAH, Research Engineer, IAN FISCHER, PUSHPENDRA SINGH, Professor — We have numerically studied the process of self-assembly in particle mixtures when they are subjected to an externally applied electric field. The inter-particle electric forces cause mixtures of micron to nano sized particles to self-assemble into molecular-like hierarchical arrangements consisting of composite particles which are organized in a pattern. As in experiments for micron sized particles, the structure of a composite particle depends on factors such as the relative sizes and the number ratio of the particles, their polarizabilities, and the electric field intensity. The minimum electric field intensity required for manipulation is larger for nanoparticles for which the electric field induced lateral forces must also overcome Brownian forces. Also, for nanoparticles, the composition of composite particles was relatively more uniform because of the mixing induced by Brownian motion. Particles of mixtures containing only positively or negatively polarizable particles arrange in chains and columns which become aligned in the electric field direction, but when both type of particles are present they come together to form clusters.

7:00PM P35.00009 Collisions and rebounds of active droplets1, KEVIN LIPPERA, MATVEY MOROZOV, MICHAEL BENZAQUEN, SEBASTIEN MICHELIN, LadHyX, UMR CNRS 7646, Ecole polytechnique, 91128 Palaiseau, France — Active droplets undergoing gradual micellar dissolution and spontaneous self-propulsion have recently received much interest as prototypical experimental realisations of synthetic micro-swimmers. While the self-propulsion of a single droplet has been widely studied and is known to arise above a critical advection-to-diffusion ratio, interactions and motion in complex environments remain mostly unexplored due to the non-linearity of the transport equation and its coupling with the flow that prevent the use classical superposition methods. Using a novel numerical framework relying on bi-spherical coordinate we solve the nonlinearly coupled hydrodynamics and solve dynamics exactly, enabling to characterise the rebound for various advection-to-diffusion ratios and to unravel the dominant interactions.

Monday, November 25, 2019 5:16PM - 7:00PM – Session P36 Microscale Flows: Moving Contact Line and Thin Film Evaporation 618

- Serafim Kalliadasis, Imperial College London
designs of hierarchical surfaces for CHF enhancement. The detailed understanding of dry spot growth dynamics sheds light on more effective topography of structured surfaces plays a significant role in increasing the critical heat flux (CHF) during thin film evaporation by enhancing capillary-assisted liquid delivery to the evaporating thin film region. As the CHF is reached, evaporation becomes dominant, leading to the formation of dry spots. In this study, the contact line dynamics during dry spot growth is investigated for thin film evaporation on hierarchical micro/nanostructured surfaces with ZnO nanorods grown on silicon micropillars of varying spacings and heights. Using laser reflection interference microscopy, the 3D meniscus shape at the micropillar level and the contact line dynamics at two length scales are directly captured. Nanoscale receding front is found ahead of bulk receding during dry spot growth on hierarchical surfaces, where the bulk receding front follows a two-stage motion, slower around the micropillars and faster in-between pillars. This nanoscale precursor film, due to the presence of nanorods, contributes significantly to the evaporative heat flux. We fill this gap with a series of experiments in capillary tubes, and analyze theoretically the striking deviation from the Cox-Voinov relation. Finally, we point out several practical applications, from spin-coating of capillary tubes to fluid displacement in porous media.

The current view of dynamic contact angle is encapsulated in the seminal experiments of Harkins (1911) and Washburn (1921). By varying the liquid’s viscosity and injection rate, he determined a relation between the dynamic contact angle and the static contact angle, now known as Cox-Voinov relation. Very little is known, however, about the dynamics of the contact line in the reverse scenario: when a more viscous liquid is displaced by a less viscous fluid. Using laser reflection interference microscopy, the 3D meniscus shape at the micropillar level and the contact line dynamics at two length scales are directly captured. Nanoscale receding front is found ahead of bulk receding during dry spot growth on hierarchical surfaces, where the bulk receding front follows a two-stage motion, slower around the micropillars and faster in-between pillars. This nanoscale precursor film, due to the presence of nanorods, contributes significantly to the evaporative heat flux. The detailed understanding of dry spot growth dynamics sheds light on more effective designs of hierarchical surfaces for CHF enhancement.

We fabricated a humidity responsive film comprising a bundle of titanium oxide tubes that changes film’s curvature corresponding to the relative humidity. The mechanism of the change in curvature of the film can be explained by adsorption, condensation and evaporation of water molecules within the surface of the film. During adsorption, a liquid bridge forms because of growth of a water layer between tubes, thus contracting the gap between tubes. When vapor pressure exceeds the equilibrium vapor pressure, condensation occurs at the meniscus of the liquid bridge, thus expanding the gap between tubes. We obtained the adsorption and desorption isotherms for the humidity responsive film by measuring physical adsorption. Additionally, we demonstrated varying motions of the humidity responsive film when a water droplet was applied on the surface. The film could distinguish between saturated and oversaturated humidity conditions, such as fog and rain, respectively. Therefore, this humidity responsive film can be applied to environmental monitoring systems and possibly even to energy harvesting systems.

6:34PM P36.00007 Transitions between motion regimes of the three phase contact line during the pattern deposition of polymer from a volatile solution

Mohammad Abo Jabal, Anna Zigelman, Technion - Israel Institute of Technology — We investigate the deposition of polymer from a volatile solution. The interplay between different transport mechanisms in the volatile solution determines the motion regime of the three phase contact line and hence the morphology of the deposit. We observe monotonic slip, stick-slip, and periodic wetting-dewetting motions of the contact line. The deposits take the form of continuous coating in the former case and parallel stripes in the two later cases. To investigate transitions between the different motion regimes, we evaporate solutions of Poly-methyl-methacrylate and Poly-dimethyl-siloxane in toluene. The transitions between particular motion regimes of the contact line are connected to two types of competitions between physical mechanisms. A transport competition between polymer diffusion and convection determines the distribution of polymer in the volatile meniscus and hence determines the distribution of spatial variations in the excess energy at the free surface of the solution. A competition between evaporative and surface energy stresses in the liquid meniscus determines the motion of the contact line. We report the temporal variations of the contact line position during each motion regime and use theory to validate our experimental findings.

6:47PM P36.00008 The resolution of the moving contact line problem

Serafim Kalliadasis, Department of Chemical Engineering, Imperial College — At the heart of the problem is its multiscale nature: a nanoscale region close to the solid boundary where the continuum hypothesis breaks down must be resolved before phenomenological macroscale parameters such as contact line friction and slip, often adopted to alleviate the singularity, can be obtained. Here we will review recent progress made by our group to rigorously analyse the moving contact line problem and related physics from the nano- to macroscopic lengthscales. Specifically, to capture nanoscale properties and to establish a link to the macroscale behaviour, we employ elements from the statistical mechanics of classical fluids, namely density-functional theory (DFT). We formulate a new and general dynamic DFT (DDFT) which is coupled to hydrodynamics and we refer to as “hydrodynamic DDFT”. It is inherently multiscale bridging the micro- to the macroscale and retaining the relevant fundamental microscopic information (fluid temperature, fluid-fluid and wall-fluid interactions) at the macroscale level. Work analysing the contact line in both equilibrium and dynamics will be presented. To benchmark existing phenomenological models and reproduce some of their key ingredients. But its multiscale nature also enables us to unravel the underlying physics of the moving contact line, not possible with any of the previous approaches, and indeed show that the physics is much more intricate than the previous models suggest.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P37 Particle Laden Flows: Turbulence Modulation

5:16PM P37.00001 A new timescale for turbulence modulation by particles

Izumi Saito, Takeshi Watanabe, Toshiyuki Gotoh, Nagoya Institute of Technology — A new timescale for turbulence modulation by particles is introduced. This timescale is inversely proportional to the number density and the radius of particles and can be regarded as a counterpart of the phase relaxation time, an important timescale in cloud physics, which characterizes the interaction between turbulence and cloud droplets by condensation-evaporation. Scaling analysis and direct numerical simulations of dilute inertial particles in homogeneous turbulence suggest that turbulence modulation by particles can be expressed as a function of the mass-loading parameter and the Damkohler number, which is defined as the ratio of the turbulence large-eddy turnover time to the new timescale.

5:29PM P37.00002 Particle shape and orientation impact on the modulation of isotropic turbulence by Kolmogorov-scale size particles

Lennart Schneiders, California Institute of Technology, Konstantin Fröhlich, Institute of Aerodynamics of RWTH Aachen University, Wolfgang Schröder, Institute of Aerodynamics of RWTH Aachen University, JARA Center for Simulation and Data Science — The modulation of decaying isotropic turbulence by non-spherical particles of Kolmogorov-scale size is investigated via direct particle-fluid simulations. A Cartesian cut-cell method with dynamic mesh refinement and dynamic load balancing is applied to explicitly resolve the stresses acting on the fluid-particle interfaces. Up to 60,000 ellipsoids are fully resolved, requiring O(10^11) mesh points. The decay rates of the fluid and particle kinetic energy are found to increase with the particle aspect ratio. This is due to the particle-induced dissipation rate and the direct transfer of kinetic energy, both of which can be substantially larger than for spherical particles depending on the particle orientation. The extra dissipation rate resulting from the translational and rotational particle motion is quantified using a recently derived analytical model. This generic expression describes the impact of individual inertial particles on the local energy balance independent of the particle shape and enables to quantify the share of the rotational particle motion in the kinetic energy budget.

5:42PM P37.00003 Experimental Estimation of Turbulence Modification by Inertial Particles at Moderate $Re_\lambda$

Martin Obligado, Legi, Daniel Odens Mora, Legi / University of Washington, Alain Cartellier, Legi — Several experimental and numerical studies have aimed at quantifying the impact of inertial particles on turbulent kinetic energy, and turbulent kinetic energy dissipation ($\epsilon_p$) of particle-laden flows. We propose a new experimental method to estimate the carrier-flow dissipation $\epsilon_p$ in the presence of inertial sub-kolmogorov particles at moderate $Re_\lambda$ (Mora et al. PRF, 2019). Its foundations rely on the unladen flow dissipation calculation using the Rice theorem, and the density of zero crossings $n_\phi$ of the longitudinal velocity fluctuation coming from a laser doppler anemometry device. We show that, under some mild assumptions, that $\epsilon_p$ can be deduced from the value of $n_\phi$. Our experimental results provide strong evidence, regarding the non-negligible effect that dense sub-kolmogorov particles have on the carrier-flow energy cascade at $\phi_i = O(10^{-5})$, and $Re_\lambda \in [200 - 600]$. Our observations are consistent with previous two-way coupling DNS studies at similar concentrations. Our results may also have an impact on distinct phenomena on particle-laden flows that depend on the coupling of the particles with the flow, such as preferential concentration and settling velocity modifications.
5:55PM P37.00004 Drag and turbulence modulation by particles and viscoelasticity in channel flow\textsuperscript{1}, AMIR ESTEGHAMATIAN, TAMER ZAKI, Johns Hopkins University — Direct numerical simulations are performed to examine the effect of neutrally-buoyant, concentric channel flow. Comparison is drawn between the single-phase conditions and semi-dilute suspensions of particles (20% solid volume fraction), at various Weissenberg numbers. Viscoelastic effects are included using the FENE-P model, and an immersed-boundary method that is tailored for simulations of non-Newtonian particle-laden flows. Comparison is made between the single-phase and particle-laden conditions. Unlike the single-phase cases, the particle-laden flows show a drag enhancement with increasing viscoelasticity above a certain Weissenberg number. This effect is due to a drastic increase in polymer stresses near the surfaces of particles. Nonetheless, Reynolds stresses are effectively diminished in the particle-laden viscoelastic cases. In fact, the onset of viscoelastic drag enhancement in the particle-laden flows occurs when the Reynolds stresses are completely eradicated and the higher viscoelasticity results in increased polymer stresses.

6:08PM P37.00005 Stability of a Lamb-Oseen vortex in two-way coupled particle-laden flows, SHAULI SHUAJ, M. HOUSSSEM KASBAOUI, School for Engineering of Matter, Transport and Energy, Arizona State University — We investigate the stability of a columnar vortex tube loaded with inertial particles in Eulerian-Lagrangian simulations. The vortex tube is represented as a Lamb-Oseen vortex with a circulation-based Reynolds number equal to $Re_p = 50$. The particles considered have a small, yet non-zero, circulation Stokes number $St = 0.01$, and are dispersed at a volume fraction $10^{-3}$. We show that when the particle feedback on the fluid is neglected, the flow is stable to infinitesimal perturbations. However, when the two-way coupling is in account, a centrifugal Rayleigh-Taylor instability may develop leading to the destruction of the vortex structure.

6:21PM P37.00006 Modulation of coherent structures by inertial particles in a turbulent channel flow, HIMANSHU DAVE, MOHAMED KASBAOUI, Arizona State University — In this study, we explore how skin friction drag can be reduced by carefully modulating the near-wall coherent structures using inertial point particles. The particles in this study have a diameter $d_p = 0.2$ in wall units and are smaller than the smallest turbulent eddies. Owing to the preferential concentration mechanism, these particles are able to modulate the coherent structures as they get expelled from the vortical regions and gather in the extensional regions of the flow. In doing so, these particles may remove momentum from the energetic core of hairpin vortices while damping fluctuations in the sweep and ejection regions. This mechanism is investigated in Euler-Lagrangian simulations of a two-way coupled turbulent channel flow at a friction Reynolds number $Re_f = 180$. The particles are inertial, with a Stokes number $St^i = 1$, and present at a semi-dilute concentration, i.e., such that the average volume fraction is low ($\langle \phi \rangle = 2.23 \times 10^{-4}$) but the mass loading is significant ($M = 0.1$). We explore how particles distribute in the near-wall region, and how they modulate the turbulent structures in the fluid.

6:34PM P37.00007 Influence of sand particle on the wake of circular cylinder\textsuperscript{1}, GUOHUA WANG, Lanzhou University, DEPARTMENT OF MECHANICS, LANZHOU UNIVERSITY TEAM — We conducted two-phase flow around a circular cylinder experiment in wind tunnel and measured air and sand particle velocities synchronously in the sand-laden flow by Particle Image Velocimetry (PIV) technique. The influence of moving sand particle (with an average diameter of $159 \mu m$) on the wake of the circular cylinder was investigated. The results show that the wake of the circular cylinder inclines downward in the sand-laden flow, and the inclination angle increases with the increase of sand concentration. Under the influence of sand particles, the effect of mean streamwise velocity in the wake decreases with the increase of particle volume fraction. The settling particles cause the air in the wake flows downwards where the mean vertical velocity is no longer equal to 0. The streamwise and vertical turbulence intensities in the wake are weakened, in which the streamwise turbulence intensity in the wake gradually changes from a bimodal to an unimodal distribution with the increase of particle volume fraction.

\textsuperscript{1}This research was supported by the grants of the National Natural Science Foundation of China (nos. 11490553, 11702122).

6:47PM P37.00008 Scale-by-scale measurements of turbulence modification by heavy particles in homogeneous turbulence\textsuperscript{1}, ROUMAISSA HASSAINI, FILIPPO COLETTI, University of Minnesota — There is substantial evidence that, even at moderate concentrations, particles can significantly alter the turbulent fluctuations, but it is still debated under which conditions these will be excited or inhibited. The issue is complicated by the multiplicity of the influencing parameters, the scarcity of systematic experimental studies, and the difficulty in measuring fluid velocity in a particle-laden flow. We target this question using a facility featuring hundreds of individually controlled jets, in which homogeneous air turbulence with negligible shear and mean flow is generated and laden with microscopic solid particles. We vary the volume fraction by two orders of magnitude and use high-speed laser imaging at multiple resolutions. We combine particle tracking velocimetry (PTV) and particle image velocimetry (PIV) to simultaneously measure the position and trajectory of particles as well as the fluid velocity down to the Kolmogorov scales. We demonstrate the impact of the particles on the turbulent kinetic energy, dissipation rate, and energy spectrum, to an increasing extent with increasing volume fraction. In the considered range of parameters, gravitational settling is found to be a deciding factor as for whether turbulence is increased or reduced at different scales.

\textsuperscript{1}This project is funded by the US Army Research Office.

7:00PM P37.00009 Turbulence collapses at a threshold particle loading in a dilute particle-gas suspension, VISWANATH KUMARAN, Indian Institute of Science, PRADEEP MURAMALLA, Indian Institute of Technology Bombay, ANKIT TYAGI, Indian Institute of Science, PARTHA GOSWAMI, Indian Institute of Technology Bombay, INDIAN INSTITUTE OF SCIENCE COLLABORATION, INDIAN INSTITUTE OF TECHNOLOGY BOMBAY COLLABORATION — In order to examine the turbulence attenuation mechanism in a dilute particle-gas suspension, Direct Numerical Simulations (DNS) of a particle-gas suspension are carried out at a Reynolds number of about 3300 based on the average gas velocity and channel width. The particle Reynolds number based on the particle diameter and the flow velocity is about 42 and the Stokes number is in the range 9.5 – 377. The particle volume fraction is in the range $0 – 3 \times 10^{-3}$, and the particle mass loading is in the range 0 – 12. As the volume fraction is increased, a discontinuous reduction in the turbulent velocity fluctuations is observed at a critical volume fraction when the volume fraction is increased by $10^{-1}$. There is a reduction, by one order of magnitude, in the mean square fluctuating velocities in all directions, in the Reynolds stress and the turbulent energy production rate. Turbulence attenuation is due to a disruption of the turbulence production mechanism, and not due to the increased dissipation due to the particles. The turbulence collapse phenomenon is universal and is observed for different particle Reynolds numbers and for different models for the drag and lift force models, though the critical volume fraction depends on drag law and force model.
Long cross-over dynamics in capillary imbibition. Rodrigo Ledesma-Aguilar, Elfege Ruiz-Gutiérrez, Steven Armstrong, Gary G Wells, Simon Leveque, Celestín Michel, Smart Materials and Surfaces Laboratory, Northumbria University, Ignacio Pagonabarra, Áura Hernández-Machado, Department of Condensed Matter Physics, University of Barcelona — We present new experimental and theoretical results of the spontaneous capillary invasion of dry capillary tubes by viscous liquids. We show how deviations from Washburn’s law, which predicts a diffusive-like growth of the advancing meniscus, persist for much of the invasion process if not all. We identify two sources of hydrodynamic resistance that account for this effect: the difference in velocity between the fluid reservoir and the fluid within the capillary, and the motion of the meniscus itself. Both contributions give rise to power-law terms in the force balance, which introduce a long cross-over from the initial acceleration of the liquid to the asymptotic limit of Washburn’s law. Such long cross-over dynamics, which we call slowly-slowing-down dynamics, is likely to govern other systems in spontaneous capillary flow where a persistent resistance to growth is present.

Partial saturation in capillary rise into deformable porous material. Javed Siddique, Penn State York, Daniel Anderson, George Mason University — We investigate the partial saturation dynamics of capillary rise into a deformable porous material. Experiments show a deviation from the classical Washburn model dynamics after early times and our aim in this work is to investigate this deviation. We consider a three-phase mixture theory model with solid, liquid, and gas phases. We compare the results of our model to experimental data.

Imbibition with solidification in alumina feeding. Attila Kovacs, James Oliver, Chris Breward, Andreas Muench, University of Oxford — Liquid aluminium is produced from alumina by electrolysis in a Hall-Héroult cell. The process by which the alumina is fed into the cell influences the overall behaviour and efficiency of the cell. We develop a one-dimensional Stefan-type model for the imbibition of molten cryolite into a cold porous lump of alumina. In the small overheat limit, we analyse the small-time behaviour using the method of matched asymptotic expansions and find there to be locally self-similar solutions that describe analytically the competition between imbibition and freezing. Depending on the balance between these effects, the problem may exhibit two self-similar solutions (one being stable and the other unstable) or such a solution may cease to exist (so that imbibition is not possible without the molten cryolite freezing first on the exterior of the porous lump). Our asymptotic predictions are validated by direct numerical simulations that are also used to investigate the late time behaviour. In particular we predict the depth of imbibition before the cryolite freezes.

Extracting permeability model parameters for skin tissue from injection experiments. Pranav Shrestha, Boris Stoebier, The University of British Columbia — Hollow microneedles are medical devices used to inject fluid, such as vaccines, into the skin. As the fluid flows into the skin, a soft porous medium, it deforms the porous matrix. The fluid flow and solid deformation are coupled — the flow-induced deformation changes the porosity and permeability of the tissue, which in turn affects fluid flow. In our experiments, we injected water into excised porcine skin, while recording fluid flow-rate and visualizing the tissue cross-section in real time using optical coherence tomography (OCT). We performed digital image correlation on the OCT images to generate strain maps for quantifying tissue deformation. We used a spherical model of tissue expansion and a two-parameter exponential relationship between permeability and volumetric strain in tissue. Applying Darcy’s law to the measured fluid flow-rate and the strain maps over time yields the two parameters through an optimization algorithm. The fluid flow estimated from the optimized permeability model matched closely with the recorded flow-rate. The permeability-strain relationship can help improve the efficiency of fluid injections into the skin.

6:34PM P38.00007 Fluid-structure interactions in a soft-walled Hele-Shaw cell¹.
SATYAJIT PRAMANIK, JIAN HUI GUAN, CHRISTOPHER W. MACMINN, University of Oxford — The interaction of viscous and interfacial flows with soft materials has recently attracted substantial interest from a variety of different perspectives. Here, we study these interactions in the context of a model problem: Flow in a deformable Hele-Shaw cell, where one wall is rigid and the other is soft. Combining experiments with mathematical modelling, we consider the coupling of flow and deformation during (a) the initial injection of viscous fluid into the empty cell (filling the problem), (b) the subsequent steady state during continued injection of the same fluid (the steady state), and (c) the relaxation of the cell after injection is stopped (the relaxation problem). We then discuss the implications of these results for hydrodynamic instabilities such as viscous fingering.

6:47PM P38.00008 Modification of water injection monitoring for evaluation of hydraulic fracturing efficiency¹.
TIEN N. PHAN, MORTEZA DEJAM, Department of Petroleum Engineering, University of Wyoming, 1000 E. University Avenue, Laramie, WY 82071-2000, USA, MOHAMMADREZA KAMYAB, Corva AI, LLC, 16285 Park Ten Pl, Ste 210, Houston, TX 77084, USA — Measuring hydraulic fracturing efficiency is not a trivial task in the absence of production data. The traditional diagnostic plots for Hall Integral (HI) and derivative Hall Integral (dHI) against cumulative water injection allow for interpretation of plugging and fracturing behavior in injection wells. In this study, we adapt this method by including instantaneous shut-in pressure and cumulative slurry volume to understand fracturing efficiency. Increasing fracturing efficiency occurs when dHI is decreasing relative to cumulative slurry volume. We compute the change of dHI for all stages of data. Features extracted from our diagnostic plots like intercept, slope, and integral of dHI are correlated with computed fracture volume and half-length from microseismic data obtained in one hydraulically fractured well in Midland basin. The interpretation from correlation matrix allows us to identify which features can be used as qualitative predictors of fracturing efficiency. Using full stages of data, our derived parameters provide the implication on which stages should generate greater fracture volumes along the lateral of one single horizontal well. This study can improve the decision-making process for on-site evaluation of stage design.

7:00PM P38.00009 Pore-Scale Modeling of Clogging and Erosion in Porous Media
EMILY DE JONG, Department of Chemical and Biological Engineering, Princeton University, NAVID BIZMARK, Princeton Institute for the Science and Technology of Materials, Princeton University, SUJIT DATTA, Department of Chemical and Biological Engineering, Princeton University — The transport of colloidal particles in porous media plays a key role in applications ranging from groundwater remediation, water filtration, and enhanced oil recovery. However, this process is difficult to model due to diverse processes that may arise, including particle advection through the pore space by fluid flow, adsorption and deposition onto the solid matrix, and erosion or suspension. Here, we analyze a continuum model to describe these physics for a single straight pore in a computationally-efficient simulation. The model accounts for geometry, advection through the pore space by fluid flow, adsorption and deposition onto the solid matrix, and erosion or resuspension. Our work thus provides a tractable description of the pore-scale physics of colloidal particle transport that can be generalized to more complex porous medium geometries.

Monday, November 25, 2019 5:16PM - 7:13PM – Session P39 Geophysical Fluid Dynamics Stratified Turbulence 6a - Elizabeth Follett, Cardiff University

5:16PM P39.00001 Analysis of Mixing in Rotating Stratified Turbulence
MATTHEW KLEMA, Colorado State University, ANNICK POUQUET, University of Colorado, DUANE ROSENBERG, 1401 Bradley Dr. Boulder, CO 80305, KARAN VENAYAGAMOORTHY, Colorado State University — This research introduces a parametric framework for the evaluation of rotating stratified turbulence (RST). Four dominant flow regimes in RST are delineated using the turbulent Froude number, Fr = /N, and the turbulent Rossby number, Ro = /k where k is the turbulent kinetic energy, / is the dissipation rate of k, N is the buoyancy frequency and is the Coriolis frequency. These four regimes reflect the relative contributions of buoyancy and rotation to the characteristics of the flow. Direct numerical simulations (DNS) are used for evaluation of the framework and analyzing the effects of forced rotation on turbulent mixing. The intensity of turbulent mixing is analyzed using the buoyancy Reynolds, ReB = /N², and the ratio of turbulent to molecular diffusivities, = /N. Results from the simulations show that forced rotation does not impact the behavior of the turbulence or impact scaling relationships with the turbulent Froude number when compared to non-rotating stratified DNS data. Ratios of the buoyancy frequency and the Coriolis rotational frequency is also shown to not be a useful ratio for the classification of stratified flow.

5:29PM P39.00002 Upward and downward transfer of energy in rotating stratified flows
ERNESTO HORNE, MOHAMMED HUSSINE HAMEDE, JEAN-MARC CHOMAZ, PAUL BILLANT, LdHyX, CNRS, Ecole Polytechnique, F-91128 Palaiseau CEDEX, France, GEOPHYSICAL FLOWS TEAM — We investigate experimentally and numerically the evolution of forced turbulence in the stronglystratified regime and for rotation rates covering the regimes associated to a direct and an inverseenergy cascade. The experiments are performed by means of a rotating table with a diameter of 2m. The energy is injected by periodically creating columnar dipoles. Direct numerical simulations (DNS) complement the experiments in order to reach higher Reynolds numbers. The turbulenceexhibits pancake structures with a large horizontal scale and a vertical thickness increasing with the rotation rate. Forstrong enough rotating rates, horizontal scales larger than the forcing scales appear in the experiments consistently with the observation of an inverse cascade in the DNS. We have found that the critical Rossby number below which the inverse cascade appears depends on the horizontal Froude number Frh.

JONATHAN AURNOU, UCLA, SUSANNE HORN, Coventry University, KEITH JULIEN, CU Boulder — Dimensional analysis is employed here to provide free-fall scaling estimates for the convective heat and momentum transport in the limit of rapid rotation, and to relate these to scalings for non-rotating Rayleigh-Bénard convection (RBC) systems. Our analysis shows that the scalings for free-fall dominated heat (Nusselt number, Nu) and momentum transfer (Reynolds number, Re) of rapidly rotating convection differ from their non-rotating RBC counterparts by a factor of Rfg, where Rfg = \tau_R^1/\tau_R is the free-fall Rossby number defined as the ratio of the characteristic rotation time \tau_R and the buoyant free-fall time \tau_R. Since Rfg < 1 in the rapidly rotating limit, our predicted rapidly rotating, free-fall transport rates remain far below the associated rates in non-rotating systems.

surrounded by slowly ascending flow. The formation and longevity of the rings depends on the Prandtl number $Pr$ for a range of Taylor and Rossby (or flux Rossby) numbers, eventually breaking down into a grid of cyclonic vortices with descending flow. The formation and breakdown of transient axisymmetric rings of up- and down-welling fluid in impulsively started rotating Rayleigh Benard convection. First observed in laboratory experiments with constant negative heat flux at the top boundary [1-3], these rings form during spin-up for a range of Taylor and Rossby (or flux Rossby) numbers, eventually breaking down into a grid of cyclonic vortices with descending flow surrounded by slowly ascending flow. The formation and longevity of the rings depends on the Prandtl number $Pr$, with no sustained rings forming for $Pr < Pr_c(Ta, Ro)$. Furthermore, in the rapidly rotating regime and for the Rayleigh numbers $O(10^5 \text{--} 10^6)$ considered here, we find that the temperature boundary conditions on the top and bottom surfaces influence the ring dynamics and their breakdown. With Dirichlet conditions, the rings are less stable than for corresponding Neumann conditions, breaking down into sheet-like structures instead of individual vortices. The distinction resides in the nature of the stability of the upper boundary layer. References: [1] Boubnov and Golitsyn, J. Fluid Mech. 167, 503 (1986) [2] Vorobieff and Ecke, Phys. Fluids 10, 2525 (1998) [3] Zhong, Patterson and Wettlaufer, Phys. Rev. Lett. 105, 044504 (2010)

6:08PM P39.00005 Transient Convective Spin-Up Dynamics, S. RAVICHANDRAN, JOHN S. WETTLAUFER, Nordita, KTH Royal Institute of Technology and Stockholm University, SE-106 91 Stockholm, Sweden — We study numerically the formation and breakdown of transient axisymmetric rings of up- and down-welling fluid in impulsively started rotating Rayleigh Benard convection. First observed in laboratory experiments with constant negative heat flux at the top boundary [1-3], these rings form during spin-up for a range of Taylor and Rossby (or flux Rossby) numbers, eventually breaking down into a grid of cyclonic vortices with descending flow surrounded by slowly ascending flow. The formation and longevity of the rings depends on the Prandtl number $Pr$, with no sustained rings forming for $Pr < Pr_c(Ta, Ro)$. Furthermore, in the rapidly rotating regime and for the Rayleigh numbers $O(10^5 \text{--} 10^6)$ considered here, we find that the temperature boundary conditions on the top and bottom surfaces influence the ring dynamics and their breakdown. With Dirichlet conditions, the rings are less stable than for corresponding Neumann conditions, breaking down into sheet-like structures instead of individual vortices. Fluids 10, 2525 (1998) [3] Zhong, Patterson and Wettlaufer, Phys. Rev. Lett. 105, 044504 (2010)

6:34PM P39.00007 Instability driven relaxation of an anticyclone, EUKOK YIM, Laboratory of Fluid Mechanics and Instabilities, EPFL, Lausanne, CH-1015, PAUL BILLANT, LadHyX, Ecole polytechnique, Palaiseau, 91120, France, FRANCOIS GALLAIRE, Laboratory of Fluid Mechanics and Instabilities, EPFL, Lausanne, CH-1015 — We study the nonlinear evolution of the centrifugal instability appearing in a columnar anticyclone using a semi-linear approach to model the transient unsteady flow evolution in a self-consistent manner. For anticyclones in a homogeneous viscous flow, the fastest growing instability is without oscillation in time but with a finite axial wavenumber. Hence, the self-consistent model is developed around the spatially averaged time dependent meanflow and the fluctuation, which reduces the problem from 2D nonlinear to 1D semi-linear. The two linear meanflow and fluctuation equations are coupled via the Reynolds stress of the fluctuations. At a given rotation ratio between the vortex angular velocity and the background rotation, only the most linearly unstable mode is considered for Reynolds numbers $Re = 800$ and $2000$ defined with the maximum angular velocity and the radius of the vortex. For both values of $Re$, the model predicts well the nonlinear evolution of the meanflow and the fluctuation amplitude. Higher harmonics are non-negligible only at the highest value of $Re$. The results show that the angular momentum of the meanflow is homogenized to a stable state via the action of the Reynolds stresses of the fluctuation.

6:47PM P39.00008 resonant excitation of modes and triadic resonance in a precessing cube, KE WIU, BRUNO WELFERT, JUAN LOPEZ, Arizona State University — The flow response of a rotating fluid-filled cube under precessional forcing is investigated numerically. The simulations are conducted over a wide range of forcing frequencies at various background rotation rates and a fixed precession angle of one degree. The periodic response is comprised of two main components: resonant excitation of the inviscid inertial eigenmodes of the cube, and inertial wave beams. The resonantly excited modes preserve the same spatio-temporal symmetries as the precessional forcing. Moreover, a symmetry-breaking response is also observed, which is due to triadic resonance, and the modes involved are identified.

7:00PM P39.00009 Aspects of Energetics of Stratified Turbulent Wakes, NIDIA CRISTINA REYES GIL, Cornell University, KRISTOPHER ROWE, Argonne National Laboratory, PETER DIAMENTISSIS, Cornell University, GREG THOMSEN, Wandering Wakes Research — The study of the turbulent wake generated by a bluff body moving through a stably stratified fluid has important applications in physical oceanography and marine engineering. Significant progress has been made towards understanding the structure and dynamics of the turbulent wake core, as well as the internal gravity wave (IGW) radiation emitted by the wake. Analysis of terms in the wake kinetic energy (KE) budget has demonstrated that viscous dissipation is a stronger sink than IGW radiation before $Nt = 10$, while the latter dominates during the mid-to-late non-equilibrium (NEQ) regime. Nevertheless, these processes do not close the KE budget: the largest gap occurring early in the NEQ regime. For a series of implicit large eddy simulations — spanning body-based initial Reynolds number $Re = 5 \times 10^3$, $10^5$ and $4 \times 10^5$, and Froude number $Fr = 4$, 16 and 64 — we calculate the complete KE budget of a stratified turbulent wake. The relative importance of viscous dissipation, IGW radiation, buoyancy flux, and nonlinear transport as sinks for wake KE is analyzed for different stages of the wake life cycle. Subsequently, numerical dissipation will be quantified and its impact compared to the physical processes in the KE budget.

Session P40 Turbulent Boundary Layers: Control and Perturbations I 6b - Jonathan Morrison, Imperial College London
5:16PM P40.00001 Experimental Studies of Streamwise Response of the Turbulent Boundary Layer to a Periodic Actuation, MITCHELL LOZIER, FLINT O. THOMAS, STANISLAV GORDEYEV, Department of Aerospace and Mechanical Engineering, University of Notre Dame — It has been established that the dynamics of large-scale structures (LSS) in turbulent boundary layers (TBL) and near-wall small-scale turbulence are correlated. In these studies, a plasma based active flow control device was placed at sixty percent of the boundary layer thickness to introduce periodic disturbances into the wake region of the turbulent boundary layer. The boundary layer Reynolds number was low enough, Reτ = 700, so no natural large-scale structure was present. Via actuation, a synthetic large-scale periodic shear-layer-like structure was introduced into the boundary layer, and the TBL response to this synthetic structure at various wall-normal and streamwise locations downstream of the actuator was studied using a single hot-wire. Due to the periodic nature of the forcing, a phase-locked triple Reynolds decomposition of velocity was used to analyze the data. The modal component of velocity corresponding to the actuation frequency and the residual turbulence levels are the parameters of interest in this study. The dynamics of the LSS and small-scale structures were quantified using several modulation coefficients that correlate changes in modal velocity and residual turbulence with respect to phase. These modulation coefficients show a strong positive correlation in the inner and log region of the boundary layer. By measuring these quantities at several streamwise locations, the evolution of the synthetic large-scale structure and its modulating effect on the near-wall turbulence can be described.

5:29PM P40.00002 Turbulent boundary layer drag recovery downstream of spanwise wall oscillation. CHRISTOPHER BRYSON, FAZLE HUSSAIN, Texas Tech University — Spanwise wall oscillation (SWO) has been well researched for producing significant drag reduction. While the dynamics within the control region has been studied, the flow recovery downstream of the control region is poorly understood. Direct numerical simulation of a TBL with SWO is performed for a range of control velocity oscillation amplitudes A∗ = {10, 20, 30} and oscillation periods T∗ = {50, 100, 200}. It has been found that stronger drag reduction within the control region correlates with faster recovery to higher saturation levels of drag, which are also higher than an uncontrolled TBL. Compared with the uncontrolled case, visualization of control cases reveal that streak spacing is higher in the saturation region with increased wall normal velocity gradients in between, thus increased drag. The flow near the wall accelerates during the recovery phase producing a mean wall normal velocity that pulls streak transient growth (STG) vortices closer to the wall. The vortices then strengthen the streaks which spawn additional streamwise λ2 vortices by STG, contributing to the increased drag. Further details in terms of the connection between vortical structures and wall shear stress will be discussed.

5:42PM P40.00003 On the structure of compliant wall deformation forced by a turbulent boundary layer1. JIN WANG, SUBHRA KOLEY, JOSEPH KATZ, Johns Hopkins University — Our previous (Zhang et al 2017) study examined the pressure-deformation correlations in a compliant wall turbulent channel flow with a stief wall and submicron deformations. Aiming to extend the scope to two-way coupling, where the deformation size is several wall units (λ∗), theoretical analysis is used for selecting a compliant material (PDMS + silicone gel) with Young’s modulus (0.158 MPa), thickness (5mm), and shear speed (7.85 m/s) comparable to the freestream velocity (U’ = 1.2-6 m/s). Time-resolved (2 kHz) Mach-Zehnder Interferometry is used for mapping the deformation, and 2D PIV for measuring the flow. The deformations increase from submicron at U’ = 1.2 m/s to well above 20 µm at 6 m/s. The primary mode is advected at 0.66λ∗ for all wavenumbers, but the peak wavenumber in both directions remains nearly constant. In addition, high-frequency low wavenumber lateral waves appearing at broad streaks dominate at low U’ but persist at high-speed. Comparisons of the measured frequency spectra to 1-D linear models (Chase 1991, Benshop et al. 2019) show a good agreement for advected modes, but not for the lateral ones. At high U’, the compliant wall causes a sharp decrease in mean velocity at y∗ =10δ∗, consistent with DNS results (Rosti and Brandt 2017).

5:55PM P40.00004 Input-output analysis of a turbulent separation bubble with a time-periodic base flow1. ALBERTO PADOVAN, CLARENCE ROWLEY, Princeton University, WEN WU, CHARLES MENEVEAU, RAJAT MITTAL, Johns Hopkins University — Direct numerical simulations are performed for three-dimensional turbulent boundary layer flow at Reθ∗ = 490, in which a suction velocity profile is imposed at the top of the computational domain to induce separation at the bottom wall. We study the input-out characteristics of perturbations about two different base flows: a spanwise-averaged, time-averaged base flow and a spanwise-averaged, time-periodic base flow. The first approach leads to the well-known resolvent analysis, through which we compute the optimal forcing and response modes at a given frequency and spanwise wavenumber. The latter approach leads to the formulation of the harmonic transfer function, a linear operator that governs the dynamics of fluctuations about time-periodic base flows. Within this framework, perturbations at different temporal frequencies are coupled to one another through the base flow, and we can therefore study the cross-frequency and energy transfer mechanisms. For the harmonic transfer function, we compute the optimal global forcing and response modes, which are full spatio-temporal flow fields. The cross-frequency modes provide insight into the spatial patterns that arise from the scattering of perturbations from the base flow.

6:08PM P40.00005 Turbulent boundary layer injected with low blowing ratio effusion film1. JEREMY BASLEY, KEVIN GOUDER, JONATHAN F MORRISON, Imperial College London — Effusion cooling of turbine blades is used in jet engines to alleviate the thermal and shear strain they sustain while beneath the hot flow exiting the combustion chamber. This study focuses on the mechanisms underlying the interactions between the film-injected momentum and the incoming high Reynolds number turbulent flow. A large-scale low-velocity experiment is carried out in the closed-loop 10x5 wind-tunnel facility. The scaled-up effusion device consists of a plenum located directly underneath a thick plate pierced along a staggered grid of inclined D = 16mm diameter holes with a pitch of 5D. This setup is placed in a turbulent boundary layer, tripped and developing over 15 m. A range of injected velocities with respect to free-stream velocity (blowing ratio) is investigated with time-resolved planar PIV, complemented with hot-wire anemometry profiles, and wall-pressure measurements. The resulting time-resolved and space-extended data sets explain the favourable outcome of low blowing ratios, for which the shear-driven mixing of the effusion film is limited to near-wall region of the boundary layer. Results also suggest the effusion film effectively restricts the penetration of fluid from the outer region into the near-wall region of the boundary layer.

6:21PM P40.00006 Classification of forcing conditions in pulsatile turbulent pipe flow using Reynolds shear stress co-spectra1, ZUIN CHENG, THOMAS O. JELLY, SIMON J. ILLINGWORTH, IVAN MARIUS, ANDREW S.H. OOI, The University of Melbourne — The turbulence dynamics of pulsatile pipe flow are investigated using data obtained from direct numerical simulations at a mean friction Reynolds number of 180, 270 and 360. The forcing conditions are achieved by applying a time-harmonic axial pressure gradient. This study directs attention towards the frequency response of single- and two-point turbulence statistics to systematic variations in the forcing frequency. We propose a classification of the applied forcing conditions based on the Reynolds shear stress frequency co-spectra and the applied forcing frequency. We perform simulations based on this classification to extend the physical understanding of the phase dependence of single- and two-point turbulence statistics under high, very-high and ultra-high forcing frequencies, focussed around the frequency response of turbulence dynamics in time (frequency) and space (wavenumber) domains. Results also reveal a decoupling behaviour when the frequency of the forcing is higher than the highest frequency (smallest time-scale) of the energy containing motions in the Reynolds shear stress co-spectra.

6:34PM P40.00007 Manipulating Near-wall Turbulent Boundary Layer by Unsteady Air-films1, CONG WANG, MORTEZA GHARIB, Caltech — Previously we have demonstrated that wall-attached air-films can be sustained in turbulent boundary layer (TBL) and dynamically modulated by pressure wave. This technique is effective in manipulating the near-wall turbulent shear flow. Here we show that in the presence of modulated air-films, the phase-averaged streamwise velocity demonstrates a Stokes type oscillatory motion. The near-wall viscous shear stress $\left(\nu \partial u/\partial y\right)$ is suppressed and negative Reynolds shear stress $(-\nu \partial v/\partial x)$ can be generated in the vicinity of air-films. Through a quadrant analysis, we identify a potential mechanism for the generation of negative Reynolds shear stress.

5:16PM P41.00001 Fully implicit force splitting scheme to two-phase lattice Boltzmann equation in pressure-velocity formulation2, TAEHUN LEE, City College of New York — We present a numerical procedure for solving the lattice Boltzmann equation (LBE) in the pressure-velocity formulation with the low Mach number approximation. We propose a unique algorithm based on the Strang splitting procedure to solve LBE for immiscible incompressible flows. Our procedure includes leading order intermolecular forcing terms within the streaming step, while keeping high-order forcing terms within the collision step such that conservative moments do not change due to collision. By coupling the finite difference/element method with a stable time-stepping technique, our scheme can easily handle stiff source term or external force. We will show that the perfect shift implementation is recovered under unity CFL condition as a special case of the proposed approach. The force splitting scheme is implemented in a fully implicit manner and applied to a novel pressure-velocity formulation of LBE. We have observed that the pressure-velocity formulation offers better numerical stability at high Reynolds numbers and reduced interfacial thickness, and the implicit formulation eliminates pressure oscillations. With the hope that this technique can be used for applications in complex geometries, benchmark calculations are performed on both uniform and non-uniform meshes.

5:29PM P41.00002 Streaming Formulation in Volumetric Lattice Boltzmann Method and Its Improvement1, HUIDAN (WHITNEY) YU, XIAOYU ZHANG, Indiana University-Purdue University Indianapolis — Volumetric lattice Boltzmann method (LVBM) has been specifically developed to deal with complex flow domains with or without willfully moving boundaries (Yu, et al, PRE, 2014). In the VLBM, fluid particles are uniformly distributed in lattice cells, instead of the traditional lattice nodes. A unique parameter, which represents the ratio of solid volume over the cell volume, is introduced to distinguish three types of lattice cells: solid cell (pure solid occupation), fluid cell (pure fluid occupation), and boundary cell (partial solid and partial fluid). Through this parameter, a volumetric bounce-back mechanism is uniquely included in the formulation of streaming process. As a result, extra interpolation/extrapolation to deal with arbitrarily oriented boundaries are avoided. Such a formulation significantly eases the handling of complicated geometries and promotes the computational efficiency without compromise of accuracy. In this work, we present the original formulation of the streaming process in VLBM and its modification. Quantitative validations in 3-D pulsatile duct flows with circular and rectangular cross sections respectively demonstrate the reliability of VLBM for solving unsteady flows.

5:42PM P41.00003 Mesoscale Modelling of Nano-Particle Growth Under Flow, ROHAN VERNEKAR, TIMM KRÜGER, School of Engineering, Institute for Multiscale ThermoFluids, University of Edinburgh — Nanoparticles have wide potential for future applications, from drug delivery to surface coatings. Control over (e.g. silica) nanoparticle morphology, size, porosity and dispersity is crucial for realisation of their use. The physics of growth of such particles under flow conditions is not well understood, thus making their industrial scale-up challenging.

We present a mesoscale lattice Boltzmann (LB) algorithm that models growth of nanoparticles under particle resolved flow conditions via chemical species deposition. The method combines fluid LB for hydrodynamics, advection-diffusion LB for species transport with resolved Newtonian nanoparticle dynamics and a novel mesoscale adsorption boundary condition for growth. The algorithm is benchmarked for various 2D cases and provides excellent results. Our method enables the study of flow effects on growth, morphology and size distribution of nanoparticle suspensions, and advances nanoscale particle synthesis modelling.

5:55PM P41.00004 Simulation of Scalar Transport in a Non-Reacting Turbulent Jet using the Lattice Boltzmann Method. CHONG WU, WAI LEE CHAN, Nanyang Technological University, Singapore — In this work, numerical simulations of a non-reacting turbulent jet was performed with a lattice Boltzmann (LB) solver that is based on the open-source Palabos framework. The computational domain consists of a square nozzle, from which a free jet of Reynolds number of 10,000 was injected into a three-dimensional, open quiescent space. A scalar distribution function was introduced to describe the mixture fraction, with its transport properties extracted from a flamelet library. Subgrid-scale turbulence was described by another independent distribution function that closes the Smagorinsky model. To this end, the LB simulations are being run to a statistically-steady state, from which results can be verified with the local scaling of turbulence theories. Meanwhile, the scalar mixing profile at different axial locations will be investigated as it is critical to the implementation of flamelet-type combustion model. In addition, computational performance and simulation results of the LB method will be compared against that of large-eddy simulations, focusing in particular on the scalability of LB method.

6:08PM P41.00005 Phase-field Modeling and Simulation of Surfactant-Laden Multi-phase Flows using a Central Moment Lattice Boltzmann Method. FARZANEH HAjabDOLLAHI, KANNAN PREMNATH, SÁMUEL WELCH, University of Colorado Denver — Surfactants modulate interfacial flows in numerous multiphase dispersed systems. We will present a robust computational technique based on unified cascaded lattice Boltzmann methods (LBM) for two-phase flows at high density ratios, and for the capturing of the interfacial motions and surfactant dynamics. The cascaded LBM for two-phase flows, which computes the pressure and velocity fields, is based on a discretized modified continuous Boltzmann equation, where the effect of collisions is modeled by relaxation of different central moments to their equilibria and includes source terms for surface tension effects. The interfacial dynamics is represented by a conservative Allen-Cahn equation which is solved by another cascaded LBM. The transport of the surfactant concentration field, based on a free-energy functional and accounts for the energetic preference of surfactants to get adsorbed on interfaces, is evolved via yet another cascaded LBM. The effect of surfactants, i.e., the lowering of the local surface tension and the generation of Marangoni stresses, are introduced via a nonlinear interface equation of state based on the Langmuir isotherm. We will demonstrate the potential of our proposed formulation for various surfactant-laden two-phase flow cases.

6:21PM P41.00006 An improved coupled Immersed-Boundary-Lattice-Boltzmann solver for the simulation of particulate flows. EMMANOULI FALAGKARI, PDRA, TIMM KRUEGER, Lecturer — Our present understanding of the fundamental physical mechanisms of particle-fluid interactions is far from complete. We focus on the accurate computation of the hydrodynamic forces and the no slip condition on the boundary using the lattice-Boltzmann method for the solution of the flow field and a multi-direct forcing (MDF) immersed-boundary method for the fluid-structure interaction. We found that certain MDF schemes can become unstable after a certain number of iterations. The source of the instability has been identified in the iterative computation of the boundary force. We propose an alternative iterative scheme that significantly enhances the numerical stability by allowing the boundary force computation to relax at a different rate. The numerical accuracy and stability of the proposed scheme is demonstrated by simulating flows laden with moving finite-size particles, including a particle in shear flow and the sedimentation of single spherical and nonspherical particles in a cavity, demonstrating the importance of the accurate boundary force computation on the particle motion and dynamics. Good agreement between the present results and other schemes is obtained.

6:34PM P41.00007 An IB-LBM for modeling heat transfer and bushfire. FANG-BAO TIAN, LI WANG, School of Engineering & IT, University of New South Wales, Australia. JASON JOHN SHARPLES, School of Science, University of New South Wales, Australia — Catastrophic bushfire has happened many times over the world in the last two decades, destroying many assets and multiple facilities. The most devastating bushfires normally involve wind and terrain interactions. In order to predict the spreading process of bushfire in various geographical and weather conditions, it is necessary to improve understanding of the physical mechanisms of bushfire-terrain wind interaction. In this work, an immersed boundary method is developed for the numerical simulation of bushfire spreading mechanisms over complex terrains under different wind conditions. In this method, the lattice-Boltzmann method is used for the fluid dynamics. Large eddy simulation and wall model have been incorporate to handle the turbulence. The heat transfer is solved by using a finite difference method. The complex terrain is modeled by using an immersed boundary method. The numerical solver is validated by several benchmark cases, including heat transfer around a cylinder in a uniform flow, flow around a sphere at Re=10,000, and bushfire burning over a lee slope which is a typical terrain configuration.

Monday, November 25, 2019 5:16PM - 7:13PM — Session P42 Boundary Layers: Rough Wall Effects

5:16PM P42.00001 Modeling Turbulent Rough-Wall Flow with Pseudo Body Forces. GILES BRETERON, JUNLIN YUAN, MOSTAPHA AghAEI JOYBARI, Michigan State University — In RANS representations of turbulent flow over rough walls, it is desirable to describe flow variables as their superficial averages, so that the flow can be solved on a smooth-wall grid. The superficially averaged ‘extra’ terms in the x-momentum equation which describe the local effect of roughness on the flow, and which can be resolved by DNS with an immersed boundary method to enforce the precise local roughness boundary conditions, are \( \langle f_p \rangle \) and \( \langle f_r \rangle \). They describe averages per unit volume of the pressure dispersion and viscous stresses on account of roughness elements. As such, they are pseudo body forces distributed in the y direction, from the roughs to crests of the roughness sublayer. The distributed body force model appears to offer a more fundamental way of modeling general surface roughness than other approaches. In this talk, we present results which illustrate the applicability of the model for different kinds of roughness in fully-developed and boundary-layer flows. We also present computed distributions of \( \langle f_p \rangle \) and \( \langle f_r \rangle \) for flows over surfaces with different roughness textures, and describe the practical implementation of such a model within a wall function, for high Reynolds-number flow.

6:08PM P43.00002 An immersed-boundary lattice Boltzmann method for modeling particle-laden flows and its extension to three-dimensional flows. XIAO WANG, Post-Doc research associate at the Institute for Multiscale Thermofluids - The University of Edinburgh — Our present understanding of the fundamental physical mechanisms of particle-fluid interactions is far from complete. We focus on the accurate computation of the hydrodynamic forces and the no slip condition on the boundary using the lattice-Boltzmann method for the solution of the flow field and a multi-direct forcing (MDF) immersed-boundary method for the fluid-structure interaction. We found that certain MDF schemes can become unstable after a certain number of iterations. The source of the instability has been identified in the iterative computation of the boundary force. We propose an alternative iterative scheme that significantly enhances the numerical stability by allowing the boundary force computation to relax at a different rate. The numerical accuracy and stability of the proposed scheme is demonstrated by simulating flows laden with moving finite-size particles, including a particle in shear flow and the sedimentation of single spherical and nonspherical particles in a cavity, demonstrating the importance of the accurate boundary force computation on the particle motion and dynamics. Good agreement between the present results and other schemes is obtained.

6:21PM P43.00003 An immersed-boundary lattice Boltzmann method for simulating unsteady particle-laden flows. CHONG WU, WAI LEE CHAN, Nanyang Technological University, Singapore — In this work, numerical simulations of a non-reacting turbulent jet was performed with a lattice Boltzmann (LB) solver that is based on the open-source Palabos framework. The computational domain consists of a square nozzle, from which a free jet of Reynolds number of 10,000 was injected into a three-dimensional, open quiescent space. A scalar distribution function was introduced to describe the mixture fraction, with its transport properties extracted from a flamelet library. Subgrid-scale turbulence was described by another independent distribution function that closes the Smagorinsky model. 5:29PM P42.00002 Multi-parameter prediction of roughness function and drag profiles in turbulent channel flows over rough walls1, MOSTAFA AGHAEI JOYYBARI, GILES J. BRERETON, JUNLIN YUAN, Department of Mechanical Engineering, Michigan State University, East Lansing, MI 48824 — We report on numerical experiments in which DNS is carried out for turbulent fully-developed channel flows over rough walls, describing 42 different surfaces at two frictional Reynolds numbers of 500 and 1000. The surfaces differ in roughness area distribution, effective slope, average inclination, porosity and degree of randomness. The dependence of equivalent sand-grain-height $k_s$ on different texture parameters was explored by using dimensional analysis and a differential evolutionary algorithm to optimize the coefficients of a single low-order multidimensional fitting function for all surfaces. It shows a strong dependence of $k_s$ on mean roughness height, effective slope and skewness, and fits the $k_s$ data with an error of no more than 20% in any of the 42 surfaces, even though the actual value of $k_s^+$ varies from 20 to 300 in these simulations. This corresponds to less than 10% error in prediction of the roughness function $\Delta u^+(k_s^+)$ for $k_s^+ \geq 25$. The same procedure is then used to model the total drag term in the Navier-Stokes equations when the Reynolds stress is described by the $i^2$-f model of Durbin (1991). It indicates a strong dependence of the drag profile on the roughness area distribution and on the profiles of $uv^+$ and $v^2$.

5:42PM P42.00003 Determination of roughness scales that accurately predict frictional drag1, KAREN FLACK, MICHAEL SCHULTZ, US Naval Academy — Significant progress has been made towards the understanding of rough-wall boundary layers and the subsequent drag penalty. Continued progress is promising since a larger range of parameter space can now be investigated. Recent advances in rapid prototyping techniques enables the generation of systematic variations of roughness scales and computationally efficient simulations with creative surface mapping techniques allows for experiments and computations to investigate similar complexity. While a universal drag prediction correlation is still elusive and may not be possible, predictive correlations for classes of surface roughness pertinent to engineering applications seem achievable. Three surface parameters based solely on surface statistics are showing promise in predictive correlations for a range of studies. These include a measure of surface elevation ($k_{rms}$, $k_s$, $k_v$) a slope parameter (ES, solidity) and the skewness of the pdf. Other candidate parameters that may be useful in a predictive correlation or a surface filter are the streamwise and spanwise correlation lengths.

5:55PM P42.00004 Turbulent boundary layer perturbation by two wall-mounted cylinders arranged in tandem at various spacings and height ratios, ALI HAMED, ADAM PETERLEIN, Department of Mechanical Engineering, Union College — The perturbation of a turbulent boundary layer by two cylindrical roughness elements in close proximity was experimentally investigated using particle image velocimetry (PIV). The two cylinders were arranged in tandem with center-to-center streamwise spacings of 2d, 4d, and 6d, where d is the diameter of the cylinders. The downstream cylinder had a fixed height (approximately 20% of the boundary layer thickness); the height of the upstream cylinder was varied to achieve upstream to downstream cylinder height ratios of 1, 0.75, and 0.5. The flow measurements were made at $Re = 57000$ (based on the boundary layer thickness and freestream velocity) and included measurements over an isolated cylinder as a baseline case. The results highlight the effects of sheltering by an upstream cylinder on the wake of the downstream cylinder. Flow features in the wake, including the downwash, upwash, recirculation zone, velocity deficit, Reynolds shear stress, and turbulent kinetic energy (TKE), are highly dependent on the degree of sheltering which is governed by both the streamwise spacing and height ratio. Additionally, proper orthogonal decomposition (POD) and quadrant analysis were used to examine the changes to the turbulence structure as a function of both the spacing and height ratio.

6:08PM P42.00005 Random roughness effects on the near-wall flow in the transitionally rough regime1, RONG MA, KARIM ALAME, KRISHNAN MAHESH, University of Minnesota — Direct numerical simulation of turbulent channel flow over a random rough wall is performed at $Re_r = 100$ and 600. The rough surface corresponds to the experiments of Flack and Schultz (personal communication). The skin friction coefficient of the random-rough channel matches with the experimental results of Flack and Schultz. The roughness effects on the near-wall regions of mean velocity, Reynolds stresses, pressure fluctuations and streamwise mean momentum balance are investigated. The statistics of wall-shear stress fluctuations in the peak (above the mean height location) and valley (below the mean height location) regions are examined. The probability distribution function of wall-shear stress shows a better collapse after subtracting the mean and normalizing by the root-mean-squared value. The distribution tail is widened by the random roughness, implying that the probability of extreme events is increased. The probability of extreme events in the random-rough channel increases with increasing $Re_r$, in accordance with previous studies on smooth-wall flows.

Computing resources were provided by the Minnesota Supercomputing Institute (MSI). We are grateful to Professor K. Flack at the United States Naval Academy for providing us with the scanned surface data used in the present work.

6:21PM P42.00006 Towards Modelling the Downstream Development of a Turbulent Boundary Layer Following a Rough-to-Smooth Step Change in Surface Condition1, MOGENG LI, University of Melbourne, CHARITHA M. DE SILVA, University of New South Wales, DANIEL CHUNG, University of Melbourne, DALE I. PULLIN, California Institute of Technology, IVAN MARUSIC, NICHOLAS HUTCHINS, University of Melbourne — In this study we examine the effect of both the friction Reynolds number $Re_f$ and the roughness Reynolds number $k_s^+$ on a turbulent boundary layer following a rough-to-smooth step change in surface condition along the flow direction. To investigate the effect of $Re_f$, a set of wind-tunnel experiments is conducted at $k_s^+ = 160$ while $Re_f$ is varied from 7100 to 21000. Similarly, to examine the dependence on $k_s^+$, a set of measurements is conducted at $Re_f = 14000$ with $k_s^+$ ranging from 110 to 230. Hot-wire profiles are obtained on a logarithmically spaced grid up to 120 boundary-layer thicknesses downstream of the step change, and the local wall-shear stress is measured directly using oil-film interferometry. Using these data, we propose a new model of the recovering mean velocity profile which accounts for the well-known non-equilibrium behaviour of the internal layer. This mean velocity distribution is then evolved downstream of the step change using the integrated streamwise momentum equation to achieve a full prediction of the mean flow recovery.

Impact of spanwise effective slope on near-wall turbulence. THOMAS JELLY, NICHOLAS HUTCHINS, University of Melbourne, ANGELA BUSSE, University of Glasgow — Whereas streamwise effective slope (ES) is widely accepted as a key scaling parameter in the context of rough-wall turbulent flows (Napoli et al., J. Fluid Mech., 613:385-394, 2008), spanwise ES has received far less attention. Here, the statistical response of near-wall turbulence to systematic changes in spanwise ES is investigated by performing direct numerical simulations of rough-walled turbulent channel flow at a friction Reynolds number of 395. For the seven irregular surfaces considered in this study, the spanwise ES ranges from 0.35 to 0.10. All surfaces were synthesised with a near-Gaussian height distribution, i.e. negligible skewness and excess kurtosis, and a streamwise ES equal to 0.35. This allows the current study to focus on the impact of spanwise ES, since skewness, kurtosis and streamwise ES have been all effectively been eliminated as parameters. Starting from a baseline isotropic case, the hydraulic and hydrodynamic properties of each surface are compared as a function of spanwise ES. Details related to the Hama roughness function, turbulence intensities and dispersive stresses will be presented and discussed. Preliminary results from a complementary experimental campaign will also be presented.

Direct numerical simulation for irregular roughness on a curved surface. HAOLIANG YU, UMBERTO CIRI, ARIF MALIK, STEFANO LEONARDI, The University of Texas at Dallas — Surface roughness is critical to aerodynamic performance. Ice accretion, insect contamination, dust accumulation, and surface erosion represent major sources affecting surface perturbations in atmospheric applications. In wind energy, for example, insect contamination on turbine surfaces can significantly increase skin drag and reduce power production. Although some experiments and numerical simulations have been carried out to study roughness effects, the contributions of different roughness parameters are not well understood, particularly when over curved surfaces. Commonly used engineering models for roughness penalty prediction also demand more insights and validation. Therefore, this study includes direct numerical simulations for irregular roughness over a curved (airfoil) surface. A precursor simulation is conducted to generate fully developed turbulent inflow. The blade geometry and roughness are defined by the ray triangle intersection test and modeled using immersed boundary method. Resulting flow fields are analyzed and compared for the various parametric cases.

The effect of surface-obstacle geometry on maximizing air exchange over rough surfaces for use in direct air carbon capture assemblies. SIMONE STEW-ART, PAOLO LUZZATTO-FEGIZ, University of California Santa Barbara — Climate mitigation scenarios from integrated assessment models show it will likely be necessary to remove previously-released atmospheric CO2. A proposed implementation of negative emission technologies is direct air capture (DAC), which consists of box-like absorbers, through which air is passed and scrubbed of CO2. While the objective has been to scale up DAC to large arrays, the flow over these arrays has never been examined. The details of this flow are crucial; it is necessary for the first row of absorbers, it must mix quickly with the surrounding atmosphere before encountering the next row, or performance will be seriously degraded. To improve CO2 extraction from DACs, approaches to maximize the mass exchanges are investigated; exploiting the concept that flow over the DAC array is equivalent to flow over obstacles that comprise a rough surface. We perform reduced-scale experiments using model arrays in a water channel to study how the array geometry influences mass transport. We find that critical roughness spacings needed to avoid the development of recirculation regions are dependent on the aspect ratio of the obstacles. Thin obstacles have smaller critical spacings and result in stronger mixing, which supports the design of DAC arrays that minimize cost and land usage.

Direct Numerical Simulation of Wind Wave Growth. JIARONG WU, LUC DEIKE, Mechanical and Aerospace Engineering, Princeton University — The growth of wind wave is still an open question as current models often diverge in both the mechanism postulated and the growth rate predicted. There have been an increasing number of numerical studies on this subject, with the development of various numerical methods and increase in computational power. The difficulty, however, arises from three aspects: the modeling of the turbulent air boundary layer; the response of water to the wind forcing; and the coupling between the two. Separate numerical studies have been done on the first two but are insufficient in revealing the whole picture of wind wave interaction. Using the open source solver Basilisk, which solves the full two-phase air water incompressible Navier-Stokes equations with adaptive grids, we perform fully coupled wind wave simulation to study a range of parameters that factor into the growth model, including the friction velocity of air, initial wave amplitude, surface tension and viscosity, and to improve the current models of wind wave growth.

High-resolution DNS of Breaking Waves. WOUTER MOSTERT, Mechanical and Aerospace Engineering, Princeton University, STEPHANE POPINET, Institut Jean Le Rond d’Alembert, CNRS UMR 7190, Sorbonne Université, LUC DEIKE, Mechanical and Aerospace Engineering, Princeton University — We present bubble and droplet size distributions resulting from breaking ocean waves in deep water, using high-resolution three-dimensional direct numerical simulation. We use the open-source Basilisk code to simulate the viscous Navier-Stokes equations in two phases with surface tension at effective resolutions of up to 40963. The interface is represented and advected with a momentum-conservative volume-of-fluid scheme. The high effective resolutions are made possible with an octree adaptive mesh refinement scheme which is robustly implemented in Basilisk. The wave is initialized in one wavelength with an unstable third-order Stokes formulation, which produces local conditions leading to a plunging breaker which entrains air and ejects spray, which are directly resolved by the mesh. Varying the Bond and Reynolds numbers, which control surface tension and viscosity relative to the gravitational and inertial effects respectively, we discuss issues such as bubble breakup in turbulent flow; dimensionality in the transition to turbulence; droplet production and breakup; and numerical grid convergence.

8:11AM Q01.00003 Effect of chemical herders on wave breaking1. LAKSHMANA CHANDRALA, FRANZ O’MEALLY, JOSEPH KATZ, Department of Mechanical engineering, Johns Hopkins University — Chemical surface-active agents (oil herders) could be used to concentrate oil slicks to facilitate in-situ burning after an oil spill. The water-insoluble but oil-soluble surfactants in commercial oil herders accumulate on the air-water interface and might alter the wave breaking process. In this study, the characteristics of mechanically generated breaking waves of varying energies are visualized in clean seawater and water treated with a herder containing 65% Span-20 and 35% 2-ethyl butanol at a concentration of 5.5 ml/m². The experiments are performed in a 6x0.3x0.6 m transparent tank and the waves are generated by translating a paddle. Multiple high-speed cameras follow the evolution of both waves. For a plunging breaker in clean water, prior to impact, the wave front contains multiple ripples and small fingers. In contrast, in treated water the wave-front is smooth, resulting in entrainment of a larger volume of air, and deeper subsequent penetration of the bubble cloud. Conversely, for relatively weak spilling breakers, adding the surfactant delays the wave breaking, and dampens the formation of capillary waves on the wave crest. Once breaking occurs, visually, there is no significant difference in the appearance and penetration of the waves.

8:24AM Q01.00004 Study of ocean wave field reconstruction and effect of control parameter selection. JIE WU, XUANTING HAO, LIAN SHEN, University of Minnesota, Twin Cities & St, Anthony Falls Laboratory — In this research, we study the reconstruction of ocean wave field by optimizing the initial wave field for wave-phase-resolved simulation to best fit measurement data with noise. In reality, the measured data often contains only part of the information needed to reconstruct the entire wave field or is contaminated by noises. We investigate the effect of different control parameter selections on the wave field reconstruction performance using synthetic wave data. The initial condition of the wave field is constructed from the JONSWAP spectrum and its evolution is simulated using the high-order spectral method. Random noises are added to the wave field at each observation time instant to serve as the noise. The result shows that by incorporating relationship between the free surface elevation and the free surface velocity potential, the error between the reconstructed wave field and the true wave field can be reduced appreciably. This study provides guidance on choosing appropriate control parameters to improve the reconstruction and prediction performance in ocean wave applications.

8:37AM Q01.00005 ABSTRACT WITHDRAWN

8:50AM Q01.00006 Hysteresis phenomena in gravity–capillary waves on deep water generated by a moving two-dimensional/three-dimensional air-blowing/air-suction forcing1. YEUNWOO CHO, BEOMCHAN PARK, Korea Advanced Institute of Science and Technology — Hysteresis phenomena in forced gravity–capillary waves on deep water where the minimum phase speed c_{min}=23cm/s are experimentally investigated. Four kinds of forcings are considered; 2-D/3-D air-blowing/air-suction forcings. For a still water initial condition, as the forcing speed increases from zero towards a certain target speed (U), there exists a certain critical speed (U_{crit}) at which the transition from linear to nonlinear states occurs. When U<U_{crit}, steady linear localized waves are observed (state I). When U_{crit}<U<U_{min}, steady nonlinear localized waves including steep gravity–capillary solitary waves are observed (state II). When U≈c_{min}, periodic shedding phenomena of nonlinear localized depressions are observed (state III). When U>c_{min}, steady linear non-local waves are observed (state IV). Next, with these state-I, III and IV waves as new initial conditions, as the forcing speed is decreased towards a certain target speed (U_{final}), a certain critical speed (U_{crit,2}) is identified at which the transition from nonlinear to linear states occurs. When U_{final}<U_{crit,2}, linear state-I waves are observed. These are hysteresis phenomena which show the dependence of a state on its history starting from different initial conditions.

9:03AM Q01.00007 Air-induced axisymmetric sloshing waves on a water surface1. UTKARSH JAIN, FRANCESCO VIOLA, DETLEF LOHSE, DEVARAJ VAN DER MEER, Physics of Fluids group, University of Twente — Here we experimentally study the surface wave trains generated by an oscillating disk placed above a water basin. The harmonic vertical motion of the disk yields a radial, periodic flow of air in the thin gap between the disk and the water. Although the disk is never in contact with the water, the oscillating air pressure in the gap is sufficient to excite a system of standing and travelling capillary-gravity waves at the free-water surface. The dynamics of these waves are measured both inside and outside the disk’s projection over the free water surface using an in-house experimental method based on total internal reflection. This allows us to reconstruct the instantaneous free surface elevation in the whole basin. To rationalize our experimental observations, we analytically solve the air flow below the disk using the lubrication equations. The resulting oscillating pressure is then coupled to the water phase through the dynamic condition at the free water surface, which forces axisymmetric waves on the entire liquid surface, for which we solve by means of Hankel transforms. Theoretical calculations and experiments show qualitatively similar behavior, and the wavenumbers measured experimentally are well reproduced by theory over a large frequency range.

9:16AM Q01.00008 Generation of Water Waves by Underwater Multi-Point Action1. LEONARDO GOMRI, JUAN F. MARÍN, ISIS VIVANCO, Departamento de Física, Universidad de Santiago de Chile, Santiago, Chile, BRUCE CARTWRIGHT2, The University of Newcastle, Callaghan, NSW 2308, Australia — Wave generation in channels is usually achieved through wavemakers (moving paddles) acting on the surface of water. Although practical for this purpose, wavemakers have issues: they perform poorly in the generation of long waves and create evanescent waves in their vicinity. In this talk, we introduce a framework for wave generation through the action of an underwater multi-point mechanism. We analyze the linear response of waves in a uniform channel in terms of the frequency and wavelength of the bottom action. The system behaves as a long-pass filter in space and a high-pass filter in time with a sharp resonance limited by viscosity. The framework naturally solves the problem of the performance for long waves and reduces evanescent waves to thin boundary layers at the bottom. We also show that a proper synchronization of an orbital motion on the bottom can produce waves that mimic deep water waves with great accuracy. This last feature has been proved to be useful and efficient to study fluid-structure interaction in simulations based on smoothed-particle hydrodynamics.

**7:45AM Q02.00001 Velocity Oscillations of a Walking Droplet**$^1$. SAM TURTON, MATTHEW DUREY, JOHN BUSH, Massachusetts Institute of Technology — Couder et al. (2005) demonstrated that a droplet bouncing on the surface of a vertically oscillating bath may destabilize to a walking state characterized by rectilinear motion across the bath surface at a constant speed. When a walking droplet is perturbed, there is experimental (Wind-Willansen et al. (2013)) and theoretical (Bacot et al. (2019)) evidence suggesting that its velocity may return to its free walking speed via over- or underdamped oscillations. By revisiting the stroboscopic pilot-wave model of Oza et al. (2013), we demonstrate that linear stability analysis of the walking state predicts velocity oscillations over a lengthscale that becomes commensurate with the Faraday wavelength as the vibrational acceleration approaches the Faraday threshold. Furthermore, we demonstrate that this model predicts that the walking state destabilizes via a subcritical Hopf bifurcation, where the associated unstable limit cycle consists of periodic velocity oscillations, also on a scale comparable to the Faraday wavelength. This behavior conditions the droplet’s histogram to develop a coherent structure on the scale of the Faraday wavelength, and so provides new insight into the emergence of quantum-like statistics from pilot-wave hydrodynamics.

**7:58AM Q02.00002 Experiments on Droplet Deformation and Lag in a Low Reynolds Number Flow**. DAVID BIGIO, ADITYA N. SANGLI, University of Maryland, College Park, MARGARET LO, Cornell University, ARTIOM KOSTIOUTK, AMIR RIAZ, University of Maryland, College Park — In low Reynolds number multiphase flows, existence of a velocity gradient in the bulk flow imposes viscous stresses on a deformable interface. Here we study the effect of a bulk flow of Castor oil, through a converging channel, on a suspended Silicone oil droplet (radius $\sim 2$ mm). We apply Lubrication theory to study the bulk flow and approximate the single phase flow profile, which agrees well with experimental determination of the flow velocity. Suspending Silicone oil droplets into the flow, we study the effect of a constant extensional rate on the droplet imposed by the bulk flow. The degree of droplet deformation depends on the initial Capillary number and heuristic deductions of the critical Capillary number are made. Experimental observations also indicate a lag in the droplet advection velocity compared to the bulk flow at the same point and we present a physical mechanism to explain the observation.

**8:11AM Q02.00003 Direct Numerical Simulations of Droplet Deformation in Low Reynolds Number Extended Flows**. ADITYA N. SANGLI, BERNARD CHANG, DAVID BIGIO, AMIR RIAZ, University of Maryland, College Park — We study the effect of stagnant and non-stagnant extensional flows on a suspended immiscible droplet using direct numerical simulations. We use projection method to solve the governing equations of motion, and the deformable interface is treated using level set method. This scheme is used to simulate the behavior of a droplet in a hyperbolic flow as a low Reynolds number numerical analogue of the classic four-roll mill experiments. Results indicate that the critical Capillary number of the droplet increases with reduction in Reynolds number and approaches results from the four-roll mill study which approximated a Stokesian flow. To study non-stagnant extensional flows, we simulate the motion of a Silicone oil droplet (radius $\sim 2$ mm) in a Castor oil matrix through a hyperbolic converging channel. Streamwise stretching of the droplet was observed and plots of droplet draw ratio vs time and position of the droplet in the flow are validated with experimental results.

**8:24AM Q02.00004 The resonance of water balloons and water drops**$^1$. CHUN-TI CHANG, National Taiwan University, PAUL STEEN, Cornell University — What happens if a sessile drop is covered with a membrane and mechanically oscillated? In this study, we examine the resonance behaviors of water balloons, and we compare them to those of drops. It turns out that balloons and drops exhibit a variety of similar dynamical behaviors: families of corresponding modes, similar scalings for onset thresholds and almost identical dispersion relations. However, balloons and drops may synchronize differently with the forcing. In this talk, we shall carefully examine different aspects of the resonance of balloons and drops. Ultimate, we shall identify the extent to which one can understand the dynamics of balloons in terms of that of drops.

**8:37AM Q02.00005 On the Basset-Boussinesq history force of a fluid sphere**. DOMINIQUE LEGENDRE, IMFT-Toulouse — We consider the Basset-Boussinesq (history) force experienced by a spherical drop. The kernel of the Basset-Boussinesq force has not been determined so far when internal circulation of the fluid occurs. We first characterize the slip at a fluid sphere interface. Under both steady and unsteady conditions, the corresponding slip length is remarkably uniform along the fluid sphere interface and is directly related to the viscosity ratio. Combining the analytical expression of the Basset-Boussinesq kernel obtained for a solid sphere with interface slip and the obtained description of the slip at the fluid-fluid interface, we were able to describe for the first time the Basset-Boussinesq history force acting on a spherical drop. This expression is valid whatever the viscosity ratio from bubbles to viscous drops.
8:50AM Q02.00006 Hydrodynamics of a hollow water droplet falling in air, MOONIKA BALLA, Indian Institute of Technology Hyderabad, India, MANOJ TRIPATHI, Indian Institute of Science Education and Research Bhopal, KIRTI SAHU, Indian Institute of Technology Hyderabad, India — We study the hydrodynamics of a compound/hollow water droplet falling in air by conducting three-dimensional numerical simulations of the Navier-Stokes and the continuity equations using a finite volume based volume-of-fluid method. The various physical parameters influencing the dynamics are the thickness of the hollow droplet, inertia and surface tension at the air-water interface. It is found that the droplet exhibits shape oscillations. The oscillations of the inner interface (inner air bubble) of the hollow droplet is periodic with a time period about half of that of a normal droplet. The deformation of the outer interface of the hollow droplet is aperiodic and breaks up when the deformation is more. Increasing the thickness of the hollow droplet decreases the oscillations of both the inner and outer interfaces. As expected, the oscillations decay with time at low inertia. As the thickness of the hollow droplet decreases a spike like structure appears at the bottom of the hollow droplet. This instability is enhanced as the surface tension and the ratio of the viscous force to the gravitational force are decreased. The velocity contours are used to explain the behaviour observed in the present study.

9:03AM Q02.00007 Force analysis acting on the moving droplet in air-flow1, YEWON KIM, HYUNGMIN PARK, Seoul National University, ALIDAD AMIRFAZLI, York University — Movement of a water droplet over a surface due to a shearing airflow was studied in a wind tunnel. Water droplets (5-20 μl) were placed on PET (hydrophilic) and PTFE (hydrophobic) surfaces; airflow velocities up to 25 m/s and accelerations between 4.4-10 m/s² were used. The Reynolds number is under 3,400 based on the free-stream air velocity (U∞) and the height of the droplet (h). High-speed cameras from top and side views were used to evaluate the droplet velocity, acceleration, and contact angle hysteresis. Droplets start to move at different air velocities depending on the droplet volume, flow acceleration, and surface wettability. Also, droplets show different acceleration patterns for different experimental case. For example, when flow acceleration is 4.4 m/s², 5μl droplet on the PTFE surface start to move at lower free-stream velocity with lower droplet acceleration compared to those on the PET surface. To understand the behavior of droplets, we constructed a model by considering the drag, adhesion, and viscous forces acting on the moving droplet. We would discuss the relation between the droplet behavior and airflow state (velocity and acceleration) and validate our force balance model for the droplet.

1Supported by grants (2017R1A4A1015523, 2017M2A8A4018482, KCG-01-2017-02, IT12041 MITACS GRA-NRF) funded by Korea government, Korea Coast Guard, and MITACS.

9:16AM Q02.00008 Droplet condensation patterns: universality or non-universality?, LAURA STRICKER, ETH Zurich, JUERGEN VOLLMER, University of Leipzig, ROBERT STYLE, ERIC DUFRESNE, ETH Zurich — When a flux of supersaturated vapour gets into contact with a solid substrate, a condensation process can originate, leading to the formation of droplets patterns on the substrate (“breath figures”). The interest for breath figures is both practical and theoretical. We present here an experimental study of three-dimensional breath figures forming on a two-dimensional substrate. By making use of scaling concepts, we indentify a series of characteristic exponents, such as the so-called polydispersity exponent, characterizing the droplet size distribution. We proof the internal consistency of the results and we compare them to the predictions of the classical theory. According to such a theory, the polydispersity exponent should be a universal number, depending only on the dimensionality of the system. However, more recent theoretical studies claimed that the polydispersity exponent should heavily depend on the micrometric details of the condensation process (e.g. contact angle and critical nucleation radius of the droplets). We investigate the issue and we try to provide an answer, based on the experimental data.

9:29AM Q02.00009 Ultrasonically-Enhanced Condensation by Induced Interfacial Droplet Ejection, THOMAS BOZIUK, MARC SMITH, ARI GLEZER, Georgia Institute of Technology — Ultrasonic (MHz range) actuation at the liquid-vapor interface of vapor flowing over a slow moving sub-cooled liquid layer exploits the differences in acoustic impedance to form a train of droplet that are ejected into the vapor. The increased interfacial surface area of the ejected droplets result in increased heat transfer between the vapor and the liquid and a significant increase in condensation without inducing a significant increase in upstream pressure. The enlarged droplets drop back into the subcooled liquid stream under gravity. A two-stream liquid-vapor experimental setup was designed to assess the effects of the acoustic actuation on the formation and ejection of the subcooled liquid droplets and the enhanced condensation over several combinations of relative flow rates and liquid subcooling, the observable increases in the sensible heat of the liquid stream as well as increased rate of mass transfer from the vapor to liquid stream. The evolution of the droplet-laden vapor within a mixing volume is visualized using high-speed imaging and is used to investigate the effects of the residence time of the droplets within the vapor volume and possible applications to acoustically-driven heat exchangers.

7:45AM Q03.00001 Effect of surfactants on jet break-up and drop formation in inkjet printing1, EVANGELIA ANTONOPoulos, OLIVER G. HARLEN, MARK A. WALKLEY, NIKIL KAPUR, University of Leeds — A key challenge in developing new applications of inkjet technology is to produce inks that can be jetted to form individual droplets and to transport functional components needed for the application. The development of mathematical models that allow fluid jetting behaviour to be determined as a function of fluid properties would allow optimisation to be carried out in-silico before creating the inks and verifying the performance. Surfactants are often added to aqueous inks in order to modify the surface tension. However, the rapid expansion of the free surface during the fast jetting process means local areas of the surface will be depleted of surfactants leading to surface tension gradients. Using high speed video we will compare the jetting behaviour of fluids with and without surfactants in an industrial inkjet print-head. We also present numerical simulation of inkjet break-up and drop formation in the presence of surfactants investigating more closely both the surfactant transport on the interface and the influence of Marangoni forces on break-up dynamics.

9:03AM Q03.00007 Three-dimensional simulations of surfactant-contaminated flows in superhydrophobic microchannels. SCOTT SMITH, FERNANDO TEMPRANO-COLETO, UCSB, FRANCOIS PEAUDECERF, ETH Zurich, JULIEN LANDEI, U. Manchester, FREDERIC GIBOU, PAOLO LUZZATTO-FEGIZ, UCSB — Trace amounts of surfactants are now known to severely limit the drag reduction along superhydrophobic surfaces, due to Marangoni stresses, as demonstrated in Peaudecerf et al. (PNAS, 2017), and Song et al. (PRF, 2018). When driving flow in superhydrophobic microchannels, surfactants adsorb onto the air-water interface (known as the plastron) and cause adverse Marangoni stresses in the opposite direction to the driving flow. There is currently an effective model that considers two-dimensional surfactant-laden flow in superhydrophobic channels (Landel et al. arXiv:1904.01194, 2019). Here we perform three-dimensional simulations of the full problem using COMSOL, in order to test our extension of this model to account for the drag of a fully three-dimensional flow. We are able to compute drag reduction as a function of the microchannel geometry, surfactant concentration, and the characteristic dimensionless numbers of the momentum and surfactant transport equations. These simulation results are then used to explore physical trends and validate our extended model.

9:16AM Q03.00008 Suspension coating on a fiber. EMILIE DRESSAIRE, BRIAN DINCIAU, UCSB, QUINTEN MAGDELAINE, SVI (CNR/SAINT GOBAIN), ETHAN MAI, UCSB, MARTIN BAZANT, MIT, ALBAN SAURET, UCSB — The thickness of the coating layer entrained by a solid withdrawn from a bath depends on the physical properties of the liquid, the withdrawal speed, but also on the substrate geometry. In particular, many common substrates that are subjected to liquid immersion and withdrawal have the general shape of a thin cylinder such as needles, wires, and fibers. We investigate glass fibers as a model substrate and demonstrate that their diameter plays a dominant role in the particle entrainment and coating by suspensions. We identify experimentally and rationalize different coating regimes of the fiber: at small capillary number, only a liquid film coats the fiber. At intermediate capillary numbers, a heterogeneous coating made of clusters of particles is observed. Finally, at large capillary number, the thickness of the entrained film is captured using the effective viscosity of the suspension. Our results demonstrate that varying the size of the fiber leads to a new degree of control in the entrainment of particles via capillary filtering.

9:29AM Q03.00009 Weakly-nonlinear evolution of surface-tension driven waves in the presence of viscosity. QUINTON FARR, ROUSLAN KRECHETNIKOV, University of Alberta — Weakly nonlinear models describing the evolution of water waves such as the Korteweg-de Vries and nonlinear Schrödinger equations have been widely studied because of their ability to capture the behavior of interesting physical phenomena through the reduction of a full problem to a much simpler system retaining only first order nonlinear effects. While a large class of these reductions for gravity-driven waves are well-understood, situations where surface tension is the only driving force require further attention. We consider wave motion on a one-dimensional thin liquid film of infinite extent and on the perimeter of a two-dimensional liquid drop, forced by surface tension in lieu of gravity. Viscosity is also included to understand the effect of dissipation. Our investigation leads to new equations governing surface tension-driven waves. We discuss their properties, special solutions, and physical implications.

7:45AM Q04.00001 Constitutive model for time-dependent flows of shear-thickening suspensions. JURRIAAN GILLISSEN, University College London, CHRISTOPHER NESS, JOSEPH PETERSON, University of Cambridge, HELEN WILSON, University College London, MICHAEL CATES, University of Cambridge — We develop a tensorial constitutive model for dense, shear-thickening particle suspensions subjected to time-dependent flow. Our model combines a recently proposed evolution equation for the suspension microstructure in rate-independent materials with ideas developed previously to explain the steady flow of shear-thickening ones, whereby friction proliferates among compressive contacts at large particle stresses. We apply our model to shear reversal, and find good qualitative agreement with particle-level, discrete-element simulations whose results we also present.

1We acknowledge financial support from the Engineering and Physical Sciences Research Council of the United Kingdom Grant No. EP/N024915/1, and from the European Research Council under the Horizon 2020 Programme, ERC grant agreement number 740269. MEC is funded by the Royal Society.

7:58AM Q04.00002 The influence of surface roughness on the rheology of immersed and dry frictional spheres. ELISABETH GUAZZELLI, MSc, CNRS, University of Paris, FRANCO TAPIA, OLIVIER POULIQUEN, Aix Marseille University, CNRS, IUSTI — Pressure-imposed rheometry is used to examine the influence of surface roughness on the rheology of immersed and dry frictional spheres in the dense regime. The quasi-static value of the effective friction coefficient is not significantly affected by particle roughness while the critical volume fraction at jamming decreases with increasing roughness. These values are found to be similar in immersed and dry conditions. Rescaling the volume fraction by the maximum volume fraction leads to collapses of rheological data on master curves. The asymptotic behaviors are examined close to the jamming transition.

8:11AM Q04.00003 Mechanism of contact network formation leading to discontinuous shear thickening in dense suspensions. PRABHU NOTT, TABISH KHAN, Indian Institute of Science — The phenomenon of discontinuous shear thickening (DST) of dense particle-liquid suspensions has received considerable attention in recent years, and it is now generally believed that the formation of a Coulomb friction-mediated particle contact network causes the dramatic rise in viscosity at a critical shear stress. A common feature of most experimental studies is that the suspension is ‘prepared’ by pre-shearing for a long time before conducting the shear rate or stress sweep. The implicit assumption in this protocol is that in the prepared state, the stress responds at a critical shear stress. A common feature of most experimental studies is that the suspension is ‘prepared’ by pre-shearing for a long time before conducting the shear rate or stress sweep. Here we present experimental evidence that paints a contrasting picture. By following another protocol, we show that the substance is required to build up the contact network that culminates in shear thickening. Our study indicates that the contact network results from a cooperative arrangement of smaller clusters of particles. We show that over the period of shear, the suspension goes through continuous shear thickening (CST), then DST, followed by jamming, and finally frictional plastic deformation.

8:24AM Q04.00004 Shear-thickening of a non-colloidal suspension with a viscoelastic matrix , MARCO ELLERO, Basque Center for Applied Mathematics, ADOLFO VAZQUEZ-QUESADA, Universidad Autonoma de Madrid, PEP ESPAOL, Universidad Nacional de Educacion a Distancia (UNED) Madrid, ROGER TANNER, University of Sydney — In this work we study the rheology of a non-colloidal suspension of rigid spherical particles interacting with a viscoelastic matrix. Three-dimensional numerical simulations under shear flow are performed using the smoothed particle hydrodynamics method and compared with experimental data using different elastic Boger fluids. The rheological properties of the Boger matrices are matched in simulation under viscometric flow conditions. Suspension rheology under dilute to semi-concentrated conditions is explored. It is found that at small Deborah numbers, relative suspension viscosities $\eta_r$ exhibit a plateau at every concentration. By increasing $\text{De}$ shear-thickening is observed. Under dilute conditions ($\varphi = 0.05$) numerical results for $\eta_r$ agree quantitatively with experimental data. By increasing the solid volume fraction towards $\varphi = 0.3$, despite the fact that the trend is well captured, the agreement remains qualitative. With regard to the specific mechanism of elastic thickening, the microstructural analysis shows that it correlates well with the averaged viscoelastic dissipation function, requiring a scaling as $\text{De}^{\alpha}$ with an exponent $\alpha$ greater than 2 to take place. Locally, flow regions responsible of the elastic thickening are well correlated to areas with significant extensional component.

8:37AM Q04.00005 A new dimensionless number governing dethickening in orthogonally perturbed shear thickened suspensions , MEERA RAMASWAMY, Department of Physics, Cornell University, ABHISHEK SHETTY, Rheology department, Anton Paar USA, ITAI COHEN, Department of Physics, Cornell University — When concentrated colloidal suspensions are under stress, their viscosity can increase by over an order of magnitude. Previous work has shown that this shear thickened viscosity can be tuned by applying fast oscillatory perturbations orthogonal to the primary shear flows in the system. In this talk, I show that dethickening in the regime where the primary shear flow has fully thickened the suspension, is governed by a single dimensionless number -- the ratio of the orthogonal shear rate amplitude to that of the primary shear rate. In contrast, a second parameter is required to describe the data in the primary shear flow regime where the suspension is thickening. Understanding these parameters will enable better strategies to tune the properties of shear thickening suspensions for applications ranging from 3D printing to the processing of cement.

8:50AM Q04.00006 ABSTRACT WITHDRAWN —

9:03AM Q04.00007 Dynamical behavior of electrореological suspensions , SUCHANDRA DAS, New Jersey Institute of Technology, SRIRAM PILLAPAKKAM, Temple University, NAGA MUSUNURI, Indiana Tech, ISLAM BE-NOUJAGUEF, New Jersey Institute of Technology, EDISON AMAH, Intel Corporation, IAN FISCHER, PUSHPENDRA SINGH, New Jersey Institute of Technology — Electrorheological suspensions are formed by suspending dielectric solid particles in a dielectric liquid. The size of the particles varies between nano and micro meters, depending on the requirements of the intended application. When an electric field is applied, the particles become polarized and form chains and columns which align in the direction of the field, and this increases the viscosity of the electrorheological suspension. This change in the suspension microstructure and viscosity happens within a few milliseconds after the electric field is applied, and when the electric field is removed the viscosity goes back to the original value, which makes the suspension suitable for the applications where a quick response time is desired. The aim of this work is to employ the experimental and direct numerical simulation techniques to study the electrorheological response and the role of parameters such as the particle size and polarizabilities in the process.

9:16AM Q04.00008 Oscillatory shear response of the rigid-rod model in nematic regime¹, GIOVANNANTONIO NATALE, University of Calgary, MARCO DE CORATO, Universitat de Barcelona — Nematic phase of rigid-rod molecules presents rheological complexities given the intrinsic anisotropy of the molecules and spatial variation of an average molecular orientation (director) in the bulk. This microscopic model has been investigated in simple shear flow showing complex dynamics (log-rolling, wagging and tumbling regimes). Oscillatory shear flow is a model transient flow field which introduces a transient and periodic perturbation to the system. Recently, large amplitude oscillatory shear (LAOS) has attracted interest given the rich rheological response that is obtained. However, the interpretation at the microstructural level of the LAOS response is still limited to specific systems. Here we perform numerical simulations of the Doi-Hess equation in oscillatory shear for the molecular orientational distribution function using Brownian dynamics and an expansion in spherical harmonics. A new methodology to switch between the nematic and isotropic orientational state thanks to the transient nature of the flow is proposed. Moreover, oscillatory shear flow is found to be more efficient than the simple shear flow to capture the full microstructural dynamics. This methodology can provide a new strategy for experimental characterization of nematic colloidal suspensions.

9:29AM Q04.00009 Extensional rheology of a dilute suspension of spheres in a dilute polymer solution¹, ARJUN SHARMA, Graduate Student, Sibley School of Mechanical and Aerospace Engineering, Cornell University, Ithaca, NY, 14853, USA, DONALD KOCH, Professor, Robert Frederick Smith School of Chemical and Biomolecular Engineering, Cornell University, Ithaca, NY 14853, USA — We investigate the steady-state rheology of a dilute suspension of spherical particles in a dilute polymer solution modeled by the FENE-P constitutive relation. This work uses a semi-analytical method based on ensemble averaged equations, a perturbation for small polymer concentration and the generalized reciprocal to determine the polymers’ influence on the particle stresslet and the particles’ influence on the polymer stress. In the undisturbed flow, polymers undergo a rapid transition from a coiled to almost fully stretched state at a critical Deborah number (ratio of polymer relaxation to flow time scale) of $D_e = 0.5$. The particle-polymer contribution enhances the averaged stress below $D_{ec}$ due to a strong local stretch enhancement in specific regions of the flow. Above $D_{ec}$, polymers passing around the particle tend to collapse in response to a time history of strain rates which on average are smaller near the particle. These insights are elucidated through a variant of the Finite-time Lyapunov exponent for the Stokes velocity around the sphere. Similar to the undisturbed stress, below $D_{ec}$ we find the particle- polymer contribution to the average stress to be independent of the maximum stretching length (L) and for higher De to scale as $L^2$ for $L \gg 1$.

Tuesday, November 26, 2019 7:45AM – 9:42AM –
Session Q05 Compressive Flows: Supersonic and Hypersonic Flows 204 - Thomas Corke, University of Notre Dame
7:45AM Q05.00001 Reducing shock related unsteadiness of supersonic flow over spiked bodies, JACOB COHEN, DEVARBATA SAHOO, S. K. KARTHICK, Aerospace Engineering, Technion-Israel Institute of Technology, Haifa - 320003, SUDIP DAS, Space Engineering & Rocketry, Birla Institute of Technology, Mesra - 835215 — Spikes, mounted at the stagnation point of a blunt body moving at supersonic speed, are utilized to reduce the forebody drag at the expense of increase in flow unsteadiness. We examine three configurations: flat, hemispherical and elliptical blunt bodies. Our goal is to distinguish between the unsteadiness mechanisms associated with each configuration, using experiments and CFD conducted at \( M = 2 \). Drag is measured by in-house built balance, whereas unsteady pressure transducers and high-rate Shadowgraph snapshots, subjected to POD and DMD analysis, are utilized to quantify the flow unsteadiness. The flat blunt case has been investigated in the past and two modes of unsteadiness have been reported: a mild flapping oscillation and a violent axial pulsation. The latter mode is used to validate our results. When a spike is attached to hemisphere/ellipse body, the upstream strong detached bow shock wave is replaced by a system of weaker oblique shocks. The flow then separates over the spike body forming of a separated flow region bounded by an axisymmetric shear layer. Within the shear layer KH vortices are formed and shocklets are attached to these vortices and all move together downstream. We find the separation angle, separation shock and the separated volume to govern the flow unsteadiness. These are further demonstrated by using the hemispherical forebody with hemispherical spike tip.

7:58AM Q05.00002 Instantaneous velocity fields in a hypersonic wake, YIBIN ZHANG, DANIEL RICHARDSON, STEVEN BERESH, KATYA CASPER, MELISSA SOEHNEL, RUSSELL SPILLERS, Sandia National Laboratories — The cold wake behind a slender object in hypersonic flow offers a challenging environment for off-body measurements. Femtosecond Laser Electronic Excitation Tagging (FLEET) is a simple (single-laser, single imaging system) diagnostic that permits flowfield visualization without seeding or physical probes. FLEET optical and imaging parameters are tailored for measurements in the wake of a sharp cone in Mach 8 nitrogen flow, over freestream Reynolds numbers from \( 4 \times 10^6 \) to \( 14 \times 10^6 \). Fluorescing FLEET lines for 2D velocity measurements and crosses for 2D measurements are written into the flow. The signal-to-noise ratio and tagging efficiency are maximized by using third harmonic FLEET at 267 nm, which has never before been implemented in a hypersonic test case. Flow tagging captures prominent wake features such as the separation shear layer, wake turbulence and two-dimensional velocity components.

8:11AM Q05.00003 Stability and dynamics of supersonic axisymmetric bluff-body wake flows, SIMON GALIVEL, SAMIR BENEDDINE, DENIS SIPP, ONERA, SEBASTIEN ESQUIEU, CEA — The dynamics of separated wake flows behind an axisymmetric bluff body, where complex aerodynamic phenomena occur, is of primary importance for a correct estimation of its drag and trajectory. Those phenomena have been widely studied in incompressible flows, showing the existence of two bifurcations in the laminar regime which first steadily breaks the axisymmetry of the baseflow and then generates vortex shedding. The corresponding laminar large scale structures persist in turbulent regime. Unfortunately, an equivalent study for supersonic conditions is absent from the literature. Thus this work focuses on a supersonic wake of such bluff body \( (M = 4) \) in the laminar regime. A detailed study of unsteady simulations shows several instabilities: the breaking of the axisymmetry, complex flapping and rotation of the backflow region and an oscillating expanded region. Global stability analyses are then carried out to identify and study the flow mechanism of these instabilities. It highlights the driving role of the separation shear layer, of the backflow region, and of the expansion fan, and shows that the dynamics is significantly different from its incompressible counterpart.

8:24AM Q05.00004 DNS of transitional hypersonic boundary layers at high enthalpies, MARIO DI RENZO, PARVIZ MOIN, JAVIER URZAY, Center for Turbulence Research, Stanford University — Aerospace vehicles flying at hypersonic speeds are subject to boundary-layer transition, which causes a strong localized increase in wall heat transfer and friction. The influences of air dissociation at high-Mach numbers on the full process, including the non-linear early stages of turbulence, remain mostly unknown, and cannot be easily accessed by linear stability analyses or parabolized stability equations. In this presentation, DNS results of a hypersonic transitional boundary layer of dissociating air at high-enthalpy conditions are discussed, with particular focus on thermochemical effects on peak values of heat and shear stress. These simulations employ a novel task-based high-order solver written in the programming language Regent that is designed for exploiting GPU-based supercomputers.

8:37AM Q05.00005 Frequency-Wavenumber Spectrum of Surface Pressure Fluctuations Induced by High-Speed Turbulent Boundary Layers, JUNJI HUANG, YUCHEN LIU, LIAN DUAN, The Ohio State University — Spatio-temporal structure of the fluctuating pressure field induced from high-speed turbulent boundary layers is analyzed by using a database of direct numerical simulations (DNS). Specifically, DNS are used to examine and compare the frequency-wavenumber spectrum of wall pressure generated by Mach 8 turbulent boundary layers developing spatially over several canonical geometries including a 2-D flat wall, the inner wall of an axisymmetric nozzle, and a sharp slender circular cone. The study provides insights into the scaling of pressure disturbance spectrum with respect to the boundary-layer parameters and the flow configuration. Such information is important to developing physics-based models that could adequately predict the magnitude, frequency content, location, and spatial extent of boundary-layer-induced pressure fluctuations at high speeds for the structural design of high-speed vehicles.
8:50AM Q05.00006 Particle Relaxation Time for Titanium Dioxide in Hypersonic Flow¹, JOSE RODRIGUEZ, University of Illinois at Urbana-Champaign, BRIAN RICE, CHRISTOPHER MCKENNA, Air Force Research Laboratory — A critical component of the experimental technique Particle Image Velocimetry (PIV) is the response time of the seeding particles. Shock waves are commonly found in high-speed flow regimes, resulting in velocity discontinuities between pre- and post-shock regions. Seeding particles experience a time delay in the normal component of velocity as they transit the shock wave, known as particle relaxation time (PRT). Ragni et al. (J. Exp. Fluids, 2011). This delay is a function of the diameter and density of the particle and the surrounding fluid's viscosity. These properties influence the particles' light-scattering ability and Stokes number (a ratio between the particle and fluid time scales) Melling et al. (J. Meas. Sci. Tech, 1997). These properties contribute to imaging quality and how accurately the particles trace the flow. The PRT for TiO₂ across an oblique shock was characterized via 2D PIV conducted in the von Karman Gas Dynamics Facility Tunnel D at Arnold Air Force Base. A 6.5 degree wedge was used to generate the oblique shock wave in a Mach 5 freestream. The PIV data was fit to exponential Stokes drag decay to obtain the PRT. These findings will be compared with results for other particles that are currently being used throughout the community.

¹Air Force Research Laboratory

9:03AM Q05.00007 Dependence of penetration and entrainment on injectant properties for a jet in supersonic crossflow¹, DAN FRIES, DEVESH RANJAN, SURESH MENON, Georgia Institute of Technology — Four gases with different molecular weights and specific heat ratios are injected as circular, sonic jets into a supersonic crossflow (Mach 1.72). The jet fluid concentration distribution is quantified using a solid particle Mie-scattering technique. To account for the freestream Mach number, the bow shock in front of the jet and boundary layer thickness, an effective momentum flux ratio and a penetration relation based on momentum balance between jet and crossflow are used to improve the collapse of jet trajectories. The trajectory results also suggest a systematic influence of injectant properties on penetration that goes beyond what has been considered in the past. Trends are presented and analyzed further by association with Particle Image Velocimetry velocity data. The development of the velocity field especially in the windward shear layer of the jet elucidates changing compressibility effects on jet spreading and crossflow fluid mass entrainment.

¹In part funded by AFOSR

9:16AM Q05.00008 Stationary-Traveling Cross-Flow Transition Study on a Sharp Cone at Mach 6¹, ERIC MATLIS, ALEXANDER ARNDT, THOMAS CORKE, University of Notre Dame, MICHAEL SEMPÈR, US Air Force Academy — Experiments at Mach 6 in the 3-D boundary layer on a right-circular cone at an angle of attack have revealed evidence of a nonlinear (quadratic) interaction between stationary and traveling cross-flow modes that affect the boundary layer transition Reynolds number. The wavenumber of the stationary modes was controlled by passive patterned roughness located at Branch I. A glow-discharge electrode surface actuator was sputter-deposited just upstream of the patterned roughness to excite the traveling modes at a particular frequency. The observed stationary-traveling interaction was documented with miniature Kulite probes and appeared as an azimuthal variation in the amplitude of the traveling cross-flow mode with azimuthal wavenumbers that corresponded to the sum and difference of the azimuthal wavenumbers of the primary stationary and traveling modes. Cross-bicoherence verified a triple phase locking between the two primary modes and the summed mode for both the “critical” and “subcritical” roughness cases.

¹Supported by AFOSR Grant FA9550-15-1-0278

9:29AM Q05.00009 Sensitivity of hypersonic boundary layers to n-periodic surface roughness-element arrays and finite-rate chemistry¹, ATHANASIOS MARGARITIS, Imperial College London, TARANEH SAYADI, Sorbonne University, OLAF MARXEN, University of Surrey, PETER SCHMID, Imperial College London — Finite-rate thermochemical effects have an order-one influence on the macroscopic behavior of hypersonic boundary layers, hence they have to be accounted for in numerical simulations. Flow stability and heat loads are significantly affected by the modelling approaches in such simulations. Highly-parametrized thermochemical models are commonly used, introducing large amount of uncertainty. Furthermore, the effect of surface roughness and its potential interaction with finite-rate chemistry effects remains unexplored. A mathematical framework for linearized analysis of n-periodic systems of roughness elements is developed, allowing us to extract information about wake synchronization from reduced-cost simulations of a single unit or a triplet of units; this modifies the restrictive assumption of single-unit periodicity. An efficient adjoint-based sensitivity analysis is used to identify critical roughness or chemical model parameters, with respect to their effect on output flow quantities. This framework is applied to generic flat-plate boundary layer configurations for validation; extensions to more complex flow configurations are readily feasible. Preliminary results of an n-periodic system analysis for reacting and non-reacting flows will be presented.

Tuesday, November 26, 2019 7:45AM - 9:42AM – Session Q06 Acoustics: General 205 - Likun Zhang, University of Mississippi

7:45AM Q06.00001 Acoustic radiation force and scattering series expansions for spheres at low frequencies,¹, PHILIP L. MARSTON, Washington State University — Even in the case considered here where spheres are taken to be in inviscid fluids and all mechanisms for power absorption are neglected, it can be helpful to consider leading-order corrections to Rayleigh scattering. Using series expansions of scattering partial-wave phase shifts (that depend on material properties) quantities of interest can be expanded in powers of kR where k is the acoustic wave number and R is the sphere radius. This has been accomplished in a unified way for several cases, though it is necessary for kR to be below all resonances in each case. Situations considered include fluid and solid spheres and empty elastic shells in traveling and standing acoustic plane waves [1, 2]. The method is easily generalized to spheres in certain acoustic beams. There has also been renewed interest in low kR expansions of the quadrupole projection of the acoustic radiation stress based on Rayleigh scattering since that is relevant to the equilibrium shape of nearly-spherical acoustically-trapped objects [3]. [1] P. L. Marston, J. Acoust. Soc. Am. 145, EL39–EL44 (2019). [2] P. L. Marston, J. Acoust. Soc. Am. 146 (accepted). [3] P. L. Marston et al., J. Acoust. Soc. Am. 69, 1499-1501 (1981).

Numerical investigation of heat transfer induced by an oscillatory flow within a thermoacoustic engine core\textsuperscript{1}, KAZUTO KUZUKI, SHINYA HASEGAWA, Tokai University — Quantification of heat transfer phenomena in a thermoacoustic engine is a key to the successful improvements in the engine performance. From this point of view, Piccolo and Pistone (Int. J. Heat Mass Tran. 49 (2006), pp. 1631-1642) presented a computational method for heat transfer analysis of the thermoacoustic engine. In their method, a time-averaged energy conservation equation is solved for the acoustic field fixed at thermoacoustic engine core, and for simplification, the acoustic field was assumed to be a standing wave. However, the actual thermoacoustic device is often designed so that a travelling wave could be achieved at the engine core part, and furthermore, there are interactions between gas motion and temperature field. The present study proposes a computational model which can consider such interactions and travelling wave. In this model, both the Rott’s acoustic approximation equation (Thermoacoustics, ASA Press, pp.102) and the time-averaged energy conservation law are simultaneously solved in two-dimensional space. From the results, heat transfer within a thermoacoustic engine core is discussed.

Linear and nonlinear propagation of single-frequency dissipative waves in ducts with slowly-varying cross section\textsuperscript{1}, PABLO L. RENDON, ICAT, Universidad Nacional Autónoma de Mexico, NIGEL PEAKE, DAMTP, University of Cambridge — Finite-amplitude sound waves propagating in ducts are subjected to a variety of competing effects. In the context of the acoustics of wind instruments, nonlinear steepening is known to occur in trombones and trumpets when these instruments are played loudly, and in aircraft engine intakes buzz-saw noise is also associated with nonlinear propagation. The main dissipative mechanisms in these ducts tend to be losses at the duct walls rather than viscous thermal attenuation. These losses are due to a Stokes boundary layer which oscillates as the waves pass. In both these contexts, the duct cross-section varies slowly, and this typically means that the wavenumber will change along the length of the duct. We use a WKBJ method to obtain equations which describe acoustic wave propagation subject to combinations of these effects, and for ducts of different geometries.

\textsuperscript{1}The authors acknowledge support from DGAPA-UNAM PAPIIT IG100717, PASPA-UNAM, and CONACYT.

3D Thermoacoustics in a Microwave Plasma\textsuperscript{1}, SETH PREE, JOHN P KOU LAKIS, SETH PUTTERMAN, University of California Los Angeles — Pulsed microwaves directed at an acoustic cavity filled with partially ionized gas may generate intense sound fields. These fields have been shown to center and confine the hottest portions of the gas to the center of a spherical cavity via a generalization of acoustic radiation pressure we have called the pycnologic acoustic force. Because partially ionized gas is luminous, the sound field is rendered visible by luminosity and temperature oscillations caused by the acoustic field’s periodic adiabatic compression. This observation indicates that the microwave absorptivity of the gas may also fluctuate as sound passes through it. If microwave absorption increases in phase with the acoustic compression, the conditions for acoustic amplification may be met. This would allow the generation of high amplitude sound and possibly confinement with a continuous wave microwave source. We will describe the apparatus, present evidence of acoustic plasma confinement, and outline the theoretical conditions for microwave plasma thermoacoustics. We will also discuss how sustaining such a high amplitude sound field and the pycnologic acoustic force with this 3D thermoacoustic effect may enable a new laboratory model of convection in a central force.

\textsuperscript{1}This research was developed with funding from the Defense Advanced Research Projects Agency (DARPA) under award D19AP00015.

Experimental study of one-dimensional acoustic metamaterials of sound-soft inclusions\textsuperscript{1}, CAMILA HORVATH, MARIA LUISA CORDERO, DFI, FCFM, Universidad de Chile, AGNÉS MAUREL, Institut Langevin, ESPCI ParisTech, CNRS UMR 7587. — We are studying the properties of a one-dimensional acoustic metamaterial. The metamaterial consists of a periodic array of rectangular cross section pillars, made of a sound penetrable material (air) built-in a medium with higher acoustic impedance (Polydimethylsiloxane). We are focused on the acoustic response, when the periodicity of the array is several orders of magnitude lower than the wavelength of the incident wave. The problem is being studied experimentally and theoretically, using homogenization methods (Marigo, 2018, RSPA; Maurel, 2014, JASA) to simulate acoustic response of the array and comparing these results with the experimental measurements. Using lithography and soft lithography techniques, we fabricate the metamaterial, shaping a microscale periodical structure of rectangular cross section air bubbles within a Polydimethylsiloxane media. In order to reproduce a one-dimensional array, the air bubbles are pillars with a length, normal to its cross section, four orders of magnitude larger than the periodicity of the structure. We study experimentally the acoustic wave transmitted and reflected by the metamaterial. We find that it behaves as a perfect reflector for a wide range of frequencies.

Analysing the structure of the acoustic analogy based-high frequency Greens function in non-axi-symmetric sheared flows via a Ray tracing solver\textsuperscript{1}, SARAH STIRRAT, MOHAMED APSAR, University of Strathclyde, ADRIAN SESCU, Mississippi State University — The chevron nozzle remains a popular approach aimed at reducing jet noise. It works by breaking up large turbulence structures and by increasing mixing, but it also effects propagation of sound. In this study, we investigate the effect of chevron-type mean flow in an acoustic analogy model where the wave propagation reduces to the solution of the Rayleigh equation and is calculated using a ray theory model for a jet represented by a transversely sheared mean flow. Since the generalised acoustic analogy (GAA) shows that the acoustic pressure is given by the convolution product of a rank-2 tensor propagator and the fluctuating Reynolds Stress, we determine the propagator (that is related to the vector adjoint Green’s function of the linearised Euler operator) using the high frequency Ray theory developed by Goldstein (J. S. V., Vol. 80, p. 499, 1982) under an isotropic model of the fluctuating Reynolds stress. We calculate the Rayleigh equation Greens function at high frequencies for a series of chevron mean flow patterns with multiple lobes. Our results reveal that the chevron jet introduces much more non-periodic spatial modulation of the Greens function with a local minima in amplitude within the jet. We conclude by discussing how this explains the observed reduction in sound.

\textsuperscript{1}We thank Dr. S.J. Leib (Ohio Aerospace Institute) for use of his ray-tracing code.
9:03AM Q06.00007 Outer streaming within a two-dimensional channel

KYLE PIETRZYK, ILENIA BATTIATO, Stanford University — Acoustic streaming is the net time-averaged flow that results from nonlinearities in an oscillating flow. Extensive research has sought to identify different physical mechanisms and regimes of acoustic streaming in systems of various geometries. While streaming in a channel maintains a simple geometry, it requires an appropriate set of scales to capture the multiple regimes of streaming that can occur. This study aims to define a set of scales and dimensionless numbers for general outer acoustic streaming within a channel. The chosen scales are validated through the recovery of slow streaming equations describing Rayleigh streaming in a channel and Eckart streaming for the case of infinitely far away channel walls. Using the scales and the time-averaged momentum equations, fast streaming is then analyzed and nonlinear Reynolds numbers, which indicate whether the streaming is nonlinear or linear, are found. With this analysis, a brief procedure for identifying regimes of acoustic streaming within a channel is provided for future analyses involving streaming in complex multi-scale systems.

9:16AM Q06.00008 Acoustic propagation in random media using polynomial chaos expansions

ALEXANDRE GOUPY, CMLA, ENS Paris-Saclay, France, CHRISTOPHE MILLET, CEA & CMLA, ENS Paris-Saclay, France, DIDIER LUCOR, LIMSI, France — Sound propagation in the atmosphere is highly dependent on the information to specify the waveguide parameters. For real-world applications, there is considerable uncertainty regarding this information, and it is more realistic to consider the wind and temperature profiles as random functions, with associated probability distribution functions. Even though the numerical methods currently-in-use allow accurate results for a given atmosphere, high dimensionality of the random functions severely limits the ability to compute the random process representing the acoustic field, and some form of sampling reduction is necessary. In this work we use polynomial chaos (gPC)-based metamodels to represent the effect of large-scale features onto the acoustic normal modes. The impact of small-scale atmospheric structures is modelled using a perturbative approach of the coupling matrix. This two-level approach allows to estimate the statistical influence of each mode as the frequency varies. An excellent agreement is obtained with the gPC-based propagation model, with a few realizations of the random process, when compared with the Monte Carlo approach, with its thousands of realizations.

9:29AM Q06.00009 Reduced Order Modeling of Spray Flame Response to Harmonic Velocity Fluctuations

VISHAL ACHARYA, Georgia Institute of Technology — Modern combustion systems are all susceptible to thermoacoustic combustion instabilities. To understand these instabilities, reduced order models are developed for the dynamics of the flame when subjected to various source fluctuations, such as due to velocity, mixture ratio, pressure etc. Prior research has significantly focused on modeling for gaseous premixed flame dynamics with recent research also increasing focus on gaseous non-premixed diffusion flames. However, reduced order modeling for spray flames has received no attention and thus this work presents a modeling framework for the dynamics of spray flames with a focus on the velocity coupled response. The response is characterized using the Flame Transfer Function (FTF). The paper uses the classical Burke-Schumann diffusion flame configuration as a basis with the fuel introduced in the form of a spray of liquid droplets. The space-time dynamics in the model uses the fast-chemistry limit applied to the mixture fraction equation for both the gaseous and liquid phases. These equations are coupled through evaporation of the liquid droplets and results in new control parameters such as a vaporization Damkohler number in addition to parameters pertaining to the spray and droplets themselves. Collectively, the effects of these new parameters on spray flame dynamics can be understood.

7:45AM Q07.00001 Transport by vortices formed by breaking internal waves on a continental slope

HARRY SWINNEY, University of Texas at Austin, GUILHERME SALVADOR-VIEIRA, MICHAEL ALLSHOUSE, Northeastern University — Oceanic internal waves generated by tidal flow over bottom topography can transport energy for thousands of kilometers, but in the open ocean material transport (a second-order effect) is not significant. However, when an internal wave impinges on a continental slope, it forms coherent vortices (called boluses) that can trap and transport particles and biota along the slope. The magnitude of such transport in the oceans is not known. While most previous studies examined bolus transport for model systems consisting of two layers of uniform density, the present laboratory experiments and numerical simulations examine how transport by boluses depends on the thickness of the pycnocline, the region in which the fluid density changes rapidly with depth. We find that bolus size, upshele displacement, and maximum available potential energy produced are optimized for a particular pycnocline thickness and are significantly larger in continuously stratified fluids than in two-layer models. Linking the observed transport relationships to ongoing observations of coastal boluses should provide more accurate estimates of the importance of bolus transport for global coastal ecosystems.

7:58AM Q07.00002 Bacterial diodes: Rectified transport of swimming cells in porous media flow

JEFFREY GUASTO, NICOLAS WAISBORD, Tufts University — Directed motility enables swimming microbes to navigate their porous habitats for resources, where self-propulsion competes with fluid flow to affect processes ranging from disease transmission and bioremediation. Despite this broad importance, how directed motility affects the self-transport and dispersion of microswimmers in flow through constricted porous remains unknown. Focusing on magnetotactic bacteria in a microfluidic porous medium, we show that upstream oriented cells, directed by a magnetic field, are localized and trapped in vortical orbits at a constriction. Vortical cell localization results in three distinct regimes of rectified bacterial conductivity through a throat, akin to a ‘bacterial diode’, whereby cells swim upstream, become trapped within a pore, or are advected downstream with increasing flow speed. Langevin simulations reveal that the trapping regime results in near-complete transport suppression, while ephemoral trapping in the downstream regime enhances dispersion. We also show that vortical cell localization persists in three-dimensional flow through a packed microfluidic bed, emphasizing the relevance of this phenomenon in realistic hydraulic networks.

8:11AM Q07.00003 Several uses of Hopf bifurcations in devices, biology and fluids

RANDALL TAGG, University of Colorado Denver — A casual conversation (c1987) with Jerry Gollub about the marginal oscillator detector used in early magnetic resonance experiments launched a fruitful direction of inquiry about Hopf bifurcations by several undergraduates and some graduate students. This includes use of a Wien bridge oscillator as a sensitive detector, uncovering some new features of this well-known circuit including aspects of dynamics on a torus near the initial bifurcation and explorations of noise near the bifurcation. Mention will be made of other perhaps unexpected aspects and potential uses of Hopf bifurcations (or closely related phenomena) in biology and fluids.

8:37AM Q07.00005 Inverted Peristaltic Pumping in Brain?1, BRUCE GLUCKMAN, FRANCESCO COSTANZO, Penn State University — Clearance of brain waste products — metabolites and macromolecules — has been implicated in diseases such as Alzheimer’s Disease. Brain does not have a lymphatic system, so the mechanics of clearance are unknown. The glymphatics model — that traveling diameter variations of penetrating cerebral arterioles due to heart-driven blood pressure pulsations induces an inverted peristaltic pumping of fluid into and through brain — is an attractive model. Here we investigate through rigorous Arbitrary Lagrangian-Eulerian fluid structure interaction modeling different physical formulations and relevant parameters, and whether the biological constraints of the system could support significant flows. Special attention is given to the explicit boundary conditions and values of the problem. The flowrates generated can be significant under many conditions, but not within biophysically relevant pressure differences that otherwise deform the brain tissue.

8:50AM Q07.00006 Stickslips with Granular Particles, JC TSAI, Inst. of Physics, Academia Sinica, CHENG-EN TSAI, National Central Univ. — We study the emergence of stick-slip instabilities with densely packed granular particles that are sheared continuously. Such behavior occurs in a route of transition between suspension dynamics and plastic flows, as a result of changing the shear rate. Counterpart experiments are designed in order to identify the origin of stick-slips between two particles. We discuss the possible connection between the system-sized avalanches and the local instabilities.

9:03AM Q07.00007 Spatially resolved dynamical transitions in shear thickening fluids1, JEFFREY URBACH, VIKRAM RATHEE, DANIEL BLAIR, Department of Physics, Georgetown University — Dense particulate suspensions exhibit a dramatic increase in average viscosity above a critical, material-dependent shear stress, but the microscopic origins of this shear thickening (ST) remains poorly understood. Using boundary stress microscopy (BSM), we have directly measured the spatially resolved surface stresses during ST, and reported clearly defined dynamic localized regions of substantially increased stress that appear intermittently at stresses above a critical value [1]. Here we present measurements that reveal localized transitions to a fully jammed solid-like phase (SLP) that makes direct contact with the shearing boundaries. The SLPs fracture, bifurcate, and interact in a complex manner that depends on the measurement conditions (constant shear rate vs constant stress). These results demonstrate the ability of BSM reveal rich spatiotemporal dynamics of the thickening transition that are not observable in standard bulk rheology.1 V. Rathee, D. L. Blair, J. S. Urbach, PNAS 114, 8740 (2017).

9:16AM Q07.00008 Exotic patterns in Faraday waves, LAURETTE TUCKERMAN, PMMH-CNRS-ESPCI-Sorbonne, RAHUL AGRAWAL, IIT Bombay, ALI-HIGO EBO-ADOU, Centre d’Etudes et de Recherche de Djibouti, LYES KAHOUADJI, Imperial College London, JUAN MARIN, NICOLAS PERINET, Universidad de Santiago de Chile, JALEL CHERGUI, DAMIR JURIC, LIMSIC-CNRS, SEUNGWON SHIN, Hongik University — For the Faraday instability, by which standing waves appear on the free surface of a vertically vibrated fluid layer, the wavelength is controlled by the forcing frequency rather than by the fluid depth, making it easy to destabilize multiple wavelengths everywhere simultaneously. In the 1990s, this technique was used to produce fascinating new phenomena such as quasipatterns by Edwards & Fauve and superlattices by Gollub, Pier & Kudrolli. This in turn sparked a renaissance of interest in Faraday waves, leading to new mathematical theories and numerical simulations. We will discuss some of the exotic patterns found in recent numerical simulations, such as quasi-hexagons alternating with beaded stripes, a supersquare divided into four subsquares with synchronized diagonal blocks, Platonic solids alternating with their duals while drifting, and a twisted sheared secondary instability of square waves.

9:29AM Q07.00009 Rotational Dynamics of Dense Granular Systems, WOLFGANG LÖSERT, University of Maryland College Park — This study builds on my postdoctoral work in the Gollub lab on particle tracking based analysis of dense granular flows. In the work presented here we analyze the reversibility of both translation and rotations of granular materials in three-dimensions under cyclic compression. Using transparent acrylic beads with cylindrical holes and index matching techniques, we are not only capable of tracking displacements but also able to follow rotations. We observe that for moderate compression amplitudes, up to one bead diameter, the translational displacements of the beads after each cycle become mostly reversible after an initial transient. However, granular rotations are irreversible. The translational and rotational displacements are only weakly correlated, indicating that rotational motion depends on more subtle changes in contact distributions. We are able to observe these changes in particle dynamics simulations. Simulations allow us to assess the forces and torques in the system undergoing cyclic forcing.

Tuesday, November 26, 2019 7:45AM - 9:29AM — Session Q08 Granular Flows II 212 - Richard Lueptow, Northwestern University

7:45AM Q08.00001 Granular flow model for stochastic additive manufacturing feedstock distributions, WILLIAM ROSENTHAL, AMANDA HOWARD, FRANCESCA GROGAN, Pacific Northwest National Laboratory, CHEMICAL DYNAMICS INITIATIVE TEAM — Selective laser sintering (SLS) additive manufacturing processes distribute layers of irregular particles which are then fused by exposure to a laser. Physical models to predict microstructure variability, especially pore characteristics, are restricted by unrealistic assumptions of powder regularity and the deposition process. 2D and 3D models for SLS feedstock particle distributions are presented which take into account particle characterization, the mechanical deposition process, and inter-particle cohesive forces. These three factors are shown to have significant effects on sub-optimal packing fractions of feedstock material, which suggest assumptions of sphericity and optimal packing may lead to inaccurate results if used in sintering models. The impact of these assumptions is illustrated by using the granular feedstock model to initialize a phase-field SLS model. Sensitivity analysis of pore structure features shows the assumptions about the granular flow characteristics play a central role in the variability of the sintered microstructure.
7:58AM Q08.00002 Rayleigh-Taylor and Rayleigh-Benard like instabilities in two-size two-densities granular flow , UMBERTO D’ORTONA, M2P2, CNRS, Aix-Marseille Univ., Centrale Marseille, NATHALIE THOMAS, CNRS, Aix-Marseille Univ — Rayleigh-Taylor and Rayleigh-Benard instabilities are among the most classical hydro-dynamical instabilities. In both cases, the buoyancy is responsible for the instability. When put into motion, dry granular materials behave as liquids. The granular segregation induces a migration of large particles to the surface, while dense particles move to the bottom. Dense and large particles migrate to the top or the bottom depending on size and density ratios. Here, large and dense particles are chosen such that they migrate to the surface. We show experimentally and numerically that a layer of dense particles put above a layer of less dense particles develops a Rayleigh-Taylor instability while flowing. If dense particles are also larger and subject to upward segregation, the two-layer system destabilizes as well. Furthermore, if the system is initially made of one homogeneous layer, the segregation first induces the formation of a dense layer at the surface which destabilizes later. This self-driven Rayleigh-Taylor instability occurs for various density and size ratios. While time evolves, a pattern of parallel stripes forms with convection cells analogous to Rayleigh-Benard cells. The motor of the instability is the granular segregation.

8:11AM Q08.00003 Interplay between hysteresis and nonlocality in granular flows . SAVIZ MOWLAVI, KEN KAMRIN, MIT — The jamming transition in granular materials is well-known to exhibit hysteresis, wherein the level of shear stress required to trigger flow is larger than that below which flow stops. From a rheological standpoint, such behavior is typically modeled as a nonmonotonic flow rule. However, the rheology of granular materials is also nonlocal due to cooperativity at the grain scale, leading to increased strengthening of the flow threshold as system size is reduced. We investigate how these two effects — hysteresis and nonlocality — couple with each other by incorporating nonmonotonicity of the flow rule into the nonlocal granular fluidity (NGF) model, a nonlocal continuum model for granular flows. Comparing predictions of the model with discrete element simulations in the case of planar shear flow with gravity, we show that the inclusion of nonlocal effects is key to explaining certain features of the hysteretic solid-liquid transition as the applied stress is ramped up and down.

8:24AM Q08.00004 Transitional Granular Packing: Rate-dependent Brittleness . CHENG-EN TSAI, National Central Univ. , JC TSAI, Institute of Physics, Academia Sinica — We discover a route of transition over driving rate that bridges two classic regimes of granular dynamics: fluid-lubricated suspension on the fast end, against the largely plastic regime at the slow limit. Here, densely packed centimeter-sized PDMS particles submerged in fluid are sheared at variable but strictly constant rates. Fluctuations on multiple components of boundary force reveal a transitional regime exhibiting brittle failure of the packing at the intermediate driving rates, accompanied by evidence from simultaneous internal imaging. Rate-dependent statistical distribution of avalanches reveals the development of ductility toward the slow limit.

8:37AM Q08.00005 An investigation of mixing ratio effects on a Couette cell granular flow using magnetic particle tracking method1 , XINGTIAN TAO, HUIXUAN WU, UNIVERSITY OF KANSAS — Optical based methods are abundant in flow measurements; however, they can hardly be used in opaque environment. Therefore, a non-optical based particle tracking method — Magnetic Particle Tracking (MPT) — is investigated and three algorithms of data processing are analyzed. These algorithms are sequential quadratic program, extended Kalman filter (EKF), and particle filter. The reconstructed position and orientation of the magnetic tracer is compared with high-speed camera image result, and the accuracy of MPT with EKF algorithm is in the order of 0.6% in position and 1.5 degree in orientation. This technique is applied to study a sheared dense granular mixture in a Couette cell. The mixture comprises of spheres and cylinders (aspect ratio equals to 1). The trajectory and angle alignment of the tracer particle is reconstructed, and its distribution in the Couette cell is depicted. The effect of the mixing ratio on this Couette cell system is characterized by using finite time Lyapunov exponent between neighboring trajectories.

8:50AM Q08.00006 Segregation force in granular flows: From single intruders to bidisperse mixtures , RICHARD M. LUEPTOW, YIFEI DUAN, LU JING, JULIO M. OTTINO, PAUL B. UMBANHOWAR, Northwestern University — Recent studies have focused on the size segregation force on a single large intruder particle in granular flows. However, a generalized scaling of the force is still lacking for combined size and density segregation as well as for mixtures (rather than a single intruder). Here we first measure the segregation force on a single intruder in DEM simulations using a spring-based force meter and provide a universal scaling law of the segregation force that predicts whether the intruder will rise or sink depending only on the size and density ratios. Interestingly, the scaled force does not increase monotonically but decreases at large size ratios, explaining experimental observations that very large intruders sink. Then we extend the measurement to bidisperse particle mixtures of varying concentration. The resulting scaling law enables prediction of the segregation direction (rise or sink) of each particle species for varying size ratio, density ratio, and species concentration. Surprisingly, the segregation may invert as the species concentration changes because the segregation force depends on the species concentration. The predictions are validated with DEM simulations and experiments in various flow configurations.

9:03AM Q08.00007 Modeling segregation pattern formation in biaxial spherical tumbler flow , MENGQI YU, PAUL UMBANHOWAR, JULIO OTTINO, RICHARD LUEPTOW, Northwestern University — Flow of size bidisperse granular particle mixtures in a half-full spherical tumbler rotating about two perpendicular axes exhibits segregation patterns that can be observed through the transparent tumbler wall. The patterns resemble predictions based on dynamical systems analysis including non-mixing structures and unstable manifolds, but also depend on the underlying flow field, relative strength of segregation, and collisional diffusion. Discrete element method (DEM) simulations enable precise characterization of the three-dimensional structures of the segregation pattern and statistical analysis of particle movement in the flow. Axial drift of large particles during rotation about a single axis results in migration toward double bands near the rotation poles. At the same time, chaotic advection redistributes large particles in regions outside of non-mixing structures. As a result of both mechanisms, large particles accumulate in regions where axial bands coincide with non-mixing structures. Comparison of particle trajectories in size bidisperse and monodisperse mixtures provides further insight into the interaction between segregation, diffusion, and the underlying flow field that results in pattern formation.
multi-turbine array at an operational wind farm where it statistically significantly increased the power production. The analytic gradient-based steering of wind turbines thus allows for wake steering and can be successfully used for wind farm control and overall power optimization. Floating wind turbines operate in a dynamic state of misalignment because of surge, heave, yaw or tilt motions from wave and wind dynamics. In this work, wake deflection from static tilt is quantified in a scaled wind tunnel experiment to verify the importance of such turbine misalignments in floating wind farms. Cross-plane stereo particle image velocimetry measurements are performed for a scaled wind turbine rotor model, in a sheared boundary layer flow. Wake deflection caused by a counter-rotating vortex pair in the wake of tilted wind turbines is observed. In a sheared boundary layer flow, and with the presence of ground obstruction, a non-symmetrical behavior is observed, for positive and negative tilt, resulting in either a flying or crashing wake.

This work was supported by the National Science Foundation through grant #CBET-1351411 and by National Science Foundation award #1539070, Collaboration Leading Operational UAS Development for Meteorology and Atmospheric Physics (CLOUDMAP).

Fernando Cunez is grateful to FAPESP (grant no. 2016/18189-0) and Erick Franklin to FAPESP (Grants No. 2016/13474-9 and No. 2018/14981-7), to CNPq (Grant No. 400284/2016-2) and to FAPEX/UNICAMP (Grants No. 2210/18 and No. 2112/19) for the financial support provided.

Tuesday, November 26, 2019 7:45AM - 9:42AM – Session Q09 Wind Turbines: Wakes

7:45AM Q09.00001 Tilt-induced wind turbine wake shape characterization1, JULIAAN BOSSUYT, NASSEM ALI, RYAN SCOTT, RAUL BAYOAN CAL, Portland State University — The wakes of yaw-misaligned wind turbines have been shown to deflect downstream by the formation of a counter-rotating vortex pair, resulting in wake curling. Intentional misalignment of wind turbines thus allows for wake steering and can be successfully used for wind farm control and overall power optimization. Floating wind turbines operate in a dynamic state of misalignment because of surge, heave, yaw or tilt motions from wave and wind dynamics. In this work, wake deflection from static tilt is quantified in a scaled wind tunnel experiment to verify the importance of such turbine misalignments in floating wind farms. Cross-plane stereo particle image velocimetry measurements are performed for a scaled wind turbine rotor model, in a sheared boundary layer flow. Wake deflection caused by a counter-rotating vortex pair in the wake of tilted wind turbines is observed. In a sheared boundary layer flow, and with the presence of ground obstruction, a non-symmetrical behavior is observed, for positive and negative tilt, resulting in either a flying or crashing wake.

7:58AM Q09.00002 Field experiment of wind farm power optimization through wake steering1, MICHAEL HOWLAND, SANJIVA LELE, JOHN DABIRI, Stanford University — Due to greedy individual wind turbine operation, aerodynamic wakes reduce total wind farm power production, thereby increasing the cost of electricity for this resource. Considering the wind farm as a collective, we designed a wake steering control method to increase the power production of wind farms. The method was tested in a multi-turbine array at an operational wind farm where it statistically significantly increased the power production. The analytic gradient-based wind farm power optimization methodology developed can optimize the yaw misalignment angles for large wind farms on the order of seconds.

1MH is funded through the National Science Foundation Graduate Research Fellowship under Grant No. DGE-1656518 and the Stanford Graduate Fellowship.

8:11AM Q09.00003 Development of wake centerline detection algorithms for the study of wind turbine wake meandering1, NICOLAS COUDOU, Université catholique de Louvain, Université de Mons, von Karman Institute for Fluid Dynamics, LAURENT BRICTEUX, Université de Mons, JEROEN VAN BEECK, von Karman Institute for Fluid Dynamics, PHILIPPE CHATELAIN, Université catholique de Louvain — The low-frequency oscillatory motion of wind turbine wakes, also known as wake meandering, is crucial in wind farms as it increases fatigue loads on downstream turbines. The study of this phenomenon requires, as a first step, the determination of the position of the wake. The wake centroid tracking proposed in this work is based on the computation of the wind ipower inside a disk of a diameter equal to the rotor diameter and shifted in a cross-flow plane. The wake center corresponds to the disk position for which the available power is minimum. Mathematically, it consists in locating the maximum of the convolution between the wake centerline can then be obtained by repeating this technique in each cross-flow plane in the wake of a machine. This method being sensitive to strong local minima of wind speed occurring for high level of inflow turbulence, an improved method based on a 3D convolution is proposed in this work. These techniques are applied to the data obtained from Large-Eddy simulations of the NREL 5-MW wind turbine subjected to synthetic turbulent inflows. The computations were performed with a vortex-particle mesh code, the presence of the wind turbine rotor being accounted for through immersed lifting lines.

8:24AM Q09.00004 Horizontal Axis Turbine Wake Measurements Using Unmanned Aerial Vehicles1, STEWART NELSON, CHRISTOPHER HEINTZ, University of Kentucky, LUKE NORMAN, RUPP CARRIVEAU, University of Windsor, SEAN BAILEY, University of Kentucky — We use up to four highly instrumented, semi-autonomous unmanned aerial vehicles (UAVs) to measure the wakes shed by horizontal axis wind turbines during a one-week measurement campaign conducted at a line of four turbines located in a wind farm in Southern Ontario, Canada. During this campaign we investigated both the evolution of the wakes during a morning boundary layer evolution, and under the effects of wake steering. For the wake steering experiments, one turbine was yawed by 30 degrees with respect to the mean wind. In this talk, we will present results from the UAVs, which acquired horizontal wind velocity profiles across the turbine wakes at hub height, and with 0.3 m horizontal resolution. We also relate these wake measurements with Supervisory Control and Data Acquisition (SCADA) and tower strain data acquired concurrently to the measurements.

1This work was supported by the National Science Foundation through grant #CBET-1351411 and by National Science Foundation award #1539070, Collaboration Leading Operational UAS Development for Meteorology and Atmospheric Physics (CLOUDMAP).
The effects of turbulence on wind turbine performance (thrust and power generation) are often assumed based on analytical considerations, and studies focusing on actual measurements or computations are scarce. For this reason, a measurement campaign was carried out to parametrically study the effect of characteristics such as turbulence intensity and integral scale on the thrust and power generated by a model-scale wind turbine. An active grid has been used to systematically vary the properties of the incoming turbulent flows, generating integral length scales ranging from one order of magnitude smaller to slightly larger than the turbine diameter. Likewise, it has been possible to vary the free-stream turbulence intensity in the range of 0.5% to more than 12%. The model is a speed-controlled wind turbine driven by the incoming flow, moving a permanent magnet DC generator used to actively control the turbine speed and to measure the torque generated by the turbine rotor. The forces on the turbine are measured with a load cell force balance. Rotor geometries with a NACA 63 series aerofoil and different diameters (150, 180 and 200 mm) are tested. Presented data will focus on the variation in power and thrust coefficients with the turbulence properties of the incoming flow.

Kinematic Shear Stress Budget and Relaxation Time-Scales in a Spatially Heterogeneous Canopy Turbulence: an Application to Finite Sized Wind Farms

The wake of a model-scale, horizontal-axis wind turbine was investigated at $3 \times 10^6 < Re_\theta < 8 \times 10^6$ with uniform inflow and with varying degree of free stream turbulence. Data was collected in the High Reynolds Number Test Facility (HRTF) at Princeton University, which enables extremely high Reynolds numbers due to its ability to pressurize the working fluid, air, up to 3500psi. Streamwise velocity measurements were obtained using a nano-scale thermal anemometry probe (NSTAP), allowing for a temporal resolution of 200kHz, and spatial resolution of 60\mu m. Mean and variance profiles were studied at several downstream distances of $0.35 < x/D < 5.1$. These spanwise profiles show the evolution of the turbine's tip vortices as they advect downstream. Freestream turbulence was injected upstream of the turbine using a turbulence generating grid, and the effects of the freestream turbulence on the turbine's wake and performance are investigated.

Effects of Freestream Turbulence on Wind Turbine Wakes

The wake of a model-scale, horizontal-axis wind turbine was investigated at $3 \times 10^6 < Re_\theta < 8 \times 10^6$ with uniform inflow and with varying degree of free stream turbulence. Data was collected in the High Reynolds Number Test Facility (HRTF) at Princeton University, which enables extremely high Reynolds numbers due to its ability to pressurize the working fluid, air, up to 3500psi. Streamwise velocity measurements were obtained using a nano-scale thermal anemometry probe (NSTAP), allowing for a temporal resolution of 200kHz, and spatial resolution of 60\mu m. Mean and variance profiles were studied at several downstream distances of $0.35 < x/D < 5.1$. These spanwise profiles show the evolution of the turbine's tip vortices as they advect downstream. Freestream turbulence was injected upstream of the turbine using a turbulence generating grid, and the effects of the freestream turbulence on the turbine’s wake and performance are investigated.

The wake of a model-scale, horizontal-axis wind turbine was investigated at $3 \times 10^6 < Re_\theta < 8 \times 10^6$ with uniform inflow and with varying degree of free stream turbulence. Data was collected in the High Reynolds Number Test Facility (HRTF) at Princeton University, which enables extremely high Reynolds numbers due to its ability to pressurize the working fluid, air, up to 3500psi. Streamwise velocity measurements were obtained using a nano-scale thermal anemometry probe (NSTAP), allowing for a temporal resolution of 200kHz, and spatial resolution of 60\mu m. Mean and variance profiles were studied at several downstream distances of $0.35 < x/D < 5.1$. These spanwise profiles show the evolution of the turbine's tip vortices as they advect downstream. Freestream turbulence was injected upstream of the turbine using a turbulence generating grid, and the effects of the freestream turbulence on the turbine’s wake and performance are investigated.

Experimental study on the effect of turbulence properties on model wind turbine performance

The effects of turbulence on wind turbine performance (thrust and power generation) are often assumed based on analytical considerations, and studies focusing on actual measurements or computations are scarce. For this reason, a measurement campaign was carried out to parametrically study the effect of characteristics such as turbulence intensity and integral scale on the thrust and power generated by a model-scale wind turbine. An active grid has been used to systematically vary the properties of the incoming turbulent flows, generating integral length scales ranging from one order of magnitude smaller to slightly larger than the turbine diameter. Likewise, it has been possible to vary the free-stream turbulence intensity in the range of 0.5% to more than 12%. The model is a speed-controlled wind turbine driven by the incoming flow, moving a permanent magnet DC generator used to actively control the turbine speed and to measure the torque generated by the turbine rotor. The forces on the turbine are measured with a load cell force balance. Rotor geometries with a NACA 63 series aerofoil and different diameters (150, 180 and 200 mm) are tested. Presented data will focus on the variation in power and thrust coefficients with the turbulence properties of the incoming flow.
7:45AM Q10.00001 Synchronization in periodically forced oscillator flows\textsuperscript{1}, BENJAMIN HERRMANN, STEVEN BRUNTON, University of Washington, RICHARD SEMAAN, Technische Universitat Braunschweig — We investigate the synchronization properties of the turbulent wake past a D-shaped bluff body with periodic Coanda blowing. Time series from experimental measurements of the base pressure are used to study the response of the global vortex shedding mode for different actuation frequencies and amplitudes. Multiple regions of synchronization are found, resulting in the so-called Arnold tongues, where the oscillation frequency of the global mode locks-on to a rational multiple of the forcing frequency. We construct a model using a sparse regression and its structure explains these nonlinear couplings as an anharmonic parametric excitation of the global mode. The model is further analyzed using phase reduction theory, predicting the presence of $2:n$ synchronization and revealing the boundaries of the respective Arnold tongues. We postulate that this phenomena is universal to periodically forced oscillator flows, and arises from resonant wave-triads that transfer energy from the $n^{th}$ harmonic of the forcing, i.e., the parent wave, to the conjugate pair of vortex shedding modes, i.e., the daughter waves with half-frequency and higher wavenumber.

7:58AM Q10.00002 Dynamics and stability of confined interfacial droplets, STUART THOMSON, MATTHEW DUREY, MILES COUCHMAN, RUBEN ROSALES, JOHN BUSH, Massachusetts Institute of Technology — Millimeter droplets may bounce on the surface of a vibrating liquid bath or “walk” by means of self-propulsion through a resonant interaction with their own wave field. The propulsive wave force exerted by the bath is balanced by the droplet’s inertia and dissipation in the form of drag. In this talk we present the results of a combined experimental and theoretical study in which we consider the dynamics and stability of droplets confined to an annular ring. Single droplets are observed to destabilize to a pulsating walking state and then to a random-walk like instability as the vibrational acceleration of the bath is increased. When multiple droplets are brought into close proximity, they may bind together to form one-dimensional lattices which exhibit several features characteristic of driven dissipative oscillator systems including periodic oscillations and a striking solitary wave-like instability. Our experimental system provides a highly tunable apparatus to study dynamical systems driven far from equilibrium at the macroscale.

8:11AM Q10.00003 Extention of Arnold’s stability theory for planar viscous shear flows, HARRY LEE, University of Michigan, SHIXIAO WANG, University of Auckland — A viscous extension of Arnold’s inviscid theory for planar parallel non-inflow shear flows is developed and a viscous Arnold’s identity is obtained. Special forms of our viscous Arnold identity are revealed that are closely related to the perturbation’s enstrophy identity derived by Synge (1938) (see also Fraternale et al. 2018). Firstly, an alternative derivation of the perturbation’s enstrophy identity for strictly parallel shear flows is acquired based on our viscous Arnold’s identity. The alternative derivation induces a weight function, inspired by which, a novel weighted perturbation’s enstrophy identity is established that extends the previously known enstrophy identity to include general non-parallel streamwise translation-invariant shear flows imposed with relaxed wall boundary conditions. As an application of the enstrophy identity, we quantitatively investigate the mechanism of linear instability/stability within the normal modal framework. The investigation finds that the critical layer is always a primary source of damping in disturbance’s enstrophy and thus it enhances stability. Moreover, a control scheme is proposed that transitions the wall settings from the no-slip condition to the free-slip condition, through which a flow is quickly stabilized.

8:24AM Q10.00004 Nonlinear stability of wall-bounded viscous flows, SHIXIAO WANG, Auckland University, HARRY LEE, University of Michigan — A viscous extension of Arnold’s inviscid theory for planar shear flows is developed and a viscous Arnold’s identity is obtained. The viscous Arnold’s identity is revealed to be closely related to the perturbation’s enstrophy identity (Synge 1938). The mechanism of linear instability/stability of wall-bounded shear flows has been re-examined by the viscous Arnold’s identity and the perturbation’s enstrophy identity. It was found that the role of non-slip wall boundary condition in a planar shear flow is strikingly different from that in the circular Taylor-Couette flow confined between two concentric rotating cylinders. For the former, the perturbation’s enstrophy is generated at the walls by the non-slip induced flow rubbing effect. For the latter, however, the perturbation’s flow circulation is rigidly fixed by the non-slip wall condition and thus it effectively stabilizes the flow globally under axisymmetric disturbances within a sub-domain of the inviscid linear stability regime. A remarkable feature of the global stability for the circular Taylor-Couette flow is its independence of the $Re$ number.

8:37AM Q10.00005 Stability and bifurcation of a freely-rotating discontinuity in a symmetrically driven square cavity, GONGQIANG HE, FTN Associates, Ltd., Baton Rouge, LA, 70808, CHENGQIANG ZHANG, Massachusetts Institute of Technology, KRISHNASWAMY NANDAKUMAR, Louisiana State University, & The Energy Research Institute, Jinan, PRC — Using a direct-forcing immersed boundary method at fully resolved grid resolutions, we study the interaction between the fluid in a symmetrically driven square cavity (i.e., top and bottom lids sliding at identical velocity), and the response of a rectangular block inside. The block is made thin enough to approximate an ideal discontinuity; it is fixed at the cavity center but can freely rotate. We scanned up to moderate Reynolds numbers using different block length $L$, and a phase diagram (Re, L) is created. For a fixed Reynolds number, a short block stabilizes at the vertical orientation ($\theta = 90$ degree). As the block becomes longer, the vertical orientation loses stability and bifurcates into a pair of new stable orientations that are symmetric regarding the vertical direction. The critical lengths for different Reynolds numbers are found, and the reason for the loss of stability is explained by energy argument and analysis of the flow patterns.

8:50AM Q10.00006 Koopman Control of Point Vortex Dynamics using Invariants, KARTIK KRISHNA, ADITYA NAIR, EURIKA KAISER, STEVE BRUNTON, University of Washington, Seattle — We seek to manipulate the behaviour of a planar system of point vortices governed by the Biot-Savart law, which is often used to simulate fluid flows in an inviscid and incompressible setting. Inspired by recent advances in Koopman operator theory, we recast the original Biot-Savart law in terms of well known invariants of vortex dynamics (e.g. the Hamiltonian). This change of variables helps us obtain a linear representation of nonlinear dynamics and reduces the dimensionality for fluid flows, where the number of vortices is very large. We then leverage tools from control theory to manipulate vortex dynamics using virtual cylinders (vorticity generating actuators). In particular, we show that increasing (decreasing) the Hamiltonian enables the clustering (declustering) of multiple vortices. We are currently extending this work to dissipative flows for discrete vortex control.

9:03AM Q10.00007 ABSTRACT WITHDRAWN
Newtonian liquids in stirred vessels; it is regularly encountered in industrial sectors like healthcare, pharmaceuticals and food processing. Stirred tanks are commonly used in industry to process particles with liquids. A viscoelastic liquid was chosen that had matching refractive index with the suspended particles and a novel combination of PLIF techniques was used to measure the concentration measurement within a Hele-Shaw cell Rayleigh-Benard convection as CO$_2$ dissolves into brine. The velocity is measured using PIV under large depth-of-field and gap-wise Poiseuille flow conditions, making reliable quantitative velocity measurement difficult due to the large velocity gradient across the gap. Previously, particle sorting has been purposeful and validated as a means to resolve this problem. The method flushes particles along the cell until all have migrated to their gap-wise equilibrium plane, thus providing an unambiguous velocity magnitude.

9:29AM Q10.00009 A 3-D Poor Man’s Boltzmann Equation, J. M. MCDONOUGH, University of Kentucky (Retired), H. W. YU, Indiana University Purdue University at Indianapolis — A 1-D “synthetic” distribution function for the poor man’s Boltzmann equation (PMBE) has been studied previously; but real applications must be in three space dimensions. In this presentation we outline derivation of the 3-D PMBE and study bifurcations of the corresponding discrete dynamical system (DDS) for this case. In particular, we first provide a brief single-mode Galerkin derivation of the PMBE, and then present time series, power spectra and regime maps to demonstrate its consistency with expected fluid flow behaviors in particular, existence of Ruelle & Takens, Feigenbaum, and Pomeau & Manneville bifurcation sequences, as well as combinations of these. We also suggest how such a DDS can be used to produce very efficient sub-grid scale synthetic distribution function models for turbulence simulations within a lattice-Boltzmann/large-eddy simulation framework.

Tuesday, November 26, 2019 7:45AM - 9:42AM — Session Q11 Experimental Techniques: Quantitative Flow Visualization II 3B - Joe Katz, Johns Hopkins University

7:45AM Q11.00001 Novel Particle Shadow Tracking Velocimetry Technique, CARLOS ECHEVERRIA, DAVID PORTA, CATALINA STERN, ENRIQUE GUZMAN, UNAM, HIDRODINAMICA Y TURBULENCIA TEAM — We present a novel, non-invasive particle tracking velocimetry technique, called Particle Shadow Tracking Velocimetry (PSTV), which is based on the shadows cast by the process particles conveyed within a gaseous phase. Ad hoc digital filters were designed and implemented, in order to detect these solid particles with a high degree of precision. To show this, the methodology relied on the measurement of an Ultra Depth of Field (UDOF) distance required for the correct determination of the detection volume. The PSTV technique produced accurate velocity field values when tested with a validation experiment. We show that the determination of the volume of study is crucial for the correct measurement of the velocity field. To do so, we studied a biphasic solid-gas flow in the compressible regime; the solid phase consisted of a polydisperse granular material with an average size of 0.3mm.

7:58AM Q11.00002 Experimental investigation of the clustering of particles in non-Newtonian liquids in stirred vessels, GIOVANNI MERIDIANO, WEHLIYE HASHI WEHLIYE, LUCA MAZZEI, PANAGIOTA ANGELI, University College London — The blending of solid particles with liquids is a crucial step in many manufacturing processes; it is regularly encountered in industrial sectors like healthcare, pharmaceuticals and food processing. Stirred tanks are commonly used in industry to process solid–liquid mixtures principally because of their flexibility, relative construction simplicity and availability. Recent studies have proposed stirred tanks as a tool to achieve the separation of the solids suspended in Newtonian liquids (Wu et al. 2015). In this study, the investigation of the clustering of particles in non-Newtonian liquids in stirred vessels is presented. A viscoelastic liquid was chosen that had matching refractive index with the suspended particles and a novel combination of PLIF and PIV/PTV techniques was used to measure the velocity fields of the particles and of the fluid simultaneously as well as the evolution of the concentration of the particles in the tank. It was found that the particles accumulated in the cores of the vortices. In addition, the accumulation speed was found to be dependent on the viscoelastic properties of the fluid and on the diameter of the solid particles.

8:11AM Q11.00003 Development of a velocity and concentration measurement method for CO$_2$ dissolution in brine within a Hele-Shaw cell, MENGYE ZHAO, KENNETH KIGER, University of Maryland, ANKUR KISLAYA, JERRY WESTERWEEL, Delft University of Technology — We perform quantitative velocity and concentration measurement within a Hele-Shaw cell Rayleigh-Benard convection as CO$_2$ dissolves into brine. The velocity is measured using PIV under large depth-of-field and gap-wise Poiseuille flow conditions, making reliable quantitative velocity measurement difficult due to the large velocity gradient across the gap. Previously, particle sorting has been purposeful and validated as a means to resolve this problem. The method flushes particles along the cell until all have migrated to their gap-wise equilibrium plane, thus providing an unambiguous velocity magnitude. However, in order to accomplish the sorting, a large portion of the test cell will not be usable for measurement. We purpose a new method to overcome this limitation. We first conduct PIV without sorting particles to obtain only the velocity direction. This provides the value of the in-plane velocity ratio ($u/v$) at every $x,y$ coordinate pair. We then obtain the CO$_2$ concentration map using fluorescent emission of a Ph sensitive dye. Having mapped the concentration, we combine the $u/v$ information and solve the CO$_2$ advection-diffusion equation to get the value of $u$ and $v$. We demonstrate this method by comparing its result with that from the particle sorting method.
A combined structured planar laser-induced fluorescence (S-PLIF) and particle image velocimetry (S-PIV) method for interfacial and near-wall measurements1. VICTOR VOULGAROPOULOS, OMAR MATAR, CHRISTOS MARKIDES, Imperial College London — The application of experimental laser-based methods to obtain spatiotemporally resolved information has been emerging as increasingly important in various fields of fluid dynamics, owing to their ability to provide a holistic picture of the phenomena involved and to play a crucial role in benchmarking numerical models. Two-phase systems consisting of fluids with strong variations in their refractive indices in the visible wavelengths, e.g., any gas-liquid system, have, however, been found to compromise traditional laser-based techniques. These optical techniques become susceptible to laser-light reflections and reflections close to the fluid interface, resulting in erroneous interface location and velocity measurements. In this work, we investigate horizontal gas-liquid stratified pipe flows employing a new structured illumination technique. We perform simultaneous structured planar laser-induced fluorescence (S-PLIF) and structured particle image velocimetry (S-PIV) measurements to obtain phase and velocity fields, by minimising total internal reflections effects encountered in traditional PLIF and PIV measurements. The wave characteristics as well as the near-wall and interfacial flow properties are discussed.

Velocity Vector Field Extraction from High Speed Thermograms through Particle Image Velocimetry Tools1. GUILLERMO ANAYA, JESUS ORTEGA, IRMA VAZQUEZ, ADRIAN CEDERBERG, PETER VOROBIEFF, University of New Mexico, CLIFFORD HO, Sandia National Laboratories — Particle Image Velocimetry (PIV) is commonly used to extract velocity from a flow field. While these assessments are usually performed using high-speed visible cameras with tracers, experiments performed at the University of New Mexico generate extensive sets of time-resolved thermograms of a falling, hot particle curtain from 400 Hz to 300 Hz. These sets of data can be processed with two commonly used PIV algorithms: DaVis and PIVLab. The comparison showed consistent velocity fields and contours, along with corresponding velocity correlations as a function of flow position. As expected, the vertical velocity component of these gravity-driven curtains follows a trend that resembles a free-falling sphere rather than a falling sphere experiencing drag. The variation of velocity magnitude displayed negligible variations due to the curtain thickness and/or inlet particle temperature which can be considered negligible for the application. The results obtained will feed the development of a statistical model to estimate the mass flow of a particle curtain using only image-correlation methods.

Experimental study on flow characteristics of vertical upward annular flow boiling in an annulus. JOSEPH SEO, SAYA LEE, DANIEL WACKER, JUNHO LEE, YASSIN HASSAN, Texas AM University — Hydraulic parameters such as outer and inner film thickness, entrainment rate, droplet deposition rate, and droplet velocity of vertical upward annular flow boiling in an annulus have been measured and studied in the present study. The experiment is performed by observing the annular flow boiling in a vertical annular tube by evaporating refrigerant (hydrofluoroether-7000) with a central heating rod. The outer film thickness is measured using planar laser induced fluorescence (PLIF) with Rhodamine-6G as a fluorescence dye while thickness of inner film which is formed at the surface of the heater is visualized and captured by shadowgraph method. The entrainment rate and deposition rate of droplets are also calculated from the image obtained by shadowgraph. Four high-speed cameras with 3000 fps of frame rate are used. The result of the measurement shows that entrainment and deposition rate of droplets is highly related with not only the wave characteristics on the film but also the onset of burn up at the surface of heating rod which are similar with the results from the studies on annular flow. The set of measurement presented in this study is expected to provide a better understanding and insight of the annular flow boiling phenomena in annuli.

A combined structured planar laser-induced fluorescence (S-PLIF) and particle image velocimetry (S-PIV) method for interfacial and near-wall measurements1. VICTOR VOULGAROPOULOS, OMAR MATAR, CHRISTOS MARKIDES, Imperial College London — The application of experimental laser-based methods to obtain spatiotemporally resolved information has been emerging as increasingly important in various fields of fluid dynamics, owing to their ability to provide a holistic picture of the phenomena involved and to play a crucial role in benchmarking numerical models. Pressure Field Estimation on Flow over a Sidewall Aneurysm. PAULO YU, VIBHAV DURGESH, University of Idaho — One of the challenges associated with the experimental fluid dynamic study of flow in an aneurysm is the inability to accurately estimate pressure distribution inside the aneurysm sac. The objective of this study is to estimate the pressure field in the sac using velocity data from Particle Image Velocimetry (PIV) measurements. An in-house experimental setup was developed and an idealized sidewall aneurysm was used for this investigation. A computer-controlled pump system was used to precisely control inflow conditions such as Reynolds number (Re) and Womersley number, which ranged from 50-250 and 2-5, respectively. PIV measurements were conducted on a vertical plane inside the aneurysm sac. Proper Orthogonal Decomposition (POD) was used for low-order reconstruction to reduce the noise in the velocity field. The pressure field was estimated numerically using pressure Poisson equation with Neumann boundary conditions. The estimated pressure field in the pipe was compared with a simulated multi-modal solution for a pulsatile flow showing good agreement. The results of the study showed the evolution of the pressure field inside the aneurysm sac and its dependence on change in Reynolds and Womersley numbers.

Feasibility Study on Sparse Processing Particle Image Velocimetry1. NAOKI KANDA, KOKI NANKAI, YUJI SAITO, Tohoku University, TAKU NONOMURA, Tohoku University, Presto, JST, KEISUKE ASA, Tohoku University — The objective of this study is to investigate accuracy and calculation time of the velocity field data estimated from sparse interrogation area of particle images by Kalman filter and PIV. This estimation method is named sparse processing particle image velocimetry (SPPIV). In this study, the PIV measurement is conducted for NACA0015 under the following conditions; the freestream velocity, the angle of attack, the chord and span of this model were 10 m/s, 16 degree, 100 mm and 300 mm, respectively. Ten proper orthogonal decomposition (POD) modes and five interrogation areas were used and the velocity field was estimated by SPPIV. The optimum location of sparse interrogation area is estimated by greedy method. In this experiment, calculation time of estimating velocity field by SPPIV was approximately 1% of conventional PIV method. In the lowest-order POD mode, the estimated POD mode by SPPIV showed approximately same trend as POD mode calculated by Conventional PIV, however POD mode calculated by SPPIV is sometimes quantitatively different from that calculated by conventional PIV. The quality of particle images and the calculation method of optimum location of sparse interrogation areas should be improved for more accuracy in the future.

9:29AM Q11.00009 Development of experimental visualization method for unsteady hydrodynamic stress field by using photoelasticity of liquid polymer\(^1\), MASAKAZU MUTO, YOSHIIUKI TAGAWA, Tokyo University of Agriculture and Technology — The experimental visualization for the unsteady hydrodynamic stress field is in demand for the medical field, because the wall shear stress at the inner blood vessel may be the principal cause of the angioopathy. In this study, we develop a visualization method for the hydrodynamic stress field by introducing liquid polymers with photoelastic effects. Photoelasticity is a non-contact optical measurement method based on phase differences obtained by changes in the polarization state of the polymer solution, which results in proportionate stress field values. In this experiment, to capture the photoelasticity phenomena at high frame rates, a high-speed polarization camera which contains the array of micro linear polarizers with four incident angles is used. As a result, we can observe an increase of phase difference of the liquid polymers (e.g. xanthan gum and carbomethyl cellulose) in milli-channel when their flow rate is increased by syringe pump. Furthermore, the sensitivity of phase difference can be changed by the type and the concentration of the polymers. Especially, this method enables us to reveal the area of hydrodynamic stress concentration in the liquid, which other invasive (contact-type) point measurement steady methods may not capture.

Tuesday, November 26, 2019 7:45AM - 9:42AM –
Session Q12 Vortex Dynamics and Vortex Flow: General II
303 - Carlo Scalo, Purdue University

7:45AM Q12.00001 Modification of Tip-Vortices using Chevron Wing Tips, ANUSHKA GOYAL, JOVAN NEDIC, McGill University — The aerodynamic performance of chevrons with varying depths, cut directly into the tips of a flat plate with a semi aspect ratio of 3 were investigated using a time resolved six axis force/torque sensor at a Reynolds number of 67,000. Results show that shallower chevrons cut directly into the tips of wings lead to a higher peak \( \frac{C_l}{C_D} \) ratio at an angle of attack of 5\(^\circ\). It is known that the formation of a tip vortex depends on the geometry of the wing tip (Sarpkaya 1983, Giuni and Green 2013). The chevrons plates formed tip vortices that have lower peak tangential velocities and larger core radii as compared to a flat plate, based on measurements taken by using a four sensor hot wire. The tip vortices formed on wing tips with deeper chevrons exhibited a turbulent core, as opposed to those formed on a flat plate. It was also found that deeper chevron plates had an impact on the wandering of the tip vortex.

7:58AM Q12.00002 Wavelength variation in seal whisker geometries and the effect on vortex structure, CHRISTIN T. MURPHY, Naval Undersea Warfare Center Division Newport, KATHLEEN M. LYONS, University of Wisconsin - Madison, WILLIAM A. HADDOCK, Brown University, WILLIAM N. MARTIN, AREN M. HELLUM, Naval Undersea Warfare Center Division Newport, KENNETH S. BREUER, Brown University, JENNIFER A. FRANCK, University of Wisconsin - Madison — Seal whiskers have a unique undulated geometry that affects water flow over the structure and influences downstream shedding. By intensifying and modifying geometric features in whisker models, we can observe their effects more clearly. In a multi-parameter analysis, wavelength is shown to be an important parameter, especially if interacting with other geometry features. This study isolated the effect of wavelength by creating four physical models of different wavelengths but constant streamwise and transverse amplitudes, peak shift, and symmetry. Flow visualization in a water tunnel, in the biologically relevant Reynolds number range of 500-2000, demonstrates the ability of the undulations to enhance the spanwise momentum transport, reduce the recirculation region, and modify the frequency spectra in the recirculation region behind the whisker. To complement the experiments, direct numerical simulations (DNS) at Re 500 are performed on the four models to correlate the flow structure visualization with resulting drag coefficients, root-mean-square lift coefficients and reduced frequencies. Agreement between experiments and simulations isolates the dominant flow structures responsible for shifts in the frequency spectra over the range of wavelengths investigated.

8:11AM Q12.00003 Direct numerical simulation of trefoil knotted vortices, XINRAN ZHAO\(^1\), CARLO SCALO\(^2\), Purdue University — 3D viscous vortex reconnection has been a topic of strong interest for the fluid mechanics community over the past several decades. This paper investigates pre- and post-reconnection dynamics of a trefoil knotted vortex for Reynolds numbers up to Re = 20,000 by means of DNS with adaptive mesh refinement. The compressible Navier-Stokes equations are solved on the block-structured computational domain with compact-finite difference scheme. An overall high-order accuracy in space can be achieved with the combination of high-order compact restriction/prolongation operators. The test refinement function is given by a Coherent-vorticity-perserving (CvP) sensor (Chapelier, Wasistho, and Scalo, 2018. J. Comput. Phys., 359, 164-182) from our previous work. The simulation on the trefoil vortex problem has shown that this sensor is capable of capturing and refining the location where the reconnection occurs and local turbulence is produced. The complete flow evolution is resolved by the DNS simulation, including the turbulence production upon reconnection, subsequent separation into a smaller and a larger vortex ring, and, finally, the formation of Kelvin waves. The DNS simulation depicts the mechanism how helicity is produced due to small-scale vortical events during the bridging process. A qualitative comparison between the present simulations and existing experiments has also been conducted and an excellent match has been found in terms of flow topology.

8:24AM Q12.00004 Vortex Force Map Method for Unsteady Incompressible Viscous Flows\(^1\), JUAN LI, XIAOWEI ZHAO, The university of Warwick — Recently, Li & Wu (2017, 2018) proposed a vortex force map method for a flat plate and extended it to general airfoils at high Reynolds numbers by adopting Howe’s (1995) force formula for the derivation of the vortex force vectors. Here, the vortex force map method is refined to have the capability of dealing with more general cases for a larger range of Reynolds numbers. Updated vortex-pressure force maps, which ensure vortices far away from the body have negligible effect on body-force, are built based on the vortex-pressure force factors derived from viscous governing equations. These maps help us identify the force contribution role of each given vortex more precisely than the ones presented previously. The impulsively started flows around a cylinder and a NACA0012 airfoil are used to demonstrate the applications of this vortex force map method. CFD is used to provide the velocity and vorticity data, as well as for validations by comparing the forces directly given by it with those from the proposed vortex force map method. In order to explore the possibility of applying this method to extracting forces from PIV data, the accuracy of this approach on small domains and under coarse sampling is demonstrated.

\(^{1}\)the Marie Sklodowska-Curie grant agreement No.765579
8:37AM Q12.00005 Vortex dynamics from a vibrating leaf upon drop impact, ZIXUAN WU, SEUNGHO KIM, SUNGWHA NUNG, Cornell University — Raindrop impact have been shown to discharge rust spores and induce dispersal from leave surface through fluid-elasticity interactions and vortex ring formations. In contrary to impacts on rigid surface, here we present an exposition on the vortex dynamics transformations resulting from drop-induced leaf oscillations. Experimentally, we utilized high-speed imaging to probe the complex vortex dynamics and (Single)-(Pair) shedding schemes from a damped harmonic oscillator (drop impacted a flexible, free-end beam) without a prescribed background flow. While low impact inertia is shown to yield single vortex shedding behavior, epitomized by the von Karman street, beam fluctuations from high inertia and to longitudinal twisting motions can give ways to paired vortex schemes and atypical vorticity generations. By tuning such interactions between drop inertia and beam elasticity, the beam vibrations show different frequency and amplitude regimes, with damping effect from lingering vortices and residual drop oscillations. Vorticity behavior of the induced airflow can then provide potential insights on more spore dispersal from simple mechanically induced vibrations.

8:50AM Q12.00006 The Propulsive Performance of Side-By-Side Foils at a Range of Re and St, AHMET GUNGOR, ARMAN HEMMATI, University of Alberta — The hydrodynamic interactions between two foils placed in side-by-side arrangement are investigated using Direct Numerical Simulation at Reynolds numbers of 1000, 2000 and 4000, and Strouhal numbers (St) ranging from 0.25 to 0.5. The transverse spacing and phase difference between the foils are kept constant. Dynamic motions of the foils are simulated using dynamic mesh morphing technique in OpenFOAM. Coefficients of thrust and power, as well as efficiency, are used to compare the performance of foils. The interactions between foils are also studied through varying the St of individual foils. The performance parameters of the system are observed to depend on both St and Re. In the range of St, the combined efficiency of the system reaches the maximum at St=0.4. The system experiences a thrust enhancement with increasing Re although the coefficient of power remains stable in the Re range. The results are used to evaluate the applicability of the scaling law developed by Floryan et al. (2017) on an isolated foil. The scaling laws for tandem foils in side-by-side arrangements are also developed.

9:03AM Q12.00007 ABSTRACT WITHDRAWN —

9:16AM Q12.00008 Drag Estimation of Isolated, Surface-mounted, Droplet-inspired Geometries, XUEQING ZHANG, BURAK A. TUNA, SERHII YARUSEVYCH, SEAN D. PETERSON, University of Waterloo — Droplet mobility on a substrate due to aerodynamic loading is of interest of many industrial applications. However, modeling this phenomenon is hindered by a lack of reliable estimations of aerodynamic forces on representative shapes. The present study investigates the wake development downstream of isolated, surface-mounted, three-dimensional droplet shapes submerged in a laminar boundary layer. The obstacle geometries considered are representative of the droplet morphologies at sessile state (‘sessile’) and at depinning (‘runback’). The incoming flow has a Reynolds number based on obstacle height of $Re = 2070$ and a boundary layer thickness of around one obstacle height, simulating the critical flow conditions at droplet depinning. Aerodynamic loading on the obstacles is estimated using the wake integral method extended to drag estimation for obstacles with high boundary layer submergence. With a laminar incoming boundary layer, the drag coefficient of the ‘sessile’ model is larger than that of the ‘runback’ model. The drag reduction for the ‘runback’ model is ascribed to the tapered front-body and short aft-body geometry, which makes the obstacle more aerodynamic. For both cases, drag coefficients decrease with increasing turbulence level in the incoming flow.

9:29AM Q12.00009 Definition of local vortical axis flow geometry, KATSUYUKI NAKAYAMA, Aichi Institute of Technology — Local vortical axis flow is defined in the vortical region in the velocity gradient field, which specifies the characteristics of the passage of a vortical axis in the core region of a vortex. The axis vector field derived from vortical axes (identified by a definition of the vortical axis) is defined, and the local axis geometry of the axis vector field is specified by the gradient tensor of its axis vector. Even though the eigenvalues of the tensor may exhibit the feature of the axis curve, it is not associated with the characteristics of the passage of the core region of a vortex. The present study specifies the convergence/divergence/rotation of a bundle of the axes in swirl plane of a vortex. The swirlity and sourcity that represent the unidirectionality and intensity of respective azimuthal and radial flows in the plane are applied to the core region of a vortex. The present study specifies the convergence/divergence/rotation of a bundle of the axes in swirl plane of a vortex. The present study specifies the convergence/divergence/rotation of a bundle of the axes in swirl plane of a vortex.

Session Q13 Convection and Buoyancy-driven Flows: Heat Transfer and Forced Convection 304 - Chenguang Zhang, MIT

7:45AM Q13.00001 Heat transport by baroclinic acoustic streaming, JACQUES ABDULLASSIH, University of New Hampshire, GUILLAUME MICHEL, Ecole Normale Superieure, CNRS, CHRISTOPHER WHITE, GREG CHINI, University of New Hampshire — Recently, Chini et al. [J. Fluid Mech., Vol. 744 (2014)] and Michel & Chini [J. Fluid Mech., Vol. 858 (2019)] demonstrated that strong acoustic streaming flows can be generated in gases subjected to an imposed cross-channel temperature gradient. In contrast with classic Rayleigh streaming, standing acoustic waves of $O(\epsilon)$ amplitude acquire vorticity owing to baroclinic torques acting throughout the domain rather than via viscous torques acting in Stokes boundary layers. More significantly, these baroclinically-driven streaming flows have a magnitude that is $O(\epsilon)$, i.e. comparable to that of the sound waves, leading to fully two-way wave/flow coupling. The present investigation extends these earlier studies by relaxing the restriction to small aspect-ratio domains, thereby enabling the (forced) heat transport across the channel to be quantified as a function of aspect ratio. This extension requires the numerical solution of a two-dimensional eigenvalue problem for the sound-wave frequency and mode structure. Nevertheless, the resulting computations are orders of magnitude faster than DNS of the compressible Navier-Stokes equations. The prospect for using baroclinic acoustic streaming as a cooling technology is evaluated.
7:58AM Q13.00002 Experiments of Flow Boiling of R245fa in a Horizontal Pipe Using Particle Image Velocimetry\textsuperscript{1}.

- Hannah Moran, Victor Voulgaropoulos, Dimitri Zogg, Omar Matar, Christos Markides, Imperial College London — A bespoke facility is used to measure flow boiling of the refrigerant R245fa in a 12.7-mm diameter stainless steel pipe, to which uniform heating of up to 135 kW/m\textsuperscript{2} may be applied. A range of measurement techniques are utilised in the facility to obtain results over a range of flow rates and heat fluxes. Differential pressure measurements are taken, whilst thermocouples at the tube walls allow the calculation of the heat transfer coefficient, and flow visualisation is accomplished using high-speed imaging. The results are then compared to other experimental work and to correlations in the literature. In addition, laser-based measurements, such as particle image velocimetry (PIV), are performed, providing detailed spatially- and temporally-resolved information on the velocity and turbulence characteristics in the liquid phase. The measurements provide new insight into the hydrodynamic and thermal interactions in these flows and help to build a comprehensive picture of the phenomena involved in the boiling process.

8:11AM Q13.00003 Vibratory control of heat transfer in fluid in containers with elastic boundaries\textsuperscript{1}.

- Nikolai Koizlov, Institute of Continuous Media Mechanics UrB RAS — An experimental study is carried on of heat transfer in a viscous fluid enclosed in cylindrical and spherical containers with vibrating elastic boundaries. The container boundary is thermally stabilized by pumping a liquid around it. Two cases are considered: the fluid bulk is heated while the boundary is cooled and the other way round. Vibrations generate steady streaming in the container, intensifying the heat transfer. The former is studied using PIV method, the latter – by evaluation of temperature difference between the fluids in the container and the thermostatic bath. The dimensionless velocity of steady flows increases with the pulsation Reynolds number, Re\textsubscript{p}. The steady flows are in competition with the free convection. The domain of dimensionless parameters (Rayleigh number, Ra, and Re\textsubscript{p}) where the free convection can be neglected is found. For this domain, the analysis of heat transfer by steady streaming as a function of the dimensionless vibration frequency is done. The obtained results can be applied for the assessment of flow structure and heat-mass transfer in oscillating elastic containers of various scale, for example liquid drops.

8:24AM Q13.00004 DNS of thermal channel flow for Re\textsubscript{x} = 5000\textsuperscript{1}.

- Francisco Alcantara Avila, Sergio Hoyas Calvo, Universitat Politècnica de València — A new DNS of a thermal channel flow has been conducted at Re\textsubscript{x} = 5000. The thermal field has been considered as a passive scalar and the Mixed Boundary Condition is employed. The Prandtl number of air, 0.71, has been used. A large enough computational box of dimensions 2\textit{h} x 2\textit{h} x 2\textit{h} has been set to obtain consistent statistics. The mesh used had a total of 6144 x 128 x 6144 \approx 5e10 points. The simulation has run on 2048 cores of the supercomputer MareNostrum. The logarithmic region of the mean temperature profile is starting to be properly developed with a von Karman constant of k\textsubscript{v} = 0.444. Maxima of the temperature intensities increase and move towards the wall with respect to other cases with lower Reynolds numbers. A power function has been obtained to calculate the Nusselt number as a function of Reynolds, for Pr = 0.71. Turbulent Prandtl number does not show remarkable differences with the ones obtained for lower Reynolds and it keeps being close to 1 near the wall. Finally, turbulent budgets for heat fluxes, temperature variance and its dissipation rate have been calculated. Scaling of all terms is analysed and discussed.

\textsuperscript{1}This work was partially supported by MINECO/FEDER, under Project No. RTI2018-102253-B-100. Francisco Alcantara Avila is partially funded by GVA/FEDER project ACIF2018. The computations of the new simulations were made possible by a generous grant of computing time from the Barcelona Supercomputing Centre, reference IM-2019-2-0016.

8:37AM Q13.00005 Toroidal-helical pipe as a passive mixing and heat transfer device in laminar flows.

- Chenguang Zhang, Massachusetts Institute of Technology, Krishnaswamy Nandakumar, Louisiana State University & The Energy Research Institute, Jia, PRC — The secondary flow of Dean vortex pair is a long-known mechanism for the enhancement of mixing and heat transfer, with example uses including circular or spiral pipes. We present a novel design of a toroidal helical pipe, which follows a three-dimensional toroidal helix (an analytical curve smoothly winding around a torus) as its pipe axis. Unlike the circle or straight helix which has constant curvatures, the toroidal helix has a spatially oscillating curvature. This unique feature causes the classic separated Dean vortex pair to couple, periodically re-orient, shrink and grow within each turn of the pipe. The complex flow pattern spans the entire cross-section and enhances mixing via advection. Using heat transfer as an example, the Nusselt number in the toroidal helical pipe varies periodically, with mean values several times higher than a straight pipe even at moderate Reynolds numbers.

- Matthias Ziefuss, Amirfarhang Mehdizadeh, Civil and Mechanical Engineering Department, School of Computing and Engineering, University of Missouri-Kansas City — Heat transfer modeling plays a major role in design and optimization of modern and efficient cooling systems. However, currently available models suffer from a fundamental shortcoming: their development is based on the general notion that an accurate prediction of the flow field will guarantee an appropriate prediction of the thermal field, known as the Reynolds Analogy. This analogy works reasonably well when applied to fluids with a Prandtl number around unity to obtain first order statistics. Concerning fluids with non-unity Prandtl number, there is no comprehensive assessment available. Thus, this investigation presents an introductory assessment of the capability of the Reynolds Analogy when applied to turbulent shear flows of fluids with small Prandtl number. The assessment includes steady and unsteady state simulations. In case of steady state simulations, it turns out that the Reynolds Analogy is not able to predict the mean temperature at an acceptable level of accuracy, while second order statistics are severely mispredicted. In case of unsteady simulations, it is shown that the Reynolds Analogy cannot be considered as an appropriate sub-grid scale model as it fails to feature basic properties of a reliable sub-grid scale model.
9:03AM Q13.00007 Investigating the Impact of Variable Properties for Cryogenic Helium in a Heat Transfer in a Microchannel. COHA SHIN, Oregon State University, MICHAEL MARTIN, SHASHANK YELLAPANTULA, MARC HENRY DE FRAHAN, RAY CROUT, National Renewable Energy Laboratory — Cryogenic helium in liquid, vapor, and supercritical phases is used for cooling in a range of applications, including quantum computers, superconducting magnets, and infrared sensors used in astronomical measurements. Properties such as density, viscosity, thermal conductivity, and specific heat vary significantly near the critical point (5.2 K and 227.46 kPa). We have simulated laminar flow in a heated square microchannel with widths ranging from 25 to 100 microns under supercritical conditions using Pecos computational fluid dynamics code with adaptive mesh refinement, embedded boundaries, and complex fluid equations of state. At temperatures between 30 and 60 K, the Soave-Redlich-Kwong equation of state is used to calculate thermodynamic properties. A temperature and pressure sensitive model is also used for transport properties. As the temperature changes due to wall heating, we observe the variations of properties in the fluid due to these models, and measure the impact on flow structure and channel heat transfer.

9:16AM Q13.00008 Flow field and heat transfer characteristics in a model solar PV farm. JAMES MCNEAL, ANDREW GLICK, NASEEM ALI, JULIAAN BOSSUYT, GERALD RECKTENWALD, Portland State University, Maseeh College Of Engineering, MARC CALAF, The University of Utah, RAL BAYOÁN CAL, Portland State University, Maseeh College Of Engineering, — Large scale solar farms supply an increasing amount of the world’s electricity supply. However, high operation temperatures can strongly reduce efficiency and panel lifetime, negatively affecting the levelized cost of energy. In this work, the convective heat transfer coefficient for a utility-scale solar farm is studied using thermal and particle image velocimetry measurements in a wind tunnel experiment. The results confirm the applicability of the scaled experimental setup to studies of large solar arrays. Further, the velocity measurements indicate the complex flow structure within the solar array, governed by wakes directed upwards due to the orientation of the solar panels.

1This work is funded by the US Department of Energy (DOE) PVRD2 program under award number DE-EE0008168.

9:29AM Q13.00009 Temperature reduction through system level flow enhancement via model solar PV farm wind tunnel experiments. ANDREW GLICK, JULIAAN BOSSUYT, NASEEM ALI, Portland State University, MARC CALAF, University of Utah, RAUL BAYOÁN CAL, Portland State University — To further facilitate the reduction in cost of photovoltaic energy, new approaches to limit module temperature increase in natural ambient conditions should be explored. Thus far only approaches based at the individual panel level have been investigated, while the more complex, systems approach remains unexplored. Here, we perform the first wind tunnel scaled solar farm experiments to investigate the potential for temperature reduction through system level flow enhancement. Results indicate that significant changes in the convective heat transfer coefficient are possible, based on wind direction, wind speed, and module inclination. We show that 30-45% increases in convection are possible through an array-flow informed approach to layout design, leading to a potential overall power increase of ~ 5% and decrease of solar panel degradation by + 0.3%/year. Previous models demonstrating the sensitivity to convection are validated through the wind tunnel results, and a new conceptual framework is provided that can lead to new means for solar PV array optimization.

1The work presented herein were funded by the US Department of Energy (DOE) PVRD2 program under award number DE-EE0008168.

Tuesday, November 26, 2019 7:45AM - 9:42AM — Session Q14 Wind Turbines: Vertical Axis

7:45AM Q14.00001 Blade-Wake Interactions in a Vertical Axis Wind Turbine. SANG-WOO AHNN, Seoul National University, HYEONGMIN KIM, Hyundai Motor Company, SEHYEONG OH, HAECHEON CHO, Seoul National University — We investigate the flow characteristics of a vertical axis wind turbine (VAWT) and its aerodynamic performance using large eddy simulation with an immersed boundary method. The VAWT considered in this study consists of three blades, and the Reynolds number is 80,000 based on the rotor diameter and free-stream velocity. The simulation results show that each blade interacts with the wakes generated by the preceding blade and also by itself in the downwind region. To examine the effect of these blade-wake interactions on the aerodynamic performance, we simulate the flows with one blade only and with two blades, respectively. The blade performance significantly deteriorates in the upwind region due to the wake induced by the preceding blade. In the downwind region where the blade performance is poor, each blade interacts with its own wake and the wake from the preceding blade, but these blade-wake interactions rather improve the aerodynamic performance of each blade. As the tip speed ratio increases, the preceding blade highly influences the performance of the following blade, but does not much on the second following blade.

1This work was supported by the National Research Foundation through the Ministry of Science and ICT (2016R1A1A02921549) and the National Supercomputing Center with supercomputing resources including technical support (KSC-2018-CHA-0030).

7:58AM Q14.00002 A design of active flow control on vertical-axis wind turbines based on resolvent analysis. HSIEH-CHEN TSAI, National Taiwan University — We design an active flow control on vertical-axis wind turbines (VAWT) combining the resolvent analysis and direct numerical simulations (DNS). The immersed boundary projection method is used to simulate the two-dimensional incompressible flow around a NACA0018 three-bladed VAWT at low Reynolds numbers. Localized body forces are placed on the surfaces of the turbine blades to mimic the streamwise plasma jets generated by Dielectric barrier discharge (DBD) actuators. The optimal actuator locations and the optimal actuation frequencies at various Reynolds numbers are determined by the resolvent analysis of the mean flow around the VAWT. Preliminary results show that by removing wake-capturing vortical structures observed in previous studies, the active flow control successively enhances the average torque generated by turbine blades.

using OpenFOAM, ASMELASH HAFTU, SHIVASUBRAMANIAN GOPALAKRISHNAN, PRABHU RAMACHANDRAN, Indian Institute of Technology Bombay — Vertical Axis Wind Turbines (VAWTs) employ one or more, straight or curved blades which rotate parallel to the axis of rotation. Blade arrangement creates complex aerodynamics and unsteadiness in the flow. The objective of this study is to demonstrate that the model for simulating Darrieus-type vertical-axis wind turbines (VAWTs) using OpenFOAM is accurate and reliable. The study utilizes CFD simulations to characterize the aerodynamic performance of a chord-wise flexible vertical-axis wind turbine (VAWT). Wind-tunnel experiments are performed for rigid and flexible airfoils, over a range of Reynolds numbers, and performance improvements in terms of lift and drag coefficients are discussed. Airfoil simulations are performed using the OpenFOAM framework to help identify any mechanisms of airfoil performance improvement. Finally, airfoil lift and drag data are used with the aforementioned DMST model to investigate any performance improvements in VAWT performance through the use of flexible blades.

8:24AM Q14.00004 2D CFD study of Darrieus type straight single bladed VAWT using OpenFOAM, ASMELASH HAFTU, SHIVASUBRAMANIAN GOPALAKRISHNAN, PRABHU RAMACHANDRAN, Indian Institute of Technology Bombay — Vertical Axis Wind Turbines (VAWTs) employ one or more, straight or curved blades which rotate parallel to the axis of rotation. Blade arrangement creates complex aerodynamics and unsteadiness in the flow. The objective of this study is to demonstrate that the model for simulating Darrieus-type vertical-axis wind turbines (VAWTs) using OpenFOAM is accurate and reliable. The study utilizes CFD simulations to characterize the aerodynamic performance of a chord-wise flexible vertical-axis wind turbine (VAWT). Wind-tunnel experiments are performed for rigid and flexible airfoils, over a range of Reynolds numbers, and performance improvements in terms of lift and drag coefficients are discussed. Airfoil simulations are performed using the OpenFOAM framework to help identify any mechanisms of airfoil performance improvement. Finally, airfoil lift and drag data are used with the aforementioned DMST model to investigate any performance improvements in VAWT performance through the use of flexible blades.

8:37AM Q14.00005 Impact of different strut geometries on the performance of H-Darrieus vertical-axis turbines, THIERRY VILLENEUVE, GUY DUMAS, Laval University — Previous studies have shown that the performance of H-Darrieus vertical-axis turbines are highly sensitive to the struts mounting structure. More precisely, the struts, that are supporting the turbine blades, are detrimental to the power extraction. Indeed, the presence of the struts leads to an additional viscous drag contribution for the moving blades that results in a negative torque contribution at the turbine shaft. In addition to this added drag contribution, the struts also affect the flow field within the turbine, and thus, the forces acting on the turbine blades. In order to better understand these interactions between the blades and the struts, URANS and DDES numerical simulations are conducted for an H-Darrieus vertical-axis turbine with different strut configurations at a high Reynolds number. The results obtained from these simulations show that the struts affect importantly the spanwise distribution of the forces on the turbine blades. Moreover, the numerical simulations provide useful insights into the flow field within the turbine and can help to develop a strut geometry that could extract energy from the flow while minimizing its interference with the blade, and thus, contributing positively to the turbine efficiency.

8:50AM Q14.00006 A Wake in the Middle of the Night: 3D-PTV Measurements around Full-Scale Vertical-Axis Wind Turbines, NATHANIEL WEI, IAN BROWNSTEIN, JENNIFER CARDONA, MICHAEL HOWLAND, Mechanical Engineering, Stanford University, JOHN DABIRI, Mechanical Engineering and Civil & Environmental Engineering, Stanford University — Studies of the wake dynamics of wind turbines are critical for the design and optimization of wind farms in order to minimize wake losses and maximize power density. To observe the inherently three-dimensional flow structures in the wakes of full-scale vertical-axis wind turbines (VAWTs), a volumetric particle-tracking velocimetry method was developed for field experiments at the Field Laboratory for Optimized Wind Energy (FLOW) in Lancaster, CA, using six cameras and artificial snow as tracer particles. Velocity and vorticity fields extending up to three turbine diameters into the wake were measured around isolated 2-kW VAWTs: one with five straight blades, and another with three helical blades. Two tip-speed ratios were examined for each turbine. The 3D flow measurements allowed the dynamics of vortical structures in the streamwise, transverse, and wall-normal directions to be analyzed. Additionally, significant differences in wake geometry between the straight- and helical-bladed turbines were observed, which can be explained using a simple vortex-line model. These results help clarify mechanisms responsible for wake recovery in VAWTs, and thus have implications for wind-farm design.

9:03AM Q14.00007 Vertical Axis Wind Turbine Design Using Design-by-Morphing and Bayesian Optimization, HARI MOAZAM SHEIKH, PHILIP S MARCUS, University of California, Berkeley — Vertical Axis Wind Turbines (VAWTs) have not been commercialized due to their low Coefficients of Performance ( Cp) compared to Horizontal Axis Wind Turbines (HAWTs). However, their low Cp’s are likely due to the historical lack of systematic optimization. Recent studies, however, have shown that VAWTs can outperform HAWTs in closely packed arrays in terms of energy produced/area. This observation, combined with their low manufacturing and maintenance costs, and versatility, have sparked renewed interest in VAWTs. In this work, we optimize a VAWT and its concentrator with two techniques: Design by Morphing (DbM), which is a novel design method, and Bayesian optimization. With DbM, the shapes of the VAWT blades and concentrators are determined by morphing baseline shapes together, and the weights of the shapes used in the morph are part of a large Degree of Freedom (DoF) design space. Searching for the optimal design in the high DoF space is not possible using conventional optimization techniques due to the high cost of data for this problem, (i.e., computing or experimentally measuring the Cp of a VAWT). Using Bayesian optimization however, a 6-DoF space is optimized with only 1000 CFD-computed data points and produces an optimized VAWT along with its concentrator.

9:16AM Q14.00008 Vertical Axis Wind Turbine Performance Scaling at High Reynolds Numbers with Varying Solidity, MARK MILLER, Pennsylvania State University, ALEXANDER PIQUE, Princeton University, SUBRAHMANYAM DUVVURI, Indian Institute of Science, MARCUS HULTMARK, Princeton University — The large physical size and numerous design configurations of the Vertical Axis Wind Turbine have made it difficult to fully characterize the operational envelope of these machines. Laboratory experiments have been performed on a limited number of configurations due to the high-cost associated with testing full-scale models in large wind tunnel facilities. Ongoing work at Princeton University and Penn State has aimed to examine VAWT operation in detail using the controlled conditions of the laboratory, while simultaneously matching the full-scale aerodynamic parameters of interest: the Reynolds number and the tip speed ratio. To achieve this, a specialized, high-pressure wind tunnel facility has been rebuilt to recreate the struts also affect the flow field within the turbine, and thus, the forces acting on the turbine blades. In order to better understand these interactions between the blades and the struts, URANS and DDES numerical simulations are conducted for an H-Darrieus vertical-axis turbine with different strut configurations at a high Reynolds number. The results obtained from these simulations show that the struts affect importantly the spanwise distribution of the forces on the turbine blades. Moreover, the numerical simulations provide useful insights into the flow field within the turbine that can help to develop a strut geometry that could extract energy from the flow while minimizing its interference with the blade, and thus, contributing positively to the turbine efficiency.

9:29AM Q14.00009 Effect of helical-shape blades on the wake flow characteristics of vertical axis wind turbines. SHUOLIN XIAO, University of Houston, RONGNAN YAO, University of Notre Dame, DANIEL ARAYA, Johns Hopkins University Applied Physics Laboratory, JOHN DABIRI, Stanford University, DI YANG, University of Houston — Vertical axis wind turbine (VAWT) is a widely used type of wind energy harvesting device. In recent years, considerable efforts have been devoted to studying the turbulent wake flow characteristics behind VAWTs. While most previous studies have focused on the VAWT’s with straight blades, limited progress has been made for understanding the wake flow dynamics of VAWTs with helical-shape blades. In this study, the characteristics of turbulent wake flows behind helical-shape VAWTs are investigated both by wind tunnel experiments using the particle image velocimetry (PIV) technique and by large-eddy simulation (LES) using the actuator-line model (ALM). This talk presents the preliminary PIV and LES-ALM results for the wake behind a helical-shape VAWT and compares them to those for a straight-blade VAWT.

Tuesday, November 26, 2019 7:45AM - 9:42AM – Session Q15 Turbulence: Wall-bounded Flows II 310 - Sheldon Green, University of British Columbia

7:45AM Q15.00001 Statistical State Dynamics Based Study of the Role of Nonlinearity in the Maintenance of Turbulence in Couette Flow1, BRIAN FARRELL, Harvard University, PETROS IOANNOU, MARIOS-ANDREAS NIKOLAIDIS, National and Kapodistrian University of Athens — While linear non-normality underlies the mechanism of energy transfer from the externally driven flow to the perturbation field, nonlinearity is also known to play an essential role in sustaining turbulence. We report a study based on the statistical state dynamics of Couette flow turbulence with the goal of better understanding the role of nonlinearity in sustaining turbulence. The statistical state dynamics implementation used is a closure at second order in a cumulant expansion of the Navier-Stokes equations in which the averaging operator is the streamwise mean. Two fundamentally non-normal mechanisms potentially contributing to maintaining the second cumulant are identified. These are parametric perturbation growth arising from interaction of the perturbations with the fluctuating mean flow and transient growth of perturbations arising from nonlinear interaction between components of the perturbation field. By the method of selectively including these mechanisms in a DNS parametric growth is found to maintain the perturbation field in the turbulent state while the mechanism of transient growth of perturbations arising from scattering by nonlinear interactions suppresses perturbation variance.

7:58AM Q15.00002 The Monin-Obukhov length in turbulent Taylor-Couette flow1, PIETER BERGHOUT, ROBERTO VERZICCO, RICHARD STEVENS, DETLEF LOHSE, Physics of Fluids Group and Max Planck Center Twente, MESA+ Institute and J. M. Burgers Centre for Fluid Dynamics, University of Twente, P.O. Box 217., DANIEL CHUNG, Department of Mechanical Engineering, University of Melbourne, Victoria 3010, Australia — Turbulent Taylor–Couette (TC) flow is the shear driven flow in-between two concentric independently rotating cylinders. In recent years, direct numerical simulations and experiments (employing particle imaging velocimetry) revealed the shape of the mean streamwise and angular velocity profiles up to very high Reynolds numbers. However, so far no theory has been able to capture the Reynolds number effects of the mean streamwise velocity profile, and the classical von-Karman logarithmic law only fits in a minimal spatial region. In this talk, we show the application of the Monin-Obukhov length to turbulent TC flow. This length scale delineates the flow regions where the production of turbulent kinetic energy is governed either by shear or by the curvature of streamlines (centrifugal effects). We then derive an equation for the mean streamwise and angular velocity profiles that convincingly collapses the profiles for varying Reynolds numbers. Finally, we extend the analysis to varying radius ratios and find an equally convincing collapse.

1This project is funded by the Priority Programme SPP 1881 Turbulent Superstructures of the Deutsche Forschungsgemeinschaft.

8:11AM Q15.00003 The balance of Reynolds stresses equations in spanwise rotating plane Couette flows at dual states1, ZHENHUA XIA, Zhejiang University — In this work, the terms in the transport equations of the Reynolds stresses are analysed in spanwise rotating plane Couette flows at two different states. Our results show that they are generally of the same shape at two different states, but the state with more roll cells has a larger value. The energy transfer between the secondary and the residual fields shows that the secondary flows are more energetic at the state with more roll cells while the residual field is more energetic in the other state. Furthermore, a local inverse energy cascade is observed in the near wall region at the latter state with less roll cells where the energy is transferred from the residual field to the secondary flow field. Our results support the conjecture that the large-scale secondary flows play a very important role in the dual states of spanwise rotating plane Couette flows.

1the National Science Foundation of China (NSF Grant Nos. 11822208, 11772297)

8:24AM Q15.00004 The moving wall effects on structures in turbulent Couette-Poiseuille flows1, JUN HYUK HWANG, JAE HWA LEE, UNIST — Direct numerical simulation of a turbulent Couette-Poiseuille flow (hereafter, CP-flow) is performed to investigate spatial development of turbulent structures in the asymmetric flows between two parallel planes. The asymmetric CP-flows are generated by imposing the constant moving wall velocity condition on the top wall in the opposite direction to the main flow, and the velocity is varied systematically. As the moving wall velocity increases, the friction Reynolds number on the moving wall increases largely, although it is increased slightly on the stationary wall. Inner-scaled mean velocity profiles show that the logarithmic layer is established clearly on the moving wall, whereas it is shortened on the stationary wall compared to that from turbulent pure Poiseuille flow at similar Reynolds number. Profiles of the turbulent intensities show that the turbulent activity increases/decreases near the moving/stationary wall with an increase of the moving wall velocity. The asymmetric features of the CP-flow are mainly attributed to significant growth of near-wall motions on the top wall throughout the elongated shear layer.

8:37AM Q15.00005 Large-eddy simulation of Taylor-Couette flow at relatively large Reynolds number , WAN CHENG, King Abdullah University of Science and Technology, DALE PULLIN, California Institute of Technology, RAVI SAMTANEY, King Abdullah University of Science and Technology — We present large-eddy simulations (LES) of the incompressible Navier-Stokes equations for Taylor-Couette flow at relatively high Reynolds numbers. The ratio of the two co-axial cylinder diameters is fixed as $\eta = R_i/R_o = 0.909$ with $R_i$, $R_o$ the inner and outer cylinder radii respectively. The outer cylinder is stationary while the inner cylinder rotates with constant angular velocity $\Omega_i$, leading to the driving Reynolds number $Re_i = (R_o - R_i) R_i \Omega_i / \nu$ with $\nu$ the kinematic viscosity of the Newtonian fluid. Wall-resolved LES is implemented using the stretched-vortex, sub-grid scale model with $Re_i$ in the range $10^5 - 3 \times 10^6$. We develop an empirical flow model for the $Re_{\tau,i} = F(\eta, Re_i)$ relationship where $Re_{\tau,i} = u_{\tau,i} (R_o - R_i)/(2 \nu)$ is the inner-cylinder friction Reynolds number. Comparison of the model behavior with experimental data [van Gils et al., PRL, 106, (2011), van Gils et al., J. Fluid Mech., 706, (2012), Merbold et al., Phys. Rev. E, 87, (2013)] direct numerical simulation [Ostilla-Mónico et al., J. Fluid Mech., 788, (2016)] and the present LES will be discussed.

8:50AM Q15.00006 Direct numerical simulations of a swirling flow in a conical diffuser$^1$, ANKIT AWASTHI, UGO PIOMELLI, Queen's University — We have performed Direct Numerical Simulations of a swirling flow in a conical diffuser using NaSt5000, a spectral-element code. This configuration is a model of the draft tube of a hydroelectric power plant, which is used to increase the flow pressure downstream of the turbine. Separation may adversely impact the performance of the diffuser and should be avoided. A conical diffuser with an opening angle of 20 degrees is chosen. Previous experimental and numerical studies can be used for validation [Clausen et al., Exp. Therm. Fluid Sci., 61(1):39–48, 1993]. The experiment uses a very short inlet section so that at the beginning of the diffuser the flow is not fully developed. The flow is extremely sensitive to the inlet boundary conditions. When the inlet boundary condition for axial and circumferential velocities at the beginning of the diffuser are taken from the experimental study, good agreement is achieved downstream. The use of fully developed pipe flow, on the other hand, results in a very different flow field. The effects of synthetic perturbation and forcing techniques to generate inflow conditions will be described. Future work will include the effect of rough walls on the separation characteristics and pressure recovery.

$^1$NSERC and Hydro Quebec

9:03AM Q15.00007 Is secondary flow of Prandtl’s second kind due to intense Reynolds-stress events$^1$, ATZORI MARCO, RICARDO VINUESA, Linné Flow Centre, KTH Mechanics, ADRIÁN LOZANO-DURÁN, Center for Turbulence Research, Stanford University, PHILIPP SCHLATTER, Linné Flow Centre, KTH Mechanics — We investigate intense Reynolds-stress events in the turbulent flow through ducts square and rectangular cross-sections, with the aim of clarifying their relation with the secondary flow of Prandtl’s second kind. The intense Reynolds-stress structures are defined as connected regions of the domain that fulfill the condition $|uu’| > Hu’v$, where $u$ and $v$ are the root-mean-square, and $H$ is a scalar threshold. In particular, we focus on the fractional contribution of these events to the mean vertical velocity, $\bar{V}$. The comparison between duct and channel flows unveils that: 1) in the core of the duct, the fractional contribution is in very good agreement with that in the channel, despite the presence of the secondary flow in the duct; 2) in the corner of the duct, the fractional contribution is in good agreement with the channel only in a small region below the corner bisector. Both in the core and in corner of the duct, the behaviour of the fractional contribution as a function of the wall distance is significantly different from that of $\bar{V}$. According to our results, the secondary flow of Prandtl’s second kind is not due to intense Reynolds-stress events.

$^1$The support by SSF (grant number BD15-0082) and by the Knut and Alice Wallenberg Foundation is acknowledged.

9:16AM Q15.00008 Quantitative contribution of laminar, turbulence and secondary flow to velocity and temperature in rhombic ducts, NAOYA FUKUSHIMA, Tokai University — In this study, Direct Numerical Simulation of turbulent flow in rhombic ducts have been carried out to investigate effects of the corner angle on the velocity and temperature distribution in the ducts. Due to anisotropy and inhomogeneity of the Reynolds stresses, secondary flow of the second kind, which goes from the center to the corner of ducts, is induced. The secondary flow affects the velocity and temperature distribution in the ducts and is supposed to enhance momentum and heat transfer. Even around the obtuse corner whose angle is 150°, the secondary flow with about 1.5 % of bulk mean velocity is still induced. The origin of the secondary flow has not been clarified yet. Fukagata, Iwamoto and Kasagi (2002) have theoretically driven the FIK-identity to evaluate quantitative contributions of laminar and turbulence to the friction in turbulent channel. In this study, the FIK-identity has been numerically applied to DNS data in the rhombic ducts to evaluate quantitative contributions of laminar, turbulence and secondary flow to the velocity and temperature distribution. From the results, the effects of the corner angle on these contributions are investigated. Finally, one possible origin of the secondary flow will be suggested.

9:29AM Q15.00009 Analysis of Thermal Boundary-Layer Structure and Scale-Dependence in Transcritical Flows at Turbulent Conditions$^1$, J ACK GUO, Department of Mechanical Engineering, Stanford University, XIANG YANG, Department of Mechanical and Nuclear Engineering, Pennsylvania State University, MATTHIAS IHME, Department of Mechanical Engineering, Stanford University — Previous literature has shown inadequacies of commonly employed scaling transformations to collapse the mean temperature profile for flows with large property gradients. This is particularly relevant for flows with large density gradients that are encountered in transcritical wall-bounded flows. Here, we examine the breakdown of the temperature law of the wall as a function of compressibility via direct numerical simulation (DNS) of transcritical channel flows at turbulent conditions. We propose scaling corrections and suggestions towards the development of more accurate temperature profiles, representing an important step towards reliable predictions of highly compressible turbulent flows. We also analyze and discuss turbulent statistics and budgets related to the temperature transport and heat transfer and provide estimates under which conditions commonly employed transformations remain valid at transcritical flow regimes.

zones in zero-pressure gradient turbulent boundary layers

within a turbulent boundary layer (Re around $10^5$) of this mechanism. A water tunnel DPIV study has been carried out to analyze the geometry and behavior of the low speed streaks forming to flow control. Upon scale actuation, the reversed flow would be prevented from moving further upstream and maintaining attached flow over streaks, of a turbulent boundary layer experiencing an adverse pressure gradient, is the main mechanism that induces scale actuation leading the passive bristling of mako denticles by reversing flow close to the surface. It is hypothesized that the reversing flow within the low speed separation control has been observed over samples of flank skin from a shortfin mako shark. It is hypothesized that this control is enabled by some UMZs with a streamwise extent of 2 boundary layer thickness, a spanwise extent of 0.1 boundary layer thickness, and surface conditions from hydraulically smooth to fully rough. In the logarithmic region, the UMZs exhibit universal behavior irrespective of Reynolds number and surface conditions. The velocity difference across the shear interfaces between UMZs scales with the friction velocity $u_*$ and the wall-normal thickness of UMZs scales with the wall-normal distance. Further, the UMZ statistics provide a direct link between the spatial organization of boundary layer turbulence and the hypothesized attached eddies used to derive velocity statistics in the logarithmic region. The observed universal behavior of the UMZs can also be used to develop and refine the representative eddies used in reduced-order models of high-Reynolds-number boundary layers.

Avalanche of drag-inducing near-wall vortices due to streak transient growth in turbulent channel flow. ERIC STOUT, Texas Tech University, XUERUI MAO, University of Nottingham, FAZLE HUSSAIN, Texas Tech University — A key question in turbulent boundary layers is the evolutionary dynamics of the coupling of near-wall streamwise vortices and streaks. A single low-speed streak in a large ($L^+ = 900$) channel flow is triggered with the typical spanwise perturbation to excite streak transient growth (STG) at Re$_t = 220$, and reveals an avalanche of streamwise vortices, as well as very long structures. Development of hairpin vortices, hook vortices, arched vortices, and very long streamwise vortices (VLSM, much longer than $s^+ = 300$) reveal the avalanche dynamics involved in the spread and development of the near-wall structures. Lift up of near-wall fluid by the streamwise vortices generate new streaks and hence STG, revealing a sequence of dynamical events involving complex interactions between streaks and streamwise vortices, undiscovered in previous studies. The interaction between streamwise vortices and the quiescent regions aid in understanding the growth of near-wall dynamics, even of turbulent spots. Visualization reveals evolution of very long streamwise vortices — a promising finding that may reveal the enigmatic genesis and dynamics of VLSM in turbulent boundary layers.

Dissipation events in wall turbulence. M. J. PHILIPP HACK, Center for Turbulence Research, Stanford University, OLIVER T. SCHMIDT, University of California San Diego — The intermittent nature of turbulent flows is characterized by periods of low intensity that are interrupted by brief extreme events during which quantities such as production or dissipation of fluctuation kinetic energy develop marked peaks. Our study examines the mechanisms of extreme dissipation events in turbulent boundary layers at moderate Reynolds numbers. Conditional sampling is applied to time-series data generated in direct numerical simulations. The results point to a connection between localized dissipation maxima and the formation of hairpin vortices via exponential instability. Specifically, time-resolved conditionally averaged velocity fields at a dissipation event show the characteristic spatial structure of an instability of varicose type, as predicted in linear analyses (M.J.P. Hack & P. Moin, J. Fluid Mech., vol. 844, 2018). Visualizations of vortex-identification criteria recover a hairpin-type structure which coincides with the region of highest dissipation. The analysis identifies the precursors of the dissipation events as perturbations in the streamwise velocity component which give rise to the varicose instability by locally augmenting the shear.

A DNS study of a shear-driven three-dimensional turbulent boundary layer with emphasis on momentum transport. HIROYUKI ABE, Japan Aerospace Exploration Agency — DNS is used to examine a non-equilibrium three-dimensional turbulent boundary layer (3DTBL) over a flat plate owing to sudden imposition of surface spanwise velocity $W_s$. Particular attention is given to the effects of crossflow and Reynolds number on momentum transport. In the simulations, three values of inlet momentum thickness Reynolds number (=300, 600 and 900) are used with several values of $W_s$. The present largest $W_s$ is twice the freestream velocity $U_0$, comparable to the maximum value in the spinning cylinder experiment by Loehmann (1976). After imposing $W_s$, the secondary Reynolds shear stress builds up and the mean spanwise velocity (crossflow) increasingly propagates to the outer region where there is a mean streamwise velocity deficit due to the skewed near-wall Reynolds stresses. As $Re$ increases, the inner region of a near equilibrium 3DTBL becomes increasingly enlarged where the structure parameter is smaller than 0.15. The mean velocity magnitude also exhibits a departure from the classical log law (i.e., a larger $K$ than in a 2DTBL). After turning off $W_s$, the recovery to a 2DTBL is slow in the outer region since the 3D effect persists there.

Direct numerical simulation of a turbulent thermal boundary layer spatially evolving on an isothermal wall from a fully turbulent adiabatic flow. MATTEO GELAIN, Safran Aircraft Engines; Laboratoire EM2C (CNRS - CentraleSupelec); OLIVIER GICQUEL, Laboratoire EM2C (CNRS - CentraleSupelec); ALEXANDRE COUILLEAUX, Safran Aircraft Engines, RONAN VICQUELIN, Laboratoire EM2C (CNRS - CentraleSupelec) — A direct numerical simulation of a spatially evolving turbulent thermal boundary layer is performed in a channel flow at $Re_t = 395$. The domain is made of two parts in the streamwise direction. Upstream, the flow is turbulent, homogeneous in temperature and the channel walls are adiabatic. The inflow conditions are extracted from a recycling plane located further downstream so that a fully developed turbulent adiabatic flow reaches the second part. In the domain located downstream, isothermal boundary conditions are prescribed at the walls. The boundary layer, initially at equilibrium, is perturbed by the abrupt change of boundary conditions and a non-equilibrium transient phase is observed until, further downstream, the flow reaches a new equilibrium state. Near-wall Reynolds stresses increase with crossflow due to the increased straining. As $Re$ increases, the inner region of a near equilibrium 3DTBL becomes increasingly enlarged where the structure parameter is smaller than 0.15. Mean and root-mean-square profiles of temperature and velocity are presented along with budgets of first- and second-order moments balance equations for the enthalpy and momentum turbulent fields.

Tuesday, November 26, 2019 7:45AM - 9:29AM – Session Q17 Focus Session: Recent Advances in Data-driven and Machine Learning Methods for Turbulent Flows

Towards (Machine) Learning of Large Eddy Lagrangian Models (of Turbulence). MICHAEL CHERTKOV, MIKHAIL STEPANOV, University of Arizona — Aimed at developing a physics-informed simulation approach compatible with modern Machine Learning, we focus here on designing, analyzing and experimenting with reduced Lagrangian, multi-particle models, which are capable of capturing fatefully turbulent dynamics within the resolved large-scale portion of the inertial range. We generalize over popular particle-based models, e.g. Molecular Dynamics (MD) and Smooth Particle Hydrodynamics (SPH), known to generate hydrodynamic behaviour at the scales (typically much) larger than the mean-particle distance. The generalization, reflected in introducing sufficient number of interpretable parameters, is inclusive: we allow variability in the choice of (a) MD pair-wise potential, (b) SPH weighting function, and (c) thermodynamic relation between pressure and density. To mimic effects of the under-resolved scales, we include in the model additional regularizations, such as dependence of the potential and of the weighting function on the inter-particle velocity. In order to generate homogeneous, isotropic and weakly-compressible turbulence we force the Lagrangian system at large scales. To gain a qualitative understanding of what can be achieved at large scales we test the model in different regimes.

This work is a part of Machine Learning for Turbulence project funded by LDRD office at LANL/DOE.
7:58AM Q17.00002 Dynamical System Analysis of Data-Driven Turbulence Models

SALAR TAGHIZADEH, FREDDIE WITHERDEN, SHARATH GIRIMAJI, Texas A&M University — Recent advances in machine learning (ML) algorithms, in conjunction with the availability of direct numerical simulation data, have resulted in a surge of interest in data-driven turbulence modelling. The idea with such models is to replace one or more components of a classical closure model with an implicit function obtained through a trained ML procedure. In training such a procedure, data is used to infer unknown turbulence constitutive relationships. However, choices of these learnable functions and the set of modelled equations can be internally inconsistent. Specifically, attributes such as fixed point behaviour, realizability, and consistency with other physical and mathematical constraints such as the rapid distortion limit may no longer be preserved. In this work, we introduce a novel procedure based on fixed point analysis for ensuring that the overall set of equations in data-driven turbulence modelling form a self-consistent dynamical system. The procedure will be showcased on a new data-driven Reynolds averaged Navier–Stokes model which we have developed.

8:11AM Q17.00003 Uncertainty quantification and optimization of spray break-up submodel using regularized multi-task neural nets.

XIANG GAO, Microsoft Research, HONGYUAN ZHANG, KRISHNA BAVANDLA, PING YI, SUO YANG, University of Minnesota — For a high-fidelity simulation of engine combustion, parameters of a spray atomization break-up submodel needs to be optimized for the specified conditions to match with the non-reactive experiment. The well-accepted KH-RT spray breakup model include at least 6 parameters and they are not independent of each other, thus cannot be optimized independently. Properly tuning is time-consuming and often need expertise-guide. We propose a regularized multi-task neural nets approach to find optimal submodel parameters \( \theta \) at the working condition \( X \) that minimizes “error” \( \epsilon \). The proposed model includes two neural nets: a predictor and an autoencoder. Predictor is trained to predict the submodel parameters \( \theta \) for a given \( X \) and \( \epsilon \). The optimal \( \theta \) then can be estimated by setting \( \epsilon \) as zero. Autoencoder is used to learn a latent representation of a pair of \( (X, \theta) \), which is encouraged by a regularization term to share the same latent space as the predictor. For an unseen condition \( X \) and estimated optimal \( \epsilon \), we can use the autoencoder to find similar \( (X, \theta) \) pairs from the training data to interpret the predictor prediction and quantify the uncertainty.

8:24AM Q17.00004 Approximate Bayesian Computation for Parameter Estimation in RANS Turbulence Models

OLGA DORONINA, University of Colorado, Boulder, SCOTT MURMAN, NASA Ames Research Center, PETER HAMLINGTON, University of Colorado, Boulder — Traditionally, turbulence model parameters have been determined through either direct inversion of model equations given some reference data or using optimization techniques. However, the former approach becomes complicated for models with many different parameters or when the model consists of partial differential equations. Here, we use an Approximate Bayesian Computation (ABC) approach to estimate unknown model parameter values, as well as their uncertainties, in a nonequilibrium anisotropy closure for Reynolds averaged Navier-Stokes (RANS) simulations. ABC does not require direct computation of a likelihood function, thereby enabling substantially faster estimation of unknown parameters as compared to full Bayesian analyses. Details of the ABC approach are described, including the use of a Markov chain Monte Carlo technique as well as the choice of summary statistics and distance function. Unknown model parameters are estimated based on reference data for different homogeneous nonequilibrium test cases. We also discuss the calibration of turbulence models in inhomogeneous flows using forward simulations of an axisymmetric bump.

8:37AM Q17.00005 Machine-learning-assisting investigation of turbulence anisotropy

JUNYI MI, CHAO JIANG, SHUJIN LAIMA, HUI LI, Harbin Institute of Technology — An anisotropy invariant map (AIM) and barycentric map (BMap), which are based the space spanned by invariants of the anisotropic stress tensor, have been playing a crucial role in stress invariant analysis to quantify turbulence anisotropy. However, these methods cannot offer any scale information about the turbulent structures, otherwise the degree of axisymmetry and anisotropy. Only a mingy portion of the turbulent flow in real world can reach the edges or vertices of the AIM or BMap, with which therefore a deeper understanding of flow details about the flow pattern regimes is rarely developed. Here we report an unsupervised machine-learning algorithm (a modified K-means method) as a classifier of flow pattern regimes, with the Reynolds stress tensor instead of their secondary quantities as input features (including the distances from the walls). Tests are performed in duct flows. As a result, (i) there is a consistent one-to-one match between the separation boundaries for different regimes in flow space and the border of invariants for this flow itself in the AIM or BMap; (ii) the size of flow regime in coordinate space leads to identifying the scales of turbulent structures. Besides, effects of the aspect ratio and Reynolds number are examined.

8:50AM Q17.00006 Predicting the stochasticity: GAN-VAE based deep learning model for turbulence prediction

CHANGLIN JIANG, AMIR BARATI FARIMANI, Carnegie Mellon University — Turbulence is a classical tempo-spatial system that has high non-linearity and prohibitively large degrees of freedom, which is basically considered impossible to solve analytically. Unlike Computational Fluid Dynamics (CFD) techniques which generally have considerable time and memory consumption, deep learning (DL) models could learn the hidden features automatically and hierarchically in multiple levels given massive dataset. Instead of solely learning to do turbulence parameterization, we seek to predict turbulence without any underlying physical rules. Our GAN-VAE based DL model could successfully simulate the ambiguous nature of turbulence by combining two distinct but complementary approaches: (a) a variational auto-encoder (VAE) which explicitly models stochasticity by latent layer sampling. (b) a generative adversarial network (GAN) that aims to produce realistic predictions. In the meantime, our model takes advantage of recent work in object detection and motion prediction, such as Convolutional Dynamic Neural Advection (CDNA) and convolutional LSTM. The model prediction is assessed with physics-based metrics like small scale statistics and flow morphology. Our results show promising capability of predicting turbulence that satisfies physical rules with high accuracy.

9:03AM Q17.00007 Using machine learning to predict low-altitude atmospheric optical turbulence

CHRIS JELLEN, JOHN BURKHARDT, CHARLES NELSON, CODY BROWNELL, U.S. Naval Academy — Laser-based systems employed within the atmosphere under layer are subject to degradation due to index of refraction fluctuations within the beam path, known as optical turbulence. Laser propagation through optical turbulence results in beam spread, loss of coherence, and reduced irradiance on target. The root causes of optical turbulence are temperature and humidity fluctuations within the atmosphere. Prediction of these parameters from basic meteorological data is required for effective implementation of any long-range laser system. A field measurement site at the U.S. Naval Academy in Annapolis, Maryland, is used to gather data related to atmospheric effects on optical propagation. A scintillimeter measures the refractive index structure constant along a 1-km path over the Severn River adjacent to the Chesapeake Bay. At each end of the scintillometer link, weather data including wind velocity, air and sea surface temperatures, etc. is captured. Using this data, machine learning techniques are used to predict the refractive index structure parameter of the atmosphere and the scintillation on target of the laser.

9:16AM Q17.00008 Convolutional Neural Networks for the Solution of the 2D Poisson Equation with Arbitrary Dirichlet Boundary Conditions, Mesh Sizes and Grid Spacings1

ALI GIRAYHAN OZBAY, Department of Aeronautics, Imperial College London, PANAGIOTIS TZIRAKIS, GEORGIOS RIZOS, BJORN SCHULLER, Department of Computing, Imperial College London, SYLVAIN LAIZET, Department of Aeronautics, Imperial College London — The Poisson equation is a problem commonly encountered in engineering, including in computational fluid dynamics where it is needed to compute corrections to the pressure field. However, solving the Poisson equation numerically can be very costly, especially for large-scale problems. We propose a fully convolutional neural network (CNN) architecture to infer the solution of the Poisson equation on a Cartesian grid of arbitrary size and grid spacing, given the right hand side term, Dirichlet boundary conditions and grid parameters. Analytical test cases indicate that our CNN architecture is capable of predicting the correct solution of a Poisson equation with mean percentage errors of a few percentage points and a reduction in wall-clock time compared to traditional solvers based on finite difference methods.

Tuesday, November 26, 2019 7:45AM - 9:29AM –
Session Q18 Compressible Turbulence 400 - Ivan Bermejo-Moreno, USC

7:45AM Q18.00001 Compressibility Effects in High Speed Turbulent Shear Layers Revisited1

KRISTEN MATSUNO2, SANJIVA LELE, Stanford University — In the past few decades, several models have been proposed to capture the consequences of compressibility on turbulence in shear flows. However, current explanations of reduced growth rates and alterations to turbulence structure with increasing Mach number remain somewhat incomplete, and comprehensive theory and modeling is elusive. In this work, compressible mixing layers over a range of convective Mach numbers (\(M_c \in [0.2, 2.0]\)) and free-stream density ratios (\(\frac{\rho_2}{\rho_1} \in [2, 1.7]\)) are directly simulated and compared to previous work. Using this database, the effect of \(M_c\) on key mechanisms in the evolution of turbulent kinetic energy (TKE) such as the pressure-dilatation correlation and the baroclinic work term are presented. The well-known effects of increasing compressibility on turbulent length scales and anisotropy are also demonstrated. Fluctuating velocity fields are decomposed into solenoidal and dilatational components via a Helmholtz decomposition, and resulting Reynolds stress components display cancellations in the transverse direction. Pressure fluctuations are analyzed to characterize acoustic communication across vortical structures.

7:58AM Q18.00002 Investigating the dynamics of vorticity and strain rate in compressible turbulent flows

NISHANT PARASHAR, SAWAN S SINHA, Indian Institute of Technology, Delhi, MOHAMMAD DANISH, Bennett University, Noida, BALAJI SRINIVASAN, Indian Institute of Technology, Madras — We examine the effect of compressibility on vorticity and strain rate dynamics for compressible turbulent flows. For this, we employ direct numerical simulations of decaying compressible isotropic turbulent flows. A Lagrangian particle tracker is used to identify the influence of compressibility on vorticity-strain rate dynamics. Time correlations between the instantaneous vorticity vector and the strain-rate eigenvector system are calculated using the Lagrangian history of fluid particles. We show that while the statistics obtained are independent of turbulent Mach number, they are found to be significantly influenced by the locally normalized dilatation rate. Further, we study the time correlations conditioned on local flow topologies (based on invariants of the velocity gradient tensor) as well. We find that the influence of dilatation rate is predominantly associated with rotation dominated flow topologies (unstable-focus-compressing and stable-focus-stretching). At last, we provide a physical explanation of all these observations by tracking the moment of inertia and angular momentum history of tetrahedral fluid elements.

8:11AM Q18.00003 Influence of compressibility on lifetimes of topologies in turbulent flows

SAWAN SINHA, Indian Institute of Technology Delhi, NISHANT PARASHAR, Indian Institute of Technology Delhi INDIA, BALAJI SRINIVASAN, Indian Institute of Technology Madras INDIA — Flow field topologies are categorized based on the nature of eigenvalues of the local velocity gradient tensor. Physically, these topologies are suggestive of the relative importance of the local strain-rate and the rotation rate-tensors. The question that how long a given topology lasts in a turbulent flow field is of fundamental importance in geophysical and astrophysical flows. It has been reported in literature that while in the former, this quest is linked to the process of raindrop formation, in the latter, the question finds its significance in context of star formations. While some earlier attempts have been made to estimate the lifetimes of topologies using surrogate methods like the conditional mean trajectories (CMT), in this work we take a more direct approach and accurately estimate topology lifetimes using well resolved direct numerical simulation data in conjunction with a Lagrangian particle tracker. In particular, we investigate and explain how initial turbulent Mach number and local dilatation rate tends to influence the lifetimes of various topologies in a compressible turbulent flow field. Finally, some modeling implications of these findings are also presented.

8:24AM Q18.00004 Multiscale analysis of passive scalar transfer in compressible isotropic turbulence1

JIANCHUN WANG, MINPING WAN, CHENYUE XIE, QINMIN ZHENG, XIAONING WANG, JIAN TENG, LIAN-PING WANG, SHIYI CHEN, Southern University of Science and Technology, Shenzhen, Guangdong 518055, P. R. China — Inter-scale transfer of a passive scalar in stationary compressible isotropic turbulence is studied by numerical simulations at a Taylor Reynolds number of approximately 250, and at turbulent Mach numbers of 0.4 and 1.0. The 5/3 scaling behavior is identified for the fluctuation spectrum of passive scalar, with the Obukhov-Corrsin constant close to that of a passive scalar spectrum in incompressible turbulence. The average subgrid-scale (SGS) flux of passive scalar normalized by the total dissipation rate is close to 1 in the inertial range. It is shown by Helmholtz decomposition that the SGS flux of passive scalar is dominated by the solenoidal mode of velocity field. Moreover, the effect of local compressibility on the SGS flux of passive scalar is investigated by conditional averaging with respect to the filtered velocity divergence. A discrete approximate deconvolution model (DADM) is proposed to reconstruct the SGS flux of passive scalar from the filtered flow fields. Numerical results show that the SGS flux of passive scalar reconstructed by DADM is in good agreement with the real SGS flux of passive scalar.

8:37AM Q18.00005 Solenoidal scaling laws for compressible mixing\textsuperscript{1}. JOHN PANICKACHERIL, JOHN, DIEGO A DONZIS, Texas A & M University, KATEPALLI R SREENIVASAN, New York University — Mixing of passive scalars in compressible turbulence does not obey the same classical Reynolds number scaling as its incompressible counterpart. In this work we first show from a large database of direct numerical simulations that even the solenoidal part of the velocity field fails to follow the classical incompressible scaling when the forcing includes a substantial dilatational component. Though the dilatational effects on the flow remain significant, our main results are that both the solenoidal energy spectrum and the passive scalar spectrum scale assume incompressible forms, and that the scalar gradient aligns with the most compressive eigenvalue of the solenoidal part, provided that only the solenoidal components are used for scaling in a consistent manner. Minor modifications to this result are also pointed out, in particular the interaction of scalar field with the dilatational part of flow field. Two parameters that are found to be important in compressible mixing are the ratio of dilatational to solenoidal rms velocities and the turbulent Mach number, whose role in mixing will also be discussed.

8:50AM Q18.00006 Reproducing the local characteristics of compressible turbulent flows at a low cost: derivation and application. GUILLAUME BEARDELL, GUILLAUME BLANQUART, California Institute of Technology — When performing Direct Numerical Simulations (DNS) of highly turbulent reacting flows, it is often prohibitively expensive to simulate complete flow geometries. For example, simulations of turbulence-flame interactions usually do not capture the full combustor, and instead focus on a specific portion of the domain, e.g., the region around the flame front. However, by doing so, one misses turbulent kinetic energy injection due to shear by the large scales. In the present work, we include these large-scale contributions, e.g., from experimental data, and we solve for the small-scale components only. The resulting equations are the same as the original compressible Navier-Stokes equations, except for the introduction of additional terms. This approach allows us to achieve high turbulent Reynolds numbers while keeping the computational cost reasonable. We have already applied this strategy to incompressible flows, but not to compressible ones, where special care must be taken regarding the energy equation. Using the finite-difference solver NGA, we apply this framework to simulations of homogeneous turbulence and premixed flames. We provide comparisons with results obtained with other forcing schemes.

9:03AM Q18.00007 The Interaction of a Homogeneous Field of Acoustic Waves with a Shock Wave. YUCHEN LIU, LIAN DUAN, The Ohio State University — Direct numerical simulations (DNS) and linear interaction analysis (LIA) are used to examine the significant flow characteristics associated with a homogeneous field of acoustic waves passing through a nominally normal shock wave. The full-fledged nonlinear simulations and the linear analysis are enabled by a pre-cursor numerical database of boundary-layer acoustic radiation that provides incident acoustic fields with high degree of physical realism and applicability. The research contributes to the fundamental understanding of the interaction of a shock wave with a field of turbulence by characterizing its behaviors in the pure dilatational limit and complements existing studies of shock/turbulence interaction with a vorticity-dominated incident turbulent field.

9:16AM Q18.00008 Tracking of flow structures in shock-turbulence interaction. JONAS BUCHMEIER, University of Southern California, ALEXANDER BUSSMANN, Technical University of Munich, XIANGYU GAO, IVAN BERMEJO-MORENO, University of Southern California — A tracking algorithm is applied to study the time evolution of flow structures, defined as isosurfaces of a field of interest. Correspondences between structures in consecutive time steps are found in a higher dimensional feature space, which includes a geometric signature of the structures, in addition to their spatial information. To allow for larger tracking steps, constraints are used to reject correspondences based on physical realizability. Accepted correspondences are used to dynamically build a graph describing the evolution and interactions of structures over time. Complex split-merge interactions resulting from large tracking steps are handled based on confidence indicators obtained from the search, physical properties and history of the involved structures. The graph is then queried to retrieve confidence information on the evolution of the structure. The algorithm applies to both shock-capturing DNS of shock-turbulence interaction ($Re_{m} = 40; M_{2} = 0.1, 0.4; M = 1.5, 3.0$). Passive scalar isosurfaces with well-defined initial shapes and turbulence structures based on the Q criterion are tracked across the shock, analyzing relations between local geometry and physical quantities mapped on the surfaces.

Tuesday, November 26, 2019 7:45AM - 9:29AM — Session Q19 CFD: Immersed Boundary Methods II 401 - Andres Goza, University of Illinois at Urbana-Champaign

7:45AM Q19.00001 A Fully Grid-Line-Based Immersed Boundary Method\textsuperscript{1}. GUANTING SU, Beihang University & University of California, Berkeley, TIANYU PAN, Beihang University, QIUSHI LI, Beihang University & Xihua University — By introducing proper variable reconstruction scheme in the vicinity of immersed boundaries, a group of immersed boundary methods (IBMs), including ghost-cell method and hybrid Cartesian method, showed promising performance when simulating unsteady, incompressible flow around complex boundaries using non-body-conformal orthogonal grids. In this work, we propose a fully grid-line-based IBM with a novel velocity reconstruction scheme which is capable of stably imposing desired linear velocity distribution along single or multiple gridline directions. Pressure boundary condition is inherently implemented with desired velocity distribution imposed. Present method greatly simplifies boundary-related operations by eliminating existing need to search for projections along off-gridline direction (e.g., normal to boundary). And with utilization of standard discretization stencils enabled on boundary-adjacent grid nodes, implicit time advancement of viscous term is straightforward. Flow simulation results are in good agreement with reference data and show that the proposed method retains second-order accuracy of the fractional-step Navier-Stokes solver incorporated.

\textsuperscript{1}The authors acknowledge the support of National Natural Science Foundation of China (Nos. 51636001 and 51706008) and Aeronautics Power Foundation of China (No. 6141B090315).

7:58AM Q19.00002 An Efficient Immersed-Boundary Formulation with Explicit Time Stepping for Incompressible Flows. NOAH OSMAN, University of Illinois at Urbana Champaign, ANDRES GOZA COLLABORATION — One of the most persistent difficulties in numerically simulating incompressible flow problems is the treatment of the stiff diffusive term. In order to maintain stability, this term is traditionally treated using an implicit time-stepping method, necessitating the solution to a large linear system at each time step. A variety of efficient techniques have been developed to solve these linear systems. However, their application in the presence of non-uniform grids and other non-canonical numerical configurations remains a challenge. We consider an alternative approach in which the diffusive term is treated explicitly, with no severe restrictions on the time step size. We present our method in an immersed-boundary formulation to enable efficient simulations of flows involving immersed bodies. To do this, we extend the Runge-Kutta Chebyshev method of Van der Houwen and Sommeijer (1980) to the differential-algebraic setting relevant to the immersed-boundary method. We demonstrate the efficacy of the method through results from canonical 2D flow problems.
8:11AM Q19.00003 Particle-resolved DNS(PR-DNS) to study the bulk settling velocity of poly-dispersed particles, YINUO YAO, OLIVER FRINGER, CRAIG CRIDDLE, Stanford University — A PR-DNS is implemented to investigate poly-dispersed particle hydrodynamics in triply-periodic flow. The particle motion is computed with a direct forcing IBM approach along with the collision model proposed by Biegert et al. (2017). The direct forcing method accurately predicts particle motions with moderate particle Reynolds numbers up to 360. To avoid the small time-step size needed to simulate collisions with the soft-sphere approach, we use the adaptive collision time model proposed by Kempe et al. (2012). Poly-dispersed particles are initialized randomly in two- and three-dimensions and subjected to gravity to settle while interacting with one another. Simulations are then run until the mean settling velocity reaches steady state. This relates the velocity to mean particle Reynolds number. Different poly-disperse particle scenarios are devised that allow for the study of the effect of the particle size distribution while keeping other bulk properties fixed. The results are discussed in the context improving energy efficiency of the fluidized bed reactors in the wastewater treatment, which are characterized by the pressure loss due to motion of poly-dispersed particles in turbulent flow. This work is supported by California Energy Commission (CEC).

8:24AM Q19.00004 Treatment of immersed boundaries for the Vortex Particle-Mesh method, THOMAS GILLIS, GREGOIRE WINCKELMANS, PHILIPPE CHATELAIN, UCLouvain — The Vortex Particle-Mesh (VPM) method combines the advantages of a particle method, i.e. low numerical dissipation and dispersion errors, with those of a Cartesian mesh-based approach: highly efficient Poisson solvers and finite difference stencils. However, the accurate treatment of the immersed boundaries in the VPM-framework is still an open challenge as the formulation of the boundary condition for the vorticity is not as straightforward as in a classical velocity-pressure formulation. This complexity is further increased since the VPM method relies on a non-body-conforming Cartesian mesh; hence the obstacle may intersect the grid at arbitrary locations. The two current state-of-the-art methods are the (iterative) penalization approach and the Boundary Element Method coupled with the VPM approach. The first one, the penalization technique, suffers from a lack of accuracy due to the smearing of the interface, hence offering an unsatisfactory surface treatment. The second one, the Boundary Element Method (BEM) approach suffers from a first order time convergence due to the splitting of the diffusion operation. This presentation focuses on this challenge: the treatment of immersed boundaries in order to accurately predict the interactions between the fluid and these structures.

8:37AM Q19.00005 An Immersed Boundary Method for Shock-Particle Interaction, IMAN BORAZJANI, J. Mike Walker 66 Department of Mechanical Engineering, Texas A&M University — A sharp-interface immersed boundary method is developed to simulate the interaction of solid particles with shocks. The inviscid and viscous fluxes of compressible flow equations in curvilinear coordinates are discretized with a third order weighted essentially non-oscillatory (WENO) and a central scheme, respectively. The equations are advanced in time using a third-order Runge-Kutta method. The sharp interface at the immersed boundaries is maintained by reconstructing the compressible flow variables along the normal direction to the boundary similar to the previous method for incompressible flows. The WENO discretization is reverted to a second order ENO scheme near the immersed boundaries to reduce the stencil size and avoid using the nodes inside the immersed boundary in the discretization. The method is validated against experimental measurements and shown to be second-order accurate in the presence of immersed boundaries. The numerical results capture all of the shock features observed in the experiments and show great agreement with the measurements.

8:50AM Q19.00006 High Order Cut-cell Methods in Multiple Dimensions, PETER BRADY, DANIEL LIVESCU, Los Alamos National Laboratory — Cut-cell methods for unsteady flow problems can greatly simplify the grid generation process and allow for high-fidelity simulations on complex geometries. However, cut-cell methods have been limited to low orders of accuracy. This is driven, largely, by the variety of procedures typically introduced to evaluate derivatives in a stable manner near the highly irregular embedded geometry. The present approach is based on two simple and intuitive design principles. These principles, and an a-priori optimization process, allow for the construction of stable 8th order approximations to elliptic and parabolic problems and stable and conservative 5th order approximations to hyperbolic problems. This is done for both explicit and compact finite differences and is accomplished without any geometric transformations, artificial stabilization or other adhoc in-situ procedures. Test cases with 2-D and 3-D geometries will be discussed.

9:03AM Q19.00007 Advanced immersed boundary method for complex moving/morphing boundaries based on hybrid ghost-cell and virtual cut-cell. KAMAU KINGORA, HAMID SADAT, University of North Texas — The state of art of sharp interface immersed boundary (IB) methods (cut-cell and ghost-cell (GC) methods) today is that they lack generality and are specialized in nature. Consequently, their extension to problems with multiple potentials is not straightforward. We propose an accurate and robust advanced immersed boundary method (AIBM) for simulation of fluid structure interaction (FSI) in complex flow. This novel sharp interface IB method entails addition of a generic virtual force to the underlying governing equation for the purpose of enforcing desired boundary conditions on different field variables like velocity, temperature, chemical species etc. AIBM employs virtual cut-cell techniques which makes AIBM easy to implement and parallelize, and also applicable to multiphase flow on grid with high aspect ratio, unlike GC method which rely on interpolation. Solid part of simulation domain is logically eliminated from computation hence AIBM is capable of simulating internal and/or external flow with large number of cells in the solid region. Fresh-cell problem is tackled by a field extension technique, enabling AIBM to simulate FSI with moving and/or deforming boundary without pressure oscillations and spurious forces. We validated the proposed method by running benchmark cases using our in-house solver, CDFFoam. The results predicted by AIBM are in good agreement with experimental studies.

9:16AM Q19.00008 Internal Flow Analysis in an Axial Pump using Large-eddy Simulation with Immersed Boundary Method. DANDAN YANG, University of Minnesota; Tsinghua University, XIANWU LUO, Tsinghua University, LIAN SHEN, University of Minnesota — Axial flow pump is widely used in drainage, irrigation, and water diversion applications. A high-fidelity numerical method is needed to study the flow physics and accurately predict the pump performance. In the present work, the transient flow past an axial pump, comprised of the hub, casing, a rotating impeller and a stationary stator, is simulated by large-eddy simulation with the immersed boundary method using a code developed in-house, which is capable of accurately simulating the turbulent flow with three dimensional complex geometries with stationary and moving boundaries. The accuracy of the present simulation method is verified by comparing the predicted hydraulic performance of the pump with experimental results. Based on the simulation results, the internal flow field in the pump is analyzed by investigating velocity and pressure distributions, and turbulent flow structures. Further, pressure oscillation and hydraulic force in the pump are also predicted. The obtained information is helpful to improve the pump design for better performance.

Tuesday, November 26, 2019 7:45AM - 9:42AM –
Session Q20 Experimental Techniques: Aerodynamics / Wind Tunnel 602 - Joanna Austin, California Institute of Technology

7:45AM Q20.00001 ABSTRACT WITHDRAWN –

7:58AM Q20.00002 Estimation of wall-shear stress and its variation in a unperturbed and perturbed plane wall-jet. SRAVAN ARTHAM, Embry Riddle Aeronautical University, SHIBANI BHATT, Embry-Riddle Aeronautical University, ZHENG ZHANG, EBENEZER GNANAMANICKAM, Embry Riddle Aeronautical University — Artham S. PhD in Aerospace Engineering from the University of Washington, focusing on the interaction of shock waves and turbulence. His research interests include flow control, computational fluid dynamics, and experimental techniques. He is currently working on the numerical simulation of shock wave interactions with turbulence and its effects on aerodynamic performance. His work has been published in several reputable journals and presented at various conferences. His mentor is Prof. Douglas Smith. His work is supported by the Air Force Office of Scientific Research under award number FA9550-16-1-0194 monitored by Dr. Douglas Smith.

8:11AM Q20.00003 Smoke visualization over a spinning cone at angle of attack in flight. ABDULLAH KURAAN, ÖMER SAVAŞ, University of California at Berkeley — Smoke visualization over a spinning truncated cone at angle of attack is carried out to study qualitatively the salient features of the flow field. A twisted wire pair is used for generating equally spaced smoke streaks in vertical planes. Detailed images of flow patterns over a spinning cone with a half angle $\theta_c = 30^\circ$ and a base diameter of 20 cm are captured with a high speed camera. The rotational speed of the cone is set at $\Omega = 5$ rev/s, the axial flow at $U_{inj} = 1$ m/s, and the angles of attack up to 36°. The Reynolds number, based on the cone size, is $\sim 10^4$. The analytic description of the axisymmetric potential flow over a fixed cone at zero incidence is reviewed for comparison of the flow field outside the boundary layer. Good agreement in the streamwise distance from the PWJ exit and in the nozzle slot width. These measurements were then curve-fit with direct numerical simulation based velocity profiles to simultaneously extract the WSS as well as a correction to the wall location. The integral method used a momentum integral approach (Mehdi, F. et al. Exp. Fluids, 2014) where PINI-based velocity profiles of the streamwise and wall-normal velocities are integrated to determine the WSS. A reduction in WSS was observed for all the cases considered. The two techniques are compared and key differences are highlighted.

8:24AM Q20.00004 Nitric Oxide Spectroscopic Measurements of a Shock-Boundary Layer Interaction in Hypervelocity Flow. NELSON YANES, JOANNA AUSTIN, California Institute of Technology — Spatially resolved emission spectra are collected in the post bow shock and reattachment shock region of hypervelocity flow over a double wedge. The Hypervelocity Expansion Tube (HET) is used to generate high Mach number, high enthalpy flow ($M = 7, h_0 = 8$ MJ/kg) over a 30-55 degree double wedge. The NO $\gamma$ band ($\Lambda^2\Sigma^+ \rightarrow X^2\Pi$) emission is measured in the UV range of 210-250 nm. Detector exposures occur at select times throughout the flow development process to study temporal changes in thermal and chemical non-equilibrium. Profiles of vibrational band intensity and spectra as a function of distance are provided. Through a fitting procedure, the experimental spectra are matched with synthetic spectra to obtain an estimate of the excitation temperature of the NO molecule. The result is a temperature profile of the post-shock NO* with downstream distance.

8:37AM Q20.00005 Fiber-Optic Michelson Interferometer System for Shock Speed Measurement in an Expansion Tube. WESLEY YU, JOANNA AUSTIN, California Institute of Technology — Shock speed and time of arrival measurements are necessary to properly characterize the flow in high-enthalpy hypersonic impulse facilities. However, the low density test conditions in expansion tubes present challenges for commonly-used wall-mounted static pressure measurements due to low signal levels relative to the amplitude of stress waves resulting from diaphragm rupture or accelerations from driver operation, and an accurate measurement of shock speed is difficult. A fiber-optic Michelson interferometer architecture is being designed and tested for use in shock speed measurements in the Hypervelocity Expansion Tube (HET) at Caltech. The static and dynamic responses of the interferometer are characterized using a pressure vessel and ultrasonic acoustic beam, respectively. Numerical simulations of the interferometer response to a shock wave at experimental conditions, taking into account the structural noise caused by diaphragm opening, indicate that adequate signal-to-noise ratios may be obtained using this technique. This result is encouraging for the development of optical methods to characterize shock speed in impulse facilities with recoil.

8:50AM Q20.00006 Fan array wind tunnels: turbulence on-demand1. CHRISTOPHER DOUGHERTY, ALEJANDRO STEFAN-ZAVALA, PETER RENN, MORTEZA GHARIB, Caltech — Naturally-occurring winds are distinctly unsteady and non-uniform, particularly in complex urban airscapes. To better understand flight in these contexts, it is imperative to be able to control wind profiles in a predictable, repeatable, and representative manner. This can effectively be accomplished with fan array wind tunnels (FAWT), a modularly built multi-source wind tunnel capable of generating a host of spatiotemporally-varying flows via software interfacing. Utilizing an array of DC-powered off-the-shelf cooling fans (in place of one singular drive section) allows for greater flow control, overall decreased mixing lengths, and comparably large useable test section areas when compared with its effective footprint. Tunnel resolution along with fan responsiveness determines the effectiveness of one of its most salient features: the ability to tailor turbulence around a desired a mean (i.e. turbulence on-demand). This decoupling adds new territories to explore in simulated flight contexts. Periodic and unsteady flows will be highlighted with brief considerations given to the future role of machine learning.

1This research was supported by the Center for Autonomous Systems and Technologies at the California Institute of Technology

9:03AM Q20.00007 Flow shaping in wind tunnels with fan array technology. GUILLAUME CATRY, NICOLAS BOSSON, GESHANTH VISVARATNAM, WindShape, FLAVIO NOCA, HEPIA / HES-SO University of Applied Sciences — In the past hundred years, wind tunnels have been built to study the flow of air around objects. In particular, the geometry of the contraction and the diffuser walls has to be carefully designed in order to achieve flat profiles in the test section and avoid boundary layer separation (both in the contraction and the diffuser). The resulting infrastructure has a large footprint and is generally unmodifiable during the whole the lifetime of the wind tunnel. We have developed a technology to shape the morphology of wind in space and time. It is based on a large number of fans (wind pixels), which are distributed arbitrarily in space and can be modulated individually. In particular, we show how this technology allows the wind profile in a test section to be controllable and does not require any a priori design of complex wind tunnel infrastructure.

9:16AM Q20.00008 A low-turbulence transverse gust generator in a wind tunnel1. DAVID OLSON, AHMED NAGUIB, MANOOCHEHR KOOCHESFAHANI, Michigan State University — There exists a broad range of aerodynamic problems where the commonly used steady uniform freestream condition is not appropriate. Airfoil-gust interactions are one such problem, with the transverse gust being particularly difficult to study experimentally. We present a novel transverse gust generator consisting of an actuated array of vortex generators mounted to a wind tunnel’s test section. The primary advantage of the design over existing gust generators is its capability to produce a reasonably-uniform transverse stream without producing turbulence in the freestream. The generator’s design can potentially allow for the time history control of the magnitude, direction, and duration of the gust strength. A simplified model for the performance of the design, and the experimental characterization of the gust generator are discussed.

9:29AM Q20.00009 Determination of drying and shrinkage characteristics of porous food material in convective drying: Model development and experimental studies. PUNIT SINGH2, PRABAL TALUKDAR2, Indian Institute of Technology, Delhi — Food materials are dried to enhance the shelf life, maintain nutritional value, lower packing cost, and reduce shipping cost. An innovative convective dryer is developed, which is similar to a small scale wind tunnel, to determine the drying and shrinkage characteristics of porous food material. A conjugate 3D numerical model is also developed in a commercial software COMSOL to determine the heat and moisture transfer distribution in the food material. The model considers several important phenomena like surface evaporation, internal evaporation, and shrinkage during the drying process to render high accuracy. Results show that the air temperature has significant effect on both drying and shrinkage characteristics as compared to the airflow velocity. Around 80% of moisture is removed in the first 30% of time and remaining 20% of moisture content is removed in the last 70% of time, because of high moisture gradient present in the beginning of drying. The bulk density of food increases initially, reaches a maximum value and finally decreases in the end of drying process. Numerical studies performed with this model will help to design and develop cold storage, estimate the processing time of various operations like cooling and heating.

Tuesday, November 26, 2019 7:45AM - 9:42AM — Session Q21 Drops: Spreading and Wetting I 603 - Sadegh Dabiri, Purdue University

7:45AM Q21.00001 Wetting dynamics on asymmetric microstructured surfaces. SUSUMU YADA, SHERVIN BAGHERI, Department of Mechanics, KTH Royal Institute of Technology, JONAS HANSSON, Division of Micro and Nanosystems, KTH Royal Institute of Technology, MINH DO-QUANG, FREDRIK LUNDELL, Department of Mechanics, KTH Royal Institute of Technology, WOUTER VAN DER WIJNGAART, Division of Micro and Nanosystems, KTH Royal Institute of Technology, GUSTAV AMBERG, Sdertorn University — Microstructured surfaces which are able to control the direction of liquid transport are common in nature for fog/water harvesting, surface lubrication, and self-cleaning, and have been inspiring enormous number of man-made structures. However, the spreading of a liquid on such surfaces have been investigated in the slow spreading regime and a fundamental understanding of the early rapid wetting is lacking. In this work, our experimental and numerical investigations on surfaces with periodic patterns of asymmetric microridges provide detailed illustrations of the rapid droplet spreading over complex surface structures. We show that the surface structures are partly wetted as the air-liquid interface above the contact line makes another contact to the structure downstream and creates a new wetting front, leaving some dry surface behind. Furthermore, we elucidate how different physics play roles in different flow directions. In one direction, the spreading is governed by the friction at the moving contact line and the Young’s force related to the local dynamic contact angle, whereas in the other direction, it is determined by the contact line pinning and the inertia of the droplet. Based on these physical insights, the effect of different surface geometry is discussed.
7:58AM Q21.00002 Wetting dynamics of a droplet on micro-pillar surfaces with radially varying pitch. RAJNEESH BHARDWAJ, MANISH KUMAR, Department of Mechanical Engineering, Indian Institute of Technology Bombay, Mumbai 400076, India, KIRTI CHANDRA SAHU, Department of Chemical Engineering, Indian Institute of Technology Hyderabad, Sangareddy 502 285, Telangana, India — We experimentally investigate the wetting dynamics of a droplet placed gently on a square-micropillar surface. These pillars are located with a radially varying pitch described by a parabolic equation. Two sets of surfaces with radially increasing and radially decreasing pitches from the center of the substrate at which the droplet is initially placed have been prepared on silicon wafer using photolithography. Due to the radial variation of the pitch, the droplet experiences a wettability gradient (either increasing or decreasing radially). We observed that on the surface with the radially increasing pitch, the droplet remains in the Cassie state and exhibits higher contact angle than the smooth surface during its spreading stage. On the other hand, in case of the surface with radially decreasing pitch, the droplet goes into the Wenzel state and assumes a lower contact angle as compared to that observed in the smooth surface. The wetted diameter of the droplet is found to be smaller in case of the radially decreasing surface than the radially increasing surface. We also studied the effect of the size of the square pillars and it is found the droplet spreads less in case of smaller size of pillars for both radially increasing and decreasing surfaces.

8:11AM Q21.00003 Cassie-Baxter to Wenzel Transition and a New Phenomenon called “the Wenzel Deviation”. ARASH AZIMI, CHAE ROHRS, PING HE, Department of Mechanical Engineering, Lamar University, Beaumont, TX 77710 — In general, on rough surfaces, two wetting regimes are possible: (1) the Cassie-Baxter state, in which the droplet sits on top of rough structures, and (2) the Wenzel state, in which the droplet completely sinks into the rough structures. In this talk, we present a numerical study of the Cassie-Baxter to Wenzel transition using a series of 3D simulations for a water droplet on micro-patterned substrates, in which the pillar height and spacing are systematically varied. The contact angles for each case are measured and compared with either the Cassie-Baxter or Wenzel equation. The total surface energy and its time evolution are discussed in detail. Energy barriers for the wetting transition are addressed. Measured contact angles show an excellent agreement for the Cassie-Baxter state, while for the Wenzel state, we find a systematic deviation from the Wenzel equation when the pillar size is large. The critical pillar size, above which the Wenzel deviation is outstanding, is identified based on simulation results and thermodynamic calculations. A modified Wenzel equation is developed to account for the Wenzel deviation.

8:24AM Q21.00004 Walking, Climbing, Bursting, and Shooting: Complex Dynamics in Drops on Vibrated Substrates1. YESH KAOHUA, Imperial College London, SEUNGWON SHIN, Hongk University, South Korea, JALEL CHERGUI, DAMIR JURIC, LIMSI, CNRS, France, RICHARD CRASTER, OMAR MATAR, Imperial College London — We use direct numerical simulations (DNS) to study the phenomena observed in the work of Brunet et al. (Phys. Rev. Lett., 99, 144501, 2007). Here a drop can climb up an inclined surface when it is subjected to a vertical oscillation in the presence of a gravity. In this talk, we present a detailed study of these climbing phenomena using DNS with a generalized Navier boundary condition in the context of a front-tracking-based multiphase method. Further detailed numerical simulations in the context of vibrated droplet are extended to different vibration configurations (horizontal, vertical, and oblique) in order to explain how these climbing phenomena occur leading to regimes characterised by droplet ‘walking, ‘bursting, and ‘shooting.’

1We thank Dr. M. Costalonga and Dr. P. Brunet for helpful discussions. Funding from PETRONAS/Royal Academy of Engineering, and EPSRC (grant number EP/K003976/1) is gratefully acknowledged.

8:37AM Q21.00005 Experimental and numerical study of wetting liquids rising up on the outer surface of a nozzle in the dripping regime. ERFAN SEDIGHI, ABOLFAZL SADEGHPOUR, Department of Mechanical and Aerospace Engineering, University of California, Los Angeles, HANGJIE JI, CLAUDIA FALCON, Department of Mathematics, University of California, Los Angeles, Y. SUNGTAEK JU, Department of Mechanical and Aerospace Engineering, University of California, Los Angeles, ANDREA BEROTTOZI, Department of Mathematics, University of California, Los Angeles — Well-wetting liquids exiting small-diameter nozzles in the dripping regime rise up along the outer nozzle surfaces. This is problematic for certain fuel injectors and direct contact heat and mass exchangers that incorporate a dense array of nozzles to distribute liquids. Such flows along nozzle outer surfaces are governed by the interplay of surface tension, non-uniform pressure within a pendant drop, gravity, and viscous forces. We experimentally and numerically (by solving the full Navier-Stokes equations) study these flows for nozzle outer diameters ranging from 0.7 to 3.2 mm, mass flow rates ranging from 0.0002 to 0.035 grams/second (g/s), and liquid viscosities ranging from 4.6 to 970 mPa.s. The apparent height of a liquid meniscus on the nozzle surface was determined by analyzing video images. We also develop an approximate analytic model to capture the dynamics of meniscus rising. Our results show that, for a single nozzle, while the mass flowrate is relatively low, the rate of initial rise decreases with further decreasing the mass flow rate. On the other hand, for flow rates higher than 0.006 g/s and viscosities less than 100 mPa.s, the rate of initial rise is almost constant.

8:50AM Q21.00006 Contact angle and interface geometry immediately after rapid initiation of the contact line motion. TAKAHIRO ITO, Chubu University, KENJI KATO, TATSURO WAKIMOTO, Osaka City University — The dynamic contact angle on non-smoothed surface generally shows different variation from that expected by the theory (eg, Cox, J. Fluid Mech., 1985). One plausible mechanism for such deviation can be the local stick-slip motion of the contact line. In this study a model is developed to describe interface deformation induced by the rapid initiation of the contact line motion. The model is based on the balance of the normal stress on the surface under the Stokes approximation. The local surface stress is modified from the expression by Huh et al (J Colloid Int Sci, 1971). The contact line velocity is replaced with ‘characteristic velocity’ in order to take the lag of the time development of the local velocity relative to the contact line speed. The finite speed of the transfer of the interface deformation is also modeled. These modifications are combined with the conventional Hoffman-Tanner-Voinov relation for the dynamic contact angle and the contact line speed. The results obtained with the developed model shows good agreement with the experimental results.

9:03AM Q21.00007 ABSTRACT WITHDRAWN
ZHICHE M. YUAN, MITSUHIRO MATSUMOTO, RYOICHI KUROSE, Department of Mechanical Engineering and Science, Kyoto University; KUROSE LAB TEAM — Super-hydrophobic surfaces are reported as promising candidates for self-cleaning, anti-icing, and dropwise condensation. Therefore, there are some experimental studies and numerical simulations of droplets on hydrophobic walls. However, regarding the durability issues, an alternative technology, improving the surface wettability by grooves, has drawn much attention, whereas the wettability of droplet on groove-decorated substrate has not been fully studied. In this study, a 3-D numerical simulation employing the Coupled Level-Set and Volume of Fluid (CLSVOF) scheme, and the Continuum Surface Force (CSF) method are applied to a liquid drop on rigid substrate, and the validity is investigated by comparing with the experiment. The numerical models are extended to predict the dynamics of a droplet on groove-decorated substrate. The results show that our numerical methods perform well on tracking the move of a droplet on micro-grooved surfaces. In addition, decoration by micro-grooves could be a useful fabrication technology to improve the surface wettability and develop robustness and durability of super-hydrophobic surfaces.

1This research was partially supported by MEXT (Ministry of Education, Culture, Sports, Science, and Technology) as Priority issue on Post-K computer.

9:29AM Q21.00009 Title: Complex Wetting: Flow profiles close to three-phase contact lines1.  
BENEDIKT B. STRAUB, HENRIK SCHMIDT, FRANZISKA HENRICH, Max Planck Institute for Polymer Research, MAS-SIMILIANO ROSSI, Technical University of Denmark, CHRISTIAN J. KAHLER, Bundeswehr University Munich, HANS-JURGEN BUTT, Max Planck Institute for Polymer Research, GÜNTHER K. AUERNHAMMER, Leibniz Institute for Polymer Research — Wetting and dewetting behavior on solid surfaces is the crucial process underlying many natural phenomena as well as technical applications. We focus on the technically relevant wetting and dewetting behavior of surfactant solutions. In recent studies, focus laid on the influence of surfactants on macroscopic quantities like the contact angle. To explore the origin of the decrease of the contact angle for increasing surfactant concentration and velocity, we focus on the flow close to the contact line. Therefore, we measure three-dimensional flow profiles with an astigmatism particle tracking velocity setup. The results show that surfactants cause a deviation of the flow field in comparison to theoretical predictions for pure liquids. In the case of a receding contact line, a new air-liquid interface is formed at the three phase contact line. The surfactant concentration at the freshly formed interface is, in comparison to the already existing air-liquid interface, not in equilibrium to the bulk surfactant concentration. This causes Marangoni stresses in the direction of the contact line along the interface. This Marangoni stresses oppose the bulk flow close to the air-liquid interface and causes a deviation of the flow field.

1The authors thank the Deutsche Forschungsgemeinschaft (DFG) for supporting this work through the SFB1194 (project A06).

Tuesday, November 26, 2019 7:45AM - 9:42AM —  
Session Q22 Drops: Instability and Breakup I —  
604 - Larry Li, HKUST

7:45AM Q22.00001 ABSTRACT WITHDRAWN —  

7:58AM Q22.00002 Direct Numerical Simulations of the Three Dimensional Dynamics of Surfactant Laden Retracting Ligaments1.  
RICARDO CONSTATE-AMORES, ASSEN BATCHVAROV, LYES KHAOUADJI, Imperial College London; SEUNGWÖN SHIN, Hongik University, South Korea; JALEL CHERGUI, DAMIR JURIC, LIMSI, CNRS, France; RICHARD CRASTER, OMAR MATAR, Imperial College London — We present three-dimensional direct numerical simulations for the retraction of surfactant-laden Newtonian ligaments. In the absence of surfactant, the dynamics is described non-dimensionally by the ligament aspect ratio and the Ohnesorge number, which relates the viscous forces to surface tension forces. The addition of surfactant leads to surface tension gradients resulting in Marangoni stresses on the interface. We consider surfactants, which are either insoluble, where molecules remain only on the interface, or soluble which allows surfactant mass transfer between the bulk and the interface via adsorption and desorption mechanisms. In addition to the ligament aspect ratio and Ohnesorge number, we take into account variation of the Peclet, Biot, and elasticity numbers to elucidate the physical mechanisms which control the dynamics of the ligament in the presence of surfactant. An analysis of the effect of surfactant concentration, surface tension, tangential velocity, and Marangoni stresses is provided and of their role in partial/complete ligament breakup suppression.

8:11AM Q22.00003 Dynamics of Viscoelastic Filaments.  
SUMEET THETE, Air Products and Chemicals, Inc.; BRADLEY WAGONER, School of Chemical Engineering, Purdue University; PRITISH KAMAT, Dow Inc.; MICHAEL HARRIS, OSMAN BASARAN, School of Chemical Engineering, Purdue University — In processes as diverse as ink-jet printing and crop spraying, slender liquid filaments are formed. These filaments may contract into a single drop or breakup into multiple smaller drops. In the aforementioned and most other applications, the latter outcome is highly undesirable as it will mar the printing quality or increase the portion of the spray fluid that can drift. In many applications, the working fluids may contain additives that render them viscoelastic in nature. While the dynamics of Newtonian filaments have been studied extensively, that of viscoelastic filaments remains largely unexplored. Using the conformation tensor formalism of Pasquali and Scriven (Pasquali and Scriven, J. Non-Newtonian Fluid Mech., 2004) implemented in a numerical algorithm based on the SUPG/FEM formation, we present the results of a study on the fate of viscoelastic filaments.
The shape of a recoiling liquid filament

Turbulent drag reduction using biopolymers and bio-inspired superhydrophobic surfaces

Skin friction accounts for over 50% of the total drag on ships, and its effective mitigation can yield significant savings in fuel, operating costs, and emissions. Despite considerable promise as an effective drag reduction strategy, high molar mass additives have been largely precluded from commercial use due to the high cost of synthetic polymers. In this context, we investigate the aqueous mucilage extracted from seeds such as flax, chia and psyllium as viable, cost-effective and eco-friendly alternatives to synthetic water-soluble polymers. Using frictional drag measurements performed in a bespoke Taylor-Couette apparatus, we show that aqueous mucilage displays comparable drag reduction efficacy as polyethylene oxide, a common synthetic polymer, at a much lower cost. We study the effects of salinity and shear-induced chain scission, and explore the use of cross-linking agents to augment the drag reduction performance of the dissolved chains. Finally, we investigate the use of scalable, randomly rough superhydrophobic walls (inspired by the natural texture on the leaves of the lotus and other plants) as a passive means to mitigate turbulent skin friction, and its synergistic use in conjunction with dilute polymer solutions to enhance the overall reduction in frictional drag.

Lubricated tribology of soft patterned substrates

We study the changes in the total frictional drag as a function of riblet wavelength and amplitude (as the key geometric parameters) and mainly centered around riblets with V-groove profiles. Here, we will discuss the impact of the variations in the cross-sectional profiles of the riblets on the changes in the total frictional drag. Using a custom-designed Taylor-Couette cell with 3D-printed texture-covered rotors, we explore the impact of different riblet textures and discuss the effect of concave vs. convex cross-sectional shapes on the ability of the riblet surfaces to reduce the total frictional torque exerted on the textured rotors. Lastly, we will compare the effectiveness of riblets with curved-profiles against the conventional V-grooves (linear profiles).

Impact of Curved Profiles on the Drag-Reducing Ability of Riblet-Textured Surfaces

We study the changes in the total frictional drag as a function of riblet wavelength and amplitude (as the key geometric parameters) and mainly centered around riblets with V-groove profiles. Here, we will discuss the impact of the variations in the cross-sectional profiles of the riblets on the changes in the total frictional drag. Using a custom-designed Taylor-Couette cell with 3D-printed texture-covered rotors, we explore the impact of different riblet textures and discuss the effect of concave vs. convex cross-sectional shapes on the ability of the riblet surfaces to reduce the total frictional torque exerted on the textured rotors. Lastly, we will compare the effectiveness of riblets with curved-profiles against the conventional V-grooves (linear profiles).

Efficient and sustainable drag reduction surface of marine algae Miyeok (Undaria pinnatifida)

Miyeok has a slippery surface in which mucilage works as a lubricant. In this study, we investigated the drag reduction effect of the mucilage-covered surface of Miyeok using a scanning white-light interference technique to evaluate the slip length. Pressure drop and skin friction effects were measured to estimate the slip effect and the corresponding drag reduction rate. The Miyeok surfaces tested in this study were found to have a slip length of 101 μm and the pressure drop was 26% reduced due to the morphological characteristics and slippery mucilage. With these effects, the mucilage surface exhibits skin friction reduction up to 35%. The present results would be helpful for understanding the drag reduction mechanism of Miyeok and developing a bioinspired LIS.

Fricion Reduction Effects of Wetted Microtexturing in Microchannel Flow

Microchannel flows are widely used in applications where small diffusion length scales are important, such as in microscale heat exchangers for electronic cooling. However, these small length scales also translate into high pumping power requirements. One possible way to alleviate the large viscous pressure losses associated with this inherent dimensional constraint is to introduce side trenches in a micro-channel to help lower the skin drag. The flow over these transverse trenches may experience two wetting states: Cassie-Baxter and Wenzel. In both states the trapped air or water can act like a cushion resulting in less shear stress. However, it has been shown that sometimes the air-water interface in the Cassie-Baxter state might act like a solid boundary due to contamination. Concurrently, penetration of the flow inside the trenches can induce the pressure drag alongside the skin drag. Therefore, the Wenzel state in the trenches can lead to a trade-off between skin and pressure drag. The aim of this work is to understand the geometrical effect that different micro-textures have on the total drag reduction by testing trenches with different aspect ratios and measuring the pressure drop through the micro-channel.

9:03 AM Q23.00007 Quantification of Laminar Drag Reduction on Liquid-Infused Structured Non-Wetting Surfaces, SANDEEP HATTE, KARTHIK NITHYANANDAM, RANGA PITCHUMANI, Department of Mechanical Engineering, Virginia Polytechnic Institute and State University — Liquid-infused structured non-wetting surfaces offer alternating no-slip and finite slip boundary conditions to the fluid flow, resulting in an effective non-zero finite slip at the interface. As a result, liquid-infused structured non-wetting surfaces offer reduced friction (drag reduction) at the interface in comparison to a bare smooth surface offering no-slip boundary condition throughout. In the present work, an analytical model is developed to quantify the effective slip length, drag reduction and friction coefficient on liquid-infused structured non-wetting surfaces under laminar fluid flow conditions. The model takes into consideration a typical structured non-wetting surface as a superposition of periodically patterned longitudinal and transverse striped geometries. The analytical model covers a full range of structural anisotropy and homogeneity and is valid for an entire range of partial slip length in the infused liquid region. Effective non-zero slip length and drag reduction data predicted from the present model show a good agreement when compared with a number of experimental and computational studies from the literature.

9:16 AM Q23.00008 Bound on the drag coefficient for flow past a flat plate using the background method, ANUJ KUMAR, Department of Applied Mathematics, Baskin School of Engineering, University of California, Santa Cruz — The background method has been a successful tool in finding bounds on mean quantities, such as heat and mass transfer, drag force, and others. Until now, most of the applications of this method focused on flows confined between planar boundaries, such as Rayleigh-Bénard convection, Poiseuille flow, and Couette flow. The extension of this method to unconfined flows, such as flow past a sphere, has remained elusive due to a number of mathematical difficulties. In particular, proving bounds on the drag coefficient for flow past an object is an open problem. We will demonstrate that the case of flow past a flat plate avoids some of these difficulties, enabling us to apply the background method to this problem for the first time. We show that at high Reynolds number, the drag coefficient is bounded by a constant. We compare our finding with observations. Finally, we make a few remarks about the issues in using the background method for flow confined between rough boundaries or flow past objects of non-zero volume.

9:29 AM Q23.00009 Numerical Study of Ice Accretion over Aircraft Wings Using Delayed Detached Eddy Simulation, SIBO LI, Department of Mechanical and Industrial Engineering, University of Illinois at Chicago, Chicago IL, USA, ROBERTO PAOLI, Leadership Computing Facility, Argonne National Laboratory, Lemont IL, USA — Ice accretion on aircraft surfaces has been the principal cause of several flight accidents in the past and represents now a source of major concern in aviation. It is a complex Multiphysics phenomenon that includes fluid dynamics, heat transfer and multi-phase flows. In this study, a mathematical model based on the delayed detached eddy simulation (DDES) is developed to study the ice accretion on 3D aircraft wings. The model is validated by comparing the computed results with experimental data. For the air flow field, the statistical results, instantaneous flow fields, and pressure fluctuations are first analyzed. Then, the droplet-phase governing equations are solved to obtain the droplet collection efficiency. To best mimic the droplets impingement, a permeable wall boundary condition is proposed. Then, the thermodynamic process of ice accretion is built based on the classical Messenger model but further including the freezing fraction as a changing variable in the icing simulation. Thus, the ice amount generated at each time step can be obtained. The DDES is able to capture the turbulent flowfield around the iced wing, which makes this model useful for not only predicting ice accretion and studying the effect of ice shape on the air flow field as well.

Tuesday, November 26, 2019 7:45 AM - 9:42 AM — Session Q24 Drops: Complex Fluids

7:45 AM Q24.00001 Numerical Simulation of Interfacial Flows of a Hydrogel, LEI LI, Department of Chemical and Biological Engineering, University of British Columbia, Vancouver V6T 1Z3, Canada., PENGTAO YUE, Department of Mathematics, Virginia Tech, Blacksburg, VA 24061-0123, The United States of America. — Hydrogels are crosslinked polymer networks swollen with an aqueous solvent, and play central roles in biomicrofluidic devices. In such applications, the gel is often in contact with a flowing fluid, thus setting up a fluid-hydrogel two-phase system. Using a recently proposed model (Y.-N. Young et al, Phys. Rev. Fluids 4, 063601, 2019), we treat the hydrogel as a poroelastic material consisting of a neo-Hookean polymer network and a Newtonian viscous solvent, and numerically study the motion and deformation of gel drops suspended in viscous flows. The gel-fluid interface is tracked by using the Arbitrary Lagrangian-Eulerian method that maps the interface to a reference configuration. The interfacial deformation is coupled with the fluid and elasticity governing equations into a monolithic solution algorithm using the finite-element library deal.ii. Our numerical simulation of a hydrogel drop in sedimentation and shear flow shows that it deforms in ways that differ from that of a viscous drop or elastic particle, and the solvent perfusion can have a significant effect on the hydrogel dynamics.

7:58 AM Q24.00002 Stability of chiral colloidal droplets, LEROY JIA, Flatiron Institute, EPHRAIM BILILIGN, University of Chicago, MICHAEL SHÉLLEY, Flatiron Institute & NYU, WILLIAM IRVINE, University of Chicago — We report experiments on a two-dimensional cohesive chiral fluid consisting of millions of spinning colloidal magnets suspended in water. Droplets made of this fluid are observed to swirl around and collapse into a single central superdroplet in a process reminiscent of the accretion of matter during the formation of a black hole. We put forth a minimal but complete hydrodynamic description of this active chiral fluid and use it to analyze the stability of the droplet states.

8:11AM Q24.00003 Central spot shaped deposition from colloidal droplet evaporation under enhanced Marangoni effect, FEI DUAN, JUNHENG REN, Nanyang Technological University — Evaporation of a colloidal droplet on a substrate can result in a residual deposit near the three-phase line, driven by the capillary flow, and form coffee ring. Under a higher evaporation rate, the more nonuniform temperature can be generated at liquid-gas interface of the sessile droplet. The evaporation induced Marangoni flow can be observed, the particles can be carried to move toward the centerline and aggregate at the center area of the droplet. We have developed a three-dimensional (3D) diffusion limited aggregation Monte Carlo method to simulate the dried patterns under the enhanced Marangoni effect. The particle motion is controlled by calculating the probabilities of six moving directions. The interactions amongst particle to particle, particle to liquid, particle to substrate have been taken into account. The results show that the final dried residuals can be formed to with a central spot inside a thin coffee ring by enhancing the Marangoni flow during drying a colloidal droplet. The results are comparable to the deposited patterns under the reduced pressure evaporation conditions. The drying patterns have been analyzed as well.

8:24AM Q24.00004 The role of surfactant in evaporation and deposition of bi-solvent biopolymer droplets, DONG-OOK KIM, ARIF ROKONI, CHUNXIAO CUI, LI-HSIN HAN, YING SUN, Drexel University — The quality of bioprinting is determined by the solvent evaporation and deposition processes of biopolymer droplets, during which instantaneous viscosity and surface tension changes occur. Such dynamics is complex and not well understood. Using high-speed interferometry and particle image velocimetry, we directly observe in real time the instantaneous drop shape and micro flows inside inkjet-printed evaporating gelatin drops containing glycerol and water. It is observed that, for bi-solvent gelatin drops with surfactants, highly viscous gelatin and glycerol accumulated near the pinned contact line at an early stage suppress the evaporation-driven outward flow and create a stagnation zone near the contact line. Lower surface tension at the contact line as compared to the drop apex induces a strong Marangoni recirculation, which in conjunction with a stagnation zone in the contact line region, causing the drop shape to transition from a spherical cap to a volcano shape during evaporation. In contrast, without surfactants, the Marangoni-induced Marangoni flow can be observed, the particles can be carried to move toward the centerline and aggregate at the center area of the colloidal droplet. We have developed a three-dimensional (3D) diffusion limited aggregation Monte Carlo method to simulate the dried patterns under the enhanced Marangoni effect. The role of surfactant in polymer droplet deposition with water-only solvent is also investigated and compared against that of bi-solvent drops.

8:37AM Q24.00005 Evaporation-driven Fracture of Colloidal Drops Undergoing a Sol-gel Transition1, ARANDEEP UPPAL, Imperial College London, MATTHEW HENNESSY, University of Oxford, RICHARD CRASTER, OMAR MATAR, Imperial College London — Evaporation of liquid from a colloidal suspension can lead to a sol-gel transition whereby the mixture is transformed into a soft, gel-like material consisting of closely-packed particles with liquid-filled voids. If a drop of colloidal fluid is placed on a solid substrate, then non-uniformities in the evaporation rate lead to a gelation front that propagates from the contact line towards the center of the drop. Afterwards, uniformly spaced, radially aligned cracks begin to form near the contact line which themselves propagate into the bulk. By varying the composition of the drop, a myriad of striking fracture patterns can be observed. To describe this evaporation-driven fracture process, we have developed a fully-coupled poroelastic-damage model. The model is systematically reduced by exploiting the small contact angle of the drop and the resulting equations are solved using the finite element method. The model confirms that fracture is driven by the generation of tensile stresses at the contact line caused by the adhesion of the solid matrix to the substrate and volumetric contraction due to fluid loss. Our simulations are able reproduce the experimentally observed fracture patterns and reveal that slip plays a key role in selecting the resulting morphology.

8:50AM Q24.00006 To jam or not to jam?, RISHTI ARORA, MICHELLE DRISCOLL, Northwestern University — The extraordinary hydrodynamic phenomenon of drop impact has inspired numerous studies exploring a variety of Newtonian and complex fluids. Although this is a century-old problem, there are only a few studies on the impact dynamics of colloidal suspension drops. The impact of a suspension drop provides a unique model system to probe the complicated interplay between hydrodynamic instability and the non-trivial rheology of complex fluids. Here, we present a comprehensive study of colloidal suspension drop impact to explore the rich flow behaviors in conditions that are inaccessible via conventional rheometry. We study the dynamics of suspension drops by impacting a millimetric size droplet on a solid glass surface while varying the volume fraction and impact conditions. We find that the extent of spreading decreases with increasing volume fraction or decreasing impact velocity. Moreover, we present a state diagram that delineates the inertial spreading regime from thickening regime and the jammed solid regime. Furthermore, we observe a variety of elastic behaviors which appears in the jammed regime and are controlled by adjusting volume fraction and impact velocity.

9:03AM Q24.00007 Onset of rebound suppression in non–Newtonian droplets post–impact on superhydrophobic surfaces, DEVRAJAN SAMANTA, SOUMYA RANJAN MISHRA, PURBARUN DHAR, Indian Institute of Technology Ropar — Droplet deposition after impact on superhydrophobic surfaces has been an important area of study in recent years for its potential application in reduction of pesticides usage. Minute amounts of long chain polymers added to water has been known to arrest the droplet rebound effect on superhydrophobic surfaces. Previous studies have attributed different reasons like extensional viscosity, dominance of elastic stresses or slowing down of contact line in retraction phase due to stretching of polymer chains. The present study attempts to unravel the existence of critical criteria of polymer concentration and impact velocity in the inhibition of droplet rebound. The impact velocity will indirectly influence the shear rate during the retraction phase, and the polymer concentration dictates the relaxation timescale of the elastic fluids. Finally, we show that the governing Weissenberg number (at onset of retraction), which quantifies both the elastic effects of polymer chains and the hydrodynamics, is the critical parameter in determining the regime of onset of rebound suppression, and that there is a critical value which determines the onset of bounce arrest. The previous three causes, which are manifestations of elastic effects in non-Newtonian fluids, can be related to the proposed Weissenberg number criterion.

9:16AM Q24.00008 Drop impact of extensible yield-stress fluids, SAMYA SEN, RANDY H EWOLDT, University of Illinois at Urbana-Champaign — We study the role of extensional rheology on the impact behavior of drops of elastoviscoplastic fluids on thin films, showing that a recently proposed and successful dimensionless group for viscoplastic fluids fails to predict impact regimes when elastic extensional effects are significant. We do this by creating a new formulation for an extensible yield-stress fluid in which extensional properties vary dramatically. The non-Newtonian fluid is an aqueous suspension of Carbopol microgel particles (a well-studied system) with the addition of high molecular weight poly(ethylene oxide) (PEO) at varying concentration. The fluids fit into the new paradigm of extensible yield-stress fluids [1]. Drop impacts onto substrates coated with the same material are recorded using high-speed cameras, and different impact regimes are identified as a function of droplet size, velocity, coating thickness, and droplet rheology. Whereas the previous dimensionless group only involves steady shear rheological properties (yield stress and Bingham plastic viscosity), we consider additional modification to account for the elastic extensional effects. [1] Nelson, A.Z., R.E. Bras, J. Liu, and R.H. Ewoldt, “Extending yield-stress fluid paradigms”, J. Rheol. 62, 357 (2018)

9:29AM Q24.00009 Drop impact of thixotropic yield-stress fluids1, RANDY H EWOLDT, SAMYA SEN, ANTHONY G MORALLES, University of Illinois at Urbana-Champaign — We use high-speed imaging to study the effect of thixotropy on drop impact of thixotropic- viscoplastic fluids onto thin films. Using a dimensionless group proposed earlier for predicting impact behavior of Carbopol, a glassy aqueous suspension of soft microgel particles, we predict the behavior of an aqueous suspension of Laponite, a colloidal clay with an attractive gel microstructure. For rejuvenated samples of both materials, the dimensionless group separates various impact regimes, gives a constant critical value for stick-slip transition as a function of dimensionless coating thickness, and gives a similar critical value across the varying microstructures studied. This is remarkable considering the different chemistries and microstructures involved. The group is less effective at predicting impact behavior of thixotropically aged Laponite suspensions, demonstrating the role of thixotropy in drop impact with viscoplastic fluids. We tune this dimensionless group to include thixotropic effects by proposing rheological techniques to estimate shear properties of thixotropically aged samples. The modified group is tested with a wide range of experimental conditions and is shown to be effective in predicting the drop impact regimes of aged Laponite samples.

Tuesday, November 26, 2019 7:45AM - 9:42AM — Session Q25 Drops: General II 607 - Anne Juel, University of Manchester

7:45AM Q25.00001 Experiments in oil-water ring-sheared drop1, SHANNON GRIFFIN, PATRICK McMACKIN, FRANK RILEY, SHREYASH GULATI, AMIR HIRSA, Rensselaer Polytechnic Institute, JUAN LOPEZ, Arizona State University — Launched to the International Space Station (ISS) in late July 2019, the ring-sheared drop (RSD) is a containerless reactor where surface tension provides fluid containment, and shear is conveyed primarily through surface shear viscosity. The RSD is a 2.5 cm diameter drop constrained by two thin rings. A stationary ring contacts the drop in one hemisphere, and a rotating ring contacts in the opposite hemisphere. The RSD allows investigation of how thin-film flow can modulate the role of Marangoni convection. Amyloid fibrils of certain brain proteins play central roles in some neurodegenerative diseases, such as Alzheimer’s or Parkinson’s. The RSD was studied in the lab using a density-matched silicone oil-water system. Through these experiments, previous computational work on the RSD was verified. Drop deformation was found to be a balance between viscous, inertial, and capillary forces. These laboratory experiments provided some evidence for the robustness of the RSD.

1This work was supported by NASA grant NNX13AQ22G.

7:58AM Q25.00002 Formation and evolution of thin water films encapsulating oil droplets crossing an oil-water interface. JOSEPH KATZ, OMRI RAM, Johns Hopkins University — This study examines phenomena occurring as mm-scale oil droplets rise through water, cross an oil-water interface, and then coalesce with a layer of the same oil. Inline holography and planar laser induced fluorescence are used for examining interfaces involving layers of silicone oil of different viscosity and hexadecane above both purified and nearly refractive index-matched sugar water. They show that for all cases, after crossing the interface, thin water films remain around these droplets, preventing them from mixing with the bulk oil. Subsequently, in a slow process, film segments located close to the contact point with the interface are attracted to the bulk water, presumably by electrostatic forces, causing the droplet to flatten, and creating a kink, where the film begins to break up into submicron droplets. The region of submicron droplets propagates from the peripheral kinks inward to the center of the droplet, and they begin to diffuse. These processes occur in less than one minute for a 4 cst oil, and about one hour for a 50 cst oil, preventing the merging of the droplet with the surrounding oil for much longer than previously presumed. These phenomena do not occur when water droplet descends across the oil-water interface, namely oil films do not form.

8:11AM Q25.00003 Nonlinear Phenomena in Trajectories of Spherical Drops with Incompressible Surfactant in Combined Buoyant and Marangoni-induced Motion. MICHAEL ROTHER, University of Minnesota Duluth — We consider the interactions of two sedimenting, spherical drops in a temperature gradient with negligible thermal convection. The drops are covered with a nearly uniform surfactant film. When drop and surrounding fluid inertia lose symmetry, as indicated by small Stokes and Reynolds numbers, respectively, the governing equations are linear, and the trajectories are symmetric. In the linear case, it is possible for two drops to fall as a pair with constant horizontal separation, but the drops must have the tandem arrangement initially. Moreover, a saddle point can occur in the trajectory phase plane. When drop inertia is considered, as measured by a finite Stokes number, with surrounding fluid inertia still unimportant, the governing equations become non-linear, and the trajectories lose symmetry. Asymmetric limit cycles can be observed. In addition, trajectories with a constant, finite horizontal gap become stable, with retrograde motion also possible. For small water drops in air, at a fixed drop size ratio, the collision efficiency vanishes, depending on the relative strength and orientation of the gravitational and thermocapillary driving forces.

8:24AM Q25.00004 ABSTRACT WITHDRAWN —

8:37AM Q25.00005 Role of Laplace pressure in the equilibrium of a pendent drop highlighted by a particle loading, L. LECACHEUX, A. SADOUFI, D. CASSAN, A. DURI, UMR IATE 1208 CIRAD/INRA/SupAgro/Universite Montpellier,2 Place Viala,34060 Montpellier,France, T. RUIZ, UMR QualiSud 95 CIRAD/Universite Montpellier,15 av Charles Flahault,34093, Montpellier — A pendent drop at the end of a capillary needle remains in near equilibrium just before breaking: the action of the capillary force must oppose the weight of the drop, to which should be added the force due to Laplace pressure (LP). Thus, for a given fluid and a fixed wet perimeter, its maximum mass should be constant. We modulated the LP by modifying the main curvatures of the drop and we observed the impact on its mass. Drops were loaded with glass beads of increasing mass and induce a stretching of the drops that modulates their main curvatures. Volumes and curvature radii are measured by image analysis. These loading experiments highlight the increase of LP with the loading and the non-linear decrease of the drop mass. However, we observe that the liquid mass in the loaded drop decreases linearly with the increase of the bead mass without verifying the mass balance. Such a result is included in a master curve which highlights the role of the LP in the equilibrium of a pendent drop just before its rupture. It challenges the validity of the well-known Tate’s law and allows the setting of functional ranges for capillary micromanipulators.
films in a steel plate illuminated by a high energy laser1. MARY LANZEROTTI, United States Military Academy, K. BRAKK, Susquehanna University, K. ALLEN, J. HARTKE, United States Military Academy, A. HIRSA, Rensselaer Polytechnic University — This talk presents preliminary observations of the formation of a single liquid drop of molten steel following bursting of a thick liquid film formed by illumination of a thin vertical steel plate by a 1075-nm continuous-wave 1000W Ytterbium fiber laser. Images of the initial hole captured by a high-speed digital camera at room temperature conditions show a rapidly expanding hole. Liquid then gathers at the lower part of the hole, forming a liquid lump where the pre-burst bulge was located. The liquid lump vibrates twice as it settles into a sphere. Gravity pulls the liquid drop down, to form a neck between the rim of the hoop and the drop. The neck pinches off, detaching a drop. The neck retracts slightly before it freezes with a small droplet that appears to form at the bottom of the neck before the neck freezes. The falling drop oscillates as it falls until it hits the mount surrounding the steel plate. The high-speed images also show an ejected droplet that is launched and then falls, apparently in front of the plate. No satellite drops are observed.

9:03AM Q25.00007 Onset time of fog collection using a single wire. YOUSHUA JIANG, CHRISTIAN MACHADO, SHAAN SAVARIYAN, NEELESH PATANKAR, KYOO-CHUL PARK, Northwestern University — Fog collection is a promising solution to water scarcity while also being of vital importance in industrial processes. To date, many studies have investigated the fog collection rate, a parameter that denotes the average performance over a period of time. However, the initial period (referred to as onset time) between the start of the fog flow and the collection of the captured liquid (a delay in time caused by droplet growth to a critical weight) has not been understood. A longer onset time results in a more serious clogging issue that deteriorates the collection rate and, therefore, understanding this phenomenon is important. Here, we study how the onset time is determined by the capture and transport of fog droplets using single, vertical wires with various surface wettabilities and diameters, under different wind speeds. We derive a scaling law that correlates the onset time with the fog capture process and droplet-surface retention force, governed by aerodynamics and interfacial phenomena, respectively. In particular, the onset time decreases with an increasing rate of fog capture or a decreasing droplet-surface retention. This study introduces a new aspect in the evaluation of fog collection and provides insights for the design of fog collectors.

9:16AM Q25.00008 Clogging-enhanced fog harvesting on the hole pattern1. JIHYE PARK, CHANGJE LEE, HYESUNG CHO, MYOUNG-WOON MOON, SANGYOUNG LEE, SEONG JIN KIM, Korea Institute of Science and Technology — Clogging has been considered as a drawback in fog-harvesting as it hinders local airflow around a hole. However, in this study, it is demonstrated that the clogging effect on the fog-harvesting performance differs between the stable clogging and the unstable clogging. Unlike the stable clogging that is stably stuck in the hole, the unstable clogging is observed to form and break up repeatedly during the fog-harvesting process. Due to this break-up, fog flow through the unstably-clogged mesh experiences much less pressure drop than that across the stably-clogged mesh even though those meshes have the same shade coefficient. Moreover, it is found that the clogging can be used even for enhancing the fog-capturing efficiency than the clogging-free mesh with the same shade coefficient by increasing the effective shade coefficient to collide with more fog drops, which suggests that the clogging could be not a simple drawback. Rather, especially for the unstable clogging, it can be used to optimize the fog-harvesting performance with maintaining low pressure drop. Moreover, the particle image velocimetry is performed to quantify the increase in the effective shade coefficient of the clogged mesh by measuring the turbulent kinetic energy of the fog flow to the mesh. 1This research was a part of the project titled ‘Development of clean-up technology for spilled oil and floating HNS using nanostructures’, funded by Korea Coast Guard, Korea.

9:29AM Q25.00009 Droplets sliding on fiber arrays. FLORIANE WEYER, University of Liege, ALEXIS DUCHESNE, University of Lille, NICOLAS VANDEVALLE, University of Liege — At a time when water becomes a scarce commodity in the most arid regions, fog harvesting has emerged as a sustainable alternative way to supply drinkable water. The small droplets from the fog impact the mesh net and, as more and more water hits the mesh fibers, the droplets fuse together and slide along the fibers due to gravity. Even though the collection process has been widely studied, the motion of the droplets on the fibers remains an open question. Here, we focus on the motion of droplets on an entanglement of fibers. We use a model system made of silicone oil droplets, to insure total wetting, sliding on nylon fibers. The movement of the droplet depends mostly on the volume of the drop, the fiber inclination and the fiber diameter. The results allow us to better understand the path chosen by the droplets once collected. These results could be used to improve the collection rate of the fog collection devices.

Tuesday, November 26, 2019 7:45AM - 9:42AM –
Session Q26 Flow Control: Turbulence 608 - Wei Zhang, Cleveland State University

7:45AM Q26.00001 Turbulent Wake Induced by a Seal-Whisker-Inspired Power Turbine Blade, WEI ZHANG, ROBERT AHLMAN, CURTIS FLACK, Cleveland State University, VIKRAM SHYAM, NASA Glenn Research Center — Power turbines operate over a large range of flow incidence and at relatively low Reynolds numbers (Re). For a fixed-wing aircraft at cruising altitude, it is challenging for current power turbine blades to maintain desirable aerodynamic performance as the Re number has dropped to substantially lower than that at sea level. Therefore, it is imperative to improve the aerodynamics of turbine blades in low Re regimes. However, the performance of state-of-the-art turbine blades for aero-propulsive systems has plateaued. Inspired by the exceptional hydrodynamics of harbor seal whiskers, this study applies the key features of the three-dimensional undulating morphology of seal whiskers to the turbine blade leading edge. Turbulent wake flows generated by a seal-whisker-inspired variable speed power turbine (VSPT) blade are quantified and compared against a baseline untreated VSPT blade in a water tunnel using Particle Image Velocimetry (PIV). Focus is on the wake velocities and turbulence statistics at a range of angles of attack (AOA = 10 to 10 degrees). Results of the seal-whisker-inspired blade will be used not only to improve the design of power turbine blades, but also to inform a wide variety of bio-inspired aerodynamic applications.
8:11 AM Q26.00003 Wall-Jet Turbulence and Mixing Control by Way of a Pulled Inlet Velocity. CRISTALE GARNICA, BERTRAND ROLLIN, Embry-Riddle Aeronautical University — Attaining skin friction reduction and increasing flow mixing is of utmost importance to enable breakthroughs in fuel efficiency, heat transfer, as well as drag and noise reduction. The turbulent plane wall-jet constitutes a typical flow configuration where turbulence phenomena associated to these engineering applications occur. Direct Numerical Simulations (DNS) are performed to investigate how skin friction and flow mixing are affected by introducing controlled perturbations, jet inlet pulsing, at the shear layer origin. The jet inlet pulse frequencies are varied in time and space to investigate its influence in the downstream domain. The forcing affects the energy of the large-scales which will consequently affect the small-scales allowing turbulence modulation. The interaction between outer layer of jet and structure near the wall, that is, near-wall jets, should be investigated. To this end, experiments of experimental and computational data from previous studies, with and without external perturbation or co-flow, are used to quantify the effect of jet inlet pulsing on wall-jet characteristics, which include eddy production, velocity profiles, maximum velocity decay, half-width jet growth, and coherent structures.

8:24 AM Q26.00004 A 2-dimensional–3-component model of turbulent flow over riblets. DAVIDE MODESTI, SEBASTIAN ENDRIKAT, Department of Mechanical Engineering, University of Melbourne, Victoria 3010, Australia, RICARDO GARCIA-MAYORAL, Department of Engineering, University of Cambridge, Cambridge CB2 1PZ, UK, NICHOLAS HUTCHINS, DANIEL CHUNG, Department of Mechanical Engineering, University of Melbourne, Victoria 3010, Australia — Riblets are streamwise-aligned grooves that are designed to reduce drag by modifying the near-wall flow with respect to that of the smooth wall. Nevertheless, drag reduction breaks down when the viscous-scaled square root of the groove area $\ell_g^+$ > 11, and this breakdown has been attributed to the formation of time-averaged secondary flow structures over riblets. This is achieved by using the 2-dimensional–3-component (2D–3C) model of Gayme et al. (J. Fluid Mech., vol. 665, 2010, pp. 99–119), in which a sustained turbulent flow is obtained by modelling the incoherent turbulent fluctuations as random forcing. We conduct 2D–3C simulations of flow over several riblet geometries and sizes and compare the results with minimal direct numerical simulations. The 2D–3C model captures the onset and the topology of the secondary flows, suggesting that they are generated by a preferential distribution of near-wall turbulence pinned by the riblet grooves. The model can be used to predict the slip velocity at the riblet crest, providing a better estimate than Stokes (purely viscous) calculations for riblets of moderate sizes, $\ell_g^+ < 20$.

8:37 AM Q26.00005 One-shot methods for nonlinear optimization of turbulent flows with heat transfer. SALEH NABI, Mitsubishi Electric Research Labs, PIYUSH GROVER, Mechanical and Materials Engineering, University of Nebraska-Lincoln, C. P. CAULFIELD, BPI & DAMTP, University of Cambridge — We consider the optimization of buoyancy-driven flows governed by Boussinesq equations using i) Direct-Adjoint-Looping (DAL), and ii) one-shot methods. Various optimization scenarios are considered: first we solve a series of inverse-design problems for which the global optimal solution is known. We demonstrate that each optimization method is able to retrieve the optimal solution in a fully turbulent regime. Next, we consider the problem of maintaining a desired temperature field with specified input energy budget. The role of an approximate Hessian as a preconditioner as well as tuned step-size for the one-shot method iterations are highlighted. It is shown, by employing an efficient optimization algorithm, the one-shot method can solve the PDE-constrained optimization problem with a cost comparable (about fourfold) to that of the simulation problem alone, and substantially cheaper than using DAL, which requires $O(10)$ direct-adjoint loops to converge. The optimization results arising from the one-shot method can be used for optimal sensor/actuator placement tasks, or to provide a reference trajectory to be used for online feedback control applications.

8:50 AM Q26.00006 Targetted modal turbulent flow control via localized heating. MATTHEW YAO, DUOSI FAN, KHALED YOUNES, JOSEPH MOULALLEM, JEAN-PIERRE HICKEY, University of Waterloo — Bidimensional empirical mode decomposition (BEMD) is an empirical method to decompose fluctuating signals into various intrinsic mode functions (IMFs); these represent different scales of the turbulent fluctuations. The scale separation flow permits an analysis of their respective contributions towards the overall skin friction of the turbulent boundary layer. We quantify the effects of selective, localized wall heating on the formation and dynamics of turbulence structures at various scales, and consequently, the effect on the skin friction for turbulent flow control. The decomposition is applied to an unheated channel flow and is compared to a channel flow with streamwise aligned heated strips. The strip spacing is dependent on the length scale of the targeted turbulent structures. The individual contribution of the various eddy sizes to the overall skin friction is then calculated and compared to the unheated base case.

9:03 AM Q26.00007 Turbulence Control in Pipe Flow by Means of Unsteady Driving. DAVIDE SCARSELLI, JOSÉ M. LOPEZ, ATUL VARSHNEY, BJÖRN HOF, IST Austria — Turbulent flows are responsible for huge energy losses in many diverse pumping applications ranging from heat exchange circuits to hydroelectric power plants. Several techniques to reduce frictional drag have been proposed over the last decades, however, very few have been tested experimentally and even less actually implemented. Based on the friction reducing properties observed in accelerating flows, we here propose a new approach to reducing drag by means of a pulsatile flow rate. We find 27% drag reduction in fully turbulent pipe flow in experiments and this is confirmed in direct numerical simulations. The optimal Reynolds number modulation is discussed. Different from many other drag reduction techniques, this operation mode does not require feedback loops, fluid additives or any modification to an existing pipeline.
9:16 AM Q26.00008 Reynolds number effect on drag control via spanwise wall oscillation in turbulent channel flows, XI CHEN, Beihang University, JIE YAO, FAZLE HUSSAIN, Texas Tech. The effect of Reynolds number ($Re$) on drag reduction (DR) by spanwise wall oscillation is studied through direct numerical simulation of incompressible turbulent channel flows with $Re$ ranging from 200 to 2000. For the non-dimensional oscillation period $T^+=100$ with maximum velocity amplitude $A^+=12$, DR decreases from 35.3% at $Re=200$ to 22.3% at $Re=2000$. The oscillation frequency $U^+$ for maximum DR slightly increases with $Re$, viz., from $U^+=0.06$ at $Re=200$ to 0.08 at $Re=2000$, with $DR_{max}=23.2%$. These results show that DR progressively decreases with increasing $Re$. Turbulent statistics and coherent structures are examined to explain the degradation of drag control effectiveness at high $Re$. FIK analysis in combination with the spanwise wavenumber spectrum of Reynolds stresses reveals that the decreased DR at higher $Re$ is due to the weakened effectiveness in suppressing the near wall large-scale turbulence, whose contribution continuously increases due to the enhanced modulation and penetration effect of the large-scale and very large-scale motions. Based on the power-law model and the log-law model, we predict more than 10% drag reduction at very high Reynolds numbers, say, $Re=10^5$.

9:29 AM Q26.00009 Constant power input simulations of drag reduced viscosity stratified turbulent channel flow, OSCAR NAZARENKO, TU Wien, ALESSIO ROCCON, TU Wien; University of Udine, FRANCESCO ZONTA, TU Wien; ALFREDO SOLDATI, TU Wien; University of Udine. In this work, we analyze the energy budgets of a turbulent channel flow in which a thin layer of fluid is used to lubricate the flow. In particular, we consider a setup in which a thin layer of fluid (viscosity $\eta_f$) is used to lubricate the flow of a thicker fluid layer (viscosity $\eta$). The system dynamics is investigated numerically using DNS of the Navier-Stokes equations coupled with a phase-field method. We consider a single-phase case and three multiphase cases. The multiphase cases differ by the value of the viscosity ratio employed: $\lambda=1.00$ (matched viscosity), $\lambda=0.50$ and $\lambda=0.25$ (less viscous lubricating layer). In order to obtain a more meaningful comparison among the different cases, simulations are performed using a Constant Power Input (CPI) framework and the power Reynolds number is kept fixed to $Re_{CPI}=12220$ (corresponding in the single-phase reference case to $Re_{ef}=300$). The results show that for all the cases considered, with respect to single-phase reference case, an increase of the thicker layer flow-rate is observed and Drag Reduction (DR) is obtained. The DR is linked to the interplay between inertial, viscous and surface tension forces which lead to an overall reduction of the turbulent dissipation.

Tuesday, November 26, 2019 7:45AM - 9:42AM — Session Q27 Flow Control: Model Reduction

7:45 AM Q27.00001 Energy-optimal phase control of unsteady fluid flows, ADITYA NAIR, University of Washington; KUNIHIKO Taira, University of California, Los Angeles; BINGNI Brunton, STEVEN BRUNTON, University of Washington. Controlling the phase of oscillation of unsteady fluid flows is crucial in terms of advancing and delaying flow field characteristics. Our goal is to design an optimal flow control strategy that alters the oscillation phase in fluid flows using minimum energy input. We perform a phase reduction analysis to construct a reduced-order model in terms of a phase-sensitivity function that tracks the phase of oscillation in response to impulse perturbations. Using the phase sensitivity function and its gradient, the optimal control law is obtained by solving the Euler-Lagrange equations as a two-point boundary value problem. We demonstrate the approach for incompressible flow over a cylinder at low Reynolds number and discuss extensions to complex flows. Multiple actuation strategies based on blowing and rotary control are also explored. Finally, we examine the synchronization and desynchronization properties of the optimally controlled flow and discuss broader implications for flow control.

7:58 AM Q27.00002 Spectral POD analysis of low Reynolds flow past finite cylinders, MATTEO CHIATTO, Department of Industrial Engineering, Università di Napoli Federico II, Italy; CAROLINE CARDINALE, JESSICA K. SHANG, Department of Mechanical Engineering, University of Rochester, NY, USA; LUIGI DE LUCA, Department of Industrial Engineering, Università di Napoli Federico II, Italy; FRANCESCO GRASSO, DynFluid Laboratory, CNAM- Arts et Metiers ParisTech, France. The need to understand the physics and to control a flow field has led scientists to develop techniques suitable for characterizing the dynamics and the topology of the flow based on simplified equations, and by exploiting experimental and/or numerical data. Major analysis techniques include POD, DMD, Spectral POD (SPOD, Towne et al. JFM 2018, 847). SPOD has the ability to represent structures evolving coherently in space and time, and it is here applied to study the flow past finite oblique cylinders. The study is aimed at investigating shedding regimes at various low Reynolds numbers. The wake behind the cylinder is experimentally investigated by means of a digital visualization technique described by Shang et al. (JFM 2018, 837). The major results consist in extracting the wake dynamics and identifying the eigen-directions associated with the most energetic structures. The wake field is reconstructed by considering just the few selected modes. Such a low dimensional decomposition is able to capture the dominant shedding modes, by comparing both image reconstruction and quantitative shedding Strouhal numbers to previous results.

8:11 AM Q27.00003 Model-Based Estimation of Vortex Sheding in Unsteady Cylinder Wakes, JIWEEN GONG, JASON MONTY, SIMON ILLINGWORTH, The University of Melbourne. This work considers single-sensor based estimation of vortex shedding in cylinder wakes at $Re=100$ in simulations and at $Re=1036$ in experiments. A model based on harmonic decomposition is developed to capture the periodic dynamics of vortex shedding. Two model-based methods are proposed to estimate time-resolved flow fields. First, Linear Estimation (LE) which implements a Kalman Filter to estimate the flow. Second, Linear-Trigonometric Estimation (LTE), which utilizes the same Kalman Filter together with a nonlinear relationship between harmonics of the vortex shedding frequency. LTE shows good performance and outperforms LE in reconstructing vortex shedding. Physically this suggests that, at the Reynolds numbers considered, the higher harmonic motions are slave to the fundamental frequency.

8:24 AM Q27.00004 The dynamical states of a circular cylinder wake influenced by a leeward control rod, MURILO CICOLIN, PETER BEARMAN, OLIVER BUXTON, Imperial College London; GUSTAVO ASSE, University of Sao Paulo. Experiments were carried out in a circulating water channel with a circular cylinder fitted with one control rod at different positions. The rod had a diameter 10 times smaller than the main cylinder. The distance between the centre of cylinders was kept constant (R/D=0.7) and the angle between them varied from 40 to 90 degrees, when at 0 degrees the control cylinder is placed in the wake on a line passing through the stagnation point of the main cylinder and its centre. Reynolds number was 20,000 for all cases, based on the main cylinders diameter. High-resolution PIV fields were acquired focusing on the two-dimensional wake of both cylinders. Results showed that for all cases the control rod induced a significant change in the wake when compared to the bare cylinder. Three main dynamical states were identified according to the position of control rod across the shear layer: immersed in the recirculation region, in the middle of shear layer or outside of it. Moreover, a bistable transitional state was identified between the first and second states. The second state shows a suppression of vortex shedding and a significant reduction of drag forces for the combined system.
8:37AM Q27.00005 Koopman mode representations of vortex dynamics in viscous flows\textsuperscript{1}. KE-CHU LEE, SAM KAUFMAN-MARTIN, SAMANEH SADRI, POORVA SHUKLA, IGOR MEZI, PAOLO LUZATTO-FEGIZ, University of California, Santa Barbara — Vortex dynamics plays an important role in transitional and turbulent flows, where instabilities introduce important criteria for safety and performance of systems like turbomachinery and aerospace vehicles. In order to control these vortical flows, accurate, general and efficient models of vortex dynamics are needed. Here we explore the ability of Koopman mode decomposition (KMD) to provide such models and uncover physical mechanisms. Using pseudo-spectral simulations, we consider vortex dynamics in viscous flow for different Reynolds numbers and different initial vortex geometries. We start with co-rotating vortex pairs, for which we find that KMD modes and eigenvalues are in close agreement with linear stability predictions. We find that the onset of symmetry-breaking is weakly sensitive to Reynolds number, but highly sensitive to small details in the initial conditions. We provide a detailed comparison of the relative abilities of KMD and proper orthogonal decomposition (POD) to capture this behavior. Finally, we consider implications for modeling and controlling more general vortex flows.

8:50AM Q27.00006 Dynamic mode analysis and control of vortical flows in pump sumps. BYUNGJIN AN, Ebara Corporation, QIONG LIU, University of California, Los Angeles, MOTOHIKO NOHMI, MASASHI OBUCHI, Ebara Corporation, KUNIHIKO TAIIRA, University of California, Los Angeles — Pump sumps are settling chambers for incoming flows prior to their removal by pumps. These pump sumps are widely used for drainage in pumping stations and power plants. During off-design operations, free surface and sub-surface vortices often appear in pump sumps, causing significant pump performance degradation and system vibrations. Modal analysis is performed to obtain insights to develop an effective and highly robust suppressing device of vortex for a scaled pump sump. Dynamic mode decomposition (DMD) is used to extract the dynamic features with respect to the vortical flow obtained from the large eddy simulation (LES). The dominant DMD modes are useful for understanding the complex vortex dynamics and developing a novel control device for the suppression of vortex formation. In addition to examining the complex flow in the pump sump, we also consider a wall-normal vortex model. Active flow control is considered for the attenuation of such vortex. The resulting increase in pressure at the vortex core suppresses the detrimental effects. A comparative analysis of steady and unsteady actuation methods is carried out through LES. The characteristics of the successful control mechanisms will be identified and discussed.

9:03AM Q27.00007 A Hybrid Low-order Model of Dynamic Lift Response to Time-varying Actuation\textsuperscript{1}. XUANHONG AN\textsuperscript{2}, Princeton University, DAVID WILLAMS\textsuperscript{3}, Illinois Institute of Technology — Time-varying actuation from a synthetic jet actuator has previously been shown to be an effective way of controlling unsteady flow separation. In order to integrate this type of actuation into a real-time control system, a low-order model of the lift response to the actuation is desired. The current work proposes a low-order approach to modeling the lift response to time-varying leading edge actuation on a stalled airfoil. Dynamic Mode Decomposition (DMD) is employed to extract from the flowfield the critical dynamical information, which is connected to the lift variation. It is shown that there are two sets of DMD modes associated with two different frequencies. These two frequencies are contained in both the actuation signal and the lift response. Based on the information provided by the critical DMD modes, we propose a hybrid low-order model which consists of a time delay decay model and a convolution integral model. This hybrid model is capable of accurately predicting the lift response of an airfoil to the time-varying actuation.

9:16AM Q27.00008 Modeling the transient response to momentum injection for flow over an airfoil in deep stall using data-driven and projection-based methods\textsuperscript{1}. KATHERINE ASZTALOS, SCOTT DAWSON, DAVID WILLIAMS, Illinois Institute of Technology — Direct numerical simulations are performed for leading-edge momentum injection control of flow over a NACA0009 airfoil at post-stall angles of attack. We consider cases where the wake is both stable (Re = 200) and unstable (Re = 500), and find that the flow response is comparable in both regimes, though with some sensitivity to the instantaneous flow state in the unstable case. We investigate the physical mechanisms governing the interactions between the disturbance and the natural flow state using both dynamic mode decomposition (which is an entirely data-driven approach), and Galerkin projection of the governing Navier-Stokes equations onto a subspace obtained from proper orthogonal decomposition. In particular, we show that projecting a linearized Galerkin projection model can accurately predict DMD modes, giving an understanding of the origin of these modes from the underlying governing equations. More generally, this also suggests a method for approximating DMD modes from non-time-resolved data. We assess the ability of the resulting models to predict the time-evolution of the flow state of the actuated system. We also study the ability of our models to capture the finite-time-horizon energy growth present in the full system.

9:29AM Q27.00009 Effect of spanwise wall oscillations on dynamics and evolution of near-wall coherent structures in a turbulent pipe flow at low and moderate Reynolds numbers\textsuperscript{1}. DANIEL COXE, RONALD ADRIAN, YULIA PEET, Arizona State University — Presented is the temporal evolution of a single conditional hairpin vortex in a turbulent pipe flow with transversely oscillated walls at low and moderate Reynolds numbers, compared to a baseline non-oscillated turbulent pipe flow case. A conditional hairpin is generated by a Linear Stochastic Estimation of a fluctuating velocity field of a non-oscillated pipe flow, obtained via Direct Numerical Simulations with a spectral-element method. An extracted hairpin is placed as an initial condition into the flow of interest and is convected downstream by a turbulent mean velocity profile. A goal of the study is to investigate the effect of wall oscillations on the development and growth of a conditional hairpin and the mechanisms associated with a potential suppression of auto-generation in a drag reduced flow. Subsequent formation and evolution of secondary and tertiary hairpins and how these processes are modified by a spanwise wall oscillation are also documented. A spatially averaged Reynolds stress profile along with the wall shear stress are presented to quantify the effects of auto-generation.

8:24AM Q28.00004 Inertial particle distribution in high Reynolds number turbulence: wavelet-based scale-dependent statistics

KEIGO MATSUDA, Center for Earth Information Science and Technology, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Yokohama, Japan, KAI SCHNEIDER, Aix-Marseille University, CNRS and Centrale Marseille, Marseille, France, KATSUNORI YOSHIMATSU, Institute of Materials and Systems for Sustainability, Nagoya University, Nagoya, Japan — The nonlinear dynamics of inertial particles in high Reynolds number turbulence, and in particular particle clustering, are important fundamental processes in atmospheric science. Here we analyze particle data from three-dimensional direct numerical simulations of particle-laden homogeneous isotropic turbulence at high Reynolds number, using Voronoi tessellation of the particle positions, considering different Stokes numbers (St). The divergence of the particle velocity can be quantified by determining the volume change rate of the Voronoi cells. We show theoretically that for random particles in random flow the divergence satisfies a PDF of the ratio X/Y, where X and Y follow normal and 1’ distributions, respectively. For inertial particles we find that the PDF of the divergence deviates from the theoretical prediction. Joint PDFs of the divergence and the Voronoi cell volume illustrate that the divergence is most prominent in cluster regions and less pronounced in void regions. Moreover, the mean value of the divergence becomes negative inside the cluster regions for St ≥ 2, corresponding to convergence of inertial particles, while for large St the mean value turns to positive values as the Voronoi cell volume becomes smaller. Finally, we show that the divergence of the inertial particle velocity exhibits no correlation with the second invariant of the fluid velocity gradient tensor, which has some impact for modeling particle laden turbulence.

8:37AM Q28.00005 Life and death of inertial particle clusters in homogeneous turbulence

YUANQING LIU, LIAN SHEN, University of Minnesota, Twin Cities, REMI ZAMANSKY, University of Toulouse, FILIPPO COLETTI, University of Minnesota, Twin Cities — Although clustering is a widely observed phenomenon in particle-laden turbulence, our understanding of the formation, evolution, and destruction of particle clusters is still incomplete. Virtually all existing definitions of a cluster rely on the spatial coherence of the particle concentration field, neglecting its temporal persistence. The latter is in fact essential to the ability of the particles to interact with each other, and to modify the carrier fluid flow. Here we leverage simulations of homogeneous isotropic turbulence laden with small heavy particles, and develop a Lagrangian framework to follow them before, during, and after their time as part of a coherent cluster. We define a criterion to establish whether a cluster survives over successive time steps, and use it to characterize its lifetime. Moreover, we investigate the recurring features of the turbulence associated to the formation and destruction of a cluster. The impact of the lifetime definition on the results is also discussed.

1Visiting Scientist, Aix-Marseille University, CNRS, I2M, Marseille, France
8:50AM Q28.00006 Clustering of gas-solids flows in a vertical duct, AARON M. LATTANZI, SARAH BEETHAM, University of Michigan, KEE ÖNN FÖNG, FILIPPO COLLETTI, University of Minnesota, JESSE CAPECIELATRO, University of Michigan — In this work, numerical simulations of moderately dense gas-solids flows in the fully-developed region of a vertical duct are performed. The simulations are performed within a volume-filtered Eulerian-Lagrangian (EL) framework and compared to novel experimental measurements. The high mass loading considered here leads to significant two-way coupling and the spontaneous generation of densely-packed clusters that fall along the duct walls. Two-phase flow statistics are extracted from the simulations and compared against detailed experimental measurements obtained from high-speed imaging and particle-tracking velocimetry. Additionally, a model for the pseudo-turbulent Reynolds stress (PTRS) was implemented within the EL framework to account for sub-grid particle-induced velocity fluctuations. Simulations with the PTRS closure allow the effect of a pseudo-turbulence model on clustered flows to be rigorously assessed for the first time.

9:03AM Q28.00007 Highly concentrated falling inertial particles in a vertical duct/riser1, KEE ÖNN FÖNG, FILIPPO COLLETTI, Univ of Minnesota - Twin Cities — Highly concentrated particle-laden turbulent flows, such as flows found in fluidized beds and falling-particle receivers, form complex and poorly understood interactions owing to the strong feedback of the dispersed phase on the fluid and possible inter-particle collisions. We present experimental observations on the velocity response and topological distribution of highly concentrated, falling inertial particles in a vertical rectangular duct. The working fluid is air laden with size-selected glass particles. The experiment is conducted in two different configurations of free-falling particles, and particles suspended by flowing air, enabling particle volume fractions as high as 3E-2. Two different resolutions are employed - a full-scale view to capture large-scale motions of the particles and cluster formation using particle image velocimetry; and a zoomed-in view to resolve the individual motions of particles using particle tracking velocimetry. The findings are discussed in the context of collective effect of particles, the influence of clusters on the mean statistics, and the partitioning of particle velocities into spatially correlated and random uncorrelated motions.

9:16AM Q28.00008 Reynolds number dependence of heavy particle preferential concentration1, XIANGJUN WANG, MINPING WAN, Southern University of Science and Technology — The preferential concentration of particles is a classical problem in particle-laden turbulence. The dependence of particle clustering on Reynolds number is still an open question. Here, the Reynolds number dependence of heavy inertial particles in homogeneous isotropic turbulence has been investigated. According to the analysis of Voronoi tessellation, the preferential concentration of small heavy particles is studied with the increase of Taylor Reynolds number from 52 to 139, with the number density of particles fixed. There are two factors that determine the extent of particle clustering. The first one is the strength of vortices in turbulence; the other is the persistent time that characteristic vortices drive particles to preferentially accumulate during one turnover time. Obviously, a larger strength of vortices and a longer persistent time contribute to a more intensive preferential concentration of particles. It is uncovered that the strength of vortices increases as Reynolds number increases, whereas the persistent time decreases with Reynolds number. Consequently, the influence of the latter defeats that of the former in present investigation. Therefore, the degree of preferential concentration decreases with Reynolds number.

Tuesday, November 26, 2019 7:45AM - 9:42AM – Session Q29 Biological Fluids Dynamics: Large Vessels 611 - Fanette Chassagne, University of Washington

7:45AM Q29.00001 Hemodynamics Assessments of Ascending Thoracic Aortic Aneurysm – the Influence of Hematocrit with Fluid-Structure Interaction Analysis, HAN HUNG YEH, SIMON RABKIN, DANA GRECOV, The University of British Columbia — An aortic aneurysm is one of the cardiovascular diseases with localized abnormal growth of a blood vessel risking rupture or dissect. The precise pathological pathway for aneurysm progression and formation is not completely understood. In the current study, ascending thoracic aortic aneurysms (ATAA) are investigated using a fully coupled fluid-structure interaction method focusing on the changes in hematocrit under normotension and hypertension. Blood was modeled as a laminar incompressible flow using the Quemada model with varying hematocrits. The arterial wall anisotropy and hyperelasticity were considered. Given the influence of hematocrit on the degree of shear-thinning of blood, the current result could provide valuable information in clinical practice. Our results suggested that with the increase in hematocrit, the shear stress distribution and the maximum shear stress magnitude along the arterial wall would increase significantly. The wall stress distributions, however, remained unchanged with respect to the changes in hematocrit. In addition, the distribution of von Mises stress indicated that elevated stress under hypertension could depend on geometry. This geometrical influence in ATAA could be a risk factor predicting further aortic expansion.

7:58AM Q29.00002 The hidden role of wall shear stress in fluid mechanics of coronary artery atherosclerosis1, AMIRHOSSEIN ARZANI, MOSTAFA MAHMOUDI, Northern Arizona University — Wall shear stress (WSS) is arguably the most important parameter in the biomechanics of atherosclerosis. Traditionally, WSS is used to quantify the frictional force on the endothelial cells and study mechanotransduction. However, WSS also provides valuable information about near-wall transport. Biologically, near-wall transport of certain biochemicals and cells influence atherosclerosis progression. The recent concept of Langrangian WSS structures (WSS manifolds) provides a connection between WSS vectors and near-wall transport. In this talk, we demonstrate the connection between WSS and near-wall localization of several atherogenic and atheroprotective biochemicals and cells in coronary artery atherosclerosis. Finally, an automated computational framework developed in FEniCS is presented to study the two-way coupling between WSS and plaque growth in coronary arteries. A phenomenological WSS driven growth model is developed to simulate plaque growth, which in turn influences the blood flow and WSS patterns.

1Funding from the American Heart Association (19AIREA34430058) is acknowledged.
8:11AM Q29.00003 Optimization of saline flushing of the coronary artery via two-lumen catheter for visualization of chronic total occlusions. SYED FAISAL, ERIC SEIBEL, ALBERTO ALISEDA, University of Washington, Seattle, WA, USA — A Chronic Total Occlusion (CTO) is caused by atherosclerotic plaque that occludes blood flow in a coronary artery. To improve treatment outcomes, visualization of the occlusion and surrounding coronary artery wall supports diagnosis and guides treatment. We investigate fluid interaction between blood and saline from different catheter designs, to understand the dynamics of blood displacement and low-Reynolds number mixing, and to optimize the catheter operating parameters involved in flushing of blood from the arterial lumen between the catheter tip and the CTO. The pressures develop during the flushing process and the time to obtain optical transparency in the lumen are measured. Suction is introduced to influence the flushing process. The incorporated changes to the artery size, as well as the arterial pulsatile blood flow, along with changes in the relative position of the fluid injection and suction lumens. The plaque morphology is varied to mimic its build up in arteries, testing the viability of the catheter uses under a wide range of physiological and anatomical conditions. A novel method of saline injection, suction and control, which helps reduce risk of the catheter failure and avoids injury to the patient, is developed.

8:24AM Q29.00004 Quantifying pumping effort and peristaltic work using balloon dilation catheters. SHASHANK ACHARYA, Department of Mechanical Engineering, Northwestern University, WENJUN KOU, Gastroenterology Division, Feinberg School of Medicine, Northwestern University, SOURAV HALDER, Theoretical and Applied Mechanics, Northwestern University, JOHN E. PANDOLFINO, PETER J. KAHRILAS, Gastroenterology Division, Feinberg School of Medicine, Northwestern University, NEELESH A. PATANKAR, Department of Mechanical Engineering, Northwestern University — Balloon catheters are widely used to study the mechanical response of blood vessels as well as the active and passive response of tubular organs like the esophagus. In this work, we focus on the EndoFLIP, a device used to characterize the esophagus’ response to dilation. We present a simplified 1D model to predict the system’s response to peristalsis and then use it to generate work curves that show how the muscle energy is being spent. We also observe the development of different pumping regimes based on the operating parameters and present work curves for each of these patterns. An extension of this 1D model is used to enhance data obtained from the device and generate work curves for patients with abnormal peristalsis. The detailed characterization of this system presented here will aid in better interpreting the data obtained from balloon dilation catheters used in patients for any tubular organs or tissue vessels.

8:37AM Q29.00005 Spatiotemporal characterization of pulmonary hypertension under pulsatile flow conditions. NARASIMHA RAO PILLALAMARRI, SENOL PISKIN, ENDER FINOL. Department of Mechanical Engineering, University of Texas at San Antonio — Pulmonary hypertension (PH) is a progressive disease characterized by elevated pressure and vascular resistance in pulmonary arteries. Nearly one quarter of a million hospitalizations occur annually in the U.S. with PH as the primary or secondary condition. A definitive diagnosis of PH requires right heart catheterization (RHC) in addition to a chest computed tomography, a walking test, and others. RHC is invasive has inherent risks and contraindications. This study aims to investigate non-invasive surrogates for RHC measures. Pulsatile hemodynamic simulations were conducted in 28 PH patient-specific geometries with a flow solver developed by customizing OpenFOAM libraries (v5.0, The OpenFOAM Foundation). Quasi patient-specific boundary conditions were implemented using a Womersley inlet velocity profile and resistance outflow conditions. Hemodynamic indices such as wall shear stress (WSS), time-averaged WSS, oscillatory shear index, and blood damage index were evaluated along with clinical metrics such as pulmonary vascular resistance and compliance to assess possible spatiotemporal correlations. The results are promising in the context of a long-term goal of identifying computational biomarkers that can serve as surrogates for invasive diagnostic protocols of PH.

8:50AM Q29.00006 Acoustic trapping and collapsing of microbubbles in stents. FEIYAN CAI, FEI LI, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, PENGFEI ZHANG, Qiu Hospital of Shandong University, HAIRONG ZHENG, Shenzhen Institutes of Advanced Technology,Chinese Academy of Sciences — Stents are commonly used in a coronary artery or any artery after angioplasty, but has the drawback to cause arterial restenosis. Targeted drug delivery has proved their efficacy at preventing coronary restenosis near stents. Here we propose a microbubble-based approach to enhance drug delivery by ultrasonically exciting the elastic resonances of the stents to generate a sound field that can trap and collapse microbubbles carrying drugs, which are consequently released preventing coronary restenosis near stents. Here we propose a microbubble-based approach to enhance drug delivery by ultrasonically exciting the elastic resonances of the stents to generate a sound field that can trap and collapse microbubbles carrying drugs, which are consequently released.

9:03AM Q29.00007 Coronary Stenosis Diagnosing System Using 2-step Machine Learning Algorithm. YOUNG WOO KIM, SUSIE RYU, HEEMIN LEE, JOON SANG LEE, Yonsei University — In this study, a two-step machine learning (ML) algorithm is introduced to estimate fractional flow reserve (FFR) along with decision (DEC) for coronary artery. This paper suggests the possibility of ML-based FFR to overcome the computational fluid dynamics (CFD) based FFR estimation, which includes calculation time and accuracy. Both synthetic model and patient model are used for the training of 2-step algorithm. In the first step, synthetic models are analyzed by CFD method and are used to train Gaussian progress regression model in order to increase the quantity of data. In this process, not only FFR but also flow characteristics are considered. Patient models are used to train the second step of the algorithm, which is based on a support vector machine. This step provides more information related to biomechanical features from the patient. In result, both the calculation time and accuracy of the model were higher for ML-based FFR than that from CFD-based FFR. This study suggests that both flow characteristics and biomechanical features should be also included in the dataset of ML algorithm, by analyzing the weight factor of each features.

reveals that there exists a constant force plateau for a narrowing of the ascending aorta and the stenosed area is subjected to abnormal hemodynamics and pressure drop. The pressure gradient across the stenosed region indicates the energy loss of the blood flow and is indicative of the extra work for the muscle of the left ventricle. The goal of this work is to develop a novel modeling approach to determine the accurate prediction of the pressure drop across the stenotic. We develop a computational method to simulate the propagation of pressure waves and the related arterial wall deformation. Blood is modeled using Navier-Stokes equations and the arterial wall consists of a thick material which accounts for the media and adventitia. Model simulations of the aortic blood flow under physiological conditions were performed using finite element method. The energy estimation is derived from weak formulation and applied to the stenosed artery to assess energy loss. The numerical simulations investigate the relation between the flow condition, pressure gradient and wall deformation for different levels of stenosis to cover the broad range of the degree of narrowing, ranging from trivial to severe.

Comparisons of the predictions coming from the second order theory are provided in order to critically assess its validity and usefulness. We find that the second order equations recover many of the anomalous features (e.g., non-constant pressure and non-zero parallel heat flux). Monte Carlo (DSMC) method have shown that at small Knudsen number the pressure and temperature profiles in the thermal stress problem do not provide accurate results. Second order equations were derived and shown to reproduce experimental results of the shock structure of gases over a large range of Mach numbers (Paolucci & Paolucci JFM, 486, 686-710 (2018)).

We apply mDMDc to patient-specific computational fluid dynamics data (velocity and wall shear stress vectors) in cerebral aneurysm and coronary artery stenosis models. Reconstruction errors are presented and different modes are compared between velocity and wall shear stress.

Session Q30 General Fluid Dynamics 612 - Samuel Paolucci, Notre Dame

7:45AM Q30.00001 Surface morphology and flow dynamics for fog harvesting , FAN KIAT CHAN, University of Illinois, Urbana-Champaign, AIDA SHAHROKHIAN, HUNTER KING, University of Akron, MATTIA GAZZOLA, University of Illinois, Urbana-Champaign — Harvesting fog as a source of fresh water is a practical solution for inhabitants of foggy coastal deserts, whether human, animal or plant. Namib desert beetles famously lean their textured bodies into the fog-laden wind: their evolved strategy has been interpreted mostly in the context of surface wetting and its role in transporting of water as it is accumulated. However, little is known about how the interplay between flow dynamics and surface morphology affects droplet interception. From experiments with controlled flow and fog delivery and sensitive accumulation measurements as well as complementary numerical flow simulations, we find mechanisms for significant enhancement of collection efficiency on two scales: millimetric surface features which affect droplet trajectories; and microscopic features which aid evaporation of lubricating film before contact.

7:58AM Q30.00002 Simple Flows Using a Second Order Theory of Fluids , SAMUEL PAOLUCCI, University of Notre Dame — The Navier-Stokes-Fourier (NSF) equations have proved very valuable in modeling fluid flows over the last two centuries. However, there are cases in which large gradients in velocity and/or thermal fields occur where it has shown that they do not provide accurate results are divided into different phases of the cardiac cycle and DMD with control is applied to each phase. We apply mDMDc: to patient-specific computational fluid dynamics data (velocity and wall shear stress vectors) in cerebral aneurysm and coronary artery stenosis models. Reconstruction errors are presented and different modes are compared between velocity and wall shear stress.

8:11AM Q30.00003 Can we always neglect the bulk viscous pressure in variable density flows? , MILTIADIS PAPALEXANDRIS, Universite catholique de Louvain — In linearly isotropic (Newtonian) fluids, the bulk viscous pressure is proportional to the velocity divergence, with the bulk viscosity of the fluid being the proportionality coefficient. Stokes’ hypothesis states that the bulk viscosity of a Newtonian fluid can be set equal to zero. Although not valid for many fluids, it is common practice to invoke this hypothesis in the study of low-Mach-number, variable-density flows. In this talk, based on simple scaling arguments we provide a necessary condition for neglecting the bulk viscous pressure from the governing equations of low-Mach number flows. More specifically, we show that the Reynolds number defined with respect to the bulk viscosity must be very large. We further show that even when this condition is satisfied, the bulk viscous pressure does not need to be taken explicitly into account because it can be combined with the dynamic pressure.

8:24AM Q30.00004 New Memory Effects in Unsteady Forces on Slip Particles , HSIEH-HUNG WEL, A.R. PREMLATA, National Cheng Kung University — For a slip particle moving unsteadily in a viscous fluid, the extent of slip is not fixed but constantly varies with time, depending on the slip length λ relative to the boundary layer thickness δ. For this dynamic slip situation, we show that even the amount of slip is minuscule, it can significantly change the characteristics of the history force. Our analysis reveals that there exists a constant force plateau for δ<δ, persisting until the slip-stick transition point δ ~ Δ after which the usual no-slip Basset 1/δ decay dominates the force response. We also analyze the unsteady force response for a stick-slip Janus particle, showing that a slightly smaller Basset force can re-emerge in place of the slip force plateau in the small δ regime. This re-entrant history force transition becomes even more evident for a slip particle having a small no-slip patch. These unusual force responses may not only provide unique hydrodynamic fingerprints for characterizing heterogeneous particles, but also have potential uses in active manipulation and sorting of these particles.
8:37AM Q30.00005 Exact Navier-Stokes solutions linear in one coordinate. JONATHAN MESTEL, Mathematics Dept, Imperial College London — If a 3D flow is independent of one coordinate it naturally reduces to a 2D flow. Similar simplification can occur if a flow varies linearly with a coordinate. For example, the advection-diffusion equation \( \nabla \cdot u = \kappa \nabla^2 c \) has solutions of the form \( c = xf(y, z) \) when the velocity has the form \( u = (xu(y, z), v(y, z), w(y, z)) \) with \( \nabla \cdot u = 0 \). The resulting system is essentially two-dimensional, but retains some 3D aspects. This talk employs similar reductions in axisymmetry to derive several previously unknown solutions to the full Navier-Stokes equations. As they extend to infinity, in some cases these similarity solutions exist without additional forcing. A family of 3D boundary layer flows is also derived, demonstrating for example that the Falkner-Skan solutions are nonunique in 3D. Finally, it is shown that these flows can coexist with other fields of advection-diffusion type. In particular, it is shown that these flows can act as dynamos, spontaneously generating magnetic fields with a related spatial structure.

8:50AM Q30.00006 Sedimentation of Triple Twisted Möbius Objects. NICOLAS MORENO, DAVID VASQUES-CORTES, MICHAEL GRUNWALD, JOHANNES SCHOEENKE, ELIOT FRIED, Okinawa Institute of Science and Technology — Screw-like objects like helic and Möbius strips exhibit both rotation and translation as they move in a fluid due to external forces such as gravity. It is expected that the orientation of the twist in the structure determines the direction of the rotational motion. Here, we conduct both computational and experimental studies on the sedimentation of rigid Möbius bands with a three-half twist. We vary the aspect ratio of the bands and analyze their trajectories. We use two different schemes to construct the bands corresponding ruled developable surfaces and ruled binormal-scroll surfaces. For developable bands, we observe that the spinning direction is consistently determined by the orientation of the band and independent of its aspect ratio. Remarkably, for binormal-scroll bands, the direction of spin depends not only on the twist orientation but also on aspect ratio. Experimentally, we track the sedimentation of 3D-printed polystyrene bands in water. Computationally, we use the particle-base method dissipative particle dynamics. The hydrodynamic properties of these objects offer exciting applications for mixing and separation in microfluidics and may also serve as prototypes for passive swimmers.

9:03AM Q30.00007 ABSTRACT WITHDRAWN —

9:16AM Q30.00008 Lubricated Rolling Over A Pool. HATEF RAHMANI, SHELDON GREEN, BORIS STOEBER, Department of Mechanical Engineering, University of British Columbia, NEIL BALMFORTH, Department of Mathematics, University of British Columbia — Film splitting flows are important in many industrial processes, such as the coating of railroad tracks with liquid friction modifiers (LFM). Here, an LFM pool deposited on the track is overridden by an advancing wheel; a liquid film coats both the wheel and rail surfaces, splitting at a meniscus behind the wheel. Lubrication theory is used to predict the meniscus position, wetted length and pressure on the wheel as a function of the peak-to-valley height of the rail, two solutions exist: below a critical load, steady planing arises in which the minimum gap and wetted length are adjusted to match the incoming and outgoing fluid fluxes. Above that load, flooding occurs with a steady minimum gap, but the incoming flux exceeds that underneath, and fluid is ploughed before the wheel. In 3D, only planing is possible, with leakage to the sides eliminating flooding states. Laser-induced fluorescence and high-speed imaging measure coated film thicknesses in experiments that are within 19% of model predictions.

9:29AM Q30.00009 Understanding the behavior of large scale structures in highly scalable Spectral element simulations of Internal Combustion Engines in the framework of large eddy simulation. TANMOY CHATTERJEE, SAUMIL PATEL, MUHSIN AMEEN, Argonne National Laboratory — In this talk, we investigate the large scale structures generated in various flow regimes (intake, compression, expansion, and exhaust strokes) of a motored, TCC-III internal combustion (IC) engine. The study is performed with a highly scalable spectral element code Nek5000. The moving boundary problem corresponding to the valves and piston motion are incorporated through a spectrally accurate arbitrary Lagrangian-Eulerian methodology. To avoid severe mesh distortions, we use a novel methodology of interpolating simulation data to a redesigned mesh in situ, thereby keeping the shape of the meshes in control during the simulations. We also use a novel overset-grid methodology to mesh the spark plug region separately in order to reduce re-meshing of the spark region and maintain stability in our simulations. Such high fidelity studies are not only crucial for understanding the multiscale engine-flow dynamics and cyclic variability of the flow features, but also serves as an efficient guideline for developing more advanced models, like species reaction, and spray injection corresponding to realistic IC engines.

Tuesday, November 26, 2019 7:45AM - 9:42AM —

Session Q31 Biological Fluid Dynamics: Locomotion Cilia 613 - David Saintillan, University of California San Diego

7:45AM Q31.00001 Hydrodynamic synchronization of spontaneously beating filaments. DAVID SAINTILLAN, BRATO CHAKRABARTI, University of California San Diego — Cilia and flagella are thin hair-like cellular projections that play a range of crucial roles from propulsion at low Reynolds number to long-range hydrodynamic transport. The movement of the cilia is produced by the bending of its core, known as the axoneme, consisting of 9+2 pairs of microtubules. In presence of ATP, molecular motors connecting microtubules undergo cycles of attachment and detachment and generate sliding forces that are converted to wavelike motion of the filaments. We present a microscopic model that accounts for the stochastic kinetics of molecular motors and mechanical feedback from the axoneme, and produces spontaneous oscillations consistent with those of sperm, cilia and Chlamydomonas. Using this model for the axoneme, we study elastohydrodynamic phase synchronization in a pair of beating filaments. Our simulations reveal that symmetric sperm-like beats lead to in-phase synchrony while both in-phase or anti-phase synchrony can emerge for asymmetric ciliary waveforms. We find that phase-synchronization is well captured by a low-dimensional Adler equation and also elucidate the role of biochemical noise in driving phase slips.

7:58AM Q31.00002 Dynamics of a cilia/cilium beating in 3D non-Newtonian flow. CHENGLEI WANG, SIMON GSELL, UMBERTO D’ORTONA, JULIEN FAVIER, Aix-Marseille Univ, CNRS, Centrale Marseille, M2P2, Marseille, France — Cilia are micro-scale hair-like organelles protruding from the surfaces of eukaryotic cells. Through fluid-structure interaction (FSI), they usually serve for fluid transport and locomotion. Such a FSI problem has been widely explored recently. In most existing works, the fluid is modeled as Newtonian. However, this is not always the case in nature, such as for the airway surface liquid (ASI) covering the epithelial surface of the respiratory system of the human body. In other words, the non-Newtonian flow could play a significant role on the cilia dynamics, which yet has been rarely studied. Therefore, this study aims to bridge this gap. Specifically, the non-Newtonian fluid is described using the power-law model, and each cilium is represented by a flexible filament. A single cilium or an array of cilia are placed in the fluid and driven at their base by a configuration-dependent torque. With a well-established numerical solver based on the immersed boundary lattice Boltzmann method (IBLBM) and the nonlinear finite element method (FEM), the cilia dynamics and their hydrodynamic interactions in the 3D non-Newtonian flow are systematically investigated, and the effects of several key parameters including the power-law index and the cilia spacing are also revealed.
8:11AM Q31.00003 The role of flexibility in sub-inertial swimming: An analysis of millimeter-scale ciliated structures1, ADRIAN HERRERA-AMAYA, Department of Mechanical Engineering, The Pennsylvania State University, FERHAT KARAKAS, DAVID W. MURPHY, Department of Mechanical Engineering, University of South Florida, MARGARET L. BYRON, Department of Mechanical Engineering, The Pennsylvania State University — Ctenes are rectangular paddle-like structures approximately one millimeter in length, composed of packed bundles of very long cilia. They are used by ctenophores (gelatinous marine zooplankton) to swim at intermediate Reynolds numbers (Re). Using Particle Shadow Velocimetry (PSV), we experimentally examine variations in the beat kinematics and fluid dynamics across ontogeny of the ctenophore Bolinopsis vitrea. In smaller animals, the cten kinematics resemble the physics of micro-cilia, using spatial asymmetry to produce net thrust. By contrast, the ctenes of larger animals show a decreased spatial asymmetry but maintain the overall thrust by increasing the velocity difference between power and recovery strokes (a strategy which would be ineffective in low Re, time-reversible flows). We also observe wall-normal displacement of the mesoglia which is detectable, nontrivial, and with a frequency approximately equal to that of the cten beating. Overall, we show that flexibility is a major parameter in ctenophore swimming, and that further study of this system could help elucidate the physics of flexible propulsors at the boundary of the viscous and inertial regimes.

8:24AM Q31.00004 Long-range self-organization of ciliary activity and flow patterns in reconstituted bronchial epithelium1, ANNIE VIALLAT, Aix Marseille University, CNRS, ETIENNE LOISEAU, SIMON GSELL, UMBERTO D’ORTONA, JULIEN FAVIER, Aix marseille university, CINAM TEAM, M2P2 TEAM — Micociliary clearance is the active transport of a complex fluid, mucus, along the airway epithelial surface. Mucus is propelled over tens of centimeters by the beating of billions of active cilia carried by the epithelial ciliated cells. How the necessary coordination of beat directions emerges during ciliogenesis and is maintained is still an open debate. Would the collective motions of ciliary beats involve the dynamics interaction between cilia as observed in long range interaction in active matter systems? The direction of ciliary beats is constrained by the long-range hydrodynamic forces created by distant cilia and mediated by mucus, and by the planar polarity of the tissue. Here, after highlighting the spontaneous emergence and growth of mucus swirls during ciliogenesis, we show that mucus is necessary to generate and maintain a global swirl, associated with a strong circular directional order of ciliary beats, spanning the whole culture. By showing that large-scale swirl and ciliary order are lost and then recovered by successively removing and adding mucus to the epithelial surface, we demonstrate that the hydrodynamic force exerted locally on each cilium by the mucus flow, itself resulting from the beats of all the cilia of the epithelium, induces its active reorientation. These results are discussed in light of a hydrodynamic model which captures the observed mucus flow patterns.

8:37AM Q31.00005 FAST, NEAREST and Flagellar Regulation1, MEURIG GALLAGHER, GEMMA CUPPLES, JACKSON KIRKMAN-BROWN, DAVID SMITH, University of Birmingham — In an age where huge amounts of data can be readily produced it is increasingly important to be able to accurately and efficiently analyse large amounts of data, and to be able to use these analyses as a marker for clinical outcome. However, semen analysis in the human is currently limited to methods such as sperm counting and analysis of fixed cells. To address this, we have developed and released FAST, a free-to-use package for the high-throughput detection and tracking of large numbers of beating flagella in experimental microscopy videos. This new ability to track the detailed flagellar waveform allows for more than just measurements of motility. Alongside FAST we have been developing NEAREST, an open source software enabling the rapid application of a meshless regularised Stokeslet method to solve mobility and resistance problems in Stokes flow. Combining FAST and NEAREST allows for detailed investigation into experimentally intractable quantities such as energy dissipation, disturbance of the surrounding medium and viscous stresses. Finally, we will discuss how the analysis capabilities provided by these tools can be combined, together with models of the elastic behaviour of flagella and learning algorithms to probe the secrets of flagellar regulation in swimming cells.

8:50AM Q31.00006 Modeling the Synchronization of Flagella on the Exterior of a Sphere, KARIN LEIDERMAN, Colorado School of Mines, FOREST MANNAN, Western Colorado University, MIKA JARVELA, Colorado School of Mines — Flagella are hair-like appendages attached to microorganisms that allow the organisms to traverse their fluid environment. The algae Volvox are phototactic, spherical swimmers with thousands of biflagellate somatic cells embedded in their surface. Their flagella coordinate their beating, which leads to forward swimming with slight rotations; the coordination of their flagella is not fully understood. In this work, we extend a previously published mathematical model of coordinated flagella on a flat surface to study coordination on the exterior surface of a sphere. The goal was to determine if factors related to the spherical shape affected flagellar synchronisation. Each beating flagella itself is modelled as a small rotating sphere, attached to a point just above the spherical surface by a spring, and the effects of all other flagella are accounted for with a regularized image system for Stokes flow outside of a sphere. We consider flagellar beating in meridional planes with slight offsets and from the anterior to posterior pole. We found that this minimal model can achieve large-scale coordination of flagella that leads to metachronal waves and also results in velocity fields that represent forward swimming with rotation. We varied parameters for meridional offsets, spring stiffness and number of flagella to study how they each affected the coordination. This study lays the groundwork for future studies to better understand their more complex coordination needed to drive their phototactic behavior.

9:03AM Q31.00007 A computational study of amoeboid motility in 3D: Role of extracellular matrix geometry, cell deformability and cell-matrix adhesion1, PROSENJIT BAGCHI, ERIC CAMPBELL, Rutgers University — Cells exhibiting amoeboid locomotion are abundant within the human body, as immune cells, epithelial cells, neuronal cells, embryonic cells, and even metastatic cancer cells migrate using the amoeboid phenotype. Amoeboid locomotion is accomplished through the use of pseudopods, or cylindrical membrane extensions which protrude, bifurcate, and retract dynamically, resulting in a net cell displacement. The modeling of amoeboid locomotion is a complex and multiscale process, where large cell deformation, protein biochemistry, and both cytosolic and extracellular fluid interactions must be considered. Furthermore, cells are often confined inside the extracellular matrix (ECM), a porous, fluid-filled medium. Adhesive interactions between the cell and underlying substrate add further layers of complexity. In this work, we present a 3D computational model of amoeboid migration in various ECM geometries. Our model couples a fluid/structure interaction for extreme cell deformation, a pseudopod generating activator-inhibitor system, cytoplasmic and extracellular fluid motion, and a fully resolved extracellular matrix. Simulation results show a strong coupling between cell deformability, matrix geometry and cell-ECM adhesion providing valuable on the mechanics of amoeboid migration.

9:16AM Q31.00008 Efficient Implementation of Elastohydrodynamic Integral Operators for Stokesian Filaments. ATTICUS HALL-MCNAIR, THOMAS MONTÉNEGRO-JOHNSON, University of Birmingham, HERMES GADLHA, University of Bristol, DAVID SMITH, MEURIG GALLAGHER, University of Birmingham — Models for simulating the dynamics of flexible biological filaments have historically been mathematically complex and numerically expensive, in part due to numerical stiffness associated with satisfying fiber inextensibility. Moreau et al. (2018) recently demonstrated that a filament could be modeled efficiently by expressing the governing elastohydrodynamic problem via integral equations written in terms of the evolving tangent angle. Combined with a method of lines discretization, the required degrees of freedom for accurate simulation are reduced, alleviating numerical stiffness and enabling efficient computational simulation. In this presentation, I outline recent work which builds upon the Moreau et al. framework, augmenting their formulation with the method of regularized stokeslets of Cortez et al. (2001, 2005) to enable the modeling of non-local hydrodynamic interactions within and between filaments. From this, the non-linear filament deformations caused by shear flows and sedimentation are modeled efficiently, revealing how fiber interactions can lead to geometric buckling instabilities. We also consider the dynamics of active moment driven swimmers for different moment types, and investigate optimal parameter pairings to produce fast swimming in active filaments.

9:29AM Q31.00009 Magnetically powered metachronal waves induce locomotion in capillary self-assemblies. YLONA COLLARD, GALIEN GROSJEAN, NICOLAS VANDEWAELLE, University of Liege — When tiny soft-ferromagnetic particles are placed along a liquid interface and exposed to a vertical magnetic field, the balance between capillary attraction and magnetic repulsion leads to self-organization into well-defined patterns. We demonstrate that precessing magnetic fields induce metachronal waves on the periphery of these assemblies, similar to the ones observed in ciliates and some arthropods. The outermost layer of particles behaves like an array of cilia or legs whose sequential movement causes a net and controllable locomotion. This bioinspired many-particle swimming strategy is effective even at low Reynolds number, using only spatially uniform fields to generate the waves. The motivations for studying these systems range from the fundamental understanding of biological processes to the development of medical and technological applications.

Tuesday, November 26, 2019 7:45AM - 9:29AM – Session Q32 Biological Fluid Dynamics: Vesicle and Micelles II

7:45AM Q32.00001 Transport phenomena in a fluid film with curvature elasticity. ARJIT MAHAPATRA, DAVID SAINTILLAN, PADMINI RANGAMANI, Department of Mechanical and Aerospace Engineering, University of California San Diego — Lipid bilayers are fluid films that are elastic in bending. Cellular membranes are lipid bilayers that contain different proteins, including ion channels, receptors, and scaffolding proteins. These proteins are known to diffuse in the plane of the membrane and to influence bending of the membrane. Experiments have shown that lipid flow in the plane of the membrane is closely coupled with the diffusion of membrane proteins. Thus there is a need for a comprehensive framework that accounts for the coupling between these processes. Here, we present a theory for the coupled in-plane viscous flow of lipids, diffusion of membrane proteins, and curvature elastic deformation of lipid bilayers. The proteins in the membrane are modeled such that they influence membrane bending by inducing a spontaneous curvature. We formulate the free energy for the system as a Helfrich-like curvature elastic energy density function modified to account for the chemical potential energy of proteins. Then, we apply the principle of virtual work to minimize the free energy and derive conservation laws and equation of motions. Finally, we present results from dimensional analysis and numerical simulations and demonstrate that asymmetry in protein distribution plays an important role in driving lipid flows.

7:58AM Q32.00002 Formation of vesicles in a viscous solvent: A hybrid coarse-grain/continuum approach. SZU-PEI FU, ROLF RYHAM, Fordham University, YUAN-NAN YOUNG, New Jersey Institute of Technology — In this talk a theoretical model for long-range, hydrophobic attraction between amphiphilic particles (such as lipid molecules) is developed to quantify the macroscopic assembly and mechanics of a lipid bilayer membrane in solvents. The non-local interactions between amphiphilic particles are obtained from the first domain variation of a hydrophobicity functional, giving rise to forces and torques (between particles) that dictate the motion of both particles and the fluid flow in the viscous solvent. Both the hydrophobic and hydrodynamic interactions between the coarse-grained amphiphilic particles are formulated into integral equations, which allow for accurate and efficient numerical simulations in two- and three-dimensions. Such hybrid coarse-grained model is validated by its capability to reproduce various physical properties of a lipid bilayer membrane. Furthermore we present simulation results of vesicle formation in both a quiescent flow and a pressure driven flow (as in the microfluidic jetting experiments). Finally we also illustrate how our hybrid model can be generalized to investigate the effects of local charges on the bending rigidity of a lipid bilayer membrane.

8:11AM Q32.00003 Hydrodynamic shear transmission across cellular membranes. DANIEL TAM, GUILLERMO AMADOR, MARIE-EVE AUBIN-TAM, TU Delft — A cell’s interactions with the environment are mediated by its cellular membrane. This nanometer-thick, liquid crystalline structure is mostly composed of a lipid bilayer, which serves as a scaffold for embedded proteins and other macromolecules. Many crucial cellular processes, such as growth, proliferation, and protein complex formation, are dependent on external mechanical stresses; therefore, understanding how cellular membranes generate and transmit forces may shed light on cell behavior and homeostasis. In this study, we use optical tweezers to both apply and measure local forces on free-standing lipid bilayers within microfluidic channels. The planar geometry of the lipid bilayer facilitates interpretation of measurements using hydrodynamic models. This technique is the first to combine multiple optical tweezers probes with planar free-standing lipid bilayers accessible on both sides of the bilayer. The aims of these measurements are to quantify fluid slip close to and transmission of shear forces across the bilayer surface, building towards a fundamental understanding of the physical principles governing the transfer of forces by and through the membrane.

8:24AM Q32.00004 Electric Field-driven Deformation and Translation of Vesicles in Microchannels. ADNAN MORSHEDE, PRASHANTA DUTT, Washington State University — Bio-mimetic vesicles like liposomes exhibit complex responses when exposed to electric pulses. Their lipid membranes bear close resemblance to biological cells. Yet the lack of internal cytoskeletons and transmembrane organelles lead to different membrane deformation characteristics. The response of these vesicles is also affected by the electrical properties of the media and vesicle size and shape. We investigated the electrodeformation and transport of bio-mimetic vesicles immersed in a fluid media under a DC electric field. The deformation characteristics of vesicle membrane was represented with a Mooney-Rivlin constitutive law. The electric field, flow field, and vesicle deformation are resolved with a hybrid immersed resolved technique. Additionally, electroosmotic flows are considered for a range of surface charge conditions. Depending on the direction and magnitude of the electroosmotic flow, tumbling, tank treading, and pure translational motions were observed. Furthermore, a logarithmic scaling is realized between the stretch ratio of the vesicle and shear rate under electroosmotic flows. Conductivity ratio of vesicle and the surrounding media is found as a key parameter in the translational motion as well.

ONR N00014-17-1-2628
8:37AM Q32.00005 Active particle penetration through a planar elastic membrane¹.

ABDALLAH DADDI-MOUSSA-IDER, BENNO LIEBCHEN, ANDREAS M. MENZEL, HARTMUT LOEWEN, Institut fuer Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universitaet Duesseldorf, Germany — Active penetration of nanoparticles through cell membranes is a fascinating phenomenon that may have important implications in various biomedical and clinical applications. Using particle-based computer simulations and theory, the penetration mechanism of an active particle through a planar elastic membrane is studied. The membrane is modeled as a self-assembled sheet of particles embedded in a Newtonian viscous fluid. A coarse-grained model is introduced to describe the mutual interactions between the membrane particles. Three distinct scenarios are identified, including trapping of the active particle, penetration through the membrane with subsequent self-healing, in addition to penetration with permanent disruption of the membrane. The latter scenario may be accompanied by a partial fragmentation of the membrane into bunches of isolated or clustered particles. Our approach might be helpful for the prediction of the transition threshold between the trapped and penetrated states in real-space experiments involving motile swimming bacteria or artificial active particles. Reference: A. Daddi-Moussa-Ider, B. Liebchen, A. M. Menzel, and H. Lwen, Theory of active particle penetration through a planar elastic membrane, New J. Phys. in press (2019).

8:50AM Q32.00006 Viscoelasticity of a bacterial extracellular polymeric substance (EPS) streamer filament using micro-rheology and microfluidics, ANDREW WHITE, MARYAM JALALI, JIAN SHENG, Texas A&M — Using Ecology-on-a-chip (eChip), we have demonstrated that polymeric aggregates can be formed around a rising oil micro-droplet by Pseudomonas. The EPS aggregate is initiated by forming trailing streamers with one end anchoring at the droplet surface and the other floating in the flow, which alters “wake” pressure field and consequently causes substantial drag on the streamers and their surrounding shear flows, viscoelastic behavior of streamers must be understood. Here, we apply micro-rheology technique to quantify real-time viscoelasticity of streamers developed in a pinned oil droplet in eChip. Using high speed microscopy, filament strain is determined by tracking trapped bacteria in real-time and concurrently viscous stresses are measured using PIV-assisted PTV of freely suspended bacteria. Stress-strain shows hysteresis of viscoelastic materials. Funded by GoMRI, ARO

9:03AM Q32.00007 Species and orientation differences in copepod behavior in a Burgers vortex, D. ELMI, S. SOUMYA, D.R. WEBSTER, Georgia Tech, D.M. FIELDS, Bigelow Laboratory for Ocean Sciences — We use a Burgers vortex experimental model to study the interaction of two marine copepod species (Temora longicornis and Acartia tonsa) with a single turbulent-like eddy structure. Tomographic-PIV experiments were performed at small-scale to quantify the velocity field of turbulent vortices modeling those that copepods encounter in their oceanic habitat. Turbulence intensities are discretized into four levels corresponding to dissipation rates of 0.002 to 0.25 cm²/s³. Three-dimensional swimming trajectories are retrieved from two orthogonal camera perspectives and overlaid on the Burgers vortex velocity structure to identify individual swimming kinematics and behavioral differences. We use apparatuses with the vortex axis aligned in horizontal and vertical directions to argue that the copepods are sensitive to the directionality of the hydrodynamic signal. By comparing the behavioral change in an observed flow field, the Pirouette-Driver or control treatment, we provide a framework to identify trends in behavioral responses. Both species of copepods increase their relative velocity as the strength of the Burgers vortex increases and the trend appears stronger in the vertically-aligned vortex. Further, the number of circular-shaped trajectories around the vortex core increases with increasing strength of the Burgers vortex for both species, and the trend is stronger for A. tonsa. These trends, together with the statistical analysis, suggest that changes in oceanic turbulence intensity as a result of climate change would affect the distribution of copepods.

9:16AM Q32.00008 An experimental implementation of a two-sphere swimmer at low Reynolds numbers, OLIVER SILVERBERG, BRENT HOSOUME, NIKHIL TRIVEDI, CONNOR TISCH, Mechanical Engineering, Santa Clara University, DANIEL PLASCENCIA, Bioengineering, Santa Clara University, MATTHEW HOLMES, ON SHUN PAK, Mechanical Engineering, Santa Clara University, LORICATION AT LOW REYNOLDS NUMBERS encounters stringent constraints due to the dominance of viscous over inertial forces. Various elegant designs have been proposed to escape from the constraints of the scalar theorem and generate self-propulsion. In this talk, we present a macroscopic experimental implementation of the PushmePullyou swimmer (J. E. Avron, O. Kenneth, D. H. Oaknin, New J. Phys., 7, 234, 2005), which consists of a pair of expandable spheres connected by an extensible link. We characterized the propulsion performance of the swimmer in the low Reynolds number regime with the use of highly viscous silicone oil and compared the results with theoretical predictions.

Session Q33 Flow Instability: Control 615 - Mathew Juniper, University of Cambridge

7:45AM Q33.00001 Shape Optimization for Stability of a Cyclone Separator, MATTHEW JUNIPER, JACK BREWSTER, University of Cambridge — A cyclone separator uses a swirling flow to remove particles from a particle-laden fluid. Cyclone separators are frequently used in domestic applications and in industries for clean contamination and in industries for gases. At practical Reynolds and swirl numbers, the steady axisymmetric flow through a cyclone becomes linearly unstable. It develops a precessing vortex core (PVC) which is responsible for increased pressure loss and unwanted acoustic noise. Unsteady mixing caused by the precession also leads to the re-entrainment of separated particles. We perform shape optimization of a cyclone separator in order to weaken this instability. The onset of the PVC appears as an unstable global mode with azimuthal wavenumber m = 1. We calculate the shape gradient of the growth rate of this global mode. We identify the boundary regions that most influence the growth-rate and then use a gradient-based method to update and optimize the geometry. We interpret this physically and also present a family of orthogonal geometry changes that cause the greatest changes in the cyclones base-flow. Theis process highlights the geometry changes that a parametrisation must be able to reproduce in order to effectively optimize a cyclone.

7:58AM Q33.00002 Control of Laminar-turbulent transition on a natural laminar flow airfoil, JOHN WYLIE, KEITH TAYLOR, MICHAEL AMITAY, Rensselaer Polytechnic Institute — Tollmen-Schlichting (T-S) waves are the principal mechanism for laminar- turbulent transition over external surfaces. The present work aims to identify T-S waves on a natural laminar flow airfoil in the presence of an adverse pressure gradient, and subsequently reduce or eliminate the amplitude of identified T-S waves, developing a new control technique to transition from turbulence to laminar. Oscillating Surface (PDOS) actuators were used at three corresponding streamwise locations. These actuators act as dynamic surface modification, which both introduce artificial T-S waves, and subsequently cancel these waves. In the study, two upstream actuators were used to excite and phase-lock the T-S waves through systematic oscillation. The downstream actuator was used to cancel the T-S waves by applying an anti-phase disturbance at the proper amplitude. Particle Image Velocimetry was used to observe the development of the T-S waves and to characterize the three-dimensional development of the T-S waves along the airfoil model. The results indicate a dampening of the T-S wave magnitude, resulting in a delay of the transition of laminar to turbulent flow in the presence of a known adverse pressure gradient.
8:11AM Q33.00003 Nonlinear Performance of Linear Sensor-Based Output Feedback Control of Transitional Channel Flow

YIYANG SUN, HUAIJIN YAO, MAZIAR S. HEMATI, University of Minnesota

A large transient energy growth (TEG) of small flow perturbations can lead to laminar-to-turbulent transition in channel flow at sub-critical Reynolds number. Full-state feedback control, such as linear quadratic regulation (LQR), has been demonstrated to suppress TEG and prevent transition; however, access to full-state information is rarely possible in practice. In this study, we investigate two sensor-based output feedback control strategies: (1) static-output-feedback LQR and (2) linear quadratic Gaussian (LQG) control. These controllers use a few sensor measurements at the walls to determine the control input. We study the nonlinear effects on TEG behavior and transition control effectiveness by performing direct numerical simulations (DNS). We find that the nonlinearity serves to saturate TEG, with amplification being reduced as the initial disturbance amplitude is increased. Accordingly, the reduction of TEG in the controlled case also decreases, indicating a degradation of control performance when nonlinear effects become substantial. For LQG control, the nonlinear effects on the relation between physical and estimated states are examined. We investigate the estimator performance in DNS and further assess its influence on the control results.

8:24AM Q33.00004 Resolvent-based Modelling, Estimation and Control of the Cylinder Wake

BO JIN, RICHARD SANDBERG, SIMON ILLINGWORTH, The University of Melbourne

We use a resolvent based approach for the modeling, estimation and control of the cylinder wake at Reynolds numbers between 40 and 120. The work has three parts. First, we consider the optimal estimation problem in which a single sensor is used to estimate the whole flow field. Second, we consider full-information control in which a single actuator uses knowledge of the entire flow field for control. Third, we consider feedback control with a single sensor for measurement and a single actuator for control. A range of Reynolds numbers is considered and the trends of optimal sensor and actuator placements for estimation and control are presented.

8:37AM Q33.00005 Experimental Study of Laminar Separation Bubbles with Active Flow Control

DAVID BORGMAN, JESSE LITTLE, University of Arizona

Laminar separation bubbles (LSB) that form under the influence of an adverse pressure gradient are examined in a low turbulence wind tunnel. The LSBs are formed along the surface of a flat plate using a displacement body that is mounted from above. Rapid formation of spanwise vortical structures due to the primary shear layer instability promotes transition to turbulence and determines the extent of the separated region. Direct numerical simulations have shown the effectiveness of vortices that exploit the shear layer instability for active flow control (AFC). AFC in the form of 2D disturbance waves leads to the formation of coherent spanwise vortical structures that can reduce or completely eliminate the LSB. With a properly chosen forcing frequency and amplitude, the secondary absolute instability can be suppressed thus delaying transition and even relaminarizing the flow downstream of reattachment. The success of this AFC strategy is strongly affected by freestream turbulence where even modest levels can reduce the control authority due to excitation of Klebanoff modes. Therefore, the question arises whether the observed transition delay and relaminarization is possible in a real environment. This motivates a study of LSB AFC on a flat plate using DBD plasma actuators.

8:50AM Q33.00006 Suppressing flow separation over a flat plate using machine learning

AMIRKHOSRO KAZEMI, Florida Atlantic University

We examine supersonic flows over a 3D cavity at Mach number of 1.4 with cavity-depth-based Reynolds number of 10,000 using LES and propose a resolvent analysis based flow control technique to suppress the pressure fluctuations over the cavity. The relevant analysis identifies the range of the forcing frequency and spanwise wavenumber for the turbulent cavity flow where energy amplifies significantly. Given these insights from resolvent analysis, we perform a series of controlled flow simulations by prescribing the unsteady actuation with various combinations of the spanwise wavelength and actuation frequency over the supersonic turbulent cavity flow. The controlled achieves over 28% of reduction in pressure fluctuations. By combining the insights from resolvent analysis with DMD of the 3D cavity flows, we uncover two main mechanisms responsible for effective suppression: (1) the unsteady actuation thickens the shear layer near the leading edge and modifies its spreading rate to reduce the receptivity to acoustic disturbances; (2) the actuation disrupts the formation of large-scale spanwise vortices which mitigates the obstruction of incoming flow and alleviates the trailing-edge impingement.

9:03AM Q33.00007 Supersonic cavity flow control using resolvent analysis

QIONG LIU, University of California, Los Angeles

We examine supersonic flows over a 3D cavity at Mach number of 1.4 with cavity-depth-based Reynolds number of 10,000 using LES and propose a resolvent analysis based flow control technique to suppress the pressure fluctuations over the cavity. The resolvent analysis identifies the range of the forcing frequency and spanwise wavenumber for the turbulent cavity flow where energy amplifies significantly. Given these insights from resolvent analysis, we perform a series of controlled flow simulations by prescribing the unsteady actuation with various combinations of the spanwise wavelength and actuation frequency over the supersonic turbulent cavity flow. The controlled achieves over 28% of reduction in pressure fluctuations. By combining the insights from resolvent analysis with DMD of the 3D cavity flows, we uncover two main mechanisms responsible for effective suppression: (1) the unsteady actuation thickens the shear layer near the leading edge and modifies its spreading rate to reduce the receptivity to acoustic disturbances; (2) the actuation disrupts the formation of large-scale spanwise vortices which mitigates the obstruction of incoming flow and alleviates the trailing-edge impingement.

ANDRE POPINHAK, ROBERT MARTINUZZI, CHRIS MORTON, University of Calgary

Estimation of an unsteady velocity field with remote sensors is an important tool for many technological applications and an integral part of flow control strategies. Many works in the current literature have implemented sensor-based flow estimation via pressure-velocity correlations in wake-flows (e.g. Hosseini et al. 2015). Using the theoretical model of von Kármán Vortex Street, the aim of this work is to (i) understand whether sensor placement impact in the performance of the estimators. (ii) What is the benefit of using Quadratic Stochastic Estimation (QSE) relative to Linear Stochastic Estimation? (iii) What is the benefit of formulating QSE into a set of orthogonal regressors? It will be shown that the discrete pressure information location relaxes the training method requirement and a proper selection of an orthogonal basis for the estimator reduces overfitting.
Asymmetric instabilities in the flow of thin films on fibers. Chase Gabbard, Joshua Bostwick, Clemson University — Understanding the dynamics of thin-film flow down a vertical fiber is valuable for many coating applications. It is well known that such flows give rise to a number of instabilities that define the bead-on-fiber morphology. These include Plateau-Rayleigh breakup, isolated bead formation, and convective instabilities, all of which leave the interface shape axisymmetric. We conduct experiments that reveal an asymmetric instability in the flow of liquid on a fiber, which depends critically upon the liquid properties, flow rate and fiber radius, and we document this dependence on the observed morphology. Multiple liquids were used to change the viscosity and surfactant is used to control the surface tension in order to capture the transition between symmetric and asymmetric. Interestingly, we observe that under certain conditions in the transition region the instability may change from asymmetric to symmetric at some distance down the fiber.

Simulating instabilities of liquid metal alloys on nanoscale using molecular dynamics simulations.1 Ryan Allaire, New Jersey Institute of Technology, Miguel Fuertes-Cabrera, Oak Ridge National Laboratory, Philip D. Rack, The University of Tennessee, Knoxville, Linda Cummings, Lou Kondic, New Jersey Institute of Technology — Classical molecular dynamics simulations are used to investigate the influence of phase separation of liquid metal alloys on Rayleigh-Plateau (RP) type instabilities of free standing alloy lines, as well as alloys deposited on substrates. The alloy geometries are created in thin strips with widths modulated by sinusoidal waves of varying amplitudes and wavelengths, corresponding to the fastest growing mode obtained from continuum RP theory. We explore the influence of temperature on the breakup process and phase separation. Both the ratio of phase separation length scales to wavelengths of the sinusoidal perturbations, and the initial location of phase separation are found to influence the RP instability development, either by modifying the stability characteristics of material. The pattern formation process is robust: the crystal structure exhibits self-healing of initial or accidental defects. Existing theories (for example, spatio-temporal stability analysis) are adapted to our problem so as to rationalize our experimental results. In turn, we aim to take advantage of our model for the directed control of the instability toward the design of materials with prescribed properties and function.

Electrohydrodynamic patterning of non-Newtonian thin films. Adham RiaD, Hadi NazariPooR, Ali MohammadTabar, Mohtada Sadrzadeh, Department of Mechanical Engineering, University of Alberta — Electrically driven instabilities of thin liquid films or electrohydrodynamic (EHD) induced patterns has gained popularity for its ability to create nano-sized features for various applications. An initially quiescent thin film of uniform thickness is sandwiched between two electrodes. A voltage is then applied across the electrodes, creating a destabilizing electrostatic pressure on the interface, causing surface deformations and patterns to evolve. A mathematical model is developed to study the effect of power-law on the EHD patterning process. Simplifying the governing equations using the long-wave approximation leads to a novel thin-film equation that describes the interface’s dynamics for both pseudo-plastic and dilatant fluids. The spatiotemporal evolution of the patterning process is then numerically simulated by solving the nonlinear thin-film equation using a finite-difference based discretization scheme and an adaptive time step solver. The results show that the patterning time is strongly influenced by the power-law index and is significantly shorter for shear thickening than shear thinning fluids. Moreover, morphological changes between patterns of shear thinning and shear thickening fluids are correlated to local viscosity variations.

Electrohydrodynamic instability of viscous falling films: numerical verification of weakly nonlinear models and higher-order effects. Tao Wei, MengQi Zhang, National University of Singapore — A study on the nonlinear stability of an electrified film flowing under gravity down an inclined plate is performed with an electric field acting normal to the plate. An asymptotic expansion is applied to derive a nonlinear evolution equation for the interfacial position in the long-wave limit, which retains terms up to 2nd-order in the small parameter. Numerical solutions to two weakly nonlinear models, considering distinct effects of hydrostatic pressure, inertia and viscous dispersion, are compared to those of the fully nonlinear equation with an electric Weber number well above the critical value from linear analysis. Single- and multiple-kump solitary waves are searched for a weakly granular dispersion problem. Two coupled Ginzburg-Landau-Lindau equations are derived from a multiple-scale analysis, which suggests that the electric destabilization occurs in the form of travelling waves of finite amplitude. The leading-order solutions show that one order-of-magnitude increase in electric supercriticality will cause one order increase in the growth rate. Reasonable agreement is found between the present results and available experiments. In particular, for realistic parameter values an electric field can reduce the film thickness.

Thin water film rise on a rough surface of a vertical plate in water entry.1 Nayoung Kim, HyungMin Park, Seoul National University — A three-phase contact line is formed as a liquid film moves over the solid surface, and the maximum velocity at which the film does not separate from the surface is affected by several liquid properties, such as viscosity, density and surface tension. In addition, it has been shown that surface roughness can also encourage the early film moves over the solid surface, and the maximum velocity at which the film does not separate from the surface is affected by several liquid properties, such as viscosity, density and surface tension. The leading-order solutions show that one order-of-magnitude increase in electric supercriticality will cause one order increase in the growth rate. Moreover, morphological changes between patterns of shear thinning and shear thickening fluids are correlated to local viscosity variations.

Simultaneous Liquid Flow and Drying on Rotating Cylinders

CHANCE PARRISH, SATISH KUMAR, Department of Chemical Engineering and Materials Science, University of Minnesota — The coating and drying of non-flat discrete objects is an important manufacturing step for a broad variety of products. Flow of a thin, non-volatile liquid film on the outside of a rotating cylinder is commonly used as a model problem for these processes. Here, we use lubrication theory to study the behavior of a volatile, particle-laden coating. Two coupled evolution equations describing variations in coating thickness and composition as a function of time and the angular coordinate are solved numerically. In the limit of a rapidly-rotating cylinder, results from linear stability analysis and nonlinear simulations demonstrate that non-uniform drying at larger drying rates may cause thickness and composition disturbances to regrow after initially decaying. When gravity is reincorporated, poor leveling of the coating thickness at lower rotation rates and larger drying rates leads to less uniform coatings. Colloidal particles hinder leveling at high concentrations through increases in the viscosity, but help prevent coating rupture at more moderate concentrations, leading to a composition “sweet spot”. A parametric study is then used to show that thickness and composition variations are minimized at a large rotation rate, low drying rate, and moderate particle concentration.

Three-dimensional numerical simulations of a thin film falling vertically down the inner surface of a rotating cylinder

JASON STAFFORD, University of Birmingham, UK, CAMILLE PETIT, OMAR MATAR, Imperial College London — A flow in which a thin film flows due to gravity on the surface of a rotating cylinder is investigated. This was performed using high resolution three-dimensional direct numerical simulations and a volume-of-fluid approach to treat the interface. The variation of the Ekman number (Ek), defined to be proportional to the rotation of the cylinder, and has a significant effect on various parameters of the flow. The centrifugal force increases with rotational speed, producing a stabilising effect (Iwasaki and Hasegawa, 1981), supressing wave formation. Key features, such as the transition from a 2D to a more complex 3D wave regime, and the local thickness of the film, are heavily influenced by this stabilisation and are investigated. Furthermore the imposed rotation results in distinct characteristics in the flow such as the development of angled waves due to the resolved velocity in the axial and azimuthal directions. Fast Fourier Transforms of the interface are performed which show how the wavelength and angle of the waves varies with Ek. Simulations have been conducted for a range of Ek to provide detailed insight on how this parameter affects the flow.

Thermally driven coalescence in thin liquid film flowing down a fiber

CLAUDIA FALCON, HANGJIE JI, Department of Mathematics, University of California, Los Angeles, ABOLFAZL SADEGHPOUR, ERFAN SEDIGHI, Y. SUNGTAEK JU, Mechanical and Aerospace Engineering Department, University of California, Los Angeles, ANDREA BERTOZZI, Department of Mathematics & Mechanical and Aerospace Engineering Department, University of California, Los Angeles — We aim at understanding the dynamics of thin fluid film flowing down a vertical fiber under streamline thermal effects, both experimentally and theoretically. Recent studies have shown the importance of determining the regime transition from absolute to convective instability. Unlike previous work, our experiments demonstrate that the onset of such irregular wavy regime can also be induced by thermal gradient away from the nozzle. The new model includes spatial-dependent viscosity and surface tension due to inhomogeneous temperature field along the fiber. The predicted coalescence positions based on this theory are useful in the design of heat and mass exchangers for applications that include cooling systems and desalination.

Rapid and multiplexed enrichment of specific DNA sequences using isotachophoresis

ASHVIN RAMACHANDRAN, Stanford University, NOBUYUKI FUTAI, Shibaura Institute of Technology, CATHERINE HOGAN, KANAGAVEE MURUGESAN, NIAZ BANAEI, JUAN G. SANTIAGO, Stanford University — We use on-chip isotachophoresis (ITP) to create electric-field-driven shock waves of ion concentration, which are formed at the interface between a high mobility leading electrolyte (LE) and a low mobility trailing electrolyte (TE). Ionic species with mobilities bracketed by these electrolyte species focus at the LE-to-TE interface. For trace sample concentrations, multiple species co-focus, pre-concentrate by 10,000x and react inside a single, order 10 um wide zone. We apply ITP to extract and purify DNA targets from complex biological samples and to immediately co-focus these with synthetic DNA/RNA probes. We complete in 30 min hybridization reactions which would normally take several days, and then separate reacted from unreacted DNA. We will present our work toward rapid and sequence-specific enrichment of rare DNA targets for two applications. First, we are developing miniaturized microfluidic capillary electrophoresis chips for use in Point-of-Care (PoC) devices, where our unique hybridization platform can perform miniaturized high-throughput DNA/RNA sequencing. Second, we have adapted our enrichment protocol for use in a clinical setting, where we can use our protocol to boost the sensitivity of a commercial PCR assay for tuberculosis. Here, we will present preliminary results from both applications.

Fast and homogenous mixing in a coaxial capillary device with two sheath flows

DIEGO A. HUYKE, ASHVIN RAMACHANDRAN, Stanford University, THOMAS KROLL, DANIEL P. DEPONTE, SLAC National Accelerator Lab, JUAN G. SANTIAGO, Stanford University — We have developed a novel microfluidic mixer with order 10 microsecond mixing times, and sample consumption of 1 to 500 nL/s. Importantly, the mixer achieves flow-area-weighted residence time distribution with a standard deviation width of 140 microsecond (for a 2.8 ms center-streamline residence time). In our mixer, the low flow rate sample stream which exits an inner capillary is hydrodynamically focused to a sub-micron radius by the high flow rate sheath stream within a tapered middle capillary. The mixed stream subsequently enters a third, outer capillary wherein its area (normal to the flow direction) is expanded 200 times to increase the sample detection volume. The latter expansion of the mixed stream decouples the upstream mixing region from the downstream probing region and increases the signal-to-noise (SNR) for line-of-sight integration techniques. The outermost capillary is constructed from glass or polyimide for, respectively, optical or hard X-ray sample detection. Analytical and numerical convection-diffusion models, design, and experimental validation of the mixer will be presented. The models will explore tradeoffs between mixing rate and homogeneity for different flow conditions. We validated the models and experimentally studied mixing performance using epifluorescence imaging of fluorescein-iodide quenching.
8:11AM Q35.00003 Joule heating-enabled nanoparticle enrichment in insulator-based dielectrophoretic microdevices. AMIRREZA MALEKANFARD, ZHIJIAN LIU, XIANGCHUN XUAN, Clemson University — Dielectrophoresis has become a popular method for particle manipulation in microfluidic devices. It requires electric field gradients that can be created using in-channel hurdles and posts etc. However, these insulating structures amplify the Joule heating effect, leading to a non-uniform fluid temperature and in turn gradients in fluid conductivity and permittivity (as well as viscosity). The action of electric field on the Joule heating-induced fluid property gradients causes a regional fluid flow in the form of vortices. This so-called electrothermal flow has been previously found to reduce the particle focusing and trapping performance in insulator-based dielectrophoretic microdevices. We demonstrate in this work that the electrothermal flow vortices can be utilized to entrain nanoparticle-based localized enrichment near the insulating tips of a ratchet microchannel. We also develop a depth-averaged numerical model to simulate the fluid, heat, charge and mass transport involved in the process. A good agreement is obtained for each of the various parametric studies.

8:24AM Q35.00004 Rapid mixing utilizing microscale magnets based on microfluidics device. RAN ZHOU, MARCEL MEIJULU, Purdue University Northwe...tualization of the nanowire diode. This non-contact measurement method suggests a relation between the permanent dipole and the depletion width of the nanowire diode. In this paper, we propose a miniaturized and integrated microfluidic device that can achieve the rapid mixing of ferrofluid and distilled water. To accomplish this, high-gradient microscale magnet was fabricated and integrated at one side of a microfluidic channel by a simple fabrication technique. The microscale magnet was fabricated by injecting and curing a mixture of neodymium powder in a structural channels, and subsequent permanent magnetization. This study further investigates the effect of the total flow rate and ferrofluid concentration on the mixing performance.

8:37AM Q35.00005 Electrical Double Layers: Predicting Overcharging and Layering of Ions using Continuum Models. ANKUR GUPTA, ANANTH GOVIND RAJAN, EMILY CARTER, HOWARD STONE, Princeton University — Electrical double layers (EDLs) form the basis for several phenomena such as electrophoresis, supercapacitor charging and discharging, and desalination. However, existing continuum models for the EDL are unable to predict experimentally-observed phenomena such as ion layering and EDL overcharging. To overcome these limitations, atomistic methods like classical density functional theory and molecular dynamics simulations have been employed to elucidate the nanoscale structure of EDLs. In this work, we bridge the gap between the continuum and atomistic approaches by proposing a modified continuum model. Our model predicts a near-wall stratified structure in EDLs wherein the cations and anions are arranged in layers, even in the dilute limit. Furthermore, we predict that for trivalent ions, the double layer can locally possess a net charge larger than the surface, a phenomenon commonly known as overcharging. Our model does not require any fitting parameters or additional boundary conditions, and only depends on the ion properties since our approach is at the continuum scale, we envision that it can be readily extended to out-of-equilibrium systems such as electrophoresis and dynamics of supercapacitors.

8:50AM Q35.00006 Electroosmotic flow in small-scale channels induced by surface-acoustic waves. MATHIAS DIETZEL, STEFFEN HARDT, Institute for Nano- and Microfluidics, TU Darmstadt — Apart from acoustic streaming as the primary effect, surface-acoustic waves (SAWs) go along with time-periodic changes of the electrostatic potential at a solid-liquid interface. This surface potential polarizes the liquid in its vicinity, i.e. it induces a dynamic Debye layer. Alternating current electroosmosis (ACEO) relies on a similar principle. We study the flow field due to the interaction of the dynamic Debye layer with the electric field of the SAW. For this purpose, we consider parallel-plates channels less than 500 nm wide, characterized by an inverse RC time of the Debye layer similar to the characteristic SAW frequencies in the MHz range. By means of numerical simulations of the unsteady Stokes, Poisson, and Navier-Stokes equations, parametric studies are conducted, varying the SAW frequency and amplitude, ionic strength, Debye parameter, as well as the phase shift between two SAWs traveling along opposite channel walls. We demonstrate that for typical SAW amplitudes sizable (time-averaged) net velocities up to 1 mm/s can be obtained, especially if the phase shift equals 180 deg to maximize the periodic electric current between the walls. This significantly exceeds the velocities induced by acoustic streaming in narrow channels.

9:03AM Q35.00007 Stern compact layer in ionic conductor liquid charging at high voltages1. FARZAD MASHAYEK, BABAK KASHIR, ANTHONY E. PERRI, ALEXANDER L. YARIN, University of Illinois at Chicago — The Stern compact layer at the conducting electrodes is studied theoretically and numerically. These electrodes are subjected to high voltages and sustain electric current. A novel approach is developed based on the Brunauer-Emmet-Teller (BET) mechanism to predict the thickness of the Stern compact layer. Non-specific (non-electric) adsorption is responsible for the formation of this layer on the oxide islands or impurities at the conducting electrodes. Concurrently, kinetics-limited faradaic reactions occur at the unscreened parts of the metallic conducting electrodes. The electron transfer occurs through the faradaic reactions characterized by the Frumkin-Butler-Volmer kinetics. The model relates the thickness of the Stern compact layer to the potential drop across it. Realistic values of the applied electrode voltage and sustained electric current density in electrostatic atomization are considered to predict the Stern compact layer properties.

9:16AM Q35.00008 A non-contact solution-based method to measure the electric dipoles of p-n silicon nanowire diodes. MINH THANG HOANG, Rutgers University, GOZDE TUTUNCUOGLU, AMAR MOHABIR, Georgia Institute of Technology, LEONARD FELDMAN, Rutgers University, MICHAEL FILLER, Georgia Institute of Technology, JERRY SHAN, Rutgers University — Dispersions of nanowires with p-n junctions are emerging as next-generation electronic colloidal materials. Developing the ability to efficiently manipulate such nanostructures for both characterization and separation based on electronic properties is crucial for scientific understanding and technological applications. Here we present a method for measuring the permanent and induced dipoles of p-n doped silicon nanowires by observing their rotation in fluid suspension under external electric fields. The permanent dipoles are formed by the opposite charges in the depletion layer at the p-n junction, while the induced dipoles are formed by nanowire polarization under the external field. The measured electrical torque exerted on the p-n nanowires due to applied DC and AC fields yields the permanent and induced dipoles. We then show how the dipoles change for nanowires of various doping concentrations and surface passivations. Numerical results also suggest a relation between the permanent dipole and the depletion width of the nanowire diode. This non-contact measurement method offers a new approach to efficiently determine the electronic properties of p-n nanowires, and is a significant step toward the high-throughput characterization and separation of complete nanowire devices.

on the sign of the diffusiophoretic coefficient $D_{diff}$. Mixing is delayed when $D_{diff} > 0$ (salt-attracting configuration), or faster when

$D_{diff} < 0$ (salt-repelling configuration). In both configurations, as for molecular diffusion alone, large scales are barely affected in the dilating
direction while the Batchelor scale for the colloids, $\ell_{c, diff}$, is strongly modified by diffusiophoresis. We propose here to measure a global effect of diffusiophoresis in the mixing process through an effective Péclet number built on this modified Batchelor scale. Whilst this small scale is obtained analytically for the stagnation point, in the case of chaotic advection, we derive it using the equation of gradients of concentration, following Raynal & Gence (1997). Comparing to numerical simulations, we show that the mixing time can be predicted by using the same function as in absence of salt, but as a function of the effective Péclet numbers computed for each configuration.

Tuesday, November 26, 2019 7:45AM - 9:42AM –
Session Q36 Microscale Flows: Drops and Bubbles 618 - Prashant Valluri, University of Edinburgh

7:45AM Q36.00001 Deformability-induced inertial focusing of viscous droplets1, SOO-JUNG HUR, MEHRAN ABOULGHASEMIBIZAKI, Johns Hopkins University — Deformability-induced lateral migration of soft objects across the streamlines in microchannels provides a robust and continuous way of manipulating droplets and cells inflow. Theoretical analysis has shown that there exists a force away from channel walls in Poiseuille flow that locates deformable particles closer to the channel center than rigid counterparts. As lateral lift forces acting on flowing objects scale with carrier fluids’ properties, the deformability can be extrapolated from the positions of objects with known sizes in the channel. Here, behaviors of nearly-neutrally buoyant microscale droplets of various sizes, interfacial tensions, and viscosities were tested to determine droplet’s physical attributes and flow conditions, enhancing their lateral migration. Fluorinated oil solutions ($\mu =1.7\text{mPas}$ and $5\text{mPas}$) containing droplets ($1\text{mPas}<\mu<1.3\text{Pas}$) were injected into a microfluidic channel at $R_e<50$. The interfacial tensions were varied by adding a controlled amount of a surfactant. The diameter, deformability, and lateral equilibrium position were determined using high-speed microscopy. Through dimensional analysis, we identified critical conditions to inertially-focus deformable droplets in Poiseuille flow. The results suggest that accurate measurements of lateral positions of deformable droplets will provide a means to establish the fundamental understanding required to estimate apparent deformability of flowing objects in high-speed.

7:58AM Q36.00002 Dynamics of High-speed Droplet Generation in Gas-liquid Microfluidic Systems1, POOYAN TIRANDAZI, JULIAN D. ARROYO, CARLOS H. HIDROVO, Northeastern University — In this work we study the interaction of liquid and gas in flow-focusing microchannels with the goal of reproducible generation of microscale droplets in air. The microfluidic channels are fabricated in Polydimethylsiloxane (PDMS) based on established lithography techniques and feature a non-planar architecture to enable the formation of liquid jets and droplets within air. A comprehensive flow map is developed based on the interaction of liquid and gas for a wide range of flow conditions and different channel sizes. In particular, we focus on the characteristics of the Dripping and Jetting modes of droplet formation and present information regarding droplet and jet sizes and breakup frequencies in this system. We show that the microfluidic chips reproducibly generate droplets with frequencies in the order of 10kHz and droplet sizes between $160\mu$m and $50\mu$m in the Dripping mode, whereas, for the Jetting we obtain droplets from $50\mu$m down to $15\mu$m at frequencies higher than 100 kHz. Finally, we briefly discuss some applications of high-speed gas-liquid microfluidics, namely for oil-free polymer particle fabrication and gas sensing using sample digitization with microdroplets.

8:11AM Q36.00003 Microfluidic droplet manipulations via modulation of interfacial tension1, THOMAS CUBAUD, Stony Brook University — The dynamic response of viscous droplets to variations of interfacial tension with the continuous phase is experimentally investigated in microchannels. Microfluidic segmented flows of oil droplets are continuously generated in methanol or ethanol to produce regular patterns that are injected into a focusing section with another alcohol solvent. To probe the role of fluid properties on droplet deformations, a range of fluid combinations are examined with focus on large droplet elongations for vanishing interfacial tension between droplets and continuous phase. This work shows the possibility to process high-viscosity fluid droplets in a variety of solvents in confined microsystems.

8:24AM Q36.00004 Crystallisation-Induced Flows in Evaporating Aqueous Saline Drops, MARINA EFSTRATIOU, JOHN CHRISTY, KHELLIL SEFIANE, Institute of Multiscale Thermofluids, School of Engineering, University of Edinburgh — When aqueous saline droplets are left to dry on hydrophilic glass slides, a ring of spaced crystals is formed. However, no experimental work has yet linked the flows arising in these droplets with the final crystal ring deposition. In our work, we have performed micro-PIV (Particle Image Velocimetry) to examine the link between the flow along the base of the drop and the final deposit. We report for the first time the existence of a nucleation-driven flow within the droplets which appears to be responsible for the formation of the crystal ring on the periphery of the drops. Three evaporation stages were observed. During stage I, a generally outward flow is manifested driven by evaporative flux, since the evaporation rate is higher on the periphery. After stage I, a transition stage II is shown during which the flow almost momentarily pauses, that is believed to occur at the point where the concentration near the periphery is that of the incipient nucleation. Stage III is governed by the appearance of strong flow jets, directed at the growing crystal, and vortices to either side of the crystal. This flow regime is driven by concentration gradients occurring due to crystal nucleation, demonstrating for the first time how crystal nucleation affects the flow.
In this work, we study the emergence of superwalking behavior in droplets. Superwalkers are droplets that travel at speeds greater than triple the speed of the fastest ones, and enable a plethora of novel multi-droplet behaviors. Physical insights from numerical simulations confirm that superwalkers arise from the interplay between the droplet and its wave field. We have studied walking droplets in the presence of two driving frequencies and have observed a new type of droplet breakup, where two aqueous phases protrude simultaneously from the branches, leading to the simultaneous droplet breakup from two interfaces. This phenomenon suggests that the changes in pressure between the interfaces and within the droplets play an important role in the emergence of superwalking behavior. Our experimental results are validated against the results obtained from this analytical model.

7:58AM Q37.00002 Experimental and theoretical investigation of capillary oscillations of a charged droplet levitated using various applied waveforms. NEHA GAWANDE, MOHIT SINGH, Y.S. MAYYA, ROCHISH THAOKAR, Indian Institute of Technology Bombay, Mumbai — A conducting charged droplet levitated in a quadrupole trap becomes unstable when the surface charge on the droplet exceeds its Rayleigh limit. However, when the charge on the droplet is in the sub-Rayleigh limit, it exhibits capillary oscillations whose amplitude and frequency depend upon the magnitude of the charge as well as on the applied electric field. In this work, we present the high-speed imaging of the surface oscillations of a highly charged droplet levitated using various applied waveforms such as sine, square and ramp wave. The surface dynamics is characterized by Fast Fourier Transformation (FFT) analysis and it is observed that the droplet oscillates with the applied frequency irrespective of the type of the waveform. To understand the experimental observation an asymptotic theory is carried out for a perfectly conducting charged droplet in the potential flow limit with viscous corrections. The analysis suggests that the droplet oscillation behavior is the result of complex interplay between the dipolar charge (FFT) analysis and it is observed that the droplet oscillates with the applied frequency irrespective of the type of the waveform. To understand the experimental observation an asymptotic theory is carried out for a perfectly conducting charged droplet in the potential flow limit with viscous corrections. The analysis suggests that the droplet oscillation behavior is the result of complex interplay between the dipolar charge.

8:11AM Q37.00003 Rheological measurements of gels via ultrasonic levitation of gel drops1. J.R. SAYLOR, XINGCHEN SHAO, Clemson University, STEVEN FREDERICKS, University of Minnesota, JOSHUA BOSTWICK, Clemson University — The application of ultrasonic levitation to the measurement of surface tension of liquid drops has a rich history. However this method has not been extended to gels which, unlike liquids, have a finite elasticity. Herein a method is presented for obtaining measurements of elasticity, surface tension, and viscosity of ultrasonically levitated gel drops. Agarose, a hydrogel, was the material explored. This approach is a significant development given that gels are of growing importance due to their relevance to biomedical applications and exhibit behaviors partially determined by their elasticities. Moreover, obtaining surface tension of gels is important but challenging since measurements cannot be made using standard Wilhelmy plate or DuNuoy ring methods, each of which cannot be applied without breaking the gel. Herein a theoretical development is presented which enables obtaining elasticity, surface tension, and viscosity of a gel drop from characteristics of its response to ultrasonic excitation. Measurements of surface tension and viscosity obtained using this approach are obtained for gel drops having viscosities ranging from 12.2 Pa to 200.3 Pa.

8:24AM Q37.00004 Delayed coalescence of drops at moving liquid/liquid interfaces2. WEHELIYE HASHI WEHELIYE, TENG DONG, ThAMeS Multiphase, Department of Chemical Engineering, University College London, WCIE 6BT, FEI WANG, Beijing Institute of Space Long March Vehicle, No1. Nadandhongmen Road, Fengtai District, Beijing, 100076, China, PANAGIOTA ANGELO2, ThAMeS Multiphase, Department of Chemical Engineering, University College London, WCIE 6BT — In this work, the delayed coalescence of drops with moving interfaces between two immiscible liquids were experimentally investigated. The aqueous phase was 78% Glycerol/water solution and the organic phase was Exxsol D80 oil. It was found that the coalescence was delayed when the interface moved and the delay time increased with the speed of the interface. The delay was attributed to the lubrication pressure in the film trapped between the drop surface and the bulk interface. Particle Image Velocimetry (PIV) was used to study the velocity fields while the structure of the thin trapped film was investigated with the Planar Laser Induce Fluorescence (PLIF) technique. The film was found to form a dimple symmetrical to the centerline when the interfaces had low velocity, while the dimple was less obvious when the interface velocity increased. Numerical simulations were carried out to investigate the profile of the lubrication pressure along the film of varying thickness.

8:37AM Q37.00005 Interfacial Instability in Spheres by Resonance, NEVIN BROSIOUS, KEVIN WARD, University of Florida, TAKEHIKO ISHIKAWA, SATOSHI MATSUMOTO, Japan Aerospace Exploration Agency, MIKE SANSOUCIE, NASA Marshall Space Flight Center, RANGA NARAYANAN, University of Florida, UNIVERSITY OF FLORIDA TEAM, JAPAN AEROSPACE EXPLORATION AGENCY COLLABORATION, NASA MARSHALL SPACE FLIGHT CENTER COLLABORATION — When a levitated spherical liquid drop is subjected to continuous periodic forcing at a frequency equal to one of its natural frequencies, it can undergo resonance and form modal structures at the surface. The natural frequencies of a liquid sphere directly depend on the modal structure, the mass of the liquid, and the surface tension. By deliberately resonating a sphere at its natural frequency we can therefore obtain the surface tension. The work presented herein compares the analytical result for natural frequency of a liquid sphere in a “self-gravitational field” by Rayleigh (1879) to experimental observations using levitated water in ambient conditions and molten metals for varying modal structures. The natural frequency of two normal modes are obtained to verify the values of surface tension. Comparisons and contrasts between experiments and theory are explained. A method for the measurement of interfacial tension of high temperature liquid metals is introduced. 8:50AM Q37.00006 Levitation of a non–volatile drop by an evaporating pool: the inverse Leidenfrost effect, S.J.S. MORRIS, UC Berkeley, MENG SHI, KAUST — Assuming axisymmetry, zero gravity, and uniform surface tension $\gamma$ and vapour pressures (viscosity $\eta$, conductivity $k$ and density $\rho$), we determine the maximum value of the force $F$ with which a heated sphere (radius $b$) can be pressed against the pool surface without rupturing it. The Laplace–Young and Reynolds equations form a coupled system of ODEs determining, in particular, film thickness $h_0/b$ at the sphere bottom as a function of $F/(2\pi b)$ with $\varepsilon = \frac{\pi k T}{\rho b^2} \Delta T$, as a parameter (latent heat $H_0$). Numerical solutions for fixed small $\varepsilon$ show that as $F/(2\pi b)$ is increased from zero, $h_0/b$ first decreases to a minimum. With further increase in $F$, $h_0$ increases until a turning point is reached. There, the slope $\partial h_0/\partial F \to \infty$, and the response curve doubles back on itself to form an upper branch. Near the turning point, the interface shows an apparent contact line with apparent contact angle $\pi$ (on the liquid side). The turning point corresponds to the contact line moving from the lower hemisphere to the upper; during this process, $F/(2\pi b)$ reaches its maximum (unity). This result is consistent with work by Adda–Bedia et al.(2016).

Session Q38 Porous Media Flow General III 620 - Pejman Sanaei, NYIT

7:45AM Q38.00001 Effects of particles diffusion and membrane pore elasticity on membrane filtration performance1, PEJMAN SANAEI, New York Institute of Technology, SHI YUE LIU, ZHENGYI CHEN, New York University — Membrane filters fouling, which is an inevitable consequence of particle removal from the feed solution, is sensitive to the flow rate and the internal morphology and structure of membrane. In a very slow filtration process or during the late stage of filtration, when the flow is naturally very slow and Peclet number is small, particle diffusion is essential and cannot be neglected. Beside this, real membranes have complex geometry, and consist of a series of bifurcating elastic pores, which decrease in size as the membrane is traversed. In this talk, we introduce two first-principle models considering asymptotic analysis based on the membrane pores aspect ratio and a distinguished limit of the particle Peclet number. We consider the effects of diffusion for a single membrane pore as well as elasticity in a membrane with branching structure on filtration performance. In the first model, pressure driven flow is considered through the pore and advection-diffusion equation for the particle concentration is coupled with novel fouling models. Furthermore, in the second model, we investigate the membrane pores evolution under two different forcing mechanisms (constant pressure and flux) and describe how the membrane is traversed. In this talk, we introduce two first-principle models considering asymptotic analysis based on the membrane pores aspect ratio and a distinguished limit of the particle Peclet number. We consider the effects of diffusion for a single membrane pore as well as elasticity in a membrane with branching structure on filtration performance. In the first model, pressure driven flow is considered through the pore and advection-diffusion equation for the particle concentration is coupled with novel fouling models. Furthermore, in the second model, we investigate the membrane pores evolution under two different forcing mechanisms (constant pressure and flux) and describe how the membrane internal morphology changes due to its fouling and elasticity.

7:58AM Q38.00002 Simulations of small particle deposition on a membrane filter pore using the immersed boundary method, SCOTT WEADY, New York University - Courant Institute, PEJMAN SANAEI, New York Institute of Technology — Membrane filters have widespread use in the medical, biotech and food science industries, among many others, and their design relies on modeling the flow and fouling mechanisms relevant to each specific application. In this talk, we describe immersed boundary method simulations of the fouling of a membrane filter pore by small particle deposition. The distribution of particles evolves according to an advection-diffusion equation driven by Stokes flow which is coupled to an adhesion model. We consider pressure driven flow through a rigid pore as well as constant flux through an elastic pore, and compare our results with those of several asymptotic models based on the order of the Péclet number and the pore aspect ratio.

8:11AM Q38.00003 Asymmetric Two-phase Flows Resistance in Homogeneous and Heterogeneous Anisotropic Porous Microstructure1, DARIO MAGGIOLO, Chalmers University of Technology, FEDERICO TOSCHI, Eindhoven University of Technology, FRANCESCO PICANO, University of Padova, SRDJAN SASIC, HENRIK STRÖM, Chalmers University of Technology — Two-phase flows in porous media exhibit anomalous behaviours at low capillary numbers due to the complex mechanism of interaction between flow spatial configuration and topology of the microstructure. In this study, we investigate the asymptotical nature of the two-phase flow resistance induced by the anisotropic features of the porous microstructure. We perform pore-scale direct numerical simulations of two-phase flows in porous media composed of solid particles with different shapes and orientations, using the Lattice-Boltzmann method. The results indicate that the infiltration of a fluid into a single pore is regulated by the topological traits of the pore, including its anisotropy. These traits determine a geometrical characteristic length of the pore \( \ell_p \), quantifying the flow resistance, which is directional-dependent: If the capillary length \( \ell_c = \gamma / \rho \) (i.e., the ratio between surface tension and capillary pressure) falls below the characteristic pore length \( \ell_c < \ell_p \), pore infiltration occurs, otherwise the fluid remains trapped. We extend the analysis to heterogeneous anisotropic microstructure in order to investigate the effect of the spatial configuration of the pores on the global flow resistance.

8:24AM Q38.00004 Hydrodynamic driven dissolution in porous media with fluid-filled cavities, MOJDEH RASOULZADEH, WYATT KUEHSTER, University of Alabama — Hydrodynamics is a key player in defining the dissolution rate and dissolution hotspots in porous media with complex pore structure including embedded cavities. The cavity boundary, the fluid velocity maintains the concentration gradient and provides a fresh source of the solvent that facilitates dissolution. Given the characteristics of cavity and the porous zone, vorticities may form, and the cavity may partially or fully participate in the overall flow. In order to predict the dissolution hotspots properly, it is crucial to define the flow field accurately. We use the analytical models of flow in a porous medium including a random distribution of fluid-filled cavities. Darcy’s law is coupled to the Stokes flow for spherical shaped cavities. On the cavity boundary, a no-jump condition on normal velocities, jump on pressures, and the generalized Beavers-Joseph-Saffman condition on tangential velocities is applied. A sequential non-iterative approach is applied to handle the coupling between the hydrodynamics and dissolution. Transport of solute is facilitated by the spontaneous dissolution of solute at every grid point where the dissolved minerals is predicted by PHREEQC. Dissolution hotspots are detected.

8:37AM Q38.00005 Viscous Transport in Erodong Porous Media, SHANG-HUAN CHIU, BRYAN QUAIFE, NICHOLAS MOORE, Florida State University — Erosion is a fluid-mechanical process that is present in many geological phenomena such as groundwater flow. We present a boundary integral equation formulation to simulate two-dimensional erosion in porous media. One numerical challenge is accurately resolving the interactions between nearly touching eroding bodies at low porosity. We present a Barycentric quadrature method to resolve these interactions and compare it with the standard trapezoid rule. We compute the velocity, vorticity, and tracer trajectories in the geometries that include dense packings of 20, 50, and 100 eroding bodies. Like in our previous work [1], we observe quick expanding channels between close bodies, flat faces developing along the regions of near contact, and bodies eventually vanishing. Finally, having computed tracer trajectories, we characterize the transport inside of eroding geometries by computing and analyzing the tortuosity and anomalous diffusion rates. 1 B. D. 9:03AM Q38.00007 Experimental study of permeability of oriented fiber arrays, QIANGHONG WU, ZENGHAO ZHU, Villanova University — In this paper, a systematic study is performed to examine the permeability of a highly organized, oriented porous layer. Despite of extensive theoretical studies for the Darcy permeability of dilute or concentrated, oriented fiber array when the flow is either perpendicular or parallel to the fiber axis, there is a lack of research for the porosity between 0.3 and 0.8. Furthermore, no experimentally validated solutions have been reported to estimate the permeability of oriented fiber arrays where the angle between the fiber axis and the flow direction is in the range of 0 degree to 90 degree. We present in this paper an experimental study to examine the Darcy permeability of 3-D printed fiber arrays with different orientations. New correlations have been obtained when the porosity of the fiber array is in the range of 0.3 and 0.8. Furthermore, we have proved that, it is appropriate to use a linear combination method, based on the permeabilities of the fiber array at two distinct orientations, to predict the permeability of the fiber array at other orientations. The study presented herein has important applications in both biological systems and industrial applications, e.g. soft porous lubrication.

9:16AM Q38.00008 Dewatering saturated, networked suspensions with a screw press, TOM EAVES, DANIEL PATERSON, University of British Columbia, DUNCAN HEWITT, University of Cambridge, NEIL BALMFORTH, MARK MARTINEZ, University of British Columbia — A model is presented for the dewatering of a saturated two-phase porous medium in a screw press. The model accounts for the detailed two-phase rheological behaviour of the pressed material and splits the press into two zones, an initial well-mixed constant-pressure region followed by an axial transport region in which the total pressure steadily increases. In this latter region, a slowly-varying helical coordinate transformation reduces the dynamics to an annular bi-axial compression of the two-phase porous medium. Unlike previous modeling, the transition point between the two zones is determined self consistently, rather than set a priori, and the pressure along the length of the press is deduced from the rheology of the two-phase flow rather than averaging the two-phase dynamics over a cross-section of the press. The model is compared to experimental observations of the dewatering of a paper-making fibre suspension and of a clay slurry, and is shown to reproduce operational data.

9:29AM Q38.00009 Rayleigh-Taylor mixing in a porous medium, GUIDO BOFFETTA, MATTEO BORGNINO, STEFANO MUSACCHIO, University of Torino — Rayleigh-Taylor mixing in a porous medium is studied by high-resolution direct numerical simulations of the Darcy-Boussinesq equations in two and three dimensions. The width of the mixing layer is found to grow linearly in the limit of small diffusivity, in agreement with the dimensional expectation. A different growth rate is observed in two and three dimensions. The characteristic transverse scale, a measure of the typical plume size, grows slower following a diffusive law: as a consequence plumes became more elongated during the time evolution. The evolution of the density flux, quantified by the Nusselt number, is studied as a function of the Darcy-Rayleigh number.

Session Q39 Geophysical Fluid Dynamics Stratified Flow III 6a - Alexis Kaminski, University of Washington

7:45AM Q39.00001 3D measurements of inclined vortex rings interacting with a density stratification, JOHAN PINAUD, JULIE ALBAGNAC, PIERRE BRANCHER, SEBASTIEN CAZIN, ZEINAB RIDA, Institut de Mecanique des Fluides de Toulouse — Vortex rings are coherent vortical structures that dominate the dynamics of numerous flows as they are generated each time an impulsive jet occurs in a homogeneous fluid. They are also considered as elementary bricks of turbulence. Their faculty to propagate along their revolution axis by self-induction confers to such structures interesting transport properties, namely, transport of momentum, mass and heat. They are therefore often qualified as good candidates for mixing. From this perspective, the present study addresses the interaction of a vortex ring with a density stratification in order to get a better understanding of the subsequent mixing mechanisms. A new 3D time-resolved technique is used and gives a highlight at short timescale on the 3D vorticity reorganization and at larger timescale on the 3D patterns of internal gravity waves forced by the impacting/penetrating vortex. The influence of the Reynolds number of the vortex ring and its angle of attack relative to isopycnals will be detailed.
Dynamics of a reactive spherical particle falling in a linearly stratified layer

**Ludovic Huguet, Victor Barge-Zwick, Michael Le Bars, CNRS, Aix Marseille Univ, Centrale Marseille, IRPHE, Marseille** — The behavior of a particle falling in a stratified layer has already been studied for regimes of small Reynolds $Re$ or Froude $Fr$ numbers. However, the dynamics of a reactive particle have been unexplored, especially for regimes of interest for geophysical applications (large $Re$ and $Fr$ numbers). In a large water tank with linear stratification, reactive spheres made of a mixture of ice and hydrohalite solidifying below $-21.1^\circ \text{C}$, are released from the top and melt while they sink. PIV is used to track their falls and the dynamics of the surrounding environment. Results are compared with non-reactive plastic spheres. For large Reynolds and Froude number, the added drag (compared to a sphere in a homogeneous fluid) of the plastic spheres due to the stratification is proportional to $(Re/Re)_0.5$. For the reactive spheres, the added drag is much larger, suggesting a strong modification of the wake due to the melting. We also characterize the generation of internal waves and the associated radiated energy. While increasing with radius for plastic spheres, the ratio of wave energy compared to the initial potential energy of the spheres is constant over the explored range for reactive ones.

Grant Agreement No.681835FLUDYCOERC-2015-CoG

Analysis of one-dimensional models for exchange flows under strong stratification

**Herman Clercx, Steven Kapteyn, Eindhoven University of Technology, Vincenzo Armenio, University of Trieste, Matias Duran Matute, Eindhoven University of Technology** — One-dimensional models of exchange flows driven by horizontal density gradients are well known for performing poorly in situations with weak turbulent mixing. The main issue with these models is that the horizontal density gradient is usually imposed as a constant, leading to non-physically high stratification known as runaway-stratification. Here, we propose two new parametrizations of the horizontal density gradient leading to one-dimensional models able to tackle strongly stratified exchange flows at high and low Schmidt number values. The models are extensively tested against results from laminar two-dimensional simulations and are shown to outperform the models using the classical constant parametrization for the horizontal density gradients.

Flavours of Stratified Shear Flows: Algorithmic Detection

**Hesam Salehipour, Woods Hole Oceanographic Institution, Tom Eaves, University of British Columbia** — It remains unknown how to relate our understanding of turbulent mixing in stratified shear flows (based on direct numerical simulation (DNS)) to oceanic measurements of 1D profiles of density and velocity. In particular, there are various pathways to turbulence in stratified shear flows which behave in categorically different ways, but a method of distinguishing between these pathways in 1D microstructure measurements has yet to be proposed. Recently, a coordinate-free algorithmic classification scheme for the nonlinear states which result from the saturation of each instability has been proposed by Eaves and Balmforth (JFM 860, 2019), and hence is ideally suited for examining 1D profiles. This study was mostly restricted to relatively idealised steady, 2D flows; however, some aspects of this scheme were seen to carry over to non-steady, 3D flows after coarse-graining of the flow profiles. In this talk, we will investigate when the classification scheme works for realistic flows. In particular, we shall examine a large number of 1D profiles obtained from DNS of both Kelvin–Helmholtz and Holmboe instabilities to investigate the performance of this scheme over a large range of Reynolds and Richardson numbers, in addition to the type of instability and the 'age of the flow.'

Turbulent Mixing in Stratified Shear Flows

**Eric D'Asaro, Applied Physics Laboratory, University of Washington** — Turbulent mixing plays an important role in setting the distribution of heat, salt, and other biogeochemical tracers in the ocean, and quantifying the turbulent fluxes of these tracers is therefore a key question. A common approach is to look for signatures of turbulent overturns in one-dimensional profiles of temperature or other tracers and subsequently infer details of the accompanying fluxes and mixing. Often, these observed profiles are interpreted in the context of classical Kelvin-Helmholtz instability, in which shear drives the formation of a large overturn that subsequently triggers transition to turbulence. However, both the linear shear instability and nonlinear flow evolution can depend sensitively on the details of the background shear and stratification. Here we present the results of a series of direct numerical simulations of stratified shear instabilities with symmetric and asymmetric initial conditions, i.e. with either coincident or vertically offset profiles of shear and stratification. Motivated by recent Lagrangian float observations of the ocean transition layer, we examine the vertical structure of the resulting overturns. We describe both the size and stratification of these structures, and discuss implications for the associated buoyancy flux.

Wake identification of stratified flows using Dynamic Mode Decomposition

**Chan-Ye Ohh, Geoffrey Spezding, University of Southern California** — Early experiments suggest that early wake information including body geometry and initial conditions in a linearly stratified fluid is lost during the wake evolution process (Meunier and Spezding Phys. Fluids 16, 296-305, 2004). Though this result was established for certain statistical quantities, it is less clear that there is no pattern remaining, and the process by which it is lost is also not established. Here we investigate how to identify, in principle, the various known regimes of stratified flow using a more sophisticated method, Dynamic Mode Decomposition (DMD), on 3D wake data from tomographic PIV and second-order DNS at low $Re (200 \leq Re \leq 1000)$ and low $Fr (0.5 \leq Fr \leq 8)$. Within the large set of modes, the dominant dynamic modes can be ranked and categorized into known regimes from a mode selection algorithm. The identification process is further refined and tested for spatially and temporally limited wake measurements.

Support from ONR Grant N00014-15-1-2506 under Dr. Peter Chang is most gratefully acknowledged.
9:03AM Q39.00007 Critical Reflection Dissipates Internal Wave Energy1, BRUCE RODENBORN, CLAYTON BELL, CHARLOTTE MABBS, Centre College — Ocean measurements show that continental slopes are eroded to the critical angle of local internal waves (Cacchione et al., Science 296, 2002). However, the feedback mechanism modifying the slopes over geologic time is not clearly understood. Other work shows that tidally driven topography creates strong boundary flows but weak tidal conversion (Dettner et al, Phys., Fluids, 25, 2013). We find a similar boundary response in internal waves reflecting from critical slopes; most of the internal wave energy is dissipated near to the boundary. We use experiments with a Reynolds number, $Re \sim 1000$, and numerical simulations that solve the full Navier-Stokes equations in the Boussinesq limit with $Re \sim 10^4 \sim 10^5$. Our data show that the rate of energy dissipation at the critical angle remains high even when viscous effects are minimized in the simulations. We also present laboratory data showing reflection from a turning depth and find high rates of energy dissipation though the no-slip boundary condition is not present. The data suggest that critical reflection dissipates energy from the internal wave field at high Reynolds numbers, and therefore, may contribute to the erosion of continental slopes.

9:16AM Q39.00008 Internal Wave Breaking in an Isothermal Atmosphere, DANIEL LECOANET, Princeton University, YUBO SU, DONG LAI, Cornell University — We present a series of two-dimensional numerical simulations of internal wave breaking in an isothermal atmosphere. Waves with a fixed frequency and wavenumber are continuously excited at the bottom of the atmosphere. As they propagate upward, their amplitude increases until they become nonlinear and break. The waves deposit their momentum and spin-up the upper layers of the atmosphere until the mean velocity is equal to the waves’ phase velocity. Waves continue to break at the shear layer at the bottom of the spun-up fluid, further depositing their momentum. We find the shear layer descends as $\exp(-t)$, as the momentum flux is constant, but the density of the atmosphere increases exponentially with depth. For simulations with sufficiently high Reynolds number, we find about 50% of the wave flux is reflected by the shear layer, 10% is transmitted into waves in the spun-up fluid, and 40% is absorbed.

9:29AM Q39.00009 Comparison of Internal Wave Kinetic Energy Estimates in Synthetic Schlieren and Particle Image Velocimetry1, KYLE HAKES, ALLISON LEE, ANNIE WESOLEK, JULIE CROCKETT, Brigham Young University — Synthetic Schlieren (SS) and Particle Image Velocimetry (PIV) are commonly employed experimental methods for investigating internal wave generation and propagation. PIV allows direct calculations of velocity and therefore kinetic energy, but at a relatively high setup cost. SS is a less expensive experimental method that is generally more easy to implement, but is not a direct measurement of velocity but instead natural frequency changes. This can be used to estimate kinetic energy but calculations are subject to the WKB approximation. Experiments were performed to investigate when the kinetic energy estimates from SS are a good approximation of the kinetic energy calculated from PIV for the same experiment. Internal waves generated by tidal flow over 4 different topographies in 4 different density profiles are explored via both SS and PIV methods for comparison. Preliminary findings indicate SS and PIV match well overall far from regions where WKB assumptions fail, and show that their ability to generate similar results depends on the shape of the topography and density profile.

Tuesday, November 26, 2019 7:45AM - 9:16AM – Session Q40 Jets: Impinging 6b - Ahmed Naguib, Michigan State University

7:45AM Q40.00001 Instability of micro jet impinging onto a pool, MAOYING ZHOU, School of Mechanical Engineering, Hangzhou Dianzi University, BO LI, State Key Laboratory of Hydroscience and Engineering, Department of Energy and Power Engineering, Tsinghua University, JUN ZOU, The State Key Lab of Fluid Power & Mechatronic Systems, Zhejiang University — A micro liquid jet discharged into a downstream pool exhibits different instabilities at certain heights. For some nozzle heights, the water jet shows a steady wave profile while for some other heights, the water jet oscillates around the nozzle axis at given frequency. A series of experiments are conducted to identify the regimes of jet state with respect to nozzle heights, Reynolds numbers and Weber numbers. For the oscillation regime, oscillating characteristics of the jet are investigated in terms of different liquid properties. A simple model is developed to describe and explain the phenomena.

7:58AM Q40.00002 Impinging Tone Identification of Under-expanded Impinging Jets by Large Eddy Simulation1, MINGHANG LI, The University of Melbourne, SHAHRAH KARAMI, Laboratory for Turbulence Research in Aerospace & Combustion (LTRAC), Monash University, RICHARD SANDBERG, The University of Melbourne, JULIO SORIA, Laboratory for Turbulence Research in Aerospace & Combustion (LTRAC), Monash University, ANDREW OOI, The University of Melbourne — The acoustic and hydrodynamic feedback mechanism to predict discrete tones was first proposed by Powell (J.Acoust.Soc.Am., vol.83(2), 1988, pp.515533). The mechanism consists of the receptivity of the shear layer at the nozzle lip as well as the acoustic contribution from the downstream sources. The first part of the mechanism has been commonly accepted, while the locations of the downstream sources are still under debate. To further understand the mechanism, this work aims to identify the locations of the impinging tones by a novel methodology utilising the cross correlation and a ray tracing method. Each potential source is found with a certain ray tracing back to the nozzle exit. Joint probability density functions are then used to identify the impinging tones. Since the mean temperature out of the main jet plume and the wall jet varies little, another simplified method that does not consider refraction effects is proposed. Data from a recent Large Eddy Simulation is used to validate the current methods. The identified source locations are quantitatively determined and consistent with the second maximum of the root mean square of the pressure on the wall.

1Australian Research Council
8:11AM Q40.00003 Volumetric flow measurements of impinging jet on circular cylinder using STB1. MIRAE KIM, EUNSEOP YEOM, Pusan National University, MATTEO NOVARA, DANIEL SCHANZ, REINHARD GEISLER, JANOS AGOCS, ANDREAS SCHROEDER, German Aerospace Center (DLR), KYUNG CHUN KIM, Pusan National University

— Jet impingement is a direct and efficient way to transfer heat and mass in various applications. In practical applications, most jet flows are impinging on curved surfaces, however, less attention has been given to circular jet impingements on convexly curved surfaces. Interactions of three-dimensional flow structures of a round jet impinging obliquely on a convex circular cylinder was studied using high-resolution volumetric flow measurements by dense 4D Lagrangian particle tracking using the Shake-The-Box method and data assimilations by FlowFit. The Lagrangian stochasticized 3D flow field confirmed that the 3D curved wall jet spreads widely in spanwise direction after impingement then merged to the jet centerline downstream. The Coanda effect on 3D wall jet flow along the cylinder wall is vividly shown with the delay of separation up to 180 degrees. The strong shear layer near the impingement area produces large-scale vortices with high vorticity. These structures distribute throughout the surface and break down to multiple vortex structures with lower vorticity. Small-scale negative vortex structures are moved away from the wall jet and are sustained longer at the edge of the wall jet.

8:24AM Q40.00004 Effect of Bi-Modal Excitation of an Impinging Jet on Cooling of a Heated Impingement Surface1. BASIL ABDELMELGIED, AHMED NAGUIB, Michigan State University — Impinging jets have many engineering applications, such as heating, cooling, and drying. This work is part of a larger study focused on using different active flow control strategies for enhancement of the cooling effectiveness of impinging jet arrays. Here, we examine the influence of bi-modal acoustic forcing on the Nusselt number ($Nu$) distribution resulting from an axisymmetric jet impinging on a heated flat surface. The forcing scheme utilizes two concurrent sinusoidal waves, at the jet’s shear layer fundamental and sub-harmonic frequencies, to take advantage of the jet’s sub-harmonic resonance. The $Nu$ distribution is measured using temperature-sensitive paint applied to a heated stretched stainless steel foil. Data are obtained for jet Reynolds number based on jet diameter of 4000, jet-exit-to-plate distance range of 2 to 4 diameters, and different forcing parameters. The results illustrate the influence of the control on the jet’s cooling effectiveness and the dependence of this influence on the flow and the forcing parameters. Flow visualization is used to examine associated changes in the flow structure.

8:37AM Q40.00005 Transient model for characterizing the erosion mixing of stratified layer and turbulent impinging jet with both density and pressure gradients1. WOOYOUGN LEE, SIMON SONG, Institute of Nano Science and Technology, Hanyang University, Seoul, Republic of Korea, YOUNG SU NA, Dept. of Thermal Hydraulics and Severe Accident Research, Korea Atomic Energy Research Institute, Daejeon, Republic of Korea — The erosion mixing phenomenon of a stratified hydrogen layer caused by a turbulent impinging jet determines the distribution and mixing characteristics of hydrogen gas in a containment building of nuclear power plants (NPPs) during a severe accident. The mixed hydrogen gas can explode when in contact with ignition sources. To prevent the risk of the hydrogen explosion, it is necessary to quantitatively analyze the transient erosion mixing process over a long period of time. We experimentally and theoretically investigate the long-term erosion mixing process by the interaction between a stratified layer and a turbulent impinging jet. As a result, we propose a transient model for predicting the interface displacement of the stratified layer and the mean axial velocity and half width of the jet. We found that the prediction accuracy strongly depends on the consideration of the density and pressure gradient of the stratified layer and the jet. The results show that the predictions are in good agreement with the experimental data.

8:50AM Q40.00006 Mixing of cold jets in cross flow into exhaust gases for cryogenic CO2 capture. ROBERT DIBBLE, FRANCISCO HERNANDEZ PEREZ, HONG IM, King Abdullah University of Science and Technology — For over a century, the widely accepted route for removal of CO2 from a gas stream has been absorption by amines. The liquid amine is sprayed downward in a vertical tower in which the exhaust stream is coming upward. In this counter-current flow, the falling amine droplets absorb CO2. The CO2-rich droplets collected at the bottom of the tower are pumped to a boiler, after which pure CO2 is extracted by heat. A new emerging process is the cryogenic carbon capture (CCC) process, in which the exhaust stream is cooled to near -90C and a cold fluid, such as methane, at -150C, is injected into the exhaust stream. The cold methane mixing with the exhaust gases forms CO2 in the “dry ice snow” form as the temperature rapidly descends below the sublimation point of CO2 (about -100C). The CO2 snow is easily collected. The methane as methane, at -150C, is injected into the exhaust stream. The cold methane mixing with the exhaust gases forms CO2 in the “dry ice snow” form as the temperature rapidly descends below the sublimation point of CO2 (about -100C). The CO2 snow is easily collected. The methane can be injected into the exhaust duct, from the wall, creating a classic “jet in cross flow” configuration. We find that more rapid mixing occurs if the methane is injected at 45 degree angle to duct wall, in both the flow direction and orthogonal to flow direction. The present study aims to explore the effect of the two angles on the mixing effectiveness. Simulations using LES show that most rapid mixing is achieved by the 45/45 degrees configuration.

9:03AM Q40.00007 Liquid Jet Impingement Cooling on Superheated Superhydrophobic Surfaces1. JACOB BUTTERFIELD, BRIAN IVERSON, DANIEL MAYNES, JULIE CROCKETT, Brigham Young University — Superhydrophobic (SH) surfaces form air cavities between nano- or micro-structures, resulting in self-cleaning properties. This is a potential solution for fouling in cooling applications, but the air cavities also impede heat transfer. Here, water jet impingement heat transfer on surfaces of varying microstructures and wettability is experimentally explored. Silicon wafers with micro-scale posts etched in a square array were used to create a range of SH surface microstructures. The SH surfaces are moved away from the wall jet and are sustained longer at the edge of the wall jet.

Tuesday, November 26, 2019 7:45AM - 9:42AM – Session Q41 Advances in CFD Algorithms II 6c - Kursat Kara, Oklahoma State University
7:45AM Q41.00001 Using Evolutionary Neural Networks to Adapt the Jacobi Iterative Method for the Pressure Poisson Equation in a Multiphase Flow, TIANKUI XIAO, Pennsylvania State University, YIPENG SHI, Peking University, XIANG YANG, Pennsylvania State University — We utilize evolutionary neural networks (ENN) to determine a set of relaxation factors for the Jacobi iterative method, which is subsequently used to solve the pressure Poisson equation of a multiphase flow. The density of the fluid and the gas differ by a factor of 1000. An iterative method usually needs to be adapted to account for the large density difference in the field, which usually involves a long process of trial and error. In this talk, we show that ENNs could shorten this process. The iterative method we adapt is the Jacobi method. This method is embarrassingly parallel, and converges at a rate if employing a set of appropriately picked relaxation factors. Our ENN uses the iterative solution at one instance as the input, and determines the relaxation factor for the next iteration. Despite the local nature of our input to the neural network, we show that the results of the ENN is very close to the global optimum.

7:58AM Q41.00002 Automatic differentiation of a spectral difference code for sensitivity analysis1, JOSE I. CARDESA, CHRISTOPHE AIRIAU, Institut de Mécanique des Fluides de Toulouse — The computational fluid dynamics code JAGUAR, developed jointly by ONERA (Toulouse) and CERFACS, is a high-order code based on spectral differences and intended for unsteady aerodynamic simulations. In order to extend its use for shape optimization and flow control, it is convenient to adapt the code so that computing flow sensitivities is an efficient yet flexible process that can be adapted to very different problems. For this reason, a fully discrete approach was chosen that relies on automatic differentiation. A test case was analyzed to validate our approach in an unsteady problem, allowing us to identify key modifications to be implemented on the code so as to streamline the differentiation process and ease its replication in other problems. Tangent and adjoint modes were used to differentiate the parallel version of the code with TAPENADE and the adjoinable MPI library. Execution times and coding strategies will be provided to illustrate the benefits and drawbacks of the different approaches.

8:11AM Q41.00003 Stability and Accuracy of Semi-Extrapolated Finite Difference Schemes, ANDREW BRANDON, SHEILA WHITMAN, MIKAYLA FELDBAUER, NARSHINI GUNPATH, Lycoming College, BRENDAN DRACHERL, Rochester Institute of Technology, CARTER ALEXANDER, Lycoming College, LUCAS WILKINS, Vanderbilt University — When numerically solving partial differential equations, finite difference methods are a popular choice. Several factors contribute to the success of a finite difference method, including stability, accuracy, and computational cost. In response to the small stability regions of explicit methods and the computational cost of implicit methods, we have developed a novel discretization technique called semi-extrapolation. Semi-extrapolation generates explicit schemes from implicit schemes by applying extrapolation in an unconventional fashion. Unlike extrapolation, which can severely curtail stability, semi-extrapolation can improve stability, as compared to analogous explicit methods. Furthermore, semi-extrapolation can have unexpected effects on accuracy. In this presentation, we will introduce this semi-extrapolation and introduce two semi-extrapolated discretizations of the Advection-Diffusion Equation will be discussed. Then, the accuracies and stabilities of these semi-extrapolated discretizations will be compared to the accuracies and stabilities of analogous mainstream finite difference discretizations.

8:24AM Q41.00004 Solving the Navier-Stokes governing equations through quantum computing, FRANK GAITAN, Laboratory for Physical Sciences — We present a quantum algorithm that solves an arbitrary set of coupled non-linear partial differential equations and show how it can be used to solve the governing equations for a Navier-Stokes fluid. To test the algorithm we examine the problem of inviscid, compressible flow through a convergent-divergent nozzle. We numerically simulate application of the algorithm to find the steady-state flow when a shock-wave is and is not present in the divergent part of the nozzle. In each case excellent agreement is found between the output of the quantum simulation and the exact analytical solution, with the simulation successfully capturing the shock-waves in the latter case. We compare the computational cost of this quantum algorithm to that of deterministic and random classical algorithms; discuss future applications, as well as the potential long-term significance of quantum computing for the fluid dynamics community.

8:37AM Q41.00005 A finite volume scheme for stochastic PDEs in the context of fluctuating hydrodynamics1, SERGIO P. PEREZ, ANTONIO RUSSO, MIGUEL A. DURAN-OLIVENCIA, PETER YATSYSYIH, JOSÉ A. CARRILLO, SERAFIM KALLIADASIS, Imperial College London — The description of soft matter systems out of equilibrium requires the inclusion of fluctuations in the standard hydrodynamic equations for the evolution of conserved quantities. The associated general framework was postulated phenomenologically by Landau et. al., yielding what is known as Landau-Lifshitz fluctuating hydrodynamics. However, the numerical applicability of the fluctuating hydrodynamics entails several challenges which still remain elusive. In particular, conservative fluctuations, i.e. stochastic fluxes under the gradient operator, need to be properly accounted for. Besides, even for the simplest limit of these equations (which corresponds to the stochastic diffusion equation), the presence of a normally-distributed flux in the time-evolution equation for the density involves non-positive solutions, which are clearly unphysical. Hence the need for a robust method capable of handling stochastic fluctuations properly. Here we present a finite-volume scheme for stochastic gradient flows with nonlinear energy functionals, based on a hybrid upwind-central discretisation of both the deterministic and stochastic fluxes. The positivity of the density is ensured by an innovative time-adapting procedure based on the concept of Brownian trees. We exemplify the applicability and versatility of our method by solving the FHH in a wide spectrum of physical settings.

8:50AM Q41.00006 A symbolic regression approach for the development of high accuracy defect correction schemes1, HARSHA VADDIREDDY, OMER SAN, Oklahoma State University — Discrete equations are used to solve partial differential equations. Using higher order numerical schemes, we can traditionally reduce the number of grid points while preserving similar level of accuracy. Although high accurate numerical schemes can be constructed by using higher order polynomials, symmetry preservation, Pad approximation or Richardson extrapolation, it is well known that simple schemes sometimes completely eliminate the induced numerical errors when discretization parameters are chosen appropriately (e.g., $dt = dx/a$ for the first order Euler upwind scheme solving the linear wave equation). Furthermore, closure approaches are often introduced to account for nonlinear interactions in discrete models. To this end, we introduce a modular symbolic regression framework for finding optimal parameters, defect correction or closure terms, if necessary, to improve the accuracy of the underlying numerical procedures. Several examples are conducted to assess the feasibility of the proposed approach.

9:03AM Q41.00007 An Unconditionally Energy-Stable Scheme for Incompressible Flows with Outflow/Open Boundaries1, SUCHUAN DONG, XIAOYU LIU, Purdue University — We present an unconditionally energy-stable scheme for simulating incompressible flows on domains with outflow/open boundaries. The scheme combines the generalized Positive Auxiliary Variable (gPAV) approach and a rotational velocity correction type strategy, and the adoption of the auxiliary variable simplifies the numerical treatment for the open boundary conditions. The scheme admits a discrete energy stability property, irrespective of the time step sizes. Within each time step the scheme entails the computation of two velocity fields and two pressure fields, by solving an individual de-coupled Helmholtz (including Poisson) type equation with a constant pre-computable coefficient matrix for each of these field variables. The auxiliary variable, being a scalar number, is given by a well-defined explicit formula within a time step, which ensures the positivity of its computed values. We present numerical results with several flows involving outflow/open boundaries in regimes where the backflow instability becomes severe to demonstrate the performance of the method and its stability at large time step sizes.

9:16AM Q41.00008 Spectral Methods for Time Series Prediction with Application to Fluid Flows, HENNING LANGE, STEVEN BRUNTON, NATHAN KUTZ, University of Washington — Forecasting the behavior of complex dynamical systems has a rich history in fluid dynamics. The Navier-Stokes equations and the dynamics of velocity fluctuations around the resulting base velocity profile are studied using the eddy-viscosity enhanced linearized equations. We utilize the second-order statistics of velocity fluctuations resulting from the stochastically forced periodic surface corrugation on skin-friction drag in turbulent channel flow. The effect of surface corrugation is modeled as a volume penalization of the time step sizes. Within each time step the scheme entails the computation of two velocity fields and two pressure fields, by solving an

9:29AM Q41.00009 On preserving accuracy of underlying discretization in overset meshes for incompressible flow1, ASHESH SHARMA, SHREYAS ANANTHAN, MICHAEL SPRAGUE, National Renewable Energy Laboratory, JAYANARAYANAN SITARAMAN, Parallel Geometric Algorithms, LLC — To accurately model the flow dynamics around wind turbines, it is crucial to capture well the many complex moving geometries involved. The need to resolve flow structures around these moving components motivates our choice of overset grids. Exchange of solution between the overlapping meshes is at the core of any overset framework. For incompressible-flow solvers, the associated linear systems arising at each time step can be solved in a coupled or a decoupled and iterative manner. In the former, monolithic linear systems are assembled and the overlapping meshes are coupled through constraint equations. In a decoupled solve, linear systems are created for each mesh, and information is exchanged at overset interfaces as a separate step after the governing equations have been solved on the individual meshes. This work examines cost and accuracy comparisons between overet coupled and decoupled solves using elliptic and hyperbolic systems representative of the incompressible Navier-Stokes equations.

Session Q42 Boundary Layers: Superhydrophobic Surfaces and Drag Reduction 6e - Julien Landel, University of Manchester

7:45AM Q42.00001 Model-based analysis of turbulent drag reduction in channel flow over corrugated surfaces, WEI RAN, University of Southern California, ARMIN ZARE, The University of Texas at Dallas, MHAHAO JOVANOVIC, University of Southern California — We develop a model-based approach to quantify the effect of spatially periodic surface corrugation on skin-friction drag in turbulent channel flow. The effect of surface corrugation is modeled as a volume penalization on the Navier-Stokes equations and the dynamics of velocity fluctuations around the resulting base velocity profile are studied using the eddy-viscosity enhanced linearized equations. We utilize the second-order statistics of velocity fluctuations resulting from the stochastically forced periodic surface corrugation on skin-friction drag in turbulent channel flow. The effect of surface corrugation is modeled as a volume penalization of the time step sizes. Within each time step the scheme entails the computation of two velocity fields and two pressure fields, by solving an

7:58AM Q42.00002 Retention of infused liquid for sustenance of drag reduction of turbulent flow over liquid infused surface, MARTAND MAYUKH GAMIELLA, EDGARDO JAVIER GARCIA CARTAGENA, STEFANO LEONARDI, The University of Texas at Dallas — Liquid infused surfaces (LIS) are composed of functionalized surface textures wetted with an immiscible, chemically-matched liquid lubricant. It has been experimentally demonstrated that grooved LIS configurations can reduce turbulent drag up to 35%. However, in practical configurations, due to high shear exerted by the flow, the infused liquid may get washed away. Previous studies have considered longitudinal bars. However, this texture cannot hold the lubricant-gas in the cavities. An alternative would be to place transversal bars to retain this lubricant. Direct numerical simulations of the flow in a channel with a rectangular mesh on the lower wall have been carried out. The aspect ratios of the cavities, the Reynolds and Weber numbers were varied. Also, two viscosity ratios between the two fluids, N=0.02 and N=0.4 were used to mimic idealized superhydrophobic and liquidinfused surfaces. In comparison to the flow over longitudinal bars, the addition of transverse bars reduces drag reduction. However, it was observed that the flow recirculates within the cavities with an expected reduction in drainage. In addition, at a higher Weber number, the interface above the mesh texture is more stable than that over longitudinal bars.
8:11AM Q42.00003 Investigation of turbulent flows over superhydrophobic surfaces with oscillatory slip length\(^1\), KIMBERLY LIU, ALI MANI, Stanford University — Superhydrophobic surfaces have been widely studied for the purposes of drag reduction; the formation of an air film on the surface allows for a slip boundary condition, greatly decreasing the wall friction and thus the overall friction drag. Experimental results of patterned superhydrophobic surfaces, with dynamic pressure control allowing for oscillation of the individual air films, show an even further drag reduction. In addition, it has been observed that under such conditions, strong oscillatory velocities are induced in the streamwise direction, reminiscent of a Stokes boundary layer (Wang and Gharib, Bull. Am. Phys. Soc. 2018). We present a numerical study that isolates two possible factors that we believe may be contributing to the significant drag reduction. We utilize direct numerical simulations (DNS) to study the effects of (1) the slip boundary condition with slip length oscillating in time and (2) oscillating streamwise wall boundary condition with nonzero bulk flow, revealing the foundational interplay between effective slip length, oscillations of slip length, and reduction of drag.

8:24AM Q42.00004 Impact of surfactant on the drag-reduction potential of superhydrophobic surfaces in turbulent flows\(^1\), JULIEN R. LANDEL, University of Manchester, SCOTT SMITH, FERNANDO TEMPRANO-COLETO, University of California Santa Barbara, FRANCOIS PEAUDECERF, ETH Zurich, FREDERIC GIBOU, PAOLO LUZZATTO-FEGIZ, University of California Santa Barbara — Recent studies, Peaudecerf et al. (PNAS 2017) and Song et al. (PRF, 2018), have shown the negative effect of surfactant on the drag-reduction performance of superhydrophobic surfaces (SHS) in laminar flow conditions. As SHS could have a large impact in reducing energy utilisation for many internal and external flow applications, particularly under turbulent flow regimes (e.g. ships, pipelines), it is important to understand and predict how surfactant-Marangoni stresses affect turbulent flows over SHS. This is crucially important, since surfactants are present in normal environmental conditions for most applications. Our existing model for SHS inclusive of surfactant (Landel et al. arXiv:1904.01194, 2019) captures the effect of surfactant for two-dimensional laminar flow. Using a technique inspired by Belyaev & Vinogradova (J. Fluid Mech. 652, 2010), we adapt our two-dimensional model to flows above three-dimensional SHS with longitudinal gratings. Then, we use the results of Fukagata et al. (Phys. Fluids 18, 2006) to relate the effect of the surfactant-affected slip length on the drag reduction of SHS in turbulent flows. We discuss the impact of the main parameters: the gas fraction, the surfactant concentration, and the Reynolds number on the drag reduction. Finally, we compare the results of our model with experimental results from the literature.

8:37AM Q42.00005 Effect of Interface Deformation and Contact Line Motion on Drag Reduction with Superhydrophobic and Liquid-Infused Surfaces in Laminar and Turbulent Flow\(^1\), RAYHANEH AKHAVAN, AMIRREZA RASTEGARI, The University of Michigan — Effect of interface deformation and contact line motion on drag reduction (DR) with super-hydrophobic (SH) and liquid-infused (LI) surfaces is investigated in laminar and turbulent flow by direct numerical simulation (DNS) using a two-phase, single relaxation time, free-energy lattice Boltzmann method. In this method, the dynamics of a diffuse interface is incorporated into the governing equations using a Peng-Robinson free-energy functional. This obviates the need for interface tracking. DNS studies were performed in channel flows with longitudinal microgrooves of width \(\frac{g}{H} \leq 64\) or \(\frac{g}{H} \leq 32\). The results show that, in both laminar and turbulent flow, interface deformation and contact line motion can significantly modify the magnitude of DR compared to results obtained with ‘idealized’, flat SH or LI interfaces. The conditions under which the contact line depins and the interface breaks down are identified by DNS.

8:50AM Q42.00006 A direct numerical simulation study of heat transfer over superhydrophobic and liquid-infused surfaces , UMBERTO CIRI, STEFANO LEONARDI, The University of Texas at Dallas — Recently, superhydrophobic (SHS) and liquid-infused surfaces (LIS) have been proposed as a wall treatment to achieve drag reduction in turbulent flows. Conceptually, these surfaces consist of a textured substrate with a secondary fluid filling the texture cavities over which the primary fluid flows. In the case of SHS, water flows over air trapped in the cavities, while for LIS a liquid lubricant is used instead of air. Turbulent drag reduction is possible because the second fluid creates a slippery interface with the primary fluid, thus reducing friction drag. While several studies have shown potential in terms of drag reduction, less attention has been dedicated to the heat transfer. The objective of this work is to study heat transfer characteristics of these surfaces and the correlation between the velocity and thermal fields (Reynolds analogy). Direct numerical simulations of turbulent flow and heat transfer are performed using different textured geometries (modeled with the immersed boundary method) and varying the viscosity ratio and interfacial tension between the two fluids. The level-set method is used to couple the dynamics of the interface between the two fluids to the Navier-Stokes equations.

9:03AM Q42.00007 Drag reduction variation with respect to changes in cavity geometry for a butterfly-inspired surface , SASHANK GAUTAM, AMY LANG, The University of Alabama — Monarch butterfly wings are covered with small scales arrange in a pattern that resembles roof shingles, with the tips pointing up forming low-profile cavities. As the flow passes over the wing, the skin friction drag depends on the direction of flow with respect to scale orientation. When the flow is transverse to the cavity orientation, a single vortex forms inside each of the cavity. Previous studies have documented this phenomenon as roller bearing effect which effects in sub-laminar drag for very low Re. Previous work focused on rectangular cavities with an aspect ratio of 2:1. This study aims to replicate the butterfly-inspired geometry with slanted wall cavities, specifically cavity models of AR 2:1 and AR 3:1 with cavity wall inclination angles of 22, 45 and 90 degrees, with the hope of optimizing the drag reduction. We hypothesize that models with AR 2:1 with 45 degrees cavity inclination angle and AR 3:1 with 22 degrees inclination angle will result in higher drag reduction. As all solid surfaces exert a no-slip condition, because of the formation of secondary vortices in the corners the primary embedded vortex will be in less contact with the cavity walls and thus be able to maintain a higher partial slip velocity as it interacts with the boundary layer.

10:44AM S01.00002 Triad interactions induced by vortex shedding in a free jet in air. MARGERITA DOTTI, Department of Chemical and Biochemical Engineering, Technical University of Denmark, Lyngby, Denmark, PREBEN BUCHHAVE, Intaras Optics, Snderskovvej 3, 3460 Birkerød, Denmark, CLARA M. VELTE, Department of Mechanical Engineering, Technical University of Denmark, Lyngby, Denmark — The non-linear processes caused by the convection term in the Navier-Stokes equation are of fundamental importance for both the understanding of turbulence and modelling turbulent flows. These so-called triad interactions in Fourier space were investigated using a single Fourier mode injected into the initial part of a round, free jet in air. We studied the downstream velocity down the measured distance as a function of the target spectrum. Furthermore, the development of the downstream velocity was also calculated by means of a simple, one-dimensional computer model. The comparison between the measured power spectra and the computational ones showed a good agreement between them, allowing us to draw some interesting conclusions regarding the fundamental non-linear processes in turbulence.

10:57AM S01.00003 Transition to vortex shedding and its impact on heat and solute transport in membrane filtration systems. JINCHENG LOU, JACOB JOHNSTON, NILS TILTON, Colorado School of Mines, DR. TILTON’S RESEARCH LAB TEAM — We perform direct numerical simulations (DNS) to investigate the hydrodynamic stability of flow over a cylinder confined in a planar channel with a permeable wall. More specifically, we investigate how cylinder configuration influences transition to laminar vortex shedding, and how this impacts thermal and concentration boundary layers forming on the permeable wall. This flow plays an important role in modern desalination processes that use permeable membranes to remove solutes from feed solutions. The efficiency of these processes is reduced by the formation of thermal and solute boundary layers on the membrane surfaces. This has motivated considerable interest in disrupting these layers using nearby obstacles that generate vortex shedding. We show that while vortex shedding can indeed increase system efficiency by increasing transmembrane flow, it also generates recirculation zones on the membrane surface that lead to solute accumulation and precipitation. Such precipitation is known to damage membranes when treating complex feed solutions. The coupled momentum, energy, and mass transport equations are solved using a finite-volume method with recent advances in immersed boundary methods to enforce no-slip and no-flux conditions to second order spatial and temporal accuracy.

11:0AM S01.00004 Controlled symmetry breaking and vortex dynamics in intersecting flows. AMY SHEN, Okinawa Institute of Science and Technology, NOA BURSTEIN, SIMON HAWARD, Okinawa Institute of Science and Technology Graduate University — Vortices are a ubiquitous feature in complex flows and turbulence, but their dynamics are challenging to study due to their typically transient nature. Here, we perform a detailed study of the vortex dynamics and interactions associated with a symmetry-breaking flow instability at a 4-way intersection. By precisely controlling the flow rate above a critical value, we are able to induce the merging of two co-rotating vortices into a single structure and similarly to induce a single vortex to split into two. Using quantitative flow velocimetry, both processes are recorded with high spatial and temporal resolution. We find that both the merging and the splitting of vortices are exponential processes, with a rate that depends on the imposed flow rate. The vortex dynamics in our system are intimately connected with the symmetry-breaking transition and are affected by the degree of vortex confinement, which we control by varying the aspect ratio of the microfluidic device. We show how the confinement affects the fundamental nature of the flow transition, which varies from super through subcritical as the aspect ratio is increased. Our results are relevant to understand and predict flow transitions and vortex dynamics in flow interactions, particularly in confined environments.

11:23AM S01.00005 Vorticity dynamics for a spatially developing liquid jet within a co-flowing gas. WILLIAM A. SIRIGNANO, ARASH ZANDIAN, University of California, Irvine, FAZLE HUSSAIN, Texas Tech University, UCI COLLABORATION, TTU COLLABORATION — A three-dimensional transient round liquid jet with coaxial outer gas flow is simulated and analyzed via vortex dynamics. Two surface-deformation types separate at an indentation of the jet stem. Local vorticity explains the deformations in the recirculation zone behind the cap that affect the cap dynamics. The Kelvin-Helmholtz (KH) instability dominates the deformation region upstream of the cap (UR), unaffected by the behind-the-cap region (BCR). Different three-dimensional UR atomization mechanisms are delineated on a gas Weber number ($W_e^g$) versus liquid Reynolds number ($Re_l$) map, consistent with temporal studies and limited experiments, in a frame moving with the liquid velocity to portray better the similarity, avoiding the common misuse of velocity ratio. Vorticity distributions show periodic vortex development and surface deformation in the UR, with lost periodicity closer to the BCR. For practical density ratios and early times in the process, axial vorticity is mainly generated by baroclinicity while streamwise vortex stretching becomes more important later only at lower relative velocities with reduced pressure gradients. Pressure and viscous forces cause azimuthal acceleration. Azimuthal viscous forces are important even at high $Re_l$.

11:36AM S01.00006 Inflow vortex past moderately yawed cylinders. MOHAMMED KHAROUBA, JEAN-LOU PIERSON, IFP Energies nouvelles, JACQUES MAGNAUDET, IMFT, Universités de Toulouse — The flow past a finite-end yawed cylindrical particle is studied numerically. Three dimensionless parameters govern the problem when the flow is steady and uniform: the aspect ratio $\frac{L}{D}$ where $L$ is the length of the cylinder and $D$ its diameter, the yaw angle $\theta$ which is the angle between the cylinder axis and the inlet velocity, and the Reynolds number based on $D$. Particular attention is paid to the effect of these parameters on the particle wake and hydrodynamic loads. The aspect ratio is prescribed in the range $[0; 20]$, the yaw angle in the range $[0; 30]$, and the Reynolds number in the range $[0; 100]$. Various types of vortex patterns are observed, including steady shedding of two counter-rotating vortices, periodic shedding of counter-rotating vortices and unsteady shedding of hairpin-shaped vortices. Results show that the dynamical regime and time evolution of the loads change drastically with the yaw angle $\theta$. The wake is found to be unsteady in the range $Re \in [360; 400]$ at small yaw angles ($\theta \leq 30$) with $\frac{L}{D} = 2$. We propose a drag law valid for low and high Reynolds numbers in the case of a cylinder aligned with the flow.

11:49AM S01.00007 Hysteresis and Bistable Behavior in Low Reynolds Number Flow Over a Cylinder With a Slanted Afterbody. FERNANDO ZIGUNOV, PRABU SELLAPPAN, FARRUKH ALVI, FAMU-FSU College of Engineering — A cylinder with a slanted afterbody is a bluff body that has a wake pattern similar to aircraft fuselage wakes. Recent work (Bulathsinghala et. al. 2017; Zigorov et. al. 2019) improved our understanding of the vortex-dominated regime of this wake, where a pair of counter-rotating vortices is formed. Steepening the slant angle above a critical value causes the vortex-dominated wake to transition to a fully-separated ("stalled") wake, with a subsequent increase in unsteadiness and a significant drop in form drag. The current investigation shows the full three-dimensional flow topology of the two wake states, reconstructed through stacked stereoscopic particle image velocimetry (SPIV) and phase-averaged stereoscopic particle image velocimetry (S-SPIV). The wake transition to the bistable state is shown to be a function of a fixed slant angle and the wake presents a hysteretical behavior when the Reynolds number is slowly varied. The hysteresis effect is further detailed in this investigation through fully time-resolved, high-speed PIV, and physical insight into the flow instability mechanisms that contribute to this effect is presented.

11:49 AM S02.00007 Neural-network-augmented Gaussian moment method for the statistics of cavitating bubble populations1. SPENCER BRYNGELSON, California Institute of Technology, ALEXIS CHARALAMPOPOULOS, THEMISTOKLIS SAPSIS, Massachusetts Institute of Technology, TIM COLONIUS, California Institute of Technology — Phase-averaged bubbly flow models are forced by moments of the bubble population dynamics. Computation of such moments requires a representation of the bubble population statistics. This has traditionally been accomplished via a classes method that evolves bins of discrete bubble sizes and computes the required moments via quadrature. We instead propose a method based upon explicit evolution of low-order moments of the bubble population and Gaussian closures. This circumvents the additional expense associated with the evolution of classes in lieu of a numerical evaluation of the associated closure integrals, which is particularly advantageous when the bubble population distributions are broad. This approach is exact for linear bubble dynamics, though has larger errors for bubble populations undergoing increasingly strong nonlinear dynamics. This problem is associated with the generation of higher-order moments, which we treat via recurrent neural networks. They are trained with Monte Carlo surrogate-truth data and augment our evolution of the low-order moments and evaluation of higher-order moments. The neural networks markedly improve model predictions, even for out-of-sample testing data.

12:02 PM S02.00008 Cavitation Collapse Near Slot Geometries, ELIJAH ANDREWS, IVO PETERS, University of Southampton — Vapor bubbles in water collapse towards a nearby solid boundary producing a jet that can clean, or damage, the boundary. It is useful to understand how different boundary geometries will affect the direction in which the jet is produced. The majority of research so far has focused on simple flat boundaries or limited cases with analytic solutions such as axisymmetric boundaries. We numerically and experimentally investigate how a slot in a flat boundary affects the jet direction of a single bubble. We use a boundary element model to predict how the jet direction depends on key parameters and show that the results collapse to a single curve when the parameters are normalized appropriately. We then experimentally verify the predicted dependencies using laser-induced cavitation and compare the experimental results to the predicted dependencies. This research provides useful insights into how jet direction is affected by slot geometries and demonstrates a method that can be used to investigate other complex geometries.

Tuesday, November 26, 2019 10:31 AM - 12:15 PM Session S03 Surface Tension IV 201 - Irmgard Bischofberger, MIT

10:31 AM S03.00001 Reverse Marangoni Propulsion of Disks and Hemispheres at Finite Reynolds Numbers1. SAMRAT SUR, University of Massachusetts - Amherst, HASSAN MASOUD, Michigan Tech, JONATHAN ROTHSTEIN, University of Massachusetts - Amherst — In this presentation, the experimentally observed phenomenon of Reverse Marangoni propulsion will be presented for both a thin cylindrical disk and a hemisphere floating on an air-water interface. Each particle was propelled by an asymmetric release of a surfactant to locally reduce the surface tension. Marangoni surfers typically propel themselves forward in the direction of high surfactant concentration. However, by systematically varying the water depth we will show that increasing confinement initially causes the velocity of the Marangoni surfer to slow, then come to rest and finally to reverse direction resulting in the Marangoni surfers moving in the direction of low surfactant concentration. Particle tracking and PIV measurements will be used to measure flow field induced by Marangoni flow beneath the disk and hemisphere and understand the origin of the reverse Marangoni flow. This phenomenon of reverse Marangoni flow has been predicted theoretically for Stokes flow at zero Reynolds number. We will show that the reverse Marangoni motion is not only dependent on the water depth confinement but also on Reynolds number. With increasing Reynolds number, increased confinement is needed to observed reverse Marangoni flow. These experimental results are in excellent agreement with the prediction of numerical simulations.

10:44 AM S03.00002 Analytical study for vapor-driven solutal Marangoni flows inside a sessile droplet1. JUNIL RYU, JUNKYU KIM, JONGHYEOK PARK, HYOUNGSOO KIM, KAIST — Flow control inside a sessile droplet is important in microfluidic mixing, materials patterning and coating applications. Recently, a solutal Marangoni flow driven by a vapor of volatile liquid has been introduced as a novel way of flow controller and mixer, which does not require external devices and pollute mixing samples. In this talk, we will present the controlled flow patterns and efficient mixing inside a sessile droplet using solutal Marangoni effects. Furthermore, we developed a theoretical model to predict the vapor-driven solutal Marangoni flows. By matching the experimental and theoretical results, we estimate the profile of vapor distribution of volatile liquid, which is very difficult to directly measure from experiments. Using this analytical model, we further investigate how the boundary condition changes the internal flow pattern. Several possible cases will be discussed during the talk.

10:57 AM S03.00003 Hydrodynamic Doppler effect in a weakly compressible two-dimensional medium. ILDOO KIM, None — This study is based on two experimental observations in flowing soap film channels. First, the vorticity field is strongly correlated with the thickness field. Second, the thickness field propagates at the Marangoni wave speed. Using the two observations, we propose and review the hypothesis that the vorticity field propagates at the Marangoni wave speed $c$. It is inferred from the hypothesis that a retarded hydrodynamic potential function can be solved in an approach similar to the Lienard-Wiechert potential of the relativistic electromagnetic theory, and the retarded potential implies an elongation effect of a vortex array by $1/(1 + v^2c^2)$ when the array recedes from the origin at $v$. The theory is compared with the experiment, and they agree within the margin of measurement error.

11:10 AM S03.00004 Marangoni-driven film climbing on a draining pre-wetted film, NAX XUE, Princeton University, MIN PACK, Baylor University, HOWARD STONE, Princeton University — In this experimental study, we report a Marangoni flow generated when a bath of surfactant contacts a pre-wetted film, which is set by gravitational drainage on a vertical substrate. High-speed interferometry is used to measure the front position of the climbing film and the film thickness profile, and the effect of the surfactant concentration and the pre-wetted film thickness on the film climbing is studied. As a result, higher surfactant concentration induces a faster and thicker climbing film. Also, for high surfactant concentrations, where Marangoni driving dominates, increasing the film thickness increases the rise speed of the climbing front since viscous resistance is less important. In contrast, for low surfactant concentrations, where Marangoni driving balances with gravitational drainage, increasing the film thickness decreases the rise speed of the climbing front while enhancing gravitational drainage. We rationalize these observations by establishing a model that analyzes the climbing front, either in the Marangoni driving dominated region or in the Marangoni balanced, drainage region. Our work highlights the possible effects of the gravitational drainage on the Marangoni flow, both by setting a pre-wetted film and by resisting the film climbing.
11:23AM S03.00005 Marangoni Instability and Interfacial Turbulence of a Water Drop at an Oil/Alcohol Interface¹, SAMI YAMANIDOZISORKHABI, GARETH H. MCKINLEY, IRMGARD BISCHOFF-BERGER, MIT — Water and ethanol are fully miscible, while anise oil and ethanol are partially miscible and anise oil and water are immiscible. Mixing of all three liquids, however, results in an equilibrium state emulsion of anise microdroplets in water/ethanol solution. Here, we study the mixing of a water drop at the interface of anise oil and ethanol until the equilibrium emulsion state is achieved. We use a combination of regular imaging and Schlieren imaging to visualize the mixing phenomenon. This mixing involves two processes: (i) introduction of a water drop at the anise oil/ethanol interface and formation of a vortex ring due to natural convection caused by exothermic mixing of water and ethanol, (ii) growth of the vortex ring at the interface due to Marangoni forces until the equilibrium state is achieved. We show that the inhomogeneities at the anise oil/ethanol interface apply non-uniform Marangoni forces on the vortex ring resulting in its deformation and a non-uniform distribution of the final mixing product, i.e., the equilibrium state emulsion, at the interface.

11:36AM S03.00006 Solutal Marangoni flow induced by a solute source. ISLAM BE-NOUAGUEF, Department of Mathematical Sciences, New Jersey Institute of Technology, Newark, New Jersey, NAGA MUNSUNURI, Department of Mechanical and Industrial Engineering, New Jersey Institute of Technology, Newark, New Jersey, DENIS BLACKMORE, Department of Mathematical Sciences, New Jersey Institute of Technology, Newark, New Jersey, IAN S. FISCHER, PUSHPELLDRA SINGH, Department of Mechanical and Industrial Engineering, New Jersey Institute of Technology, Newark, New Jersey — The study of the solutocapillary flow induced in a waterbody due to the presence of a solute source or sink on its surface is reported. The surface tension of water increases with increasing salt concentration, and so, for example, when a freshwater source is present on the surface the local salt concentration is reduced which in turn makes the interfacial tension near the source smaller than that away from the source where the salt concentration is larger. This gives rise to an interfacial gradient away from the source which drives the flow. We have analytically studied the axially symmetric analytic solution to this problem and have made a comparison with the experimental data obtained by the PIV (Particle Image Velocimetry) and PLIF (planar laser-induced fluorescence) techniques. It is shown that a freshwater source gives rise to a doublet flow such that the flow comes towards the source within a conical region with its vertex at the source and outside the conical region the flow moves away from the source. The half cone angle increases with increasing source strength and for a typical solutocapillary flow it is ~70-80 degrees.

11:49AM S03.00007 Influence of nonlinear temperature dependence of surface tension on longwave oscillatory Marangoni patterns. ALEXANDER MIKISHEV, Sam Houston State University, ALEXANDER NEPOMNYYASHCHY, Technion — In most theoretical papers on Marangoni convection the authors assume the linear dependence of the surface tension on temperature. However, according to experiments, that dependence is more complex. In the present work, we consider the influence of nonlinear temperature dependence of surface tension on the nonlinear dynamics of waves created by an oscillatory source within a conical region with its vertex at the source and outside the conical region the flow moves away from the source. We have analytically studied the axially symmetric analytic solution to this problem and have made a comparison with the experimental data obtained by the PIV (Particle Image Velocimetry) and PLIF (planar laser-induced fluorescence) techniques. It is shown that a freshwater source gives rise to a doublet flow such that the flow comes towards the source within a conical region with its vertex at the source and outside the conical region the flow moves away from the source. The half cone angle increases with increasing source strength and for a typical solutocapillary flow it is ~70-80 degrees.

12:02PM S03.00008 Surface tension-driven flows induced by polymerization waves¹, REDA TIANI, Universit Libre de Bruxelles, JOHN A. POJMAN, Louisiana State University, LAURENCE RONGY, Universit Libre de Bruxelles, DEPARTMENT OF CHEMISTRY (LOUISIANA STATE UNIVERSITY) COLLABORATION — Thermal frontal polymerization (FP) is a process in which a monomer-initiator mixture is converted into a polymer via a localized reaction zone that propagates due to the interplay between heat diffusion and exothermic polymerization whose reaction rate increases with temperature following Arrhenius’ dependence. Recent experiments considering horizontally propagating FP have evidenced the presence of hydrodynamic flows that interfere with the dynamics of polymerization waves and even possibly prevent their initiation. Since those experiments are conducted in systems open to the air, surface tension-driven (or Marangoni) flows, due to temperature gradients between the cold monomer-initiator mixture and the hot polymer solution, are expected to play an important role in the observed experimental results. In this work, we present a two-dimensional model that includes the oscillatory instability recently discovered in [1] in the limit of small Biot number Bi and wavenumber k, k ≈ Bi^{1/2}. Near the critical Marangoni number, that dependence is described by a Taylor series around the reference temperature value. The set of amplitude equations governing the nonlinear interaction of waves has been derived. The stability of different wave patterns and wave pattern selection are investigated. REFERENCE: [1] S. Shklyaev, A. Ababuzhev, and M. Khenner, Phys. Rev. E, 85, 016328 (2012).

Tuesday, November 26, 2019 10:31AM - 12:15PM — Session S04 Nano Flows 203 - Yuan-Nan Young, New Jersey Institute of Technology

10:31AM S04.00001 Correlations at Liquid/Solid Interfaces Relating Molecular Configurational Effects to the Kapitza Resistance¹, HIROKI KAI-FU, SANDRA TROIAN, California Institute of Technology, 1200 E. California Blvd., MC 128-95, Pasadena, CA 91125 — Todays electronic systems for banking, medicine and transportation rely critically on ever more powerful integrated chips which can generate local power densities in excess of 100 W/cm² leading to catastrophic thermal failure. Such excess heat has become the limiting factor in information processing. Liquid cooling is therefore being used to mitigate this problem. Fundamental understanding of thermal resistance at liquid/solid (L/S) interfaces is therefore indispensable to future design. Interfacial thermal transport is normally quantified by the Kapitza resistance although its relation to phonon transport at L/S interfaces is still lacking. Computational studies have mostly focused on the effects of liquid wettability and contact density, whose enhancement favors formation of absorbed layers that lower the resistance. Using non-equilibrium molecular dynamic simulations of a monoatomic Lennard-Jones liquid confined between solid walls, we examine interface configuration effects by varying the intermolecular distance representing the L/S potential minimum. These studies reveal how configuration of the liquid and solid molecules at the interface in the absence of liquid flow controls the magnitude of the Kapitza resistance.

10:44AM S04.00002 Nanoscale Capillary Bridges and the Role of Hydration Forces1
CARLOS COLOSQUI, SIJIA HUANG, Stony Brook University; YUAN YOUNG, New Jersey Institute of Technology; HOWARD STONE, Princeton University — This talk presents results from theoretical and numerical analysis of a nano water bridge (of height 1 to 10 nm) studied via both fully atomistic molecular dynamics (MD) simulations and continuum-based models based on the Young-Laplace equation. For nanoscale separations between two flat walls, surface forces (e.g., van der Waals and hydration forces) significantly affect the capillary bridge shape, as well as the liquid-solid contact area and contact angle. Nevertheless, the local radius of the capillary bridge is reasonably well described by the classical Young-Laplace equation for surprisingly small heights of about 3 nm (i.e., 10 molecular layers). On the other hand, the curvature predicted by the classical Young-Laplace equation is constant and differs significantly from that reported by MD simulations. As a result, when the water bridge height is smaller than 5-10 nm we observe large differences between adhesion forces obtained from MD simulations and those predicted by Young-Laplace. To accurately account for results from fully atomistic MD simulations we must extend the Young-Laplace description by including a disjoining pressure that considers hydration forces associated with molecular layering and structural changes in the water near the walls.

10:57AM S04.00003 Effect of Charge Inversion on Nanoconfined Flow of Multivalent Electrolyte Solutions1
ANDRES ROJANO, ANDRES CORDOBA, Universidad de Concepcion, JENS HONORÉ WALTHER, Technical University of Denmark, HARVEY A. ZAMBRANO, Universidad Tecnica Federico Santa Maria — Miniaturized devices integrated by nanoparticles have great potential for clinical and biotechnological analysis due to amplified sensitivity, faster response and increased portability. The transport properties of an electrolyte solution flowing through a nanopore in which the electrical double layer occupies a considerable part of the cross section can be altered by the interfacial charge inversion (CI). Hence, an exhaustive understanding of the fluid transport in presence of CI is essential to develop more efficient nanofluidic devices. Here, molecular dynamics simulations of multivalent electrolyte solutions in silica nanochannels are conducted to study the effect of CI on hydrodynamic properties. The solutions consist of water as solvent, chlorine as co-ion and different shares of counter-ions i.e. sodium, magnesium and aluminum. From atomistic trajectories, we find that the magnitude of the effective viscosity is correlated to the concentration and valence of the counter-ions in the solution. Additionally, we show that the CI value is directly related to the hydration shell size of the counter-ions. Moreover, the results suggest that higher CI produces a gel-like region adjacent to the channel wall that increases the interfacial viscosity and friction coefficient.

11:04AM S04.00005 The impact of ligand-receptor binding on the rolling behavior of nanoparticles
HUILIN YE, ZHIQIANG SHEN, YING LI, University of Connecticut — The adhesive rolling of nano-sized particle (NP) plays an essential role in the delivery of therapeutic or imaging agents to diseased microvasculatures. We investigate the adhesive behaviors of NPs on a substrate under the shear flow. Based on the energy balance analysis, we theoretically derive the steady rolling equation for different sized NPs. Contrary to the fundamental Stokes prediction, it is found that smaller NPs move faster than their larger counterparts under the ligand-receptor binding (LRB) effect. Further, the hydrodynamic strength (quantified by shear rate γ) is demonstrated to be associated with the steady rolling velocity (v) of NPs as R = v/γ (R is radius of NP). This scaling is attributed to the size dependence of the adhesive kinetics that is described by energy based stochastic model. We also find the enlargement of flow strength will trigger the transition from adhesive rolling to free rolling of NPs, due to the saturation of stretching of biological bonds forming between ligands and receptors. The size dependence of the rolling behavior may provide a guidance for engineering efficient NPs in biomedical applications.

11:18AM S04.00006 Size determines the adhesive rolling of nanoparticle: smaller rolls faster
ANDRES ROJANO, ANDRES CORDOBA, Universidad de Concepcion, JENS HONORÉ WALTHER, Technical University of Denmark, HARVEY A. ZAMBRANO, Universidad Tecnica Federico Santa Maria — Design of efficient nanofluidic platforms requires effective reduction of flow resistance within the channel network. With this purpose, 2D-materials can be deposited on polymeric substrates increasing the transport efficiency of water solutions through nanopores. In the present work, we show that significant drag reduction can be achieved in a polyamide nanoslit pore by using graphene and boron nitride as wall coatings. Here, Molecular Dynamics simulations are performed to study water flow through uncoated and coated polyamide nanoslit pores. From atomistic trajectories, we investigate interfacial properties and evaluate the effect that the polymeric matrix has on water structure inside the pores. Furthermore, we compute density and temperature profiles, molecular orientations, friction coefficient and velocity profiles. Using these observables, we analyze the correlation between local water structure, flow enhancement and slip length. Our results indicate that in coated pores the interactions between water molecules and the underlying polyamide substrate have a significant influence on the flow rates. The insights reported in this work may assist the design of strategies to achieve low friction water transport in nanostructured pores.

11:36AM S04.00006 Size determines the adhesive rolling of nanoparticle: smaller rolls faster
HUILIN YE, ZHIQIANG SHEN, YING LI, University of Connecticut — The adhesive rolling of nano-sized particle (NP) plays an essential role in the delivery of therapeutic or imaging agents to diseased microvasculatures. We investigate the adhesive behaviors of NPs on a substrate under the shear flow. Based on the energy balance analysis, we theoretically derive the steady rolling equation for different sized NPs. Contrary to the fundamental Stokes prediction, it is found that smaller NPs move faster than their larger counterparts under the ligand-receptor binding (LRB) effect. Further, the hydrodynamic strength (quantified by shear rate γ) is demonstrated to be associated with the steady rolling velocity (v) of NPs as R = v/γ (R is radius of NP). This scaling is attributed to the size dependence of the adhesive kinetics that is described by energy based stochastic model. We also find the enlargement of flow strength will trigger the transition from adhesive rolling to free rolling of NPs, due to the saturation of stretching of biological bonds forming between ligands and receptors. The size dependence of the rolling behavior may provide a guidance for engineering efficient NPs in biomedical applications.
Simulation of the Canonical Shock-Turbulence Interaction, ROZIE ZANGENEH, Prairie View AM

Therefore can avoid Jacobian evaluation. For an accurate, non-oscillatory solution which unlike the existing methods, does not involve Riemann solvers or characteristic decomposition, the use of high-bandwidth schemes with minimal dissipation and dispersion. The existing methods such as ENO, WENO, and RKDG method schemes that can capture flow discontinuity at the shock while capturing broadband spatial and temporal variations in a turbulent flow suggests such as shocks and contact surfaces, in high-speed compressible flows with interactions of shear driven turbulence, requires dissipation numerical shock with adequately low dissipation for the minimum influence of Large Eddy Simulation (LES) of turbulent flows. To this end, high-resolution shock fronts from background noise. This algorithm is also capable of separating entangled shock fronts through pattern recognization, which extract the pixel locations of the shocks. The edge detection algorithm takes advantage of shock waves' light intensity feature to distinguish correction to any optical distortions is applied to the photographs. Next, noise removal and edge detection algorithms are implemented to large amount of schlieren photographs. Here we present an automated algorithm to track individual shock fronts and triple points. First, experimental studies of multiple shock wave interaction to study transition from regular to irregular reflection rely on the processing of a experimental models are supported by extensive molecular-dynamics simulations, as well as evidence from some directly comparable experiments.

12:02PM S04.00008 Measuring the hydrodynamic wall position and viscoelastic friction coefficient by molecular dynamics1, TAKESHI OMORI, NAOKI INOUE, Osaka University, LAURENT JOLY, SAMY MERABIA, Claude Bernard University Lyon 1, YASUTAKA YAMAGUCHI, Osaka University — Flows in nanofluidic systems are controlled by the hydrodynamic boundary condition (BC), involving the friction coefficient and the hydrodynamic wall position. Here we considered a liquid nano-slab confined between two walls, where we derived, from the Stokes equation and the Navier slip BC, analytical expressions for the liquid response to an oscillatory tangential motion of the walls in terms of the wall shear stress and mean fluid velocity. By fitting these expressions to molecular dynamics simulation results, we could extract both the viscoelastic friction coefficient and hydrodynamic wall position for walls with three different wettabilities, hence fully characterizing the frequency-dependent hydrodynamic boundary condition. The proposed methodology applies to a variety of liquid-solid interfaces of interest, e.g. for flows of complex fluids or fluids at a low temperature. It should also support methodological developments on the characterization of the hydrodynamic slip in general, the further development of the quartz crystal microbalance measurement technique.

Tuesday, November 26, 2019 10:31AM - 12:15PM — Session S05 Compressible Flows: Shock Interactions 204 — Dale Pullin, Caltech

10:31AM S05.00001 Evolution of perturbed planar shock waves1, DALE PULLIN, NAJJIAN SHEN, California Institute of Technology, RAVI SAMTANEY, King Abdullah University of Science and Technology, VINCENT WHEATLEY, University of Queensland — We consider the evolution of a planar gas-dynamic shock wave subject to smooth initial perturbations in both Mach number and shock-shape profile. A complex-variable formulation for the general shock motion is developed based on an expansion of the Euler equations proposed by Best [Shock Waves, 1, 4, (1991)]. The zeroth-order truncation of Best’s system corresponds to the equations of Whitham’s geometrical shock dynamics (GSD) while higher-order corrections provide a hierarchical description that can be closed at any order, as detailed initial flow conditions for the flow immediately behind the shock are prescribed. Solutions to the first- and second-order closure of Best’s system for the evolution of planar perturbations are explored numerically to investigate the development of a finite-time singularity in the shock shape profile. Results are compared to those obtained using GSD [Mostert et al., J. Fluid Mech., 246, (2016)].

10:44AM S05.00002 Image processing and edge detection techniques to quantify regular to irregular shock wave transition obtained from experiments1, LINGZHI ZHENG, presenter, BENJAMIN KATKO, BARRY LAWLOR, CLAIRE MCGUIRE, JANE ZANTESON, KEVIN NGUYEN, VERONICA ELIASSON, coauthor — Experimental studies of multiple shock wave interaction to study transition from regular to irregular reflection rely on the processing of a large amount of schlieren photographs. Here we present an automated algorithm to track individual shock fronts and triple points. First, correction to any optical distortions is applied to the photographs. Next, noise removal and edge detection algorithms are implemented to extract the pixel locations of the shocks. The edge detection algorithm takes advantage of shock waves’ light intensity feature to distinguish shock fronts from background noise. This algorithm is also capable of separating entangled shock fronts through pattern recognition, which utilizes a discretization method to reduce complex shock geometries to localized linear patterns. Collectively, the algorithms can track shock wave characteristics to sub-pixel precision. Extractable characteristics include positions and propagation velocities of shock fronts, vertical and horizontal velocities of the Mach stem, and triple point trajectories during shock interactions. This algorithm can process large volumes of data with minimal manual operations, making image processing more efficient and productive.

10:57AM S05.00003 On the Use of Non-Staggered Central Schemes for Large Eddy Simulation of the Canonical Shock-Turbulence Interaction, ROZIE ZANGENEH, Prairie View AM

The objective of this study is to investigate the ability of the semi-discrete, non-staggered central scheme to capture the shock with adequately low dissipation for the minimum influence of Large Eddy Simulation (LES) of turbulent flows. To this end, high-resolution LES simulations are performed to study the interaction of a stationary shock with fully developed turbulent flows. The presence of discontinuities, such as shocks and contact surfaces, in high-speed compressible flows with interactions of shear driven turbulence, requires dissipation numerical schemes that can capture flow discontinuity at the shock while capturing broadband spatial and temporal variations in a turbulent flow suggests the use of high-bandwidth schemes with minimal dissipation and dispersion. The existing methods such as ENO, WENO, and RKDG method typically involve Riemann solvers, characteristic decomposition and Jacobian evaluation, making them complex and difficult to implement in a collocated polyhedral framework. Here, a central scheme which developed by Nessyahu and Tadmor is introduced as an alternative approach for an accurate, non-oscillatory solution which unlike the existing methods, does not involve Riemann solvers or characteristic decomposition, therefore can avoid Jacobian evaluation.
11:10AM S05.00004 Phase Analysis of Disturbances within Transitional Shock Boundary Layer Interactions.~1 JAMES THREADGILL, JESSE LITTLE, University of Arizona — Two-dimensional laminar/transitional Shock Boundary Layer Interactions (SBLIs) have been investigated to assess the influence of Reynolds number and interaction strength, and to probe unsteadiness mechanisms. SBLIs are induced by various ramps (15° < θ < 28°) mounted to a flat plate in Mach 4 flow (Re/L = 4.6×10^6 m^{-1}) at various locations (1.2×10^5 < Reₐ < 2.5×10^5). Oil-flow visualization and high-speed schlieren (50 kHz) have been employed to characterize the flow. The naturally laminar incoming boundary layer experiences significant separation within the SBLI (24 < L/δ₀ < 40). Strong SBLIs with high Reynolds numbers initiate transition within the elongated separated shear layer, promoting unsteadiness. Low-frequency separation shock motion is observed, similar to strong turbulent SBLIs (Stₐ ≈ 0.03). This motion is incoherent with all upstream features, supporting claims of a downstream mechanism driving SBLI unsteadiness. Phase analysis shows that the reattachment shock motion precedes the shear layer which precedes the separation shock motion. In addition, an upstream propagating convective density disturbance was identified within the separated flow (u ≈ -0.2u∞) which directly influences subsequent motion of the separation shock. These observations provide vital input when characterizing complex turbulent unsteady SBLI mechanisms.

1This investigation has been made possible by the support of the Raytheon Company and is greatly appreciated.

11:23AM S05.00005 A Compression - Ramp Shock/Boundary-Layer Interaction Over a Compliant Panel at Mach 5.~1 MUSTAFA MUSTA, LEON VANSTONE, MARC EITNER, JAYANT SIROHI, NOEL CLEMENS, University of Texas at Austin — A compression ramp induced shock wave/boundary layer interaction over a rigid and compliant surface was studied in a Mach 5 flow using high-speed stereo digital image correlation (DIC) and high-speed pressure-sensitive paint (PSP). The compliant panel, made of polycarbonate, is 2 mm thick and gives a fundamental first three mode frequency of about 700, 949, and 1350 Hz. The compression ramp, located at the downstream end of the compliant panel, is the compression angle of 28-degree compression ramp with 1-inch fence distance. The DIC will give time-resolved measurements of the displacement of the compliant panel, and the PSP will give the surface pressure over the entire panel. The simultaneous high-speed pressure and displacement measurements will allow analyzing the structural response of the compliant panel, flow unsteadiness, and the shock-foot in frequency and the time domain and compare with the rigid panel case.

1This study is sponsored by Sandia National Laboratories

11:36AM S05.00006 Thermally driven unsteadiness of Shock Boundary Layer Interaction SANG LEE, BRIAN ROMERO, University of New Mexico, TONGHUN LEE, University of Illinois at Urbana-Champaign — Deficiencies still remain in understanding the unsteadiness associated with the shock interacting with the incoming turbulent boundary layer flow exposed to thermal variation which is caused by the difference in the wall temperature and that of the ambient flow. The present study examines the effects of wall temperature on the dynamics of the unsteady separation bubble in a shock boundary layer interaction region at various Mach numbers. High order numerical simulations of a compression ramp are validated with existing experimental and numerical data at low Mach numbers, then various ratios of wall temperature to recovery temperature are investigated for increasing Mach numbers.

11:49AM S05.00007 Predictability of wall-modeled large-eddy simulation for shock wave/turbulent boundary layer interacting separated flows1 YUMA FUKUSHIMA, SOSHI KAWAI, Tohoku University — In this talk, we first discuss the important flow features (such as separation and reattachment) of the shock wave and turbulent boundary layers interaction based on wall-resolved large-eddy simulation (WRLES) database. By using the WRLES database, we then investigate the capability of the wall-stress-model-based equilibrium and non-equilibrium wall-modeling in LES [Kawai and Larsson, PoF 2012, 2013] for predicting the boundary layer separation and reattachment induced by a strong pressure gradient of the shock wave. In this study, we focus on non-equilibrium terms in the streamwise momentum equation (pressure gradient and convection terms) that are important in the flow separation and reattachment and investigate how these terms are treated in the wall-modeled LES (WMLES). We also discuss the WMLES of transonic airfoil buffet phenomena at high Reynolds number, where the unsteady shock wave induces the separation and reattachment.

1This work was supported in part by MEXT as a social and scientific priority issue to be tackled by using post-K computer. A part of this research used computational resources of the K computer provided by the RIKEN Advanced Institute for Computational Science (Project ID:hp150254,hp160205,hp170267,hp180185,hp180158,hp190164).

12:02PM S05.00008 Direct numerical simulations (DNS) to study the effect of particle motion and Reynolds number on the drag force during shock-particle interactions YASH MEHTA, JONATHAN D. REGELE, Los Alamos National Laboratory — The large disparity between length and time scales associated with explosive dispersal of particles makes the numerical study of these flows extremely challenging. With the recent availability of large-scale computational resources, the number of particle-resolved studies are increasing but most neglect particle motion, viscous effects or both. In the present study, we are interested in studying the effect of viscosity as well as motion on the drag forces experienced by a cluster of spherical particles during shock interaction. We are also interested in studying the anomalous drag reported by Bordoloi et al. (JFM Rapids 2017) in their experiments of a shock interacting with a dilute cloud of micro-particles. Towards this end, as a first step, we perform a direct numerical simulation of a spherical particle under shock-wave loading by solving the Navier-Stokes equations. We use an adaptive wavelet collocation method solver with volume penalization IBM for the particles.LA-UR-19-27293

Tuesday, November 26, 2019 10:31AM - 12:15PM — Session S06 Acoustics: Aeroacoustics II 205 - Aaron Towne, University of Michigan
10:31AM S06.00001 Aeroacoustic source localization and source level estimation during wind tunnel testing of a flat plate with and without a gap. ALEXANDER DOUGLASS, Mechanical Engineering, University of Michigan, NATASHA CHANG, Naval Surface Warfare Center Puget Sound Detachment, DAVID DOWLING, Mechanical Engineering, University of Michigan — Acoustic measurements in wind tunnels are notoriously difficult because of machinery noise from the tunnel, and aerodynamic noise generated within the tunnel and by the test model; and because the potentially-weak signals of interest may share a common frequency range with these noise sources. Thus, when model changes are made, localizing any new aeroacoustic source(s) and determining their level(s) is challenging. This presentation provides such experimental results for the aeroacoustic source associated with addition of a 6 mm gap in a 0.5-m-by-1.0-m flat plate aligned with the flow direction. When present, the gap was located 0.40-m from the plate’s leading edge. The measurements were collected in the Anechoic Flow Facility of the Naval Surface Warfare Center – Carderock Division at nominal air speeds of 19 and 30 m/s using a 0.6-m-diameter spiral microphone array with 24 elements placed 1.24 m from the plate and separated from the air flow by a thin barrier. Measurements in the 4-to-12 kHz frequency range were processed using conventional and high-resolution beamforming methods with and without noise-reference subtraction. Source location and level estimation for the gap-induced aeroacoustic sound source was successful at nominal signal-to-noise ratios of ~20 dB.

1Supported by NAVSEA through the NEEC.

10:44AM S06.00002 Mixed-porosity airfoil acoustics. AREN HELLUM, NUWC-Newport — Porous materials have been shown to reduce the noise produced by lifting surfaces. Acoustic and wake velocity measurements have been made on several arrangements of porous material including full-chord impermeability, full-chord porosity, and multiple chordwise variations of mixed porosity. The “mixed” porosity arrangements are produced by changing the area fraction constructed of porous material. Two different porous materials have been employed. The results are made nondimensional and compared to published data. These comparisons indicate that the noise reduction associated with poroelastic foils is associated with the porosity rather than the elasticity of the material. A percolation-based physical model to explain elevated noise production at high frequencies is also proposed.

10:57AM S06.00003 Approximate Solutions for Nonlinear Acoustic Pulses Propagating Upstream in a Subsonic Flow. FATEMEH BAHMANI, Chalmers University of Technology, MARK CRAMER, Virginia Polytechnic Institute and State University, TOMAS GRONSTEDT, Chalmers University of Technology — We have studied acoustic pulses traveling upstream in one dimensional subsonic flow. A sinusoidal pressure pulse is imposed at the right boundary and the transient wave propagation is studied. The undisturbed flow is assumed to be inviscid with uniform density and entropy. The flow velocity is taken to be uniform. N-waves are observed to form after the shock formation time. Due to interactions of the shocks with the waves in front and behind it, the wave amplitude decreases and the wavelength increases as the pulse wave propagates upstream. The variation of pressure coefficient with time and the strength of the pressure disturbances are presented. This solution provides a rough estimation of upstream traveling pulses and can be used to guide and check computations in many practical fluid mechanics applications.

11:10AM S06.00004 Reduced-Order Inversion of Volumetric PIV for Noise Source Characterization. ADAM NICKELS, JEFF HARRIS, Applied Research Laboratory Pennsylvania State University, ALEXANDER MYCHKOVSKY, JAMES WISWALL, KRISTIN CODY, Naval Nuclear Laboratory, TED BAGWELL, Applied Research Laboratory Pennsylvania State University — Flow induced noise sources are often highly three-dimensional, turbulent phenomenon that require knowledge of the three-dimensional velocity-gradient tensor over significant spatial and temporal domains to fully characterize. To address these needs, volumetric-PIV is used to measure the cross-section of a turbulent jet, providing direct measurements of the time-dependent velocity-gradient tensor. Synchronously obtained acoustic pressure measurements allow for correlation of near field quantities with acoustic features of the flow. To better elucidate the spatially and temporally coherent flow features related to the acoustic source, spectral-POD is applied to the velocity field and correlated with the acoustic pressure.

11:23AM S06.00005 Flow-based decomposition of turbulent-jet noise. MARCO RAIOLO, University Carlos III of Madrid, DANIELE RAGNI, TU Delft — Turbulent jet noise is a complex phenomenon characterized by the interaction of modal and non-modal features in the flow field, the former usually defined as wave-packets in literature. In this work the velocity field of a turbulent round jet at Re=30000 is measured using low-repetition rate tomographic Particle Image Velocimetry. Features in the flow field are extracted on a statistical basis using Proper Orthogonal Decomposition, revealing both non-modal features and features with a clear modal behavior in the streamwise direction which are compatible with the wave-packets reported in literature. The temporal evolution of both velocity and pressure of these features, not readily available from the measurements, is estimated through the Galerkin projection of advection equation and of the Euler pressure equation. This approach is advantageous since it also provides estimates of the interaction between several features/modes. Finally, a similar Galerkin projection is attempted on the Lighthill’s equation in order to provide a flow-based decomposition of the far-field noise produced by the jet and to estimate the noise emission due to the cross-interaction of the flow-field modes.

11:36AM S06.00006 Lagrangian Analysis of Intermittent Sound Sources in a Flow-through Square Duct Containing Two Circular Orifice Plates. VINEETH NAIR, C.P. PREMCHAND, Indian Institute of Technology Bombay, Mumbai - 400076, K.V. REEJA, P.R. MIDHUN, MANIKANDAN RAGHUNATHAN, RAMAN I. SUJITH, Indian Institute of Technology Madras, Chennai - 600036 — Tonal sound production in pipe flow through orifices is a manifestation of self-sustained pressure oscillations that occur when positive feedback is established between an acoustic mode of the pipe and vortex shedding. These oscillations, which can be established in segmented solid rocket motors, gas transport pipelines, and automobile exhaust systems are undesirable as they result in structural damage due to fatigue failure. The onset of such oscillations (instability) in turbulent flows for changes in operating conditions from stable operation happens via an intermittent regime comprising bursts of pressure oscillations that are governed by slow (hydrodynamic) and fast (acoustic) time scales. In this study, we focus on the establishment of self-sustained oscillations in the flow through a square pipe containing two circular orifice plates by varying the mass flow rate through the pipe. We extract the coherent structures responsible for sound production at the acoustic time scale from measured time-resolved velocity fields using dynamic mode decomposition (DMD) and the framework of Lagrangian Coherent Structures (LCS). We find that there are noticeable similarities in the sound-producing coherent structures obtained during the bursting stage of intermittency and instability.

1We are thankful to IRCC - IIT Bombay for their financial support (Grant No. 16IRCCSG006).
10:31AM S07.00001 Representative subsampling of sedimenting blood1. HOWARD STONE, Princeton University, BHARGAV RALLABANDI, UC Riverside, JANINE NUNES, ANTONIO PERAZZO, Princeton University, SERGEY GERTHEIN, Abbott Point of Care — It is often necessary to extract a small amount of a suspension, such as blood, from a larger sample of the same material for the purposes of diagnostics, testing or imaging. A practical challenge is that blood sediments noticeably on the time scale of a few minutes, making a representative subsampling of the original sample challenging. Guided by experimental data, we develop a Kynch sedimentation model to discuss design considerations that ensure a representative subsampling of blood, from a container of constant cross-sectional area, for the entire range of physiologically relevant hematocrit over a specified time of interest. Additionally, we show that this design may be modified to exploit the sedimentation and perform the subsampling to achieve either higher or lower hematocrit relative to that of the original sample. Thus, our method provides a simple tool to either concentrate or dilute small quantities of blood or other sedimenting suspensions.

1We thank Abbott Point of Care Inc. and the NSF, CBET-1702693, for partial support of this work.

10:44AM S07.00002 Rearrangement Dynamics in Dense Particulate Systems1. DOUGLAS DURIAN2, University of Pennsylvania — Together at Penn, Jerry Gollub and I jointly supervised the PhD theses of two superlative graduate students as part of Penns MRSEC. Kerstin Nordstrom (assistant professor, Mount Holyoke) and Jennifer Rieser (postdoc, Georgia Tech). In this talk I will review Kerstins work on dynamical heterogeneities in a compressed suspension of hydrogel particles under shear. In particular, flow is mediated by intermittent rearrangements that diverge in size as a universal power law of the local relaxation time, i.e. the reciprocal of the pitter-pattering sound of raindrops on lakes and pools to the thunderous rumble of falls plunging into the rivers flowing below, these sounds can elucidate the mechanisms and evolution behind their origins. Particularly, solid objects can create different sounds when they impact the water surface water depending on their size, shape, speed, etc. Herein, we study these sounds by driving hydrogelic spheres into a quiescent tank and capture the accompanying sounds with in-air microphones and sub-surface hydrophones. Spheres (diameter: 10 mm-24 mm) impacting water at low to high velocities (1-6 m/s) were tested, revealing that the specific sealing phenomena of the cavities have distinct acoustic signatures. Synchronizing high-speed images of these impacts with audio signals captured by acoustic sensors reveal interesting and unique distinct sounds created by the unique cavity sizes, bubble shedding patterns and in some cases the rebounding Worthington jets. These observations help tie the water entry hydrodynamics and acoustics together in a definitive way.

Tuesday, November 26, 2019 10:31AM - 12:15PM — Session S07 Non-Linear Dynamics and Chaos IV 211 - Patrick Tabeling, ESPCI Paris

10:31AM S07.00003 Disentangling Resolution, Precision, and Inherent Stochasticity in Fluid Mixing, NICHOLAS GUELLETTE, LEI FANG, Stanford University, SANJEEVA BALASURIYA, University of Adelaide — Reliable measurement, simulation, and analysis of dynamical systems rely on appropriately bounded uncertainty. Errors that lead to uncertainty naturally arise from finite precision or resolution, but an additional unappreciated source of uncertainty is the effective stochasticity associated with nonlinear dynamics. Here we describe and quantify the interplay between these three sources of uncertainty using a recently developed framework known as stochastic sensitivity theory. Using fluid mixing as a test case and considering data from an analytical flow, a laboratory experiment, and geophysical observations, we show how to delimit regimes that are limited by finite resolution or by inherent stochasticity. We arrive at the surprising conclusion that in some cases, refining the resolution of a measurement or simulation can actually be counterproductive and lead to an outcome that is less faithful to the true dynamics.

10:45AM S07.00004 Nonlinear Granular Electrostatics, TROY SHINBROT, Rutgers University — Anyone who has run a sandblasting machine can attest that flowing sand generates a robust and painful stream of electric shocks to the operator. The same mechanism that produces these shocks also generates lightning in sandstorms, and influences the formation of asteroids as well as industrial systems such as fluidized beds. We describe recent progress showing that multiple length and time scales are involved in granular charging, which produces surprising effects. These include distinct charge patterns and oppositely charged surfaces, and competing charging and discharging times that can predictably lead to decreased electrification with increased frequency of vibration of granular beds. None of this work is of the calibre of Jerry Gollub’s, but I present it as an homage: work that I think he would have enjoyed.

10:57AM S07.00005 Chaos and disorder in microfluidics1. PATRICK TABELING, ESPCI — Dynamics obviously plays an important role in microfluidics: how long does it take for a biochemical reaction to develop, how long does it take for a microdroplet to form... More specifically, chaotic dynamics plays an important role in the domain of micromixing. Devices based on chaotic mixing, designed to accelerate mixing, are now currently used in the laboratories. To celebrate the memory of Jerry, I will show a few examples where chaos and disorder, in the way he liked to think about, are exploited to develop certain functionalities in microfluidic devices.

1ESPCL, IPGG, CNRS, Horizon2020
where the internal deformation radius is a maximum. That is partially stabilized by viscosity. Calculations of the growth rate at several latitudes indicate that the instability is enhanced in the Tropics. Despite a highly idealized formulation that assumes a purely meridional basic state and makes a local f-plane approximation, the stability analysis successfully predicts a length scale of the disturbance, a latitude for its origin, and a critical Reynolds number that agree well with accompanying numerical results. Realistic western boundary current profiles undergo a horizontal shear instability that is partially stabilized by viscosity. Calculations of the growth rate at several latitudes indicate that the instability is enhanced in the Tropics where the internal deformation radius is a maximum.

Institution — A linear stability analysis of the shallow-water system in the tropical ocean examines the stability of the western boundary current and its latitudinal dependence. Despite a highly idealized formulation that assumes a purely meridional basic state and makes a local f-plane approximation, the stability analysis successfully predicts a length scale of the disturbance, a latitude for its origin, and a critical Reynolds number that agree well with accompanying numerical results. Realistic western boundary current profiles undergo a horizontal shear instability that is partially stabilized by viscosity. Calculations of the growth rate at several latitudes indicate that the instability is enhanced in the Tropics where the internal deformation radius is a maximum.

12:02PM S07.00008 Watercolors - Measuring the light field in natural waters, NICHOLAS TUFILLARO, dynamic penguin, llc. --- Visible light is one the few wavelengths that has any significant transmissivity through natural waters: oceans, lakes, streams, and ponds. Light is a primary tool for investigating biological or physical processes in water from sensors in orbit, instruments on ships, or spectrometers in the water itself. I will focus on describing how to see — in vivo — the activities of phytoplankton in natural waters, both individual micro-swimmers (~10 microns) up to large assemblages of diatoms (~10 km), and how these measurements are used to understand and gauge biological productivity at both the watershed and global scale. The talk will also discuss a few challenges in trying to do precision measurements in natural environments, instead of the our more natural habitat, the 'lab,' and some of the changes that are helpful to optical instrument designs, measurement procedures, and data analysis.

Tuesday, November 26, 2019 10:31AM - 12:15PM — Session S08 Flow Instability: General I 212 - Bud Homsy, University of British Columbia

10:31AM S08.00001 Investigation on Chemical Garden Pattern in Hele-Shaw cell by Interfacial Rheology, TARO MAEDA, YUICHIRO NAGATSU, Department of chemical engineering, Tokyo University of Agriculture and Technology — Chemical garden is an experiment with a precipitation reaction. Precipitation is formed by placing a precipitating salt such as cobalt chloride in a aqueous solution of sodium silicate. In recent years there have been several reports on pseudo 2D chemical garden experiments in Hele-Shaw cell. We also experimentally investigate the influence of concentration of CoCl₂ on chemical garden patterns in Hele-Shaw cell. As the displaced fluid, 3.13 M sodium silicate solution is used, while 0.10~6.25 M cobalt chloride solution is used for injection liquid. Filament pattern is observed at high concentration, spiral pattern is confirmed at middle concentration and flower pattern is emerged at low concentration. These results show that the change in concentration affects the chemical reaction rates and the precipitation rates. Therefore, we analyze such influences by performing some interfacial rheological experiments. We find that the result of interfacial LAOS (large amplitude oscillatory shear) measurement is linked to the selection of formed pattern.

10:44AM S08.00002 Geometrically-weighted Modal Analysis Technique, KOUROSH SHOELE, TSOKANG WANG, Florida State University — Modal decomposition techniques have been used to analyze complex flow and explore how they can be explained with a low-dimensional model. The data-driven methods such as proper orthogonal decomposition (POD) and dynamic mode decomposition (DMD) are used to extract coherent structures in the form of spatial modes. However, the classical data-driven modal decomposition methods have no spatial recognition and are not applicable to time-dependent grids which is common in shape-changing applications. We propose a novel method, the geometrically-weighted modal analysis, utilizing differential geometry mapping techniques to solve this issue. The deforming geometries are transformed into fixed domain based on their geometric characteristics and with the use of divergence-free mapping then the modal analysis is applied. Through different examples, we demonstrate the capability of this method to accurately capture the flow feature and dynamics of complex fluid-structure interaction systems.

10:57AM S08.00003 Experimental Study of Roll-Hydrothermal Wave Coexistence in Convection Driven by Buoyancy and Thermocapillarity, MICHAEL SCHATZ, BRETT TREHONG, Georgia Institute of Technology, JOSHUA BARNETT, Stanford University, MINAMI YODA, ROMAN GRIGORIEV, Georgia Institute of Technology — Buoyancy-thermocapillary convective flow in a volatile fluid with a free surface and a horizontal temperature gradient arises in a variety of situations. Previous work examining buoyancy-thermocapillary flow in a rectangular geometry showed that hydrothermal waves are usually found in the limit where the dynamic Bond number approaches zero while a stationary convection roll pattern is found in the limit where the dynamic Bond number is of order unity while the Marangoni number is held as a control parameter. Linear stability analysis predicts a dynamic Bond number regime in between these limits in which static convection rolls coexist in the domain with hydrothermal waves that propagate along the direction of the temperature gradient [Grigoriev and Qin, JFM 838, 248 (2018)]. By probing this regime over a range of dynamic Bond numbers, we examined these predicted dynamics using an experimental cell containing silicone oil imaged with a shadowgraph technique.

This work was supported by the National Science Foundation under Grant No. CMMI-1511470.
11:10AM S08.00004 Stability analysis of supersonic round jet with temperature non-uniformity, MONIKA CHAUHAN, K. TODD LOWE, LUCA MASSA, Virginia Tech — We perform parallel and parabolized stability analyses of round supersonic jets supported by the adiabatic expansion in turbulent nozzle. We carry out Reynolds-average Navier-Stokes calculations in two and three dimensions and test various turbulence models to resolve the effects of incoherent turbulence created by the nozzle walls on coherent structures in the shear layer. The computed mean profiles are in reasonable agreement with the experiments using the SST turbulence model and show the presence of a region of low momentum near the axis due to matching of Mach number in the cold and hot streams. After validating the mean profiles against the experimental data, we determine the stability characteristics with axisymmetric injection at the upstream of the throat. We find that the maximum axisymmetric mode is weakened by cold injection at the axis, while the first and second circumferential modes are of similar magnitude but exist for a reduced range of Strouhal numbers. Next, we evaluate the effect of circumferential temperature non-uniformity in the mean profile by calculating the stability of three-dimensional mean-profiles with resonant coupling against the circumferential instability modes.

11:23AM S08.00005 Centrifugal instabilities in curved free shear layers: direct computations in the nonlinear regime, OMAR ES-SAHLI, ADRIAN SESCU, Mississippi State University, USA, MOHAMMED APSAR, University of Stratchclyde,UK — Curved free shear layers abound in many engineering applications involving complex geometries, such as backward facing step flows, wall injection, the flow inside side-dump combustors, or flows around vertical axis wind turbines. Most of the previous studies involving centrifugal instabilities have been focused on wall-bound flows, where the so-called Taylor vortices in enclosed geometries or Görtler vortices in boundary layer flows on concave surfaces are generated. Centrifugal instabilities in curved free shear layers, however, did not receive sufficient attention partly because these flows are mostly dominated by Kelvin-Helmholtz instabilities. Under certain conditions, however, longitudinal instabilities in the form of Görtler vortices can occur, which – alone or in combination with Kelvin-Helmholtz type instabilities – may be susceptible to secondary instabilities and ultimately to turbulence. We study the development and growth of nonlinear Görtler vortices evolving inside curved free shear layers in both incompressible and compressible regimes, using direct numerical solution to the Navier-Stokes equations. Results for different flow conditions are reported, along with discussions of challenges associated with simulating these types of flows.

11:36AM S08.00006 Kelvin-Helmholtz shear instability with strong thermal nonequilibrium1, MYOUNGKYU LEE, MICHAEL A. GALLIS, JACQUELINE H. CHEN, Sandia National Laboratories — The effect of strong thermal nonequilibrium on the Kelvin-Helmholtz (K-H) instability is studied with the Direct Simulation Monte Carlo (DSMC) method. Transport properties of gases vary with temperature and, in general, are a function of a single temperature, which assumes the translational, rotational, and vibrational energies are locally in equilibrium at macroscopic scales. The local equilibrium assumption is invalid when flows with K-H instability undergo certain conditions whereby the residence time is short compared to thermal relaxation time scales, for example, in reactive turbulent jet flows at high Mach number with strong temperature and/or velocity gradients. The DSMC method models the fluid flows using molecule-simulators, following the probability density functions for different energy modes. First, we demonstrate the validity of the DSMC method by simulating helium-argon flows undergoing K-H instability with DSMC and compare the result with solutions from continuum direct numerical simulation. Next, hydrogen and air are used as working fluids to introduce a strong thermal gradient and nonequilibrium. Finally, we analyze the energy transfer between length-scales as a function of the nonequilibrium ratio, e.g., \[ \phi_{\text{gb}} = \frac{3T_{\text{ vib}} (T_r + T_{\text{rot}} + T_{\text{tr}})}{T_{\text{rot}} + T_{\text{tr}} + T_{\text{tot}}} \].

1This research was supported by the US DoE, Office of Basic Energy Sciences, and used resources of the National Energy Research Scientific Computing Center, a US DoE Office of Science User Facility (Contract No. DE-AC02-05CH11231).

11:49AM S08.00007 Direct Numerical Simulations of the Span-wise Asymmetric Kelvin-Helmoltz Instability, SCOTT WIELAND, DAVID FRITTS, THOMAS LUND, GATS Inc. — Recent advancements in computational power have allowed the study of more complex fluid interactions, including exploring previously untouched regimes of the Kelvin-Helmholtz instability (KHI). Theory has predicted interesting effects stemming from the introduction of span-wise variations to the perturbations and shear layer of KHI. To investigate this, direct numerical simulations have been carried out using the Complex Geometry Compressible Atmospheric Model. These simulations have been performed at a Reynolds number of 5000 with a Richardson number of 0.05 and have explored both the effects of span-wise asymmetries in the shear layer thickness and the perturbations applied as initial conditions. The results obtained confirm the predicted development of the interactions between misaligned billows as characteristic x-shaped “knots.” These knots, though, produce intense events at faster time scales expressed as vorticity and energy dissipation at least an order of magnitude higher than the standard KHI developing in the background. These results will also be compared to observations of similar KHI events obtained from imaging of the polar mesospheric cloud layer and from measurements taken from the Andes LIDAR Observatory.

12:02PM S08.00008 ABSTRACT WITHDRAWN –

Tuesday, November 26, 2019 10:31AM - 12:15PM –
Session S09 Industrial Applications: General 213 - Dana Greco, University of British Columbia

10:31AM S09.00001 Aerodynamic Performance of a Rim Driven Thruster, MAXWELL KOGLER, CONOR PACE, HASAN RAZA, MICHAEL VU, OLEG GOUSHCHA, Manhattan College — Rim driven thruster consists of a fan actuated into a rotational motion by a mechanism located at its outer radius, rather than by a centerline shaft as seen in conventional fan designs. Such configuration eliminates a need for a centerline hub containing driving mechanism, allowing for an undisturbed core flow of fluid through the centerline region of the fan. In this study we present a rim driven thruster actuated by an interaction between electric and magnetic fields, similar to the brushless motor with entire fan and supporting structure resembling rotor and stator, respectfully. This thruster operates in air and can be used as a propulsion system in airplanes. The aerodynamic performance was evaluated experimentally by measuring upstream and downstream velocity fields and thrust forces at various flight conditions. Results from the experiments are compared to the predictions made by the Blade Element Theory.
10:44AM S09.00002 Effect of surface roughness on numerical modeling of full-scale self-propulsion\(^1\), HENRIK MIKKESEN, JENS HONORE WALTHER, Technical University of Denmark — When predicting the full-scale performance of a vessel, the resistance from surface roughness is important, since it can account for up to 15\% of the total resistance for a newly built vessel. We compare full-scale computational fluid dynamics (CFD) simulations with speed trial measurement from six sister ro-ro vessels. The study includes extensive validation and verification of both resistance, open-water and self-propulsion simulations. Full-scale resistance and open water as well as model scale self-propulsion simulations show good agreement with towing tank measurements and predictions. However, the full-scale self-propulsion simulations using the traditional approach of including the roughness estimated by the empirical formulae of Tounsi significantly underestimates the power from the speed trials. By including the effect of hull and propeller roughness directly into the CFD simulation, by modifying the wall functions, the discrepancy between CFD and speed trail measurements now reach an acceptable level. As a result, full-scale CFD simulations is becoming a viable and accurate alternative to transitional towing tank experiments.

\(^1\)The research was supported by The Danish Maritime Fund under grant 2018-11.

10:57AM S09.00003 Thermal mapping of Hollow Cathodes to model the thermal loads of Iodine Ion Propulsion\(^1\), PAUL WINNER, Embry-Riddle Aeronautical University, Daytona Beach, DR. RICHARD BRANAM COLLABORATION, KIRK BOEHM COLLABORATION — Iodine possesses desirable qualities that could make it a potential fuel of choice in future space missions requiring ion propulsion, potentially replacing Xenon; if the thruster can have similar endurance despite Iodine’s corrosiveness. A computer-aided design model of a hollow cathode with a Lanthanum Hexaboride insert was created in Solidworks, using its thermal load simulator to generate an approximate temperature model of it in operation. Data was then collected to refine the model by getting temperature readings of a hollow cathode in operation by attaching type K thermocouples to the outside and inside of the hollow cathode and firing it in a vacuum chamber. Differences between the thermal model and the experimental data will be discussed in addition to the assumptions made within the thermal model. Based on the data, the hollow cathode is far below expected temperatures, though there are several sources of error to explain this discrepancy.

\(^1\)NSF Grant #1659710

11:10AM S09.00004 Electrohydrodynamics of charge-injecting high-voltage electrodes, XUEWEI ZHANG, Texas A&M University Kingsville — In liquid dielectrics, initiation of electrical breakdown usually takes place at the electrode/liquid interface under a much lower electric field than required by molecular ionization, even if the material is highly purified. One of the main causes is the fact that there exist micro-protrusions and micro-voids on the electrode surface. Small use of charge injection to improve electrical breakdown strength has been demonstrated in previous works. The objective of this paper is to propose and numerically study a new design of charge injecting electrodes inspired by inkjet printer. In a needle-plane configuration, the needle electrode is hollow and has microchannels connecting its interior to the outside, both filled with the same dielectric liquid. The highly inhomogeneous electric field has electrostriction effect, creating a low-pressure region at the needle tip. The pressure difference across the microchannels will drive liquid flow from inside the electrode to the outside. During this, the liquid jets will be electrified and carrying the charge with the same sign as the electrode (homocharge). We build the electrohydrodynamic model and develop a numerical program to simulate this process. The steady-state simulation results confirm that the hollow electrode with microchannels can effectively inject homocharges which enhance the electrical conductivity and lower the electric field in the region near the electrode surface.

11:23AM S09.00005 Modelling Purification of Flue Gas in Porous Catalytic Media\(^1\), KRISTIAN KIRADJIEV, CHRISBreward, IAN GRIFFITHS, University of Oxford, DONALD SCHWENDEMAN, RPI, UWE BEUSCHER, VASUDEVAN VENKATESHWARAN, W. L. Gore and Associates — In this talk, we present a mathematical model for flue-gas purification in a porous filter with catalyst. In particular, we consider a device that converts gaseous sulphur dioxide into liquid sulphuric acid which accumulates, causing clogging. Using the theory of homogenisation, we develop a multiscale model that takes into account local properties of the filter to describe the overall device operation. We explore the effect of changing various dimensionless parameters on the filter efficiency. We also consider asymptotic reductions to the full system and compare them with full numerical solutions.

11:36AM S09.00006 Enhancement of convective cooling in solar photovoltaics, MARC CALAF, BROOKE STANISLAWSKI, TODD HARMAN, University of Utah, RAUL B. CAL, Portland State University — At present, most research on solar photovoltaics (PV) is focused on improving cell efficiency at 25°C, while most world-record efficiencies have been measured, and which neglects the fact that in outdoor conditions the air temperature grows significantly higher. Reduction of undesirable thermal effects can be achieved by either decreasing heat generation at the cell level or by increasing heat dissipation. Here, heat dissipation is exploited through enhanced convection, which has remained fairly unexplored. It is now well-accepted that solar module temperature increases lead to undesired power losses. The rate of efficiency decrease per degree of temperature rise is quantified by the “temperature coefficient.” For a silicon cell, the efficiency of the cell drops by about 0.4% with the increase of every one degree Celsius above 25°C, and solar modules in real atmospheric conditions can typically operate at upwards of 25°C above the ambient temperature. While ongoing efforts continue to reduce the thermal loadings and manipulation the operating temperatures of solar PV modules is sought out within large-scale solar farms by developing new solar farm arrangements that boost the convective heat transfer between the modules and the atmospheric flow. For this purpose, large-eddy simulations of realistic solar PV farms are conducted, where results will illustrate whether there exists any preferential solar farm arrangement for enhanced cooling and hence increased solar PV efficiency.

11:49AM S09.00007 Effect of moving ground and rotating wheels on the flow over a high speed passenger train, MOHAMMAD ASIF SULTAN, DIBYENDU KONAR, Research Scholar, Indian Institute of Technology Kharagpur, SUBHRANU ROY, Professor, Indian Institute of Technology Kharagpur — High speed passenger trains are gradually coming up successfully as a mode of modern transportation. The impact of moving ground and rotating wheels on the flow around a high speed train has been numerically investigated. A Reynolds number of 1.85x10\(^6\) based on the air flow velocity and height of the train is used in the CFD modelling using k-\(\varepsilon\) turbulence model. The total aerodynamic drag were calculated for the three cases: stationary ground, moving ground, moving ground with rotating wheels. Moving ground boundary condition is found to eliminate the boundary layer near the ground which affects the flow beneath the train and changes the pressure distribution. The rotating wheel boundary condition tends to increase the velocity of flow in the bogie region. With moving ground, there is 10.2% increment in the total drag which further increases by 1% when rotating wheels are considered. The simulations show that bogies also have a major contribution on the total drag. It is around 15.2% with stationary ground, increases to 22.8% while ground is moving and finally attains 25.1% when the most realistic case of both moving ground and wheel rotation is considered.
coefficients computed via RANS and the experiments. Reynolds number varying between $Re \leq 5 	imes 10^5$, where $L$ is the streamwise length of the bump. The results obtained by solving the Reynolds-averaged Navier-Stokes (RANS) equations using the Spalart-Allmaras model. The new bump geometry is defined by a Gaussian profile along the span of the cone. The continuous variation of the cone diameter regulate the changes in the shedding frequencies and in some cases controversial. In particular, in LES performed by different groups it was found that increasing grid resolution or decreasing subgrid-scale dissipation leads to a deterioration of the agreement with the experiments with a too short mean recirculation region on the cylinder side. We show that this paradox can be explained by the fact that the upstream corners in the numerical simulations are perfectly sharp while they have a certain degree of roundness in experiments. Indeed, highly-resolved LES are presented showing that even very small values of the corner curvature radius have a dramatic impact on the numerical solution on the cylinder lateral sides. Sensitivity studies carried out by the BARC contributors were not conclusive in detail to characterize the flow over a cone. The continuous variation of the cone diameter regulate the changes in the shedding frequencies along the span of the cone.

10:44AM S10.00002 Vortex formation at the apex of an oblique cone in uniform cross-stream, AL SHAHRIAR, KOUROSH SHOELE, RAJAN KUMAR, Florida State University — The present investigation is concentrating on the dynamics of the vortex in the wake region of the cone for high angle of attacks. As the flow built up from the tip toward the base, it is associated with the swept boundary layer, 3D coherent and turbulent structures, asymmetric vortices and no fixed length scale. Based on the base diameter, the study was conducted for moderate to higher Reynolds number with LES and a wall function. Semi-body conformal grid has been generated for higher accuracy and resolution near the body. The tip of the cone has been found very sensitive to the coherent structures formed downstream of the flow. The instantaneous frequencies, wavelengths, turbulent structure, and shedding angles have analyzed and in some cases controversial. In particular, in LES performed by different groups it was found that increasing grid resolution or decreasing subgrid-scale dissipation leads to a deterioration of the agreement with the experiments with a too short mean recirculation region on the cylinder side. We show that this paradox can be explained by the fact that the upstream corners in the numerical simulations are perfectly sharp while they have a certain degree of roundness in experiments. Indeed, highly-resolved LES are presented showing that even very small values of the corner curvature radius have a dramatic impact on the numerical solution on the cylinder sides leading to a very good agreement with experimental data.

10:57AM S10.00003 Effect of corner rounding on the flow around a 5:1 rectangular cylinder. A paradox explained?, BENEDETTO ROCCHIO, ALESSANDRO MARIOTTI, MARIA VITTORIA SALVETTI, DIC, University of Pisa — The high Reynolds number flow around a rectangular cylinder, having chord-to-depth ratio equal to 5, is the object of the benchmark BARC, collecting several experimental and numerical results. This configuration is characterized, in particular, by flow separation at the upstream corners and reattachment on the cylinder side. A large dispersion was observed in the numerical predictions of the flow features and quantities on the cylinder lateral sides. Sensitivity studies carried out by the BARC contributors were not conclusive and in some cases controversial. In particular, in LES performed by different groups it was found that increasing grid resolution or decreasing subgrid-scale dissipation leads to a deterioration of the agreement with the experiments with a too short mean recirculation region on the cylinder side. We show that this paradox can be explained by the fact that the upstream corners in the numerical simulations are perfectly sharp while they have a certain degree of roundness in experiments. Indeed, highly-resolved LES are presented showing that even very small values of the corner curvature radius have a dramatic impact on the numerical solution on the cylinder sides leading to a very good agreement with experimental data.

11:10AM S10.00004 RANS simulations of a turbulent separated flow validation test-case., MADALINE SAMUELL, OWEN WILLIAMS, ANTONINO FERRANTE, University of Washington, Seattle — A new validation bump-geometry for turbulent separation has been analyzed experimentally, in our $3' \times 3'$ wind-tunnel, and computationally, by solving the Reynolds-averaged Navier-Stokes (RANS) equations using the Spalart-Allmaras model. The new bump geometry is defined by a Gaussian profile in the streamwise direction and an error function in the spanwise direction, such that the turbulent flow over the bump separates, under the adverse pressure gradient, in the downstream region of the bump. Sensitivities of skin-friction and pressure coefficients, as well as the extent of separation to various geometric and flow parameters (e.g., bump height to length ratio, distance of the bump from the top-wall to length ratio, boundary layer thickness of incoming flow on bottom and top walls) have been analyzed. The study has been performed for a range of Reynolds number varying between $0.59 \times 10^6 \leq Re_L \leq 3.5 \times 10^6$, where $L$ is the streamwise length of the bump. The results obtained by using different turbulence models have also been compared. Initial two-dimensional RANS simulations show discrepancies between the pressure coefficients computed via RANS and the experiments.

11:23AM S10.00005 Wall-modeled LES of flow around a prolate spheroid at various angles of attack., XINYI HUANG, XIANG YANG, Pennsylvania State University — We conduct wall-modeled large-eddy simulations (WMLES) of flow around a 6:1 prolate spheroid at various angles of attack (AOA) from $10^\circ$ to $30^\circ$. An equilibrium wall model is used with a coarse mesh deploying 10 to 20 cells within one local boundary layer thickness. The Reynolds number based on the long axis length and the freestream velocity is $4.2 \times 10^6$. This flow was extensively examined experimentally by Simpson et al., in the 90s. We examine the pressure coefficients at a few streamwise locations in the azimuthal direction, as well as the locations of flow separation. Our WMLES results agree reasonably well with the previous measurements, and regions of secondary separation are also captured. WMLES provide more detailed flow information than Reynolds Averaged Navier Stokes. In our simulations, a pair of counter-rotating vortices is reproduced. These vortices originate from the leeward surface and extends in the streamwise direction, leading to notable downwash. The resulting wake is non-axisymmetric. Skewness of the wake is measured and compared to predictions of a lift line model.

11:49AM S10.00007 Lagrangian Flow Separation in External Aerodynamics

—

KLOSE, GUSTAAF JACOBS, San Diego State University, MATTIA SERRA, Harvard University — Kinematic aspects of flow separation in external aerodynamics are investigated by revealing the initial motion of upwelling fluid material from the wall and its relation to the long-term attracting manifolds in the flow field. With direct numerical simulations of a circular cylinder and a cambered NACA 65(1)-412 airfoil, the location of initial fluid upwelling, the so-called spiking point, is determined from the curvature of advected material lines and from high-order numerical derivatives of the wall-normal velocity. While the short-time kinematics are governed by the formation of a material spike upstream of the zero-skin-friction point, over longer times the trajectories of the fluid tracers are guided by attracting ridges in the finite-time Lyapunov exponents once they leave the vicinity of the wall. The combination of initial fluid upwelling, asymptotic separation line, and attracting Lagrangian Coherent Structures draws a comprehensive picture of the mechanics of flow separation in external aerodynamics.

11:36AM S10.00006 High Schmidt Number Washout of Sodium Hypochlorite or a Viscosifying Solute Shielded by Topography

—

MIN, PAUL F. FISCHER, ARNE J. PEARLSTEIN, Department of Mechanical Science and Engineering, University of Illinois at Urbana-Champaign — In many cleaning applications, including washing of fresh-cut produce, surface topography shields soluble contaminants from “washout.” Here, we report computations of washout by two-dimensional flow downstream of a backward-facing step, with a contaminant initially confined to a square domain just downstream of the step, with edge length equal to the step height. We consider three cases. In the first, we focus on removal of NaClO for Reynolds numbers (Re) of 10 and 100 (based on step height) at a Schmidt number (Sc) of 2650. For Re = 100, there is a time in the washout process when the maximum concentration shifts from the relatively inaccessible bottom corner behind the step, to a point in the interior of the recirculation zone downstream of the step. The size of the recirculation zone affects washout efficiency, corresponding to a strong Re dependence on Re. In the second case, we model washout of organic exudate that leaks from freshly cut produce, using data for the viscosifying sugar acid sodium gluconate (NaG) at Re = 100 and an infinite-dilution Sc of 4165, accounting for the dependence of viscosity on concentration. Finally, we show results for the case in which NaClO is present in the free-stream, and reacts with NaG downstream of the step.

10:44AM S11.00002 Towards quantification of biologically generated turbulence through 3D scanning particle image velocimetry

1

FU, Stanford University, ISABEL HOUGHTON, The Data Institute, University of San Francisco, JOHN DABIRI, Caltech — The role of biologically generated turbulence in scalar transport and ocean mixing remains inadequately understood. Though the turbulent scales created by a single swimmer might be limited to those of the individual organism, recent work has suggested that the larger sizes associated with the aggregates of vertically migrating swimmers can introduce mixing scales relevant to the surrounding water column. Quantifying this process requires that the entire flow field and the full range of mixing scales, from the size of the aggregate to below that of the individual animal, be resolved. While there have been significant advancements in volumetric velocity measurements, the spatial resolution associated with these techniques is typically insufficient for exploring common species of vertically migrating swimmers. Here, we present a scanning particle image velocimetry apparatus for quantifying three-dimensional configurations of vertically migrating swimmers and their volumetric, three-component velocity fields and demonstrate its use on the vertical migrations of brine shrimp Artemia salina.

10:57AM S11.00003 Simultaneous measurements of large-scale flow dynamics and small-scale turbulent properties by a hybrid method combining cross-correlation and optical-flow schemes

1

TIAN, ZHEN-YUAN GAO, SHI-DI HUANG, Department of Mechanics and Aerospace Engineering, Southern University of Science and Technology, TIANSHU LIU, Department of Mechanical and Aerospace Engineering, Western Michigan University — Particle image velocimetry (PIV) has been established a standard technique based on cross-correlation scheme for velocity field measurement. While PIV holds advantages in the measurements of large-scale flow dynamics, its accuracy in measuring small-scale turbulent quantities is always unsatisfactory due to limited spatial resolution. On the other hand, optical flow method is born with the capability of extracting high-resolution velocity field up to one vector per pixel [J. Fluid Mech. (2008), vol. 614, pp. 253–291]. In this work, we utilize a hybrid method, combining cross-correlation and optical flow schemes, to analyze the PIV images of global field measured in turbulent Rayleigh-Bénard system. Both the large-scale flow structures and small-scale turbulent properties are obtained simultaneously. It is found that the time-averaged velocity fields are consistent with the results obtained by standard PIV technique. Furthermore, the kinetic energy dissipation and structure functions obtained from present method are compared with those obtained from standard PIV method.

11:10AM S11.00004 Time-resolved turbulent velocity field reconstruction using a long short-term memory (LSTM). ZHIWEN DENG, Shanghai Jiao Tong University and Pusan National University, YINGZHENG LIU, Shanghai Jiao Tong University, KYUNG CHUN KIM, Pusan National University — This paper focuses on the time-resolved turbulent flow reconstruction from discrete point measurements and non-time-resolved PIV measurements using an artificial intelligence framework based on LSTM. To this end, an LSTM-based proper orthogonal decomposition (POD) model is proposed to establish the relationship between velocity signals and time-varying POD coefficients obtained from non-TR-PIV measurements. An inverted flag flow at Re=6,200 was experimentally measured using TR-PIV for the construction of training and testing datasets and for validation. Two different time-step configurations were employed to investigate the robustness and learning ability of the LSTM-based POD model: a single-time-step structure and a multi-time-step structure. The results demonstrate that the LSTM-based POD model has great potential for time-series reconstruction since it can successfully recover the temporal resolution of POD coefficients with remarkable accuracy, even in high-order POD modes. In addition, a relative error reconstruction analysis was conducted to compare the performance of different time-step configurations further, and the results demonstrated that the POD model with multi-time-step structure provided better reconstruction of the flow fields.

11:23AM S11.00005 Extending ”Postage-Stamp PIV” to MHz Rates for Measurement of Turbulent Velocity Spectra. STEVEN BERESH, RUSSELL SPILLERS, MELISSA SOEHNEL, SETH SPITZER, Sandia National Laboratories — Previously, time-resolved particle image velocimetry using a pulse-burst laser demonstrated direct measurement of turbulent velocity spectra at very high frequencies without frozen turbulence assumptions. By accepting reduced laser pulse energy and confining the measurement to a field of view of only 128 x 120 pixels, sequences of 4000 images at 400 kHz were acquired, giving rise to the moniker of ”postage-stamp PIV.” Still, the data reached frequency limitations of approximately 120 kHz due to noise interference. To raise the effective frequency response, the increased speeds of the most recently available cameras obtained data at a sampling rate of 990 kHz, but require overcoming drawbacks in these cameras that can have unfortunate properties for accurate PIV measurements. The increased framing rate oversamples the data and therefore a conventional image-pair correlation can be replaced by multiple-frame image interrogation. The increased accuracy of multiple-frame methods lowers the noise floor and therefore reveals higher-frequency content showing deviation from the theoretical -5/3 power law of the inertial subrange, likely because the turbulent fluctuations have not reached isotropy.

11:36AM S11.00006 Wall Tracking Method for High Resolution Boundary Layer Measurements on a Wing-Fuselage Model. DAVID JEON, California Institute of Technology, CHRISTIAN WILLERT, Deutsches Zentrum für Luft- und Raumfahrt, Kln, DAMIAN HIRSCH, MORTEZA GHARIB, California Institute of Technology — Turbulent boundary layer experiments pose a problem with the large range of length scales that need to be resolved. Measurement techniques tend to focus at either end of this scale. Techniques like holographic PIV primarily measure the region nearest to the wall. Those like conventional PIV typically only resolve down to the log layer. A variation on PIV has been developed by one of us (Willert), where a long-range micro PIV setup is used to resolve down to sub-layer scales. This type of micro PIV setup was used on a wing-fuselage model to measure the boundary layer on the model at Re=2700, from y+=1 in the sub-layer nearly to the outer edge of the boundary layer. In addition, wall shear stress can be computed both using the profile in the sub-layer and the Clauser method through the log-layer and compared against each other. The greatest problem faced with this technique is compensating for apparent wall motion. For example, at the conditions where we can resolve down to y+=1, the apparent wall motion is on the order of 10 wall units. After compensation, this drops below 0.1 wall units. Therefore, the wall tracking method used is critical to get data close to the wall.

11:49AM S11.00007 Turbulence characteristics of flow through an open cell metal foam. YOUNGWOO KIM, CHANHEE MOON, KYUNG CHUN KIM, Pusan National University — Random nature of stochastic foam provides favourable geometrical properties for thermal applications such as large specific surface area and high porosity. However, notwithstanding intensive investigations for the last two decades, hydrodynamic characteristics of stochastic foam are still poorly understood. Current 3-D printing technology supports printing of transparent complex structures. This study investigates turbulence characteristics of a stochastic foam. Using micro-tomography and stereo-lithography, a transparent stochastic foam was printed. Quantitative flow visualization was performed using refractive index matching technique and time-resolved particle image velocimetry. Mixing and turbulence characteristics were discussed. Mechanical mixing and high turbulence in the stochastic foam is beneficial for thermal applications, but large wake area behind the struts cause high pressure drop. On the basis of the results, a new concept of turbulence due to complex geometry can be named as “structure generated turbulence (S3T)”.

1This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (MSIT) (No. 2011-0030013, No. 2018R1A2B2007117).

12:02PM S11.00008 Smartphone PIV. DAVID ARMUJO, LORI CALDWELL, SARBAJIT MUKHERJEE, VLADIMIR KULYUKIN, ANGELA MINICHIELLO, TADD TRUSCOTT, Utah State University — We are developing a smartphone app that performs particle image velocimetry (PIV). This app is called Mobile Instructional Particle Image Velocimetry (mPIV). The intent is to increase the availability of PIV systems to high school and undergraduate students. PIV is used to measure the velocity within a flow field by illuminating neutrally buoyant particles with a laser sheet and recording the motion with a video camera. In mPIV the particles are illuminated with a laser pointer spread into a laser sheet, and the camera is a smartphone. This work is accomplished by integrating the image capture, pre-processing, PIV calculations, and vector output post-processing onto a mobile device. The Java app will be compatible with any smartphone running Android 5.0 Lollipop (API 21) or higher. The system accuracy is benchmarked by comparing a free stream flow field miPIV output with a lab grade system. Results indicate that the system performs well where the illumination quality is high and the flow speeds are below the motion blur limit. Even when these perfect scenarios are not met, students can see flow structures and average velocities that reveal information about the flow field in a way that can inspire them to further study fluid mechanics and its applications.
results also naturally extend to higher dimensional versions of this problem. We maintain a triangulation of the points as they move, while encoding curves as edge weights that enumerate transverse intersections. These output of experiments, this constitutes the problem of topological advection. The current best known topological advection algorithm blends a coherent sets. Since topological entropy is given by the exponential stretching rate of material curves and coherent sets are defined to have problems typically involve either quantifying mixing (e.g. with topological entropy) or finding barriers to mixing (e.g. by identifying Lagrangian vortex. An underlying assumption in past work was that the vortex zone was topologically separated from its exterior. In the present talk, we investigate a series of more challenging examples where this topological condition breaks down. We show that the HLD technique can still describe the topological features of such flows and yield an estimate of the topological entropy.

10:44AM S12.00002 Computation of Topological Entropy in Three Dimensions from Fluid Trajectories1, ERIC ROBERTS, SUZANNE SINDI, University of California, Merced, SPENCER SMITH, Mount Holyoke, KEVIN MITCHELL, University of California, Merced — We introduce and verify an algorithm for estimating a three-dimensional flow’s topological entropy, a measure quantifying the complexity of chaotic dynamics. Analogous to the topological entropy calculation from the “braiding” of system trajectories in two dimensions by Thiffeault, we achieve this in three dimensions by exploiting the collective motion of an ensemble of potentially-sparse system trajectories; as the ensemble evolves in time, the points repeatedly stretch and fold two-dimensional rubber sheets. The topological entropy is bounded below by the exponential growth rate of this sheet, thereby quantifying the flow complexity. New to three-dimensional entropy calculations is the introduction of computational geometry tools: we maintain a Delaunay triangulation of points as they move to record the evolution and growth of a sheet. Because this algorithm requires only trajectory data and no knowledge of governing equations, these results aid greatly in a wide variety of natural and industrial fluid systems, including the large-scale dispersion of pollutants in the Earth’s atmosphere and oceans and the rapidly developing field of microfluidics, all while remaining generally applicable to theorists and experimentalists alike.

1NSF grant number 1808926 titled “Self-mixing Active Fluids.”

10:57AM S12.00003 Topological Advection, SPENCER SMITH, Mount Holyoke College — Fluid advection problems typically involve either quantifying mixing (e.g. with topological entropy) or finding barriers to mixing (e.g. by identifying Lagrangian coherent sets). Since topological entropy is given by the exponential stretching rate of material curves and coherent sets are defined to have boundaries which do not appreciably stretch, both advection problems have a common formulation: find the future state of material curves under the action of the flow. When our knowledge of the fluid system is through sparse data (finite set of trajectories), which is the natural output of experiments, this constitutes the problem of topological advection. The current best known topological advection algorithm blends a braid theory representation of trajectories with a clever coordinate system on the space of closed material curves. I will present a new algorithm which solves the topological advection problem more efficiently and perhaps more naturally. It uses ideas from computational geometry to maintain a triangulation of the points as they move, while encoding curves as edge weights that enumerate transverse intersections. These results also naturally extend to higher dimensional versions of this problem.

11:10AM S12.00004 Topological Helical Vorticity Compression in Ideal Fluids, THOMAS MACHON, University of Bristol — We show how an additional topological conserved quantity arises in ideal fluids whenever the helicity vanishes in such a way that the vorticity field is tangent to a family of surfaces. We give examples of vorticity fields for which this quantity does not vanish, and interpret it as measuring helical compression of vortex lines. We show that if this invariant does not vanish then the flow is not steady, giving a topological obstruction for a vorticity field to come from a steady flow. Finally we discuss relations to the Hamiltonian formulation of the Euler equations.

11:23AM S12.00005 Topological Flow Data Analysis Part 1- Theory and Applications1, TAKASHI SAKAJO, Kyoto University, TOMOKI UDA, Tohoku University, TOMOO YOKOYAMA, Kyoto University of Education — We have investigated a mathematical theory classifying the topological structures of streamline patterns for 2D incompressible (Hamiltonian) vector fields on surfaces such as a plane and a spherical surface, in which a unique combinatorial structure, called partially Cyclically Ordered rooted Tree (COT), and its associated graph (Reeb graph) are assigned to every streamline topology. With the COT representation, one can identify the topological streamline structures without ambiguity and predict the possible transition of streamline patterns with a mathematical rigor. In addition, Uda has recently developed a software converting the values of stream function on structured/non-structured grid points in the plane into the COT representation automatically. It enables us to conduct the classification of streamline topologies for a large amount of flow datasets and the snapshots of time-series of flow evolutions obtained by measurements and numerical simulations, which we call Topological Flow Data Analysis (TFDA). In the three consecutive talks Part1-Part3, we introduce the recent developments of TFDA. In the first part followed by two talks, we will present an overview of basic theory and its applications to atmospheric data.

1This work is supported by Japan Science and Technology.

11:36AM S12.00006 Topological Flow Data Analysis Part 2- Implementation and Software Demonstration1, TOMOKI UDA, Tohoku University, TOMOO YOKOYAMA, Kyoto University of Education, TAKASHI SAKAJO, Kyoto University — Topological data analysis attracts researchers in many fields and it also plays important roles in Topological Flow Data Analysis (TFDA). In the TFDA basis by Sakajo and Yokoyama, streamline patterns are identified by partially Cyclically Ordered rooted Trees (COTs) under topological classification. Since their theory is applicable to a wide range of physical phenomena, there is a rise in demand for an algorithm converting given flow data to COTs. A Reeb graph of a real-valued function, which consists of certain topological sets, is a central key to the conversion. The author has proposed a new algorithm so that the Reeb graph with certain mathematical properties are obtained. Because our formulation is based on persistent homology in topological data analysis, a stability is ensured in our algorithm. We also establish a consistency theorem that bridges a gap between discrete data and continuous data. Furthermore, we do not assume any interpolation, and hence any mesh-like input data are accepted. Thanks to these nice properties we can effectively construct a COT-representation from discrete flow data. In the second part of our series presentations, we will provide quick explanations for the algorithm and demonstrate usage of a library “paclose” for TFDA.

1This work is supported by Japan Science and Technology.
11:49AM S12.00007 Topological Flow Data Analysis Part 3 - Foundation of describing flows on 3D spaces¹, TOMOO YOKOYAMA, Kyoto University of Education / Japan Science and Technology Agency, TAKASHI SAKAIJO, Kyoto University, TOMOKI UDA, Tohoku University — Topologies of flows on 3D spaces are quite complicated. Though every loop (e.g. periodic orbit) separates surfaces but chaotic stationary 2D flows on surfaces do not appear, no loops separate any 3D spaces but chaotic behaviors appear in stationary flows on 3D spaces. Moreover, periodic orbits are unknotted in 2D spaces but they can be easily linked in 3D spaces. Therefore we need the information both of chaos and of linking of infinitely many periodic orbits to analyze flows on 3D spaces. Hence it's very hard to describe topology of flows on 3D spaces in general. However, if there is uniformity (resp. symmetry) of flows, we can use slices of flows on 3D spaces to analyze the topology of such flows as medical doctors use X-ray photographs or computerized tomography images to analyze blood currents. On the other hand, the resulting flows on the slices are not incompressible even if the original 3D flow is incompressible. Thus we need to describe generic 2D flows. Therefore we constructed a classification of generic surface flows, which are called flows of finite type. In the third part of this sequential talks, we will explain the background of representations of 2D flows and introduce a representation of 2D flows of finite type and analyze topologies of flows on 3D spaces.

¹This work is supported by Japan Science and Technology.

12:02PM S12.00008 Topological equivalence between 3D buoyancy-driven and lid-driven cavity flows¹, SEBASTIAN CONTRERAS, Eindhoven University of Technology, IMAN ATAIEI, Delft University of Technology, MICHEL SPEETJENS, Eindhoven University of Technology, CHRIS KLEIJN, MARK TUMMERS, Delft University of Technology, HERMAN CLERCX, Eindhoven University of Technology — The present study concerns Lagrangian transport and (chaotic) advection in three-dimensional (3D) flows in cavities under steady and laminar conditions. The main goal is to investigate topological equivalences in 3D streamline patterns and their response to nonlinear effects between flow classes driven by different forcing. To this end we consider two classical systems that are important in both natural and industrial applications: a buoyancy-driven flow (laterally-heated configuration) and a lid-driven flow governed by the Grashof (Gr) and the Reynolds (Re) numbers, respectively. Symmetries imply fundamental similarities between the streamline patterns of these flows. Moreover, nonlinearities induced by buoyancy (increasing Gr) in the buoyancy-driven flow versus fluid inertia (increasing Re) and forcing protocol in the lid-driven flow cause similar bifurcations of the flow topology. These analogies imply that Lagrangian transport is governed by universal mechanisms and differences are restricted to the manner in which these phenomena are triggered. Experimental validation of key aspects of the Lagrangian dynamics is carried out by particle image velocimetry and 3D particle-tracking velocimetry.

Tuesday, November 26, 2019 10:31AM - 12:15PM — Session S13 Convection and Buoyancy-driven Flows: Free Convection 304 - Olga Shishkina, Max-Planck Institut

10:31AM S13.00001 Multiscaling analysis of buoyancy-driven turbulence in a differentially heated vertical channel, TIE WEI, New Mexico Tech — A multiscaling analysis is presented for the turbulent flow and heat transfer in a differentially heated vertical channel (DHVC). Based on the characteristics of force balance, a three-layer structure is proposed for the mean momentum balance (MMB) equation. In Layer I, a viscous inner layer adjacent to the wall, the force balance is between the viscous force and the buoyancy force. In Layer II, the outer layer, the force balance is between the Reynolds shear force and the buoyancy force. A multiscaling analysis of the MMB equation is developed for the inner and outer layers. A proper scale for the Reynolds shear stress is found to be \( \tau_u U_{\text{max}} \) where \( \tau_u \) is the friction velocity and \( U_{\text{max}} \) is the maximum streamwise velocity. The structure for the mean heat (MHB) equation can be divided into three layers based on the characteristics of the diffusional and turbulent heat flux. The outer scaling of the MHB equation in a DHVC is similar to passive scalar transport in forced convection. However, the inner scaling for the thermal inner layer in a DHVC is distinctly different from that in forced convection. The multiscaling analysis of the MMB and MHB equations agree well with the direct numerical simulation data of DHVC.

10:44AM S13.00002 Superstructures in turbulent thermal convection in slender cells¹, OLGA SHISHKINA, LUKAS ZWIRNER, Max Planck Institute for Dynamics and Self-Organization, Goettingen — The large scale circulation (LSC) in turbulent Rayleigh–Bénard convection and inclined convection of small-Prandtl-number fluids in slender geometries (cylindrical containers of the diameter-to-height aspect ratio smaller than one) is investigated. We investigate in detail the structures of the so-called single-roll and multiple-roll LSCs, their strength and path lengths and their relation to the strength of the volume-averaged heat transport in the system. The problems of the LSC extraction in experiments and numerical simulations and interpretation of the different LSC modes will be also discussed.

¹This work is supported by the Deutsche Forschungsgemeinschaft (DFG) under the grants Sh405/7 (SPP 1881 “Turbulent superstructures”) and Sh405/4 (Heisenberg fellowship). We acknowledge the Leibniz Supercomputing Centre (LRZ) for providing computing resources.

10:57AM S13.00003 Turbulent natural convection in a cavity with a free surface under non-Oberbeck-Boussinesq conditions, WILLIAM HAY, MILTIADIS PAPALEXANDRIS, Université catholique de Louvain — Turbulent natural convection of liquids is encountered in many environmental and industrial applications. For example, in the oceans, the buoyant flow of water due to temperature and concentration gradients has been studied extensively over the years. More recently, highly turbulent flows of a similar nature are being studied to better understand thermal mixing in nuclear spent fuel pools under accidental conditions. In such a case, the Rayleigh number can be as high as \( 10^{14} \). Moreover, due to significant temperature variations, the water transport properties can no longer be considered as constant. Therefore, the validity of the Oberbeck-Boussinesq approximation for the flows of interest becomes questionable. In this talk we present results from both direct numerical and large-eddy simulations of a cubic domain, periodic in the longitudinal direction, with a free-slip upper boundary and with water as the working fluid under non-Oberbeck-Boussinesq conditions. Over a series of simulations at increasing Rayleigh number we assess the impact of the free-slip boundary and variable fluid properties on the turbulent flow statistics.
11:10AM S13.00004 Influence of shroud–chimney configuration on heat transfer from horizontal cylinder: Experimental and numerical investigation. 1, MOHAMMED A. SAMHA, Rochester Institute of Technology - Dubai, OMAR ALI, Zakho University, MOHANAD TAH M. ALI, Rochester Institute of Technology - Dubai — In our prior study, the novel shroud–chimney configuration SCC (semicircular shrouds and expended chimney) has been numerically demonstrated to passively augment natural convection heat transfer from a horizontal cylinder. However, in order to implement such a configuration for practical utilizations, the heat flow properties must be experimentally observed and understood. In this work, well-controlled experiments are carried out to show the impact of SCC on the heat transfer from a horizontal cylinder subjected to constant measured heat fluxes. Circumferential temperature measurements at the cylinder surface, shrouds and ambient are performed using thermocouples. The emissivity of the cylinder is measured using a thermal camera that is needed for estimating the heat radiation. All presented cases are numerically simulated for validation. The measurements show that SCC promotes the convection heat transfer from the cylinder agreeing well with the numerical results. This validates the capability of this simple inexpensive passive method for practical uses. Furthermore, a parametric study is presented to show the optimum range of the design parameters for the best SCC performance.

11:23AM S13.00005 Turbulent thermal convection: the differential heating effects. 1, PHILIPP REITER, Max-Planck Institute for Dynamics and Self-Organization, Göttingen, RODION STEPANOV, Institute of Continuous Media Mechanics, Perm, OLGA SHISHKINA, Max-Planck Institute for Dynamics and Self-Organization, Göttingen — A significant class of geophysical and astrophysical flows are excited by temperature variations along a surface of the fluid layer. Using 3D direct numerical simulations, we study the effects of different temperature and velocity boundary conditions in Rayleigh-Benard convection and horizontal convection, under the requirement that the area-averaged temperature of the heated and cooled plates are kept constant. For these systems we analyze the global flow structures and the heat transport and investigate their dependences on the particular parameters of the boundary conditions. To explain our findings, we exploit a decomposition of the flow fields into the mean and fluctuation components. For some configurations (in horizontal convection) we also extract different Rayleigh-number regimes and present stability thresholds above which the flow exhibits characteristic global structures and give theoretical explanations for the underlying mechanisms of these structures.

1This work is supported by the Deutsche Forschungsgemeinschaft (DFG) under the grants Sh405/10 and Sh405/4 (Heisenberg fellowship) and SPP 1881 (“Turbulent superstructures”). We acknowledge the Leibniz Supercomputing Centre (LRZ) for providing computing resources.

11:36AM S13.00006 The Effect of Horizontal Buoyancy on Turbulent Thermal Convection. LU ZHANG, KE-QING XIA, Southern University of Science and Technology, The Chinese University of Hong Kong — We study the effect of horizontal buoyancy on heat transport in turbulent thermal convection system. Experimentally, a condition of increasing horizontal buoyancy (Ra_H = \alpha g \sin \beta \Delta T^3 / \nu \kappa) under fixed vertical thermal driving strength (Ra_v = \alpha g \cos \beta \Delta T^3 / \nu \kappa) is achieved by simultaneously tilting the convection cell by an angle \beta and increasing the imposed global temperature difference \Delta. Furthermore, we propose a vector formed Nusselt number Nu to quantify the global heat transport. For fixed vertical buoyancy, we find that the vertical heat transport increase monotonically with the horizontal buoyancy and the horizontal heat transport is also non-negligible. We also conduct direct numerical simulations, the results of which confirm our experimental findings and highlights the richness in convective transport.

11:49AM S13.00007 Numerical analysis of 3-D laminar natural convection heat transfer from solid vertical cylindrical heat sinks with straight longitudinal fins and comparison with horizontal heat sinks of the same configuration. DIBYENDU KONAR, Research Scholar, Dept. of Mechanical Eng., Indian Institute of Technology, Kharagpur - 721302, INDIA., SHUBHAM MISHRA, Research Scholar, Dept. of Mechanical Eng., Indian Inst of Technology, MOHAMMAD ASIF SULTAN, VIDYADHAR KARLAPALEM, Research Scholar, Dept. of Mechanical Eng., Indian Institute of Technology, Kharagpur - 721302, INDIA., SUBHRANU ROY, Professor, Dept. of Mechanical Eng., Indian Institute of Technology, Kharagpur - 721320, INDIA. — Of the various challenges facing the electronics industry, keeping components cool is utmost important, since overheating reduces the reliability and operating life of a device. Among various cooling methods, natural convection has been deemed fit owing to its distinctive advantages over forced convection. Longitudinal fins are generally used for vertical cylindrical heat sinks since the geometry eases air flow between successive fins. In the present study, CFD analysis of conjugate natural convection from such heat sinks have been carried out in the laminar regime. 15 different heat sinks modelling heat sinks of LED bulbs of dimensions obtained from literature have been developed. Effect of non dimensional fin spacing, fin length and Rayleigh number on the thermal resistance of the heat sink have been studied and values compared with those of horizontal sinks available in literature. It is observed that compared to the horizontal sink, the thermal resistance of the vertical sink is decreased by different percentages for different configurations. Contour plots to capture temperature profiles around the vertical heat sink have been developed. Correlations for Nusselt number have been formulated which are found to show appreciable agreement with computational data.

12:02PM S13.00008 Linear stability analysis of radiatively-driven convection in a lake. 1, TODD CHRISTOPHER, WILFRIED COENEN, STEFAN LLEWELLYN SMITH, University of California, San Diego — Observations of springtime warming of ice-free Lake Superior show that an instability arises each day at the surface and propagates down though the water column on a time scale of hours before restratification occurs at night. This situation is modeled using the Boussinesq approximation, leading to a Rayleigh-Benard-like configuration, except with a periodically-varying forcing term to capture the diurnal heat flux into the system. The forcing term is considered first as either a varying temperature or a varying heat flux at the boundary, but radiative heating in the bulk of the fluid is also investigated. A linear stability analysis of the system leads to a Floquet differential equation eigenvalue problem for the critical Rayleigh number. This problem is solved using a pseudospectral numerical method. The results found agree with the literature where applicable, while extending previous work to cover different boundary conditions and different forms for the forcing term.

10:31AM S14.00001 Fluid-Structure Interactions of Structure-Borne Traveling Waves, PATRICK MUSGRAVE, AUSTIN PHOENIX, U.S. Naval Research Laboratory — Structure-Borne Traveling Waves (SBTWs) are a promising means of underwater propulsion, but the coupled fluid-structural dynamics are poorly understood. SBTWs operate by taking advantage of a structure’s inherent modal properties (mode shapes and natural frequencies). This enables traveling wave generation using two actuation points instead of requiring a large array of actuators. However, the fundamental reliance of SBTWs on structural properties also introduces coupling with the surrounding fluid. This study extends SBTW generation to underwater and accounts for the two-way coupled, fluid-structure interactions. SBTWs are analytically and experimentally generated on a slender, cantilever beam in quiescent fluid. An analytic model is developed coupling a linear Euler-Bernoulli beam with a potential flow solution for the surrounding fluid. The structural response is solved via a Galerkin-type solution. SBTWs are then generated by applying multi-input forcing to the coupled system. The model is experimentally validated against a cantilever beam in quiescent water. Experimental SBTWs are generated using flush-mounted piezoelectric actuators and the structural response measured using non-contact scanning laser vibrometry. Analytic and experimental SBTWs are compared at several frequencies and with varying wave forms (i.e. wavelength and wave speed). The results demonstrate that SBTWs can be generated in water and the fluid-structure interactions accurately captured.

10:44AM S14.00002 Fluid-Structure Simulations of a Flexible Heaving Airfoil, JONATHAN CAPPOLA, DAVID MACPHEE, The University of Alabama — Motivated by experimental studies in biomimetic propulsion, a computational framework is used to simulate the heaving of a two-dimensional NACA airfoil with chordwise flexibility. A strongly-coupled fluid-structure interaction solver is developed using finite-strain solid deformation and a translating reference frame within the OpenFOAM framework. Using this model, we investigate any possible performance improvements of a flexible airfoil over the rigid in varying oscillating frequency and material elastic modulus. Flow structures and stress configurations are analyzed and discussed as related to simulated thrust and lift enhancements.

10:57AM S14.00003 Numerical and Experimental Investigation of Oscillating Flexible Foils with Application in Energy Harvesting, KIANA KAMKRANI FARD, PENGLEI MA, MICHAEL PRIER, JAMES LIBURDY, Oregon State University — The effect of relative leading edge motion of a flapping airfoil in energy harvesting regime is studied in reduced frequencies of \( k = f c / U = 0.06 \sim 0.14 \), pitching amplitude of \( \theta = 70^\circ \) and heaving amplitude of \( h_0/c = 0.5 \). A low order discrete vortex model with a vortex shedding criterion at the leading edge is used to estimate the transient lift force and the results are compared to 2-D CFD and direct force measurements via load cell. Positive leading edge motions in which the leading edge rotates in the same direction as the pitch angle and reduces effective angle of attack, are shown to improve the heaving power coefficient and efficiency compared to the rigid case by shifting the primary peak later in the stroke where the heaving velocity is higher. Whereas negative leading edge motions, in which the leading edge rotates in the opposite direction as the pitch angle and increases effective angle of attack, are shown to negatively influence the heaving power coefficient and efficiency compared to the rigid case, by reducing the primary peaks.

11:0AM S14.00004 An Alternative Geometry for a Galloping Energy Harvester, SAM TUCKER HARVEY, PETR DENISSENKO, IGOR KHOVANOV, University of Warwick — Interest in aeroelastic energy harvesters has grown substantially in recent years due to their potential for low maintenance and low cost energy solutions, particularly with regard to autonomous electrical devices, such as wireless sensors. The development of aeroelastic energy harvesters to date has focused mainly on the flutter of airfoils, the galloping of prismatic structures and vortex induced vibrations as a means to generate energy. In this work an alternative geometry for a galloping energy harvester, initially inspired by the trembling of aspen leaves in barely noticeable flows, is investigated in two alternative configurations. The dynamics of a prototype device have been characterised experimentally with the use of a motion tracking system, while the flow patterns generated around the device have been evaluated by smoke wire visualisation and particle image velocimetry (PIV). In the second configuration the presence of a leading edge vortex is found to coincide with higher potential energy harvesting performance. The interaction of multiple harvesters within the flow field is also demonstrated to result in phase locking synchronisation.

11:23AM S14.00005 Unsteady loads mitigation using flexible wings, GABRIELE PISSETTA, IGNAZIO MARIA VIOLA, School of Engineering, University of Edinburgh — In nature, fluid flows are inherently unsteady, and any wing-like device immersed in them experiences loads fluctuations. In some cases, these fluctuations may result in fatigue failures, and thus they strongly affect the reliability of the whole device. An effective control strategy would consist in a passive device capable of applying fast, local control action. This can be achieved using a flexible structure. In this presentation, we consider the loads on a tidal turbine operating in a shear flow, and we introduce a novel blade design to reduce the load fluctuations. We show that a blade with a flexible trailing edge can mitigate the fluctuations of the blade root bending moment, without affecting the mean torque, and thus the power generated by the turbine. Using a numerical method based on the semianalitical model, we model the loads flexibility as a torsional spring, and we perform a parametric study to identify the optimal spring parameters. The dynamic analysis of the system shows that the fluctuations of the root bending moment can be reduced by 93%. Our results prove the potential of a flexible structure to alleviate the loads fluctuations arising on a wing in an unsteady flow, and they underpin the development of more sophisticated models of flexible wings.

11:36AM S14.00006 A numerical study of a vertical axis turbine with chordwise-flexible blades operating at low tip speed ratios, PIERRE-OLIVIER DESCOTEAUX, MATHIEU OLIVIER, Universit Laval — This talk will present high-fidelity numerical simulations allowing the performance evaluation of a Vertical-Axis Turbine (VAT) equipped with chordwise-flexible blades. The simulations are carried out with a partitioned Fluid-Structure Interaction (FSI) code in which an in-house structural finite-element solver is linked to a finite-volume flow solver based on the OpenFOAM library. The idea behind this study is to take advantage of the strongly changing flow conditions acting on the blades when the VAT operates at low tip speed ratios. In such cases, the unsteadiness of flow forces can be used to alter the shape of the blade. This analysis will show under which conditions it is possible to increase the efficiency of a VAT by allowing passive foil deformations at a high Reynolds number. The FSI effects related to the flexibility and inertia of the blade will be investigated and the mechanisms that allow efficiency improvements, such as stall mitigation, will be described and compared against rigid-blade VAT operating in the same regime.

11:49AM S14.00007 Fully-resolved wave-structure interaction simulations of a two-dimensional submerged point absorber with three degrees of freedom, PANAGIOTIS DAFNAKIS, Politecnico di Torino, AMNEET PAL BHALLA, San Diego State University, GIULIANA MATTIAZZO, GIOVANNI BRACCO, Politecnico di Torino, SAN DIEGO STATE UNIVERSITY TEAM, POLITECNICO DI TORINO TEAM — A fully-resolved wave structure interaction (WSI) framework is developed to simulate a submerged point absorber. The WSI model is based on the fictitious domain Brinkman penalization method in which the solid body is treated as a porous body of vanishing permeability. For validating the model, forced damped-oscillation of a cylinder in various damping regimes along with several grid convergence studies are performed. The WSI model is compared against Cummins equation based Simulink model to demonstrate the differences between the potential flow theory and the nonlinear Navier-Stokes based methodologies. Time domain simulations are carried out for one, two, and three degrees of freedom buoy in order to analyze the surge, heave and pitching motion of the device using two methods. Furthermore, the WSI model is used to calculate the conversion efficiency of the point absorber for various wave and device parameters.

Tuesday, November 26, 2019 10:31AM - 12:02PM — Session S15: Compressibility Effects 310 - Simo A. Makiharju, UC Berkeley

10:31AM S15.00001 Experimental study on the effect of nozzle flexibility on the evolution of a starting liquid jet¹, DAEHYUN CHOI, HYUNGMIN PARK, Seoul National University — Jet flow is universal phenomena in propulsion, cooling, mixing, and coating. Compared to a jet flow issued from a rigid nozzle, the effect of deformable nozzle has not been understood well. The purpose of this study is to characterize how the flexibility of the nozzle affects the evolution of a starting jet. The nozzle shape is thin-walled circular pipe, and is made of silicone rubber. The flexibility of the nozzle is adjusted as stiff, flexible, and highly flexible cases. The piston-motor system generates a starting jet (Reynolds number of 3,000) that accelerates initially and then reaches a constant speed in a time duration of 0.2 seconds. We use 2D particle image velocimetry (PIV), and 3D digital image correlation (DIC) for measuring the velocity field of the water jet and the deformation of the nozzle, respectively. We find that the nozzle experiences a sudden expansion process as the jet evolves, and gain in fluidic impulse is obtained. When the jet reaches a constant velocity, the nozzle exhibits periodic or static movements according to the flexibility, affecting the performance of the jet mixing, which is quantified by the entrainment rate. A discussion of a dimensionless number that governs the jet-flexible nozzle interaction will be finally discussed.

10:44AM S15.00002 Super jets: the breakup of liquid jets in super- and normal-fluid helium-4, NATHAN SPEIRS, KENNETH LANGLEY, King Abdullah University of Science and Technology, PETER TABOREK, University of California Irvine, SIGURDUR THORODDSEN, King Abdullah University of Science and Technology — We experimentally examine the breakup of super and normal-fluid liquid helium-4 in an atmosphere of its own vapor as the temperature is varied from 1.2 K to the critical point. The jets evolve through five different breakup modes over the large range of Ohnesorge number, Reynolds number, and gas-liquid density ratio that we examine. As jets approach and pass through the critical point the liquid phase vanishes and we see a transition from liquid breakup to turbulent gaseous structures. This unique parameter space allows us to delve into the underlying physics of the various breakup modes and propose new quantitative transition criteria supported by dimensional analysis and a large three-dimensional data set.

10:57AM S15.00003 Structures Within Sub- and Supersonic Submerged Gas Jets, JASON T. PARKER, SIMO A. MAKIHARJU, University of California, Berkeley — Sub- and supersonic submerged gas jets (SGJs) are used in steel making, underwater propulsion, and wastewater treatment. Prior experiments on SGJ dynamics have used optical techniques to study the gas-liquid interface, but to the authors’ knowledge no experimental data exists for the internal phase fraction distribution. Observations by previous investigators suggest that a turbulence peak may explain jet pinch-off (JPO) onset and location. It is unclear whether coherent structures within the SGJ appear and grow before JPO. Grow and Champagne (1971) discovered coherent structures on the surface of a gas jet in air, suggesting that coherent structures may also exist inside a SGJ. Furthermore, validation of numerical models has relied on comparisons between CFD models and high-speed footage that only shows the boundary of the SGJ. In addition to providing a measurement of the internal phase fractions to probe SGJ physics, the present experiments provide validation data for CFD models. The tested gas exit velocities span Mach 0.6 to 1.4. We utilize 13kHz X-ray densitometry located 10-15 nozzle diameters downstream of the orifice to coincide with the predicted turbulence peak and the location of most frequent JPO.

11:10AM S15.00004 Thrust and Flow Field Characteristics of Asymmetric Turbulent Pulsed Jets, CESAR LEOS¹, Member, ROBERT FREEMAN², None, ISAAC CHOUTAPALLI³, Member — An experimental study was conducted to study the effect of nozzle exit Mach number and the nozzle exit geometry on the characteristics of a free pulsed jet and pulsed jet ejector. Four converging nozzles of various exit geometry (circular, diamond, elliptic, and rectangular) were utilized to perform the study. The diameter of the axisymmetric circular nozzle is 50.8 mm and the asymmetric nozzles had the same exit area as that of the circular nozzle with aspect ratio 2:1. Both the thrust and flow field measurements were conducted for nozzle exit Mach numbers 0.10, 0.20 and 0.30 over a range of pulsing frequencies from 24Hz to 180Hz. The force measurements showed that, for a given nozzle geometry, the free pulsed jet and pulsed ejector thrust augmentor exhibited a weak dependence on the nozzle exit Mach number and a strong dependence on the pulsing frequency. Furthermore, strong evidence of thrust augmentation dependence on nozzle geometry, exit Mach number, and pulsing frequency was observed for the nozzle cohort. Flow field measurements using PIV showed that the phase-averaged and global flow characteristics of the free pulsed jet and pulsed ejector are dependent on pulsing frequency and nozzle exit geometry, with a weak dependence on the nozzle exit Mach number.

11:23AM S15.00005 Hybrid Large Eddy Simulation and Lagrangian Particle Simulation of Passive Scalar Mixing in a Supersonic Jet

YOUNG TAI, TOMOAKI WATANABE, KOJI NAGATA, Department of Aerospace Engineering, Nagoya University — Large eddy simulation combined with Lagrangian particle simulation (LES-LPS) is developed for predicting passive scalar mixing in supersonic turbulent flows. LPS solves a governing equation of passive scalar with notional particles, where the velocity of fluid particles is provided by LES while a molecular diffusion term is modeled by a mixing model. We propose a mixing volume model that computes the molecular diffusion term based on spatial averaging. In this model, the coarse-grained scalar dissipation rate is computed from a coarse-grained scalar gradient estimated from particles with an aid of a subgrid-scale model of the scalar dissipation rate. The LES-LPS with the proposed mixing model is applied to a supersonic planar jet with passive scalar transfer. The LES-LPS is evaluated by comparing the results with direct numerical simulation (DNS) databases. In the present study, the number of mixing particles \( N_{m} \) is between 8 and 24. A mean scalar profile is well predicted by the LES-LPS for all of these parameters. However, root-mean-squared scalar fluctuations tend to increase with \( N_{m} \). Comparisons of other statistics, such as probability density functions, confirm that the LES-LPS with \( N_{m} = 12 \) well predicts the passive scalar in the supersonic turbulent jet.

11:36AM S15.00006 Investigating the Turbulence Physics of a Supercritical Carbon Dioxide Round Jet

JULIA REAM, Florida State University, MARC HENRY DE FRAHAN, MICHAEL MARTIN, SHASHANK YELAPANTULA, RAY GROUT, National Renewable Energy Laboratory — In this investigation, we study Supercritical Carbon Dioxide (sCO2) jets to gain a better understanding of the underlying physics associated with supercritical fluid flow. sCO2 is a promising working fluid for advanced cycles including those for power generation (e.g., Brayton cycle) due to increased power density. Open questions remain about how the fundamental physics of these flows are impacted by non-ideal variation in the physical properties. We use a second order finite volume method with adaptive mesh refinement as implemented in the first-principles simulation code PeleC to establish the impact of a cubic equation of state on turbulent flow physics. The Soave-Redlich-Kwong equation of state is used to close the system of equations. We simulate a sCO2 turbulent round jet at 600 K and 10 MPa. We then examine velocity and Reynolds stress profiles at different downstream locations and contrast these with established theory. These conditions are above the critical point of 304.25 K and 7.39 MPa, where new insight is needed for engineering design. We then explore cases in which the temperature of the jet and that of the ambient fluid differ, capturing effects of widely varying thermal properties of supercritical fluids.

11:49AM S15.00007 Effect of Mach Number and Stagnation Temperature on the Performance of a Pulsed Jet Ejector

GREG ACOSTA, ROBERT FREEMAN, ISAAC CHOUTAPALLI, The University of Texas - Rio Grande Valley — An experimental study was carried out to investigate the effect of Mach number and stagnation temperature on the performance characteristics of a pulsed jet ejector. The nozzle exit Mach number was varied from 0.3 to 0.8, and the temperature ratio \( \Gamma \) was varied from 1.04 to 1.77. The thrust measurements on a free pulsed jet showed that the thrust varied marginally with the primary jet Mach number at a given pulsed frequency. The thrust measurements on the pulsed jet ejected showed that the thrust augmentation ratio is a weak function of the primary jet Mach number and is mainly dependent on the ejector area ratio. An increase in the temperature ratio for the pulsed jet ejector with the primary jet operating at Mach 0.80, resulted in a decrease in thrust augmentation ratio. The global flow field of the free pulsed jet showed that within the subsonic regime, the primary jet Mach number has a minimal effect on the centerline velocity decay and jet spreading for a given Strouhal number. The phase averaged flow field showed that the vortex ring circulation varies minimally with the jet Mach number for a given Strouhal number. The turbulence field showed that the magnitude of the peak turbulent stresses decreased as the jet Mach number is increased.

Tuesday, November 26, 2019 10:31AM - 12:15PM Session S16 Tidal Energy

4c3 - Arindam Banerjee, Lehigh University

10:31AM S16.00001 A hybrid approach for power prediction of tidal stream turbine using transient blade element momentum theory

CONG HAN, ASHWIN VINOD, ARINDAM BANERJEE, Lehigh University, THOMAS LAKE, MICHAEL TOGNERI, IAN MASTERS, Swansea University — Blade Element Momentum (BEM) method is traditionally used to evaluate hydrodynamic performance of wind/tidal turbine blades. Steady-state BEM predictions are based on the assumption that the inflow is uniform at the rotor plane. Majority of tidal energy sites have high levels of Free-Stream Turbulence (FST) and power prediction in those scenarios needs to account for fluctuations in the free-stream. In addition, any variation in hydrofoil (lift-drag) dynamics due to FST needs to be also accounted for. A hybrid approach was implemented to predict the performance of a tidal turbine model in a water tunnel test section. Lift/drag characteristics of a SG6043 hydrofoil was measured in a water tunnel facility fitted with an active grid turbulence generator at Lehigh University. The inflow properties measured using an ADV along with lift/drag measurements are used as an input to the BEM code. Validation of simulation and verification of the hybrid model is done by comparing the transient BEM predictions to the experimental torque-thrust measurements with a scaled turbine model under elevated FST conditions.

10:44AM S16.00002 Wake dynamics behind two closely spaced vertical axis turbines

CATHERINE WILSON, VALENTINE MUHAWÉNIMANA, STEPHANIE MUELLER, PABLO OÙRO, Cardiff University, ALDO BENAVIDES, CARLOS DUQUE, Universidad Nacional de Colombia, CARDIFF UNIVERSITY COLLABORATION, UNIVERSITY OF WARWICK COLLABORATION — The technology for harnessing kinetic energy from rivers via turbines has evolved at a slower pace than in wind or tidal environments. Widely adopted in these fields due to the high energy conversion rates, vertical axis turbines operate at high rotational speeds in high velocity environments, which can drastically impact ecosystems. Alternatively, vertical axis turbines are designed to operate at lower rotational speeds, and with the advantage of their rectangular cross-section, efficiently extract kinetic energy from river streams while reducing environmental impact. This research tested two small-scale vertical axis turbines in a hydraulic flume, measuring their wakes up to 10 diameters downstream and across the flume width. The three-bladed devices rotated at a constant speed equivalent to their optimum energy conversion rate. Flow velocity measurements results in terms of mean velocities and turbulence fluctuations show that the individual wakes merge into a single low-velocity wake and this directly affects the flow processes involved. Flow measurements also captured the tip vortices developed during the upstroke and downstroke rotation of the turbines. Comparisons of these wake dynamics were analysed for two lateral spacings of 1.5 and 2.0 turbine diameters.
turbine-wake interaction
interactions and hypothesize how operating conditions affect array performance. By contrasting configuration and control cases, we explore the hydrodynamic formulation of the model has a strong influence in both instantaneous and mean flow field, especially in the topology and dynamics of turbulent interactions between the flow and the turbine blades. In this study we present a comprehensive analysis of the hydrodynamic behaviour of the wake generated downstream a tidal turbine using three different actuator approaches to represent turbines in the flow: Actuator Disks Model (ADM), a model based on Blade-Element Momentum (BEM) theory and an Actuator Lines Model (ALM). Each computational turbine models interactions such as shear, large temporal fluctuations and turbulence. Through URANS tandem cross-flow turbine simulations, this study provides some physical insight into turbine-wake interactions and on the effect of flow perturbations on effective performance coefficients. Although the different types of perturbation affect significantly and differently the dimensional power of turbines, they are found to yield similar predictions for confined turbines. However, because of turbine-wake interaction, the characteristics of the local flow also include different types of perturbation such as shear, large temporal fluctuations and turbulence. Through URANS large tandem cross-flow turbine simulations, this study provides some physical insight into turbine-wake interactions and on the effect of flow perturbations on effective performance coefficients. Although the different types of perturbation affect significantly and differently the dimensional power of turbines, they are found to yield similar effective performance coefficients, which is quite encouraging for the future developments of simplified turbine models.

Numerical Simulation of a Drag-driven Vertical Axis Hydrokinetic Turbine in Open Channel Flow, JINJIN GAO, Hohai University / University of Minnesota, Twin cities, YUAN ZHENG, Hohai University, MICHELE GUALA, LIAN SHEN, University of Minnesota — A drag-driven vertical axis hydrokinetic turbine, partially embedded in a relatively shallow channel streambank, is expected to partially absorb the kinetic energy of the river. To study its performance and wake characteristics, numerical simulation of the turbine in an open channel flow is conducted. Large-eddy simulation of the flow in an arbitrarily complex domain involving moving or stationary boundaries is carried out to investigate the structure of turbulence in the wake of the turbine and optimize its performance. The complex turbine geometry, including the rotor and the cavity along the bank, is captured by the immersed boundary method. Coupled level-set and volume-of-fluid method is used to capture the deformable free surface. The power coefficients of the turbine at different angular velocities, and tip speed ratios, are calculated and compared against the experimental data. The simulation results reveal the wake flow structures generated by the turbine and will be used to improve the blade design.

The complex turbine geometry, including the rotor and the cavity along the bank, is captured by the immersed boundary method. Coupled level-set and volume-of-fluid method is used to capture the deformable free surface. The power coefficients of the turbine at different angular velocities, and tip speed ratios, are calculated and compared against the experimental data. The simulation results reveal the wake flow structures generated by the turbine and will be used to improve the blade design.

Cross-Flow Turbine Array Interactions, ISABEL SCHERL, BENJAMIN STROM, STEVEN L. BRUNTON, BRIAN L. POLAGYE, University of Washington — Cross-flow turbines, also known as vertical-axis turbines, use blades that rotate about an axis perpendicular to the incoming flow to convert the kinetic energy in moving fluid to mechanical energy. Arrays of cross-flow turbines with optimized geometries and control strategies have been shown to out-perform geometrically-identical turbines in isolation. In this work, the performance of a two-turbine array in a recirculating water channel was experimentally optimized across sixty-four unique array configurations. For each configuration, turbine performance was optimized using tip-speed ratio control where rotation rate for each turbine is optimized individually and using coordinated control where we operated the turbines at equal rotation rates and optimized the rotation rate and phase difference between the two rotors. By contrasting configuration and control cases, we explore the hydrodynamic interactions and hypothesize how operating conditions affect array performance.

Reliability of effective performance coefficients in the context of turbine-wake interaction, OLIVIER GAUVIN-TREMBLAY, GUY DUMAS, CFD Laboratory LMFN, Universit Laval — In the planning of turbine array deployment and for the performance prediction of its constituent turbines, the use of effective performance coefficients within the simplified turbine models is found to be very useful. Instead of being based on the far field upstream velocity as conventional drag and power coefficients, the effective coefficients are based on a local velocity, representative of the local conditions experienced by each turbine in the array. It has already been shown that effective performance coefficients take inherently into account blockage effects and allow good performance predictions for confined turbines. However, because of turbine-wake interaction, the characteristics of the local flow also include different types of perturbation such as shear, large temporal fluctuations and turbulence. Through URANS tandem cross-flow turbine simulations, this study provides some physical insight into turbine-wake interactions and on the effect of flow perturbations on effective performance coefficients. Although the different types of perturbation affect significantly and differently the dimensional power of turbines, they are found to yield similar effective performance coefficients, which is quite encouraging for the future developments of simplified turbine models.

The authors acknowledge the Natural Sciences and Engineering Research Council of Canada (NSERC) for their financial support as well as Compute Canada for their supercomputer allocation.
10:02PM S16.00008 Performance Assessment of a Wells Turbine with Morphing Blades, KELLIS KINCAID, DAVID MACPHEE, The University of Alabama — Wells turbines are often used to harvest energy from ocean waves when paired with an oscillating water column. Due to the necessity of self-rectifying characteristics in this design, blades are typically mounted normal to the flow direction, resulting in a narrow effective operating region and unfavorable attack angles as flow rate through the turbine increases. Various methods have been proposed to solve this issue, including guide vanes, active and passively actuated blades, and a static blade setting angle which takes advantage of the asymmetric nature of the reversing flow through the turbine in realistic operating conditions. In this work, we model a flexible blade with a static blade setting angle which takes advantage of the asymmetric nature of the reversing flow through the turbine in realistic operating conditions. The model uses a solver based in the OpenFOAM framework to investigate any performance gains realized by incorporating a flexible or “morphing” trailing edge to the turbine blades. With this modification, blades can deflect passively due to aerodynamic forces, resulting in lower effective angles of attack, higher torque output, and delayed onset of stall. In this work, simulation results for both flexible and rigid turbines are analyzed and compared, with discussions on flow structures and material deformations as they relate to turbine performance.

Tuesday, November 26, 2019 10:31AM - 12:15PM — Session S17 Tandem and Flapping Wings 4c4 - Bo Cheng, Pennsylvania State University

10:31AM S17.00001 Effect of the rear wing size on the thrust performance of the two-dimensional tandem flapping wing,1 — SUNIL MANOHAR DASH, NISHANTH S, JIT SINHA, Indian Institute of Technology, Kharagpur, KIM BOON LUA, National Chiao Tung University, Taiwan, IIT KARHAGPUR - NCTU TAIWAN COLLABORATION — In this numerical study, the effect of the size of the rear wing on the thrust performance of 2D elliptical tandem flapping wing is investigated. Here, size ratio (SR), defined as the ratio of the chord of the rear to the front wing, is varied from 0.5 to 1.5 at an interval of 0.25 while keeping the aspect ratio (ratio of wing chord to thickness) AR—8, wing spacing (distance from trailing-edge of front wing to leading-edge of rear wing) λ— chord of the front wing, and phase angle ϕ = 0 deg constant. Reynolds number based on the chord and Strouhal number based on the excursion distance of the front wing are set as 5000 and 0.32, respectively. For different SRs, we notice that time-average (Ct) and peak transient (Ctp) thrust coefficients of the rear flapping wing in tandem configuration can be up to 80% higher compare to those of single flapping wing of same size. This enhanced thrust performance in tandem wing flapping is attributed to the constructive interaction of the shed vortices from the front wing with the leading-edge vortex of the rear wing. Note that the formation and interaction of the vortices is modified with SR. When SR increases, Ctp shifts towards starting of the flapping stroke and maximum Ctp and Ct are seen at SR=0.5 and SR=0.75, respectively.

10:44AM S17.00002 Multi-fidelity Kinematic Parameter Optimization of Flapping Airfoil, HONGYU ZHENG, FANGFANG XIE, YAO ZHENG, Zhejiang University, CENTER FOR ENGINEERING AND SCIENTIFIC COMPUTATION TEAM — We have constructed a multi-fidelity framework for kinetic optimization of flapping foil with inline motion. We employ multi-fidelity Gaussian process regression and Bayesian optimization to effectively synthesize the aerodynamic performance of flapping foil with the kinetic parameters under multi-resolution direct numerical simulations. The objective of this work is to demonstrate that the multi-fidelity framework can be used efficiently to discover optimal kinetic parameters of foil with desired aerodynamic performance using a limited number of expensive high-fidelity simulations combined with a larger number of inexpensive low-fidelity simulations. We efficiently identify the optimal kinetic parameters of asymmetric flapping foil with target aerodynamic forces in the design space of heaving amplitude, pitching amplitude, angle of attack (AOA) and the stroke angle. Specially, it is found that the AOA can affect the magnitude of the aerodynamic forces by violating the generation of leading-edge Vortex while its combination effect with the stoke angle can determine the attitude and trajectory of flapping airfoil.

10:57AM S17.00003 Physics-informed Predictive Model of Flapping Flight Aerodynamics using Gaussian Process Regression1 — YAGIZ BAYILG, KEEGAN HARRIS, The Pennsylvania State University, YU PAN, HAIBO DONG, University of Virginia, BO CHENG, The Pennsylvania State University — An accurate and computationally efficient model for predicting the aerodynamic force, moment and power of flapping flight can significantly advance the understanding animal flight and the design of bioinspired micro aerial vehicles. In this work, we develop such a predictive model based on Gaussian Process (GP), informed by quasi-steady aerodynamic model and trained by Computational Fluid Dynamics (CFD) simulation data for a wide range of flapping wing kinematics. The GP receives instantaneous wing kinematics as the input and uses statistical inference methods to predict the resulting forces, moment and power. The training set consists of a nominal wing trajectory and a set of trajectories highlighting a deviation from the vanilla trajectory in one particular kinematic feature. The resulting GP model is tested on a separate set of wing trajectories with a mixed change of kinematic features and is shown to provide more accurate predictions than the conventional quasi-steady models. The accuracy of the predictions relies on the proximity to the training set, and for a relatively wide range of trajectories, they show excellent agreement with the CFD results. The GP model also provides uncertainty information, indicating the regions where the prediction has a high variance.

11:10AM S17.00004 Aerodynamic stability analysis of the dual-wing flapping flight for the large birds, TENGYU HOU, School of Mechanical Engineering, Shanghai Jiao Tong University, Shanghai, 200240, China, YANG XIANG, HONG LIU, J. C. Wu Center for Aerodynamics, School of Aeronautics and Astronautics, Shanghai Jiao Tong University, Shanghai, 200240, China — By dual-wing flapping, large birds obtain lift and thrust to sustain flight. Insects obtain good maneuverability and dynamic stability through high frequency flap. The airliners show good performance based on the principle of steady aerodynamics. Different from the two examples before, birds have a lower flapping frequency to maintain their stability for forward flight. Through the observation of bird flap behavior and human speculation, we can easily generate the idea that the bird’s flap can show stability only within a certain range of flapping frequency. In this article, we model birds based on a quasi-steady mathematical model, and observe the stability of the mathematical model by applying different perturbation excitations to the model. The results of theoretical analysis show that for a given parameter model, it is possible to maintain stable flight only within a certain range of flapping frequency. Moreover, we find that the model can resist disturbances of different degree in different frequency ranges. Then, we compare the dual-wing to the single-wing model. Our work shows that the flight stability of birds and the flapping frequency are closely related, which may provide effective theoretical guidance for the design of flapping wing air vehicles.
Rolling and twisting of finite foil

11:23AM S17.00005  ANDHINI NOVRTA ZURMAN NASUTION, BHARATHRAM GANAPATHISUBRAMANI, GABRIEL D. WEYMOUTH, University of Southampton — Strip theory in flapping foils, i.e. reconstructing a 3-dimensional (3D) behavior from a spanwise sequence of 2D strips, has a potential to give fast predictions but the modeling errors are poorly understood. In this work, finite foils with an elliptic tip are simulated with a sinusoidal motion of pure rolling and combined rolling-twisting. Their spanwise cross-sections are compared with 2D simulations of the same kinematics. The 3D pressure distributions are strongly correlated with the 2D, but have very different amplitudes. The spanwise velocity of the cross-sections also increases with the local velocity caused by the kinematics. The pure rolling motion indicates that maximum lift coefficient ($C_L_{max}$) at each cross-section augments linearly with local velocity square except at the tip. It is discovered that the slope of $C_L$ along the span declines as the aspect ratio is reduced with the same scaling as Prandtl’s finite-wing theory. Similar behavior is found by Green and Smits [2008] to scale the thrust coefficients of pitching panel for different aspect ratios. With these discoveries, the 2D $C_L_{max}$s can be corrected with the scaling to find their corresponding 3D cross-sections at different aspect ratios, enabling quantitative strip theory predictions of 3D flapping flight.

Vortex models for the unsteady aerodynamics of tandem foils

11:36AM S17.00006  JAVIER ALAMINOS-QUESADA, University of Malaga, JEFF ELDREDGE, University of California, Los Angeles — Configurations of multiple wings and fins arise in various contexts, including biological flying and pitching, biologically-inspired and rotary wing vehicles, and formations of vehicles. Here, we present two-dimensional potential flow models for the separated flows of multiple unsteady foils. In the special case of a longitudinal tandem configuration, these models are evaluated and compared directly with high-fidelity numerical simulations at low Reynolds number. In addition, we have obtained the optimal configuration for an accelerating pair of foils with respect to the separation distance between them. Finally, we consider potential flow models of the trailing airfoil in which the effect of the leading airfoil’s wake is replaced by a time-varying vortexicity flux into the separated flow of the trailer.

A numerical study of flapping wings in tandem configuration at low Reynolds number

11:49AM S17.00007  GONZALO ARRANZ, OSCAR FLORES, MANUEL GARCIA-VILLALBA, Universidad Carlos III de Madrid — Direct numerical simulations of wings in - in line tandem configuration are presented. % The wings undergo a two-dimensional optimal kinematics. % This optimal motion is a combination of heaving and pitching of the airfoils in a uniform free-stream at a Reynolds number 1000 and Strouhal number 0.7. % The objective of the study is to analyze how three-dimensional effects influence the aerodynamic performance of the wings. % To that end, wings of two different aspect ratios, 2 and 4, undergoing the two-dimensional kinematics are considered. % Simulations show that the interaction between the vortical structures of the wings is similar to the 2D case. % However, it is found that 3D effects are detrimental in terms of hind-wing’s thrust generation. % On the contrary, the propulsive efficiency remains constant both in 2D and 3D, for both aspect ratios. % Simulations of flapping motion are also presented and compared to the previous wings in heaving motion. % It is found that aerodynamic forces and propulsive efficiency decrease when the wings are in flapping motion due to a sub-optimal motion of the inboard region of the flapping wings.

A numerical study of flapping wings in tandem configuration at low Reynolds number

12:02PM S17.00008  JOHANNES KISSING, BASTIAN STUMPF, Technische Universität Darmstadt, Fluid Mechanics and Aerodynamics (SLA), JOCHEN KRIEGSEIS, Karlsruhe Institute of Technology (KIT), Institute of Fluid Mechanics (ISTM), CAMERON TROPEA, Technische Universität Darmstadt, Fluid Mechanics and Aerodynamics (SLA) — In order to achieve higher manoeuvrability, novel micro-air vehicle designs adapt flapping wings from biological flight to realize hovering and forward flight. The increased lift of flapping wings is mainly due to the circulatory lift of the leading-edge vortex (LEV), which forms on the wing and induces transient lift as it grows. Subsequently, the unsteady lift drops when the vortex detaches from the airfoil. In order to attain higher overall lift, the current project aims to delay the detachment of the LEV by manipulating the flow field at topologically critical locations with a dielectric barrier discharge plasma actuator (DBD-PA). Time-resolved particle-image velocimetry measurements are used to characterize the flow field around a flat plate, which executes a combined pitching and plunging motion at a Reynolds number of 24,000, a reduced frequency of 0.48 and a Strouhal number of 0.1. A prolongation of the growth phase of the LEV, marked by a longer circulation-accumulation phase and a decreased convection of the LEV, is achieved by compressing secondary structures ahead of the main vortex. Temporal variations of the excitation onset are found to be the key factor between spatial control authority of the DBD-PA and the determined effectiveness of flow control.

Can we achieve statistically stationary Homogeneous Shear Turbulence?

10:31AM S18.00001  CHANDRU DHANAPANI, GUILLAUME BLANQUART, California Institute of Technology — Homogeneous shear turbulence (HST) is an idealized version of the shear turbulence observed in practical free shear flows, and can be simulated using simple computational domains. One of the numerically-efficient configurations to simulate turbulent flows is to use triply periodic domains. However, owing to the mean stream-wise velocity being non-homogeneous, periodic boundary conditions cannot be used along one of the directions. Several studies included shear periodic boundary conditions in the cross-stream direction. However, in these simulations, the turbulence statistics grew exponentially with time, whereas the turbulence observed in free shear flows is statistically stationary. The authors fixed this problem earlier by performing HST simulations with only shear production and neglected shear convection, thereby obtaining statistically stationary shear turbulence. The current study improves upon the previous simulations by including shear convection, by introducing an inflow/outflow in the cross-stream direction. The turbulence statistics reach a statistically stationary state, and the Reynolds shear stress and the anisotropy values agree very well with the results from experiments and simulations of mixing layers, planar jets, and round jets.

Tuesday, November 26, 2019 10:31AM - 12:02PM

Session S18 Turbulent General 400 - Robert Breidenthal, University of Washington
Benard convection boundary layer. ROBERT BREIDENTHAL, University of Washington — Density effects are known to be weak in the free shear layer, yet they are commonly assumed to be strong in the compressible boundary layer. This apparent inconsistency is addressed in a single model by assuming that the acoustic signaling speed rather than density variations always controls the physics, in both free shear and wall flows. The model assumes that turbulent transport by an eddy requires information to propagate across the diameter of that eddy during the period of one eddy rotation, the time interval of importance in the physics. The turbulent fluxes are dominated by these 'sonic' eddies, whose rotational Mach number is underdamped, and the density gradients are neglected. To investigate this effect, large eddy simulations (LES) are performed to propagate a two dimensional fire front using the level-set method which is advanced in time by a third-order Runge-Kutta algorithm. The heat flux generated from the fire is fed back to LES as boundary condition and the effect of buoyancy on wind propagation is included to model a realistic fire weather interaction. From the simulation data, the effects of small scale turbulence structures and change in local atmospheric conditions on fire speed are analyzed. The LES simulation results are compared with the weather research and forecast (WRF) model simulation for wildland fire.

11:49AM S18.00007 On the Inertial Range Scaling in the High-R∞ Limit . CHRISTIAN KUECHLER, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany, GREGORY P. BEWLEY, Cornell University, Ithaca, USA, EBERHARD BODENSCHATZ, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — We investigate in a decaying laboratory flow the universal scaling laws Kolmogorov predicted in 1941 to emerge in the limit of infinite $R_\lambda$. In the past it has been found that this limit requires extreme $R_\lambda$, which are difficult to create in a well-controlled turbulent flow. The Variable Density Turbulence Tunnel (Bodenschatz et al., 2014) is the first wind tunnel capable of producing $R_\lambda > 5000$ and fully resolved inertial scales. It combines the low kinematic viscosity of pressurized SF6 and a unique mosaic-like active grid with individually controllable tiles (Griffin et al., 2019). To resolve the smallest scales present in the flow, we use Nanoscale Thermal Anemometry Probes developed and generously provided by Princeton University (e.g. Bailey et al. (2009), Vallikivi et al. (2014)). We present results that are consistent with Kolmogorov scaling and structure functions differ from conventional scaling laws of isotropic turbulence when studying the logarithmic derivatives of these statistics. However, these local scaling exponents approach a universal form when $R_\lambda > 2000$. We show that these results are well-described by the generalized self-similar spectrum of decaying turbulence introduced by Yang et al. (2018).

10:31AM S19.00001 A unified AMR framework for multiphase flow and fluid-structure interaction problems with both non-subcycling and subcycling . YADONG ZENG, LIAN SHEN, University of Minnesota — In the present work, we developed a unified structured adaptive mesh refinement (SAMR) framework for multiphase flow and fluid-structure interaction problems. The coarsest grid covers the whole computational domain, and is dynamically refined onto higher levels to obtain higher resolution in local regions. Both non-subcycling, where a uniform time step is employed for all variables on composite levels, and subcycling, in which variables on different levels advance in time at different rates, are being refined in the SAMR framework. While the former is easier to implement, the latter can significantly reduce the computational time while maintaining the same order of accuracy. For multiphase flow problems, the level set function is used to capture the interface, and re-initialization across different levels is applied. For fluid-structure interaction problems, a direct forcing immersed boundary method is coupled with SAMR. Validation cases are presented to demonstrate the accuracy and robustness of the proposed computational framework.
10:44AM S19.00002 An optimal sparse sensing approach for adaptive mesh refinement in unsteady flows. DANIEL FOTI, University of Memphis, SVEN GIORNO, KARTHIK DURAISAMY. University of Michigan — Complex physical flows are often characterized by coherent structures, which have a crucial role in turbulent flows. In order to accurately simulate the flow field, the coherent structures need to be adequately resolved with a sufficiently fine mesh. Furthermore, local mesh refinement in areas of interest can be employed to reduce time while preserving accuracy. While mesh adaptation techniques are well-established for steady flows, refinement methodology for unsteady, spatially-evolving flows is less straightforward. Residual and error-minimization based methods require precise definitions for spatio-temporal error, and feature or gradient based methods rely overly on user intuition of the flow, while adjoint-based methods can become expensive for finite volume methods. We introduce a novel approach for adaptive mesh refinement where selection is obtained similar to a computationally expedient discrete empirical interpolation method using rank-revealing QR. This method seeks optimal locations for grid adaptation from the basis of a proper orthogonal decomposition, which organizes velocity flow field features into optimal orthogonal modes based on energy. The methodology is tested on a series of cases including shock formation and flows dominated by coherent structures.

10:57AM S19.00003 Slug Flow Prediction for Subsea Applications Using Dynamic Anisotropic Mesh Optimisation with Tetrahedral Control-Volume Finite Elements. CLAIRE HEANEY, LYES KAHOUDJI, LLUIS VIA-ESTREM, ASIRI OBEYSEKARA, PABLO SALINAS, CHRISTOPHER PAIN, OMAR MATAR, Imperial College London — We present a three-dimensional Direct Numerical Simulation of two-phase air-water flow inside complex pipe configurations with very large aspect ratios (Length/Diameter ¿100) for subsea applications. We focus on the challenging slug flow regimes using a dynamically unstructured mesh, which can modify and adapt to the complex air-water interface in order to represent optimally these flows. The number of unknowns of the resulting model is reduced by a mixed control-volume and finite element formulation and a volume-of-fluid method for the interface-capturing based on a compressive control-volume advection method. The resulting slug length and frequency are compared with experimental data for horizontal pipes.

11:0AM S19.00004 LES of Compressible Gas Flow Impinging on a Wall using High Order Schemes in an Unstructured Grid. DOUGLAS FONTES, MICHAEL KINZEL, University of Central Florida — In this work, compressible gas flow impinging on a wall is solved using large eddy simulation in an unstructured mesh. In this kind of flow, complex phenomena such as shock waves, high gradients, turbulence, and wall interaction can arise. In most Computational Fluid Dynamics (CFD) codes, typically with unstructured grids, spatial schemes are limited to first and second order due to the difficulties of obtaining the information of neighboring elements. This limitation results in a higher computational cost to achieve a specific accuracy. Higher-order schemes in unstructured grids, using a flux reconstruction method, have been implemented in an open source code termed as PyFR. Thus, the present effort explores the application of PyFR to perform Large Eddy Simulation (LES) for an impinging jet case discretized with an unstructured mesh. In this study, we will identify turbulent structures and the formation of instabilities. In addition, comparisons will be developed with RANS prediction. All numerical predictions will be compared to an experimental case in order to analyze the numerical accuracy in terms of experimental results.

11:23AM S19.00005 DEM and Coarse-grained modeling of bubble and particle behavior in fluidized beds. OSCAR ANTEPARA, ANN ALMGREN, MICHELE ROSSO, ROBERTO PORCU, Lawrence Berkeley National Laboratory, JORDAN MUSSER, National Energy Technology Laboratory, WILLIAM FULLMER, National Energy Technology Laboratory; Leidos Research Support Team, CHRISTOPHER BOYCE, Department of Chemical Engineering, Columbia University — MFiX-Exa is a new code being developed by the National Energy Technology Laboratory and Lawrence Berkeley National Laboratory as part of the U.S. Department of Energy’s Exascale Computing Project. MFiX-Exa originated by combining discrete element method (DEM) modules of the classic MFiX code (https://mfix.netl.doe.gov) with a low Mach number projection method for the continuous fluid phase. The new algorithm is implemented using the AMReX software for massively parallel block-structured applications (https://amrex-codes.github.io). In this work, we present the coarse-grained(CG) DEM technique in which several particles are lumped into a single Lagrangian parcel. The work focuses on comparisons, in terms of computational time and accuracy, between the traditional (single particle) DEM and the CG-DEM. The problem of interest is a cylindrical gas-solid fluidized bed containing several million 1 mm particles. Comparisons are also made to the experimental data which include bubble characteristics, bed height, and particle velocity distributions. The results assess how accurately the models can reproduce the main characteristics of the gas-solid fluidized bed and the reduction of computational time between the models.

11:36AM S19.00006 Wavelet-based adaptive simulations of flapping insects. THOMAS ENGELS, LMD-CNRS, Ecole Normale Superieure-PEL, KAI SCHNEIDER, Aix-Marseille Univ, JULIUS REISS, Technische Univ, MARIE FARGE, LMD-CNRS, Ecole Normale Superieure-PEL, DMITRY KOLOMINSKYI, Japan Agency for Marine-Earth Sci and Tech (JAMSTEC) — We present a novel wavelet-based approach to compute multiscale flows generated by complex, time-dependent geometries, motivated by the spectacular flight capabilities of flying insects. Our framework is inherently based on dynamically evolving grids. Our approach is developed in a datastructure based on locally regular Cartesian blocks, which are indexed in a tree-like fashion. The blocks are distributed among MPI processes and allow an efficient parallelization for large scale supercomputers. To avoid solving elliptic problems, we approximate an incompressible fluid using the method of artificial compressibility. Since our grid is locally Cartesian, we use the volume penalization method to include moving obstacles without the need for a boundary-conformal grid. We employ biorthogonal interpolating wavelets as refinement indicators and prediction operators, and combine them with a 4th order finite difference discretization. Using thresholding of wavelet coefficients, we show that the precision of the underlying uniform discretization is maintained on our adaptive grids, while reducing the computational effort. We derive scaling relations for the numerical parameters, and present validation cases to assess its accuracy and performance on massively parallel computer architectures.

Wicking plays a key role in many industrial and biological applications such as passive capillary-driven cooling technology, oil recovery, inject printing and DNA chips. Nowadays, the attempt to design an appropriate surface to enhance the wicking capabilities is getting always more significant. In fact, the control of the wetting properties has increased enormously over the past few decades. These properties are strongly related to the spreading features of a surface. Due to the advances in nanotechnology, it has been possible to tune the wettability of a surface by modifying its topography. Different works have reported the effect of the height of micro/nano structures on the wicking transport, but they have shown contrasting results. In this work, the effect of the height on Si random nanowires has been investigated. In this regard, different nanowire arrays with different heights were fabricated. Therefore, a method to characterize accurately both the wettability and wicking of super-hydrophilic surfaces has been developed and validated. After a proper characterization of the samples, it has been observed that taller nanowires provide stronger wicking.

**10:44AM S21.00002 The Spreading of Superfluid Drops**¹, MATTHEW WALLACE, DAVID MALLIN, MICHAEL MILGIE, University of California, Irvine, KENNETH LANGLEY, ANDRES AGUIRRE-PABLO, SIGUDUR THORODDSEN, King Abdullah University of Science and Technology, PETER TABOREK, University of California, Irvine — We have used video microscopy and interferometry to investigate the spreading of normal and superfluid helium drops impacting on a sapphire substrate in a saturated atmosphere of its own vapor. We find that in spite of having zero viscosity, the short-term spreading of superfluid drops (time t less than 30 ms) is nearly identical to normal helium; in both cases, the drop spreads to a characteristic diameter of 5 mm and assumes a pancake-like shape. Both normal and superfluid drops shrink with time; the normal helium drops last up to 15 minutes, but the superfluid drops last only 2-15 seconds. Superfluid drops shrink via superflow through a fluid film at the contact line, flowing at the Feynman critical velocity. Remarkably, the drops undergo a two-phase geometry-dependent retraction. During the first phase, the drop is toroidally-shaped and the radius shrinks linearly in time; in the second phase the drop assumes the shape of a spherical cap and shrinks with the square root of time. Superfluid outflow causes the drop edges to become ragged and frayed, and causes droplets of fluid that appear to form spontaneously outside the expanding drop (exodroplets.) We provide detailed maps of drop topography and contact angle.

¹King Abdullah University of Science and Technology

**10:57AM S21.00003 Simulation of Droplet Spreading Dynamics by Particle Finite Element Method Based Model and Hydrodynamic Lubrication** , ELAF MAHROUS, R. VALENY ROY, University of Delaware, ALEX JARAUTA, MARC SECANEL, University of Alberta, PAVEL RYZHAKOV, Cimne. International Centre for Numerical Method in Engineering — Modeling droplet dynamics is an active area of research. Of particular interest is the prediction of spreading rates and spatio-temporal evolutions of droplets of varying physical properties such as surface tensions on substrates with different wettability. We adopt two distinct numerical approaches: Particle finite element method (PFEM) and hydrodynamic lubrication. PFEM is advantageous due to its ability to track evolving fluid domains and provide an accurate mesh-based boundary description which facilitates the computation of the surface tension in droplet problems. An alternative modeling approach is hydrodynamic lubrication which is based on a small slope approximation, thus requiring small contact angles. The key advantage of this approach is its low computational requirements. Using a no-slip prevents any contact line movement, and applying perfect slip leads to unrealistically large velocities. A particular challenge is to relieve this singularity while accounting for dynamic contact angles. We show how this can be resolved for both methods. Also, we compare their contact line velocities with hydrodynamic analytic model, as well as with experimental results of capillary driven water droplets on substrates with widely differing properties.

**11:10AM S21.00004 Oil drop spreading on a liquid substrate** , VARUN KULKARNI, SUHAS TAMVADA, SUSHANT ANAND, University of Illinois at Chicago — Several systems in nature such as oil spills, food dressings, and pharmaceutical drugs demonstrate an interaction of oil and water. The process of merger of a single drop and the underlying bulk liquid represents one such scenario which has so far not received much attention in literature. In this study we use high speed imaging to experimentally investigate the dynamics of oil drop deformation and spreading during a gentle deposition of an oil drop onto an air-water interface. After contact with the bulk the merger of the oil drop and its spreading is found to either proceed in stages or instantly depending on the viscosity of the oil drop as characterized by its Ohnesorge number ($Oh = \mu p / (\rho p D^2)$). The topological features during transition scale as a function of the drop viscosity and are theoretically validated using appropriate force balances. It is found that the spreading behavior of the drop depends dominantly on the viscosity of the oil, ultimately determining the extent of film coverage over the liquid substrate. To validate the spreading behavior of the oils, a theoretical model based on the damped harmonic motion is also presented.

**11:23AM S21.00005 ABSTRACT WITHDRAWN —**

**11:36AM S21.00006 Water-air dynamic contact angle hysteresis on rough metal substrates**¹, MARINA MACHADO², JOSEPH MURPHY², WILLIAM RICE³, VLADIMIR ALVARADO², University of Wyoming — Ice adhesion measurements for impact ice and statically frozen water are critical for solving important aerospace challenges, such as ice-resistant coatings. The surprisingly large spread of ice adhesion values obtained on seemingly very similar materials indicate that additional considerations, such as surface roughness and contact-line spreading, need to be incorporated into the analysis of ice adhesion. In this work, we focus on the dynamics of contact angle on metal substrates of interest, such as stainless steel and aluminum, using a pendant-drop system over a frequency range 0-10 Hz. Surface roughness of metal substrates is measured using confocal microscope profilometry mapping. Dynamic contact angle hysteresis turns out to be a weak function of frequency in the range examined, but a strong function of the type, e.g., anisotropy and spatial correlation, and degree of surface roughness. These results might partially explain differences and large spread reported in the literature regarding impact ice adhesion.

10:57AM S22.00003 Jet atomization of brine to achieve zero liquid discharge1, CHRIS-TIAN MACHADO, YOUSHUA JIANG, KYOO-CHUL PARK, Northwestern University — Achieving zero liquid discharge in brine management facilities is critical to solving the environmental problems associated with returning high salinity water to its source. One such pathway for reducing the amount of discharged brine is by utilizing evaporation. To accelerate the evaporation of water in brine, the bulk brine solution should be atomized into microdroplets (i.e., fog) using a high pressure flow. In this study, brine with systematically varying concentrations of salt (NaCl) and surfactant (cetrimonium bromide (CTAB)) was atomized at different compressed air pressures. Results show that the rate of fog droplet generation decreases with increasing salinity. To combat this effect, adding a low surface tension surfactant and increasing compressed air pressure have shown to improve the rate of atomization. Quantitative data analysis was performed to understand the effects of the brine's physico-chemical properties, such as density, surface tension, and viscosity, as well as external variables such as compressed air pressure on overall droplet generation. This study introduces a new approach of brine evaporation using recovered thermal energy, and provides insights in jet atomization.

10:44AM S22.00002 Dynamics of impulsively induced viscoelastic jets, EMRE TURKOZ, ExxonMobil Research and Engineering, Corporate Strategic Research, HOWARD STONE, CRAIG ARNOLD, LUC DEIKE, Princeton University — Understanding the physics of viscoelastic liquid jets and their breakup is relevant to jet-based printing and deposition techniques. In this study, we study the behavior of jets induced from viscoelastic liquid films. We use the mechanical impulse provided by a laser pulse to actuate jet formation. The parameter space governing the maximum jet length and the droplet size of the resulting viscoelastic liquid jets is investigated using simulations, which are validated with experiments. To investigate the effect of viscoelasticity, we present direct numerical simulations and solve the two-phase axisymmetric momentum equations together with the volume-of-fluid technique for interface tracking and the log-conformation transformation to solve the viscoelastic constitutive equation. We show that changing the Deborah number, which denotes the ratio between the elastic and capillary time scales, can change the resulting droplet size and the maximum jet length, so that it is possible to increase the resolution of jet-based printing and deposition techniques by modifying the elasticity of the liquid material to be printed.

10:31AM S22.00001 Deformation and breakup of droplets in an oblique continuous air stream, SURENDRA KUMAR SONI, PAVAN KUMAR KIRAR, PANKAJ KOLHE, KIRTI SAHU, Indian Institute of Technology Hyderabad, India — We experimentally investigate the deformation and breakup of droplets interacting with an oblique continuous air stream. A high-speed imaging system is employed to record the trajectories and topological changes of the droplets of different liquids. The droplet size, the orientation of the air nozzle to the horizontal and fluid properties are varied to study different breakup modes. We found that droplet possessing initial momentum prior to entering the continuous air stream exhibits a variation in the required Weber number for the vibrational to the bag breakup transition with a change in the angle of the air stream. The critical Weber numbers for the bag-type breakup are obtained as a function of the Eotvos number, angle of inclination of the air stream and the Ohnesorge number. It is found that although the droplet follows a rectilinear motion initially that transforms to a curvilinear motion at later times when the droplet undergoes topological changes.

Session S22 Drops: Instability and Breakup II 604 - Larry Li, HKUST

11:49AM S21.00007 Droplet Depinning under Forcing by Wind and Gravity1, EDWARD WHITE, Texas A&M University, ALIREZA HOOSHANGINEJAD, University of Minnesota, ROGER SIMON, ELEAZAR HERRERA HERNAN-DEZ, Texas A&M University, SUNGYON LEE, University of Minnesota — Partially wetting drops are ubiquitous in nature and industry. In many cases such as rain drops on windows, droplets are subject to combined effects of gravity and wind forcing. Stability of water drops under forcing by wind and gravity is relevant to aircraft icing, heat exchangers, and fuel cells. Recent studies by Schmucker and White (2012) demonstrate a sharp transition in the trend of critical wind speed for droplet depinning from any inclined surface as a function of droplet size. To investigate what marks this self similar behavior, we conduct additional experiments of water drops on an inclined aluminum surface subject to forcing by wind. We find that the transition coincides with the onset of depinning for the advancing contact line. Inspired by this observation, we develop a mathematical model to rationalize the original experimental results of Schmucker and White.

10:42PM S21.00008 Impulse-driven drop, HAMED HABIBI, ROUSLAN KRECHETNIKOV, University of Alberta — Drop deformation and disintegration regimes have been studied in many contexts ranging from an impact on a solid surface or a liquid layer of varying thickness to an aerodynamic shock wave propagating in air and hitting a suspended liquid drop. As a counterpart, we study deformation and disintegration of a sessile drop on a stiff membrane in the context of an impulsive acceleration. The key objectives are here to elucidate the effects of viscosity, surface tension, and wetting on the drop deformation and disintegration as well as to convey the physical mechanisms behind the observed transient responses of the initially static drop of controlled shape and size. Hence, the significant amount of experimental data – used to map the possible drop morphological changes along with the transitions between them: crown height, radius, and instability wavelength in the crown regimes; drop detachment and disintegration times as well as probability density functions of the secondary droplets in the disintegration regimes – is interpreted with phenomenological models, scalings, and estimates highlighting the rich multiscale physics of the impulse-driven drop phenomena.

Tuesday, November 26, 2019 10:31AM - 12:02PM

10:57AM S22.00003 Jet atomization of brine to achieve zero liquid discharge1, CHRIS-TIAN MACHADO, YOUSHUA JIANG, KYOO-CHUL PARK, Northwestern University — Achieving zero liquid discharge in brine management facilities is critical to solving the environmental problems associated with returning high salinity water to its source. One such pathway for reducing the amount of discharged brine is by utilizing evaporation. To accelerate the evaporation of water in brine, the bulk brine solution should be atomized into microdroplets (i.e., fog) using a high pressure flow. In this study, brine with systematically varying concentrations of salt (NaCl) and surfactant (cetrimonium bromide (CTAB)) was atomized at different compressed air pressures. Results show that the rate of fog droplet generation decreases with increasing salinity. To combat this effect, adding a low surface tension surfactant and increasing compressed air pressure have shown to improve the rate of atomization. 11:10AM S22.00004 Thin-Film Breakup Dynamics of a Binary Mixture Drop during Evaporation, H. ALEX GUO, Department of Mechanical Engineering and Materials Science, Duke University, Durham, North Carolina 27708, THOMAS P. WITELSKI, Department of Mathematics, Duke University, Durham, North Carolina 27708, CHUAN-HUA CHEN, Department of Mechanical Engineering and Materials Science, Duke University, Durham, North Carolina 27708 — When a drop consisting of two volatile liquids evaporates on a solid substrate, the parent drop frequently bursts into tiny droplets. Although the bursting originates from solutal Marangoni stresses, like the wine-tear phenomenon, the binary-drop setup is distinct with its moving contact line and the dramatic bursting of the entire parent drop before complete evaporation. For a drop of water and isopropanol, a ridge develops at the contact line when the drop spreads on the silicon substrate. When evaporation drives the contact line to eventually recede, the ridge formed during spreading fragments into tiny droplets. We have developed a numerical model for the thin-film evolution of the binary drop. The model accounts for the liquids differential evaporation, which generates Marangoni stresses. Our model captures the ridge formation process, and predicts a threshold mixing ratio for the Marangoni bursting that is experimentally observed.
Evaporation-Induced Breakup of a Droplet in a Shallow Well

11:23 AM S22.00005

Kris F. WiedenhofT, H. Alex GuO, Department of Mechanical Engineering and Materials Science, Duke University, Durham, North Carolina 27708, Thomas P. Wietelski, Department of Mathematics, Duke University, Durham, North Carolina 27708, Chuan-Hua Chen, Department of Mechanical Engineering and Materials Science, Duke University, Durham, North Carolina 27708 — Droplet evaporation is most frequently studied on a flat substrate, for which surface defects are typically accounted for by contact angle hysteresis. To directly investigate the effect of surface defects, we study droplets levitated in an electrodynamic balance and the contact radius. We have developed a thin-film evaporation model that captures the annular breakup pattern as well as the range of aspect ratio achievable. The annular breakup presents a drop evaporation mode that is distinct from the widely reported modes with constant contact angle or constant curvature. To understand the effect of surface defects, we study droplet evaporation in a shallow circular well, created by etching a smooth silicon substrate. An inkjet printer is used to print water droplets onto the well, and the droplets are observed using high-speed cameras. We find that the droplet breaks in the upward direction. The experimental observations are validated with BEM (boundary element method) simulations and a reasonable agreement is observed between the two.

Thermal Atomization during Droplet Impingement on Superhydrophobic Substrates

11:36 AM S22.00006

Mohit Singh, Neha GawanDe, Y.S. Mayya, Ruchi Thakor, Indian Institute of Technology Bombay — Experimental observations are reported on the effect of the initial perturbation on the mechanism of Rayleigh breakup phenomenon of a charged droplet (diameter~100-250 μm), levitated in an electrodynamic (ED) balance. As the droplet undergoes evaporation, the droplet size decreases with a corresponding increase in the surface charge density near to the Rayleigh limit, leading to its breakup. All the successive events such as droplet deformation, breakup and relaxation of the drop after jet ejection have been captured using a high-speed camera at around 200 thousand fps. It is observed that the droplet surface exhibits finite amplitude of oscillations with higher prolate deformation on account of unbalanced gravity. These perturbations lead to subcritical Rayleigh breakup of the droplet. There exists a “x” phase shift between the centre of mass motion and applied field which causes the asymmetric breakup in such a way that the droplet breaks in the upward direction. The experimental observations are validated with BEM simulations and a reasonable agreement is observed between the two.

Thermal Atomization during Droplet Impingement on Superhydrophobic Substrates

11:49 AM S22.00007

Preston Emerson, Julie Crockett, Daniel Maynes, BYU — Water droplets impinging on superheated substrates may be characterized by dynamic droplet boiling, causing an upward ejection of miniscule secondary droplets, called droplet boiling. In this study, droplets impact superheated superhydrophobic substrates of varying microstructure configuration for a range of superheat temperatures between 120 and 320 degrees Celsius. Thermal atomization is captured using a high-speed camera and is quantified by estimating the amount of liquid sprays present for each impingement event using a 2D imaging processing technique. The start time, quantity, and velocity of the atomization sprays is shown to depend on the microstructure configuration of the substrate (most notably the height and center-to-center spacing of the structures) and the Weber number of the impinging droplet. The droplet boiling regimes are identified for the range substrate temperatures and the Leidenfrost temperature is estimated for each scenario.

Dynamic buckling of collapsing viscous bubbles

10:31 AM S23.00001

Alexandros Oratis, Boston University, John Bush, Massachusetts Institute of Technology, Howard Stone, Princeton University, James Bird, Boston University — When air bubbles rise to the surface of a liquid, they create a thin-film dome that eventually ruptures. In liquids with relatively low viscosity, film rupture is followed by rapid film retraction dominated by surface tension and inertia, and typically occurs over a period of milliseconds. In liquids with relatively high viscosity, viscous dissipation slows the film retraction sufficiently that the bubble collapses. As it does so, radial wrinkles appear on its surface. Previous investigations have concluded that gravity is responsible for both the bubble collapse and the wrinkling instability. We here demonstrate that experiments yield the same radial wrinkle pattern independent of the bubble orientation relative to gravity. We develop an alternative model for the wrinkles in which surface tension initiates a dynamic buckling instability.

Flow and mixing dynamics of phase-transforming multicomponent fluids

10:44 AM S23.00002

Hector Gomez, Saikat Mukherjee, Purdue University — We develop a continuum model for two-component flow, where one of the components is an non-condensable gas and the other one is a fluid that undergoes liquid-vapor phase transformations accompanied by changes in its miscibility with the gas. We derive the model from a Gibbs free energy that includes gradients of the fluid density and gas concentration, leading to a generalization of the classical equations of multiphase flow hydrodynamics. High-fidelity numerical simulations of the model show very complex interplay between flow, mixing and phase transformations. The model predicts quantitatively the saturation vapor pressure of water for a given mixture of air and water vapor at different temperatures. When applied to the problem of collapse of cavitation bubbles, the model shows that even very small amounts of gas dissolved in the liquid phase can have a significant impact on the dynamics of the collapsing bubble.

Bursting Bubbles and The Formation of Gas Jets and Vortex Rings

10:57 AM S23.00003

Ali Al Dasouqi, David Murphy, University of South Florida — Bursting bubbles play an important role in ocean-atmosphere and industrial processes (e.g., marine aerosol formation, froth flotation for metal concentration) and food science (e.g., beer). Earlier work focused on the fluid dynamics of droplet formation (film and jet drops) and film cap retraction, but the ejection of pressurized gas from inside a bursting bubble, which may affect the spatial distribution of generated droplets, is much less studied. Here we examine the gas flow emerging from the bursting of smoke-filled bubbles floating at an air-water interface using two synchronized orthogonal high-speed cameras filming at 5-10 kHz. We describe the bubble bursting and subsequent formation of vortex rings for bubbles ranging in size from 400 microns to 4 cm. No vortex rings are formed for bubbles less than 1 mm diameter. The number of initially formed vortices increases from one for a 1.4 mm bubble up to six for a 39 mm bubble. Using stereophotogrammetric tracking, the initial speed of the gas jet released from the bursting bubble also is quantified and can reach up to 9.6 m/s for a 39 mm bubble. Jet speed is found to be a function of film retraction speed, bubble diameter, and bubble submergence. Successful vortex ring formation also is found to rely on film retraction behavior.
11:10AM S23.00004 Collective Effects in Bursting Bubbles Aerosol Production

BAPTISTE NEEL, LUC DEIKE, Princeton University — The bursting of surface bubbles, understood as a production mechanism of sea spray aerosols, is a key feature of gas and mass transfers between ocean and atmosphere. While the case of a single bursting bubble has been extensively studied recently, little is known about collective effects in this context. Our experimental study characterizes the dynamical and statistical properties of an ensemble of initially mono-disperse air bubbles at the water surface, and the resulting spray droplets being produced. After rising in a still bath, the bubbles stand at the free surface, where they coalesce and move around before they eventually burst. The addition of surface active agents, because they prevent bubbles coalescence above a certain concentration, modify the features of the surface bubbles population (coalescence and lifetime), whose consequences on the spray production are discussed.

11:23AM S23.00005 Jet drops produced by bursting bubbles: number, size, velocity and resulting mass transfer

ALEXIS BERNY, THOMAS SEON, Sorbonne Université, CNRS, UMR 7190, Institut Jean le Rond D’Alembert, F-75005 Paris, France, LUC DEIKE, Department of Mechanical and Aerospace Engineering, Princeton University, Princeton, New Jersey 08544 USA, STEPHANE POPINET, Sorbonne Université, CNRS, UMR 7190, Institut Jean le Rond D’Alembert, F-75005 Paris, France — When a bubble bursts at a liquid-air interface, it produces a jet that may break up and eject drops called jet drops. Numerous studies focused on this phenomenon motivated by the wide range of application, from the bubble in a glass of champagne to spray generation at the surface of the ocean. Here, we solve the two-phase Navier-Stokes equations in axi-symmetrical coordinates with the free software basilisk. We first compare the size and velocity of the first drop in our simulations with the recent experimental, numerical and theoretical results from the literature, before characterizing the number, size and velocity of all ejected droplets. This approach is done for a wide range of controlling parameters, defined as the Laplace and Bond numbers. The resulting total vertical momentum and mass transfer is then discussed.

1This work was supported by the National Science Foundation under Grant No. 1849762. to L.D. and the Cooperative Institute for Earth System modeling between Princeton and GFDL NOAA. A.B. was supported by the International Fund to L.D. from Princeton University during part of this study.

11:36AM S23.00006 The physics of bubble bursting followed by jet ejection

JOSE M. LOPEZ-HERRERA, ALFONSO M. GANAN-CALVO, Universidad de Sevilla, ETSI, 41092 Sevilla, Spain — Under the light of recent research on this phenomenon, and performing exhaustive simulations, dimensional and similarity analysis, the collapse of a supercritical bubble and the subsequent ejection of a microjet are studied here in great detail. The different models proposed, their description of the physics involved, their degree of innovation and their predictive abilities comparing with experiments are put into perspective. In particular, the conditions under which the phenomenon can be described around an elusive temporal singularity, and the resulting self-similar flow configuration are carefully analyzed. Using high resolution numerical simulation techniques of free-surface flows, this study demonstrates the existence of said singularity and the value of the critical parameter for which it appears, showing the natural change in the time scaling law of the self-similar flow sufficiently close to the singularity. This self-similar flow shows a rich topology that is discussed in this work.

11:49AM S23.00007 Compressibility Effects for Spherical Bubble Collapse in Water

ROY BATY, SCOTT RAMSEY, CORY AHRENS, JASON ALBRIGHT, Los Alamos National Laboratory — This presentation outlines the derivation and solution of a potential flow equation used to model the effect of compressibility on bubble collapse in water. An unsteady potential flow equation is developed by adding a perturbation term to a classical incompressible flow solution describing the radial motion of a spherical bubble. The potential equation is obtained by linearizing a perturbation term about an incompressible flow field modeling the collapse of a spherical cavity in water. The potential equation describes the unsteady radial motion of a one-dimensional, inviscid, spherical bubble. The potential equation is performed for an arbitrary isotropic equation of state for water over the pressure and density range observed for cavitation. The resulting linearizing a perturbation term about an incompressible flow field modeling the collapse of a spherical cavity in water. The compressible potential equation is developed by adding a perturbation term to a classical incompressible flow solution describing the radial motion of a spherical bubble as a function of time. The flow is assumed to be one-dimensional and inviscid. Both linear and nonlinear forms of the compressible potential equation are presented assuming a general isentropic equation of state for water. The linear compressible potential flow equation is obtained by linearizing the perturbation term about the incompressible collapsing flow field. The linear and nonlinear compressible potential flow equations are integrated numerically for an analytical equation of state approximating water in the kilobar pressure range.

12:02PM S23.00008 Lie Symmetries of a Potential Flow Equation Modeling Compressibility Effects of Spherical Bubble Collapse in Water

SCOTT RAMSEY, ROY BATY, ERIC ALBRIGHT, CORY AHRENS, Los Alamos National Laboratory — This work applies analytical methods for differential equations to derive Lie symmetries associated with a potential flow equation used to model the effect of compressibility on bubble collapse in water. The compressible potential equation describes the unsteady radial motion of a one-dimensional, inviscid, spherical bubble. The potential equation is obtained by linearizing a perturbation term about an incompressible flow field modeling the collapse of a spherical cavity in water. The symmetry analysis is performed for an arbitrary isotropic equation of state for water over the pressure and density range observed for cavitation. The resulting symmetry groups obtained from the Lie analysis are then related to a general form of the method of characteristics developed to integrate second order hyperbolic equations.

Tuesday, November 26, 2019 10:31AM - 12:15PM —
Session S24 Drops: Electric Field Effects II

10:31AM S24.00001 Sorption-controlled electrohydrodynamics of a surfactant-covered viscous drop

HEREVE NGANGUIA, Indiana University of Pennsylvania, WEI-FAN HU, National Chung Hsing University, MING-CHIH LAI, National Chiao Tung University, YUAN-NAN YOUNG, New Jersey Institute of Technology — Surfactants physico-chemistry is often exploited to control the dynamics of viscous drops and bubbles. For instance, the adsorption-desorption kinetics plays a critical role in the deformation of drops in extensional and shear flows. By contrast these kinetics effects have yet to be accounted for drops in an electric field to the best of our knowledge. In this talk we present work on the effects of sorption kinetics on a surfactant-covered viscous drop in an electric field (both dc and ac). Specifically, we look at the dependence of drops deformation on three dimensionless numbers: the electric capillary number $Ca_E$, Biot number $Bi$, and Peclet number $Pe$. We present the numerical methods employed for simulations, and discuss preliminary results from our findings as well as future extensions. We also illustrate how our results may be applied to explain recent experiments on extreme drop deformation under an electric field (Brosseau and Vlahovska, PRL 2017).
10:44AM S24.00002 Electrocoalescence behavior exhibited by anchored aqueous droplets in air , RAUNAQ HASIB, ROCHISH THAOKAR, Indian Institute of Technology Bombay — Electrocoalescence of droplets is the preferred method in phase separation owing to its low energy consumption. In this work, effect of droplet conductivity on electrocoalescence phenomena is studied for an anchored droplet-in-air system under the influence of direct current electric field. Phase diagrams representing the coalescence/non-coalescence behaviour are constructed for three different droplet conductivities. Droplets of deionized water, 0.01 M NaCl solution, and 1 M NaCl solution are used for low, moderate and high conductivity experiments, respectively. Subsequent events after first non-coalescence event are also studied and an effort is made to explain and categorize the behaviour under different regimes. Beyond the critical electrocapillary number (estimated to be ~0.25), the stabilizing capillary force cannot balance the destabilizing electric force which leads to contact of droplets. Variation in drop conductivity, cone angle, and separation distance between droplets do not influence the critical electrocapillary number. Low light experiments were conducted to detect presence of sparks during the non-coalescence events. The non-coalescence mechanism is observed to differ with change in droplet conductivity.

10:57AM S24.00003 A study of non-coalescence of aqueous droplets suspended in castor oil under electric field , SUBHANKAR ROY, ROCHISH THAOKAR, Indian Institute of Technology Bombay — Experimental and numerical investigations are carried out to study the effect of electric field on coalescence and non-coalescence behaviour of two water droplets suspended in an insulating oil (castor oil). Unlike immediate breakup of the bridge, as reported in earlier studies like Ristenpart et al. (2009) [Non-coalescence of oppositely charged drops. Nature 461 (7262), 377–380], the non-coalescence behaviour observed in our experiments show that at higher than critical electric fields the droplets form a bridge which starts thickening thereby exhibiting a tendency to coalesce. However, soon this phenomenon slows and comes to a stop, and the thickened bridge starts thinning dramatically, initiating the phenomenon of eventual non-coalescence. Numerical simulations using boundary integral method are able to explain the physics behind the thickening of this bridge, followed by thinning and non-coalescence. The fundamental reason is the competing meridional and azimuthal curvatures of the bridge under the effect of electric field induced Maxwell stresses which determine the Laplace pressure inside the bridge to become either positive or negative thereby determining the direction of fluid flow towards or away from the centre of the bridge. Velocity and pressure profiles confirm this postulation, thus enabling us to predict this behaviour of transitory coalescence followed by non-coalescence.

11:07AM S24.00004 Abstract withdrawn

11:23AM S24.00005 Shaping of Charged Sprays , PAUL W. VESELY1, RUDOLF J. SCHICK, Spraying Systems Co. — Spraying by conventional hydraulic and air-assisted nozzles presents issues with overspray and uneven application. Electrostatic atomization provides an alternative method to spray oils and other electrically insulating fluids, utilizing the repulsive force of like charges instead of high fluid and air pressure. A spray plume of charged droplets provides a very high transfer efficiency when spraying onto grounded conductive substrates. A plane-to-plane electrostatic atomization nozzle produces a full cone spray plume, but for many conveyor coating processes, a flat spray is required to provide a uniform coating across a substrate. Flat plate electrodes were added outside of the electrostatic atomization nozzle near the orifice to generate an electric field that acts on the negatively charged spray plume shaping it into a flat fan plume. Various shaped and sized electrodes operating at a range of voltages of negative polarity were investigated for their effectiveness in forming the full cone spray plume, high-speed imaging, phase Doppler interferometry, and particle imaging velocimetry systems were used to investigate the effect of the external electrode configurations tested.

11:36AM S24.00006 Resolving anomalies in contrasting droplet dynamics under direct and alternating current electrical forcing, KIRTI SAHU, Indian Institute of Technology Hyderabad, SUMAN CHAKRABORTY, Indian Institute of Technology Kharagpur, India — Electrically driven dynamics of droplets has given rise to several apparent anomalies, as attributable to complex interconnections between the underlying physical forces and geometrical dimension driven morpho-dynamic topology. In sharp contrast to reported theory on electro-mechanics of droplets that trivially predicts shape oscillations of a droplet subjected to alternating current electric field about the steady state deformation under an equivalent root mean square direct current electric field under all possible electrical conductivity and permittivity contrasts of the droplet and the carrier phase, here we bring out a novel dimensionality driven physical paradigm under which the same does not necessarily hold true. Our results reveal a dramatic reversal in shape transition to an elongated profile in a direction orthogonal to the electric field, in contrast to the classically postulated elongated shape in the direction of the electric field, as the electric field is changed from alternating to a direct one, for contrasting permittivity and electrical conductivity ratios. We attribute these findings to dimensionality driven topological transitions and validate the same with reported experiments.

11:49AM S24.00007 Electrical impedance of a deforming conducting drop , PRIYA GAMHIRE, V KUMARAN, Indian Institute of Science Bangalore — Deformation of drops under electric field, both direct and alternating, has been a subject of study for nearly 5 decades now. Yet, most theoretical models describing the deformation assume fluids to be either perfect or leaky dielectrics to simplify the analysis. In a real scenario, fluids are rarely dielectric and therefore a complete theoretical description of a conducting drop deforming under an alternating electric field is lacking. Additionally, to validate the models, deformation of drops is estimated in practice via optical methods which can involve expensive piece of equipment such as high-speed cameras. If the deformation can be correlated to drop properties such as its electric impedance, it can potentially be developed into an electronic method of quantifying the deformation extending the utility of experiments. In this presentation, our attempts to find solutions to both the aforementioned points will be discussed. To describe the deformation, a Debye-Falkenhagen theoretical approach is used which describes ionic double layers. Also, an attempt made to correlate changes in the electrical impedance of the drop and its deformation will be discussed.

12:02PM S24.00008 A lattice-Boltzmann model of Electrocapillarity1 , ELFEGO RUIZ GUTIERREZ, RODRIGO LEDESMA AGUILAR, GARY G. WELLS, GLEN MCHALE, Smart Materials and Surfaces Laboratory, Northumbria University, ANDREW M. J. EDWARDS, CARL V. BROWN, MICHAEL I. NEWTON, School of Science and Technology, Nottingham Trent University — Deformation of droplets due to electric fields thus forming a bridge which connects two droplets. In contrast, the stabilizing capillary force cannot balance the destabilizing electric force which leads to contact of droplets.

10:31AM S25.00001 Experimental Study of Cavitation Inception in a Pair of Interacting Vortices\textsuperscript{1}, DANIEL KNISTER, ELIZABETH CALLISON, HARISH GANESH, STEVEN CECCIO, University of Michigan - Ann Arbor — Cavitation inception in shear flows often occurs in secondary stream-wise vortices (braids) stretched by spanwise vortices. Stretching of the weaker secondary stream-wise vortices can lead to a rapid drop in core pressure below the vapor pressure, and thus inception of captured cavitation nuclei in the stretching core. Understanding of the relationship between the stretching process, pressure drop, and nuclei size is critical for understanding inception. As a model experiment of this phenomenon, two parallel vortices are created by a pair of hydrofoils in a re-circulating water channel following the study of Chang et al. (2012). Cavitation inception and occurrence caused due to interaction between two secondary hydrofoils is studied using high speed video and synchronized hydrophone measurements, with the vortices visualized by cavitation and dye injection and SPIV. We will discuss the hydrodynamic performance of the new configuration, including the parameters that lead to the desired vortex interactions and inception in the weaker (secondary) vortex.

10:44AM S25.00002 Shock-cavity interactions in a shock-compressed polymer medium in the fluid regime\textsuperscript{2}, EMILIO ESCAURIZA, University of Oxford, NIRMAL RAI, University of Iowa, DAVID CHAPMAN, University of Oxford, JOAO PEDRO DUARTE, Imperial College London, LUKASZ FARBANIEC, LIAM SMITH, JOHN JOHNSSON, MICHAEL RUTHERFORD, University of Oxford, MARGIE OLBINADO, ALEXANDER RACK, ESFR, H S UDAYKUMAR, University of Iowa, DANIEL EAKINS, University of Oxford, UNIVERSITY OF OXFORD TEAM, UNIVERSITY OF IOWA TEAM, ESFR TEAM — The study of shock-cavity interactions is important for a wide range of applications, from the medical sciences to the development of mixing mechanisms. However, due to constraints posed by optical imaging, observing the phenomenon directly has proven challenging. We present observations of shock-induced collapse in a solid medium through ultra-high-speed radiography, performed at the ESRF synchrotron. The radiography allowed the tracking of the time evolution of sub-surface interfaces during the collapse process. Shock loading of the PMMA cavity targets was achieved through plate impact with a 2-stage gas gun. As the shock strength was well in excess of the yield strength of the solid medium, the collapse shape was typical of a cavity collapsing in a fluid, with the generation of a jet and the formation of toroidal vortices after jet impact against the far cavity interface. The dependence of the collapse time on shock pressure was investigated, revealing a power law relationship. The results showcase the capabilities of high-speed synchrotron radiography for observing sub-surface phenomena in liquid and solid media.

10:57AM S25.00003 Analysis of the mechanisms of cavitation erosion\textsuperscript{3}, BEN ZHAO, OLIVIER COUTIER-DELGOSHA, Virginia Tech — Erosion related to the collapse of a single cavitation bubble is investigated. The bubble is created using a pulsed high intensity laser focused in a water tank, and the mechanisms of erosion are studied with high speed visualizations, a small time response hydrophone, and a pressure sensor mounted on the material. The effects of the distance of the bubble to the wall, the bubble size, and the softness of the material are investigated. A specific attention is paid to the feedback on the material on the bubble collapse, depending on the material stiffness. First results based on the use of two lasers creating two interacting bubbles will be also presented.

11:10AM S25.00004 Temperature measurements in cavitation bubbles\textsuperscript{4}, MEROUANE HAMDJI, Arts et Metiers ParisTech, OLIVIER COUTIER-DELGOSHA, Virginia Tech, MICHAEL BAUDOIN, University of Lille — The present work focuses on the analysis of the extreme conditions encountered during the process of collapse of cavitation bubbles. The objective is to characterize the temperature variations inside the vapor/gas bubble, and also in the surrounding liquid. The work is based on an experimental approach where temperature measurements are performed with a fast response cold wire thermometer. Specific thin cold wires obtained by Nickel metallic coating, whose resistance varies according to the local temperature, have been developed. They have been applied to configurations of single bubbles created by a travelling pressure wave. In most of the tests, the temperature peak magnitude measured at the end of the collapse was typical of a cavity collapsing in a fluid, with the generation of a jet and the formation of toroidal vortices after jet impact against the far cavity interface. The dependence of the collapse time on shock pressure was investigated, revealing a power law relationship. The results showcase the capabilities of high-speed synchrotron radiography for observing sub-surface phenomena in liquid and solid media.

11:29AM S25.00005 Inertial cavitation threshold in a viscoelastic medium\textsuperscript{5}, KAZUYA MURAKAMI, ERIC JOHNSON, University of Michigan — Cavitation bubbles play a significant role in medicine such as histotripsy or traumatic brain injury. Elevated temperatures, high strain rates, and shock waves are generated by the bubble dynamics, which may damage the surrounding tissue. These phenomena are thought to originate from inertially dominated bubble oscillations. It is thus important to determine a criterion governing inertial cavitation in tissue. For this reason, we numerically investigate the threshold for inertial cavitation in a tissue-mimicking, viscoelastic medium. We use a Rayleigh-Plesset-type equation, where compressibility, heat diffusion, mass transfer and nonlinear elasticity are taken into account. We apply a negative pressure pulse to a bubble and examine its expansion and subsequent collapse. In particular, we investigate the amount of energy dissipated by various means and determine the conditions under which inertia becomes dominant. Since viscoelasticity reduces bubble growth, the inertial cavitation threshold becomes higher in tissue-like media.

11:36AM S25.00006 ABSTRACT WITHDRAWN —

11:49AM S25.00007 The promotion effect of polymer nanoparticles on laser-induced thermal cavitation\textsuperscript{6}, MAN HU, FENG WANG, DAOSHENG DENG, Fudan University, Shanghai, China — Laser impacting on liquids, ranging from a single droplet to soft biological tissues, can generate cavitation. By immersing nanoparticles into water, cavitation can be manipulated. Here, we report CO\textsubscript{2} laser impacting on distilled water with polymer nanoparticles immersed in to produce thermal cavitation at the air/water interface. The promotion effect of nanoparticles on the inception of cavitation is investigated. With proper concentration nanoparticles being introduced in, thermal cavitation is clearly observed at the air/water interface from high speed imaging, but no cavitation for water with no nanoparticles. Based on this phenomenon, three regimes (no cavitation, cavitation, and pseudo-cavitation) are identified within a broad range of nanoparticles concentration and size. Moreover, this interfacial cavitation allows the direct visualization of spatial-temporal evolution of temperature, which reveals that the polymer nanoparticles not only act as preexistent nuclei to promote nucleation for cavitation, but also likely affect temperature to change the nucleation rate as well.

Tuesday, November 26, 2019 10:31AM - 12:15PM – Session S26 Flow Control: Plasma Actuation B 608 - Jesse Little, University of Arizona

10:31AM S26.00001 Active flow control of the laminar separation bubble on a plunging airfoil near stall1. JESSE LITTLE, MARK AGATE, ARTH PANDE, University of Arizona — The effects of small amplitude, high frequency plunging motion on the X-56A airfoil are examined experimentally at Re=200,000 for 12 degrees angle of attack. The purpose of this research is to study the aerodynamic influence of structural motion when the wing is vibrating close to its eigenfrequency near static stall. Specific focus is placed on the laminar separation bubble (LSB) near the leading edge and its control via plasma actuation. In the baseline case, the leading edge bubble bursts during the oscillation cycle causing moment stall. A collaborative computational effort has shown that small amplitude forcing at a frequency that is most amplified by the primary instability of the LSB generates coherent spanwise vortices that entrain freestream momentum, thus reducing separation all while maintaining a laminar flow state. Results (PIV and surface pressure) indicate that the most effective control for the lift increase can be achieved for the case that the streamwise vortex generated by the VG-PA collides with the opposite streamwise vortex. In addition, from the results of 0.05 \( c \), 0.1 \( c \), 0.2 \( c \), 0.3 \( c \), and 0.4 \( c \), where \( c \) means the chord length. The maximum lift is attained in the case with 0.1\( c \). On the other hand, a streamwise vortex generated by the VG-PA in a boundary layer flow has been investigated to clarify the distribution of the vortex. The streamwise vortex is distributed from the actuator to 0.1\( c \) away from the actuator in the induced flow direction. It means that the most effective control for the lift increase can be achieved for the case that the streamwise vortex generated by the VG-PA collides with the opposite streamwise vortex. In addition, from the results of 0.05\( c \) and 0.1\( c \), the location of the streamwise vortex collision is also important factor for the effective control.

10:44AM S26.00002 Viscous Drag Reduction on a NACA 63012A Airfoil1. KATHERINE YATES2, ALAN DUONG3, THOMAS CORKE3, FLINT THOMAS4, University of Notre Dame — A series of wind tunnel experiments were performed in which an array of flush mounted pulsed-DC plasma actuators were utilized to reduce the skin friction drag on a NACA 63012A airfoil over a Mach number range of 0.20 \( \leq M_{\infty} \leq 0.50 \) at zero angle of attack. The array of plasma actuators were designed to inhibit the lift-up and subsequent break-up of the low-speed wall streak structure to prevent the formation of streamwise vortices; a key element in wall-bounded turbulence generation. Experiments were performed with two sets of actuator arrays: 1) with the electrodes aligned in the mean flow direction and 2) with the electrodes oriented 5 degrees offset to the oncoming flow. The aerodynamic load (viscous drag) was measured directly using an integrated floating element force balance. Viscous drag reduction of up to 47\% was observed depending on the operating parameters of the plasma actuators. Net power savings were also achieved across the range of Mach numbers tested.

10:57AM S26.00003 Active Turbulent Boundary Layer Drag Reduction using Pulsed-DC DBD Plasma Actuators1. ALAN DUONG2, THOMAS CORKE3, FLINT THOMAS4, University of Notre Dame — Experiments were performed involving the use of an active flow control scheme designed to inhibit the lift-up and subsequent break-up of the low-speed wall streak structure to reduce skin friction drag in a turbulent boundary layer. The flow control utilized an array of pulsed-DC plasma actuators that was designed to produce a steady span-wise velocity component on the order of \( u_c \) in order to reduce the mean flow distortion caused by the quasi-steady wall streak structure first observed by Kline et al (1967). This flow control method has been successful in reducing the viscous drag over a decade of Mach numbers and is capable of reducing the skin friction coefficient up to 68\% while maintaining net power savings. The work presented here investigates the underlying flow physics of a pulsed-DC drag reduced boundary layer in a controlled, low-speed environment. The plasma actuator array in this paper was successful in reducing the skin friction velocity by 37\%, which corresponds to a decrease of 50\% in the skin friction coefficient, measured directly by means of a floating element force balance. Detailed two-component velocity measurements were done with xwire hotwires in the wallnormal and spanwise directions downstream of the actuator.

11:10AM S26.00004 On spatial arrangement of vortex-generator type plasma actuator for separation control of airfoil flow. MAKOTO SATO, CHINATSU KOBAYASHI, Kogakuin University — LESs on separation control flows around a NACA4418 have been conducted. In the separation control, a vortex-generator type plasma actuator (VG-PA) has been adapted. The flow conditions and the configurations of the plasma actuator are set based on the previous experimental study. The Reynolds number is 85000 with angle of attack 18 deg. The effects of spanwise spacing of the VG-PA have been mainly investigated. The spacing of the VG-PA is set as 0.05c, 0.1c, 0.2c, 0.3c, and 0.4c, where c means the chord length. The maximum lift is attained in the case with 0.1c. On the other hand, a streamwise vortex generated by the VG-PA in a boundary layer flow has been investigated to clarify the distribution of the vortex. The streamwise vortex is distributed from the actuator to 0.1c away from the actuator in the induced flow direction. It means that the most effective control for the lift increase can be achieved for the case that the streamwise vortex generated by the VG-PA collides with the opposite streamwise vortex. In addition, from the results of 0.05c and 0.1c, the location of the streamwise vortex collision is also important factor for the effective control.
11:23AM S26.00005 Effects of the Layout of DBD Plasma Actuators on its Anti-/De-Icing Performance for Aircraft Icing Mitigation\textsuperscript{1}, CEM KOLBAKIR, HAIYANG HU, YANG LIU, HUI HU, Iowa State University — An experimental study was performed to evaluate the effects of different layouts of DBD plasma actuators on their anti-/de-icing performances for aircraft icing mitigations. An array of DBD plasma actuators were designed and embedded on the surface of a NACA0012 airfoil/wing model in different layout configurations (i.e., different alignment directions of the plasm actuators (e.g., spanwise vs. streamwise), width of the exposed electrodes and the gap between the electrodes). The experimental study was carried out in the Icing Research Tunnel available at Iowa State University (i.e., ISU-IRT). While the dynamic anti-icing operation is recorded by using a high-resolution imaging system, a high-speed Infrared (IR) thermal imaging camera is used to quantitatively map the temperature distributions over the surface of the airfoil model during the anti-/deicing processes. The findings derived from the present study are very helpful to explore/optimize design paradigms for the development of novel plasma-based anti-/de-icing strategies tailored specifically for aircraft inflight icing mitigation to ensure safer and more efficient aircraft operation in atmospheric icing conditions. /abstract- Cem Kolbakir, Haiyang Hu, Yang Li

11:36AM S26.00006 Transient flow control effect of Quasi-DC filamentary plasma in Mach 2 and Mach 4 supersonic flows\textsuperscript{1}, YASUMASA WATANABE, University of Notre Dame, The University of Tokyo, SKYE ELLIOTT, ALEC HOUGHT, SERGEY LEONOV, University of Notre Dame — This study explores the effect of pulse-periodic quasi-DC filamentary plasma on the flow structure over 15-degree compression ramp in Mach 2 and Mach 4 airflows. A major attention is focused on transient phenomena related to plasma-flow interaction. Experiments were conducted in supersonic wind tunnel SBR-50 at the University of Notre Dame. Pulse-periodic plasma generator, operating at the frequency ranging from 250 to 5000 Hz, was installed flush-mounted crossflow in front of the compression ramp. Flow stagnation pressure and temperature were varied as 1-4 bar and 300-600K respectively. The transient flow structure and plasma filament behavior were visualized with schlieren method and high speed camera. The surface pressure distribution on the wall surface and at the ramp was measured with fast pressure transducers. The plasma generated upstream of the compression ramp shifts the shock position from the ramp to the electrode location, subsequently forming a separation zone and resulting in pressure change behind electrodes and over the ramp surface both in cases of Mach 2 and Mach 4 flows. Pressure change was characterized as a function of flow/plasma parameters.

11:49AM S26.00007 Numerical, Experimental and Analytical Investigation of the Planar Electrohydrodynamic Wall Jet, PATRICK FILLINGHAM, YIFEI GUAN, RAVI SANKAR VADI, IGOR NOVOS-SELOV, University of Washington — Classical laminar wall jet theory is used for the examination of the flow induced by Electrohydrodynamic (EHD) actuators. The planar EHD wall jet, induced by both corona discharge and dielectric barrier discharge (DBD), is investigated experimentally and computationally. The thrust generated by the actuators is measured while the velocity profiles downstream of the cathode are measured using hot-wire anemometry. A multiphysics computational model couples the Navier-Stokes, electrical field, and ion transport equations. Experimental investigations of EHD actuators in the literature are used for model validation. The wall jet resulting from both DBD and Corona actuators was found to adhere to the analytical solution for a planar laminar wall jets, allowing for the calculation of the momentum generated by EHD actuators with only information about the downstream maximum velocity. The model allows for characterization of the thrust generated by any EHD actuator attached to a wall using only two velocity measurements.

12:02PM S26.00008 Drag reduction on a three-dimensional model vehicle by a wire-to-plate DBD plasma actuator\textsuperscript{1}, DONGRI KIM, ZHI WU, HYUNGROK DO, HAECHEON CHOI, Seoul National University — We apply a wire-to-plate DBD plasma actuator to a three-dimensional model vehicle (Ahmed body) for drag reduction. With a thin wire (diameter of 11 \( \mu \text{m} \)) as an exposed electrode, the performance and efficiency enhance far more than those of the conventional plate-to-plate actuator. By varying the actuator length in the spanwise direction, the drag reduction up to 10\% is obtained at the Reynolds number of 96,000 based on the free-stream velocity and model height. With surface-pressure and PIV measurements, it is shown that drag reduction occurs mainly due to entrainment induced by streamwise momentum addition and flow changes at the actuator ends, which significantly modify the evolution of the flow in the center region and corner vortices at the lateral sides of the slanted surface of the model. Other configurations of plasma actuator are being tested and their results will be also given in the presentation.

10:31AM S27.00001 Lagrangian description of the unsteady flow induced by a jellyfish, JIN-TAE KIM, LEONARDO P CHAMORRO, University of Illinois at Urbana-Champaign — The unsteady flow induced by a single pulse of Aurelia aurita was quantified via 3D particle tracking velocimetry. Inspection of the flow included Lagrangian statistics, velocity and acceleration probability density functions (PDF), acceleration variance as well as pair dispersion. PDF of the Lagrangian velocity components indicated more intense mixing in the radial direction and revealed three stages dominated by flow acceleration, mixing, and dissipation. During the mixing phase, the flow shares characteristics of homogeneous isotropic turbulence. We show that a single pulse may induce rich dynamics, where pair dispersion exhibits a super-diffusive \( t^{1.5} \) regime during the accelerated flow due to large-scale flow inhomogeneity; this is followed by a coherent \( t^{2} \)-Batchelor scaling in the mixed wake and then \( t^{3/2} \)-Brownian motions in a late stage dominated by flow dissipation. Kolmogorov microscales during the fully mixed phase were obtained with three distinct approaches, namely, Heisenberg-Yaglom relation of the Lagrangian acceleration variance, the fluctuating rate of the strain tensor in the Eulerian frame and the Batchelor scaling in pair dispersion, which showed good agreement.
10:44AM S27.00002 Metabolic costs of enhancing propulsion in artificially controlled live jellyfish†, NICOLE XU, JOHN DABIRI, Stanford University — Artificial control of animal locomotion has the potential to address previously inaccessible questions about the biology of swimming organisms and animal-fluid interactions, where we are otherwise limited to observations of natural behavior. This work presents a biohybrid robot that uses a self-contained microelectronic system to induce swimming in live jellyfish. By driving body contractions at an optimal frequency range faster than observed in natural behavior, swimming speed can increase nearly threefold, with only a twofold increase in cost of transport to the animal. Robotic control was also used to characterize the metabolic response of the jellyfish to swimming in the enhanced mode, and it was determined that the animals can sustainably support the associated metabolic costs. These experimental results are consistent with an adapted hydrodynamic model developed to characterize enhanced propulsion. This capability can potentially be leveraged in applications such as ocean monitoring, and to enable further studies of swimming organisms in more user-controlled, systematic experiments.

10:57AM S27.00003 Swimming via size-change: High efficiency propulsion using resonant fluid-structure interactions, GABRIEL WEYMOUTH, Gabriel Weymouth — Cephalopods use large-scale structural deformation to propel themselves underwater, changing their internal volume by 20-50%. In this work, the hydroelastic response of a swimmer comprised of a fluid-filled elastic-membrane is studied via analytic, numerical, and experimental methods. The self-propelled soft-body fluid and solid dynamics are shown to benefit greatly from the jet flow, the internal added-mass variation, and the pulsation in tune with the swimmer’s immersed fundamental frequency. It is shown that even a simplistic size-changing structure can utilize these physical mechanisms to achieve quasi-propulsive power ratios of greater than 100%, i.e. self-propulsion for these swimmers requires less energy than towing at the same speed.

11:10AM S27.00004 Validating Improved Efficiency of Bioinspired Unsteady Jetting Propulsion†, MICHAEL KRIEG, University of Hawaii, KAMRAN MOHSENI, University of Florida — Jetting propulsion has historically been considered inefficient, as the rate of momentum transfer for a continuous jet scales with the velocity squared; whereas, the rate of kinetic energy scales with the velocity cubed. For steady jets, efficiency decreases with the ratio of jet velocity to vehicle velocity. Several animals propel themselves with high velocity jets, but none jet continuously. They pause between jetting to refill, and expel the next jet starting from rest resulting in a leading vortex ring. Vortex ring formation induces a converging radial velocity increasing hydrodynamic impulse and increasing cavity pressure. Also, fluid acceleration generates propulsion without significant wake energy. This study validates improved propulsive efficiency on a freely swimming autonomous underwater vehicle (AUV). We have developed AUVs that use such thrusters for maneuvering, and previously validated propulsive efficiency measurement using motion capture position data and motor frequency data. But in a maneuvering configuration the thrusters have lower propulsive efficiency due to losses from vehicle drag. With a streamlined AUV, we demonstrate that propulsive efficiency of unsteady jetting rivals that of unducted propellers, and is nearly double the efficiency in a maneuvering configuration.

11:23AM S27.00005 Yaw Turning Experiments of a Bio-Inspired Vessel with Undulating Fin Propulsion†, MOHAMMAD I UDDIN, GONZALO A. GARCIA, OSCAR M. CURET, Florida Atlantic University — Navigation of autonomous underwater vehicles (AUVs) in tight spaces, coastal zones and close to submerge structures remains a challenge. One of the problems preventing AUVs to navigate in these complex environments is an adequate propulsion system that allows the vessel to move in multiple directions and/or perform precise station-keeping. We present an underwater vehicle equipped with a bio-inspired fin propulsion. The propulsion system is a single flexible undulating fin that runs along the length of the robot which control forward and directional maneuvers. We establish a dynamic and control model relating different fin kinematics to performance in yaw turning maneuvers. Turning performance were tested during free-swimming experiments and compared with a numerical model. In particular, fin kinematics for two turning characteristic were considered: heading change or correction and minimum radius turns. In addition, the flow generated by the fin for turning kinematics were measured using particle image velocimetry. These experiments will be useful to establish optimal combination of the yaw turning parameters of undulating fin propulsion.

†This material is based upon work supported by the National Science Foundation under Grant No 1751548

11:36AM S27.00006 Maneuver Control of an Undulating-Fin Underwater Vessel with a Central Pattern Generator†, ALBERT ESPINOZA, Universidad Ana C. Mendez - Gurabo, GONZALO GARCIA, OSCAR CURET, Florida Atlantic University — Undulating fin propulsion for underwater vehicles provides key advantages over traditional propeller-based methods, including increased maneuverability and high efficiency at low speed. However, some of the challenges of controlling the motion of the vessel using an undulating fin propulsion are the high coupling of the propulsive forces and torques, and the extensive parameter space of the propulsive surface. In this work, we implemented a Central Pattern Generator (CPG) to control the fin and provide a smooth transition between rapidly-changing fin wave control commands. We developed a numerical model of an underwater vehicle propelled by a single undulating fin equipped with a central pattern generator to control the swimming motion and perform different maneuvers. The model includes a 6 degree-of-freedom motion of the vessel and a discretized hydrodynamic model of the fin. This model was used to study the effects of CPG dynamics on vessel response for different swimming modes, including straight line and forward-reverse motion. The results were compared to experiments using a robotic underwater vehicle.

†This material is based upon work supported by the National Science Foundation under Grant No 1751548
11:49AM S27.00007 Reinforcement Learning for a Bio-Inspired Vehicle with Undulating Fin Propulsion.1, GONZALO GARCIA, MOHAMMAD UDDIN, SIDDHARTHA VERMA, OSCAR CURET, Florida Atlantic University — Undulating fins provide natural swimmers with fascinating locomotion capabilities. However, the use of undulating fin propulsion for underwater vessel to perform specific maneuvers is non-trivial. Currently, researchers implement ad-hoc fin kinematics such as sinusoidal traveling waves due to ease of implementation, or use kinematics based on live animals. In the proposed work, we integrate reinforcement learning with simulations and underwater robotic experiments to determine optimal undulating fin kinematics for a variety of swimming performance. A six degree-of-freedom numerical model is used to simulate the motion of a vessel with an undulating fin. The swimmer is modeled as a rigid body with a single fin running along the length of the body. A reinforcement learning algorithm was developed to determine the optimal kinematics of the fin for basic locomotion, including straight swimming and turning. We find that a model-free self-learning approach can be used to generate more complex actuation combination for improved performance. The simulation results are compared to the performance of a bio-inspired vehicle with an undulating fin propulsion. The results indicate that the use of reinforcement learning could be particularly useful for unsupervised decision-making, especially in the presence of unpredictable disturbances or flow conditions.

12:02PM S27.00008 Experiments with Impulsive Motion of a Foil to Generate Large Lift and Thrust Forces, MIRANDA KOTIDIS, MICHAEL TRIANTAFYLLOU, Massachusetts Institute of Technology — As underwater vehicles become increasingly versatile and capable, bio-inspired propulsion systems are becoming a viable possibility for future vehicles. In particular, flapping foil actuators are promising in their abilities for propulsion and maneuvering. Current underwater vehicles rely on propellers, which form a jet wake to produce propulsion forces, and as such, experience an inherent delay between the movement of the propeller and the vehicle feeling a propulsive force. To mitigate this shortcoming, flapping foils were moved in swift, one-time strokes to produce large, transient forces in still water. These strokes take advantage of added mass/inertial effects to produce propulsive forces almost instantaneously. Various combinations of heave and pitch motions were tested and dye visualization was performed with a custom wing to elucidate the wake and vortical structures produced by these strokes.

Tuesday, November 26, 2019 10:31AM - 12:15PM – Session S28 Particle Laden Flows: Particle Resolved Simulations

10:31AM S28.00001 Cohesive Sediment in Turbulence, KUNPENG ZHAO, FLORIAN POMES, RAPHAEL OUILLON, THOMAS KOELLNER, BERNHARD VOWINCKEL, ECKART MEIBURG, UC Santa Barbara — We investigate the balance between flocculation and break-up of cohesive particles in turbulent flows by means of grain-resolving direct numerical simulations. As a first step, we consider the model problem of inertial particles moving in a steady-state, cellular flow field consisting of counterrotating vortices. The dynamics of these particles are characterized by their Stokes number and Cohesion number, as well as by the ratio of their diameter to the vortex size. These one-way coupled simulations provide information on the competition between hydrodynamic, cohesive and collision forces, the equilibrium floc size distribution, and on the time scale of the floc formation process. We find that the equilibrium floc size grows with the Cohesion number, and that flocculation progresses most rapidly for a suitably defined Stokes number near unity. In a subsequent step, we explore how these findings translate to cohesive particles moving in homogeneous isotropic turbulence.

10:44AM S28.00002 Interface-resolved simulations of small inertial particles in a turbulent channel flow1, FRANCESCO PICANO, University of Padova, PEDRO COSTA, LUCA BRANDT, KTH Mechanics — Turbulent flows laden with small inertial particles are found in different contexts. Dealing with very dilute conditions, the so-called one-way coupling regime takes place with particles transported by the fluid without back and mutual reactions. Even in this regime, models for particle dynamics are crucial to accurately simulate their transport. In this work, we compare data from interface-resolved and one-way-coupled point-particle direct numerical simulations (DNS) of a turbulent channel flow laden with small inertial particles, with high particle-to-fluid density ratio of 100 and particle diameter of 3 viscous units. The most dilute flow considered, solid volume fraction \(O(10^{-5})\) shows the particle feedback on the flow to be negligible, whereas differences with respect to the unladen case are found for volume fraction \(O(10^{-4})\). The most dilute case is taken as the benchmark for accessing the validity of usual point-particle model considering only a non-linear drag. In the bulk of the channel, particle velocity statistics from the point-particle DNS agree well with those from the interface-resolved DNS, while major differences are found close to the wall. We show that they are due to particle-wall interactions that are not reproduced by usual point-particle model.

10:57AM S28.00003 Consolidation of freshly deposited cohesive and noncohesive sediment: Particle-resolved simulations, ECKART MEIBURG, BERNARD VOWINCKEL, EDWARD BIEGERT, PAOLO LUZZATTO-FEGIZ, UC Santa Barbara — We analyze the consolidation of freshly deposited cohesive and noncohesive sediment by means of particle-resolved direct Navier-Stokes simulations based on the immersed boundary method. The computational model is parametrized by material properties and does not involve any arbitrary calibrations. We obtain the stress balance of the fluid-particle mixture from first principles and link it to the classical effective stress concept. The detailed data sets obtained from our simulations allow us to evaluate all terms of the derived stress balance. We compare the setting of cohesive sediment to its noncohesive counterpart, which corresponds to the settling of the individual primary particles. The simulation results yield a complete parametrization of the Gibson equation, which has been the method of choice to analyze self-weight consolidation.
11:10AM S28.00004 Particle resolved simulations of a sphere settling in simple shear flows of yield-stress fluids\textsuperscript{1}, MOHAMMAD SARABJIAN, Ohio university, MARCO E. ROSTI, LUCA BRANDT, KTH Mechanics, SARAH HORMOZI, Ohio university — We perform 3D numerical simulations to investigate the sedimentation of a single sphere in the absence and presence of a simple cross shear flow in a yield-stress fluid. In our simulations the settling flow is considered to be the primary flow, whereas the linear cross shear flow is a secondary flow. To study the effects of elasticity and plasticity of the carrying fluid on the sphere drag as well as the flow dynamics, the fluid is modeled using the elastoviscoplastic (EVP) constitutive laws proposed by Saramito. We find that the drag on the sphere settling in the absence or the presence of cross flow is an increasing function of material plasticity at constant elasticity, while it is a decreasing function of material elasticity at constant plasticity. The present methodology handles general boundary conditions for the scalars. Dirichlet (Neumann) for infinitely fast (finite rate) surface reactions, and coupled heat and mass transfer description between the solid and fluid phases. A comparison with the inviscid case is also made to quantify the impact of density gradients.

\textsuperscript{1}National Science Foundation, American Chemical Society Petroleum Research, European Research Council

11:23AM S28.00005 A penalization method for DNS of weakly compressible reacting gas-solid flows\textsuperscript{1}, BAPTISTE HARDY, JURAY DE WILDE, GREGOIRE WINCKELMANS, Université catholique de Louvain — Gas-solid flows are encountered in many environmental and industrial phenomena. Simulating such flows at large scales requires closure models for interfacial mass, momentum and heat transfer. Particle-resolved simulations can support the development of improved closure laws, from first principles. The present study combines a penalization method to account for the solid phase with a weakly compressible approximation for the gas phase. Strong thermal effects from chemical reactions in the solid phase can induce significant density gradients near the particles and affect interfacial transfer laws. The present methodology handles general boundary conditions for the scalars. Dirichlet (Neumann) for infinitely fast (finite rate) surface reactions, and coupled heat and mass transfer description between the solid and fluid phases. A comparison with the inviscible case is also made to quantify the impact of density gradients.

\textsuperscript{1}Baptiste Hardy is a research fellow of the P.N.R.S-Fonds de la Recherche Scientifique, under grant n 1.A.700.18F. Computational resources have been provided by the Consortium des Equipements de Calcul Intensif (CECI), funded by the Fonds de la Recherche Scientifique de Belgique (F.R.S.-FNRS) under Grant No. 2.5020.11 and by the Walloon Region

11:36AM S28.00006 Near-wall and collision dynamics of particles at a stagnation point on a wall\textsuperscript{1}, QING LI, MICHELÈNE ABBAS, Laboratoire de Génie Chimique, Toulouse, France, JEFFREY F. MORRIS, Levich institute, City College of New York, ERIC CLIMENT, Institut de Mécanique des Fluides de Toulouse, France, JACQUES MAGNAUDET, (Institut de Mécanique des Fluides de Toulouse, France) — We present highly resolved immersed boundary simulations of neutrally-buoyant sphere (radius $a$) motion in axisymmetric stagnation (Hiemenz) flow at a wall. Far from the wall, the particle behaves as a tracer, decelerated by the ambient pressure of the Hiemenz flow. Near the wall, slip velocity and excess hydrodynamic force (in addition to ambient pressure), $F_{slip}$ play a role. Inertia is characterized by $a/\delta$ for boundary layer thickness, $\delta$. At $F_{slip}/F_{drag} \approx 2$ to 10 transitions at $a/\delta = 2$ at the wall due lubrication. The particle reaches $O(10^{-4})$ separations with $O(1)$ velocity, motivating a model for contact and rebound. Flow and collision are studied for one and two particles, with single particle motion dominated by lubrication pressure and hydrodynamic drag (latter toward the wall). For two identical particles on the axis, certain separations lead to particle collision before the lower (closer to wall) particle hits the wall; the resulting momentum exchange leads to larger impact velocity than for one particle. Dynamics of the colliding pair includes rebound without contact with the wall for the lower of two particles, due to lubrication from the upper particle from drag allowing the pressure force to dominate.

11:49AM S28.00007 Rigid particle-laden flows computations with a distributed Lagrange multipliers/fictitious-domain method on an adaptive quad/oct-tree grid. CAN SELCUK, Department of Mathematics, University of British Columbia, STEPHANE POPINET, Institut Jean le Rond d’Alembert Université Pierre et Marie Curie, ANTHONY WACHS, Department of Mathematics, department of Chemical & Biological Engineering, University of British Columbia — Modeling rigid particle-laden flows requires an accurate description of the flow field in the close vicinity of the particles (i.e. in the boundary layers). One of the numerical difficulties lies on the extremely fine grid necessary to fully capture the flow dynamics near the particle boundary (as e.g. lubrication force). In such scenario, fixed Cartesian grids are prohibitive as the required number of computational cells becomes impractical. To overcome this difficulty, we combine an adaptive mesh refinement (AMR) technique with a distributed Lagrange multipliers/fictitious-domain method (DLM/FD) (Glowinski et al. 1999). The solver is implemented within the code Basilisk (Popinet, 2015) which provides a set of adaptive-multigrid solvers on quad/oct-trees. The method is validated against various test cases involving spherical particles in different flow regimes: from Stokes flow to highly inertial flows. To compute flows laden with non-spherical particles, we couple our AMR-DLM/FD solver to the granular solver Grains3D (Wachs et al. 2012). With this numerical tool, the dynamics of multiple particles of complex shape freely moving in a fluid on adaptive quad/oct-tree becomes accessible. As an illustration, we present the case of 600 free falling cubes in a large container.

12:02PM S28.00008 Chaotic Orbits of Tumbling Ellipsoids in Viscous and Inviscid Fluids\textsuperscript{1}, ERICH ESSMANN, PRASHANT VALLURI, School of Engineering, University of Edinburgh, STEPHANE POPINET, Sorbonne Université, Institut Jean le Rond d’Alembert, RAMA GOVINDARAJAN, ICTS-TIFR, Bangalore — It was shown that the equations of motions of an immersed tri-axial ellipsoid become non-integrable under certain inviscid conditions, (Kozlov and Onishchenko, 1982). Non-integrability is a strong function of density ratio and the initial energy ratio. In viscous systems, we have noted evidence of chaotic orbits for symmetric ellipsoids. Due to vortex shedding behaviour in this context breaking the symmetry of the system. We show how chaos can be exploited under viscous environments to promote mixing.

Comparisons of the resistance curves for the rigid replicas and live biofilm will be discussed and flow measurements will be additive manufacturing using in situ measurements of the biofilm surface profile collected at several flow speeds and growth incubation times. The hydrodynamic performance of the biofilm was determined through pressure drop measurements as well as planar particle image velocimetry of the channel flow. Comparisons of the resistance curves for the rigid replicas and live biofilm will be discussed and flow measurements will be presented.

Facility at the University of Michigan. Experiments evaluating the drag produced by the live biofilm were then compared to those of solid, three-dimensional printed, rigid replicas to differentiate the measured drag forces and their components. These rigid replicas were generated via additive manufacturing using in situ measurements of the biofilm surface profile collected at several flow speeds and growth incubation times. The hydrodynamic performance of the biofilm was determined through pressure drop measurements as well as planar particle image velocimetry of the channel flow. Comparisons of the resistance curves for the rigid replicas and live biofilm will be discussed and flow measurements will be presented.

ELIZABETH CALLISON, JOEL HARTENBERGER, JAMES GOSE, University of Michigan, MARC PERLIN, Texas A&M University, STEVEN CECCIO, University of Michigan — Soft biofilms can form at flow boundaries, producing increased friction drag which can adversely affect the performance of hydrodynamic systems. The underlying mechanisms of drag production in soft biofilms are not well understood. Surface roughness, compliance, and the presence of streamers within the boundary layer flow can all contribute to the development of friction drag by turbulent boundary layers. To examine the drag producing flow, flat plates covered in biofilms were studied in the Skin-Friction Flow Facility at the University of Michigan. Experiments evaluating the drag produced by the live biofilm were then compared to those of solid, three-dimensional printed, rigid replicas to differentiate the measured drag forces and their components. These rigid replicas were generated via additive manufacturing using in situ measurements of the biofilm surface profile collected at several flow speeds and growth incubation times. The hydrodynamic performance of the biofilm was determined through pressure drop measurements as well as planar particle image velocimetry of the channel flow. Comparisons of the resistance curves for the rigid replicas and live biofilm will be discussed and flow measurements will be presented.

11:36 AM S29.00006 Ion-Mediated Swelling in a Model of Gastric Mucus Gel. OWEN LEWIS, Florida State University, JAMES KEENER, AARON FOGELSON, University of Utah — The gastric mucus layer serves a protective function in the human stomach, shielding the epithelium from the digestive machinery of the stomach, but it is not understood how this gel layer is maintained in vivo. Mucus degradation via digestion of the gel network at the lumen must be balanced by secretion and swelling of new mucus at the stomach wall. These processes are dependent on the local ionic composition of the gel solvent, which varies throughout the layer. Here, we present a comprehensive model of mucus-like polyelectrolyte gel based on a two-phase framework. This model extends classical theory to account for the dependence of the Flory interaction parameter and standard free energies on transient, ion-mediated crosslinks within the gel network. We present a computational investigation of the dynamic swelling behavior of the model. In particular, we quantify the rate at which a globule of crosslinked gel swells when exposed to an ionic bath as a function of bath concentration and network chemistry. We show that the swelling rate has a non-monotone dependence on the molarity of the bath solution, in part due to the existence of an additional chemical pressure not predicted by classical theory.

11:49 AM S29.00007 Active carpets, part 1: Transport driven by bacterial clusters and topological defects1. FRANCISCA GUZMAN-LASTRA, Universidad Mayor, ARNOLD MATHIJSSEN, Stanford University, ANDREAS KAISER, Retired, HARTMUT LOEWEN, Heinrich-Heine University — Biological activity is highly concentrated on surfaces, from molecular motors and ciliary arrays to sessile suspension feeders and biofilms; together they form the class of ‘active carpets’. While the physics of active suspensions has raised considerable interest, it remains unclear how energy and momentum injection from active surfaces can drive living systems out of equilibrium. Here we demonstrate that active carpets of bacteria or self-propelled colloids generate coherent flows towards the substrate, and we propose that these currents provide efficient pathways to replenish nutrients that feed back into activity. A full theory is developed in terms of gradients in the active matter density and velocity, and applied to bacterial turbulence, topological defects and clustering. Currents with complex spatiotemporal patterns are obtained, which are tunable through confinement. Our findings show that diversity in carpet architecture is essential to maintain biofunctionality.

12:02 PM S29.00008 Active carpets, part 2: Generalisation of Fick’s laws for enhanced diffusion and particle capture by life at interfaces1, ARNOLD JTM MATHIJSSEN2, Stanford University, FRANCISCA GUZMAN-LASTRA, Universidad Mayor, Santiago, Chile, MANU PRAKASH, Stanford University, HARTMUT LOEWEN, Heinrich Heine University Düsseldorf — Fluctuations lie at the core of biological processes, facilitating diffusive transport and driving the cell’s molecular machinery. Fick’s laws of diffusion are well established in classical thermodynamics, but living systems operate far from thermal equilibrium as energy is injected locally by activity, which can give rise to surprising effects not captured by passive diffusion. Especially on surfaces this metabolic activity is highly concentrated, from molecular motors through ciliary arrays to sessile suspension feeders and bacterial biofilms, together forming the class of ‘active carpets’. Here, we consider the flows generated by these different active surfaces and show how they can enhance diffusion, directed transport, and particle capture. We derive the diffusion coefficients as a function of distance from these active carpets and we formulate the corresponding generalised Fick’s laws. These laws feature remarkable solutions, including non-Boltzmannian sedimentation profiles with particles hovering a finite distance above the active carpet, and enhanced particle capture by a raised diffusive flux. Our results shed new light on the non-equilibrium properties of materials with active boundary conditions and life at interfaces.

Session S31 Biological Fluid Dynamics: Collective Behavior 613 - Hamid Karani, Northwestern University

10:31 AM S31.00001 Shrinking spinning fire ant rafts. HUNGTANG KO, DAVID HU, Georgia Institute of Technology — Fire ants make rafts to stay afloat during flooding seasons. The ability to respond to different fluid environments is critical to raft sustainability. To investigate the response, we built an experiment setup to create two fluid conditions for the fire ant raft: rigid-body rotation and Taylor-Couette vortex. We found that following a rapid expansion phase, the fire ant raft shrinks at a much longer time scale under all conditions. We discovered that the additional shear from the Couette vortex help stabilize the ant raft while the centrifugal force didn’t have appreciable effects. Furthermore, the result suggests that rotation can inhibit the exploration behavior of individual fire ants on the raft.

10:44 AM S31.00002 Insights on rotor ensemble dynamics using a new scalable computational platform. WEN YAN, MICHAEL SHELLEY, Flatiron Institute, Simons Foundation — Suspensions of Stokes rotors consist of immersed particles that are driven to rotate, with that rotation creating flow fields that can create large-scale coupling and dynamics. Such rotor systems are typically driven by external means, such as a rotating magnetic field. Here we study the dynamics of closely packed rotor systems using a new method that combines a high-order accurate fluid solver, based on integral equation methods, and a temporally stable particle-particle collision solver based on geometric constraint optimization. This new computational technique is scalable on parallel computer clusters and allows us to simulate the development of large-scale dynamics. We first report the internal dynamics of a monolayer consisting of 10,000 rotors, each driven by a torque perpendicular to the monolayer. This shows both large-scale collective dynamics and complex small-scale interactions. In the second example, we turn the torque sideways and find a Kelvin-Helmholtz-like instability of the monolayer induced by the particles’ rotational flows and steric interactions.
On the locomotion and collective behavior of biopolymer-producing bacteria

JUANES, MIT — Viscous environments are ubiquitous in nature and engineering applications — such as mucous in lungs and oil recovery systems; ranging from swarms and jets to dynamic clusters and vortices. We elucidate the role of complex physical interactions between colloidal particles and show that different emergent states are identified by competing characteristic time and length scales. More specifically, we show that the time scales during the run and tumbling phases play a major role in establishing different stable collective states. Our findings show the potential for dynamic transitioning between states at constant concentration and activity (speed) of active particles by solely tuning the kinematic time and length scales of individual random walkers.

Rheology of Bacteria Superfluids in Viscous Environments

CHUI, MIT, KAREN FAHRNER, Harvard University, CARINE DOUARCHE, HAROLD AURADOU, Université Paris-Sud, CNRS, RUBEN JUANES, MIT — Viscous environments are ubiquitous in nature and engineering applications — such as mucous in lungs and oil recovery strategies in the earth’s subsurface — and in all these environments, bacteria also thrive. It has been well documented that active suspensions of bacteria can behave as a superfluid, in terms of reducing the viscosity of the surrounding fluid by their collective motion, but it is not known what their effect is when they are introduced to a viscous environment. Here, we investigate experimentally how viscous environments can change the ability of pusher-type bacteria (E. coli) in creating a superfluid regime. Using a Couette rheometer, we measure stress as a function of the applied shear rate, and define the apparent viscosity of $E. coli$ suspensions, varying both the density of the bacteria population within the suspension and the viscosity of the suspending fluid. We find that the bacteria suspensions remain capable of behaving as a superfluid by reducing their surrounding viscosity to zero, and that changes in solvent viscosity mainly affects the range of shear rates over which the superfluid regime is possible. From the data, we assemble the ingredients needed to build a theoretical model that describes the effective viscosity of an active fluid as a function of the bacteria density and its environment (shear rate, solvent viscosity). Beyond the value for developing a theoretical model, our results open the possibility of giving an empirical guidance for numerical simulations involving bacteria and fluid flow.

Predator-Prey Interactions using Deep Reinforcement Learning

LOO, MOHAMMAD-REZA ALAM, University of California, Berkeley — Here we unveil synergistic cooperation of micro-swimmers to form a stealth swarm that minimally disturbs the surrounding fluid. We call this mode of swarming the ‘concealed mode, which can be achieved when a group of swimmers actively collaborate to cancel out one another’s disturbing flows. We then demonstrate how such a concealed swarm can remain stealth while actively gathered around a favorite spot (e.g. a nutrient source), pointing toward a target (e.g. attacking a prey flock), or tracking a desired trajectory in space. Our findings also provide a clear road map to control and lead stealth flocks of swimming micro-robots formed through their active collaboration in minimally disturbing the host medium.

10:31AM S32.00001 Space-time characteristics of wind turbulent pressure field at wave surface. XUANTING HAO, LIAN SHEN, University of Minnesota — The wind pressure field at the wave surface, with fluctuations several orders of magnitude smaller than the mean atmospheric pressure, has a notable impact on the wave energy growth. The time-variant and irregular wave field poses great challenge to the full space-time measurement of the surface pressure. We present a simulation-based study of the space-time characteristics of the surface pressure field. The numerical tool is a combined turbulence solver and wave-phase-resolved model, where the wind turbulence is simulated with large-eddy simulation and the nonlinear wave field simulated using a high-order spectral method. The joint probability distribution of the surface pressure and the vertical surface velocity is found to resemble that of turbulent flows over a compliant wall. We also conduct spectral analysis on the surface pressure field to obtain the wavenumber-frequency spectrum. While the turbulent pressure fluctuations have a convection velocity comparable to turbulent flows over a fixed flat wall, a distinct wave effect is identified. The wavenumber/frequency peak of the wave-coherent pressure field is found to deviate from that of the wave field, suggesting nonlinearity in the turbulence-wave interactions.

10:44AM S32.00002 Effect of the presence of long waves on the wave growth rate of short waves. TAO CAO, LIAN SHEN, University of Minnesota — We performed a DNS study of the turbulent wind over two slowly progressive water waves with different wave lengths. It is shown that the presence of the long wave results in a significant reduction of the form drag on the short wave. To explain the underlying physical mechanism, we obtained the momentum equations for the wave-coherent motions induced by the long wave and the short wave, respectively. We first showed that the asymmetric wave-induced pressure across the surface wave crest is responsible for the form drag on the wave surface and is mainly caused by the wave-induced advection associated with the vertical wave-induced velocity that is in-phase with the surface elevation. It is further found that in the presence of the long wave, the wave-induced advection corresponding to the short wave is significantly reduced, which results in a smaller asymmetric pressure on the short wave, and thereby a lower form drag. Moreover, we observed that the extent of the reduction of the form drag on the short wave depends on the wave age of the long wave. The smaller the wave age of the long wave, the larger the reduction of the form drag on the short wave.

10:57AM S32.00003 Numerical simulations of the turbulent flow over an ocean wavefield. DEVIN CONROY, LAURA BRANDT, JAMES ROTTMAN, Leidos — The air-sea dynamics for wind driven ocean waves are crucial for understanding and predicting the weather and global climate, as well as for predicting forces on ships and offshore wind farms for design and operation. The wind-wave problem has been an active area of research for many years, spanning observational, experimental, theoretical, and numerical studies. Here we leverage the Large Eddy Simulation technique with a sub-grid scale sea surface roughness model for the interfacial stress and an interface capturing Volume-of-Fluid method to obtain highly accurate phase resolved simulations over a sufficiently large domain size. We investigate the dynamics of the air-sea interaction, starting with a JONSWAP spectrum, to understand the generation of turbulence, wind-wave growth, non-linear surface dynamics, and wave breaking on the overall energy budget. We find that the wind stress tends to add energy at small length scales (<0.1 m), due to the surface shear and turbulent pressure fluctuations in the air above the surface. Preliminary results also indicate that under strong wind forcing (or low wave age), air separation occurs near wave crests that later undergo breakage.

11:10AM S32.00004 ABSTRACT WITHDRAWN

11:23AM S32.00005 A kinetic approach to estimate air-sea exchanges driven by sea spray in high winds. FABRICE VERON, University of Delaware, LUC MIEUSSENS, University of Bordeaux, France — Sea-spray is known to be a fundamental component of air-sea heat flux in high wind speed conditions where water drops are frequently ejected from the sea surface because of breaking waves and breaking related phenomena such as bubble entrainment and whitecaps. Once ejected from the ocean surface, these drops are transported and dispersed in the Atmospheric Boundary Layer (ABL) where they interact and exchange momentum, heat, and moisture with the ambient atmosphere. However, understanding of these spray fluxes pathways, and our ability to model them remains limited. In this work, we borrow the framework from established kinetic gas theory, and apply these mathematical tools to model the transport of spray droplets and the exchanges of heat, momentum, and moisture between the drops and the atmosphere. Within this framework, one of the most vexing component of this spray flux problem, i.e. the feedback from the drops on the atmosphere, is relatively straightforward to account for. This work is largely exploratory and in the early stages of development. We will present an overview of the approach as well as preliminary results.

11:36AM S32.00006 An Experimental Study of Droplet Generation by Plunging Breaking Water Waves, MARTIN A. ERININ, SOPHIE WANG, REN LIU, DAVID TOWLE, XINAN LIU, JAMES H. DUNCAN, University of Maryland — The production of droplets by strong, moderate, and weak plunging breakers is studied experimentally in a laboratory. The water waves are generated mechanically using a dispersively focused wave packet technique with an average wave packet frequency of 1.15 Hz for all three waves. Surface profile histories of the breaking wave crests are measured using a cinematic laser-induced fluorescence technique. The temporal evolution of the phase averaged surface profile of the breaker, obtained from 10 runs for each wave, are used to characterize the breakers. Droplets are measured using a cinematic digital in-line holographic system positioned at 26 streamwise locations along a horizontal plane (herein called the measurement plane) that is 1 cm above the maximum wave crest height. The droplet radii (r > 100 μm), positions and trajectories are determined from the holograms. Counting only the droplets that are moving up across the measurement plane, the spatio-temporal distribution of droplet generation by the breakers is obtained. Droplet statistics including total number, mean diameter and speed are presented. The relative importance of the various droplet generation mechanisms in the three waves are discussed and correlated with the mean wave profile characteristics.

The amplitudes of individual modes are defined such that the total standard deviation of the two perturbations are the same and all modes are initially linear. The DNS results are compared with implicit large eddy simulations (ILES) of the same initial conditions in the high Reynolds number limit case for comparisons is shock interaction with a solid cylinder. Langmuir circulation (LC) beneath an initially quiescent air-water interface appear shortly after the initiation of wind-driven gravity-capillary waves and provide the laminar-turbulent transition in wind speeds between 3 and 6 m/s. LES reveals Langmuir turbulence characterized by multiple scales ranging from small bursting eddies at the surface that coalesce to give rise to larger (centimeter-scale) LC over time. The growing LC scales lead to increased vertical scalar transport at depths below the interface and thus greater scalar transfer efficiency. Simulations were performed with a fixed wind stress corresponding to a 5 m/s wind speed but with different wave forcing parameters. It is observed that longer wavelengths lead to more coherent, larger centimeter-scale LC providing greater contribution to the turbulent vertical scalar flux. In all cases, the molecular diffusive scalar flux at the water surface relaxes to the same statistically steady value after transition to Langmuir turbulence occurs, despite the different wave forcing across the simulations.

12:02PM S32.00008 Large-eddy simulation (LES) of small-scale Langmuir circulation and scalar transport1, ANDRES TEJADA-MARTINEZ, AMINE HAFSI, University of South Florida, CIGDEM AKAN, University of North Florida, FABRICE VERON, University of Delaware — Previous laboratory experiments have revealed that small-scale (centimeter-scale) Langmuir circulation (LC) beneath an initially quiescent air-water interface appear shortly after the initiation of wind-driven gravity-capillary waves and provide the laminar-turbulent transition in wind speeds between 3 and 6 m/s. LES reveals Langmuir turbulence characterized by multiple scales ranging from small bursting eddies at the surface that coalesce to give rise to larger (centimeter-scale) LC over time. The growing LC scales lead to increased vertical scalar transport at depths below the interface and thus greater scalar transfer efficiency. Simulations were performed with a fixed wind stress corresponding to a 5 m/s wind speed but with different wave forcing parameters. It is observed that longer wavelengths lead to more coherent, larger centimeter-scale LC providing greater contribution to the turbulent vertical scalar flux. In all cases, the molecular diffusive scalar flux at the water surface relaxes to the same statistically steady value after transition to Langmuir turbulence occurs, despite the different wave forcing across the simulations.

Session S33 Flow Instability: Richtmyer-Meshkov, Computational

10:31AM S33.00001 Direct numerical simulation of Richtmyer-Meshkov instability with broadband initial perturbations, MICHAEL GROOM, BEN THORNBERRY, The University of Sydney — The effects of Reynolds number on the early to intermediate time behaviour of a mixing layer induced by Richtmyer-Meshkov instability (RMI) are investigated through a series of direct numerical simulations (DNS) using the finite-volume code FLAMENCO. This study presents, for the first time, results from direct numerical simulations of RMI evolving from amplitude perturbations containing a broad bandwidth of initial modes. In particular, two different broadband perturbations are analysed, defined by their initial radial power spectra $P(k) = C_k^m$ where $m = -1, -2$. The amplitudes of individual modes are defined such that the total standard deviation of the two perturbations are the same and all modes are initially linear. The DNS results are compared with implicit large eddy simulations (ILES) of the same initial conditions in the high Reynolds number limit, showing that although there is significant suppression of turbulence in the low Reynolds number DNS, the growth in integral component for further insight into droplet dynamics and exchange fluxes.

10:44AM S33.00002 Additive Manufacturing and Richtmyer-Meshkov Initial Condition Studies, TIFFANY DESJARDINS, ADAM MARTINEZ, JOHN CHARONKO, KATHY PRESTRIDGE, Los Alamos National Laboratory — With the advances in materials and additive manufacturing we have begun to re-explore the application of membranes in RMI experiments. At the Vertical Shock Tube facility, we are using AM techniques to develop shaped membranes for studies of different types of initial interfaces, motivated by the need to explore non-diffuse initial conditions with specific geometrical configurations. The need for understanding of features in applications such as inertial confinement fusion (ICF) drives this work. The goal is the development of a barrier at the initial interface that repeatedly breaks, minimally influences the growth of the instability, and can be shaped to look at desired interface configurations. We have found a material fragile enough that when hit with an M = 1.2 shock, it is returned to a near complete dust state. The particles are heavy enough to lag behind the interface region and preliminary experiments studying single modes will be presented.

10:57AM S33.00003 Validation of a Simplified WENO Scheme with Artificial Viscosity for a Shock Interface Interactions1, BRIAN ROMERO, SVETLANA POROSEVA, PETER VOROBIEFF, University of New Mexico — The goal of this work is to validate numerical simulation of the shock-driven evolution of an initially axisymmetric cylindrical particle cloud (or a heavy gas column) against laboratory experiments. In the initial conditions in the experiment, there is a density gradient in gas, an average density gradient due to the particle seeding, or both. The cylindrical column is comprised of a mixture of sulfur hexafluoride, acetonitrile, and air, and surrounded by air, leading to the representative Atwood number of 0.61. The Mach number in experiments varied from 1.2 to 2.0. Simulations were conducted at Mach numbers matching the experiment using a simplified WENO scheme incorporating a new C-method for artificial viscosity. The initial modeling/validation exercises featured a two-dimensional simulation of shock interaction with the gas column, with variations in the level of initial diffusion on the density interface. From a sharp interface to a diffuse boundary matching the conditions measured in experiment. Further studies include 3D problems with multiple gas species and immersed boundary conditions, and shock wave refraction for various values of the gas constant $\gamma$. The limit case for comparisons is shock interaction with a solid cylinder.

11:10AM S33.00004 Numerical Simulation of Richtmyer-Meshkov Instability in Converging Geometries, ZUOLI XIAO, JINXIN WU, College of Engineering, Peking University — A high-order turbulence solver in curvilinear coordinates is developed for numerical simulation of multi-species compressible flows with discontinuities, in which high-order compact finite difference schemes and localized artificial diffusivities are employed to satisfy the need for high accuracy and discontinuity capturing. The Richtmyer-Meshkov instability (RMI) induced mixing flows driven by implooding shock in both cylindrical and spherical geometries are numerically investigated using direct numerical simulation method. The detailed evolutions of RMI are compared with experimental data and theoretical results, and reasonably good consistency is observed both qualitatively and quantitatively before reshock. The vortex dynamics of RMI after shock impingement is also discussed, and an initially limited circulation on the interface during shock-interface interaction is calculated from the simulation, which is in accordance with the results of theoretical prediction. Moreover, effects of the modes and amplitude of initial perturbations, as well as the incident shock Mach number on the interfacial growth rate are evaluated during the shock implosion and reflection from the center.

11:23AM S33.00005 A Comparison of Two- and Three-Dimensional Single-Mode Reshocked Richtmyer-Meshkov Instability Growth, OLEG SCHILLING, Lawrence Livermore National Laboratory — The growth dynamics of two- and three-dimensional single-mode reshocked Richtmyer-Meshkov instability are compared using data from high-resolution implicit LES of a model of the Mach 1.3 air(acetone) and sulfur hexafluoride Jacobs and Krivets shock tube experiment. The numerical amplitude growth is compared to the predictions of several nonlinear instability growth models. The dynamics of reshock are described, and the post-reshock mixing layer amplitude growth rate is compared to the predictions of several reshock models. It is shown that using two-dimensional simulations to understand three-dimensional dynamics is valid only at early-to-intermediate times before reshock. At intermediate-to-late times the three-dimensional growth is larger than the two-dimensional growth. The reshock dynamics are also different between two and three dimensions.

11:36AM S33.00006 Effects of the secondary baroclinic vorticity on turbulent energy cascade in the Richtmyer-Meshkov instability, NAIFU PENG, YUE YANG, Peking University — We study turbulent mixing in the Richtmyer-Meshkov instability (RMI) induced by a planar shock wave at Mach 1.5 with multimode interfacial perturbations between air and SF6. By separating different types of the perturbations, we develop a double-density model for simplifying the RMI, and find that the effects of the secondary baroclinic vorticity (SBV) play an important role during the flow evolution. The SBV, caused by the misalignment of the pressure gradient produced by the velocity perturbation and the density gradient near the interface, leads to the nonlinear evolution of the interface with the generation of spike- and bubble-like structures. Moreover, the SBV produces small-scale vortical structures and affects the turbulent energy cascade in the mixing zone. The kinetic energy spectrum affected by the SBV is closer to the —μ/3 scaling law than the classical —5/3 law for constant-density homogeneous isotropic turbulence.

11:49AM S33.00007 Computational study of the interactions of two bubbles along an interface undergoing the Richtmyer-Meshkov instability, MICHAEL WADAS, ERIC JOHNSEN, University of Michigan — In addition to its prevalence in astrophysics, the shock-driven growth of interfacial perturbations (the Richtmyer-Meshkov instability, or RMI) has important practical consequences in applications of fusion research. Our objective is to numerically investigate the generation of vortex dipoles that escape the confines of the mixing region, as well as the reacceleration of bubbles, by focusing on the interaction of two adjacent bubbles of different sizes subjected to the RMI. Our hypothesis is that the escape of a vortex dipole can be predicted from the initial conditions based on the vorticity associated with the bubbles. Simulations are performed using an in-house, high-order accurate Discontinuous-Galerkin code. We demonstrate deviations from existing bubble merging models in the non-linear regime caused by the interaction of adjacent pairs of spikes, which had not previously been considered. We further develop a criterion that predicts the regime that will emerge for a given interface.

12:02PM S33.00008 Impulse-driven Richtmyer-Meshkov instability in Hall-magnetohydrodynamics, NAIJIAN SHEN, DALE PULLIN, California Institute of Technology, VINCENT WHEATLEY, University of Queensland, RAVI SAMTANEY, King Abdullah University of Science and Technology — We utilize the incompressible, Hall-MHD model for conducting fluids to investigate the effect of Hall current on the stability of an impulsively-accelerated, perturbed density interface, or contact discontinuity (CD) separating two fluids in the presence of a background magnetic field. This is used as a simple model, in a conducting fluid, of a Richtmyer-Meshkov (RM) flow that is characterized in a neutral-fluid by a shock-wave-density-interface interaction. The linearized equations of motion are formulated for a sinusoidal interface perturbation, and then solved as an initial-value problem using a Laplace transform method. The presence of the magnetic field is found to suppress the incipient interfacial growth associated with neutral-gas, RM instability (RMI). When the ion skin depth is finite, the vorticity dynamics that drive the suppression of the RMI differs markedly from the ideal MHD, RM flow. Hall MHD allows the presence of a tangential slip velocity leading to finite circulation deposition at the CD. Vorticity is produced by the perturbed magnetic fields and transported to infinity by a dispersive wave system leading to decay of the velocity slip at the interface with the effect that that interface growth remains bounded but distorted by damped oscillations.

KAUST Office of Sponsored Research
Numerical simulations are carried out, which reveal the development of large-amplitude waves in the axisymmetric, and non-axisymmetric cases. Extensions to non-isothermal situations are outlined.

10:44AM S34.00002 Reduced-order Models for Two-phase Annular Flows in Vertical Pipes 1

1. THOMAS EWERS, Imperial College London, ALEXANDER WRAY, University of Strathclyde, OMAR MATAR, Imperial College London — We study the dynamics of two-phase annular flow in vertical pipes. The conditions considered are such that there is no mass exchange between the phases due, for instance, to liquid entrainment into the gas, and bubble entrainment within the liquid. The gas is assumed to be turbulent, whilst the liquid phase exists in the form of a thin film adjacent to the wall. Reduced-order models are derived using asymptotic reduction for both axisymmetric and non-axisymmetric cases. The turbulence in the gas is modelled using a mixing length relation, while the method of weighted residuals is used in the film wherein inertial contributions are significant but the flow remains laminar. Numerical computations are carried out, which reveal the development of large-amplitude waves in the axisymmetric, and non-axisymmetric cases. Extensions to non-isothermal situations are outlined.

10:57AM S34.00003 Analysis of Blast Driven Instability and Mixing from the Energetic Dispersal of a Perturbed Particle Bed

1. FREDERICK OUELLET, RAHUL BABU KONERU, JOSHUA GARRNO, S. BALACHANDAR, University of Florida, BERTRAND ROLLIN, Embry-Riddle Aeronautical University — The evolution of particle clouds following interactions with a blast wave and contact interface resulting from detonating a high-energy explosive is a difficult problem for both numerical simulations and physical experiments. Experimentally, it is challenging to accurately characterize the initial states of both the explosive and the surrounding particle bed. Limitations also exist in the available diagnostic tools and measurable data which can be extracted from experiments. Thus, simulations can be a cheaper method to analyze the physics governing the interactions between the expanding particle cloud and the highly compressible, post-detonation fluid flow. Using multiphase, compressible flow simulations in an Eulerian-Lagrangian frame, the impact of perturbing a particle bed surrounding an explosive charge is analyzed. The analysis focuses on the multiphase instabilities and late-time behavior displayed by the dispersing particle cloud and discusses the associated underlying physical phenomena. Effects of the instabilities on the mixing behavior of the detonation products with the surrounding air are also discussed. The perturbations are varied to unravel the effects of the initial particle distribution and its persistence in the late time particle cloud and the background fluid flow. Inspired by work on two-fluid interfacial instabilities, this study relates to work in the emerging field of shock-driven multiphase instabilities but at extreme conditions and moderate initial particle loadings.

11:00AM S34.00004 On hydrodynamic instabilities in pseudo-boiling with supercritical fluids 1

1. REBECCA BARNEY, UC Davis, ROBERT NOURGALIEV, Lawrence Livermore National Laboratory, JEAN-PIERRE DELPLANQUE, UC Davis, ROSE MCCALLEN, Lawrence Livermore National Laboratory — We investigate hydrodynamic instabilities arising in mixed forced and natural convection laminar flow at supercritical thermodynamic conditions. Fluid in this regime is compressible, with highly varying properties, even for vanishingly small Mach numbers. Hydrodynamic stability is influenced by the occurrence of pseudo-phase change near the channel wall, as defined by the peak of the specific heat above the critical point. While the fluid properties do not explicitly exhibit a discontinuous change, the steep continuous property changes create flow patterns which qualitatively look like boiling. Of interest is investigating this boiling-like phenomenon to characterize the heat transfer in the supercritical regime. Due to the highly-varying density and specific heat fields, we solve the fully compressible Navier-Stokes equations. An advanced equation of state for supercritical water was implemented in an Arbitrary Lagrangian-Eulerian multi-physics simulation tool developed at Lawrence Livermore National Laboratory. A newly developed, robust, 5th order in both space and time, fully implicit, all-speed, reconstructed discontinuous Galerkin method is used to enable the numerical simulations. As the bottom wall is heated, the density decreases at the wall increasing the flow instabilities. The Richardson number indicates when the flow is dominated by forced or natural convection and provides a map/correlation between buoyancy effects and unstable flow features.

11:23AM S34.00005 A new mechanism for the generation of interface distortions in liquid jets 1

1. HANUL HWANG, PARVIZ MOIN, M. J. PHILLIPP HACK, Center for Turbulence Research, Stanford University — The onset of the atomization process of liquid jets is commonly understood as a sequence of exponential instabilities whose amplification eventually leads to a distortion of the interface and the breakup of the jet into droplets. Our study analyzes the amplification of interface perturbations of liquid jets through an optimization problem within a spatial linear framework. The objective functional is the interface potential energy due to surface tension. We demonstrate that a multi-phase Orr mechanism can serve as an alternative pathway for the generation of interface distortions by redistributing energy from the mean shear into perturbations of the jet surface. Parameter studies show that the amplification of interface disturbances scales with both Reynolds number and Weber number. Analysis of the budget of the perturbation kinetic energy provides further insight into the underlying physics. For high Weber numbers, the amplification of the surface distortion is bounded by viscous effects, whereas surface tension limits the growth in the case of low Weber numbers.

11:36AM S34.00006 Squeezing to Bending Transitions of Interfacial Electrohydrodynamic Instabilities for Digitization and Mixing of Two-Phase Microflows1. JOYDIP CHAUDHURI2, TAPAS KUMAR MANDAL2, DIPANKAR BANDYOPADHYAY2, IIT Guwahati. — External field induced interfacial instabilities have shown significant potential in the miniaturization of flow patterns inside the microfluidic devices. Electric field induced instabilities in a trilayer oil-water microflow is explored with the help of analytical models and computational fluid dynamics simulations. Twin oil-water interfaces undergo either in-phase bending or anti-phase squeezing mode of deformation when a direct current (DC) electric field is applied locally. The selection of modes depends on the magnitudes of applied DC field intensity and oil-water interfacial tension. The growth of the squeezing mode leads to a time-periodic dripping of droplets at lower field intensities, whereas, bending mode develops into ‘whiplash’ ejection of miniaturized droplets having octuplet microvortices inside and outside, at higher field intensities. A transition from purely laminar flow is observed during the switch over to bending mode, resembling von Kármán vortex street formation. Use of alternating current (AC) electric field with variation in frequency and waveform is also found to create on-demand and time-periodic array of flow features following the mode selection.

11:49AM S34.00007 Phase transitions to condensate formation in two-dimensional turbulence1. MORITZ LINKMANN, Fachbereich Physik, Philipps-University of Marburg, GUIDO BOFFETTA, Dipt. Fisica, University of Torino, Italy, M. CRISTINA MARCHETTI, Dept. Physics, UC Santa Barbara, USA, BRUNO ECKHARDT, Fachbereich Physik, Philipps-University of Marburg — Two-dimensional (2d) and quasi-2d flows occur at macro- and mesoscale in a variety of physical systems. Examples include stratified layers in Earth’s atmosphere and the ocean, soap films and more recently also dense bacterial suspensions, where the collective motion of microswimmers induces patterns of mesoscale vortices. A characteristic feature of 2d turbulence is the occurrence of an inverse energy cascade. In absence of large-scale friction the inverse energy cascade results in the formation of large-scale coherent structures, so-called condensates. We here study the formation of the condensate as a function of the kind and amplitude of the forcing. Direct numerical simulations show that the condensate appears in a phase transition. For prescribed energy dissipation the transition is second order; for active matter, where the forcing is due to a small-scale instability, the transition is first order. The phase transition separates two markedly different types of 2d dynamics: in turbulence with a condensate, energy input is mostly balanced by dissipation in the condensate and intermediate scales follow an inertial cascade; without a condensate dissipation is spread over the intermediate scales and the properties of the energy transfer are different and non-universal.

Session S35 Microscale Flows: Devices

10:31AM S35.00001 Hydrostatic and hydrodynamic bulge testing of pre-stressed thick elastic plates for microfluidic applications1. VISHAL ANAND, IVAN C. CHRISTOV, School of Mechanical Engineering, Purdue University, West Lafayette, Indiana 47907, USA — Bulge tests are used to characterize material properties of elastic sheets. We present a theory of hydrodynamic bulge tests based on the fluid–structure interaction between a deformable top wall of a rectangular microchannel and a viscous Newtonian fluid flow within. Taking into account uniform isotropic pre-stress within the wall, we derive a model for the deformation using first-order shear-deformation theory for thick plates. It is shown that pre-stress reduces the transverse deformation. Then, the mechanics problem is coupled to flow under the lubrication approximation, in a perturbative manner, to capture both the effect of (non-constant) hydrodynamic pressure on the deformation and the effect of wall deformation on the channel’s hydrodynamic resistance. We obtain an analytical expression for the flow rate–pressure drop relation and show how it can be used to characterize the material properties (e.g., Young’s modulus or pre-tension) of an elastic sheet without measuring its deformation, which is difficult to do accurately at the microscale. Direct numerical simulations are performed using the commercial software ANSYS to explore the range of validity of the proposed bulge testing theory.

10:44AM S35.00002 Theory of the bulging effect of soft microchannels with thick walls1. XIAOJIA WANG, IVAN C. CHRISTOV, School of Mechanical Engineering, Purdue University, West Lafayette, Indiana 47907, USA — Long and shallow microchannels embedded in thick soft materials have been widely used in microfluidic devices. However, the bulging effect due to the fluid–structure interactions between the internal viscous flow and the soft walls has not been thoroughly understood. Previous models either contained a fitting parameter or were specialized to channels with thin walls. We present a theoretical study of the steady-state response of a deformable microchannel with a thick wall. Using lubrication theory for low-Reynolds-number flows and the linear elastic theory for isotropic solids, we obtain perturbative solutions for the flow and deformation. Specifically, only the channel’s top wall deformation is considered, and its thickness-to-width ratio is assumed to be ($t/w)^2 \gg 1$. Then, we show that the deformation at each stream-wise cross-section can be considered independently, and that the top wall can be regarded as a simply supported rectangle subject to uniform transverse pressure at its bottom. The stress and displacement fields are found using Fourier series. Then, the channel shape and the hydrodynamic resistance are calculated, yielding a new flow rate–pressure drop relation without any fitting parameters. Our results agree favorably with previously reported experiments.

and provide examples of connection patterns in serial and parallel.

flow field. The design, based on a valve system, provides greater versatility and flexibility than previous designs. We modulized all the controllers and provide examples of connection patterns in serial and parallel.

11:10AM S35.00004 Flow manipulation via the effects of shape geometry and topology

1. TEJASWIN PARTHASARATHY, YASHRAJ BHOSALE, FAN KIAT CHAN, MATTIA GAZZOLA, University of Illinois, Urbana-Champaign — We demonstrate the importance of body curvature effects in achieving controlled flow manipulation in streaming settings. Here, we focus on microfluidic applications for inertial particle transport and mixing. We then challenge our understanding to explain prior experimental observations in two-dimensional flows. We further extend our exploration to three-dimensional flows where strategies related to body topology become accessible.

1 NSF CAREER Grant No. CBET-1846752 (MG)

11:23AM S35.00005 Regularized Inversed Holographic Volume Reconstruction for 3D flow diagnostics

1. JIARONG HONG, MALLERY KEVIN, University of Minnesota — We introduce regularized inverse holographic volume reconstruction (RIHVR) for 3D flow diagnostics using a single camera digital inline holographic particle tracking velocimetry (DIH-PTV). RIHVR solves an inverse problem whereby the 3D optical field best matching the recorded hologram is iteratively reconstructed utilizing the sparsity and spatial smoothness of the volume to regularize the solution. The reconstruction in RIHVR is substantially noise-free with improved axial resolution and increased maximum tracer concentration relative to prior DIH-PTV methods. The use of sparsity regularization in RIHVR enables a sparse data representation which reduces memory requirements and allows processing very large holographic images while simplifying the identification and tracking of individual particles. Using synthetic data, RIHVR shows a 40% improvement in localization accuracy and a 4x reduction in the RMS velocity fluctuation in addition to a threefold increase in the allowable tracer concentration. RIHVR further demonstrates its capability through measurements of microfiber dynamics with nanometer resolution in all three directions, swimming tracks of algae in a dense suspension, and the rotation rate of non-spherical particles in a T-junction flow.

11:36AM S35.00006 Understanding the Flow Mechanism in Micro Pulsating Heat Pipes Using Image Recognition

1. CHIHIRO KAMIJIMA, YUTA YOSHIMOTO, SHU TAKAGI, IKUYA KINEFUCHI, Department of Mechanical Engineering, The University of Tokyo — Heat generation in electronic devices has recently become a significant issue owing to their miniaturization and integration. Pulsating heat pipes (PHPs), which facilitate heat transfer via self-oscillation of liquid slugs, are promising devices thanks to their simple walkless structure and ease of miniaturization. However, complex and chaotic flow mechanism of PHPs has yet to be understood sufficiently, necessitating further investigation for device optimization. In this study, we fabricate a micro-PHP with a hydraulic diameter of 350 µm, and measure the PHP thermal conductivities using FC-72 as a working fluid under various conditions. We also visualize inner flows with a high speed camera and extract flow patterns using an image recognition technique. The results show that long and thin liquid films generated on the channel walls are of importance for effective heat transfer. Additionally, we model inner flows and heat transfer of the micro-PHP, and conduct numerical analyses using the extracted flow patterns. We find that latent heat transfer via the liquid films accounts for a significant portion of the overall heat transfer, while sensible heat transfer by the liquid slugs is negligible small.

11:49AM S35.00007 Experimental and numerical analysis of the reaction yield in a T-microreactor

1. ALESSANDRO MARIOTTI, CHIARA GALLETTI, ELISABETTA BRUNAZZI, ROBERTO MAURI, MARIA VITTORIA SALVETTI, DICI - University of Pisa — Microfluidic devices are attracting considerable interest in pharmaceutical and fine chemistry industry, because they allow continuous reactions with an unprecedented control over operating conditions. One critical issue in the use of microreactors is to obtain an efficient mixing and a high reaction yield while the flow being laminar, due to the small dimensions. In this context, the simplest and most studied configuration is the T-shaped one. The flow regimes occurring in these devices as the Reynolds number varies and the related mixing are well characterized in the literature. On the other hand, there is a little understanding of the effect of flow regimes on the yield of a chemical reaction. The present work is aimed at analyzing this aspect through the synergic use of experiments and numerical simulations. PIV measurements are used to characterize the flow pattern and optical techniques are employed to measure the reaction yield because the test-reaction is accomodated by discoloration. Simulations are based on finite-volume technique and local grid-adaptation. The chosen test-reaction is catalyzed by an acid in a homogeneous phase and this allow to easily investigate the combined effect of the Damkholer and of the Reynolds numbers on the reaction yield.

12:02PM S35.00008 A PDMS based passive microfluidic device for generating Platelet rich plasma

1. VIJAI LAXMI, SIDDHARTH TRIPATHI, SUHAS S JOSHI, AMIT AGRAWAL, Indian Institute of Technology Bombay, Bombay, Mumbai — Platelets are a pool of various growth factors which act as a soft tissue healer, and are also linked to various pathophysiological diseases. Platelet rich plasma (PRP) finds wide applications in platelet transfusion and biomedical research. Therefore, there is merit in selectively extracting platelets from blood. Clinically, platelets rich plasma is separated based on centrifugation process, which is however time consuming and leads to activation of platelets. The existing microdevices suffer from low throughput and have been tested only with dilute blood. Here, we design and test a passive PDMS based microdevice for obtaining PRP from whole human blood. The features involved in the microdevice are simple, and its fabrication involves a single layer of photolithography. The microdevice utilizes hydrodynamic forces for its operation, which are based on the biophysical laws and geometrical effects. The microdevice separates plasma with 14 - fold enrichment of platelets in it, while working in 0.2 ml/min to 0.4 ml/min flow rate range. The quality of the outlet sample is also checked by measuring the activation level of platelets, less than 5% platelets are found to be activated. These features make the presented microdevice unique.

1 Indian Institute of technology Bombay, Mumbai
than that of water-oil, allows for facile generation of microfibers. Needed for fibers based on water-oil systems. Moreover, the ultra-low interfacial tension of the ATPS, which is three orders of magnitude lower, enables many different microstructures. The all-aqueous nature of this system allows for generation of biocompatible materials, not requiring washing steps when preparing the fibers. The nonequilibrium all-aqueous fiber formation system may have important biotechnological applications, specifically for generation of scaffolds with well-defined microstructures of PEGDA fibers upon photopolymerization of the jet. We study the dynamics of the equilibration process, and the transient dynamics of these evolving fluid structures can be used as liquid templates to tune the size or the internal and surface properties of the fibers. A jet of a PEGDA-rich phase is formed in a continuous DEX-rich phase, inside a microfluidic device. As the ATPS equilibrates, a jet is formed due to the difference in interfacial tension. The jet is then jetted out of the device, and the microfibers are collected outside. The microfibers are then characterized using optical microscopy and scanning electron microscopy (SEM). This work confirms our previous work and shows that the nonequilibrium all-aqueous fiber formation system is a promising method for the fabrication of microfibers. This work presents a model for the nonequilibrium all-aqueous fiber formation system, including the transient dynamics of viscous peeling based soft actuators. The experimental data is compared with the suggested model, showing very good agreement.
of the field applied. In our work, we studied the influence of the field rotational frequency on the length and rotational speed of the chains as is a key factor in these dynamics. When it is increased, we observe the formation of rotating clusters with frequencies that differ from the one long chains aligned with the field. When the magnetic field is rotating, a competition between magnetic and viscous forces takes place, leading to the rotation of the chains following the magnetic field along with the reduction of their length. The frequency of the rotating magnetic field is a key factor in these dynamics. When it is increased, we observe the formation of rotating clusters with frequencies that differ from the one of the field applied. In our work, we studied the influence of the field rotational frequency on the length and rotational speed of the chains as well as on the main features of the clusters. In order to have the needed temporal resolution, we used a microscope combined with a high-speed camera. Thanks to this technology, we were able to determine a critical frequency between the two regimes mentioned above.

Superparamagnetic colloids under rotating magnetic field, FLORENCE MIGNOLET, GEOFFROY LUMAY, University of Liege — Colloids made of superparamagnetic micrograins offer the possibility to be controlled remotely with a magnetic field. This remote control enables various applications such as mixing, transport of fluids through microscale channels or propulsion in a viscous fluid. It is well known that when a constant magnetic field is applied on superparamagnetic colloids, they form long chains aligned with the field. When the magnetic field is rotating, a competition between magnetic and viscous forces takes place, leading to the rotation of the chains following the magnetic field along with the reduction of their length. The frequency of the rotating magnetic field is a key factor in these dynamics. When it is increased, we observe the formation of rotating clusters with frequencies that differ from the one of the field applied. In our work, we studied the influence of the field rotational frequency on the length and rotational speed of the chains as well as on the main features of the clusters. In order to have the needed temporal resolution, we used a microscope combined with a high-speed camera. Thanks to this technology, we were able to determine a critical frequency between the two regimes mentioned above.

Lateral migration of an electrophoretic particle in Newtonian and viscoelastic pressure driven flows, AKASH CHOUDHARY, Indian Institute of Technology Madras, DI LI, Clemson University, South Carolina, RENGANATHAN T, Indian Institute of Technology Madras, XIANGCHUN XUAN, Clemson University, South Carolina, PUSHPAVANAM S, Indian Institute of Technology Madras — In recent years there has been a growing interest towards incorporation of electrokinetics to inertial and viscoelastic focusing techniques to achieve higher throughput and external control over the focusing positions. This is performed by applying a DC electric field parallel to the flow. In this work, we investigate the effects of electrokinetics on the particle migration in pressure-driven flows of Newtonian and viscoelastic fluids through experiments and theoretical analysis. Using Lorentz reciprocal theorem in conjunction with perturbation expansion (in Reynolds or Deborah number), we derive analytical expressions which describe the lateral migration at the leading order. We find that that the direction of migration in inertial-Newtonian flow and inertialess-viscoelastic flow is towards the regions of high shear, provided the electrokinetic motion is in the direction of the imposed Poiseuille flow. The trajectories obtained from the theoretical analysis, in agreement with experiments, demonstrate that the interaction of electrokinetic and rheological effects can result in an enhancement in migration by an order of magnitude. Furthermore, it is revealed that the magnitude of the background shear and particle zeta potential primarily governs the migration.

**Tuesday, November 26, 2019 10:31AM - 12:15PM — Session S37 Particle Laden Flows: Simulations**

Particle number decomposition DEM parallel algorithm for particle laden flows, ZHENPING ZHU, University of Minnesota, Twin Cities; Xidian University, XIAOJING ZHENG, Xidian University, LIAN SHEN, University of Minnesota, Twin Cities — Domain decomposition is the most commonly used parallel algorithm in simulations of particle laden flows. However, there are two limitations of this algorithm. Firstly, particles are generally distributed unevenly over the different sub-domains in anisotropic flows, leading to problems of loading balance, especially when gravity effect is strong. Secondly, as particles naturally cross borders between sub-domains, passing values between sub-domains can be complicated. In this study, we develop a new particle number decomposition algorithm to overcome these two limitations. In this method, each core deals with almost the same number of particles to achieve efficient loading balance. We further develop a low storage method that can effectively store the particles information in each core, while substantially reducing the complexity of passing values among different cores. The new algorithm is easy to implement, and existing serial DEM algorithms remain unchanged in the parallel version. It also has high parallel efficiency and can compute millions of fully resolved particles.

Optimization of Finite Element Simulations of Colliding, Particle-laden Flows on Unstructured Grids, GRANT RYDQUIST, MAHDI ESMAILY, Cornell University — When simulating fluid systems in complex geometries, it is often necessary to discretize the system using a large number of unstructured elements to achieve accurate results. However, this can pose a number of problems when the simulation must also include Lagrangian particles. In such simulations, it is necessary to search for the element that contains a particle at each time step in order to accurately interpolate fluid properties to the location of the particle. While this operation is expensive for structured grids, in unstructured grids a standard implementation of this search algorithm requires $O(N_pN_e)$ operations, and can become prohibitively expensive for fine grids with many particles. A second situation which can lead to increased computational cost in simulations with Lagrangian particles is when binary collisions between particles must be captured. In general, each particle must be checked against every other particle to check for potential collisions, resulting in $O(N_p^2)$ calculations. In this work, we present a new technique to drastically reduce the computational cost in both of these situations through an optimization problem. In both of these cases, application of this optimization problem has led to a cost that is $O(N_p)$. 

**Tuesday, November 26, 2019 12:02PM - 1:00PM — Session S36 Microfluidics**
10:57AM S37.00003 Numerical modeling of inertial particles in under-expanded jets

YUAN YAO, University of Michigan, Ann Arbor, JASON RABINOVITCH, Jet Propulsion Laboratory, JESSE CAPECÉLÁTRO, University of Michigan, Ann Arbor — Inertial particle dynamics in flows that exhibit strong gas-phase compressibility and turbulence is crucial to many practical engineering applications. Such examples include coal dust explosions, shock wave lithotripsy, combustion/detonation, etc. Compared to their low-speed counterparts, particle-laden compressible flows like the examples listed here typically introduce new length- and time-scales and additional physics that further complicate modeling efforts. In this presentation, we perform three-dimensional Eulerian-Lagrangian simulations of particle-laden under-expanded jets to study the dynamics of inertial particles in compressible flows. The gas-phase equations are solved using a high-order, energy stable finite difference discretization. Particle trajectories and velocity distribution together with DMD modes are a high-order, energy stable finite difference discretization. A combined ghost-point / direct-forcing immersed boundary method is employed to model the nozzle geometry. The focus of the present work is to assess the capability to simulate particle dynamics through a series of compression and expansion waves (Mach diamonds). Particle trajectories and velocity distribution together with DMD modes are compared between different drag models and experiments. Two-way coupling effects on the structure of the Mach diamonds are also reported.

This work was funded by the Jet Propulsion Lab Center Innovation Fund. Computational resources provided by NASA Advanced Supercomputing.

11:00AM S37.00004 Particle Scale Heat Transfer Calculations and Flow Characteristics in a Fluidized Bed with Immersed Tube by CFD-DEM Approach

ANGELO VIGNOLO, Andrea Vigniolo, University of Insubria, Italy, COSIMO LIVI, GIANLUCA DI STASO, HERMAN J.H. CLERCX, Eindhoven University of Technology — The survival of fish passing through a hydroelectric power plant is a critical challenge to understand and address adverse environment impacts. Alternative routes to bypass fish in extreme hydraulic conditions are designed in many power plants, fish bypass still remains a critical issue. A computational fluid dynamics based tool, biological performance assessment (BioPA) method, has been developed to assess the biological performance of fish passage during the turbine design phase in new and existing turbine designs. The current work reports high fidelity turbulent flow investigations to predict the behavior, trajectories, and collisions of inertial particles in an idealized hydro-turbine model to predict the biological impact of hydro turbines on fish passage. Turbulent flow simulations were conducted using detailed eddy simulation to accurately capture the flow recirculation and wake region proximate to representative geometry of the distributor of a typical hydro turbine. The flow field proximate to the distributor geometry significantly impacts the trajectory and collision of particles. Naturally buoyant spherical and cylindrical particles were released at the upstream of the distributor. The trajectory and collision rate of the particles to distributor wall is computed and further compared with corresponding experimental results for different conditions.

11:20AM S37.00005 CFD tools for characterizing particle passage through an idealized hydro-turbine model

RAJESH SINGH, Pacific Northwest National Laboratory, PEDRO ROMERO-GOMEZ, Andritz HYDRO GmbH, 4030 Linz, Austria, MARSHALL RICHMOND, SAMUEL HARDING, WILLIAM PERKINS, Pacific Northwest National Laboratory — The survival of fish passing through a hydroelectric power plant is a critical challenge to understand and address adverse environment impacts. Alternative routes to bypass fish in extreme hydraulic conditions are designed in many power plants, fish bypass still remains a critical issue. A computational fluid dynamics based tool, biological performance assessment (BioPA) method, has been developed to assess the biological performance of fish passage during the turbine design phase in new and existing turbine designs. The current work reports high fidelity turbulent flow investigations to predict the behavior, trajectories, and collisions of inertial particles in an idealized hydro-turbine model to predict the biological impact of hydro turbines on fish passage. Turbulent flow simulations were conducted using detailed eddy simulation to accurately capture the flow recirculation and wake region proximate to representative geometry of the distributor of a typical hydro turbine. The flow field proximate to the distributor geometry significantly impacts the trajectory and collision of particles. Naturally buoyant spherical and cylindrical particles were released at the upstream of the distributor. The trajectory and collision rate of the particles to distributor wall is computed and further compared with corresponding experimental results for different conditions.

11:30AM S37.00006 An AMR moving cut-cell algorithm for particle-laden flows

ARTHUR GHIGO, Department of Mathematics, University of British Columbia, STEPHANE POPINET, Institut Jean le Rond d’Alembert — The capability to simulate a two-way coupled interaction between an arbitrary-shape colloidal particle and a fluid is important for a range of practical applications, however the computational cost can become burdensome. We propose a systematic error analysis of finite-size particle dynamics using the Hermite regularized Lattice Boltzmann method, for different particles resolution, addressing translational and rotational systems separately. The motivation is the understanding of the degree of accuracy provided by different boundary condition models at the fluid-solid interface, with a focus on cases where particles are discretized using few lattice grid points. We show that through a second-order accurate interpolated bounce-back scheme a strong error suppression can be achieved with respect to the standard first-order accurate approach, allowing to simulate smaller particles and thus improving computational performances. An improved version of the former interpolation scheme is developed in order to compute particle boundary position also when the particle is crossing a link between two fluid nodes, showing that the capability to resolve non-spherical particles is further enhanced.
12:02PM S37.00008 Qualitative Benchmarking of a Developmental CFD-DEM Code1

WILLIAM FULLMER2, JORDAN MUSSE, National Energy Technology Laboratory, ANN ALMGREN, MICHELE ROSSO, OSCAR ANTEPARA, ROBERTO PORCU, JOHANNES BLASCHKE, Lawrence Berkeley National Laboratory —

MFIX-Exa is a new code being developed by the National Energy Technology Laboratory and Lawrence Berkeley National Laboratory as part of the U.S. Department of Energy’s Exascale Computing Project. MFIX-Exa originated by combining the discrete element method (DEM) modules of the classic MFIX code (mfix.netl.doe.gov) with a modern low Mach number projection method for the continuous fluid phase. The new algorithm is implemented using the AMReX software framework for massively parallel block-structured applications (amrex-codes.github.io). This work utilizes a set of qualitative benchmarks which emphasize the phenomenology of a given problem rather than averaged statistical measures typically used in fluid-particle validation studies. The following cases are considered: 1) clustering of inelastic particles in the gas-solid homogenous cooling system, 2) granular RayleighTaylor instability of particles draining into a gas, 3) rapid injection of a single bubble into a particle bed at incipient fluidization, 4) ordered left-right bubbling pattern of a periodically fluidized bed, 5) segregation of “Brazil nuts” to the top of a small bed, 6) axial banding (segregation) of bi-disperse rotating tumbler. A range of agreement with the expected phenomena is observed and reported.

Tuesday, November 26, 2019 10:31AM - 11:49AM —
Session S38 Porous Media Flow Mixing and Turbulence 620 - Xiaoliang He, PNPL

10:31AM S38.00001 Pore-scale Direct Numerical Simulation of Turbulent Flows through a Randomly-Packed Porous Medium1

XIAOLIANG HE, MARSHALL RICHMOND, WILLIAM PERKINS, TIMOTHY SCHEIBE, Pacific Northwest National Laboratory, SOURABH APTE, Oregon State University — Turbulent flows through randomly-packed porous media are ubiquitous in both natural and engineered systems. It is of great value to understand the important turbulence characteristics in the randomly packed beds of relevance for heat transfer applications in chemical/nuclear reactors, as well as some environmental problems such as hyperviscous exchange at the interface between free stream water and the underlying sediment. Currently, very few pore-scale direct numerical simulations (DNS) of high Reynolds number flows through packed beds have been conducted and almost all of these studies focused on structurally packed or dilute systems. In the present work, DNS are performed in a randomly-packed triply-periodic porous medium with a porosity of 0.37. The Eulerian and Lagrangian statistics of turbulence, TKE budget, anisotropy distribution in confined pore geometries are investigated. These observations are compared with our previous work on triple-periodic, face centered cubic (FCC), to understand the influence of the heterogeneity on the turbulent statistics. It is observed that the integral length scale in the random packing is larger than that from structured packing.

1The computation is performed using Cascade HPC at EMSL

10:44AM S38.00002 Transition to turbulence in randomly packed porous media: scale evolution of vortical structures

REZA M. ZIAZI, JAMES LIBURDY, Oregon State University — Vortical structures are the driving mechanism behind the process of transition to turbulence in randomly structured porous media that is observed in many natural processes; natural canopy forest fires and biological systems such as cardiovascular and respiratory. The investigation of vortex evolution during the onset of turbulence is performed by using time-resolved PIV to identify the flow structures, and measure the scale and energy of swirling structures as related to pore- and macro-scale Reynolds numbers. Objective local region-type (λ1) versus non-local (λ2) vortex identification methods are employed to detect the asymptotic scales at larger Re during transition from 100 to 1000. The direct measure of the size, strength, and number density of vortical structures are observed to show a similar trend and asymptote to turbulent scales at higher pore-scale Reynolds numbers. The shear and rotational contribution of vortical structures are influenced differently from pore- versus macro-scale Reynolds numbers which interprets the scale evolution during transition process.

10:57AM S38.00003 Dispersion and stretching in 3D Porous media

BLOEN METZGER, Aix-Marseille University, IUSTI-CNRS UMR 7343, 13453 Marseille, France, GEP TEAM, OSUR TEAM — Mixing processes in complex flows are governed by the dispersion and stretching induced by the flow in question. However, even for the apparently simple case of a viscous flow through an isotropic porous medium, the statistics of these crucial kinematics quantities remain uncertain. We experimentally tackle this problem using an index-matched porous medium composed of randomly packed solid spheres. The 3D Eulerian velocity-field is characterized with an unprecedented resolution. The dispersion of advective particles is measured and explained in terms of the velocity statistics. Last, the stretching laws are measured for the first time using a Lagrangian stretching reconstruction method. These results provide solid grounds for a full description of mixing processes in porous media.

11:10AM S38.00004 Geometric disorder regulates dispersion in viscoelastic porous media flows

DEREK M. WALKAMA, NICOLAS WAISSBORD, JEFFREY S. GUASTO, Tufts University — In this work, we study the dispersion of microparticles in viscoelastic fluid flow through model, microfluidic porous media, comprising arrays of either hexagonally ordered or randomly disordered pillars. Similar to previous work at high Peclet number, we show that a viscoelastic flow instability in the ordered medium enhances dispersion transverse to the mean flow direction with increasing Weissenberg number (Wi). In contrast, we demonstrate that geometric disorder has two main consequences for transport: First, disorder quenches the elastic instability and thus, suppresses transverse dispersion due to a lack of chaotic velocity fluctuations. Second, we observe an enhancement of longitudinal dispersion, which corresponds with the emergence of channelized flow within the disordered medium. These filamentous flows strengthen in intensity with increasing Wi, where the origin of the increased longitudinal transport stems from their strongly-correlated streamwise flow speed.
10:31AM S39.00001 Turbulence in Forced Stratified Exchange Flows. KATHERINE M. SMITH, JOHN R. TAYLOR, JAMIE PARTRIDGE, ADRIEN LEFAUVE, PAUL LINDEN, Department of Applied Mathematics and Theoretical Physics (DAMTP), University of Cambridge and The BP Institute, University of Cambridge — Continuously forced, stratified exchange flows occur in many geophysical systems, such as ocean basins, between continental shelves and the deep ocean, and at the mouth of rivers and estuaries. These exchange flows can be sensitive to instabilities that promote the growth of turbulence and increase mixing between the two differing flows. While these mixing processes are assumed to be important to global ocean budgets, they are unresolved within Earth system models and therefore must be fully understood in order to accurately parameterize the internal waves. This talk presents results from three-dimensional direct numerical simulations of stratified exchange flows that are continuously forced by weakly relaxing the buoyancy and streamwise velocity. The response of different domain geometries was investigated, and the results of simulations show that the slope of the side walls dramatically affects the surface mixed layer. Mixing is enhanced and penetrates deeper in the vertical as slope inclination grows. Under resonant forcing, surface shear stress and resonant frequencies of the internal waves. The response of different domain geometries was investigated, obtained varying the inclination angle of the side walls, from zero (vertical walls) to 90°. When the frequency of the forcing is close to the first mode, resonant internal seiche occurs, in other cases forcing conditions are non-resonant. The results of simulations show that the slope of the side walls dramatically affects the surface mixed layer. Mixing is enhanced and penetrates deeper in the vertical as slope inclination grows. Under resonant forcing, surface waves are much more energetic and there is less change in the density profile compared to non-resonant conditions.

10:44AM S39.00002 Large Eddy Simulation of the response of a stratified reservoir with inclined walls to an oscillating surface shear stress. SARA MARKOVIC, VINCENZO ARMENIO, Dipartimento di Ingegneria e Architettura, Università di Trieste, 34127 Trieste, Italy — We present results of numerical simulations of the response of a reservoir with two-layer stratification to an oscillating surface shear stress. The simulations are carried out at a laboratory scale, using Large Eddy Simulation. We solve the three dimensional Navier-Stokes equations under the Boussinesq approximation for the density field using a model based on buoyantBoussinesqPimpleFoam implemented in the OpenFOAM library. The model was validated by reproducing experimental results for reservoir response to surface shear stress and resonant frequencies of the internal waves. The response of different domain geometries was investigated, obtained varying the inclination angle of the side walls, from zero (vertical walls) to 90°. When the frequency of the forcing is close to the first mode, resonant internal seiche occurs, in other cases forcing conditions are non-resonant. The results of simulations show that the slope of the side walls dramatically affects the surface mixed layer. Mixing is enhanced and penetrates deeper in the vertical as slope inclination grows. Under resonant forcing, surface waves are much more energetic and there is less change in the density profile compared to non-resonant conditions.

10:57AM S39.00003 Interaction between an inclined gravity current and a pycnocline in a two-layer stratification. YUKINOBU TANIMOTO, NICHOLAS OUELLETTE, JEFFREY KOSEFF, Department of Civil and Environmental Engineering, Stanford University — A series of laboratory experiments were conducted to investigate the characteristics of a dense gravity current flowing down an inclined slope into a quiescent two-layer stratification. The presence of the pycnocline causes the gravity current to split and intrude into the ambient at two distinct levels of neutral buoyancy, as opposed to the classical description of gravity currents in stratified media as being either a pure underflow or interflow. The splitting behavior is observed to be dependent on the Richardson number (Ri) of the gravity current, formulated as the ratio of the excess density and the ambient stratification. For low Ri, underflow is more dominant, while at higher Ri interflow is more prominent. As Ri increases, however, we find that the splitting behavior eventually becomes independent of Ri. Additionally, we have also identified two different types of waves that form on the pycnocline in response to the intrusion of the gravity current. An underflow-dominated regime causes a pycnocline displacement where the speed of the wave crest is locked to the gravity current, whereas an interflow- dominated regime launches an internal wave that moves much faster than the gravity current head or interfacial intrusion.

11:10AM S39.00004 Modelling stratified wall-bounded turbulence using resolvent analysis1, MUHAMMAD AHMED, ANDREW THOMPSON, BEVERLEY MCKEON, California Institute of Technology — The effects of an active scalar have on incompressible wall-bounded turbulence are investigated using the resolvent framework (McKeon & Sharma, 2010, JFM). The state of the flow system is expressed as the result of applying the linear resolvent operator to the nonlinear terms in the governing Navier-Stokes equations with the Boussinesq approximation. To investigate the relationship between velocity and scalar fluctuations, the formulation is extended to include a scalar equation (Dawson et al., 2018, AIAA) and a scalar component acting in the wall-normal direction in the momentum equations. It is found that the Richardson number has a significant effect on the shape and phase of the velocity and scalar modes across the critical layer. In addition, it is shown that active scalar modes have a significant impact on the energy transfer between velocity mode components at varying scales. Furthermore, we visualise mode combinations that are representative of coherent structure observed in the atmosphere and oceans to gain a better understanding of the spatial wavenumber spectrum observed in nature.

11:23AM S39.00005 Large-eddy simulations of stratified turbulence: an anisotropic subgrid-scale closure, SINA KHANI, University of Washington, MICHAEL WAITE, University of Waterloo — The horizontal and vertical grid spacings are generally equal in large-eddy simulations (LES) of stratified turbulence. In simulations of larger-scale motions, however, it is computationally affordable to use different grid spacings in the horizontal and vertical. In this talk, we introduce a new subgrid-scale (SGS) parameterizations based on horizontal filtering of equations of motions in stratified turbulence. The horizontal and vertical SGS dissipations and fluxes are determined based on a Reynolds decomposition of the flow. Our model can successfully reproduce the flow characteristics, moments and parameters, such as time series of kinetic and potential energy, horizontal and vertical wavenumber energy spectra and mixing efficiency, similar to those in direct numerical simulations while the computational cost is considerably reduced in LES. We suggest that our new SGS model can also improve the dissipative performance of the horizontal Smagorinsky closure in current atmospheric and oceanic models without adding any ad hoc energizing terms at smaller scales.

11:36AM S39.00006 Wall shear stress fluctuations induced by shallow-water Langmuir turbulence, BINGQING DENG, ANQING XUAN, LIAN SHEN, University of Minnesota — In shallow water with the existence of surface waves, large-scale full-depth Langmuir circulations can be generated due to the interaction between wind-driven currents and the Stokes drift of shallow-water waves. We perform wall-resolved LES of the Craik-Leibovich equation to study shallow-water Langmuir turbulence. It is found that the full-depth Langmuir circulations directly leave large-scale footprint near the water bottom and hence have significant contributions to the wall shear stress fluctuations. The full-depth Langmuir circulations also alter the distribution of other coherent structures, so that the distribution of the wall shear stress fluctuations contributed by other coherent structures is different from the wall turbulence in the absence of Stokes drift of surface waves. The magnitude of the wall shear stress fluctuations at various locations is predicted by the velocity fluctuations induced by the full-depth Langmuir circulations.

11:49AM S39.00007 DNS of stratified Ekman layers over rough surfaces, SUNGWON LEE, IMAN GOHARI, SUTANU SARKAR, University of California, San Diego, UNIVERSITÉ DE CALIFORNIE, SAN DIEGO TEAM — We investigate the evolution of stratified Ekman boundary layers in the presence of surface roughness. The roughness elements are 2-dimensional bumps and the neutral flow is in the transitional rough regime. A cooling buoyancy flux which is applied for a finite time period is responsible for the stabilizing stratification. The Reynolds number is moderate so that a broad parametric study of the influence of roughness height ($h^+$) and cooling flux (normalized Obukhov length, $L^+$) can be performed using direct numerical simulation (DNS). A cooling flux corresponding to $L^+ \approx 700$ is sufficient to cause the initial collapse of turbulence for both smooth and rough surfaces. Buoyancy and the slope of the surface roughness elements act in conjunction to affect the state of boundary-layer turbulence after the initial transient. The final value of the bulk Richardson number ($Ri_b$), which is a function of both $L^+$ and roughness properties, is found to provide guidance on the overall state of the flow, e.g., weak or strongly stable in the sense of Mahrt (1998); continuous, globally intermittent or locally intermittent.

12:02PM S39.00008 Multiphase plumes in a rotating environment, DARIA FRANK, University of Cambridge, JULIEN LANDEL, University of Manchester, STUART DALZIEL, PAUL LINDEN, University of Cambridge — The Deepwater Horizon (DwH) blowout in 2010 resulted in a formation of a multiphase plume consisting of oil droplets and gas bubbles. The multiphase component of a plume is commonly characterised by the so-called slip velocity. Additionally, the duration of the DwH spill of several months implies that the plume is likely to have been affected by the Earth’s rotation as was conjectured by previous numerical and experimental studies. The complex interplay between the slip velocity of the multiphase effluent and the system rotation as well as their combined effects on the internal plume dynamics and the associated subsurface dispersion of pollutants are still poorly understood. Yet, characterising these effects is important for oil spill mitigation purposes. In this talk, we present results from small-scale laboratory experiments on bubble plumes released into a rotating environment that were conducted for a wide range of Rosby numbers and several bubble slip velocities. By performing a rigorous image analysis, we focus on three particular aspects of the problem: the evolution of the plume structure during its initial rise, the subsurface dispersion of the effluent once the plume has risen through the entire water column and the lateral spreading of the plume on the water surface.
10:31AM S40.00001 Wall-bounded turbulence control using a Monte-Carlo approach
1, OSCAR FLORES, ROBERTO PASTOR, Universidad Carlos III de Madrid, ALBERTO VELA-MARTIN, Universidad Politécnica de Madrid — Wall-bounded turbulence is very important in engineering applications involving fluids. Indeed, wherever flow control is sought in engineering applications both sensing and actuation are restricted to devices placed at solid walls. In the present work we tackle the classical problem of skin friction control in wall-bounded turbulence for the case of localised actuation using a Monte Carlo approach. To that end, DNS of a minimal channel of the buffer layer (Re = 180) are run using GPUs. The actuation is a volumetric vertical force applied close to the wall on a characteristic volume L3 and with duration T. Several forcing are considered, with L = [50, 100] and T = [25, 50, 100]. Their effect is evaluated for O(104) episodes, directly comparing the instantaneous skin friction of forced and unforced simulations. The statistical analysis shows that drag increase and decrease are equally probable when the forcing is randomly applied. Episodes with drag decrease show a positive (negative) vertical force being applied to passing sweep (ejection) events, in agreement with opposition control strategies. Preliminary results also suggest that a skin friction sensor upstream of the forcing is a better trigger for the forcing than a wall-pressure sensor at the same location.

10:44AM S40.00002 Selective opposition-like control of large-scale structures in wall-bounded turbulence
2, JOSEPH IBRAHIM, University of Cambridge, ANNA GUSEVA, School of Aeronautics, Universidad Politécnica de Madrid, RICARDO GARCIA-MAYORAL, University of Cambridge — We investigate the effect of controlling large-scale, logarithmic-layer turbulent structures, which have a characteristic size and aspect ratio that scale with the distance from the wall. The aim is to quantify the effect of suppressing these structures while leaving the near-wall turbulent dynamics unaltered. We conduct direct numerical simulations of turbulent channel flows at Re ≈ 500–1000 and artificially remove certain streamwise and spanwise wavelengths of the wall-normal velocity across a range of heights. The wavelengths chosen depend on the target height (and size) of the structures that we wish to target. Our preliminary results suggest that the reduction in drag is observed as a positive, outward shift in the mean velocity profile above the target height that scales in outer units.

10:57AM S40.00003 Direct Numerical Simulation of oscillatory boundary layers in the intermittently turbulent regime: coherent structures, laminarization and scaling
, DIMITRIOS K. FYTANIDIS, JOSE M. MIER, MÁRCHELO H. GARCIA, PAUL FISCHER, University of Illinois at Urbana-Champaign — Experiments conducted at the Ven Te Chow HydroSystems Laboratory (UIUC) in the transitional regime of oscillatory boundary layer flows with smooth bed, show changes in the phase shift between bed shear stress and free-stream velocity maxima (Mier J.M., 2015). Nevertheless, limited by the point-wise measurements (Laser Doppler Velocimetry), it was not possible to relate this finding with the development of three-dimensional flow structures. In this work, Nek5000 is used to perform Direct Numerical Simulation (DNS) of oscillatory boundary layer flows in moderately high Re numbers. DNS results of mean flow and turbulent statistics compare well with experimental observations. Coherent structures and their effect on turbulence characteristics are examined. Vortex tubes have minimal effect on turbulent statistics and friction factor, while turbulent spots defined as sporadic, highly-energetic, lambda-shaped structures, have a significant effect. Analysis of phase shift between free-stream velocity and bed shear stress maxima agrees with the experimental observations. Theoretical analysis is performed for the prediction of laminarization during acceleration phase. A generalized logarithmic law is proposed for accelerating flows using a novel composite acceleration-shear velocity scale.

11:10AM S40.00004 The interfaces with the freestream of a spatially developing boundary layer
1, JAMES WALLACE, University of Maryland, XIAOHUA WU, Royal Military College of Canada. JEAN-PIERRE HICKEY, University of Waterloo — We have investigated the interfaces with the freestream turbulence of the laminar boundary-layer (LBFTI), turbulent spots (TSFTI) and the turbulent boundary-layer (BFITI) using direct simulation of a zero pressure-gradient, smooth-wall boundary-layer flow developing from a laminar state, through transition, to a developed turbulent state. Probability density functions of temperature and its derivatives are used to select the interface identification thresholds. These interfaces are confirmed to be physical by the distinctive quasi-step-jump behavior in the swirling strength and temperature statistics along traverses normal to the BFITI and TSFTI. No interface normal inflection is detected across the LBFTI for swirling strength, temperature, vorticity magnitude, Reynolds shear stress, streamwise and normal velocity or turbulent kinetic energy. This casts serious doubt on the shear-sheltering hypothesis/theory which asserts that freestream fluctuations are blocked by the LBFTI. In the early stage of transition, quasi-spanwise structures exist on the LBFTI. The TSFTI shape is dominated by head prints of concentrated hairpin vortices. Further downstream, the BFITI geometry is strongly modulated by groves of hairpin vortices.

11:23AM S40.00005 Multi-structure turbulence in a boundary layer interacting with a uniformly sheared flow
1, STAVROS TAVOULARIS, CURTIS LIVINGSTON, University of Ottawa — Turbulence generated by two or more distinct production mechanisms and having two or more types of large-scale structure has been termed multi-structure. Depending on the conditions, such flows may retain a non-canonical character or relax to a canonical flow. This study investigates a case in which both production mechanisms persist as the flow evolves. It examines the multi-structure-turbulence region of a turbulent boundary layer (TBL) developing along a smooth wall in a water tunnel, while being adjacent to a nearly homogeneous, uniformly sheared flow (USF). Detailed measurements are collected with laser Doppler velocimetry, particle image velocimetry and hot film anemometry. The mean shear and the turbulent shear stress change direction from the TBL to the USF and vanish near the TBL edge. The statistical properties of the turbulence in the multi-structure region have been measured and compared to those in canonical TBL and USF. Particular interest focusses on the variation of the dissipation parameter across the flow and the shapes and orientations of the coherent structures in the multi-structure region.

10:36AM S40.00006 Development of a turbulent boundary layer subjected to free-stream turbulence

YANNICK JOOSS, LEON LI, TANIA BRACCHI, R. JASON HEARST, Norwegian University of Science and Technology — Turbulent boundary layers are a fundamental flow that exists in a wide range of natural processes and technical applications. Over the past three decades the effect of free-stream turbulence on the features of a canonical zero-pressure-gradient turbulent boundary layer has been studied extensively, with particular focus on single downstream positions. Nonetheless, there has been little attention given to the influence of varying free-stream turbulence intensity $u'_\infty/U_\infty$ on the actual streamwise development of a boundary layer. This study addresses this gap with hot-wire measurements in a water channel. Free-stream turbulence is created and varied with an active grid. Wall-normal boundary layer scans are performed along the centerline of the channel at multiple streamwise positions. The resulting mean velocity profiles and turbulent fluctuations in the boundary layer for four different free-stream turbulence conditions are analyzed. Further insight is gained by looking at the spectral distribution of energy at selected streamwise positions.

10:31AM S41.00001 Surrogate-model Optimisation Strategies for non-Newtonian Gelling1

ADAM KUTNAR, Imperial College London, LACHLAN MASON, Alan Turing Institute, UK, INDRANIL PAN, RICHARD CRASTER, OMAR MATAR, Imperial College London — Highly resolved simulations have advanced to the extent that they are routinely relied upon in engineering design. The trade-off for this accuracy, however, can be prohibitively high computational cost. These costs are further compounded when multiple calls to an expensive simulation code are required, for example when determining the optimal parameters for manufacturing an engineering performance metric. Here, simple strategies such as grid searching do not scale well with the number of optimisation parameter dimensions. In this study, we investigate industrial gelling phenomena for non-Newtonian fluids in eccentric annuli. The task is to minimise gelling under engineering constraints on both flow and geometric properties. We achieve computational tractability via a surrogate model optimisation strategy and demonstrate its benefits to industrial simulation practitioners, including a reduction in design lead times, by benchmarking against conventional grid and random sampling methods. Best practices are highlighted for a class of generic fluid dynamics optimisation problems.

10:44AM S41.00002 Geometric parameter optimization of a liquid jet liquid ejector1

IVAN KORKISCHKO, CECCO, Nuclear and Energy Research Institute, Sao Paulo, Brazil, FELIPE SILVA MAFFEI, Dept. Mechanical Engineering, POLI, University of Sao Paulo, Sao Paulo, Brazil, RAFAEL DOS SANTOS GIORIA, Dept. Mining and Petroleum Engineering, POLI, University of Sao Paulo, Sao Paulo, Brazil, JULIO ROMANO MENEGHINI, Dept. Mechanical Engineering, POLI, University of Sao Paulo, Sao Paulo, Brazil — Ejectors are devices employed as pumps or compressors, which work transferring momentum from a primary fluid (high pressure) to a secondary fluid (low pressure). On the one hand, their main advantages over standard pumps and compressors are no moving parts, no need of lubricants and seals, and low noise and maintenance. On the other hand, ejectors have low efficiency compared to other devices and a very narrow region of optimal operation. Thus, ejectors certainly benefit from optimization studies. This investigation was based on a CFD model of a liquid jet liquid (LJL) ejector. The finite element method was used, coupled with the k-epsilon turbulence model. The optimization study had three steps. First, the constants of the turbulence model were recalibrated to minimize the difference between the numerical and experimental efficiency curves. Second, using the main geometric parameters as control variables, the peak efficiency was maximized. Finally, the optimized geometry was further improved, considering the transitions between the different ejector components, which were originally sharp corners. The optimized round corners increased the ejector efficiency.

10:57AM S41.00003 Direct Numerical Simulations of Mixing: From Aeration Tanks to Food Mixers1

SEUNGWON SHIN, Hongik University, South Korea, LYES KAHOUADJI, Imperial College London, JALEL CHERGUI, DAMIR JURIC, LIMSI, CNRS, France, RICHARD CRASTER, OMAR MATAR, Imperial College London — The dynamics of stirred tanks has been studied over a wide range of laboratory and industrially conditions and scales, in order to improve the mixing efficiency. We use a three-dimensional two-phase flow dynamics solver coupled with a direct Forcing Method to handle accurately the fluid structure interaction occurring in any of the stirred tank. The numerical framework employed here circumvents numerous meshing issues normally associated with constructing complex geometries (impellers, baffles, etc.) within typical computational fluid dynamics packages. All these solid structures are constructed via a module that defines solid objects by means of a static distance function. Typical examples will be presented such us aeration (bubbling mixing), cavern formation (stirring viscoplastic fluids), and typical Egg Beaters with different types of fluid rheology.

1Helpful discussions with Andrew Russel and Prof. Paul Luckham of Imperial are gratefully acknowledged as is funding via a PETRONAS/Royal Academy of Engineering Research Chair for OKM.

11:00AM S41.00004 Numerical Simulation of Crude-Oil Fouling with the Volume-of-Fluid Method1

GABRIEL GONCALVES, Imperial College London, MIRCO MAGNINI, University of Nottingham, OMAR MATAR, Imperial College London — In oil production or processing pipelines, the change in thermodynamical conditions may cause components of crude-oil to precipitate and adhere to the wall, leading to undesired changes in the hydraulics and thermal performance of the system over time. Although significant progress has been achieved in understanding qualitatively the main mechanisms of wax formation and removal, quantitative comparisons with experimental data are still heavily dependent on calibration to experimental data. In order to perform high-fidelity simulations in arbitrary geometries, a two-phase multi-component solver with heat transfer and phase change was implemented in the OpenFOAM open-source framework. The volume-of-fluid method is used for tracking the interface between fouling layer and liquid phase. The implementation was compared with previous calculations performed in a commercial CFD platform and preliminarily validated with experimental data from the literature.

1CNPq funding for GG, and PETRONAS/Royal Academy of Engineering Research Chair for OKM is gratefully acknowledged.
11:23AM S41.00005 Three-dimensional Numerical Simulations of Turbulent Surfactant-laden Jets, JALEL CHERGUI, LIMSI, CNRS, France, RICARDO CONSTANE-AMORES, ASSEN BATCHVAROV, LYES KAHOUADJI, Imperial College London, SEUNGWON SHIN, Hongik University, South Korea, DAMIR JURIC, LIMSI, CNRS, France, RICHARD CRASTER, OMAR MATAR, Imperial College London — Liquid atomisation processes are widely used to break down a liquid stream into smaller droplets to enhance its mixing with a stagnant phase. These streams may be contaminated with surfactants, whose concentration variations lead to gradients in surface tension and associated Marangoni stresses. Here, we study, for the first time, the effect of surfactant on the complex interfacial dynamics associated with a turbulent jet. We use a hybrid front-tracking/level-set method to capture the dynamics of the complex topological changes in this flow. The numerical method allows the natural tracking of the concentration of interfacial surfactant species and the faithful modelling of its spatio-temporal evolution. Our model also accounts for surfactant solubility and bulk-interface mass exchange. We perform a full parametric study of the effect of surfactant properties on the dynamics. The effect of Marangoni stresses is analysed in terms of the mechanisms giving rise to the droplet size distributions depending on the elasticity number. An attempt to understand the interaction between the observed vortical structures accompanying the flow and the regions of elevated surfactant concentration will also be presented.

1Funding from BP, EPSRC, PETRONAS, Royal Academy of Engineering (Research Chair for OKM).

11:36AM S41.00006 Computational Investigation of the Retropulsive Jet Produced by Antral Contraction Waves in a Model Stomach, KATHLEEN FEIGL, Michigan Technological University, SAMER ALOKAILY, University of Petra, FRANZ TANNER, Michigan Technological University — Numerical simulations are performed to investigate the retropulsive jet that is produced by peristaltic motion during the mixing and digestion process in a model human stomach. The geometrical model for the stomach consists of an axisymmetric conical-shaped tube with a wall at one end which represents the antrum and closed pylorus. The antral contraction waves which produce the peristaltic flow, and consequently the retropulsive jet near the closed pylorus, are modeled as traveling waves along the tube boundary which deform the computational mesh. This geometrical model and the boundary deformation algorithm are implemented into a C++ library and then coupled with the open source code OpenFOAM. The effect of various parameters on the retropulsive jet near the pylorus is investigated. These parameters include the fluid viscosity, wave speed, wave width and maximum relative occlusion. The retropulsive jet is quantified by its peak velocity and jet length along the centerline at maximum relative occlusion. For each wave geometry, it is found that the velocity and pressure curves scale with wave speed at low Reynolds numbers. Between different wave geometries, scaling laws are proposed and tested for the peak centerline velocity and jet length at low Reynolds numbers.

11:49AM S41.00007 Hydrodynamics of solid objects impacting on free surface fluid, DEEPAK KUMAR PANDEY, HEECHANG LIM, Pusan National University — The impact studies of different shape and size of solid objects and curved plates on the free surface of fluid have a great practical significance from engineering perspectives. It is worth noting here that such type of impact phenomena can be correlated with slamming of ship bow, seaplanes, submarines, military projectiles, etc. in the seawater. The objectives of this paper are to experimentally and numerically analyze the field variables (pressure distribution, splashing, wave propagation, etc.) arising out of free fall of different shape and size of solid objects (square prism, rectangular prism, triangular pyramid, cylinder, sphere, etc.) on the free surface of the fluid. The fluids employed were water and oils having different viscosity. During the experiments, free-falling solid objects as projectiles were allowed to impact the free surface of the fluid. The height and the angle of the free falling solid objects were also varied in order to observe its effect on splashing and wave propagation. The interface behaviors and wave propagation have been captured using a high-speed camera. However, pressure sensors and strain gauges were employed in order to record the pressure and impact load at different locations. The simulation results validate the experimental results.

12:02PM S41.00008 Active learning methodologies for surrogate model development in CFD applications, INDRANIL PAN, GABRIEL GONCALVES, ASSEN BATCHVAROV, YUXIN LIU, YUJI LIU, VIK-NESWARAN SATHSIVAM, NICHOLAS YIAKOMI, Imperial College London, LACHLAN MASON, Alan Turing Institute, OMAR MATAR, Imperial College London — Computational fluid dynamic simulations typically have high computational costs, such that for parametric analysis and engineering design an inexpensive surrogate model, which is capable of reproducing the trends of some variables of interest, may be desired. However, generating regressions based on a full grid-based parametric variation is generally infeasible even for a system with moderate number of parameters. In this work, a wide array of active learning techniques were coupled with different regression models to achieve high predictive performance under the constraints of a limited function evaluation budget. The case studies involve flows of industrial relevance and the results outline some best practices for such simulations and highlights future research directions.

1CNPq funding for GG, and PETRONAS/Royal Academy of Engineering Research Chair for OKM is gratefully acknowledged.
